
WARNING

- In some cases, you may need to create the file path based on the structure above if it does not already exist. For example, you may need to add the `python` folder within the `libraries` folder if it does not already exist.
- This method of managing custom wheel files will not be supported on the Azure Synapse Runtime for Apache Spark 3.0. Please refer to the Workspace packages feature to manage custom wheel files.

IMPORTANT

To install custom libraries using the Azure DataLake Storage method, you must have the **Storage Blob Data Contributor** or **Storage Blob Data Owner** permissions on the primary Gen2 Storage account that is linked to the Azure Synapse Analytics workspace.

Next steps

- View the default libraries: Apache Spark version support
- Troubleshoot library installation errors: Troubleshoot library errors
- Create a private Conda channel using your Azure Data Lake Storage Account: Conda private channels

Manage libraries for Apache Spark pools in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Once you have identified the Scala, Java or Python packages that you would like to use or update for your Spark application, you can install or remove them into a Spark pool. Pool-level libraries are available to all notebooks and jobs running on the pool.

There are two primary ways to install a library on a Spark pool:

- Install a workspace library that has been uploaded as a workspace package.
- For updating Python libraries, provide a *requirements.txt* or *Conda environment.yml* environment specification to install packages from repositories like PyPI, Conda-Forge, and more. Read the section about environment specification for further information.

After the changes are saved, a Spark job will run the installation and cache the resulting environment for later reuse. Once the job is complete, new Spark jobs or notebook sessions will use the updated pool libraries.

> **IMPORTANT**
>
> - If the package you are installing is large or takes a long time to install, this affects the Spark instance start up time.
> - Altering the PySpark, Python, Scala/Java, .NET, or Spark version is not supported.
> - Installing packages from external repositories like PyPI, Conda-Forge, or the default Conda channels is not supported within data exfiltration protection enabled workspaces.

Manage packages from Synapse Studio or Azure portal

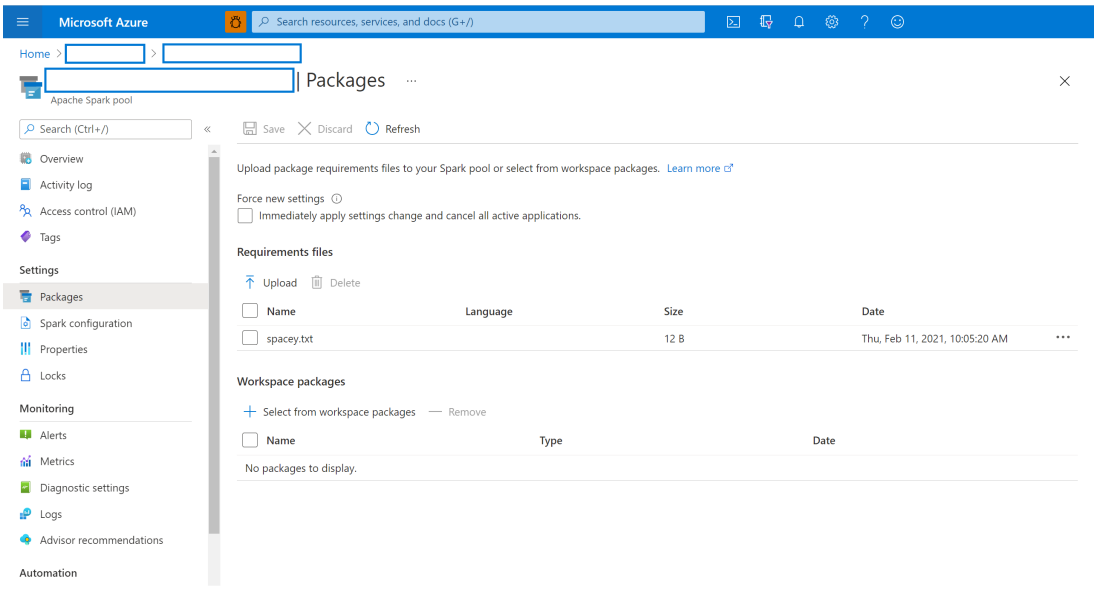
Spark pool libraries can be managed either from the Synapse Studio or Azure portal.

To update or add libraries to a Spark pool:

1. Navigate to your Azure Synapse Analytics workspace from the Azure portal.

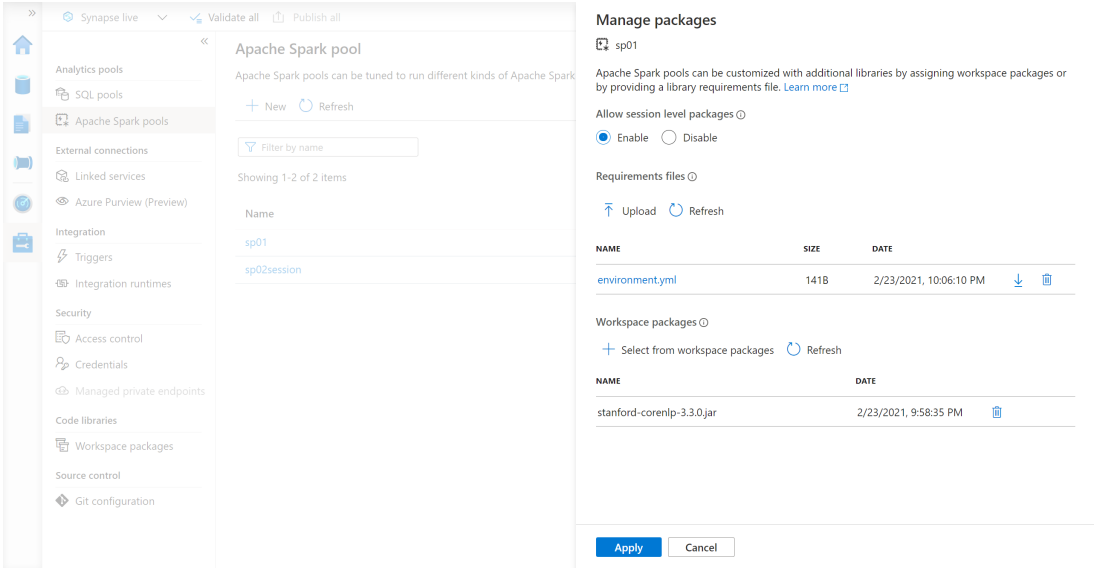
   If you are updating from the **Azure portal**:

   - Under the **Synapse resources** section, select the **Apache Spark pools** tab and select a Spark pool from the list.
   - Select the **Packages** from the **Settings** section of the Spark pool.



If you are updating from the **Synapse Studio**:

- Select **Manage** from the main navigation panel and then select **Apache Spark pools**.
- Select the **Packages** section for a specific Spark pool.



2. For Python feed libraries, upload the environment configuration file using the file selector in the **Packages** section of the page.
3. You can also select additional **workspace packages** to add Jar or Wheel files to your pool.
4. You can also remove the deprecated packages from **Workspace packages** section, your pool will no longer attach these packages.
5. Once you save your changes, a system job will be triggered to install and cache the specified libraries. This process helps reduce overall session startup time.
6. Once the job has successfully completed, all new sessions will pick up the updated pool libraries.

> **IMPORTANT**
>
> By selecting the option to **Force new settings**, you will end the all current sessions for the selected Spark pool. Once the sessions are ended, you will have to wait for the pool to restart.
>
> If this setting is unchecked, then you will have to wait for the current Spark session to end or stop it manually. Once the session has ended, you will need to let the pool restart.

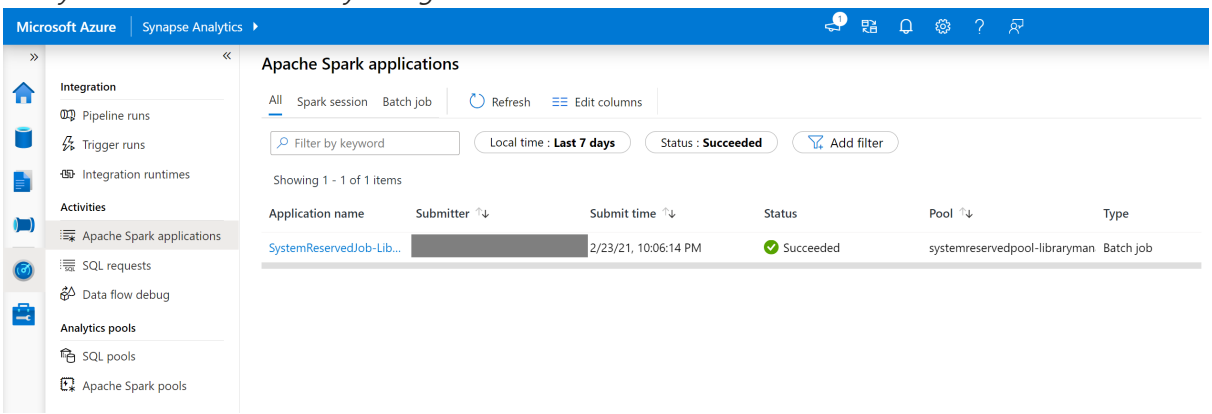
Track installation progress

A system reserved Spark job is initiated each time a pool is updated with a new set of libraries. This Spark job helps monitor the status of the library installation. If the installation fails due to library conflicts or other issues, the Spark pool will revert to its previous or default state.

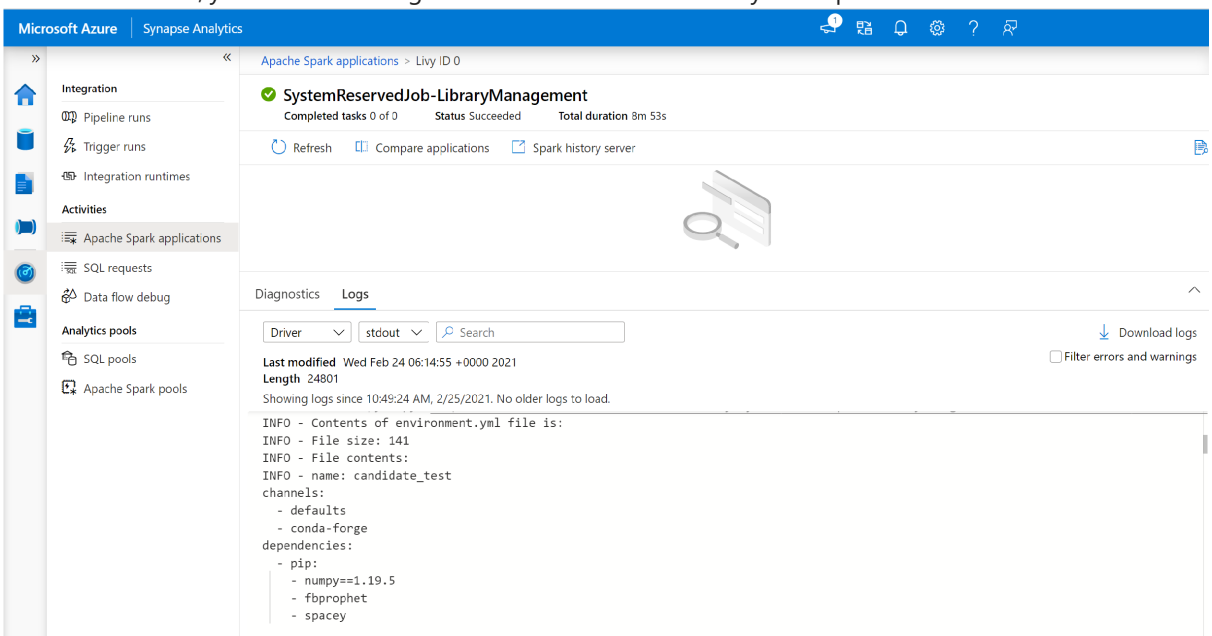
In addition, users can also inspect the installation logs to identify dependency conflicts or see which libraries were installed during the pool update.

To view these logs:

1. Navigate to the Spark applications list in the **Monitor** tab.
2. Select the system Spark application job that corresponds to your pool update. These system jobs run under the *SystemReservedJob-LibraryManagement* title.



3. Switch to view the **driver** and **stdout** logs.
4. Within the results, you will see the logs related to the installation of your dependencies.



Environment specification formats

PIP requirements.txt

A *requirements.txt* file (output from the `pip freeze` command) can be used to upgrade the environment. When a pool is updated, the packages listed in this file are downloaded from PyPI. The full dependencies are then cached and saved for later reuse of the pool.

The following snippet shows the format for the requirements file. The PyPI package name is listed along with an exact version. This file follows the format described in the pip freeze reference documentation.

This example pins a specific version.

```
absl-py==0.7.0
adal==1.2.1
alabaster==0.7.10
```

YML format

In addition, you can also provide an *environment.yml* file to update the pool environment. The packages listed in this file are downloaded from the default Conda channels, Conda-Forge, and PyPI. You can specify other channels or remove the default channels by using the configuration options.

This example specifies the channels and Conda/PyPI dependencies.

```
name: stats2
channels:
- defaults
dependencies:
- bokeh
- numpy
- pip:
  - matplotlib
  - koalas==1.7.0
```

For details on creating an environment from this environment.yml file, see Creating an environment from an environment.yml file.

Next steps

- View the default libraries: Apache Spark version support
- Troubleshoot library installation errors: Troubleshoot library errors

Manage session-scoped packages

8/19/2022 • 2 minutes to read • Edit Online

In addition to pool level packages, you can also specify session-scoped libraries at the beginning of a notebook session. Session-scoped libraries let you specify and use custom Python environments or jar packages within a notebook session.

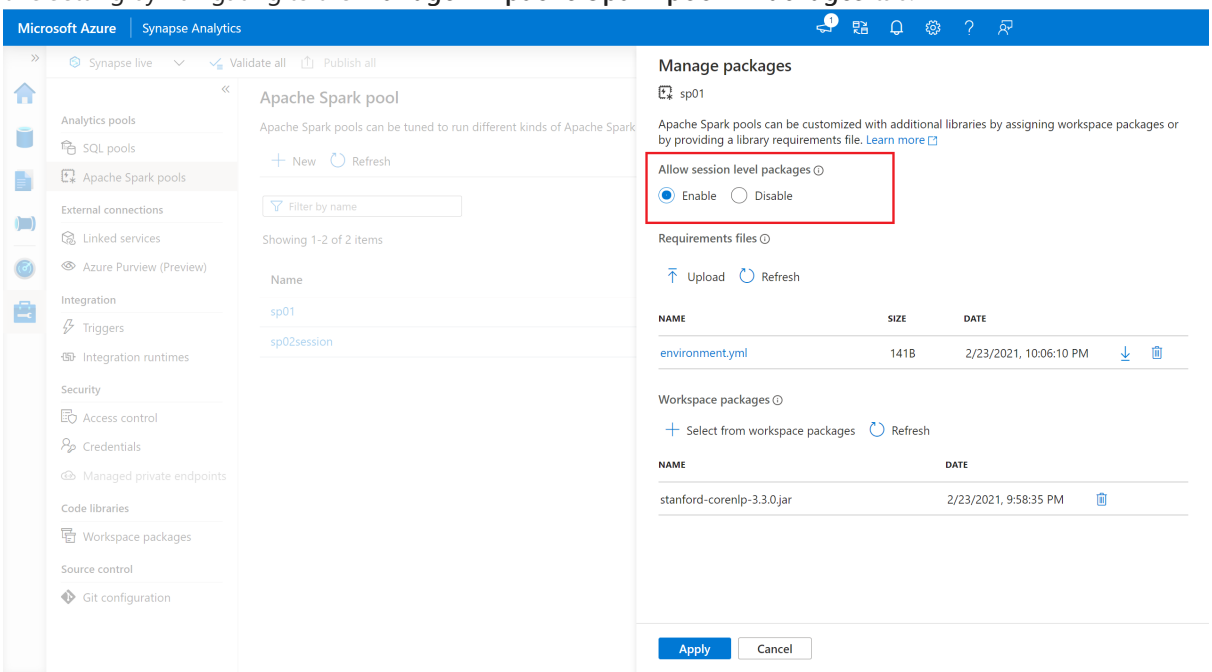
When using session-scoped libraries, it is important to keep the following points in mind:

- When you install session-scoped libraries, only the current notebook has access to the specified libraries.
- These libraries will not impact other sessions or jobs using the same Spark pool.
- These libraries are installed on top of the base runtime and pool level libraries.
- Notebook libraries will take the highest precedence.

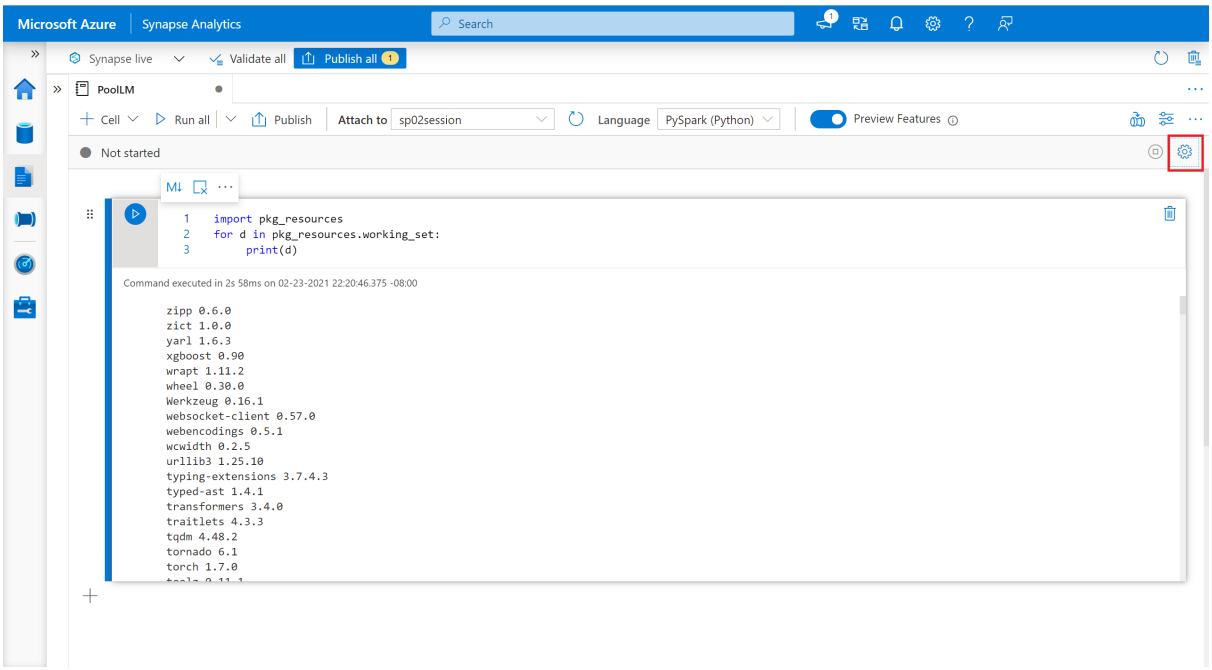
Session-scoped Python packages

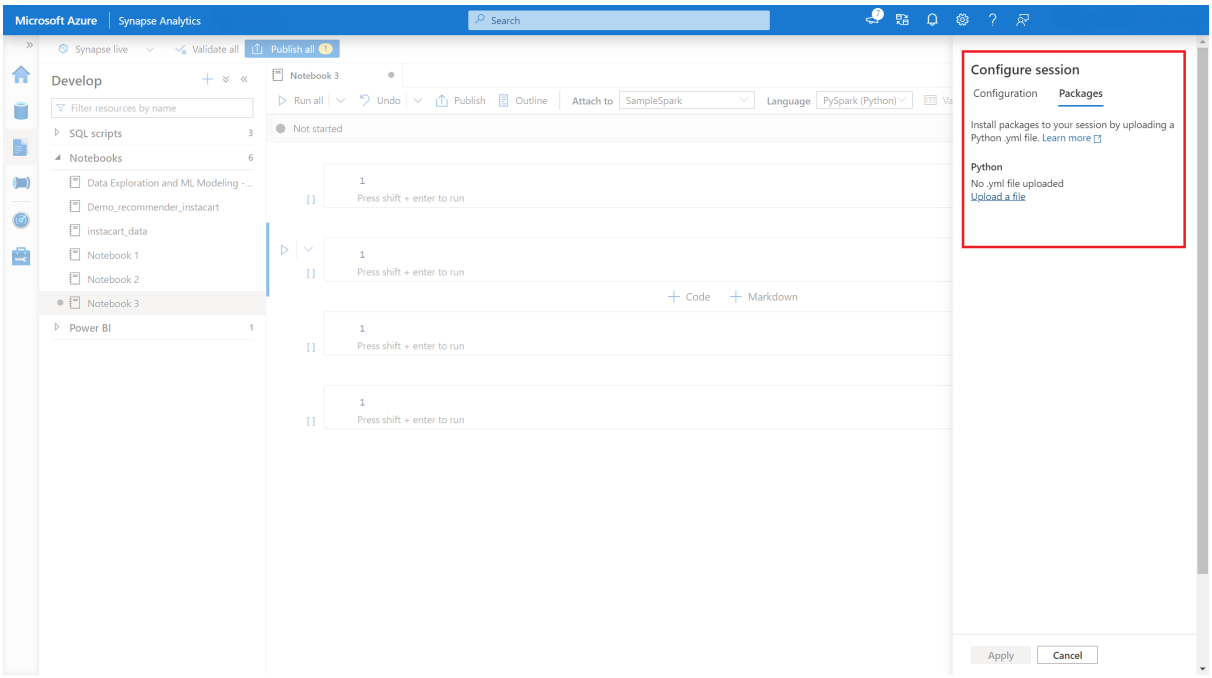
To specify session-scoped Python packages:

1. Navigate to the selected Spark pool and ensure that you have enabled session-level libraries. You can enable this setting by navigating to the **Manage** > **Apache Spark pool** > **Packages** tab.



2. Once the setting has been applied, you can open a notebook and select **Configure Session** > **Packages**.





3. Here, you can upload a Conda *environment.yml* file to install or upgrade packages within a session. Once you start your session, the specified libraries will be installed. Once your session ends, these libraries will no longer be available as they are specific to your session.

Verify installed libraries

To verify if the correct versions of the correct libraries are installed from PyPI, run the following code:

```
import pkg_resources
for d in pkg_resources.working_set:
     print(d)
```

In some cases, to view the package versions from Conda, you may need to inspect the package version individually.

Session-scoped Java or Scala packages

To specify session-scoped Java or Scala packages, you can use the `%%configure` option:

```
%%configure -f
{
    "conf": {
        "spark.jars": "abfss://<<file system>>@<<storage account>.dfs.core.windows.net/<<path to JAR
file>>",
    }
}
```

We recommend you to run the %%configure at the beginning of your notebook. You can refer to this document for the full list of valid parameters.

Next steps

- View the default libraries: Apache Spark version support
- Manage the packages outside Synapse Studio portal: Manage packages through Az commands and REST APIs

Troubleshoot library installation errors

8/19/2022 • 5 minutes to read • Edit Online

To make third party or locally built code available to your applications, you can install a library onto one of your serverless Apache Spark pools. The packages listed in the requirements.txt file are downloaded from PyPi at the time of pool startup. This requirements file is used every time a Spark instance is created from that Spark pool. Once a library is installed for a Spark pool, it's available for all sessions using the same pool.

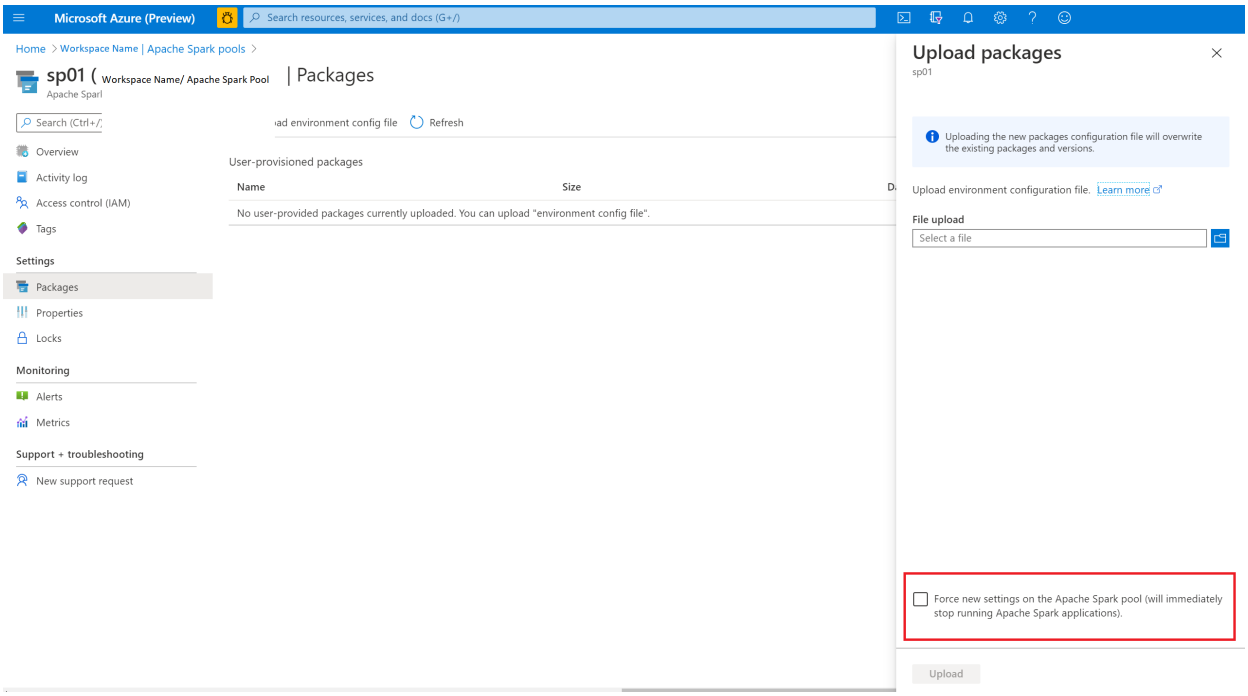
In some cases, you may find that a library isn't appearing in your Apache Spark pool. This case often occurs when there's an error in the provided requirements.txt or specified libraries. When an error occurs in the library installation process, the Apache Spark pool will revert back to libraries specified in the Synapse base runtime.

The goal of this document is to provide common issues and to help you debug library installation errors.

Force update your Apache Spark pool

When you update the libraries in your Apache Spark pool, these changes will be picked up once the pool has restarted. If you have active jobs, these jobs will continue to run on the original version of the spark pool.

You can force the changes to apply by selecting the option to **Force new settings**. This setting will end the all current sessions for the selected Spark pool. Once the sessions are ended, you'll have to wait for the pool to restart.



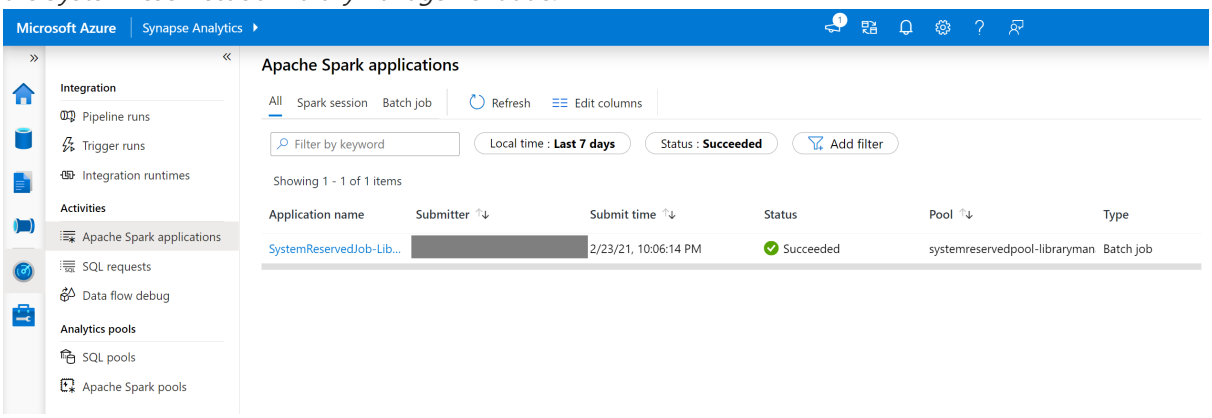
Track installation progress

A system reserved Spark job is started each time a pool is updated with a new set of libraries. This Spark job helps monitor the status of the library installation. If the installation fails because of library conflicts or other issues, the Spark pool will revert to its previous or default state.

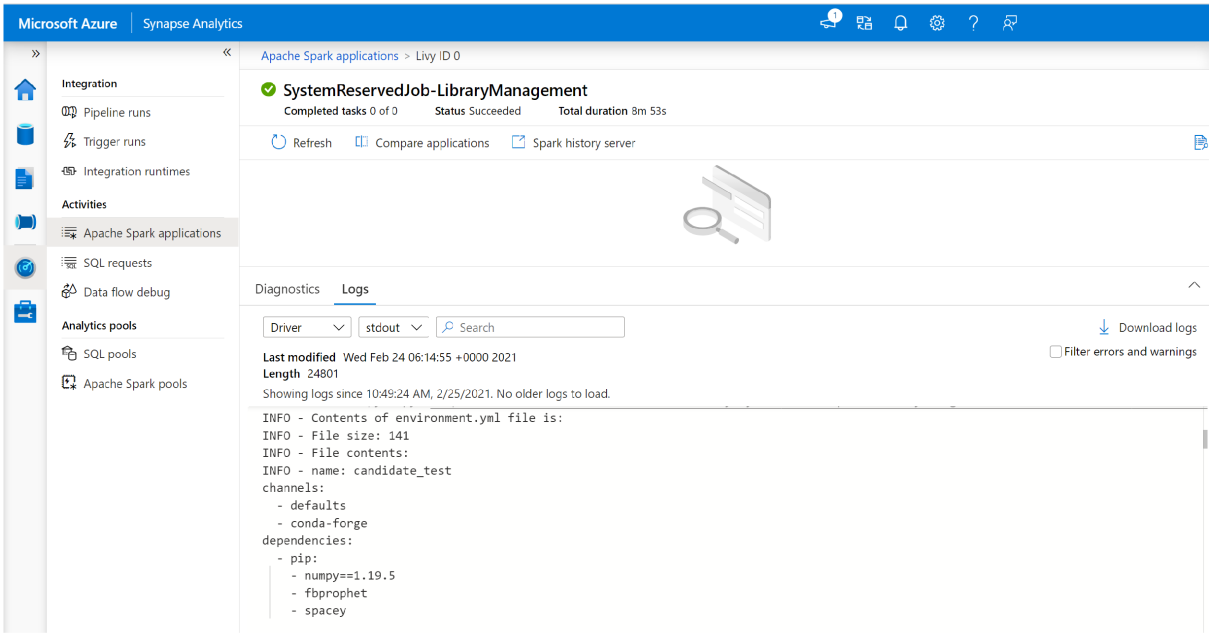
In addition, users can also inspect the installation logs to identify dependency conflicts or see which libraries were installed during the pool update.

To view these logs:

1. Navigate to the Spark applications list in the **Monitor** tab.
2. Select the system Spark application job that corresponds to your pool update. These system jobs run under the *SystemReservedJob-LibraryManagement* title.



3. Switch to view the **driver** and **stdout** logs.
4. Within the results, you'll see the logs related to the installation of your packages.

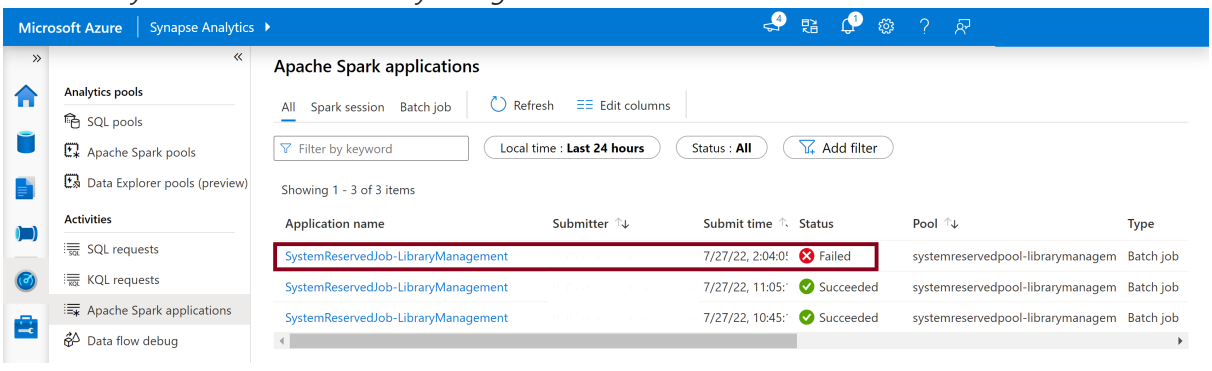


Track installation failures

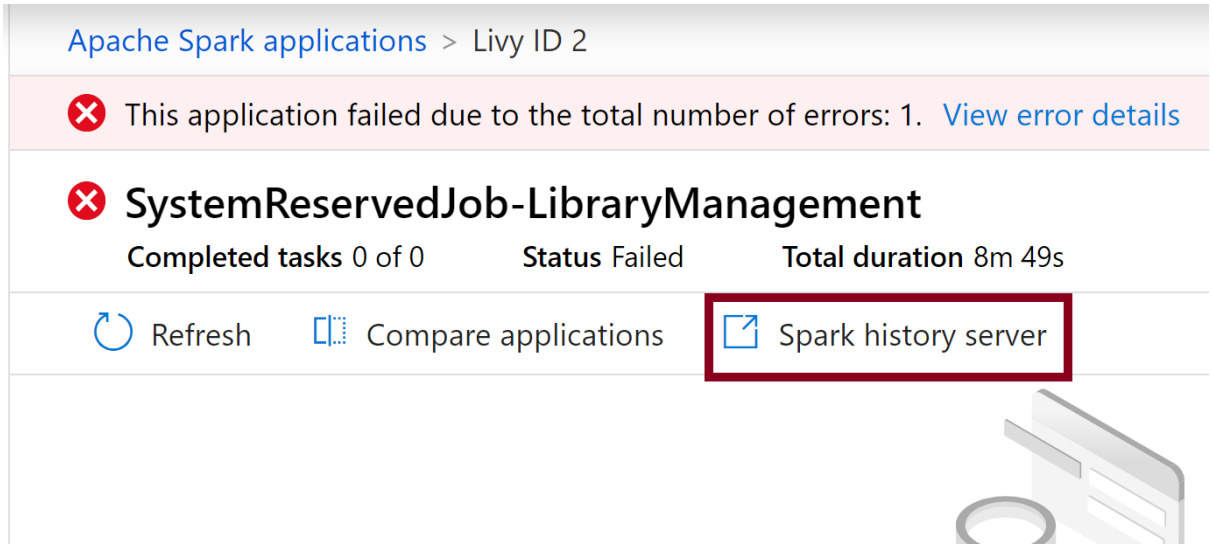
In certain cases, users can also inspect the full installation logs available in the Spark History Server to identify complicated dependency conflicts. The logs available through the Spark UI could be truncated and accessing the full installation logs through the Spark History Server would be useful in complex library installation scenarios.

To view the full installation logs:

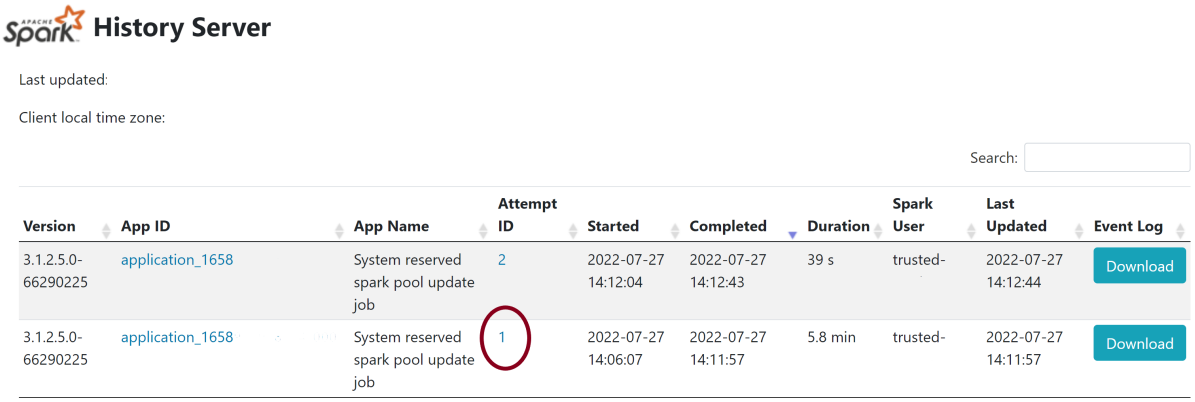
1. Navigate to the Spark applications list in the **Monitor** tab.
2. Select the system Spark application job that corresponds to the failed pool update. These system jobs run under the *SystemReservedJob-LibraryManagement* title.



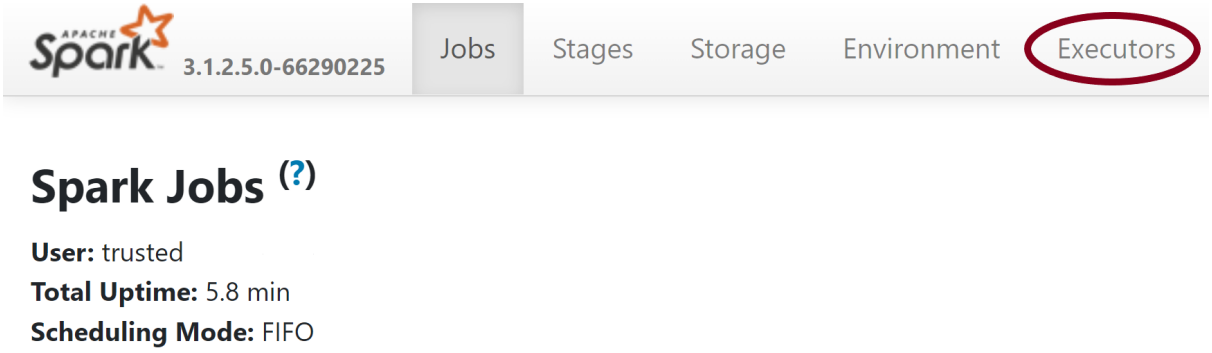
3. Select the highlighted **Spark history server** option which would open the Spark history server details page in a new tab.



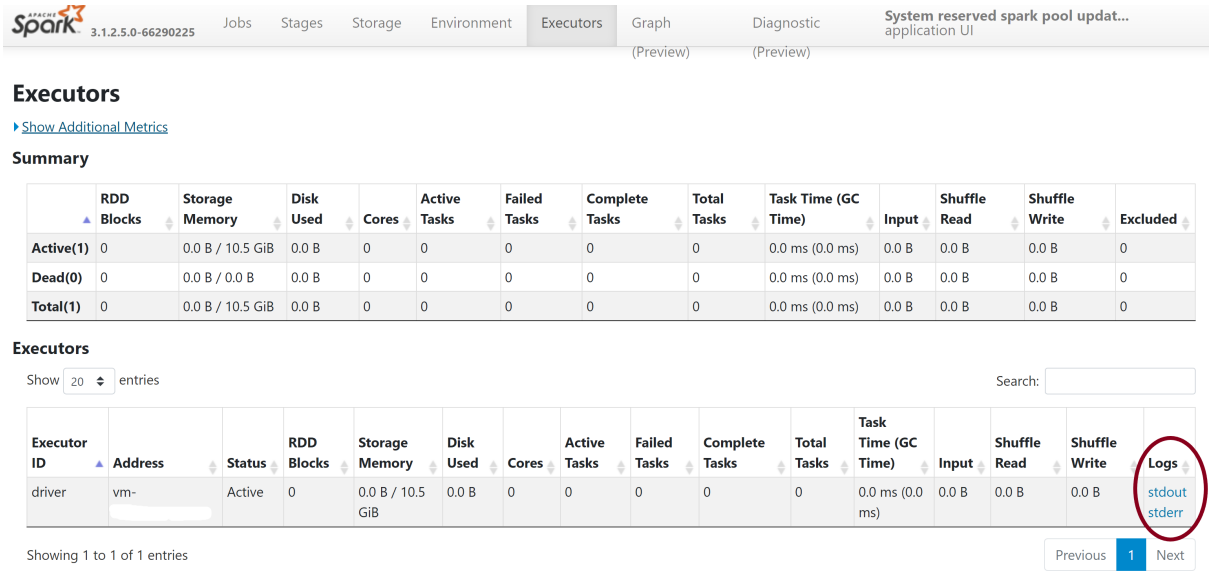
4. In this page, you will see 2 attempts, select **Attempt 1** as shown below.



5. On the top navigation bar in the Spark history server page, switch to the **Executors** tab.



6. Download the **stdout** and **stderr** log files to access the full library management output and error logs.



Validate your permissions

To install and update libraries, you must have the **Storage Blob Data Contributor** or **Storage Blob Data Owner** permissions on the primary Azure Data Lake Storage Gen2 Storage account that is linked to the Azure Synapse Analytics workspace.

To validate that you have these permissions, you can run the following code:

```
from pyspark.sql.types import StructType,StructField, StringType, IntegerType
data2 = [("James","Smith","Joe","4355","M",3000),
    ("Michael","Rose","Edward","40288","F",4000)
  ]

schema = StructType([ \
    StructField("firstname",StringType(),True), \
    StructField("middlename",StringType(),True), \
    StructField("lastname",StringType(),True), \
    StructField("id", StringType(), True), \
    StructField("gender", StringType(), True), \
    StructField("salary", IntegerType(), True) \
  ])

df = spark.createDataFrame(data=data2,schema=schema)

df.write.csv("abfss://<<ENTER NAME OF FILE SYSTEM>>@<<ENTER NAME OF PRIMARY STORAGE
ACCOUNT>>.dfs.core.windows.net/validate_permissions.csv")
```

If you receive an error, you are likely missing the required permissions. To learn how to obtain the required permissions, visit this document: Assign Storage Blob Data Contributor or Storage Blob Data Owner permissions.

In addition, if you are running a Pipeline, then the Workspace MSI must have Storage Blob Data Owner or Storage Blob Data Contributor permissions as well. To learn how to grant your workspace identity this permission, visit: Grant permissions to workspace managed identity.

Check the environment configuration file

An environment configuration file can be used to upgrade the Conda environment. This acceptable file formats for Python pool management are listed as Environment Specifications.

It is important to note the following restrictions:

- The contents of the requirements file must not include extra blank lines or characters.
- The Synapse Runtime includes a set of libraries that are pre-installed onto every serverless Apache Spark pool. Packages that come pre-installed onto the base runtime cannot be removed or uninstalled.
- Altering the PySpark, Python, Scala/Java, .NET, or Spark version is not supported.
- Python session-scoped libraries only accepts files with a YML extension.

Validate wheel files

The Synapse serverless Apache Spark pools are based off the Linux distribution. When downloading and installing Wheel files directly from PyPI, be sure to select the version that is built on Linux and runs on the same Python version as the Spark pool.

> **IMPORTANT**
> Custom packages can be added or modified between sessions. However, you'll need to wait for the pool and session to restart to see the updated package.

Check for dependency conflicts

In general, Python dependency resolution can be tricky to manage. To help debug dependency conflicts locally, you can create your own virtual environment based off the Synapse Runtime and validate your changes.

To recreate the environment and validate your updates:

1. Download the template to locally recreate the Synapse runtime. There may be slight differences between the template and the actual Synapse environment.
2. Create a virtual environment using the following instructions. This environment allows you to create an isolated Python installation with the specified list of libraries.

   ```
   conda myenv create -f environment.yml
   conda activate myenv
   ```

3. Use `pip install -r <provide your req.txt file>` to update the virtual environment with your specified packages. If the installation results in an error, then there may be a conflict between what is pre-installed in the Synapse base runtime and what is specified in the provided requirements file. These dependency conflicts must be resolved in order to get the updated libraries on your serverless Apache Spark pool.

> **IMPORTANT**
> Issues may arrise when using pip and conda together. When combining pip and conda, it's best to follow these recommended best practices.

Create a custom Conda channel for package management

8/19/2022 • 3 minutes to read • Edit Online

When installing Python packages, the Conda package manager uses channels to look for packages. You may need to create a custom Conda channel for various reasons. For example, you may find that:

- your workspace is data exfiltration protected and outbound connections are blocked.
- you have packages that you don't want to upload to public repositories.
- you want to set up an alternate repository for the users within your workspace.

In this article, we'll provide a step-by-step guide to help you create your custom Conda channel within your Azure Data Lake Storage account.

Set up your local machine

1. Install Conda on your local machine.You can refer to the Azure Synapse Spark runtime to identify the Conda version that is used on the same runtime.

2. To create a custom channel, install conda-build.

```
conda install conda-build
```

3. Organize all the packages in for the platform you want to serve. In this example, we will install Anaconda archive on your local machine.

```
sudo wget https://repo.continuum.io/archive/Anaconda3-4.4.0-Linux-x86_64.sh
sudo chmod +x Anaconda3-4.4.0-Linux-x86_64.sh
sudo bash Anaconda3-4.4.0-Linux-x86_64.sh -b -p /usr/lib/anaconda3
export PATH="/usr/lib/anaconda3/bin:$PATH"
sudo chmod 777 -R /usr/lib/anaconda3
```

4. To create a similar environment to what is created available in the Azure Synapse runtime, you may download this template. There may be slight differences between the template and the actual Azure Synapse Environment. Once downloaded, you can run the following command:

```
apt-get -yq install gcc g++
conda env update --prune -f base_environment.yml
```

Mount the storage account onto your machine

Next, we will mount the Azure Data Lake Storage Gen2 account onto your local machine. This process can also be done with a WASB account; however, we will go through an example for the ADLSg2 account

For more information on how to mount the storage account on your local machine, you can visit this page.

1. You can install blobfuse from the Linux Software Repository for Microsoft products.

```
wget https://packages.microsoft.com/config/ubuntu/16.04/packages-microsoft-prod.deb
sudo dpkg -i packages-microsoft-prod.deb
sudo apt-get update
sudo apt-get install blobfuse fuse
export AZURE_STORAGE_ACCOUNT=<storage-account-name>
export AZURE_STORAGE_SAS_TOKEN="<SAS>"
export AZURE_STORAGE_BLOB_ENDPOINT=*.dfs.core.windows.net
```

2. Create your mountpoint (`mkdir /path/to/mount`) and mount a Blob container with blobfuse. In this example, let's use the value **privatechannel** for the **mycontainer** variable.

```
sudo mkdir /home/trusted-service-user/privatechannel
sudo mkdir -p /mnt/blobfusetmp
blobfuse /home/trusted-service-user/privatechannel --container-name=privatechannel --tmp-
path=/mnt/blobfusetmp --use-adls=true --log-level=LOG_DEBUG
sudo chown trusted-service-user /mnt/blobfusetmp
```

Create the channel

In the next set of steps, we will create a custom Conda channel.

1. On your local machine, create a directory to organize all the packages for your custom channel. Organize all the `tar.bz2` packages from https://repo.anaconda.com/pkgs/main/linux-64/ into the subdirectory. Be sure to also include all dependent tar.bz2 packages as well.

```
cd ~/privatechannel/
mkdir -p channel/linux64

<Add all .tar.bz2 from https://repo.anaconda.com/pkgs/main/linux-64/>
// Note: Add all dependent .tar.bz2 as well

cd channel
mkdir noarch
echo '{}' > noarch/repodata.json
bzip2 -k noarch/repodata.json

// Create channel
conda index channel/noarch
conda index channel/linux-64
conda index channel
```

2. Now, you may check the storage account where your `privatechannel/channel` directory would have been created.

> **NOTE**
> Conda does not honor the SAS token associated to a container. Therefore, you must mark the container "privatechannel" as public access.

For more information, you can also visit the Conda user guide to creating custom channels.

Storage account permissions

Now, we will need to validate the permissions on the storage account. To set these permissions, navigate to the path where custom channel will be created. Then, create a SAS token for `privatechannel` that has read, list, and

execute permissions.

The channel name will now be the blob SAS URL that is generated from this process.

Create a sample Conda environment configuration file

Last, verify the installation process by creating a sample Conda `environment.yml` file. If you have in a data exfiltration protection enabled workspace, you must specify the `nodefaults` channel in your environment file.

Here is an example Conda configuration file:

```
name: sample
channels:
  - https://<<storage account name>>.blob.core.windows.net/privatechannel/channel?<<SAS Token>
  - nodefaults
dependencies:
  - openssl
  - ncurses
```

Once you've created the sample Conda file, you can create a virtual Conda environment. You can verify this locally by running the following commands:

```
conda env create --file sample.yml
source activate env
conda list
```

Now that you've verified your custom channel, you can use the Python pool management process to update the libraries on your Apache Spark pool.

Next steps

Manage packages outside Synapse Analytics Studio UIs

8/19/2022 • 2 minutes to read • Edit Online

You may want to manage your libraries for your serverless Apache Spark pools without going into the Synapse Analytics UI pages. For example, you may find that:

- you develop a custom package and want to upload it to your workspace and use it in your Spark pool. And you want to finish the steps on your local tools without visiting the package management UIs.
- you are updating your packages through the CI/CD process

In this article, we'll provide a general guide to help you managing libraries through Azure PowerShell cmdlets or REST APIs.

Manage packages through Azure PowerShell cmdlets

Add new libraries

1. New-AzSynapseWorkspacePackage command can be used to **upload new libraries to workspace**.

```
New-AzSynapseWorkspacePackage -WorkspaceName ContosoWorkspace -Package ".\ContosoPackage.whl"
```

2. The combination of New-AzSynapseWorkspacePackage and Update-AzSynapseSparkPool commands can be used to **upload new libraries to workspace** and **attach the library to a Spark pool**.

```
$package = New-AzSynapseWorkspacePackage -WorkspaceName ContosoWorkspace -Package
".\ContosoPackage.whl"
Update-AzSynapseSparkPool -WorkspaceName ContosoWorkspace -Name ContosoSparkPool -PackageAction Add -
Package $package
```

3. If you want to attach an **existing workspace library** to your Spark pool, please refer to the command combination of Get-AzSynapseWorkspacePackage and Update-AzSynapseSparkPool.

```
$packages = Get-AzSynapseWorkspacePackage -WorkspaceName ContosoWorkspace
Update-AzSynapseSparkPool -WorkspaceName ContosoWorkspace -Name ContosoSparkPool -PackageAction Add -
Package $packages
```

Remove libraries

1. In order to **remove a installed package** from your Spark pool, please refer to the command combination of Get-AzSynapseWorkspacePackage and Update-AzSynapseSparkPool.

```
$package = Get-AzSynapseWorkspacePackage -WorkspaceName ContosoWorkspace -Name ContosoPackage
Update-AzSynapseSparkPool -WorkspaceName ContosoWorkspace -Name ContosoSparkPool -PackageAction
Remove -Package $package
```

2. You can also retrieve a Spark pool and **remove all attached workspace libraries** from the pool by calling Get-AzSynapseSparkPool and Update-AzSynapseSparkPool commands.

```
$pool = Get-AzSynapseSparkPool -ResourceGroupName ContosoResourceGroup -WorkspaceName
ContosoWorkspace -Name ContosoSparkPool
$pool | Update-AzSynapseSparkPool -PackageAction Remove -Package $pool.WorkspacePackages
```

For more Azure PowerShell cmdlets capabilities, please refer to Azure PowerShell cmdlets for Azure Synapse Analytics.

Manage packages through REST APIs

Manage the workspace packages

With the ability of REST APIs, you can add/delete packages or list all uploaded files of your workspace. See the full supported APIs, please refer to Overview of workspace library APIs.

Manage the Spark pool packages

You can leverage the Spark pool REST API to attach or remove your custom or open source libraries to your Spark pools.

1. For custom libraries, please specify the list of custom files as the **customLibraries** property in request body.

```
"customLibraries": [
    {
        "name": "samplejartestfile.jar",
        "path": "<workspace-name>/libraries/<jar-name>.jar",
        "containerName": "prep",
        "uploadedTimestamp": "1970-01-01T00:00:00Z",
        "type": "jar"
    }
]
```

2. You can also update your Spark pool libraries by specifying the **libraryRequirements** property in request body.

```
"libraryRequirements": {
      "content": "",
      "filename": "requirements.txt"
}
```

Next steps

- View the default libraries: Apache Spark version support
- Manage Spark pool level packages through Synapse Studio portal: Python package management on Notebook Session

Create, develop, and maintain Synapse notebooks in Azure Synapse Analytics

8/19/2022 • 19 minutes to read • Edit Online

A Synapse notebook is a web interface for you to create files that contain live code, visualizations, and narrative text. Notebooks are a good place to validate ideas and use quick experiments to get insights from your data. Notebooks are also widely used in data preparation, data visualization, machine learning, and other Big Data scenarios.

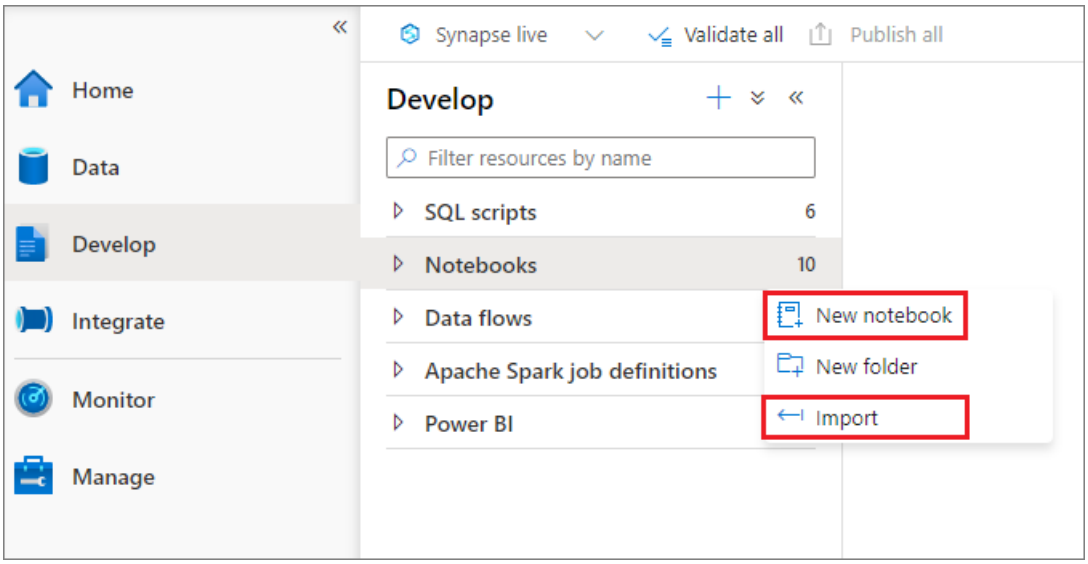
With a Synapse notebook, you can:

- Get started with zero setup effort.
- Keep data secure with built-in enterprise security features.
- Analyze data across raw formats (CSV, txt, JSON, etc.), processed file formats (parquet, Delta Lake, ORC, etc.), and SQL tabular data files against Spark and SQL.
- Be productive with enhanced authoring capabilities and built-in data visualization.

This article describes how to use notebooks in Synapse Studio.

Create a notebook

There are two ways to create a notebook. You can create a new notebook or import an existing notebook to a Synapse workspace from the **Object Explorer**. Synapse notebooks recognize standard Jupyter Notebook IPYNB files.



Develop notebooks

Notebooks consist of cells, which are individual blocks of code or text that can be run independently or as a group.

We provide rich operations to develop notebooks:

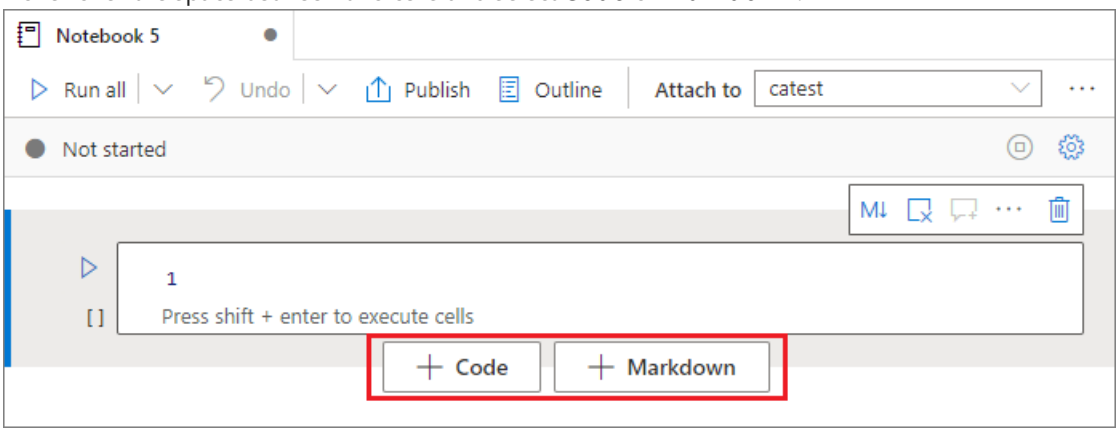
- Add a cell
- Set a primary language
- Use multiple languages

- Use temp tables to reference data across languages
- IDE-style IntelliSense
- Code Snippets
- Format text cell with toolbar buttons
- Undo/Redo cell operation
- Code cell commenting
- Move a cell
- Delete a cell
- Collapse a cell input
- Collapse a cell output
- Notebook outline

Add a cell

There are multiple ways to add a new cell to your notebook.

1. Hover over the space between two cells and select **Code** or **Markdown**.



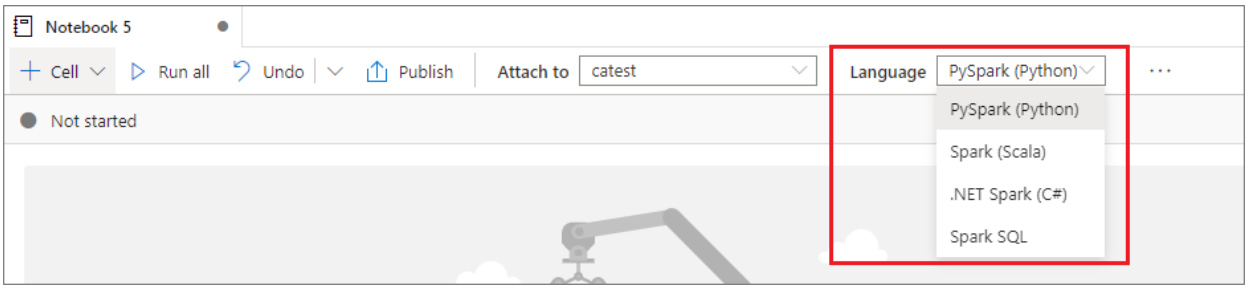
2. Use aznb Shortcut keys under command mode. Press **A** to insert a cell above the current cell. Press **B** to insert a cell below the current cell.

Set a primary language

Synapse notebooks support four Apache Spark languages:

- PySpark (Python)
- Spark (Scala)
- Spark SQL
- .NET Spark (C#)

You can set the primary language for new added cells from the dropdown list in the top command bar.

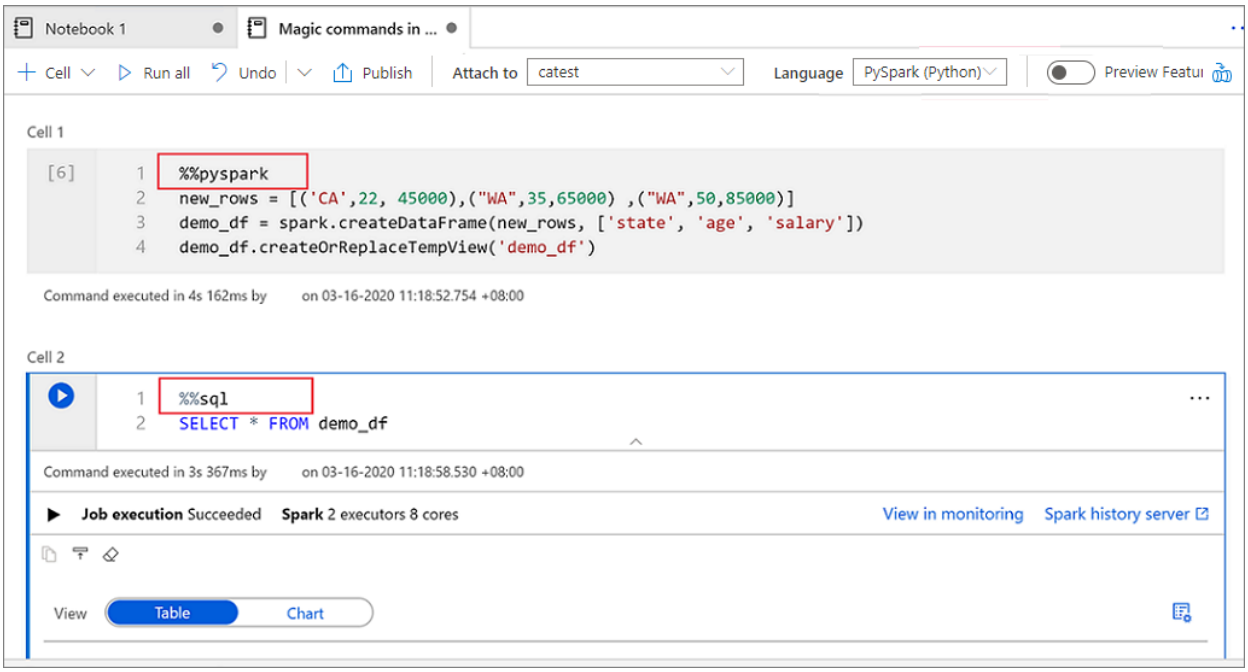


Use multiple languages

You can use multiple languages in one notebook by specifying the correct language magic command at the beginning of a cell. The following table lists the magic commands to switch cell languages.

MAGIC COMMAND	LANGUAGE	DESCRIPTION
%%pyspark	Python	Execute a **Python** query against Spark Context.
%%spark	Scala	Execute a **Scala** query against Spark Context.
%%sql	SparkSQL	Execute a **SparkSQL** query against Spark Context.
%%csharp	.NET for Spark C#	Execute a **.NET for Spark C#** query against Spark Context.

The following image is an example of how you can write a PySpark query using the **%%pyspark** magic command or a SparkSQL query with the **%%sql** magic command in a **Spark(Scala)** notebook. Notice that the primary language for the notebook is set to pySpark.



Use temp tables to reference data across languages

You cannot reference data or variables directly across different languages in a Synapse notebook. In Spark, a temporary table can be referenced across languages. Here is an example of how to read a `Scala` DataFrame in `PySpark` and `SparkSQL` using a Spark temp table as a workaround.

1. In Cell 1, read a DataFrame from a SQL pool connector using Scala and create a temporary table.

```
%%spark
val scalaDataFrame = spark.read.sqlanalytics("mySQLPoolDatabase.dbo.mySQLPoolTable")
scalaDataFrame.createOrReplaceTempView( "mydataframetable" )
```

2. In Cell 2, query the data using Spark SQL.

```
%%sql
SELECT * FROM mydataframetable
```

3. In Cell 3, use the data in PySpark.

```
%%pyspark
myNewPythonDataFrame = spark.sql("SELECT * FROM mydataframetable")
```

IDE-style IntelliSense

Synapse notebooks are integrated with the Monaco editor to bring IDE-style IntelliSense to the cell editor. Syntax highlight, error marker, and automatic code completions help you to write code and identify issues quicker.

The IntelliSense features are at different levels of maturity for different languages. Use the following table to see what's supported.

LANGUAGES	SYNTAX HIGHLIGHT	SYNTAX ERROR MARKER	SYNTAX CODE COMPLETION	VARIABLE CODE COMPLETION	SYSTEM FUNCTION CODE COMPLETION	USER FUNCTION CODE COMPLETION	SMART INDENT	CODE FOLDING
PySpark (Python)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Spark (Scala)	Yes	Yes	Yes	Yes	Yes	Yes	-	Yes
SparkSQL	Yes	Yes	Yes	Yes	Yes	-	-	-
.NET for Spark (C#)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

> **NOTE**
> An active Spark session is required to benefit the Variable Code Completion, System Function Code Completion, User Function Code Completion for .NET for Spark (C#).

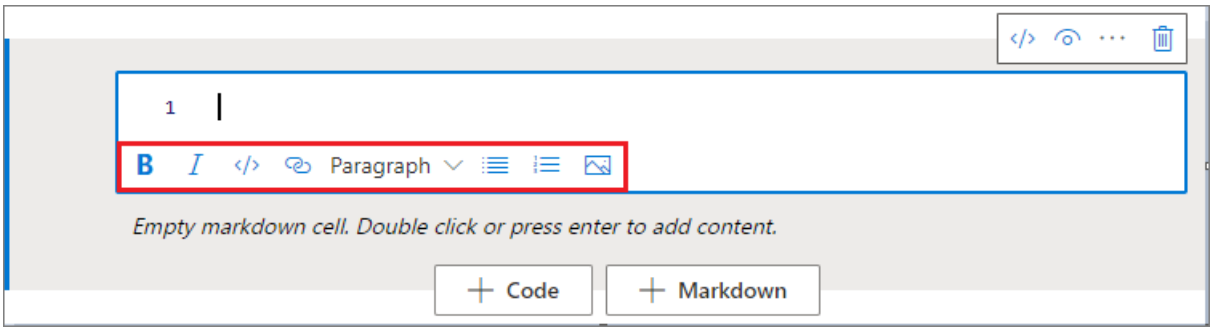
Code Snippets

Synapse notebooks provide code snippets that make it easier to enter common used code patterns, such as configuring your Spark session, reading data as a Spark DataFrame, or drawing charts with matplotlib etc.

Snippets appear in Shortcut keys of IDE style IntelliSense mixed with other suggestions. The code snippets contents align with the code cell language. You can see available snippets by typing **Snippet** or any keywords appear in the snippet title in the code cell editor. For example, by typing **read** you can see the list of snippets to read data from various data sources.

Format text cell with toolbar buttons

You can use the format buttons in the text cells toolbar to do common markdown actions. It includes bolding text, italicizing text, paragraph/headers through a dropdown, inserting code, inserting unordered list, inserting ordered list, inserting hyperlink and inserting image from URL.



Undo/Redo cell operation

Select the **Undo** / **Redo** button or press **Z** / **Shift+Z** to revoke the most recent cell operations. Now you can undo/redo up to the latest 10 historical cell operations.

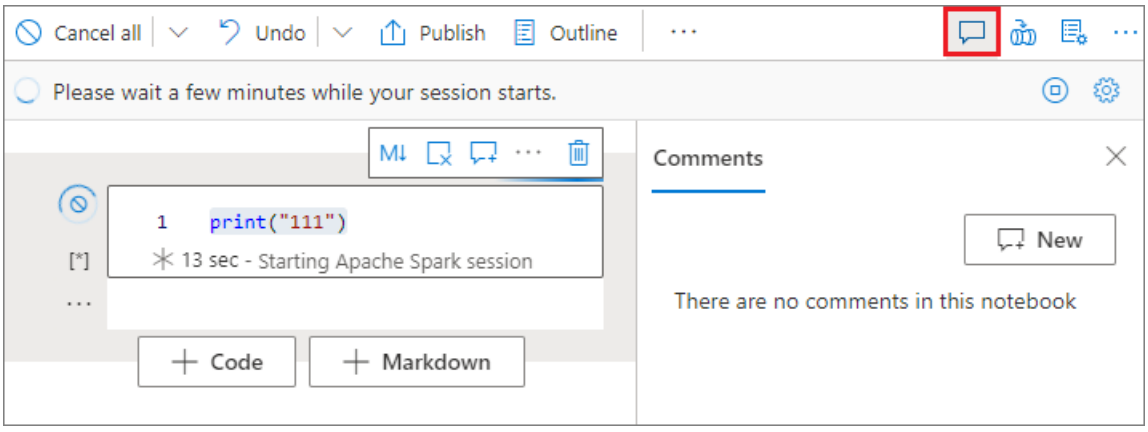
Supported undo cell operations:

- Insert/Delete cell: You could revoke the delete operations by selecting **Undo**, the text content will be kept along with the cell.
- Reorder cell.
- Toggle parameter.
- Convert between Code cell and Markdown cell.

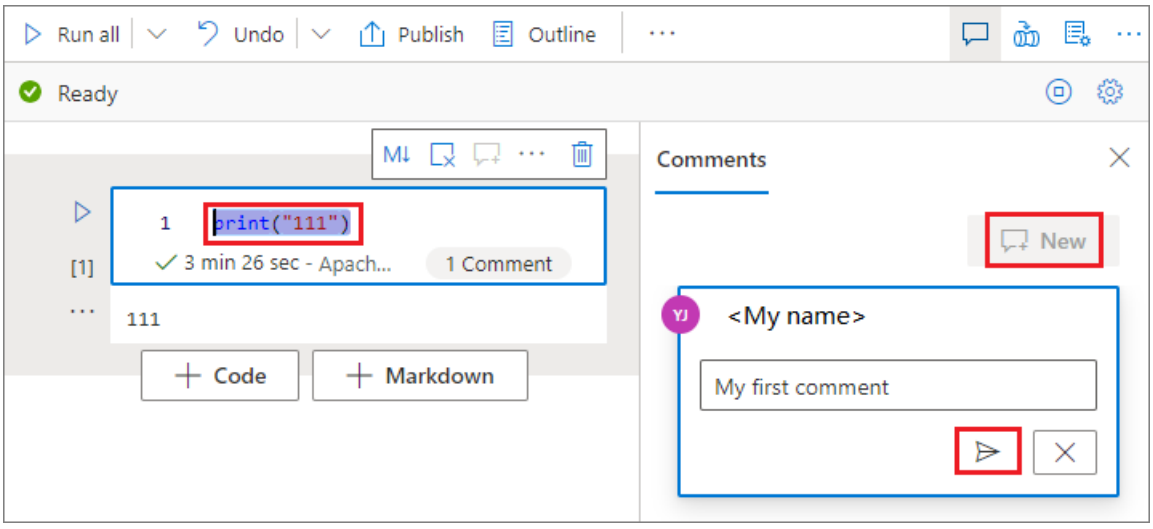
> **NOTE**
> In-cell text operations and code cell commenting operations are not undoable. Now you can undo/redo up to the latest 10 historical cell operations.

Code cell commenting

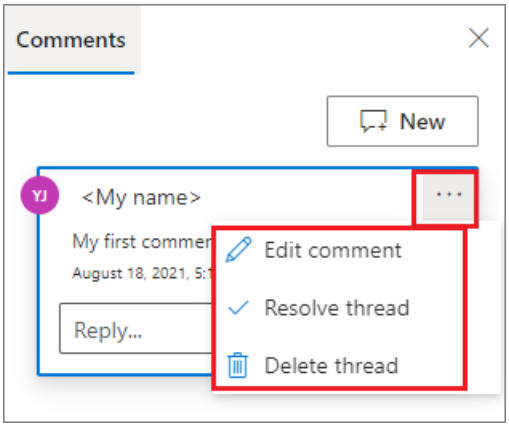
1. Select **Comments** button on the notebook toolbar to open **Comments** pane.



2. Select code in the code cell, click **New** in the **Comments** pane, add comments then click **Post comment** button to save.

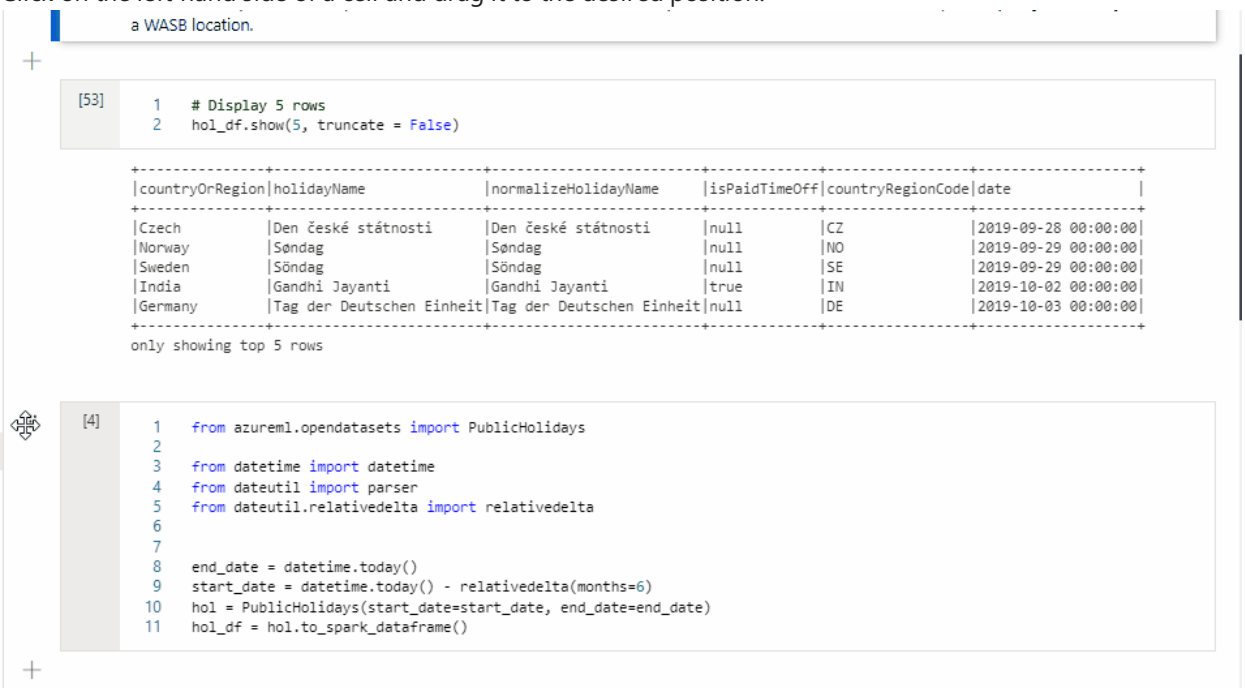


3. You could perform **Edit comment**, **Resolve thread**, or **Delete thread** by clicking the **More** button besides your comment.



Move a cell

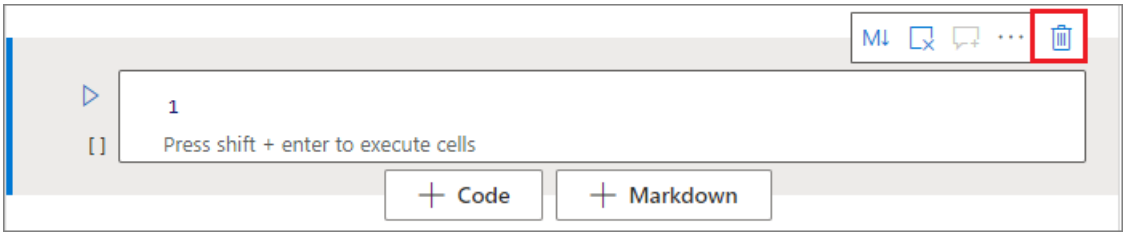
Click on the left-hand side of a cell and drag it to the desired position.



Delete a cell

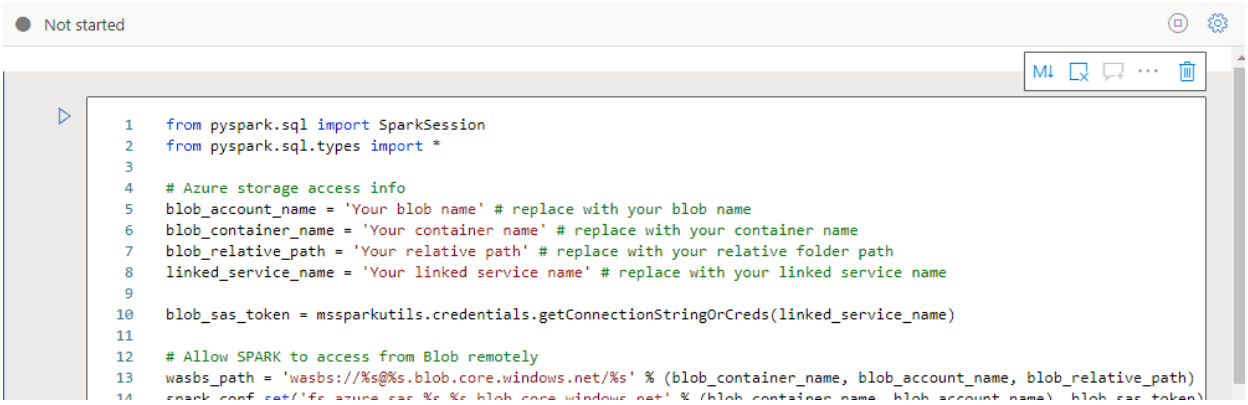
To delete a cell, select the delete button at the right hand of the cell.

You can also use shortcut keys under command mode. Press **Shift+D** to delete the current cell.



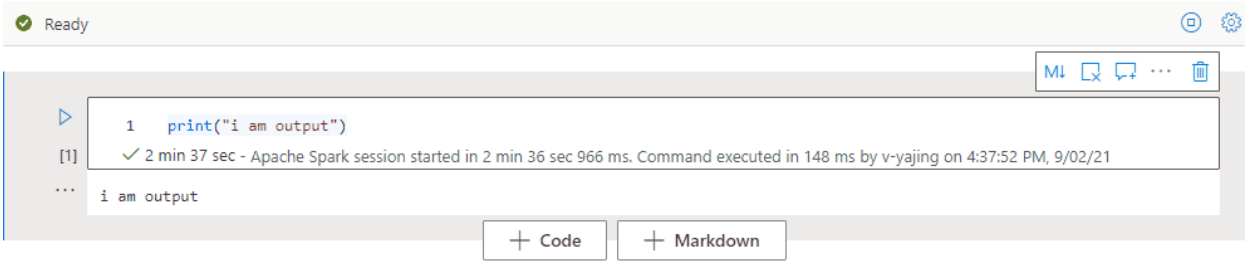
Collapse a cell input

Select the **More commands** ellipses (...) on the cell toolbar and **Hide input** to collapse current cell's input. To expand it, Select the **Show input** while the cell is collapsed.



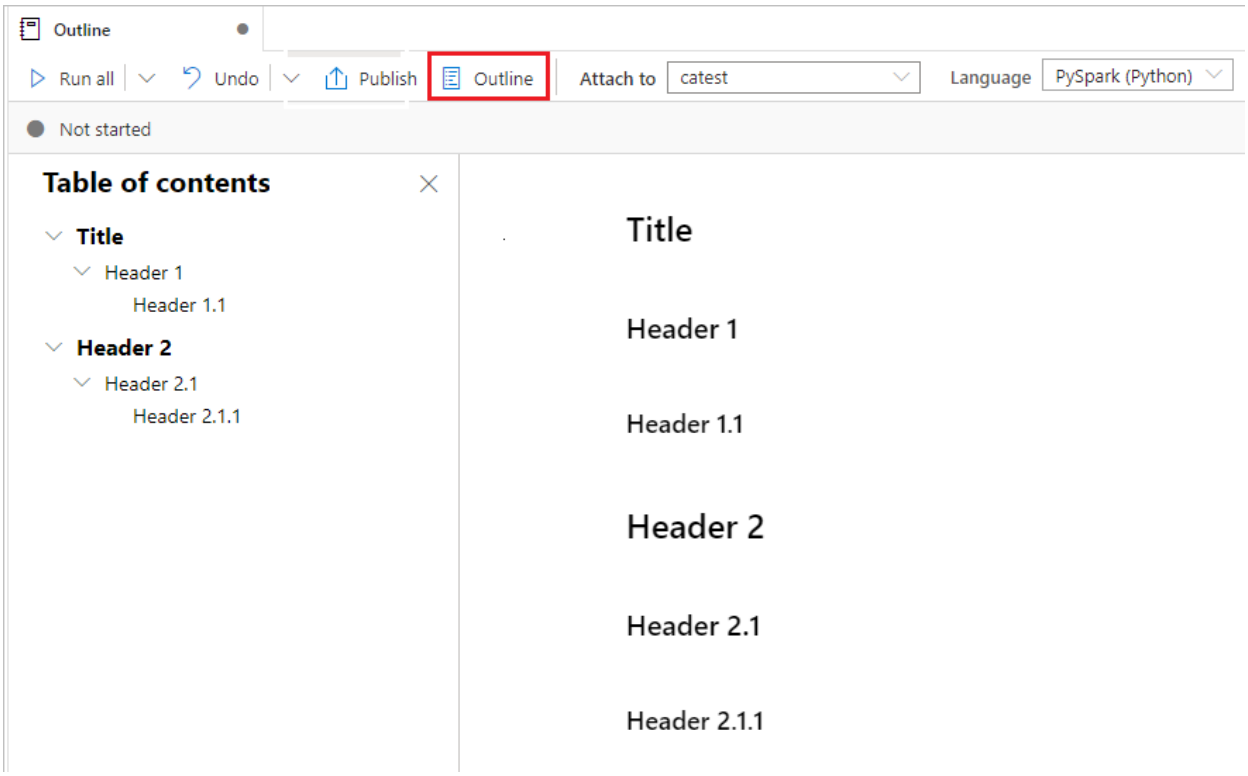
Collapse a cell output

Select the **More commands** ellipses (...) on the cell toolbar and **Hide output** to collapse current cell's output. To expand it, select the **Show output** while the cell's output is hidden.



Notebook outline

The Outlines (Table of Contents) presents the first markdown header of any markdown cell in a sidebar window for quick navigation. The Outlines sidebar is resizable and collapsible to fit the screen in the best ways possible. You can select the **Outline** button on the notebook command bar to open or hide sidebar



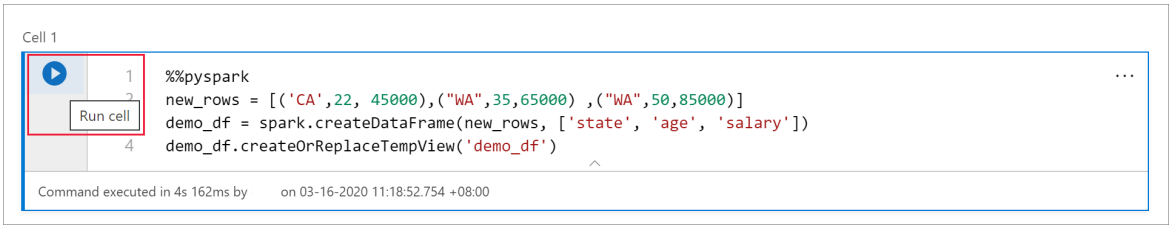
Run notebooks

You can run the code cells in your notebook individually or all at once. The status and progress of each cell is represented in the notebook.

Run a cell

There are several ways to run the code in a cell.

1. Hover on the cell you want to run and select the **Run Cell** button or press **Ctrl+Enter**.



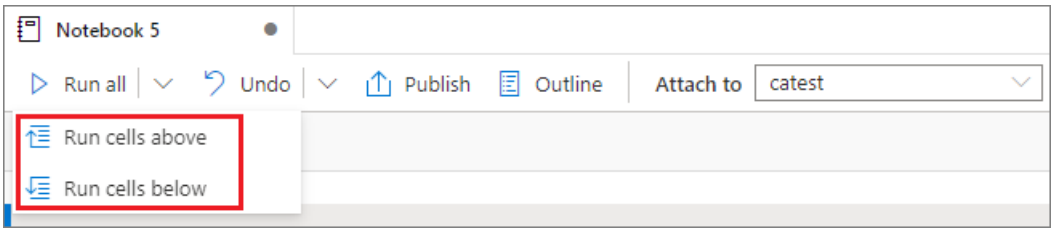
2. Use Shortcut keys under command mode. Press **Shift+Enter** to run the current cell and select the cell below. Press **Alt+Enter** to run the current cell and insert a new cell below.

Run all cells

Select the **Run All** button to run all the cells in current notebook in sequence.

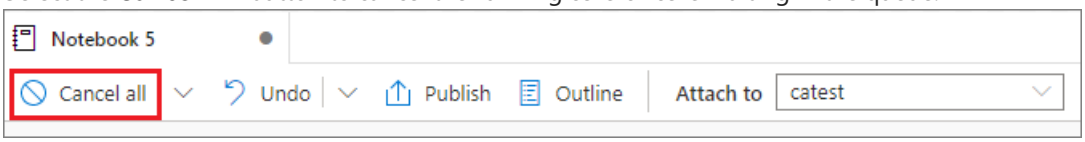
Run all cells above or below

Expand the dropdown list from **Run all** button, then select **Run cells above** to run all the cells above the current in sequence. Select **Run cells below** to run all the cells below the current in sequence.



Cancel all running cells

Select the **Cancel All** button to cancel the running cells or cells waiting in the queue.



Notebook reference

You can use `%run <notebook path>` magic command to reference another notebook within current notebook's context. All the variables defined in the reference notebook are available in the current notebook. `%run` magic command supports nested calls but not support recursive calls. You will receive an exception if the statement depth is larger than **five**.

Example:

```
%run /<path>/Notebook1 { "parameterInt": 1, "parameterFloat": 2.5, "parameterBool": true, "parameterString": "abc" }
```

.

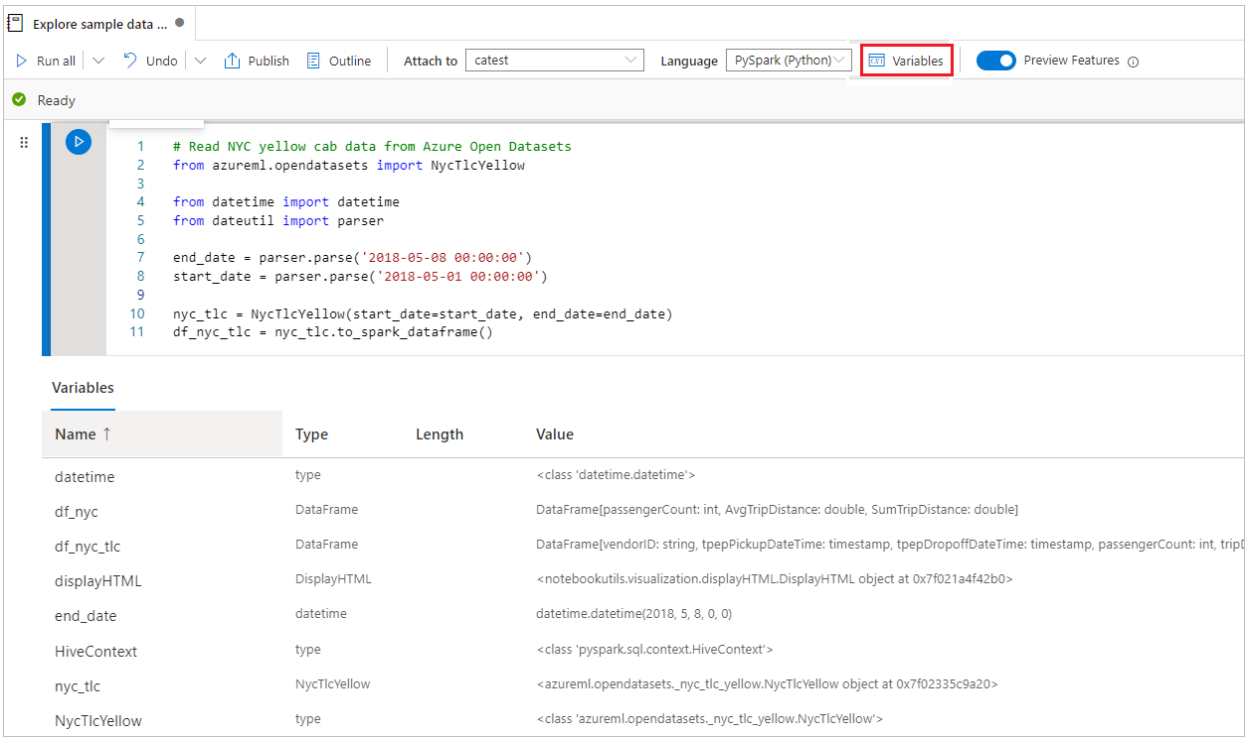
Notebook reference works in both interactive mode and Synapse pipeline.

> **NOTE**
>
> - `%run` command currently only supports to pass a absolute path or notebook name only as parameter, relative path is not supported.
> - `%run` command currently only supports to 4 parameter value types: `int`, `float`, `bool`, `string`, variable replacement operation is not supported.
> - The referenced notebooks are required to be published. You need to publish the notebooks to reference them unless Reference unpublished notebook is enabled. Synapse Studio does not recognize the unpublished notebooks from the Git repo.
> - Referenced notebooks do not support statement that depth is larger than **five**.

Variable explorer

Synapse notebook provides a built-in variables explorer for you to see the list of the variables name, type, length, and value in the current Spark session for PySpark (Python) cells. More variables will show up automatically as they are defined in the code cells. Clicking on each column header will sort the variables in the table.

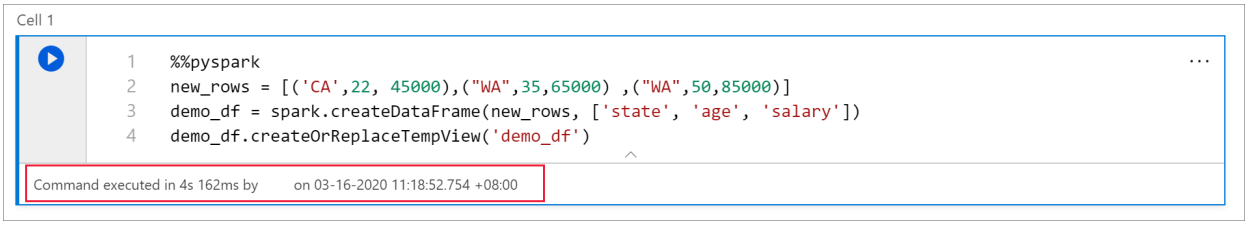
You can select the **Variables** button on the notebook command bar to open or hide the variable explorer.



> **NOTE**
>
> Variable explorer only supports python.

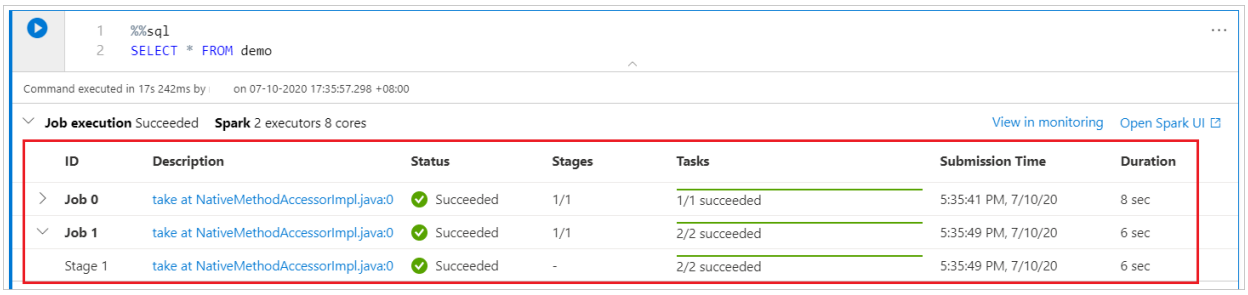
Cell status indicator

A step-by-step cell execution status is displayed beneath the cell to help you see its current progress. Once the cell run is complete, an execution summary with the total duration and end time are shown and kept there for future reference.



Spark progress indicator

Synapse notebook is purely Spark based. Code cells are executed on the serverless Apache Spark pool remotely. A Spark job progress indicator is provided with a real-time progress bar appears to help you understand the job execution status. The number of tasks per each job or stage help you to identify the parallel level of your spark job. You can also drill deeper to the Spark UI of a specific job (or stage) via selecting the link on the job (or stage) name.

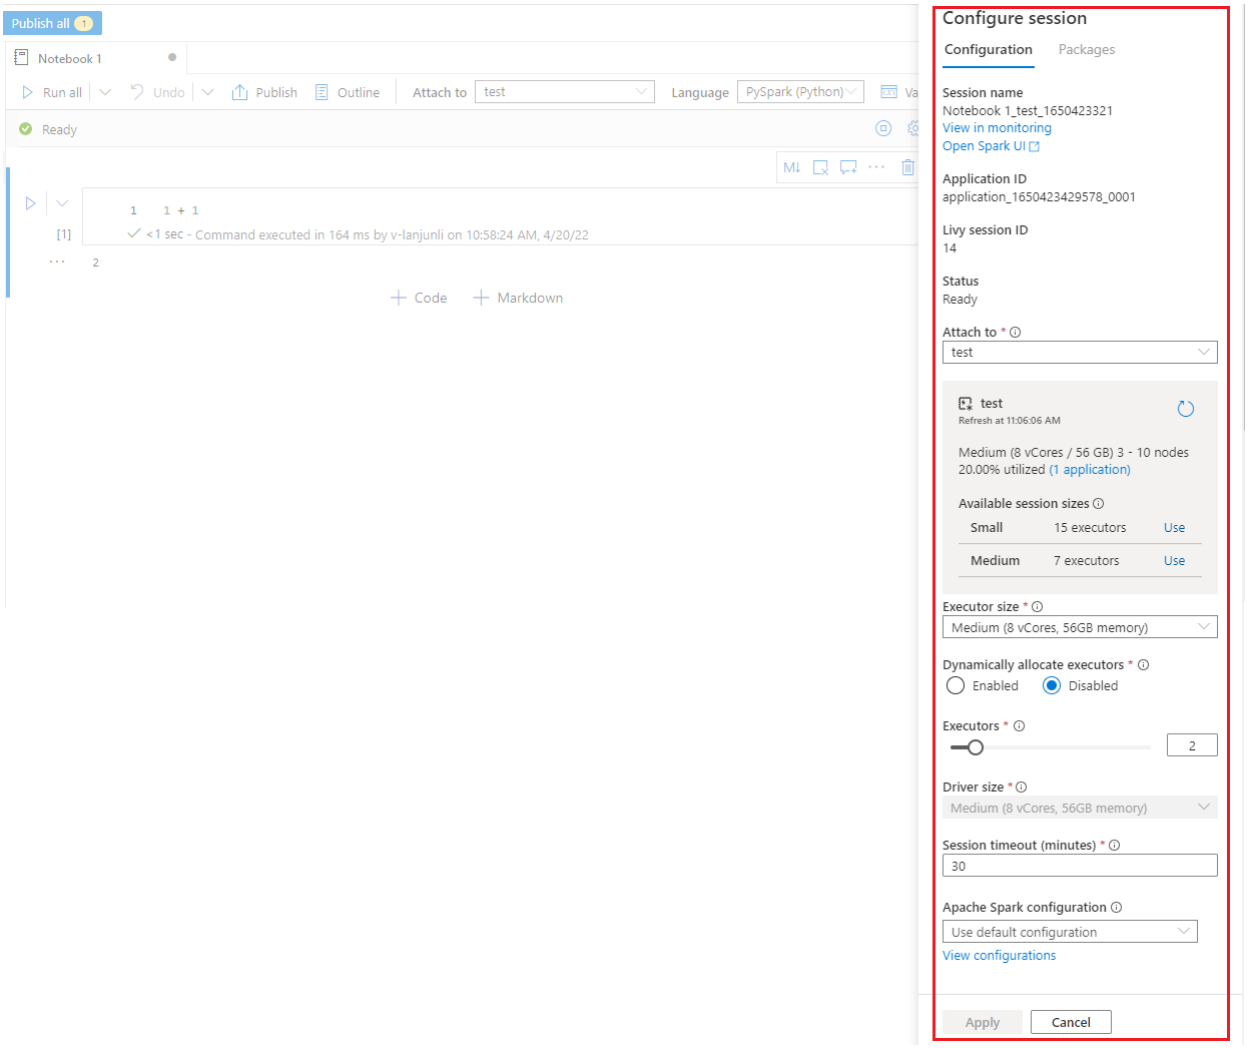


Spark session configuration

You can specify the timeout duration, the number, and the size of executors to give to the current Spark session

in **Configure session**. Restart the Spark session is for configuration changes to take effect. All cached notebook variables are cleared.

You can also create a configuration from the Apache Spark configuration or select an existing configuration. For details, please refer to Apache Spark Configuration Management.



Spark session configuration magic command

You can also specify spark session settings via a magic command **%%configure**. The spark session needs to restart to make the settings effect. We recommend you to run the **%%configure** at the beginning of your notebook. Here is a sample, refer to https://github.com/cloudera/livy#request-body for full list of valid parameters.

```
%%configure
{
    //You can get a list of valid parameters to config the session from
https://github.com/cloudera/livy#request-body.
    "driverMemory":"28g", // Recommended values: ["28g", "56g", "112g", "224g", "400g", "472g"]
    "driverCores":4, // Recommended values: [4, 8, 16, 32, 64, 80]
    "executorMemory":"28g",
    "executorCores":4,
    "jars":
["abfs[s]://<file_system>@<account_name>.dfs.core.windows.net/<path>/myjar.jar","wasb[s]://<containername>@<
accountname>.blob.core.windows.net/<path>/myjar1.jar"],
    "conf":{
    //Example of standard spark property, to find more available properties please
visit:https://spark.apache.org/docs/latest/configuration.html#application-properties.
        "spark.driver.maxResultSize":"10g",
    //Example of customized property, you can specify count of lines that Spark SQL returns by configuring
"livy.rsc.sql.num-rows".
        "livy.rsc.sql.num-rows":"3000"
    }
}
```

NOTE

- "DriverMemory" and "ExecutorMemory" are recommended to set as same value in %%configure, so do "driverCores" and "executorCores".
- You can use %%configure in Synapse pipelines, but if it's not set in the first code cell, the pipeline run will fail due to cannot restart session.
- The %%configure used in mssparkutils.notebook.run is going to be ignored but used in %run notebook will continue executing.
- The standard Spark configuration properties must be used in the "conf" body. We do not support first level reference for the Spark configuration properties.
- Some special spark properties including "spark.driver.cores", "spark.executor.cores", "spark.driver.memory", "spark.executor.memory", "spark.executor.instances" won't take effect in "conf" body.

Parameterized session configuration from pipeline

Parameterized session configuration allows you to replace the value in %%configure magic with Pipeline run (Notebook activity) parameters. When preparing %%configure code cell, you can override default values (also configurable, 4 and "2000" in the below example) with an object like this:

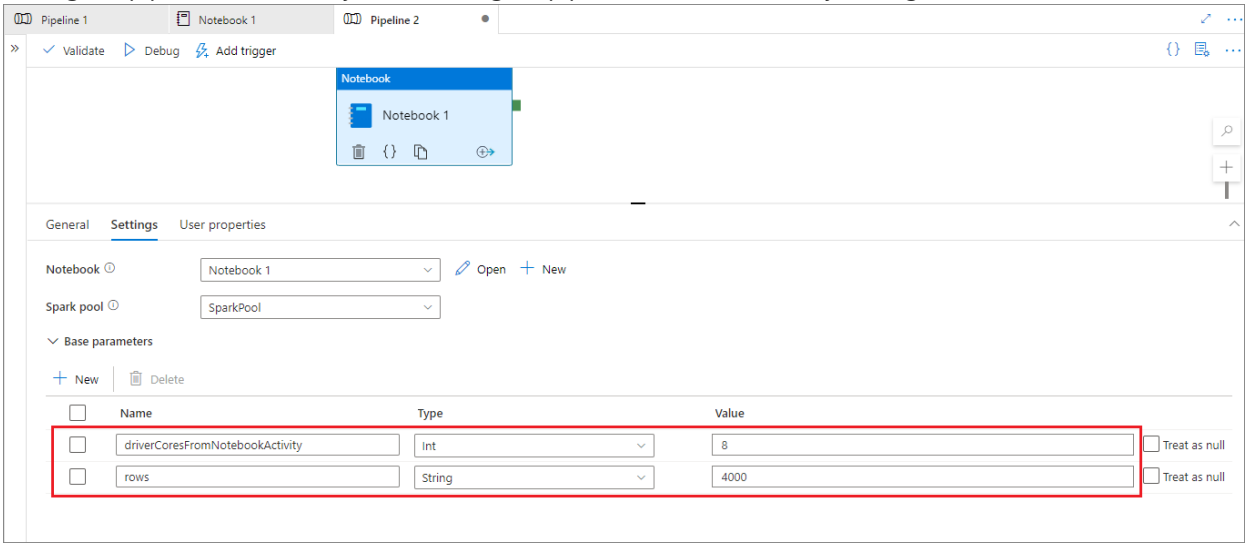
```
{
      "activityParameterName": "paramterNameInPipelineNotebookActivity",
      "defaultValue": "defaultValueIfNoParamterFromPipelineNotebookActivity"
}
```

```
%%configure

{
    "driverCores":
    {
        "activityParameterName": "driverCoresFromNotebookActivity",
        "defaultValue": 4
    },
    "conf":
    {
        "livy.rsc.sql.num-rows":
        {
            "activityParameterName": "rows",
            "defaultValue": "2000"
        }
    }
}
```

Notebook will use default value if run a notebook in interactive mode directly or no parameter that match "activityParameterName" is given from Pipeline Notebook activity.

During the pipeline run mode, you can configure pipeline Notebook activity settings as below:



If you want to change the session configuration, pipeline Notebook activity parameters name should be same as activityParameterName in the notebook. When running this pipeline, in this example driverCores in %%configure will be replaced by 8 and livy.rsc.sql.num-rows will be replaced by 4000.

> **NOTE**
> If run pipeline failed because of using this new %%configure magic, you can check more error information by running %%configure magic cell in the interactive mode of the notebook.

Bring data to a notebook

You can load data from Azure Blob Storage, Azure Data Lake Store Gen 2, and SQL pool as shown in the code samples below.

Read a CSV from Azure Data Lake Store Gen2 as a Spark DataFrame

```
from pyspark.sql import SparkSession
from pyspark.sql.types import *
account_name = "Your account name"
container_name = "Your container name"
relative_path = "Your path"
adls_path = 'abfss://%s@%s.dfs.core.windows.net/%s' % (container_name, account_name, relative_path)

df1 = spark.read.option('header', 'true') \
                .option('delimiter', ',') \
                .csv(adls_path + '/Testfile.csv')
```

Read a CSV from Azure Blob Storage as a Spark DataFrame

```
from pyspark.sql import SparkSession

# Azure storage access info
blob_account_name = 'Your account name' # replace with your blob name
blob_container_name = 'Your container name' # replace with your container name
blob_relative_path = 'Your path' # replace with your relative folder path
linked_service_name = 'Your linked service name' # replace with your linked service name

blob_sas_token = mssparkutils.credentials.getConnectionStringOrCreds(linked_service_name)

# Allow SPARK to access from Blob remotely

wasb_path = 'wasbs://%s@%s.blob.core.windows.net/%s' % (blob_container_name, blob_account_name,
blob_relative_path)

spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name, blob_account_name),
blob_sas_token)
print('Remote blob path: ' + wasb_path)

df = spark.read.option("header", "true") \
            .option("delimiter","|") \
            .schema(schema) \
            .csv(wasbs_path)
```

Read data from the primary storage account

You can access data in the primary storage account directly. There's no need to provide the secret keys. In Data Explorer, right-click on a file and select **New notebook** to see a new notebook with data extractor autogenerated.

IPython Widgets

Widgets are eventful python objects that have a representation in the browser, often as a control like a slider, textbox etc. IPython Widgets only works in Python environment, it's not supported in other languages (e.g. Scala, SQL, C#) yet.

To use IPython Widget

1. You need to import `ipywidgets` module first to use the Jupyter Widget framework.

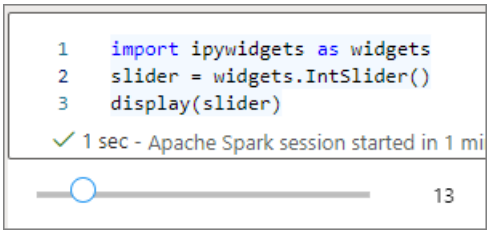
```
import ipywidgets as widgets
```

2. You can use top-level `display` function to render a widget, or leave an expression of **widget** type at the last line of code cell.

```
slider = widgets.IntSlider()
display(slider)
```

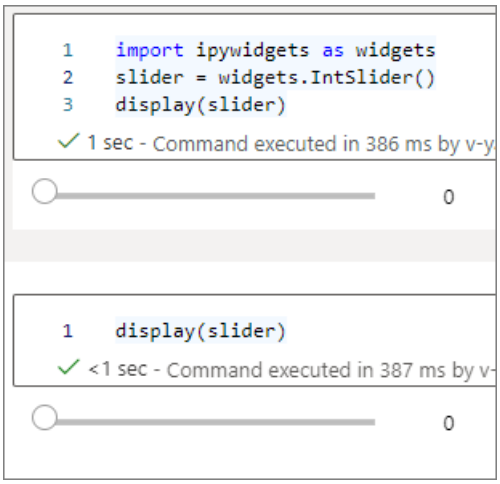
```
slider = widgets.IntSlider()
slider
```

3. Run the cell, the widget will display at the output area.



4. You can use multiple `display()` calls to render the same widget instance multiple times, but they will remain in sync with each other.

```
slider = widgets.IntSlider()
display(slider)
display(slider)
```



5. To render two widgets independent of each other, create two widget instances:

```
slider1 = widgets.IntSlider()
slider2 = widgets.IntSlider()
display(slider1)
display(slider2)
```

Supported widgets

WIDGETS TYPE	WIDGETS
Numeric widgets	IntSlider, FloatSlider, FloatLogSlider, IntRangeSlider, FloatRangeSlider, IntProgress, FloatProgress, BoundedIntText, BoundedFloatText, IntText, FloatText
Boolean widgets	ToggleButton, Checkbox, Valid
Selection widgets	Dropdown, RadioButtons, Select, SelectionSlider, SelectionRangeSlider, ToggleButtons, SelectMultiple
String Widgets	Text, Text area, Combobox, Password, Label, HTML, HTML Math, Image, Button
Play (Animation) widgets	Date picker, Color picker, Controller
Container/Layout widgets	Box, HBox, VBox, GridBox, Accordion, Tabs, Stacked

Known limitations

1. The following widgets are not supported yet, you could follow the corresponding workaround as below:

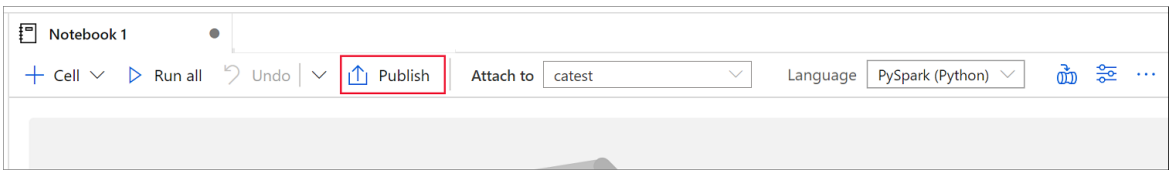
FUNCTIONALITY	WORKAROUND
`Output` widget	You can use `print()` function instead to write text into stdout.
`widgets.jslink()`	You can use `widgets.link()` function to link two similar widgets.
`FileUpload` widget	Not support yet.

2. Global `display` function provided by Synapse does not support displaying multiple widgets in 1 call (i.e. `display(a, b)`), which is different from IPython `display` function.
3. If you close a notebook that contains IPython Widget, you will not be able to see or interact with it until you execute the corresponding cell again.

Save notebooks

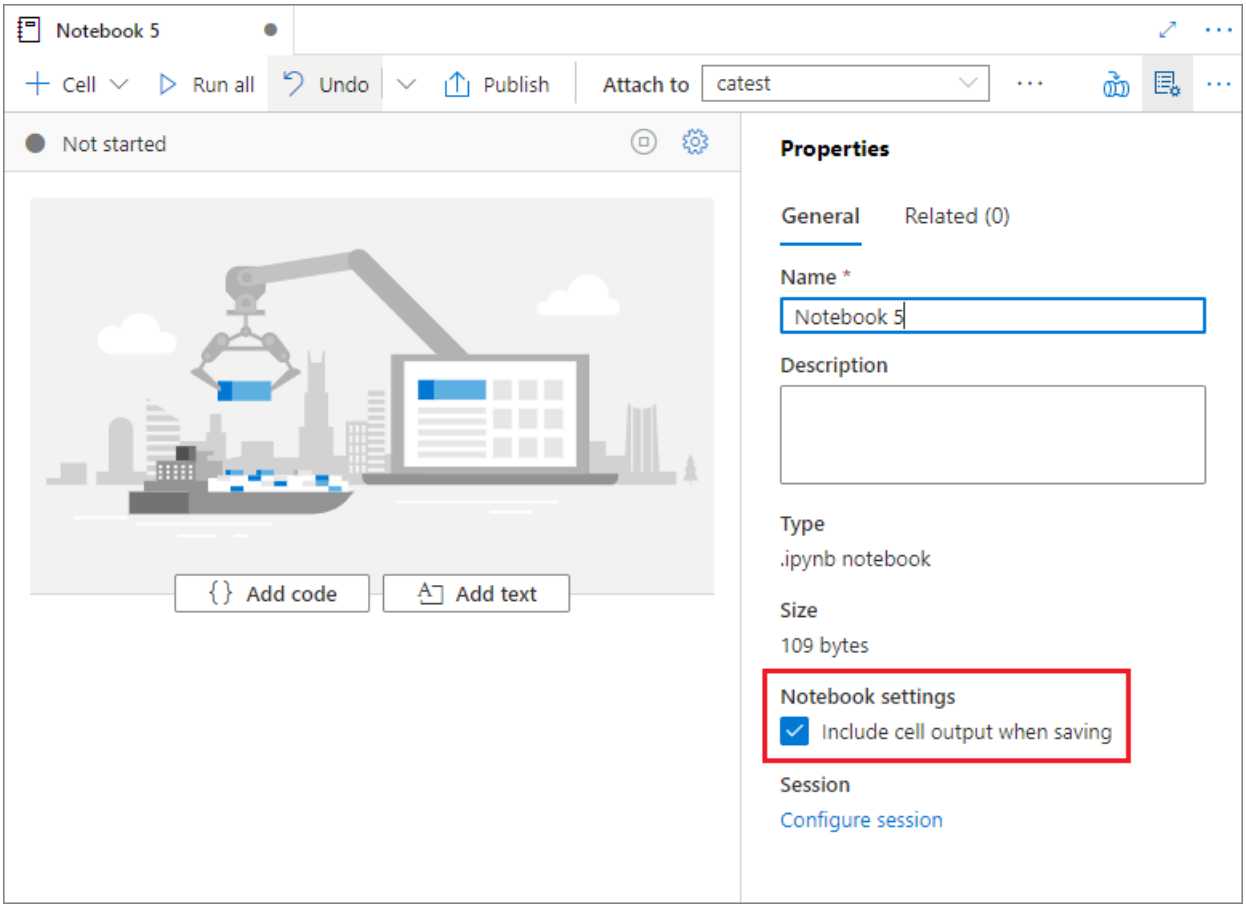
You can save a single notebook or all notebooks in your workspace.

1. To save changes you made to a single notebook, select the **Publish** button on the notebook command bar.



2. To save all notebooks in your workspace, select the **Publish all** button on the workspace command bar.

In the notebook properties, you can configure whether to include the cell output when saving.



Magic commands

You can use familiar Jupyter magic commands in Synapse notebooks. Review the following list as the current available magic commands. Tell us your use cases on GitHub so that we can continue to build out more magic commands to meet your needs.

> **NOTE**
> Only following magic commands are supported in Synapse pipeline : %%pyspark, %%spark, %%csharp, %%sql.

Available line magics: %lsmagic, %time, %timeit, %history, %run, %load

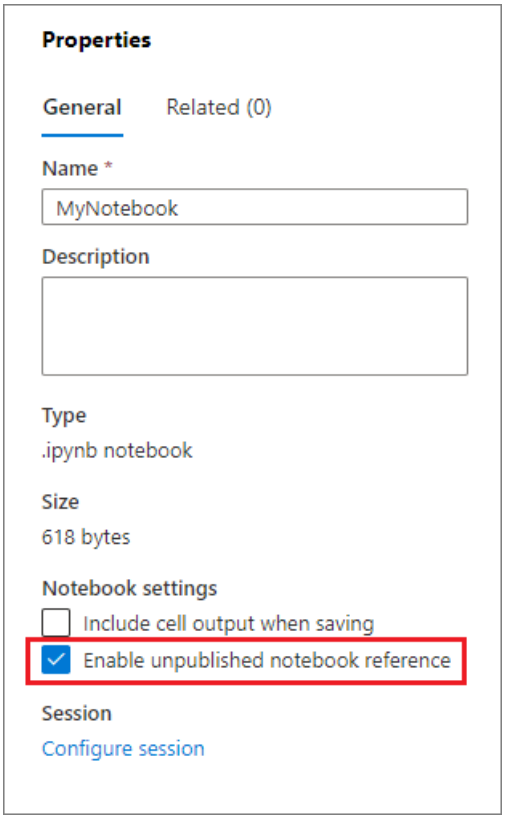
Available cell magics: %%time, %%timeit, %%capture, %%writefile, %%sql, %%pyspark, %%spark, %%csharp, %%html, %%configure

Reference unpublished notebook

Reference unpublished notebook is helpful when you want to debug "locally", when enabling this feature, notebook run will fetch the current content in web cache, if you run a cell including a reference notebooks statement, you will reference the presenting notebooks in the current notebook browser instead of a saved versions in cluster, that means the changes in your notebook editor can be referenced immediately by other

notebooks without having to be published(Live mode) or committed(Git mode), by leveraging this approach you can easily avoid common libraries getting polluted during developing or debugging process.

You can enable Reference unpublished notebook from Properties panel:



For different cases comparison please check the table below:

Notice that %run and mssparkutils.notebook.run has same behavior here. We use `%run` here as an example.

CASE	DISABLE	ENABLE
Live Mode		
- Nb1 (Published) `%run Nb1`	Run published version of Nb1	Run published version of Nb1
- Nb1 (New) `%run Nb1`	Error	Run new Nb1
- Nb1 (Previously published, edited) `%run Nb1`	Run **published** version of Nb1	Run **edited** version of Nb1
Git Mode		
- Nb1 (Published) `%run Nb1`	Run published version of Nb1	Run published version of Nb1
- Nb1 (New) `%run Nb1`	Error	Run new Nb1
- Nb1 (Not published, committed) `%run Nb1`	Error	Run committed Nb1

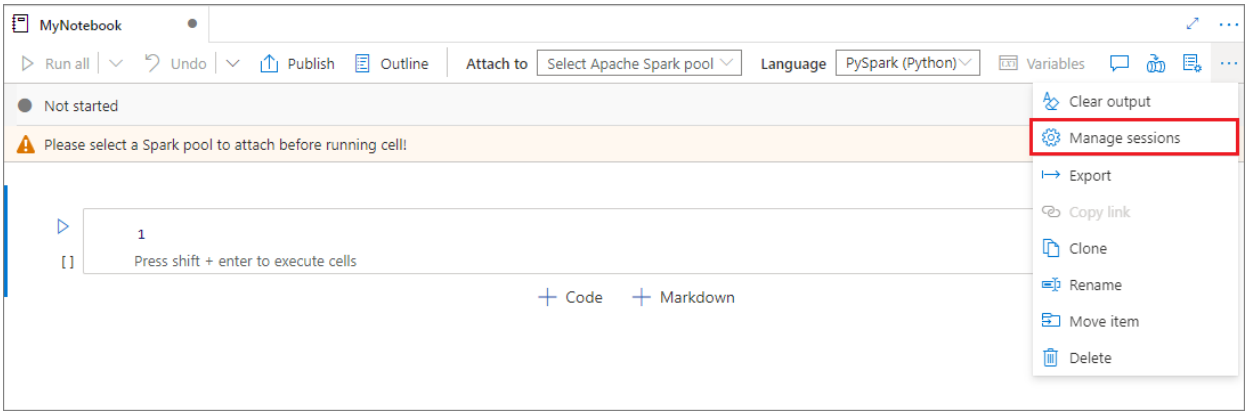
CASE	DISABLE	ENABLE
- Nb1 (Previously published, committed) `%run Nb1`	Run **published** version of Nb1	Run **committed** version of Nb1
- Nb1 (Previously published, new in current branch) `%run Nb1`	Run **published** version of Nb1	Run **new** Nb1
- Nb1 (Not published, previously committed, edited) `%run Nb1`	Error	Run **edited** version of Nb1
- Nb1 (Previously published and committed, edited) `%run Nb1`	Run **published** version of Nb1	Run **edited** version of Nb1

Conclusion

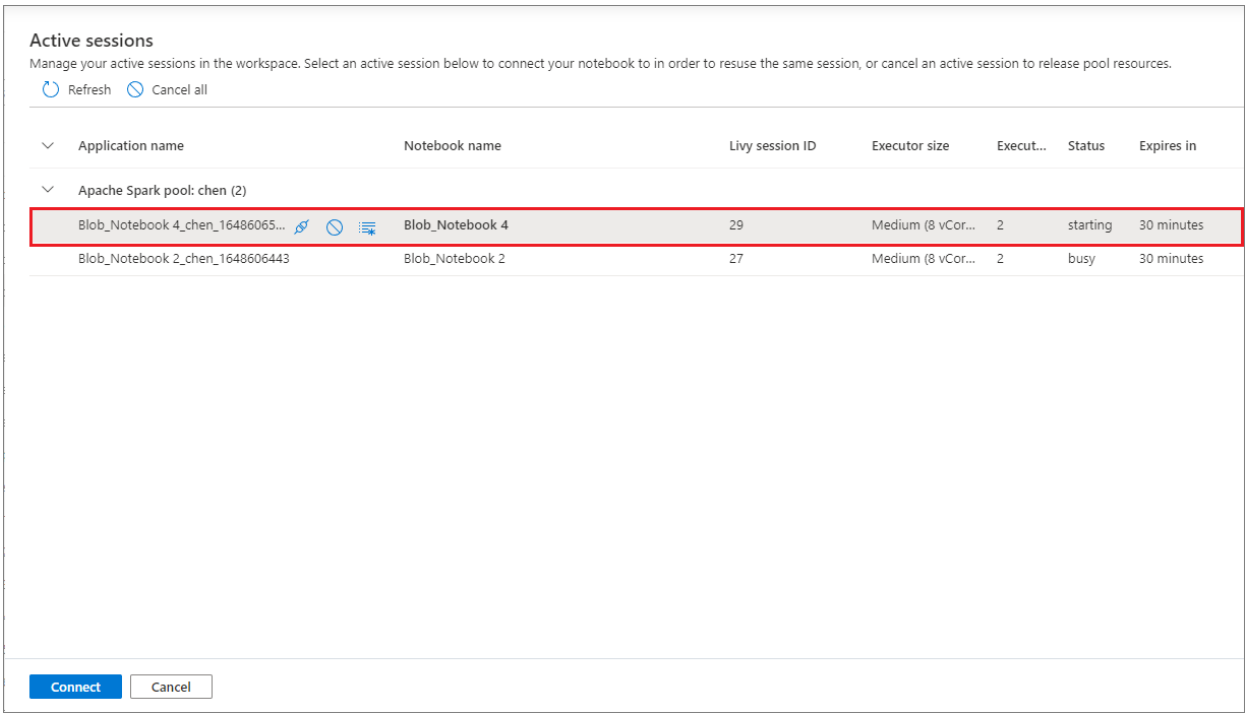
- If disabled, always run **published** version.
- If enabled, priority is: edited / new > committed > published.

Active session management

You can reuse your notebook sessions conveniently now without having to start new ones. Synapse notebook now supports managing your active sessions in the **Manage sessions** list, you can see all the sessions in the current workspace started by you from notebook.



In the **Active sessions** list you can see the session information and the corresponding notebook that is currently attached to the session. You can operate Detach with notebook, Stop the session, and View in monitoring from here. Moreover, you can easily connect your selected notebook to an active session in the list started from another notebook, the session will be detached from the previous notebook (if it's not idle) then attach to the current one.



Python logging in Notebook

You can find Python logs and set different log levels and format following the sample code below:

```
import logging

# Customize the logging format for all loggers
FORMAT = "%(asctime)s - %(name)s - %(levelname)s - %(message)s"
formatter = logging.Formatter(fmt=FORMAT)
for handler in logging.getLogger().handlers:
    handler.setFormatter(formatter)

# Customize log level for all loggers
logging.getLogger().setLevel(logging.INFO)

# Customize the log level for a specific logger
customizedLogger = logging.getLogger('customized')
customizedLogger.setLevel(logging.WARNING)

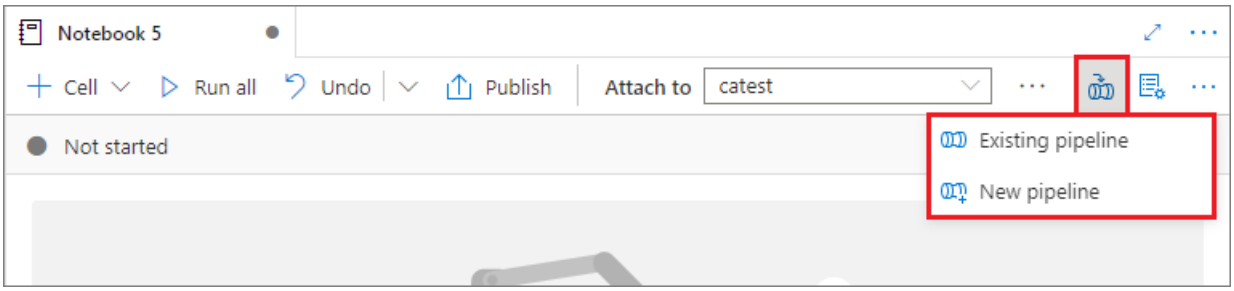
# logger that use the default global log level
defaultLogger = logging.getLogger('default')
defaultLogger.debug("default debug message")
defaultLogger.info("default info message")
defaultLogger.warning("default warning message")
defaultLogger.error("default error message")
defaultLogger.critical("default critical message")

# logger that use the customized log level
customizedLogger.debug("customized debug message")
customizedLogger.info("customized info message")
customizedLogger.warning("customized warning message")
customizedLogger.error("customized error message")
customizedLogger.critical("customized critical message")
```

Integrate a notebook

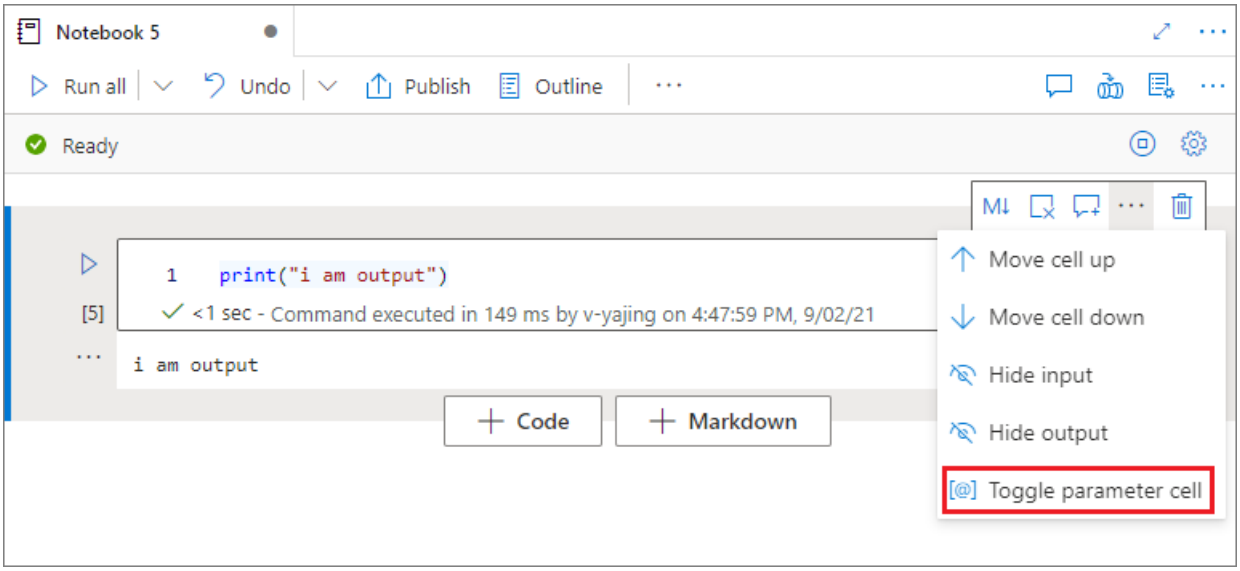
Add a notebook to a pipeline

Select the **Add to pipeline** button on the upper right corner to add a notebook to an existing pipeline or create a new pipeline.



Designate a parameters cell

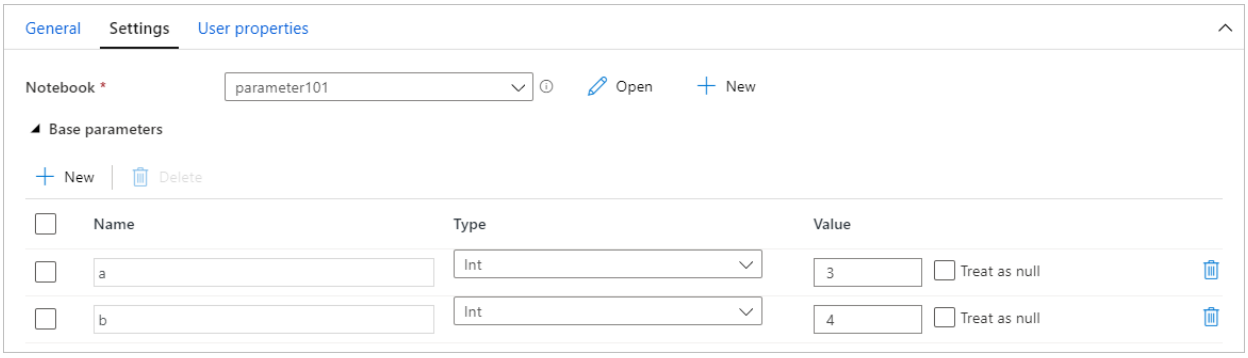
To parameterize your notebook, select the ellipses (...) to access the **more commands** at the cell toolbar. Then select **Toggle parameter cell** to designate the cell as the parameters cell.



Azure Data Factory looks for the parameters cell and treats this cell as defaults for the parameters passed in at execution time. The execution engine will add a new cell beneath the parameters cell with input parameters in order to overwrite the default values.

Assign parameters values from a pipeline

Once you've created a notebook with parameters, you can execute it from a pipeline with the Synapse Notebook activity. After you add the activity to your pipeline canvas, you will be able to set the parameters values under **Base parameters** section on the **Settings** tab.

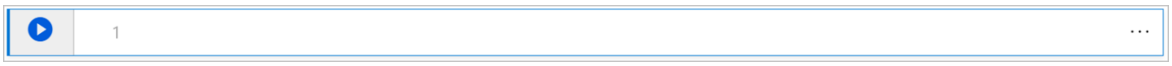


When assigning parameter values, you can use the pipeline expression language or system variables.

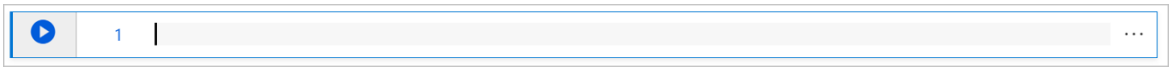
Shortcut keys

Similar to Jupyter Notebooks, Synapse notebooks have a modal user interface. The keyboard does different things depending on which mode the notebook cell is in. Synapse notebooks support the following two modes for a given code cell: command mode and edit mode.

1. A cell is in command mode when there is no text cursor prompting you to type. When a cell is in Command mode, you can edit the notebook as a whole but not type into individual cells. Enter command mode by pressing `ESC` or using the mouse to select outside of a cell's editor area.



2. Edit mode is indicated by a text cursor prompting you to type in the editor area. When a cell is in edit mode, you can type into the cell. Enter edit mode by pressing `Enter` or using the mouse to select on a cell's editor area.



Shortcut keys under command mode

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Run the current cell and select below	Shift+Enter
Run the current cell and insert below	Alt+Enter
Run current cell	Ctrl+Enter
Select cell above	Up
Select cell below	Down
Select previous cell	K
Select next cell	J
Insert cell above	A
Insert cell below	B
Delete selected cells	Shift+D
Switch to edit mode	Enter

Shortcut keys under edit mode

Using the following keystroke shortcuts, you can more easily navigate and run code in Synapse notebooks when in Edit mode.

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Move cursor up	Up
Move cursor down	Down
Undo	Ctrl + Z
Redo	Ctrl + Y

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Comment/Uncomment	Ctrl + /
Delete word before	Ctrl + Backspace
Delete word after	Ctrl + Delete
Go to cell start	Ctrl + Home
Go to cell end	Ctrl + End
Go one word left	Ctrl + Left
Go one word right	Ctrl + Right
Select all	Ctrl + A
Indent	Ctrl +]
Dedent	Ctrl + [
Switch to command mode	Esc

Visualize data

8/19/2022 • 6 minutes to read • Edit Online

Azure Synapse is an integrated analytics service that accelerates time to insight, across data warehouses and big data analytics systems. Data visualization is a key component in being able to gain insight into your data. It helps make big and small data easier for humans to understand. It also makes it easier to detect patterns, trends, and outliers in groups of data.

When using Apache Spark in Azure Synapse Analytics, there are various built-in options to help you visualize your data, including Synapse notebook chart options, access to popular open-source libraries, and integration with Synapse SQL and Power BI.

Notebook chart options

When using an Azure Synapse notebook, you can turn your tabular results view into a customized chart using chart options. Here, you can visualize your data without having to write any code.

display(df) function

The `display` function allows you to turn SQL queries and Apache Spark dataframes and RDDs into rich data visualizations.The `display` function can be used on dataframes or RDDs created in PySpark, Scala, Java, and .NET.

To access the chart options:

1. The output of `%%sql` magic commands appear in the rendered table view by default. You can also call `display(df)` on Spark DataFrames or Resilient Distributed Datasets (RDD) function to produce the rendered table view.
2. Once you have a rendered table view, switch to the Chart View.
3. You can now customize your visualization by specifying the following values:

CONFIGURATION	DESCRIPTION
Chart Type	The `display` function supports a wide range of chart types, including bar charts, scatter plots, line graphs, and more
Key	Specify the range of values for the x-axis
Value	Specify the range of values for the y-axis values
Series Group	Used to determine the groups for the aggregation
Aggregation	Method to aggregate data in your visualization

> **NOTE**
>
> By default the `display(df)` function will only take the first 1000 rows of the data to render the charts. Check the **Aggregation over all results** and click the **Apply** button, you will apply the chart generation from the whole dataset. A Spark job will be triggered when the chart setting changes. Please note that it may take several minutes to complete the calculation and render the chart.

4. Once done, you can view and interact with your final visualization!

display(df) statistic details

You can use `display(df, summary = true)` to check the statistics summary of a given Apache Spark DataFrame that include the column name, column type, unique values, and missing values for each column. You can also select on specific column to see its minimum value, maximum value, mean value and standard deviation.

displayHTML() option

Azure Synapse Analytics notebooks support HTML graphics using the `displayHTML` function.

The following image is an example of creating visualizations using D3.js.

Run the following code to create the visualization above.

```
displayHTML("""<!DOCTYPE html>
<meta charset="utf-8">

<!-- Load d3.js -->
<script src="https://d3js.org/d3.v4.js"></script>

<!-- Create a div where the graph will take place -->
<div id="my_dataviz"></div>
<script>

// set the dimensions and margins of the graph
var margin = {top: 10, right: 30, bottom: 30, left: 40},
  width = 400 - margin.left - margin.right,
  height = 400 - margin.top - margin.bottom;

// append the svg object to the body of the page
var svg = d3.select("#my_dataviz")
.append("svg")
  .attr("width", width + margin.left + margin.right)
  .attr("height", height + margin.top + margin.bottom)
.append("g")
  .attr("transform",
        "translate(" + margin.left + "," + margin.top + ")");

// Create Data
var data = [12,19,11,13,12,22,13,4,15,16,18,19,20,12,11,9]

// Compute summary statistics used for the box:
var data_sorted = data.sort(d3.ascending)
var q1 = d3.quantile(data_sorted, .25)
var median = d3.quantile(data_sorted, .5)
var q3 = d3.quantile(data_sorted, .75)
var interQuantileRange = q3 - q1
var min = q1 - 1.5 * interQuantileRange
var max = q1 + 1.5 * interQuantileRange

// Show the Y scale
var y = d3.scaleLinear()
```

```
  .domain([0,24])
  .range([height, 0]);
svg.call(d3.axisLeft(y))

// a few features for the box
var center = 200
var width = 100

// Show the main vertical line
svg
.append("line")
  .attr("x1", center)
  .attr("x2", center)
  .attr("y1", y(min) )
  .attr("y2", y(max) )
  .attr("stroke", "black")

// Show the box
svg
.append("rect")
  .attr("x", center - width/2)
  .attr("y", y(q3) )
  .attr("height", (y(q1)-y(q3)) )
  .attr("width", width )
  .attr("stroke", "black")
  .style("fill", "#69b3a2")

// show median, min and max horizontal lines
svg
.selectAll("toto")
.data([min, median, max])
.enter()
.append("line")
  .attr("x1", center-width/2)
  .attr("x2", center+width/2)
  .attr("y1", function(d){ return(y(d))} )
  .attr("y2", function(d){ return(y(d))} )
  .attr("stroke", "black")
</script>

"""
)
```

Popular Libraries

When it comes to data visualization, Python offers multiple graphing libraries that come packed with many different features. By default, every Apache Spark Pool in Azure Synapse Analytics contains a set of curated and popular open-source libraries. You can also add or manage additional libraries & versions by using the Azure Synapse Analytics library management capabilities.

Matplotlib

You can render standard plotting libraries, like Matplotlib, using the built-in rendering functions for each library.

The following image is an example of creating a bar chart using **Matplotlib**.

Run the following sample code to draw the image above.

```
# Bar chart

import matplotlib.pyplot as plt

x1 = [1, 3, 4, 5, 6, 7, 9]
y1 = [4, 7, 2, 4, 7, 8, 3]

x2 = [2, 4, 6, 8, 10]
y2 = [5, 6, 2, 6, 2]

plt.bar(x1, y1, label="Blue Bar", color='b')
plt.bar(x2, y2, label="Green Bar", color='g')
plt.plot()

plt.xlabel("bar number")
plt.ylabel("bar height")
plt.title("Bar Chart Example")
plt.legend()
plt.show()
```

Bokeh

You can render HTML or interactive libraries, like **bokeh**, using the `displayHTML(df)`.

The following image is an example of plotting glyphs over a map using **bokeh**.

Run the following sample code to draw the image above.

```
from bokeh.plotting import figure, output_file
from bokeh.tile_providers import get_provider, Vendors
from bokeh.embed import file_html
from bokeh.resources import CDN
from bokeh.models import ColumnDataSource

tile_provider = get_provider(Vendors.CARTODBPOSITRON)

# range bounds supplied in web mercator coordinates
p = figure(x_range=(-9000000,-8000000), y_range=(4000000,5000000),
           x_axis_type="mercator", y_axis_type="mercator")
p.add_tile(tile_provider)

# plot datapoints on the map
source = ColumnDataSource(
    data=dict(x=[ -8800000, -8500000 , -8800000],
              y=[4200000, 4500000, 4900000])
)

p.circle(x="x", y="y", size=15, fill_color="blue", fill_alpha=0.8, source=source)

# create an html document that embeds the Bokeh plot
html = file_html(p, CDN, "my plot1")

# display this html
displayHTML(html)
```

Plotly

You can render HTML or interactive libraries like **Plotly**, using the **displayHTML()**.

Run the following sample code to draw the image below.

```
from urllib.request import urlopen
import json
with urlopen('https://raw.githubusercontent.com/plotly/datasets/master/geojson-counties-fips.json') as
response:
    counties = json.load(response)

import pandas as pd
df = pd.read_csv("https://raw.githubusercontent.com/plotly/datasets/master/fips-unemp-16.csv",
                   dtype={"fips": str})

import plotly
import plotly.express as px

fig = px.choropleth(df, geojson=counties, locations='fips', color='unemp',
                           color_continuous_scale="Viridis",
                           range_color=(0, 12),
                           scope="usa",
                           labels={'unemp':'unemployment rate'}
                          )
fig.update_layout(margin={"r":0,"t":0,"l":0,"b":0})

# create an html document that embeds the Plotly plot
h = plotly.offline.plot(fig, output_type='div')

# display this html
displayHTML(h)
```

Pandas

You can view html output of pandas dataframe as the default output, notebook will automatically show the styled html content.

```
import pandas as pd
import numpy as np

df = pd.DataFrame([[38.0, 2.0, 18.0, 22.0, 21, np.nan],[19, 439, 6, 452, 226,232]],

                  index=pd.Index(['Tumour (Positive)', 'Non-Tumour (Negative)'], name='Actual Label:'),

                  columns=pd.MultiIndex.from_product([['Decision Tree', 'Regression', 'Random'],['Tumour',
'Non-Tumour']], names=['Model:', 'Predicted:']))

df
```

Additional libraries

Beyond these libraries, the Azure Synapse Analytics Runtime also includes the following set of libraries that are often used for data visualization:

- Seaborn

You can visit the Azure Synapse Analytics Runtime documentation for the most up to date information about the available libraries and versions.

Connect to Power BI using Apache Spark & SQL On-Demand

Azure Synapse Analytics integrates deeply with Power BI allowing data engineers to build analytics solutions.

Azure Synapse Analytics allows the different workspace computational engines to share databases and tables between its Spark pools and serverless SQL pool. Using the shared metadata model,you can query your Apache

Spark tables using SQL on-demand. Once done, you can connect your SQL on-demand endpoint to Power BI to easily query your synced Spark tables.

Next steps

- For more information on how to set up the Spark SQL DW Connector: Synapse SQL connector
- View the default libraries: Azure Synapse Analytics runtime

Tutorial: Create an Apache Spark application with IntelliJ using a Synapse workspace

8/19/2022 • 7 minutes to read • Edit Online

This tutorial shows you how to use the Azure Toolkit for IntelliJ plug-in to develop Apache Spark applications, which are written in Scala, and then submit them to a serverless Apache Spark pool directly from the IntelliJ integrated development environment (IDE). You can use the plug-in in a few ways:

- Develop and submit a Scala Spark application on a Spark pool.
- Access your Spark pools resources.
- Develop and run a Scala Spark application locally.

In this tutorial, you learn how to:

- Use the Azure Toolkit for IntelliJ plug-in
- Develop Apache Spark applications
- Submit application to Spark pools

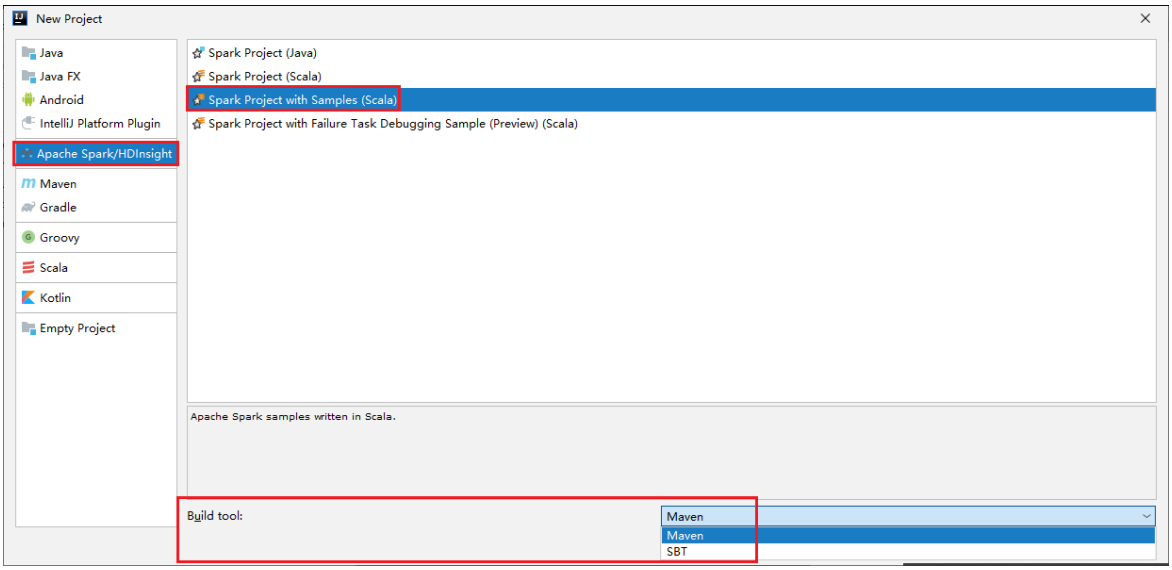
Prerequisites

- IntelliJ IDEA Community Version.
- Azure toolkit plugin 3.27.0-2019.2 – Install from IntelliJ Plugin repository
- JDK (Version 1.8).
- Scala Plugin – Install from IntelliJ Plugin repository.
- The following prerequisite is only for Windows users:

  While you're running the local Spark Scala application on a Windows computer, you might get an exception, as explained in SPARK-2356. The exception occurs because WinUtils.exe is missing on Windows. To resolve this error, download the WinUtils executable to a location such as **C:\WinUtils\bin**. Then, add the environment variable **HADOOP_HOME**, and set the value of the variable to **C:\WinUtils**.

Create a Spark Scala application for a Spark pool

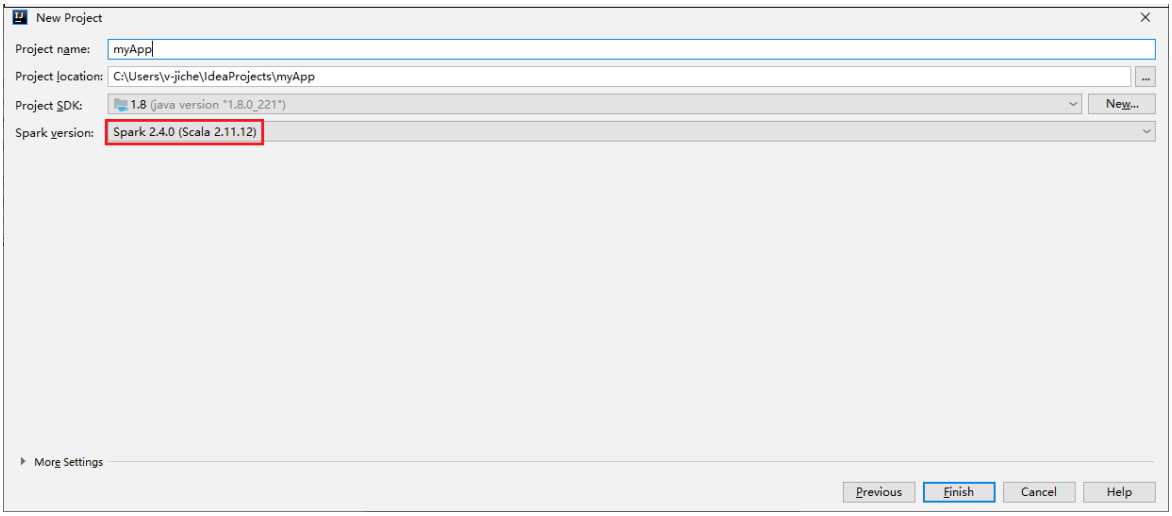
1. Start IntelliJ IDEA, and select **Create New Project** to open the **New Project** window.
2. Select **Apache Spark/HDInsight** from the left pane.
3. Select **Spark Project with Samples(Scala)** from the main window.
4. From the **Build tool** drop-down list, select one of the following types:
   - **Maven** for Scala project-creation wizard support.
   - **SBT** for managing the dependencies and building for the Scala project.



5. Select **Next**.

6. In the **New Project** window, provide the following information:

PROPERTY	DESCRIPTION
Project name	Enter a name. This tutorial uses `myApp`.
Project location	Enter the wanted location to save your project.
Project SDK	It might be blank on your first use of IDEA. Select **New...** and navigate to your JDK.
Spark Version	The creation wizard integrates the proper version for Spark SDK and Scala SDK. Synapse only supports **Spark 2.4.0**.



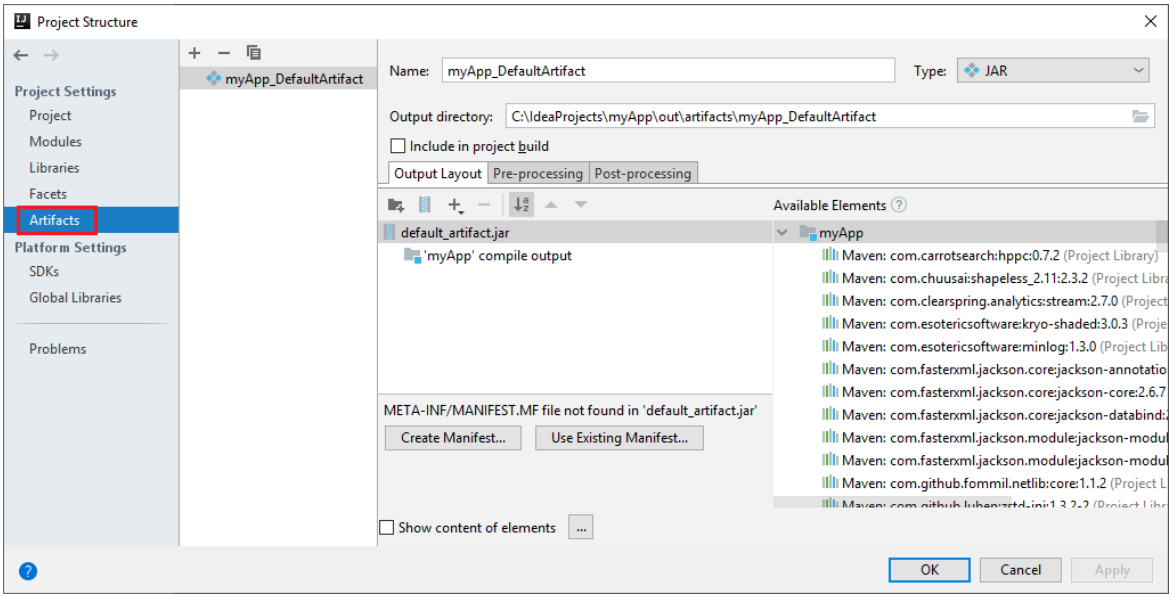
7. Select **Finish**. It may take a few minutes before the project becomes available.

8. The Spark project automatically creates an artifact for you. To view the artifact, do the following operating:

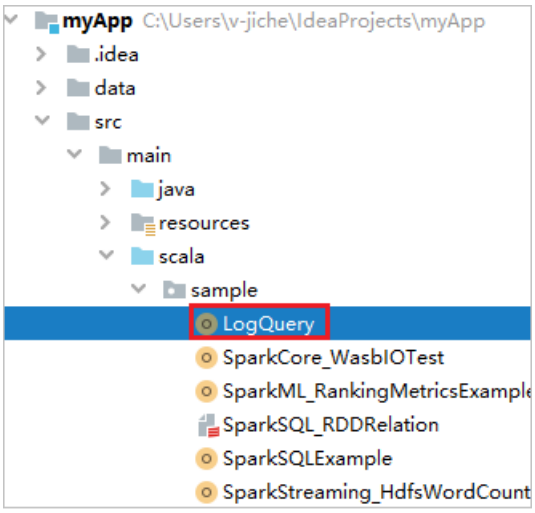
   a. From the menu bar, navigate to **File** > **Project Structure...**.

   b. From the **Project Structure** window, select **Artifacts**.

c. Select **Cancel** after viewing the artifact.



9. Find **LogQuery** from **myApp** > **src** > **main** > **scala**> **sample**> **LogQuery**. This tutorial uses **LogQuery** to run.

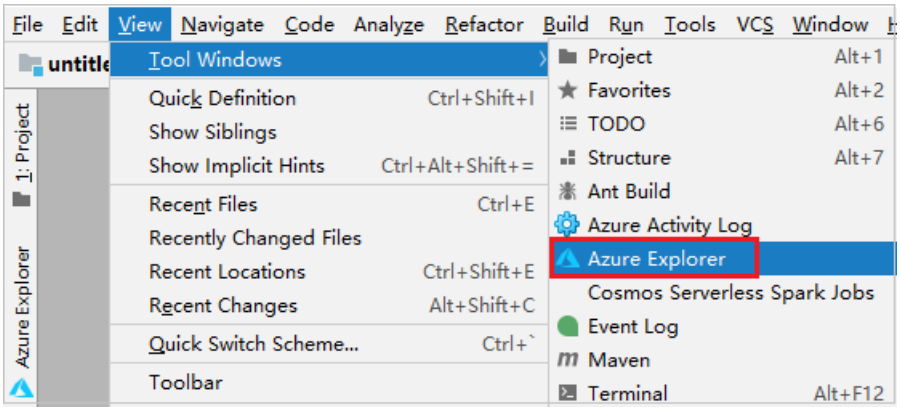


Connect to your Spark pools

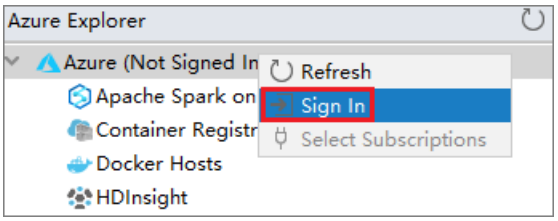
Sign in to Azure subscription to connect to your Spark pools.

Sign in to your Azure subscription

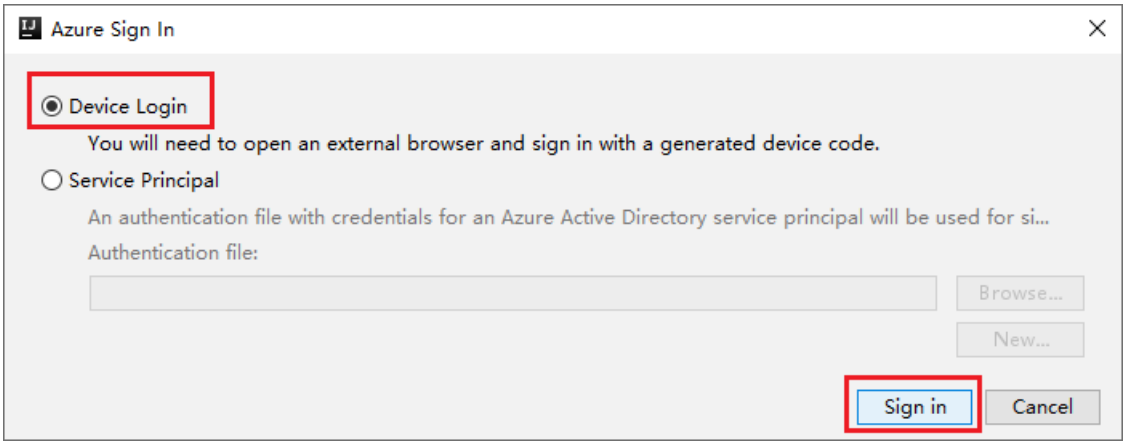
1. From the menu bar, navigate to **View** > **Tool Windows** > **Azure Explorer**.



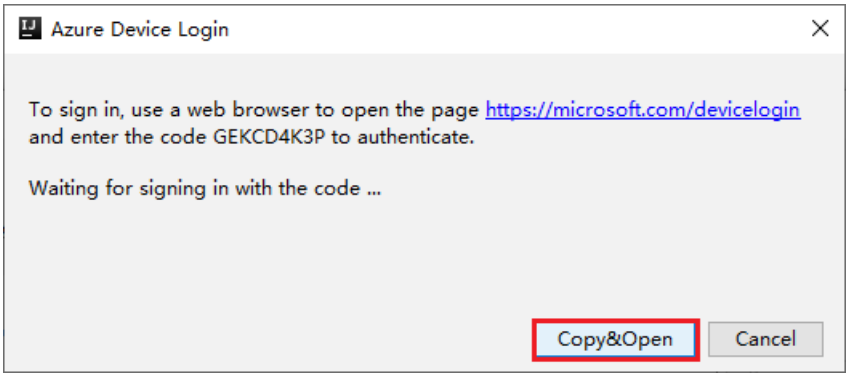
2. From Azure Explorer, right-click the **Azure** node, and then select **Sign In**.



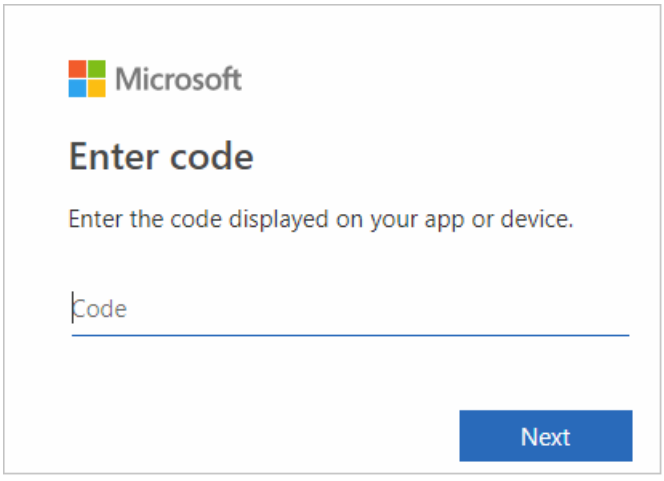
3. In the **Azure Sign In** dialog box, choose **Device Login**, and then select **Sign in**.



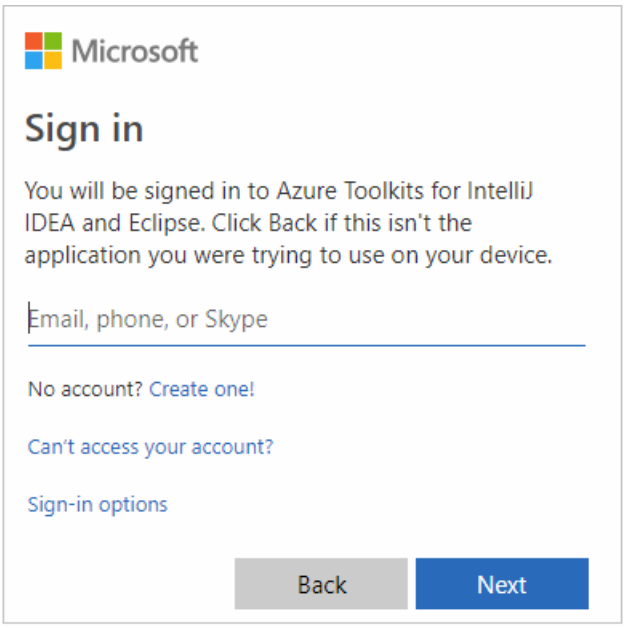
4. In the **Azure Device Login** dialog box, select **Copy&Open**.



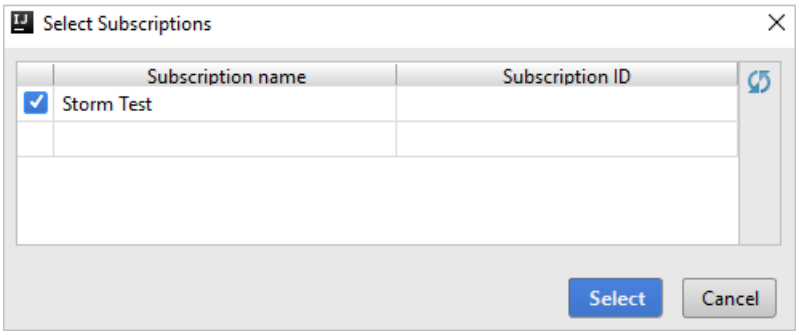
5. In the browser interface, paste the code, and then select **Next**.



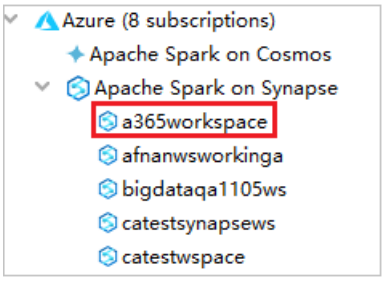
6. Enter your Azure credentials, and then close the browser.



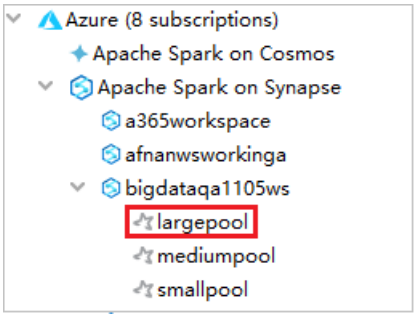
7. After you're signed in, the **Select Subscriptions** dialog box lists all the Azure subscriptions that are associated with the credentials. Select your subscription and then select **Select**.



8. From **Azure Explorer**, expand **Apache Spark on Synapse** to view the Workspaces that are in your subscriptions.



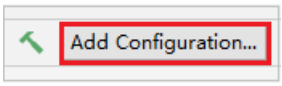
9. To view the Spark pools, you can further expand a workspace.



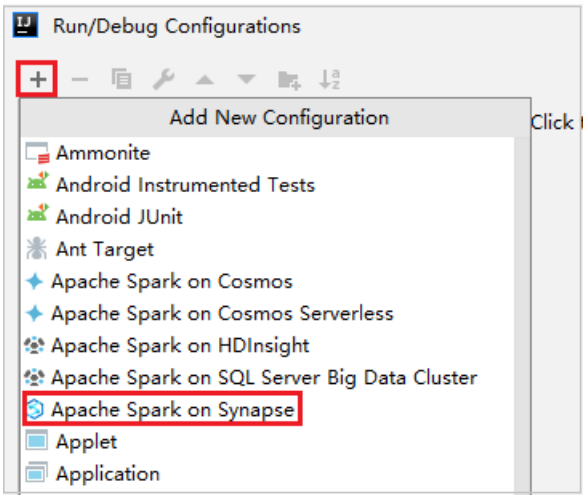
Remote Run a Spark Scala application on a Spark pool

After creating a Scala application, you can remotely run it.

1. Open **Run/Debug Configurations** window by selecting the icon.



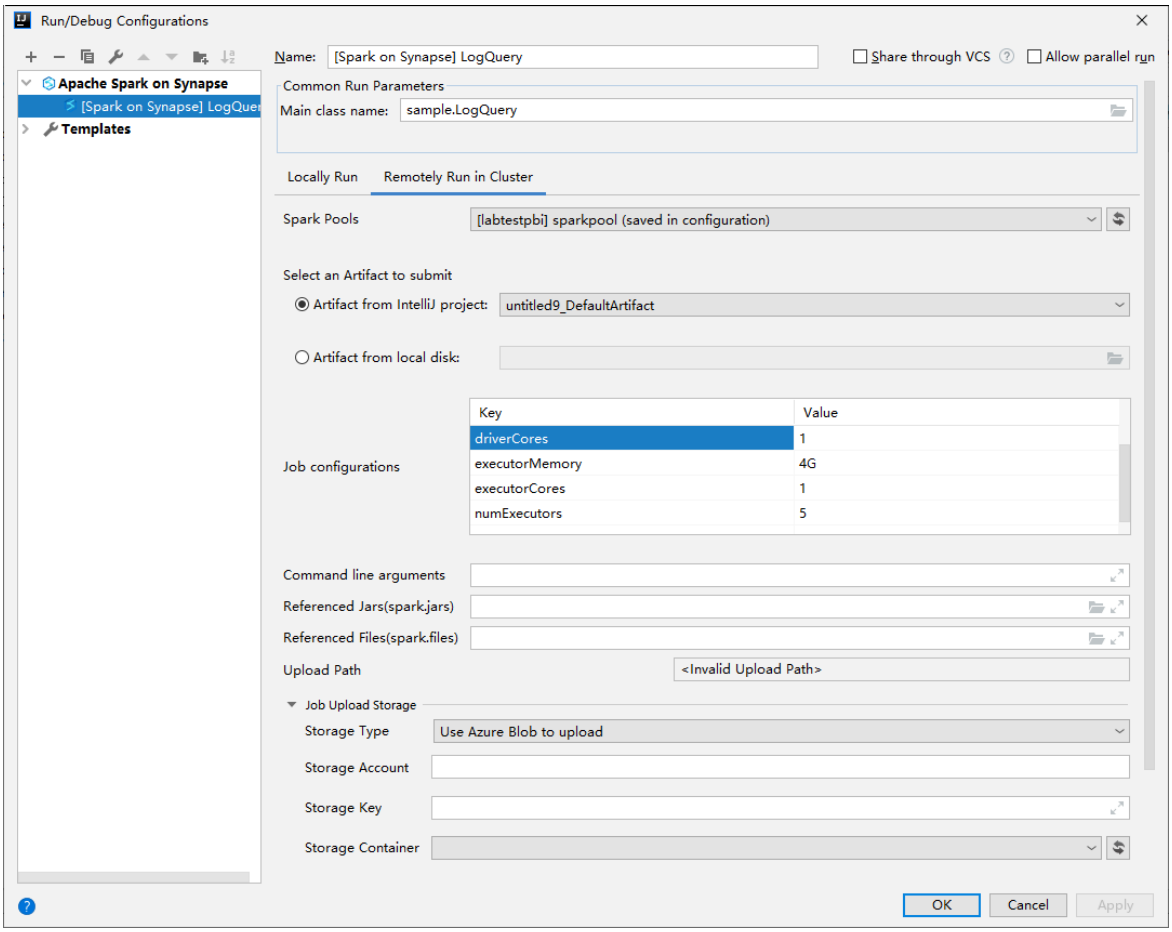
2. In the **Run/Debug Configurations** dialog window, select **+**, then select **Apache Spark on Synapse**.



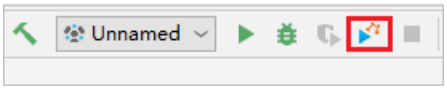
3. In the **Run/Debug Configurations** window, provide the following values, and then select **OK**:

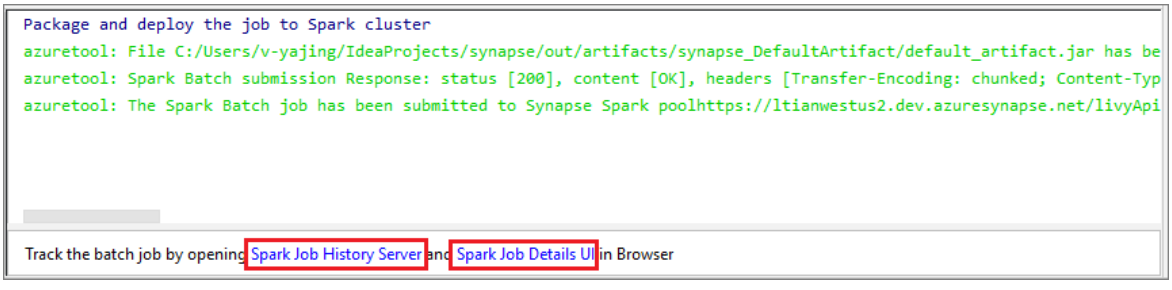
PROPERTY	VALUE
Spark pools	Select the Spark pools on which you want to run your application.
Select an Artifact to submit	Leave default setting.
Main class name	The default value is the main class from the selected file. You can change the class by selecting the ellipsis(...) and choosing another class.
Job configurations	You can change the default key and values. For more information, see Apache Livy REST API.
Command-line arguments	You can enter arguments separated by space for the main class if needed.
Referenced Jars and Referenced Files	You can enter the paths for the referenced Jars and files if any. You can also browse files in the Azure virtual file system, which currently only supports ADLS Gen2 cluster. For more information: Apache Spark Configuration and How to upload resources to cluster.
Job Upload Storage	Expand to reveal additional options.
Storage Type	Select **Use Azure Blob to upload** or **Use cluster default storage account to upload** from the drop-down list.
Storage Account	Enter your storage account.
Storage Key	Enter your storage key.

PROPERTY	VALUE
Storage Container	Select your storage container from the drop-down list once **Storage Account** and **Storage Key** has been entered.



4. Select **SparkJobRun** icon to submit your project to the selected Spark pool. The **Remote Spark Job in Cluster** tab displays the job execution progress at the bottom. You can stop the application by selecting the red button.



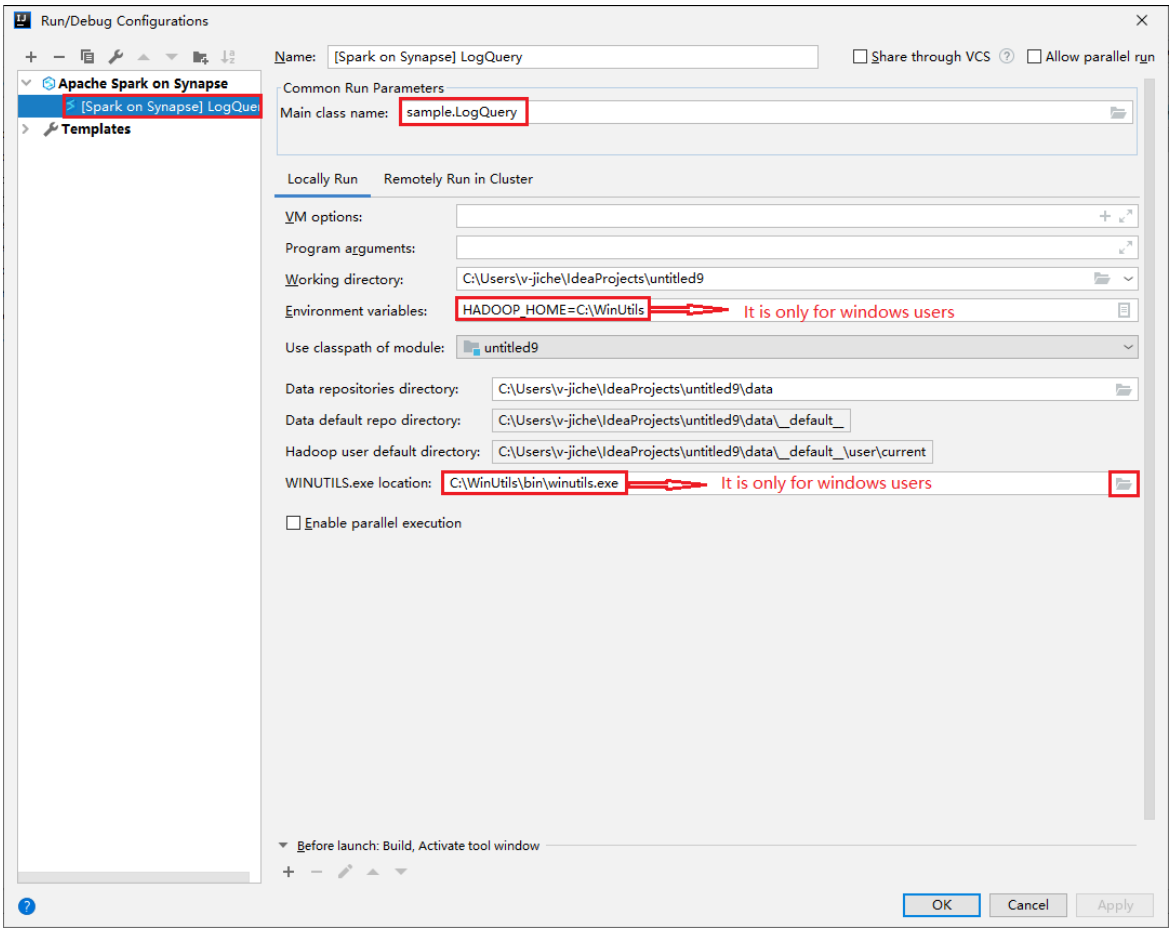


Local Run/Debug Apache Spark applications

You can follow the instructions below to set up your local run and local debug for your Apache Spark job.

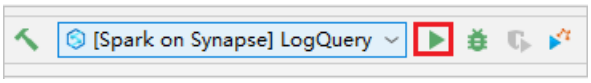
Scenario 1: Do local run

1. Open the **Run/Debug Configurations** dialog, select the plus sign (+). Then select the **Apache Spark on Synapse** option. Enter information for **Name**, **Main class name** to save.

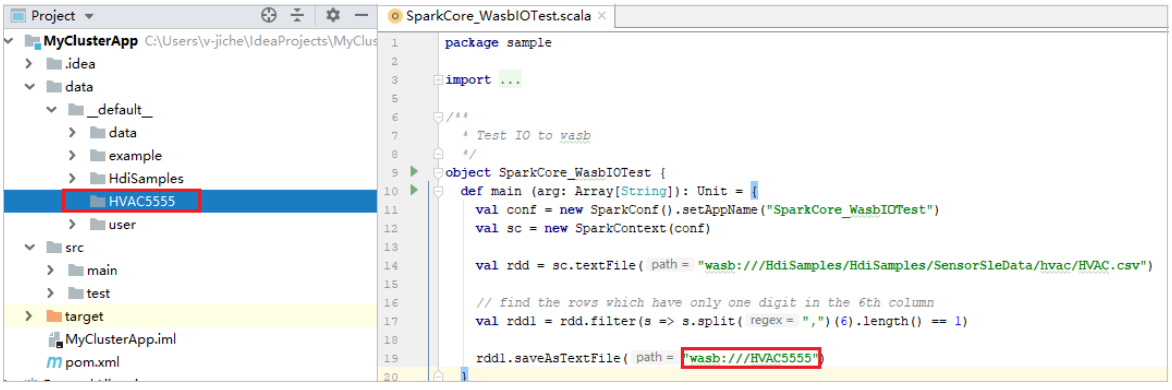


- Environment variables and WinUtils.exe Location are only for windows users.
- Environment variables: The system environment variable can be auto detected if you have set it before and no need to manually add.
- WinUtils.exe Location: You can specify the WinUtils location by selecting the folder icon on the right.

2. Then select the local play button.



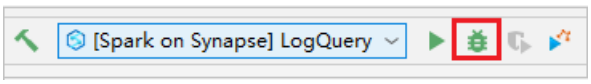
3. Once local run completed, if script includes output, you can check the output file from **data** > **default**.



Scenario 2: Do local debugging

1. Open the **LogQuery** script, set breakpoints.

2. Select **Local debug** icon to do local debugging.

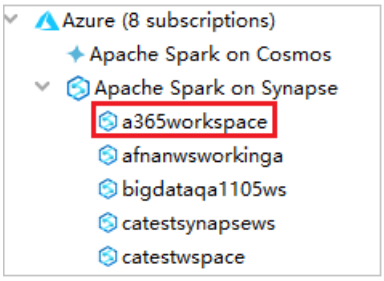


Access and manage Synapse Workspace

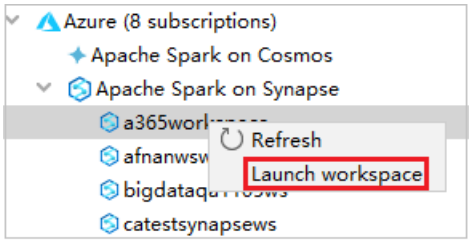
You can perform different operations in Azure Explorer within Azure Toolkit for IntelliJ. From the menu bar, navigate to **View** > **Tool Windows** > **Azure Explorer**.

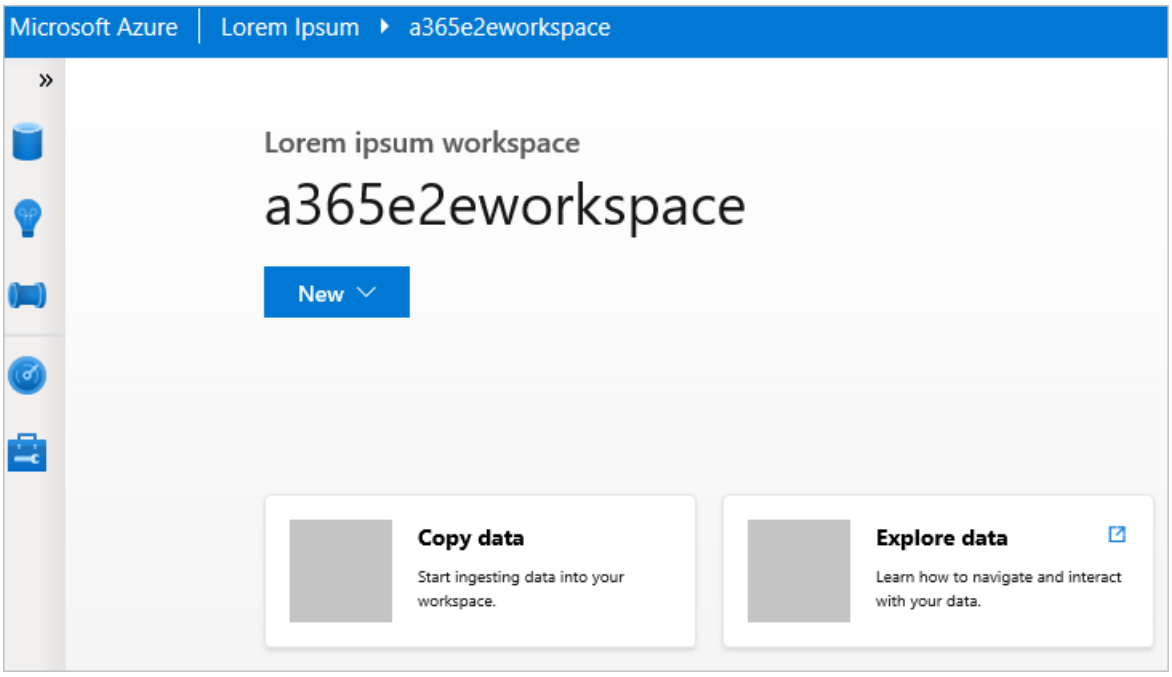
Launch workspace

1. From Azure Explorer, navigate to **Apache Spark on Synapse**, then expand it.



2. Right-click a workspace, then select **Launch workspace**, website will be opened.





Spark console

You can run Spark Local Console(Scala) or run Spark Livy Interactive Session Console(Scala).

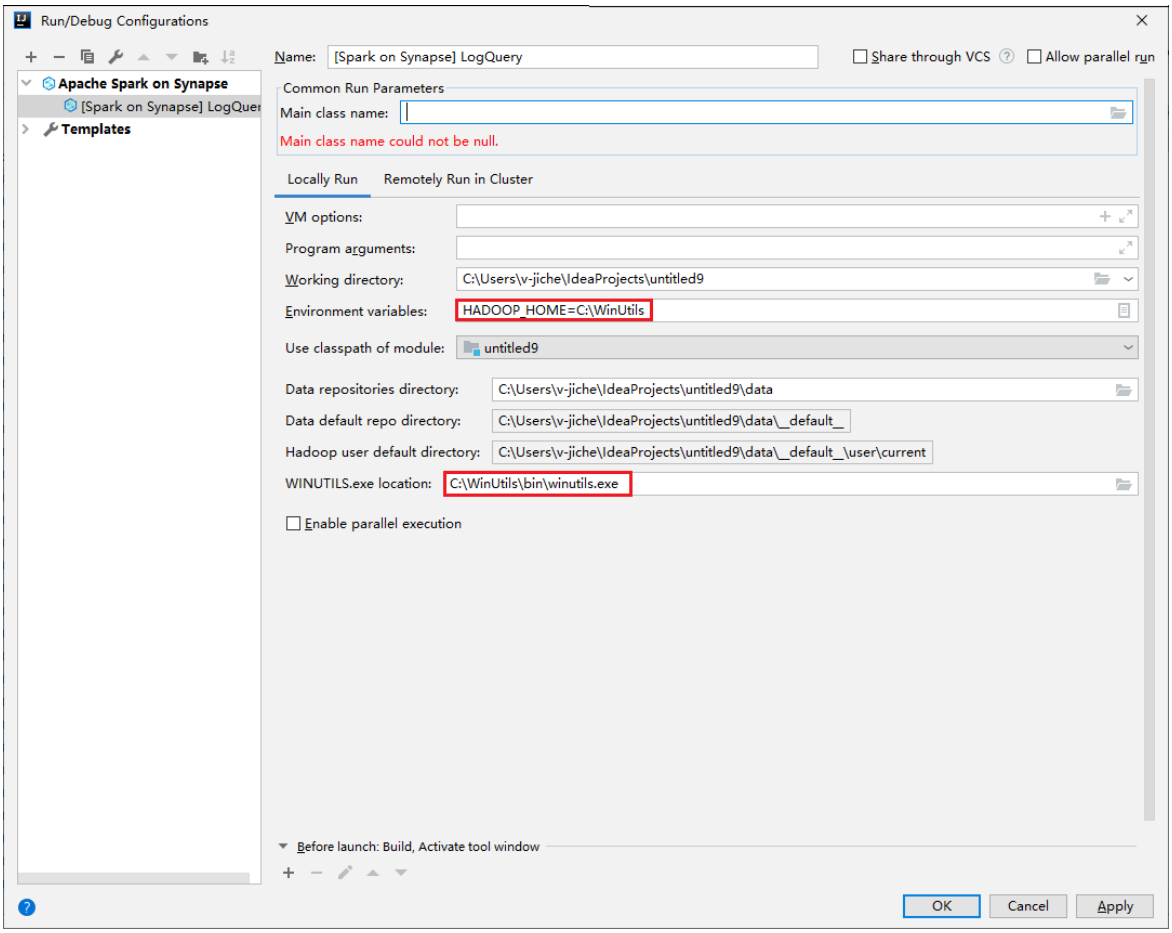
Spark local console (Scala)

Ensure you've satisfied the WINUTILS.EXE prerequisite.

1. From the menu bar, navigate to **Run** > **Edit Configurations...**.
2. From the **Run/Debug Configurations** window, in the left pane, navigate to **Apache Spark on Synapse** > **[Spark on Synapse] myApp**.
3. From the main window, select the **Locally Run** tab.

4. Provide the following values, and then select **OK**:

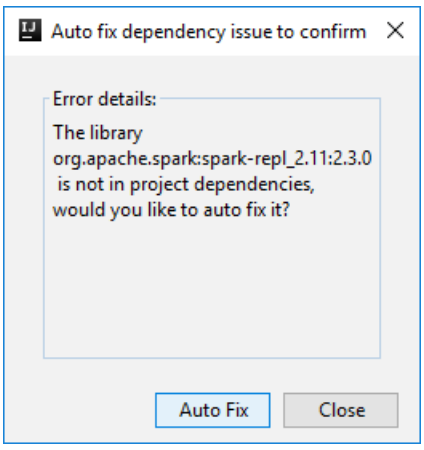
PROPERTY	VALUE
Environment variables	Ensure the value for HADOOP_HOME is correct.
WINUTILS.exe location	Ensure the path is correct.

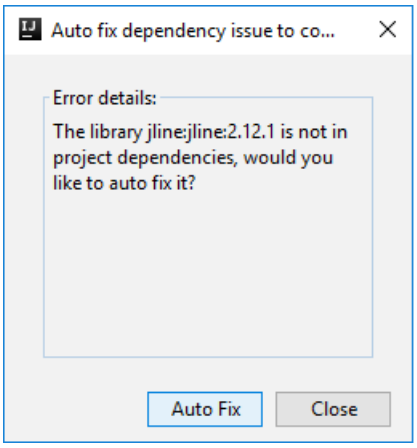


5. From Project, navigate to **myApp** > **src** > **main** > **scala** > **myApp**.

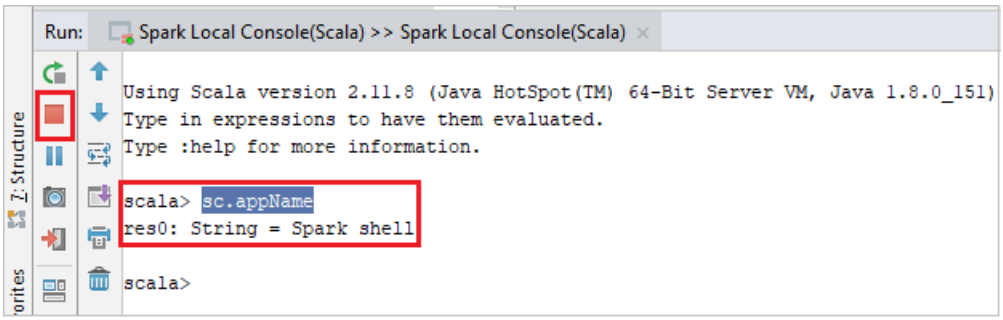
6. From the menu bar, navigate to **Tools** > **Spark console** > **Run Spark Local Console(Scala)**.

7. Then two dialogs may be displayed to ask you if you want to auto fix dependencies. If so, select **Auto Fix**.





8. The console should look similar to the picture below. In the console window type `sc.appName`, and then press ctrl+Enter. The result will be shown. You can stop the local console by selecting red button.

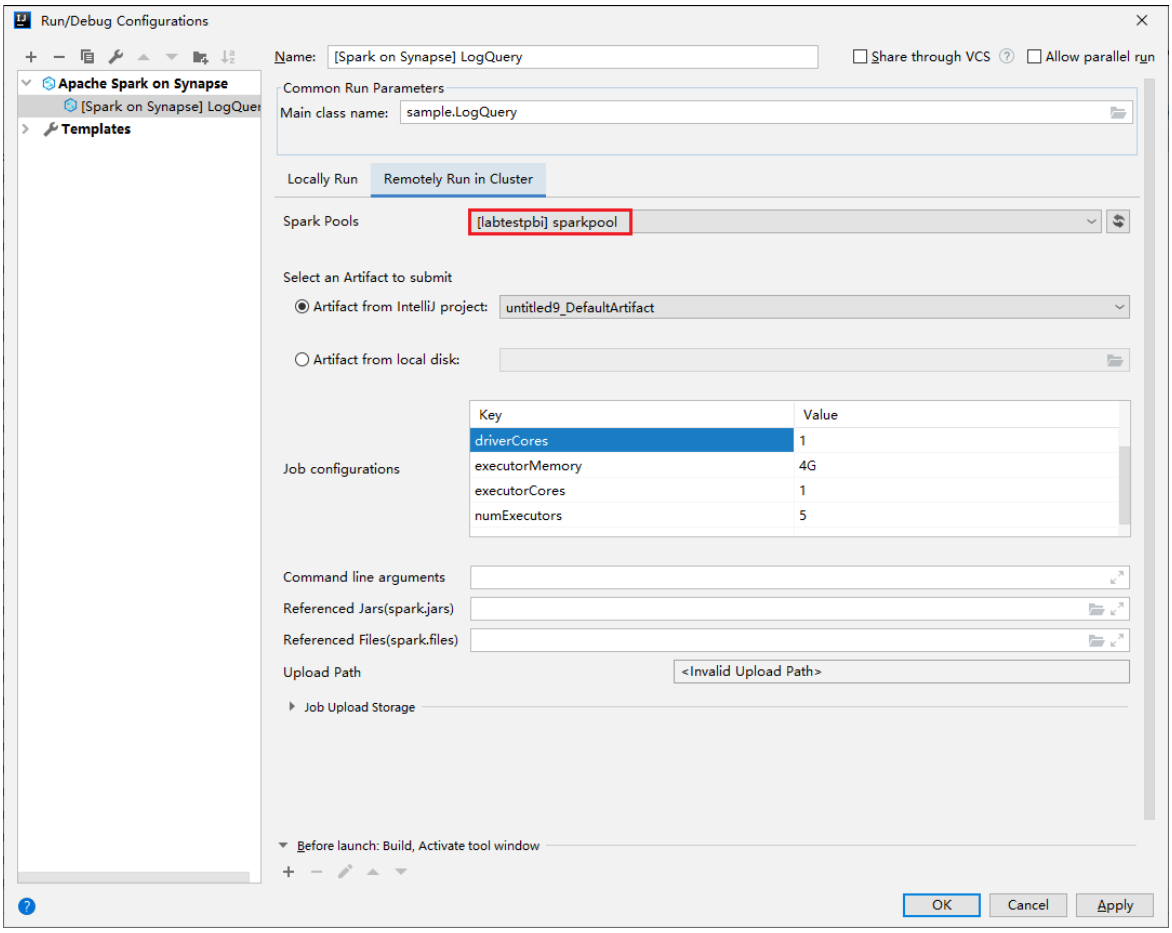


Spark Livy interactive session console (Scala)

It's only supported on IntelliJ 2018.2 and 2018.3.

1. From the menu bar, navigate to **Run** > **Edit Configurations...**.
2. From the **Run/Debug Configurations** window, in the left pane, navigate to **Apache Spark on synapse** > **[Spark on synapse] myApp**.
3. From the main window, select the **Remotely Run in Cluster** tab.
4. Provide the following values, and then select **OK**:

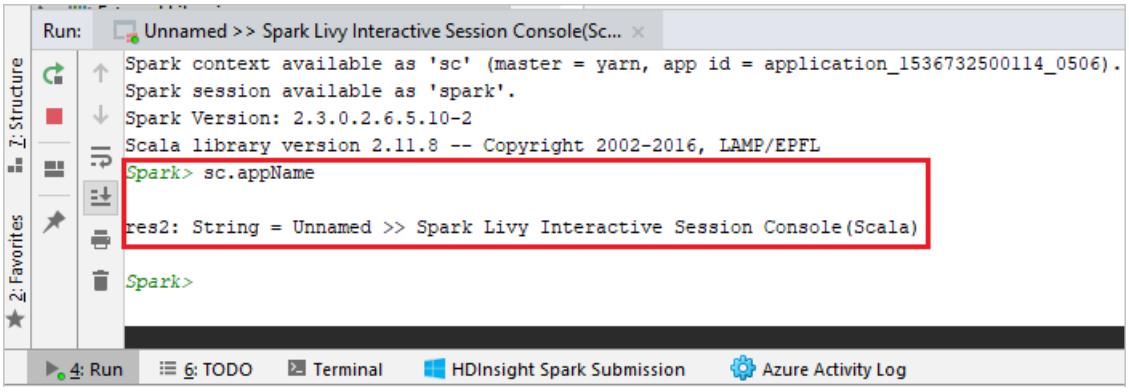
PROPERTY	VALUE
Main class name	Select the Main class name.
Spark pools	Select the Spark pools on which you want to run your application.



5. From Project, navigate to **myApp** > **src** > **main** > **scala** > **myApp**.

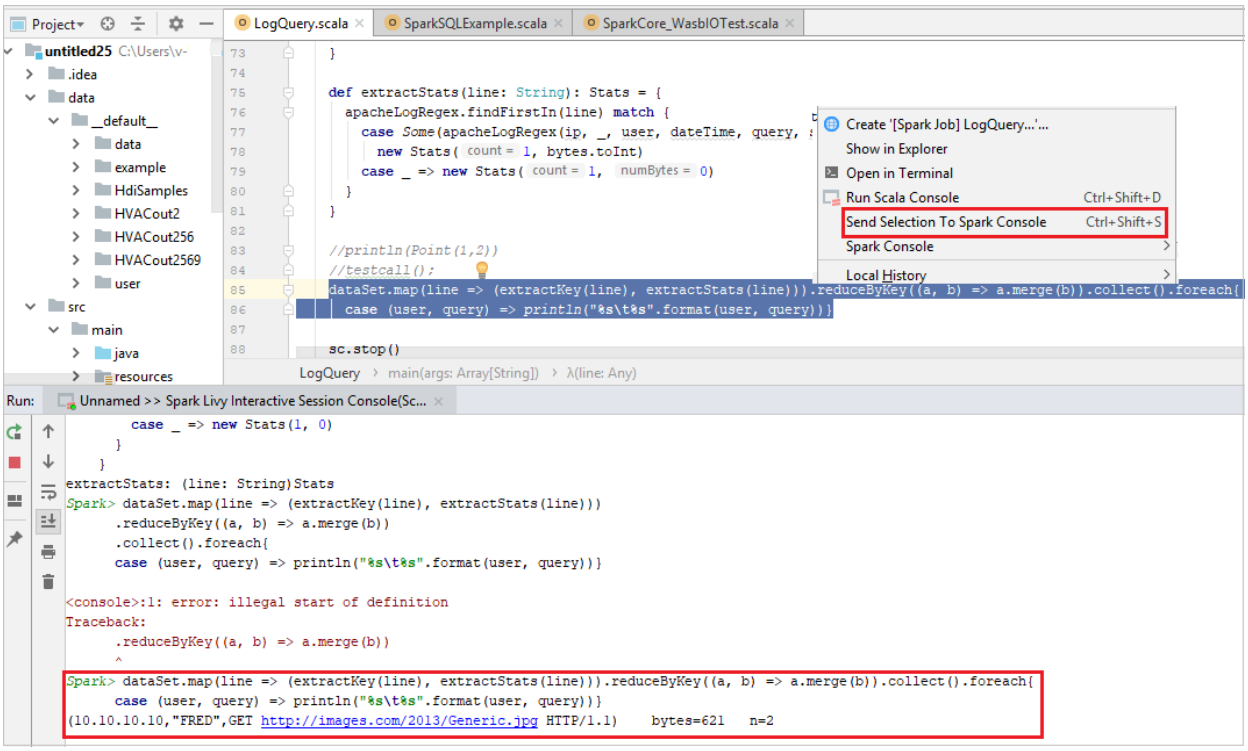
6. From the menu bar, navigate to **Tools** > **Spark console** > **Run Spark Livy Interactive Session Console(Scala)**.

7. The console should look similar to the picture below. In the console window type `sc.appName`, and then press ctrl+Enter. The result will be shown. You can stop the local console by selecting red button.



Send selection to Spark console

You may want to see the script result by sending some code to the local console or Livy Interactive Session Console(Scala). To do so, you can highlight some code in the Scala file, then right-click **Send Selection To Spark console**. The selected code will be sent to the console and be done. The result will be displayed after the code in the console. The console will check the existing errors.



Next steps

- Azure Synapse Analytics
- Create a new Apache Spark pool for an Azure Synapse Analytics workspace

Tutorial: Create an Apache Spark application with VSCode using a Synapse workspace

8/19/2022 • 7 minutes to read • Edit Online

Learn how to use Apache Spark & Hive Tools for Visual Studio Code. Use the tools to create and submit Apache Hive batch jobs, interactive Hive queries, and PySpark scripts for Apache Spark. First we'll describe how to install Spark & Hive Tools in Visual Studio Code. Then we'll walk through how to submit jobs to Spark & Hive Tools.

Spark & Hive Tools can be installed on platforms that are supported by Visual Studio Code. Note the following prerequisites for different platforms.

Prerequisites

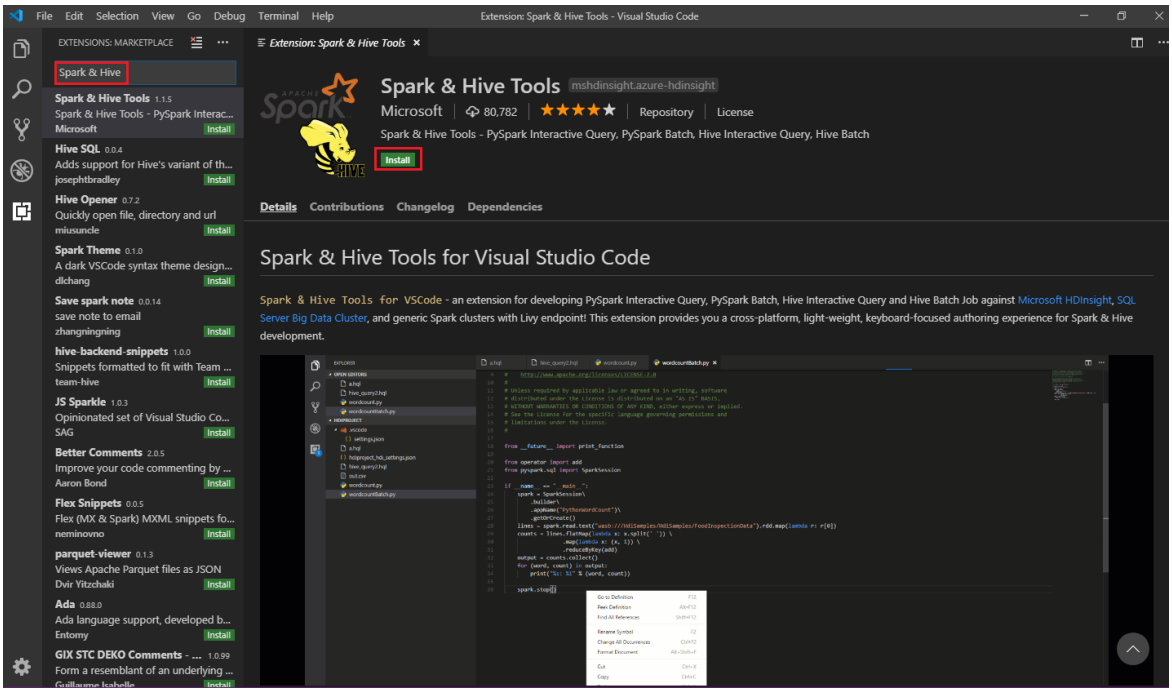
The following items are required for completing the steps in this article:

- A serverless Apache Spark pool. To create a serverless Apache Spark pool, see Create Apache Spark pool using Azure portal.
- Visual Studio Code.
- Mono. Mono is required only for Linux and macOS.
- A PySpark interactive environment for Visual Studio Code.
- A local directory. This article uses **C:\HD\Synaseexample**.

Install Spark & Hive Tools

After you meet the prerequisites, you can install Spark & Hive Tools for Visual Studio Code by following these steps:

1. Open Visual Studio Code.
2. From the menu bar, navigate to **View** > **Extensions**.
3. In the search box, enter **Spark & Hive**.
4. Select **Spark & Hive Tools** from the search results, and then select **Install**:



5. Select **Reload** when necessary.

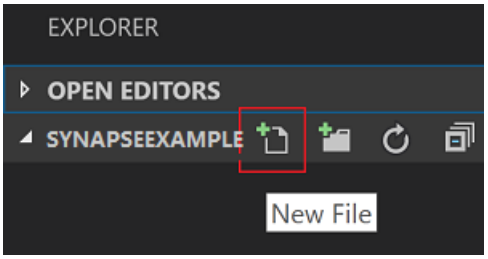
> **NOTE**
>
> **Synapse PySpark installation error** is an known issue.

Open a work folder

To open a work folder and to create a file in Visual Studio Code, follow these steps:

1. From the menu bar, navigate to **File** > **Open Folder...** > **C:\HD\Synaseexample**, and then select the **Select Folder** button. The folder appears in the **Explorer** view on the left.

2. In **Explorer** view, select the **Synaseexample** folder, and then select the **New File** icon next to the work folder:



3. Name the new file by using the `.py` (Spark script) file extension. This example uses **HelloWorld.py**.

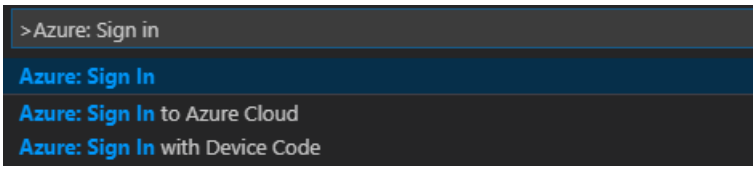
Connect to your Spark pools

Sign in to Azure subscription to connect to your Spark pools.

Sign in to your Azure subscription

Follow these steps to connect to Azure:

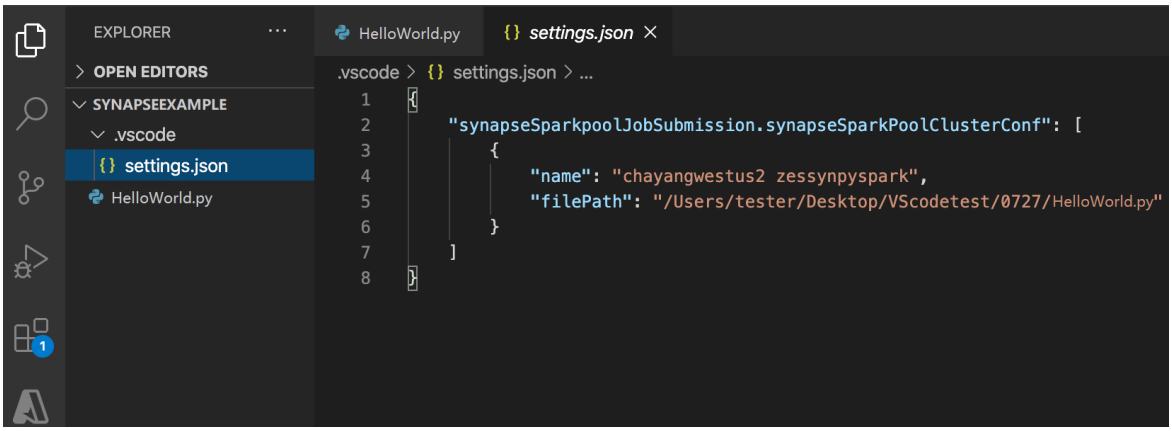
1. From the menu bar, navigate to **View** > **Command Palette...**, and enter **Azure: Sign In**:



2. Follow the sign-in instructions to sign in to Azure. After you're connected, your Azure account name shows on the status bar at the bottom of the Visual Studio Code window.

Set the default Spark pool

1. Reopen the **Synaseexample** folder that was discussed earlier, if closed.
2. Select the **HelloWorld.py** file that was created earlier. It opens in the script editor.
3. Right-click the script editor, and then select **Synapse: Set default Spark pool**.
4. Connect to your Azure account if you haven't yet done so.
5. Select a Spark pool as the default Spark pool for the current script file.
6. Use **Synapse: PySpark Interactive** to submit this file. And the tools automatically update the **.VSCode\settings.json** configuration file:



Submit interactive Synapse PySpark queries to Spark pool (Not supported anymore)

> **NOTE**
> For Synapse Pyspark interactive, since its dependency will not be maintained anymore by other team, this will not be maintained anymore as well. If you trying to use Synapse Pyspark interactive, please switch to use Azure Synapse Analytics instead. And it's a long term change.

Users can perform Synapse PySpark interactive on Spark pool in the following ways:

Using the Synapse PySpark interactive command in PY file

Using the PySpark interactive command to submit the queries, follow these steps:

1. Reopen the **Synaseexample** folder that was discussed earlier, if closed.
2. Create a new **HelloWorld.py** file, following the earlier steps.
3. Copy and paste the following code into the script file:

```
import sys
from operator import add
from pyspark.sql import SparkSession, Row

spark = SparkSession\
 .builder\
 .appName("PythonWordCount")\
 .getOrCreate()

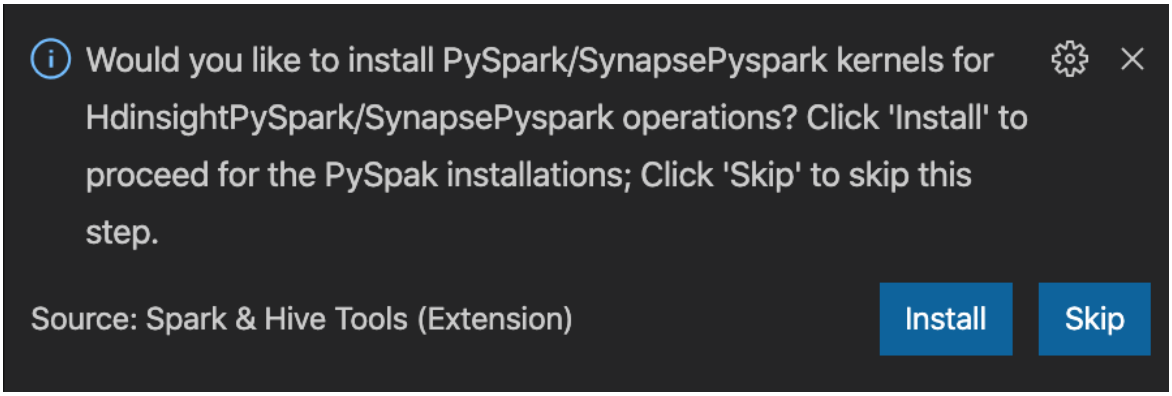
data = [Row(col1='pyspark and spark', col2=1), Row(col1='pyspark', col2=2), Row(col1='spark vs hadoop',
col2=2), Row(col1='spark', col2=2), Row(col1='hadoop', col2=2)]
df = spark.createDataFrame(data)
lines = df.rdd.map(lambda r: r[0])

counters = lines.flatMap(lambda x: x.split(' ')) \
 .map(lambda x: (x, 1)) \
 .reduceByKey(add)

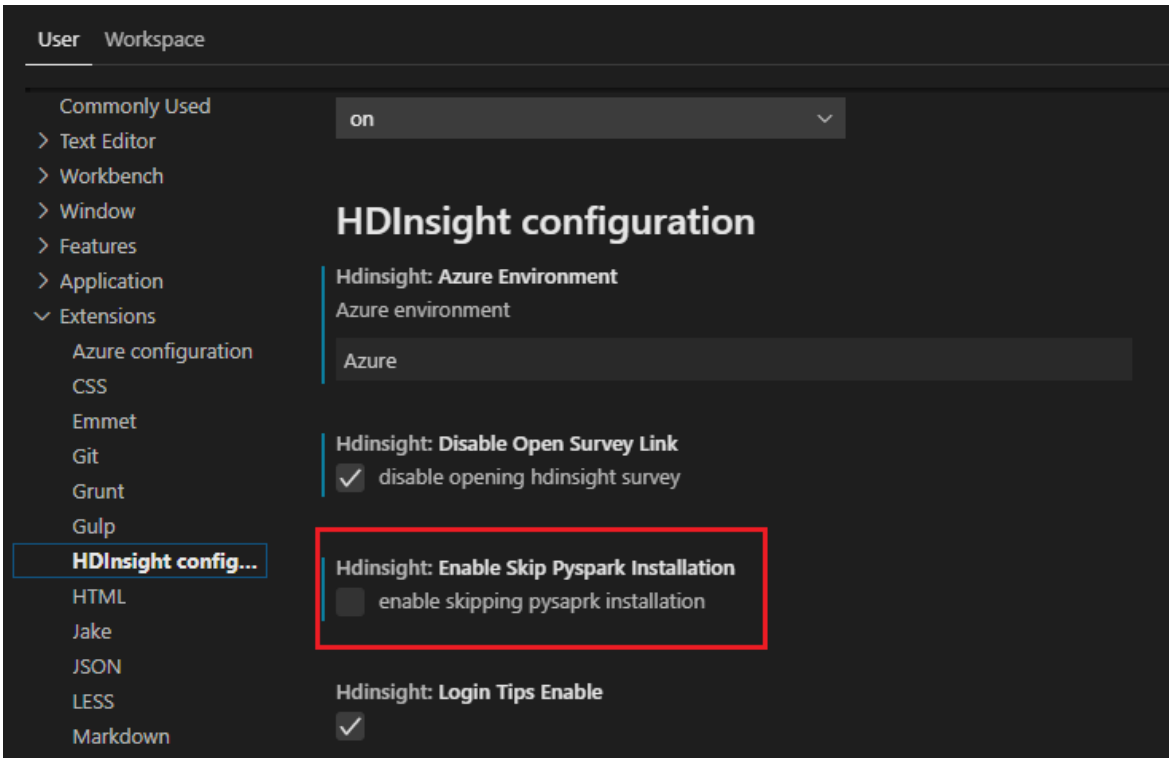
output = counters.collect()
sortedCollection = sorted(output, key = lambda r: r[1], reverse = True)

for (word, count) in sortedCollection:
 print("%s: %i" % (word, count))
```

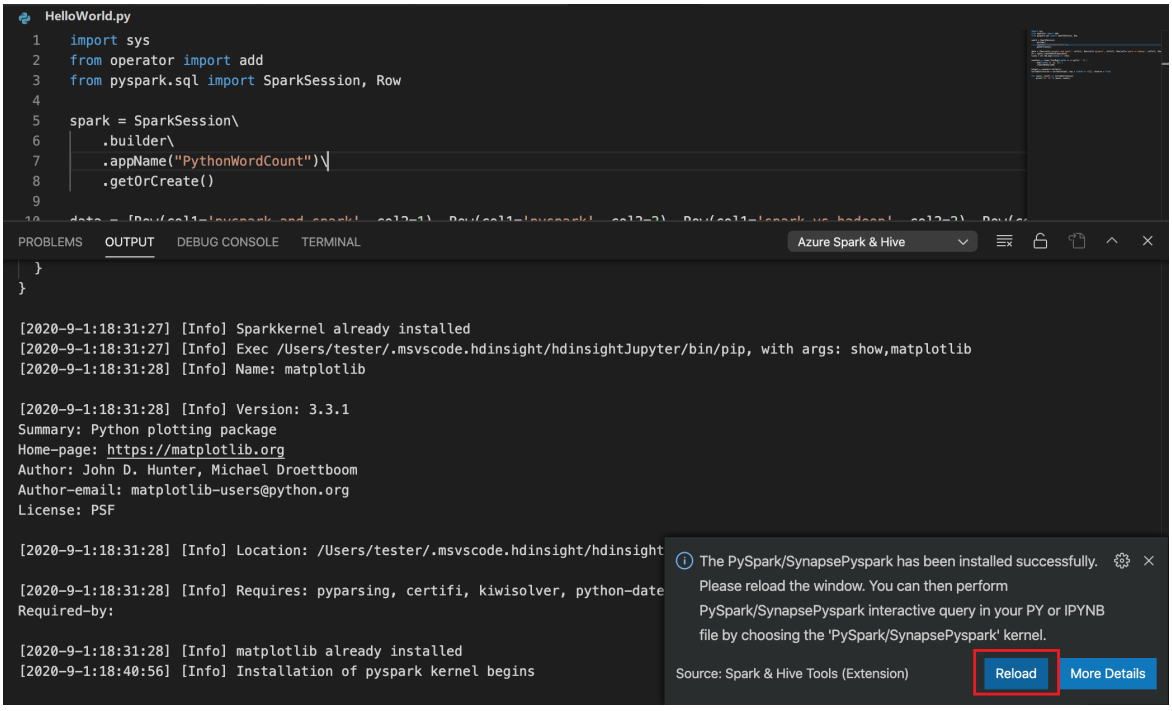
4. The prompt to install PySpark/Synapse Pyspark kernel is displayed in the lower right corner of the window. You can click on **Install** button to proceed for the PySpark/Synapse Pyspark installations; or click on **Skip** button to skip this step.



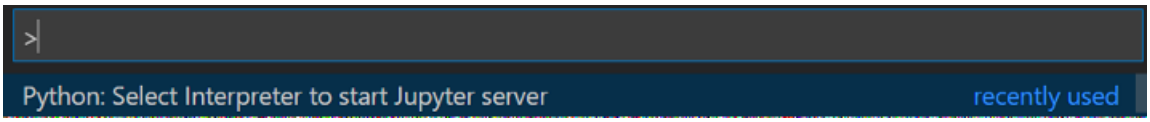
5. If you need to install it later, you can navigate to **File** > **Preference** > **Settings**, then uncheck **Hdinsight: Enable Skip Pyspark Installation** in the settings.



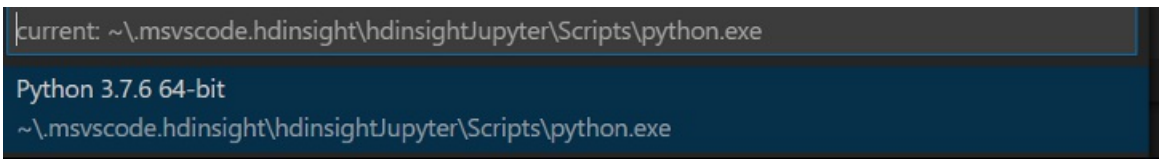
6. If the installation is successful in step 4, the "PySpark/Synapse Pyspark installed successfully" message box is displayed in the lower right corner of the window. Click on **Reload** button to reload the window.



7. From the menu bar, navigate to **View** > **Command Palette...** or use the **Shift + Ctrl + P** keyboard shortcut, and enter **Python: Select Interpreter to start Jupyter Server**.



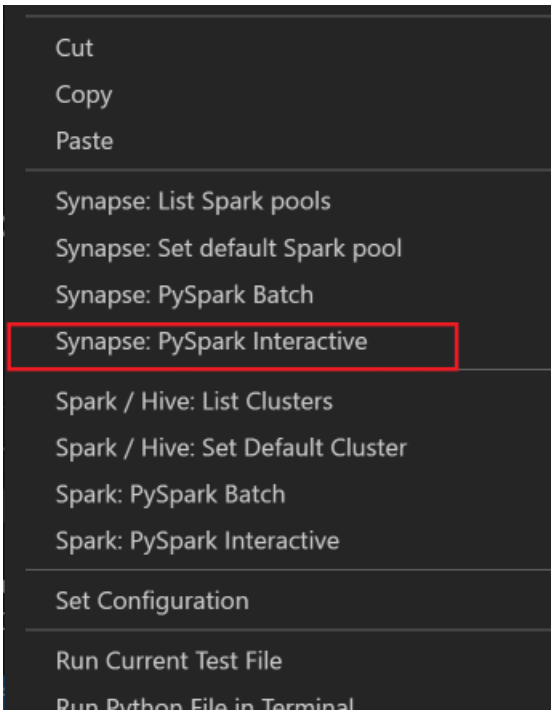
8. Select the Python option below.



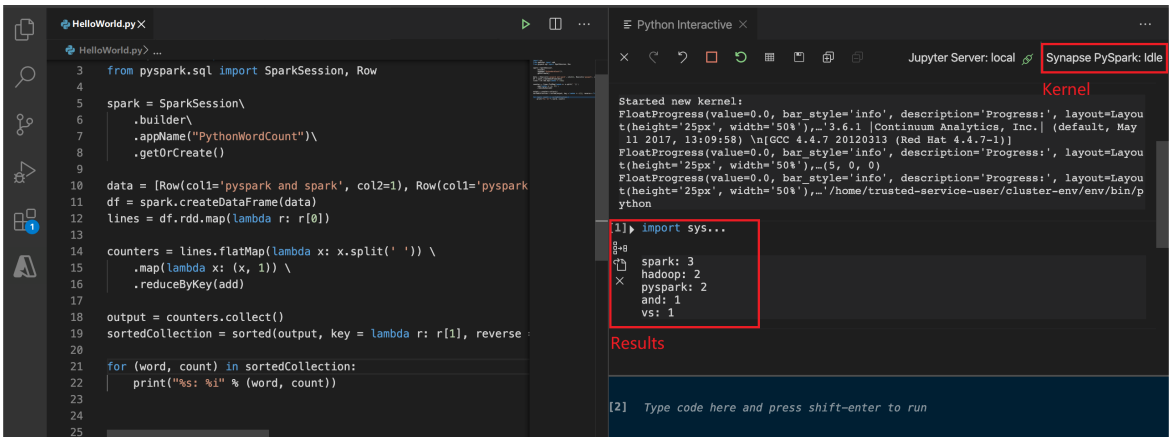
9. From the menu bar, navigate to **View** > **Command Palette...** or use the **Shift + Ctrl + P** keyboard shortcut, and enter **Developer: Reload Window**.

10. Connect to your Azure account if you haven't yet done so.

11. Select all the code, right-click the script editor, and select **Synapse: Pyspark Interactive** to submit the query.

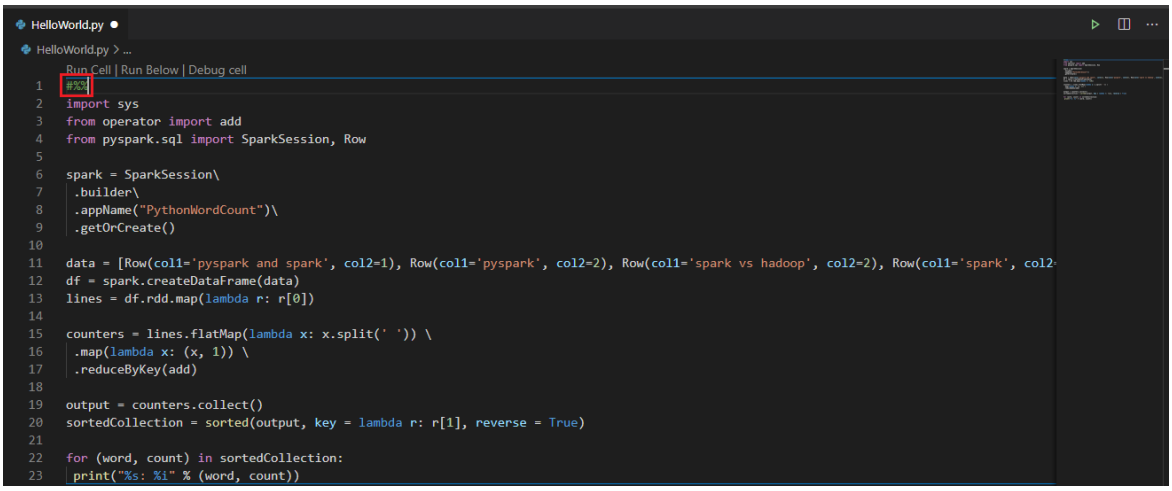


12. Select the Spark pool, if you haven't specified a default Spark pool. After a few moments, the **Python Interactive** results appear in a new tab. Click on PySpark to switch the kernel to **Synapse PySpark**, then, submit the selected code again, and the code will run successfully. The tools also let you submit a block of code instead of the whole script file by using the context menu:

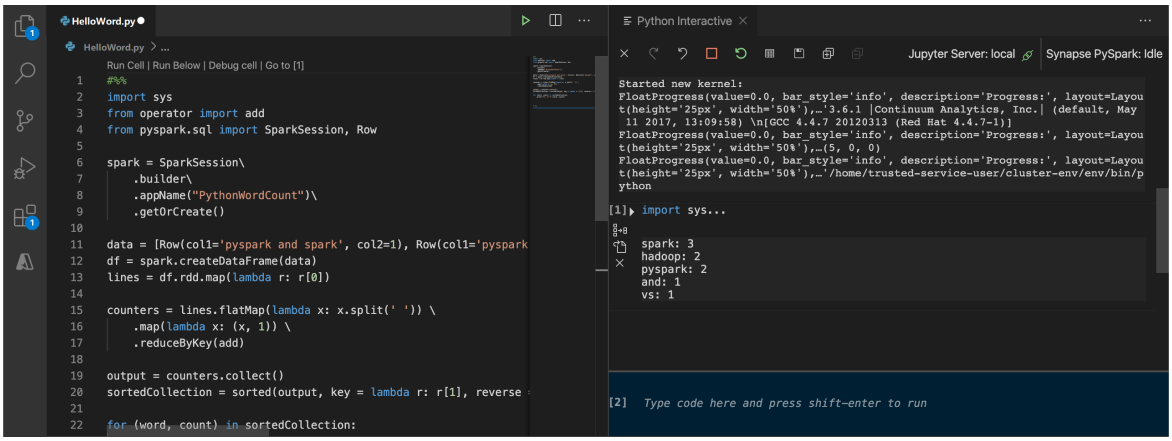


Perform interactive query in PY file using a #%% comment

1. Add **#%%** before the code to get notebook experience.



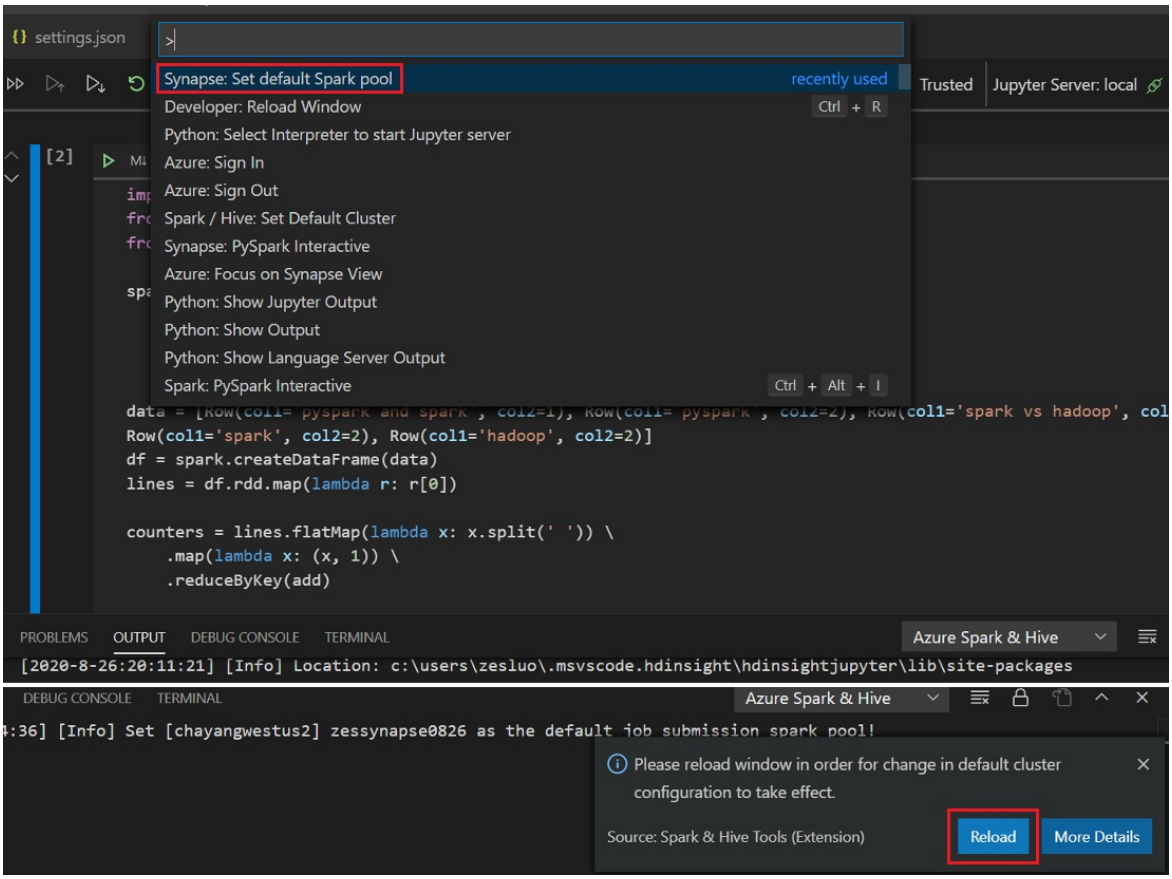
2. Click on **Run Cell**. After a few moments, the Python Interactive results appear in a new tab. Click on PySpark to switch the kernel to **Synapse PySpark**, then, click on **Run Cell** again, and the code will run successfully.



Leverage IPYNB support from Python extension

1. You can create a Jupyter Notebook by command from the Command Palette or by creating a new .ipynb file in your workspace. For more information, see Working with Jupyter Notebooks in Visual Studio Code

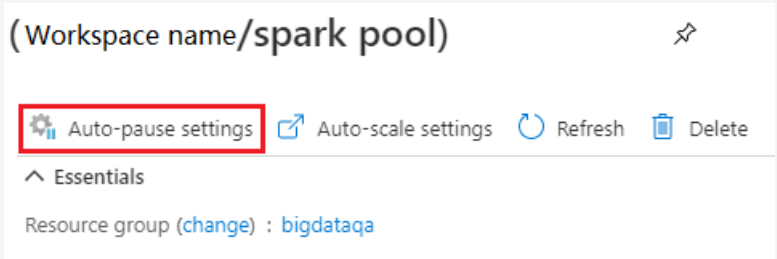
2. Click on **Run cell** button, follow the prompts to **Set the default spark pool** (strongly encourage to set default cluster/pool every time before opening a notebook) and then, **Reload** window.



3. Click on PySpark to switch kernel to **Synapse Pyspark**, and then click on **Run Cell**, after a while, the result will be displayed.

NOTE

1. Ms-python >=2020.5.78807 version is not supported on this extention is a known issue.
2. Switch to Synapse Pyspark kernel, disabling auto-settings in Azure Portal is encouraged. Otherwise it may take a long while to wake up the cluster and set synapse kernel for the first time use.



Spark session config

You can specify the timeout duration, the number, and the size of executors to give to the current Spark session in **Configure session**. Restart the Spark session is for configuration changes to take effect. All cached

notebook variables are cleared.

```
%%configure -f
{
    // refer to https://github.com/cloudera/livy#request-body for a list of valid parameters to config the
session.
    "driverMemory":"2g",
    "driverCores":3,
    "executorMemory":"2g",
    "executorCores":2,
    "jars":[],
    "conf":{
        "spark.driver.maxResultSize":"10g"
    }
}
```

> **NOTE**
> Display function and Spark SQL may not be rendered properly in the output cell.

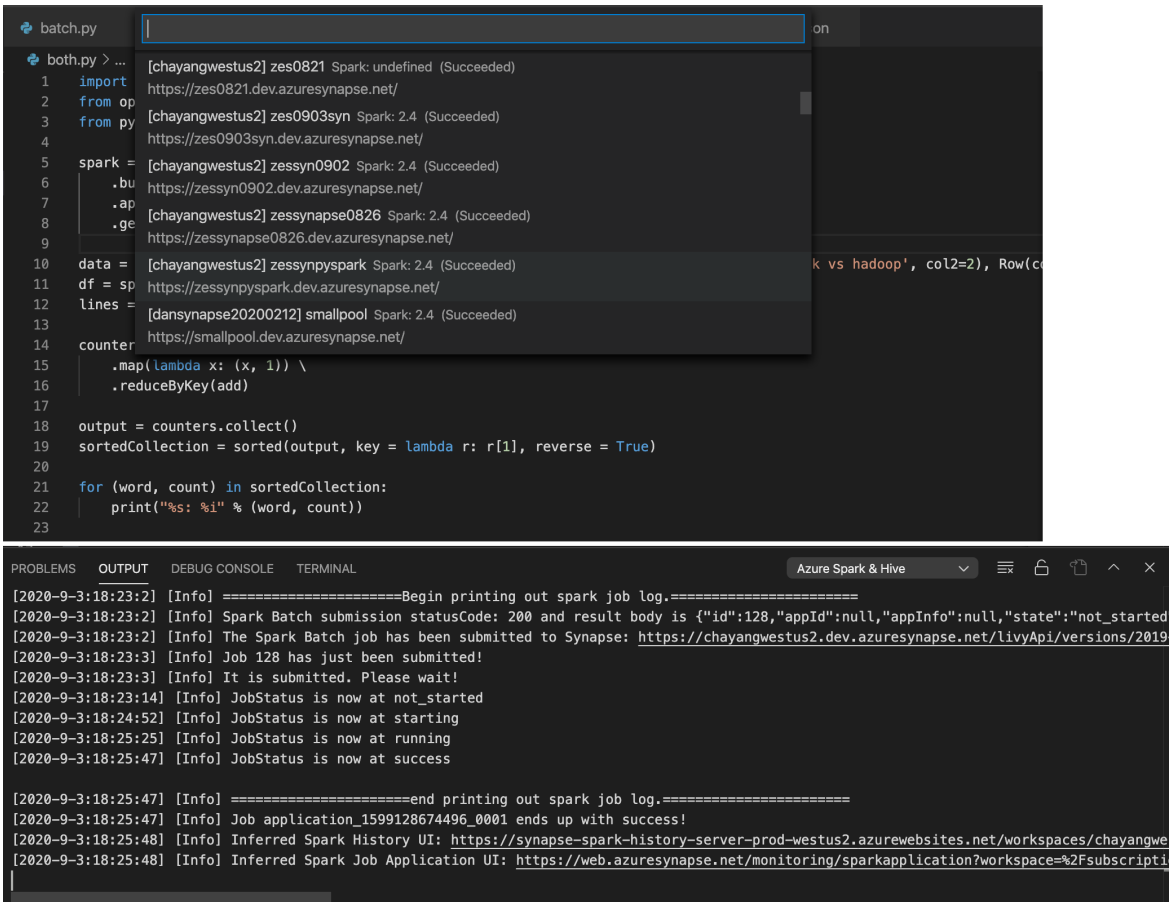
Submit PySpark batch job to Spark pool

1. Reopen the **Synaseexample** folder that you discussed earlier, if closed.
2. Create a new **BatchFile.py** file by following the earlier steps.
3. Copy and paste the following code into the script file:

```
from __future__ import print_function
import sys
from operator import add
from pyspark.sql import SparkSession
if __name__ == "__main__":
    spark = SparkSession\
        .builder\
        .appName("PythonWordCount")\
        .getOrCreate()

    lines = spark.read.text('/HdiSamples/HdiSamples/SensorSampleData/hvac/HVAC.csv').rdd.map(lambda
r: r[0])
    counts = lines.flatMap(lambda x: x.split(' '))\
                .map(lambda x: (x, 1))\
                .reduceByKey(add)
    output = counts.collect()
    for (word, count) in output:
        print("%s: %i" % (word, count))
    spark.stop()
```

4. Connect to your Azure account if you haven't yet done so.
5. Right-click the script editor, and then select **Synapse: PySpark Batch**.
6. Select a Spark pool to submit your PySpark job to:



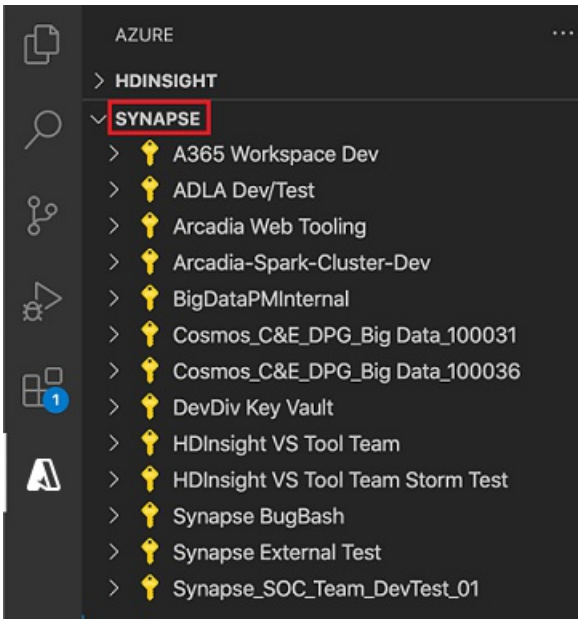
After you submit a batch job to spark pool, submission logs appear in the **OUTPUT** window in Visual Studio Code. The **Spark UI** URL and **Spark Job Application UI** URL are also shown. You can open the URL in a web browser to track the job status.

Access and manage Synapse Workspace

You can perform different operations in Azure Explorer within Spark & Hive tools for VSCode. From the Azure Explorer.

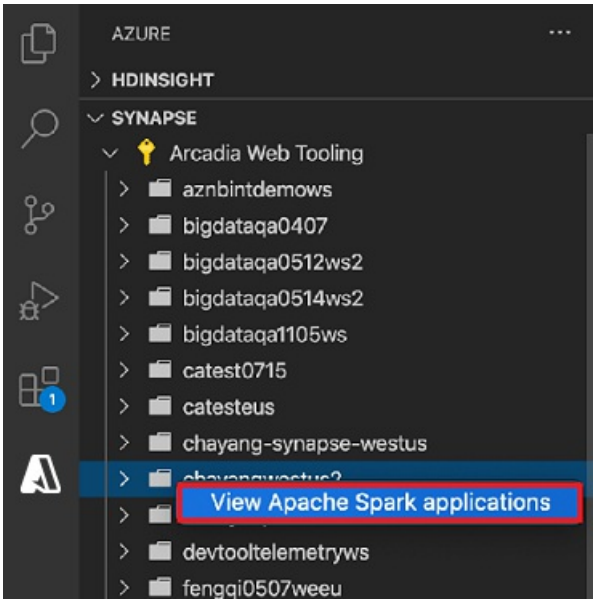
Launch workspace

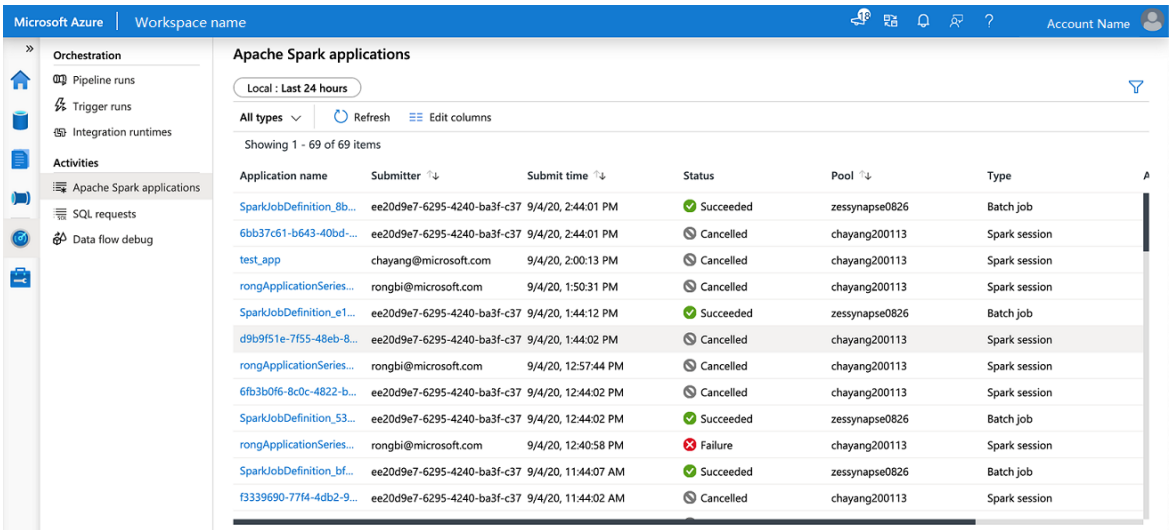
1. From Azure Explorer, navigate to **SYNAPSE**, expand it, and display the Synapse Subscription list.



2. Click on Subscription of Synapse workspace, expand it, and display the workspace list.

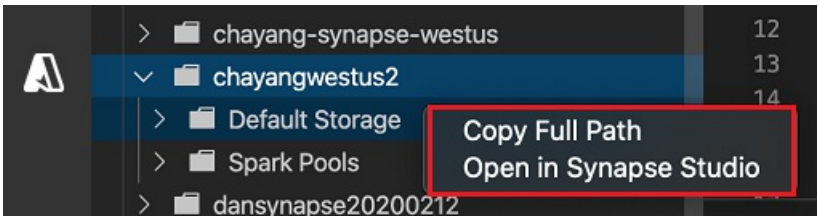
3. Right-click a workspace, then select **View Apache Spark applications**, the Apache Spark application page in the Synapse Studio website will be opened.



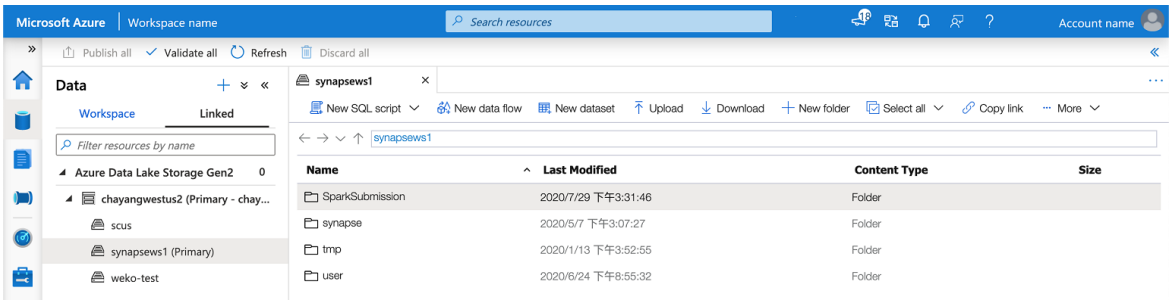


4. Expand a workspace, **Default Storage** and **Spark Pools** are displayed.

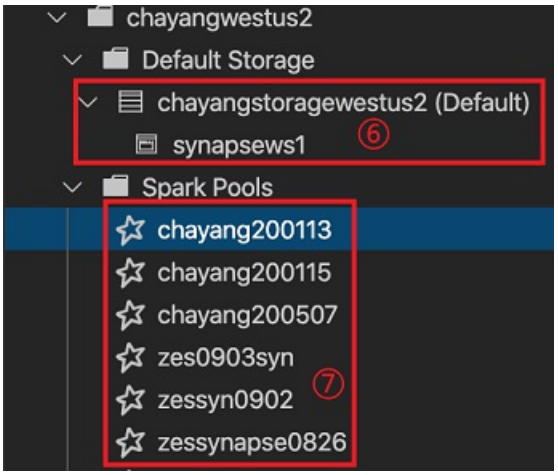
5. Right-click on **Default Storage**, the **Copy Full Path** and **Open in Synapse Studio** are displayed.



- Click on **Copy Full Path**, the Primary ADLS Gen2 account URL will be copied, you can paste it where you need。
- Click on **Open in Synapse Studio**, the Primary Storage Account will be opened in Synapse Studio.

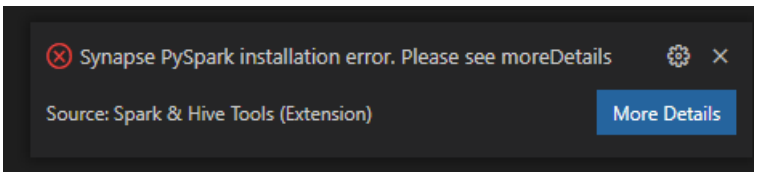


6. Expand the **Default Storage**, the Primary Storage Account is displayed.
7. Expand the **Spark Pools**, all spark pools in the workspace are displayed.



Known issues

Synapse PySpark installation error.



Not supported submit interactive Synapse PySpark queries to Spark pool anymore

For Synapse Pyspark interactive, since its dependency will not be maintained anymore by other team, this will not be maintained anymore as well. If you trying to use Synapse Pyspark interactive, please switch to use Azure Synapse Analytics instead. And it's a long term change.

Next steps

- Azure Synapse Analytics

- Create a new Apache Spark pool for an Azure Synapse Analytics workspace

Use .NET for Apache Spark with Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

.NET for Apache Spark provides free, open-source, and cross-platform .NET support for Spark.

It provides .NET bindings for Spark, which allows you to access Spark APIs through C# and F#. With .NET for Apache Spark, you can also write and execute user-defined functions for Spark written in .NET. The .NET APIs for Spark enable you to access all aspects of Spark DataFrames that help you analyze your data, including Spark SQL, Delta Lake, and Structured Streaming.

You can analyze data with .NET for Apache Spark through Spark batch job definitions or with interactive Azure Synapse Analytics notebooks. In this article, you learn how to use .NET for Apache Spark with Azure Synapse using both techniques.

Submit batch jobs using the Spark job definition

Visit the tutorial to learn how to use Azure Synapse Analytics to create Apache Spark job definitions for Synapse Spark pools. If you haven't packaged your app to submit to Azure Synapse, complete the following steps.

1. Run the following commands to publish your app. Be sure to replace *mySparkApp* with the path to your app.

   ```
   cd mySparkApp
   dotnet publish -c Release -f netcoreapp3.1 -r ubuntu.18.04-x64
   ```

2. Zip the contents of the publish folder, `publish.zip` for example, that was created as a result of Step 1. All the assemblies should be in the first layer of the ZIP file and there should be no intermediate folder layer. This means when you unzip `publish.zip`, all assemblies are extracted into your current working directory.

   On Windows:

   Use an extraction program, like 7-Zip or WinZip, to extract the file into the bin directory with all the published binaries.

   On Linux:

   Open a bash shell and cd into the bin directory with all the published binaries and run the following command.

   ```
   zip -r publish.zip
   ```

.NET for Apache Spark in Azure Synapse Analytics notebooks

Notebooks are a great option for prototyping your .NET for Apache Spark pipelines and scenarios. You can start working with, understanding, filtering, displaying, and visualizing your data quickly and efficiently.

Data engineers, data scientists, business analysts, and machine learning engineers are all able to collaborate over a shared, interactive document. You see immediate results from data exploration, and can visualize your

data in the same notebook.

How to use .NET for Apache Spark notebooks

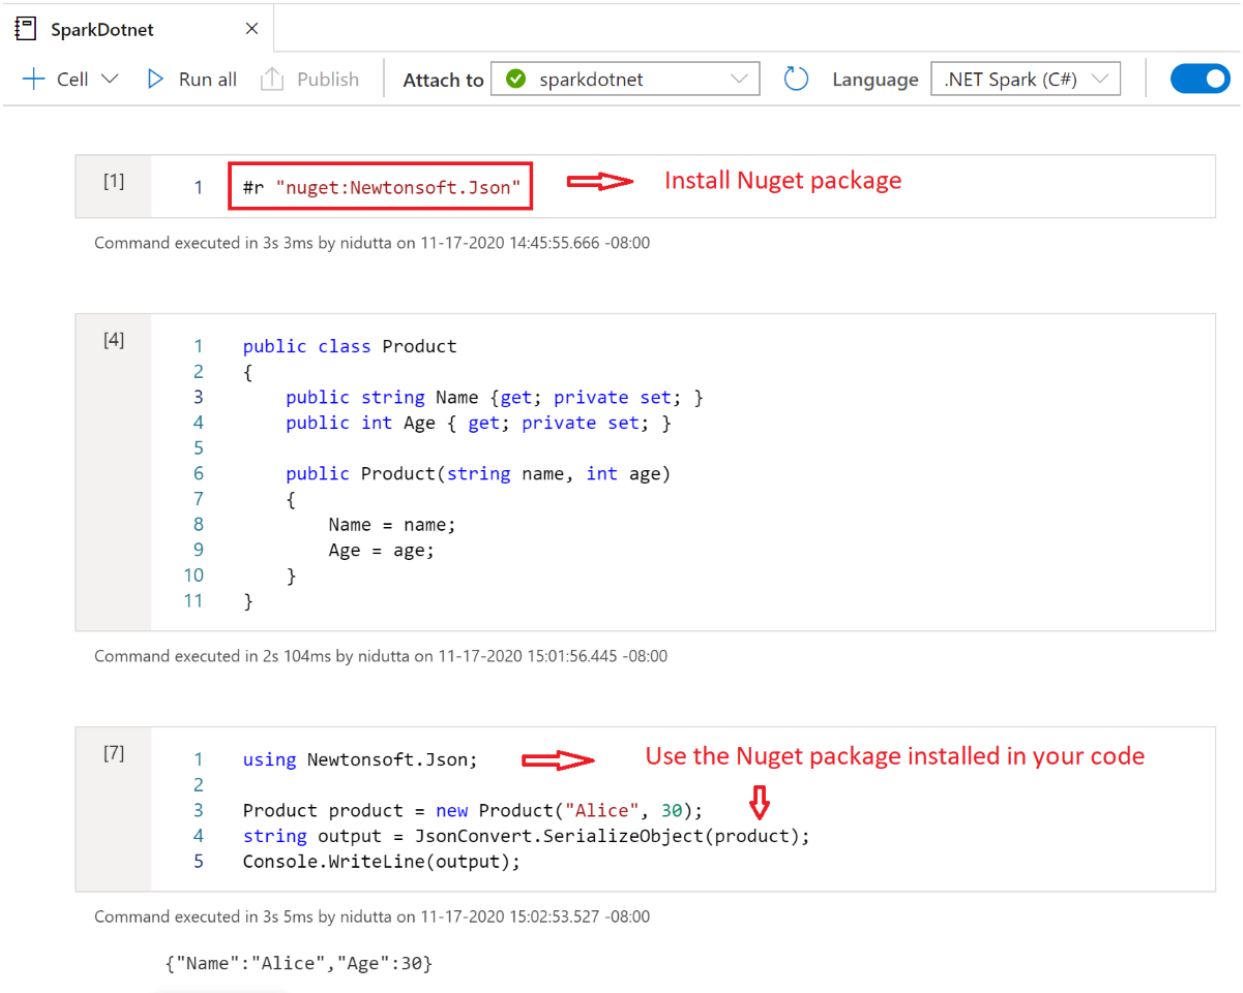
When you create a new notebook, you choose a language kernel that you wish to express your business logic. Kernel support is available for several languages, including C#.

To use .NET for Apache Spark in your Azure Synapse Analytics notebook, select **.NET Spark (C#)** as your kernel and attach the notebook to an existing serverless Apache Spark pool.

The .NET Spark notebook is based on the .NET interactive experiences and provides interactive C# experiences with the ability to use .NET for Spark out of the box with the Spark session variable `spark` already predefined.

Install NuGet packages in notebooks

You can install NuGet packages of your choice into your notebook by using the `#r nuget` magic command before the name of the NuGet package. The following diagram shows an example:



To learn more about how to work with NuGet packages in notebooks, see the .NET Interactive Documentation.

.NET for Apache Spark C# kernel features

The following features are available when you use .NET for Apache Spark in the Azure Synapse Analytics notebook:

- Declarative HTML: Generate output from your cells using HTML-syntax, such as headers, bulleted lists, and even displaying images.
- Simple C# statements (such as assignments, printing to console, throwing exceptions, and so on).
- Multi-line C# code blocks (such as if statements, foreach loops, class definitions, and so on).
- Access to the standard C# library (such as System, LINQ, Enumerables, and so on).
- Support for C# 8.0 language features.

- `spark` as a pre-defined variable to give you access to your Apache Spark session.
- Support for defining .NET user-defined functions that can run within Apache Spark. We recommend Write and call UDFs in .NET for Apache Spark Interactive environments for learning how to use UDFs in .NET for Apache Spark Interactive experiences.
- Support for visualizing output from your Spark jobs using different charts (such as line, bar, or histogram) and layouts (such as single, overlaid, and so on) using the `XPlot.Plotly` library.
- Ability to include NuGet packages into your C# notebook.

Secure credentials with linked services using the TokenLibrary

8/19/2022 • 5 minutes to read • Edit Online

Accessing data from external sources is a common pattern. Unless the external data source allows anonymous access, chances are you need to secure your connection with a credential, secret, or connection string.

Synapse uses Azure Active Directory (AAD) passthrough by default for authentication between resources. If you need to connect to a resource using other credentials, use the TokenLibrary directly. The TokenLibrary simplifies the process of retrieving SAS tokens, AAD tokens, connection strings, and secrets stored in a linked service or from an Azure Key Vault.

AAD passthrough uses permissions assigned to you as a user in AAD, rather than permissions assigned to Synapse or a separate service principal. For example, if you want to use AAD passthrough to access a blob in a storage account, then you should go to that storage account and assign blob contributor role to yourself.

When retrieving secrets from Azure Key Vault, we recommend creating a linked service to your Azure Key Vault. Ensure that the Synapse workspace managed service identity (MSI) has Secret Get privileges on your Azure Key Vault. Synapse will authenticate to Azure Key Vault using the Synapse workspace managed service identity. If you connect directly to Azure Key Vault without a linked service, you will authenticate using your user Azure Active Directory credential.

For more information, see linked services.

Usage

TokenLibrary.help()

This function displays the help documentation for the TokenLibrary.

```
TokenLibrary.help()
```

```
TokenLibrary.help()
```

```
Console.WriteLine(TokenLibrary.help());
```

TokenLibrary for Azure Data Lake Storage Gen2

ADLS Gen2 Primary Storage

Accessing files from the primary Azure Data Lake Storage uses Azure Active Directory passthrough for authentication by default and doesn't require the explicit use of the TokenLibrary.

```
val df = spark.read.csv("abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>")
display(df.limit(10))
```

```
df = spark.read.csv('abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>')
display(df.limit(10))
```

ADLS Gen2 storage with linked services

Synapse provides an integrated linked services experience when connecting to Azure Data Lake Storage Gen2. Linked Services can be configured to authenticate using an **Account Key**, **Service Principal**, **Managed Identity**, or **Credential**.

When the linked service authentication method is set to **Account Key**, the linked service will authenticate using the provided storage account key, request a SAS key, and automatically apply it to the storage request using the **LinkedServiceBasedSASProvider**.

Synapse allows users to set the linked service for a particular storage account. This makes it possible to read/write data from **multiple storage accounts** in a single spark application/query. Once we set **spark.storage.synapse.{source_full_storage_account_name}.linkedServiceName** for each storage account that will be used, Synapse figures out which linked service to use for a particular read/write operation. However if our spark job only deals with a single storage account, we can simply omit the storage account name and use **spark.storage.synapse.linkedServiceName**

```
val sc = spark.sparkContext
val source_full_storage_account_name = "teststorage.dfs.core.windows.net"
spark.conf.set(f"spark.storage.synapse.{source_full_storage_account_name}.linkedServiceName", "<LINKED
SERVICE NAME>")
spark.conf.set(f"fs.azure.account.auth.type.{source_full_storage_account_name}", "SAS")
spark.conf.set(f"fs.azure.sas.token.provider.type.{source_full_storage_account_name}",
"com.microsoft.azure.synapse.tokenlibrary.LinkedServiceBasedSASProvider")

val df = spark.read.csv("abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>")

display(df.limit(10))
```

```
%%pyspark
# Python code
val source_full_storage_account_name = "teststorage.dfs.core.windows.net"
spark.conf.set(f"spark.storage.synapse.{source_full_storage_account_name}.linkedServiceName", "<lINKED
SERVICE NAME>")
spark.conf.set(f"fs.azure.account.auth.type.{source_full_storage_account_name}", "SAS")
spark.conf.set(f"fs.azure.sas.token.provider.type.{source_full_storage_account_name}",
"com.microsoft.azure.synapse.tokenlibrary.LinkedServiceBasedSASProvider")

df = spark.read.csv('abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<DIRECTORY PATH>')

df.show()
```

When the linked service authentication method is set to **Managed Identity** or **Service Principal**, the linked service will use the Managed Identity or Service Principal token with the **LinkedServiceBasedTokenProvider** provider.

```
val sc = spark.sparkContext
val source_full_storage_account_name = "teststorage.dfs.core.windows.net"
spark.conf.set(f"spark.storage.synapse.{source_full_storage_account_name}.linkedServiceName", "<LINKED
SERVICE NAME>")
spark.conf.set(f"fs.azure.account.oauth.provider.type.{source_full_storage_account_name}",
"com.microsoft.azure.synapse.tokenlibrary.LinkedServiceBasedTokenProvider")
val df = spark.read.csv("abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>")

display(df.limit(10))
```

```
%%pyspark
# Python code
val source_full_storage_account_name = "teststorage.dfs.core.windows.net"
spark.conf.set(f"spark.storage.synapse.{source_full_storage_account_name}.linkedServiceName", "<LINKED
SERVICE NAME>")
spark.conf.set(f"fs.azure.account.oauth.provider.type.{source_full_storage_account_name}",
"com.microsoft.azure.synapse.tokenlibrary.LinkedServiceBasedTokenProvider")

df = spark.read.csv('abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<DIRECTORY PATH>')

df.show()
```

ADLS Gen2 storage (without linked services)

Connect to ADLS Gen2 storage directly by using a SAS key use the **ConfBasedSASProvider** and provide the SAS key to the **spark.storage.synapse.sas** configuration setting.

```
%%spark
spark.conf.set("fs.azure.account.auth.type", "SAS")
spark.conf.set("fs.azure.sas.token.provider.type",
"com.microsoft.azure.synapse.tokenlibrary.ConfBasedSASProvider")
spark.conf.set("spark.storage.synapse.sas", "<SAS KEY>")

val df = spark.read.csv("abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>")

display(df.limit(10))
```

```
%%pyspark

spark.conf.set("fs.azure.account.auth.type", "SAS")
spark.conf.set("fs.azure.sas.token.provider.type",
"com.microsoft.azure.synapse.tokenlibrary.ConfBasedSASProvider")
spark.conf.set("spark.storage.synapse.sas", "<SAS KEY>")

df = spark.read.csv('abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>')

display(df.limit(10))
```

ADLS Gen2 storage with Azure Key Vault

Connect to ADLS Gen2 storage using a SAS token stored in Azure Key Vault secret.

```
%%spark
spark.conf.set("fs.azure.account.auth.type", "SAS")
spark.conf.set("fs.azure.sas.token.provider.type",
"com.microsoft.azure.synapse.tokenlibrary.AkvBasedSASProvider")
spark.conf.set("spark.storage.synapse.akv", "<AZURE KEY VAULT NAME>")
spark.conf.set("spark.storage.akv.secret", "<SECRET KEY>")

val df = spark.read.csv("abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>")

display(df.limit(10))
```

```
%%pyspark
spark.conf.set("fs.azure.account.auth.type", "SAS")
spark.conf.set("fs.azure.sas.token.provider.type",
"com.microsoft.azure.synapse.tokenlibrary.AkvBasedSASProvider")
spark.conf.set("spark.storage.synapse.akv", "<AZURE KEY VAULT NAME>")
spark.conf.set("spark.storage.akv.secret", "<SECRET KEY>")

df = spark.read.csv('abfss://<CONTAINER>@<ACCOUNT>.dfs.core.windows.net/<FILE PATH>')

display(df.limit(10))
```

TokenLibrary for other linked services

To connect to other linked services, you can make a direct call to the TokenLibrary.

getConnectionString()

To retrieve the connection string, use the **getConnectionString** function and pass in the **linked service name**.

```
%%spark
// retrieve connectionstring from TokenLibrary

import com.microsoft.azure.synapse.tokenlibrary.TokenLibrary

val connectionString: String = TokenLibrary.getConnectionString("<LINKED SERVICE NAME>")
println(connectionString)
```

```
%%pyspark
# retrieve connectionstring from TokenLibrary

from pyspark.sql import SparkSession

sc = SparkSession.builder.getOrCreate()
token_library = sc._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
connection_string = token_library.getConnectionString("<LINKED SERVICE NAME>")
print(connection_string)
```

```
%%csharp
// retrieve connectionstring from TokenLibrary

using Microsoft.Spark.Extensions.Azure.Synapse.Analytics.Utils;

string connectionString = TokenLibrary.GetConnectionString(<LINKED SERVICE NAME>);
Console.WriteLine(connectionString);
```

getConnectionStringAsMap()

The getConnectionStringAsMap is a helper function available in Scala and Python to parse specific values from a *key=value* pair in the connection string such as

```
DefaultEndpointsProtocol=https;AccountName=<ACCOUNT NAME>;AccountKey=<ACCOUNT KEY>
```

use the **getConnectionStringAsMap** function and pass the key to return the value. In the above connection string example,

TokenLibrary.getConnectionStringAsMap("DefaultEndpointsProtocol")

would return

"https"

```
// Linked services can be used for storing and retrieving credentials (e.g, account key)
// Example connection string (for storage): "DefaultEndpointsProtocol=https;AccountName=
<accountname>;AccountKey=<accountkey>"
import com.microsoft.azure.synapse.tokenlibrary.TokenLibrary

val accountKey: String = TokenLibrary.getConnectionStringAsMap("<LINKED SERVICE NAME">).get("<KEY NAME>")
println(accountKey)
```

```
# Linked services can be used for storing and retrieving credentials (e.g, account key)
# Example connection string (for storage): "DefaultEndpointsProtocol=https;AccountName=
<accountname>;AccountKey=<accountkey>"
from pyspark.sql import SparkSession

sc = SparkSession.builder.getOrCreate()
token_library = sc._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
accountKey = token_library.getConnectionStringAsMap("<LINKED SERVICE NAME>").get("<KEY NAME>")
print(accountKey)
```

getSecret()

To retrieve a secret stored from Azure Key Vault, we recommend that you create a linked service to Azure Key Vault within the Synapse workspace. The Synapse workspace managed service identity will need to be granted **GET** Secrets permission to the Azure Key Vault. The linked service will use the managed service identity to connect to Azure Key Vault service to retrieve the secret. Otherwise, connecting directly to Azure Key Vault will use the user's Azure Active Directory (AAD) credential. In this case, the user will need to be granted the Get Secret permissions in Azure Key Vault.

```
TokenLibrary.getSecret("<AZURE KEY VAULT NAME>", "<SECRET KEY>" [, <LINKED SERVICE NAME>])
```

To retrieve a secret from Azure Key Vault, use the **TokenLibrary.getSecret()** function.

```
import com.microsoft.azure.synapse.tokenlibrary.TokenLibrary

val connectionString: String = TokenLibrary.getSecret("<AZURE KEY VAULT NAME>", "<SECRET KEY>", "<LINKED
SERVICE NAME>")
println(connectionString)
```

```
import sys
from pyspark.sql import SparkSession

sc = SparkSession.builder.getOrCreate()
token_library = sc._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary

connection_string = token_library.getSecret("<AZURE KEY VAULT NAME>", "<SECRET KEY>", "<LINKED SERVICE
NAME>")
print(connection_string)
```

```
using Microsoft.Spark.Extensions.Azure.Synapse.Analytics.Utils;

string connectionString = TokenLibrary.GetSecret("<AZURE KEY VAULT NAME>", "<SECRET KEY>", "<LINKED SERVICE
NAME>");
Console.WriteLine(connectionString);
```

Optimize Apache Spark jobs in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

Learn how to optimize an Apache Spark cluster configuration for your particular workload. The most common challenge is memory pressure, because of improper configurations (particularly wrong-sized executors), long-running operations, and tasks that result in Cartesian operations. You can speed up jobs with appropriate caching, and by allowing for data skew. For the best performance, monitor and review long-running and resource-consuming Spark job executions.

The following sections describe common Spark job optimizations and recommendations.

Choose the data abstraction

Earlier Spark versions use RDDs to abstract data, Spark 1.3, and 1.6 introduced DataFrames and DataSets, respectively. Consider the following relative merits:

- **DataFrames**
  - Best choice in most situations.
  - Provides query optimization through Catalyst.
  - Whole-stage code generation.
  - Direct memory access.
  - Low garbage collection (GC) overhead.
  - Not as developer-friendly as DataSets, as there are no compile-time checks or domain object programming.
- **DataSets**
  - Good in complex ETL pipelines where the performance impact is acceptable.
  - Not good in aggregations where the performance impact can be considerable.
  - Provides query optimization through Catalyst.
  - Developer-friendly by providing domain object programming and compile-time checks.
  - Adds serialization/deserialization overhead.
  - High GC overhead.
  - Breaks whole-stage code generation.
- **RDDs**
  - You don't need to use RDDs, unless you need to build a new custom RDD.
  - No query optimization through Catalyst.
  - No whole-stage code generation.
  - High GC overhead.
  - Must use Spark 1.x legacy APIs.

Use optimal data format

Spark supports many formats, such as csv, json, xml, parquet, orc, and avro. Spark can be extended to support many more formats with external data sources - for more information, see Apache Spark packages.

The best format for performance is parquet with *snappy compression*, which is the default in Spark 2.x. Parquet stores data in columnar format, and is highly optimized in Spark. In addition, while *snappy compression* may

result in larger files than say gzip compression. Due to the splittable nature of those files, they will decompress faster.

Use the cache

Spark provides its own native caching mechanisms, which can be used through different methods such as `.persist()`, `.cache()`, and `CACHE TABLE`. This native caching is effective with small data sets as well as in ETL pipelines where you need to cache intermediate results. However, Spark native caching currently doesn't work well with partitioning, since a cached table doesn't keep the partitioning data.

Use memory efficiently

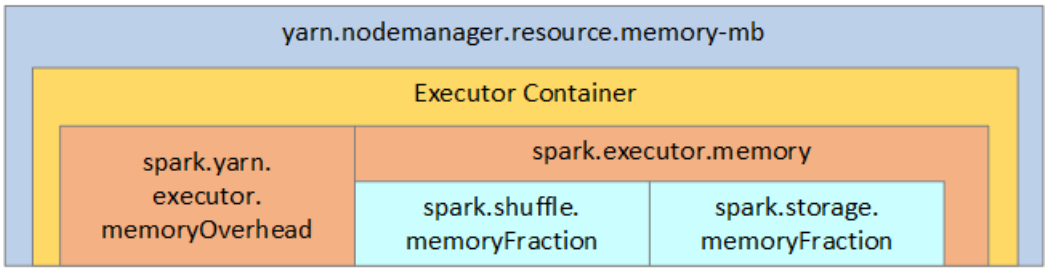
Spark operates by placing data in memory, so managing memory resources is a key aspect of optimizing the execution of Spark jobs. There are several techniques you can apply to use your cluster's memory efficiently.

- Prefer smaller data partitions and account for data size, types, and distribution in your partitioning strategy.
- Consider the newer, more efficient Kryo data serialization, rather than the default Java serialization.
- Monitor and tune Spark configuration settings.

For your reference, the Spark memory structure and some key executor memory parameters are shown in the next image.

Spark memory considerations

Apache Spark in Azure Synapse uses YARN Apache Hadoop YARN, YARN controls the maximum sum of memory used by all containers on each Spark node. The following diagram shows the key objects and their relationships.



To address 'out of memory' messages, try:

- Review DAG Management Shuffles. Reduce by map-side reducing, pre-partition (or bucketize) source data, maximize single shuffles, and reduce the amount of data sent.
- Prefer `ReduceByKey` with its fixed memory limit to `GroupByKey`, which provides aggregations, windowing, and other functions but it has an unbounded memory limit.
- Prefer `TreeReduce`, which does more work on the executors or partitions, to `Reduce`, which does all work on the driver.
- Leverage DataFrames rather than the lower-level RDD objects.
- Create ComplexTypes that encapsulate actions, such as "Top N", various aggregations, or windowing operations.

Optimize data serialization

Spark jobs are distributed, so appropriate data serialization is important for the best performance. There are two serialization options for Spark:

- Java serialization is the default.
- Kryo serialization is a newer format and can result in faster and more compact serialization than Java. Kryo

requires that you register the classes in your program, and it doesn't yet support all Serializable types.

Use bucketing

Bucketing is similar to data partitioning, but each bucket can hold a set of column values rather than just one. Bucketing works well for partitioning on large (in the millions or more) numbers of values, such as product identifiers. A bucket is determined by hashing the bucket key of the row. Bucketed tables offer unique optimizations because they store metadata about how they were bucketed and sorted.

Some advanced bucketing features are:

- Query optimization based on bucketing meta-information.
- Optimized aggregations.
- Optimized joins.

You can use partitioning and bucketing at the same time.

Optimize joins and shuffles

If you have slow jobs on a Join or Shuffle, the cause is probably *data skew*, which is asymmetry in your job data. For example, a map job may take 20 seconds, but running a job where the data is joined or shuffled takes hours. To fix data skew, you should salt the entire key, or use an *isolated salt* for only some subset of keys. If you're using an isolated salt, you should further filter to isolate your subset of salted keys in map joins. Another option is to introduce a bucket column and pre-aggregate in buckets first.

Another factor causing slow joins could be the join type. By default, Spark uses the `SortMerge` join type. This type of join is best suited for large data sets, but is otherwise computationally expensive because it must first sort the left and right sides of data before merging them.

A `Broadcast` join is best suited for smaller data sets, or where one side of the join is much smaller than the other side. This type of join broadcasts one side to all executors, and so requires more memory for broadcasts in general.

You can change the join type in your configuration by setting `spark.sql.autoBroadcastJoinThreshold`, or you can set a join hint using the DataFrame APIs (`dataframe.join(broadcast(df2))`).

```
// Option 1
spark.conf.set("spark.sql.autoBroadcastJoinThreshold", 1*1024*1024*1024)

// Option 2
val df1 = spark.table("FactTableA")
val df2 = spark.table("dimMP")
df1.join(broadcast(df2), Seq("PK")).
    createOrReplaceTempView("V_JOIN")

sql("SELECT col1, col2 FROM V_JOIN")
```

If you're using bucketed tables, then you have a third join type, the `Merge` join. A correctly pre-partitioned and pre-sorted dataset will skip the expensive sort phase from a `SortMerge` join.

The order of joins matters, particularly in more complex queries. Start with the most selective joins. Also, move joins that increase the number of rows after aggregations when possible.

To manage parallelism for Cartesian joins, you can add nested structures, windowing, and perhaps skip one or more steps in your Spark Job.

Select the correct executor size

When deciding your executor configuration, consider the Java garbage collection (GC) overhead.

- Factors to reduce executor size:
  - Reduce heap size below 32 GB to keep GC overhead < 10%.
  - Reduce the number of cores to keep GC overhead < 10%.
- Factors to increase executor size:
  - Reduce communication overhead between executors.
  - Reduce the number of open connections between executors (N2) on larger clusters (>100 executors).
  - Increase heap size to accommodate for memory-intensive tasks.
  - Optional: Reduce per-executor memory overhead.
  - Optional: Increase utilization and concurrency by oversubscribing CPU.

As a general rule of thumb when selecting the executor size:

- Start with 30 GB per executor and distribute available machine cores.
- Increase the number of executor cores for larger clusters (> 100 executors).
- Modify size based both on trial runs and on the preceding factors such as GC overhead.

When running concurrent queries, consider the following:

- Start with 30 GB per executor and all machine cores.
- Create multiple parallel Spark applications by oversubscribing CPU (around 30% latency improvement).
- Distribute queries across parallel applications.
- Modify size based both on trial runs and on the preceding factors such as GC overhead.

Monitor your query performance for outliers or other performance issues, by looking at the timeline view, SQL graph, job statistics, and so forth. Sometimes one or a few of the executors are slower than the others, and tasks take much longer to execute. This frequently happens on larger clusters (> 30 nodes). In this case, divide the work into a larger number of tasks so the scheduler can compensate for slow tasks.

For example, have at least twice as many tasks as the number of executor cores in the application. You can also enable speculative execution of tasks with `conf: spark.speculation = true`.

Optimize job execution

- Cache as necessary, for example if you use the data twice, then cache it.
- Broadcast variables to all executors. The variables are only serialized once, resulting in faster lookups.
- Use the thread pool on the driver, which results in faster operation for many tasks.

Key to Spark 2.x query performance is the Tungsten engine, which depends on whole-stage code generation. In some cases, whole-stage code generation may be disabled.

For example, if you use a non-mutable type (`string`) in the aggregation expression, `SortAggregate` appears instead of `HashAggregate`. For example, for better performance, try the following and then re-enable code generation:

```
MAX(AMOUNT) -> MAX(cast(AMOUNT as DOUBLE))
```

Hyperspace: An indexing subsystem for Apache Spark

8/19/2022 • 38 minutes to read • Edit Online

Hyperspace introduces the ability for Apache Spark users to create indexes on their datasets, such as CSV, JSON, and Parquet, and use them for potential query and workload acceleration.

In this article, we highlight the basics of Hyperspace, emphasize its simplicity, and show how it can be used by just about anyone.

Disclaimer: Hyperspace helps accelerate your workloads or queries under two circumstances:

- Queries contain filters on predicates with high selectivity. For example, you might want to select 100 matching rows from a million candidate rows.
- Queries contain a join that requires heavy shuffles. For example, you might want to join a 100-GB dataset with a 10-GB dataset.

You might want to carefully monitor your workloads and determine whether indexing is helping you on a case-by-case basis.

This document is also available in notebook form, for Python, C#, and Scala.

Setup

To begin with, start a new Spark session. Since this document is a tutorial merely to illustrate what Hyperspace can offer, you will make a configuration change that allows us to highlight what Hyperspace is doing on small datasets.

By default, Spark uses broadcast join to optimize join queries when the data size for one side of join is small (which is the case for the sample data we use in this tutorial). Therefore, we disable broadcast joins so that later when we run join queries, Spark uses sort-merge join. This is mainly to show how Hyperspace indexes would be used at scale for accelerating join queries.

The output of running the following cell shows a reference to the successfully created Spark session and prints out '-1' as the value for the modified join config, which indicates that broadcast join is successfully disabled.

```
// Start your Spark session
spark

// Disable BroadcastHashJoin, so Spark will use standard SortMergeJoin. Currently, Hyperspace indexes
utilize SortMergeJoin to speed up query.
spark.conf.set("spark.sql.autoBroadcastJoinThreshold", -1)

// Verify that BroadcastHashJoin is set correctly
println(spark.conf.get("spark.sql.autoBroadcastJoinThreshold"))
```

```
# Start your Spark session.
spark

# Disable BroadcastHashJoin, so Spark will use standard SortMergeJoin. Currently, Hyperspace indexes utilize
SortMergeJoin to speed up query.
spark.conf.set("spark.sql.autoBroadcastJoinThreshold", -1)

# Verify that BroadcastHashJoin is set correctly
print(spark.conf.get("spark.sql.autoBroadcastJoinThreshold"))
```

```
// Disable BroadcastHashJoin, so Spark will use standard SortMergeJoin. Currently, Hyperspace indexes
utilize SortMergeJoin to speed up query.
spark.Conf().Set("spark.sql.autoBroadcastJoinThreshold", -1);

// Verify that BroadcastHashJoin is set correctly.
Console.WriteLine(spark.Conf().Get("spark.sql.autoBroadcastJoinThreshold"));
```

Results in:

```
res3: org.apache.spark.sql.SparkSession = org.apache.spark.sql.SparkSession@297e957d
-1
```

Data preparation

To prepare your environment, you'll create sample data records and save them as Parquet data files. Parquet is used for illustration, but you can also use other formats such as CSV. In the subsequent cells, you'll see how you can create several Hyperspace indexes on this sample dataset and make Spark use them when running queries.

The example records correspond to two datasets: department and employee. You should configure the "empLocation" and "deptLocation" paths so that on the storage account they point to your desired location to save generated data files.

The output of running the following cell shows contents of our datasets as lists of triplets followed by references to dataFrames created to save the content of each dataset in our preferred location.

```
import org.apache.spark.sql.DataFrame

// Sample department records
val departments = Seq(
      (10, "Accounting", "New York"),
      (20, "Research", "Dallas"),
      (30, "Sales", "Chicago"),
      (40, "Operations", "Boston"))

// Sample employee records
val employees = Seq(
      (7369, "SMITH", 20),
      (7499, "ALLEN", 30),
      (7521, "WARD", 30),
      (7566, "JONES", 20),
      (7698, "BLAKE", 30),
      (7782, "CLARK", 10),
      (7788, "SCOTT", 20),
      (7839, "KING", 10),
      (7844, "TURNER", 30),
      (7876, "ADAMS", 20),
      (7900, "JAMES", 30),
      (7934, "MILLER", 10),
      (7902, "FORD", 20),
      (7654, "MARTIN", 30))

// Save sample data in the Parquet format
import spark.implicits._
val empData: DataFrame = employees.toDF("empId", "empName", "deptId")
val deptData: DataFrame = departments.toDF("deptId", "deptName", "location")

val empLocation: String = "/<yourpath>/employees.parquet"       //TODO ** customize this location path **
val deptLocation: String = "/<yourpath>/departments.parquet"     //TODO ** customize this location path **
empData.write.mode("overwrite").parquet(empLocation)
deptData.write.mode("overwrite").parquet(deptLocation)
```

```
from pyspark.sql.types import StructField, StructType, StringType, IntegerType

# Sample department records
departments = [(10, "Accounting", "New York"), (20, "Research", "Dallas"), (30, "Sales", "Chicago"), (40,
"Operations", "Boston")]

# Sample employee records
employees = [(7369, "SMITH", 20), (7499, "ALLEN", 30), (7521, "WARD", 30), (7566, "JONES", 20), (7698,
"BLAKE", 30)]

# Create a schema for the dataframe
dept_schema = StructType([StructField('deptId', IntegerType(), True), StructField('deptName', StringType(),
True), StructField('location', StringType(), True)])
emp_schema = StructType([StructField('empId', IntegerType(), True), StructField('empName', StringType(),
True), StructField('deptId', IntegerType(), True)])

departments_df = spark.createDataFrame(departments, dept_schema)
employees_df = spark.createDataFrame(employees, emp_schema)

#TODO ** customize this location path **
emp_Location = "/<yourpath>/employees.parquet"
dept_Location = "/<yourpath>/departments.parquet"

employees_df.write.mode("overwrite").parquet(emp_Location)
departments_df.write.mode("overwrite").parquet(dept_Location)
```

```
using Microsoft.Spark.Sql.Types;

// Sample department records
var departments = new List<GenericRow>()
{
    new GenericRow(new object[] {10, "Accounting", "New York"}),
    new GenericRow(new object[] {20, "Research", "Dallas"}),
    new GenericRow(new object[] {30, "Sales", "Chicago"}),
    new GenericRow(new object[] {40, "Operations", "Boston"})
};

// Sample employee records
var employees = new List<GenericRow>() {
      new GenericRow(new object[] {7369, "SMITH", 20}),
      new GenericRow(new object[] {7499, "ALLEN", 30}),
      new GenericRow(new object[] {7521, "WARD", 30}),
      new GenericRow(new object[] {7566, "JONES", 20}),
      new GenericRow(new object[] {7698, "BLAKE", 30}),
      new GenericRow(new object[] {7782, "CLARK", 10}),
      new GenericRow(new object[] {7788, "SCOTT", 20}),
      new GenericRow(new object[] {7839, "KING", 10}),
      new GenericRow(new object[] {7844, "TURNER", 30}),
      new GenericRow(new object[] {7876, "ADAMS", 20}),
      new GenericRow(new object[] {7900, "JAMES", 30}),
      new GenericRow(new object[] {7934, "MILLER", 10}),
      new GenericRow(new object[] {7902, "FORD", 20}),
      new GenericRow(new object[] {7654, "MARTIN", 30})
};

// Save sample data in the Parquet format
var departmentSchema = new StructType(new List<StructField>()
{
    new StructField("deptId", new IntegerType()),
    new StructField("deptName", new StringType()),
    new StructField("location", new StringType())
});
var employeeSchema = new StructType(new List<StructField>()
{
    new StructField("empId", new IntegerType()),
    new StructField("empName", new StringType()),
    new StructField("deptId", new IntegerType())
});

DataFrame empData = spark.CreateDataFrame(employees, employeeSchema);
DataFrame deptData = spark.CreateDataFrame(departments, departmentSchema);

string empLocation = "/<yourpath>/employees.parquet";       //TODO ** customize this location path **
string deptLocation = "/<yourpath>/departments.parquet";     //TODO ** customize this location path **
empData.Write().Mode("overwrite").Parquet(empLocation);
deptData.Write().Mode("overwrite").Parquet(deptLocation);
```

Results in:

```
departments: Seq[(Int, String, String)] = List((10,Accounting,New York), (20,Research,Dallas),
(30,Sales,Chicago), (40,Operations,Boston))
employees: Seq[(Int, String, Int)] = List((7369,SMITH,20), (7499,ALLEN,30), (7521,WARD,30), (7566,JONES,20),
(7698,BLAKE,30), (7782,CLARK,10), (7788,SCOTT,20), (7839,KING,10), (7844,TURNER,30), (7876,ADAMS,20),
(7900,JAMES,30), (7934,MILLER,10), (7902,FORD,20), (7654,MARTIN,30))

empData: org.apache.spark.sql.DataFrame = [empId: int, empName: string ... 1 more field]
deptData: org.apache.spark.sql.DataFrame = [deptId: int, deptName: string ... 1 more field]
empLocation: String = /your-path/employees.parquet
deptLocation: String = /your-path/departments.parquet
```

Let's verify the contents of the Parquet files we created to make sure they contain expected records in the correct format. Later, we'll use these data files to create Hyperspace indexes and run sample queries.

Running the following cell produces and output that displays the rows in employee and department dataFrames in a tabular form. There should be 14 employees and 4 departments, each matching with one of triplets you created in the previous cell.

```
// empLocation and deptLocation are the user defined locations above to save parquet files
val empDF: DataFrame = spark.read.parquet(empLocation)
val deptDF: DataFrame = spark.read.parquet(deptLocation)

// Verify the data is available and correct
empDF.show()
deptDF.show()
```

```
# emp_Location and dept_Location are the user-defined locations above to save parquet files
emp_DF = spark.read.parquet(emp_Location)
dept_DF = spark.read.parquet(dept_Location)

# Verify the data is available and correct
emp_DF.show()
dept_DF.show()
```

```
// empLocation and deptLocation are the user-defined locations above to save parquet files
DataFrame empDF = spark.Read().Parquet(empLocation);
DataFrame deptDF = spark.Read().Parquet(deptLocation);

// Verify the data is available and correct
empDF.Show();
deptDF.Show();
```

Results in:

```
empDF: org.apache.spark.sql.DataFrame = [empId: int, empName: string ... 1 more field]
deptDF: org.apache.spark.sql.DataFrame = [deptId: int, deptName: string ... 1 more field]
```

```
|EmpId|EmpName|DeptId|
|-----|-------|------|
| 7499|  ALLEN|    30|
| 7521|   WARD|    30|
| 7369|  SMITH|    20|
| 7844| TURNER|    30|
| 7876|  ADAMS|    20|
| 7900|  JAMES|    30|
| 7934| MILLER|    10|
| 7839|   KING|    10|
| 7566|  JONES|    20|
| 7698|  BLAKE|    30|
| 7782|  CLARK|    10|
| 7788|  SCOTT|    20|
| 7902|   FORD|    20|

Indexes

Hyperspace lets you create indexes on records scanned from persisted data files. After they're successfully created, an entry that corresponds to the index is added to the Hyperspace's metadata. This metadata is later used by Apache Spark's optimizer (with our extensions) during query processing to find and use proper indexes.

After indexes are created, you can perform several actions:

- **Refresh if the underlying data changes.** You can refresh an existing index to capture the changes.
- **Delete if the index isn't needed.** You can perform a soft delete, that is, the index isn't physically deleted but is marked as "deleted" so that it's no longer used in your workloads.
- **Vacuum if an index is no longer required.** You can vacuum an index, which forces a physical deletion of the index contents and associated metadata completely from Hyperspace's metadata.

Refresh if the underlying data changes, you can refresh an existing index to capture that. Delete if the index is not needed, you can perform a soft-delete that is, index is not physically deleted but is marked as 'deleted' so it is no longer used in your workloads.

The following sections show how such index management operations can be done in Hyperspace.

First, you need to import the required libraries and create an instance of Hyperspace. Later, you'll use this instance to invoke different Hyperspace APIs to create indexes on your sample data and modify those indexes.

The output of running the following cell shows a reference to the created instance of Hyperspace.

```
// Create an instance of Hyperspace
import com.microsoft.hyperspace._

val hyperspace: Hyperspace = Hyperspace()
```

```
from hyperspace import *

# Create an instance of Hyperspace
hyperspace = Hyperspace(spark)
```

```
// Create an instance of Hyperspace
using Microsoft.Spark.Extensions.Hyperspace;

Hyperspace hyperspace = new Hyperspace(spark);
```

Results in:

```
hyperspace: com.microsoft.hyperspace.Hyperspace = com.microsoft.hyperspace.Hyperspace@1432f740
```

Create indexes

To create a Hyperspace index, you need to provide two pieces of information:

- A Spark DataFrame that references the data to be indexed.
- An index configuration object, IndexConfig, which specifies the index name and the indexed and included columns of the index.

You start by creating three Hyperspace indexes on our sample data: two indexes on the department dataset named "deptIndex1" and "deptIndex2" and one index on the employee dataset named "empIndex". For each index, you need a corresponding IndexConfig to capture the name along with columns lists for the indexed and included columns. Running the following cell creates these IndexConfigs, and its output lists them.

> **NOTE**
> An index column is a column that appears in your filters or join conditions. An included column is a column that appears in your select/project.

For instance, in the following query:

```
SELECT X
FROM T
WHERE Y = 2
```

Y can be an index column, and X can be an included column.

```
// Create index configurations
import com.microsoft.hyperspace.index.IndexConfig

val empIndexConfig: IndexConfig = IndexConfig("empIndex", Seq("deptId"), Seq("empName"))
val deptIndexConfig1: IndexConfig = IndexConfig("deptIndex1", Seq("deptId"), Seq("deptName"))
val deptIndexConfig2: IndexConfig = IndexConfig("deptIndex2", Seq("location"), Seq("deptName"))
```

```
# Create index configurations

emp_IndexConfig = IndexConfig("empIndex1", ["deptId"], ["empName"])
dept_IndexConfig1 = IndexConfig("deptIndex1", ["deptId"], ["deptName"])
dept_IndexConfig2 = IndexConfig("deptIndex2", ["location"], ["deptName"])
```

```
using Microsoft.Spark.Extensions.Hyperspace.Index;

var empIndexConfig = new IndexConfig("empIndex", new string[] {"deptId"}, new string[] {"empName"});
var deptIndexConfig1 = new IndexConfig("deptIndex1", new string[] {"deptId"}, new string[] {"deptName"});
var deptIndexConfig2 = new IndexConfig("deptIndex2", new string[] {"location"}, new string[] {"deptName"});
```

Results in:

```
empIndexConfig: com.microsoft.hyperspace.index.IndexConfig = [indexName: empIndex; indexedColumns: deptid;
includedColumns: empname]
deptIndexConfig1: com.microsoft.hyperspace.index.IndexConfig = [indexName: deptIndex1; indexedColumns:
deptid; includedColumns: deptname]
deptIndexConfig2: com.microsoft.hyperspace.index.IndexConfig = [indexName: deptIndex2; indexedColumns:
location; includedColumns: deptname]
```

Now, you create three indexes using your index configurations. For this purpose, you invoke "createIndex" command on our Hyperspace instance. This command requires an index configuration and the dataFrame containing rows to be indexed. Running the following cell creates three indexes.

```
// Create indexes from configurations
import com.microsoft.hyperspace.index.Index

hyperspace.createIndex(empDF, empIndexConfig)
hyperspace.createIndex(deptDF, deptIndexConfig1)
hyperspace.createIndex(deptDF, deptIndexConfig2)
```

```
# Create indexes from configurations

hyperspace.createIndex(emp_DF, emp_IndexConfig)
hyperspace.createIndex(dept_DF, dept_IndexConfig1)
hyperspace.createIndex(dept_DF, dept_IndexConfig2)
```

```
// Create indexes from configurations
hyperspace.CreateIndex(empDF, empIndexConfig);
hyperspace.CreateIndex(deptDF, deptIndexConfig1);
hyperspace.CreateIndex(deptDF, deptIndexConfig2);
```

List indexes

The code that follows shows how you can list all available indexes in a Hyperspace instance. It uses "indexes" API that returns information about existing indexes as a Spark DataFrame so you can perform additional operations.

For instance, you can invoke valid operations on this DataFrame for checking its content or analyzing it further (for example filtering specific indexes or grouping them according to some desired property).

The following cell uses DataFrame's 'show' action to fully print the rows and show details of our indexes in a tabular form. For each index, you can see all information Hyperspace has stored about it in the metadata. You will immediately notice the following:

- config.indexName, config.indexedColumns, config.includedColumns, and status.status are the fields that a user normally refers to.
- dfSignature is automatically generated by Hyperspace and is unique for each index. Hyperspace uses this signature internally to maintain the index and exploit it at query time.

In the following output, all three indexes should have "ACTIVE" as status and their name, indexed columns, and included columns should match with what we defined in index configurations above.

```
hyperspace.indexes.show
```

```
hyperspace.indexes().show()
```

```
hyperspace.Indexes().Show();
```

Results in:

```
|Config.IndexName|Config.IndexedColumns|Config.IncludedColumns|        SchemaString|   SignatureProvider|
DfSignature|      SerializedPlan|NumBuckets|             DirPath|Status.Value|Stats.IndexSize|
|----------------|---------------------|----------------------|--------------------|--------------------|---
----------------|--------------------|----------|--------------------|------------|---------------|
|      deptIndex1|             [deptId]|            [deptName]|`deptId`
INT,`dep...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
ACTIVE|              0|
|      deptIndex2|           [location]|            [deptName]|`location`
STRING...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
ACTIVE|              0|
|        empIndex|             [deptId]|             [empName]|`deptId`
INT,`emp...|com.microsoft.cha...|30768c6c9b2533004...|Relation[empId#32...|       200|abfss://datasets@...|
ACTIVE|              0|
```

Delete indexes

You can drop an existing index by using the "deleteIndex" API and providing the index name. Index deletion does a soft delete: It mainly updates index's status in the Hyperspace metadata from "ACTIVE" to "DELETED". This will exclude the dropped index from any future query optimization and Hyperspace no longer picks that index for any query.

However, index files for a deleted index still remain available (since it is a soft-delete), so that the index could be restored if user asks for.

The following cell deletes index with name "deptIndex2" and lists Hyperspace metadata after that. The output should be similar to above cell for "List Indexes" except for "deptIndex2", which now should have its status changed into "DELETED".

```
hyperspace.deleteIndex("deptIndex2")

hyperspace.indexes.show
```

```
hyperspace.deleteIndex("deptIndex2")
hyperspace.indexes().show()
```

```
hyperspace.DeleteIndex("deptIndex2");

hyperspace.Indexes().Show();
```

Results in:

```
|Config.IndexName|Config.IndexedColumns|Config.IncludedColumns|        SchemaString|   SignatureProvider|
DfSignature|      SerializedPlan|NumBuckets|             DirPath|Status.Value|Stats.IndexSize|
|----------------|---------------------|----------------------|--------------------|--------------------|---
----------------|--------------------|----------|--------------------|------------|---------------|
|      deptIndex1|             [deptId]|            [deptName]|`deptId`
INT,`dep...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
ACTIVE|              0|
|      deptIndex2|           [location]|            [deptName]|`location`
STRING...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
DELETED|              0|
|        empIndex|             [deptId]|             [empName]|`deptId`
INT,`emp...|com.microsoft.cha...|30768c6c9b2533004...|Relation[empId#32...|       200|abfss://datasets@...|
ACTIVE|              0|
```

Restore indexes

You can use the "restoreIndex" API to restore a deleted index. This will bring back the latest version of index into ACTIVE status and makes it usable again for queries. The following cell shows an example of "restoreIndex" usage. You delete "deptIndex1" and restore it. The output shows "deptIndex1" first went into the "DELETED" status after invoking "deleteIndex" command and came back to the "ACTIVE" status after calling "restoreIndex".

```
hyperspace.deleteIndex("deptIndex1")

hyperspace.indexes.show

hyperspace.restoreIndex("deptIndex1")

hyperspace.indexes.show
```

```
hyperspace.deleteIndex("deptIndex1")
hyperspace.indexes().show()
hyperspace.restoreIndex("deptIndex1")
hyperspace.indexes().show()
```

```
hyperspace.DeleteIndex("deptIndex1");
hyperspace.Indexes().Show();
hyperspace.RestoreIndex("deptIndex1");
hyperspace.Indexes().Show();
```

Results in:

```
|Config.IndexName|Config.IndexedColumns|Config.IncludedColumns|        SchemaString|   SignatureProvider|
DfSignature|      SerializedPlan|NumBuckets|             DirPath|Status.Value|Stats.indexSize|
|----------------|--------------------|----------------------|--------------------|--------------------|---
-----------------|--------------------|----------|--------------------|------------|---------------|
|      deptIndex1|             [deptId]|            [deptName]|`deptId`

ACTIVE|              0|
```

```
|Config.IndexName|Config.IndexedColumns|Config.IncludedColumns|        SchemaString|   SignatureProvider|
DfSignature|      SerializedPlan|NumBuckets|             DirPath|Status.value|Stats.IndexSize|
|----------------|--------------------|----------------------|--------------------|--------------------|---
-----------------|--------------------|----------|--------------------|------------|---------------|
|      deptIndex1|             [deptId]|            [deptName]|`deptId`
INT,`dep...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
ACTIVE|              0|
|      deptIndex2|           [location]|            [deptName]|`location`
STRING...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
DELETED|              0|
|        empIndex|             [deptId]|             [empName]|`deptId`
INT,`emp...|com.microsoft.cha...|30768c6c9b2533004...|Relation[empId#32...|       200|abfss://datasets@...|
ACTIVE|              0|
```

Vacuum indexes

You can perform a hard delete, that is, fully remove files and the metadata entry for a deleted index by using the **vacuumIndex** command. This action is irreversible. It physically deletes all the index files, which is why it's a hard delete.

The following cell vacuums the "deptIndex2" index and shows Hyperspace metadata after vacuuming. You should see metadata entries for two indexes "deptIndex1" and "empIndex" both with "ACTIVE" status and no entry for "deptIndex2".

```
hyperspace.vacuumIndex("deptIndex2")

hyperspace.indexes.show
```

```
hyperspace.vacuumIndex("deptIndex2")
hyperspace.indexes().show()
```

```
hyperspace.VacuumIndex("deptIndex2");
hyperspace.Indexes().Show();
```

Results in:

```
|Config.IndexName|Config.IndexedColumns|Config.IncludedColumns|        SchemaString|   SignatureProvider|
DfSignature|      SerializedPlan|NumBuckets|             DirPath|Status.Value|Stats.IndexSize|
|----------------|---------------------|----------------------|--------------------|--------------------|---
-----------------|--------------------|----------|--------------------|------------|---------------|
|      deptIndex1|             [deptId]|            [deptName]|`deptId`
INT,`dep...|com.microsoft.cha...|0effc1610ae2e7c49...|Relation[deptId#3...|       200|abfss://datasets@...|
ACTIVE|              0|
|        empIndex|             [deptId]|             [empName]|`deptId`
INT,`emp...|com.microsoft.cha...|30768c6c9b2533004...|Relation[empId#32...|       200|abfss://datasets@...|
ACTIVE|              0|
```

Enable or disable Hyperspace

Hyperspace provides APIs to enable or disable index usage with Spark.

- By using the **enableHyperspace** command, Hyperspace optimization rules become visible to the Spark optimizer and exploit existing Hyperspace indexes to optimize user queries.
- By using the **disableHyperspace** command, Hyperspace rules no longer apply during query optimization. Disabling Hyperspace has no impact on created indexes because they remain intact.

The following cell shows how you can use these commands to enable or disable Hyperspace. The output shows a reference to the existing Spark session whose configuration is updated.

```
// Enable Hyperspace
spark.enableHyperspace

// Disable Hyperspace
spark.disableHyperspace
```

```
# Enable Hyperspace
Hyperspace.enable(spark)

# Disable Hyperspace
Hyperspace.disable(spark)
```

```
// Enable Hyperspace
spark.EnableHyperspace();

// Disable Hyperspace
spark.DisableHyperspace();
```

Results in:

```
res48: org.apache.spark.sql.Spark™Session = org.apache.spark.sql.SparkSession@39fe1ddb
res51: org.apache.spark.sql.Spark™Session = org.apache.spark.sql.SparkSession@39fe1ddb
```

Index usage

To make Spark use Hyperspace indexes during query processing, you need to make sure that Hyperspace is enabled.

The following cell enables Hyperspace and creates two DataFrames containing your sample data records, which you use for running example queries. For each DataFrame, a few sample rows are printed.

```
// Enable Hyperspace
spark.enableHyperspace

val empDFrame: DataFrame = spark.read.parquet(empLocation)
val deptDFrame: DataFrame = spark.read.parquet(deptLocation)

empDFrame.show(5)
deptDFrame.show(5)
```

```
# Enable Hyperspace
Hyperspace.enable(spark)

emp_DF = spark.read.parquet(emp_Location)
dept_DF = spark.read.parquet(dept_Location)

emp_DF.show(5)
dept_DF.show(5)
```

```
// Enable Hyperspace
spark.EnableHyperspace();

DataFrame empDFrame = spark.Read().Parquet(empLocation);
DataFrame deptDFrame = spark.Read().Parquet(deptLocation);

empDFrame.Show(5);
deptDFrame.Show(5);
```

Results in:

```
res53: org.apache.spark.sql.Spark™Session = org.apache.spark.sql.Spark™Session@39fe1ddb
empDFrame: org.apache.spark.sql.DataFrame = [empId: int, empName: string ... 1 more field]
deptDFrame: org.apache.spark.sql.DataFrame = [deptId: int, deptName: string ... 1 more field]
```

```
|empId|empName|deptId|
|-----|-------|------|
| 7499|  ALLEN|    30|
| 7521|   WARD|    30|
| 7369|  SMITH|    20|
| 7844| TURNER|    30|
| 7876|  ADAMS|    20|
```

This only shows the top 5 rows

```
|deptId|  deptName|location|
|------|----------|--------|
|    10|Accounting|New York|
|    40|Operations|  Boston|
|    20|  Research|  Dallas|
|    30|     Sales| Chicago|
```

Index types

Currently, Hyperspace has rules to exploit indexes for two groups of queries:

- Selection queries with lookup or range selection filtering predicates.
- Join queries with an equality join predicate (that is, equijoins).

Indexes for accelerating filters

The first example query does a lookup on department records, as shown in the following cell. In SQL, this query looks like the following example:

```
SELECT deptName
FROM departments
WHERE deptId = 20
```

The output of running the following cell shows:

- Query result, which is a single department name.
- Query plan that Spark used to run the query.

In the query plan, the **FileScan** operator at the bottom of the plan shows the data source where the records were read from. The location of this file indicates the path to the latest version of the "deptIndex1" index. This information shows that according to the query and using Hyperspace optimization rules, Spark decided to exploit the proper index at runtime.

```
// Filter with equality predicate

val eqFilter: DataFrame = deptDFrame.filter("deptId = 20").select("deptName")
eqFilter.show()

eqFilter.explain(true)
```

```
# Filter with equality predicate

eqFilter = dept_DF.filter("""deptId = 20""").select("""deptName""")
eqFilter.show()

eqFilter.explain(True)
```

```
DataFrame eqFilter = deptDFrame.Filter("deptId = 20").Select("deptName");
eqFilter.Show();

eqFilter.Explain(true);
```

Results in:

```
eqFilter: org.apache.spark.sql.DataFrame = [deptName: string]
```

```
|DeptName|
|--------|
|Research|
```

```
== Parsed Logical Plan ==
'Project [unresolvedalias('deptName, None)]
+- Filter (deptId#533 = 20)
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Analyzed Logical Plan ==
deptName: string
Project [deptName#534]
+- Filter (deptId#533 = 20)
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Optimized Logical Plan ==
Project [deptName#534]
+- Filter (isnotnull(deptId#533) && (deptId#533 = 20))
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Physical Plan ==
*(1) Project [deptName#534]
+- *(1) Filter (isnotnull(deptId#533) && (deptId#533 = 20))
   +- *(1) FileScan parquet [deptId#533,deptName#534] Batched: true, Format: Parquet, Location:
InMemoryFileIndex[abfss://datasets@hyperspacebenchmark.dfs.core.windows.net/hyperspaceon...,
PartitionFilters: [], PushedFilters: [IsNotNull(deptId), EqualTo(deptId,20)], ReadSchema:
struct<deptId:int,deptName:string>
```

The second example is a range selection query on department records. In SQL, this query looks like the following example:

```
SELECT deptName
FROM departments
WHERE deptId > 20
```

Similar to the first example, the output of the following cell shows the query results (names of two departments) and the query plan. The location of the data file in the **FileScan** operator shows that "deptIndex1" was used to run the query.

```
// Filter with range selection predicate

val rangeFilter: DataFrame = deptDFrame.filter("deptId > 20").select("deptName")
rangeFilter.show()

rangeFilter.explain(true)
```

```
# Filter with range selection predicate

rangeFilter = dept_DF.filter("""deptId > 20""").select("deptName")
rangeFilter.show()

rangeFilter.explain(True)
```

```
// Filter with range selection predicate
DataFrame rangeFilter = deptDFrame.Filter("deptId > 20").Select("deptName");
rangeFilter.Show();

rangeFilter.Explain(true);
```

Results in:

```
rangeFilter: org.apache.spark.sql.DataFrame = [deptName: string]
```

```
|  DeptName|
|----------|
|Operations|
|     Sales|
```

```
== Parsed Logical Plan ==
'Project [unresolvedalias('deptName, None)]
+- Filter (deptId#533 > 20)
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Analyzed Logical Plan ==
deptName: string
Project [deptName#534]
+- Filter (deptId#533 > 20)
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Optimized Logical Plan ==
Project [deptName#534]
+- Filter (isnotnull(deptId#533) && (deptId#533 > 20))
   +- Relation[deptId#533,deptName#534,location#535] parquet

== Physical Plan ==
*(1) Project [deptName#534]
+- *(1) Filter (isnotnull(deptId#533) && (deptId#533 > 20))
   +- *(1) FileScan parquet [deptId#533,deptName#534] Batched: true, Format: Parquet, Location:
InMemoryFileIndex[abfss://datasets@hyperspacebenchmark.dfs.core.windows.net/hyperspaceon...,
PartitionFilters: [], PushedFilters: [IsNotNull(deptId), GreaterThan(deptId,20)], ReadSchema:
struct<deptId:int,deptName:string>
```

The third example is a query joining department and employee records on the department ID. The equivalent SQL statement is shown as follows:

```
SELECT employees.deptId, empName, departments.deptId, deptName
FROM   employees, departments
WHERE  employees.deptId = departments.deptId
```

The output of running the following cell shows the query results, which are the names of 14 employees and the name of the department each employee works in. The query plan is also included in the output. Notice how the file locations for two **FileScan** operators show that Spark used "empIndex" and "deptIndex1" indexes to run the query.

```
// Join

val eqJoin: DataFrame =
      empDFrame.
      join(deptDFrame, empDFrame("deptId") === deptDFrame("deptId")).
      select(empDFrame("empName"), deptDFrame("deptName"))

eqJoin.show()

eqJoin.explain(true)
```

```
# Join

eqJoin = emp_DF.join(dept_DF, emp_DF.deptId == dept_DF.deptId).select(emp_DF.empName, dept_DF.deptName)

eqJoin.show()

eqJoin.explain(True)
```

```
// Join
DataFrame eqJoin =
      empDFrame
      .Join(deptDFrame, empDFrame.Col("deptId") == deptDFrame.Col("deptId"))
      .Select(empDFrame.Col("empName"), deptDFrame.Col("deptName"));

eqJoin.Show();

eqJoin.Explain(true);
```

Results in:

```
eqJoin: org.apache.spark.sql.DataFrame = [empName: string, deptName: string]
```

```

```

Support for SQL semantics

The index usage is transparent to whether you use the DataFrame API or Spark SQL. The following example shows the same join example as before, in SQL form, showing the use of indexes if applicable.

```
empDFrame.createOrReplaceTempView("EMP")
deptDFrame.createOrReplaceTempView("DEPT")

val joinQuery = spark.sql("SELECT EMP.empName, DEPT.deptName FROM EMP, DEPT WHERE EMP.deptId = DEPT.deptId")

joinQuery.show()
joinQuery.explain(true)
```

```
from pyspark.sql import SparkSession

emp_DF.createOrReplaceTempView("EMP")
dept_DF.createOrReplaceTempView("DEPT")

joinQuery = spark.sql("SELECT EMP.empName, DEPT.deptName FROM EMP, DEPT WHERE EMP.deptId = DEPT.deptId")

joinQuery.show()
joinQuery.explain(True)
```

```
empDFrame.CreateOrReplaceTempView("EMP");
deptDFrame.CreateOrReplaceTempView("DEPT");

var joinQuery = spark.Sql("SELECT EMP.empName, DEPT.deptName FROM EMP, DEPT WHERE EMP.deptId =
DEPT.deptId");

joinQuery.Show();
joinQuery.Explain(true);
```

Results in:

```
joinQuery: org.apache.spark.sql.DataFrame = [empName: string, deptName: string]
```

```
|empName|  deptName|
|-------|----------|
|  SMITH|  Research|

```

Explain API

Indexes are great, but how do you know if they're being used? Hyperspace allows users to compare their original plan versus the updated index-dependent plan before running their query. You have an option to choose from HTML, plaintext, or console mode to display the command output.

The following cell shows an example with HTML. The highlighted section represents the difference between original and updated plans along with the indexes being used.

```
spark.conf.set("spark.hyperspace.explain.displayMode", "html")
hyperspace.explain(eqJoin)(displayHTML(_))
```

```
eqJoin = emp_DF.join(dept_DF, emp_DF.deptId == dept_DF.deptId).select(emp_DF.empName, dept_DF.deptName)

spark.conf.set("spark.hyperspace.explain.displayMode", "html")
hyperspace.explain(eqJoin, True, displayHTML)
```

```
spark.Conf().Set("spark.hyperspace.explain.displayMode", "html");
spark.Conf().Set("spark.hyperspace.explain.displayMode.highlight.beginTag", "<b
style=\"background:LightGreen\">");
spark.Conf().Set("spark.hyperspace.explain.displayMode.highlight.endTag", "</b>");

hyperspace.Explain(eqJoin, false, input => DisplayHTML(input));
```

Results in:

Plan with indexes

```

Indexes used

```
deptIndex1:abfss://datasets@hyperspacebenchmark.dfs.core.windows.net/<container>/indexes/public/deptIndex1/v
__=0
empIndex:abfss://datasets@hyperspacebenchmark.dfs.core.windows.net/<container>/indexes/public/empIndex/v__=0
```

Refresh indexes

If the original data on which an index was created changes, the index will no longer capture the latest state of data. You can refresh a stale index by using the **refreshIndex** command. This command causes the index to be fully rebuilt and updates it according to the latest data records. We'll show you how to incrementally refresh your index in other notebooks.

The following two cells show an example for this scenario:

- The first cell adds two more departments to the original departments data. It reads and prints a list of departments to verify new departments are added correctly. The output shows six departments in total: four old ones and two new. Invoking **refreshIndex** updates "deptIndex1" so that the index captures new departments.
- The second cell runs our range selection query example. The results should now contain four departments: two are the ones seen before when we ran the preceding query, and two are the new departments we added.

Specific index refresh

```
val extraDepartments = Seq(
      (50, "Inovation", "Seattle"),
      (60, "Human Resources", "San Francisco"))

val extraDeptData: DataFrame = extraDepartments.toDF("deptId", "deptName", "location")
extraDeptData.write.mode("Append").parquet(deptLocation)

val deptDFrameUpdated: DataFrame = spark.read.parquet(deptLocation)

deptDFrameUpdated.show(10)

hyperspace.refreshIndex("deptIndex1")
```

```

extra_Departments = [(50, "Inovation", "Seattle"), (60, "Human Resources", "San Francisco")]

extra_departments_df = spark.createDataFrame(extra_Departments, dept_schema)
extra_departments_df.write.mode("Append").parquet(dept_Location)

dept_DFrame_Updated = spark.read.parquet(dept_Location)

dept_DFrame_Updated.show(10)
```

```

var extraDepartments = new List<GenericRow>()
{
    new GenericRow(new object[] {50, "Inovation", "Seattle"}),
    new GenericRow(new object[] {60, "Human Resources", "San Francisco"})
};

DataFrame extraDeptData = spark.CreateDataFrame(extraDepartments, departmentSchema);
extraDeptData.Write().Mode("Append").Parquet(deptLocation);

DataFrame deptDFrameUpdated = spark.Read().Parquet(deptLocation);

deptDFrameUpdated.Show(10);

hyperspace.RefreshIndex("deptIndex1");
```

Results in:

```
extraDepartments: Seq[(Int, String, String)] = List((50,Inovation,Seattle), (60,Human Resources,San
Francisco))
extraDeptData: org.apache.spark.sql.DataFrame = [deptId: int, deptName: string ... 1 more field]
deptDFrameUpdated: org.apache.spark.sql.DataFrame = [deptId: int, deptName: string ... 1 more field]
```

```
|deptId|       deptName|     location|
|------|---------------|-------------|
|    60|Human Resources|San Francisco|
|    10|     Accounting|     New York|
|    50|      Inovation|      Seattle|
|    40|     Operations|       Boston|
|    20|       Research|       Dallas|
|    30|          Sales|      Chicago|
```

Range selection

```
val newRangeFilter: DataFrame = deptDFrameUpdated.filter("deptId > 20").select("deptName")
newRangeFilter.show()

newRangeFilter.explain(true)
```

```
newRangeFilter = dept_DFrame_Updated.filter("deptId > 20").select("deptName")
newRangeFilter.show()

newRangeFilter.explain(True)
```

```
DataFrame newRangeFilter = deptDFrameUpdated.Filter("deptId > 20").Select("deptName");
newRangeFilter.Show();

newRangeFilter.Explain(true);
```

Results in:

```
newRangeFilter: org.apache.spark.sql.DataFrame = [deptName: string]
```

```
|       DeptName|
|---------------|
|Human Resources|
|      Inovation|
|     Operations|
|          Sales|
```

```

```

Hybrid scan for mutable datasets

Often, if your underlying source data had some new files appended or existing files deleted, your index will get stale and Hyperspace decides not to use it. However, there are times when you just want to use the index without having to refresh it every time. There could be multiple reasons for doing so:

- You don't want to continuously refresh your index, but instead want to do it periodically because you understand your workloads the best.
- You added/removed only a few files and don't want to wait for yet another refresh job to finish.

To allow you to still use a stale index, Hyperspace introduces hybrid scan, a novel technique that allows users to utilize outdated or stale indexes (for example, the underlying source data had some new files appended or existing files deleted) without refreshing indexes.

To achieve this, when you set the appropriate configuration to enable hybrid scan, Hyperspace modifies the query plan to leverage the changes as following:

- Appended files can be merged to index data by using Union or BucketUnion (for join). Shuffling appended data can also be applied before merging, if needed.
- Deleted files can be handled by injecting Filter-NOT-IN condition on lineage column of index data, so that the indexed rows from the deleted files can be excluded at query time.

You can check the transformation of the query plan in following examples.

> **NOTE**
> Currently, hybrid scan is supported only for non-partitioned data.

Hybrid scan for appended files - non-partitioned data

Non-partitioned data is used in the following example. In this example, we expect that the Join index can be used for the query and BucketUnion is introduced for appended files.

```
val testData = Seq(
    ("orange", 3, "2020-10-01"),
    ("banana", 1, "2020-10-01"),
    ("carrot", 5, "2020-10-02"),
    ("beetroot", 12, "2020-10-02"),
    ("orange", 2, "2020-10-03"),
    ("banana", 11, "2020-10-03"),
    ("carrot", 3, "2020-10-03"),
    ("beetroot", 2, "2020-10-04"),
    ("cucumber", 7, "2020-10-05"),
    ("pepper", 20, "2020-10-06")
    ).toDF("name", "qty", "date")

val testDataLocation = s"$dataPath/productTable"

testData.write.mode("overwrite").parquet(testDataLocation)
val testDF = spark.read.parquet(testDataLocation)
```

```
testdata = [
    ("orange", 3, "2020-10-01"),
    ("banana", 1, "2020-10-01"),
    ("carrot", 5, "2020-10-02"),
    ("beetroot", 12, "2020-10-02"),
    ("orange", 2, "2020-10-03"),
    ("banana", 11, "2020-10-03"),
    ("carrot", 3, "2020-10-03"),
    ("beetroot", 2, "2020-10-04"),
    ("cucumber", 7, "2020-10-05"),
    ("pepper", 20, "2020-10-06")
]

testdata_location = data_path + "/productTable"
from pyspark.sql.types import StructField, StructType, StringType, IntegerType
testdata_schema = StructType([
    StructField('name', StringType(), True),
    StructField('qty', IntegerType(), True),
    StructField('date', StringType(), True)])

test_df = spark.createDataFrame(testdata, testdata_schema)
test_df.write.mode("overwrite").parquet(testdata_location)
test_df = spark.read.parquet(testdata_location)
```

```
using Microsoft.Spark.Sql.Types;

var products = new List<GenericRow>() {
    new GenericRow(new object[] {"orange", 3, "2020-10-01"}),

```
// Append new files.
var appendProducts = new List<GenericRow>()
{
    new GenericRow(new object[] {"orange", 13, "2020-11-01"}),
    new GenericRow(new object[] {"banana", 5, "2020-11-01"})
};

DataFrame appendData = spark.CreateDataFrame(appendProducts, productsSchema);
appendData.Write().Mode("Append").Parquet(testDataLocation);
```

Hybrid scan is disabled by default. Therefore, you will see that because we appended new data, Hyperspace will decide *not* to use the index.

In the output, you will see no plan differences (hence, no highlighting).

```
// Hybrid Scan configs are false by default.
spark.conf.set("spark.hyperspace.index.hybridscan.enabled", "false")
spark.conf.set("spark.hyperspace.index.hybridscan.delete.enabled", "false")

val testDFWithAppend = spark.read.parquet(testDataLocation)
val filter1 = testDFWithAppend.filter("name = 'banana'")
val filter2 = testDFWithAppend.filter("qty > 10")
val query = filter1.join(filter2, "name")
hyperspace.explain(query)(displayHTML(_))
query.show
```

```
# Hybrid Scan configs are false by default.
spark.conf.set("spark.hyperspace.index.hybridscan.enabled", "false")
spark.conf.set("spark.hyperspace.index.hybridscan.delete.enabled", "false")

test_df_with_append = spark.read.parquet(testdata_location)
filter1 = test_df_with_append.filter("name = 'banana'")
filter2 = test_df_with_append.filter("qty > 10")
query = filter1.join(filter2, "name")
hyperspace.explain(query, True, displayHTML)
query.show()
```

```
// Hybrid Scan configs are false by default.
spark.Conf().Set("spark.hyperspace.index.hybridscan.enabled", "false");
spark.Conf().Set("spark.hyperspace.index.hybridscan.delete.enabled", "false");

DataFrame testDFWithAppend = spark.Read().Parquet(testDataLocation);
DataFrame filter1 = testDFWithAppend.Filter("name = 'banana'");
DataFrame filter2 = testDFWithAppend.Filter("qty > 10");
DataFrame query = filter1.Join(filter2, filter1.Col("name") == filter2.Col("name"));

query.Show();

hyperspace.Explain(query, true, input => DisplayHTML(input));
```

Enable hybrid scan

In plan with indexes, you can see Exchange hash partitioning required only for appended files so that we could still utilize the "shuffled" index data with appended files. BucketUnion is used to merge "shuffled" appended files with the index data.

```
// Enable Hybrid Scan config. "delete" config is not necessary since we only appended data.
spark.conf.set("spark.hyperspace.index.hybridscan.enabled", "true")
spark.enableHyperspace
// Need to redefine query to recalculate the query plan.
val query = filter1.join(filter2, "name")
hyperspace.explain(query)(displayHTML(_))
query.show
```

```
# Enable Hybrid Scan config. "delete" config is not necessary.
spark.conf.set("spark.hyperspace.index.hybridscan.enabled", "true")

# Need to redefine query to recalculate the query plan.
query = filter1.join(filter2, "name")
hyperspace.explain(query, True, displayHTML)
query.show()
```

```
// Enable Hybrid Scan config. "delete" config is not necessary.
spark.Conf().Set("spark.hyperspace.index.hybridscan.enabled", "true");
spark.EnableHyperspace();
// Need to redefine query to recalculate the query plan.
DataFrame query = filter1.Join(filter2, filter1.Col("name") == filter2.Col("name"));

query.Show();

hyperspace.Explain(query, true, input => DisplayHTML(input));
```

Incremental index refresh

When you're ready to update your indexes but don't want to rebuild your entire index, Hyperspace supports updating indexes in an incremental manner using the `hs.refreshIndex("name", "incremental")` API. This will eliminates the need for a full rebuild of index from scratch, utilizing previously created index files as well as updating indexes on only the newly added data.

Of course, be sure to use the complementary `optimizeIndex` API (shown below) periodically to make sure you do not see performance regressions. We recommend calling optimize at least once for every 10 times you call `refreshIndex(..., "incremental")`, assuming the data you added/removed is < 10% of the original dataset. For instance, if your original dataset is 100 GB, and you've added/removed data in increments/decrements of 1 GB, you can call `refreshIndex` 10 times before calling `optimizeIndex`. Please note that this example is simply used for illustration and you have to adapt this for your workloads.

In the example below, notice the addition of a Sort node in the query plan when indexes are used. This is because partial indexes are created on the appended data files, causing Spark to introduce a `Sort`. Please also note that `Shuffle` i.e. Exchange is still eliminated from the plan, giving you the appropriate acceleration.

```
def query(): DataFrame = {
    val testDFWithAppend = spark.read.parquet(testDataLocation)
    val filter1 = testDFWithAppend.filter("name = 'banana'")
    val filter2 = testDFWithAppend.filter("qty > 10")
    filter1.join(filter2, "name")
}

hyperspace.refreshIndex("productIndex2", "incremental")

hyperspace.explain(query())(displayHTML(_))
query().show
```

```
def query():
    test_df_with_append = spark.read.parquet(testdata_location)
    filter1 = test_df_with_append.filter("name = 'banana'")
    filter2 = test_df_with_append.filter("qty > 10")
    return filter1.join(filter2, "name")

hyperspace.refreshIndex("productIndex2", "incremental")

hyperspace.explain(query(), True, displayHTML)
query().show()
```

Optimize index layout

After calling incremental refreshes multiple times on newly appended data (e.g. if the user writes to data in small batches or in case of streaming scenarios), the number of index files tend to become large affecting the performance of the index (large number of small files problem). Hyperspace provides `hyperspace.optimizeIndex("indexName")` API to optimize the index layout and reduce the large files problem.

In the plan below, notice that Hyperspace has removed the additional Sort node in the query plan. Optimize can help avoiding sorting for any index bucket which contains only one file. However, this will only be true if ALL the index buckets have at most 1 file per bucket, after `optimizeIndex`.

```
// Append some more data and call refresh again.
val appendData = Seq(
    ("orange", 13, "2020-11-01"),
    ("banana", 5, "2020-11-01")).toDF("name", "qty", "date")
appendData.write.mode("append").parquet(testDataLocation)

hyperspace.refreshIndex("productIndex2", "incremental")
```

```
# Append some more data and call refresh again.
append_data = [
    ("orange", 13, "2020-11-01"),
    ("banana", 5, "2020-11-01")
]
append_df = spark.createDataFrame(append_data, testdata_schema)
append_df.write.mode("append").parquet(testdata_location)

hyperspace.refreshIndex("productIndex2", "incremental"
```

```
// Call optimize. Ensure that Sort is removed after optimization (This is possible here because after
optimize, in this case, every bucket contains only 1 file.).
hyperspace.optimizeIndex("productIndex2")

hyperspace.explain(query())(displayHTML(_))
```

```
# Call optimize. Ensure that Sort is removed after optimization (This is possible here because after
optimize, in this case, every bucket contains only 1 file.).
hyperspace.optimizeIndex("productIndex2")

hyperspace.explain(query(), True, displayHTML)
```

Optimize modes

The default mode for optimization is "quick" mode where files smaller than a predefined threshold are picked for optimization. To maximize the effect of optimization, Hyperspace allows another optimize mode "full" as shown below. This mode picks ALL index files for optimization irrespective of their file size and creates the best possible layout of the index. This is also slower than the default optimize mode because more data is being processed here.

```
hyperspace.optimizeIndex("productIndex2", "full")

hyperspace.explain(query())(displayHTML(_))
```

```
hyperspace.optimizeIndex("productIndex2", "full")

hyperspace.explain(query(), True, displayHTML)
```

Result in:

```
=============================================================
Plan with indexes:
=============================================================
Project [name#1000, qty#1001, date#1002, qty#1007, date#1008]

Apache Spark GPU-accelerated pools in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Apache Spark is a parallel processing framework that supports in-memory processing to boost the performance of big-data analytic applications. Apache Spark in Azure Synapse Analytics is one of Microsoft's implementations of Apache Spark in the cloud.

Azure Synapse now offers the ability to create Azure Synapse GPU-enabled pools to run Spark workloads using underlying RAPIDS libraries that use the massive parallel processing power of GPUs to accelerate processing. The RAPIDS Accelerator for Apache Spark allows you to run your existing Spark applications **without any code change** by just enabling a configuration setting, which comes pre-configured for a GPU-enabled pool. You can choose to turn on/off the RAPIDS-based GPU acceleration for your workload or parts of your workload by setting this configuration:

```
spark.conf.set('spark.rapids.sql.enabled','true/false')
```

NOTE

Azure Synapse GPU-enabled pools are currently in Public Preview.

RAPIDS Accelerator for Apache Spark

The Spark RAPIDS accelerator is a plugin that works by overriding the physical plan of a Spark job by supported GPU operations, and running those operations on the GPUs, thereby accelerating processing. This library is currently in preview and doesn't support all Spark operations (here is a list of currently supported operators, and more support is being added incrementally through new releases).

Cluster configuration options

The RAPIDS Accelerator plugin only supports a one-to-one mapping between GPUs and executors. This means a Spark job would need to request executor and driver resources that can be accommodated by the pool resources (according to the number of available GPU and CPU cores). In order to meet this condition and ensure optimal utilization of all the pool resources, we require the following configuration of drivers and executors for a Spark application running on GPU-enabled pools:

POOL SIZE	DRIVER SIZE OPTIONS	DRIVER CORES	DRIVER MEMORY (GB)	EXECUTOR CORES	EXECUTOR MEMORY (GB)	NUMBER OF EXECUTORS
GPU-Large	Small driver	4	30	12	60	Number of nodes in pool
GPU-Large	Medium driver	7	30	9	60	Number of nodes in pool

POOL SIZE	DRIVER SIZE OPTIONS	DRIVER CORES	DRIVER MEMORY (GB)	EXECUTOR CORES	EXECUTOR MEMORY (GB)	NUMBER OF EXECUTORS
GPU-XLarge	Medium driver	8	40	14	80	4 * Number of nodes in pool
GPU-XLarge	Large driver	12	40	13	80	4 * Number of nodes in pool

Any workload that does not meet one of the above configurations will not be accepted. This is done to make sure Spark jobs are being run with the most efficient and performant configuration utilizing all available resources on the pool.

The user can set the above configuration through their workload. For notebooks, the user can use the `%%configure` magic command to set one of the above configurations as shown below. For example, using a large pool with three nodes:

```
%%configure -f
{
    "driverMemory": "30g",
    "driverCores": 4,
    "executorMemory": "60g",
    "executorCores": 12,
    "numExecutors": 3
}
```

Run a sample Spark job through notebook on an Azure Synapse GPU-accelerated pool

It would be good to be familiar with the basic concepts of how to use a notebook in Azure Synapse Analytics before proceeding with this section. Let's walk through the steps to run a Spark application utilizing GPU acceleration. You can write a Spark application in all the four languages supported inside Synapse, PySpark (Python), Spark (Scala), SparkSQL, and .NET for Spark (C#).

1. Create a GPU-enabled pool as described in this quickstart.
2. Create a notebook and attach it to the GPU-enabled pool you created in the first step.
3. Set the configurations as explained in the previous section.
4. Create a sample dataframe by copying the below code in the first cell of your notebook:

- Scala
- Python
- C#

```
import org.apache.spark.sql.types.{IntegerType, StringType, StructField, StructType}
import org.apache.spark.sql.Row
import scala.collection.JavaConversions._

val schema = StructType( Array(
  StructField("emp_id", IntegerType),
  StructField("name", StringType),
  StructField("emp_dept_id", IntegerType),
  StructField("salary", IntegerType)
))

val emp = Seq(Row(1, "Smith", 10, 100000),
    Row(2, "Rose", 20, 97600),
    Row(3, "Williams", 20, 110000),
    Row(4, "Jones", 10, 80000),
    Row(5, "Brown", 40, 60000),
    Row(6, "Brown", 30, 78000)
  )

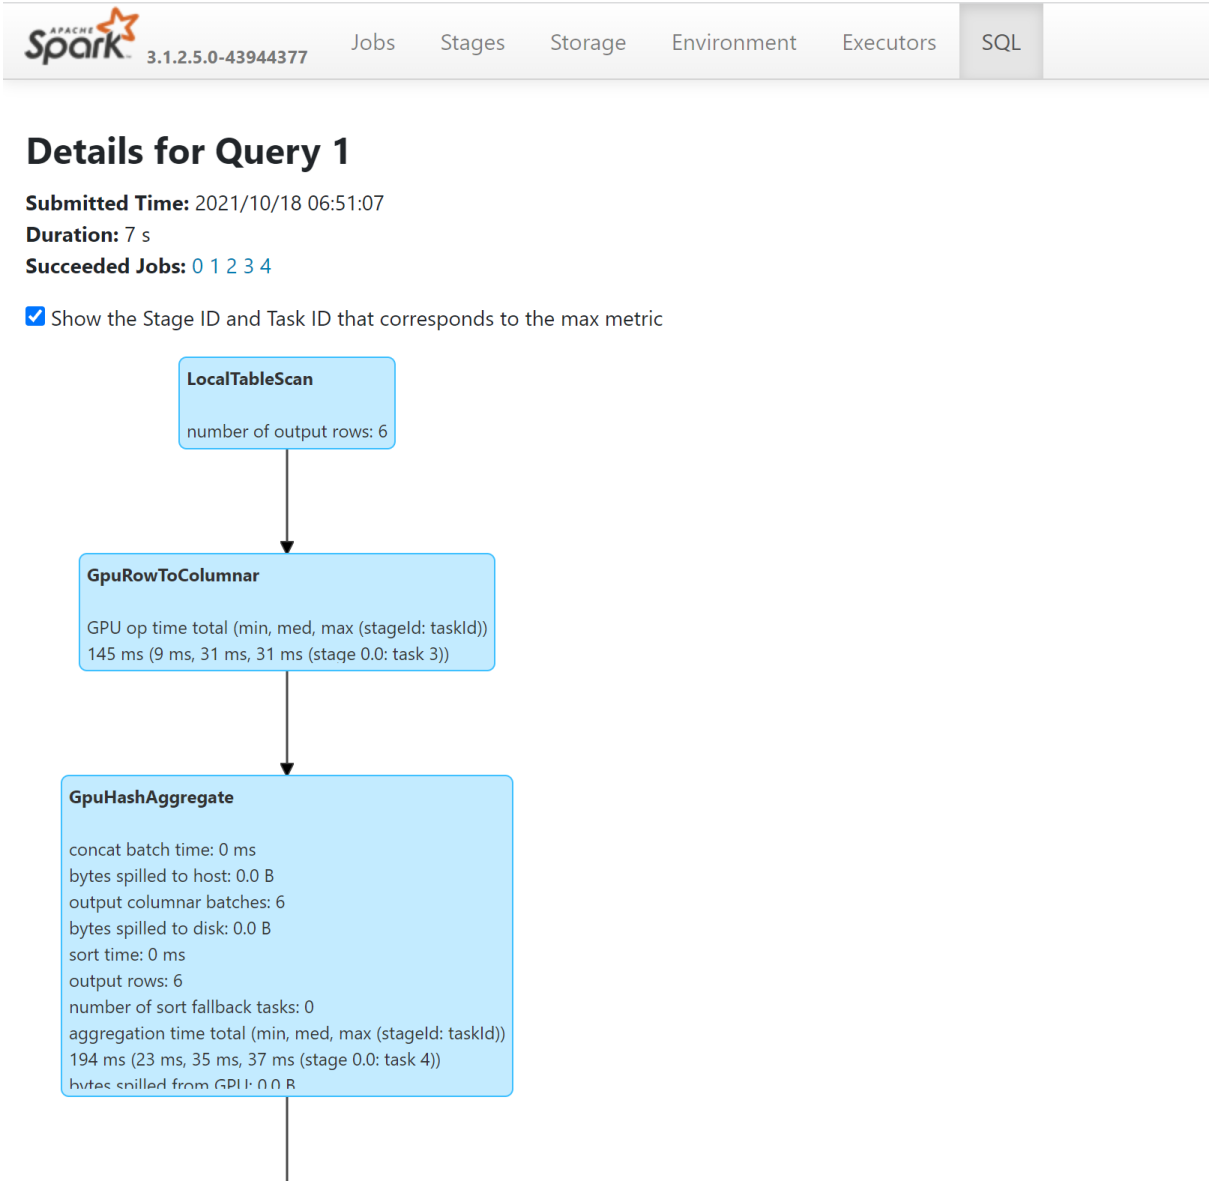
val empDF = spark.createDataFrame(emp, schema)
```

5. Now let's do an aggregate by getting the maximum salary per department ID and display the result:

- Scala
- Python
- C#

```
val resultDF = empDF.groupBy("emp_dept_id").max("salary")
resultDF.show()
```

6. You can see the operations in your query that ran on GPUs by looking into the SQL plan through the Spark History Server:



How to tune your application for GPUs

Most Spark jobs can see improved performance through tuning configuration settings from defaults, and the same holds true for jobs leveraging the RAPIDS accelerator plugin for Apache Spark. This documentation provides guidelines on how to tune a Spark job to run on GPUs using the RAPIDS plugin.

Quotas and resource constraints in Azure Synapse GPU-enabled pools

Workspace level

Every Azure Synapse workspace comes with a default quota of 50 GPU vCores. In order to increase your quota of GPU cores, please submit a support request through the Azure portal.

Use extended Apache Spark history server to debug and diagnose Apache Spark applications

8/19/2022 • 7 minutes to read • Edit Online

This article provides guidance on how to use the extended Apache Spark history server to debug and diagnose completed and running Spark applications.

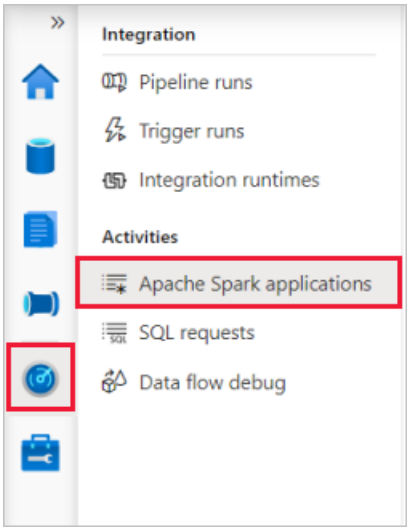
The extension includes a data tab, graph tab, and diagnosis tab. Use the **Data** tab to check the input and output data of the Spark job. The **Graph** tab shows you the data flow and replay of the job graph. The **Diagnosis** tab shows you **Data Skew**, **Time Skew**, and **Executor Usage Analysis**.

Access the Apache Spark history server

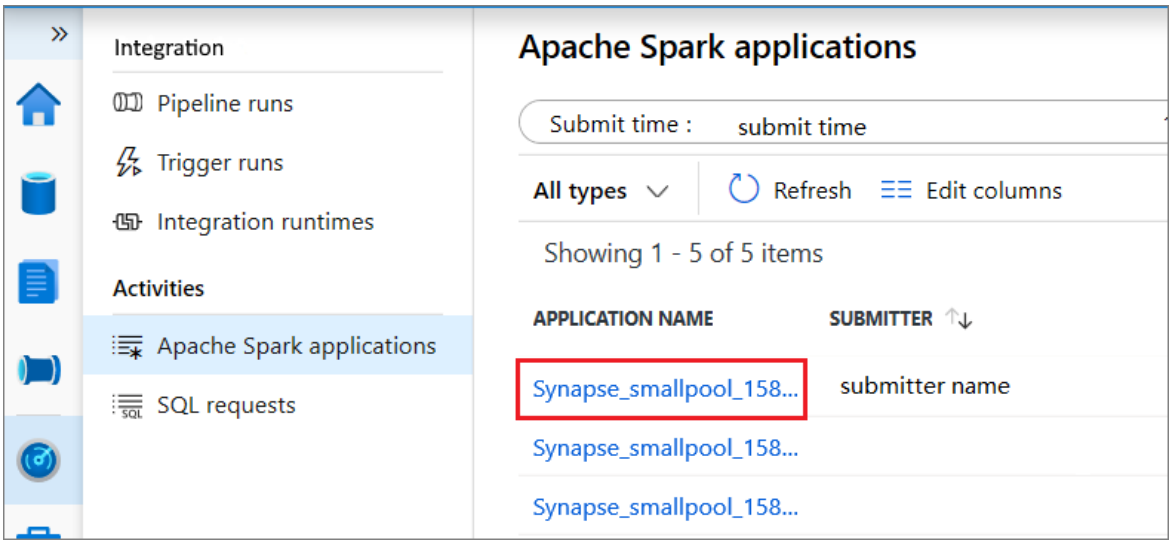
Apache Spark history server is the web user interface for completed and running Spark applications. You can open the Apache Spark history server web interface from the Azure Synapse Analytics.

Open the Spark History Server web UI from Apache spark applications node

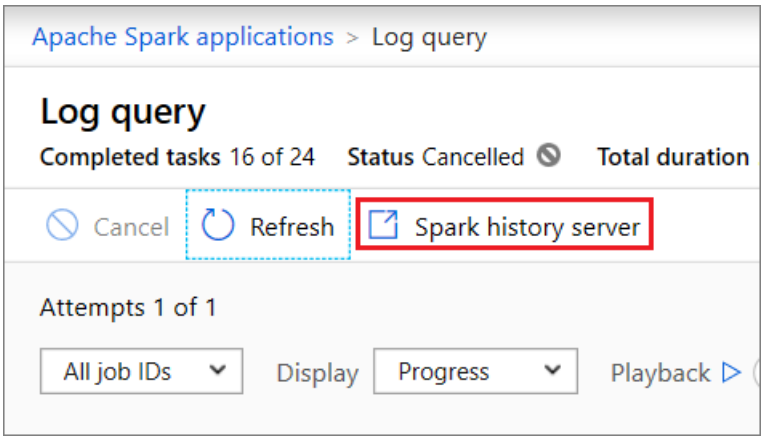
1. Open Azure Synapse Analytics.
2. Select **Monitor**, then select **Apache Spark Applications**.



3. Select an application, then open **Log query** by selecting it.

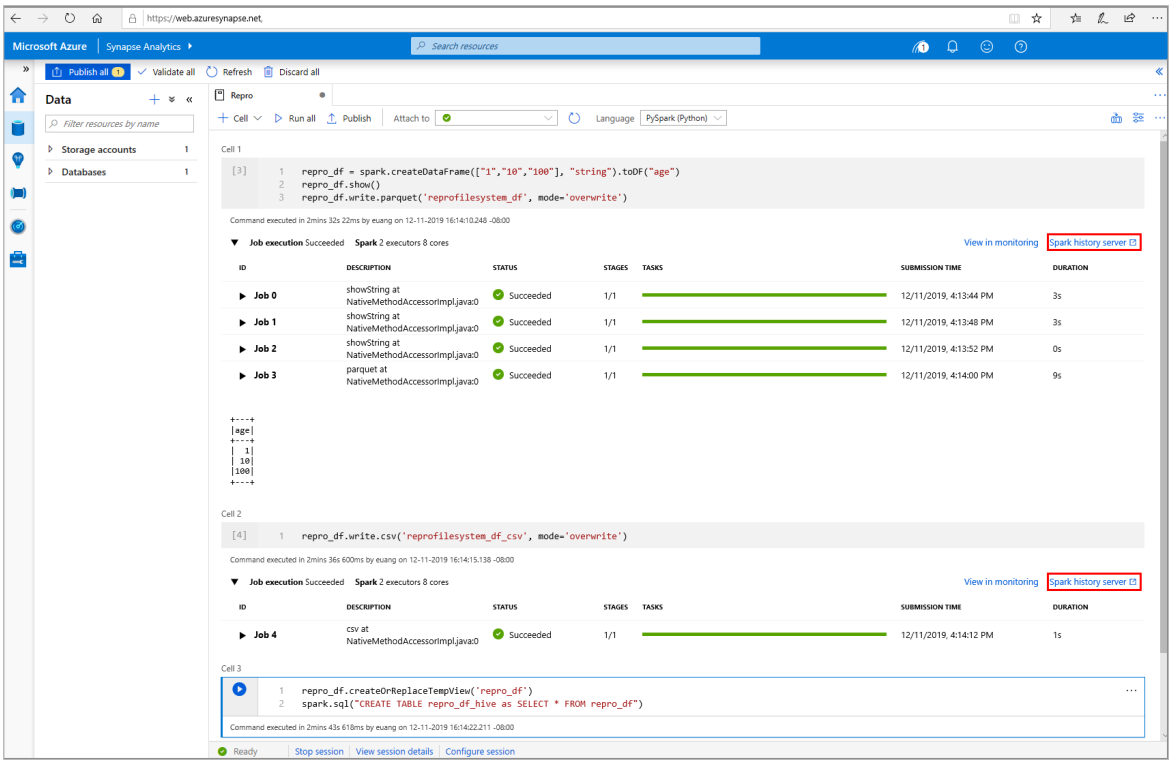


4. Select **Spark history server**, then the Spark History Server web UI will show up.

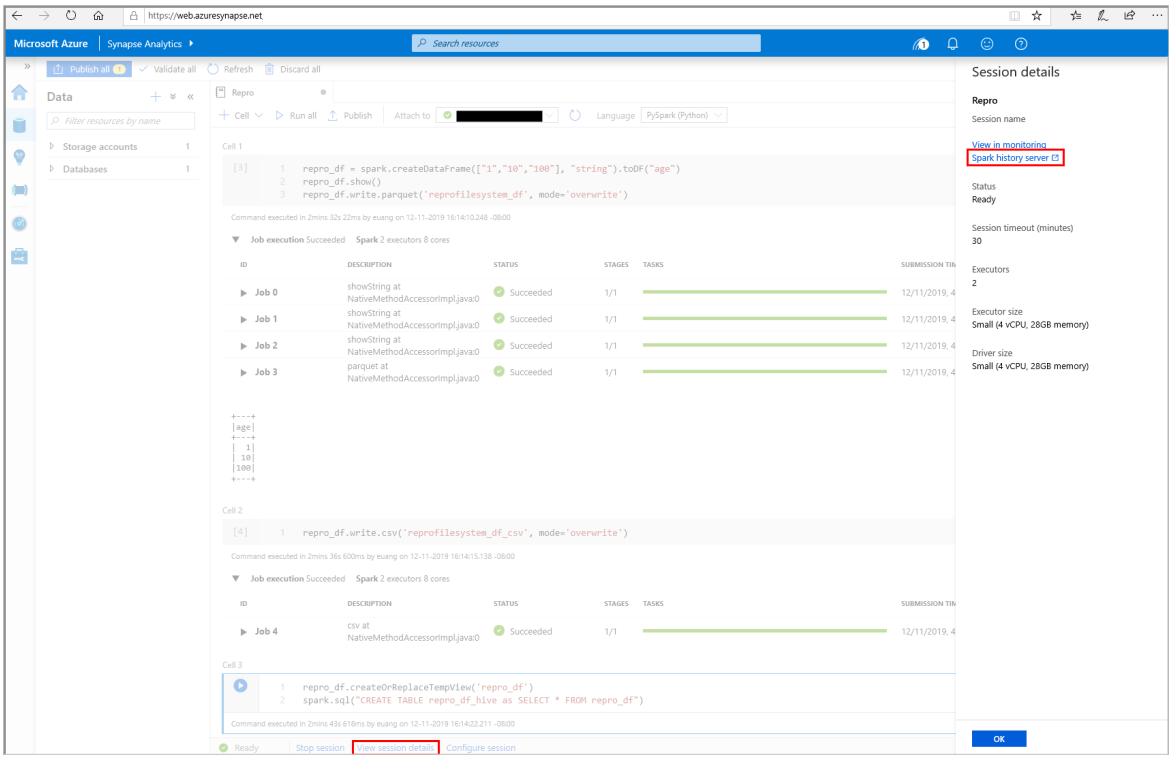


Open the Spark History Server web UI from Data node

1. From your Synapse Studio notebook, select **Spark history server** from the job execution output cell or from the status panel at the bottom of the notebook document. Select **Session details**.



2. Select **Spark history server** from the slide out panel.

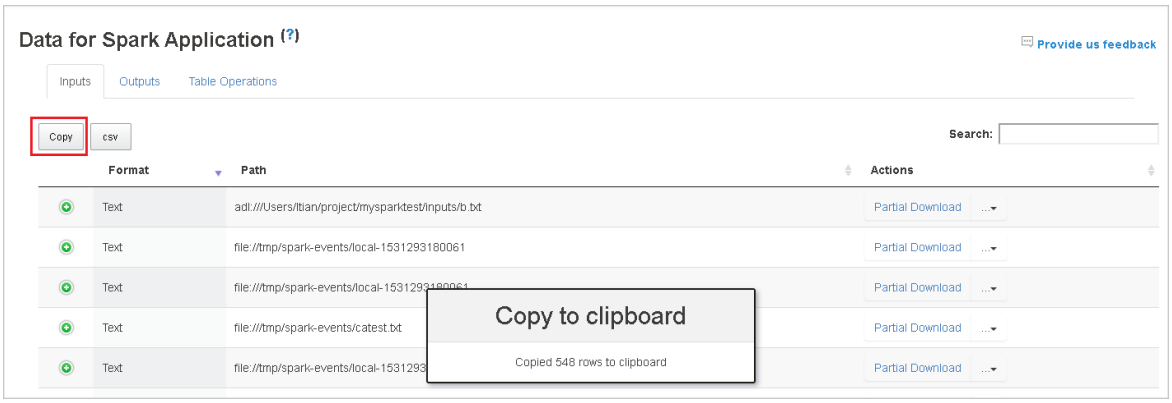


Explore the Data tab in Spark history server

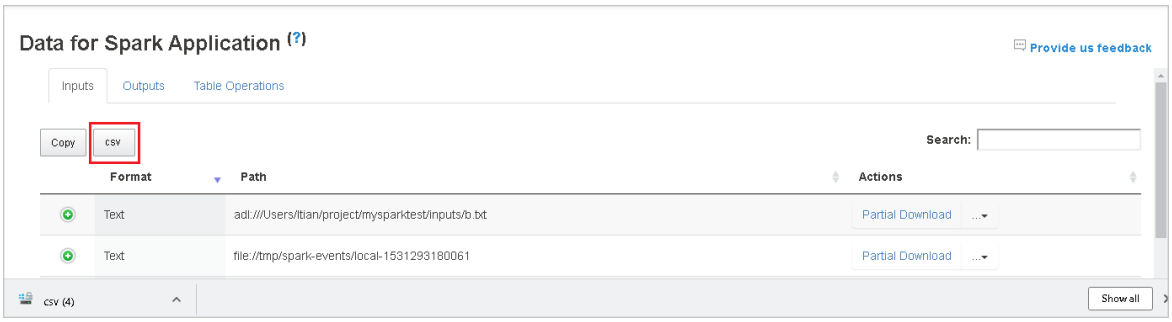
Select the Job ID for the job you want to view. Then select **Data** on the tool menu to get the data view. This section shows you how to do various tasks in the Data tab.

- Check the **Inputs**, **Outputs**, and **Table Operations** by selecting the tabs separately.

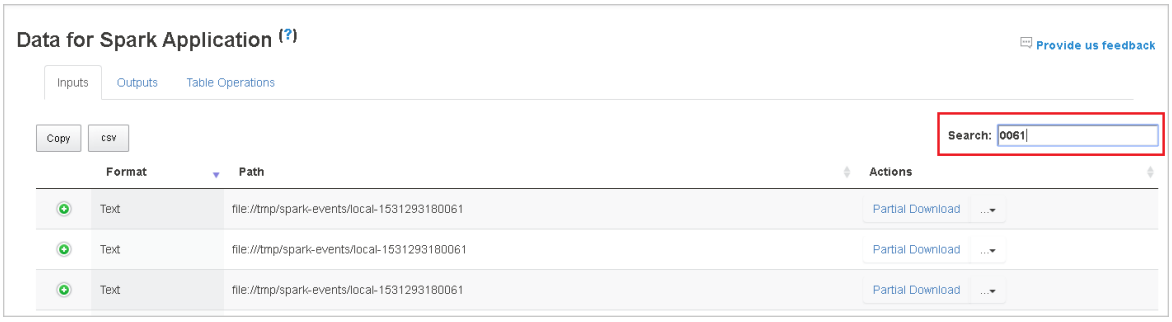
- Copy all rows by selecting **Copy**.



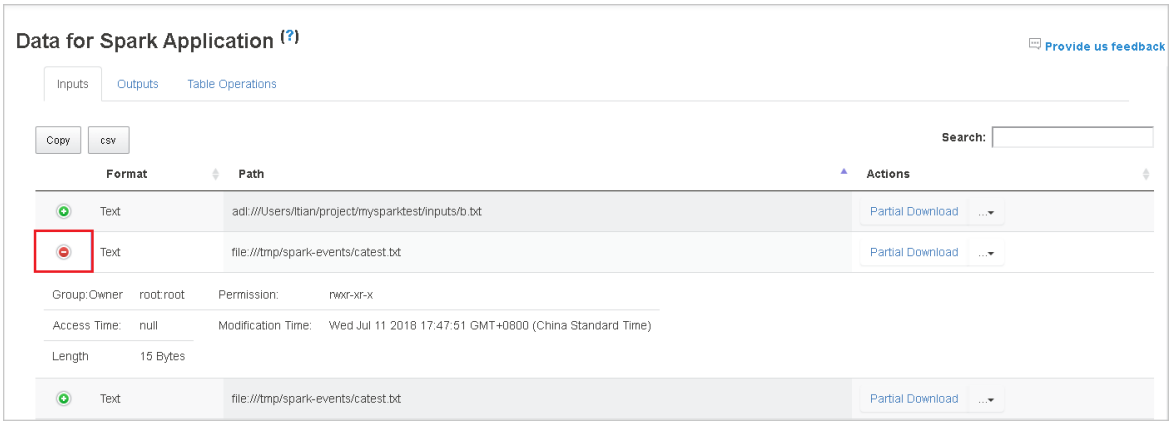
- Save all data as CSV file by selecting **csv**.



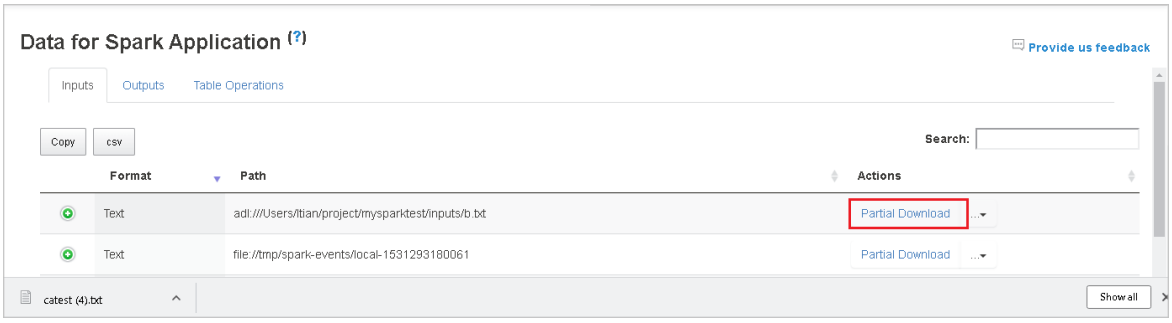
- Search by entering keywords in field **Search**. The search results display immediately.



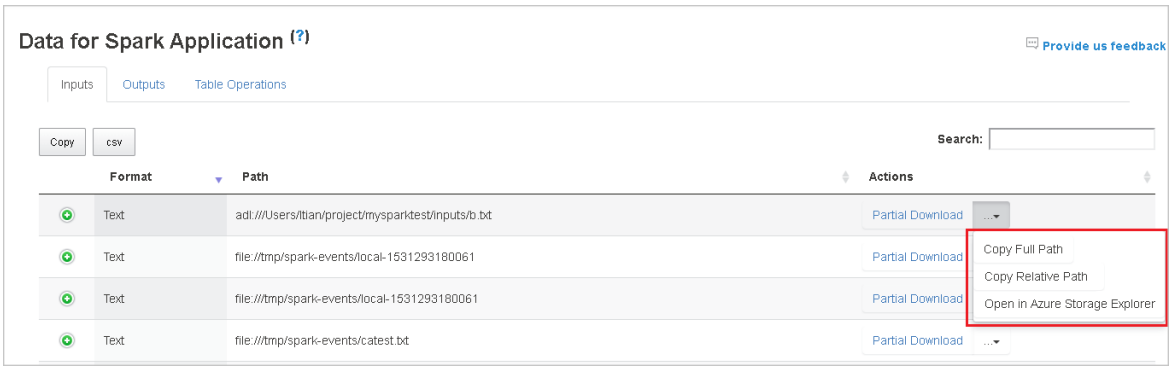
- Select the column header to sort table, select the plus sign to expand a row to show more details, or select the minus sign to collapse a row.



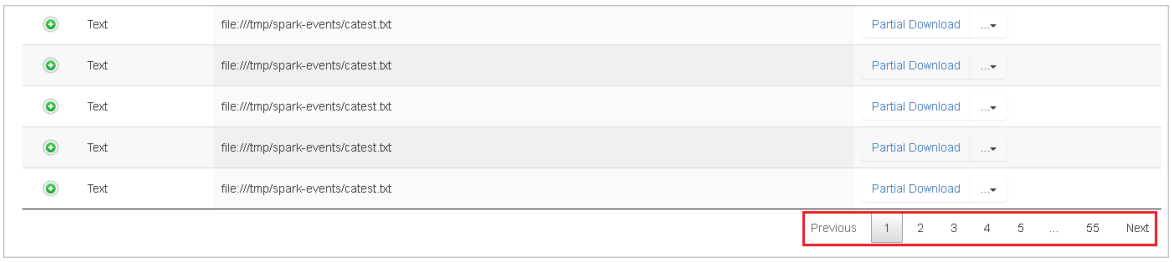
- Download a single file by selecting **Partial Download**. The selected file is downloaded to local. If the file no longer exists, a new tab appears with an error message.



- To copy a full path or relative path, select the **Copy Full Path** or **Copy Relative Path** options that expand from the drop-down menu. For Azure Data Lake Storage files, **Open in Azure Storage Explorer** launches Azure Storage Explorer and locates the folder when you are signed in.

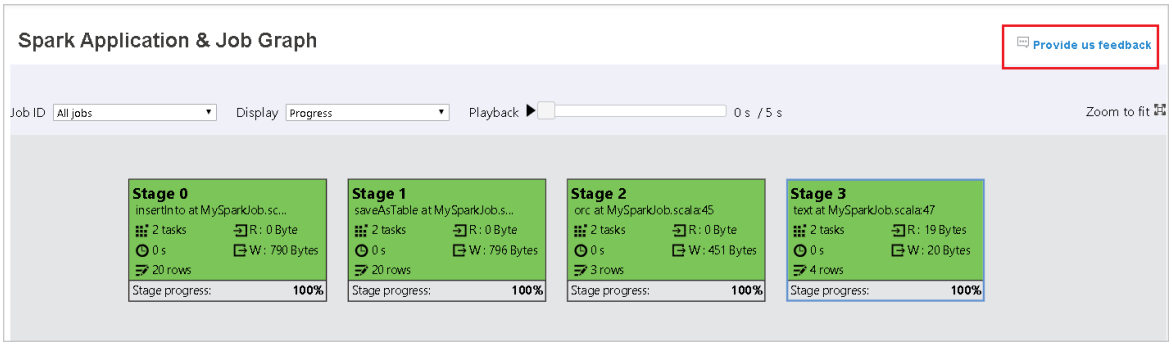


- Select page numbers below the table to navigate pages when there are too many rows to display in one page.



- Hover on the question mark beside **Data** to show the tooltip, or select the question mark to get more information.

- Send feedback with issues by selecting **Provide us feedback**.

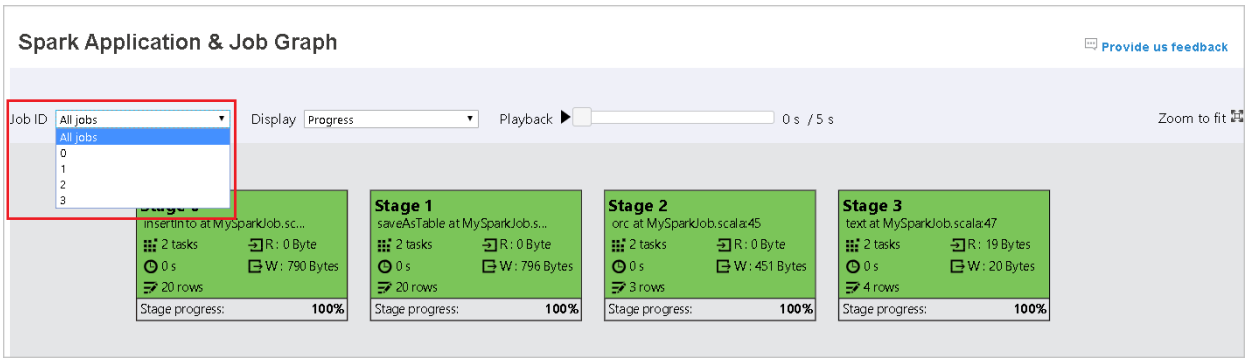


Graph tab in Apache Spark history server

Select the Job ID for the job you want to view. Then, select **Graph** on the tool menu to get the job graph view.

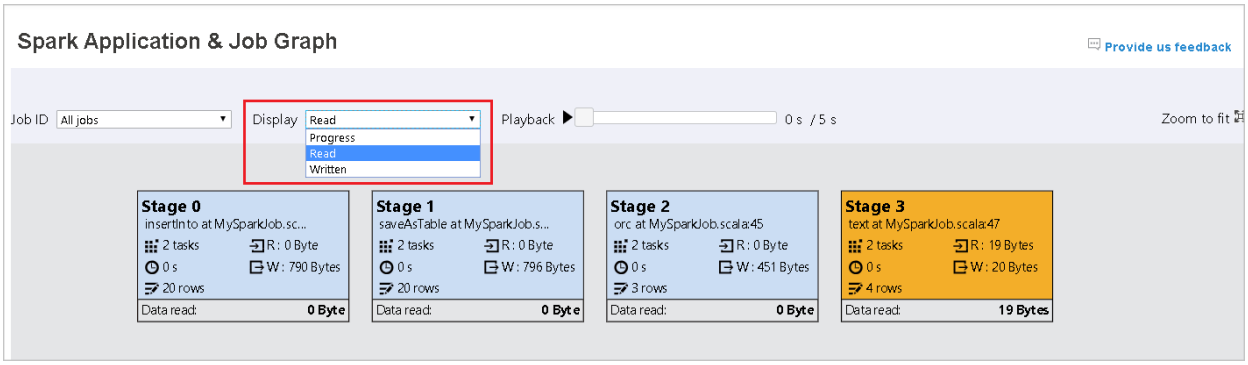
Overview

You can see an overview of your job in the generated job graph. By default, the graph shows all jobs. You can filter this view by **Job ID**.



Display

By default, the **Progress** display is selected. You can check the data flow by selecting **Read** or **Written** in the **Display** dropdown list.



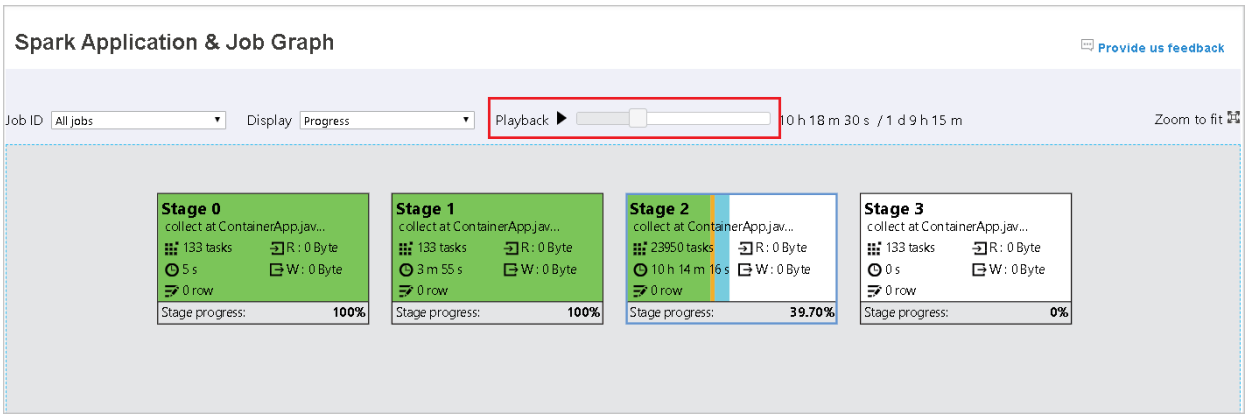
The graph node displays the colors shown in the heatmap legend.

Playback

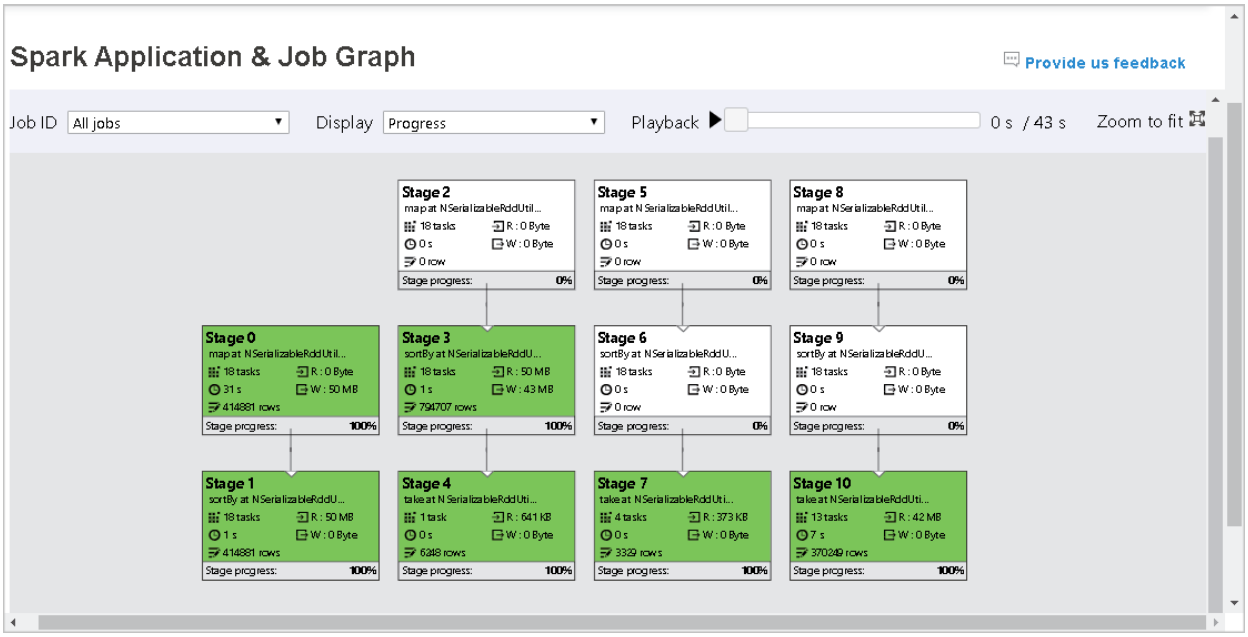
To playback the job, select **Playback**. You can select **Stop** at any time to stop. The task colors show different statuses when playing back:

COLOR	MEANING
Green	Succeeded: The job has completed successfully.
Orange	Retried: Instances of tasks that failed but do not affect the final result of the job. These tasks had duplicate or retry instances that may succeed later.
Blue	Running: The task is running.
White	Waiting or skipped: The task is waiting to run, or the stage has skipped.
Red	Failed: The task has failed.

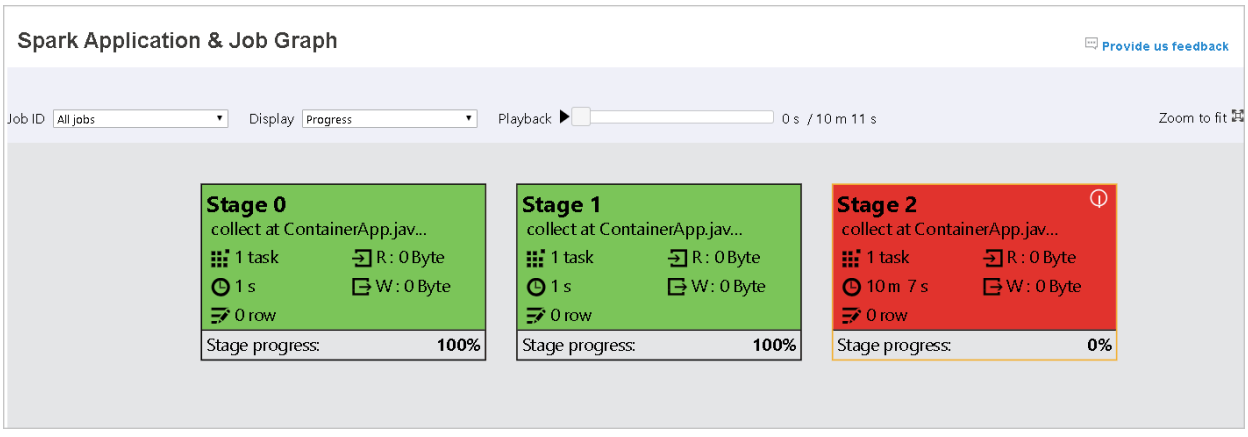
The following image shows Green, Orange, and Blue status colors.



The following image shows Green and White status colors.



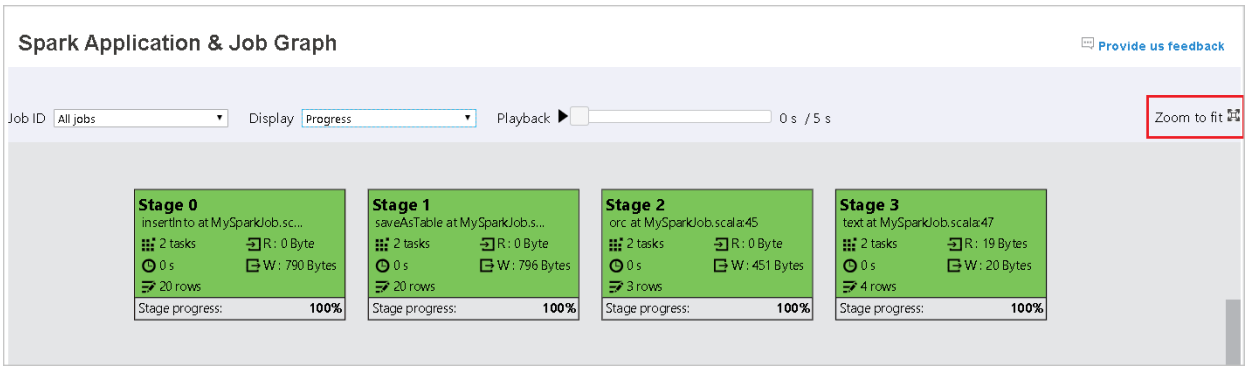
The following image shows Red and Green status colors.



> **NOTE**
>
> Playback for each job is allowed. For incomplete jobs, playback is not supported.

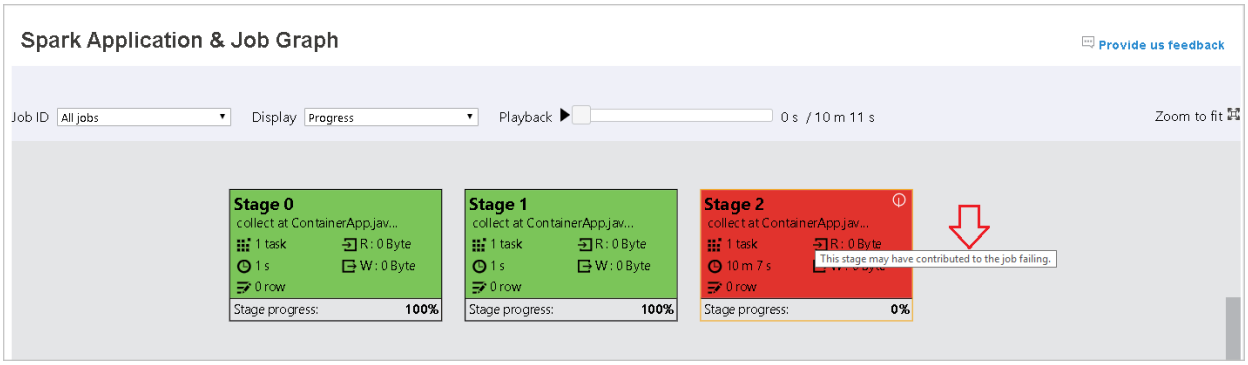
Zoom

Use your mouse scroll to zoom in and out on the job graph, or select **Zoom to fit** to make it fit to screen.



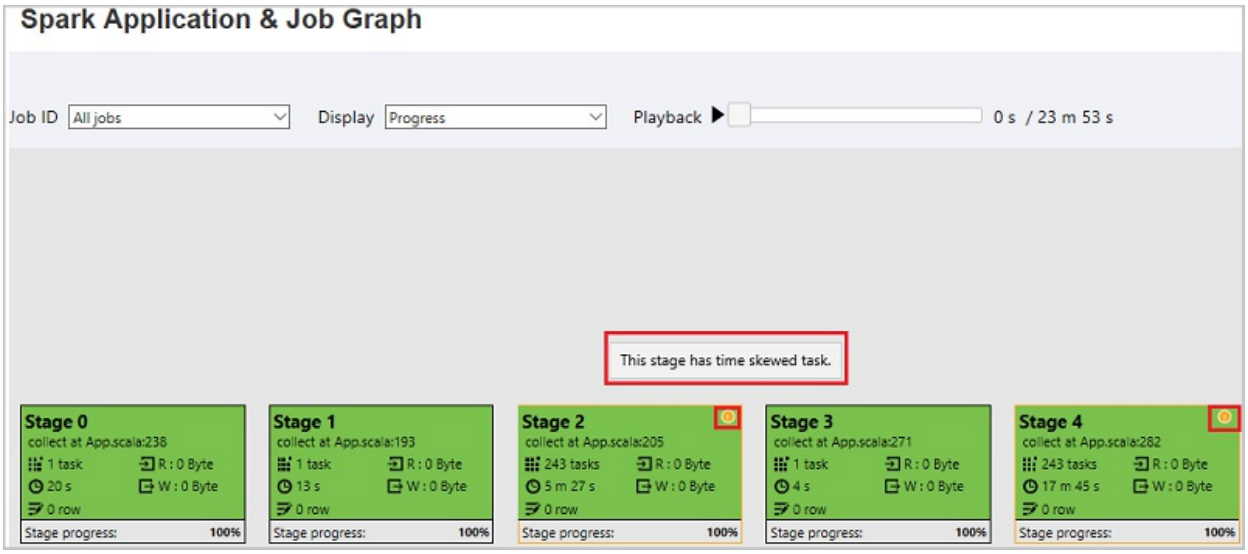
Tooltips

Hover on graph node to see the tooltip when there are failed tasks, and select a stage to open its stage page.



On the job graph tab, stages have a tooltip and a small icon displayed if they have tasks that meet the following conditions:

CONDITION	DESCRIPTION
Data skew	data read size > average data read size of all tasks inside this stage * 2 and data read size > 10 MB
Time skew	execution time > average execution time of all tasks inside this stage * 2 and execution time > 2 minutes



Graph node description

The job graph node displays the following information of each stage:

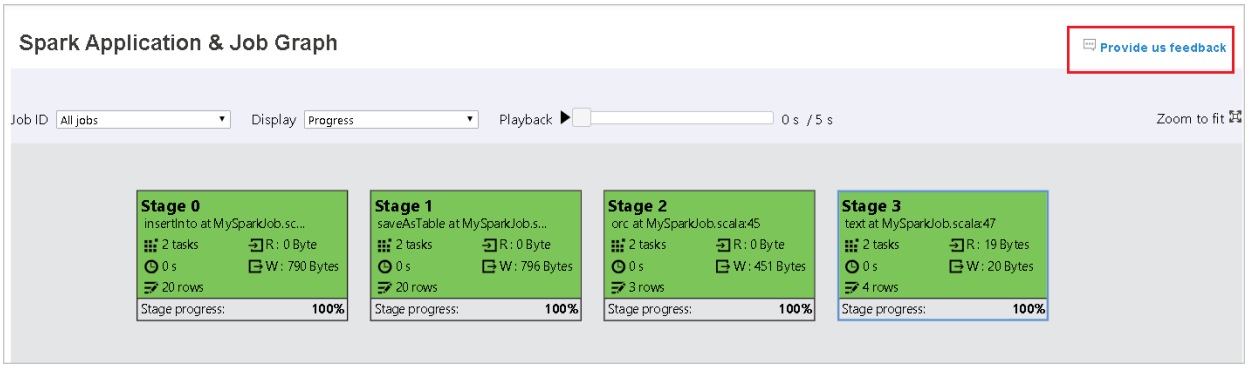
- ID.
- Name or description.

- Total task number.
- Data read: the sum of input size and shuffle read size.
- Data write: the sum of output size and shuffle writes size.
- Execution time: the time between start time of the first attempt and completion time of the last attempt.
- Row count: the sum of input records, output records, shuffle read records and shuffle write records.
- Progress.

> **NOTE**
>
> By default, the job graph node displays information from the last attempt of each stage (except for stage execution time). However, during playback, the graph node shows information of each attempt.
>
> The data size of read and write is 1MB = 1000 KB = 1000 * 1000 Bytes.

Provide feedback

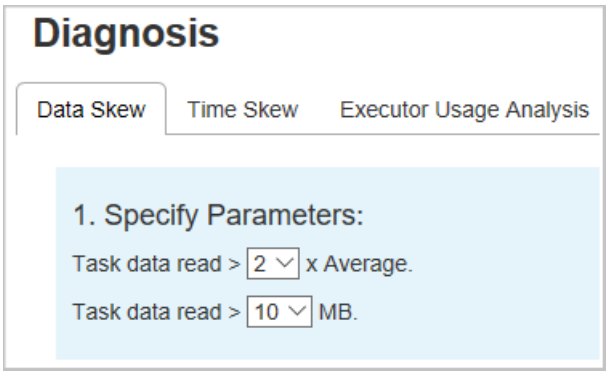
Send feedback with issues by selecting **Provide us feedback**.



Explore the Diagnosis tab in Apache Spark history server

To access the Diagnosis tab, select a job ID. Then select **Diagnosis** on the tool menu to get the job Diagnosis view. The diagnosis tab includes **Data Skew**, **Time Skew**, and **Executor Usage Analysis**.

Check the **Data Skew**, **Time Skew**, and **Executor Usage Analysis** by selecting the tabs respectively.



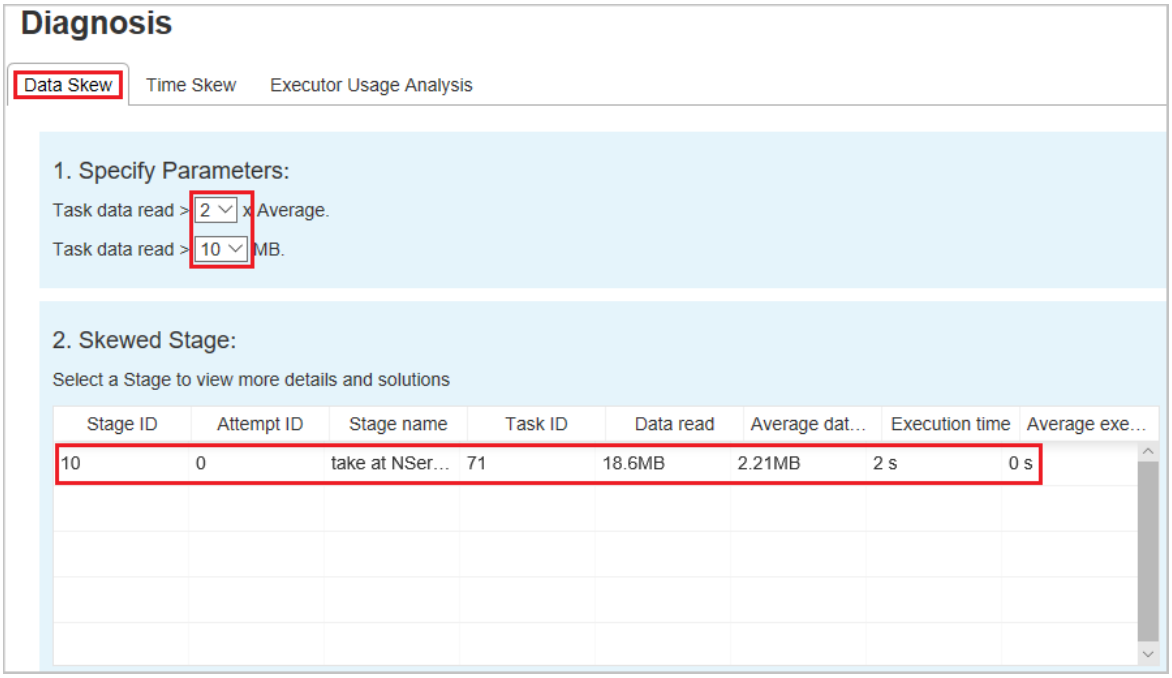
Data Skew

When you select the **Data Skew** tab, the corresponding skewed tasks are displayed based on the specified parameters.

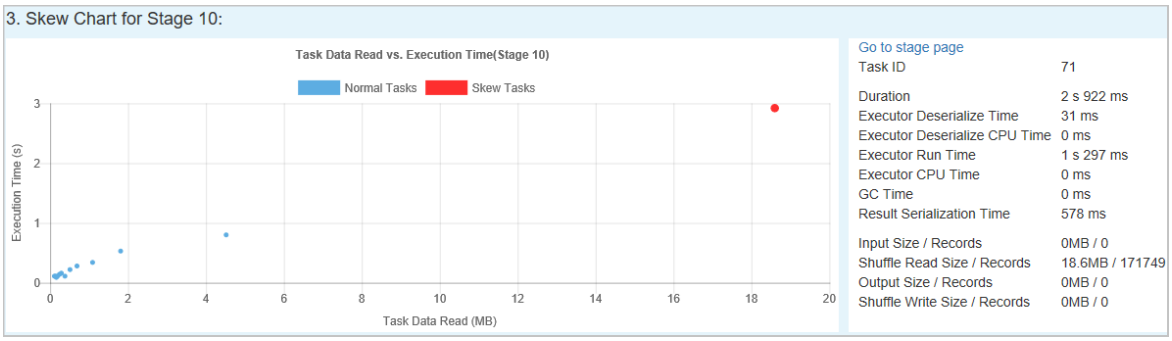
- **Specify Parameters** - The first section displays the parameters, which are used to detect Data Skew. The default rule is: Task Data Read is greater than three times of the average task data read, and the task data read is more than 10 MB. If you want to define your own rule for skewed tasks, you can choose your

parameters. The **Skewed Stage** and **Skew Char** sections are refreshed accordingly.

- **Skewed Stage** - The second section displays stages, which have skewed tasks meeting the criteria specified above. If there is more than one skewed task in a stage, the skewed stage table only displays the most skewed task (for example, the largest data for data skew).



- **Skew Chart** – When a row in the skew stage table is selected, the skew chart displays more task distribution details based on data read and execution time. The skewed tasks are marked in red and the normal tasks are marked in blue. The chart displays up to 100 sample tasks, and the task details are displayed in right bottom panel.

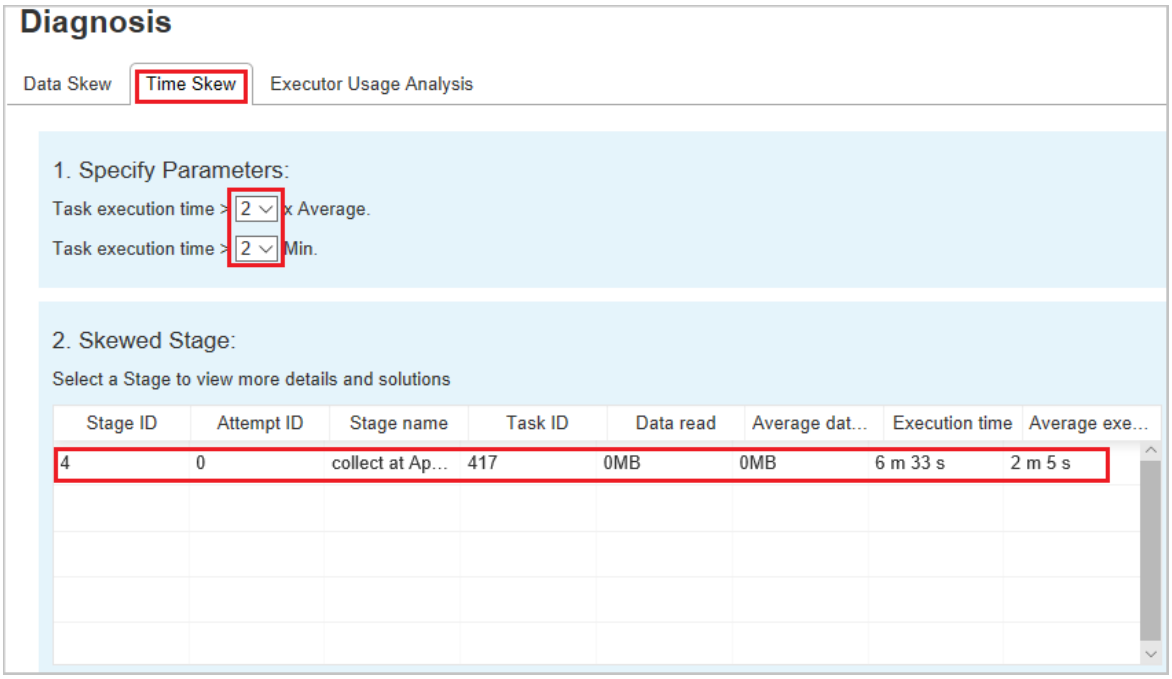


Time Skew

The **Time Skew** tab displays skewed tasks based on task execution time.

- **Specify Parameters** - The first section displays the parameters, which are used to detect Time Skew. The default criteria to detect time skew is: task execution time is greater than three times of average execution time and task execution time is greater than 30 seconds. You can change the parameters based on your needs. The **Skewed Stage** and **Skew Chart** display the corresponding stages and tasks information just like the **Data Skew** tab above.

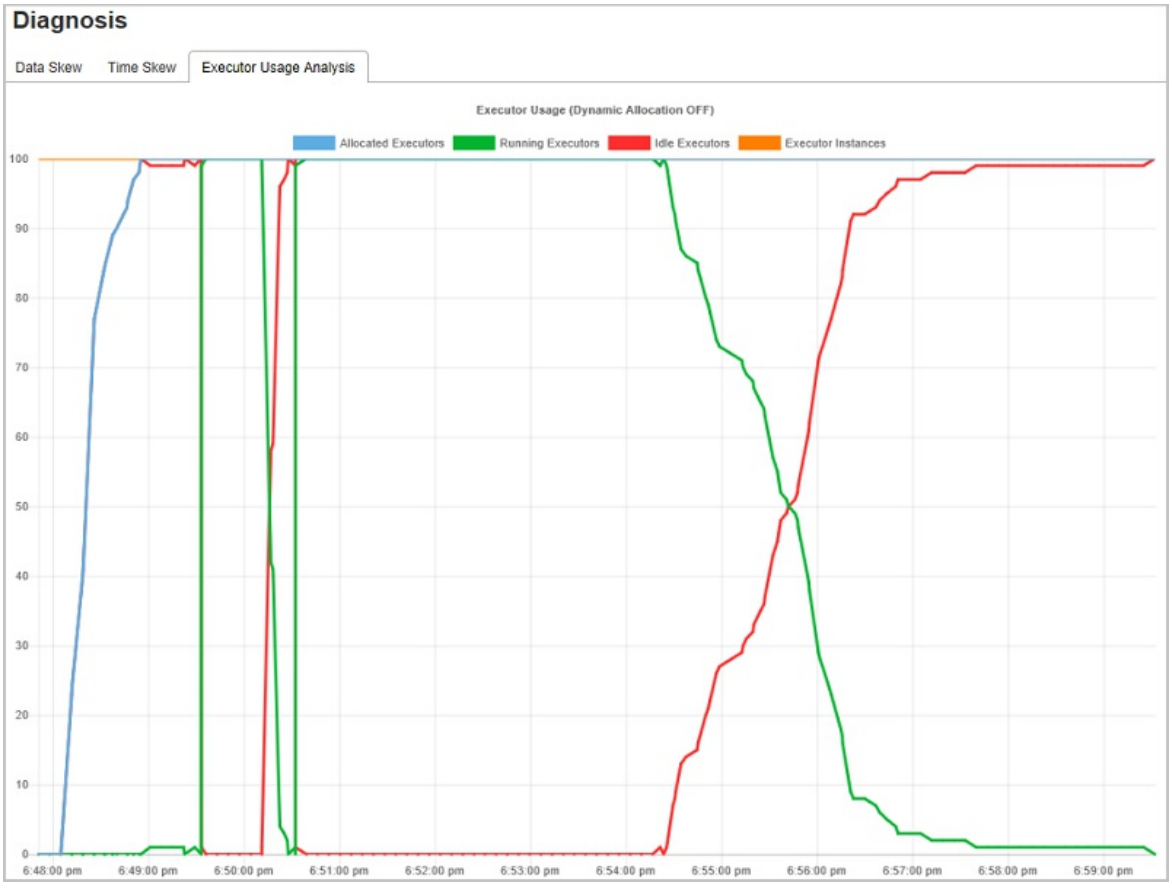
- Select **Time Skew**, then filtered result is displayed in **Skewed Stage** section according to the parameters set in section **Specify Parameters**. Select one item in **Skewed Stage** section, then the corresponding chart is drafted in section3, and the task details are displayed in right bottom panel.



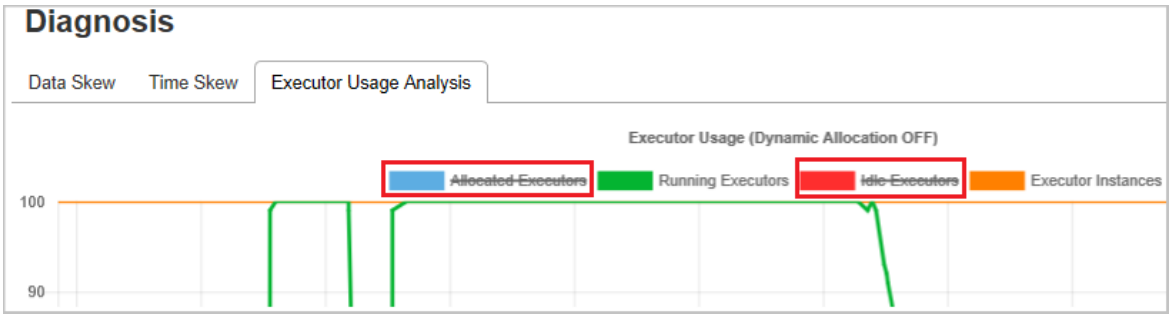
Executor Usage Analysis

The Executor Usage Graph visualizes the Spark job executor's allocation and running status.

1. Select **Executor Usage Analysis**, then four types curves about executor usage are drafted, including **Allocated Executors**, **Running Executors**, **Idle Executors**, and **Max Executor Instances**. For allocated executors, each "Executor added" or "Executor removed" event increases or decreases the allocated executors. You can check "Event Timeline" in the "Jobs" tab for more comparison.



2. Select the color icon to select or unselect the corresponding content in all drafts.



Known issues

Input/output data using Resilient Distributed Datasets (RDDs) doesn't show in the data tab.

- Azure Synapse Analytics
- .NET for Apache Spark documentation

Use Synapse Studio to monitor your Apache Spark applications

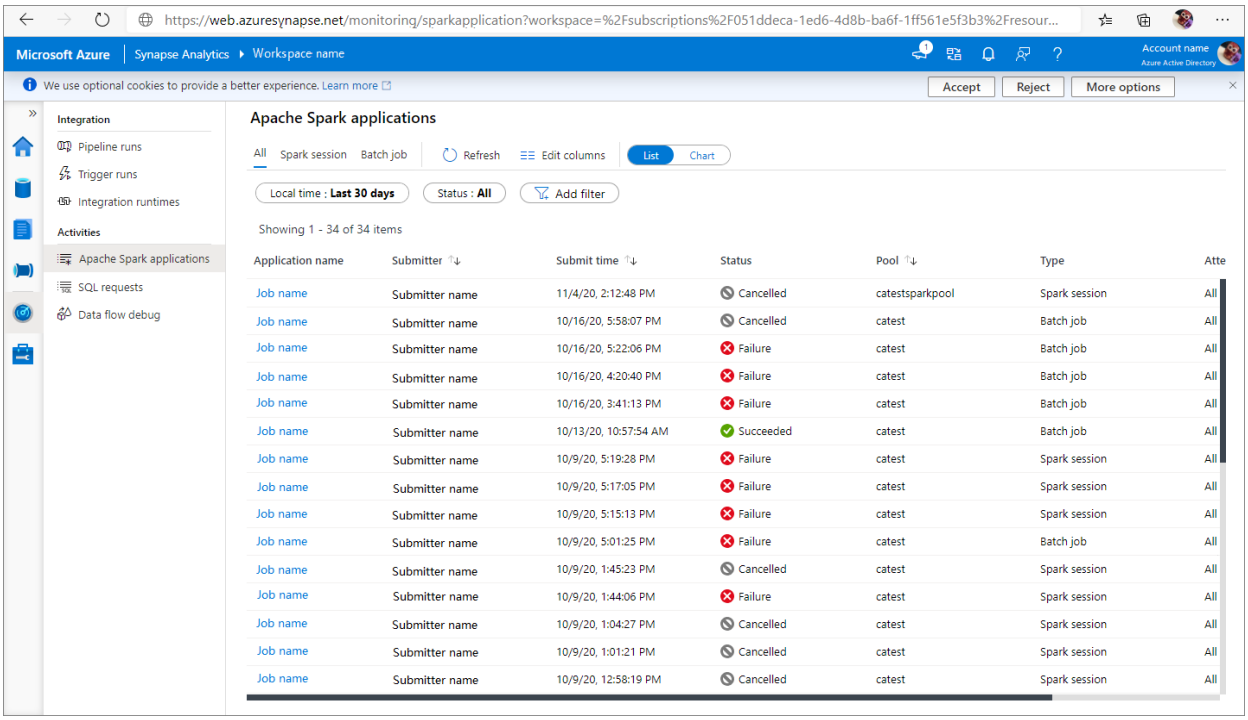
8/19/2022 • 5 minutes to read • Edit Online

With Azure Synapse Analytics, you can use Apache Spark to run notebooks, jobs, and other kinds of applications on your Apache Spark pools in your workspace.

This article explains how to monitor your Apache Spark applications, allowing you to keep an eye on the latest status, issues, and progress.

View Apache Spark applications

You can view all Apache Spark applications from **Monitor** -> **Apache Spark applications**.

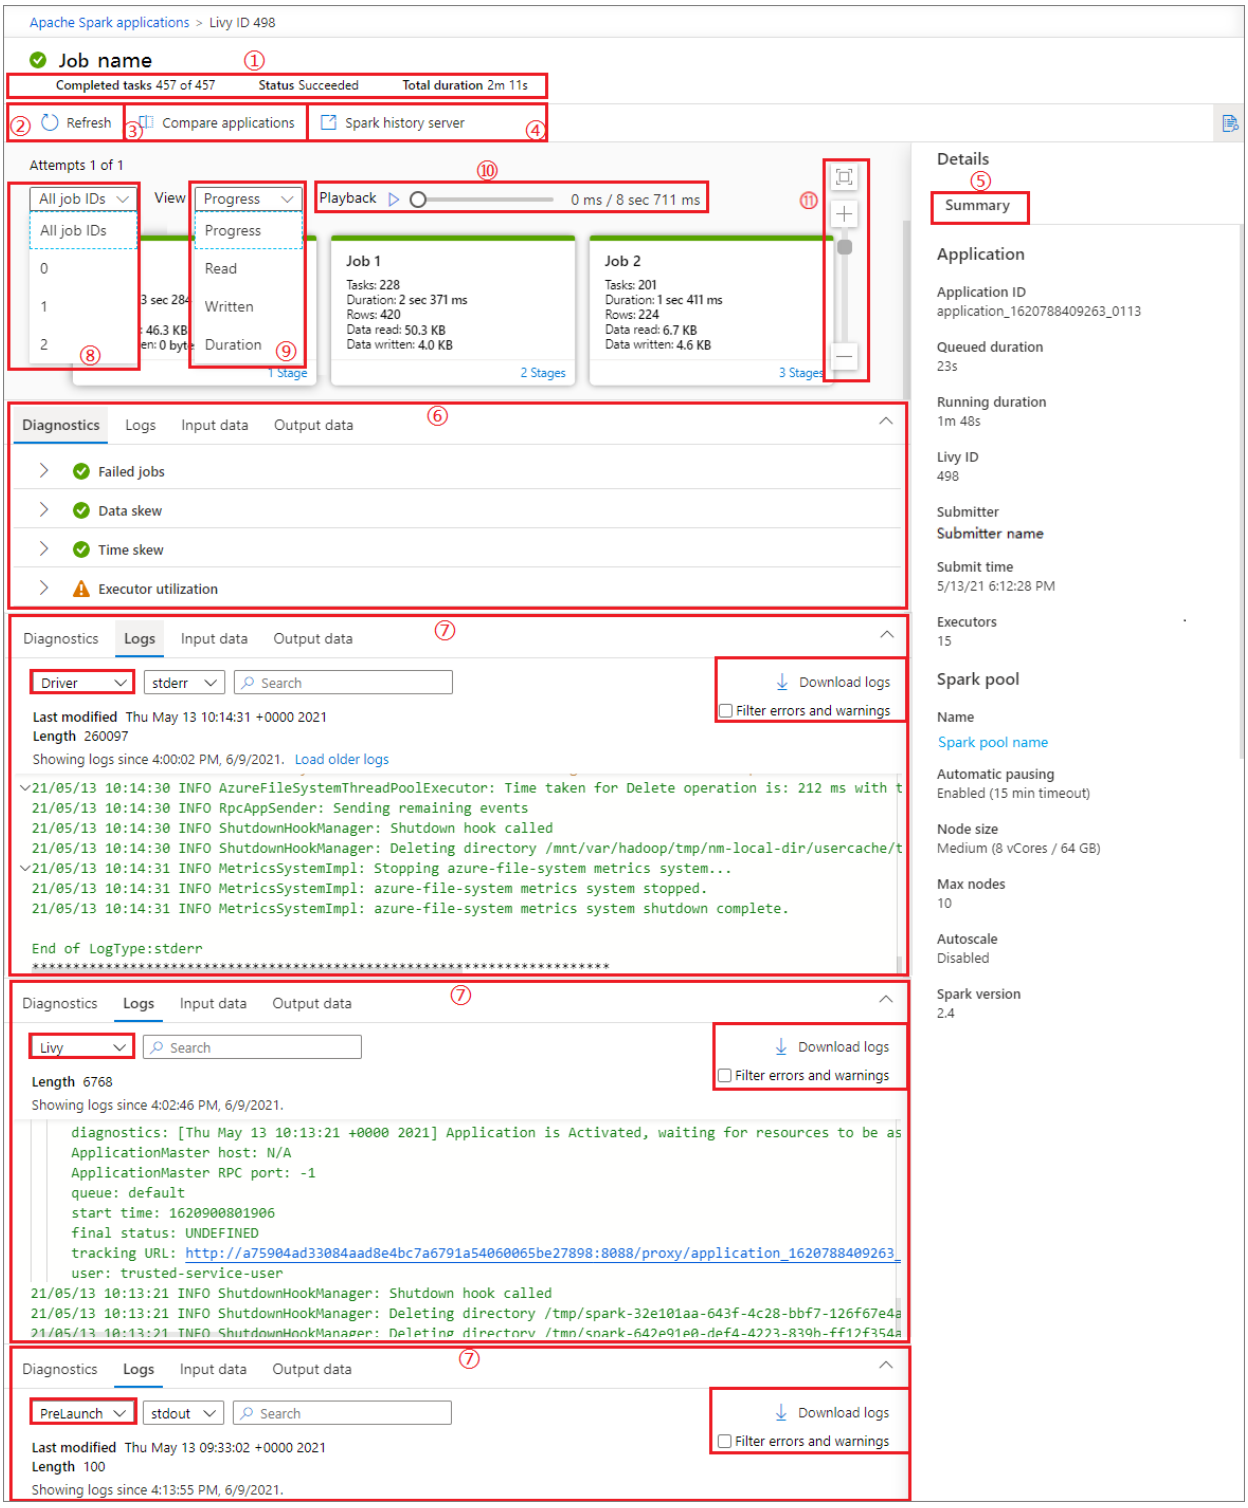


View completed Apache Spark applications

Open **Monitor**, then select **Apache Spark applications**. To view the details about the completed Apache Spark applications, select the Apache Spark application.

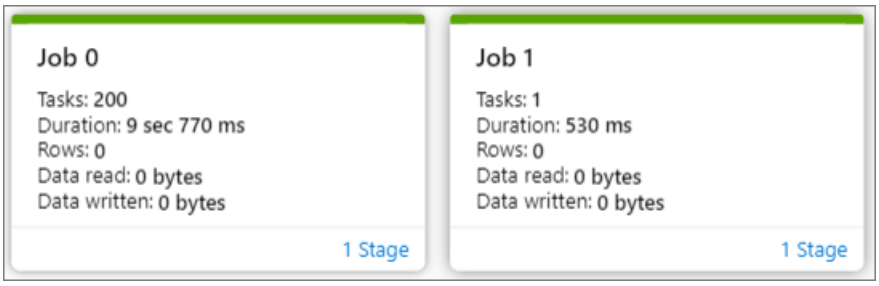
1. Check the **Completed tasks**, **Status**, and **Total duration**.
2. **Refresh** the job.
3. Click on **Compare applications** to use the comparison feature, for more information on this feature, see the Compare Apache Spark applications.
4. Click on **Spark history server** to open the History Server page.
5. Check the **Summary** info.

6. Check the diagnostics in **Diagnostic** tab.
7. Check the **Logs**. You can view full log of **Livy**, **Prelaunch**, and **Driver** logs via selecting different options in the drop-down list. And you can directly retrieve the required log information by searching keywords. Click **Download log** to download the log information to the local, and select the **Filter errors and warnings** check box to filter the errors and warnings you need.
8. You can see an overview of your job in the generated job graph. By default, the graph shows all jobs. You can filter this view by **Job ID**.
9. By default, the **Progress** display is selected. You can check the data flow by selecting **Progress/Read/Written/Duration** in the **View** dropdown list.
10. To play back the job, click on **Playback** button. You can click on **Stop** button at any time to stop.
11. Use scroll bar to zoom in and zoom out the job graph, you can also select **Zoom to Fit** to make it fit the screen.



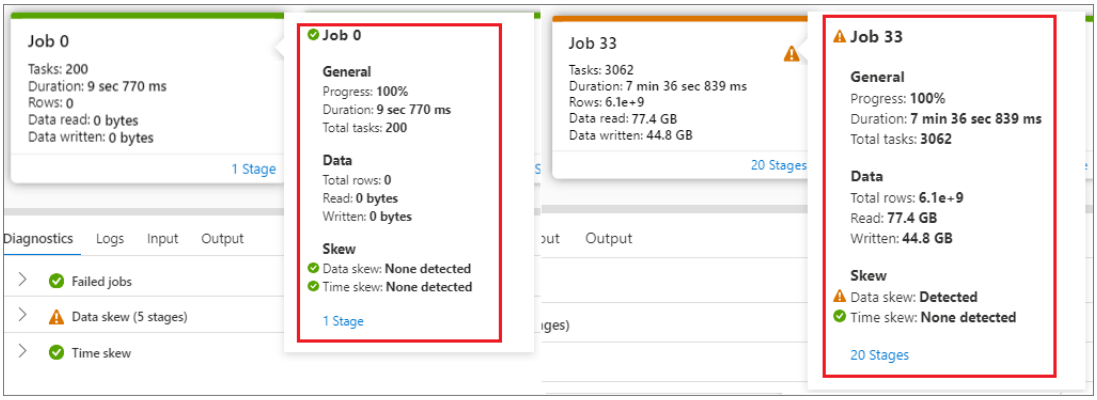
12. The job graph node displays the following information of each stage:

    - Job ID
    - Task number
    - Duration time
    - Row count
    - Data read: the sum of input size and shuffle read size
    - Data written: the sum of output size and shuffle writes size
    - Stage number



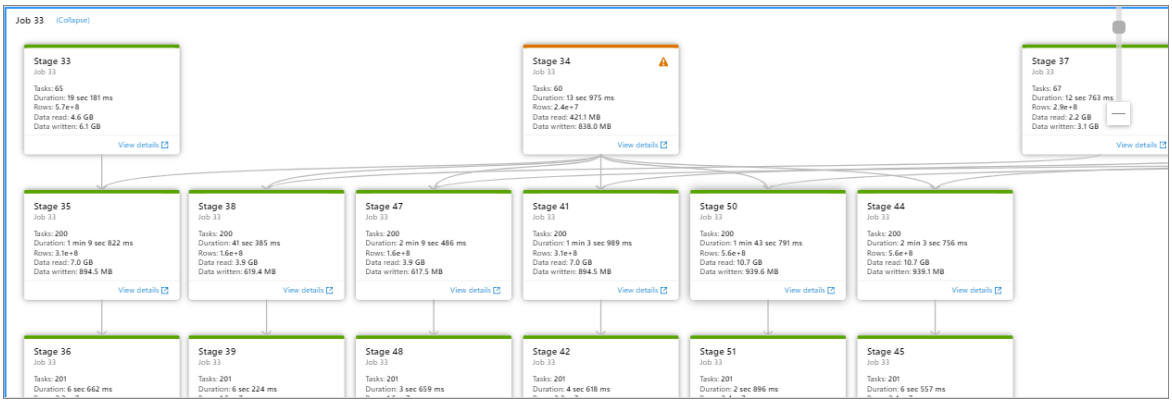
13. Hover the mouse over a job, and the job details will be displayed in the tooltip:

    - Icon of job status: If the job status is successful, it will be displayed as a green "Ã"; if the job detects a problem, it will display a yellow "!"
    - Job ID
    - General part:
        - Progress
        - Duration time
        - Total tasks number
    - Data part:
        - Total rows number
        - Read size
        - Written size
    - Skew part:
        - Data skew
        - Time skew
    - Stage number



14. Click **Stage number** to expand all the stages contained in the job. Click **Collapse** next to the Job ID to collapse all the stages in the job.

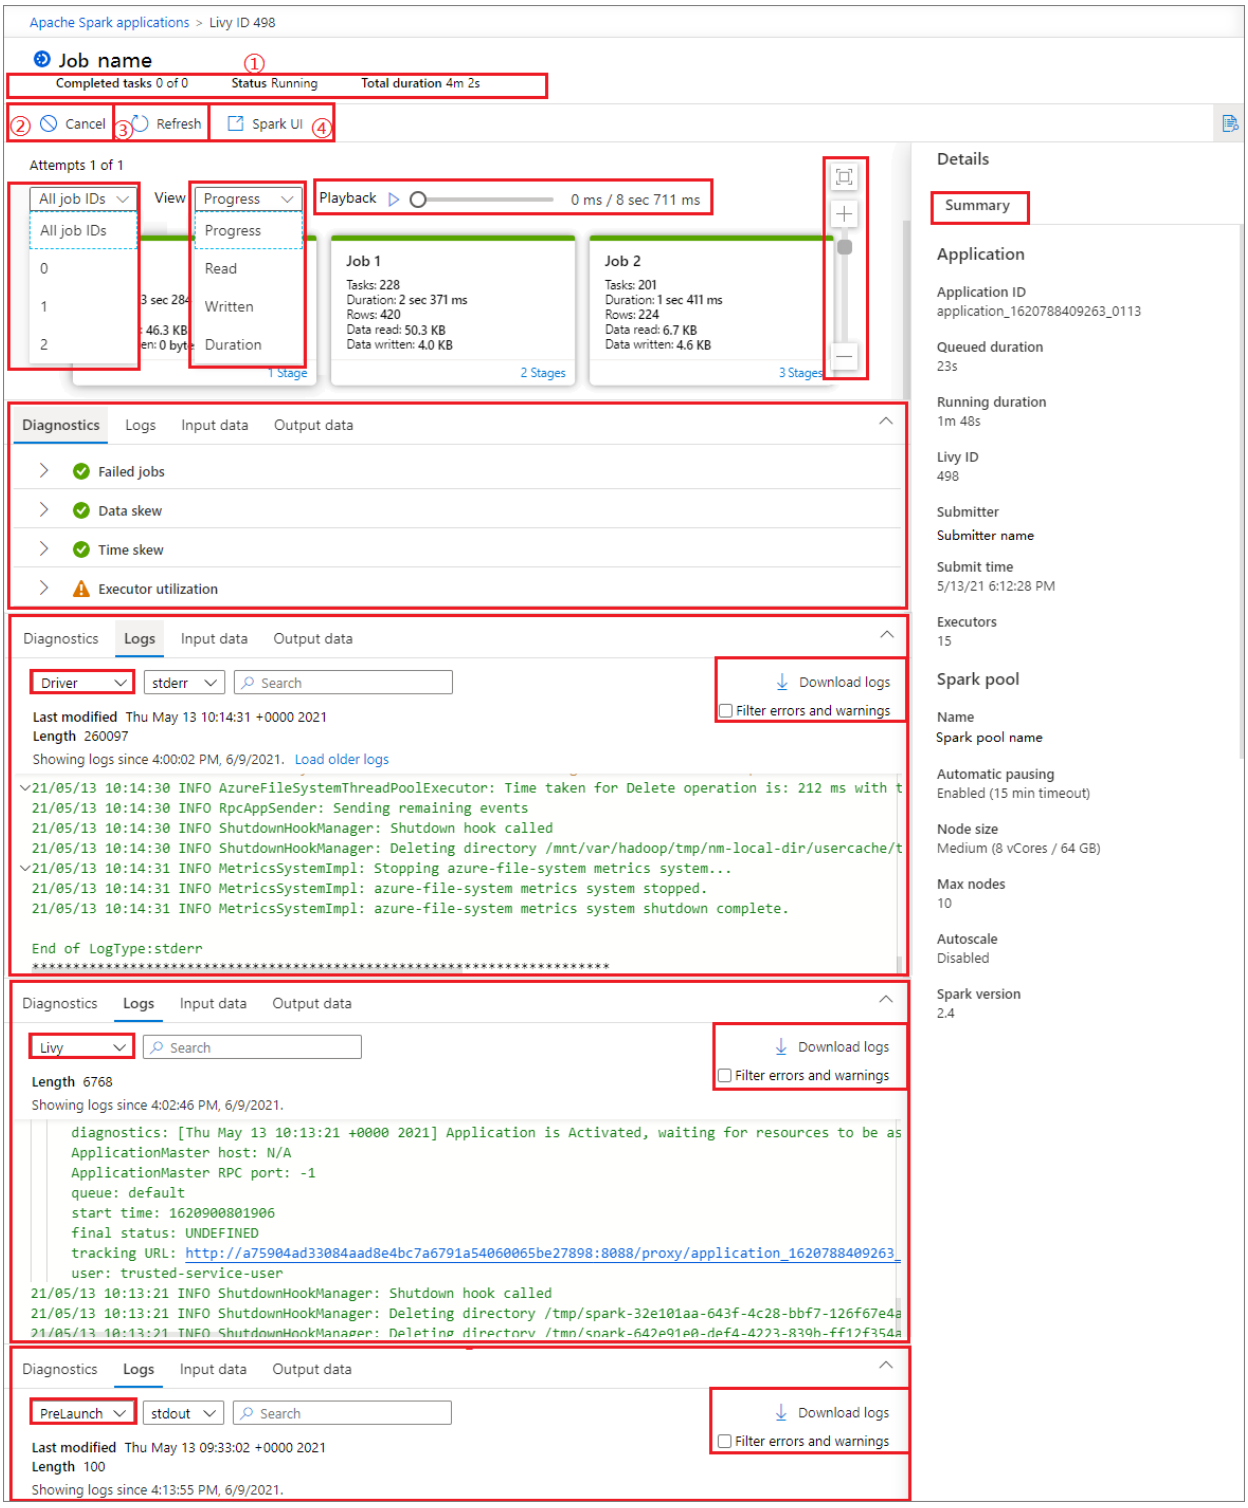
15. Click on **View details** in a stage graph, then the details for a stage will appear.



Monitor Apache Spark application progress

Open **Monitor**, then select **Apache Spark applications**. To view the details about the Apache Spark applications that are running, select the submitted Apache Spark application. If the Apache Spark application is still running, you can monitor the progress.

1. Check the **Completed tasks**, **Status**, and **Total duration**.
2. **Cancel** the Apache Spark application.
3. **Refresh** the Job.
4. Click on **Spark UI** button to go to Spark Job page.
5. For **Job graph**, **Summary**, **Diagnostics**, **Logs**. You can see an overview of your job in the generated job graph. Refer to steps 5 - 15 of View completed Apache Spark applications.



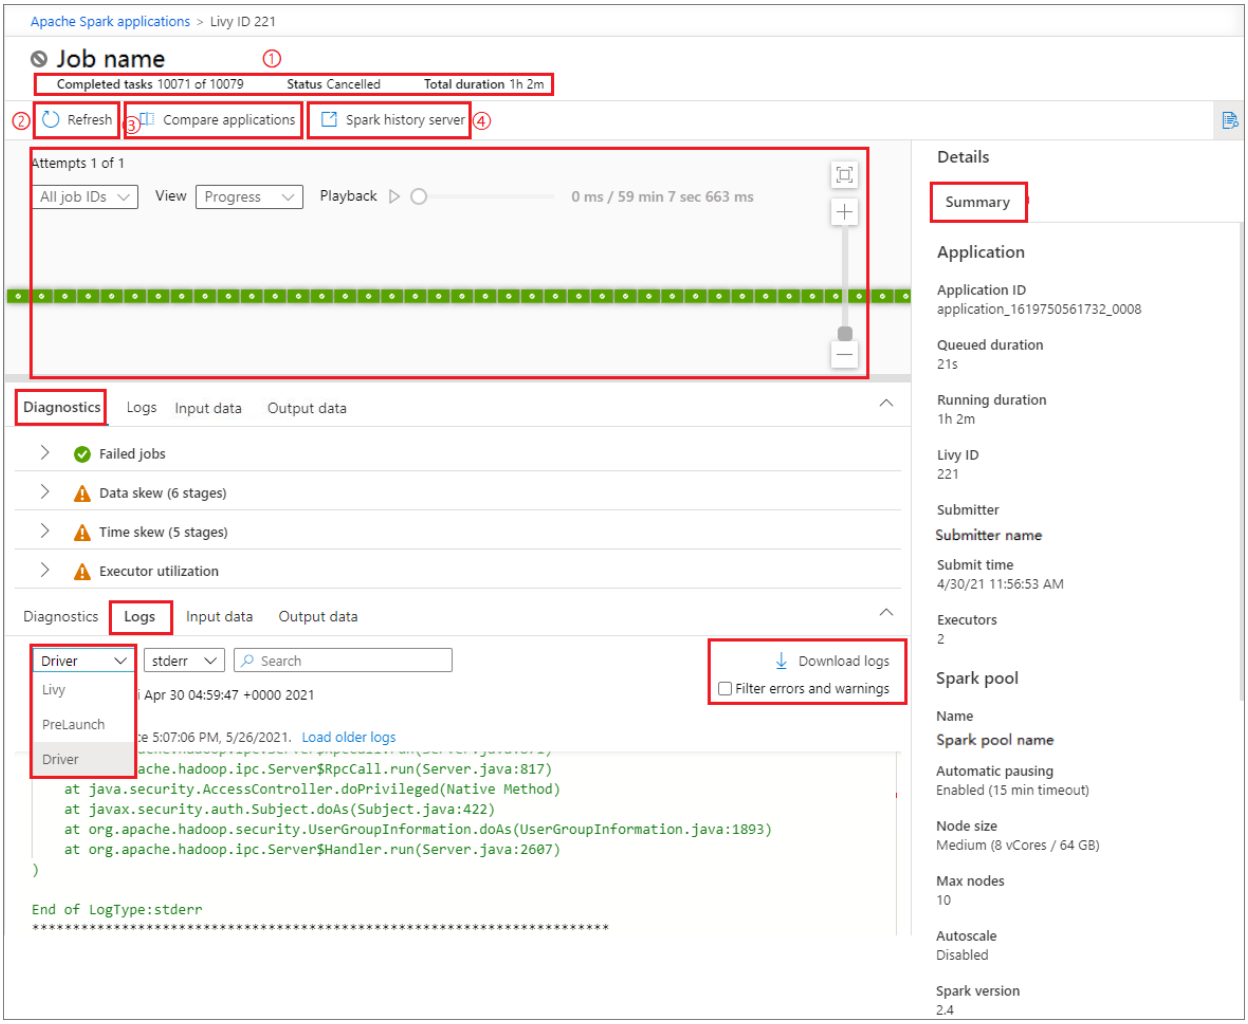
View canceled Apache Spark applications

Open **Monitor**, then select **Apache Spark applications**. To view the details about the canceled Apache Spark applications, select the Apache Spark application.

1. Check the **Completed tasks**, **Status**, and **Total duration**.
2. **Refresh** the Job.
3. Click on **Compare applications** to use the comparison feature, for more information on this feature, see the Compare Apache Spark applications.

4. Open Apache history server link by clicking **Spark history server**.

5. View the graph. You can see an overview of your job in the generated job graph. Refer to steps 5 - 15 of View completed Apache Spark applications.



Debug failed Apache Spark application

Open **Monitor**, then select **Apache Spark applications**. To view the details about the failed Apache Spark applications, select the Apache Spark application.

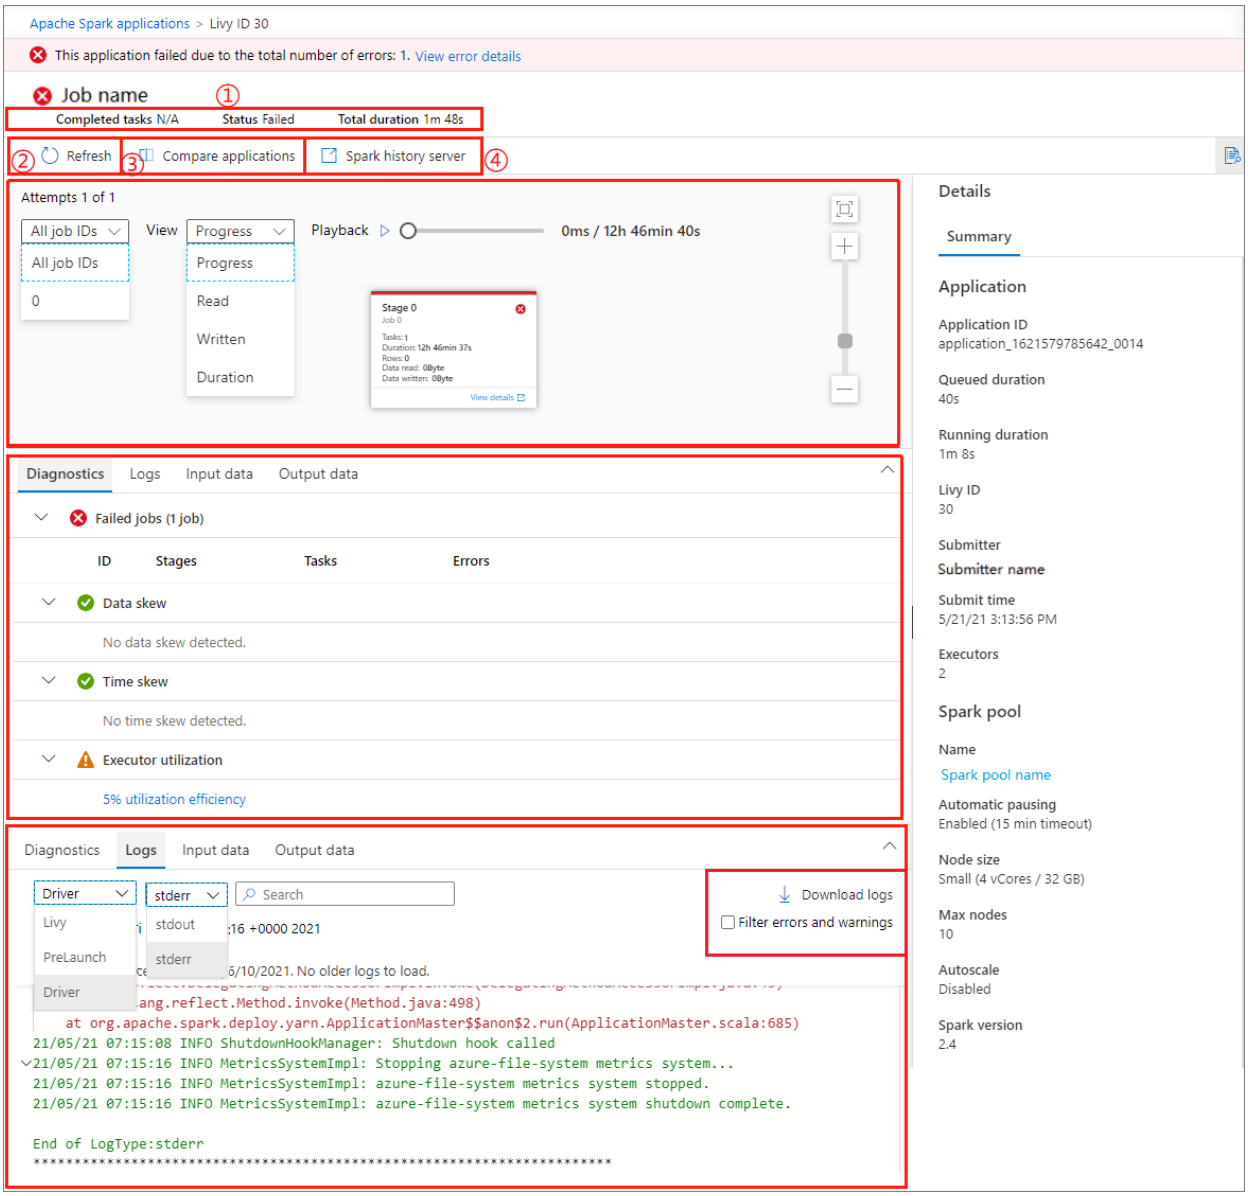
1. Check the **Completed tasks**, **Status**, and **Total duration**.

2. **Refresh** the Job.

3. Click on **Compare applications** to use the comparison feature, for more information on this feature, see the Compare Apache Spark applications.

4. Open Apache history server link by clicking **Spark history server**.

5. View the graph. You can see an overview of your job in the generated job graph. Refer to steps 5 - 15 of View completed Apache Spark applications.

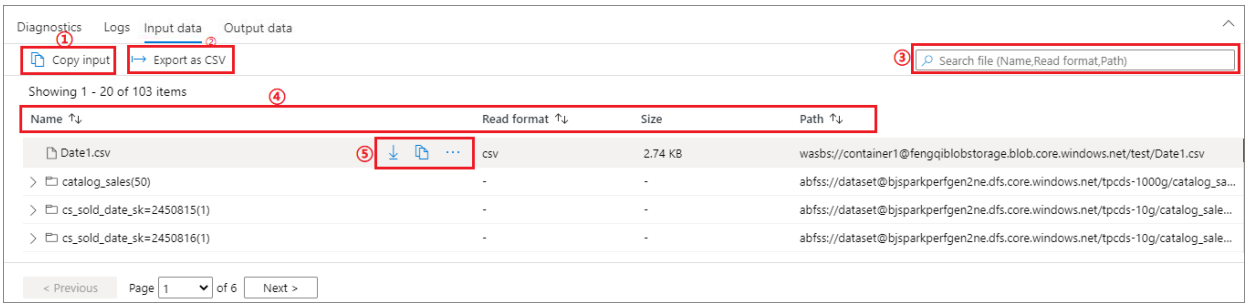


View input data/output data

Select an Apache Spark application, and click on **Input data/Output data tab** to view dates of the input and output for Apache Spark application. This function can help you debug the Spark job. And the data source supports three storage methods: gen1, gen2, and blob.

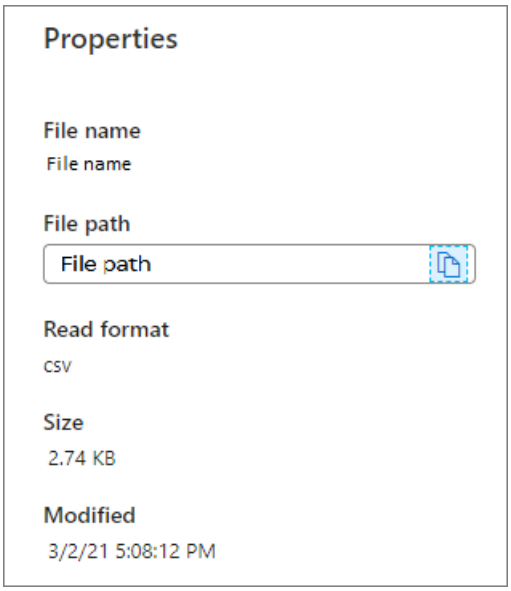
Input data tab

1. Click on the **Copy input** button to paste the input file to the local.
2. Click the **Export to CSV** button to export the input file in CSV format.
3. You can search files by input keywords in **Search box** (keywords include file name, read format and path).
4. You can sort the input files by clicking **Name**, **Read format**, and **path**.
5. Use the mouse to hover over an input file, the icon of the **Download/Copy path/More** button will appear.



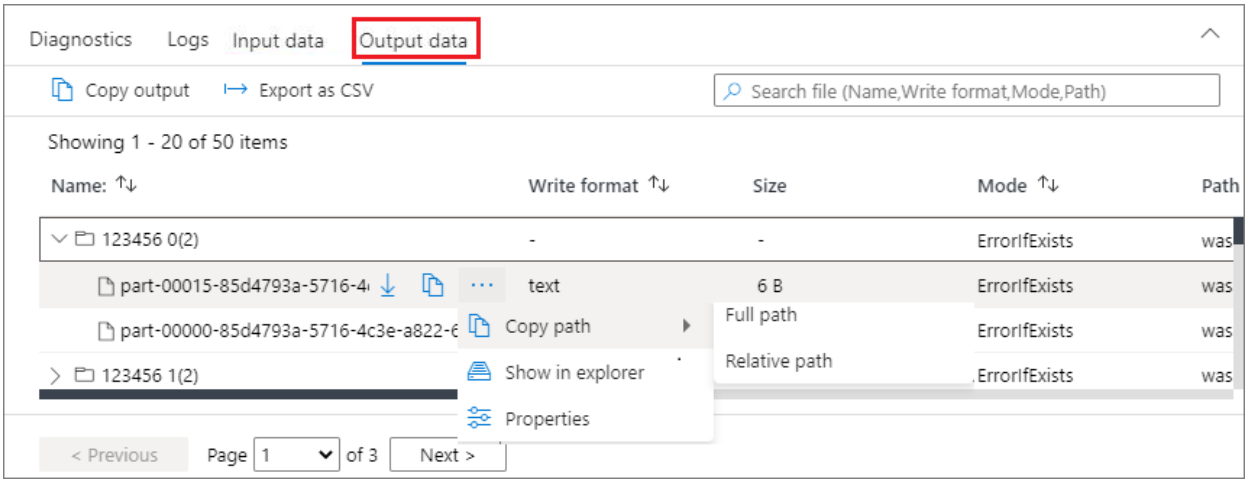
6. Click on **More** button. The **Copy path/Show in explorer/Properties** will appear in the context menu.

- Copy path: can copy **Full path** and **Relative path**.
- Show in explorer: can jump to the linked storage account (Data->Linked).
- Properties: show the basic properties of the file (File name/File path/Read format/Size/Modified).



Output data tab

Displays the same features as the input tab.

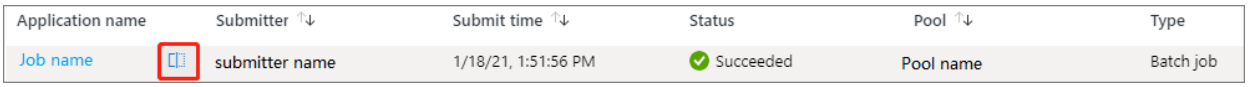


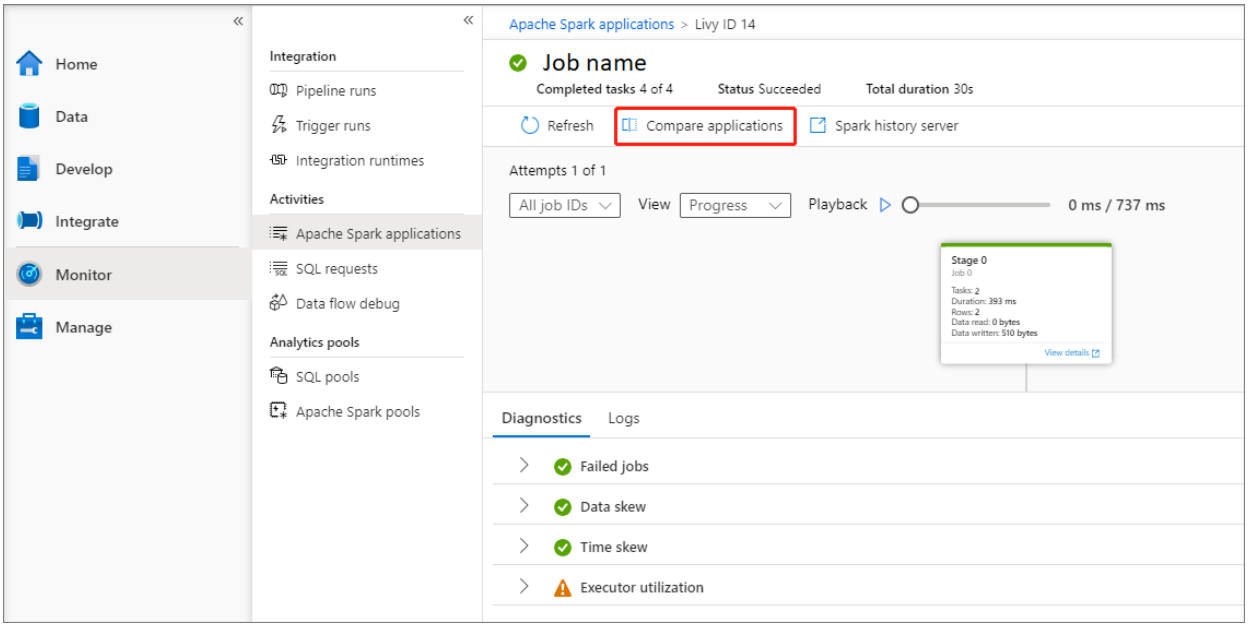
Compare Apache Spark Applications

There are two ways to compare applications. You can compare by choosing **Compare Application**, or click the **Compare in notebook** button to view it in the notebook.

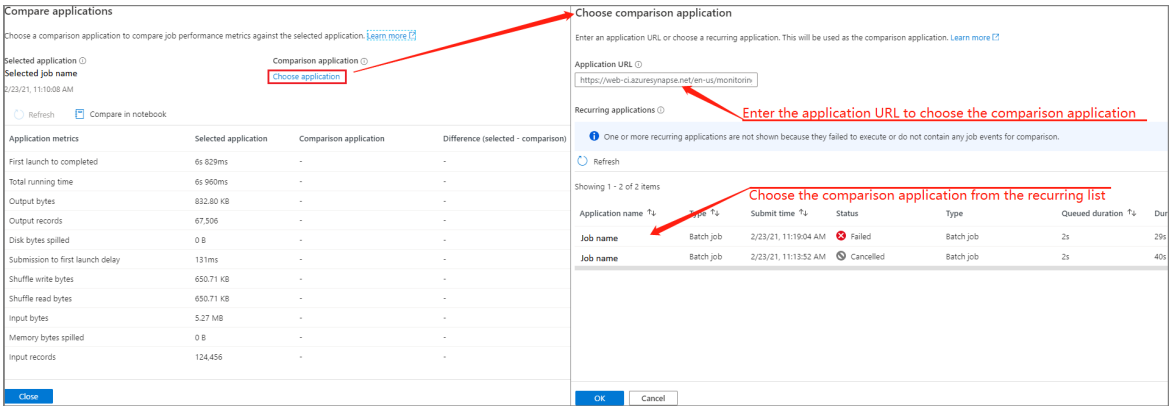
Compare by application

Click on **Compare applications** button and choose an application to compare performance. You can see the difference between the two applications.

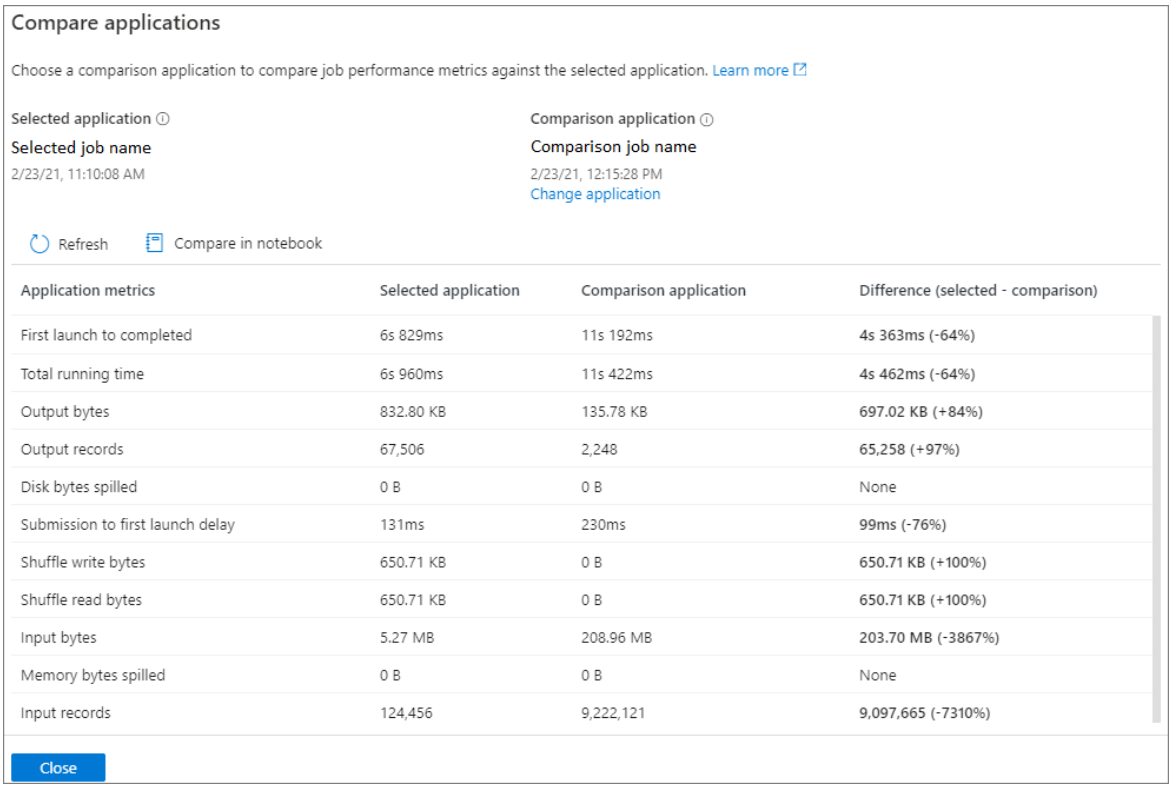




1. Use the mouse to hover over an application, and then the **Compare applications** icon is displayed.
2. Click on the **Compare applications** icon, and the Compare applications page will pop up.
3. Click on **Choose application** button to open **Choose comparison application** page.
4. When choosing the comparison application, you need to either enter the application URL, or choose from the recurring list. Then, click **OK** button.

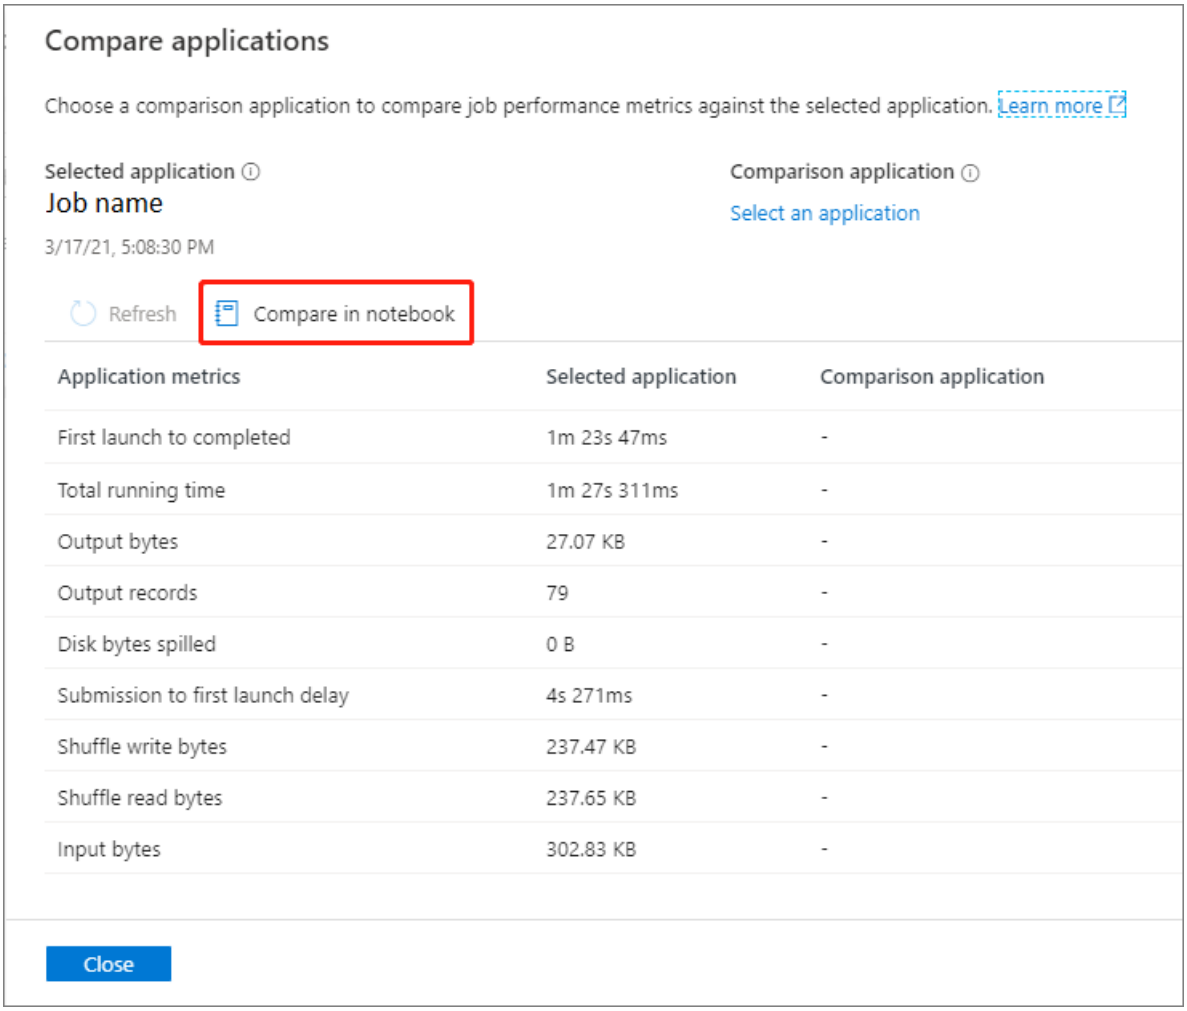


5. The comparison result will be displayed on the compare applications page.

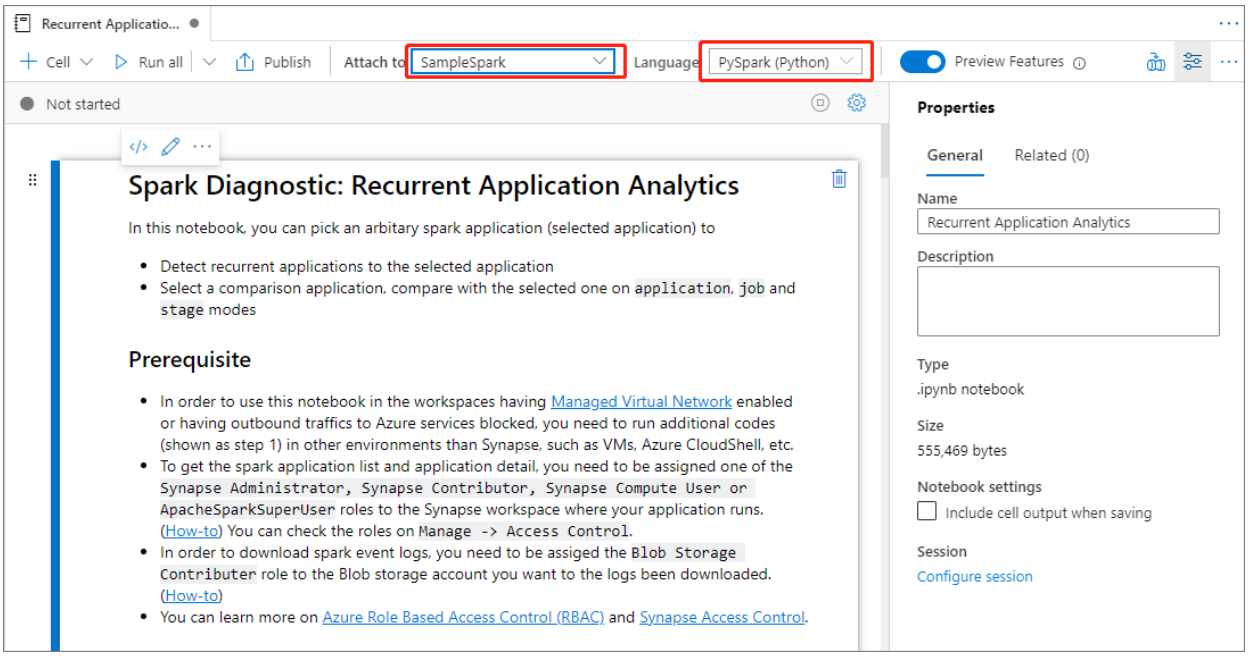


Compare in notebook

Click the **Compare in Notebook** button on the **Compare applications** page to open the notebook. The default name of the *.ipynb* file is **Recurrent Application Analytics**.



In the Notebook: Recurrent Application Analytics file, you can run it directly after setting the Spark pool and Language.



Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs using Synapse Studio article.

Use Synapse Studio to monitor your Apache Spark pools

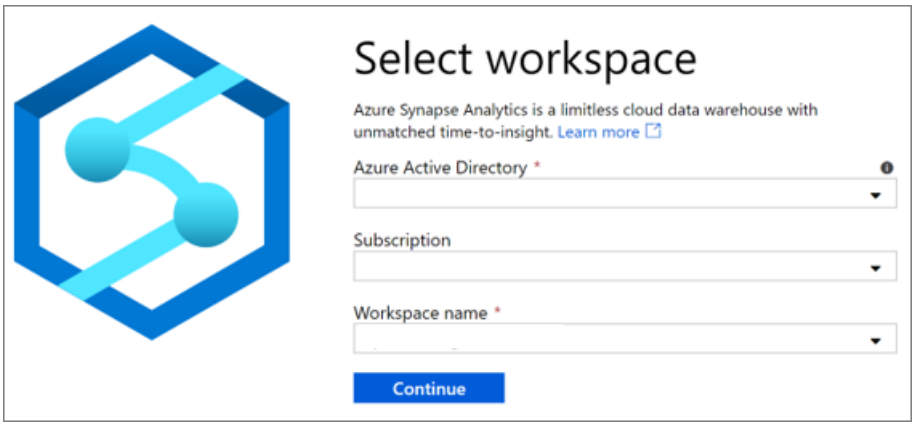
8/19/2022 • 2 minutes to read • Edit Online

With Azure Synapse Analytics, you can use Apache Spark to run notebooks, jobs, and other kinds of applications on Apache Spark pools in your workspace.

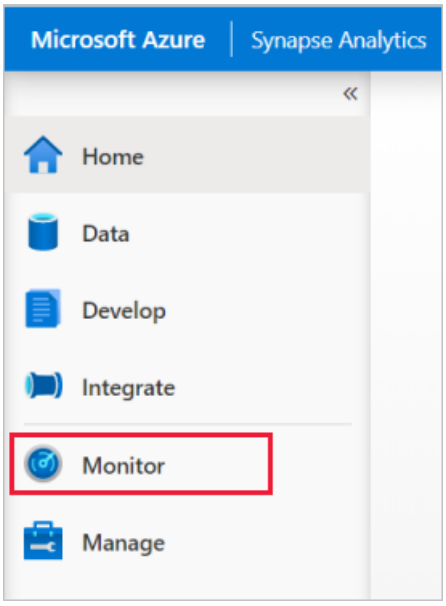
This article explains how to monitor your Apache Spark pools, allowing you to keep an eye on the status of your pools, including how many vCores are in use by different workspace users.

Access Apache Spark pools list

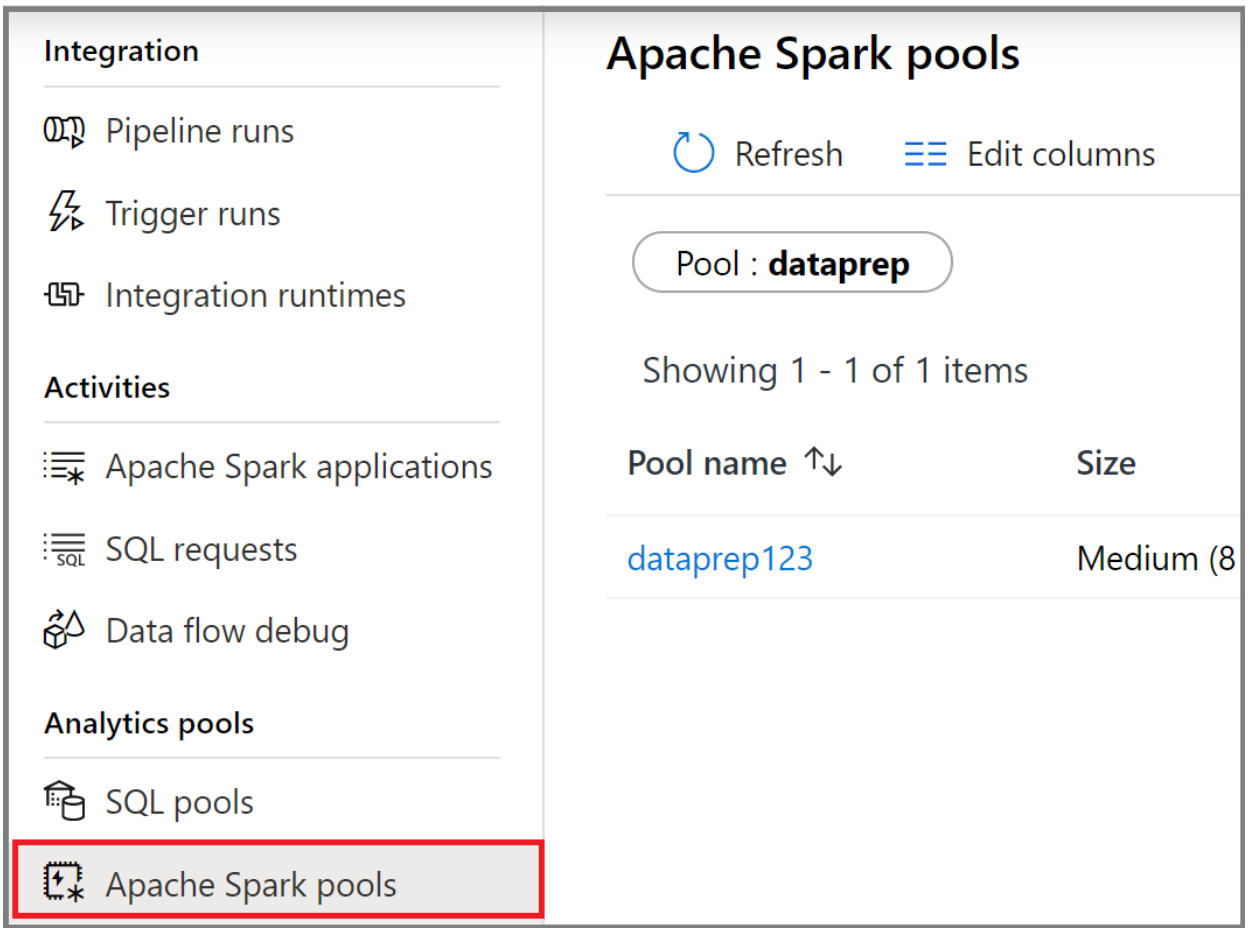
To see the list of Apache Spark pools in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.



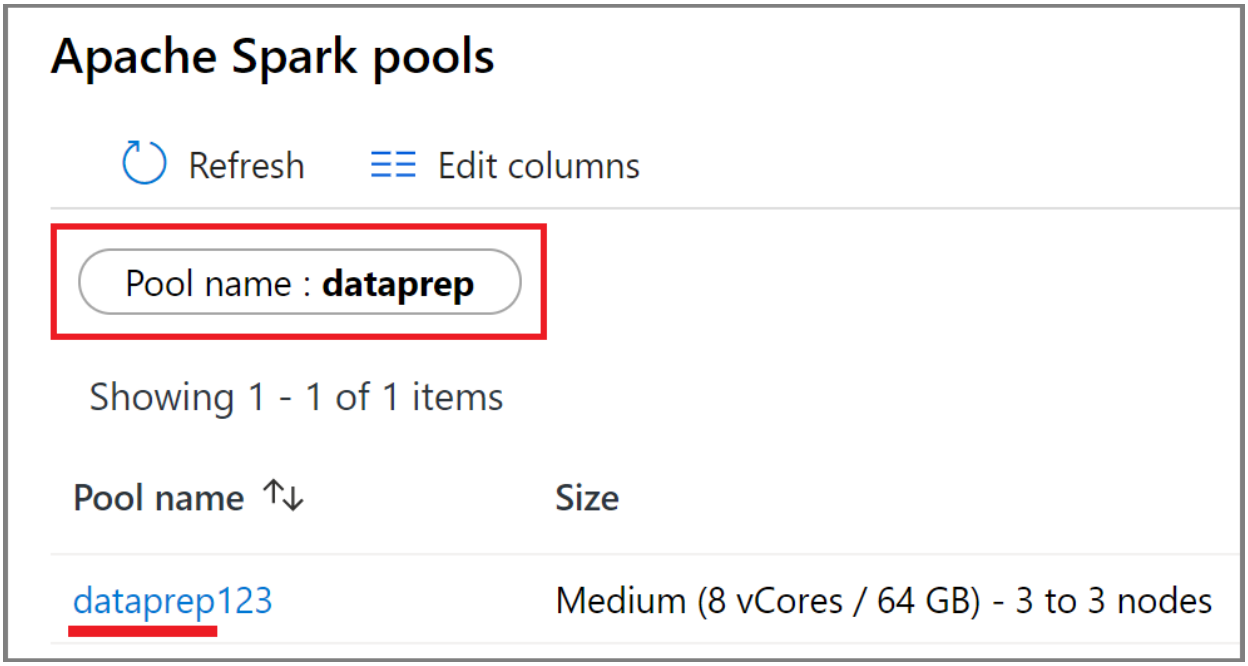
Select **Apache Spark pools** to view the list of Apache Spark pools.



Filter your Apache Spark pools

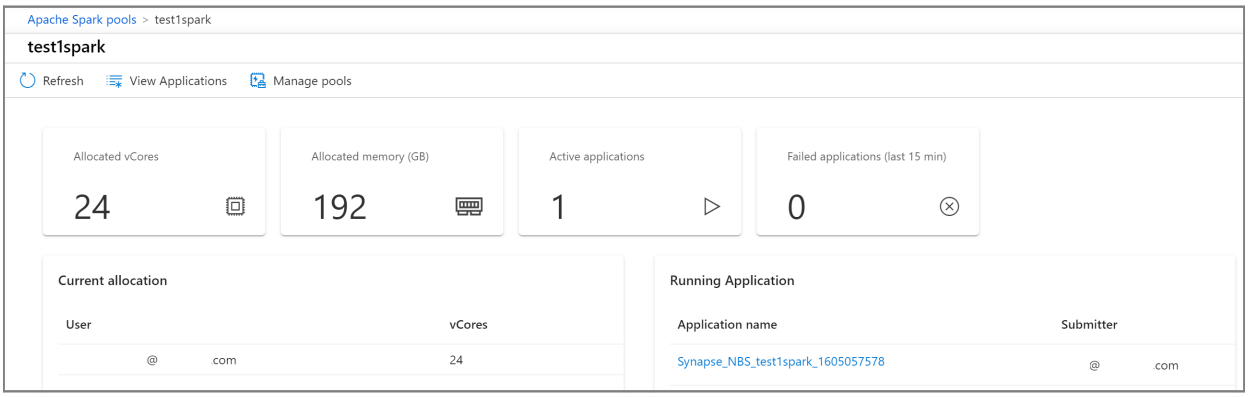
You can filter the list of Apache Spark pools to the ones that interest you. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the Apache Spark pools containing the name "dataprep":



View details about a specific Apache Spark pool

To view the details about one of your Apache Spark pools, select the Apache Spark pool to view the details.



Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs in Synapse Studio article.

For more information on monitoring Apache Spark applications, see the Monitor Apache Spark applications in Synapse Studio article.

Collect Apache Spark applications metrics using APIs

8/19/2022 • 4 minutes to read • Edit Online

Overview

In this tutorial, you will learn how to integrate your existing on-premises Prometheus server with Azure Synapse workspace for near real-time Apache Spark application metrics using the Synapse Prometheus connector.

This tutorial also introduces the Azure Synapse REST metrics APIs. You can fetch Apache Spark application metrics data through the REST APIs to build your own monitoring and diagnosis toolkit or integrate with your monitoring systems.

Use Azure Synapse Prometheus connector for your on-premises Prometheus servers

Azure Synapse Prometheus connector is an open-source project. The Synapse Prometheus connector uses a file-based service discovery method to allow you to:

- Authenticate to Synapse workspace via an AAD service principal.
- Fetch workspace Apache Spark applications list.
- Pull Apache Spark application metrics through Prometheus file-based configuration.

1. Prerequisite

You need to have a Prometheus server deployed on a Linux VM.

2. Create a service principal

To use the Azure Synapse Prometheus connector in your on-premises Prometheus server, you should follow the steps below to create a service principal.

2.1 Create a service principal:

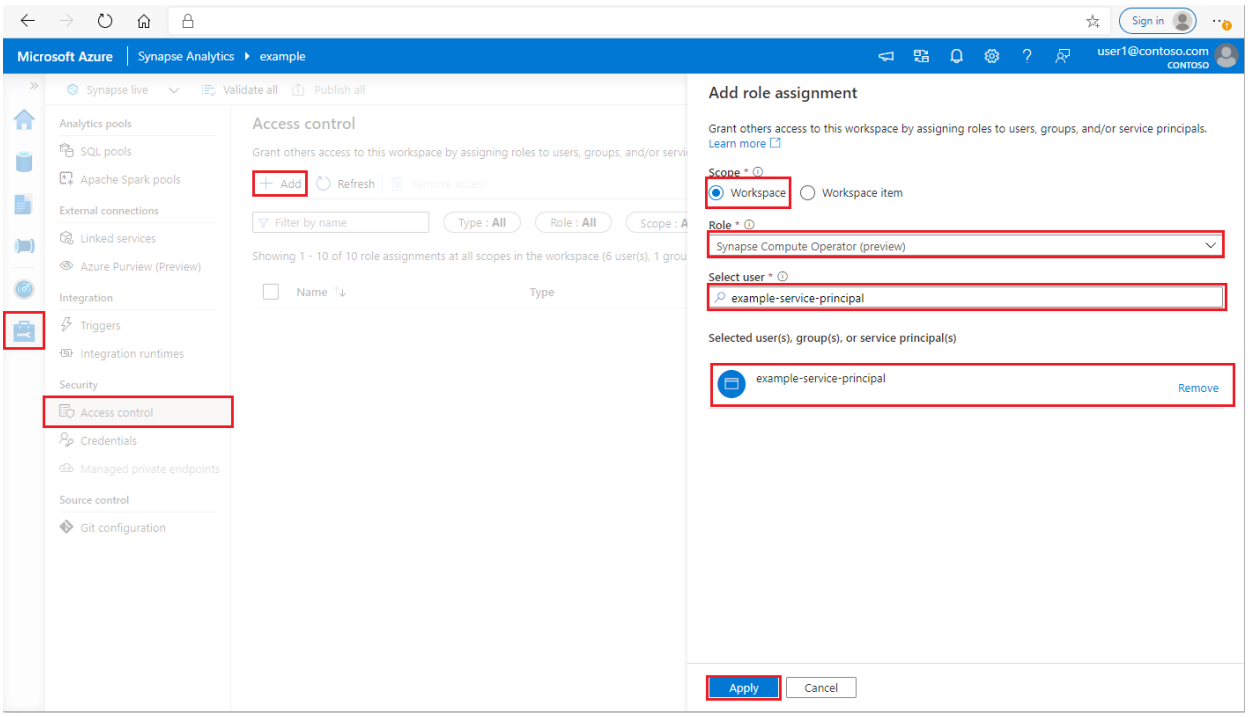
```
az ad sp create-for-rbac --name <service_principal_name> --role Contributor --scopes
/subscriptions/<subscription_id>
```

The result should look like:

```
{
  "appId": "abcdef...",
  "displayName": "<service_principal_name>",
  "name": "http://<service_principal_name>",
  "password": "abc....",
  "tenant": "<tenant_id>"
}
```

Note down the appId, password, and tenant ID.

2.2 Add corresponding permissions to the service principal created in the above step.



1. Log in to your Azure Synapse Analytics workspace as Synapse Administrator
2. In Synapse Studio, on the left-side pane, select **Manage > Access control**
3. Click the Add button on the upper left to **add a role assignment**
4. For Scope, choose **Workspace**
5. For Role, choose **Synapse Compute Operator**
6. For Select user, input your **<service_principal_name>** and click your service principal
7. Click **Apply** (Wait 3 minutes for permission to take effect.)

3. Download the Azure Synapse Prometheus Connector

Use the commands to install the Azure Synapse Prometheus Connector.

```
git clone https://github.com/microsoft/azure-synapse-spark-metrics.git
cd ./azure-synapse-spark-metrics/synapse-prometheus-connector/src
python pip install -r requirements.txt
```

4. Create a config file for Azure Synapse workspaces

Create a config.yaml file in config folder, and fill in the following fields: workspace_name, tenant_id, service_principal_name and service_principal_password. You can add multiple workspaces in the yaml config.

```
workspaces:
  - workspace_name: <your_workspace_name>
    tenant_id: <tenant_id>
    service_principal_name: <service_principal_app_id>
    service_principal_password: "<service_principal_password>"
```

5. Update the Prometheus config

Add following config section in your Prometheus scrape_config, and replace the <your_workspace_name> to your workspace name and the <path_to_synapse_connector> to your cloned synapse-prometheus-connector folder

```
- job_name: synapse-prometheus-connector
  static_configs:
  - labels:
      __metrics_path__: /metrics
      __scheme__: http
    targets:
    - localhost:8000
- job_name: synapse-workspace-<your_workspace_name>
  bearer_token_file: <path_to_synapse_connector>/output/workspace/<your_workspace_name>/bearer_token
  file_sd_configs:
  - files:
    - <path_to_synapse_connector>/output/workspace/<your_workspace_name>/application_discovery.json
    refresh_interval: 10s
  metric_relabel_configs:
  - source_labels: [ __name__ ]
    target_label: __name__
    regex: metrics_application_[0-9]+_[0-9]+_(.+)
    replacement: spark_$1
  - source_labels: [ __name__ ]
    target_label: __name__
    regex: metrics_(.+)
    replacement: spark_$1
```

6. Start the connector in the Prometheus server VM

Start a connector server in the Prometheus server VM as follows.

```
python main.py
```

Wait for a few seconds and the connector should start working. And you can see the "synapse-prometheus-connector" in the Prometheus service discovery page.

Use Azure Synapse Prometheus or REST metrics APIs to collect metrics data

1. Authentication

You can use the client credentials flow to get an access token. To access the metrics API, you should get an Azure AD access token for the service principal, which has proper permission to access the APIs.

PARAMETER	REQUIRED	DESCRIPTION
tenant_id	True	Your Azure service principal (application) tenant ID
grant_type	True	Specifies the requested grant type. In a Client Credentials Grant flow, the value must be client_credentials.
client_id	True	The application (service principal) ID of the application you registered in Azure portal or Azure CLI.
client_secret	True	The secret generated for the application (service principal)
resource	True	Synapse resource uri, should be 'https://dev.azuresynapse.net'

```
curl -X GET -H 'Content-Type: application/x-www-form-urlencoded' \
  -d 'grant_type=client_credentials&client_id=<service_principal_app_id>&resource=
<azure_synapse_resource_id>&client_secret=<service_principal_secret>' \
  https://login.microsoftonline.com/<tenant_id>/oauth2/token
```

Response looks like:

```
{
  "token_type": "Bearer",
  "expires_in": "599",
  "ext_expires_in": "599",
  "expires_on": "1575500666",
  "not_before": "1575499766",
  "resource": "2ff8...f879c1d",
  "access_token": "ABC0eXAiOiJKV1Q......un_f1mSgCHlA"
}
```

2. List running applications in the Azure Synapse workspace

To get list of Apache Spark applications for a Synapse workspace, you can follow this document Monitoring - Get Apache Spark Job List.

3. Collect Apache Spark application metrics with the Prometheus or REST APIs

Collect Apache Spark application metrics with the Prometheus API

Get latest metrics of the specified Apache Spark application by Prometheus API

```
GET
https://{endpoint}/livyApi/versions/{livyApiVersion}/sparkpools/{sparkPoolName}/sessions/{sessionId}/applica
tions/{sparkApplicationId}/metrics/executors/prometheus?format=html
```

PARAMETER	REQUIRED	DESCRIPTION
endpoint	True	The workspace development endpoint, for example `https://myworkspace.dev.azuresynapse.net.`
livyApiVersion	True	Valid api-version for the request. Currently, it is 2019-11-01-preview
sparkPoolName	True	Name of the spark pool.
sessionId	True	Identifier for the session.
sparkApplicationId	True	Spark Application ID

Sample Request:

```
GET https://myworkspace.dev.azuresynapse.net/livyApi/versions/2019-11-01-
preview/sparkpools/mysparkpool/sessions/1/applications/application_1605509647837_0001/metrics/executors/prom
etheus?format=html
```

Sample Response:

Status code: 200 Response looks like:

```
metrics_executor_rddBlocks{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 0
metrics_executor_memoryUsed_bytes{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 74992
metrics_executor_diskUsed_bytes{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 0
metrics_executor_totalCores{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 0
metrics_executor_maxTasks{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 0
metrics_executor_activeTasks{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 1
metrics_executor_failedTasks_total{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 0
metrics_executor_completedTasks_total{application_id="application_1605509647837_0001",
application_name="mynotebook_mysparkpool_1605509570802", executor_id="driver"} 2
...
```

Collect Apache Spark application metrics with the REST API

```
GET
https://{endpoint}/livyApi/versions/{livyApiVersion}/sparkpools/{sparkPoolName}/sessions/{sessionId}/applica
tions/{sparkApplicationId}/executors
```

PARAMETER	REQUIRED	DESCRIPTION
endpoint	True	The workspace development endpoint, for example `https://myworkspace.dev.azuresynapse.net.`
livyApiVersion	True	Valid api-version for the request. Currently, it is 2019-11-01-preview
sparkPoolName	True	Name of the spark pool.
sessionId	True	Identifier for the session.
sparkApplicationId	True	Spark Application ID

Sample Request

```
GET https://myworkspace.dev.azuresynapse.net/livyApi/versions/2019-11-01-
preview/sparkpools/mysparkpool/sessions/1/applications/application_1605509647837_0001/executors
```

Sample Response Status code: 200

```

    },
    // ...
]
```

4. Build your own diagnosis and monitoring tools

The Prometheus API and the REST APIs provide rich metrics data about the Apache Spark application running information.You can collect the application-related metrics data through the Prometheus API and the REST APIs. And build your own diagnosis and monitoring tools that are more suitable for your needs.

Monitor Apache Spark Applications metrics with Prometheus and Grafana

8/19/2022 • 4 minutes to read • Edit Online

Overview

In this tutorial, you will learn how to deploy the Apache Spark application metrics solution to an Azure Kubernetes Service (AKS) cluster and learn how to integrate the Grafana dashboards.

You can use this solution to collect and query the Apache Spark metrics data near real time. The integrated Grafana dashboards allow you to diagnose and monitor your Apache Spark application. The source code and the configurations have been open-sourced on GitHub.

Prerequisites

1. Azure CLI
2. Helm client 3.30+
3. kubectl
4. Azure Kubernetes Service (AKS)

Or use the Azure Cloud Shell, which already includes the Azure CLI, Helm client and kubectl out of the box.

Log in to Azure

```
az login
az account set --subscription "<subscription_id>"
```

Create an Azure Kubernetes service instance (AKS)

Use the Azure CLI command to create a Kubernetes cluster in your subscription.

```
az aks create --name <kubernetes_name> --resource-group <kubernetes_resource_group> --location <location> --
node-vm-size Standard_D2s_v3
az aks get-credentials --name <kubernetes_name> --resource-group <kubernetes_resource_group>
```

Note: This step can be skipped if you already have an AKS cluster.

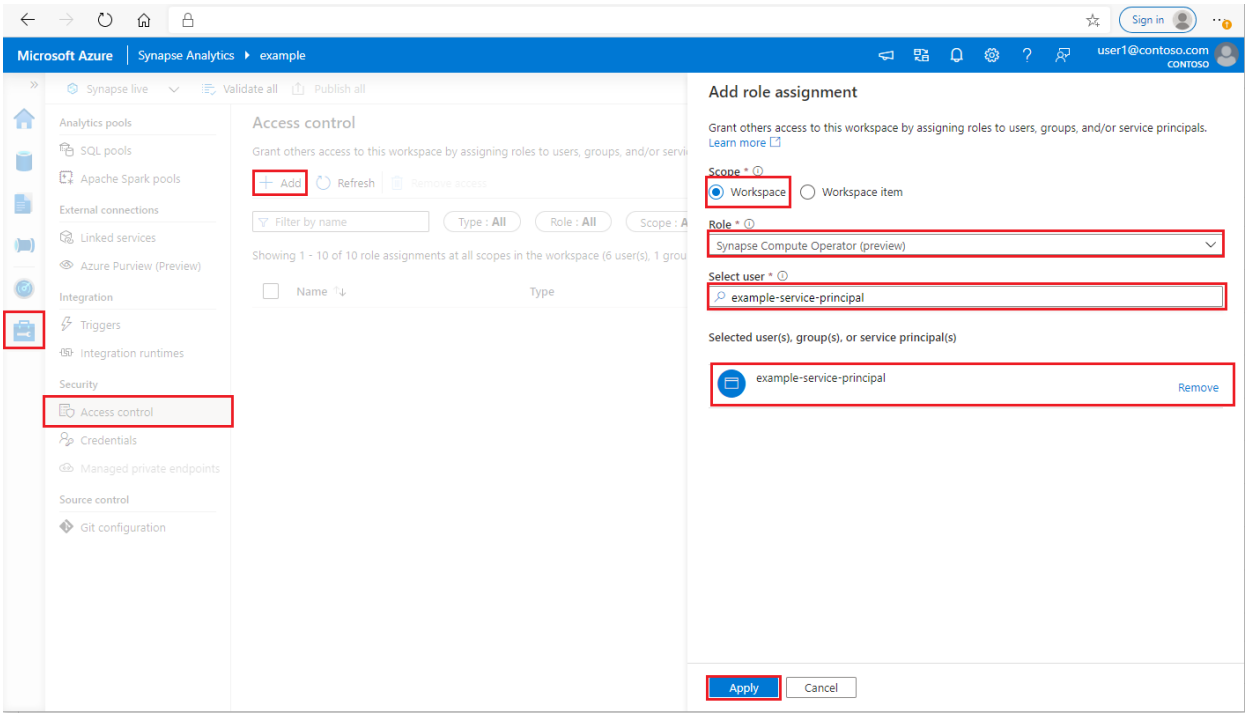
Create a service principal and grant permission to Synapse workspace

```
az ad sp create-for-rbac --name <service_principal_name> --role Contributor --scopes
/subscriptions/<subscription_id>
```

The result should look like:

```
{
  "appId": "abcdef...",
  "displayName": "<service_principal_name>",
  "name": "http://<service_principal_name>",
  "password": "abc....",
  "tenant": "<tenant_id>"
}
```

Note down the appId, password, and tenantID.



1. Log in to your Azure Synapse Analytics workspace as Synapse Administrator
2. In Synapse Studio, on the left-side pane, select **Manage > Access control**
3. Click the Add button on the upper left to **add a role assignment**
4. For Scope, choose **Workspace**
5. For Role, choose **Synapse Compute Operator**
6. For Select user, input your **<service_principal_name>** and click your service principal
7. Click **Apply** (Wait 3 minutes for permission to take effect.)

> **NOTE**
>
> Please make sure your service principal is at least "Reader" role in your Synapse workspace. Go to Access Control (IAM) tab of the Azure portal and check the permission settings.

Install connector, Prometheus server, Grafana dashboard

1. Add synapse-charts repo to Helm client.

```
helm repo add synapse-charts https://github.com/microsoft/azure-synapse-spark-metrics/releases/download/helm-chart
```

2. Install components through Helm client:

```
helm install spo synapse-charts/synapse-prometheus-operator --create-namespace --namespace spo \
    --set synapse.workspaces[0].workspace_name="<workspace_name>" \
    --set synapse.workspaces[0].tenant_id="<tenant_id>" \
    --set synapse.workspaces[0].service_principal_name="<service_principal_app_id>" \
    --set synapse.workspaces[0].service_principal_password="<service_principal_password>" \
    --set synapse.workspaces[0].subscription_id="<subscription_id>" \
    --set synapse.workspaces[0].resource_group="<workspace_resource_group_name>"
```

- workspace_name: Synapse workspace name.
- subscription_id: Synapse workspace subscription ID.
- workspace_resource_group_name: Synapse workspace resource group name.
- tenant_id: Synapse workspace tenant ID.
- service_principal_app_id: The service principal "appId"
- service_principal_password: The service principal password you created.

Log in to Grafana

Get the default password and address of Grafana. You may change the password in the Grafana settings.

```
kubectl get secret --namespace spo spo-grafana -o jsonpath="{.data.admin-password}" | base64 --decode ; echo
kubectl -n spo get svc spo-grafana
```

Get service ip, copy & paste the external ip to browser, and login with username "admin" and the password.

Use Grafana Dashboards

Find Synapse Dashboard on the upper left corner of the Grafana page (Home -> Synapse Workspace / Synapse Application), try to run an example code in Synapse Studio and wait a few seconds for the metrics pulling.

Also, you can use the "Synapse Workspace / Workspace" and "Synapse Workspace / Apache Spark pools" dashboards to get an overview of your workspace and your Apache Spark pools.

Uninstall

Remove the components by Helm command as follows.

```
helm delete <release_name> -n <namespace>
```

Delete the AKS cluster.

```
az aks delete --name <kubernetes_cluster_name> --resource-group <kubernetes_cluster_rg>
```

Components introduction

Azure Synapse Analytics provides a Helm chart based on Prometheus Operator and Synapse Prometheus Connector. The Helm chart includes Prometheus server, Grafana server, and Grafana dashboards for Apache Spark application-level metrics. You can use Prometheus, a popular open-source monitoring system, to collect these metrics in near real-time and use Grafana for visualization.

Synapse Prometheus Connector

Synapse Prometheus Connector helps to connect Azure Synapse Apache Spark pool and your Prometheus server. It implements:

1. Authentication: It is AAD-based authentication and can automatically refresh the AAD token of the service principal for application discovery, metrics ingestion and other functions.
2. Apache Spark application discovery: When you submit applications in the target workspace, Synapse Prometheus Connector can automatically discover these applications.
3. Apache Spark application metadata: It collects basic application information and exports the data to Prometheus.

Synapse Prometheus Connector is released as a docker image hosted on Microsoft Container Registry. It is open-source and is located in Azure Synapse Apache Spark application metrics.

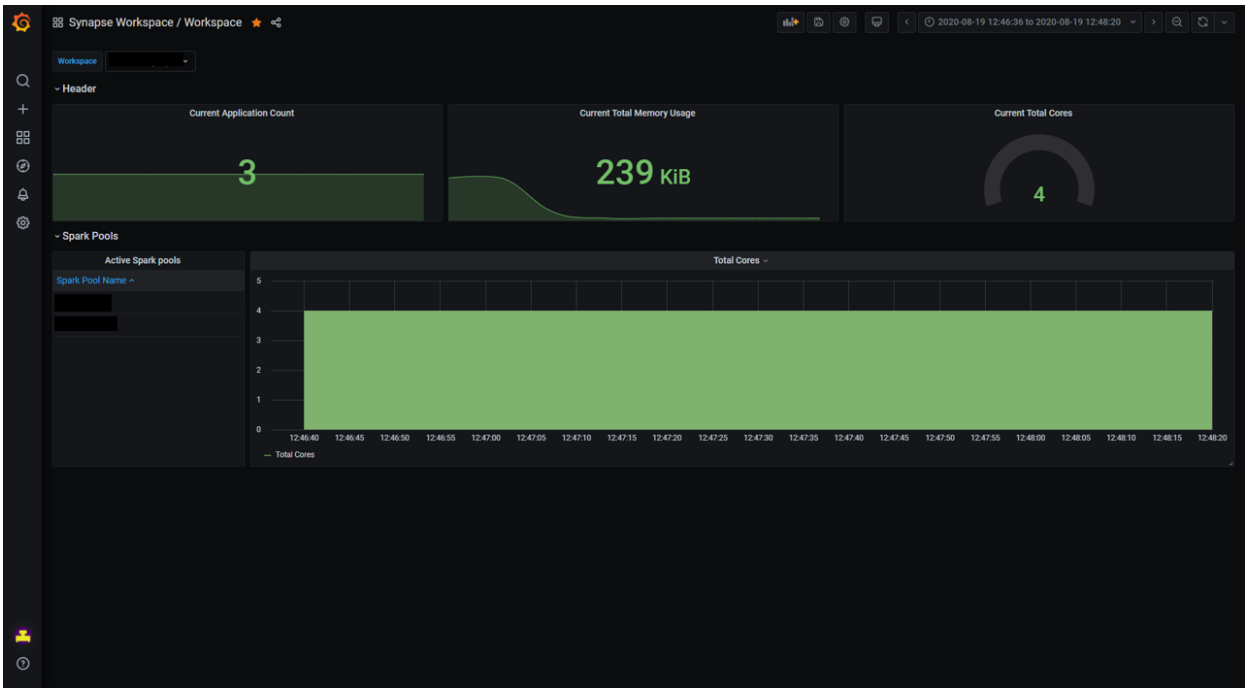
Prometheus server

Prometheus is an open-source monitoring and alerting toolkit. Prometheus graduated from the Cloud Native Computing Foundation (CNCF) and became the de facto standard for cloud-native monitoring. Prometheus can help us collect, query, and store massive amounts of time series data, and it can be easily integrated with Grafana. In this solution, we deploy the Prometheus component based on the helm chart.

Grafana and dashboards

Grafana is open-source visualization and analytics software. It allows you to query, visualize, alert on, and explore your metrics. Azure Synapse Analytics provides a set of default Grafana dashboards to visualize Apache Spark application-level metrics.

The "Synapse Workspace / Workspace" dashboard provides a workspace level view of all the Apache Spark pools, application counts, cpu cores, etc.



The "Synapse Workspace / Apache Spark pools" dashboard contains the metrics of Apache Spark applications running in the selected Apache Spark pool during the time period.

The "Synapse Workspace / Apache Spark Application" dashboard contains the selected Apache Spark application.

The above dashboard templates have been open-sourced in Azure Synapse Apache Spark application metrics.

Monitor Apache Spark applications with Azure Log Analytics

8/19/2022 • 8 minutes to read • Edit Online

In this tutorial, you learn how to enable the Synapse Studio connector that's built in to Log Analytics. You can then collect and send Apache Spark application metrics and logs to your Log Analytics workspace. Finally, you can use an Azure Monitor workbook to visualize the metrics and logs.

Configure workspace information

Follow these steps to configure the necessary information in Synapse Studio.

Step 1: Create a Log Analytics workspace

Consult one of the following resources to create this workspace:

- Create a workspace in the Azure portal.
- Create a workspace with Azure CLI.
- Create and configure a workspace in Azure Monitor by using PowerShell.

Step 2: Prepare an Apache Spark configuration file

Use any of the following options to prepare the file.

Option 1: Configure with Log Analytics workspace ID and key

Copy the following Apache Spark configuration, save it as *spark_loganalytics_conf.txt*, and fill in the following parameters:

- `<LOG_ANALYTICS_WORKSPACE_ID>`: Log Analytics workspace ID.
- `<LOG_ANALYTICS_WORKSPACE_KEY>`: Log Analytics key. To find this, in the Azure portal, go to **Azure Log Analytics workspace** > **Agents management** > **Primary key**.

```
spark.synapse.logAnalytics.enabled true
spark.synapse.logAnalytics.workspaceId <LOG_ANALYTICS_WORKSPACE_ID>
spark.synapse.logAnalytics.secret <LOG_ANALYTICS_WORKSPACE_KEY>
```

Option 2: Configure with Azure Key Vault

> **NOTE**
> You need to grant read secret permission to the users who will submit Apache Spark applications. For more information, see Provide access to Key Vault keys, certificates, and secrets with an Azure role-based access control. When you enable this feature in a Synapse pipeline, you need to use **Option 3**. This is necessary to obtain the secret from Azure Key Vault with workspace managed identity.

To configure Azure Key Vault to store the workspace key, follow these steps:

1. Create and go to your key vault in the Azure portal.
2. On the settings page for the key vault, select **Secrets**.
3. Select **Generate/Import**.
4. On the **Create a secret** screen, choose the following values:
   - **Name**: Enter a name for the secret. For the default, enter `SparkLogAnalyticsSecret`.
   - **Value**: Enter the `<LOG_ANALYTICS_WORKSPACE_KEY>` for the secret.

- Leave the other values to their defaults. Then select **Create**.

5. Copy the following Apache Spark configuration, save it as *spark_loganalytics_conf.txt*, and fill in the following parameters:

   - `<LOG_ANALYTICS_WORKSPACE_ID>`: The Log Analytics workspace ID.
   - `<AZURE_KEY_VAULT_NAME>`: The key vault name that you configured.
   - `<AZURE_KEY_VAULT_SECRET_KEY_NAME>` (optional): The secret name in the key vault for the workspace key. The default is `SparkLogAnalyticsSecret`.

```
spark.synapse.logAnalytics.enabled true
spark.synapse.logAnalytics.workspaceId <LOG_ANALYTICS_WORKSPACE_ID>
spark.synapse.logAnalytics.keyVault.name <AZURE_KEY_VAULT_NAME>
spark.synapse.logAnalytics.keyVault.key.secret <AZURE_KEY_VAULT_SECRET_KEY_NAME>
```

> **NOTE**
>
> You can also store the workspace ID in Key Vault. Refer to the preceding steps, and store the workspace ID with the secret name `SparkLogAnalyticsWorkspaceId`. Alternatively, you can use the configuration `spark.synapse.logAnalytics.keyVault.key.workspaceId` to specify the workspace ID secret name in Key Vault.

Option 3. Configure with a linked service

> **NOTE**
>
> In this option, you need to grant read secret permission to workspace managed identity. For more information, see Provide access to Key Vault keys, certificates, and secrets with an Azure role-based access control.

To configure a Key Vault linked service in Synapse Studio to store the workspace key, follow these steps:

1. Follow all the steps in the preceding section, "Option 2."
2. Create a Key Vault linked service in Synapse Studio:

   a. Go to **Synapse Studio** > **Manage** > **Linked services**, and then select **New**.

   b. In the search box, search for **Azure Key Vault**.

   c. Enter a name for the linked service.

   d. Choose your key vault, and select **Create**.

3. Add a `spark.synapse.logAnalytics.keyVault.linkedServiceName` item to the Apache Spark configuration.

```
spark.synapse.logAnalytics.enabled true
spark.synapse.logAnalytics.workspaceId <LOG_ANALYTICS_WORKSPACE_ID>
spark.synapse.logAnalytics.keyVault.name <AZURE_KEY_VAULT_NAME>
spark.synapse.logAnalytics.keyVault.key.secret <AZURE_KEY_VAULT_SECRET_KEY_NAME>
spark.synapse.logAnalytics.keyVault.linkedServiceName <LINKED_SERVICE_NAME>
```

Available Apache Spark configuration

CONFIGURATION NAME	DEFAULT VALUE	DESCRIPTION
spark.synapse.logAnalytics.enabled	false	To enable the Log Analytics sink for the Spark applications, true. Otherwise, false.
spark.synapse.logAnalytics.workspaceId	-	The destination Log Analytics workspace ID.

CONFIGURATION NAME	DEFAULT VALUE	DESCRIPTION
spark.synapse.logAnalytics.secret	-	The destination Log Analytics workspace secret.
spark.synapse.logAnalytics.keyVault.linkedServiceName	-	The Key Vault linked service name for the Log Analytics workspace ID and key.
spark.synapse.logAnalytics.keyVault.name	-	The Key Vault name for the Log Analytics ID and key.
spark.synapse.logAnalytics.keyVault.key.workspaceId	SparkLogAnalyticsWorkspaceId	The Key Vault secret name for the Log Analytics workspace ID.
spark.synapse.logAnalytics.keyVault.key.secret	SparkLogAnalyticsSecret	The Key Vault secret name for the Log Analytics workspace
spark.synapse.logAnalytics.uriSuffix	ods.opinsights.azure.com	The destination Log Analytics workspace URI suffix. If your workspace isn't in Azure global, you need to update the URI suffix according to the respective cloud.
spark.synapse.logAnalytics.filter.eventName.match	-	Optional. The comma-separated spark event names, you can specify which events to collect. For example: `SparkListenerJobStart,SparkListenerJobEnd`
spark.synapse.logAnalytics.filter.loggerName.match	-	Optional. The comma-separated log4j logger names, you can specify which logs to collect. For example: `org.apache.spark.SparkContext,org.example.Logg`
spark.synapse.logAnalytics.filter.metricName.match	-	Optional. The comma-separated spark metric name suffixes, you can specify which metrics to collect. For example: `jvm.heap.used`

NOTE

- For Azure China, the `spark.synapse.logAnalytics.uriSuffix` parameter should be `ods.opinsights.azure.cn`.
- For Azure Government, the `spark.synapse.logAnalytics.uriSuffix` parameter should be `ods.opinsights.azure.us`.

Step 3: Upload your Apache Spark configuration to an Apache Spark pool

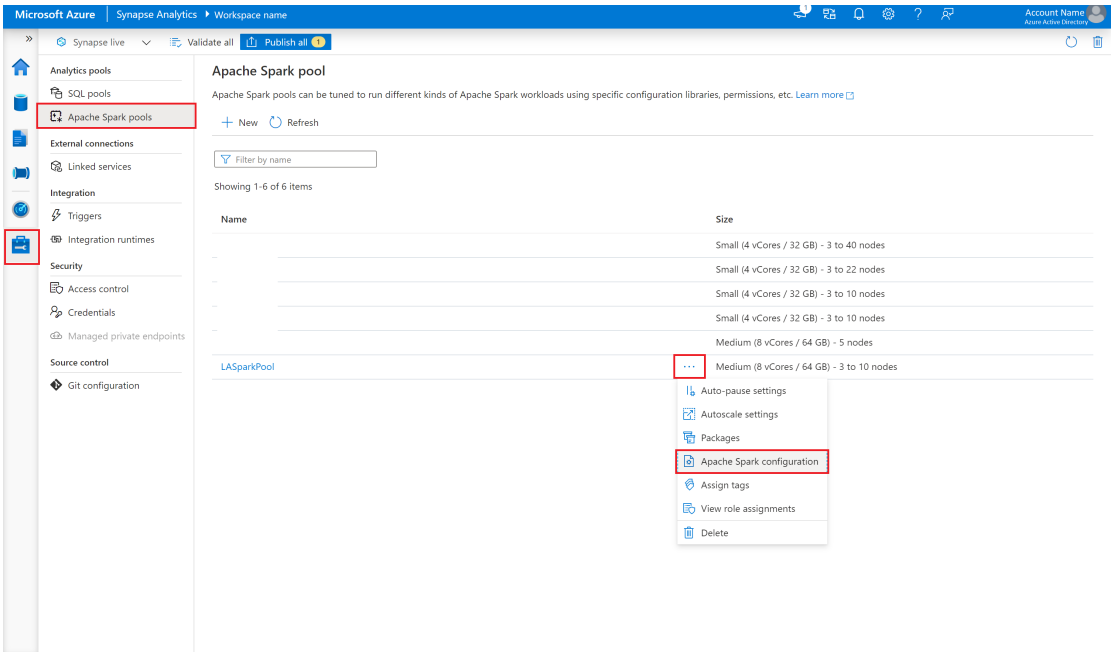
NOTE

This step will be replaced by step 4.

You can upload the configuration file to your Azure Synapse Analytics Apache Spark pool. In Synapse Studio:

1. Select **Manage** > **Apache Spark pools**.
2. Next to your Apache Spark pool, select the **...** button.
3. Select **Apache Spark configuration**.
4. Select **Upload**, and choose the *spark_loganalytics_conf.txt* file.

5. Select **Upload**, and then select **Apply**.

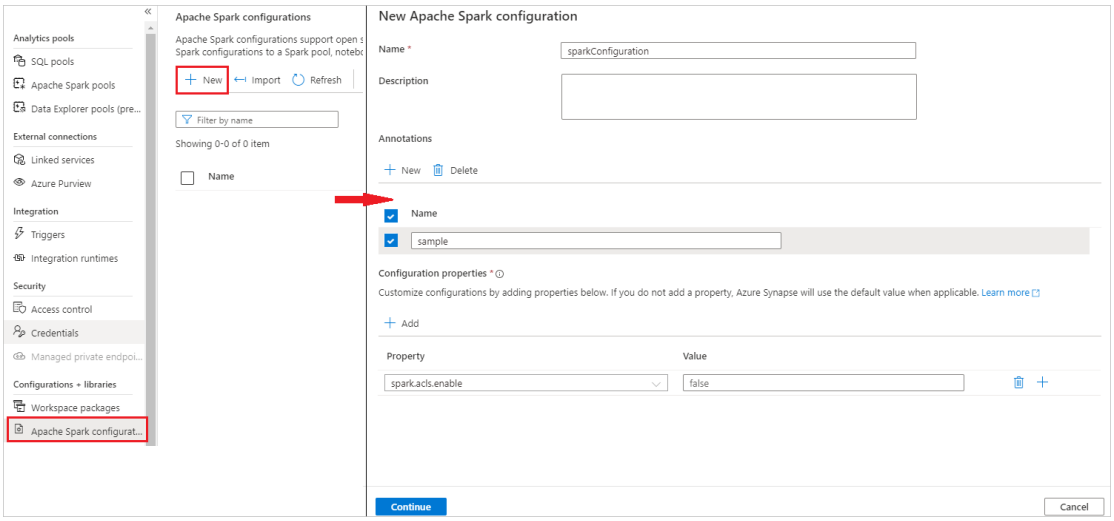


> **NOTE**
>
> All the Apache Spark applications submitted to the Apache Spark pool will use the configuration setting to push the Apache Spark application metrics and logs to your specified workspace.

Step 4: Create an Apache Spark Configuration

You can create an Apache Spark Configuration to your workspace, and when you create Notebook or Apache spark job definition can select the Apache Spark configuration that you want to use with your Apache Spark pool. When you select it, the details of the configuration are displayed.

1. Select **Manage** > **Apache Spark configurations**.
2. Click on **New** button to create a new Apache Spark configuration, or click on **Import** a local .json file to your workspace.
3. **New Apache Spark configuration** page will be opened after you click on **New** button.
4. For **Name**, you can enter your preferred and valid name.
5. For **Description**, you can input some description in it.
6. For **Annotations**, you can add annotations by clicking the **New** button, and also you can delete existing annotations by selecting and clicking **Delete** button.
7. For **Configuration properties**, customize the configuration by clicking **Add** button to add properties. If you do not add a property, Azure Synapse will use the default value when applicable.



Submit an Apache Spark application and view the logs and metrics

Here's how:

1. Submit an Apache Spark application to the Apache Spark pool configured in the previous step. You can use any of the following ways to do so:
   - Run a notebook in Synapse Studio.
   - In Synapse Studio, submit an Apache Spark batch job through an Apache Spark job definition.
   - Run a pipeline that contains Apache Spark activity.
2. Go to the specified Log Analytics workspace, and then view the application metrics and logs when the Apache Spark application starts to run.

Write custom application logs

You can use the Apache Log4j library to write custom logs.

Example for Scala:

```
%%spark
val logger = org.apache.log4j.LogManager.getLogger("com.contoso.LoggerExample")
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

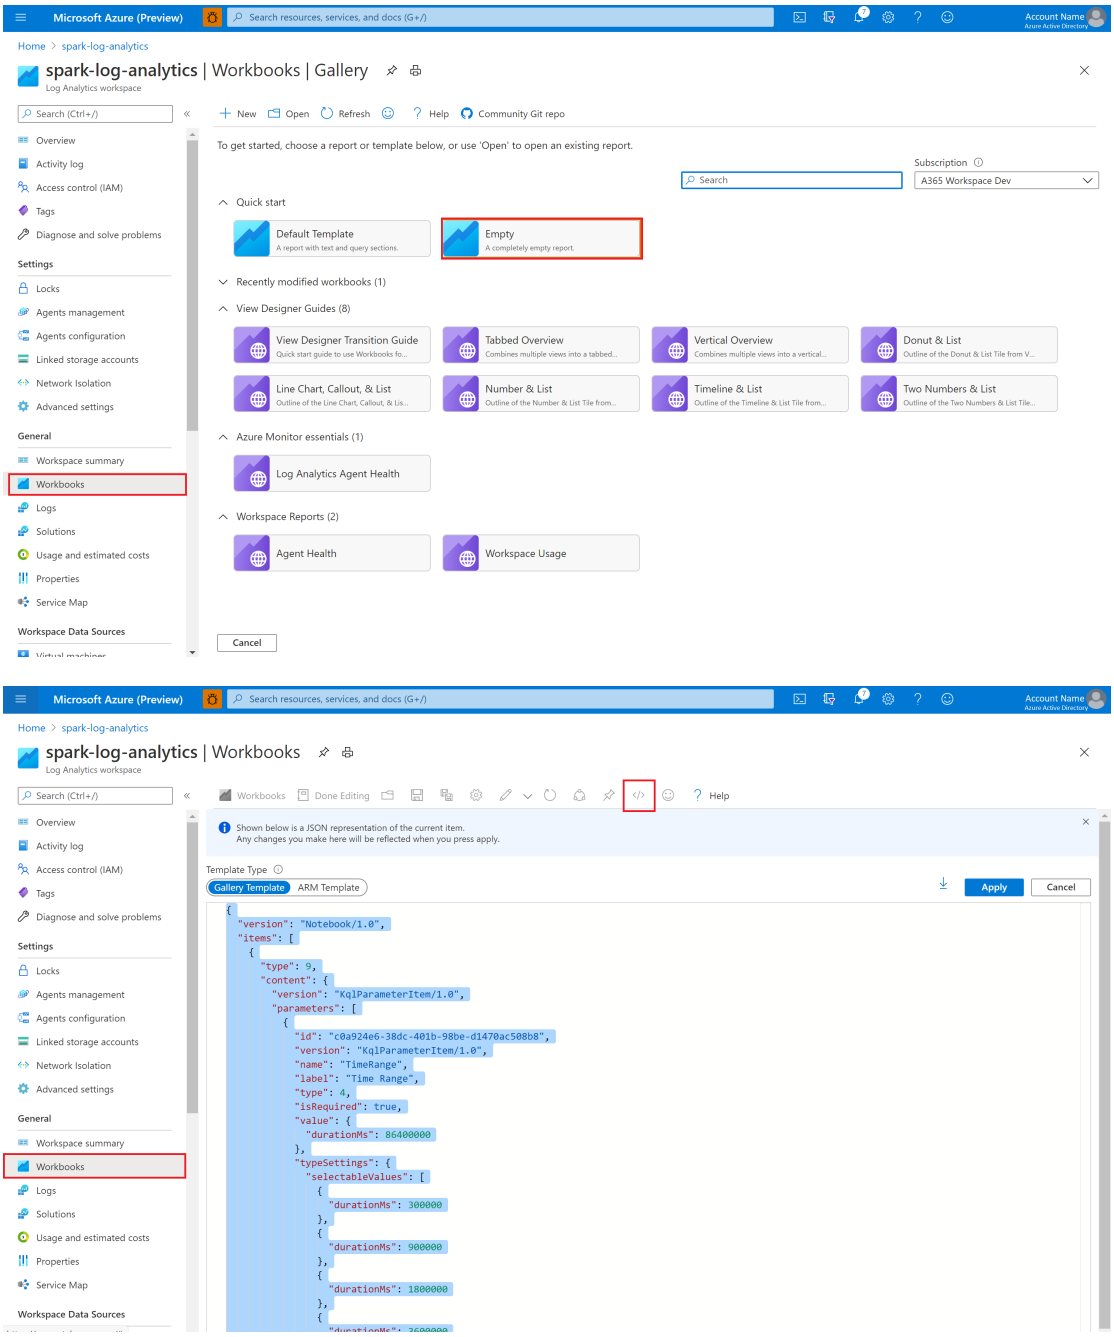
Example for PySpark:

```
%%pyspark
logger = sc._jvm.org.apache.log4j.LogManager.getLogger("com.contoso.PythonLoggerExample")
logger.info("info message")
logger.warn("warn message")
logger.error("error message")
```

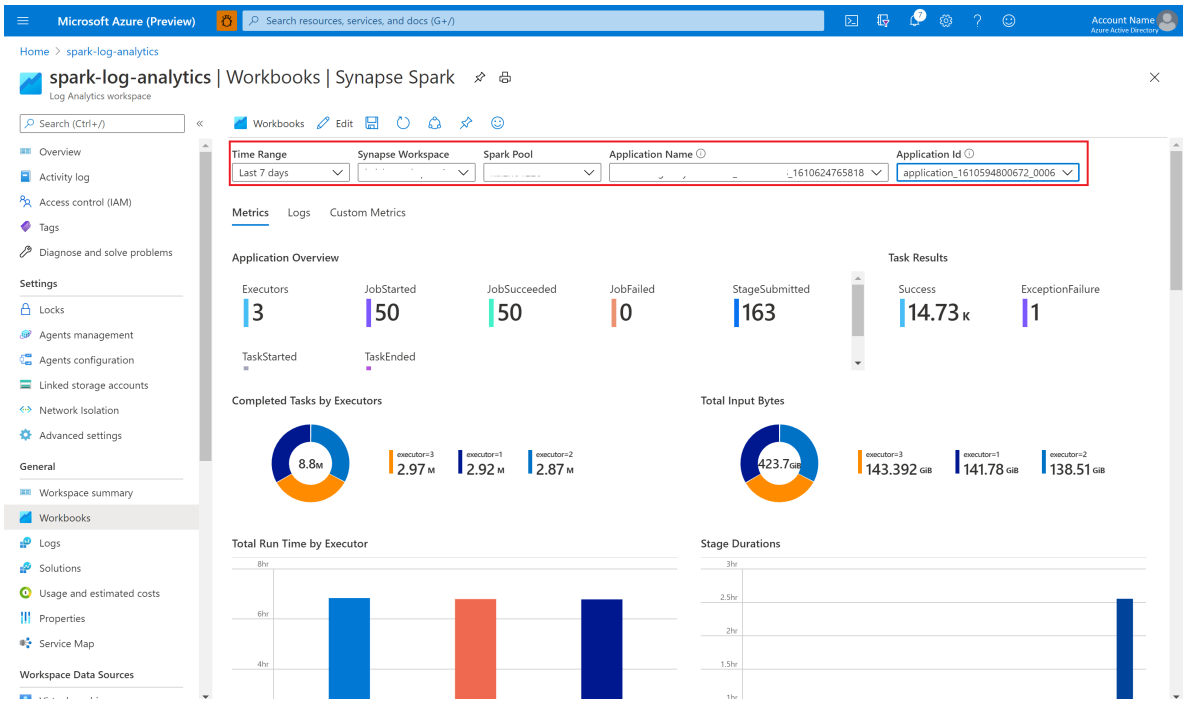
Use the sample workbook to visualize the metrics and logs

1. Download the workbook.
2. Open and copy the workbook file content.
3. In the Azure portal, select **Log Analytics workspace** > **Workbooks**.
4. Open the **Empty** workbook. Use the **Advanced Editor** mode by selecting the **</>** icon.
5. Paste over any JSON code that exists.

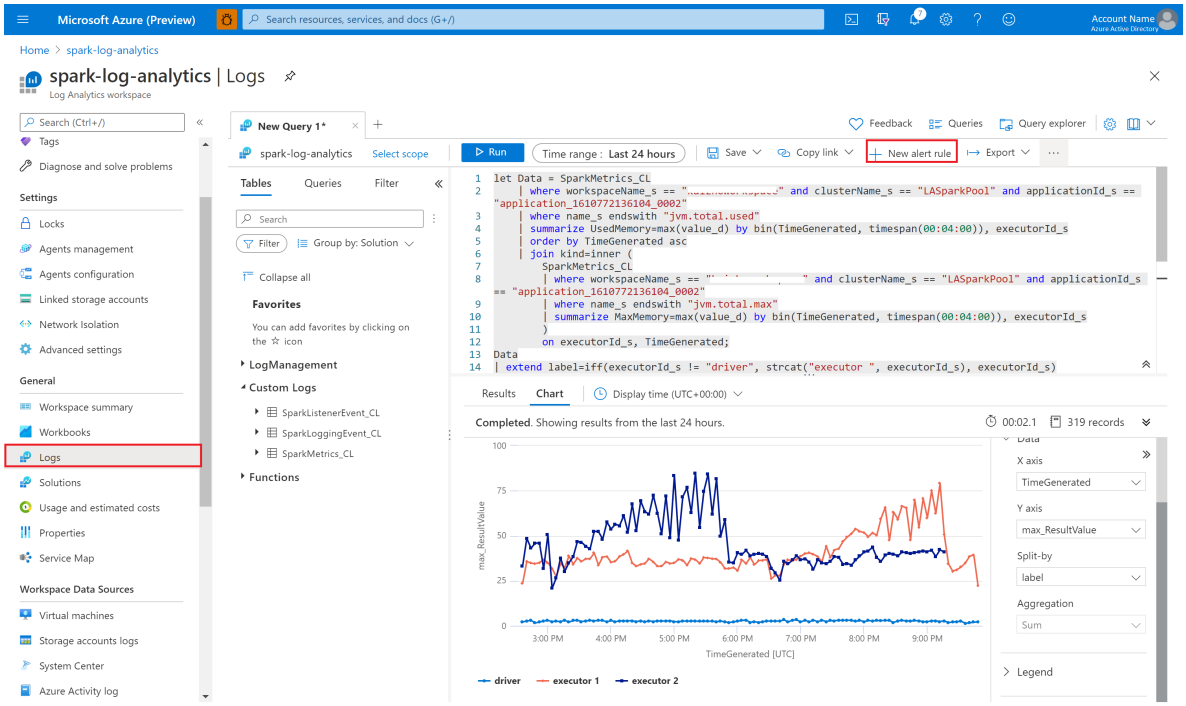
6. Select **Apply**, and then select **Done Editing**.



Then, submit your Apache Spark application to the configured Apache Spark pool. After the application goes to a running state, choose the running application in the workbook dropdown list.



You can customize the workbook. For example, you can use Kusto queries and configure alerts.



Query data with Kusto

The following is an example of querying Apache Spark events:

```
SparkListenerEvent_CL
| where workspaceName_s == "{SynapseWorkspace}" and clusterName_s == "{SparkPool}" and livyId_s == "
{LivyId}"
| order by TimeGenerated desc
| limit 100
```

Here's an example of querying the Apache Spark application driver and executors logs:

```
SparkLoggingEvent_CL
| where workspaceName_s == "{SynapseWorkspace}" and clusterName_s == "{SparkPool}" and livyId_s == "
{LivyId}"
| order by TimeGenerated desc
| limit 100
```

And here's an example of querying Apache Spark metrics:

```
SparkMetrics_CL
| where workspaceName_s == "{SynapseWorkspace}" and clusterName_s == "{SparkPool}" and livyId_s == "
{LivyId}"
| where name_s endswith "jvm.total.used"
| summarize max(value_d) by bin(TimeGenerated, 30s), executorId_s
| order by TimeGenerated asc
```

Create and manage alerts

Users can query to evaluate metrics and logs at a set frequency, and fire an alert based on the results. For more information, see Create, view, and manage log alerts by using Azure Monitor.

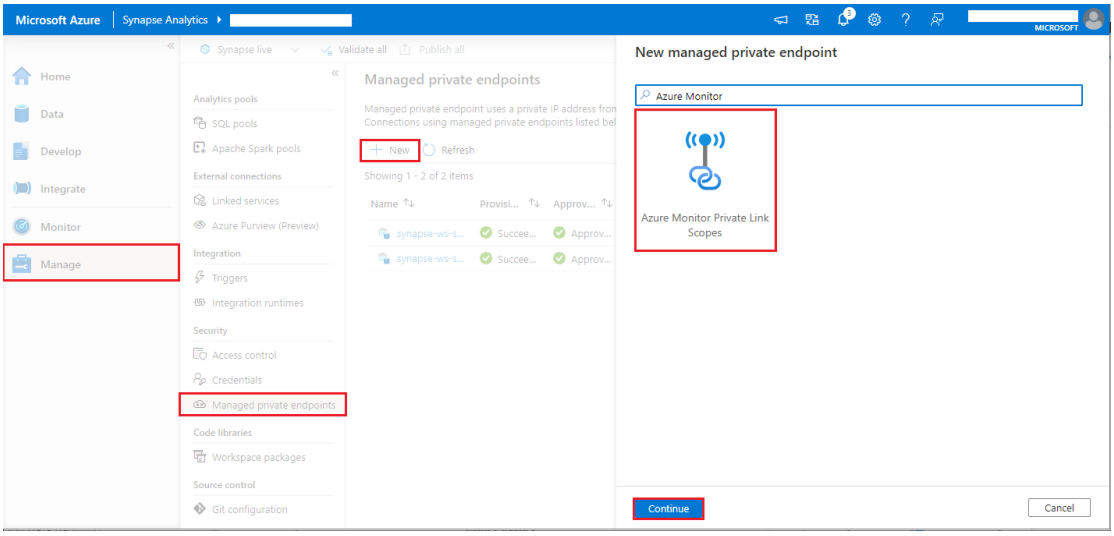
Synapse workspace with data exfiltration protection enabled

After the Synapse workspace is created with data exfiltration protection enabled.

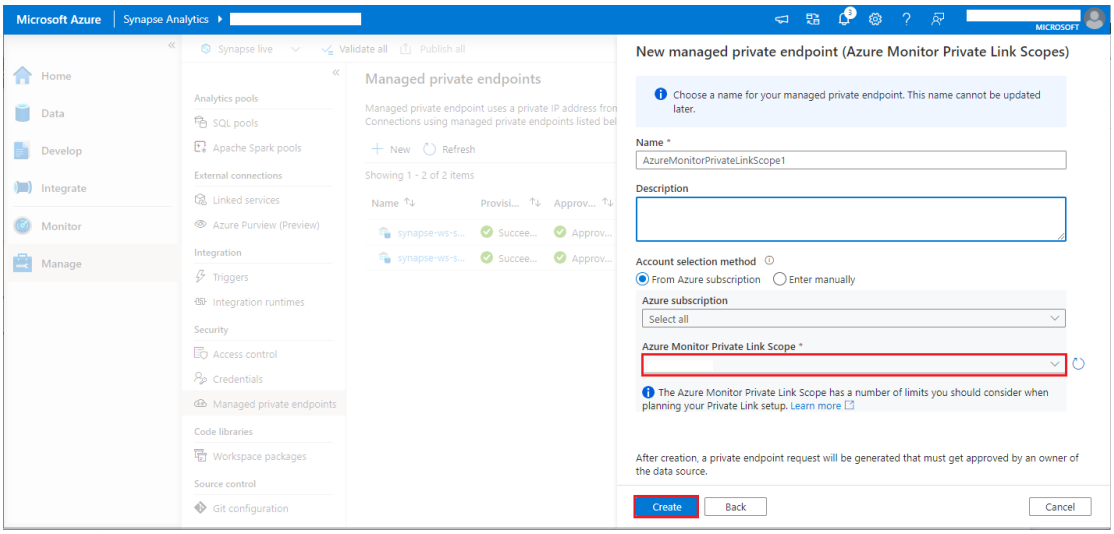
When you want to enable this feature, you need to create managed private endpoint connection requests to Azure Monitor private link scopes (A M P L S) in the workspace's approved Azure AD tenants.

You can follow below steps to create a managed private endpoint connection to Azure Monitor private link scopes (A M P L S):

1. If there is no existing A M P L S, you can follow Azure Monitor Private Link connection setup to create one.
2. Navigate to your A M P L S in Azure portal, on the **Azure Monitor Resources** page, click **Add** to add connection to your Azure Log Analytics workspace.
3. Navigate to **Synapse Studio > Manage > Managed private endpoints**, click **New** button, select **Azure Monitor Private Link Scopes**, and **continue**.



4. Choose your Azure Monitor Private Link Scope you created, and click **Create** button.



5. Wait a few minutes for private endpoint provisioning.
6. Navigate to your A M P L S in Azure portal again, on the **Private Endpoint connections** page, select the connection provisioned and **Approve**.

> **NOTE**
>
> - The A M P L S object has a number of limits you should consider when planning your Private Link setup. See A M P L S limits for a deeper review of these limits.
> - Check if you have right permission to create managed private endpoint.

Next steps

- Use serverless Apache Spark pool in Synapse Studio.
- Run a Spark application in notebook.
- Create Apache Spark job definition in Azure Studio.
- Collect Apache Spark applications logs and metrics with Azure Storage account.
- Collect Apache Spark applications logs and metrics with Azure Event Hubs.

Collect your Apache Spark applications logs and metrics using Azure Storage account

8/19/2022 • 3 minutes to read • Edit Online

The Synapse Apache Spark diagnostic emitter extension is a library that enables the Apache Spark application to emit the logs, event logs, and metrics to one or more destinations, including Azure Log Analytics, Azure Storage, and Azure Event Hubs.

In this tutorial, you learn how to use the Synapse Apache Spark diagnostic emitter extension to emit Apache Spark applications' logs, event logs, and metrics to your Azure storage account.

Collect logs and metrics to storage account

Step 1: Create a storage account

To collect diagnostic logs and metrics to storage account, you can use existing Azure Storage accounts. Or if you don't have one, you can create an Azure blob storage account or create a storage account to use with Azure Data Lake Storage Gen2.

Step 2: Create an Apache Spark configuration file

Create a `diagnostic-emitter-azure-storage-conf.txt` and copy following contents to the file. Or download a sample template file for Apache Spark pool configuration.

```
spark.synapse.diagnostic.emitters MyDestination1
spark.synapse.diagnostic.emitter.MyDestination1.type AzureStorage
spark.synapse.diagnostic.emitter.MyDestination1.categories Log,EventLog,Metrics
spark.synapse.diagnostic.emitter.MyDestination1.uri https://<my-blob-
storage>.blob.core.windows.net/<container-name>/<folder-name>
spark.synapse.diagnostic.emitter.MyDestination1.auth AccessKey
spark.synapse.diagnostic.emitter.MyDestination1.secret <storage-access-key>
```

Fill in the following parameters in the configuration file: `<my-blob-storage>`, `<container-name>`, `<folder-name>`, `<storage-access-key>`. For more description of the parameters, you can refer to Azure Storage configurations

Step 3: Upload the Apache Spark configuration file to Spark pool

1. Navigate to your Apache Spark pool in Synapse Studio **(Manage -> Apache Spark pools)**
2. Click the **"..."** button on the right of your Apache Spark pool and select **Apache Spark configuration**
3. Click **Upload** and choose the ".txt" configuration file. And click **Apply**.

Step 4: View the logs files in Azure storage account

After you submit a job to the configured Apache Spark pool, you should be able to see the logs and metrics files in destination storage account. The logs will be placed in corresponding paths according to different applications by `<workspaceName>.<sparkPoolName>.<livySessionId>`. All the logs files will be in JSON lines format (also called newline-delimited JSON, ndjson), which is convenient for data processing.

Available configurations

CONFIGURATION	DESCRIPTION

CONFIGURATION	DESCRIPTION
`spark.synapse.diagnostic.emitters`	Required. The comma-separated destination names of diagnostic emitters. For example, `MyDest1,MyDest2`
`spark.synapse.diagnostic.emitter.<destination>.type`	Required. Built-in destination type. To enable Azure storage destination, `AzureStorage` needs to be included in this field.
`spark.synapse.diagnostic.emitter.<destination>.categories`	Optional. The comma-separated selected log categories. Available values include `DriverLog`, `ExecutorLog`, `EventLog`, `Metrics`. If not set, the default value is **all** categories.
`spark.synapse.diagnostic.emitter.<destination>.auth`	Required. `AccessKey` for using storage account access key authorization. `SAS` for shared access signatures authorization.
`spark.synapse.diagnostic.emitter.<destination>.uri`	Required. The destination blob container folder uri. Should match pattern `https://<my-blob-storage>.blob.core.windows.net/<container-name>/<folder-name>` .
`spark.synapse.diagnostic.emitter.<destination>.secret`	Optional. The secret (AccessKey or SAS) content.
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault`	Required if `.secret` is not specified. The Azure Key vault name where the secret (AccessKey or SAS) is stored.
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault.secretName`	Required if `.secret.keyVault` is specified. The Azure Key vault secret name where the secret (AccessKey or SAS) is stored.
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault.linkedService`	Optional. The Azure Key vault linked service name. When enabled in Synapse pipeline, this is necessary to obtain the secret from AKV. (Please make sure MSI has read permission on the AKV).
`spark.synapse.diagnostic.emitter.<destination>.filter.eventName.match`	Optional. The comma-separated spark event names, you can specify which events to collect. For example: `SparkListenerApplicationStart,SparkListenerApplicationEnd`
`spark.synapse.diagnostic.emitter.<destination>.filter.loggerName.match`	Optional. The comma-separated log4j logger names, you can specify which logs to collect. For example: `org.apache.spark.SparkContext,org.example.Logger`
`spark.synapse.diagnostic.emitter.<destination>.filter.metricName.match`	Optional. The comma-separated spark metric name suffixes, you can specify which metrics to collect. For example: `jvm.heap.used`

Log data sample

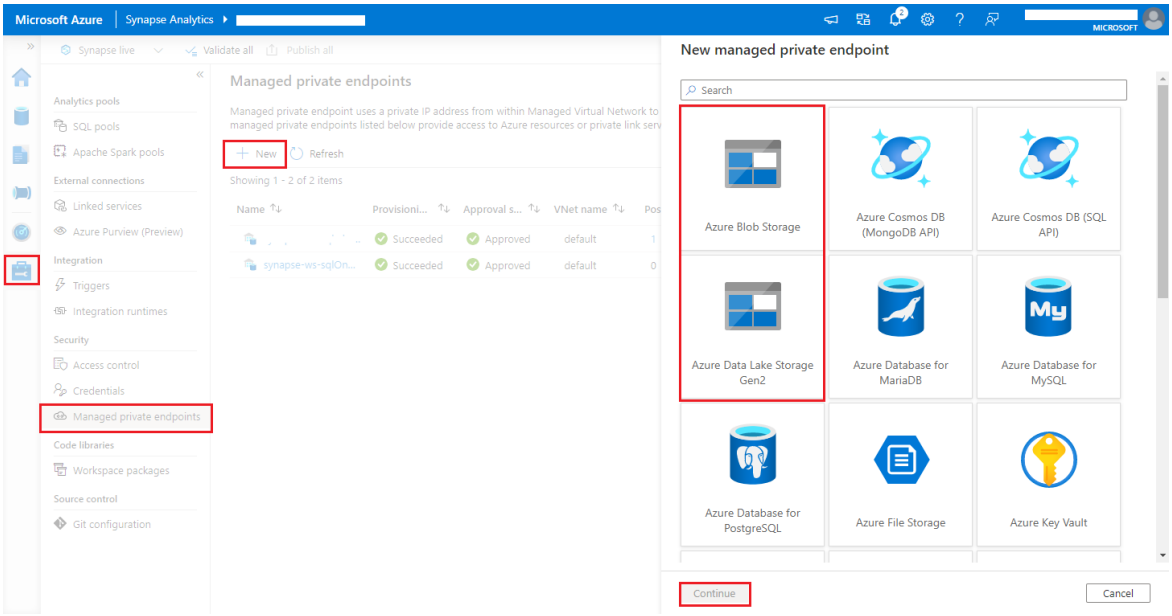
Here is a sample log record in JSON format:

```
{
    "timestamp": "2021-01-02T12:34:56.789Z",
    "category": "Log|EventLog|Metrics",
    "workspaceName": "<my-workspace-name>",
    "sparkPool": "<spark-pool-name>",
    "livyId": "<livy-session-id>",
    "applicationId": "<application-id>",
    "applicationName": "<application-name>",
    "executorId": "<driver-or-executor-id>",
    "properties": {
        // The message properties of logs, events and metrics.
        "timestamp": "2021-01-02T12:34:56.789Z",
        "message": "Registering signal handler for TERM",
        "logger_name": "org.apache.spark.util.SignalUtils",
        "level": "INFO",
        "thread_name": "main"
        // ...
    }
}
```

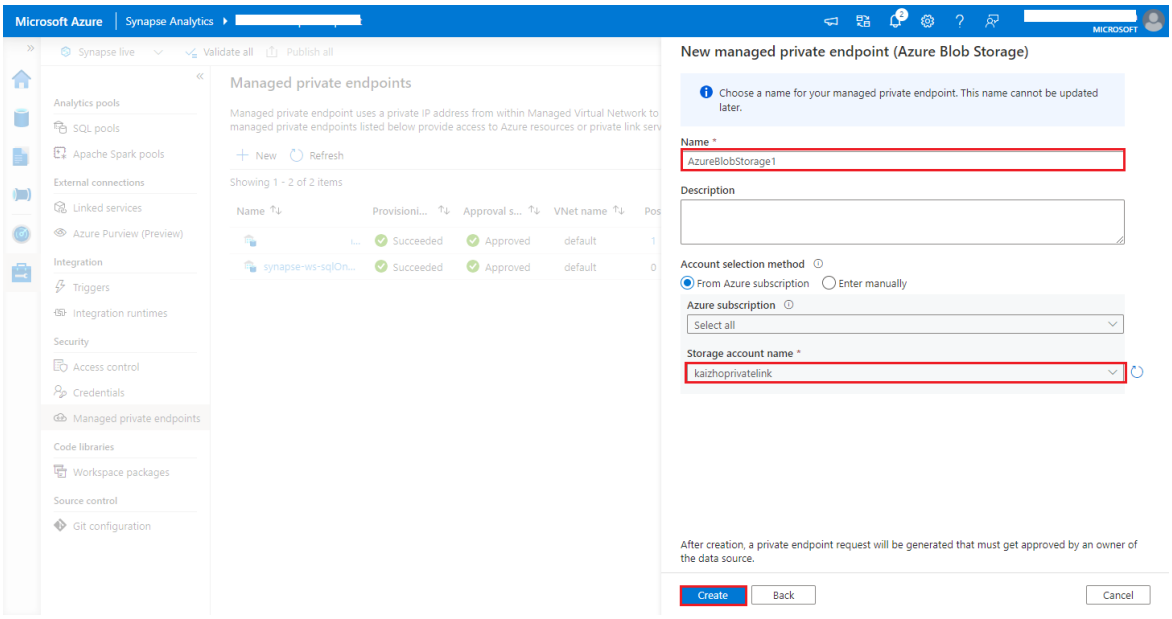
Synapse workspace with data exfiltration protection enabled

Azure Synapse Analytics workspaces support enabling data exfiltration protection for workspaces. With exfiltration protection, the logs and metrics cannot be sent out to the destination endpoints directly. You can create corresponding managed private endpoints for different destination endpoints or create IP firewall rules in this scenario.

1. Navigate to **Synapse Studio** > **Manage** > **Managed private endpoints**, click **New** button, select **Azure Blob Storage** or **Azure Data Lake Storage Gen2** and **continue**.



2. Choose your Azure Storage account in the **Storage account name**, and click **Create** button.



3. Wait a few minutes for private endpoint provisioning.
4. Navigate to your storage account in Azure portal, on the **Networking** > **Private Endpoint connections** page, select the connection provisioned and **Approve**.

Collect your Apache Spark applications logs and metrics using Azure Event Hubs

8/19/2022 • 2 minutes to read • Edit Online

The Synapse Apache Spark diagnostic emitter extension is a library that enables the Apache Spark application to emit the logs, event logs, and metrics to one or more destinations, including Azure Log Analytics, Azure Storage, and Azure Event Hubs.

In this tutorial, you learn how to use the Synapse Apache Spark diagnostic emitter extension to emit Apache Spark applications' logs, event logs, and metrics to your Azure Event Hubs.

Collect logs and metrics to Azure Event Hubs

Step 1: Create an Azure Event Hub instance

To collect diagnostic logs and metrics to Azure Event Hubs, you can use existing Azure Event Hubs instance. Or if you don't have one, you can create an event hub.

Step 2: Create an Apache Spark configuration file

Create a `diagnostic-emitter-azure-event-hub-conf.txt` and copy following contents to the file. Or download a sample template file for Apache Spark pool configuration.

```
spark.synapse.diagnostic.emitters MyDestination1
spark.synapse.diagnostic.emitter.MyDestination1.type AzureEventHub
spark.synapse.diagnostic.emitter.MyDestination1.categories Log,EventLog,Metrics
spark.synapse.diagnostic.emitter.MyDestination1.secret <connection-string>
```

Fill in the following parameters in the configuration file: `<connection-string>`. For more description of the parameters, you can refer to Azure EventHub configurations

Step 3: Upload the Apache Spark configuration file to Apache Spark pool

1. Navigate to your Apache Spark pool in Synapse Studio **(Manage -> Apache Spark pools)**
2. Click the **"..."** button on the right of your Apache Spark pool and select **Apache Spark configuration**
3. Click **Upload** and choose the ".txt" configuration file, and click **Apply**.

Available configurations

CONFIGURATION	DESCRIPTION
`spark.synapse.diagnostic.emitters`	Required. The comma-separated destination names of diagnostic emitters.
`spark.synapse.diagnostic.emitter.<destination>.type`	Required. Built-in destination type. To enable Azure Event Hubs destination, the value should be `AzureEventHub`.
`spark.synapse.diagnostic.emitter.<destination>.categories`	Optional. The comma-separated selected log categories. Available values include `DriverLog`, `ExecutorLog`, `EventLog`, `Metrics`. If not set, the default value is **all** categories.

CONFIGURATION	DESCRIPTION
`spark.synapse.diagnostic.emitter.<destination>.secret`	Optional. The Azure Eventhub instance connection string. This field should match this pattern `Endpoint=sb://<FQDN>/;SharedAccessKeyName=<KeyName>;SharedAccessKey=<KeyValue>;EntityPath=<PathName>`
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault`	Required if `.secret` is not specified. The Azure Key vault name where the secret (connection string) is stored.
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault.secretName`	Required if `.secret.keyVault` is specified. The Azure Key vault secret name where the secret (connection string) is stored.
`spark.synapse.diagnostic.emitter.<destination>.secret.keyVault.linkedService`	Optional. The Azure Key vault linked service name. When enabled in Synapse pipeline, this is necessary to obtain the secret from AKV. (Please make sure MSI has read permission on the AKV).
`spark.synapse.diagnostic.emitter.<destination>.filter.eventName.match`	Optional. The comma-separated spark event names, you can specify which events to collect. For example: `SparkListenerApplicationStart,SparkListenerApplicationEnd`
`spark.synapse.diagnostic.emitter.<destination>.filter.loggerName.match`	Optional. The comma-separated log4j logger names, you can specify which logs to collect. For example: `org.apache.spark.SparkContext,org.example.Logger`
`spark.synapse.diagnostic.emitter.<destination>.filter.metricName.match`	Optional. The comma-separated spark metric name suffixes, you can specify which metrics to collect. For example: `jvm.heap.used`

NOTE

The Azure Eventhub instance connection string should always contains the `EntityPath`, which is the name of the Azure Event Hubs instance.

Log data sample

Here is a sample log record in JSON format:

```
{
    "timestamp": "2021-01-02T12:34:56.789Z",
    "category": "Log|EventLog|Metrics",
    "workspaceName": "<my-workspace-name>",
    "sparkPool": "<spark-pool-name>",
    "livyId": "<livy-session-id>",
    "applicationId": "<application-id>",
    "applicationName": "<application-name>",
    "executorId": "<driver-or-executor-id>",
    "properties": {
        // The message properties of logs, events and metrics.
        "timestamp": "2021-01-02T12:34:56.789Z",
        "message": "Registering signal handler for TERM",
        "logger_name": "org.apache.spark.util.SignalUtils",
        "level": "INFO",
        "thread_name": "main"
        // ...
    }
}
```

Synapse workspace with data exfiltration protection enabled

Azure Synapse Analytics workspaces support enabling data exfiltration protection for workspaces. With exfiltration protection, the logs and metrics cannot be sent out to the destination endpoints directly. You can create corresponding managed private endpoints for different destination endpoints or create IP firewall rules in this scenario.

Manage Apache Spark configuration

8/19/2022 • 4 minutes to read • Edit Online

In this tutorial, you will learn how to create an Apache Spark configuration for your synapse studio. The created Apache Spark configuration can be managed in a standardized manner and when you create Notebook or Apache spark job definition can select the Apache Spark configuration that you want to use with your Apache Spark pool. When you select it, the details of the configuration are displayed.

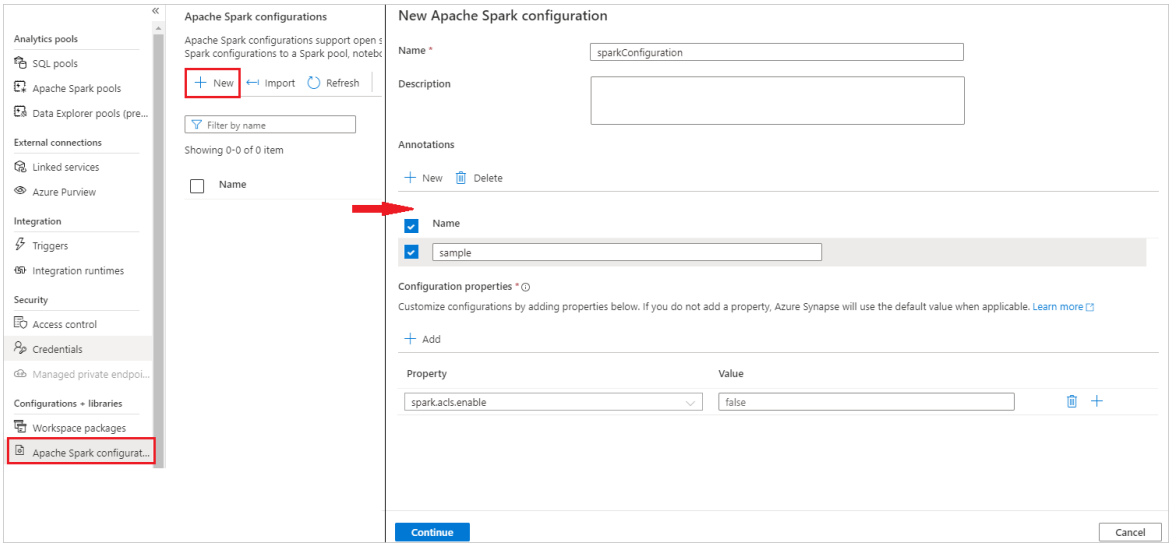
Create an Apache Spark Configuration

You can create custom configurations from different entry points, such as from the Apache Spark configurations page, from the Apache Spark configuration page of an existing spark pool.

Create custom configurations in Apache Spark configurations

Follow the steps below to create an Apache Spark Configuration in Synapse Studio.

1. Select **Manage** > **Apache Spark configurations**.
2. Click on **New** button to create a new Apache Spark configuration, or click on **Import** a local .json file to your workspace.
3. **New Apache Spark configuration** page will be opened after you click on **New** button.
4. For **Name**, you can enter your preferred and valid name.
5. For **Description**, you can input some description in it.
6. For **Annotations**, you can add annotations by clicking the **New** button, and also you can delete existing annotations by selecting and clicking **Delete** button.
7. For **Configuration properties**, customize the configuration by clicking **Add** button to add properties. If you do not add a property, Azure Synapse will use the default value when applicable.



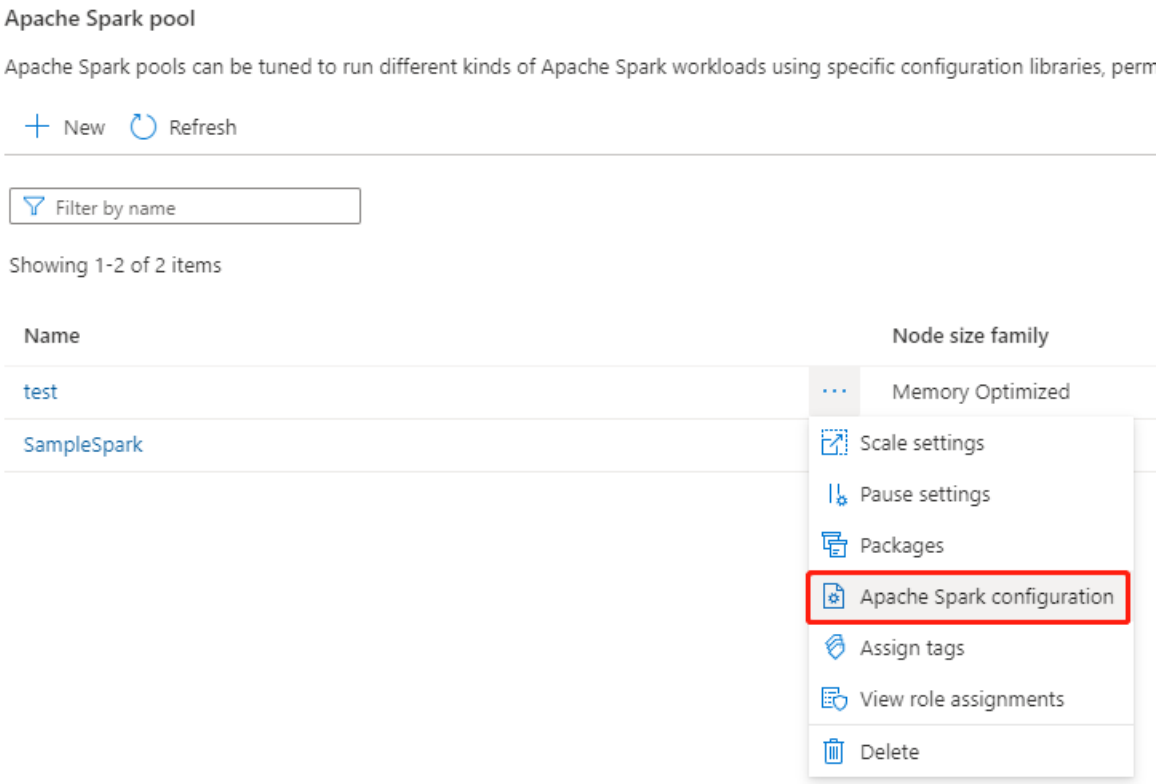
8. Click on **Continue** button.
9. Click on **Create** button when the validation succeeded.
10. Publish all

> **NOTE**
>
> **Upload Apache Spark configuration** feature has been removed, but Synapse Studio will keep your previously uploaded configuration.

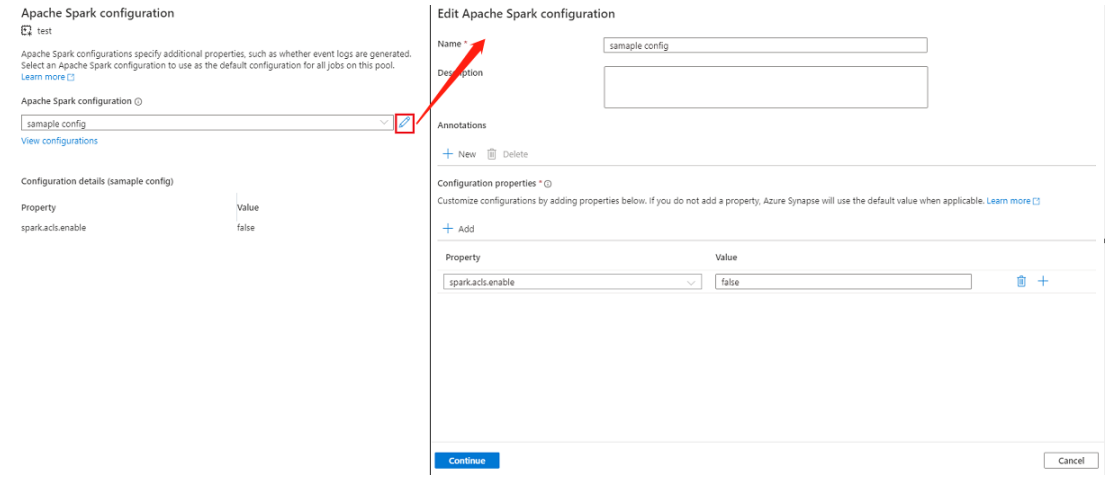
Create an Apache Spark Configuration in already existing Apache Spark pool

Follow the steps below to create an Apache Spark configuration in an existing Apache Spark pool.

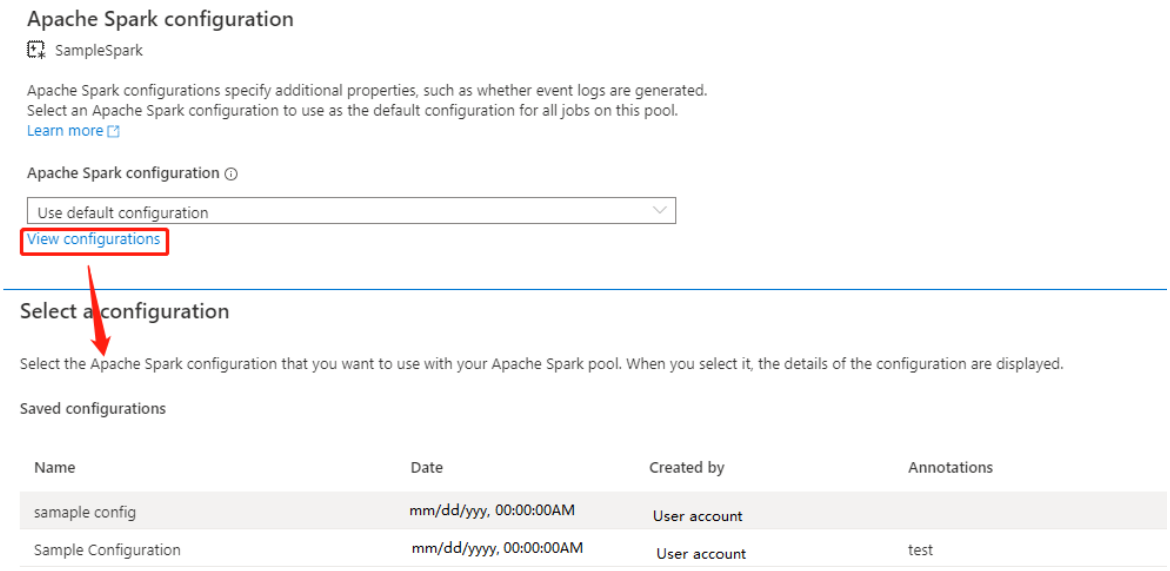
1. Select an existing Apache Spark pool, and click on action "..." button.
2. Select the **Apache Spark configuration** in the content list.



3. For Apache Spark configuration, you can select an already created configuration from the drop-down list, or click on **+New** to create a new configuration.
   - If you click **+New**, the Apache Spark Configuration page will open, and you can create a new configuration by following the steps in Create custom configurations in Apache Spark configurations.
   - If you select an existing configuration, the configuration details will be displayed at the bottom of the page, you can also click the **Edit** button to edit the existing configuration.



4. Click **View Configurations** to open the **Select a Configuration** page. All configurations will be displayed on this page. You can select a configuration that you want to use on this Apache Spark pool.

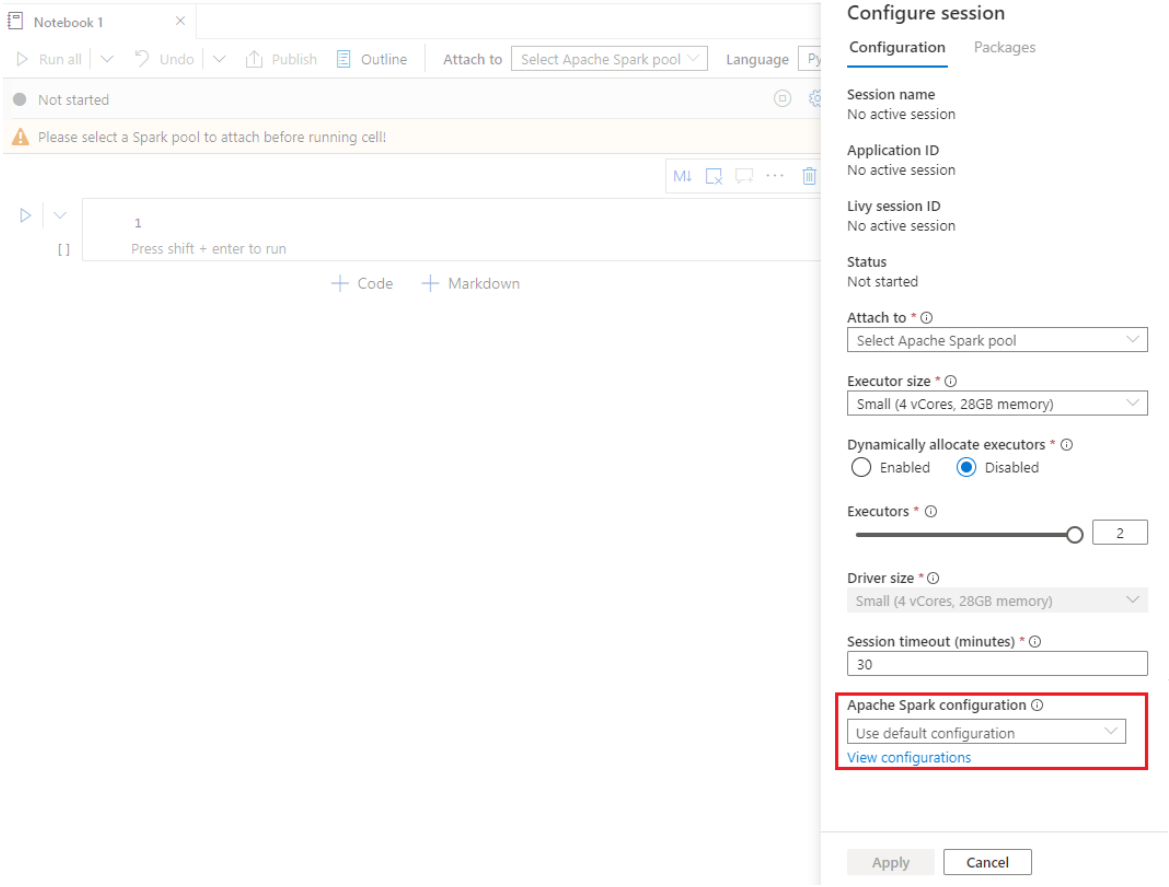


5. Click on **Apply** button to save your action.

Create an Apache Spark Configuration in the Notebook's configure session

If you need to use a custom Apache Spark Configuration when creating a Notebook, you can create and configure it in the **configure session** by following the steps below.

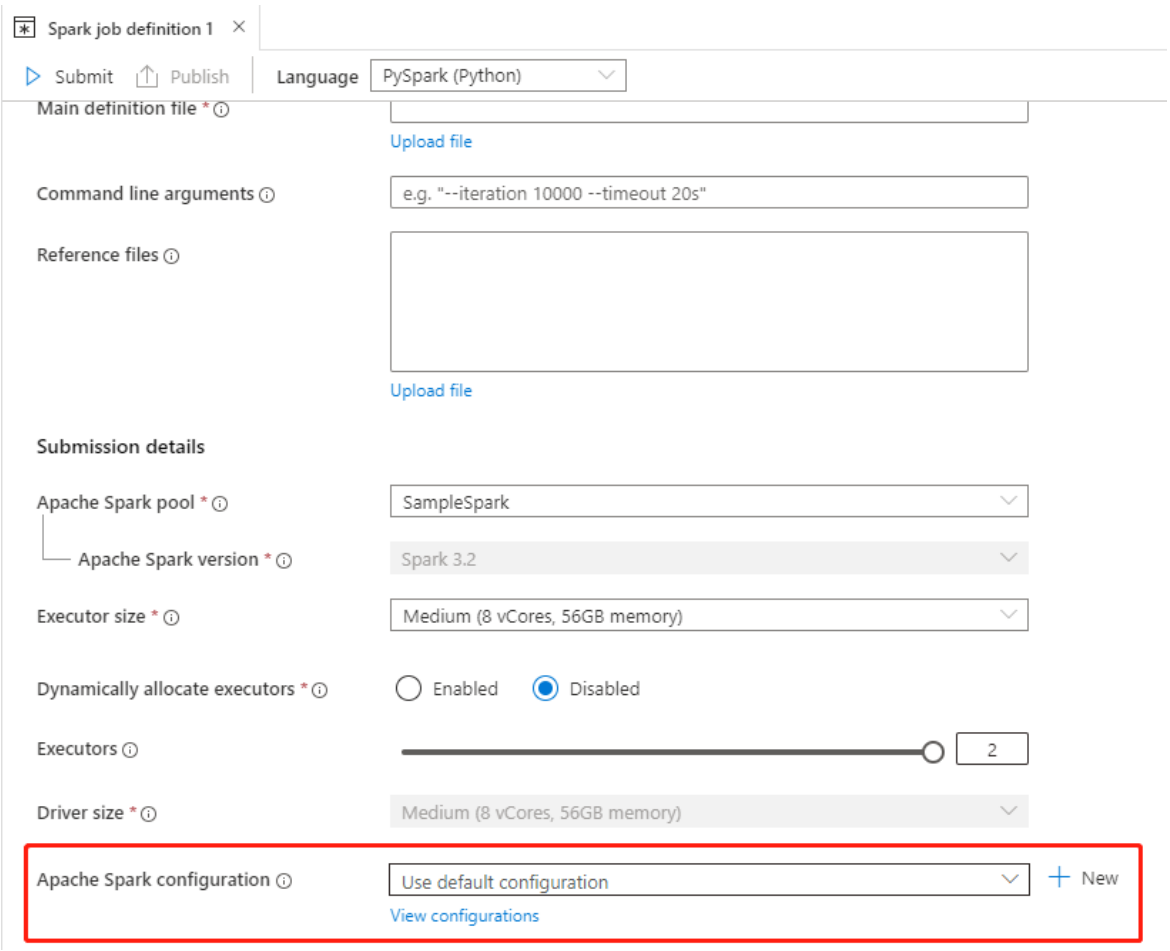
1. Create a new/Open an existing Notebook.
2. Open the **Properties** of this notebook.
3. Click on **Configure session** to open the Configure session page.
4. Scroll down the configure session page, for Apache Spark configuration, expand the drop-down menu, you can click on New button to create a new configuration. Or select an existing configuration, if you select an existing configuration, click the **Edit** icon to go to the Edit Apache Spark configuration page to edit the configuration.
5. Click **View Configurations** to open the **Select a Configuration** page. All configurations will be displayed on this page. You can select a configuration that you want to use.



Create an Apache Spark Configuration in Apache Spark job definitions

When you are creating a spark job definition, you need to use Apache Spark configuration, which can be created by following the steps below:

1. Create a new/Open an existing Apache Spark job definitions.
2. For **Apache Spark configuration**, you can click on New button to create a new configuration. Or select an existing configuration in the drop-down menu, if you select an existing configuration, click the **Edit** icon to go to the Edit Apache Spark configuration page to edit the configuration.
3. Click **View Configurations** to open the **Select a Configuration** page. All configurations will be displayed on this page. You can select a configuration that you want to use.



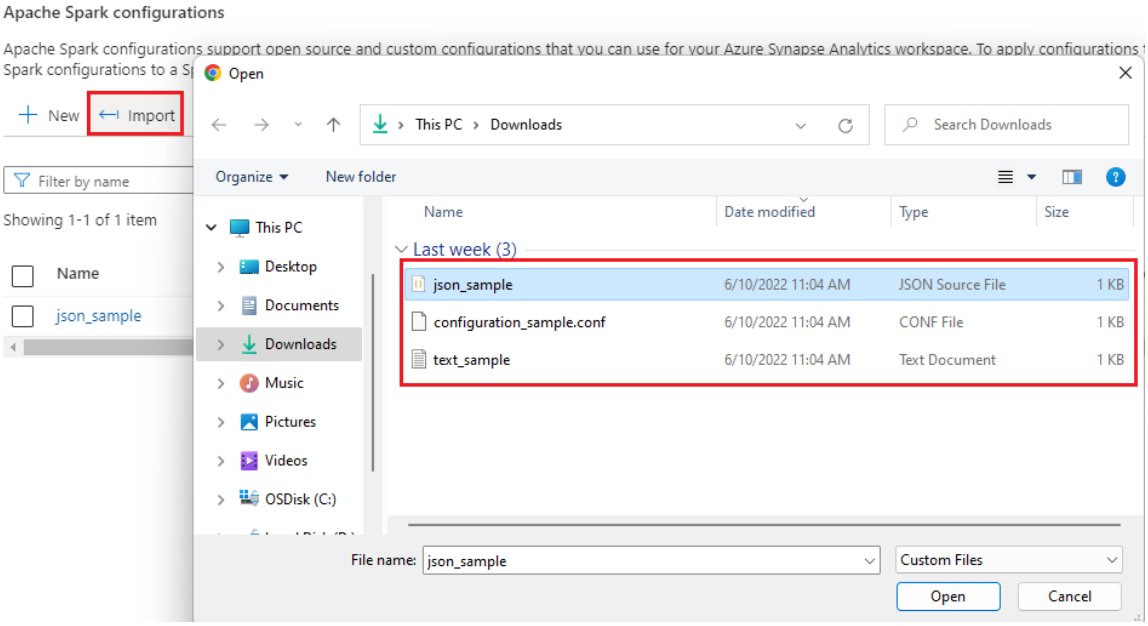
NOTE

If the Apache Spark configuration in the Notebook and Apache Spark job definition does not do anything special, the default configuration will be used when running the job.

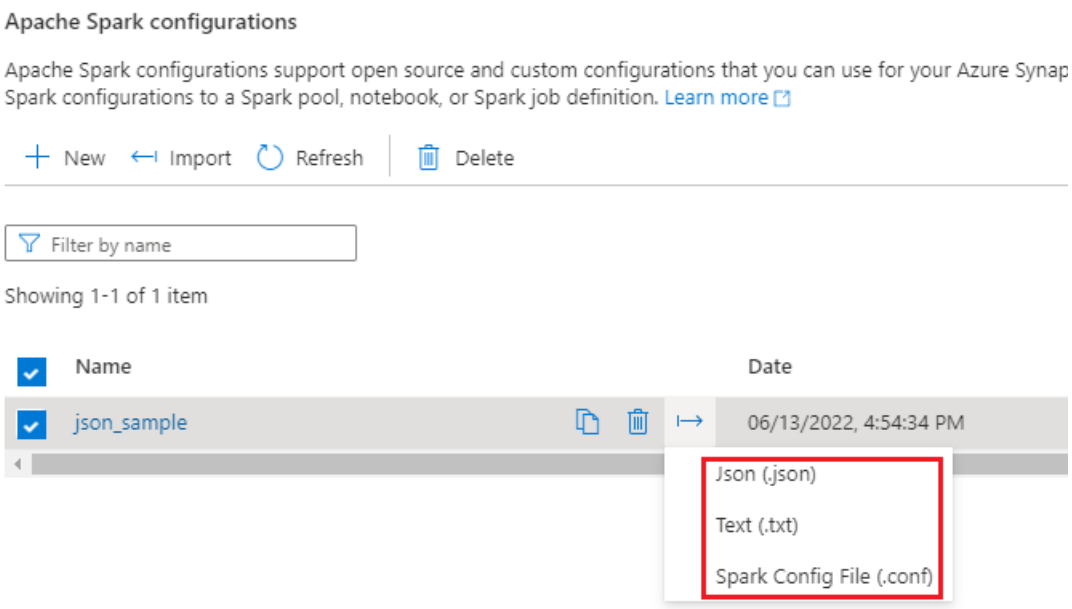
Import and Export an Apache Spark configuration

You can import .txt/.conf/.json config in three formats and then convert it to artifact and publish it. And can also export to one of these three formats.

- Import .txt/.conf/.json configuration from local.



- Export .txt/.conf/.json configuration to local.



For .txt config file and .conf config file, you can refer to the following examples:

```
spark.synapse.key1 sample
spark.synapse.key2 true
# spark.synapse.key3 sample2
```

For .json config file, you can refer to the following examples:

```
{
 "configs": {
   "spark.synapse.key1": "hello world",
  "spark.synapse.key2": "true"
 },
 "annotations": [
   "Sample"
 ]
}
```

Next steps

- Use serverless Apache Spark pool in Synapse Studio.
- Run a Spark application in notebook.
- Create Apache Spark job definition in Azure Studio.
- Collect Apache Spark applications logs and metrics with Azure Storage account.
- Collect Apache Spark applications logs and metrics with Azure Event Hubs.

Spark Advisor

8/19/2022 • 2 minutes to read • Edit Online

Spark Advisor is a system to automatically analyze commands/queries, and show the appropriate advice when customer executes code or query. After applying the advice, you would have chance to improve your execution performance, decrease cost and fix the execution failures.

Advice provided

May return inconsistent results when using 'randomSplit'

Inconsistent or inaccurate results may be returned when working with the results of the 'randomSplit' method. Use Apache Spark (RDD) caching before using the 'randomSplit' method.

Method randomSplit() is equivalent to performing sample() on your data frame multiple times, with each sample refetching, partitioning, and sorting your data frame within partitions. The data distribution across partitions and sorting order is important for both randomSplit() and sample(). If either changes upon data refetch, there may be duplicates, or missing values across splits and the same sample using the same seed may produce different results.

These inconsistencies may not happen on every run, but to eliminate them completely, cache your data frame, repartition on a column(s), or apply aggregate functions such as groupBy.

Table/view name is already in use

A view already exists with the same name as the created table, or a table already exists with the same name as the created view. When this name is used in queries or applications, only the view will be returned no matter, which one created first. To avoid conflicts, rename either the table or the view.

Hints related advise

Unable to recognize a hint

The selected query contains a hint that isn't recognized. Verify that the hint is spelled correctly.

```
spark.sql("SELECT /*+ unknownHint */ * FROM t1")
```

Unable to find a specified relation name(s)

Unable to find the relation(s) specified in the hint. Verify that the relation(s) are spelled correctly and accessible within the scope of the hint.

```
spark.sql("SELECT /*+ BROADCAST(unknownTable) */ * FROM t1 INNER JOIN t2 ON t1.str = t2.str")
```

A hint in the query prevents another hint from being applied

The selected query contains a hint that prevents another hint from being applied.

```
spark.sql("SELECT /*+ BROADCAST(t1), MERGE(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.str = t2.str")
```

Enable 'spark.advise.divisionExprConvertRule.enable' to reduce

rounding error propagation

This query contains the expression with Double type. We recommend that you enable the configuration 'spark.advise.divisionExprConvertRule.enable', which can help reduce the division expressions and to reduce the rounding error propagation.

```
"t.a/t.b/t.c" convert into "t.a/(t.b * t.c)"
```

Enable 'spark.advise.nonEqJoinConvertRule.enable' to improve query performance

This query contains time consuming join due to "Or" condition within query. We recommend that you enable the configuration 'spark.advise.nonEqJoinConvertRule.enable', which can help to convert the join triggered by "Or" condition to SMJ or BHJ to accelerate this query.

Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs using Synapse Studio article.

Interact with Azure Cosmos DB using Apache Spark 3 in Azure Synapse Link

8/19/2022 • 7 minutes to read • Edit Online

In this article, you'll learn how to interact with Azure Cosmos DB using Synapse Apache Spark 3. With its full support for Scala, Python, SparkSQL, and C#, Synapse Apache Spark 3 is central to analytics, data engineering, data science, and data exploration scenarios in Azure Synapse Link for Azure Cosmos DB.

The following capabilities are supported while interacting with Azure Cosmos DB:

- Synapse Apache Spark 3 allows you to analyze data in your Azure Cosmos DB containers that are enabled with Azure Synapse Link in near real-time without impacting the performance of your transactional workloads. The following two options are available to query the Azure Cosmos DB analytical store from Spark:
  - Load to Spark DataFrame
  - Create Spark table
- Synapse Apache Spark also allows you to ingest data into Azure Cosmos DB. It is important to note that data is always ingested into Azure Cosmos DB containers through the transactional store. When Synapse Link is enabled, any new inserts, updates, and deletes are then automatically synced to the analytical store.
- Synapse Apache Spark also supports Spark structured streaming with Azure Cosmos DB as a source as well as a sink.

The following sections walk you through the syntax of above capabilities. You can also checkout the learn module on how to Query Azure Cosmos DB with Apache Spark for Azure Synapse Analytics. Gestures in Azure Synapse Analytics workspace are designed to provide an easy out-of-the-box experience to get started. Gestures are visible when you right-click on an Azure Cosmos DB container in the **Data** tab of the Synapse workspace. With gestures, you can quickly generate code and tailor it to your needs. Gestures are also perfect for discovering data with a single click.

> **IMPORTANT**
>
> You should be aware of some constraints in the analytical schema that could lead to the unexpected behavior in data loading operations. As an example, only first 1000 properties from transactional schema are available in the analytical schema, properties with spaces are not available, etc. If you are experiencing some unexpected results, check the analytical store schema constraints for more details.

Query Azure Cosmos DB analytical store

Before you learn about the two possible options to query Azure Cosmos DB analytical store, loading to Spark DataFrame and creating Spark table, it is worth exploring the differences in experience so you can choose the option that works for your needs.

The difference in experience is around whether underlying data changes in the Azure Cosmos DB container should be automatically reflected in the analysis performed in Spark. When either a Spark DataFrame is registered or a Spark table is created against a container's analytical store, metadata around the current snapshot of data in the analytical store is fetched to Spark for efficient pushdown of subsequent analysis. It is important to note that since Spark follows a lazy evaluation policy, unless an action is invoked on the Spark DataFrame or a SparkSQL query is executed against the Spark table, actual data is not fetched from the underlying container's analytical store.

In the case of **loading to Spark DataFrame**, the fetched metadata is cached through the lifetime of the Spark session and hence subsequent actions invoked on the DataFrame are evaluated against the snapshot of the analytical store at the time of DataFrame creation.

On the other hand, in the case of **creating a Spark table**, the metadata of the analytical store state is not cached in Spark and is reloaded on every SparkSQL query execution against the Spark table.

Thus, you can choose between loading to Spark DataFrame and creating a Spark table based on whether you want your Spark analysis to be evaluated against a fixed snapshot of the analytical store or against the latest snapshot of the analytical store respectively.

> **NOTE**
>
> To query the Azure Cosmos DB API of Mongo DB accounts, learn more about the full fidelity schema representation in the analytical store and the extended property names to be used.

> **NOTE**
>
> Please note that all `options` in the commands below are case sensitive.

Load to Spark DataFrame

In this example, you'll create a Spark DataFrame that points to the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking Spark actions against the DataFrame. This operation doesn't impact the transactional store.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

df = spark.read.format("cosmos.olap")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val df_olap = spark.read.format("cosmos.olap").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    load()
```

Create Spark table

In this example, you'll create a Spark table that points the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking SparkSQL queries against the table. This operation neither impacts the transactional store nor does it incur any data movement. If you decide to delete this Spark table, the underlying Azure Cosmos DB container and the corresponding analytical store will not be affected.

This scenario is convenient to reuse Spark tables through third-party tools and provide accessibility to the underlying data for the run-time.

The syntax to create a Spark table is as follows:

```
%%sql
-- To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
spark.cosmos.preferredRegions '<Region1>,<Region2>' in the config options

create table call_center using cosmos.olap options (
    spark.synapse.linkedService '<enter linked service name>',
    spark.cosmos.container '<enter container name>'
)
```

NOTE

If you have scenarios where the schema of the underlying Azure Cosmos DB container changes over time; and if you want the updated schema to automatically reflect in the queries against the Spark table, you can achieve this by setting the `spark.cosmos.autoSchemaMerge` option to `true` in the Spark table options.

Write Spark DataFrame to Azure Cosmos DB container

In this example, you'll write a Spark DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume request units provisioned on the Azure Cosmos DB container or the shared database.

The syntax in **Python** would be the following:

```
# Write a Spark DataFrame into an Azure Cosmos DB container
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

YOURDATAFRAME.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .mode('append')\
    .save()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

import org.apache.spark.sql.SaveMode

df.write.format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    mode(SaveMode.Append).
    save()
```

Load streaming DataFrame from container

In this gesture, you'll use Spark Streaming capability to load data from a container into a dataframe. The data will be stored in the primary data lake account (and file system) you connected to the workspace.

> **NOTE**
>
> If you are looking to reference external libraries in Synapse Apache Spark, learn more here. For instance, if you are looking to ingest a Spark DataFrame to a container of Cosmos DB API for Mongo DB, you can leverage the Mongo DB connector for Spark here.

Load streaming DataFrame from Azure Cosmos DB container

In this example, you'll use Spark's structured streaming capability to load data from an Azure Cosmos DB container into a Spark streaming DataFrame using the change feed functionality in Azure Cosmos DB. The checkpoint data used by Spark will be stored in the primary data lake account (and file system) that you connected to the workspace.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

dfStream = spark.readStream\
    .format("cosmos.oltp.changeFeed")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.changeFeed.startFrom", "Beginning")\
    .option("spark.cosmos.changeFeed.mode", "Incremental")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val dfStream = spark.readStream.
    format("cosmos.oltp.changeFeed").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.changeFeed.startFrom", "Beginning").
    option("spark.cosmos.changeFeed.mode", "Incremental").
    load()
```

Write streaming DataFrame to Azure Cosmos DB container

In this example, you'll write a streaming DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database. If the folder */localWriteCheckpointFolder* isn't created (in the example below), it will be automatically created.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

streamQuery = dfStream\
    .writeStream\
    .format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("checkpointLocation", "/tmp/myRunId/")\
    .outputMode("append")\
    .start()

streamQuery.awaitTermination()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val query = dfStream.
            writeStream.
            format("cosmos.oltp").
            outputMode("append").
            option("spark.synapse.linkedService", "<enter linked service name>").
            option("spark.cosmos.container", "<enter container name>").
            option("checkpointLocation", "/tmp/myRunId/").
            start()

query.awaitTermination()
```

Next steps

- Learn what is supported in Azure Synapse Link for Azure Cosmos DB
- Connect to Synapse Link for Azure Cosmos DB
- Checkout the learn module on how to Query Azure Cosmos DB with Apache Spark for Azure Synapse Analytics.

Interact with Azure Cosmos DB using Apache Spark 2 in Azure Synapse Link

8/19/2022 • 9 minutes to read • Edit Online

> **NOTE**
> For Synapse Link for Cosmos DB using Spark 3, refer to this article Azure Synapse Link for Azure Cosmos DB on Spark 3

In this article, you'll learn how to interact with Azure Cosmos DB using Synapse Apache Spark 2. With its full support for Scala, Python, SparkSQL, and C#, Synapse Apache Spark is central to analytics, data engineering, data science, and data exploration scenarios in Azure Synapse Link for Azure Cosmos DB.

The following capabilities are supported while interacting with Azure Cosmos DB:

- Synapse Apache Spark allows you to analyze data in your Azure Cosmos DB containers that are enabled with Azure Synapse Link in near real-time without impacting the performance of your transactional workloads. The following two options are available to query the Azure Cosmos DB analytical store from Spark:
  - Load to Spark DataFrame
  - Create Spark table
- Synapse Apache Spark also allows you to ingest data into Azure Cosmos DB. It is important to note that data is always ingested into Azure Cosmos DB containers through the transactional store. When Synapse Link is enabled, any new inserts, updates, and deletes are then automatically synced to the analytical store.
- Synapse Apache Spark also supports Spark structured streaming with Azure Cosmos DB as a source as well as a sink.

The following sections walk you through the syntax of above capabilities. You can also checkout the learn module on how to Query Azure Cosmos DB with Apache Spark for Azure Synapse Analytics. Gestures in Azure Synapse Analytics workspace are designed to provide an easy out-of-the-box experience to get started. Gestures are visible when you right-click on an Azure Cosmos DB container in the **Data** tab of the Synapse workspace. With gestures, you can quickly generate code and tailor it to your needs. Gestures are also perfect for discovering data with a single click.

> **IMPORTANT**
> You should be aware of some constraints in the analytical schema that could lead to the unexpected behavior in data loading operations. As an example, only first 1000 properties from transactional schema are available in the analytical schema, properties with spaces are not available, etc. If you are experiencing some unexpected results, check the analytical store schema constraints for more details.

Query Azure Cosmos DB analytical store

Before you learn about the two possible options to query Azure Cosmos DB analytical store, loading to Spark DataFrame and creating Spark table, it is worth exploring the differences in experience so you can choose the option that works for your needs.

The difference in experience is around whether underlying data changes in the Azure Cosmos DB container should be automatically reflected in the analysis performed in Spark. When either a Spark DataFrame is registered or a Spark table is created against a container's analytical store, metadata around the current

snapshot of data in the analytical store is fetched to Spark for efficient pushdown of subsequent analysis. It is important to note that since Spark follows a lazy evaluation policy, unless an action is invoked on the Spark DataFrame or a SparkSQL query is executed against the Spark table, actual data is not fetched from the underlying container's analytical store.

In the case of **loading to Spark DataFrame**, the fetched metadata is cached through the lifetime of the Spark session and hence subsequent actions invoked on the DataFrame are evaluated against the snapshot of the analytical store at the time of DataFrame creation.

On the other hand, in the case of **creating a Spark table**, the metadata of the analytical store state is not cached in Spark and is reloaded on every SparkSQL query execution against the Spark table.

Thus, you can choose between loading to Spark DataFrame and creating a Spark table based on whether you want your Spark analysis to be evaluated against a fixed snapshot of the analytical store or against the latest snapshot of the analytical store respectively.

If your analytical queries have frequently used filters, you have the option to partition based on these fields for better query performance. You can periodically execute partitioning job from an Azure Synapse Spark notebook, to trigger partitioning on analytical store. This partitioned store points to the ADLS Gen2 primary storage account that is linked to your Azure Synapse workspace. To learn more, see the introduction to custom partitioning and how to configure custom partitioning articles.

> **NOTE**
> To query the Azure Cosmos DB API of Mongo DB accounts, learn more about the full fidelity schema representation in the analytical store and the extended property names to be used.

> **NOTE**
> Please note that all `options` in the commands below are case sensitive. For example, you must use `Gateway` while `gateway` will return an error.

Load to Spark DataFrame

In this example, you'll create a Spark DataFrame that points to the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking Spark actions against the DataFrame. This operation doesn't impact the transactional store.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

df = spark.read.format("cosmos.olap")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val df_olap = spark.read.format("cosmos.olap").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    load()
```

Create Spark table

In this example, you'll create a Spark table that points the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking SparkSQL queries against the table. This operation neither impacts the transactional store nor does it incur any data movement. If you decide to delete this Spark table, the underlying Azure Cosmos DB container and the corresponding analytical store will not be affected.

This scenario is convenient to reuse Spark tables through third-party tools and provide accessibility to the underlying data for the run-time.

The syntax to create a Spark table is as follows:

```
%%sql
-- To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
spark.cosmos.preferredRegions '<Region1>,<Region2>' in the config options

create table call_center using cosmos.olap options (
    spark.synapse.linkedService '<enter linked service name>',
    spark.cosmos.container '<enter container name>'
)
```

> **NOTE**
>
> If you have scenarios where the schema of the underlying Azure Cosmos DB container changes over time; and if you want the updated schema to automatically reflect in the queries against the Spark table, you can achieve this by setting the `spark.cosmos.autoSchemaMerge` option to `true` in the Spark table options.

Write Spark DataFrame to Azure Cosmos DB container

In this example, you'll write a Spark DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume request units provisioned on the Azure Cosmos DB container or the shared database.

The syntax in **Python** would be the following:

```
# Write a Spark DataFrame into an Azure Cosmos DB container
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

YOURDATAFRAME.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.write.upsertEnabled", "true")\
    .mode('append')\
    .save()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

import org.apache.spark.sql.SaveMode

df.write.format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.write.upsertEnabled", "true").
    mode(SaveMode.Overwrite).
    save()
```

Load streaming DataFrame from container

In this gesture, you'll use Spark Streaming capability to load data from a container into a dataframe. The data will be stored in the primary data lake account (and file system) you connected to the workspace.

> **NOTE**
> If you are looking to reference external libraries in Synapse Apache Spark, learn more here. For instance, if you are looking to ingest a Spark DataFrame to a container of Cosmos DB API for Mongo DB, you can leverage the Mongo DB connector for Spark here.

Load streaming DataFrame from Azure Cosmos DB container

In this example, you'll use Spark's structured streaming capability to load data from an Azure Cosmos DB container into a Spark streaming DataFrame using the change feed functionality in Azure Cosmos DB. The checkpoint data used by Spark will be stored in the primary data lake account (and file system) that you connected to the workspace.

If the folder */localReadCheckpointFolder* isn't created (in the example below), it will be automatically created. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

dfStream = spark.readStream\
    .format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.changeFeed.readEnabled", "true")\
    .option("spark.cosmos.changeFeed.startFromTheBeginning", "true")\
    .option("spark.cosmos.changeFeed.checkpointLocation", "/localReadCheckpointFolder")\
    .option("spark.cosmos.changeFeed.queryName", "streamQuery")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val dfStream = spark.readStream.
    format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.changeFeed.readEnabled", "true").
    option("spark.cosmos.changeFeed.startFromTheBeginning", "true").
    option("spark.cosmos.changeFeed.checkpointLocation", "/localReadCheckpointFolder").
    option("spark.cosmos.changeFeed.queryName", "streamQuery").
    load()
```

Write streaming DataFrame to Azure Cosmos DB container

In this example, you'll write a streaming DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database. If the folder */localWriteCheckpointFolder* isn't created (in the example below), it will be automatically created.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

# If you are using managed private endpoints for Azure Cosmos DB analytical store and using batch
writes/reads and/or streaming writes/reads to transactional store you should set connectionMode to Gateway.

def writeBatchToCosmos(batchDF, batchId):
  batchDF.persist()
  print("--> BatchId: {}, Document count: {} : {}".format(batchId, batchDF.count(),
datetime.datetime.utcnow().strftime("%Y-%m-%d %H:%M:%S.%f")))
  batchDF.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.write.upsertEnabled", "true")\
    .mode('append')\
    .save()
  print("<-- BatchId: {}, Document count: {} : {}".format(batchId, batchDF.count(),
datetime.datetime.utcnow().strftime("%Y-%m-%d %H:%M:%S.%f")))
  batchDF.unpersist()

streamQuery = dfStream\
        .writeStream\
        .foreachBatch(writeBatchToCosmos) \
        .option("checkpointLocation", "/localWriteCheckpointFolder")\
        .start()

streamQuery.awaitTermination()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

// If you are using managed private endpoints for Azure Cosmos DB analytical store and using batch
writes/reads and/or streaming writes/reads to transactional store you should set connectionMode to Gateway.

val query = dfStream.
            writeStream.
            foreachBatch { (batchDF: DataFrame, batchId: Long) =>
              batchDF.persist()
              batchDF.write.format("cosmos.oltp").
                option("spark.synapse.linkedService", "<enter linked service name>").
                option("spark.cosmos.container", "<enter container name>").
                option("spark.cosmos.write.upsertEnabled", "true").
                mode(SaveMode.Overwrite).
                save()
              println(s"BatchId: $batchId, Document count: ${batchDF.count()}")
              batchDF.unpersist()
              ()
            }.
            option("checkpointLocation", "/localWriteCheckpointFolder").
            start()

query.awaitTermination()
```

Azure Data Explorer (Kusto) connector for Apache Spark

8/19/2022 • 2 minutes to read • Edit Online

The Azure Data Explorer (Kusto) connector for Apache Spark is designed to efficiently transfer data between Kusto clusters and Spark. This connector is available in Python, Java, and .NET. It is built in to the Azure Synapse Apache Spark 2.4 runtime.

Authentication

When using Azure Synapse Notebooks or Apache Spark job definitions, the authentication between systems is made seamless with the linked service. The Token Service connects with Azure Active Directory to obtain security tokens for use when accessing the Kusto cluster.

For Azure Synapse Pipelines, the authentication will use the service principal name. Currently, managed identities are not supported with the Azure Data Explorer connector.

Prerequisites

- Connect to Azure Data Explorer: You will need to set up a Linked Service to connect to an existing Kusto cluster.

Limitations

- The Azure Data Explorer (Kusto) connector is currently only supported on the Azure Synapse Apache Spark 2.4 runtime.
- The Azure Data Explorer linked service can only be configured with the Service Principal Name.
- Within Azure Synapse Notebooks or Apache Spark Job Definitions, the Azure Data Explorer connector will use AAD pass-through to connect to the Kusto Cluster.

Use the Azure Data Explorer (Kusto) connector

The following section provides a simple example of how to write data to a Kusto table and read data from a Kusto table. See the Azure Data Explorer (Kusto) connector project for detailed documentation.

Read data

```
kustoDf  = spark.read \
            .format("com.microsoft.kusto.spark.synapse.datasource") \
            .option("spark.synapse.linkedService", "<link service name>") \
            .option("kustoDatabase", "<Database name>") \
            .option("kustoQuery", "<KQL Query>") \
            .load()

display(kustoDf)
```

You can also batch read with forced distribution mode and other advanced options. For additional information, you can refer to Kusto source options reference.

```
crp = sc._jvm.com.microsoft.azure.kusto.data.ClientRequestProperties()
crp.setOption("norequesttimeout",True)
crp.toString()

kustoDf  = spark.read \
            .format("com.microsoft.kusto.spark.synapse.datasource") \
            .option("spark.synapse.linkedService", "<link service name>") \
            .option("kustoDatabase", "<Database name>") \
            .option("kustoQuery", "<KQL Query>") \
            .option("clientRequestPropertiesJson", crp.toString()) \
            .option("readMode", 'ForceDistributedMode') \
            .load()

display(kustoDf)
```

Write data

```
df.write \
    .format("com.microsoft.kusto.spark.synapse.datasource") \
    .option("spark.synapse.linkedService", "<link service name>") \
    .option("kustoDatabase", "<Database name>") \
    .option("kustoTable", "<Table name>") \
    .mode("Append") \
    .save()
```

In addition, you can also batch write data by providing additional ingestion properties. For more info on the supported ingestion properties, you can visit the Kusto ingestion properties reference material.

```
extentsCreationTime = sc._jvm.org.joda.time.DateTime.now().plusDays(1)
csvMap = "[{\"Name\":\"ColA\",\"Ordinal\":0},{\"Name\":\"ColB\",\"Ordinal\":1}]"
# Alternatively use an existing csv mapping configured on the table and pass it as the last parameter of
SparkIngestionProperties or use none

sp = sc._jvm.com.microsoft.kusto.spark.datasink.SparkIngestionProperties(
       False, ["dropByTags"], ["ingestByTags"], ["tags"], ["ingestIfNotExistsTags"], extentsCreationTime,
csvMap, None)

df.write \
   .format("com.microsoft.kusto.spark.synapse.datasource") \
   .option("spark.synapse.linkedService", "<link service name>") \
   .option("kustoDatabase", "<Database name>") \
   .option("kustoTable", "<Table name>") \
   .option("sparkIngestionPropertiesJson", sp.toString()) \
   .option("tableCreateOptions","CreateIfNotExist") \
   .mode("Append") \
   .save()
```

Common Data Model (CDM) Connector for Azure Synapse Spark

8/19/2022 • 22 minutes to read • Edit Online

The Synapse Spark Common Data Model (CDM) format reader/writer enables a Spark program to read and write CDM entities in a CDM folder via Spark dataframes.

For information on defining CDM documents using CDM 1.0 see. What is CDM and how to use it.

High level functionality

The following capabilities are supported:

- Reading data from an entity in a CDM folder into a Spark dataframe
- Writing from a Spark dataframe to an entity in a CDM folder based on a CDM entity definition
- Writing from a Spark dataframe to an entity in a CDM folder based on the dataframe schema

Capabilities

- Supports reading and writing to CDM folders in ADLS gen2 with HNS enabled.
- Supports reading from CDM folders described by either manifest or model.json files.
- Supports writing to CDM folders described by a manifest file.
- Supports data in CSV format with/without column headers and with user selectable delimiter character.
- Supports data in Apache Parquet format, including nested Parquet.
- Supports submanifests on read, optional use of entity-scoped submanifests on write.
- Supports writing data using user modifiable partition patterns.
- Supports use of managed identity Synapse and credentials.
- Supports resolving CDM aliases locations used in imports using CDM adapter definitions described in a config.json.

Limitations

The following scenarios aren't supported:

- Programmatic access to entity metadata after reading an entity.
- Programmatic access to set or override metadata when writing an entity.
- Schema drift - where data in a dataframe being written includes extra attributes not included in the entity definition.
- Schema evolution - where entity partitions reference different versions of the entity definition
- Write support for model.json isn't supported.
- Executing `com.microsoft.cdm.BuildInfo.version` will verify the version

Spark 2.4 and Spark 3.1 are supported.

Reading data

When reading data, the connector uses metadata in the CDM folder to create the dataframe based on the resolved entity definition for the specified entity, as referenced in the manifest. Entity attribute names are used

as dataframe column names. Attribute datatypes are mapped to the column datatype. When the dataframe is loaded, it's populated from the entity partitions identified in the manifest.

The connector looks in the specified manifest and any first-level submanifests for the specified entity. If the required entity is in a second-level or lower submanifest, or if there are multiple entities of the same name in different submanifests, then the user should specify the submanifest that contains the required entity rather than the root manifest. Entity partitions can be in a mix of formats (CSV, Parquet, etc.). All the entity data files identified in the manifest are combined into one dataset regardless of format and loaded to the dataframe.

When reading CSV data, the connector uses the Spark FAILFAST option by default. It will return an error if the number of columns isn't equal to the number of attributes in the entity. Alternatively, as of 0.19, permissive mode is now supported. This mode is only supported for CSV files. With the permissive mode, when a CSV row has fewer number of columns than the entity schema, null values will be assigned for the missing columns. When a CSV row has more columns than the entity schema, the columns greater than the entity schema column count will be truncated to the schema column count. Usage is as follows:

```
.option("entity", "permissive") or .option("mode", "failfast")
```

For example, here's an example python sample.

Writing data

When writing to a CDM folder, if the entity doesn't already exist in the CDM folder, a new entity and definition is created and added to the CDM folder and referenced in the manifest. Two writing modes are supported:

Explicit write: the physical entity definition is based on a logical CDM entity definition that the user specifies.

- The specified logical entity definition is read and resolved to create the physical entity definition used in the CDM folder. If import statements in any directly or indirectly referenced CDM definition file include aliases, then a config.json file that maps these aliases to CDM adapters and storage locations must be provided. For more on the use of aliases, see *Aliases and adapter configuration* below.
- If the dataframe schema doesn't match the referenced entity definition, an error is returned. Ensure that the column datatypes in the dataframe match the attribute datatypes in the entity, including for decimal data, precision and scale set via traits in CDM.
- If the dataframe is inconsistent with the entity definition an error is returned.
- If the dataframe is consistent:
  - If the entity already exists in the manifest, the provided entity definition is resolved and validated against the definition in the CDM folder. If the definitions don't match, an error is returned, otherwise data is written and the partition information in the manifest is updated
    - If the entity doesn't exist in the CDM folder, a resolved copy of the entity definition is written to the manifest in the CDM folder and data is written and the partition information in the manifest is updated.

Implicit write: the entity definition is derived from the dataframe structure.

- If the entity doesn't exist in the CDM folder, the implicit definition is used to create the resolved entity definition in the target CDM folder.
- If the entity exists in the CDM folder, the implicit definition is validated against the existing entity definition. If the definitions don't match an error is returned, otherwise data is written and a derived logical entity definition(s) is written into a subfolder of the entity folder. Data is written to data folder(s) within an entity subfolder. A save mode determines whether the new data overwrites or is appended to existing data, or an error is returned if data exists. The default is to return an error if data already exists.

CDM alias integration

CDM definition files use aliases in import statements to simplify the import statement and allow the location of the imported content to be late bound at execution time. Using aliases:

- Facilitates easy organization of CDM files so that related CDM definitions can be grouped together at different locations.
- Allows CDM content to be accessed from different deployed locations at runtime.

The snippet below shows the use of aliases in import statements in a CDM definition file.

```
"imports": [
{
  "corpusPath": "cdm:/foundations.cdm.json"
},
{
  "corpusPath": "core:/TrackedEntity.cdm.json"
},
{
  "corpusPath": "Customer.cdm.json"
}
]
```

In the example above, 'cdm' is used as an alias for the location of the CDM foundations file, and 'core' is used as an alias for the location of the TrackedEntity definition file.

Aliases are text labels that are matched to a namespace value in an adapter entry in a CDM config.json file. An adapter entry specifies the adapter type (for example "adls", "CDN", "GitHub", "local", etc.) and a URL that defines a location. Some adapters support other configuration options, such as a connection timeout. While aliases are arbitrary text labels, the 'cdm' alias is treated in a special manner as described below.

The Spark CDM Connector will look in the entity definition model root location for the config.json file to load. If the config.json file is at some other location or the user seeks to override the config.json file in the model root, then the user can provide the location of a config.json file using the *configPath* option. The config.json file must contain adapter entries for all the aliases used in the CDM code being resolved or an error will be reported.

By being able to override the config.json, the user can provide runtime-accessible locations for CDM definitions. Ensure that the content referenced at runtime is consistent with the definitions used when the CDM was originally authored.

By convention, the *cdm* alias is used to refer to the location of the root-level standard CDM definitions, including the foundations.cdm.json file, which includes the CDM primitive datatypes and a core set of trait definitions required for most CDM entity definitions. The *cdm* alias can be resolved like any other alias using an adapter entry in the config.json file. Alternatively, if an adapter isn't specified or a null entry is provided, then the *cdm* alias will be resolved by default to the CDM public CDN at `https://cdm-schema.microsoft.com/logical/`. The user can also use the *cdmSource* option to override how the cdm alias is resolved (see the option details below). Using the *cdmsource* option is useful if the cdm alias is the only alias used in the CDM definitions being resolved as it can avoid needing to create or reference a config.json file.

Parameters, options and save mode

For both read and write, the Spark CDM Connector library name is provided as a parameter. A set of options are used to parameterize the behavior of the connector. When writing, a save mode is also supported.

The connector library name, options and save mode are formatted as follows:

- dataframe.read.format("com.microsoft.cdm") [.option("option", "value")]*

- dataframe.write.format("com.microsoft.cdm") [.option("option", "value")]* .mode(savemode.<saveMode>)

Here's an example of how the connector is used for read, showing some of the options. More examples are provided later.

```
val readDf = spark.read.format("com.microsoft.cdm")
  .option("storage", "mystorageaccount.dfs.core.windows.net")
  .option("manifestPath", "customerleads/default.manifest.cdm.json")
  .option("entity", "Customer")
  .load()
```

Common READ and WRITE options

The following options identify the entity in the CDM folder that is either being read or written to.

OPTION	DESCRIPTION	PATTERN AND EXAMPLE USAGE
storage	The endpoint URL for the ADLS gen2 storage account with HNS enabled in which the CDM folder is located. Use the *dfs*.core.windows.net URL	<accountName>.dfs.core.windows.net "myAccount.dfs.core.windows.net"
manifestPath	The relative path to the manifest or model.json file in the storage account. For read, can be a root manifest or a submanifest or a model.json. For write, must be a root manifest.	<container>/{<folderPath>/} <manifestFileName>, "mycontainer/default.manifest.cdm.json" "models/hr/employees.manifest.cdm.json" "models/hr/employees/model.json" (read only)
entity	The name of the source or target entity in the manifest. When writing an entity for the first time in a folder, the resolved entity definition will be given this name. Entity name is case sensitive.	<entityName> "customer"
maxCDMThreads	The maximum number of concurrent reads while resolving an entity definition.	Any valid integer. for example - 5

> **NOTE**
> You no longer need to specify a logical entity definition in addition to the physical entity definition in the CDM folder on read.

Explicit write options

The following options identify the logical entity definition that defines the entity being written. The logical entity definition will be resolved to a physical definition that defines how the entity will be written.

OPTION	DESCRIPTION	PATTERN / EXAMPLE USAGE
entityDefinitionStorage	The ADLS gen2 storage account containing the entity definition. Required if different to the storage account hosting the CDM folder.	<accountName>.dfs.core.windows.net "myAccount.dfs.core.windows.net"

OPTION	DESCRIPTION	PATTERN / EXAMPLE USAGE
entityDefinitionModelRoot	The location of the model root or corpus within the account.	<container>/<folderPath> "crm/core"
entityDefinitionPath	Location of the entity. File path to the CDM definition file relative to the model root, including the name of the entity in that file.	<folderPath>/<entityName>.cdm.json/<entityName> "sales/customer.cdm.json/customer"
configPath	The container and folder path to a config.json file that contains the adapter configurations for all aliases included in the entity definition file and any directly or indirectly referenced CDM files. **Not required if the config.json is in the model root folder.**	<container><folderPath>
useCdmStandardModelRoot	Indicates the model root is located at https://cdm-schema.microsoft.com/CDM/logical/ Used to reference entity types defined in the CDM Content Delivery Network (CDN). Overrides: entityDefinitionStorage, entityDefinitionModelRoot if specified.	"useCdmStandardModelRoot"
cdmSource	Defines how the 'cdm' alias if present in CDM definition files is resolved. If this option is used, it overrides any *cdm* adapter specified in the config.json file. Values are "builtin" or "referenced". Default value is "referenced" If set to *referenced*, then the latest published standard CDM definitions at `https://cdm-schema.microsoft.com/logical/` are used. If set to *builtin* then the CDM base definitions built in to the CDM object model used by the Spark CDM Connector will be used. Note: 1). The Spark CDM Connector may not be using the latest CDM SDK so may not contain the latest published standard definitions. 2). The built-in definitions only include the top-level CDM content such as foundations.cdm.json, primitives.cdm.json, etc. If you wish to use lower-level standard CDM definitions, either use *referenced* or include a cdm adapter in the config.json.	"builtin"|"referenced".

In the example above, the full path to the customer entity definition object is: `https://myAccount.dfs.core.windows.net/models/crm/core/sales/customer.cdm.json/customer`, where 'models' is the container in ADLS.

Implicit write options

If a logical entity definition isn't specified on write, the entity will be written implicitly, based on the dataframe schema.

When writing implicitly, a timestamp column will normally be interpreted as a CDM DateTime datatype. This can be overridden to create an attribute of CDM Time datatype by providing a metadata object associated with the column that specifies the datatype. See Handling CDM Time data below for details.

Initially, this is supported for CSV files only. Support for writing time data to Parquet will be added in a later release.

Folder structure and data format options

Folder organization and file format can be changed with the following options.

OPTION	DESCRIPTION	PATTERN / EXAMPLE USAGE
useSubManifest	If true, causes the target entity to be included in the root manifest via a submanifest. The submanifest and the entity definition are written into an entity folder beneath the root. Default is false.	"true"|"false"
format	Defines the file format. Current supported file formats are CSV and Parquet. Default is "csv"	"csv"|"parquet"
delimiter	CSV only. Defines the delimiter used. Default is comma.	"|"
columnHeaders	CSV only. If true, will add a first row to data files with column headers. Default is "true"	"true"|"false"
compression	Write only. Parquet only. Defines the compression format used. Default is "snappy"	"uncompressed" | "snappy" | "gzip" | "lzo".
dataFolderFormat	Allows user-definable data folder structure within an entity folder. Allows the use of date and time values to be substituted into folder names using DateTimeFormatter formatting. Non-formatter content must be enclosed in single quotes. Default format is `"yyyy"-"MM"-"dd"` producing folder names like 2020-07-30	`year "yyyy" / month "MM"` `"Data"`

Save mode

The save mode specifies how existing entity data in the CDM folder is handled when writing a dataframe. Options are to overwrite, append to, or error if data already exists. The default save mode is ErrorIfExists

MODE	DESCRIPTION
SaveMode.Overwrite	Will overwrite the existing entity definition if it's changed and replace existing data partitions with the data partitions being written.

MODE	DESCRIPTION
SaveMode.Append	Will append data being written in new partitions alongside the existing partitions. Note: append doesn't support changing the schema; if the schema of the data being written is incompatible with the existing entity definition an error will be thrown.
SaveMode.ErrorIfExists	Will return an error if partitions already exist.

See *Folder and file organization* below for details of how data files are named and organized on write.

Authentication

There are three modes of authentication that can be used with the Spark CDM Connector to read/write the CDM metadata and data partitions: Credential Passthrough, SasToken, and App Registration.

Credential pass-through

In Synapse, the Spark CDM Connector supports use of Managed identities for Azure resource to mediate access to the Azure datalake storage account containing the CDM folder. A managed identity is automatically created for every Synapse workspace. The connector uses the managed identity of the workspace that contains the notebook in which the connector is called to authenticate to the storage accounts being addressed.

You must ensure the identity used is granted access to the appropriate storage accounts. Grant **Storage Blob Data Contributor** to allow the library to write to CDM folders, or **Storage Blob Data Reader** to allow only read access. In both cases, no extra connector options are required.

SAS token access control options

SaS Token Credential authentication to storage accounts is an extra option for authentication to storage. With SAS token authentication, the SaS token can be at the container or folder level. The appropriate permissions (read/write) are required – read manifest/partition only needs read level support, while write requires read and write support.

OPTION	DESCRIPTION	PATTERN AND EXAMPLE USAGE
sasToken	The sastoken to access the relative storageAccount with the correct permissions	<token>

Credential-based access control options

As an alternative to using a managed identity or a user identity, explicit credentials can be provided to enable the Spark CDM connector to access data. In Azure Active Directory, create an App Registration and then grant this App Registration access to the storage account using either of the following roles: **Storage Blob Data Contributor** to allow the library to write to CDM folders, or **Storage Blob Data Reader** to allow only read.

Once permissions are created, you can pass the app ID, app key, and tenant ID to the connector on each call to it using the options below. It's recommended to use Azure Key Vault to secure these values to ensure they aren't stored in clear text in your notebook file.

OPTION	DESCRIPTION	PATTERN AND EXAMPLE USAGE
appId	The app registration ID used to authenticate to the storage account	<guid>

OPTION	DESCRIPTION	PATTERN AND EXAMPLE USAGE
appKey	The registered app key or secret	<encrypted secret>
tenantId	The Azure Active Directory tenant ID under which the app is registered.	<guid>

Examples

The following examples all use appId, appKey and tenantId variables initialized earlier in the code based on an Azure app registration that has been given Storage Blob Data Contributor permissions on the storage for write and Storage Blob Data Reader permissions for read.

Read

This code reads the Person entity from the CDM folder with manifest in `mystorage.dfs.core.windows.net/cdmdata/contacts/root.manifest.cdm.json`.

```
val df = spark.read.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/contacts/root.manifest.cdm.json")
 .option("entity", "Person")
 .load()
```

Implicit Write – using dataframe schema only

This code writes the dataframe *df* to a CDM folder with a manifest to `mystorage.dfs.core.windows.net/cdmdata/Contacts/default.manifest.cdm.json` with an Event entity.

Event data is written as parquet files, compressed with gzip, that are appended to the folder (new files are added without deleting existing files).

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/Contacts/default.manifest.cdm.json")
 .option("entity", "Event")
 .option("format", "parquet")
 .option("compression", "gzip")
 .mode(SaveMode.Append)
 .save()
```

Explicit Write - using an entity definition stored in ADLS

This code writes the dataframe *df* to a CDM folder with manifest at `https://_mystorage_.dfs.core.windows.net/cdmdata/Contacts/root.manifest.cdm.json` with the entity Person. Person data is written as new CSV files (by default) which overwrite existing files in the folder. The Person entity definition is retrieved from `https://_mystorage_.dfs.core.windows.net/models/cdmmodels/core/Contacts/Person.cdm.json`

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/contacts/root.manifest.cdm.json")
 .option("entity", "Person")
 .option("entityDefinitionModelRoot", "cdmmodels/core")
 .option("entityDefinitionPath", "/Contacts/Person.cdm.json/Person")
 .mode(SaveMode.Overwrite)
 .save()
```

Explicit Write - using an entity defined in the CDM GitHub

This code writes the dataframe *df* to a CDM folder with the manifest at `https://_mystorage_.dfs.core.windows.net/cdmdata/Teams/root.manifest.cdm.json` and a submanifest containing the TeamMembership entity, created in a TeamMembership subdirectory. TeamMembership data is written to CSV files (the default) that overwrite any existing data files. The TeamMembership entity definition is retrieved from the CDM CDN, at: https://cdm-schema.microsoft.com/logical/core/applicationCommon/TeamMembership.cdm.json

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/Teams/root.manifest.cdm.json")
 .option("entity", "TeamMembership")
 .option("useCdmStandardModelRoot", true)
 .option("entityDefinitionPath", "core/applicationCommon/TeamMembership.cdm.json/Tea
mMembership")
 .option("useSubManifest", true)
 .mode(SaveMode.Overwrite)
 .save()
```

Other considerations

Spark to CDM datatype mapping

The following datatype mappings are applied when converting CDM to/from Spark.

SPARK	CDM
ShortType	SmallInteger
IntegerType	Integer
LongType	BigInteger
DateType	Date
Timestamp	DateTime (optionally Time, see below)
StringType	String
DoubleType	Double
DecimalType(x,y)	Decimal (x,y) (default scale and precision are 18,4)
FloatType	Float
BooleanType	Boolean

SPARK	CDM
ByteType	Byte

The CDM Binary datatype isn't supported.

Handling CDM Date, DateTime, and DateTimeOffset data

CDM Date and DateTime datatype values are handled as normal for Spark and Parquet, and in CSV are read/written in ISO 8601 format.

CDM *DateTime* datatype values are *interpreted as UTC*, and in CSV written in ISO 8601 format, for example, 2020-03-13 09:49:00Z.

CDM *DateTimeOffset* values intended for recording local time instants are handled differently in Spark and parquet from CSV. While CSV and other formats can express a local time instant as a structure, comprising a datetime and a UTC offset, formatted in CSV like, 2020-03-13 09:49:00-08:00, Parquet and Spark don't support such structures. Instead, they use a TIMESTAMP datatype that allows an instant to be recorded in UTC time (or in some unspecified time zone).

The Spark CDM connector will convert a DateTimeOffset value in CSV to a UTC timestamp. This will be persisted as a Timestamp in parquet and if subsequently persisted to CSV, the value will be serialized as a DateTimeOffset with a +00:00 offset. Importantly, there's no loss of temporal accuracy – the serialized values represent the same instant as the original values, although the offset is lost. Spark systems use their system time as the baseline and normally express time using that local time. UTC times can always be computed by applying the local system offset. For Azure systems in all regions, system time is always UTC, so all timestamp values will normally be in UTC.

As Azure system values are always UTC, when using implicit write, where a CDM definition is derived from a dataframe, timestamp columns are translated to attributes with CDM DateTime datatype, which implies a UTC time.

If it's important to persist a local time and the data will be processed in Spark or persisted in parquet, then it's recommended to use a DateTime attribute and keep the offset in a separate attribute, for example as a signed integer value representing minutes. In CDM, DateTime values are UTC, so the offset must be applied when needed to compute local time.

In most cases, persisting local time isn't important. Local times are often only required in a UI for user convenience and based on the user's time zone, so not storing a UTC time is often a better solution.

Handling CDM time data

Spark doesn't support an explicit Time datatype. An attribute with the CDM *Time* datatype is represented in a Spark dataframe as a column with a Timestamp datatype in a dataframe. When a time value is read, the timestamp in the dataframe will be initialized with the Spark epoch date 01/01/1970 plus the time value as read from the source.

When using explicit write, a timestamp column can be mapped to either a DateTime or Time attribute. If a timestamp is mapped to a Time attribute, the date portion of the timestamp is stripped off.

When using implicit write, a Timestamp column is mapped by default to a DateTime attribute. To map a timestamp column to a Time attribute, you must add a metadata object to the column in the dataframe that indicates that the timestamp should be interpreted as a time value. The code below shows how this is done in Scala.

```
val md = new MetadataBuilder().putString("dataType", "Time")
val schema = StructType(List(
StructField("ATimeColumn", TimeStampType, true, md))
```

Time value accuracy

The Spark CDM Connector supports time values in either DateTime or Time with seconds having up to six decimal places, based on the format of the data either in the file being read (CSV or Parquet) or as defined in the dataframe, enabling accuracy from single seconds to microseconds.

Folder and file naming and organization

When writing CDM folders, the default folder organization illustrated below is used.

By default, data files are written into folders created for the current date, named like '2010-07-31'. The folder structure and names can be customized using the dateFolderFormat option, described earlier.

Data file names are based on the following pattern: <entity>-<jobid>-*.<fileformat>.

The number of data partitions written can be controlled using the sparkContext.parallelize() method. The number of partitions is either determined by the number of executors in the Spark cluster or can be specified explicitly. The Scala example below creates a dataframe with two partitions.

```
val df= spark.createDataFrame(spark.sparkContext.parallelize(data, 2), schema)
```

Explicit Write (defined by a referenced entity definition)

```
+-- <CDMFolder>
     |-- default.manifest.cdm.json     << with entity ref and partition info
     +-- <Entity>
          |-- <entity>.cdm.json        << resolved physical entity definition
          |-- <data folder>
          |-- <data folder>
          +-- ...
```

Explicit Write with sub-manifest:

```
+-- <CDMFolder>
    |-- default.manifest.cdm.json       << contains reference to sub-manifest
    +-- <Entity>
         |-- <entity>.cdm.json
         |-- <entity>.manifest.cdm.json << sub-manifest with partition info
         |-- <data folder>
         |-- <data folder>
         +-- ...
```

Implicit (entity definition is derived from dataframe schema):

```
+-- <CDMFolder>
    |-- default.manifest.cdm.json
    +-- <Entity>
         |-- <entity>.cdm.json          << resolved physical entity definition
         +-- LogicalDefinition
         |   +-- <entity>.cdm.json      << logical entity definition(s)
         |-- <data folder>
         |-- <data folder>
         +-- ...
```

Implicit Write with sub-manifest:

```
+-- <CDMFolder>
    |-- default.manifest.cdm.json       << contains reference to sub-manifest
    +-- <Entity>
        |-- <entity>.cdm.json           << resolved physical entity definition
        |-- <entity>.manifest.cdm.json  << sub-manifest with reference to the entity and partition info
        +-- LogicalDefinition
        |   +-- <entity>.cdm.json       << logical entity definition(s)
        |-- <data folder>
        |-- <data folder>
        +-- ...
```

Samples

See https://github.com/Azure/spark-cdm-connector/tree/master/samples for sample code and CDM files.

Examples

The following examples all use appId, appKey and tenantId variables initialized earlier in the code based on an Azure app registration that has been given Storage Blob Data Contributor permissions on the storage for write and Storage Blob Data Reader permissions for read.

Read

This code reads the Person entity from the CDM folder with manifest in `mystorage.dfs.core.windows.net/cdmdata/contacts/root.manifest.cdm.json`.

```
val df = spark.read.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/contacts/root.manifest.cdm.json")
 .option("entity", "Person")
 .load()
```

Implicit write – using dataframe schema only

This code writes the dataframe *df* to a CDM folder with a manifest to `mystorage.dfs.core.windows.net/cdmdata/Contacts/default.manifest.cdm.json` with an Event entity.

Event data is written as Parquet files, compressed with gzip, that are appended to the folder (new files are added without deleting existing files).

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/Contacts/default.manifest.cdm.json")
 .option("entity", "Event")
 .option("format", "parquet")
 .option("compression", "gzip")
 .mode(SaveMode.Append)
 .save()
```

Explicit write - using an entity definition stored in ADLS

This code writes the dataframe *df* to a CDM folder with manifest at `https://mystorage.dfs.core.windows.net/cdmdata/Contacts/root.manifest.cdm.json` with the entity Person. Person data is written as new CSV files (by default) which overwrite existing files in the folder. The Person entity definition is retrieved from `https://mystorage.dfs.core.windows.net/models/cdmmodels/core/Contacts/Person.cdm.json`

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/contacts/root.manifest.cdm.json")
 .option("entity", "Person")
 .option("entityDefinitionModelRoot", "cdmmodels/core")
 .option("entityDefinitionPath", "/Contacts/Person.cdm.json/Person")
 .mode(SaveMode.Overwrite)
 .save()
```

Explicit write - using an entity defined in the CDM GitHub

This code writes the dataframe *df* to a CDM folder with the manifest at `https://_mystorage_.dfs.core.windows.net/cdmdata/Teams/root.manifest.cdm.json` and a submanifest containing the TeamMembership entity, created in a TeamMembership subdirectory. TeamMembership data is written to CSV files (the default) that overwrite any existing data files. The TeamMembership entity definition is retrieved from the CDM CDN, at: https://cdm-schema.microsoft.com/logical/core/applicationCommon/TeamMembership.cdm.json

```
df.write.format("com.microsoft.cdm")
 .option("storage", "mystorage.dfs.core.windows.net")
 .option("manifestPath", "cdmdata/Teams/root.manifest.cdm.json")
 .option("entity", "TeamMembership")
 .option("useCdmStandardModelRoot", true)
 .option("entityDefinitionPath", "core/applicationCommon/TeamMembership.cdm.json/Tea
mMembership")
 .option("useSubManifest", true)
 .mode(SaveMode.Overwrite)
 .save()
```

Other considerations

Spark to CDM datatype mapping

The following datatype mappings are applied when converting CDM to/from Spark.

SPARK	CDM
ShortType	SmallInteger
IntegerType	Integer
LongType	BigInteger
DateType	Date
Timestamp	DateTime (optionally Time, see below)
StringType	String
DoubleType	Double
DecimalType(x,y)	Decimal (x,y) (default scale and precision are 18,4)
FloatType	Float
BooleanType	Boolean

SPARK	CDM
ByteType	Byte

The CDM Binary datatype isn't supported.

Troubleshooting and known issues

- Ensure the decimal precision and scale of decimal data type fields used in the dataframe match the data type used in the CDM entity definition - requires precision and scale traits are defined on the data type. If the precision and scale aren't defined explicitly in CDM, the default used is Decimal(18,4). For model.json files, Decimal is assumed to be Decimal(18,4).
- Folder and file names in the options below shouldn't include spaces or special characters, such as "=": manifestPath, entityDefinitionModelRoot, entityDefinitionPath, dataFolderFormat.

Unsupported features

The following features aren't yet supported:

- Overriding a timestamp column to be interpreted as a CDM Time rather than a DateTime is initially supported for CSV files only. Support for writing Time data to Parquet will be added in a later release.
- Parquet Map type and arrays of primitive types and arrays of array types aren't currently supported by CDM so aren't supported by the Spark CDM Connector.

Next steps

You can now look at the other Apache Spark connectors:

- Apache Spark Kusto connector
- Apache Spark SQL connector

Azure Synapse Dedicated SQL Pool Connector for Apache Spark

8/19/2022 • 21 minutes to read • Edit Online

Introduction

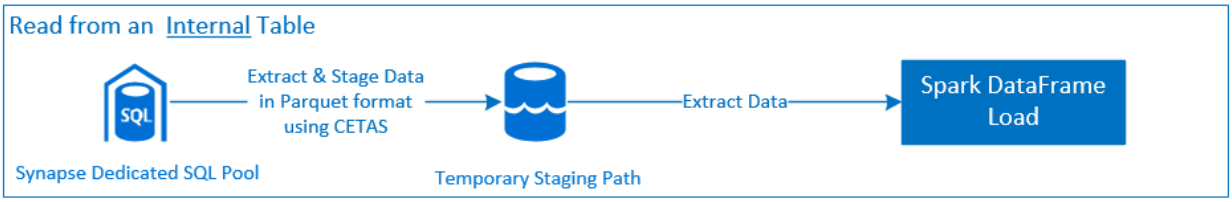
The Azure Synapse Dedicated SQL Pool Connector for Apache Spark in Azure Synapse Analytics enables efficient transfer of large data sets between the Apache Spark runtime and the Dedicated SQL pool. The connector is shipped as a default library with Azure Synapse Workspace. The connector is implemented using `Scala` language. The connector supports Scala and Python. To use the Connector with other notebook language choices, use the Spark magic command - `%%spark`.

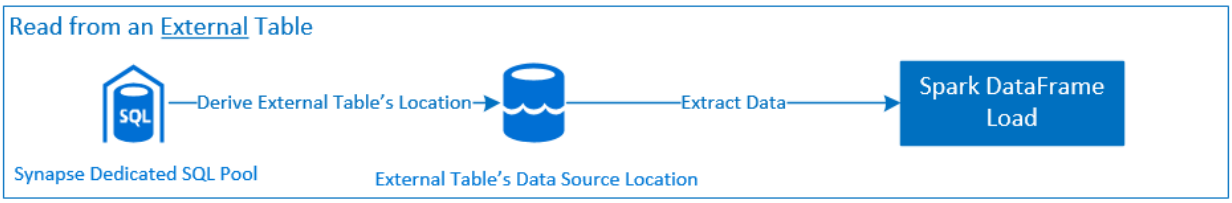
At a high-level, the connector provides the following capabilities:

- Read from Azure Synapse Dedicated SQL Pool:
  - Read large data sets from Synapse Dedicated SQL Pool Tables (Internal and External) and Views.
  - Comprehensive predicate push down support, where filters on DataFrame get mapped to corresponding SQL predicate push down.
  - Support for column pruning.
- Write to Azure Synapse Dedicated SQL Pool:
  - Ingest large volume data to Internal and External table types.
  - Supports following DataFrame save mode preferences:
    - `Append`
    - `ErrorIfExists`
    - `Ignore`
    - `Overwrite`
  - Write to External Table type supports Parquet and Delimited Text file format (example - CSV).
  - To write data to internal tables, the connector now uses COPY statement instead of CETAS/CTAS approach.
  - Enhancements to optimize end-to-end write throughput performance.
  - Introduces an optional call-back handle (a Scala function argument) that clients can use to receive post-write metrics.
    - Few examples include - number of records, duration to complete certain action, and failure reason.

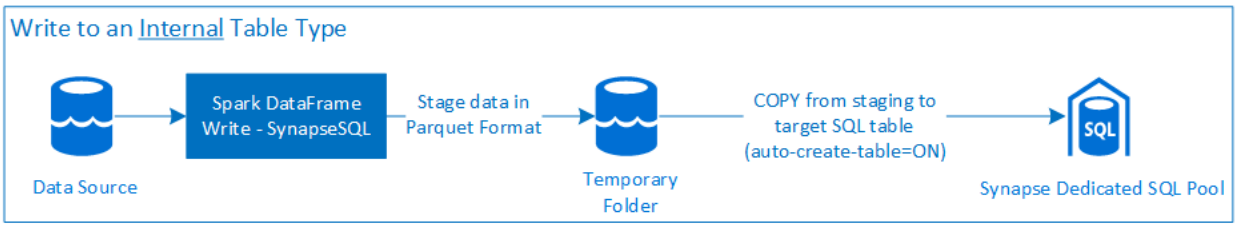
Orchestration approach

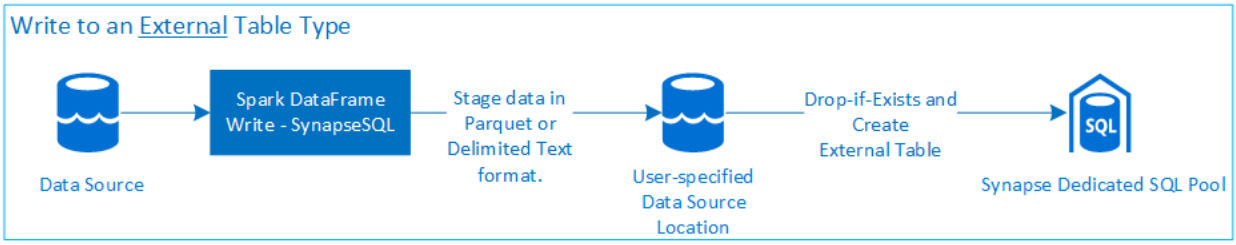
Read





Write





Pre-requisites

Pre-requisites such as setting up required Azure resources and steps to configure them are discussed in this section.

Azure resources

Review and setup following dependent Azure Resources:

- Azure Data Lake Storage - used as the primary storage account for the Azure Synapse Workspace.
- Azure Synapse Workspace - create notebooks, build and deploy DataFrame based ingress-egress workflows.
- Dedicated SQL Pool (formerly SQL DW) - provides enterprise Data Warehousing features.
- Azure Synapse Serverless Spark Pool - Spark runtime where the jobs are executed as Spark Applications.

Prepare the database

Connect to the Synapse Dedicated SQL Pool database and run following setup statements:

- Create a database user that is mapped to the Azure Active Directory User Identity used to sign in to the Azure Synapse Workspace.

```
CREATE USER [username@domain.com] FROM EXTERNAL PROVIDER;
```

- Create schema in which tables will be defined, such that the Connector can successfully write-to and read-from respective tables.

```
CREATE SCHEMA [<schema_name>];
```

Authentication

Azure Active Directory based authentication

Azure Active Directory based authentication is an integrated authentication approach. The user is required to successfully log in to the Azure Synapse Analytics Workspace.

Basic authentication

A basic authentication approach requires user to configure `username` and `password` options. Refer to the section - Configuration options to learn about relevant configuration parameters for reading from and writing to tables in Azure Synapse Dedicated SQL Pool.

Authorization

Azure Data Lake Storage Gen2

There are two ways to grant access permissions to Azure Data Lake Storage Gen2 - Storage Account:

- Role based Access Control role - Storage Blob Data Contributor role
  - Assigning the `Storage Blob Data Contributor Role` grants the User permissions to read, write and delete from the Azure Storage Blob Containers.
  - RBAC offers a coarse control approach at the container level.
- Access Control Lists (ACL)
  - ACL approach allows for fine-grained controls over specific paths and/or files under a given folder.
  - ACL checks aren't enforced if the User is already granted permissions using RBAC approach.
  - There are two broad types of ACL permissions:
    - Access Permissions (applied at a specific level or object).
    - Default Permissions (automatically applied for all child objects at the time of their creation).
  - Type of permissions include:
    - `Execute` enables ability to traverse or navigate the folder hierarchies.
    - `Read` enables ability to read.
    - `Write` enables ability to write.
  - It's important to configure ACLs such that the Connector can successfully write and read from the storage locations.

> **NOTE**
>
> - If you'd like to run notebooks using Synapse Workspace pipelines you must also grant above listed access permissions to the Synapse Workspace default managed identity. The workspace's default managed identity name is same as the name of the workspace.
> - To use the Synapse workspace with secured storage accounts, a managed private end point must be configured from the notebook. The managed private end point must be approved from the ADLS Gen2 storage account's `Private endpoint connections` section in the `Networking` pane.

Azure Synapse Dedicated SQL Pool

To enable successful interaction with Azure Synapse Dedicated SQL Pool, following authorization is necessary unless you're a user also configured as an `Active Directory Admin` on the Dedicated SQL End Point:

- Read scenario
  - Grant the user `db_exporter` using the system stored procedure `sp_addrolemember`.

```
EXEC sp_addrolemember 'db_exporter', [<your_domain_user>@<your_domain_name>.com];
```

- Write scenario
  - Connector uses the COPY command to write data from staging to the internal table's managed

location.

- Configure required permissions described here.
- Following is a quick access snippet of the same:

```
--Make sure your user has the permissions to CREATE tables in the [dbo] schema
GRANT CREATE TABLE TO [<your_domain_user>@<your_domain_name>.com];
GRANT ALTER ON SCHEMA::<target_database_schema_name> TO
[<your_domain_user>@<your_domain_name>.com];

--Make sure your user has ADMINISTER DATABASE BULK OPERATIONS permissions
GRANT ADMINISTER DATABASE BULK OPERATIONS TO
[<your_domain_user>@<your_domain_name>.com];

--Make sure your user has INSERT permissions on the target table
GRANT INSERT ON <your_table> TO [<your_domain_user>@<your_domain_name>.com]
```

API documentation

Azure Synapse Dedicated SQL Pool Connector for Apache Spark - API Documentation.

Configuration options

To successfully bootstrap and orchestrate the read or write operation, the Connector expects certain configuration parameters. The object definition - `com.microsoft.spark.sqlanalytics.utils.Constants` provides a list of standardized constants for each parameter key.

Following is the list of configuration options based on usage scenario:

- **Read using Azure AD based authentication**
  - Credentials are auto-mapped, and user isn't required to provide specific configuration options.
  - Three-part table name argument on `synapsesql` method is required to read from respective table in Azure Synapse Dedicated SQL Pool.
- **Read using basic authentication**
  - Azure Synapse Dedicated SQL End Point
    - `Constants.SERVER` - Synapse Dedicated SQL Pool End Point (Server FQDN)
    - `Constants.USER` - SQL User Name.
    - `Constants.PASSWORD` - SQL User Password.
  - Azure Data Lake Storage (Gen 2) End Point - Staging Folders
    - `Constants.DATA_SOURCE` - Storage path set on the data source location parameter is used for data staging.
- **Write using Azure AD based authentication**
  - Azure Synapse Dedicated SQL End Point
    - By default, the Connector infers the Synapse Dedicated SQL end point by using the database name set on the `synapsesql` method's three-part table name parameter.
    - Alternatively, users can use the `Constants.SERVER` option to specify the sql end point. Ensure the end point hosts the corresponding database with respective schema.
  - Azure Data Lake Storage (Gen 2) End Point - Staging Folders
    - For Internal Table Type:
      - Configure either `Constants.TEMP_FOLDER` or `Constants.DATA_SOURCE` option.
      - If user chose to provide `Constants.DATA_SOURCE` option, staging folder will be derived by using the `location` value from the DataSource.
      - If both are provided, then the `Constants.TEMP_FOLDER` option value will be used.

    - In the absence of a staging folder option, the Connector will derive one based on the runtime configuration - `spark.sqlanalyticsconnector.stagingdir.prefix`.
  - For External Table Type:
    - `Constants.DATA_SOURCE` is a required configuration option.
    - The connector uses the storage path set on the data source's location parameter in combination with the `location` argument to the `synapsesql` method and derives the absolute path to persist external table data.
    - If the `location` argument to `synapsesql` method isn't specified, then the connector will derive the location value as `<base_path>/dbName/schemaName/tableName`.
- **Write using basic authentication**
  - Azure Synapse Dedicated SQL End Point
    - `Constants.SERVER` - - Synapse Dedicated SQL Pool End Point (Server FQDN).
    - `Constants.USER` - SQL User Name.
    - `Constants.PASSWORD` - SQL User Password.
    - `Constants.STAGING_STORAGE_ACCOUNT_KEY` associated with Storage Account that hosts `Constants.TEMP_FOLDERS` (internal table types only) or `Constants.DATA_SOURCE`.
  - Azure Data Lake Storage (Gen 2) End Point - Staging Folders
    - SQL basic authentication credentials don't apply to access storage end points.
    - Hence, ensure to assign relevant storage access permissions as described in the section Azure Data Lake Storage Gen2.

Code templates

This section presents reference code templates to describe how to use and invoke the Azure Synapse Dedicated SQL Pool Connector for Apache Spark.

> **NOTE**
>
> Using the Connector in Python-
>
> - The connector is supported in Python for Spark 3 only. For Spark 2.4, we can use the Scala connector API to interact with content from a DataFrame in PySpark by using DataFrame.createOrReplaceTempView or DataFrame.createOrReplaceGlobalTempView. See Section - Using materialized data across cells.
> - The call back handle is not available in Python.

Read from Azure Synapse Dedicated SQL Pool

Read Request - `synapsesql` method signature

- Scala
- Python

```
synapsesql(tableName:String) => org.apache.spark.sql.DataFrame
```

Read using Azure AD based authentication

- Scala
- Python

```
//Use case is to read data from an internal table in Synapse Dedicated SQL Pool DB
//Azure Active Directory based authentication approach is preferred here.
import org.apache.spark.sql.DataFrame
import com.microsoft.spark.sqlanalytics.utils.Constants
import org.apache.spark.sql.SqlAnalyticsConnector._

//Read from existing internal table
val dfToReadFromTable:DataFrame = spark.read.
    //If `Constants.SERVER` is not provided, the `<database_name>` from the three-part table name argument
    //to `synapsesql` method is used to infer the Synapse Dedicated SQL End Point.
    option(Constants.SERVER, "<sql-server-name>.sql.azuresynapse.net").
    //Defaults to storage path defined in the runtime configurations
    option(Constants.TEMP_FOLDER,
"abfss://<container_name>@<storage_account_name>.dfs.core.windows.net/<some_base_path_for_temporary_staging_
folders>").
    //Three-part table name from where data will be read.
    synapsesql("<database_name>.<schema_name>.<table_name>").
    //Column-pruning i.e., query select column values.
    select("<some_column_1>", "<some_column_5>", "<some_column_n>").
    //Push-down filter criteria that gets translated to SQL Push-down Predicates.
    filter(col("Title").startsWith("E")).
    //Fetch a sample of 10 records
    limit(10)

//Show contents of the dataframe
dfToReadFromTable.show()
```

Read using basic authentication

- Scala
- Python

```
//Use case is to read data from an internal table in Synapse Dedicated SQL Pool DB
//Azure Active Directory based authentication approach is preferred here.
import org.apache.spark.sql.DataFrame
import com.microsoft.spark.sqlanalytics.utils.Constants
import org.apache.spark.sql.SqlAnalyticsConnector._

//Read from existing internal table
val dfToReadFromTable:DataFrame = spark.read.
    //If `Constants.SERVER` is not provided, the `<database_name>` from the three-part table name argument
    //to `synapsesql` method is used to infer the Synapse Dedicated SQL End Point.
    option(Constants.SERVER, "<sql-server-name>.sql.azuresynapse.net").
    //Set database user name
    option(Constants.USER, "<user_name>").
    //Set user's password to the database
    option(Constants.PASSWORD, "<user_password>").
    //Set name of the data source definition that is defined with database scoped credentials.
    //Data extracted from the SQL query will be staged to the storage path defined on the data source's
location setting.
    option(Constants.DATA_SOURCE, "<data_source_name>").
    //Three-part table name from where data will be read.
    synapsesql("<database_name>.<schema_name>.<table_name>").
    //Column-pruning i.e., query select column values.
    select("<some_column_1>", "<some_column_5>", "<some_column_n>").
    //Push-down filter criteria that gets translated to SQL Push-down Predicates.
    filter(col("Title").startsWith("E")).
    //Fetch a sample of 10 records
    limit(10)

//Show contents of the dataframe
dfToReadFromTable.show()
```

Write to Azure Synapse Dedicated SQL Pool

Write Request - `synapsesql` method signature

The method signature for the Connector version built for Spark 2.4.8 has one less argument, than that applied to the Spark 3.1.2 version. Following are the two method signatures:

- Spark Pool Version 2.4.8

```
synapsesql(tableName:String,
           tableType:String = Constants.INTERNAL,
           location:Option[String] = None):Unit
```

- Spark Pool Version 3.1.2

- Scala
- Python

```
synapsesql(tableName:String,
           tableType:String = Constants.INTERNAL,
           location:Option[String] = None,
           callBackHandle=Option[(Map[String, Any], Option[Throwable])=>Unit]):Unit
```

Write using Azure AD based authentication

Following is a comprehensive code template that describes how to use the Connector for write scenarios:

- Scala
- Python

```
//Add required imports
import org.apache.spark.sql.DataFrame
import org.apache.spark.sql.SaveMode
import com.microsoft.spark.sqlanalytics.utils.Constants
import org.apache.spark.sql.SqlAnalyticsConnector._

//Define read options for example, if reading from CSV source, configure header and delimiter options.
val
pathToInputSource="abfss://<storage_container_name>@<storage_account_name>.dfs.core.windows.net/<some_folder
>/<some_dataset>.csv"

//Define read configuration for the input CSV
val dfReadOptions:Map[String, String] = Map("header" -> "true", "delimiter" -> ",")

//Initialize DataFrame that reads CSV data from a given source
val readDF:DataFrame=spark.
            read.
            options(dfReadOptions).
            csv(pathToInputSource).
            limit(1000) //Reads first 1000 rows from the source CSV input.

//Setup and trigger the read DataFrame for write to Synapse Dedicated SQL Pool.
//Fully qualified SQL Server DNS name can be obtained using one of the following methods:
//    1. Synapse Workspace - Manage Pane - SQL Pools - <Properties view of the corresponding Dedicated SQL
Pool>
//    2. From Azure Portal, follow the bread-crumbs for <Portal_Home> -> <Resource_Group> -> <Dedicated SQL
Pool> and then go to Connection Strings/JDBC tab.
//If `Constants.SERVER` is not provided, the value will be inferred by using the `database_name` in the
three-part table name argument to the `synapsesql` method.
//Like-wise, if `Constants.TEMP_FOLDER` is not provided, the connector will use the runtime staging
directory config (see section on Configuration Options for details).
val writeOptionsWithAADAuth:Map[String, String] = Map(Constants.SERVER -> "<dedicated-pool-sql-server-
name>.sql.azuresynapse.net",
                                            Constants.TEMP_FOLDER ->
"abfss://<storage_container_name>@<storage_account_name>.dfs.core.windows.net/<some_temp_folder>")

//Setup optional callback/feedback function that can receive post write metrics of the job performed.
var errorDuringWrite:Option[Throwable] = None
val callBackFunctionToReceivePostWriteMetrics: (Map[String, Any], Option[Throwable]) => Unit =
    (feedback: Map[String, Any], errorState: Option[Throwable]) => {
    println(s"Feedback map - ${feedback.map{case(key, value) => s"$key -> $value"}.mkString("
{",",\n","}")}")
    errorDuringWrite = errorState
}

//Configure and submit the request to write to Synapse Dedicated SQL Pool (note - default SaveMode is set to
ErrorIfExists)
//Sample below is using AAD-based authentication approach; See further examples to leverage SQL Basic auth.
readDF.
    write.
    //Configure required configurations.
    options(writeOptionsWithAADAuth).
    //Choose a save mode that is apt for your use case.
    mode(SaveMode.Overwrite).
    synapsesql(tableName = "<database_name>.<schema_name>.<table_name>",
                //For external table type value is Constants.EXTERNAL
                tableType = Constants.INTERNAL,
                //Optional parameter that is used to specify external table's base folder; defaults to
`database_name/schema_name/table_name`
                location = None,
                //Optional parameter to receive a callback.
                callBackHandle = Some(callBackFunctionToReceivePostWriteMetrics))

//If write request has failed, raise an error and fail the Cell's execution.
if(errorDuringWrite.isDefined) throw errorDuringWrite.get
```

Write using basic authentication

Following code snippet replaces the write definition described in the Write using Azure AD based authentication section, to submit write request using SQL basic authentication approach:

- Scala
- Python

```
//Define write options to use SQL basic authentication
val writeOptionsWithBasicAuth:Map[String, String] = Map(Constants.SERVER -> "<dedicated-pool-sql-server-
name>.sql.azuresynapse.net",
                                        //Set database user name
                                        Constants.USER -> "<user_name>",
                                        //Set database user's password
                                        Constants.PASSWORD -> "<user_password>",
                                        //Required only when writing to an external table. For write to
internal table, this can be used instead of TEMP_FOLDER option.
                                        Constants.DATA_SOURCE -> "<Name of the datasource as defined in
the target database>"
                                        //To be used only when writing to internal tables. Storage path
will be used for data staging.
                                        Constants.TEMP_FOLDER ->
"abfss://<storage_container_name>@<storage_account_name>.dfs.core.windows.net/<some_temp_folder>")

//Configure and submit the request to write to Synapse Dedicated SQL Pool.
readDF.
    write.
    options(writeOptionsWithBasicAuth).
    //Choose a save mode that is apt for your use case.
    mode(SaveMode.Overwrite).
    synapsesql(tableName = "<database_name>.<schema_name>.<table_name>",
                //For external table type value is Constants.EXTERNAL
                tableType = Constants.INTERNAL,
                //Not required for writing to an internal table
                location = None,
                //Optional parameter.
                callBackHandle = Some(callBackFunctionToReceivePostWriteMetrics))
```

In a basic authentication approach, in order to read data from a source storage path other configuration options are required. Following code snippet provides an example to read from an Azure Data Lake Storage Gen2 data source using Service Principal credentials:

```
//Specify options that Spark runtime must support when interfacing and consuming source data
val storageAccountName="<storageAccountName>"
val storageContainerName="<storageContainerName>"
val subscriptionId="<AzureSubscriptionID>"
val spnClientId="<ServicePrincipalClientID>"
val spnSecretKeyUsedAsAuthCred="<spn_secret_key_value>"
val dfReadOptions:Map[String, String]=Map("header"->"true",
                                "delimiter"->",",
                                "fs.defaultFS" ->
s"abfss://$storageContainerName@$storageAccountName.dfs.core.windows.net",
                                s"fs.azure.account.auth.type.$storageAccountName.dfs.core.windows.net" ->
"OAuth",

s"fs.azure.account.oauth.provider.type.$storageAccountName.dfs.core.windows.net" ->
                                    "org.apache.hadoop.fs.azurebfs.oauth2.ClientCredsTokenProvider",
                                "fs.azure.account.oauth2.client.id" -> s"$spnClientId",
                                "fs.azure.account.oauth2.client.secret" -> s"$spnSecretKeyUsedAsAuthCred",
                                "fs.azure.account.oauth2.client.endpoint" ->
s"https://login.microsoftonline.com/$subscriptionId/oauth2/token",
                                "fs.AbstractFileSystem.abfss.impl" -> "org.apache.hadoop.fs.azurebfs.Abfs",
                                "fs.abfss.impl" -> "org.apache.hadoop.fs.azurebfs.SecureAzureBlobFileSystem")
//Initialize the Storage Path string, where source data is maintained/kept.
val
pathToInputSource=s"abfss://$storageContainerName@$storageAccountName.dfs.core.windows.net/<base_path_for_so
urce_data>/<specific_file (or) collection_of_files>"
//Define data frame to interface with the data source
val df:DataFrame = spark.
           read.
           options(dfReadOptions).
           csv(pathToInputSource).
           limit(100)
```

Supported DataFrame save modes

Following save modes are supported when writing source data to a destination table in Azure Synapse Dedicated SQL Pool:

- ErrorIfExists (default save mode)
  - If destination table exists, then the write is aborted with an exception returned to the callee. Else, a new table is created with data from the staging folders.
- Ignore
  - If the destination table exists, then the write will ignore the write request without returning an error. Else, a new table is created with data from the staging folders.
- Overwrite
  - If the destination table exists, then existing data in the destination is replaced with data from the staging folders. Else, a new table is created with data from the staging folders.
- Append
  - If the destination table exists, then the new data is appended to it. Else, a new table is created with data from the staging folders.

Write request callback handle

The new write path API changes introduced an experimental feature to provide the client with a key->value map of post-write metrics. Keys for the metrics are defined in the new Object definition - `Constants.FeedbackConstants`. Metrics can be retrieved as a JSON string by passing in the callback handle (a `Scala Function`). Following is the function signature:

```
//Function signature is expected to have two arguments - a `scala.collection.immutable.Map[String, Any]` and
an Option[Throwable]
//Post-write if there's a reference of this handle passed to the `synapsesql` signature, it will be invoked
by the closing process.
//These arguments will have valid objects in either Success or Failure case. In case of Failure the second
argument will be a `Some(Throwable)`.
(Map[String, Any], Option[Throwable]) => Unit
```

Following are some notable metrics (presented in camel case):

- `WriteFailureCause`
- `DataStagingSparkJobDurationInMilliseconds`
- `NumberOfRecordsStagedForSQLCommit`
- `SQLStatementExecutionDurationInMilliseconds`
- `rows_processed`

Following is a sample JSON string with post-write metrics:

```
{
 SparkApplicationId -> <spark_yarn_application_id>,
 SQLStatementExecutionDurationInMilliseconds -> 10113,
 WriteRequestReceivedAtEPOCH -> 1647523790633,
 WriteRequestProcessedAtEPOCH -> 1647523808379,
 StagingDataFileSystemCheckDurationInMilliseconds -> 60,
 command -> "COPY INTO [schema_name].[table_name] ...",
 NumberOfRecordsStagedForSQLCommit -> 100,
 DataStagingSparkJobEndedAtEPOCH -> 1647523797245,
 SchemaInferenceAssertionCompletedAtEPOCH -> 1647523790920,
 DataStagingSparkJobDurationInMilliseconds -> 5252,
 rows_processed -> 100,
 SaveModeApplied -> TRUNCATE_COPY,
 DurationInMillisecondsToValidateFileFormat -> 75,
 status -> Completed,
 SparkApplicationName -> <spark_application_name>,
 ThreePartFullyQualifiedTargetTableName -> <database_name>.<schema_name>.<table_name>,
 request_id -> <query_id_as_retrieved_from_synapse_dedicated_sql_db_query_reference>,
 StagingFolderConfigurationCheckDurationInMilliseconds -> 2,
 JDBCConfigurationsSetupAtEPOCH -> 193,
 StagingFolderConfigurationCheckCompletedAtEPOCH -> 1647523791012,
 FileFormatValidationsCompletedAtEPOCHTime -> 1647523790995,
 SchemaInferenceCheckDurationInMilliseconds -> 91,
 SaveModeRequested -> Overwrite,
 DataStagingSparkJobStartedAtEPOCH -> 1647523791993,
 DurationInMillisecondsTakenToGenerateWriteSQLStatements -> 4
}
```

More code samples

Using materialized data across cells

Spark DataFrame's `createOrReplaceTempView` can be used to access data fetched in another cell, by registering a temporary view.

- Cell where data is fetched (say with Notebook language preference as `Scala`)

```
//Necessary imports
import org.apache.spark.sql.DataFrame
import org.apache.spark.sql.SaveMode
import com.microsoft.spark.sqlanalytics.utils.Constants
import org.apache.spark.sql.SqlAnalyticsConnector._

//Configure options and read from Synapse Dedicated SQL Pool.
val readDF = spark.read.
    //Set Synapse Dedicated SQL End Point name.
    option(Constants.SERVER, "<synapse-dedicated-sql-end-point>.sql.azuresynapse.net").
    //Set database user name.
    option(Constants.USER, "<user_name>").
    //Set database user's password.
    option(Constants.PASSWORD, "<user_password>").
    //Set name of the data source definition that is defined with database scoped credentials.
    option(Constants.DATA_SOURCE,"<data_source_name>").
    //Set the three-part table name from which the read must be performed.
    synapsesql("<database_name>.<schema_name>.<table_name>").
    //Optional - specify number of records the DataFrame would read.
    limit(10)
//Register the temporary view (scope - current active Spark Session)
readDF.createOrReplaceTempView("<temporary_view_name>")
```

- Now, change the language preference on the Notebook to `PySpark (Python)` and fetch data from the registered view `<temporary_view_name>`

```
spark.sql("select * from <temporary_view_name>").show()
```

Response handling

Invoking `synapsesql` has two possible end states - Success or a Failed State. This section describes how to handle the request response for each scenario.

Read request response

Upon completion, the read response snippet is displayed in the cell's output. Failure in the current cell will also cancel subsequent cell executions. Detailed error information is available in the Spark Application Logs.

Write request response

By default, a write response is printed to the cell output. On failure, the current cell is marked as failed, and subsequent cell executions will be aborted. The other approach is to pass the callback handle option to the `synapsesql` method. The callback handle will provide programmatic access to the write response.

Other considerations

- When reading from the Azure Synapse Dedicated SQL Pool tables:
  - Consider applying necessary filters on the DataFrame to take advantage of the Connector's column-pruning feature.
  - Read scenario doesn't support the `TOP(n-rows)` clause, when framing the `SELECT` query statements. The choice to limit data is to use the DataFrame's limit(.) clause.
    - Refer the example - Using materialized data across cells section.
- When writing to the Azure Synapse Dedicated SQL Pool tables:
  - For internal table types:
    - Tables are created with ROUND_ROBIN data distribution.
    - Column types are inferred from the DataFrame that would read data from source. String columns are mapped to `NVARCHAR(4000)`.
  - For external table types:
    - DataFrame's initial parallelism drives the data organization for the external table.

    - Column types are inferred from the DataFrame that would read data from source.
  - Better data distribution across executors can be achieved by tuning the `spark.sql.files.maxPartitionBytes` and the DataFrame's `repartition` parameter.
  - When writing large data sets, it's important to factor in the impact of DWU Performance Level setting that limits transaction size.
- Monitor Azure Data Lake Storage Gen2 utilization trends to spot throttling behaviors that can impact read and write performance.

Azure SQL Database and SQL Server connector for Apache Spark

8/19/2022 • 2 minutes to read • Edit Online

The Apache Spark connector for Azure SQL Database and SQL Server enables these databases to act as input data sources and output data sinks for Apache Spark jobs. It allows you to use real-time transactional data in big data analytics and persist results for ad-hoc queries or reporting.

Compared to the built-in JDBC connector, this connector provides the ability to bulk insert data into SQL databases. It can outperform row-by-row insertion with 10x to 20x faster performance. The Spark connector for SQL Server and Azure SQL Database also supports Azure Active Directory (Azure AD) authentication, enabling you to connect securely to your Azure SQL databases from Azure Synapse Analytics.

This article covers how to use the DataFrame API to connect to SQL databases using the MS SQL connector. This article provides detailed examples using the PySpark API. For all of the supported arguments and samples for connecting to SQL databases using the MS SQL connector, see Azure Data SQL samples.

Connection details

In this example, we will use the Microsoft Spark utilities to facilitate acquiring secrets from a pre-configured Key Vault. To learn more about Microsoft Spark utilities, please visit introduction to Microsoft Spark Utilities.

```
servername = "<< server name >>"
dbname = "<< database name >>"
url = servername + ";" + "databaseName=" + dbname + ";"
dbtable = "<< table name >> "
user = "<< username >>"
password = mssparkutils.credentials.getSecret('azure key vault name','secret name')
```

NOTE

Currently, there is no linked service or AAD pass-through support with the Azure SQL connector.

Use the Azure SQL and SQL Server connector

Read data

```
#Read from SQL table using MS SQL Connector
print("read data from SQL server table  ")
jdbcDF = spark.read \
        .format("com.microsoft.sqlserver.jdbc.spark") \
        .option("url", url) \
        .option("dbtable", dbtable) \
        .option("user", user) \
        .option("password", password).load()

jdbcDF.show(5)
```

Write data

```
try:
  df.write \
    .format("com.microsoft.sqlserver.jdbc.spark") \
    .mode("overwrite") \
    .option("url", url) \
    .option("dbtable", dbtable) \
    .option("user", user) \
    .option("password", password) \
    .save()
except ValueError as error :
    print("MSSQL Connector write failed", error)

print("MSSQL Connector write(overwrite) succeeded  ")
```

Append data

```
try:
  df.write \
    .format("com.microsoft.sqlserver.jdbc.spark") \
    .mode("append") \
    .option("url", url) \
    .option("dbtable", table_name) \
    .option("user", username) \
    .option("password", password) \
    .save()
except ValueError as error :
    print("Connector write failed", error)
```

Azure Active Directory authentication

Python example with service principal

```
import adal

# Located in App Registrations from Azure Portal
tenant_id = "<< tenant id >> "

# Located in App Registrations from Azure Portal
resource_app_id_url = "https://database.windows.net/"

# Authority
authority = "https://login.windows.net/" + tenant_id

context = adal.AuthenticationContext(authority)
token = context.acquire_token_with_client_credentials(resource_app_id_url, service_principal_id,
service_principal_secret)
access_token = token["accessToken"]

jdbc_df = spark.read \
        .format("com.microsoft.sqlserver.jdbc.spark") \
        .option("url", url) \
        .option("dbtable", dbtable) \
        .option("accessToken", access_token) \
        .option("encrypt", "true") \
        .option("hostNameInCertificate", "*.database.windows.net") \
        .load()
```

Python example with Active Directory password

```
jdbc_df = spark.read \
        .format("com.microsoft.sqlserver.jdbc.spark") \
        .option("url", url) \
        .option("dbtable", table_name) \
        .option("authentication", "ActiveDirectoryPassword") \
        .option("user", user_name) \
        .option("password", password) \
        .option("encrypt", "true") \
        .option("hostNameInCertificate", "*.database.windows.net") \
        .load()
```

Use external Hive Metastore for Synapse Spark Pool

8/19/2022 • 8 minutes to read • Edit Online

Azure Synapse Analytics allows Apache Spark pools in the same workspace to share a managed HMS (Hive Metastore) compatible metastore as their catalog. When customers want to persist the Hive catalog metadata outside of the workspace, and share catalog objects with other computational engines outside of the workspace, such as HDInsight and Azure Databricks, they can connect to an external Hive Metastore. In this article, you can learn how to connect Synapse Spark to an external Apache Hive Metastore.

Supported Hive Metastore versions

The feature works with both Spark 2.4 and Spark 3.1. The following table shows the supported Hive Metastore versions for each Spark version.

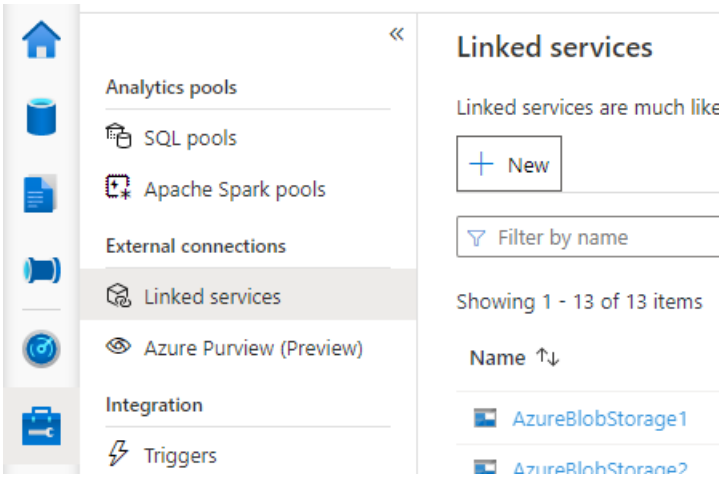
SPARK VERSION	HMS 0.13.X	HMS 1.2.X	HMS 2.1.X	HMS 2.3.X	HMS 3.1.X
2.4	Yes	Yes	Yes	Yes	No
3.1	Yes	Yes	Yes	Yes	Yes

Set up linked service to Hive Metastore

> **NOTE**
> Only Azure SQL Database and Azure Database for MySQL are supported as an external Hive Metastore. And currently we only support User-Password authentication. If the provided database is blank, please provision it via Hive Schema Tool to create database schema.

Follow below steps to set up a linked service to the external Hive Metastore in Synapse workspace.

1. Open Synapse Studio, go to **Manage** > **Linked services** at left, click **New** to create a new linked service.



2. Choose **Azure SQL Database** or **Azure Database for MySQL** based on your database type, click **Continue**.

3. Provide **Name** of the linked service. Record the name of the linked service, this info will be used to

configure Spark shortly.

4. You can either select **Azure SQL Database/Azure Database for MySQL** for the external Hive Metastore from Azure subscription list, or enter the info manually.
5. Provide **User name** and **Password** to set up the connection.
6. **Test connection** to verify the username and password.
7. Click **Create** to create the linked service.

Test connection and get the metastore version in notebook

Some network security rule settings may block access from Spark pool to the external Hive Metastore DB. Before you configure the Spark pool, run below code in any Spark pool notebook to test connection to the external Hive Metastore DB.

You can also get your Hive Metastore version from the output results. The Hive Metastore version will be used in the Spark configuration.

Connection testing code for Azure SQL

```
%%spark
import java.sql.DriverManager
/** this JDBC url could be copied from Azure portal > Azure SQL database > Connection strings > JDBC **/
val url = s"jdbc:sqlserver://{your_servername_here}.database.windows.net:1433;database=
{your_database_here};user={your_username_here};password=
{your_password_here};encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;
loginTimeout=30;"
try {
    val connection = DriverManager.getConnection(url)
    val result = connection.createStatement().executeQuery("select t.SCHEMA_VERSION from VERSION t")
    result.next();
    println(s"Successful to test connection. Hive Metastore version is ${result.getString(1)}")
} catch {
    case ex: Throwable => println(s"Failed to establish connection:\n $ex")
}
```

Connection testing code for Azure Database for MySQL

```
%%spark
import java.sql.DriverManager
/** this JDBC url could be copied from Azure portal > Azure Database for MySQL > Connection strings > JDBC
**/
val url = s"jdbc:mysql://{your_servername_here}.mysql.database.azure.com:3306/{your_database_here}?
useSSL=true"
try {
    val connection = DriverManager.getConnection(url, "{your_username_here}", "{your_password_here}");
    val result = connection.createStatement().executeQuery("select t.SCHEMA_VERSION from VERSION t")
    result.next();
    println(s"Successful to test connection. Hive Metastore version is ${result.getString(1)}")
} catch {
    case ex: Throwable => println(s"Failed to establish connection:\n $ex")
}
```

Configure Spark to use the external Hive Metastore

After creating the linked service to the external Hive Metastore successfully, you need to setup a few Spark configurations to use the external Hive Metastore. You can both set up the configuration at Spark pool level, or at Spark session level.

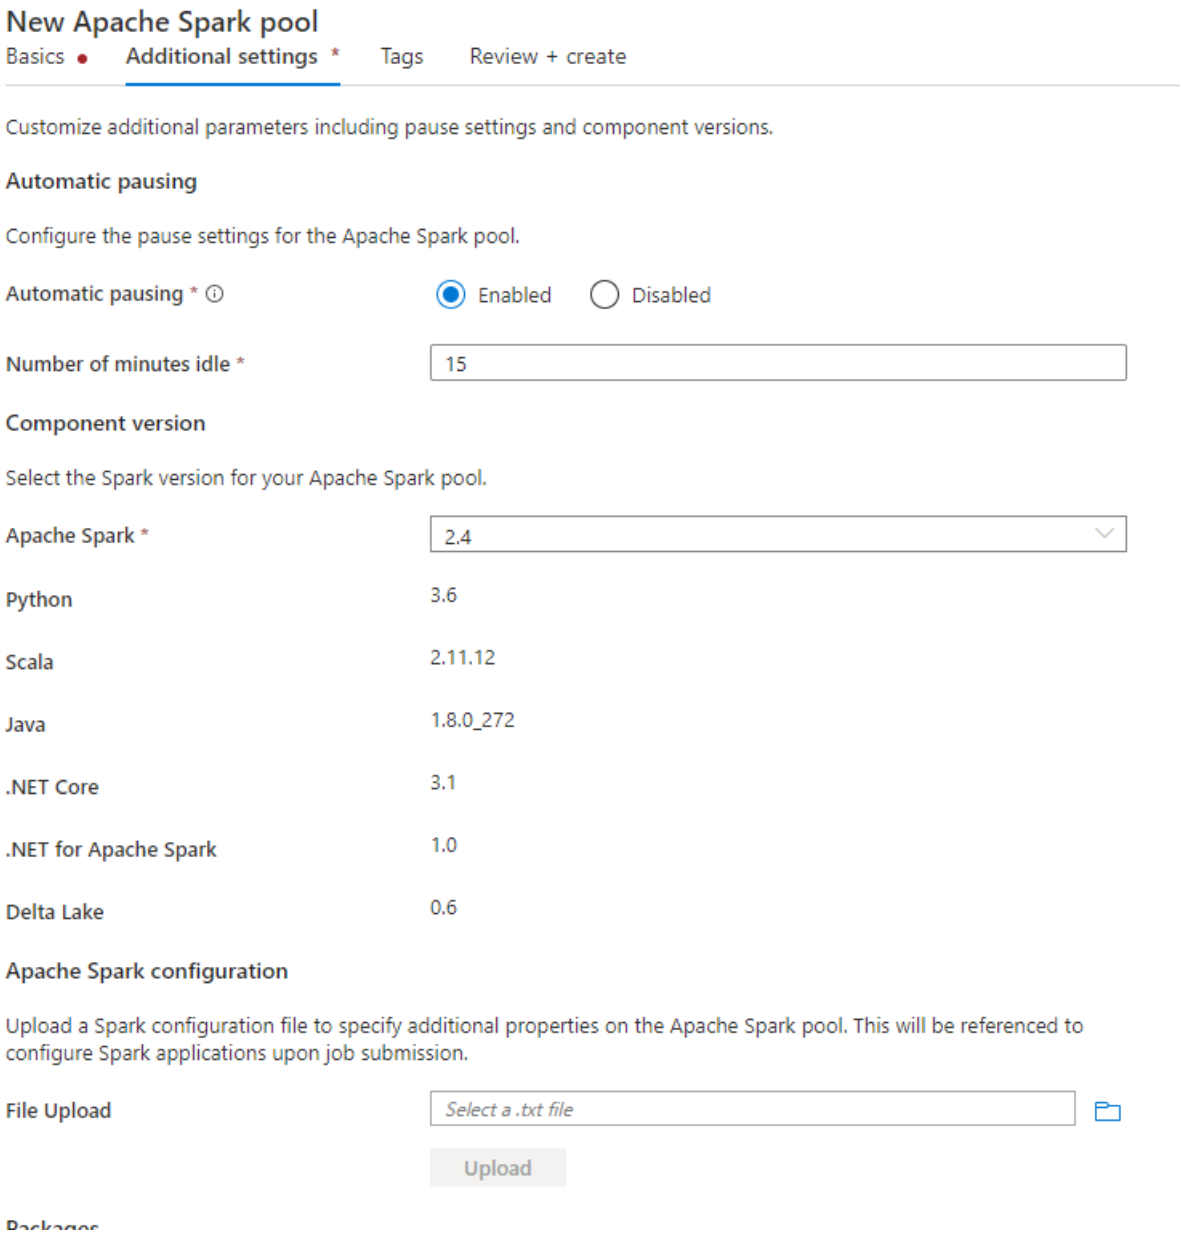
Here are the configurations and descriptions:

> **NOTE**
>
> Synapse aims to work smoothly with computes from HDI. However HMS 3.1 in HDI 4.0 is not fully compatible with the OSS HMS 3.1. For OSS HMS 3.1, please check here.

SPARK CONFIG	DESCRIPTION
`spark.sql.hive.metastore.version`	Supported versions: • `0.13` • `1.2` • `2.1` • `2.3` • `3.1` Make sure you use the first 2 parts without the 3rd part
`spark.sql.hive.metastore.jars`	• Version 0.13: `/opt/hive-metastore/lib-0.13/*:/usr/hdp/current/hadoop-client/lib/*` • Version 1.2: `/opt/hive-metastore/lib-1.2/*:/usr/hdp/current/hadoop-client/lib/*` • Version 2.1: `/opt/hive-metastore/lib-2.1/*:/usr/hdp/current/hadoop-client/lib/*` • Version 2.3: `/opt/hive-metastore/lib-2.3/*:/usr/hdp/current/hadoop-client/lib/*` • Version 3.1: `/opt/hive-metastore/lib-3.1/*:/usr/hdp/current/hadoop-client/lib/*`
`spark.hadoop.hive.synapse.externalmetastore.linkedservice.name`	Name of your linked service

Configure at Spark pool level

When creating the Spark pool, under **Additional Settings** tab, put below configurations in a text file and upload it in **Apache Spark configuration** section. You can also use the context menu for an existing Spark pool, choose Apache Spark configuration to add these configurations.



Update metastore version and linked service name, and save below configs in a text file for Spark pool configuration:

```
spark.sql.hive.metastore.version <your hms version, Make sure you use the first 2 parts without the 3rd part>
spark.hadoop.hive.synapse.externalmetastore.linkedservice.name <your linked service name>
spark.sql.hive.metastore.jars /opt/hive-metastore/lib-<your hms version, 2 parts>/*:/usr/hdp/current/hadoop-client/lib/*
```

Here is an example for metastore version 2.1 with linked service named as HiveCatalog21:

```
spark.sql.hive.metastore.version 2.1
spark.hadoop.hive.synapse.externalmetastore.linkedservice.name HiveCatalog21
spark.sql.hive.metastore.jars /opt/hive-metastore/lib-2.1/*:/usr/hdp/current/hadoop-client/lib/*
```

Configure at Spark session level

For notebook session, you can also configure the Spark session in notebook using `%%configure` magic command. Here is the code.

```
%%configure -f
{
    "conf":{
        "spark.sql.hive.metastore.version":"<your hms version, 2 parts>",
        "spark.hadoop.hive.synapse.externalmetastore.linkedservice.name":"<your linked service name>",
        "spark.sql.hive.metastore.jars":"/opt/hive-metastore/lib-<your hms version, 2
parts>/*:/usr/hdp/current/hadoop-client/lib/*"
    }
}
```

For batch job, same configuration can also be applied via `SparkConf`.

Run queries to verify the connection

After all these settings, try listing catalog objects by running below query in Spark notebook to check the connectivity to the external Hive Metastore.

```
spark.sql("show databases").show()
```

Set up storage connection

The linked service to Hive Metastore database just provides access to Hive catalog metadata. To query the existing tables, you need to set up connection to the storage account that stores the underlying data for your Hive tables as well.

Set up connection to Azure Data Lake Storage Gen 2

Workspace primary storage account

If the underlying data of your Hive tables is stored in the workspace primary storage account, you don't need to do extra settings. It will just work as long as you followed storage setting up instructions during workspace creation.

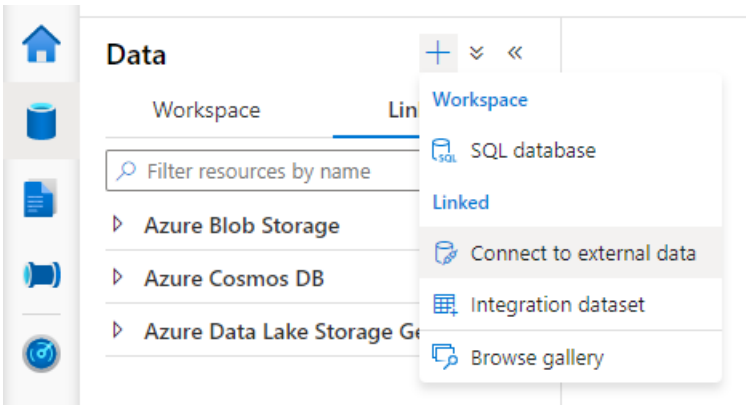
Other ADLS Gen 2 account

If the underlying data of your Hive catalogs is stored in another ADLS Gen 2 account, you need to make sure the users who run Spark queries have **Storage Blob Data Contributor** role on the ADLS Gen2 storage account.

Set up connection to Blob Storage

If the underlying data of your Hive tables are stored in Azure Blob storage account, set up the connection follow below steps:

1. Open Synapse Studio, go to **Data** > **Linked tab** > **Add** button > **Connect to external data**.



2. Choose **Azure Blob Storage** and click **Continue**.
3. Provide **Name** of the linked service. Record the name of the linked service, this info will be used in Spark configuration shortly.

4. Select the Azure Blob Storage account. Make sure Authentication method is **Account key**. Currently Spark pool can only access Blob Storage account via account key.
5. **Test connection** and click **Create**.
6. After creating the linked service to Blob Storage account, when you run Spark queries, make sure you run below Spark code in the notebook to get access to the the Blob Storage account for the Spark session. Learn more about why you need to do this here.

```
%%pyspark
blob_account_name = "<your blob storage account name>"
blob_container_name = "<your container name>"
from pyspark.sql import SparkSession
sc = SparkSession.builder.getOrCreate()
token_library = sc._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
blob_sas_token = token_library.getConnectionString("<blob storage linked service name>")
spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name, blob_account_name),
blob_sas_token)
```

After setting up storage connections, you can query the existing tables in the Hive Metastore.

Known limitations

- Synapse Studio object explorer will continue to show objects in managed Synapse metastore instead of the external HMS.
- SQL <-> Spark synchronization doesn't work when using external HMS.
- Only Azure SQL Database and Azure Database for MySQL are supported as external Hive Metastore database. Only SQL authorization is supported.
- Currently Spark only works on external Hive tables and non-transactional/non-ACID managed Hive tables. It doesn't support Hive ACID/transactional tables.
- Apache Ranger integration is not supported.

Troubleshooting

See below error when querying a Hive table with data stored in Blob Storage

```
No credentials found for account xxxxx.blob.core.windows.net in the configuration, and its container xxxxx
is not accessible using anonymous credentials. Please check if the container exists first. If it is not
publicly available, you have to provide account credentials.
```

When use key authentication to your storage account via linked service, you need to take an extra step to get the token for Spark session. Run below code to configure your Spark session before running the query. Learn more about why you need to do this here.

```
%%pyspark
blob_account_name = "<your blob storage account name>"
blob_container_name = "<your container name>"
from pyspark.sql import SparkSession
sc = SparkSession.builder.getOrCreate()
token_library = sc._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
blob_sas_token = token_library.getConnectionString("<blob storage linked service name>")
spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name, blob_account_name),
blob_sas_token)
```

See below error when query a table stored in ADLS Gen2 account

```
Operation failed: "This request is not authorized to perform this operation using this permission.", 403,
HEAD
```

This could happen because the user who runs Spark query doesn't have enough access to the underlying storage account. Make sure the user who runs Spark queries has **Storage Blob Data Contributor** role on the ADLS Gen2 storage account. This step can be done after creating the linked service.

HMS schema related settings

To avoid changing HMS backend schema/version, following hive configs are set by system by default:

```
spark.hadoop.hive.metastore.schema.verification true
spark.hadoop.hive.metastore.schema.verification.record.version false
spark.hadoop.datanucleus.fixedDatastore true
spark.hadoop.datanucleus.schema.autoCreateAll false
```

If your HMS version is `1.2.1` or `1.2.2`, there's an issue in Hive that claims requiring only `1.2.0` if you turn `spark.hadoop.hive.metastore.schema.verification` to `true`. Our suggestion is either you can modify your HMS version to `1.2.0`, or overwrite below two configurations to work around:

```
spark.hadoop.hive.metastore.schema.verification false
spark.hadoop.hive.synapse.externalmetastore.schema.usedefault false
```

If you need to migrate your HMS version, we recommend using hive schema tool. And if the HMS has been used by HDInsight clusters, we suggest using HDI provided version.

HMS schema change for OSS HMS 3.1

Synapse aims to work smoothly with computes from HDI. However HMS 3.1 in HDI 4.0 is not fully compatible with the OSS HMS 3.1. So please apply the following manually to your HMS 3.1 if it's not provisioned by HDI.

```
-- HIVE-19416
ALTER TABLE TBLS ADD WRITE_ID bigint NOT NULL DEFAULT(0);
ALTER TABLE PARTITIONS ADD WRITE_ID bigint NOT NULL DEFAULT(0);
```

When sharing the metastore with HDInsight 4.0 Spark cluster, I cannot see the tables

If you want to share the Hive catalog with a spark cluster in HDInsight 4.0, please ensure your property `spark.hadoop.metastore.catalog.default` in Synapse spark aligns with the value in HDInsight spark. The default value for HDI spark is `spark` and the default value for Synapse spark is `hive`.

When sharing the Hive Metastore with HDInsight 4.0 Hive cluster, I can list the tables successfully, but only get empty result when I query the table

As mentioned in the limitations, Synapse Spark pool only supports external hive tables and non-transactional/ACID managed tables, it doesn't support Hive ACID/transactional tables currently. In HDInsight 4.0 Hive clusters, all managed tables are created as ACID/transactional tables by default, that's why you get empty results when querying those tables.

What is Azure Synapse Link for Azure Cosmos DB?

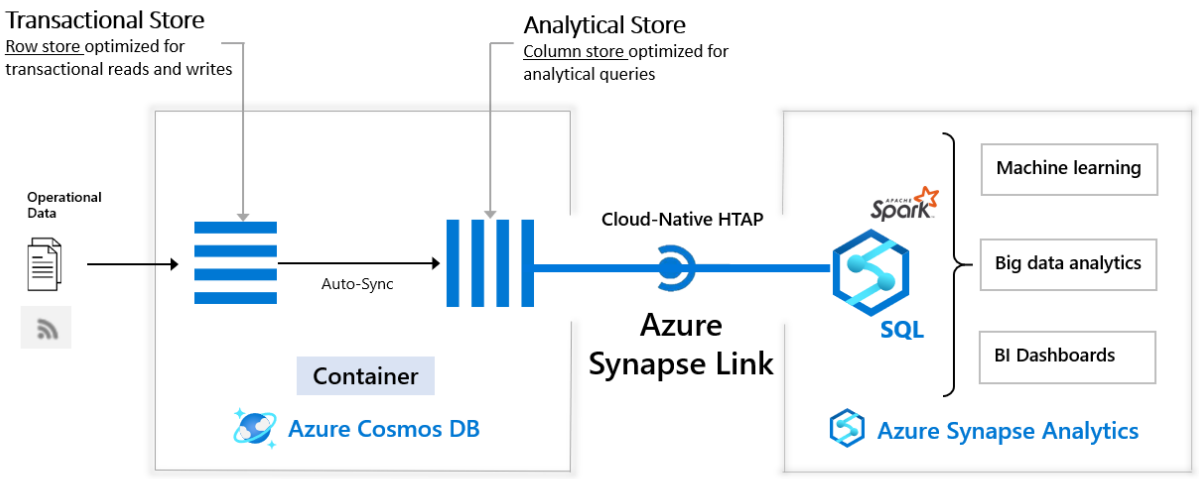
8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: SQL API Azure Cosmos DB API for MongoDB

Azure Synapse Link for Azure Cosmos DB is a cloud-native hybrid transactional and analytical processing (HTAP) capability that enables near real time analytics over operational data in Azure Cosmos DB. Azure Synapse Link creates a tight seamless integration between Azure Cosmos DB and Azure Synapse Analytics.

Using Azure Cosmos DB analytical store, a fully isolated column store, Azure Synapse Link enables no Extract-Transform-Load (ETL) analytics in Azure Synapse Analytics against your operational data at scale. Business analysts, data engineers, and data scientists can now use Synapse Spark or Synapse SQL interchangeably to run near real time business intelligence, analytics, and machine learning pipelines. You can achieve this without impacting the performance of your transactional workloads on Azure Cosmos DB.

The following image shows the Azure Synapse Link integration with Azure Cosmos DB and Azure Synapse Analytics:



Benefits

To analyze large operational datasets while minimizing the impact on the performance of mission-critical transactional workloads, traditionally, the operational data in Azure Cosmos DB is extracted and processed by Extract-Transform-Load (ETL) pipelines. ETL pipelines require many layers of data movement resulting in much operational complexity, and performance impact on your transactional workloads. It also increases the latency to analyze the operational data from the time of origin.

When compared to the traditional ETL-based solutions, Azure Synapse Link for Azure Cosmos DB offers several advantages such as:

Reduced complexity with No ETL jobs to manage

Azure Synapse Link allows you to directly access Azure Cosmos DB analytical store using Azure Synapse Analytics without complex data movement. Any updates made to the operational data are visible in the analytical store in near real-time with no ETL or change feed jobs. You can run large-scale analytics against analytical store, from Azure Synapse Analytics, without additional data transformation.

Near real-time insights into your operational data

You can now get rich insights on your operational data in near real-time, using Azure Synapse Link. ETL-based systems tend to have higher latency for analyzing your operational data, due to many layers needed to extract, transform, and load the operational data. With native integration of Azure Cosmos DB analytical store with Azure Synapse Analytics, you can analyze operational data in near real-time enabling new business scenarios.

No impact on operational workloads

With Azure Synapse Link, you can run analytical queries against an Azure Cosmos DB analytical store, a column store representation of you data, while the transactional operations are processed using provisioned throughput for the transactional workload, over the Cosmos DB row-based transactional store. The analytical workload is independent of the transactional workload traffic, not consuming any of the provisioned throughput of your operational data.

Optimized for large-scale analytics workloads

Azure Cosmos DB analytical store is optimized to provide scalability, elasticity, and performance for analytical workloads without any dependency on the compute run-times. The storage technology is self-managed to optimize your analytics workloads. With built-in support into Azure Synapse Analytics, accessing this storage layer provides simplicity and high performance.

Cost-effective

With Azure Synapse Link, you can get a cost-optimized, fully managed solution for operational analytics. It eliminates extra storage and compute layers required in traditional ETL pipelines for analyzing operational data.

Azure Cosmos DB analytical store follows a consumption-based pricing model, which is based on data storage and analytical read/write operations and queries executed. It doesn't require you to provision any throughput, as you do today for the transactional workloads. Accessing your data with highly elastic compute engines from Azure Synapse Analytics makes the overall cost of running storage and compute very efficient.

Analytics for locally available, globally distributed, multi-region writes

You can run analytical queries effectively against the nearest regional copy of the data in Azure Cosmos DB. Azure Cosmos DB provides the state-of-the-art capability to run the globally distributed analytical workloads along with transactional workloads in an active-active manner.

Enable HTAP scenarios for your operational data

Synapse Link brings together Azure Cosmos DB analytical store with Azure Synapse Analytics runtime support. This integration enables you to build cloud native HTAP (Hybrid transactional/analytical processing) solutions that generate insights based on real-time updates to your operational data over large datasets. It unlocks new business scenarios to raise alerts based on live trends, build near real-time dashboards, and business experiences based on user behavior.

Azure Cosmos DB analytical store

Azure Cosmos DB analytical store is a column-oriented representation of your operational data in Azure Cosmos DB. This analytical store is suitable for fast, cost-effective queries on large operational data sets, without copying data and impacting the performance of your transactional workloads.

Analytical store automatically picks up high frequency inserts, updates, deletes in your transactional workloads in near real-time, as a fully managed capability ("auto-sync") of Azure Cosmos DB. No change feed or ETL is required.

If you have a globally distributed Azure Cosmos DB account, after you enable analytical store for a container, it will be available in all regions for that account. For more information on the analytical store, see Azure Cosmos DB Analytical store overview article.

Integration with Azure Synapse Analytics

With Synapse Link, you can now directly connect to your Azure Cosmos DB containers from Azure Synapse

Analytics and access the analytical store with no separate connectors. Azure Synapse Analytics currently supports Synapse Link with Synapse Apache Spark and serverless SQL pool.

You can query the data from Azure Cosmos DB analytical store simultaneously, with interop across different analytics run times supported by Azure Synapse Analytics. No additional data transformations are required to analyze the operational data. You can query and analyze the analytical store data using:

- Synapse Apache Spark with full support for Scala, Python, SparkSQL, and C#. Synapse Spark is central to data engineering and data science scenarios
- Serverless SQL pool with T-SQL language and support for familiar BI tools (for example, Power BI Premium, etc.)

> **NOTE**
> From Azure Synapse Analytics, you can access both analytical and transactional stores in your Azure Cosmos DB container. However, if you want to run large-scale analytics or scans on your operational data, we recommend that you use analytical store to avoid performance impact on transactional workloads.

> **NOTE**
> You can run analytics with low latency in an Azure region by connecting your Azure Cosmos DB container to Synapse runtime in that region.

This integration enables the following HTAP scenarios for different users:

- A BI Engineer, who wants to model and publish a Power BI report to access the live operational data in Azure Cosmos DB directly through Synapse SQL.
- A Data Analyst, who wants to derive insights from the operational data in an Azure Cosmos DB container by querying it with Synapse SQL, read the data at scale and combine those findings with other data sources.
- A Data Scientist, who wants to use Synapse Spark to find a feature to improve their model and train that model without doing complex data engineering. They can also write the results of the model post inference into Azure Cosmos DB for real-time scoring on the data through Spark Synapse.
- A Data Engineer, who wants to make data accessible for consumers, by creating SQL or Spark tables over Azure Cosmos DB containers, without manual ETL processes.

For more information on Azure Synapse Analytics runtime support for Azure Cosmos DB, see Azure Synapse Analytics for Cosmos DB support.

When to use Azure Synapse Link for Azure Cosmos DB?

Synapse Link is recommended in the following cases:

- If you're an Azure Cosmos DB customer and you want to run analytics, BI, and machine learning over your operational data. In such cases, Synapse Link provides a more integrated analytics experience without impacting your transactional store's provisioned throughput. For example:
  - If you're running analytics or BI on your Azure Cosmos DB operational data directly using separate connectors today, or
  - If you're running ETL processes to extract operational data into a separate analytics system.

In such cases, Synapse Link provides a more integrated analytics experience without impacting your

transactional store's provisioned throughput.

Synapse Link isn't recommended if you're looking for traditional data warehouse requirements such as high concurrency, workload management, and persistence of aggregates across multiple data sources. For more information, see common scenarios that can be powered with Azure Synapse Link for Azure Cosmos DB.

Limitations

- Azure Synapse Link for Azure Cosmos DB is not supported for Gremlin API, Cassandra API, and Table API. It is supported for SQL API and API for Mongo DB.
- Accessing the Azure Cosmos DB analytics store with Azure Synapse Dedicated SQL Pool currently isn't supported.
- Enabling Synapse Link on existing Cosmos DB containers is only supported for SQL API accounts. Synapse Link can be enabled on new containers for both SQL API and MongoDB API accounts.
- Although analytical store data is not backed up, and therefore cannot be restored, you can rebuild your analytical store by reenabling Synapse Link in the restored container. Click here for more information.
- Currently Synapse Link isn't fully compatible with continuous backup mode. Click here for more information.
- Granular Role-based Access (RBAC)s isn't supported when querying from Synapse. Users that have access to your Synapse workspace and have access to the Cosmos DB account can access all containers within that account. We currently don't support more granular access to the containers.
- Currently Azure Synapse Workspaces don't support linked services using `Managed Identity`. Always use the `MasterKey` option.

Security

Synapse Link enables you to run near real-time analytics over your mission-critical data in Azure Cosmos DB. It is vital to make sure that critical business data is stored securely across both transactional and analytical stores. Azure Synapse Link for Azure Cosmos DB is designed to help meet these security requirements through the following features:

- **Network isolation using private endpoints** - You can control network access to the data in the transactional and analytical stores independently. Network isolation is done using separate managed private endpoints for each store, within managed virtual networks in Azure Synapse workspaces. To learn more, see how to Configure private endpoints for analytical store article.
- **Data encryption with customer-managed keys** - You can seamlessly encrypt the data across transactional and analytical stores using the same customer-managed keys in an automatic and transparent manner. Azure Synapse Link only supports configuring customer-managed keys using your Azure Cosmos DB account's managed identity. You must configure your account's managed identity in your Azure Key Vault access policy before enabling Azure Synapse Link on your account. To learn more, see how to Configure customer-managed keys using Azure Cosmos DB accounts' managed identities article.
- **Secure key management** - Accessing the data in analytical store from Synapse Spark and Synapse serverless SQL pools requires managing Azure Cosmos DB keys within Synapse Analytics workspaces. Instead of using the Azure Cosmos DB account keys inline in Spark jobs or SQL scripts, Azure Synapse Link provides more secure capabilities:
  - When using Synapse serverless SQL pools, you can query the Azure Cosmos DB analytical store by pre-creating SQL credentials storing the account keys and referencing these in the `OPENROWSET`

function. To learn more, see Query with a serverless SQL pool in Azure Synapse Link article.

- When using Synapse Spark, you can store the account keys in linked service objects pointing to an Azure Cosmos DB database and reference this in the Spark configuration at runtime. To learn more, see Copy data into a dedicated SQL pool using Apache Spark article.

Pricing

The billing model of Azure Synapse Link includes the costs incurred by using the Azure Cosmos DB analytical store and the Synapse runtime. To learn more, see the Azure Cosmos DB analytical store pricing and Azure Synapse Analytics pricing articles.

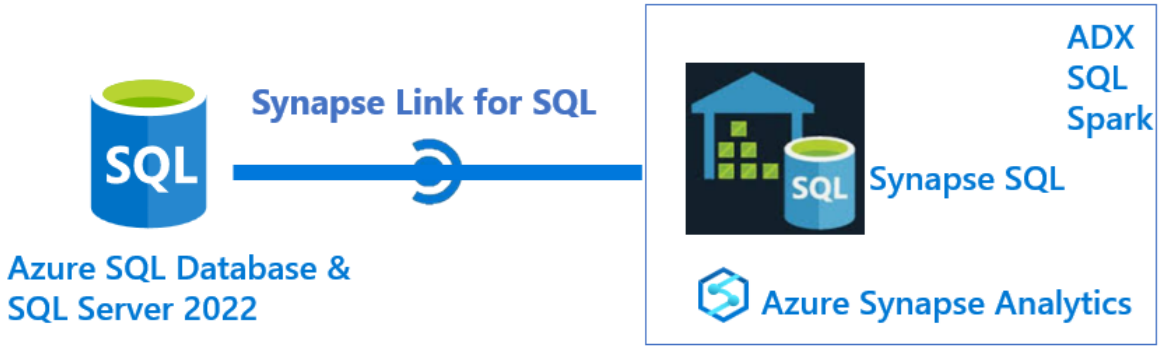
What is Azure Synapse Link for SQL? (Preview)

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Link for SQL enables near real time analytics over operational data in Azure SQL Database or SQL Server 2022. With a seamless integration between operational stores including Azure SQL Database and SQL Server 2022 and Azure Synapse Analytics, Azure Synapse Link for SQL enables you to run analytics, business intelligence and machine learning scenarios on your operational data with minimum impact on source databases with a new change feed technology.

> **IMPORTANT**
>
> Azure Synapse Link for Azure SQL is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

The following image shows the Azure Synapse Link integration with Azure SQL DB, SQL Server 2022, and Azure Synapse Analytics:



Benefit

Azure Synapse Link for SQL provides fully managed and turnkey experience for you to land operational data in Azure Synapse Analytics dedicated SQL pools. It does this by continuously replicating the data from Azure SQL Database or SQL Server 2022 with full consistency. By using Azure Synapse Link for SQL, you can get the following benefits:

- **Minimum impact on operational workload** With the new change feed technology in Azure SQL Database and SQL Server 2022, Azure Synapse Link for SQL can automatically extract incremental changes from Azure SQL Database or SQL Server 2022. It then replicates to Azure Synapse Analytics dedicated SQL pool with minimal impact on the operational workload.
- **Reduced complexity with No ETL jobs to manage** After going through a few clicks including selecting your operational database and tables, updates made to the operational data in Azure SQL Database or SQL Server 2022 are visible in the Azure Synapse Analytics dedicated SQL pool. They're available in near real-time with no ETL or data integration logic. You can focus on analytical and reporting logic against operational data via all the capabilities within Azure Synapse Analytics.
- **Near real-time insights into your operational data** You can now get rich insights by analyzing operational data in Azure SQL Database or SQL Server 2022 in near real-time to enable new business scenarios including operational BI reporting, real time scoring and personalization, or supply chain

forecasting etc. via Azure Synapse link for SQL.

Quickstart: Connect to Azure Synapse Link for Azure Cosmos DB

8/19/2022 • 2 minutes to read • Edit Online

This article describes how to access an Azure Cosmos DB database from Azure Synapse Analytics studio with Synapse Link.

Prerequisites

Before you connect an Azure Cosmos DB account to your workspace, there are a few things that you need.

- Existing Azure Cosmos DB account or create a new account following this quickstart
- Existing Synapse workspace or create a new workspace following this quickstart

Enable Azure Cosmos DB analytical store

To run large-scale analytics into Azure Cosmos DB without impacting your operational performance, we recommend enabling Synapse Link for Azure Cosmos DB. This function brings HTAP capability to a container and built-in support in Azure Synapse. Follow this quickstart to enable Synapse Link for Cosmos DB containers.

Navigate to Synapse Studio

From your Synapse workspace, select **Launch Synapse Studio**. On the Synapse Studio home page, select **Data, which will take you to the **Data Object Explorer**.

Connect an Azure Cosmos DB database to a Synapse workspace

Connecting an Azure Cosmos DB database is done as linked service. A Cosmos DB linked service enables users to browse and explore data, read, and write from Apache Spark for Azure Synapse Analytics or SQL into Azure Cosmos DB.

From the Data Object Explorer, you can directly connect an Azure Cosmos DB database by doing the following steps:

1. Select **+** icon near Data
2. Select **Connect to external data**
3. Select the API that you want to connect to: SQL or MongoDB
4. Select ***Continue***
5. Name the linked service. The name will be displayed in the Object Explorer and used by Synapse run-times to connect to the database and containers. We recommend using a friendly name.
6. Select the **Cosmos DB account name** and **database name**
7. (Optional) If no region is specified, Synapse run-time operations will be routed toward the nearest region where the analytical store is enabled. However, you can set manually which region you want your users to access Cosmos DB analytical store. Select **Additional connection properties** and then **New**. Under **Property Name**, write ***PreferredRegions*** and set the **Value** to the region you want (example: WestUS2, there is no space between words and numbers)
8. Select ***Create***

Azure Cosmos DB databases are visible under the tab **Linked** in the Azure Cosmos DB section. You can

differentiate an HTAP enabled Azure Cosmos DB container from an OLTP only container with the following icons:

Synapse container:

OLTP only container:

Quickly interact with code-generated actions

When you right-click into a container, you'll have a list of gestures that will trigger a Spark or SQL run-time. Writing into a container will happen through the Transactional Store of Azure Cosmos DB and will consume Request Units.

What is Azure Cosmos DB analytical store?

8/19/2022 • 28 minutes to read • Edit Online

APPLIES TO: SQL API Azure Cosmos DB API for MongoDB

Azure Cosmos DB analytical store is a fully isolated column store for enabling large-scale analytics against operational data in your Azure Cosmos DB, without any impact to your transactional workloads.

Azure Cosmos DB transactional store is schema-agnostic, and it allows you to iterate on your transactional applications without having to deal with schema or index management. In contrast to this, Azure Cosmos DB analytical store is schematized to optimize for analytical query performance. This article describes in detailed about analytical storage.

Challenges with large-scale analytics on operational data

The multi-model operational data in an Azure Cosmos DB container is internally stored in an indexed row-based "transactional store". Row store format is designed to allow fast transactional reads and writes in the order-of-milliseconds response times, and operational queries. If your dataset grows large, complex analytical queries can be expensive in terms of provisioned throughput on the data stored in this format. High consumption of provisioned throughput in turn, impacts the performance of transactional workloads that are used by your real-time applications and services.

Traditionally, to analyze large amounts of data, operational data is extracted from Azure Cosmos DB's transactional store and stored in a separate data layer. For example, the data is stored in a data warehouse or data lake in a suitable format. This data is later used for large-scale analytics and analyzed using compute engine such as the Apache Spark clusters. This separation of analytical storage and compute layers from operational data results in additional latency, because the ETL(Extract, Transform, Load) pipelines are run less frequently to minimize the potential impact on your transactional workloads.

The ETL pipelines also become complex when handling updates to the operational data when compared to handling only newly ingested operational data.

Column-oriented analytical store

Azure Cosmos DB analytical store addresses the complexity and latency challenges that occur with the traditional ETL pipelines. Azure Cosmos DB analytical store can automatically sync your operational data into a separate column store. Column store format is suitable for large-scale analytical queries to be performed in an optimized manner, resulting in improving the latency of such queries.

Using Azure Synapse Link, you can now build no-ETL HTAP solutions by directly linking to Azure Cosmos DB analytical store from Azure Synapse Analytics. It enables you to run near real-time large-scale analytics on your operational data.

Features of analytical store

When you enable analytical store on an Azure Cosmos DB container, a new column-store is internally created based on the operational data in your container. This column store is persisted separately from the row-oriented transactional store for that container. The inserts, updates, and deletes to your operational data are automatically synced to analytical store. You don't need the Change Feed or ETL to sync the data.

Column store for analytical workloads on operational data

Analytical workloads typically involve aggregations and sequential scans of selected fields. By storing the data in a column-major order, the analytical store allows a group of values for each field to be serialized together. This format reduces the IOPS required to scan or compute statistics over specific fields. It dramatically improves the query response times for scans over large data sets.

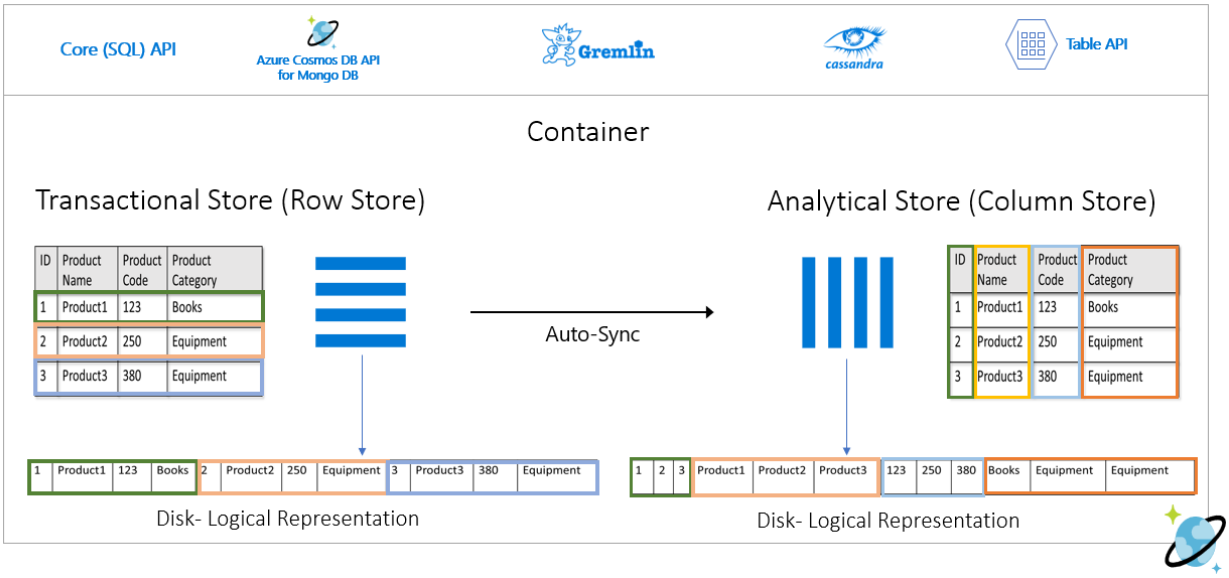
For example, if your operational tables are in the following format:

ID	Product Name	Product Code	Product Category
1	Product1	123	Books
2	Product2	250	Equipment
3	Product3	380	Equipment

The row store persists the above data in a serialized format, per row, on the disk. This format allows for faster transactional reads, writes, and operational queries, such as, "Return information about Product1". However, as the dataset grows large and if you want to run complex analytical queries on the data it can be expensive. For example, if you want to get "the sales trends for a product under the category named 'Equipment' across different business units and months", you need to run a complex query. Large scans on this dataset can get expensive in terms of provisioned throughput and can also impact the performance of the transactional workloads powering your real-time applications and services.

Analytical store, which is a column store, is better suited for such queries because it serializes similar fields of data together and reduces the disk IOPS.

The following image shows transactional row store vs. analytical column store in Azure Cosmos DB:



Decoupled performance for analytical workloads

There's no impact on the performance of your transactional workloads due to analytical queries, as the analytical store is separate from the transactional store. Analytical store doesn't need separate request units (RUs) to be allocated.

Auto-Sync

Auto-Sync refers to the fully managed capability of Azure Cosmos DB where the inserts, updates, deletes to operational data are automatically synced from transactional store to analytical store in near real time. Auto-

sync latency is usually within 2 minutes. In cases of shared throughput database with a large number of containers, auto-sync latency of individual containers could be higher and take up to 5 minutes. We would like to learn more how this latency fits your scenarios. For that, please reach out to the Azure Cosmos DB Team.

At the end of each execution of the automatic sync process, your transactional data will be immediately available for Azure Synapse Analytics runtimes:

- Azure Synapse Analytics Spark pools can read all data, including the most recent updates, through Spark tables, which are updated automatically, or via the `spark.read` command, that always reads the last state of the data.
- Azure Synapse Analytics SQL Serverless pools can read all data, including the most recent updates, through views, which are updated automatically, or via `SELECT` together with the `OPENROWSET` commands, which always reads the latest status of the data.

> **NOTE**
> Your transactional data will be synchronized to analytical store even if your transactional time-to-live (TTL) is smaller than 2 minutes.

> **NOTE**
> Please note that if you delete your container, analytical store is also deleted.

Scalability & elasticity

By using horizontal partitioning, Azure Cosmos DB transactional store can elastically scale the storage and throughput without any downtime. Horizontal partitioning in the transactional store provides scalability & elasticity in auto-sync to ensure data is synced to the analytical store in near real time. The data sync happens regardless of the transactional traffic throughput, whether it's 1000 operations/sec or 1 million operations/sec, and it doesn't impact the provisioned throughput in the transactional store.

Automatically handle schema updates

Azure Cosmos DB transactional store is schema-agnostic, and it allows you to iterate on your transactional applications without having to deal with schema or index management. In contrast to this, Azure Cosmos DB analytical store is schematized to optimize for analytical query performance. With the auto-sync capability, Azure Cosmos DB manages the schema inference over the latest updates from the transactional store. It also manages the schema representation in the analytical store out-of-the-box which, includes handling nested data types.

As your schema evolves, and new properties are added over time, the analytical store automatically presents a unionized schema across all historical schemas in the transactional store.

> **NOTE**
> In the context of analytical store, we consider the following structures as property:
>
> - JSON "elements" or "string-value pairs separated by a `:` ".
> - JSON objects, delimited by `{` and `}`.
> - JSON arrays, delimited by `[` and `]`.

Schema constraints

The following constraints are applicable on the operational data in Azure Cosmos DB when you enable analytical store to automatically infer and represent the schema correctly:

- You can have a maximum of 1000 properties across all nested levels in the document schema and a maximum nesting depth of 127.
  - Only the first 1000 properties are represented in the analytical store.
  - Only the first 127 nested levels are represented in the analytical store.
  - The first level of a JSON document is its `/` root level.
  - Properties in the first level of the document will be represented as columns.
- Sample scenarios:
  - If your document's first level has 2000 properties, only the first 1000 will be represented.
  - If your documents have five levels with 200 properties in each one, all properties will be represented.
  - If your documents have 10 levels with 400 properties in each one, only the two first levels will be fully represented in analytical store. Half of the third level will also be represented.
- The hypothetical document below contains four properties and three levels.
  - The levels are `root`, `myArray`, and the nested structure within the `myArray`.
  - The properties are `id`, `myArray`, `myArray.nested1`, and `myArray.nested2`.
  - The analytical store representation will have two columns, `id`, and `myArray`. You can use Spark or T-SQL functions to also expose the nested structures as columns.

```
{
  "id": "1",
  "myArray": [
    "string1",
    "string2",
    {
      "nested1": "abc",
      "nested2": "cde"
    }
  ]
}
```

- While JSON documents (and Cosmos DB collections/containers) are case-sensitive from the uniqueness perspective, analytical store isn't.
  - **In the same document:** Properties names in the same level should be unique when compared case-insensitively. For example, the following JSON document has "Name" and "name" in the same level. While it's a valid JSON document, it doesn't satisfy the uniqueness constraint and hence won't be fully represented in the analytical store. In this example, "Name" and "name" are the same when compared in a case-insensitive manner. Only `"Name": "fred"` will be represented in analytical store, because it's the first occurrence. And `"name": "john"` won't be represented at all.

    ```
    {"id": 1, "Name": "fred", "name": "john"}
    ```

  - **In different documents:** Properties in the same level and with the same name, but in different cases, will be represented within the same column, using the name format of the first occurrence. For example, the following JSON documents have `"Name"` and `"name"` in the same level. Since the first document format is `"Name"`, this is what will be used to represent the property name in analytical store. In other words, the column name in analytical store will be `"Name"`. Both `"fred"` and `"john"` will be represented, in the `"Name"` column.

```
{"id": 1, "Name": "fred"}
{"id": 2, "name": "john"}
```

- The first document of the collection defines the initial analytical store schema.
  - Documents with more properties than the initial schema will generate new columns in analytical store.
  - Columns can't be removed.
  - The deletion of all documents in a collection doesn't reset the analytical store schema.
  - There's not schema versioning. The last version inferred from transactional store is what you'll see in analytical store.
- Currently Azure Synapse Spark can't read properties that contain some special characters in their names, listed below. Azure Synapse SQL serverless isn't affected.
  - :
  - `
  - ,
  - ;
  - {}
  - ()
  - \n
  - \t
  - =
  - "

> **NOTE**
> White spaces are also listed in the Spark error message returned when you reach this limitation. But we have added a special treatment for white spaces, please check out more details in the items below.

- If you have properties names using the characters listed above, the alternatives are:
  - Change your data model in advance to avoid these characters.
  - Since currently we don't support schema reset, you can change your application to add a redundant property with a similar name, avoiding these characters.
  - Use Change Feed to create a materialized view of your container without these characters in properties names.
  - Use the `dropColumn` Spark option to ignore the affected columns and load all other columns into a DataFrame. The syntax is:

```
# Removing one column:
df = spark.read\
     .format("cosmos.olap")\
     .option("spark.synapse.linkedService","<your-linked-service-name>")\
     .option("spark.synapse.container","<your-container-name>")\
     .option("spark.synapse.dropColumn","FirstName,LastName")\
     .load()

# Removing multiple columns:
df = spark.read\
     .format("cosmos.olap")\
     .option("spark.synapse.linkedService","<your-linked-service-name>")\
     .option("spark.synapse.container","<your-container-name>")\
     .option("spark.synapse.dropColumn","FirstName,LastName;StreetName,StreetNumber")\
     .option("spark.cosmos.dropMultiColumnSeparator", ";")\
     .load()
```

- Azure Synapse Spark now supports properties with white spaces in their names. For that, you need to use the `allowWhiteSpaceInFieldNames` Spark option to load the affected columns into a DataFrame, keeping the original name. The syntax is:

```
df = spark.read\
     .format("cosmos.olap")\
     .option("spark.synapse.linkedService","<your-linked-service-name>")\
     .option("spark.synapse.container","<your-container-name>")\
     .option("spark.cosmos.allowWhiteSpaceInFieldNames", "true")\
    .load()
```

- The following BSON datatypes aren't supported and won't be represented in analytical store:
  - Decimal128
  - Regular Expression
  - DB Pointer
  - JavaScript
  - Symbol
  - MinKey/MaxKey
- When using DateTime strings that follow the ISO 8601 UTC standard, expect the following behavior:
  - Spark pools in Azure Synapse will represent these columns as `string`.
  - SQL serverless pools in Azure Synapse will represent these columns as `varchar(8000)`.
- Properties with `UNIQUEIDENTIFIER (guid)` types are represented as `string` in analytical store and should be converted to `VARCHAR` in **SQL** or to `string` in **Spark** for correct visualization.
- SQL serverless pools in Azure Synapse support result sets with up to 1000 columns, and exposing nested columns also counts towards that limit. Please consider this information when designing your data architecture and modeling your transactional data.
- If you rename a property, in one or many documents, it will be considered a new column. If you execute the same rename in all documents in the collection, all data will be migrated to the new column and the old column will be represented with `NULL` values.

Schema representation

There are two types of schema representation in the analytical store. These types define the schema representation method for all containers in the database account and have tradeoffs between the simplicity of query experience versus the convenience of a more inclusive columnar representation for polymorphic schemas.

- Well-defined schema representation, default option for SQL (CORE) API accounts.
- Full fidelity schema representation, default option for Azure Cosmos DB API for MongoDB accounts.

Well-defined schema representation

The well-defined schema representation creates a simple tabular representation of the schema-agnostic data in the transactional store. The well-defined schema representation has the following considerations:

- The first document defines the base schema and property must always have the same type across all documents. The only exceptions are:
  - From `NULL` to any other data type. The first non-null occurrence defines the column data type. Any document not following the first non-null datatype won't be represented in analytical store.
  - From `float` to `integer`. All documents will be represented in analytical store.
  - From `integer` to `float`. All documents will be represented in analytical store. However, to read this data with Azure Synapse SQL serverless pools, you must use a WITH clause to convert the column to `varchar`. And after this initial conversion, it's possible to convert it again to a number. Please check the example below, where **num** initial value was an integer and the second one was a float.

```
SELECT CAST (num as float) as num
FROM OPENROWSET(PROVIDER = 'CosmosDB',
                CONNECTION = '<your-connection',
                OBJECT = 'IntToFloat',
                SERVER_CREDENTIAL = 'your-credential'
)
WITH (num varchar(100)) AS [IntToFloat]
```

- Properties that don't follow the base schema data type won't be represented in analytical store. For example, consider the documents below: the first one defined the analytical store base schema. The second document, where `id` is `"2"`, **doesn't** have a well-defined schema since property `"code"` is a string and the first document has `"code"` as a number. In this case, the analytical store registers the data type of `"code"` as `integer` for lifetime of the container. The second document will still be included in analytical store, but its `"code"` property won't.
  - `{"id": "1", "code":123}`
  - `{"id": "2", "code": "123"}`

> **NOTE**
> The condition above doesn't apply for `NULL` properties. For example, `{"a":123} and {"a":NULL}` is still well-defined.

> **NOTE**
> The condition above doesn't change if you update `"code"` of document `"1"` to a string in your transactional store. In analytical store, `"code"` will be kept as `integer` since currently we don't support schema reset.

- Array types must contain a single repeated type. For example, `{"a": ["str",12]}` isn't a well-defined schema because the array contains a mix of integer and string types.

> **NOTE**
> If the Azure Cosmos DB analytical store follows the well-defined schema representation and the specification above is violated by certain items, those items won't be included in the analytical store.

- Expect different behavior in regard to different types in well-defined schema:
  - Spark pools in Azure Synapse will represent these values as `undefined`.
  - SQL serverless pools in Azure Synapse will represent these values as `NULL`.
- Expect different behavior in regard to explicit `NULL` values:
  - Spark pools in Azure Synapse will read these values as `0` (zero). And it will change to `undefined` as soon as the column has a non-null value.
  - SQL serverless pools in Azure Synapse will read these values as `NULL`.
- Expect different behavior in regard to missing columns:
  - Spark pools in Azure Synapse will represent these columns as `undefined`.
  - SQL serverless pools in Azure Synapse will represent these columns as `NULL`.

Full fidelity schema representation

The full fidelity schema representation is designed to handle the full breadth of polymorphic schemas in the schema-agnostic operational data. In this schema representation, no items are dropped from the analytical store even if the well-defined schema constraints (that is no mixed data type fields nor mixed data type arrays) are violated.

This is achieved by translating the leaf properties of the operational data into the analytical store with distinct columns based on the data type of values in the property. The leaf property names are extended with data types as a suffix in the analytical store schema such that they can be queries without ambiguity.

In the full fidelity schema representation, each datatype of each property will generate a column for that datatype. Each of them count as one of the 1000 maximum properties.

For example, let's take the following sample document in the transactional store:

```
{
name: "John Doe",
age: 32,
profession: "Doctor",
address: {
  streetNo: 15850,
  streetName: "NE 40th St.",
  zip: 98052
},
salary: 1000000
}
```

The leaf property `streetNo` within the nested object `address` will be represented in the analytical store schema as a column `address.object.streetNo.int32`. The datatype is added as a suffix to the column. This way, if another document is added to the transactional store where the value of leaf property `streetNo` is "123" (note it's a string), the schema of the analytical store automatically evolves without altering the type of a previously written column. A new column added to the analytical store as `address.object.streetNo.string` where this value of "123" is stored.

Data type to suffix map for full fidelity schema

Here's a map of all the property data types and their suffix representations in the analytical store in full fidelity schema representation:

ORIGINAL DATA TYPE	SUFFIX	EXAMPLE
Double	".float64"	24.99

ORIGINAL DATA TYPE	SUFFIX	EXAMPLE
Array	".array"	["a", "b"]
Binary	".binary"	0
Boolean	".bool"	True
Int32	".int32"	123
Int64	".int64"	255486129307
NULL	".NULL"	NULL
String	".string"	"ABC"
Timestamp	".timestamp"	Timestamp(0, 0)
ObjectId	".objectId"	ObjectId("5f3f7b59330ec25c132623a2")
Document	".object"	{"a": "a"}

- Expect different behavior in regard to explicit `NULL` values:
  - Spark pools in Azure Synapse will read these values as `0` (zero).
  - SQL serverless pools in Azure Synapse will read these values as `NULL`.
- Expect different behavior in regard to missing columns:
  - Spark pools in Azure Synapse will represent these columns as `undefined`.
  - SQL serverless pools in Azure Synapse will represent these columns as `NULL`.

Working with the MongoDB `_id` field

the MongoDB `_id` field is fundamental to every collection in MongoDB and originally has a hexadecimal representation. As you can see in the table above, `Full Fidelity Schema` will preserve its characteristics, creating a challenge for its vizualiation in Azure Synapse Analytics. For correct visualization, you must convert the `_id` datatype as below:

Spark

```
import org.apache.spark.sql.types._
val simpleSchema = StructType(Array(
    StructField("_id", StructType(Array(StructField("objectId",BinaryType,true)) ),true),
    StructField("id", StringType, true)
  ))

df = spark.read.format("cosmos.olap")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .schema(simpleSchema)
    .load()

df.select("id", "_id.objectId").show()
```

SQL

```
SELECT TOP 100 id=CAST(_id as VARBINARY(1000))
FROM OPENROWSET('CosmosDB',
                'Your-account;Database=your-database;Key=your-key',
                HTAP) WITH (_id VARCHAR(1000)) as HTAP
```

Full fidelity schema for SQL API accounts

It's possible to use full fidelity Schema for SQL (Core) API accounts, instead of the default option, by setting the schema type when enabling Synapse Link on a Cosmos DB account for the first time. Here are the considerations about changing the default schema representation type:

- This option is only valid for accounts that **don't** have Synapse Link already enabled.
- It isn't possible to reset the schema representation type, from well-defined to full fidelity or vice-versa.
- Currently Azure Cosmos DB API for MongoDB isn't compatible with this possibility of changing the schema representation. All MongoDB accounts will always have full fidelity schema representation type.
- Currently this change can't be made through the Azure portal. All database accounts that have Synapse Link enabled by the Azure portal will have the default schema representation type, well-defined schema.

The schema representation type decision must be made at the same time that Synapse Link is enabled on the account, using Azure CLI or PowerShell.

With the Azure CLI:

```
az cosmosdb create --name MyCosmosDBDatabaseAccount --resource-group MyResourceGroup --subscription
MySubscription --analytical-storage-schema-type "FullFidelity" --enable-analytical-storage true
```

> **NOTE**
> In the command above, replace `create` with `update` for existing accounts.

With the PowerShell:

```
 New-AzCosmosDBAccount -ResourceGroupName MyResourceGroup -Name MyCosmosDBDatabaseAccount  -
EnableAnalyticalStorage true -AnalyticalStorageSchemaType "FullFidelity"
```

> **NOTE**
> In the command above, replace `New-AzCosmosDBAccount` with `Update-AzCosmosDBAccount` for existing accounts.

Analytical Time-to-Live (TTL)

Analytical TTL (ATTL) indicates how long data should be retained in your analytical store, for a container.

Analytical store is enabled when ATTL is set with a value other than `NULL` and `0`. When enabled, inserts, updates, deletes to operational data are automatically synced from transactional store to analytical store, irrespective of the transactional TTL (TTTL) configuration. The retention of this transactional data in analytical store can be controlled at container level by the `AnalyticalStoreTimeToLiveInSeconds` property.

The possible ATTL configurations are:

- If the value is set to `0` or set to `NULL`: the analytical store is disabled and no data is replicated from transactional store to analytical store
- If the value is set to `-1`: the analytical store retains all historical data, irrespective of the retention of the

data in the transactional store. This setting indicates that the analytical store has infinite retention of your operational data

- If the value is set to any positive integer `n` number: items will expire from the analytical store `n` seconds after their last modified time in the transactional store. This setting can be leveraged if you want to retain your operational data for a limited period of time in the analytical store, irrespective of the retention of the data in the transactional store

Some points to consider:

- After the analytical store is enabled with an ATTL value, it can be updated to a different valid value later.
- While TTTL can be set at the container or item level, ATTL can only be set at the container level currently.
- You can achieve longer retention of your operational data in the analytical store by setting ATTL >= TTTL at the container level.
- The analytical store can be made to mirror the transactional store by setting ATTL = TTTL.
- If you have ATTL bigger than TTTL, at some point in time you'll have data that only exists in analytical store. This data is read only.

How to enable analytical store on a container:

- From the Azure portal, the ATTL option, when turned on, is set to the default value of -1. You can change this value to 'n' seconds, by navigating to container settings under Data Explorer.
- From the Azure Management SDK, Azure Cosmos DB SDKs, PowerShell, or Azure CLI, the ATTL option can be enabled by setting it to either -1 or 'n' seconds.

To learn more, see how to configure analytical TTL on a container.

Cost-effective analytics on historical data

Data tiering refers to the separation of data between storage infrastructures optimized for different scenarios. Thereby improving the overall performance and cost-effectiveness of the end-to-end data stack. With analytical store, Azure Cosmos DB now supports automatic tiering of data from the transactional store to analytical store with different data layouts. With analytical store optimized in terms of storage cost compared to the transactional store, allows you to retain much longer horizons of operational data for historical analysis.

After the analytical store is enabled, based on the data retention needs of the transactional workloads, you can configure `transactional TTL` property to have records automatically deleted from the transactional store after a certain time period. Similarly, the `analytical TTL` allows you to manage the lifecycle of data retained in the analytical store, independent from the transactional store. By enabling analytical store and configuring transactional and analytical `TTL` properties, you can seamlessly tier and define the data retention period for the two stores.

> **NOTE**
>
> When `analytical TTL` is bigger than `transactional TTL`, your container will have data that only exists in analytical store. This data is read only and currently we don't support document level `TTL` in analytical store. If your container data may need an update or a delete at some point in time in the future, don't use `analytical TTL` bigger than `transactional TTL`. This capability is recommended for data that won't need updates or deletes in the future.

> **NOTE**
> If your scenario doesn't demand physical deletes, you can adopt a logical delete/update approach. Insert in transactional store another version of the same document that only exists in analytical store but needs a logical delete/update. Maybe with a flag indicating that it's a delete or an update of an expired document. Both versions of the same document will co-exist in analytical store, and your application should only consider the last one.

Resilience

Analytical store relies on Azure Storage and offers the following protection against physical failure:

- Single region Azure Cosmos DB database accounts allocate analytical store in Locally Redundant Storage (LRS) Azure Storage accounts.
- If any geo-region replication is configured for the Azure Cosmos DB database account, analytical store is allocated in Zone-Redundant Storage (ZRS) Azure storage accounts.

Backup

Although analytical store has built-in protection against physical failures, backup can be necessary for accidental deletes or updates in transactional store. In those cases, you can restore a container and use the restored container to backfill the data in the original container, or fully rebuild analytical store if necessary.

> **NOTE**
> Currently analytical store isn't backuped and can't be restored, and your backup policy can't be planned relying on that.

Synapse Link, and analytical store by consequence, has different compatibility levels with Azure Cosmos DB backup modes:

- Periodic backup mode is fully compatible with Synapse Link and these 2 features can be used in the same database account.
- Continuous backup mode isn't fully supported yet:
  - Database accounts with Synapse Link enabled currently can't use continuous backup mode.
  - Database accounts with continuous backup mode enabled can enable Synapse Link through a support case. This capability is in preview now.
  - Database accounts that have neither continuous backup nor Synapse Link enabled can use these two features together through a support case. This capability is in preview now.

Backup Polices

There two possible backup polices and to understand how to use them, two details about Cosmos DB backups are very important:

- The original container is restored without analytical store in both backup modes.
- Cosmos DB doesn't support containers overwrite from a restore.

Now let's see how to use backup and restores from the analytical store perspective.

Restoring a container with TTTL >= ATTL

When `transactional TTL` is equal or bigger than `analytical TTL`, all data in analytical store still exists in transactional store. In case of a restore, you have two possible situations:

- To use the restored container as a replacement for the original container. To rebuild analytical store, just enable Synapse Link at account level and container level.
- To use the restored container as a data source to backfill or update the data in the original container. In this

case, analytical store will automatically reflect the data operations.

Restoring a container with TTTL < ATTL

When `transactional TTL` is smaller than `analytical TTL`, some data only exists in analytical store and won't be in the restored container. Again your have two possible situations:

- To use the restored container as a replacement for the original container. In this case, when you enable Synapse Link at container level, only the data that was in transactional store will be included in the new analytical store. But please note that the analytical store of the original container remains available for queries as long as the original container exists. You may want to change your application to query both.
- To use the restored container as a data source to backfill or update the data in the original container:
- Analytical store will automatically reflect the data operations for the data that is in transactional store.
- If you re-insert data that was previously removed from transactional store due to `transactional TTL`, this data will be duplicated in analytical store.

Example:

- Container `OnlineOrders` has TTTL set to one month and ATTL set for one year.
- When you restore it to `OnlineOrdersNew` and turn on analytical store to rebuild it, there will be only one month of data in both transactional and analytical store.
- Original container `OnlineOrders` isn't deleted and its analytical store is still available.
- New data is only ingested into `OnlineOrdersNew`.
- Analytical queries will do a UNION ALL from analytical stores while the original data is still relevant.

If you want to delete the original container but don't want to lose its analytical store data, you can persist the analytical store of the original container in another Azure data service. Synapse Analytics has the capability to perform joins between data stored in different locations. An example: A Synapse Analytics query joins analytical store data with external tables located in Azure Blob Storage, Azure Data Lake Store, etc.

It's important to note that the data in the analytical store has a different schema than what exists in the transactional store. While you can generate snapshots of your analytical store data, and export it to any Azure Data service, at no RUs costs, we can't guarantee the use of this snapshot to back feed the transactional store. This process isn't supported.

Global Distribution

If you have a globally distributed Azure Cosmos DB account, after you enable analytical store for a container, it will be available in all regions of that account. Any changes to operational data are globally replicated in all regions. You can run analytical queries effectively against the nearest regional copy of your data in Azure Cosmos DB.

Partitioning

Analytical store partitioning iscompletelyindependent of partitioning inthetransactional store. By default, data in analytical store isn't partitioned. If your analytical queries have frequently used filters, you have the option to partition based on these fields for better query performance. To learn more, see introduction to custom partitioning and how to configure custom partitioning.

Security

- **Authentication with the analytical store** is the same as the transactional store for a given database. You can use primary, secondary, or read-only keys for authentication. You can leverage linked service in Synapse Studio to prevent pasting the Azure Cosmos DB keys in the Spark notebooks. For Azure Synapse SQL serverless, you can use SQL credentials to also prevent pasting the Azure Cosmos DB keys in the

SQL notebooks. The Access to these Linked Services or to these SQL credentials are available to anyone who has access to the workspace. Please note that the Cosmos DB read only key can also be used.

- **Network isolation using private endpoints** - You can control network access to the data in the transactional and analytical stores independently. Network isolation is done using separate managed private endpoints for each store, within managed virtual networks in Azure Synapse workspaces. To learn more, see how to Configure private endpoints for analytical store article.
- **Data encryption at rest** - Your analytical store encryption is enabled by default.
- **Data encryption with customer-managed keys** - You can seamlessly encrypt the data across transactional and analytical stores using the same customer-managed keys in an automatic and transparent manner. Azure Synapse Link only supports configuring customer-managed keys using your Azure Cosmos DB account's managed identity. You must configure your account's managed identity in your Azure Key Vault access policy before enabling Azure Synapse Link on your account. To learn more, see how to Configure customer-managed keys using Azure Cosmos DB accounts' managed identities article.

Support for multiple Azure Synapse Analytics runtimes

The analytical store is optimized to provide scalability, elasticity, and performance for analytical workloads without any dependency on the compute run-times. The storage technology is self-managed to optimize your analytics workloads without manual efforts.

By decoupling the analytical storage system from the analytical compute system, data in Azure Cosmos DB analytical store can be queried simultaneously from the different analytics runtimes supported by Azure Synapse Analytics. As of today, Azure Synapse Analytics supports Apache Spark and serverless SQL pool with Azure Cosmos DB analytical store.

> **NOTE**
> You can only read from analytical store using Azure Synapse Analytics runtimes. And the opposite is also true, Azure Synapse Analytics runtimes can only read from analytical store. Only the auto-sync process can change data in analytical store. You can write data back to Cosmos DB transactional store using Azure Synapse Analytics Spark pool, using the built-in Azure Cosmos DB OLTP SDK.

Pricing

Analytical store follows a consumption-based pricing model where you're charged for:

- Storage: the volume of the data retained in the analytical store every month including historical data as defined by analytical TTL.
- Analytical write operations: the fully managed synchronization of operational data updates to the analytical store from the transactional store (auto-sync)
- Analytical read operations: the read operations performed against the analytical store from Azure Synapse Analytics Spark pool and serverless SQL pool run times.

Analytical store pricing is separate from the transaction store pricing model. There's no concept of provisioned RUs in the analytical store. See Azure Cosmos DB pricing page for full details on the pricing model for analytical store.

Data in the analytics store can only be accessed through Azure Synapse Link, which is done in the Azure Synapse Analytics runtimes: Azure Synapse Apache Spark pools and Azure Synapse serverless SQL pools. See Azure Synapse Analytics pricing page for full details on the pricing model to access data in analytical store.

In order to get a high-level cost estimate to enable analytical store on an Azure Cosmos DB container, from the analytical store perspective, you can use the Azure Cosmos DB Capacity planner and get an estimate of your analytical storage and write operations costs. Analytical read operations costs depends on the analytics workload characteristics but as a high-level estimate, scan of 1 TB of data in analytical store typically results in 130,000 analytical read operations, and results in a cost of $0.065.

> **NOTE**
>
> Analytical store read operations estimates aren't included in the Cosmos DB cost calculator since they are a function of your analytical workload. While the above estimate is for scanning 1TB of data in analytical store, applying filters reduces the volume of data scanned and this determines the exact number of analytical read operations given the consumption pricing model. A proof-of-concept around the analytical workload would provide a more finer estimate of analytical read operations. This estimate doesn't include the cost of Azure Synapse Analytics.

Azure Synapse Link for Azure Cosmos DB supported features

8/19/2022 • 2 minutes to read • Edit Online

This article describes the functionalities that are currently supported in Azure Synapse Link for Azure Cosmos DB.

Azure Synapse support

There are two types of containers in Azure Cosmos DB:

- HTAP container - A container with Synapse Link enabled. This container has both transactional store and analytical store.
- OLTP container - A container with Synaspe Link not enabled. This container has only transactional store and no analytical store.

You can connect to an Azure Cosmos DB container without enabling Synapse Link. In this scenario, you can only read/write to the transactional store. What follows is a list of the currently supported features within Synapse Link for Azure Cosmos DB.

CATEGORY	DESCRIPTION	APACHE SPARK POOL	SERVERLESS SQL POOL
Run-time Support	Supported Azure Synapse runtime to access Azure Cosmos DB	✓	✓
Azure Cosmos DB API support	Supported Azure Cosmos DB API kind	SQL / MongoDB	SQL / MongoDB
Object	Objects such as a table that can be created, pointing directly to Azure Cosmos DB container	Dataframe, View, Table	View
Read	Type of Azure Cosmos DB container that can be read	OLTP / HTAP	HTAP
Write	Can the Azure Synapse runtime be used to write data to an Azure Cosmos DB container	Yes	No

- If you write data into an Azure Cosmos DB container from Spark, this process happens through the transactional store of Azure Cosmos DB. It will impact the transactional performance of Azure Cosmos DB by consuming Request Units.
- Dedicated SQL pool integration through external tables is currently not supported.

Supported code-generated actions for Spark

GESTURE	DESCRIPTION	OLTP	HTAP
Load to DataFrame	Load and read data into a Spark DataFrame	✓	✓
Create Spark table	Create a table pointing to an Azure Cosmos DB container	✓	✓
Write DataFrame to container	Write data into a container	✓	✓
Load streaming DataFrame from container	Stream data using Azure Cosmos DB change feed	✓	✓
Write streaming DataFrame to container	Stream data using Azure Cosmos DB change feed	✓	✓

Supported code-generated actions for serverless SQL pool

GESTURE	DESCRIPTION	OLTP	HTAP
Explore data	Explore data from a container with familiar T-SQL syntax and automatic schema inference	X	✓
Create views and build BI reports	Create a SQL view to have direct access to a container for BI through serverless SQL pool	X	✓
Join disparate data sources along with Cosmos DB data	Store results of query reading data from Cosmos DB containers along with data in Azure Blob Storage or Azure Data Lake Storage using CETAS	X	✓

Azure Synapse Link for Azure Cosmos DB: Near real-time analytics use cases

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: SQL API Azure Cosmos DB API for MongoDB

Azure Synapse Link for Azure Cosmos DB is a cloud native hybrid transactional and analytical processing (HTAP) capability that enables you to run near real-time analytics over operational data. Synapse Link creates a tight seamless integration between Azure Cosmos DB and Azure Synapse Analytics.

You might be curious to understand what industry use cases can leverage this cloud native HTAP capability for near real-time analytics over operational data. Here are three common use cases for Azure Synapse Link for Azure Cosmos DB:

- Supply chain analytics, forecasting & reporting
- Real-time personalization
- Predictive maintenance, anomaly detection in IOT scenarios

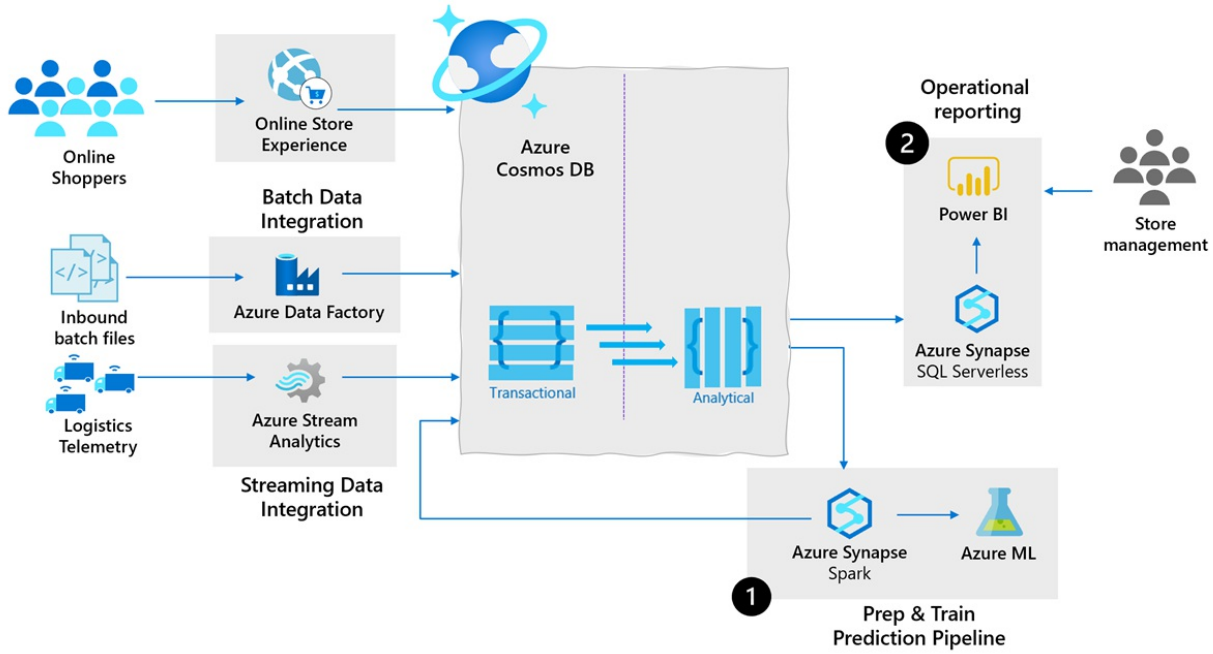
> **NOTE**
> Azure Synapse Link for Azure Cosmos DB targets the scenario where enterprise teams are looking to run near real-time analytics. These analytics are run without ETL over operational data generated across transactional applications built on Azure Cosmos DB. This does not replace the need for a separate data warehouse when there are traditional data warehouse requirements such as workload management, high concurrency, persistence aggregates across multiple data sources.

Supply chain analytics, forecasting & reporting

Research studies show that embedding big data analytics in supply chain operations leads to improvements in order-to-cycle delivery times and supply chain efficiency.

Manufacturers are onboarding to cloud-native technologies to break out of constraints of legacy Enterprise Resource Planning (ERP) and Supply Chain Management (SCM) systems. With supply chains generating increasing volumes of operational data every minute (order, shipment, transaction data), manufacturers need an operational database. This operational database should scale to handle the data volumes as well as an analytical platform to get to a level of real-time contextual intelligence to stay ahead of the curve.

The following architecture shows the power of leveraging Azure Cosmos DB as the cloud-native operational database and Synapse Link in supply chain analytics:



Based on previous architecture, you can achieve the following use cases with Synapse Link for Azure Cosmos DB:

- **Prepare & train predictive pipeline:** Generate insights over the operational data across the supply chain using machine learning translates. This way you can lower inventory, operations costs, and reduce the order-to-delivery times for customers.

  Synapse Link allows you to analyze the changing operational data in Azure Cosmos DB without any manual ETL processes. It saves you from additional cost, latency, and operational complexity. Synapse Link enables data engineers and data scientists to build robust predictive pipelines:

  - Query operational data from Azure Cosmos DB analytical store by leveraging native integration with Apache Spark pools in Azure Synapse Analytics. You can query the data in an interactive notebook or scheduled remote jobs without complex data engineering.
  - Build Machine Learning (ML) models with Spark ML algorithms and Azure ML integration in Azure Synapse Analytics.
  - Write back the results after model inference into Azure Cosmos DB for operational near-real-time scoring.

- **Operational reporting:** Supply chain teams need flexible and custom reports over real-time, accurate operational data. These reports are required to obtain a snapshot view of supply chain effectiveness, profitability, and productivity. It allows data analysts and other key stakeholders to constantly reevaluate the business and identify areas to tweak to reduce operational costs.

  Synapse Link for Azure Cosmos DB enables rich business intelligence (BI)/reporting scenarios:

  - Query operational data from Azure Cosmos DB analytical store by using native integration with serverless SQL pool and full expressiveness of T-SQL language.
  - Model and publish auto refreshing BI dashboards over Azure Cosmos DB through serverless SQL pool support for familiar BI tools. For example, Azure Analysis Services, Power BI Premium, etc.

The following is some guidance for data integration for batch & streaming data into Azure Cosmos DB:

- **Batch data integration & orchestration:** With supply chains getting more complex, supply chain data platforms need to integrate with variety of data sources and formats. Azure Synapse comes built-in with the same data integration engine and experiences as Azure Data Factory. This integration allows data

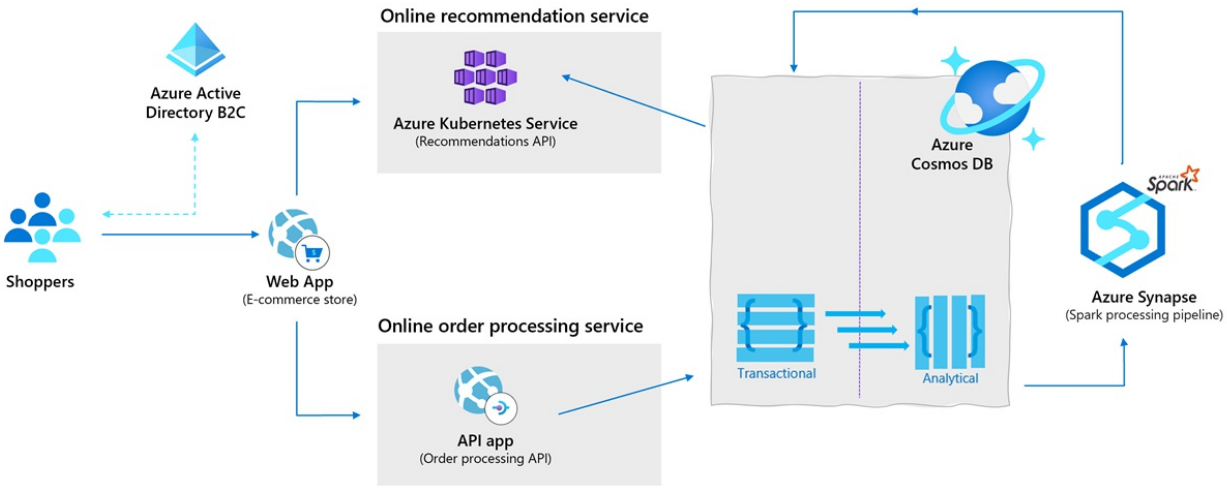
engineers to create rich data pipelines without a separate orchestration engine:

  - Move data from 85+ supported data sources to Azure Cosmos DB with Azure Data Factory.
  - Write code-free ETL pipelines to Azure Cosmos DB including relational-to-hierarchical and hierarchical-to-hierarchical mappings with mapping data flows.

- **Streaming data integration & processing:** With the growth of Industrial IoT (sensors tracking assets from 'floor-to-store', connected logistics fleets, etc.), there is an explosion of real-time data being generated in a streaming fashion that needs to be integrated with traditional slow moving data for generating insights. Azure Stream Analytics is a recommended service for streaming ETL and processing on Azure with a wide range of scenarios. Azure Stream Analytics supports Azure Cosmos DB as a native data sink.

Real-time personalization

Retailers today must build secure and scalable e-commerce solutions that meet the demands of both customers and business. These e-commerce solutions need to engage customers through customized products and offers, process transactions quickly and securely, and focus on fulfillment and customer service. Azure Cosmos DB along with the latest Synapse Link for Azure Cosmos DB allows retailers to generate personalized recommendations for customers in real time. They use low-latency and tunable consistency settings for immediate insights as shown in the following architecture:



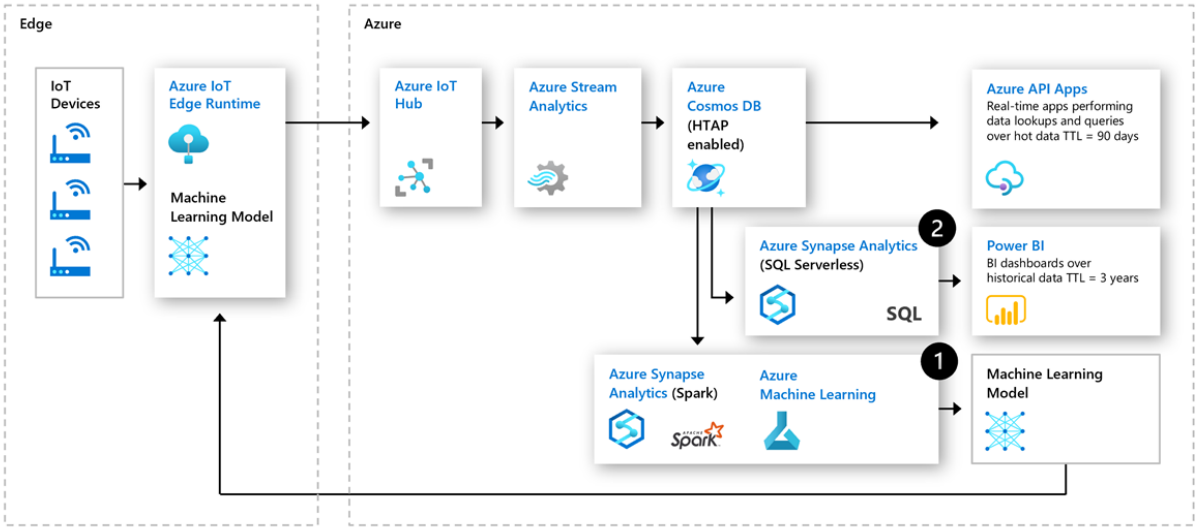
Synapse Link for Azure Cosmos DB use case:

- **Prepare & train predictive pipeline:** You can generate insights over the operational data across your business units or customer segments using Synapse Spark and machine learning models. This translates to personalized delivery to target customer segments, predictive end-user experiences and targeted marketing to fit your end-user requirements.

IOT predictive maintenance

Industrial IOT innovations have drastically reduced downtimes of machinery and increased overall efficiency across all fields of industry. One of such innovations is predictive maintenance analytics for machinery at the edge of the cloud.

The following is an architecture leveraging the cloud native HTAP capabilities of Azure Synapse Link for Azure Cosmos DB in IoT predictive maintenance:



Synapse Link for Azure Cosmos DB use cases:

- **Prepare & train predictive pipeline:** The historical operational data from IoT device sensors could be used to train predictive models such as anomaly detectors. These anomaly detectors are then deployed back to the edge for real-time monitoring. Such a virtuous loop allows for continuous retraining of the predictive models.
- **Operational reporting:** With the growth of digital twin initiatives, companies are collecting vast amounts of operational data from large number of sensors to build a digital copy of each machine. This data powers BI needs to understand trends over historical data in addition to real-time applications over recent hot data.

Sample scenario: HTAP for Azure Cosmos DB

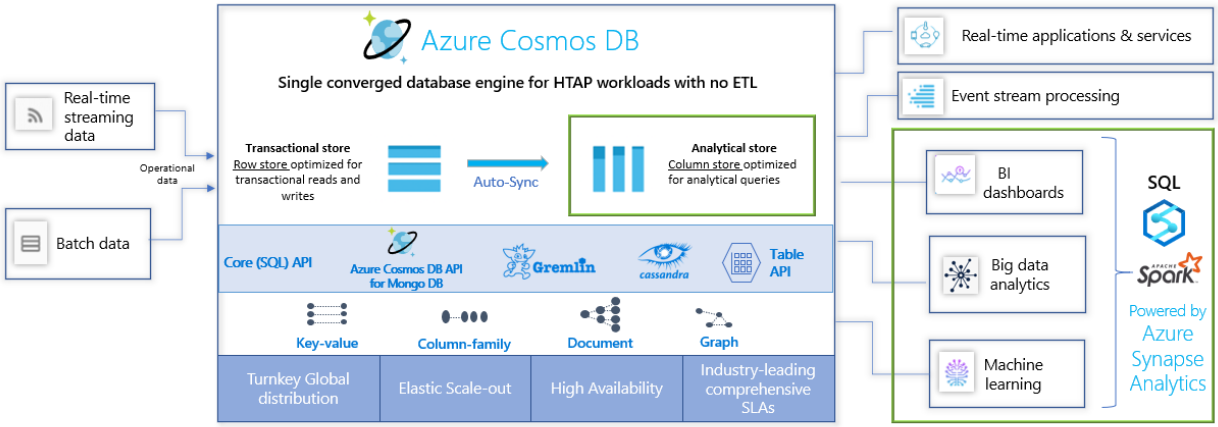
For nearly a decade, Azure Cosmos DB has been used by thousands of customers for mission critical applications that require elastic scale, turnkey global distribution, multi-region write replication for low latency and high availability of both reads & writes in their transactional workloads.

The following list shows an overview of the various workload patterns that are supported with operational data using Azure Cosmos DB:

- Real-time apps & services
- Event stream processing
- BI dashboards
- Big data analytics
- Machine learning

Azure Synapse Link enables Azure Cosmos DB to not just power transactional workloads but also perform near real-time analytical workloads over historical operational data. It happens with no ETL requirements and guaranteed performance isolation from the transactional workloads.

The following image shows workload patterns using Azure Cosmos DB:



Let us take the example of an e-commerce company CompanyXYZ with global operations across 20 countries/regions to illustrate the benefits of choosing Azure Cosmos DB as the single real-time database powering both transactional and analytical requirements of an inventory management platform.

- CompanyXYZ's core business depends on the inventory management system – hence availability & reliability are core pillar requirements. Benefits of using Azure Cosmos DB:
  - By virtue of deep integration with Azure infrastructure, and transparent multi-region writes, global replication, Azure Cosmos DB provides industry-leading 99.999% high availability against regional outages.
- CompanyXYZ's supply chain partners may be in separate geographic locations but they may have to see a single view of the product inventory across the globe to support their local operations. This includes the need to be able to read updates made by other supply chain partners in real time. As well as being able to make updates without worrying about conflicts with other partners at high throughput. Benefits of using Azure Cosmos DB:
  - With its unique multi-region writes replication protocol and latch-free, write-optimized transactional store, Azure Cosmos DB guarantees less than 10-ms latencies for both indexed reads and writes at the 99th percentile globally.
  - High throughput ingestion of both batch & streaming data feeds with real-time indexing in transactional store.
  - Azure Cosmos DB transactional store provides three more options than the two extremes of strong and eventual consistency levels to achieve the availability vs performance tradeoffs closest to the business need.
- CompanyXYZ's supply chain partners have highly fluctuating traffic patterns ranging from hundreds to millions of requests/s and thus the inventory management platform needs to deal with unexpected burstiness in traffic. Benefits of using Azure Cosmos DB:
  - Azure Cosmos DB's transactional store supports elastic scalability of storage and throughput using horizontal partitioning. Containers and databases configured in Autopilot mode can automatically and instantly scale the provisioned throughput based on the application needs without impacting the availability, latency, throughput, or performance of the workload globally.
- CompanyXYZ needs to establish a secure analytics platform to house system-wide historical inventory data to enable analytics and insights across supply chain partner, business units and functions. The analytics platform needs to enable collaboration across the system, traditional BI/reporting use cases, advanced analytics use cases and predictive intelligent solutions over the operational inventory data.

Benefits of using Synapse Link for Azure Cosmos DB:

- By using Azure Cosmos DB analytical store, a fully isolated column store, Synapse Link enables no Extract-Transform-Load (ETL) analytics in Azure Synapse Analytics against globally distributed operational data at scale. Business analysts, data engineers and data scientists can now use Synapse Spark or Synapse SQL in an interoperable manner to run near real-time business intelligence, analytics, and machine learning pipelines without impacting the performance of their transactional workloads on Azure Cosmos DB. See the benefits of Synapse Link in Azure Cosmos DB for more details.

Azure Synapse Link for Azure SQL Database (Preview)

8/19/2022 • 3 minutes to read • Edit Online

This article helps you to understand the functions of Azure Synapse Link for Azure SQL Database. You can use the Azure Synapse Link for SQL functionality to replicate your operational data into an Azure Synapse Analytics dedicated SQL pool from Azure SQL Database.

> **IMPORTANT**
>
> Azure Synapse Link for SQL is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Link connection

A link connection identifies a mapping relationship between an Azure SQL database and an Azure Synapse Analytics dedicated SQL pool. You can create, manage, monitor and delete link connections in your Synapse workspace. When creating a link connection, you can select both source database and a destination Synapse dedicated SQL pool so that the operational data from your source database will be automatically replicated to the specified destination Synapse dedicated SQL pool. You can also add or remove one or more tables from your source database to be replicated.

You can start or stop a link connection. When started, a link connection will start from a full initial load from your source database followed by incremental change feeds via the change feed feature in Azure SQL database. When you stop a link connection, the updates made to the operational data won't be synchronized to your Synapse dedicated SQL pool. For more information, see Azure Synapse Link change feed for SQL Server 2022 and Azure SQL Database.

You need to select compute core counts for each link connection to replicate your data. The core counts represent the compute power and it impacts your data replication latency and cost.

You also have the chance to make a trade-off between cost and latency by selecting the continuous or batch mode to replicate the data. When you select continuous mode, the runtime will be running continuously so that any changes applied to your SQL DB or SQL Server will be replicated to Synapse with low latency. When you select batch mode with specified interval, the changes applied to your SQL DB or SQL Server will be accumulated and replicated to Synapse in a batch mode with specified interval. By doing so, you can save cost as you are only charged for the time when the runtime is required to replicate your data. After each batch of data is replicated, the runtime will be shut down automatically.

Monitoring

You can monitor Azure Synapse Link for SQL at the link and table levels. For each link connection, you'll see the following status:

- **Initial:** a link connection is created but not started. You will not be charged in initial state.
- **Starting:** a link connection is setting up compute engines to replicate data.
- **Running:** a link connection is replicating data.
- **Stopping:** a link connection is shutting down the compute engines.
- **Stopped:** a link connection is stopped. You will not be charged in stopped state.

For each table, you'll see the following status:

- **Snapshotting:** a source table is initially loaded to the destination with full snapshot.
- **Replicating:** any updates on source table are replicated to the destination.
- **Failed:** the data on source table can't be replicated to destination due to a fatal error. If you want to retry after fixing the error, remove the table from link connection and add it back.
- **Suspended:** replication is suspended for this table due to an error. It will be resumed after the error is resolved.

Transactional consistency across tables

You can enable transactional consistency across tables for each link connection. However, it limits overall replication throughput.

Known limitations

A consolidated list of known limitations and issues can be found at Known limitations and issues with Azure Synapse Link for SQL (Preview).

Next steps

- To learn more, see how to Configure Synapse Link for Azure SQL Database (Preview).

Azure Synapse Link for SQL Server 2022 (Preview)

8/19/2022 • 4 minutes to read • Edit Online

This article helps you to understand the functions of Azure Synapse Link for SQL Server 2022. You can use the Azure Synapse Link for SQL functionality to replicate your operational data into an Azure Synapse Analytics dedicated SQL pool from SQL Server 2022.

> **IMPORTANT**
>
> Azure Synapse Link for SQL is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Link connection

A link connection identifies a mapping relationship between an SQL Server 2022 and an Azure Synapse Analytics dedicated SQL pool. You can create, manage, monitor and delete link connections in your Synapse workspace. When creating a link connection, you can select both source database and destination Synapse dedicated SQL pool so that the operational data from your source database will be automatically replicated to the specified destination Synapse dedicated SQL pool. You can also add or remove one or more tables from your source database to be replicated.

You can start or stop a link connection. When started, a link connection will start from a full initial load from your source database followed by incremental change feeds via change feed feature in SQL Server 2022. When you stop a link connection, the updates made to the operational data won't be synchronized to your Synapse dedicated SQL pool. For more information, see Azure Synapse Link change feed for SQL Server 2022 and Azure SQL Database.

You need to select compute core counts for each link connection to replicate your data. The core counts represent the compute power and it impacts your data replication latency and cost.

You also have the chance to make a trade-off between cost and latency by selecting the continuous or batch mode to replicate the data. When you select continuous mode, the runtime will be running continuously so that any changes applied to your SQL DB or SQL Server will be replicated to Synapse with low latency. When you select batch mode with specified interval, the changes applied to your SQL DB or SQL Server will be accumulated and replicated to Synapse in a batch mode with specified interval. By doing so, you can save cost as you are only charged for the time when the runtime is required to replicate your data. After each batch of data is replicated, the runtime will be shut down automatically.

Landing zone

The landing zone is an interim staging store required for Azure Synapse Link for SQL Server 2022. First, the operational data is loaded from the SQL Server 2022 to the landing zone. Next, the data is copied from the landing zone to the Synapse dedicated SQL pool. You need to provide your own Azure Data Lake Storage Gen2 account to be used as a landing zone. It is not supported to use this landing zone for anything other than Azure Synapse Link for SQL.

The shared access signature (SAS) token from your Azure Data Lake Storage Gen2 account is required for a link connection to get access to the landing zone. Be aware that the SAS token has an expiration date. Make sure to rotate the SAS token before the expiration date to ensure the SAS token is valid. Otherwise, Azure Synapse Link for SQL will fail to replicate the data from SQL Server 2022.

Self-hosted integration runtime

Self-hosted integration runtime is a software agent that you can download and install on an on-premises machine or a virtual machine. It is required for Azure Synapse Link for SQL Server 2022 to get access the data on SQL Server 2022 on premises that is behind the firewall. Currently, the self-hosted IR is only supported on a Windows operating system. For more information, see Create a self-hosted integration runtime

Monitoring

You can monitor Azure Synapse Link for SQL at the link and table levels. For each link connection, you'll see the following status:

- **Initial:** a link connection is created but not started. You will not be charged in initial state.
- **Starting:** a link connection is setting up compute engines to replicate data.
- **Running:** a link connection is replicating data.
- **Stopping:** a link connection is shutting down the compute engines.
- **Stopped:** a link connection is stopped. You will not be charged in stopped state.

For each table, you'll see the following status:

- **Snapshotting:** a source table is initially loaded to the destination with full snapshot.
- **Replicating:** any updates on source table are replicated to the destination.
- **Failed:** the data on source table can't be replicated to destination. If you want to retry after fixing the error, remove the table from link connection and add it back.
- **Suspended:** replication is suspended for this table due to an error. It will be resumed after the error is resolved.

For more information, see Manage Synapse Link for SQL change feed.

Transactional consistency across tables

You can enable transactional consistency across table for each link connection. However, it limits overall replication throughput.

Known limitations

A consolidated list of known limitations and issues can be found at Known limitations and issues with Azure Synapse Link for SQL (Preview).

Next steps

- To learn more, see how to Configure Synapse Link for SQL Server 2022 (Preview).

Configure and use Azure Synapse Link for Azure Cosmos DB

8/19/2022 • 13 minutes to read • Edit Online

APPLIES TO: SQL API Azure Cosmos DB API for MongoDB

Azure Synapse Link for Azure Cosmos DB is a cloud-native hybrid transactional and analytical processing (HTAP) capability that enables you to run near real-time analytics over operational data in Azure Cosmos DB. Synapse Link creates a tight seamless integration between Azure Cosmos DB and Azure Synapse Analytics.

Azure Synapse Link is available for Azure Cosmos DB SQL API or for Azure Cosmos DB API for Mongo DB accounts. Use the following steps to run analytical queries with the Azure Synapse Link for Azure Cosmos DB:

- Enable Azure Synapse Link for your Azure Cosmos DB accounts
- Create an analytical store enabled container
- Enable analytical store in an existing container
- Optional - Update analytical store ttl for a container
- Optional - Disable analytical store in a container
- Connect your Azure Cosmos database to an Azure Synapse workspace
- Query the analytical store using Azure Synapse Spark Pool
- Query the analytical store using Azure Synapse serverless SQL pool
- Use Azure Synapse serverless SQL pool to analyze and visualize data in Power BI

You can also checkout the learn module on how to configure Azure Synapse Link for Azure Cosmos DB.

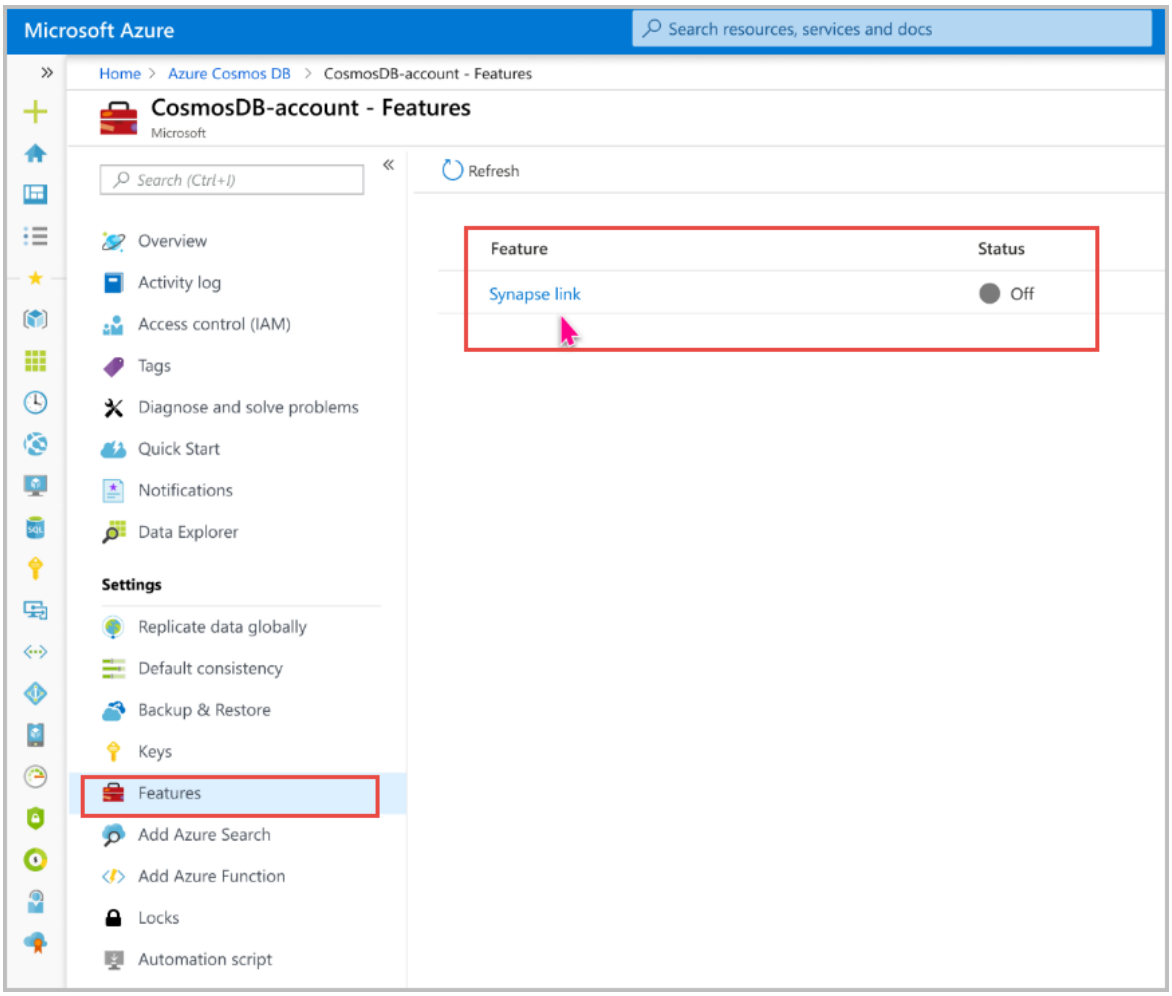
Enable Azure Synapse Link for Azure Cosmos DB accounts

> **NOTE**
> If you want to use customer-managed keys with Azure Synapse Link, you must configure your account's managed identity in your Azure Key Vault access policy before enabling Synapse Link on your account. To learn more, see how to Configure customer-managed keys using Azure Cosmos DB accounts' managed identities article.

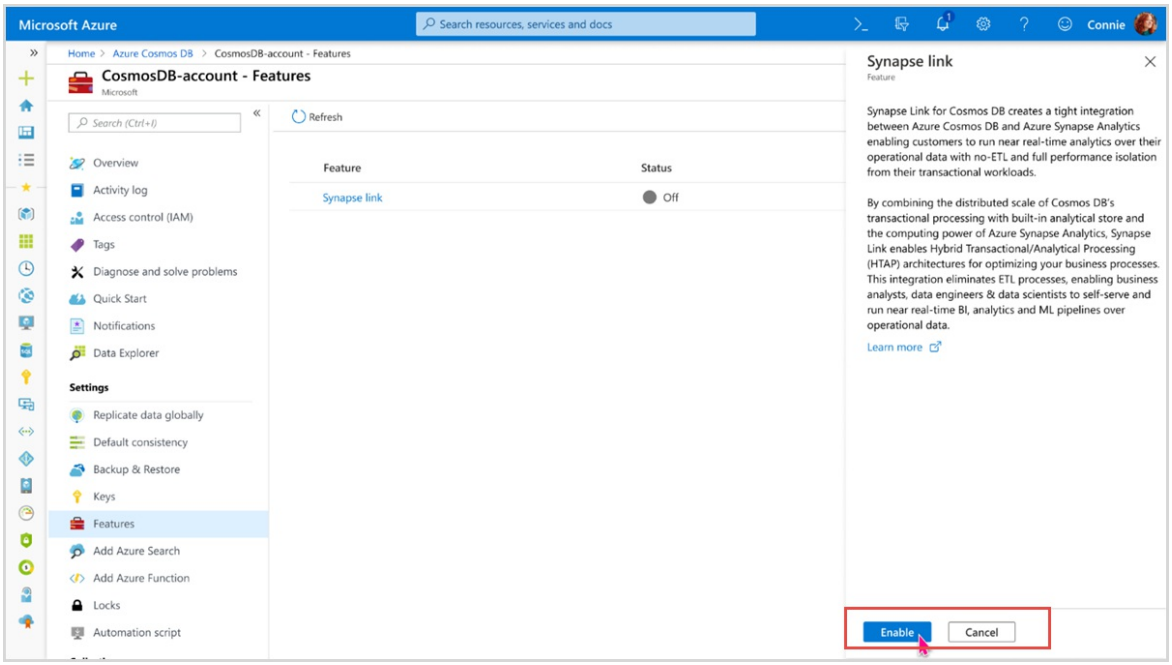
> **NOTE**
> If you want to use Full Fidelity Schema for SQL (CORE) API accounts, you can't use the Azure portal to enable Synapse Link. This option can't be changed after Synapse Link is enabled in your account and to set it you must use Azure CLI or PowerShell. For more information, check analytical store schema representation documentation.

Azure portal

1. Sign into the Azure portal.
2. Create a new Azure account, or select an existing Azure Cosmos DB account.
3. Navigate to your Azure Cosmos DB account and open the **Features** pane.
4. Select **Synapse Link** from the features list.



5. Next it prompts you to enable synapse link on your account. Select **Enable**. This process can take 1 to 5 minutes to complete.



6. Your account is now enabled to use Synapse Link. Next see how to create analytical store enabled containers to automatically start replicating your operational data from the transactional store to the analytical store.

> **NOTE**
>
> Turning on Synapse Link does not turn on the analytical store automatically. Once you enable Synapse Link on the Cosmos DB account, enable analytical store on containers to start using Synapse Link.

Command-Line Tools

Enable Synapse Link in your Cosmos DB SQL API or MongoDB API account using Azure CLI or PowerShell.

Azure CLI

Use `--enable-analytical-storage true` for both **create** or **update** operations. You also need to choose the representation schema type. For SQL API accounts you can use `--analytical-storage-schema-type` with the values `FullFidelity` or `WellDefined`. For MongoDB API accounts, always use `--analytical-storage-schema-type FullFidelity`.

- Create a new Azure Cosmos DB account with Synapse Link enabled
- Update an existing Azure Cosmos DB account to enable Synapse Link

PowerShell

Use `EnableAnalyticalStorage true` for both **create** or **update** operations. You also need to choose the representation schema type. For SQL API accounts you can use `--analytical-storage-schema-type` with the values `FullFidelity` or `WellDefined`. For MongoDB API accounts, always use `-AnalyticalStorageSchemaType FullFidelity`.

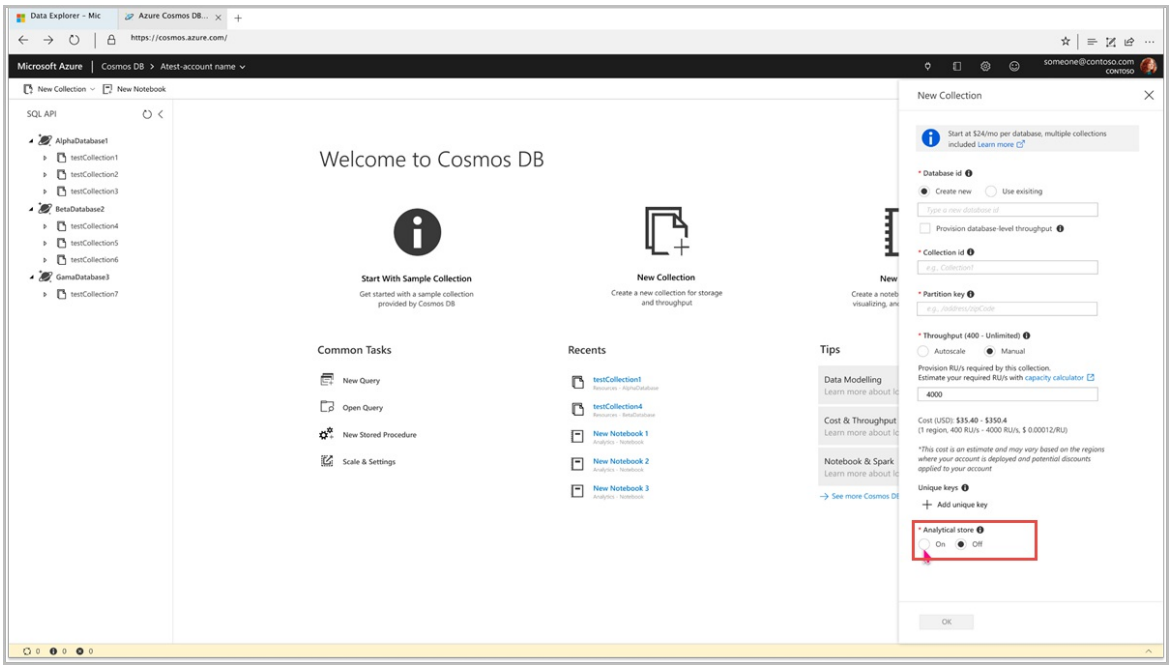
- Create a new Azure Cosmos DB account with Synapse Link enabled
- Update an existing Azure Cosmos DB account to enable Synapse Link

Create an analytical store enabled container

You can turn on analytical store when creating an Azure Cosmos DB container by using one of the following options.

Azure portal

1. Sign in to the Azure portal or the Azure Cosmos DB Explorer.
2. Navigate to your Azure Cosmos DB account and open the **Data Explorer** tab.
3. Select **New Container** and enter a name for your database, container, partition key and throughput details. Turn on the **Analytical store** option. After you enable the analytical store, it creates a container with `analytical TTL` property set to the default value of -1 (infinite retention). This analytical store that retains all the historical versions of records and can be changed later.



4. If you have previously not enabled Synapse Link on this account, it will prompt you to do so because it's a pre-requisite to create an analytical store enabled container. If prompted, select **Enable Synapse Link**. This process can take 1 to 5 minutes to complete.

5. Select **OK**, to create an analytical store enabled Azure Cosmos DB container.

6. After the container is created, verify that analytical store has been enabled by clicking **Settings**, right below Documents in Data Explorer, and check if the **Analytical Store Time to Live** option is turned on.

Azure Cosmos DB SDKs

Set the `analytical TTL` property to the required value to create an analytical store enabled container. For the list of allowed values, see the analytical TTL supported values article.

.NET SDK

The following code creates a container with analytical store by using the .NET SDK. Set the `AnalyticalStoreTimeToLiveInSeconds` property to the required value in seconds or use `-1` for infinite retention. This setting can be changed later.

```
// Create a container with a partition key, and analytical TTL configured to -1 (infinite retention)
ContainerProperties properties = new ContainerProperties()
{
    Id = "myContainerId",
    PartitionKeyPath = "/id",
    AnalyticalStoreTimeToLiveInSeconds = -1,
};
CosmosClient cosmosClient = new CosmosClient("myConnectionString");
await cosmosClient.GetDatabase("myDatabase").CreateContainerAsync(properties);
```

Java V4 SDK

The following code creates a container with analytical store by using the Java V4 SDK. Set the `AnalyticalStoreTimeToLiveInSeconds` property to the required value in seconds or use `-1` for infinite retention. This setting can be changed later.

```
// Create a container with a partition key and  analytical TTL configured to  -1 (infinite retention)
CosmosContainerProperties containerProperties = new CosmosContainerProperties("myContainer",
"/myPartitionKey");

containerProperties.setAnalyticalStoreTimeToLiveInSeconds(-1);

container = database.createContainerIfNotExists(containerProperties, 400).block().getContainer();
```

Python V4 SDK

The following code creates a container with analytical store by using the Python V4 SDK. Set the `analytical_storage_ttl` property to the required value in seconds or use `-1` for infinite retention. This setting can be changed later.

```
# Azure Cosmos DB Python SDK, for SQL API only.
# Creating an analytical store enabled container.

import azure.cosmos as cosmos
import azure.cosmos.cosmos_client as cosmos_client
import azure.cosmos.exceptions as exceptions
from azure.cosmos.partition_key import PartitionKey

HOST = 'your-cosmos-db-account-URI'
KEY = 'your-cosmos-db-account-key'
DATABASE = 'your-cosmos-db-database-name'
CONTAINER = 'your-cosmos-db-container-name'

# Client
client = cosmos_client.CosmosClient(HOST,  KEY )

# Database client
try:
    db = client.create_database(DATABASE)

except exceptions.CosmosResourceExistsError:
    db = client.get_database_client(DATABASE)

# Creating the container with analytical store enabled
try:
    container = db.create_container(
        id=CONTAINER,
        partition_key=PartitionKey(path='/id', kind='Hash'),analytical_storage_ttl=-1
    )
    properties = container.read()
    print('Container with id \'{0}\' created'.format(container.id))
    print('Partition Key - \'{0}\''.format(properties['partitionKey']))

except exceptions.CosmosResourceExistsError:
    print('A container with already exists')
```

Command-Line Tools

Set the `analytical TTL` property to the required value to create an analytical store enabled container. For the list of allowed values, see the analytical TTL supported values article.

Azure CLI

The following options create a container with analytical store by using Azure CLI. Set the `--analytical-storage-ttl` property to the required value in seconds or use `-1` for infinite retention. This setting can be changed later.

- Create an Azure Cosmos DB MongoDB collection
- Create an Azure Cosmos DB SQL API container

PowerShell

The following options create a container with analytical store by using PowerShell. Set the `-AnalyticalStorageTtl` property to the required value in seconds or use `-1` for infinite retention. This setting can be changed later.

- Create an Azure Cosmos DB MongoDB collection
- Create an Azure Cosmos DB SQL API container

Enable analytical store in an existing container

> **NOTE**
> You can turn on analytical store on existing Azure Cosmos DB SQL API containers. This capability is general available and can be used for production workloads.

Please note the following details when enabling Azure Synapse Link on your existing containers:

- The same performance isolation of the analytical store auto-sync process applies to the initial sync and there is no performance impact on your OLTP workload.
- A container's initial sync with analytical store total time will vary depending on the data volume and on the documents complexity. This process can take anywhere from a few seconds to multiple days. Please use the Azure portal to monitor the migration progress.
- The throughput of your container, or database account, also influences the total initial sync time. Although RU/s are not used in this migration, the total RU/s available influences the performance of the process. You can temporarily increase your environment's available RUs to speed up the process.
- You won't be able to query analytical store of an existing container while Synapse Link is being enabled on that container. Your OLTP workload isn't impacted and you can keep on reading data normally. Data ingested after the start of the initial sync will be merged into analytical store by the regular analytical store auto-sync process.
- Currently existing MongoDB API collections are not supported. The alternative is to migrate the data into a new collection, created with analytical store turned on.

Azure portal

1. Sign in to the Azure portal.
2. Navigate to your Azure Cosmos DB account and open the **Azure Synapse Link"** tab in the **Integrations** left navigation section. In this tab you can enable Synapse Link in your database account and you can enable Synapse Link on your existing containers.
3. After you click the blue **Enable Synapse Link on your container(s)** button, you will start to see the progress of your containers initial sync progress.
4. Optionally, you can go to the **Power BI** tab, also in the **Integrations** section, to create Power BI dashboards on your Synapse Link enabled containers.

Command-Line Tools

Set the `analytical TTL` property to `-1` for infinite retention or use a positive integer to specify the number of seconds that the data will be retain in analytical store. For more information, see the analytical TTL supported values article.

Azure CLI

- Use az cosmosdb sql container update to update `--analytical-storage-ttl`.
- Check the migration status in the Azure portal.

PowerShell

- Use Update Analytical ttl to update `-AnalyticalStorageTtl`.
- Check the migration status in the Azure portal.

Optional - Update the analytical store time to live

After the analytical store is enabled with a particular TTL value, you may want to update it to a different valid value. You can update the value by using the Azure portal, Azure CLI, PowerShell, or Cosmos DB SDKs. For information on the various Analytical TTL config options, see the analytical TTL supported values article.

Azure portal

If you created an analytical store enabled container through the Azure portal, it contains a default `analytical TTL` of `-1`. Use the following steps to update this value:

1. Sign in to the Azure portal or the Azure Cosmos DB Explorer.
2. Navigate to your Azure Cosmos DB account and open the **Data Explorer** tab.
3. Select an existing container that has analytical store enabled. Expand it and modify the following values:
   a. Open the **Scale & Settings** window.
   b. Under **Setting** find, **Analytical Storage Time to Live**.
   c. Select **On (no default)** or select **On** and set a TTL value.
   d. Click **Save** to save the changes.

.NET SDK

The following code shows how to update the TTL for analytical store by using the .NET SDK:

```
// Get the container, update AnalyticalStorageTimeToLiveInSeconds
ContainerResponse containerResponse = await client.GetContainer("database",
"container").ReadContainerAsync();
// Update analytical store TTL
containerResponse.Resource. AnalyticalStorageTimeToLiveInSeconds = 60 * 60 * 24 * 180  // Expire analytical
store data in 6 months;
await client.GetContainer("database", "container").ReplaceContainerAsync(containerResponse.Resource);
```

Java V4 SDK

The following code shows how to update the TTL for analytical store by using the Java V4 SDK:

```
CosmosContainerProperties containerProperties = new CosmosContainerProperties("myContainer",
"/myPartitionKey");

// Update analytical store TTL to expire analytical store data in 6 months;
containerProperties.setAnalyticalStoreTimeToLiveInSeconds (60 * 60 * 24 * 180 );

// Update container settings
container.replace(containerProperties).block();
```

Python V4 SDK

Currently not supported.

Azure CLI

The following links show how to update containers analytical TTL by using Azure CLI:

- Azure Cosmos DB API for Mongo DB
- Azure Cosmos DB SQL API

PowerShell

The following links show how to update containers analytical TTL by using PowerShell:

- Azure Cosmos DB API for Mongo DB
- Azure Cosmos DB SQL API

Optional - Disable analytical store in a SQL API container

Analytical store can be disabled in SQL API containers using Azure CLI or PowerShell.

> **NOTE**
> Please note that currently this action can't be undone. If analytical store is disabled in a container, it can never be re-enabled.

> **NOTE**
> Please note that disabling analitical store is not available for MongoDB API collections.

Azure CLI

Set `--analytical-storage-ttl` parameter to 0 using the `az cosmosdb sql container update` Azure CLI command.

PowerShell

Set `-AnalyticalStorageTtl` paramenter to 0 using the `Update-AzCosmosDBSqlContainer` PowerShell command.

Connect to a Synapse workspace

Use the instructions in Connect to Azure Synapse Link on how to access an Azure Cosmos DB database from Azure Synapse Analytics Studio with Azure Synapse Link.

Query analytical store using Apache Spark for Azure Synapse Analytics

Use the instructions in the Query Azure Cosmos DB analytical store using Spark 3 article on how to query with Synapse Spark 3. That article gives some examples on how you can interact with the analytical store from Synapse gestures. Those gestures are visible when you right-click on a container. With gestures, you can quickly generate code and tweak it to your needs. They are also perfect for discovering data with a single click.

For Spark 2 integration use the instruction in the Query Azure Cosmos DB analytical store using Spark 2 article.

Query the analytical store using serverless SQL pool in Azure Synapse Analytics

Serverless SQL pool allows you to query and analyze data in your Azure Cosmos DB containers that are enabled with Azure Synapse Link. You can analyze data in near real-time without impacting the performance of your transactional workloads. It offers a familiar T-SQL syntax to query data from the analytical store and integrated connectivity to a wide range of BI and ad-hoc querying tools via the T-SQL interface. To learn more, see the Query analytical store using serverless SQL pool article.

Use serverless SQL pool to analyze and visualize data in Power BI

You can use integrated BI experience in Azure Cosmos DB portal, to build BI dashboards using Synapse Link with just a few clicks. To learn more, see how to build BI dashboards using Synapse Link. This integrated experience

will create simple T-SQL views in Synapse serverless SQL pools, for your Cosmos DB containers. You can build BI dashboards over these views, which will query your Azure Cosmos DB containers in real-time, using Direct Query, reflecting latest changes to your data. There is no performance or cost impact to your transactional workloads, and no complexity of managing ETL pipelines.

If you want to use advance T-SQL views with joins across your containers or build BI dashboards in import] (/power-bi/connect-data/service-dataset-modes-understand#import-mode) mode, see how to use Serverless SQL pool to analyze Azure Cosmos DB data with Synapse Link article.

Configure custom partitioning

Custom partitioning enables you to partition analytical store dataonfields that are commonly used as filters inanalyticalqueriesresulting in improved query performance.To learn more, see the introduction to custom partitioning and how to configure custom partitioning articles.

Azure Resource Manager template

The Azure Resource Manager template creates a Synapse Link enabled Azure Cosmos DB account for SQL API. This template creates a Core (SQL) API account in one region with a container configured with analytical TTL enabled, and an option to use manual or autoscale throughput. To deploy this template, click on **Deploy to Azure** on the readme page.

Getting started with Azure Synapse Link - Samples

You can find samples to get started with Azure Synapse Link on GitHub. These showcase end-to-end solutions with IoT and retail scenarios. You can also find the samples corresponding to Azure Cosmos DB API for MongoDB in the same repo under the MongoDB folder.

Connect to Azure Synapse Link for Azure Cosmos DB

8/19/2022 • 2 minutes to read • Edit Online

This article describes how to access an Azure Cosmos DB database from Azure Synapse Analytics Studio with Azure Synapse Link.

Prerequisites

Before you connect an Azure Cosmos DB database to your workspace, you'll need an:

- Existing Azure Cosmos DB database, or create a new account by following the steps in Quickstart: Manage an Azure Cosmos DB account.
- Existing Azure Synapse workspace, or create a new workspace by following the steps in Quickstart: Create a Synapse workspace.

Enable Synapse Link on an Azure Cosmos DB database account

To run large-scale analytics into Azure Cosmos DB without affecting your operational performance, we recommend enabling Synapse Link for Azure Cosmos DB. Synapse Link brings HTAP capability to a container and built-in support in Azure Synapse.

Go to Synapse Studio

From your Azure Synapse workspace, select **Launch Synapse Studio**. On the Synapse Studio home page, select **Data**, which takes you to the Data Object Explorer.

Connect an Azure Cosmos DB database to an Azure Synapse workspace

Connecting an Azure Cosmos DB database is done as a linked service. With an Azure Cosmos DB linked service, you can browse and explore data, read, and write from Apache Spark for Azure Synapse Analytics or SQL into Azure Cosmos DB.

From the Data Object Explorer, you can directly connect to an Azure Cosmos DB database by following these steps:

1. Select the **+** icon near **Data**.
2. Select **Connect to external data**.
3. Select the API that you want to connect to, for example, **SQL API** or **API for MongoDB**.
4. Select **Continue**.
5. Use a friendly name to name the linked service. The name will appear in the Data Object Explorer and is used by Azure Synapse runtimes to connect to the database and containers.
6. Select the **Azure Cosmos DB account name** and the **database name**.
7. (Optional) If no region is specified, Azure Synapse runtime operations will be routed toward the nearest region where the analytical store is enabled. You can also manually set the region you want your users to use to access the Azure Cosmos DB analytical store. Select **Additional connection properties**, and then select **New**. Under **Property Name**, enter **PreferredRegions**. Set the **Value** to the region you want, for example, **WestUS2**. (There are no spaces between the words and the number.)

8. Select **Create**.

Azure Cosmos DB databases appear on the **Linked** tab under the **Azure Cosmos DB** section. With Azure Cosmos DB, you can differentiate an HTAP-enabled container from an OLTP-only container through the following icons:

OLTP-only container:

HTAP-enabled container:

Quickly interact with code-generated actions

By right-clicking into a container, you have a list of gestures that will trigger a Spark or SQL runtime. Writing into a container will happen through the Transactional Store of Azure Cosmos DB and will consume Request Units.

Next steps

- Learn how to query the analytical store with Spark 3
- Learn how to query the analytical store with Spark 2

Integrated Power BI experience in Azure Cosmos DB portal for Synapse Link enabled accounts

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: SQL API

With the integrated Power BI experience, you can visualize your Azure Cosmos DB data in near real time in just a few clicks. It uses the built-in Power BI integration feature in the Azure portal along with Azure Synapse Link.

Synapse Link enables you to build Power BI dashboards with no performance or cost impact to your transactional workloads, and no ETL pipelines. With DirectQuery, you can build dashboards using live data from your Azure Cosmos DB accounts, without importing or copying the data into Power BI.

Build a Power BI report

Use the following steps to build a Power BI report from Azure Cosmos DB data in DirectQuery mode:

1. Sign into the Azure portal and navigate to your Azure Cosmos DB account.
2. From the **Integrations** section, open the **Power BI** pane and select **Get started**.

   > **NOTE**
   > Currently, this option is only available for SQL API accounts.

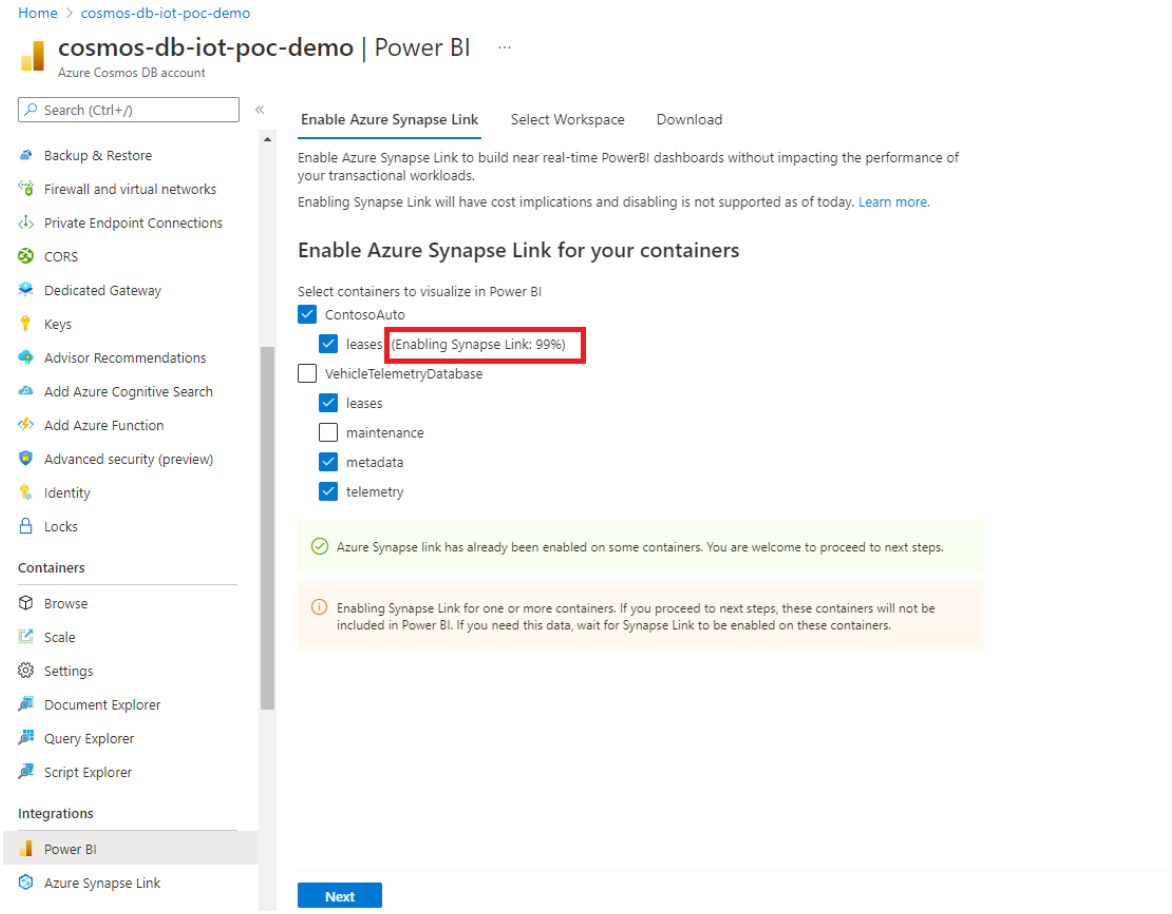
3. From the **Enable Azure Synapse Link** tab, if your account is not already enabled with Synapse Link, you can enable it from **Enable Azure Synapse link for this account** section. If Synapse Link is already enabled for your account, you will not see this tab.

   > **NOTE**
   > Once enabled, you cannot disable Azure Synapse Link. Enabling Azure Synapse Link has cost implications. See Azure Synapse Link pricing section for more details.

4. Next from the **Enable Azure Synapse Link for your containers** section, choose the required containers to enable Synapse Link.

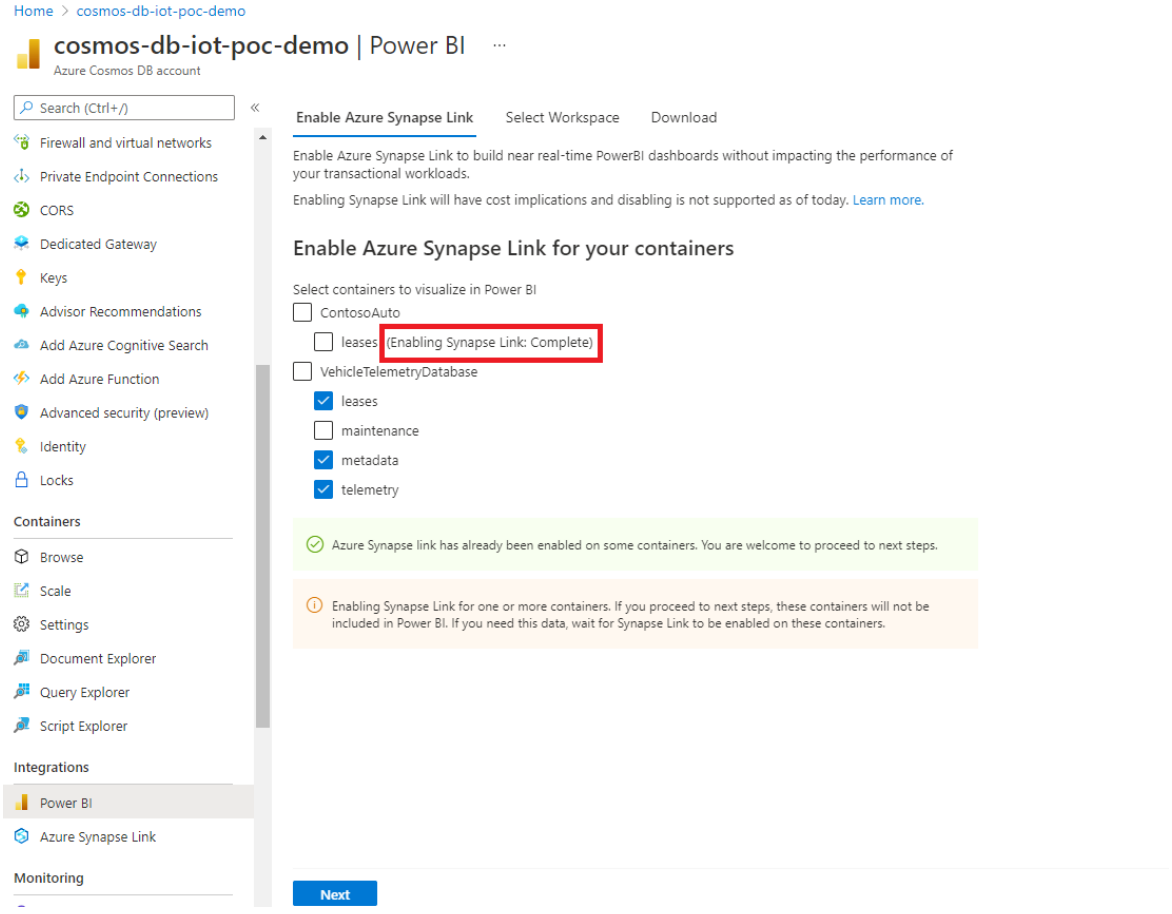
   - If you already enabled Synapse Link on some containers, you will see the checkbox next to the container name is selected. You may optionally deselect them, based on the data you'd like to visualize in Power BI.
   - If Synapse Link is not enabled, you can enable this on your existing containers.

     If enabling Synapse Link is in progress on any of the containers, the data from those containers will not be included. You should come back to this tab later and import data when the containers are enabled.



5. Depending on the amount of data in your containers, it may take a while to enable Synapse Link. To learn more, see enable Synapse Link on existing containers article.

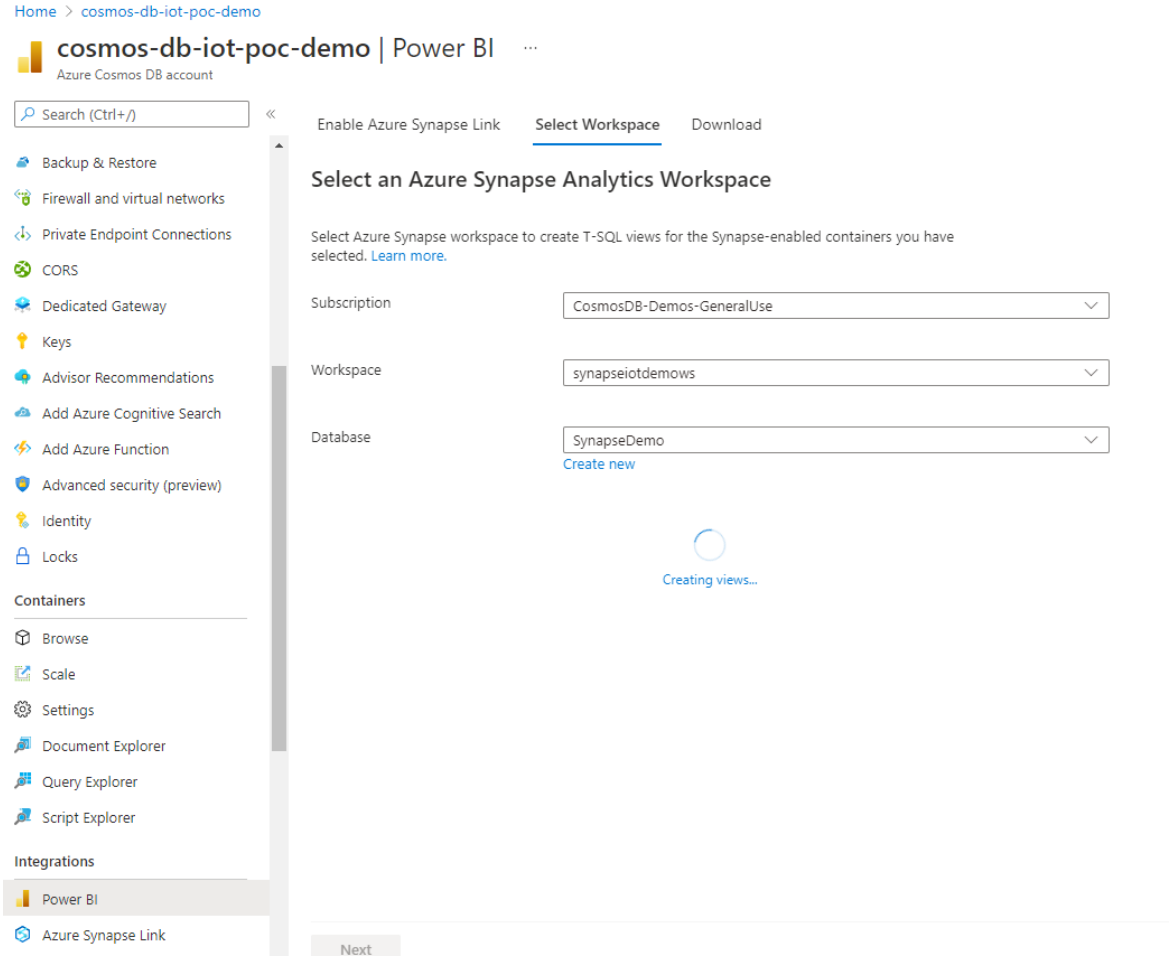
   You can check the progress in the portal as shown in the following screen. Containers are enabled with Synapse Link when the progress reaches 100%.



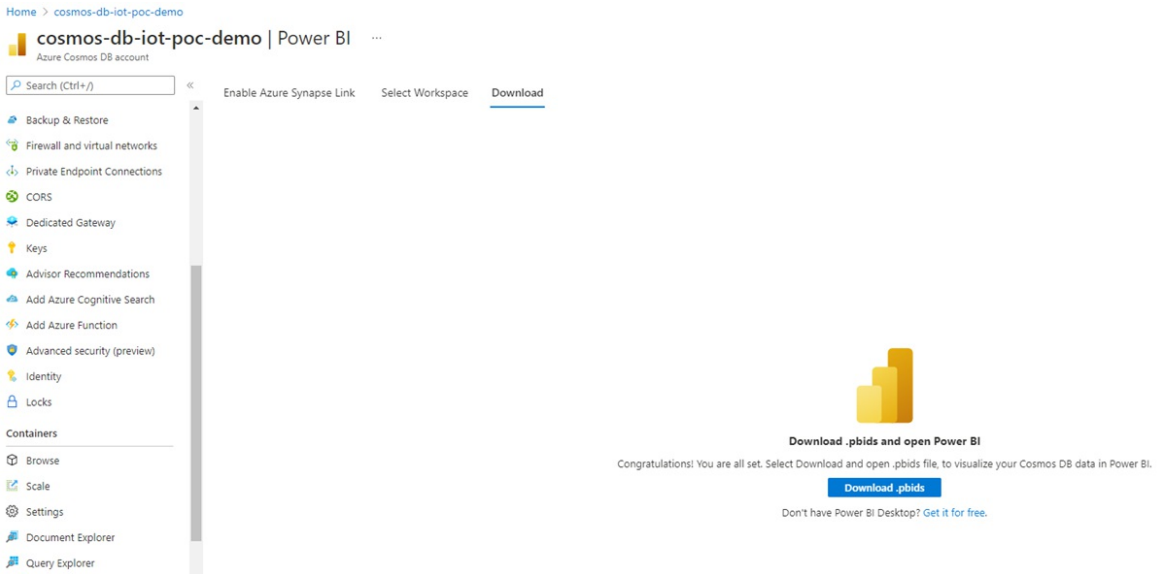
6. From the **Select workspace** tab, choose the Azure Synapse Analytics workspace and select **Next**. This will automatically create T-SQL views in Synapse Analytics, for the containers selected earlier. For more information on T-SQL views required to connect your Cosmos DB to Power BI, see Prepare views article.

> **NOTE**
>
> Your Cosmos DB container proprieties will be represented as columns in T-SQL views, including deep nested JSON data. This is a quick start for your BI dashboards. These views will be available in your Synapse workspace/database; you can also use these exact same views in Synapse Workspace for data exploration, data science, data engineering, etc. Please note that advanced scenarios may demand more complex views or fine tuning of these views, for better performance. For more information. see best practices for Synapse Link when using Synapse serverless SQL pools article.

7. You can either choose an existing workspace or create a new one. To select an existing workspace, provide the **Subscription**, **Workspace**, and the **Database** details. Azure portal will use your Azure AD credentials to automatically connect to your Synapse workspace and create T-SQL views. Make sure you have "Synapse administrator" permissions to this workspace.

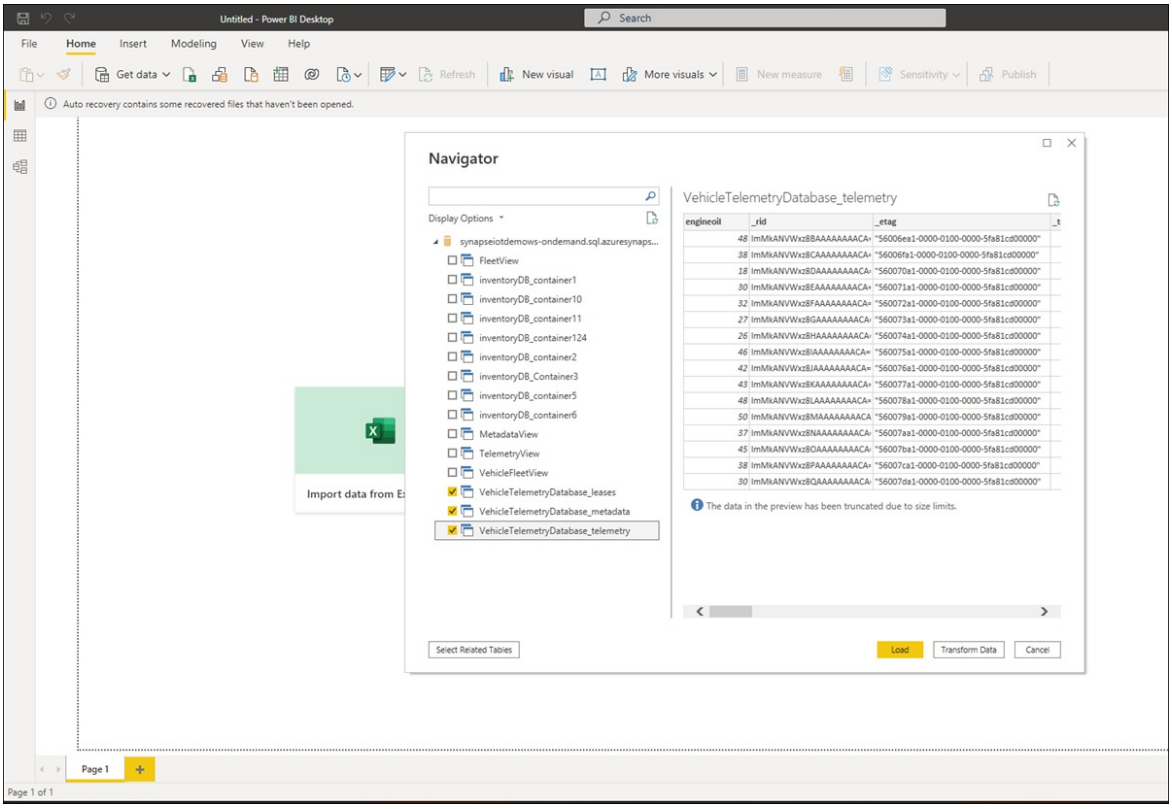


8. Next, select **Download .pbids** to download the Power BI data source file. Open the downloaded file. It contains the required connection information and opens a Power BI dashboard.



9. You can now connect to Azure Cosmos DB data from Power BI, using Synapse Link. A list of T-SQL views corresponding to the data in each container are displayed.

   For example, the following screen shows vehicle fleet data. You can load this data for further analysis or transform it before loading.



10. You can now start building the dashboard using Azure Cosmos DB's analytical data. Any changes to your data will be reflected in the dashboard, as soon as the data is replicated to analytical store, which typically happens in a couple of minutes.

Next steps

- Connect serverless SQL pool to Power BI Desktop & create report
- Use Power BI and serverless Synapse SQL pool to analyze Azure Cosmos DB data with Synapse Link

Use Power BI and serverless Synapse SQL pool to analyze Azure Cosmos DB data with Synapse Link

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: SQL API Azure Cosmos DB API for MongoDB

In this article, you learn how to build a serverless SQL pool database and views over Synapse Link for Azure Cosmos DB. You will query the Azure Cosmos DB containers and then build a model with Power BI over those views to reflect that query.

With Azure Synapse Link, you can build near real-time dashboards in Power BI to analyze your Azure Cosmos DB data. There is no performance or cost impact to your transactional workloads, and no complexity of managing ETL pipelines. You can use either DirectQuery or import modes.

> **NOTE**
> You can build Power BI dashboards with just a few clicks using Azure Cosmos DB portal. For more information, see Integrated Power BI experience in Azure Cosmos DB portal for Synapse Link enabled accounts. This will automatically create T-SQL views in Synapse serverless SQL pools on your Cosmos DB containers. You can simply download the .pbids file that connects to these T-SQL views to start building your BI dashboards.

In this scenario, you will use dummy data about Surface product sales in a partner retail store. You will analyze the revenue per store based on the proximity to large households and the impact of advertising for a specific week. In this article, you create two views named **RetailSales** and **StoreDemographics** and a query between them. You can get the sample product data from this GitHub repo.

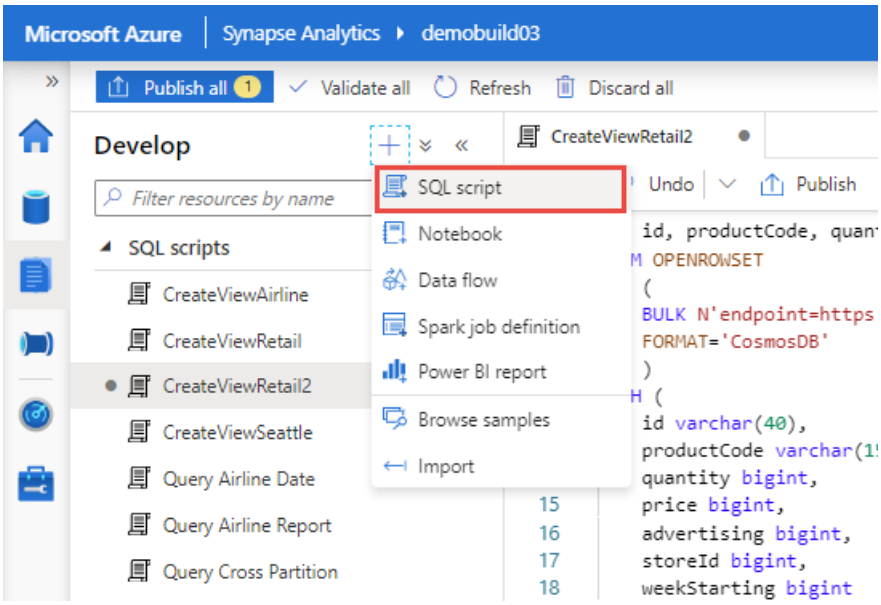
Prerequisites

Make sure to create the following resources before you start:

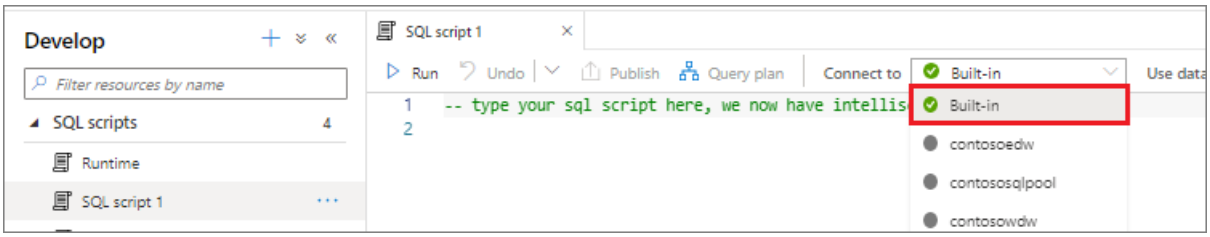
- Create an Azure Cosmos DB account of kind SQL(core) or MongoDB.
- Enable Azure Synapse Link for your Azure Cosmos account
- Create a database within the Azure Cosmos account and two containers that have analytical store enabled.
- Load products data into the Azure Cosmos containers as described in this batch data ingestion notebook.
- Create a Synapse workspace named **SynapseLinkBI**.
- Connect the Azure Cosmos database to the Synapse workspace.

Create a database and views

From the Synapse workspace go the **Develop** tab, select the **+** icon, and select **SQL Script**.



Every workspace comes with a serverless SQL endpoint. After creating a SQL script, from the tool bar on the top connect to **Built-in**.



Creating views in the **master** or **default** databases is not recommended or supported. Create a new database, named **RetailCosmosDB**, and a SQL view over the Synapse Link enabled containers. The following command shows how to create a database:

```
--Createdatabase
CreatedatabaseRetailCosmosDB
```

Next, create multiple views across different Synapse Link enabled Azure Cosmos containers. Views will allow you to use T-SQL to join and query Azure Cosmos DB data sitting in different containers. Make sure to select the **RetailCosmosDB** database when creating the views.

The following scripts show how to create views on each container. For simplicity, let's use the automatic schema inference feature of serverless SQL pool over Synapse Link enabled containers:

RetailSales view:

```
--Create view for RetailSales container
CREATEVIEW RetailSales
AS
SELECT  *
FROM OPENROWSET (
    'CosmosDB', N'account=<Your Azure Cosmos account name>;database=<Your Azure Cosmos database
name>;region=<Your Azure Cosmos DB Region>;key=<Your Azure Cosmos DB key here>',RetailSales)
AS q1
```

Make sure to insert your Azure Cosmos DB region and the primary key in the previous SQL script. All the characters in the region name should be in lower case without spaces. Unlike the other parameters of the `OPENROWSET` command, the container name parameter should be specified without quotes around it.

StoreDemographics view:

```
--Create view for StoreDemographics container
CREATEVIEWStoreDemographics
AS
SELECT  *
FROM OPENROWSET (
    'CosmosDB', N'account=<Your Azure Cosmos account name>;database=<Your Azure Cosmos database
name>;region=<Your Azure Cosmos DB Region>;key=<Your Azure Cosmos DB key here>', StoreDemographics)
AS q1
```

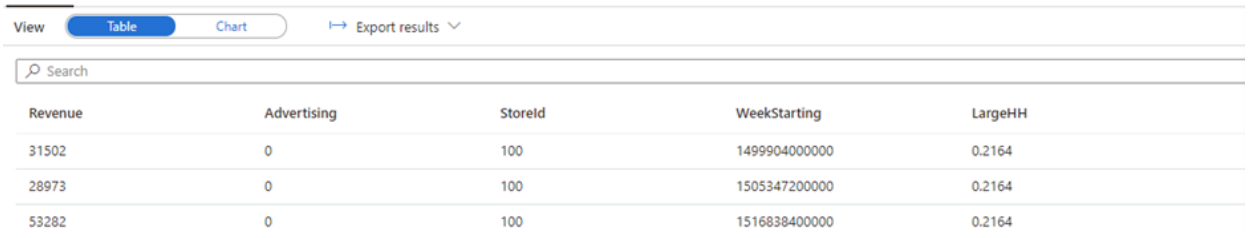
Now run the SQL script by selecting the **Run** command.

Query the views

Now that the two views are created, let's define the query to join those two views as follows:

```
SELECT
sum(p.[revenue]) as revenue
,p.[advertising]
,p.[storeId]
,p.[weekStarting]
,q.[largeHH]
 FROM [dbo].[RetailSales] as p
INNER JOIN [dbo].[StoreDemographics] as q ON q.[storeId] = p.[storeId]
GROUP BY p.[advertising], p.[storeId], p.[weekStarting], q.[largeHH]
```

Select **Run** that gives the following table as result:



Revenue	Advertising	StoreId	WeekStarting	LargeHH
31502	0	100	1499904000000	0.2164
28973	0	100	1505347200000	0.2164
53282	0	100	1516838400000	0.2164

Model views over containers with Power BI

Next open the Power BI desktop and connect to the serverless SQL endpoint by using the following steps:

1. Open the Power BI Desktop application. Select **Get data** and select **more**.
2. Choose **Azure Synapse Analytics (SQL DW)** from the list of connection options.
3. Enter the name of the SQL endpoint where the database is located. Enter `SynapseLinkBI-ondemand.sql.azuresynapse.net` within the **Server** field. In this example, **SynapseLinkBI** is name of the workspace. Replace it if you have given a different name to your workspace. Select **Direct Query** for data connectivity mode and then **OK**.
4. Select the preferred authentication method such as Azure AD.
5. Select the **RetailCosmosDB** database and the **RetailSales**, **StoreDemographics** views.
6. Select **Load** to load the two views into the direct query mode.
7. Select **Model** to create a relationship between the two views through the **storeId** column.
8. Drag the **StoreId** column from the **RetailSales** view towards the **StoreId** column in the **StoreDemographics** view.
9. Select the Many to one (*:1) relationship because there are multiple rows with the same store ID in the

RetailSales view. **StoreDemographics** has only one store ID row (it is a dimension table).

Now navigate to the **report** window and create a report to compare the relative importance of household size to the average revenue per store based on the scattered representation of revenue and LargeHH index:

1. Select **Scatter chart**.
2. Drag and drop **LargeHH** from the **StoreDemographics** view into the X-axis.
3. Drag and drop **Revenue** from **RetailSales** view into the Y-axis. Select **Average** to get the average sales per product per store and per week.
4. Drag and drop the **productCode** from **RetailSales** view into the legend to select a specific product line. After you choose these options, you should see a graph like the following screenshot:

Integrated Power BI experience in Azure Cosmos DB portal for Synapse Link enabled accounts

Use T-SQL to query Azure Cosmos DB data using Azure Synapse Link

Use serverless SQL pool to analyze Azure Open Datasets and visualize the results in Azure Synapse Studio

Interact with Azure Cosmos DB using Apache Spark 3 in Azure Synapse Link

8/19/2022 • 7 minutes to read • Edit Online

In this article, you'll learn how to interact with Azure Cosmos DB using Synapse Apache Spark 3. With its full support for Scala, Python, SparkSQL, and C#, Synapse Apache Spark 3 is central to analytics, data engineering, data science, and data exploration scenarios in Azure Synapse Link for Azure Cosmos DB.

The following capabilities are supported while interacting with Azure Cosmos DB:

- Synapse Apache Spark 3 allows you to analyze data in your Azure Cosmos DB containers that are enabled with Azure Synapse Link in near real-time without impacting the performance of your transactional workloads. The following two options are available to query the Azure Cosmos DB analytical store from Spark:
  - Load to Spark DataFrame
  - Create Spark table
- Synapse Apache Spark also allows you to ingest data into Azure Cosmos DB. It is important to note that data is always ingested into Azure Cosmos DB containers through the transactional store. When Synapse Link is enabled, any new inserts, updates, and deletes are then automatically synced to the analytical store.
- Synapse Apache Spark also supports Spark structured streaming with Azure Cosmos DB as a source as well as a sink.

The following sections walk you through the syntax of above capabilities. You can also checkout the learn module on how to Query Azure Cosmos DB with Apache Spark for Azure Synapse Analytics. Gestures in Azure Synapse Analytics workspace are designed to provide an easy out-of-the-box experience to get started. Gestures are visible when you right-click on an Azure Cosmos DB container in the **Data** tab of the Synapse workspace. With gestures, you can quickly generate code and tailor it to your needs. Gestures are also perfect for discovering data with a single click.

> **IMPORTANT**
>
> You should be aware of some constraints in the analytical schema that could lead to the unexpected behavior in data loading operations. As an example, only first 1000 properties from transactional schema are available in the analytical schema, properties with spaces are not available, etc. If you are experiencing some unexpected results, check the analytical store schema constraints for more details.

Query Azure Cosmos DB analytical store

Before you learn about the two possible options to query Azure Cosmos DB analytical store, loading to Spark DataFrame and creating Spark table, it is worth exploring the differences in experience so you can choose the option that works for your needs.

The difference in experience is around whether underlying data changes in the Azure Cosmos DB container should be automatically reflected in the analysis performed in Spark. When either a Spark DataFrame is registered or a Spark table is created against a container's analytical store, metadata around the current snapshot of data in the analytical store is fetched to Spark for efficient pushdown of subsequent analysis. It is important to note that since Spark follows a lazy evaluation policy, unless an action is invoked on the Spark DataFrame or a SparkSQL query is executed against the Spark table, actual data is not fetched from the underlying container's analytical store.

In the case of **loading to Spark DataFrame**, the fetched metadata is cached through the lifetime of the Spark session and hence subsequent actions invoked on the DataFrame are evaluated against the snapshot of the analytical store at the time of DataFrame creation.

On the other hand, in the case of **creating a Spark table**, the metadata of the analytical store state is not cached in Spark and is reloaded on every SparkSQL query execution against the Spark table.

Thus, you can choose between loading to Spark DataFrame and creating a Spark table based on whether you want your Spark analysis to be evaluated against a fixed snapshot of the analytical store or against the latest snapshot of the analytical store respectively.

> **NOTE**
>
> To query the Azure Cosmos DB API of Mongo DB accounts, learn more about the full fidelity schema representation in the analytical store and the extended property names to be used.

> **NOTE**
>
> Please note that all `options` in the commands below are case sensitive.

Load to Spark DataFrame

In this example, you'll create a Spark DataFrame that points to the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking Spark actions against the DataFrame. This operation doesn't impact the transactional store.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

df = spark.read.format("cosmos.olap")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val df_olap = spark.read.format("cosmos.olap").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    load()
```

Create Spark table

In this example, you'll create a Spark table that points the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking SparkSQL queries against the table. This operation neither impacts the transactional store nor does it incur any data movement. If you decide to delete this Spark table, the underlying Azure Cosmos DB container and the corresponding analytical store will not be affected.

This scenario is convenient to reuse Spark tables through third-party tools and provide accessibility to the underlying data for the run-time.

The syntax to create a Spark table is as follows:

```
%%sql
-- To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
spark.cosmos.preferredRegions '<Region1>,<Region2>' in the config options

create table call_center using cosmos.olap options (
    spark.synapse.linkedService '<enter linked service name>',
    spark.cosmos.container '<enter container name>'
)
```

NOTE

If you have scenarios where the schema of the underlying Azure Cosmos DB container changes over time; and if you want the updated schema to automatically reflect in the queries against the Spark table, you can achieve this by setting the `spark.cosmos.autoSchemaMerge` option to `true` in the Spark table options.

Write Spark DataFrame to Azure Cosmos DB container

In this example, you'll write a Spark DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume request units provisioned on the Azure Cosmos DB container or the shared database.

The syntax in **Python** would be the following:

```
# Write a Spark DataFrame into an Azure Cosmos DB container
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

YOURDATAFRAME.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .mode('append')\
    .save()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

import org.apache.spark.sql.SaveMode

df.write.format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    mode(SaveMode.Append).
    save()
```

Load streaming DataFrame from container

In this gesture, you'll use Spark Streaming capability to load data from a container into a dataframe. The data will be stored in the primary data lake account (and file system) you connected to the workspace.

> **NOTE**
>
> If you are looking to reference external libraries in Synapse Apache Spark, learn more here. For instance, if you are looking to ingest a Spark DataFrame to a container of Cosmos DB API for Mongo DB, you can leverage the Mongo DB connector for Spark here.

Load streaming DataFrame from Azure Cosmos DB container

In this example, you'll use Spark's structured streaming capability to load data from an Azure Cosmos DB container into a Spark streaming DataFrame using the change feed functionality in Azure Cosmos DB. The checkpoint data used by Spark will be stored in the primary data lake account (and file system) that you connected to the workspace.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

dfStream = spark.readStream\
    .format("cosmos.oltp.changeFeed")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.changeFeed.startFrom", "Beginning")\
    .option("spark.cosmos.changeFeed.mode", "Incremental")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val dfStream = spark.readStream.
    format("cosmos.oltp.changeFeed").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.changeFeed.startFrom", "Beginning").
    option("spark.cosmos.changeFeed.mode", "Incremental").
    load()
```

Write streaming DataFrame to Azure Cosmos DB container

In this example, you'll write a streaming DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database. If the folder */localWriteCheckpointFolder* isn't created (in the example below), it will be automatically created.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

streamQuery = dfStream\
    .writeStream\
    .format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("checkpointLocation", "/tmp/myRunId/")\
    .outputMode("append")\
    .start()

streamQuery.awaitTermination()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val query = dfStream.
            writeStream.
            format("cosmos.oltp").
            outputMode("append").
            option("spark.synapse.linkedService", "<enter linked service name>").
            option("spark.cosmos.container", "<enter container name>").
            option("checkpointLocation", "/tmp/myRunId/").
            start()

query.awaitTermination()
```

Query Azure Cosmos DB analytical store

Before you learn about the two possible options to query Azure Cosmos DB analytical store, loading to Spark DataFrame and creating Spark table, it is worth exploring the differences in experience so you can choose the option that works for your needs.

The difference in experience is around whether underlying data changes in the Azure Cosmos DB container should be automatically reflected in the analysis performed in Spark. When either a Spark DataFrame is registered or a Spark table is created against a container's analytical store, metadata around the current

snapshot of data in the analytical store is fetched to Spark for efficient pushdown of subsequent analysis. It is important to note that since Spark follows a lazy evaluation policy, unless an action is invoked on the Spark DataFrame or a SparkSQL query is executed against the Spark table, actual data is not fetched from the underlying container's analytical store.

In the case of **loading to Spark DataFrame**, the fetched metadata is cached through the lifetime of the Spark session and hence subsequent actions invoked on the DataFrame are evaluated against the snapshot of the analytical store at the time of DataFrame creation.

On the other hand, in the case of **creating a Spark table**, the metadata of the analytical store state is not cached in Spark and is reloaded on every SparkSQL query execution against the Spark table.

Thus, you can choose between loading to Spark DataFrame and creating a Spark table based on whether you want your Spark analysis to be evaluated against a fixed snapshot of the analytical store or against the latest snapshot of the analytical store respectively.

If your analytical queries have frequently used filters, you have the option to partition based on these fields for better query performance. You can periodically execute partitioning job from an Azure Synapse Spark notebook, to trigger partitioning on analytical store. This partitioned store points to the ADLS Gen2 primary storage account that is linked to your Azure Synapse workspace. To learn more, see the introduction to custom partitioning and how to configure custom partitioning articles.

> **NOTE**
> To query the Azure Cosmos DB API of Mongo DB accounts, learn more about the full fidelity schema representation in the analytical store and the extended property names to be used.

> **NOTE**
> Please note that all `options` in the commands below are case sensitive. For example, you must use `Gateway` while `gateway` will return an error.

Load to Spark DataFrame

In this example, you'll create a Spark DataFrame that points to the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking Spark actions against the DataFrame. This operation doesn't impact the transactional store.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

df = spark.read.format("cosmos.olap")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val df_olap = spark.read.format("cosmos.olap").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    load()
```

Create Spark table

In this example, you'll create a Spark table that points the Azure Cosmos DB analytical store. You can then perform additional analysis by invoking SparkSQL queries against the table. This operation neither impacts the transactional store nor does it incur any data movement. If you decide to delete this Spark table, the underlying Azure Cosmos DB container and the corresponding analytical store will not be affected.

This scenario is convenient to reuse Spark tables through third-party tools and provide accessibility to the underlying data for the run-time.

The syntax to create a Spark table is as follows:

```
%%sql
-- To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
spark.cosmos.preferredRegions '<Region1>,<Region2>' in the config options

create table call_center using cosmos.olap options (
    spark.synapse.linkedService '<enter linked service name>',
    spark.cosmos.container '<enter container name>'
)
```

> **NOTE**
>
> If you have scenarios where the schema of the underlying Azure Cosmos DB container changes over time; and if you want the updated schema to automatically reflect in the queries against the Spark table, you can achieve this by setting the `spark.cosmos.autoSchemaMerge` option to `true` in the Spark table options.

Write Spark DataFrame to Azure Cosmos DB container

In this example, you'll write a Spark DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume request units provisioned on the Azure Cosmos DB container or the shared database.

The syntax in **Python** would be the following:

```
# Write a Spark DataFrame into an Azure Cosmos DB container
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

YOURDATAFRAME.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.write.upsertEnabled", "true")\
    .mode('append')\
    .save()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

import org.apache.spark.sql.SaveMode

df.write.format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.write.upsertEnabled", "true").
    mode(SaveMode.Overwrite).
    save()
```

Load streaming DataFrame from container

In this gesture, you'll use Spark Streaming capability to load data from a container into a dataframe. The data will be stored in the primary data lake account (and file system) you connected to the workspace.

> **NOTE**
> If you are looking to reference external libraries in Synapse Apache Spark, learn more here. For instance, if you are looking to ingest a Spark DataFrame to a container of Cosmos DB API for Mongo DB, you can leverage the Mongo DB connector for Spark here.

Load streaming DataFrame from Azure Cosmos DB container

In this example, you'll use Spark's structured streaming capability to load data from an Azure Cosmos DB container into a Spark streaming DataFrame using the change feed functionality in Azure Cosmos DB. The checkpoint data used by Spark will be stored in the primary data lake account (and file system) that you connected to the workspace.

If the folder */localReadCheckpointFolder* isn't created (in the example below), it will be automatically created. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

dfStream = spark.readStream\
    .format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.changeFeed.readEnabled", "true")\
    .option("spark.cosmos.changeFeed.startFromTheBeginning", "true")\
    .option("spark.cosmos.changeFeed.checkpointLocation", "/localReadCheckpointFolder")\
    .option("spark.cosmos.changeFeed.queryName", "streamQuery")\
    .load()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

val dfStream = spark.readStream.
    format("cosmos.oltp").
    option("spark.synapse.linkedService", "<enter linked service name>").
    option("spark.cosmos.container", "<enter container name>").
    option("spark.cosmos.changeFeed.readEnabled", "true").
    option("spark.cosmos.changeFeed.startFromTheBeginning", "true").
    option("spark.cosmos.changeFeed.checkpointLocation", "/localReadCheckpointFolder").
    option("spark.cosmos.changeFeed.queryName", "streamQuery").
    load()
```

Write streaming DataFrame to Azure Cosmos DB container

In this example, you'll write a streaming DataFrame into an Azure Cosmos DB container. This operation will impact the performance of transactional workloads and consume Request Units provisioned on the Azure Cosmos DB container or shared database. If the folder */localWriteCheckpointFolder* isn't created (in the example below), it will be automatically created.

The syntax in **Python** would be the following:

```
# To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

# If you are using managed private endpoints for Azure Cosmos DB analytical store and using batch
writes/reads and/or streaming writes/reads to transactional store you should set connectionMode to Gateway.

def writeBatchToCosmos(batchDF, batchId):
  batchDF.persist()
  print("--> BatchId: {}, Document count: {} : {}".format(batchId, batchDF.count(),
datetime.datetime.utcnow().strftime("%Y-%m-%d %H:%M:%S.%f")))
  batchDF.write.format("cosmos.oltp")\
    .option("spark.synapse.linkedService", "<enter linked service name>")\
    .option("spark.cosmos.container", "<enter container name>")\
    .option("spark.cosmos.write.upsertEnabled", "true")\
    .mode('append')\
    .save()
  print("<-- BatchId: {}, Document count: {} : {}".format(batchId, batchDF.count(),
datetime.datetime.utcnow().strftime("%Y-%m-%d %H:%M:%S.%f")))
  batchDF.unpersist()

streamQuery = dfStream\
        .writeStream\
        .foreachBatch(writeBatchToCosmos) \
        .option("checkpointLocation", "/localWriteCheckpointFolder")\
        .start()

streamQuery.awaitTermination()
```

The equivalent syntax in **Scala** would be the following:

```
// To select a preferred list of regions in a multi-region Azure Cosmos DB account, add
.option("spark.cosmos.preferredRegions", "<Region1>,<Region2>")

// If you are using managed private endpoints for Azure Cosmos DB analytical store and using batch
writes/reads and/or streaming writes/reads to transactional store you should set connectionMode to Gateway.

val query = dfStream.
            writeStream.
            foreachBatch { (batchDF: DataFrame, batchId: Long) =>
              batchDF.persist()
              batchDF.write.format("cosmos.oltp").
                option("spark.synapse.linkedService", "<enter linked service name>").
                option("spark.cosmos.container", "<enter container name>").
                option("spark.cosmos.write.upsertEnabled", "true").
                mode(SaveMode.Overwrite).
                save()
              println(s"BatchId: $batchId, Document count: ${batchDF.count()}")
              batchDF.unpersist()
              ()
            }.
            option("checkpointLocation", "/localWriteCheckpointFolder").
            start()

query.awaitTermination()
```

Copy data from Azure Cosmos DB into a dedicated SQL pool using Apache Spark

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Link for Azure Cosmos DB enables users to run near real-time analytics over operational data in Azure Cosmos DB. However, there are times when some data needs to be aggregated and enriched to serve data warehouse users. Curating and exporting Azure Synapse Link data can be done with just a few cells in a notebook.

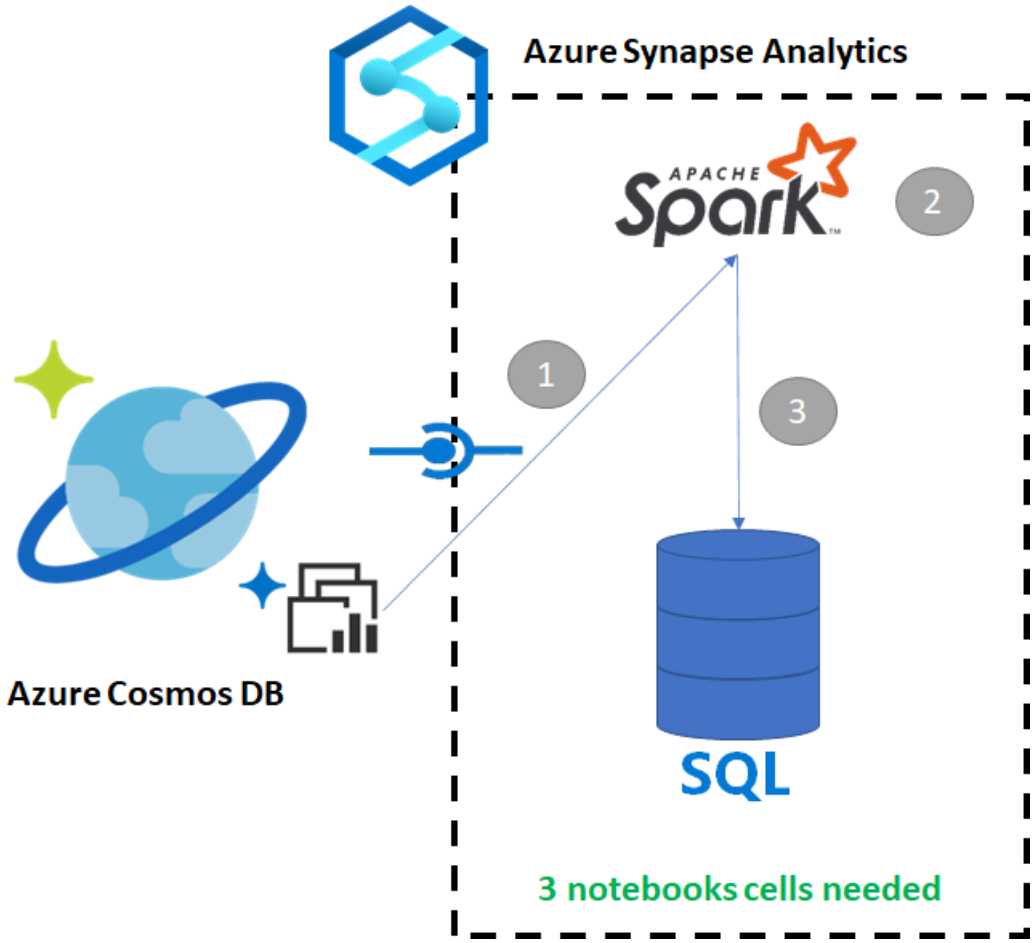
Prerequisites

- Provision a Synapse workspace with:
  - Serverless Apache Spark pool
  - dedicated SQL pool
- Provision a Cosmos DB account with a HTAP container with data
- Connect the Azure Cosmos DB HTAP container to the workspace
- Have the right setup to import data into a dedicated SQL pool from Spark

Steps

In this tutorial, you'll connect to the analytical store so there's no impact on the transactional store (it won't consume any Request Units). We'll go through the following steps:

1. Read the Cosmos DB HTAP container into a Spark dataframe
2. Aggregate the results in a new dataframe
3. Ingest the data into a dedicated SQL pool



Data

In that example, we use an HTAP container called **RetailSales**. It's part of a linked service called **ConnectedData**, and has the following schema:

- _rid: string (nullable = true)
- _ts: long (nullable = true)
- logQuantity: double (nullable = true)
- productCode: string (nullable = true)
- quantity: long (nullable = true)
- price: long (nullable = true)
- id: string (nullable = true)
- advertising: long (nullable = true)
- storeId: long (nullable = true)
- weekStarting: long (nullable = true)
- _etag: string (nullable = true)

We'll aggregate the sales (*quantity*, *revenue* (price x quantity) by *productCode* and *weekStarting* for reporting purposes. Finally, we'll export that data into a dedicated SQL pool table called `dbo.productsales`.

Configure a Spark Notebook

Create a Spark notebook with Scala as Spark (Scala) as the main language. We use the notebook's default setting for the session.

Read the data in Spark

Read the Cosmos DB HTAP container with Spark into a dataframe in the first cell.

```
val df_olap = spark.read.format("cosmos.olap").
    option("spark.synapse.linkedService", "ConnectedData").
    option("spark.cosmos.container", "RetailSales").
    load()
```

Aggregate the results in a new dataframe

In the second cell, we run the transformation and aggregates needed for the new dataframe before loading it into a dedicated SQL pool database.

```
// Select relevant columns and create revenue
val df_olap_step1 =
df_olap.select("productCode","weekStarting","quantity","price").withColumn("revenue",col("quantity")*col("pr
ice"))
//Aggregate revenue, quantity sold and avg. price by week and product ID
val df_olap_aggr = df_olap_step1.groupBy("productCode","weekStarting").agg(sum("quantity") as
"Sum_quantity",sum("revenue") as "Sum_revenue").
    withColumn("AvgPrice",col("Sum_revenue")/col("Sum_quantity"))
```

Load the results into a dedicated SQL pool

In the third cell, we load the data into a dedicated SQL pool. It will automatically create a temporary external table, external data source, and external file format that will be deleted once the job is done.

```
df_olap_aggr.write.sqlanalytics("userpool.dbo.productsales", Constants.INTERNAL)
```

Query the results with SQL

You can query the result using a simple SQL query such as the following SQL script:

```
SELECT  [productCode]
,[weekStarting]
,[Sum_quantity]
,[Sum_revenue]
,[AvgPrice]
 FROM [dbo].[productsales]
```

Your query will present the following results in a chart mode:

Query Azure Cosmos DB data with a serverless SQL pool in Azure Synapse Link

8/19/2022 • 15 minutes to read • Edit Online

A serverless SQL pool allows you to analyze data in your Azure Cosmos DB containers that are enabled with Azure Synapse Link in near real time without affecting the performance of your transactional workloads. It offers a familiar T-SQL syntax to query data from the analytical store and integrated connectivity to a wide range of business intelligence (BI) and ad-hoc querying tools via the T-SQL interface.

For querying Azure Cosmos DB, the full SELECT surface area is supported through the OPENROWSET function, which includes the majority of SQL functions and operators. You can also store results of the query that reads data from Azure Cosmos DB along with data in Azure Blob Storage or Azure Data Lake Storage by using create external table as select (CETAS). You can't currently store serverless SQL pool query results to Azure Cosmos DB by using CETAS.

In this article, you'll learn how to write a query with a serverless SQL pool that will query data from Azure Cosmos DB containers that are enabled with Azure Synapse Link. You can then learn more about building serverless SQL pool views over Azure Cosmos DB containers and connecting them to Power BI models in this tutorial. This tutorial uses a container with an Azure Cosmos DB well-defined schema. You can also check out the learn module on how to Query Azure Cosmos DB with SQL Serverless for Azure Synapse Analytics

Prerequisites

- Make sure that you have prepared Analytical store:
  - Enable analytical store on your Cosmos DB containers.
  - Get the connection string with a read-only key that you will use to query analytical store.
  - Get the read-only key that will be used to access Cosmos DB container
- Make sure that you have applied all best practices, such as:
  - Ensure that your Cosmos DB analytical storage is in the same region as serverless SQL pool.
  - Ensure that the client application (Power BI, Analysis service) is in the same region as serverless SQL pool.
  - If you are returning a large amount of data (bigger than 80GB), consider using caching layer such as Analysis services and load the partitions smaller than 80GB in the Analysis services model.
  - If you are filtering data using string columns, make sure that you are using the `OPENROWSET` function with the explicit `WITH` clause that has the smallest possible types (for example, don't use VARCHAR(1000) if you know that the property has up to 5 characters).

Overview

Serverless SQL pool enables you to query Azure Cosmos DB analytical storage using `OPENROWSET` function.

- `OPENROWSET` with inline key. This syntax can be used to query Azure Cosmos DB collections without need to prepare credentials.
- `OPENROWSET` that referenced credential that contains the Cosmos DB account key. This syntax can be used to create views on Azure Cosmos DB collections.

- OPENROWSET with key
- OPENROWSET with credential

To support querying and analyzing data in an Azure Cosmos DB analytical store, a serverless SQL pool is used. The serverless SQL pool uses the `OPENROWSET` SQL syntax, so you must first convert your Azure Cosmos DB connection string to this format:

```
OPENROWSET(
       'CosmosDB',
       '<SQL connection string for Azure Cosmos DB>',
       <Container name>
    )  [ < with clause > ] AS alias
```

The SQL connection string for Azure Cosmos DB specifies the Azure Cosmos DB account name, database name, database account master key, and an optional region name to the `OPENROWSET` function. Some of this information can be taken from the standard Azure Cosmos DB connection string.

Converting from the standard Azure Cosmos DB connection string format:

```
AccountEndpoint=https://<database account name>.documents.azure.com:443/;AccountKey=<database account master key>;
```

The SQL connection string has the following format:

```
'account=<database account name>;database=<database name>;region=<region name>;key=<database account master key>'
```

The region is optional. If omitted, the container's primary region is used.

The Azure Cosmos DB container name is specified without quotation marks in the `OPENROWSET` syntax. If the container name has any special characters, for example, a dash (-), the name should be wrapped within square brackets (`[]`) in the `OPENROWSET` syntax.

IMPORTANT

Make sure that you're using some UTF-8 database collation, for example, `Latin1_General_100_CI_AS_SC_UTF8`, because string values in an Azure Cosmos DB analytical store are encoded as UTF-8 text. A mismatch between text encoding in the file and collation might cause unexpected text conversion errors. You can easily change default collation of the current database by using the T-SQL statement `alter database current collate Latin1_General_100_CI_AI_SC_UTF8`.

NOTE

A serverless SQL pool doesn't support querying an Azure Cosmos DB transactional store.

Sample dataset

The examples in this article are based on data from the European Centre for Disease Prevention and Control (ECDC) COVID-19 Cases and COVID-19 Open Research Dataset (CORD-19), doi:10.5281/zenodo.3715505.

You can see the license and the structure of data on these pages. You can also download sample data for the ECDC and CORD-19 datasets.

To follow along with this article showcasing how to query Azure Cosmos DB data with a serverless SQL pool, make sure that you create the following resources:

- An Azure Cosmos DB database account that's Azure Synapse Link enabled.
- An Azure Cosmos DB database named `covid`.
- Two Azure Cosmos DB containers named `Ecdc` and `Cord19` loaded with the preceding sample datasets.

You can use the following connection string for testing purpose:
`Account=synapselink-cosmosdb-sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtFpJjC8Hg==`
. Note that this connection will not guarantee performance because this account might be located in remote region compared to your Synapse SQL endpoint.

Explore Azure Cosmos DB data with automatic schema inference

The easiest way to explore data in Azure Cosmos DB is by using the automatic schema inference capability. By omitting the `WITH` clause from the `OPENROWSET` statement, you can instruct the serverless SQL pool to

autodetect (infer) the schema of the analytical store of the Azure Cosmos DB container.

- OPENROWSET with key
- OPENROWSET with credential

```
SELECT TOP 10 *
FROM OPENROWSET(
       'CosmosDB',
       'Account=synapselink-cosmosdb-
sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtF
pJjC8Hg==',
       Ecdc) as documents
```

In the preceding example, we instructed the serverless SQL pool to connect to the `covid` database in the Azure Cosmos DB account `MyCosmosDbAccount` authenticated by using the Azure Cosmos DB key (the dummy in the preceding example). We then accessed the `Ecdc` container's analytical store in the `West US 2` region. Since there's no projection of specific properties, the `OPENROWSET` function will return all properties from the Azure Cosmos DB items.

Assuming that the items in the Azure Cosmos DB container have `date_rep`, `cases`, and `geo_id` properties, the results of this query are shown in the following table:

DATE_REP	CASES	GEO_ID
2020-08-13	254	RS
2020-08-12	235	RS
2020-08-11	163	RS

If you need to explore data from the other container in the same Azure Cosmos DB database, you can use the same connection string and reference the required container as the third parameter:

```
SELECT TOP 10 *
FROM OPENROWSET(
       'CosmosDB',
       'Account=synapselink-cosmosdb-
sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtF
pJjC8Hg==',
       Cord19) as cord19
```

Explicitly specify schema

While automatic schema inference capability in `OPENROWSET` provides a simple, easy-to-use querience, your business scenarios might require you to explicitly specify the schema to read-only relevant properties from the Azure Cosmos DB data.

The `OPENROWSET` function enables you to explicitly specify what properties you want to read from the data in the container and to specify their data types.

Let's imagine that we've imported some data from the ECDC COVID dataset with the following structure into Azure Cosmos DB:

```
{"date_rep":"2020-08-13","cases":254,"countries_and_territories":"Serbia","geo_id":"RS"}
{"date_rep":"2020-08-12","cases":235,"countries_and_territories":"Serbia","geo_id":"RS"}
{"date_rep":"2020-08-11","cases":163,"countries_and_territories":"Serbia","geo_id":"RS"}
```

These flat JSON documents in Azure Cosmos DB can be represented as a set of rows and columns in Synapse SQL. The `OPENROWSET` function enables you to specify a subset of properties that you want to read and the exact column types in the `WITH` clause:

- OPENROWSET with key
- OPENROWSET with credential

```
SELECT TOP 10 *
FROM OPENROWSET(
      'CosmosDB',
      'Account=synapselink-cosmosdb-
sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtF
pJjC8Hg==',
       Ecdc
    ) with ( date_rep varchar(20), cases bigint, geo_id varchar(6) ) as rows
```

The result of this query might look like the following table:

DATE_REP	CASES	GEO_ID
2020-08-13	254	RS
2020-08-12	235	RS
2020-08-11	163	RS

For more information about the SQL types that should be used for Azure Cosmos DB values, see the rules for SQL type mappings at the end of the article.

Create view

Creating views in the `master` or default databases is not recommended or supported. So you need to create a user database for your views.

Once you identify the schema, you can prepare a view on top of your Azure Cosmos DB data. You should place your Azure Cosmos DB account key in a separate credential and reference this credential from `OPENROWSET` function. Do not keep your account key in the view definition.

```
CREATE CREDENTIAL MyCosmosDbAccountCredential
WITH IDENTITY = 'SHARED ACCESS SIGNATURE', SECRET =
's5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtFpJjC8Hg==';
GO
CREATE OR ALTER VIEW Ecdc
AS SELECT *
FROM OPENROWSET(
      PROVIDER = 'CosmosDB',
      CONNECTION = 'Account=synapselink-cosmosdb-sqlsample;Database=covid',
      OBJECT = 'Ecdc',
      SERVER_CREDENTIAL = 'MyCosmosDbAccountCredential'
    ) with ( date_rep varchar(20), cases bigint, geo_id varchar(6) ) as rows
```

Do not use `OPENROWSET` without explicitly defined schema because it might impact your performance. Make sure that you use the smallest possible sizes for your columns (for example VARCHAR(100) instead of default VARCHAR(8000)). You should use some UTF-8 collation as default database collation or set it as explicit column collation to avoid UTF-8 conversion issue. Collation `Latin1_General_100_BIN2_UTF8` provides best performance when you filter data using some string columns.

Query nested objects

With Azure Cosmos DB, you can represent more complex data models by composing them as nested objects or arrays. The autosync capability of Azure Synapse Link for Azure Cosmos DB manages the schema representation in the analytical store out of the box, which includes handling nested data types that allow for rich querying from the serverless SQL pool.

For example, the CORD-19 dataset has JSON documents that follow this structure:

```
{
    "paper_id": <str>,                  # 40-character sha1 of the PDF
    "metadata": {
        "title": <str>,
        "authors": <array of objects>    # list of author dicts, in order
        ...
     }
     ...
}
```

The nested objects and arrays in Azure Cosmos DB are represented as JSON strings in the query result when the `OPENROWSET` function reads them. You can specify the paths to nested values in the objects when you use the `WITH` clause:

```
SELECT TOP 10 *
FROM OPENROWSET(
       'CosmosDB',
       'Account=synapselink-cosmosdb-
sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtF
pJjC8Hg==',
       Cord19)
WITH (  paper_id    varchar(8000),
        title        varchar(1000) '$.metadata.title',
        metadata     varchar(max),
        authors      varchar(max) '$.metadata.authors'
) AS docs;
```

The result of this query might look like the following table:

PAPER_ID	TITLE	METADATA	AUTHORS
bb11206963e831f...	Supplementary Information An eco-epidemi...	`{"title":"Supplementary Informati…`	`[{"first":"Julien","last":"Mélade","suffix"`
bb1206963e831f1...	The Use of Convalescent Sera in Immune-E...	`{"title":"The Use of Convalescent…`	`[{"first":"Antonio","last":"Lavazza","suff…`
bb378eca9aac649...	Tylosema esculentum (Marama) Tuber and B...	`{"title":"Tylosema esculentum (Ma…`	`[{"first":"Walter","last":"Chingwaru","suf…`

Learn more about analyzing complex data types like Parquet files and containers in Azure Synapse Link for Azure Cosmos DB or nested structures in a serverless SQL pool.

IMPORTANT

If you see unexpected characters in your text like `MÃƒÂ©lade` instead of `Mélade`, then your database collation isn't set to UTF-8 collation. Change collation of the database to UTF-8 collation by using a SQL statement like `ALTER DATABASE MyLdw COLLATE LATIN1_GENERAL_100_CI_AS_SC_UTF8`.

Flatten nested arrays

Azure Cosmos DB data might have nested subarrays like the author's array from a CORD-19 dataset:

```
{
    "paper_id": <str>,                    # 40-character sha1 of the PDF
    "metadata": {
        "title": <str>,
        "authors": [                      # list of author dicts, in order
            {
                "first": <str>,
                "middle": <list of str>,
                "last": <str>,
                "suffix": <str>,
                "affiliation": <dict>,
                "email": <str>
            },
            ...
        ],
        ...
}
```

In some cases, you might need to "join" the properties from the top item (metadata) with all elements of the array (authors). A serverless SQL pool enables you to flatten nested structures by applying the `OPENJSON` function on the nested array:

```
SELECT
    *
FROM
    OPENROWSET(
      'CosmosDB',
      'Account=synapselink-cosmosdb-
sqlsample;Database=covid;Key=s5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtF
pJjC8Hg==',
       Cord19
    ) WITH ( title varchar(1000) '$.metadata.title',
             authors varchar(max) '$.metadata.authors' ) AS docs
      CROSS APPLY OPENJSON ( authors )
                  WITH (
                       first varchar(50),
                       last varchar(50),
                       affiliation nvarchar(max) as json
                  ) AS a
```

The result of this query might look like the following table:

TITLE	AUTHORS	FIRST	LAST	AFFILIATION
Supplementary Information An eco-epidemi…	[{"first":"Julien","last":"Mélade","suffix":"","affiliation":{"laboratory":"Centre de Recher…	Julien	Mélade	{"laboratory":"Centre de Recher…
Supplementary Information An eco-epidemi…	[{"first":"Nicolas","last":"##4#","suffix":"","affiliation":{"laboratory":"","institution":"U…	Nicolas	##4#	{"laboratory":"","institution":"U…
Supplementary Information An eco-epidemi…	[{"first":"Beza","last":"Ramazindrazana","suffix":"","affiliation":{"laboratory":"Centre de Recher…	Beza	Ramazindrazana	{"laboratory":"Centre de Recher…
Supplementary Information An eco-epidemi…	[{"first":"Olivier","last":"Flores","suffix":"","affiliation":{"laboratory":"UMR C53 CIRAD, …	Olivier	Flores	{"laboratory":"UMR C53 CIRAD, …

IMPORTANT

If you see unexpected characters in your text like `MÃƒÃ©lade` instead of `Mélade`, then your database collation isn't set to UTF-8 collation. Change collation of the database to UTF-8 collation by using a SQL statement like `ALTER DATABASE MyLdw COLLATE LATIN1_GENERAL_100_CI_AS_SC_UTF8`.

Azure Cosmos DB to SQL type mappings

Although Azure Cosmos DB transactional store is schema-agnostic, the analytical store is schematized to optimize for analytical query performance. With the autosync capability of Azure Synapse Link, Azure Cosmos DB manages the schema representation in the analytical store out of the box, which includes handling nested data types. Since a serverless SQL pool queries the analytical store, it's important to understand how to map Azure Cosmos DB input data types to SQL data types.

Azure Cosmos DB accounts of SQL (Core) API support JSON property types of number, string, Boolean, null, nested object, or array. You would need to choose SQL types that match these JSON types if you're using the `WITH` clause in `OPENROWSET`. The following table shows the SQL column types that should be used for different property types in Azure Cosmos DB.

AZURE COSMOS DB PROPERTY TYPE	SQL COLUMN TYPE
Boolean	bit
Integer	bigint
Decimal	float
String	varchar (UTF-8 database collation)
Date time (ISO-formatted string)	varchar(30)
Date time (UNIX timestamp)	bigint
Null	`any SQL type`
Nested object or array	varchar(max) (UTF-8 database collation), serialized as JSON text

Full fidelity schema

Azure Cosmos DB full fidelity schema records both values and their best match types for every property in a container. The `OPENROWSET` function on a container with full fidelity schema provides both the type and the actual value in each cell. Let's assume that the following query reads the items from a container with full fidelity schema:

```
SELECT *
FROM OPENROWSET(
      'CosmosDB',
      'account=MyCosmosDbAccount;database=covid;region=westus2;key=C0Sm0sDbKey==',
       Ecdc
    ) as rows
```

The result of this query will return types and values formatted as JSON text:

DATE_REP	CASES	GEO_ID
{"date":"2020-08-13"}	{"int32":"254"}	{"string":"RS"}
{"date":"2020-08-12"}	{"int32":"235"}	{"string":"RS"}
{"date":"2020-08-11"}	{"int32":"316"}	{"string":"RS"}
{"date":"2020-08-10"}	{"int32":"281"}	{"string":"RS"}
{"date":"2020-08-09"}	{"int32":"295"}	{"string":"RS"}
{"string":"2020/08/08"}	{"int32":"312"}	{"string":"RS"}
{"date":"2020-08-07"}	{"float64":"339.0"}	{"string":"RS"}

For every value, you can see the type identified in an Azure Cosmos DB container item. Most of the values for the `date_rep` property contain `date` values, but some of them are incorrectly stored as strings in Azure Cosmos DB. Full fidelity schema will return both correctly typed `date` values and incorrectly formatted `string` values. The number of cases is information stored as an `int32` value, but there's one value that's entered as a decimal number. This value has the `float64` type. If there are some values that exceed the largest `int32` number, they would be stored as the `int64` type. All `geo_id` values in this example are stored as `string` types.

> **IMPORTANT**
>
> The `OPENROWSET` function without a `WITH` clause exposes both values with expected types and the values with incorrectly entered types. This function is designed for data exploration and not for reporting. Don't parse JSON values returned from this function to build reports. Use an explicit WITH clause to create your reports. You should clean up the values that have incorrect types in the Azure Cosmos DB container to apply corrections in the full fidelity analytical store.

If you need to query Azure Cosmos DB accounts of the Mongo DB API kind, you can learn more about the full fidelity schema representation in the analytical store and the extended property names to be used in What is Azure Cosmos DB Analytical Store?.

Query items with full fidelity schema

While querying full fidelity schema, you need to explicitly specify the SQL type and the expected Azure Cosmos DB property type in the `WITH` clause.

In the following example, we'll assume that `string` is the correct type for the `geo_id` property and `int32` is the correct type for the `cases` property:

```
SELECT geo_id, cases = SUM(cases)
FROM OPENROWSET(
      'CosmosDB'
      'account=MyCosmosDbAccount;database=covid;region=westus2;key=C0Sm0sDbKey==',
       Ecdc
    ) WITH ( geo_id VARCHAR(50) '$.geo_id.string',
             cases INT '$.cases.int32'
    ) as rows
GROUP BY geo_id
```

Values for `geo_id` and `cases` that have other types will be returned as `NULL` values. This query will reference only the `cases` with the specified type in the expression (`cases.int32`).

If you have values with other types (`cases.int64`, `cases.float64`) that can't be cleaned in an Azure Cosmos DB container, you would need to explicitly reference them in a `WITH` clause and combine the results. The following query aggregates both `int32`, `int64`, and `float64` stored in the `cases` column:

```
SELECT geo_id, cases = SUM(cases_int) + SUM(cases_bigint) + SUM(cases_float)
FROM OPENROWSET(
      'CosmosDB',
      'account=MyCosmosDbAccount;database=covid;region=westus2;key=C0Sm0sDbKey==',
       Ecdc
    ) WITH ( geo_id VARCHAR(50) '$.geo_id.string',
             cases_int INT '$.cases.int32',
             cases_bigint BIGINT '$.cases.int64',
             cases_float FLOAT '$.cases.float64'
    ) as rows
GROUP BY geo_id
```

In this example, the number of cases is stored either as `int32`, `int64`, or `float64` values. All values must be extracted to calculate the number of cases per country.

Troubleshooting

Review the self-help page to find the known issues or troubleshooting steps that can help you to resolve potential problems with Cosmos DB queries.

Next steps

For more information, see the following articles:

- Use Power BI and serverless SQL pool with Azure Synapse Link
- Create and use views in a serverless SQL pool
- Tutorial on building serverless SQL pool views over Azure Cosmos DB and connecting them to Power BI models via DirectQuery
- Visit the Azure Synapse link for Cosmos DB self-help page if you are getting some errors or experiencing performance issues.
- Checkout the learn module on how to Query Azure Cosmos DB with SQL Serverless for Azure Synapse Analytics.

Get started with Azure Synapse Link for Azure SQL Database (Preview)

8/19/2022 • 6 minutes to read • Edit Online

This article provides a step-by-step guide for getting started with Azure Synapse Link for Azure SQL Database. For more information, see Synapse Link for Azure SQL Database (Preview).

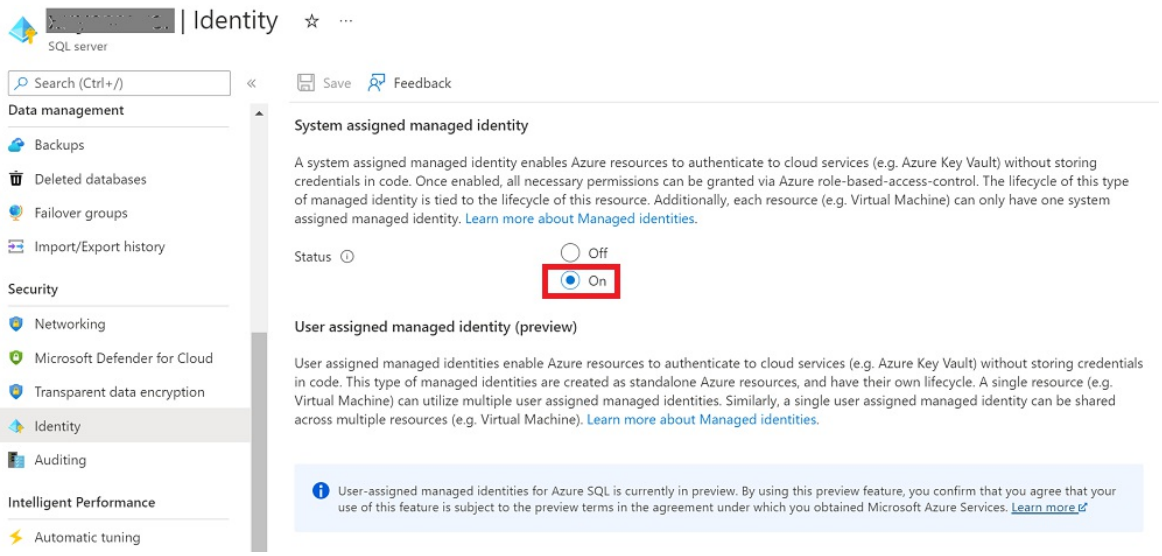
> **IMPORTANT**
>
> Azure Synapse Link for SQL is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

Prerequisites

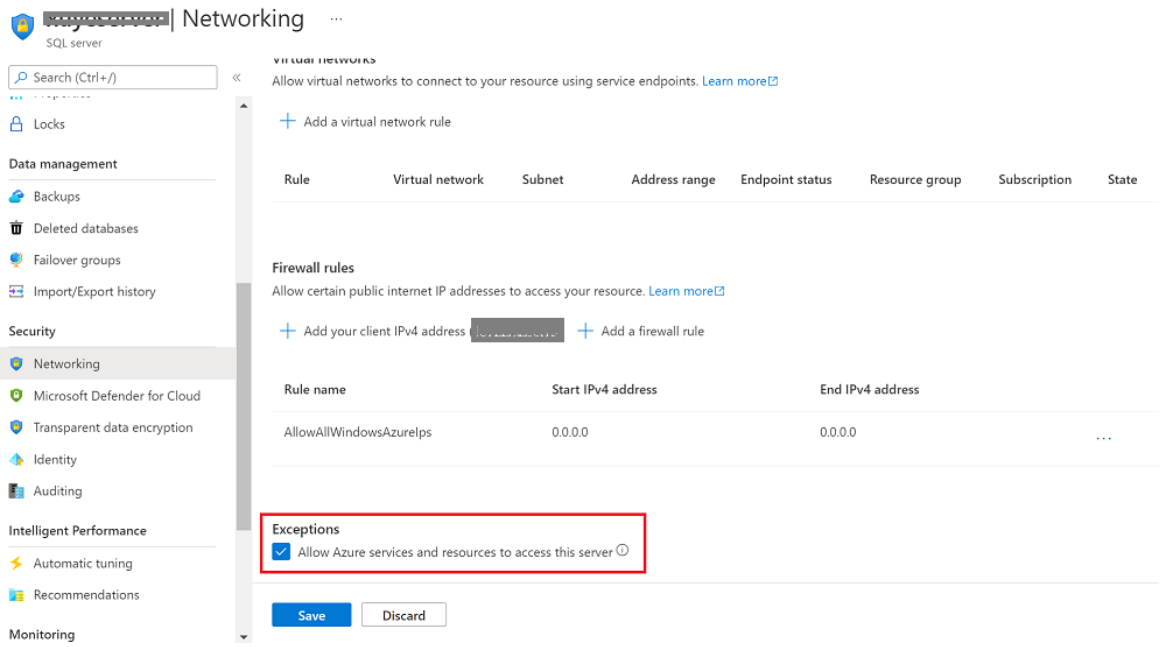
- Create a new Synapse workspace to get Azure Synapse Link for SQL. Make sure to check "Disable Managed virtual network" and "Allow connections from all IP address" when creating Synapse workspace.
- For DTU-based provisioning, make sure your Azure SQL Database service is at least Standard tier with a minimum of 100 DTUs. Free, Basic, or Standard tiers with fewer than 100 DTUs provisioned are not supported.

Configure your source Azure SQL Database

1. Go to Azure portal, navigate to your Azure SQL Server, select **Identity**, and then set **System assigned managed identity** to **On**.

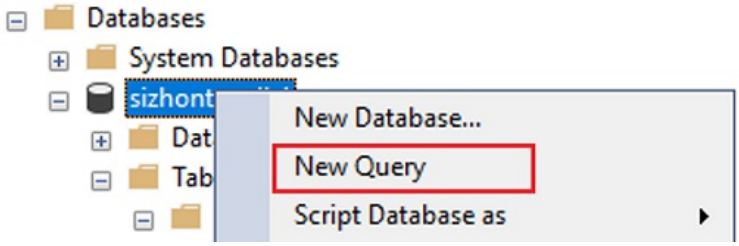


2. Navigate to **Networking**, then check **Allow Azure services and resources to access this server**.



3. Using Microsoft SQL Server Management Studio (SSMS) or Azure Data Studio, connect to the Azure SQL Server. If you want to have your Synapse workspace connect to your Azure SQL Database using a managed identity, set the Azure Active Directory admin on Azure SQL Server, and use the same admin name to connect to Azure SQL Server with administrative privileges in order to have the privileges in step 5.

4. Expand **Databases**, right select the database you created above, and select **New Query**.



5. If you want to have your Synapse workspace connect to your source Azure SQL Database using a managed identity, run the following script to provide the managed identity permission to the source database.

   You can skip this step if you instead want to have your Synapse workspace connect to your source Azure SQL Database via SQL authentication.

```
CREATE USER <workspace name> FROM EXTERNAL PROVIDER;
ALTER ROLE [db_owner] ADD MEMBER <workspace name>;
```

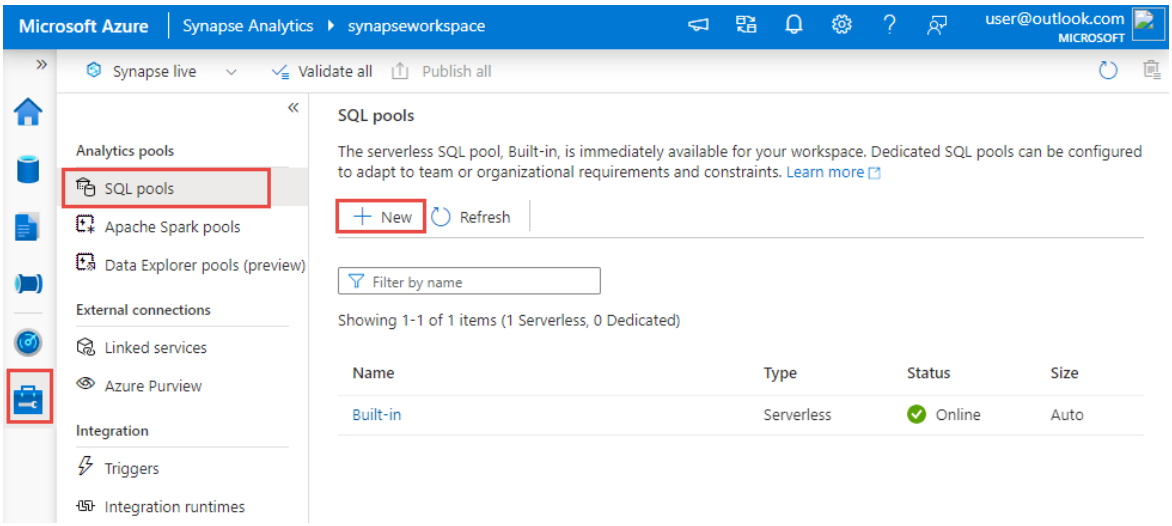
6. You can create a table with your own schema; the following is just an example for a `CREATE TABLE` query. You can also insert some rows into this table to ensure there's data to be replicated.

```
CREATE TABLE myTestTable1 (c1 int primary key, c2 int, c3 nvarchar(50))
```

Create your target Synapse SQL pool

1. Launch Synapse Studio.

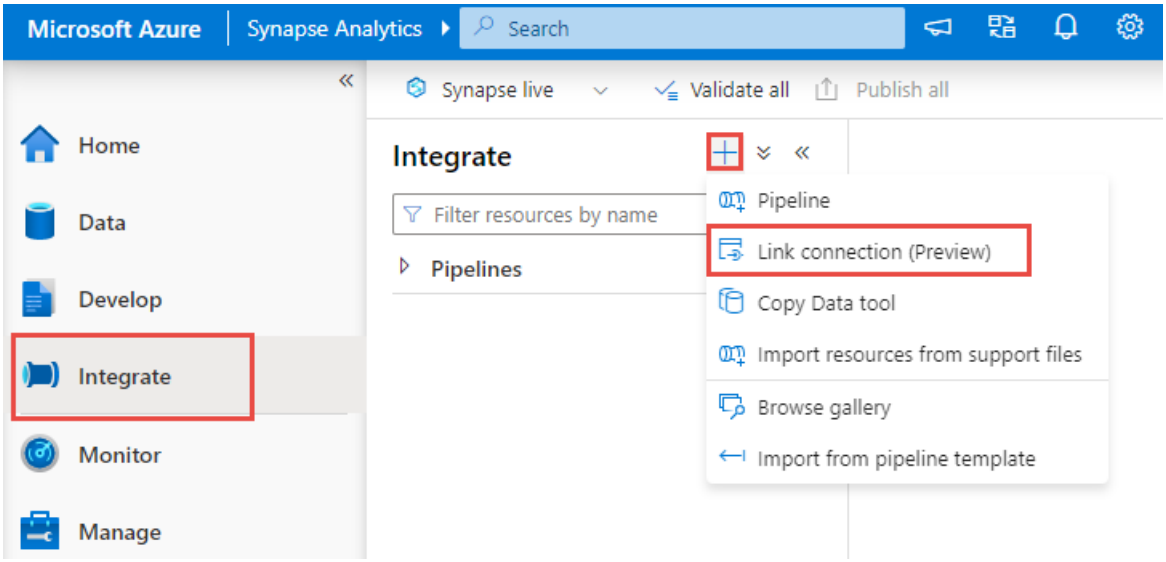
2. Open the **Manage** hub, navigate to **SQL pools**, and select **+ New**.



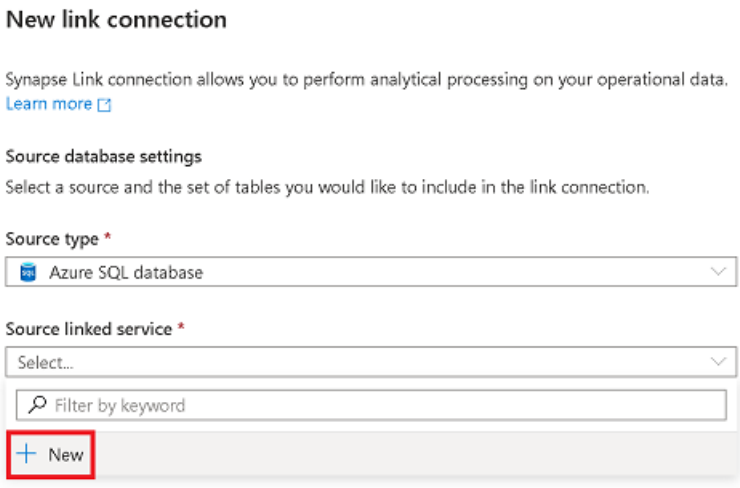
3. Enter a unique pool name, use the default settings, and create the dedicated pool.
4. You need to create a schema if your expected schema is not available in target Synapse SQL database. If your schema is dbo, you can skip this step.

Create the Azure Synapse Link connection

1. Open the **Integrate** hub, and select **+ Link connection(Preview)**.

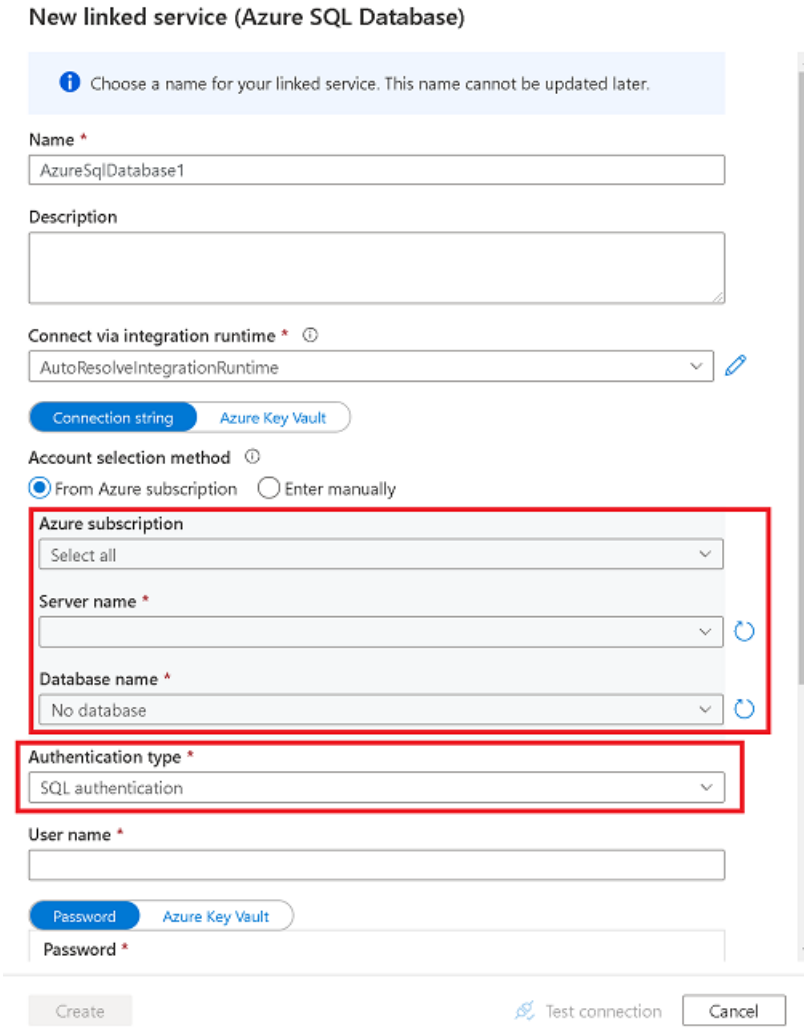


2. Under **Source linked service**, select **New**.



3. Enter the information for your source Azure SQL Database.

- Select the subscription, server, and database corresponding to your Azure SQL Database.
- If you wish to connect your Synapse workspace to the source DB using the workspace's managed identity, set **Authentication type** to **Managed Identity**.
- If you wish to use SQL authentication instead and know the username/password to use, select **SQL Authentication** instead.



4. Select **Test connection** to ensure the firewall rules are properly configured and the workspace can successfully connect to the source Azure SQL Database.

5. Select **Create**.

> **NOTE**
>
> The linked service that you create here is not dedicated to Azure Synapse Link for SQL - it can be used by any workspace user that has the appropriate permissions. Please take time to understand the scope of users who may have access to this linked service and its credentials. For more information on permissions in Azure Synapse workspaces, see Azure Synapse workspace access control overview - Azure Synapse Analytics.

6. Select one or more source tables to replicate to your Synapse workspace and select **Continue**.

> **NOTE**
>
> A given source table can only be enabled in at most one link connection at a time.

7. Select a target Synapse SQL database and pool.

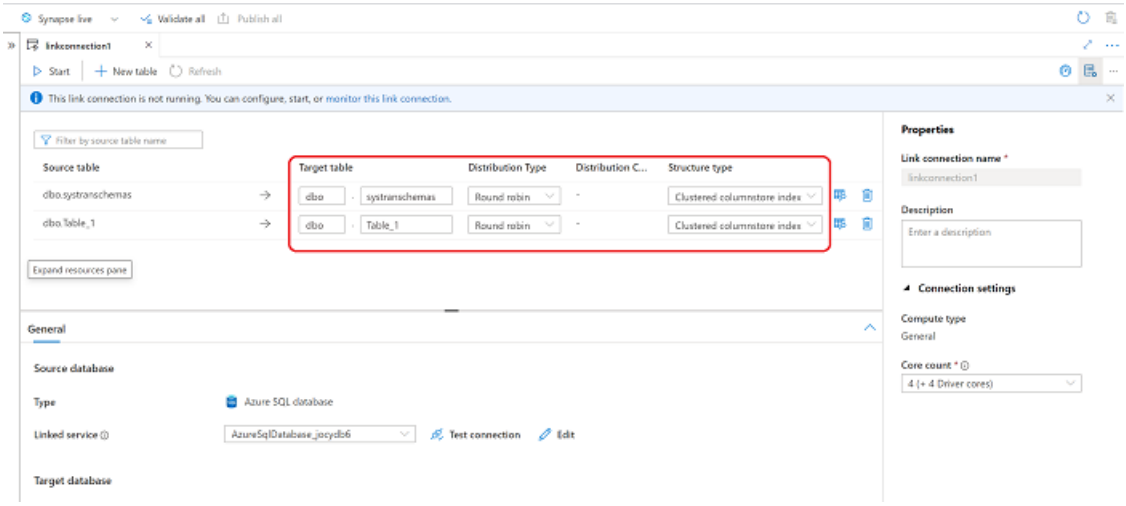
8. Provide a name for your Azure Synapse Link connection, and select the number of cores. These cores will be used for the movement of data from the source to the target.

   > **NOTE**
   >
   > We recommend starting low and increasing as needed.

9. Select **OK**.

10. With the new Azure Synapse Link connection open, you can update the target table name, distribution type and structure type.

    > **NOTE**
    >
    > - Consider heap table for structure type when your data contains varchar(max), nvarchar(max), and varbinary(max).
    > - Make sure the schema in your Synapse dedicated SQL pool has already been created before you start the link connection. Azure Synapse Link for SQL will create tables automatically under your schema in the Synapse dedicated SQL pool.



11. Select **Publish all** to save the new link connection to the service.

Start the Azure Synapse Link connection

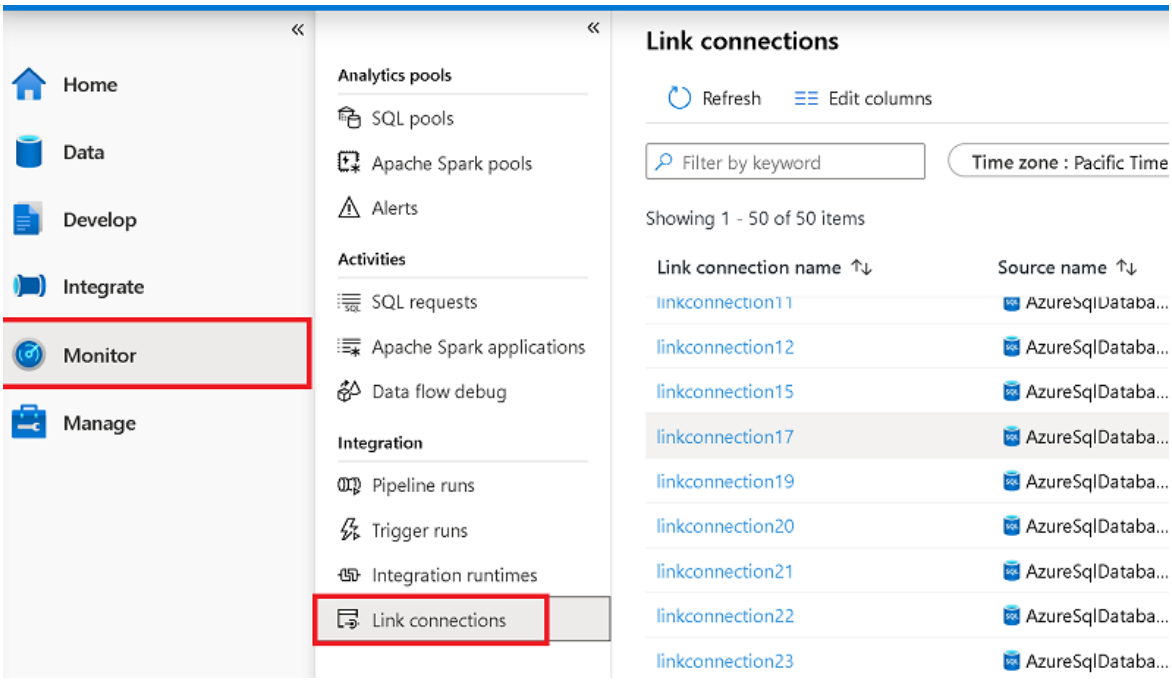
1. Select **Start** and wait a few minutes for the data to be replicated.

   > **NOTE**
   >
   > When being started, a link connection will start from a full initial load from your source database followed by incremental change feeds via the change feed feature in Azure SQL database. For more information, see Azure Synapse Link for SQL change feed.

Monitor the status of the Azure Synapse Link connection

You may monitor the status of your Azure Synapse Link connection, see which tables are being initially copied over (Snapshotting), and see which tables are in continuous replication mode (Replicating).

1. Navigate to the **Monitor** hub, and select **Link connections**.



2. Open the Azure Synapse Link connection you started and view the status of each table.
3. Select **Refresh** on the monitoring view for your connection to observe any updates to the status.

Query replicated data

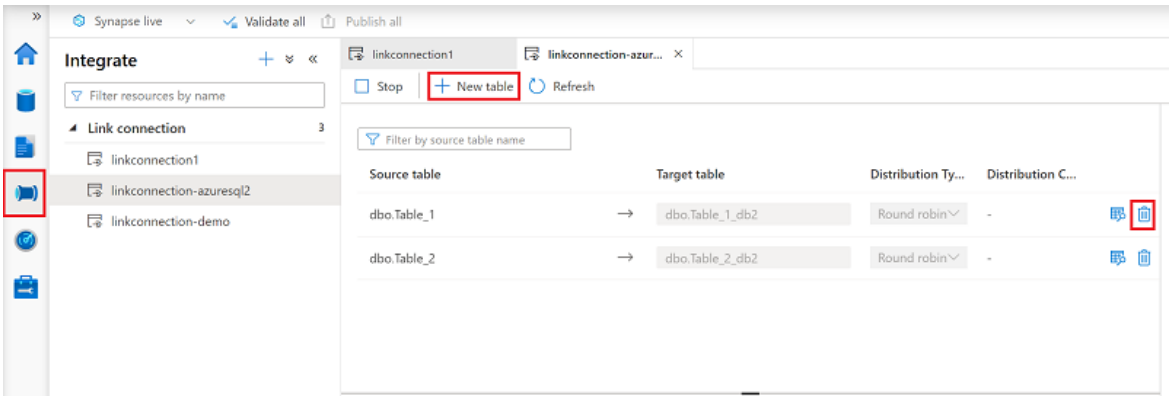
Wait for a few minutes, then check the target database has the expected table and data. You can also now explore the replicated tables in your target Synapse dedicated SQL pool.

1. In the **Data** hub, under **Workspace**, open your target database, and within **Tables**, right-click one of your target tables.
2. Choose **New SQL script**, then **Select TOP 100 rows**.
3. Run this query to view the replicated data in your target Synapse dedicated SQL pool.
4. You can also query the target database with SSMS (or other tools). Use the dedicated SQL endpoint for your workspace as the server name. This is typically `<workspacename>.sql.azuresynapse.net`. Add `Database=databasename@poolname` as another connection string parameter when connecting via SSMS (or other tools).

Add/remove table in existing Azure Synapse Link connection

You can add/remove tables on Synapse Studio as following:

1. Open the **Integrate Hub**.
2. Select the **Link connection** you want to edit and open it.
3. Select **+New** table to add tables on Synapse Studio or select the trash can icon to the right or a table to remove an existing table. You can add or remove tables when the link connection is running.

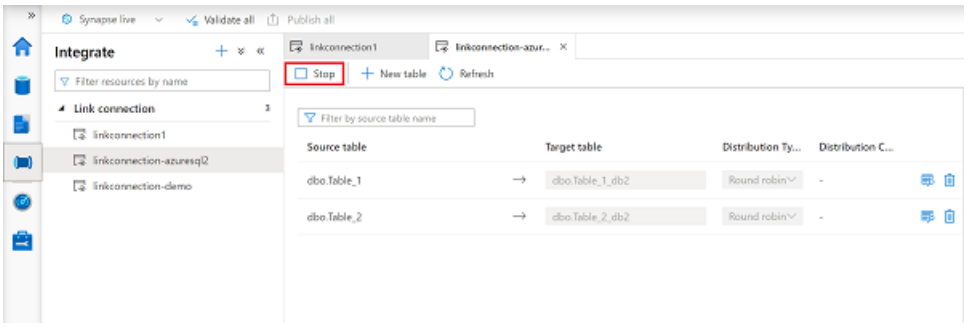


> **NOTE**
>
> You can directly add or remove tables when a link connection is running.

Stop the Azure Synapse Link connection

You can stop the Azure Synapse Link connection in Synapse Studio as follows:

1. Open the **Integrate Hub** of your Synapse workspace.
2. Select the **Link connection** you want to edit and open it.
3. Select **Stop** to stop the link connection, and it will stop replicating your data.



> **NOTE**
>
> If you restart a link connection after stopping it, it will start from a full initial load from your source database followed by incremental change feeds.

Next steps

If you are using a different type of database, see how to:

- Configure Azure Synapse Link for Azure Cosmos DB
- Configure Azure Synapse Link for Dataverse
- Get started with Azure Synapse Link for SQL Server 2022

Known limitations and issues with Azure Synapse Link for SQL

8/19/2022 • 5 minutes to read • Edit Online

This article lists the known limitations and issues with Azure Synapse Link for SQL.

Known limitations

This is the list of known limitations for Azure Synapse Link for SQL.

Azure SQL DB and SQL Server 2022

- Users must use an Azure Synapse Analytics workspace created on or after May 24, 2022, to get access to Azure Synapse Link for SQL functionality.
- Running Azure Synapse Analytics in a managed virtual network isn't supported. Users need to check "Disable Managed virtual network" and "Allow connections from all IP addresses" when creating their workspace.
- Source tables must have primary keys.
- The following data types aren't supported for primary keys in the source tables:
  - real
  - float
  - hierarchyid
  - sql_variant
  - timestamp
- Source table row size can't exceed 7,500 bytes. For tables where variable-length columns are stored off-row, a 24-byte pointer is stored in the main record.
- Tables enabled for Azure Synapse Link for SQL can have a maximum of 1,020 columns (not 1,024).
- While a database can have multiple links enabled, a given table can't belong to multiple links.
- When a database owner doesn't have a mapped log in, Azure Synapse link for SQL will run into an error when enabling a link connection. User can set database owner to a valid user with the `ALTER AUTHORIZATION` command to fix this issue.
- If the source table contains computed columns or columns with data types that aren't supported by Azure Synapse Analytics dedicated SQL pools, these columns won't be replicated to Azure Synapse Analytics. Unsupported columns include:
  - image
  - text
  - xml
  - timestamp
  - sql_variant
  - UDT
  - geometry
  - geography
- A maximum of 5,000 tables can be added to a single link connection.
- When a source column is of type datetime2(7) or time(7), the last digit will be truncated when data is replicated to Azure Synapse Analytics.
- The following table DDL operations aren't allowed on source tables when they are enabled for Azure Synapse Link for SQL. All other DDL operations are allowed, but they won't be replicated to Azure Synapse Analytics.

    - Switch Partition
    - Add/Drop/Alter Column
    - Alter Primary Key
    - Drop/Truncate Table
    - Rename Table
- If DDL + DML is executed in an explicit transaction (between `BEGIN TRANSACTION` and `END TRANSACTION` statements), replication for corresponding tables will fail within the link connection.

  > **NOTE**
  > If a table is critical for transactional consistency at the link connection level, please review the state of the Azure Synapse Link table in the Monitoring tab.

- Azure Synapse Link for SQL can't be enabled if any of the following features are in use for the source table:
    - Change Data Capture
    - Temporal history table
    - Always encrypted
    - In-Memory OLTP
    - Column Store Index
    - Graph
- System tables can't be replicated.
- The security configuration from the source database will **NOT** be reflected in the target dedicated SQL pool.
- Enabling Azure Synapse Link for SQL will create a new schema called `changefeed`. Don't use this schema, as it is reserved for system use.
- Source tables with non-default collations: UTF8, Japanese can't be replicated to Synapse. Here's the supported collations in Synapse SQL Pool.
- Single row updates (including off-page storage) of > 370MB are not supported.

Azure SQL DB only

- Azure Synapse Link for SQL isn't supported on Free, Basic or Standard tier with fewer than 100 DTUs.
- Azure Synapse Link for SQL isn't supported on SQL Managed Instances.
- Users need to check "Allow Azure services and resources to access this server" in the firewall settings of their source database server.
- Service principal isn't supported for authenticating to source Azure SQL DB, so when creating Azure SQL DB linked Service, choose SQL authentication, user-assigned managed identity (UAMI) or service assigned managed Identity (SAMI).
- Azure Synapse Link can't be enabled on the secondary database once a GeoDR failover has happened if the secondary database has a different name from the primary database.
- If you enabled Azure Synapse Link for SQL on your database as an Microsoft Azure Active Directory (Azure AD) user, Point-in-time restore (PITR) will fail. PITR will only work when you enable Azure Synapse Link for SQL on your database as a SQL user.
- If you create a database as an Azure AD user and enable Azure Synapse Link for SQL, a SQL authentication user (for example, even sysadmin role) won't be able to disable/make changes to Azure Synapse Link for SQL artifacts. However, another Azure AD user will be able to enable/disable Azure Synapse Link for SQL on the same database. Similarly, if you create a database as an SQL authentication user, enabling/disabling Azure Synapse Link for SQL as an Azure AD user won't work.
- When enabling Azure Synapse Link for SQL on your Azure SQL Database, you should ensure that aggressive log truncation is disabled.

SQL Server 2022 only

- Azure Synapse Link for SQL works with SQL Server on Linux, but HA scenarios with Linux Pacemaker aren't supported. Shelf hosted IR cannot be installed on Linux environment.
- Azure Synapse Link for SQL can't be enabled on databases that are transactional replication publishers or distributors.
- If the SAS key of landing zone expires and gets rotated during the snapshot process, the new key won't get picked up. The snapshot will fail and restart automatically with the new key.
- Prior to breaking an Availability Group, disable any running links. Otherwise both databases will attempt to write their changes to the landing zone.
- When using asynchronous replicas, transactions need to be written to all replicas prior to them being published to Azure Synapse Link for SQL.
- Azure Synapse Link for SQL isn't supported on databases with database mirroring enabled.
- Restoring an Azure Synapse Link for SQL-enabled database from on-premises to Azure SQL Managed Instance isn't supported.
- Azure Synapse Link for SQL is not supported on databases that are using Managed Instance Link.

Known issues

Deleting an Azure Synapse Analytics workspace with a running link could cause log in source database to fill

- Applies To - Azure SQL Database and SQL Server 2022
- Issue - When you delete an Azure Synapse Analytics workspace it is possible that running links might not be stopped, which will cause the source database to think that the link is still operational and could lead to the log filling and not being truncated.
- Resolution - There are two possible resolutions to this situation:

1. Stop any running links prior to deleting the Azure Synapse Analytics workspace.
2. Manually clean up the link definition in the source database.
   a. Find the table_group_id for the link(s) that need to be stopped using the following query:

```
SELECT table_group_id, workspace_id, synapse_workgroup_name
FROM [changefeed].[change_feed_table_groups]
WHERE synapse_workgroup_name = <synapse workspace name>
```

   b. Drop each link identified using the following procedure:

```
EXEC sys.sp_change_feed_drop_table_group @table_group_id = <table_group_id>
```

   c. Optionally, if you are disabling all of the table groups for a given database, you can also disable change feed on the database with the following command:

```
EXEC sys.sp_change_feed_disable_db
```

Next steps

If you are using a different type of database, see how to:

- Configure Synapse Link for Azure Cosmos DB
- Configure Synapse Link for Dataverse

Get started with Azure Synapse Link for SQL Server 2022 (Preview)

8/19/2022 • 8 minutes to read • Edit Online

This article provides a step-by-step guide for getting started with Azure Synapse Link for SQL Server 2022. For more information, see Get started with Azure Synapse Link for SQL Server 2022 (Preview).

> **IMPORTANT**
>
> Azure Synapse Link for SQL is currently in PREVIEW. See the Supplemental Terms of Use for Microsoft Azure Previews for legal terms that apply to Azure features that are in beta, preview, or otherwise not yet released into general availability.

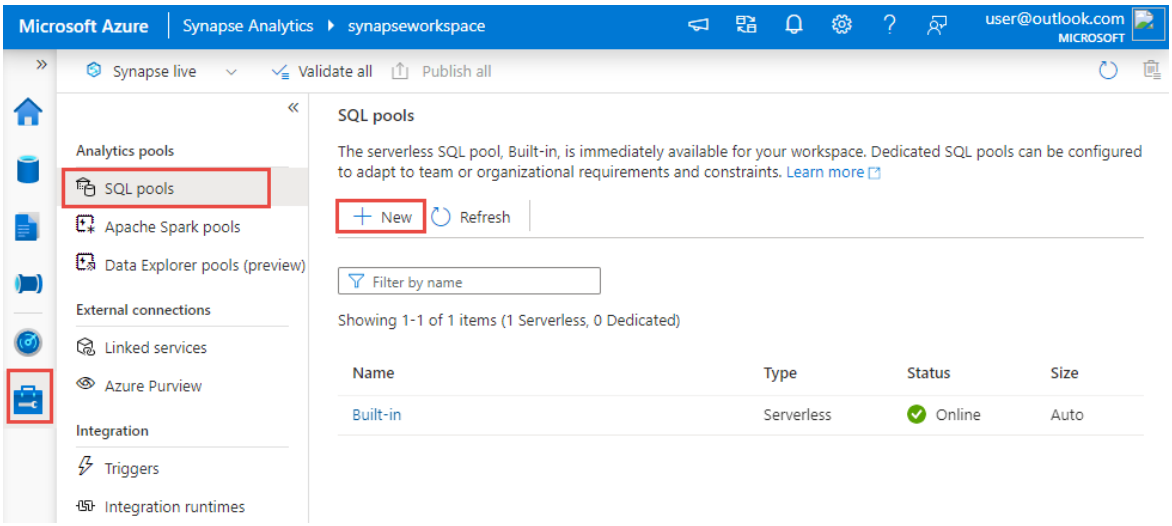
Prerequisites

- Create a new Synapse workspace to get Azure Synapse Link for SQL. Ensure to check "Disable Managed virtual network" and "Allow connections from all IP address" when creating Synapse workspace. If you have a workspace created after May 24, 2022, you do not need to create a new workspace.
- Create an Azure Data Lake Storage Gen2 account (different from the account created with the Azure Synapse Analytics workspace) used as the landing zone to stage the data submitted by SQL Server 2022. See how to create a Azure Data Lake Storage Gen2 account article for more details.
- Make sure your database in SQL Server 2022 has a master key created.

```
CREATE MASTER KEY ENCRYPTION BY PASSWORD = '<a new password>'
```

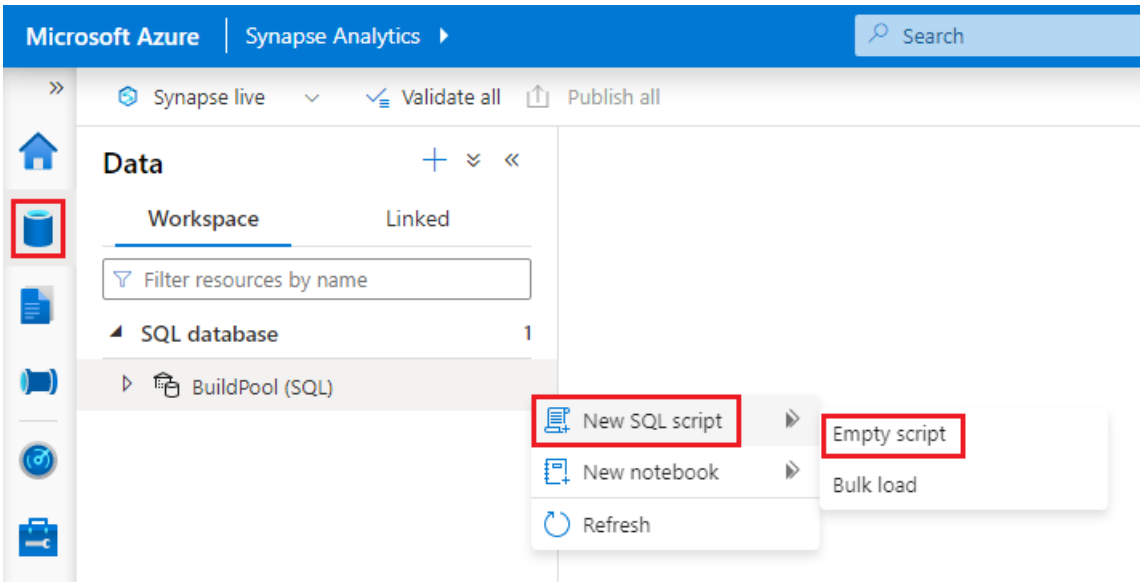
Create your target Synapse dedicated SQL pool

1. Launch Synapse Studio.
2. Open the **Manage** hub, navigate to **SQL pools**, and select **+ New**.



3. Enter a unique pool name, use the default settings, and create the dedicated pool.
4. From the **Data** hub, under **Workspace**, you should see your new Synapse SQL database listed under

Databases. From your new Synapse SQL database, select **New SQL script**, then **Empty script**.

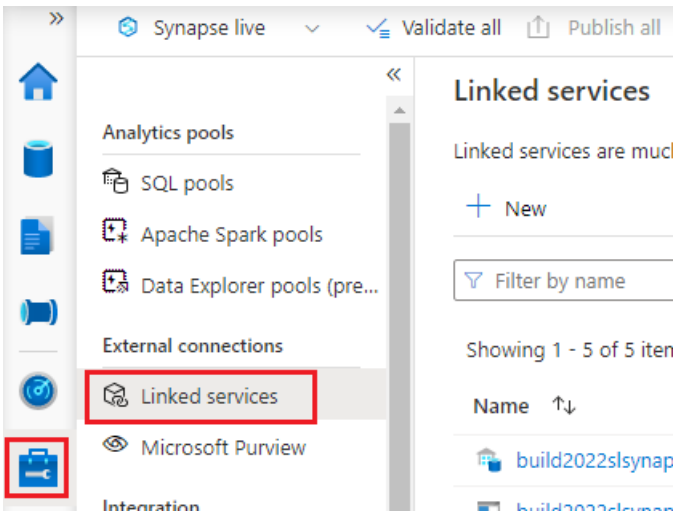


5. Paste the following script and select **Run** to create the master key for your target Synapse SQL database. You also need to create a schema if your expected schema is not available in target Synapse SQL database.

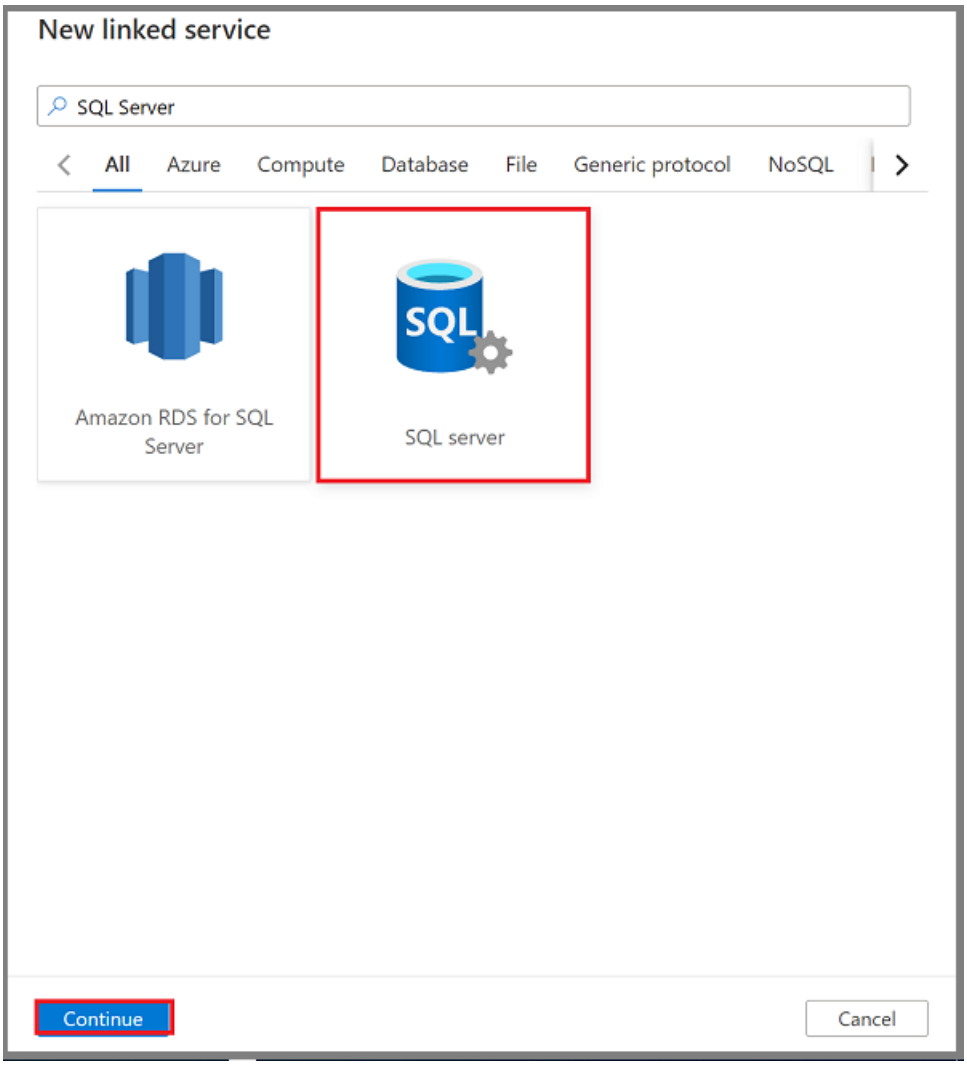
```
CREATE MASTER KEY
```

Create linked service for your source SQL Server 2022

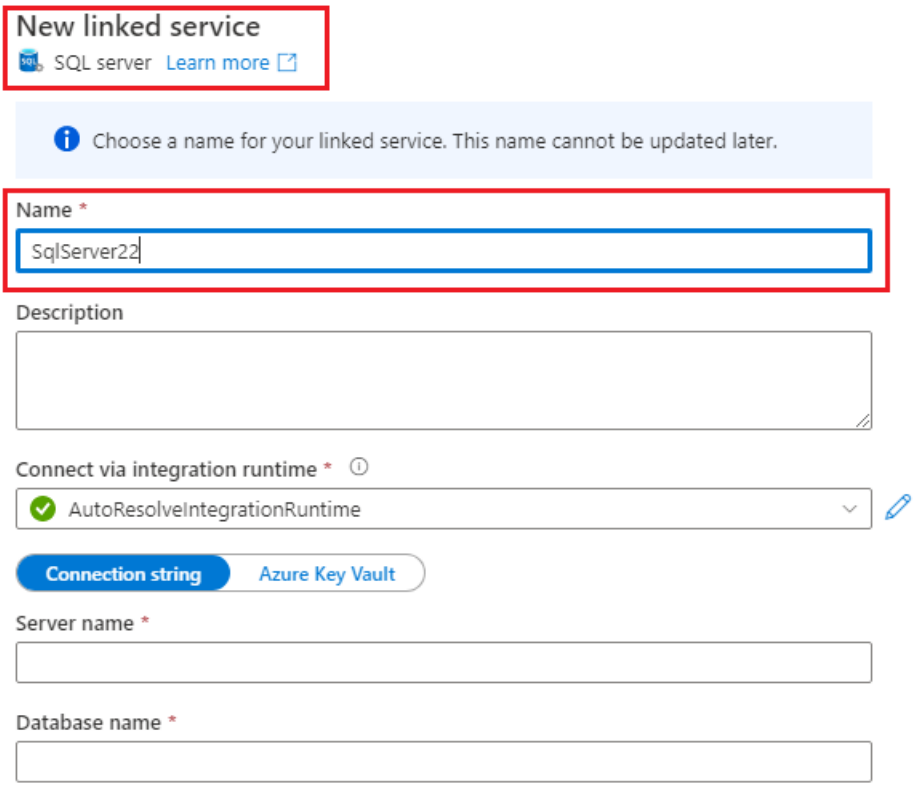
1. Open the **Manage** hub, and navigate to **Linked services**.



2. Press **+ New**, select **SQL Server** and select **Continue**.



3. Enter the **name** of linked service of SQL Server 2022.



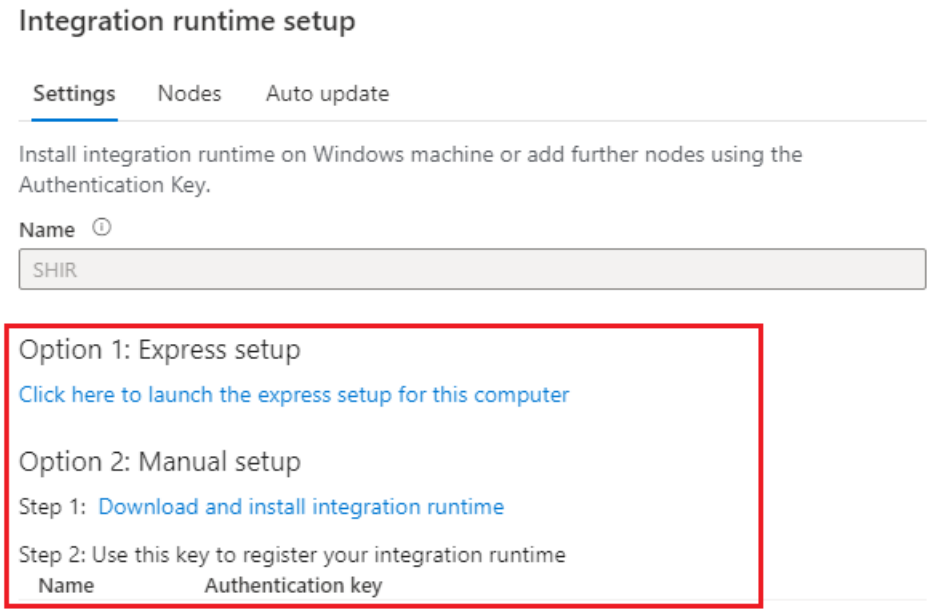
4. When selecting the integration runtime, choose your **self-hosted integration runtime**. If your synapse workspace doesn't have self-hosted integration runtime available, create one.

5. Use the following steps to create a self-hosted integration runtime to connect to your source SQL Server 2022 (optional)

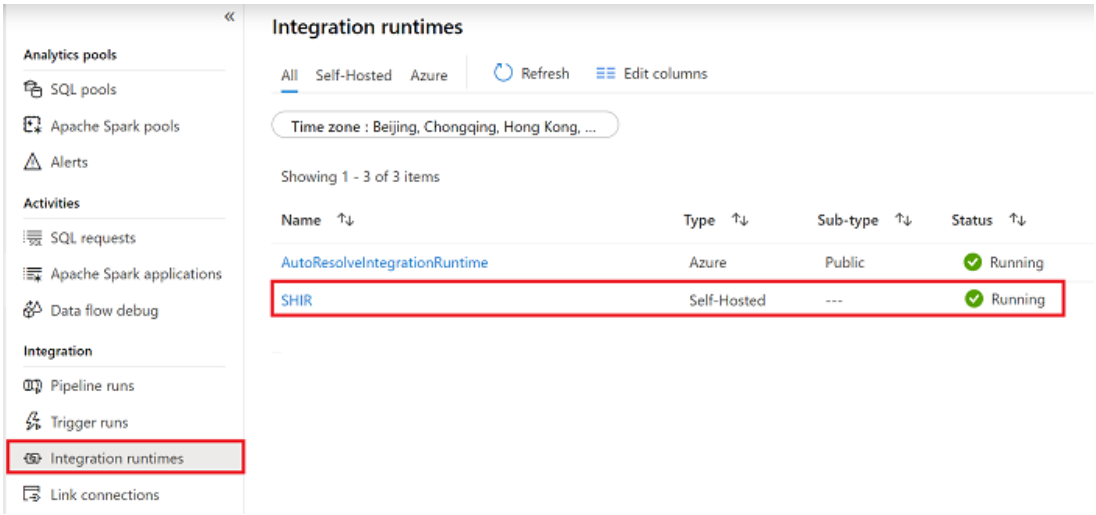
   - Select **+New**.

   - Select **Self-hosted** and select **continue**.
   - Input the **name** of Self-hosted integration runtime and select **Create**.

   - Now a self-hosted integration runtime is available in your Synapse workspace. Follow the prompts in the UI to **download**, **install** and use the key to **register** your integration runtime agent on your windows machine, which has direct access on your SQL Server 2022. For more information, see Create a self-hosted integration runtime - Azure Data Factory & Azure Synapse



- Select **Close**, and go to monitoring page to make sure your self-hosted integration runtime is running by selecting **refresh** to get the latest status of integration runtime.

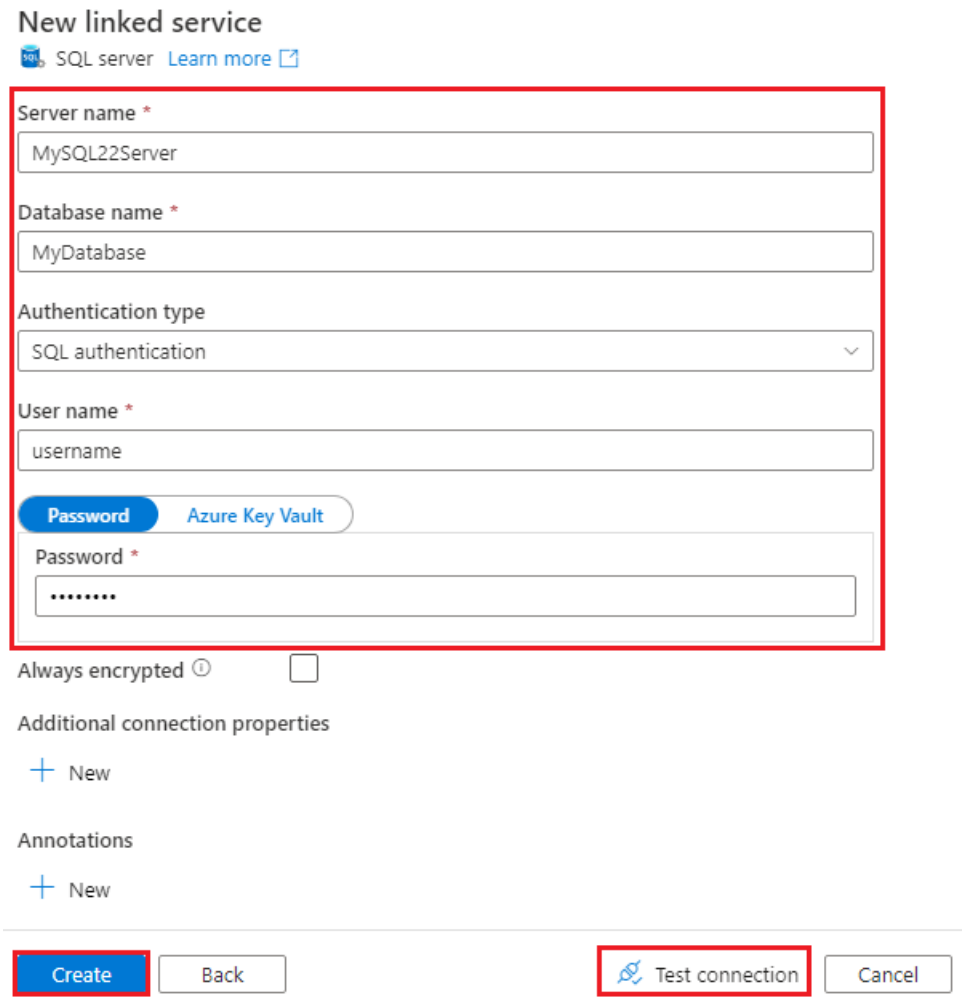


6. Continue to input the rest information on your linked service including **SQL Server name**, **Database name**, **Authentication type**, **User name** and **Password** to connect to your SQL Server 2022.

> **NOTE**
>
> We recommend that you enable encryption on this connection. To enable encryption, add the `Encrypt` property with a value of `true` as an Additional connection property, and also set the `Trust Server Certificate` property to either `true` or `false` - depending on your server configuration. For more information, see Enable encrypted connections to the Database Engine.

7. Select **Test Connection** to ensure your self-hosted integration runtime can access on your SQL Server.

8. Select **Create**, and you'll have your new linked service connecting to SQL Server 2022 available in your workspace.

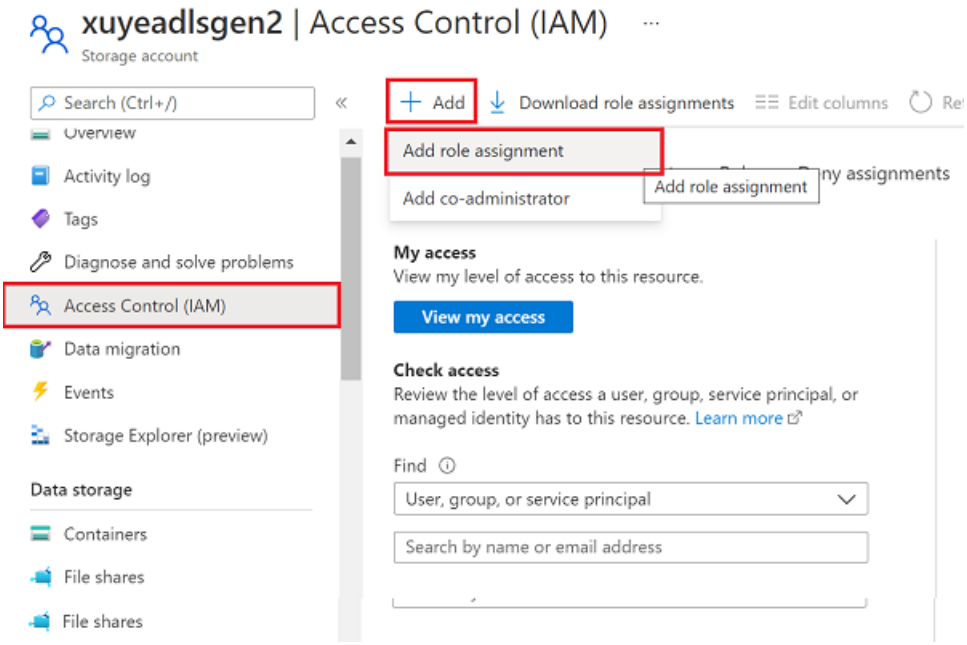


NOTE

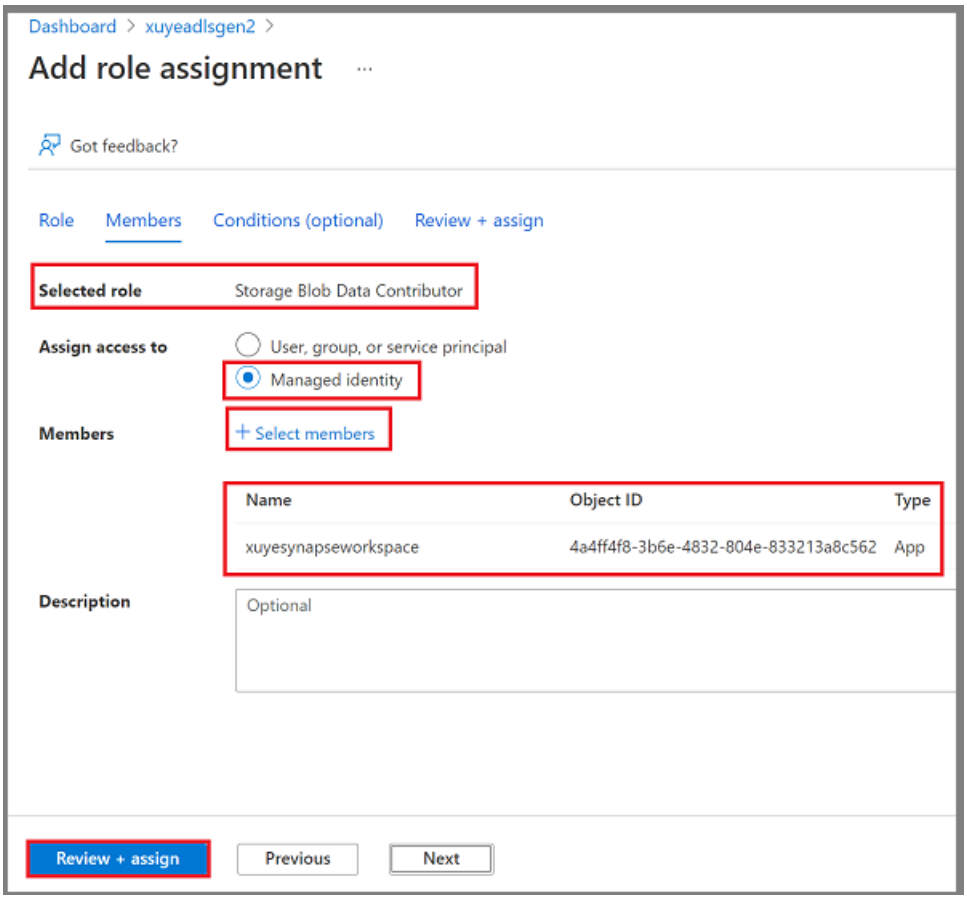
The linked service that you create here is not dedicated to Azure Synapse Link for SQL - it can be used by any workspace user that has the appropriate permissions. Please take time to understand the scope of users who may have access to this linked service and its credentials. For more information on permissions in Azure Synapse workspaces, see Azure Synapse workspace access control overview - Azure Synapse Analytics.

Create linked service to connect to your landing zone on Azure Data Lake Storage Gen2

1. Go to your created Azure Data Lake Storage Gen2 account, navigate to **Access Control (IAM)**, select **+Add**, and select **Add role assignment**.

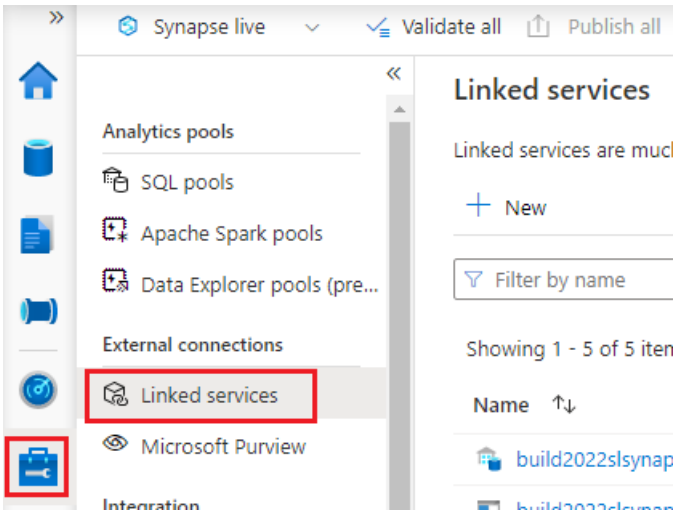


2. Select **Storage Blob Data Contributor** for the selected role, choose **Managed identity** in Managed identity, and select your Synapse workspace in **Members**. This may take a few minutes to take effect to add role assignment.

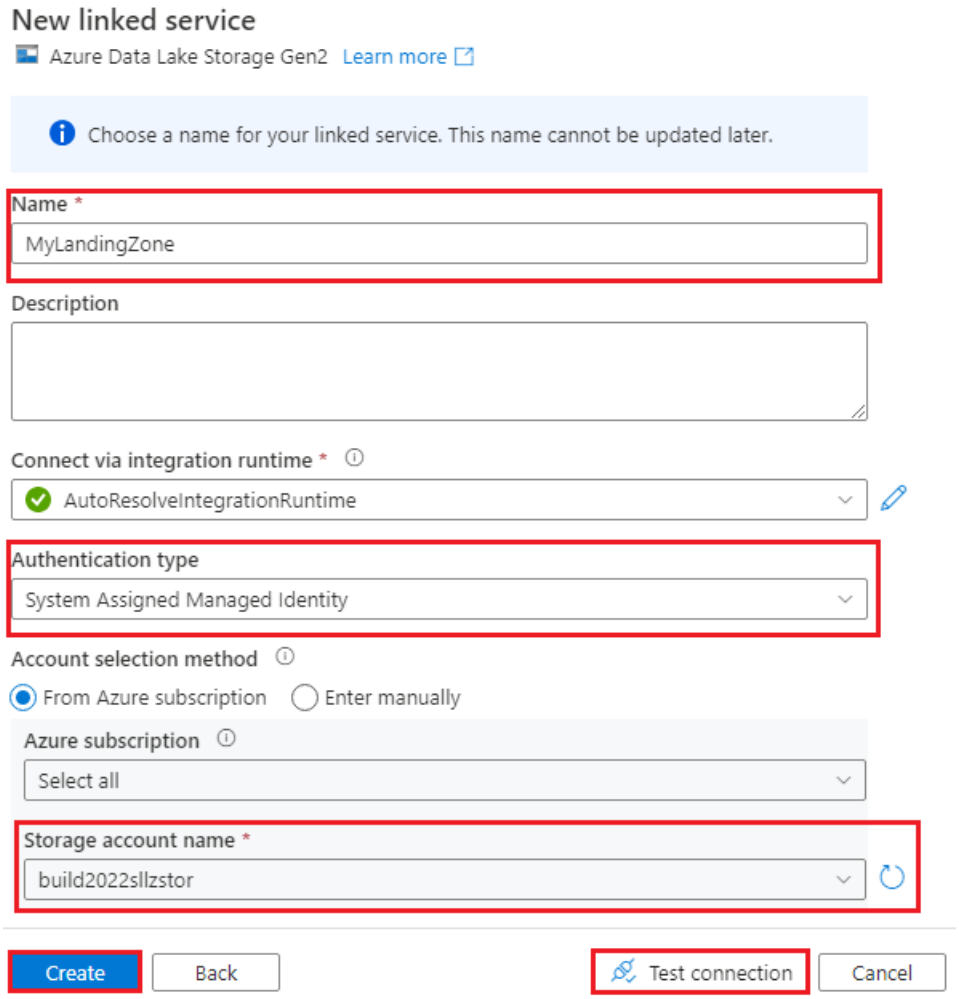


> **NOTE**
>
> Make sure that you have granted your Synapse workspace managed identity permissions to ADLS Gen2 storage account used as the landing zone. For more information, see how to Grant permissions to managed identity in Synapse workspace - Azure Synapse Analytics

3. Open the **Manage** hub in your Synapse workspace, and navigate to **Linked services**.



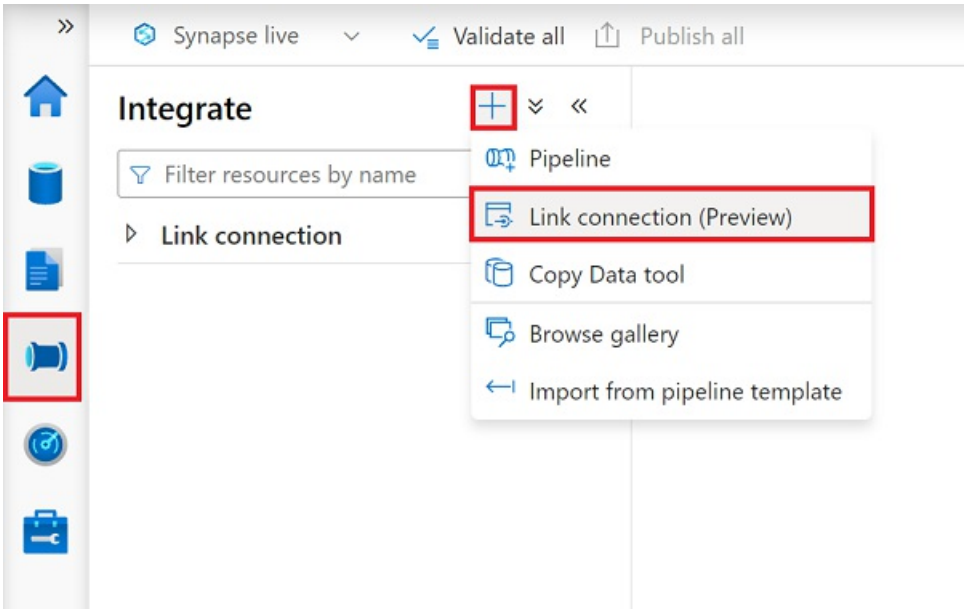
4. Press **+ New** and select **Azure Data Lake Storage Gen2**.
5. Input the following settings:
   - Enter the **name** of linked service for your landing zone.
   - Input **Authentication method**, and it must be **Managed Identity**.
   - Select the **Storage account name** which had already been created.
6. Select **Test Connection** to ensure you get access on your Azure Data Lake Storage Gen2.
7. Select **Create** and you'll have your new linked service connecting to Azure Data Lake Storage Gen2.



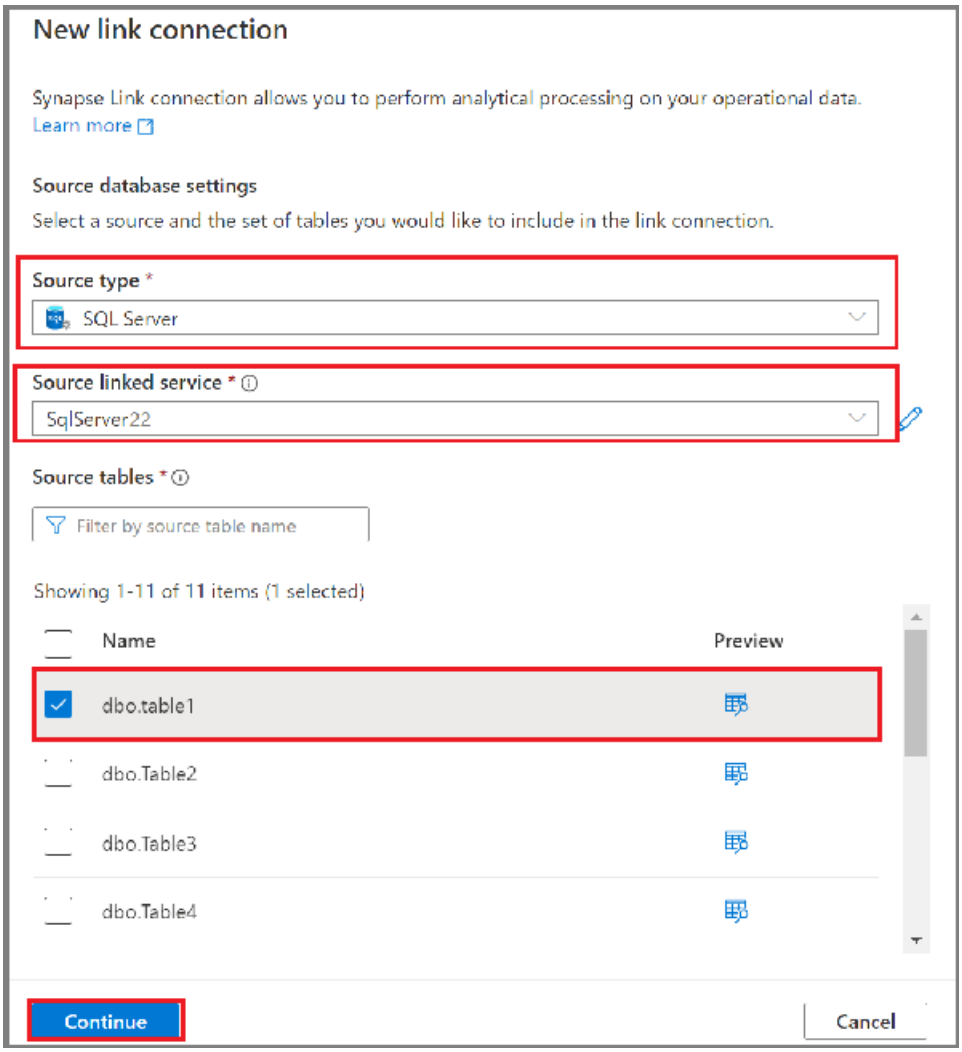
> **NOTE**
>
> The linked service that you create here is not dedicated to Azure Synapse Link for SQL - it can be used by any workspace user that has the appropriate permissions. Please take time to understand the scope of users who may have access to this linked service and its credentials. For more information on permissions in Azure Synapse workspaces, see Azure Synapse workspace access control overview - Azure Synapse Analytics.

Create the Azure Synapse Link connection

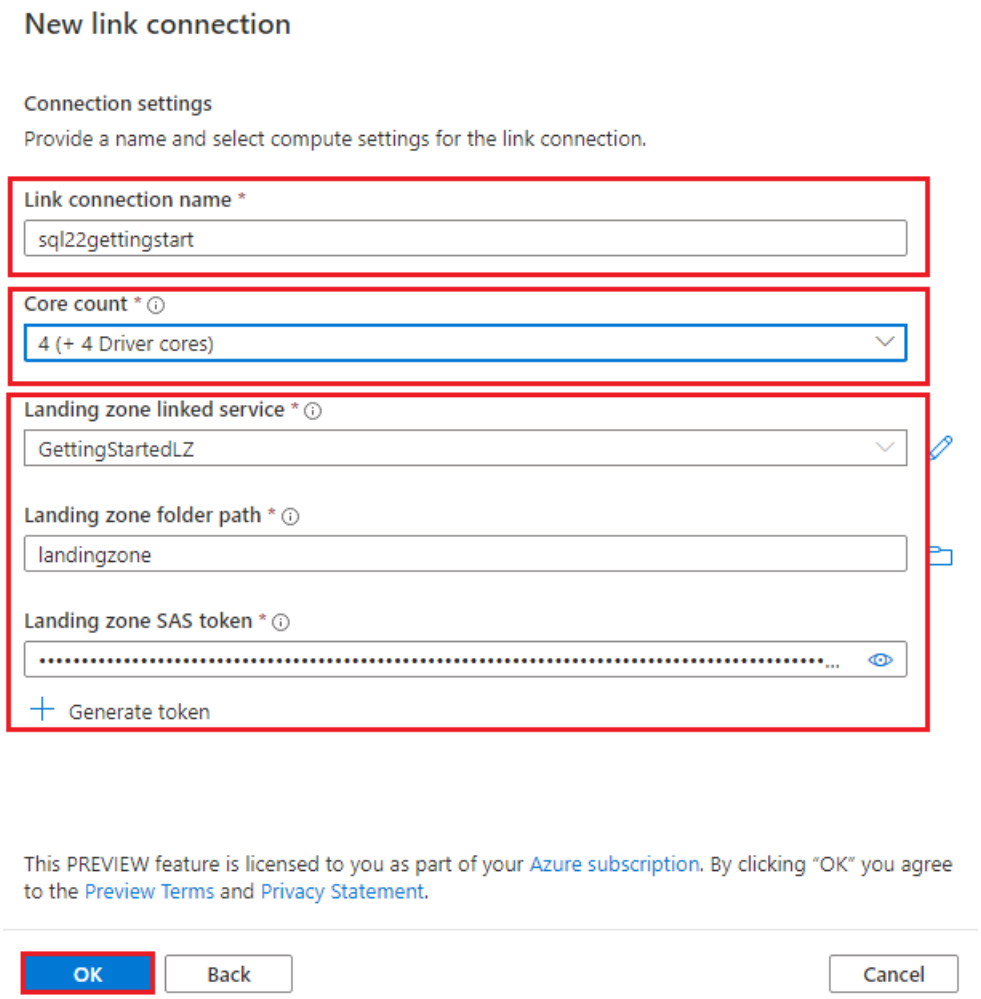
1. From the Synapse studio, open the **Integrate** hub, and select **+Link connection(Preview)**.



2. Input your source database:
   - Select Source type to **SQL Server**.
   - Select your source **linked service** to connect to your SQL Server 2022.
   - Select **table names** from your SQL Server to be replicated to your Synapse SQL pool.
   - Select **Continue**.



3. Select a target database name from **Synapse SQL Dedicated Pools**.
4. Select **Continue**.
5. Input your link connection settings:
   - Input your **link connection name**.
   - Select your **Core count**. We recommend starting from small number and increasing as needed.
   - Configure your landing zone. Select your **linked service** connecting to your landing zone.
   - Input your ADLS Gen2 **container name or container/folder name** as landing zone folder path for staging the data. The container is required to be created first.
   - Input your ADLS Gen2 shared access signature (SAS) token. SAS token is required for SQL change feed to get access on landing zone. If your ADLS Gen2 doesn't have SAS token, you can create one by selecting **+Generate token**.
   - Select **OK**.



6. With the new Azure Synapse Link connection open, you have chance to update the target table name, distribution type and structure type.

> **NOTE**
>
> - Consider heap table for structure type when your data contains varchar(max), nvarchar(max), and varbinary(max).
> - Make sure the schema in your Synapse SQL pool has already been created before you start the link connection. Azure Synapse Link will help you to create tables automatically under your schema in Azure Synapse SQL Pool.

7. Select **Publish all** to save the new link connection to the service.

Start the Azure Synapse Link connection

1. Select **Start** and wait a few minutes for the data to be replicated.

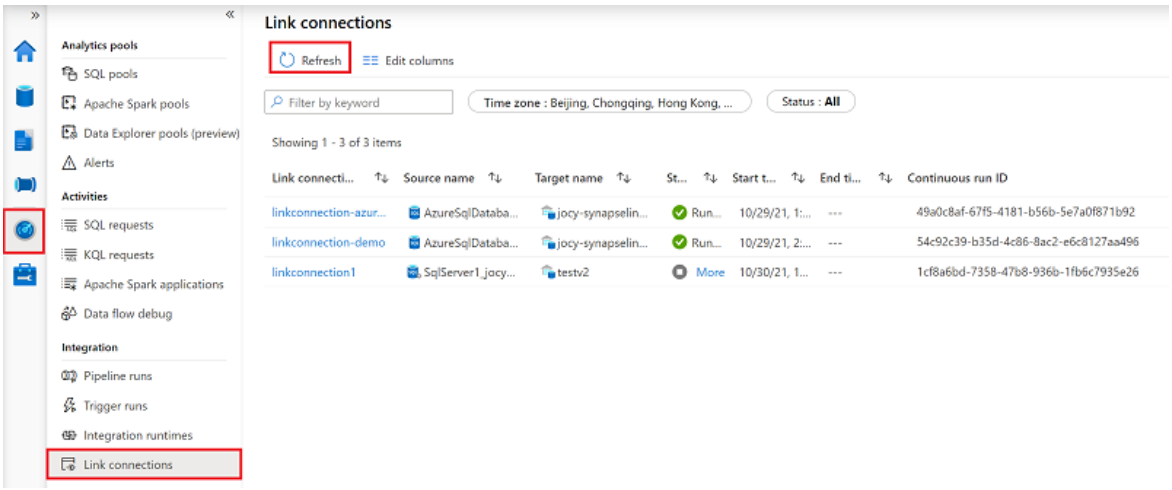
> **NOTE**
>
> When being started, a link connection will start from a full initial load from your source database followed by incremental change feeds via the change feed feature in SQL Server 2022. For more information, see Azure Synapse Link for SQL change feed.

Monitor Azure Synapse Link for SQL Server 2022

You may monitor the status of your Azure Synapse Link connection, see which tables are being initially copied

over (Snapshotting), and see which tables are in continuous replication mode (Replicating).

1. Navigate to the **Monitor hub** of your Synapse workspace.
2. Select **Link connections**.
3. Open the link connection you started and view the status of each table.
4. Select **Refresh** on the monitoring view for your connection to observe any updates to the status.



Query replicated data

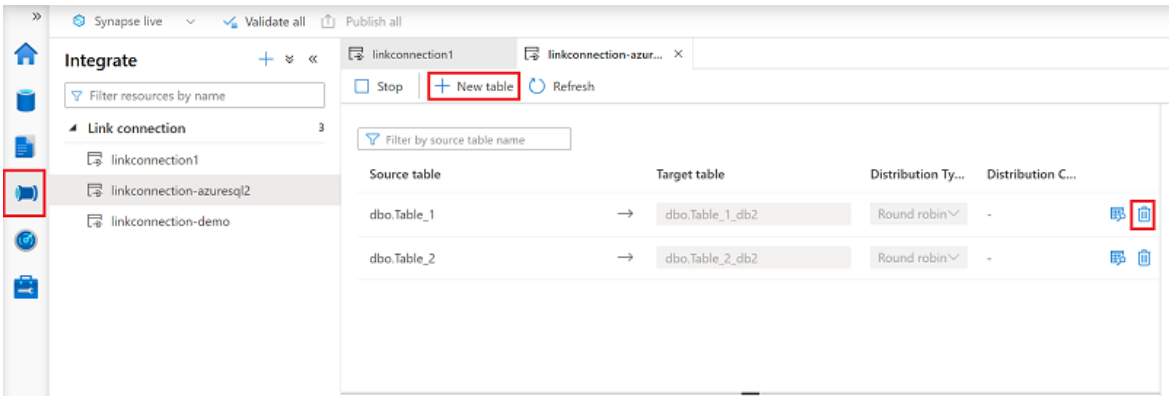
Wait for a few minutes, then check the target database has the expected table and data. See the data available in your Synapse dedicated SQL pool destination store. You can also now explore the replicated tables in your target Synapse dedicated SQL pool.

1. In the **Data** hub, under **Workspace**, open your target database, and within **Tables**, right-click one of your target tables.
2. Choose **New SQL script**, then **Select TOP 100 rows**.
3. Run this query to view the replicated data in your target Synapse dedicated SQL pool.
4. You can also query the target database with SSMS (or other tools). Use the dedicated SQL endpoint for your workspace as the server name. This is typically `<workspacename>.sql.azuresynapse.net`. Add `Database=databasename@poolname` as an extra connection string parameter when connecting via SSMS (or other tools).

Add/remove table in existing Azure Synapse Link connection

You can add/remove tables on Synapse Studio as follows:

1. Open the **Integrate Hub**.
2. Select the **Link connection** you want to edit and open it.
3. Select **+New** table to add tables on Synapse Studio or select the trash can icon to the right of a table to remove an existing table. You can add or remove tables when the link connection is running.



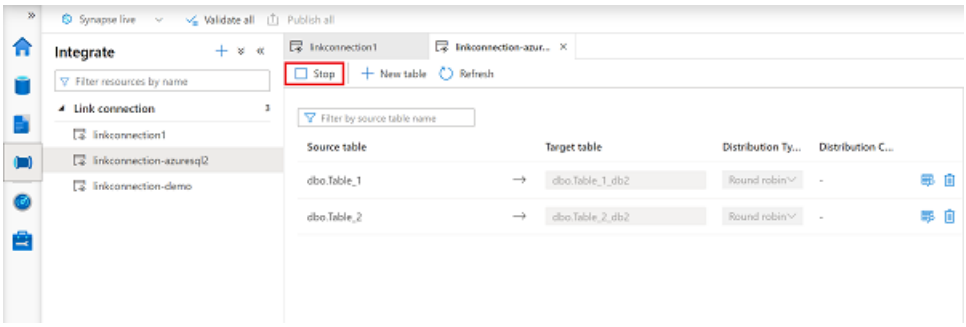
NOTE

You can directly add or remove tables when a link connection is running.

Stop the Azure Synapse Link connection

You can stop the Azure Synapse Link connection on Synapse Studio as follows:

1. Open the **Integrate Hub** of your Synapse workspace.
2. Select the **Link connection** you want to edit and open it.
3. Select **Stop** to stop the link connection, and it will stop replicating your data.



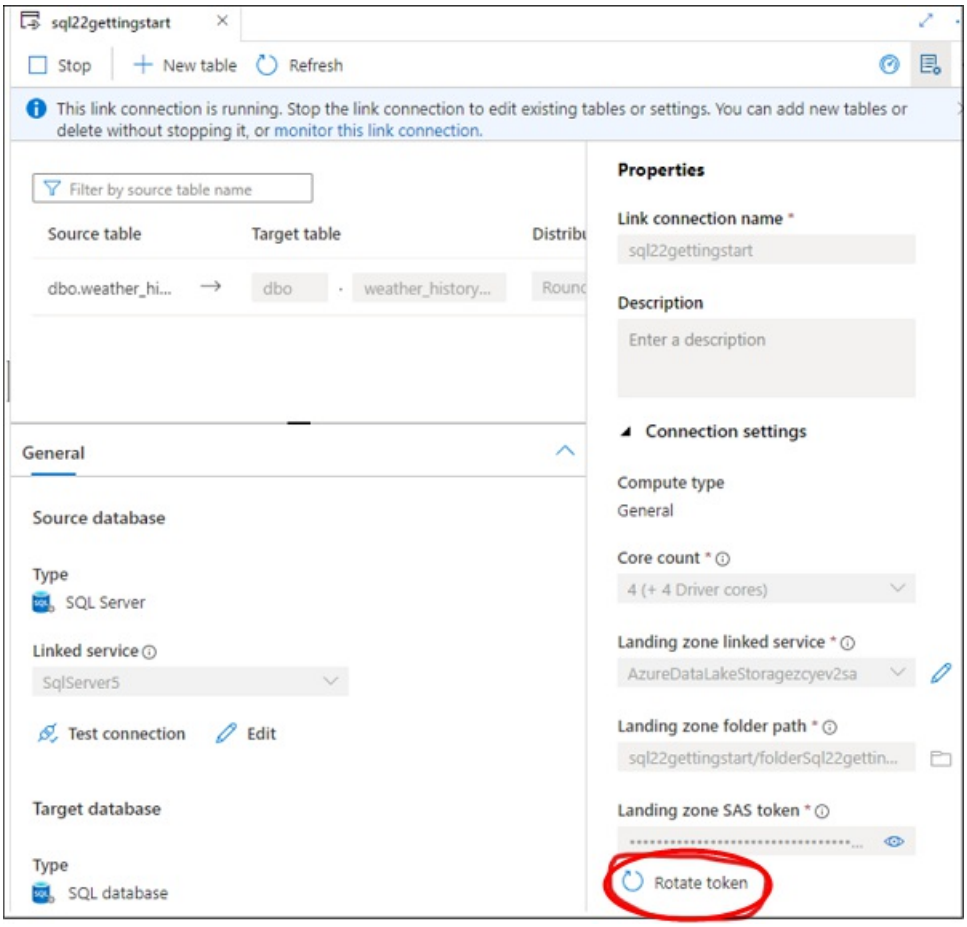
NOTE

If you restart a link connection after stopping it, it will start from a full initial load from your source database followed by incremental change feeds.

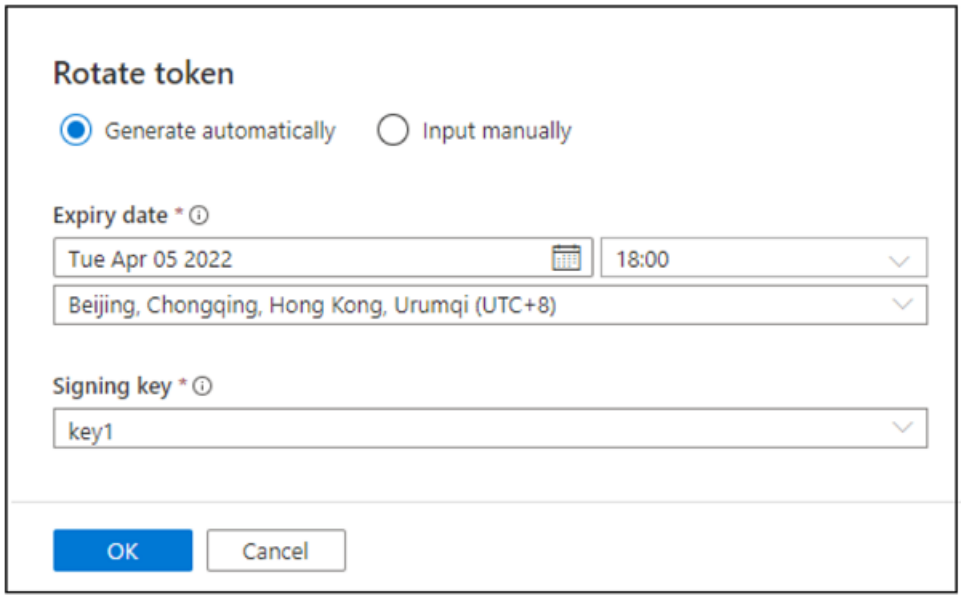
Rotate the SAS token for landing zone

A SAS token is required for SQL change feed to get access to the landing zone and push data there. It has an expiration date so you need to rotate the SAS token before the expiration date. Otherwise, Azure Synapse Link will fail to replicate the data from SQL Server to the Synapse dedicated SQL pool.

1. Open the **Integrate Hub** of your Synapse workspace.
2. Select the **Link connection** you want to edit and open it.
3. Select **Rotate token**.



4. Select **Generate automatically** or **Input manually** to get the new SAS token, and then select **OK**.



Next steps

If you are using a different type of database, see how to:

- Configure Azure Synapse Link for Azure Cosmos DB
- Configure Azure Synapse Link for Dataverse
- Get started with Azure Synapse Link for Azure SQL Database

Known limitations and issues with Azure Synapse Link for SQL

8/19/2022 • 5 minutes to read • Edit Online

This article lists the known limitations and issues with Azure Synapse Link for SQL.

Known limitations

This is the list of known limitations for Azure Synapse Link for SQL.

Azure SQL DB and SQL Server 2022

- Users must use an Azure Synapse Analytics workspace created on or after May 24, 2022, to get access to Azure Synapse Link for SQL functionality.
- Running Azure Synapse Analytics in a managed virtual network isn't supported. Users need to check "Disable Managed virtual network" and "Allow connections from all IP addresses" when creating their workspace.
- Source tables must have primary keys.
- The following data types aren't supported for primary keys in the source tables:
  - real
  - float
  - hierarchyid
  - sql_variant
  - timestamp
- Source table row size can't exceed 7,500 bytes. For tables where variable-length columns are stored off-row, a 24-byte pointer is stored in the main record.
- Tables enabled for Azure Synapse Link for SQL can have a maximum of 1,020 columns (not 1,024).
- While a database can have multiple links enabled, a given table can't belong to multiple links.
- When a database owner doesn't have a mapped log in, Azure Synapse link for SQL will run into an error when enabling a link connection. User can set database owner to a valid user with the `ALTER AUTHORIZATION` command to fix this issue.
- If the source table contains computed columns or columns with data types that aren't supported by Azure Synapse Analytics dedicated SQL pools, these columns won't be replicated to Azure Synapse Analytics. Unsupported columns include:
  - image
  - text
  - xml
  - timestamp
  - sql_variant
  - UDT
  - geometry
  - geography
- A maximum of 5,000 tables can be added to a single link connection.
- When a source column is of type datetime2(7) or time(7), the last digit will be truncated when data is replicated to Azure Synapse Analytics.
- The following table DDL operations aren't allowed on source tables when they are enabled for Azure Synapse Link for SQL. All other DDL operations are allowed, but they won't be replicated to Azure Synapse Analytics.

    - Switch Partition
    - Add/Drop/Alter Column
    - Alter Primary Key
    - Drop/Truncate Table
    - Rename Table
- If DDL + DML is executed in an explicit transaction (between `BEGIN TRANSACTION` and `END TRANSACTION` statements), replication for corresponding tables will fail within the link connection.

  > **NOTE**
  > If a table is critical for transactional consistency at the link connection level, please review the state of the Azure Synapse Link table in the Monitoring tab.

- Azure Synapse Link for SQL can't be enabled if any of the following features are in use for the source table:
    - Change Data Capture
    - Temporal history table
    - Always encrypted
    - In-Memory OLTP
    - Column Store Index
    - Graph
- System tables can't be replicated.
- The security configuration from the source database will **NOT** be reflected in the target dedicated SQL pool.
- Enabling Azure Synapse Link for SQL will create a new schema called `changefeed`. Don't use this schema, as it is reserved for system use.
- Source tables with non-default collations: UTF8, Japanese can't be replicated to Synapse. Here's the supported collations in Synapse SQL Pool.
- Single row updates (including off-page storage) of > 370MB are not supported.

Azure SQL DB only

- Azure Synapse Link for SQL isn't supported on Free, Basic or Standard tier with fewer than 100 DTUs.
- Azure Synapse Link for SQL isn't supported on SQL Managed Instances.
- Users need to check "Allow Azure services and resources to access this server" in the firewall settings of their source database server.
- Service principal isn't supported for authenticating to source Azure SQL DB, so when creating Azure SQL DB linked Service, choose SQL authentication, user-assigned managed identity (UAMI) or service assigned managed Identity (SAMI).
- Azure Synapse Link can't be enabled on the secondary database once a GeoDR failover has happened if the secondary database has a different name from the primary database.
- If you enabled Azure Synapse Link for SQL on your database as an Microsoft Azure Active Directory (Azure AD) user, Point-in-time restore (PITR) will fail. PITR will only work when you enable Azure Synapse Link for SQL on your database as a SQL user.
- If you create a database as an Azure AD user and enable Azure Synapse Link for SQL, a SQL authentication user (for example, even sysadmin role) won't be able to disable/make changes to Azure Synapse Link for SQL artifacts. However, another Azure AD user will be able to enable/disable Azure Synapse Link for SQL on the same database. Similarly, if you create a database as an SQL authentication user, enabling/disabling Azure Synapse Link for SQL as an Azure AD user won't work.
- When enabling Azure Synapse Link for SQL on your Azure SQL Database, you should ensure that aggressive log truncation is disabled.

SQL Server 2022 only

- Azure Synapse Link for SQL works with SQL Server on Linux, but HA scenarios with Linux Pacemaker aren't supported. Shelf hosted IR cannot be installed on Linux environment.
- Azure Synapse Link for SQL can't be enabled on databases that are transactional replication publishers or distributors.
- If the SAS key of landing zone expires and gets rotated during the snapshot process, the new key won't get picked up. The snapshot will fail and restart automatically with the new key.
- Prior to breaking an Availability Group, disable any running links. Otherwise both databases will attempt to write their changes to the landing zone.
- When using asynchronous replicas, transactions need to be written to all replicas prior to them being published to Azure Synapse Link for SQL.
- Azure Synapse Link for SQL isn't supported on databases with database mirroring enabled.
- Restoring an Azure Synapse Link for SQL-enabled database from on-premises to Azure SQL Managed Instance isn't supported.
- Azure Synapse Link for SQL is not supported on databases that are using Managed Instance Link.

Known issues

Deleting an Azure Synapse Analytics workspace with a running link could cause log in source database to fill

- Applies To - Azure SQL Database and SQL Server 2022
- Issue - When you delete an Azure Synapse Analytics workspace it is possible that running links might not be stopped, which will cause the source database to think that the link is still operational and could lead to the log filling and not being truncated.
- Resolution - There are two possible resolutions to this situation:

1. Stop any running links prior to deleting the Azure Synapse Analytics workspace.
2. Manually clean up the link definition in the source database.
   a. Find the table_group_id for the link(s) that need to be stopped using the following query:

```
SELECT table_group_id, workspace_id, synapse_workgroup_name
FROM [changefeed].[change_feed_table_groups]
WHERE synapse_workgroup_name = <synapse workspace name>
```

   b. Drop each link identified using the following procedure:

```
EXEC sys.sp_change_feed_drop_table_group @table_group_id = <table_group_id>
```

   c. Optionally, if you are disabling all of the table groups for a given database, you can also disable change feed on the database with the following command:

```
EXEC sys.sp_change_feed_disable_db
```

Next steps

Quickstart: Load data into dedicated SQL pool using the copy activity

8/19/2022 • 5 minutes to read • Edit Online

Azure Synapse Analytics offers various analytics engines to help you ingest, transform, model, and analyze your data. A dedicated SQL pool offers T-SQL based compute and storage capabilities. After creating a dedicated SQL pool in your Synapse workspace, data can be loaded, modeled, processed, and delivered for faster analytic insight.

In this quickstart, you learn how to *load data from Azure SQL Database into Azure Synapse Analytics*. You can follow similar steps to copy data from other types of data stores. This similar flow applies to data copy for other sources and sinks as well.

Prerequisites

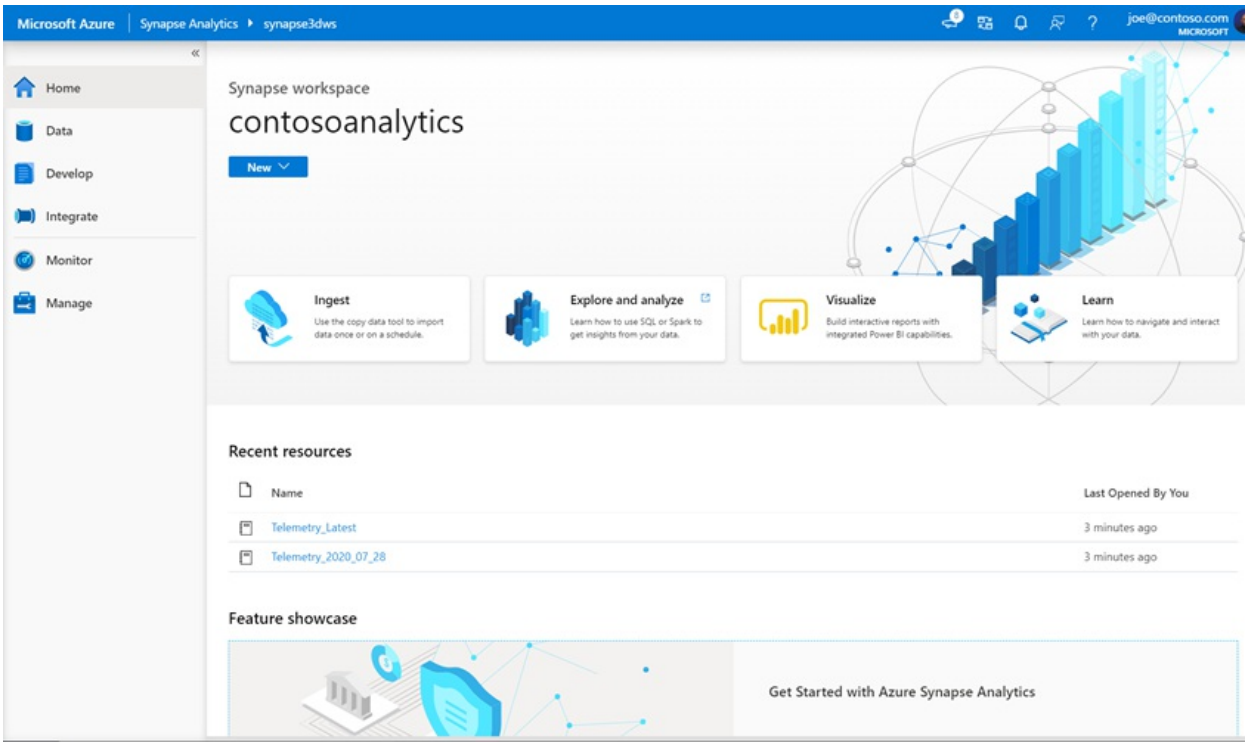
- Azure subscription: If you don't have an Azure subscription, create a free account before you begin.
- Azure Synapse workspace: Create a Synapse workspace using the Azure portal following the instructions in Quickstart: Create a Synapse workspace.
- Azure SQL Database: This tutorial copies data from the Adventure Works LT sample dataset in Azure SQL Database. You can create this sample database in SQL Database by following the instructions in Create a sample database in Azure SQL Database. Or you can use other data stores by following similar steps.
- Azure storage account: Azure Storage is used as the *staging* area in the copy operation. If you don't have an Azure storage account, see the instructions in Create a storage account.
- Azure Synapse Analytics: You use a dedicated SQL pool as a sink data store. If you don't have an Azure Synapse Analytics instance, see Create a dedicated SQL pool for steps to create one.

Navigate to the Synapse Studio

After your Synapse workspace is created, you have two ways to open Synapse Studio:

- Open your Synapse workspace in the Azure portal. Select **Open** on the Open Synapse Studio card under Getting started.
- Open Azure Synapse Analytics and sign in to your workspace.

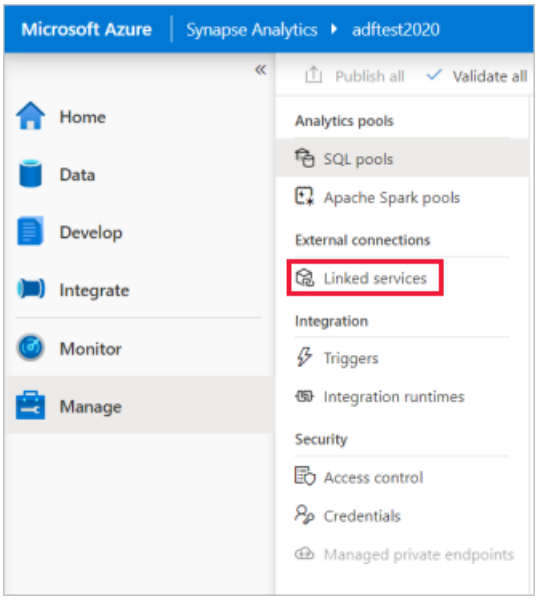
In this quickstart, we use the workspace named "adftest2020" as an example. It will automatically navigate you to the Synapse Studio home page.



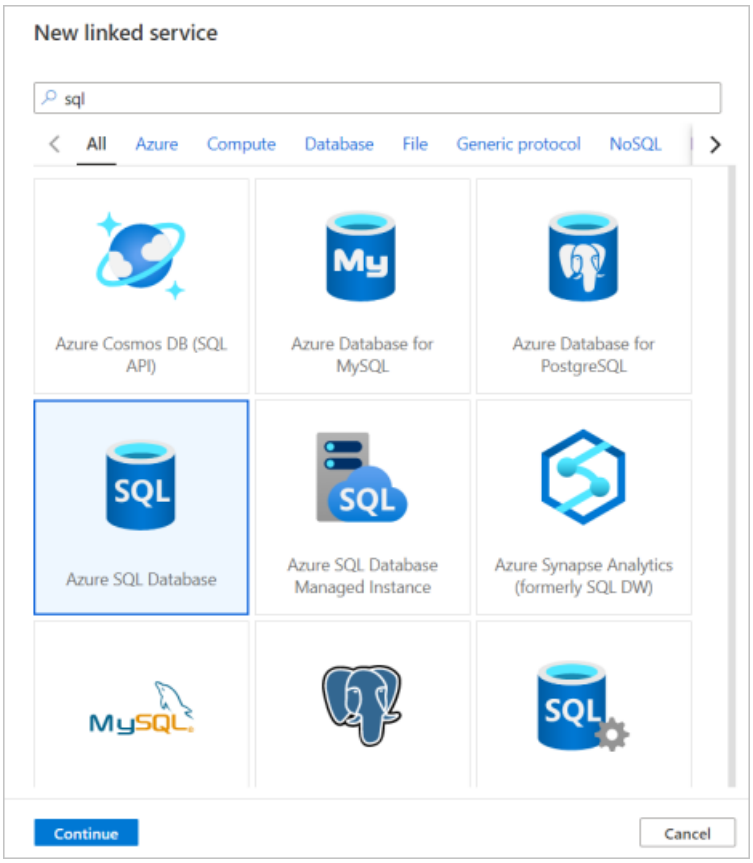
Create linked services

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll create following two kinds of linked services: Azure SQL Database and Azure Data Lake Storage Gen2 (ADLS Gen2) linked services.

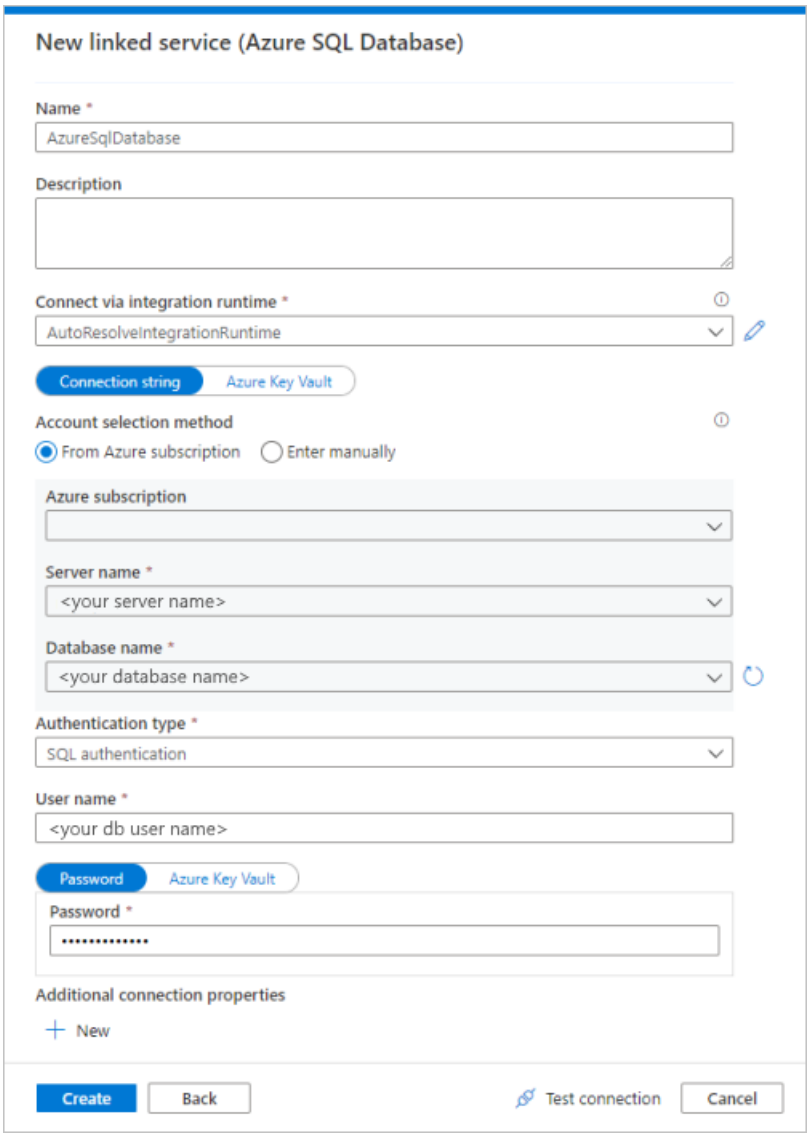
1. On the Synapse Studio home page, select the **Manage** tab in the left navigation.
2. Under External connections, select Linked services.



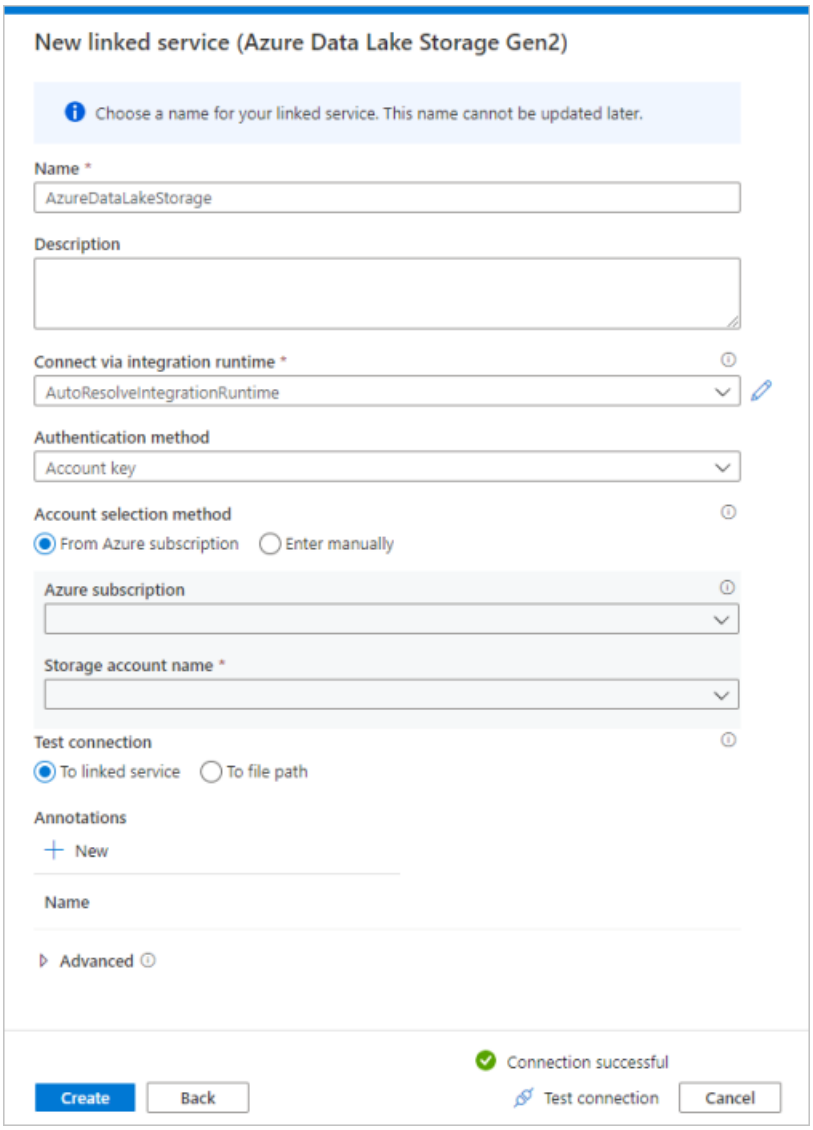
3. To add a linked service, select **New**.
4. Select **Azure SQL Database** from the gallery, and then select **Continue**. You can type "sql" in the search box to filter the connectors.



5. In the New Linked Service page, select your server name and DB name from the dropdown list, and specify the username and password. Click **Test connection** to validate the settings, then select **Create**.



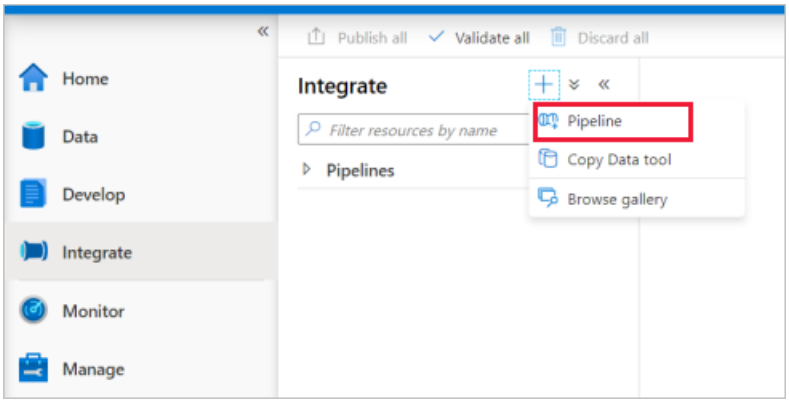
6. Repeat steps 3-4, but select **Azure Data Lake Storage Gen2** instead from the gallery. In the New Linked Service page, select your storage account name from the dropdown list. Click **Test connection** to validate the settings, then select **Create**.



Create a pipeline

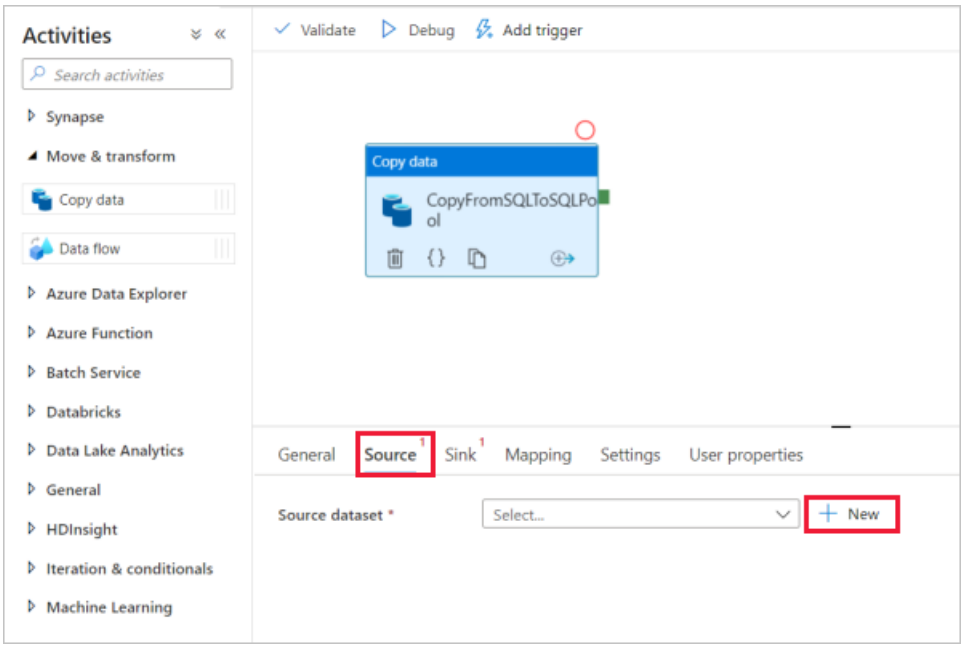
A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline containing a copy activity that ingests data from Azure SQL Database into a dedicated SQL pool.

1. Go to the **Integrate** tab. Select on the plus icon next to the pipelines header and select Pipeline.



2. Under *Move and Transform* in the *Activities* pane, drag **Copy data** onto the pipeline canvas.

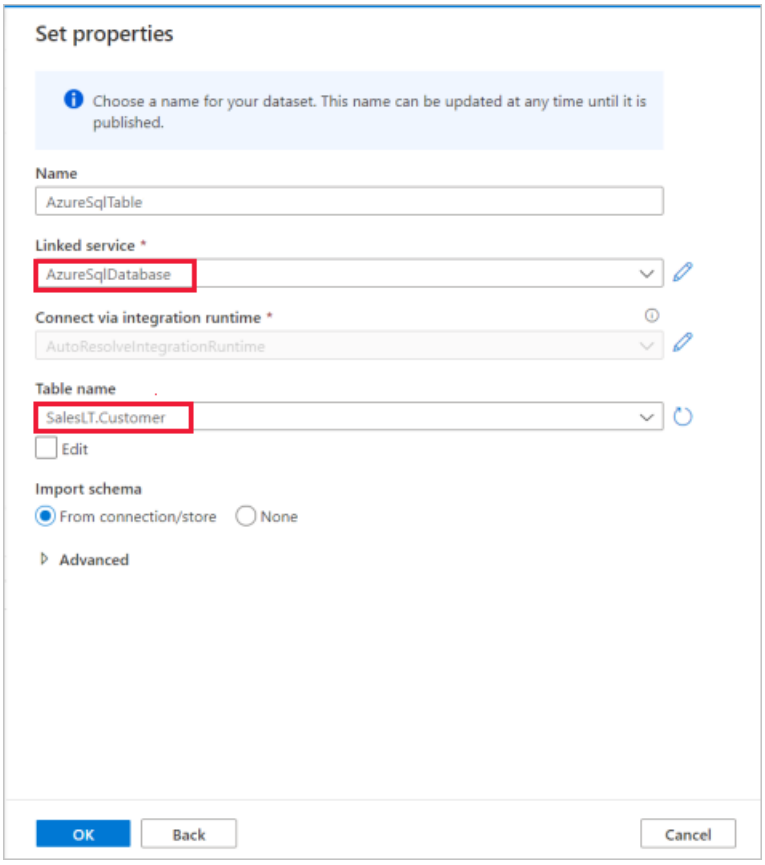
3. Select on the copy activity and go to the Source tab. Select **New** to create a new source dataset.



4. Select **Azure SQL Database** as your data store and select **Continue**.

5. In the *Set properties* pane, select the Azure SQL Database linked service you created in earlier step.

6. Under Table name, select a sample table to use in following copy activity. In this quickstart, we use "SalesLT.Customer" table as an example.



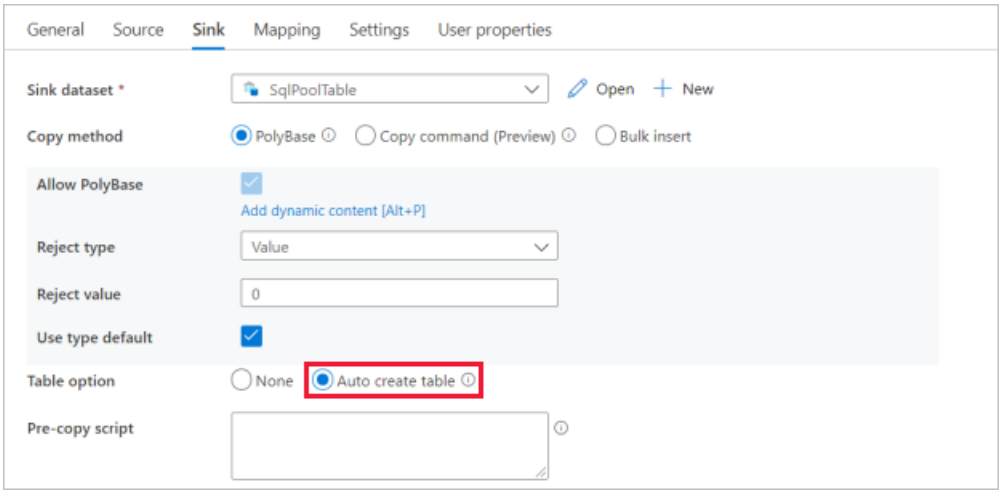
7. Select **OK** when finished.

8. Select the copy activity and go to the Sink tab. Select **New** to create a new sink dataset.

9. Select **Azure Synapse dedicated SQL pool** as your data store and select **Continue**.

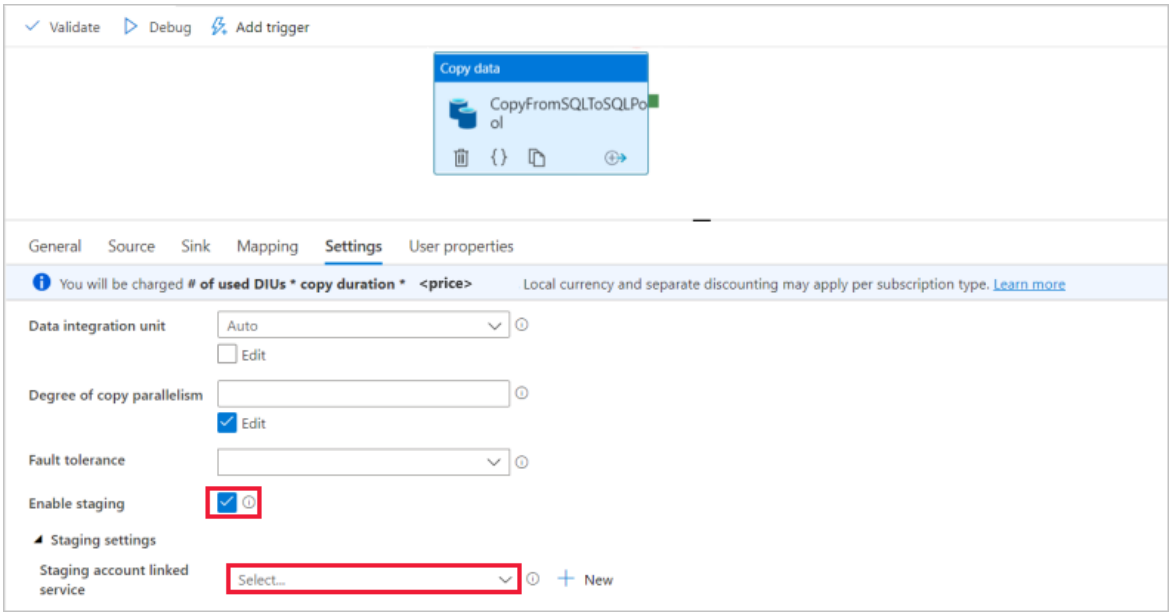
10. In the **Set properties** pane, select the SQL Analytics pool you created in earlier step. If you're writing to an existing table, under *Table name* select it from the dropdown. Otherwise, check "Edit" and enter in your new table name. Select **OK** when finished.

11. For Sink dataset settings, enable **Auto create table** in the Table option field.



12. In the **Settings** page, select the checkbox for **Enable staging**. This option applies if your source data is not compatible with PolyBase. In **Staging settings** section, select the Azure Data Lake Storage Gen2 linked service you created in earlier step as the staging storage.

    The storage is used for staging the data before it loads into Azure Synapse Analytics by using PolyBase. After the copy is complete, the interim data in Azure Data Lake Storage Gen2 is automatically cleaned up.

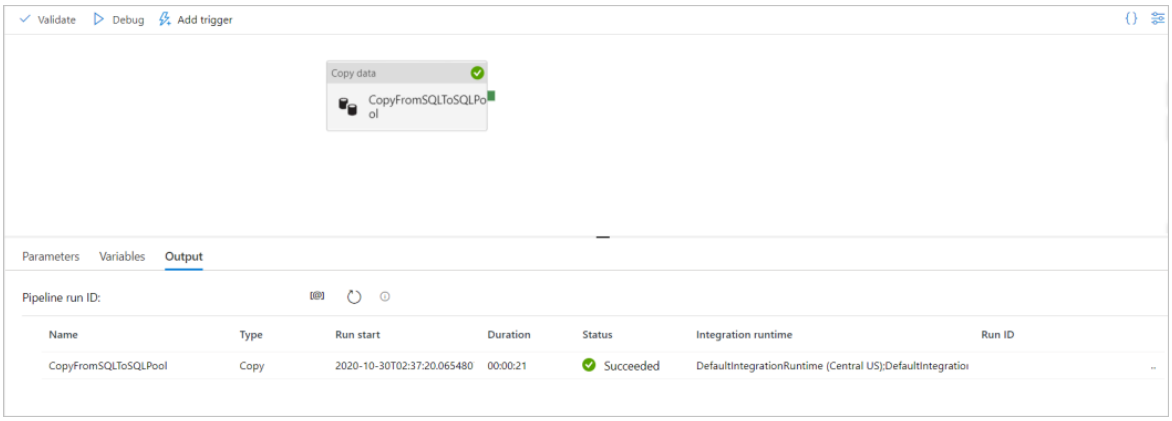


13. To validate the pipeline, select **Validate** on the toolbar. You see the result of the Pipeline validation output on the right side of the page.

Debug and publish the pipeline

Once you've finished configuring your pipeline, you can execute a debug run before you publish your artifacts to verify everything is correct.

1. To debug the pipeline, select **Debug** on the toolbar. You see the status of the pipeline run in the **Output** tab at the bottom of the window.



2. Once the pipeline run succeeds, in the top toolbar, select **Publish all**. This action publishes entities (datasets, and pipelines) you created to the Synapse Analytics service.

3. Wait until you see the **Successfully published** message. To see notification messages, select the bell button on the top-right.

Trigger and monitor the pipeline

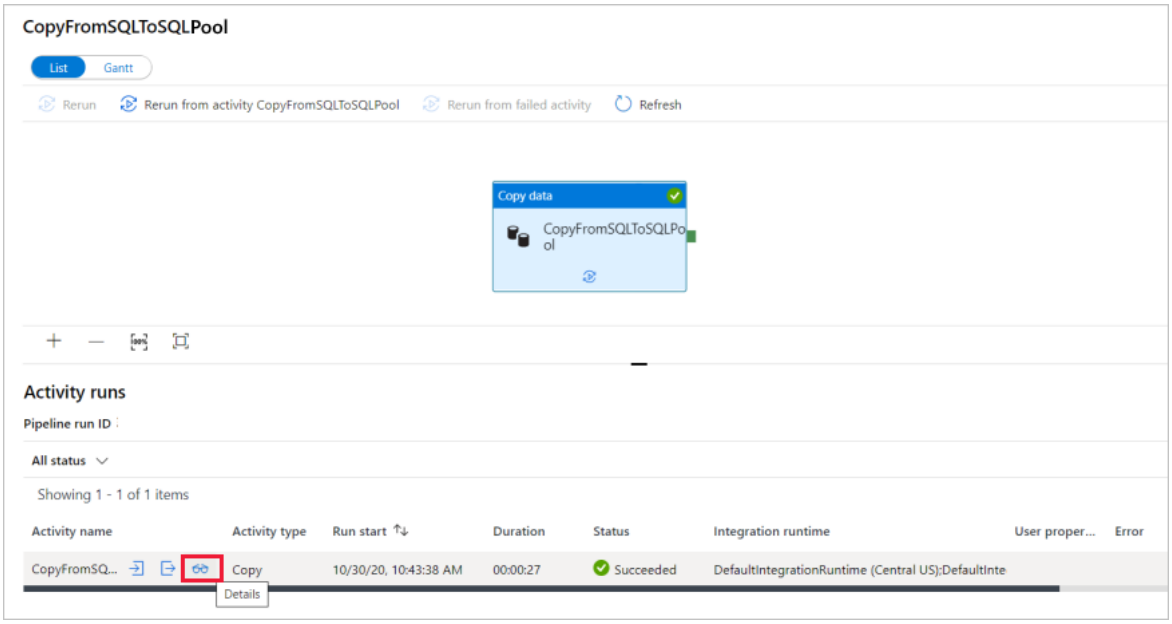
In this section, you manually trigger the pipeline published in the previous step.

1. Select **Add Trigger** on the toolbar, and then select **Trigger Now**. On the **Pipeline Run** page, select **OK**.

2. Go to the **Monitor** tab located in the left sidebar. You see a pipeline run that is triggered by a manual trigger.

3. When the pipeline run completes successfully, select the link under the **Pipeline name** column to view activity run details or to rerun the pipeline. In this example, there's only one activity, so you see only one entry in the list.

4. For details about the copy operation, select the **Details** link (eyeglasses icon) under the **Activity name** column. You can monitor details like the volume of data copied from the source to the sink, data throughput, execution steps with corresponding duration, and used configurations.



5. To switch back to the pipeline runs view, select the **All pipeline runs** link at the top. Select **Refresh** to refresh the list.

6. Verify your data is correctly written in the dedicated SQL pool.

Pipeline and activities Connector overview Copy activity

Quickstart: Transform data using mapping data flows

8/19/2022 • 7 minutes to read • Edit Online

In this quickstart, you'll use Azure Synapse Analytics to create a pipeline that transforms data from an Azure Data Lake Storage Gen2 (ADLS Gen2) source to an ADLS Gen2 sink using mapping data flow. The configuration pattern in this quickstart can be expanded upon when transforming data using mapping data flow

In this quickstart, you do the following steps:

- Create a pipeline with a Data Flow activity in Azure Synapse Analytics.
- Build a mapping data flow with four transformations.
- Test run the pipeline.
- Monitor a Data Flow activity

Prerequisites

- **Azure subscription**: If you don't have an Azure subscription, create a free account before you begin.
- **Azure Synapse workspace**: Create a Synapse workspace using the Azure portal following the instructions in Quickstart: Create a Synapse workspace.
- **Azure storage account**: You use ADLS storage as *source* and *sink* data stores. If you don't have a storage account, see Create an Azure storage account for steps to create one.

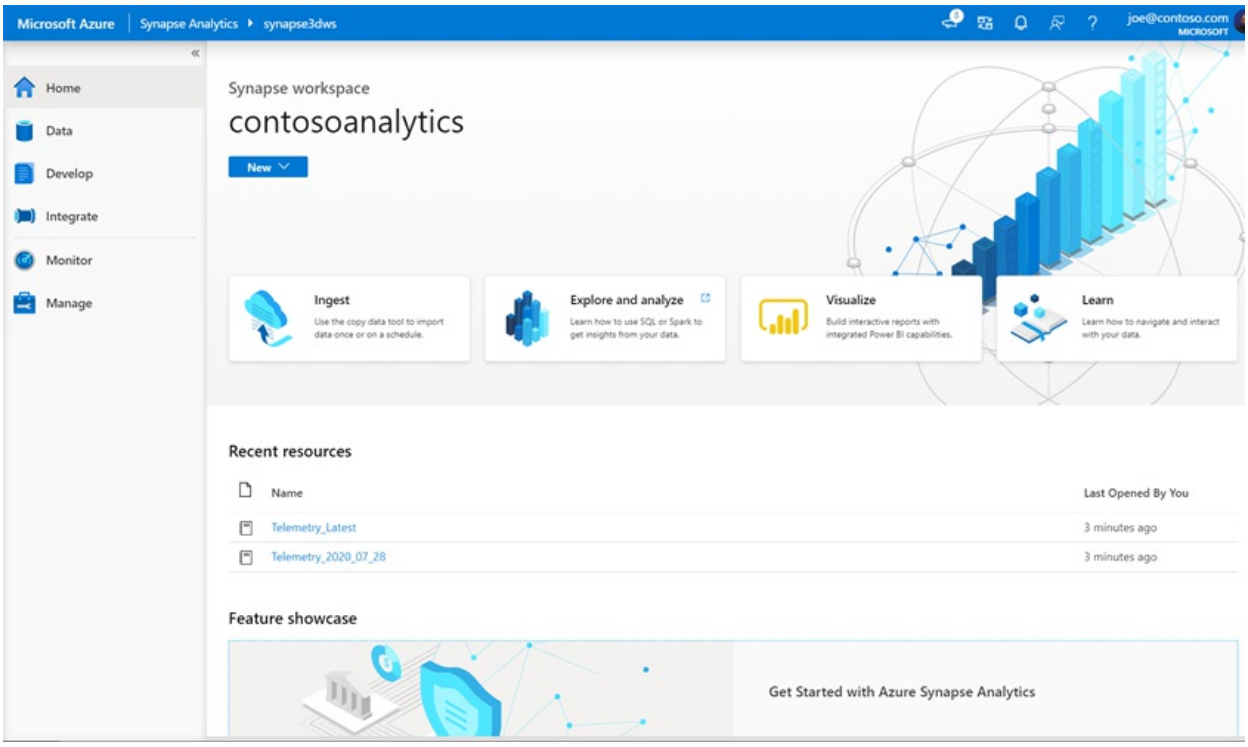
  The file that we are transforming in this tutorial is MoviesDB.csv, which can be found here. To retrieve the file from GitHub, copy the contents to a text editor of your choice to save locally as a .csv file. To upload the file to your storage account, see Upload blobs with the Azure portal. The examples will be referencing a container named 'sample-data'.

Navigate to the Synapse Studio

After your Azure Synapse workspace is created, you have two ways to open Synapse Studio:

- Open your Synapse workspace in the Azure portal. Select **Open** on the Open Synapse Studio card under Getting started.
- Open Azure Synapse Analytics and sign in to your workspace.

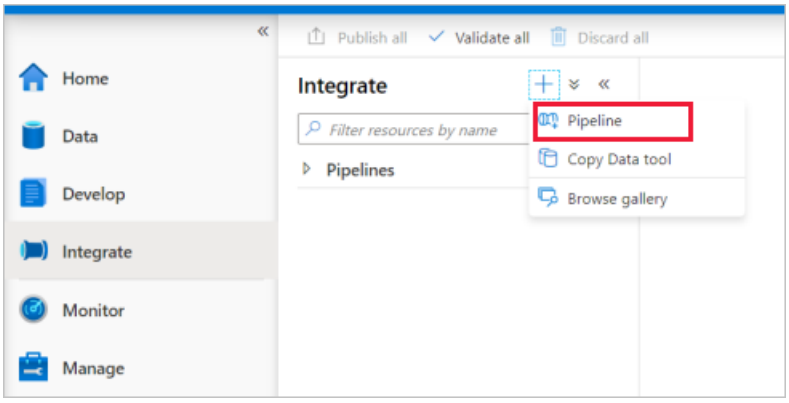
In this quickstart, we use the workspace named "adftest2020" as an example. It will automatically navigate you to the Synapse Studio home page.



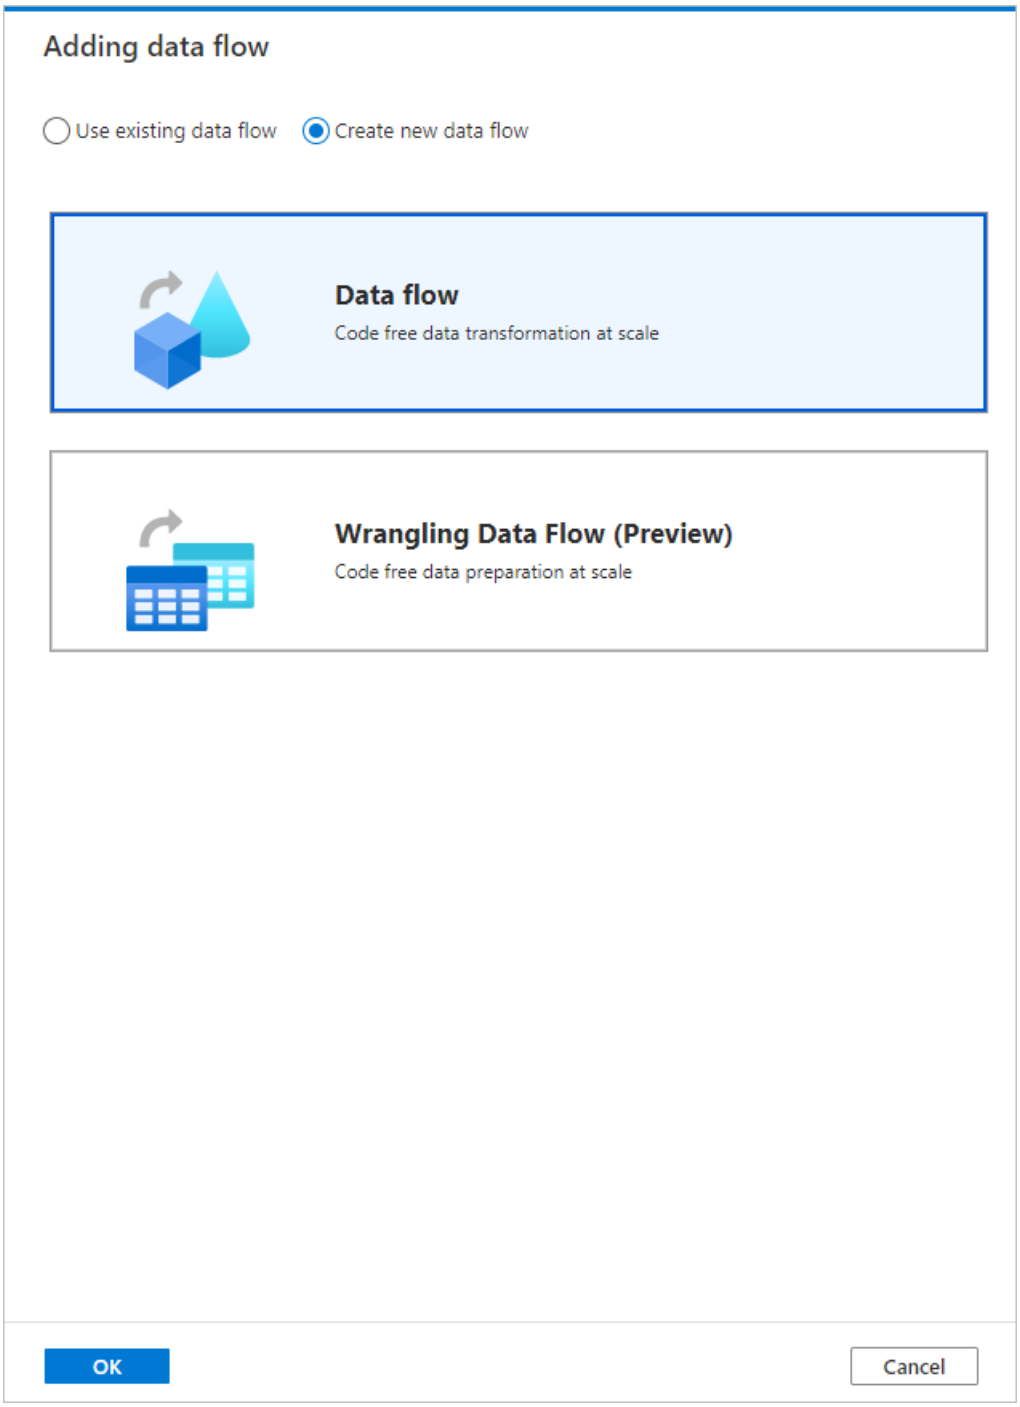
Create a pipeline with a Data Flow activity

A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline that contains a Data Flow activity.

1. Go to the **Integrate** tab. Select on the plus icon next to the pipelines header and select Pipeline.



2. In the **Properties** settings page of the pipeline, enter **TransformMovies** for **Name**.
3. Under *Move and Transform* in the *Activities* pane, drag **Data flow** onto the pipeline canvas.
4. In the **Adding data flow** page pop-up, select **Create new data flow** -> **Data flow**. Click **OK** when done.

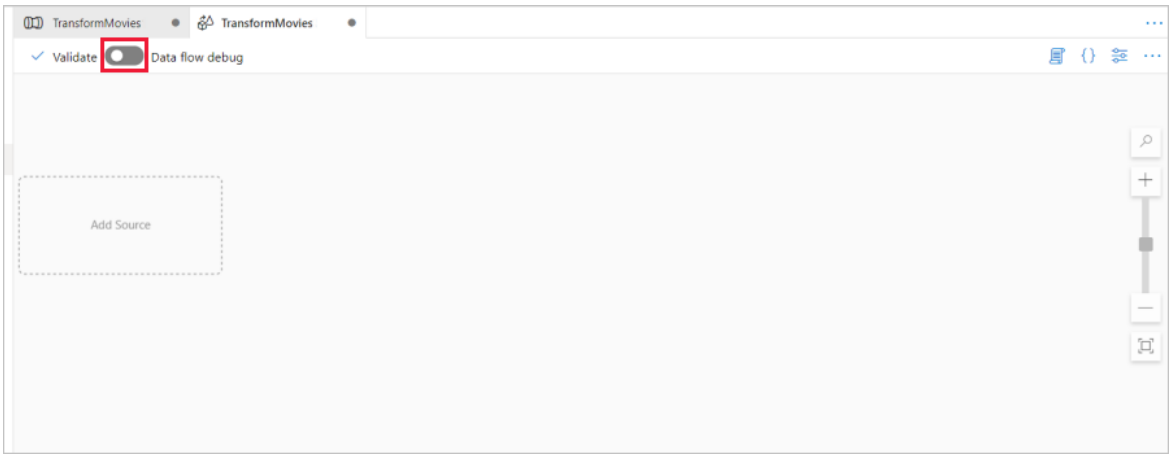


5. Name your data flow **TransformMovies** on the **Properties** page.

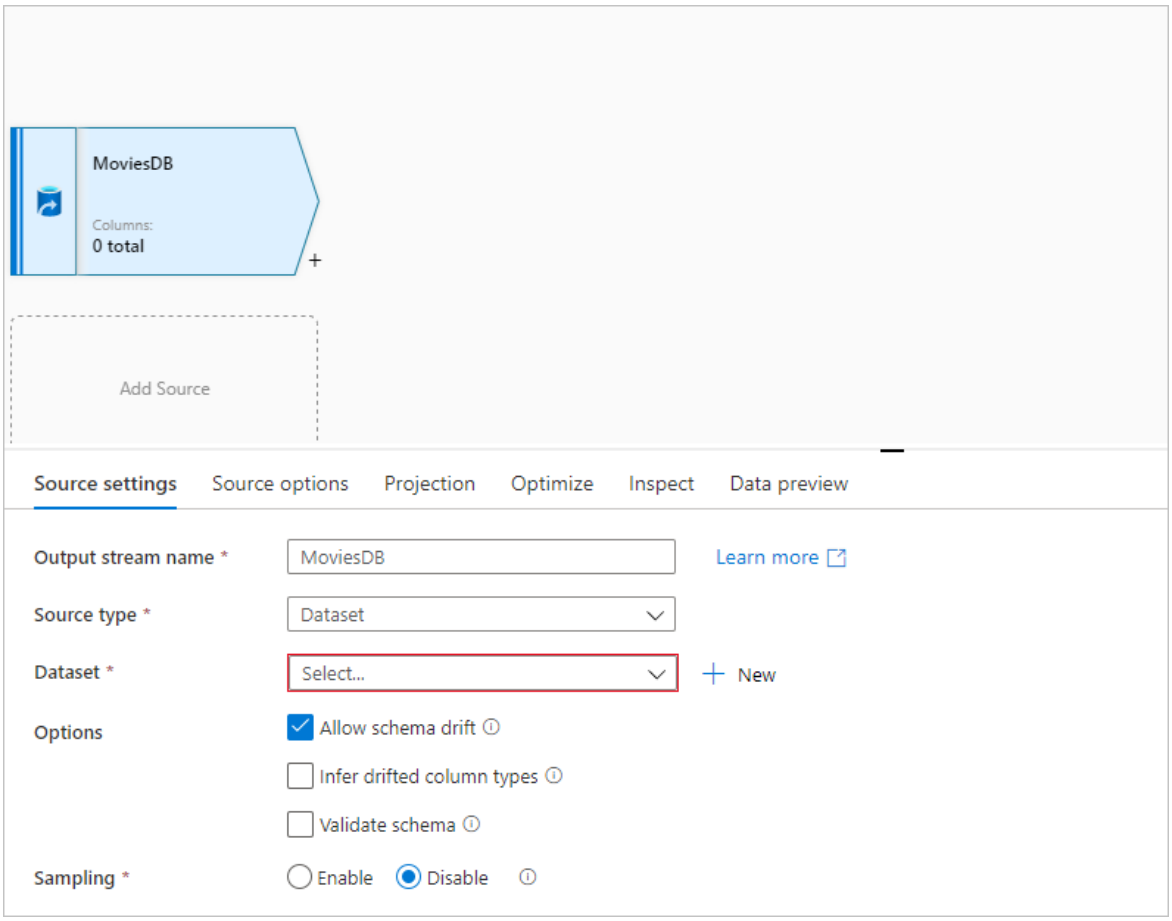
Build transformation logic in the data flow canvas

Once you create your Data Flow, you'll be automatically sent to the data flow canvas. In this step, you'll build a data flow that takes the MoviesDB.csv in ADLS storage and aggregates the average rating of comedies from 1910 to 2000. You'll then write this file back to the ADLS storage.

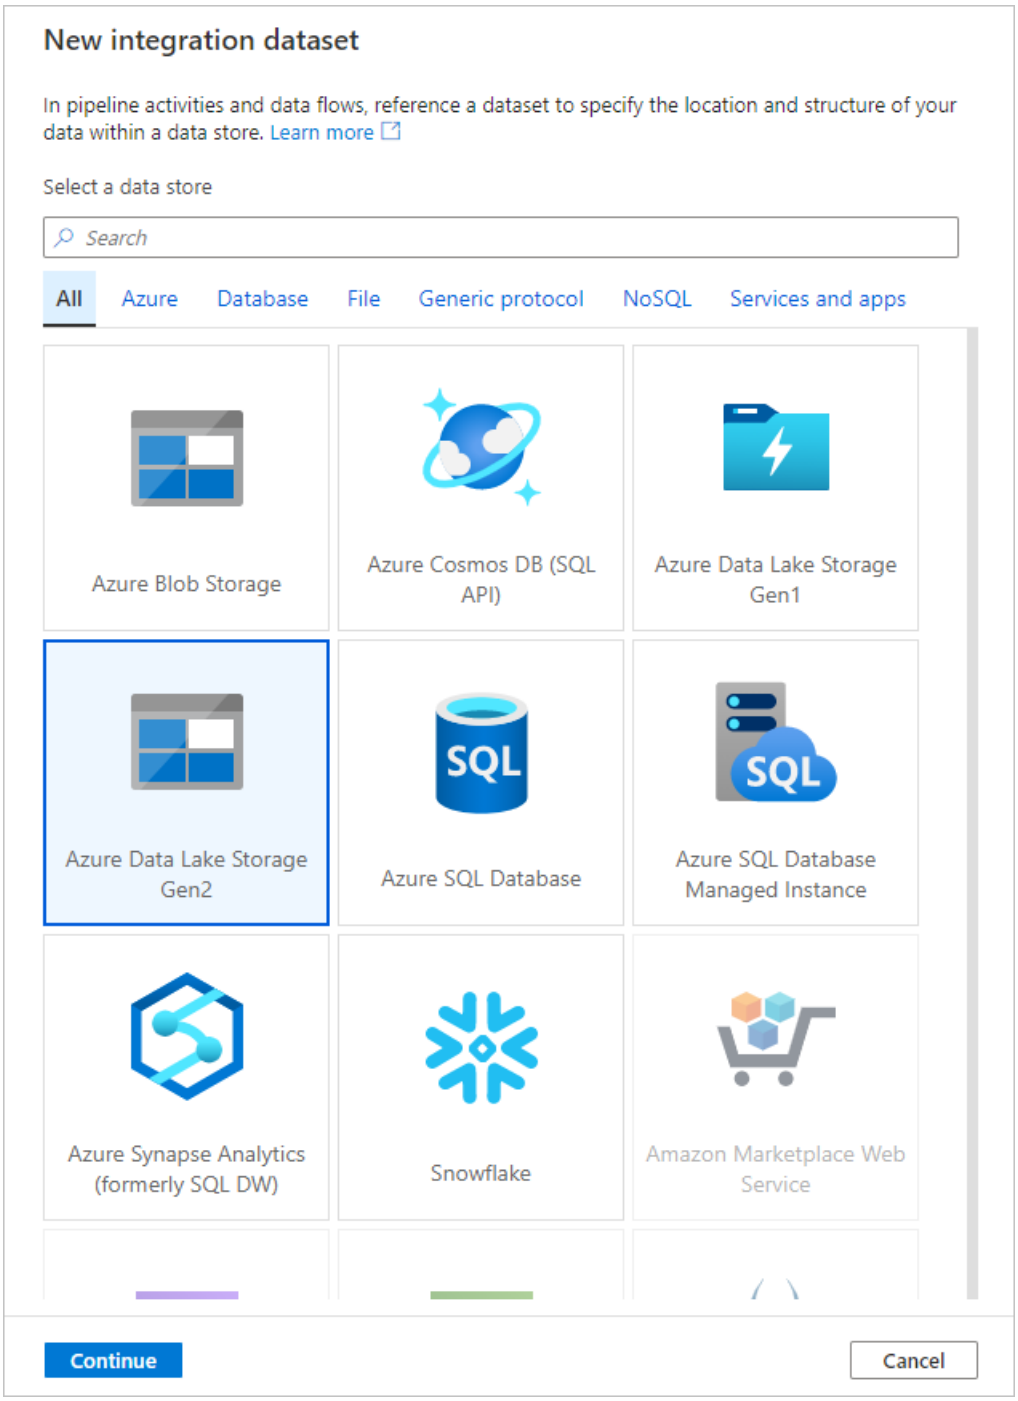
1. Above the data flow canvas, slide the **Data flow debug** slider on. Debug mode allows for interactive testing of transformation logic against a live Spark cluster. Data Flow clusters take 5-7 minutes to warm up and users are recommended to turn on debug first if they plan to do Data Flow development. For more information, see Debug Mode.



2. In the data flow canvas, add a source by clicking on the **Add Source** box.
3. Name your source **MoviesDB**. Click on **New** to create a new source dataset.



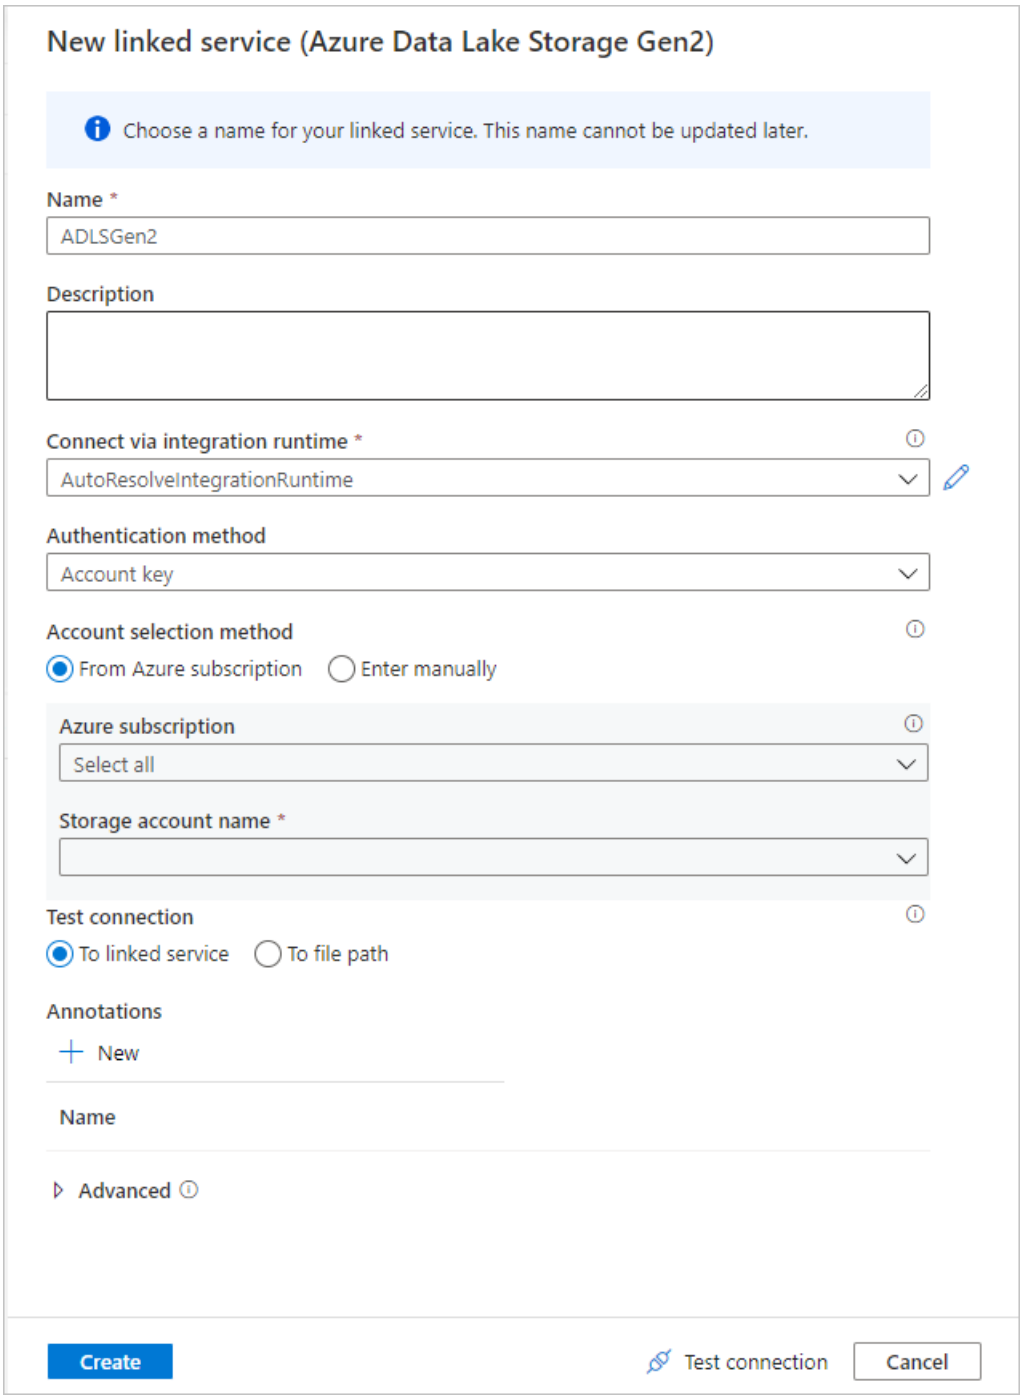
4. Choose **Azure Data Lake Storage Gen2**. Click Continue.



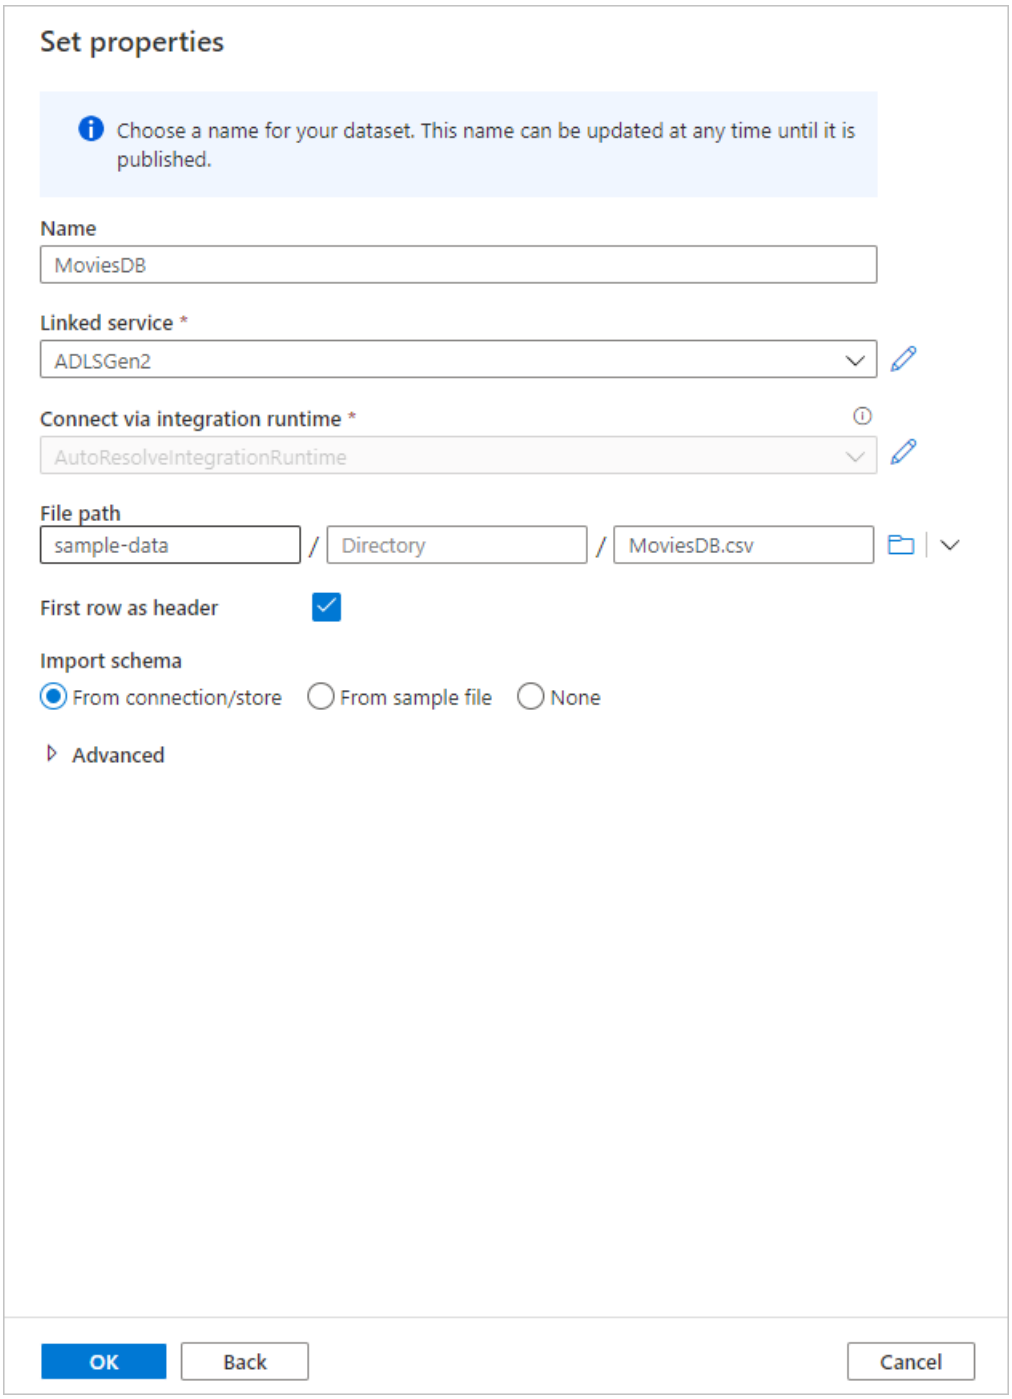
5. Choose **DelimitedText**. Click Continue.

6. Name your dataset **MoviesDB**. In the linked service dropdown, choose **New**.

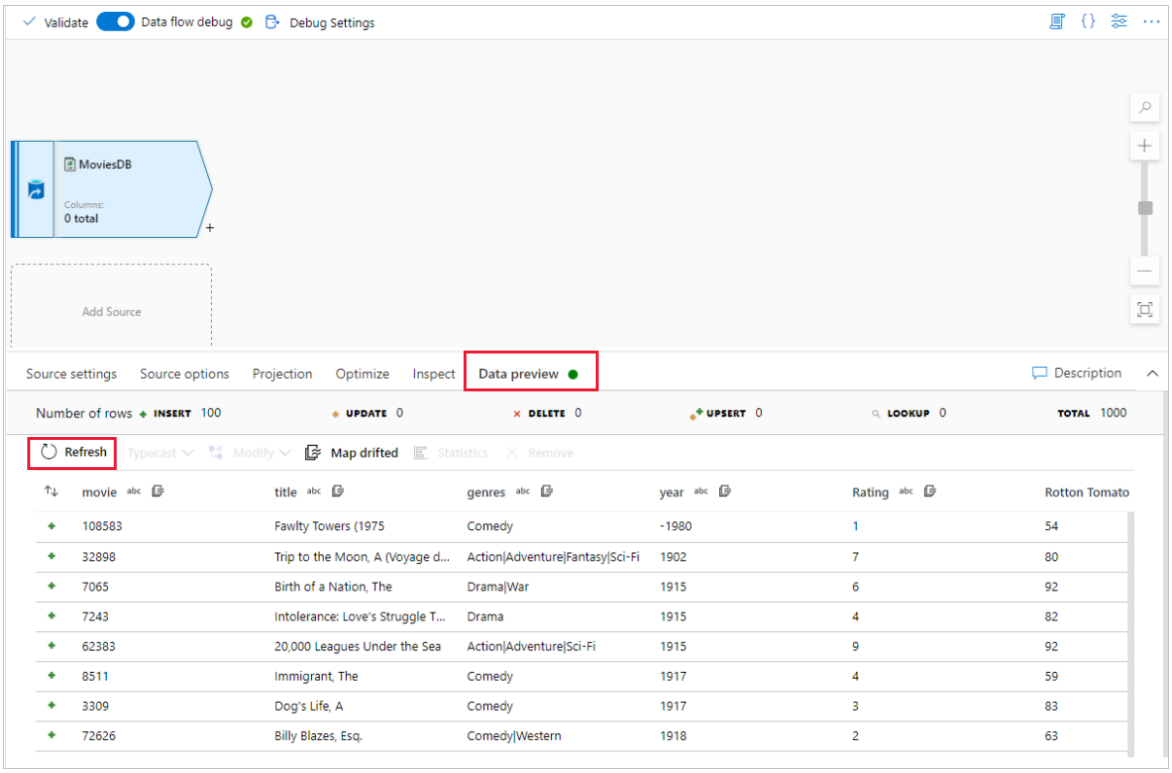
7. In the linked service creation screen, name your ADLS Gen2 linked service **ADLSGen2** and specify your authentication method. Then enter your connection credentials. In this quickstart, we're using Account key to connect to our storage account. You can click **Test connection** to verify your credentials were entered correctly. Click **Create** when finished.



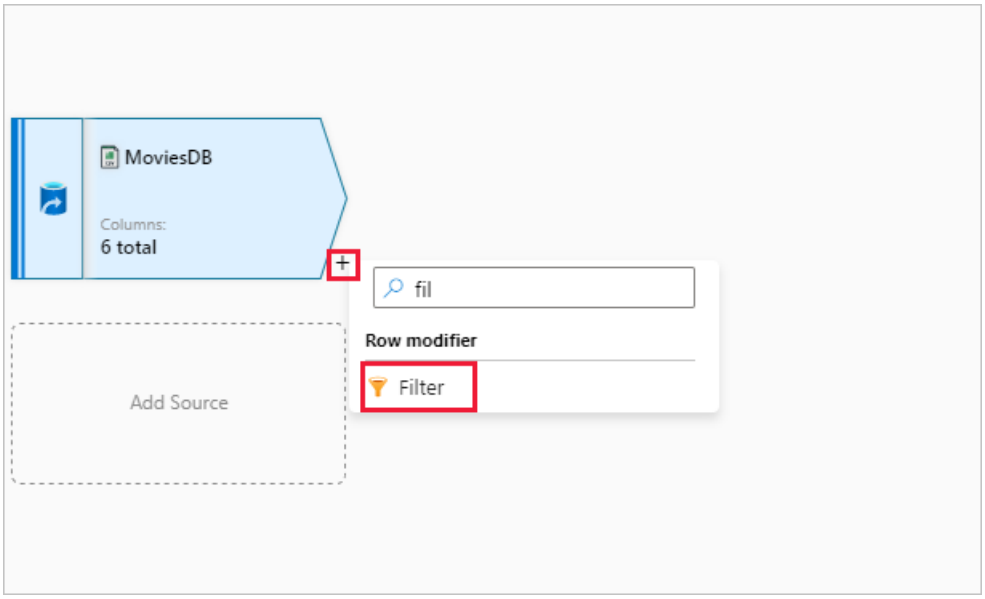
8. Once you're back at the dataset creation screen, under the **File path** field, enter where your file is located. In this quickstart, the file "MoviesDB.csv" is located in container "sample-data". As the file has headers, check **First row as header**. Select **From connection/store** to import the header schema directly from the file in storage. Click **OK** when done.



9. If your debug cluster has started, go to the **Data Preview** tab of the source transformation and click **Refresh** to get a snapshot of the data. You can use data preview to verify your transformation is configured correctly.



10. Next to your source node on the data flow canvas, click on the plus icon to add a new transformation. The first transformation you're adding is a **Filter**.



11. Name your filter transformation **FilterYears**. Click on the expression box next to **Filter on** to open the expression builder. Here you'll specify your filtering condition.

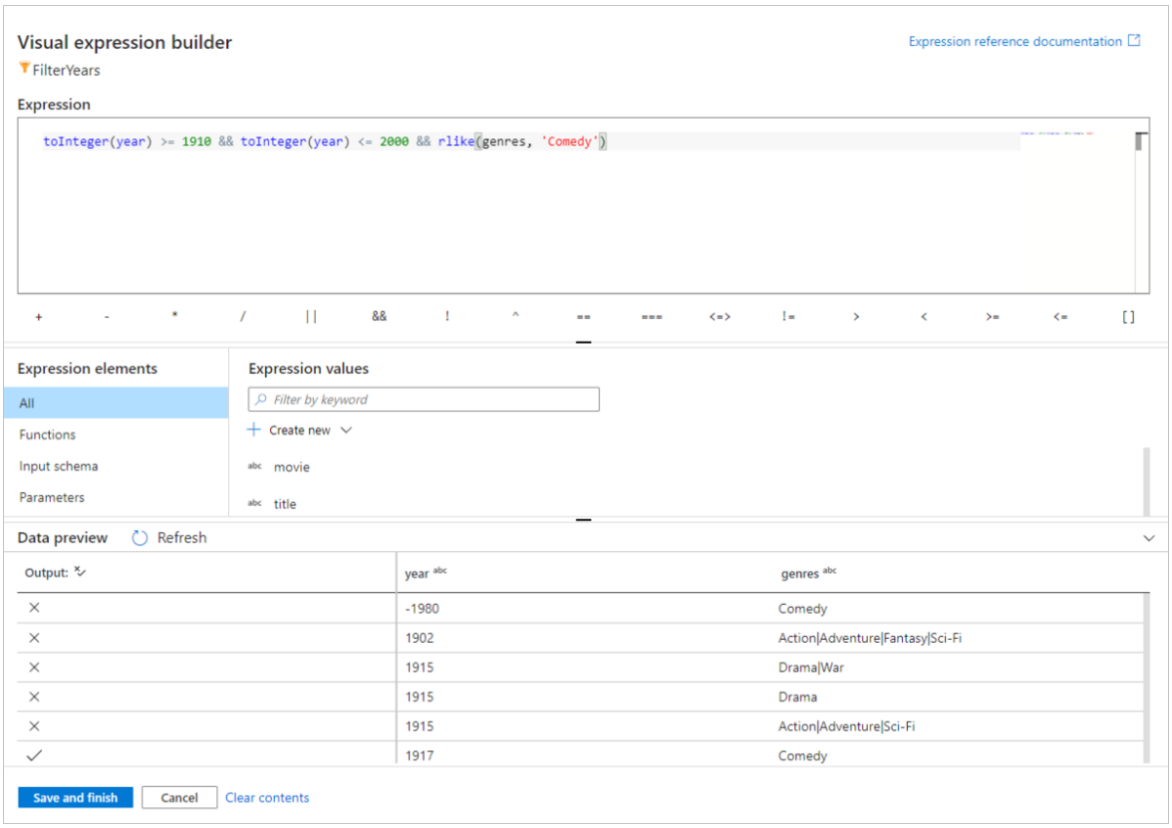
12. The data flow expression builder lets you interactively build expressions to use in various transformations. Expressions can include built-in functions, columns from the input schema, and user-defined parameters. For more information on how to build expressions, see Data Flow expression builder.

    In this quickstart, you want to filter movies of genre comedy that came out between the years 1910 and 2000. As year is currently a string, you need to convert it to an integer using the `toInteger()` function. Use the greater than or equals to (>=) and less than or equals to (<=) operators to compare against literal year values 1910 and 200-. Union these expressions together with the `&&` (and) operator. The expression comes out as:

    ```
    toInteger(year) >= 1910 && toInteger(year) <= 2000
    ```

To find which movies are comedies, you can use the `rlike()` function to find pattern 'Comedy' in the column genres. Union the `rlike` expression with the year comparison to get:

```
toInteger(year) >= 1910 && toInteger(year) <= 2000 && rlike(genres, 'Comedy')
```

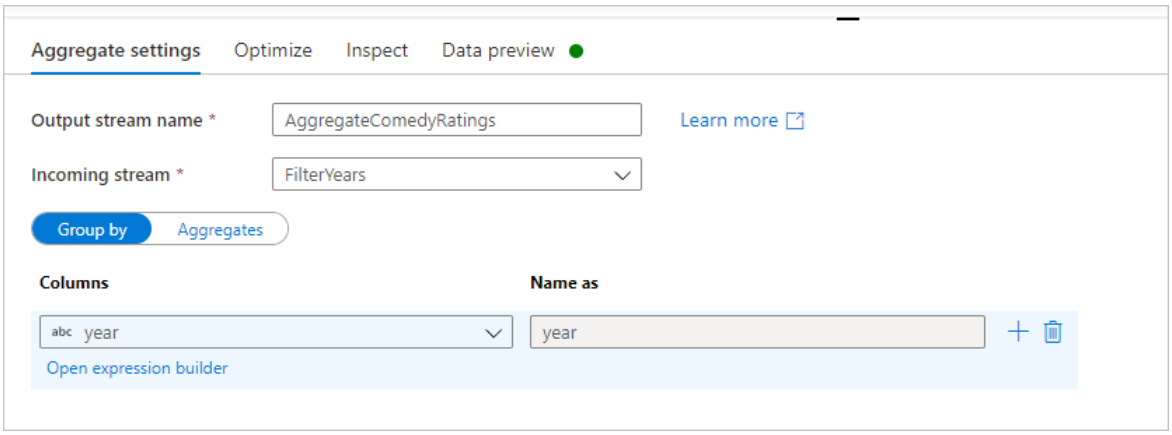


If you've a debug cluster active, you can verify your logic by clicking **Refresh** to see expression output compared to the inputs used. There's more than one right answer on how you can accomplish this logic using the data flow expression language.

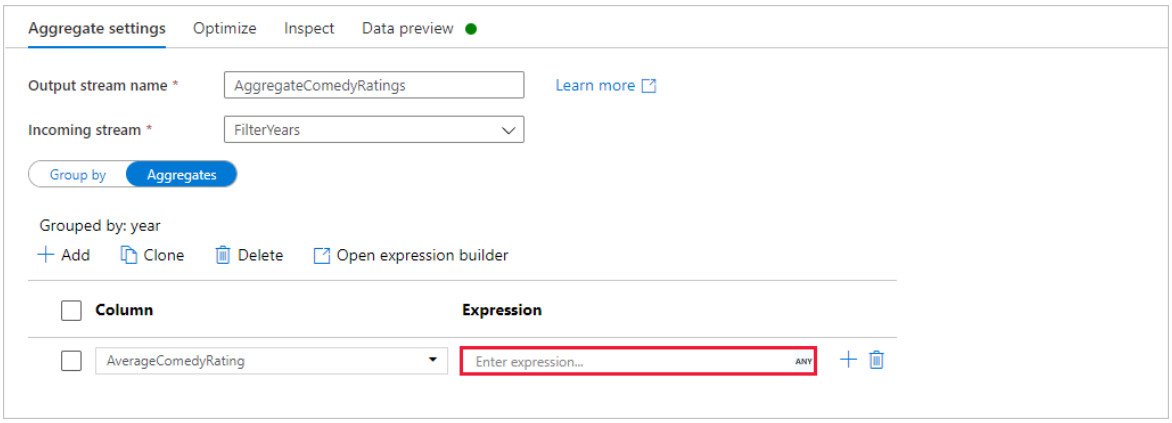
Click **Save and Finish** once you're done with your expression.

13. Fetch a **Data Preview** to verify the filter is working correctly.
14. The next transformation you'll add is an **Aggregate** transformation under **Schema modifier**.

15. Name your aggregate transformation **AggregateComedyRatings**. In the **Group by** tab, select **year** from the dropdown to group the aggregations by the year the movie came out.



16. Go to the **Aggregates** tab. In the left text box, name the aggregate column **AverageComedyRating**. Click on the right expression box to enter the aggregate expression via the expression builder.

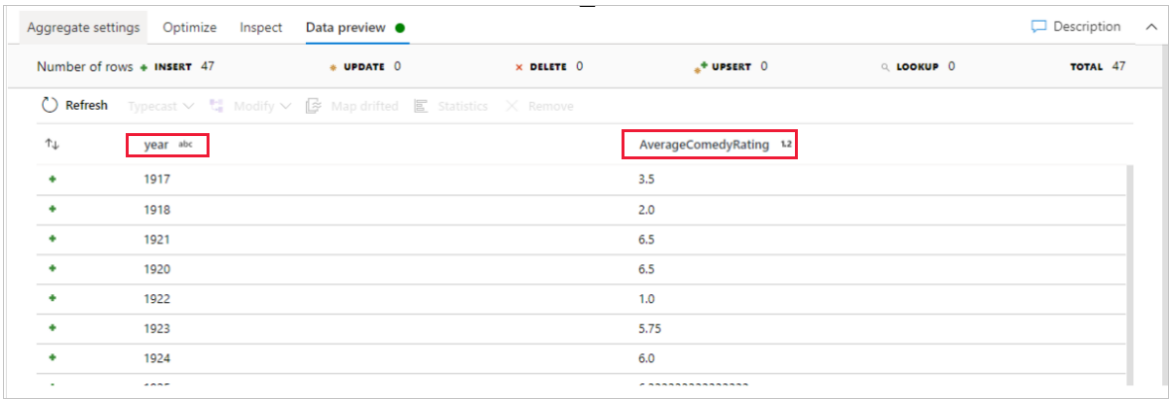


17. To get the average of column **Rating**, use the `avg()` aggregate function. As **Rating** is a string and `avg()` takes in a numerical input, we must convert the value to a number via the `toInteger()` function. This expression looks like:

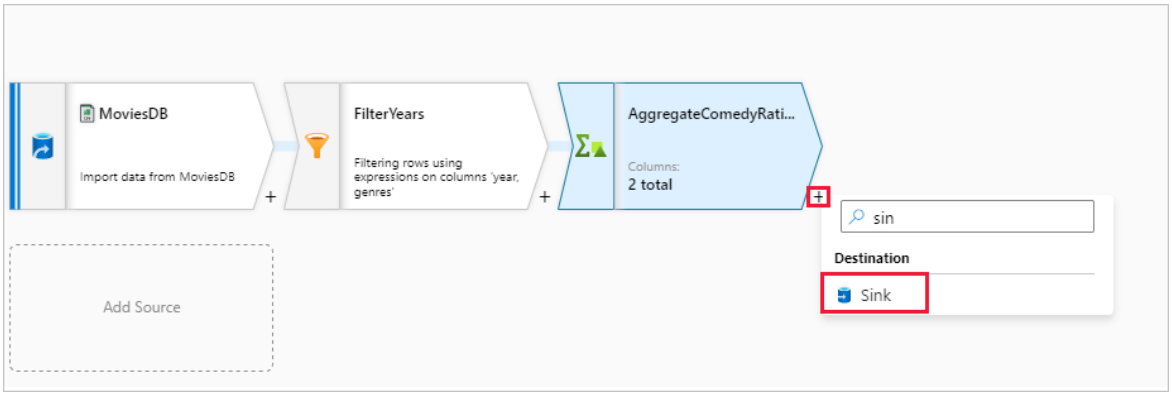
    ```
    avg(toInteger(Rating))
    ```

    Click **Save and Finish** when done.

18. Go to the **Data Preview** tab to view the transformation output. Notice only two columns are there, **year** and **AverageComedyRating**.



19. Next, you want to add a **Sink** transformation under **Destination**.

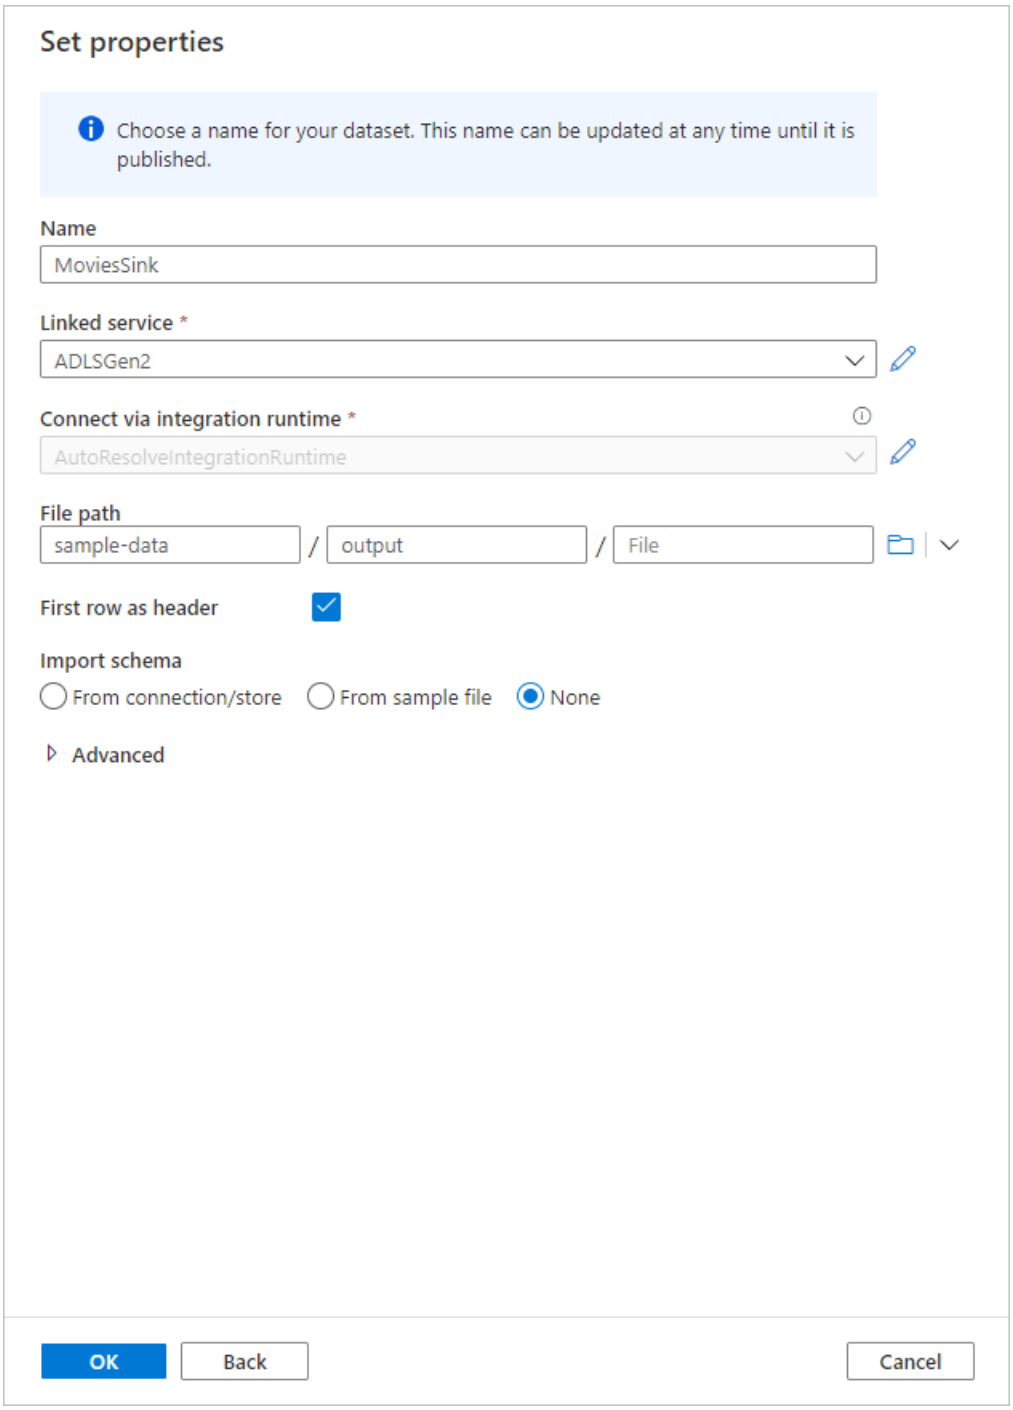


20. Name your sink **Sink**. Click **New** to create your sink dataset.

21. Choose **Azure Data Lake Storage Gen2**. Click Continue.

22. Choose **DelimitedText**. Click Continue.

23. Name your sink dataset **MoviesSink**. For linked service, choose the ADLS Gen2 linked service you created in step 7. Enter an output folder to write your data to. In this quickstart, we're writing to folder 'output' in container 'sample-data'. The folder doesn't need to exist beforehand and can be dynamically created. Set **First row as header** as true and select **None** for **Import schema**. Click **OK** when done.

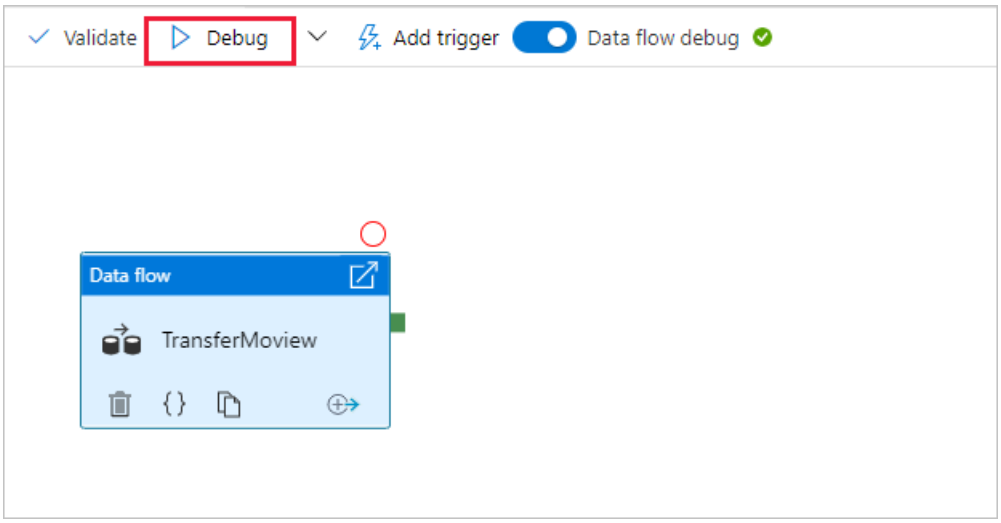


Now you've finished building your data flow. You're ready to run it in your pipeline.

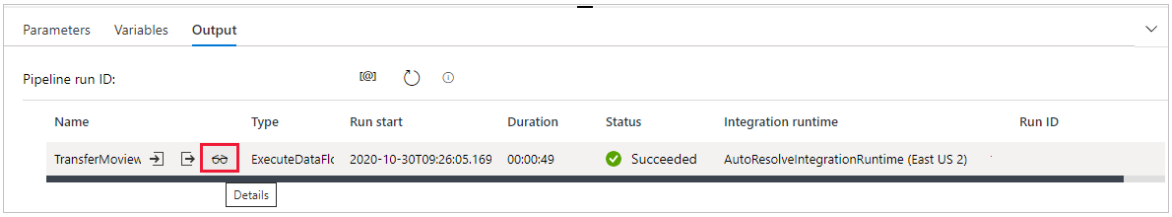
Running and monitoring the Data Flow

You can debug a pipeline before you publish it. In this step, you're going to trigger a debug run of the data flow pipeline. While data preview doesn't write data, a debug run will write data to your sink destination.

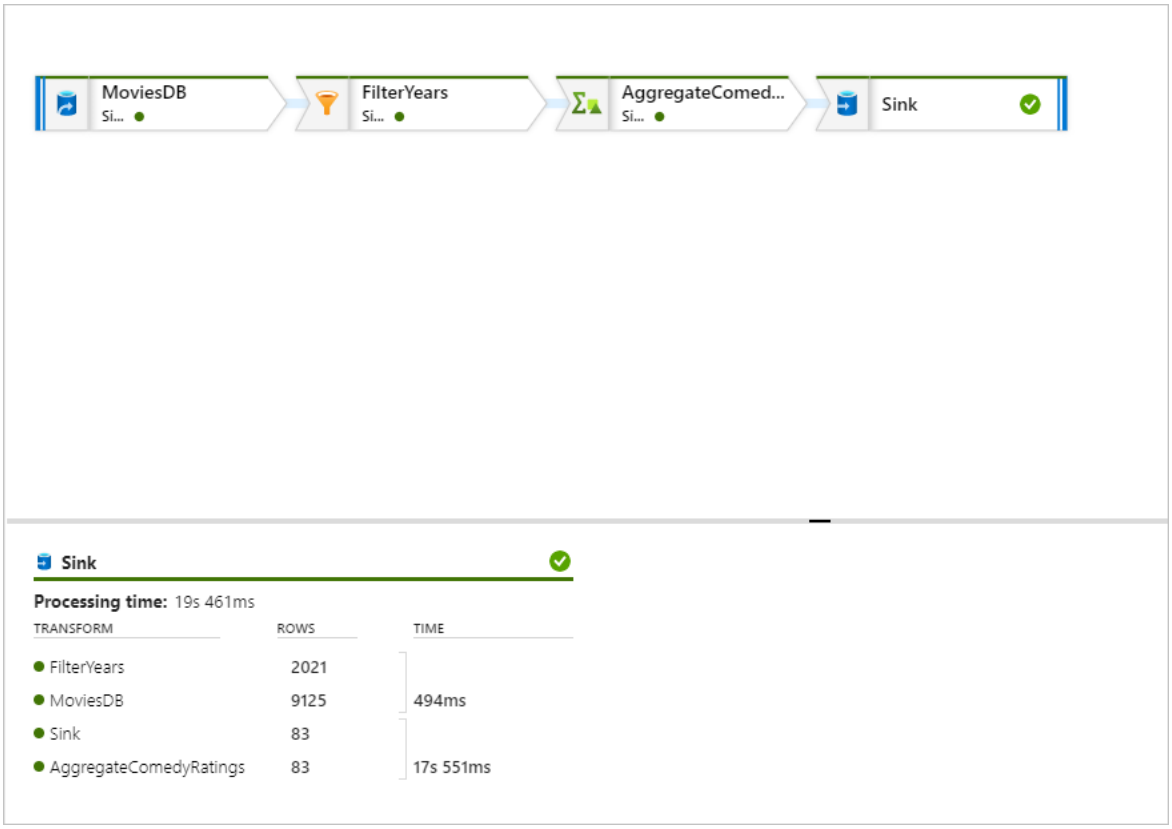
1. Go to the pipeline canvas. Click **Debug** to trigger a debug run.



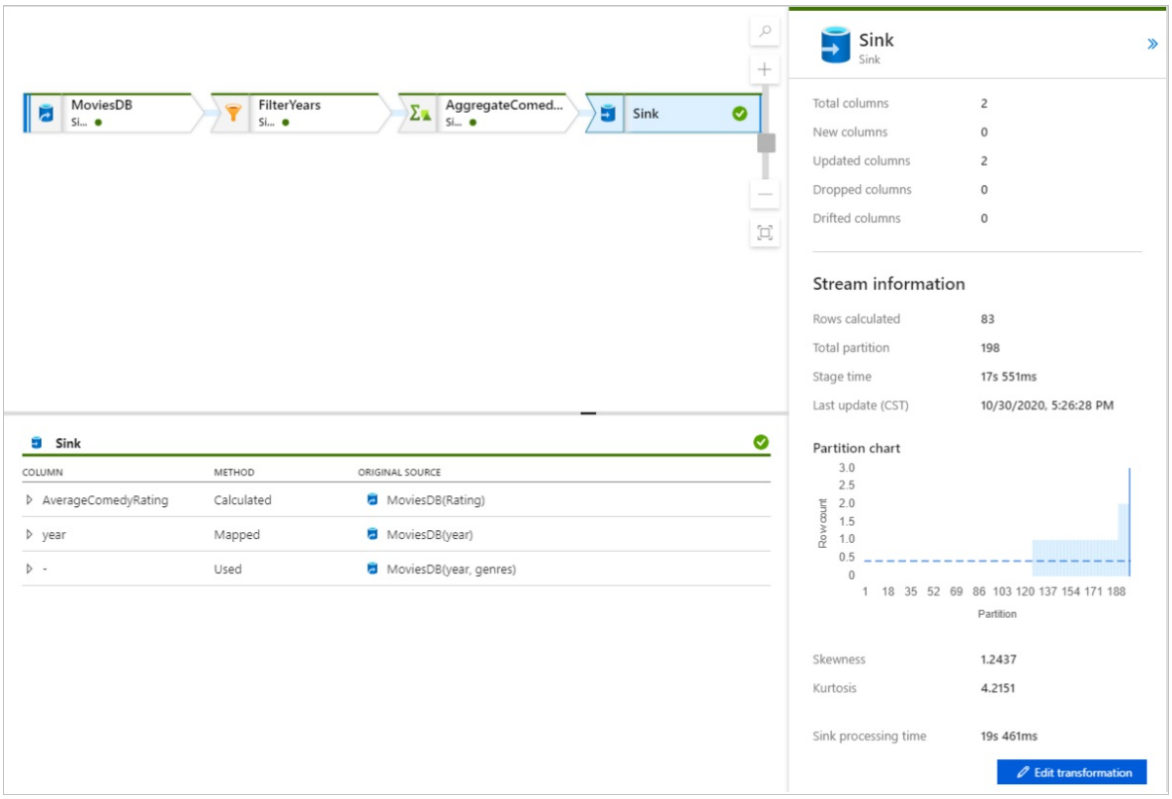
2. Pipeline debug of Data Flow activities uses the active debug cluster but still take at least a minute to initialize. You can track the progress via the **Output** tab. Once the run is successful, click on the eyeglasses icon to open the monitoring pane.



3. In the monitoring pane, you can see the number of rows and time spent in each transformation step.



4. Click on a transformation to get detailed information about the columns and partitioning of the data.



If you followed this quickstart correctly, you should have written 83 rows and 2 columns into your sink folder. You can verify the data by checking your blob storage.

Pipeline and activities Mapping data flow overview Data flow expression language

Quickstart: Transform data using Apache Spark job definition.

8/19/2022 • 3 minutes to read • Edit Online

In this quickstart, you'll use Azure Synapse Analytics to create a pipeline using Apache Spark job definition.

Prerequisites

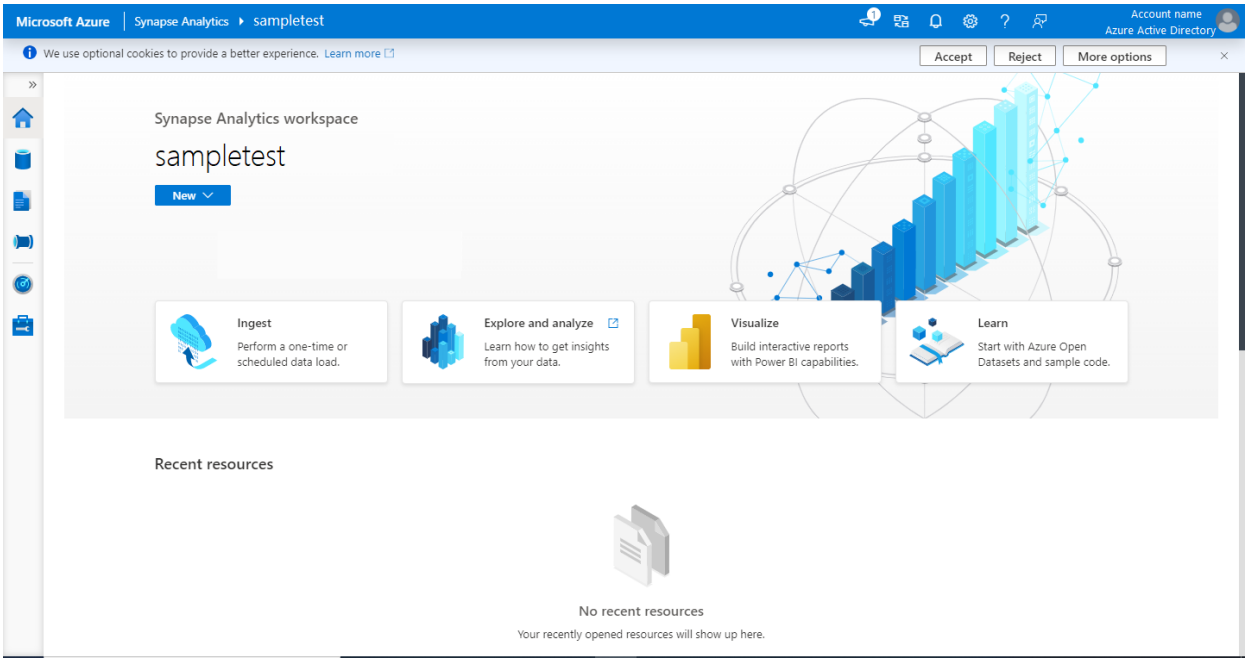
- **Azure subscription**: If you don't have an Azure subscription, create a free account before you begin.
- **Azure Synapse workspace**: Create a Synapse workspace using the Azure portal following the instructions in Quickstart: Create a Synapse workspace.
- **Apache Spark job definition**: Create an Apache Spark job definition in the Synapse workspace following the instructions in Tutorial: Create Apache Spark job definition in Synapse Studio.

Navigate to the Synapse Studio

After your Azure Synapse workspace is created, you have two ways to open Synapse Studio:

- Open your Synapse workspace in the Azure portal. Select **Open** on the Open Synapse Studio card under Getting started.
- Open Azure Synapse Analytics and sign in to your workspace.

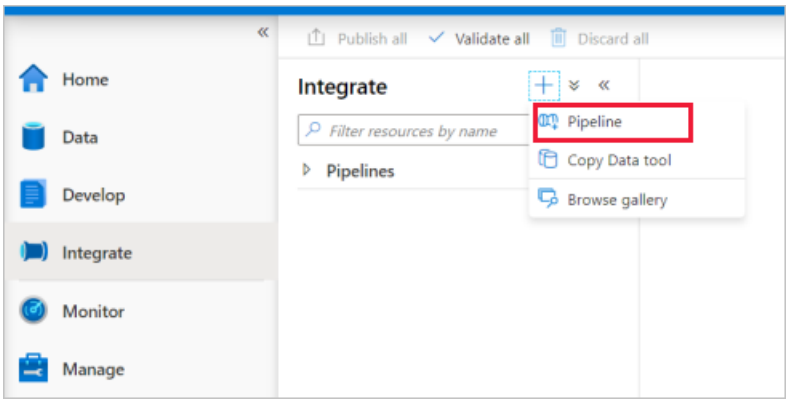
In this quickstart, we use the workspace named "sampletest" as an example. It will automatically navigate you to the Synapse Studio home page.



Create a pipeline with an Apache Spark job definition

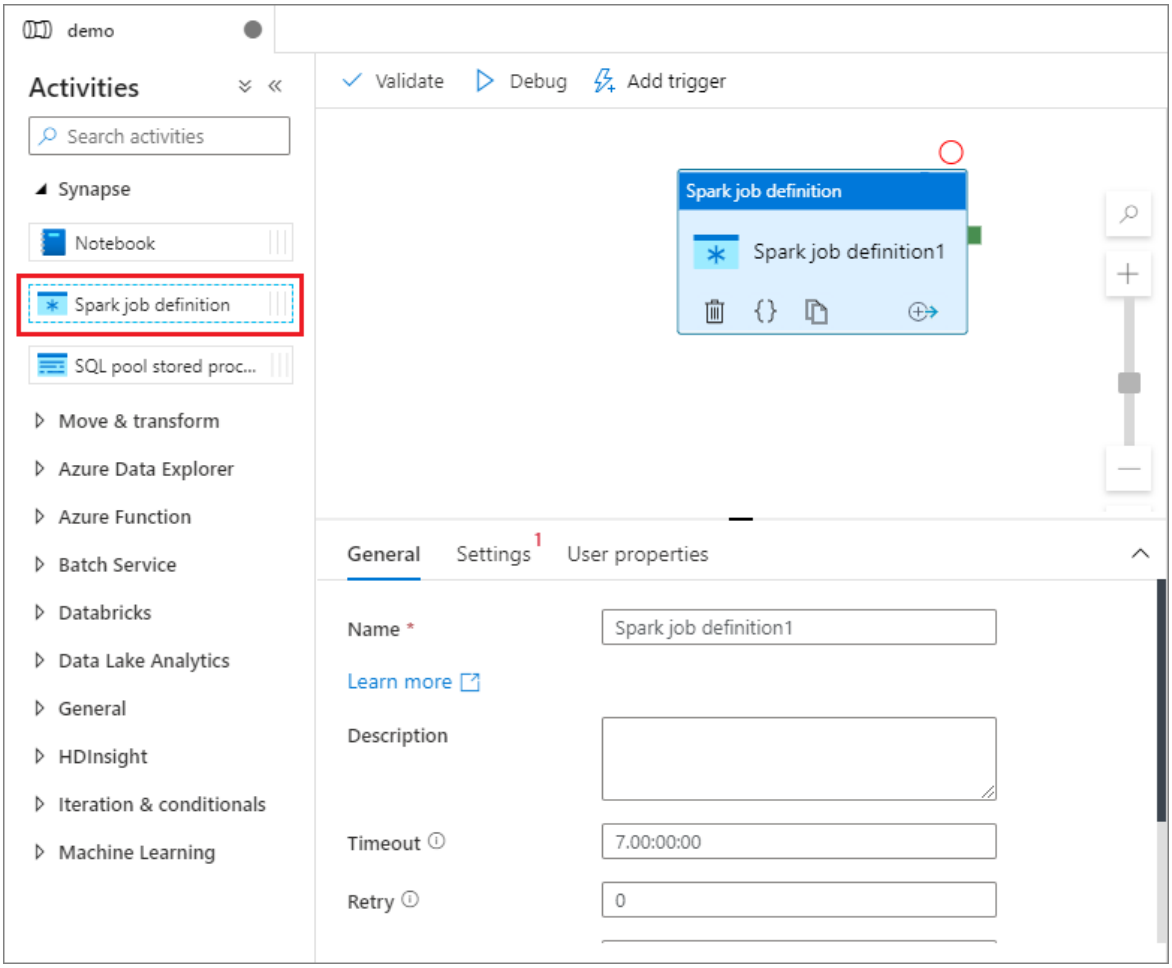
A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline that contains an Apache Spark job definition activity.

1. Go to the **Integrate** tab. Select the plus icon next to the pipelines header and select **Pipeline**.



2. In the **Properties** settings page of the pipeline, enter **demo** for **Name**.

3. Under **Synapse** in the **Activities** pane, drag **Spark job definition** onto the pipeline canvas.



Set Apache Spark job definition canvas

Once you create your Apache Spark job definition, you'll be automatically sent to the Spark job definition canvas.

General settings

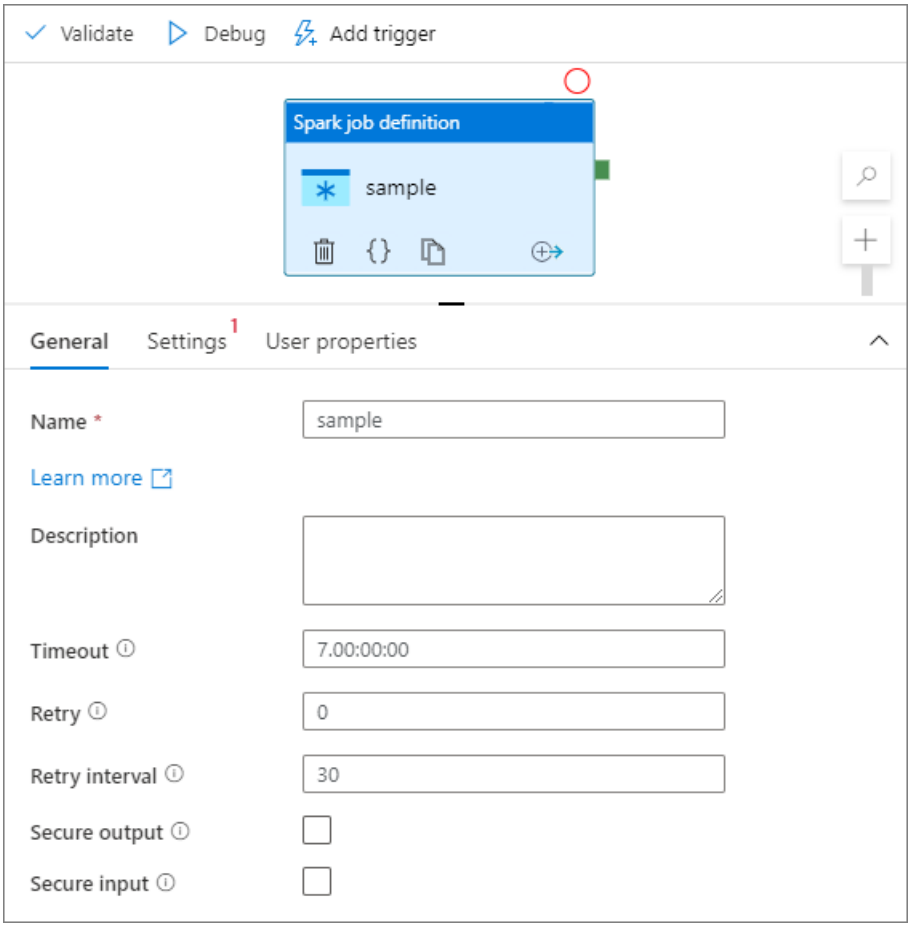
1. Select the spark job definition module on the canvas.

2. In the **General** tab, enter **sample** for **Name**.

3. (Option) You can also enter a description.

4. Timeout: Maximum amount of time an activity can run. Default is seven days, which is also the maximum amount of time allowed. Format is in D.HH:MM:SS.

5. Retry: Maximum number of retry attempts.
6. Retry interval: The number of seconds between each retry attempt.
7. Secure output: When checked, output from the activity won't be captured in logging.
8. Secure input: When checked, input from the activity won't be captured in logging.



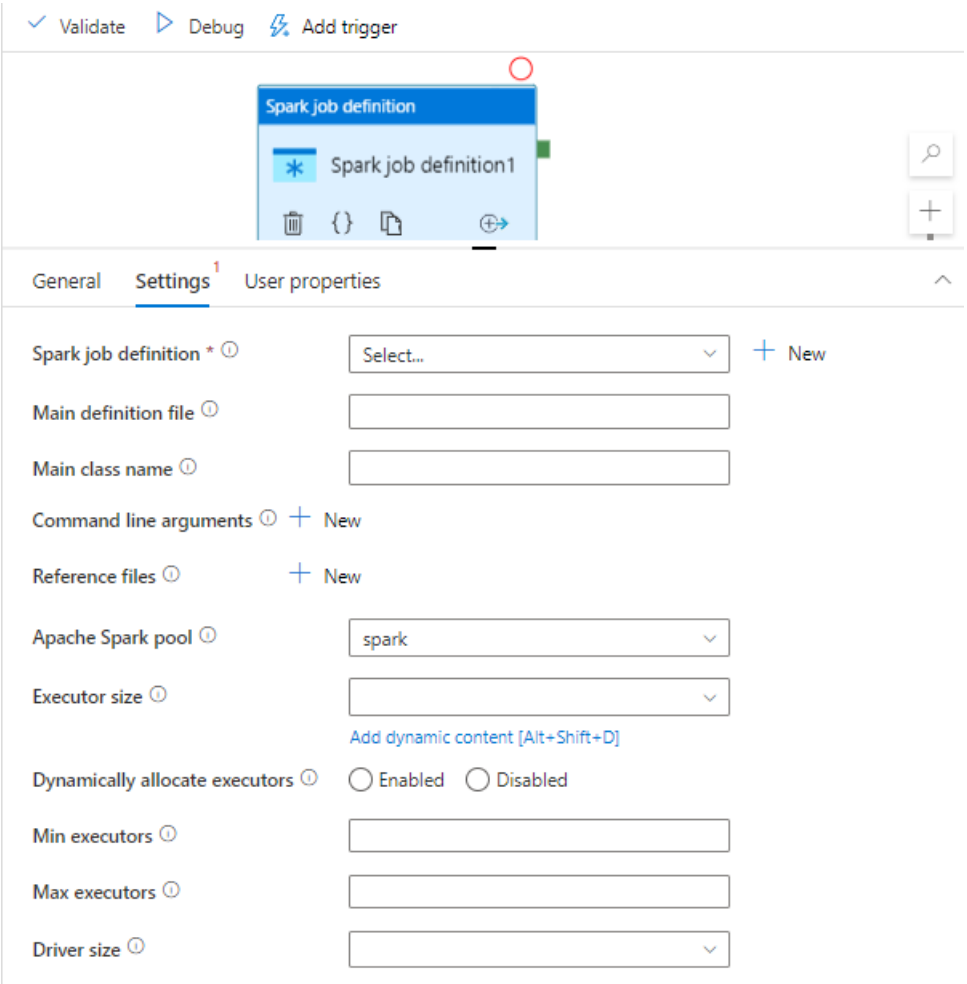
Settings tab

On this panel, you can reference to the Spark job definition to run.

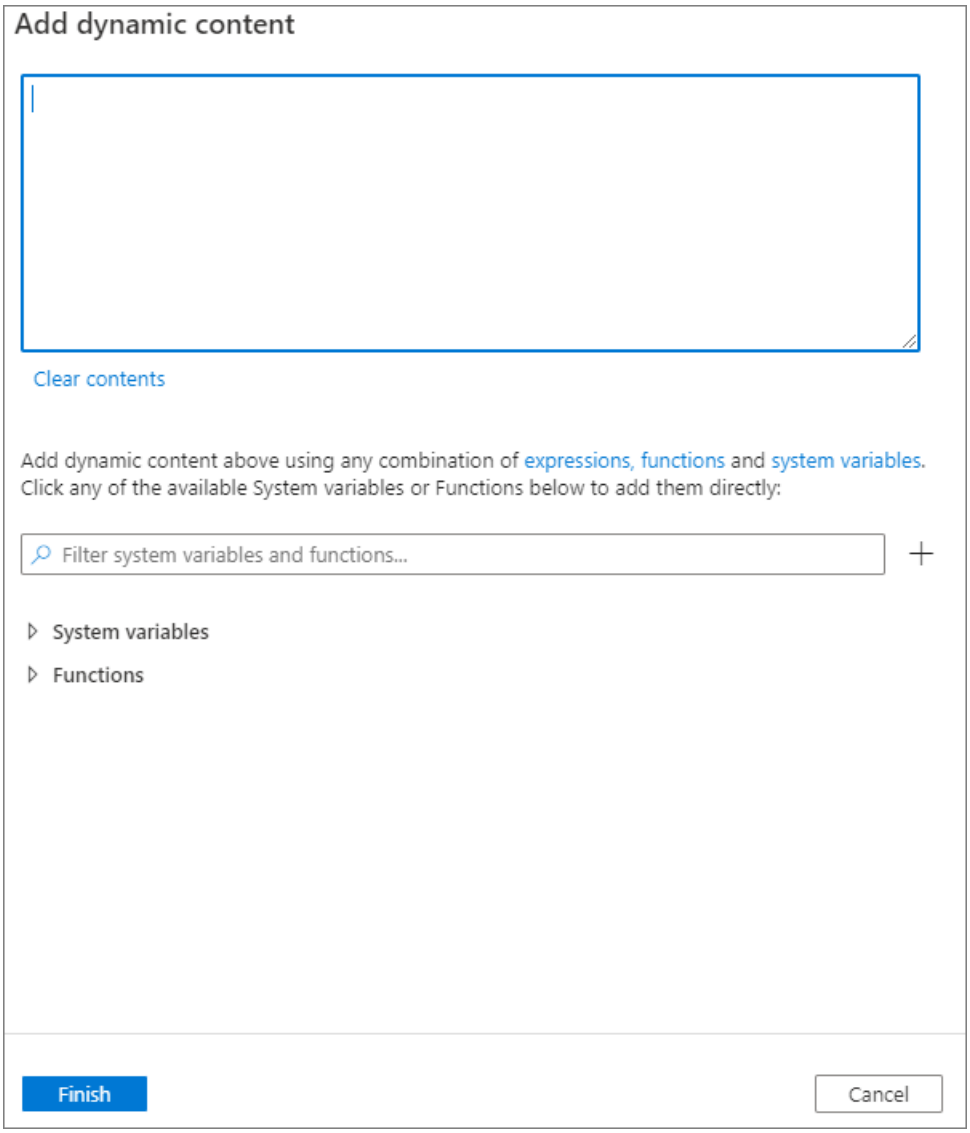
- Expand the Spark job definition list, you can choose an existing Apache Spark job definition. You can also create a new Apache Spark job definition by selecting the **New** button to reference the Spark job definition to be run.
- (Optional) You can fill in information for Apache Spark job definition. If the following settings are empty, the settings of the spark job definition itself will be used to run; if the following settings are not empty, these settings will replace the settings of the spark job definition itself.

PROPERTY	DESCRIPTION
Main definition file	The main file used for the job. Select a PY/JAR/ZIP file from your storage. You can select **Upload file** to upload the file to a storage account. Sample: `abfss://…/path/to/wordcount.jar`
Main class name	The fully qualified identifier or the main class that is in the main definition file. Sample: `WordCount`

PROPERTY	DESCRIPTION
Command-line arguments	You can add command-line arguments by clicking the **New** button. It should be noted that adding command-line arguments will override the command-line arguments defined by the Spark job definition. *Sample:* `abfss://…/path/to/shakespeare.txt` `abfss://…/path/to/result`
Apache Spark pool	You can select Apache Spark pool from the list.
Dynamically allocate executors	This setting maps to the dynamic allocation property in Spark configuration for Spark Application executors allocation.
Min executors	Min number of executors to be allocated in the specified Spark pool for the job.
Max executors	Max number of executors to be allocated in the specified Spark pool for the job.
Driver size	Number of cores and memory to be used for driver given in the specified Apache Spark pool for the job.



- You can add dynamic content by clicking the **Add Dynamic Content** button or by pressing the shortcut key `Alt+Shift+D`. In the **Add Dynamic Content** page, you can use any combination of expressions, functions, and system variables to add to dynamic content.



User properties tab

You can add properties for Apache Spark job definition activity in this panel.

Pipelines and activities in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 18 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

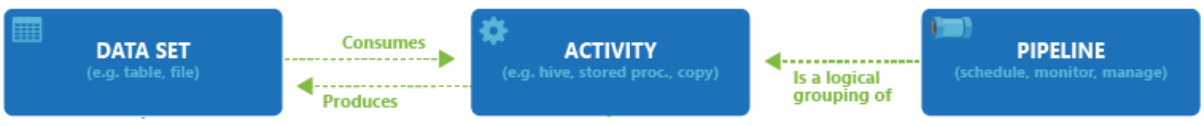
This article helps you understand pipelines and activities in Azure Data Factory and Azure Synapse Analytics and use them to construct end-to-end data-driven workflows for your data movement and data processing scenarios.

Overview

A Data Factory or Synapse Workspace can have one or more pipelines. A pipeline is a logical grouping of activities that together perform a task. For example, a pipeline could contain a set of activities that ingest and clean log data, and then kick off a mapping data flow to analyze the log data. The pipeline allows you to manage the activities as a set instead of each one individually. You deploy and schedule the pipeline instead of the activities independently.

The activities in a pipeline define actions to perform on your data. For example, you may use a copy activity to copy data from SQL Server to an Azure Blob Storage. Then, use a data flow activity or a Databricks Notebook activity to process and transform data from the blob storage to an Azure Synapse Analytics pool on top of which business intelligence reporting solutions are built.

Azure Data Factory and Azure Synapse Analytics have three groupings of activities: data movement activities, data transformation activities, and control activities. An activity can take zero or more input datasets and produce one or more output datasets. The following diagram shows the relationship between pipeline, activity, and dataset:



An input dataset represents the input for an activity in the pipeline, and an output dataset represents the output for the activity. Datasets identify data within different data stores, such as tables, files, folders, and documents. After you create a dataset, you can use it with activities in a pipeline. For example, a dataset can be an input/output dataset of a Copy Activity or an HDInsightHive Activity. For more information about datasets, see

Datasets in Azure Data Factory article.

Data movement activities

Copy Activity in Data Factory copies data from a source data store to a sink data store. Data Factory supports the data stores listed in the table in this section. Data from any source can be written to any sink. Click a data store to learn how to copy data to and from that store.

Data transformation activities

Azure Data Factory and Azure Synapse Analytics support the following transformation activities that can be added either individually or chained with another activity.

DATA TRANSFORMATION ACTIVITY	COMPUTE ENVIRONMENT
Data Flow	Apache Spark clusters managed by Azure Data Factory
Azure Function	Azure Functions
Hive	HDInsight [Hadoop]
Pig	HDInsight [Hadoop]

DATA TRANSFORMATION ACTIVITY	COMPUTE ENVIRONMENT
MapReduce	HDInsight [Hadoop]
Hadoop Streaming	HDInsight [Hadoop]
Spark	HDInsight [Hadoop]
ML Studio (classic) activities: Batch Execution and Update Resource	Azure VM
Stored Procedure	Azure SQL, Azure Synapse Analytics, or SQL Server
U-SQL	Azure Data Lake Analytics
Custom Activity	Azure Batch
Databricks Notebook	Azure Databricks
Databricks Jar Activity	Azure Databricks
Databricks Python Activity	Azure Databricks

For more information, see the data transformation activities article.

Control flow activities

The following control flow activities are supported:

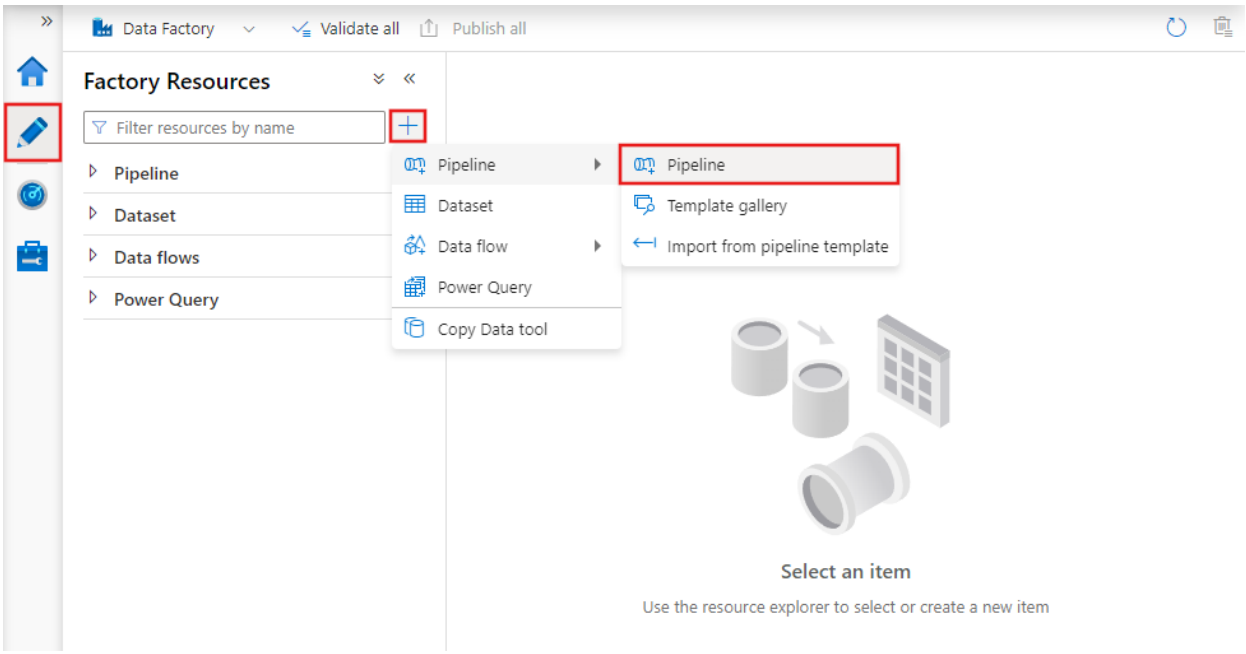
CONTROL ACTIVITY	DESCRIPTION
Append Variable	Add a value to an existing array variable.
Execute Pipeline	Execute Pipeline activity allows a Data Factory or Synapse pipeline to invoke another pipeline.
Filter	Apply a filter expression to an input array
For Each	ForEach Activity defines a repeating control flow in your pipeline. This activity is used to iterate over a collection and executes specified activities in a loop. The loop implementation of this activity is similar to the Foreach looping structure in programming languages.
Get Metadata	GetMetadata activity can be used to retrieve metadata of any data in a Data Factory or Synapse pipeline.
If Condition Activity	The If Condition can be used to branch based on condition that evaluates to true or false. The If Condition activity provides the same functionality that an if statement provides in programming languages. It evaluates a set of activities when the condition evaluates to `true` and another set of activities when the condition evaluates to `false.`

CONTROL ACTIVITY	DESCRIPTION
Lookup Activity	Lookup Activity can be used to read or look up a record/ table name/ value from any external source. This output can further be referenced by succeeding activities.
Set Variable	Set the value of an existing variable.
Until Activity	Implements Do-Until loop that is similar to Do-Until looping structure in programming languages. It executes a set of activities in a loop until the condition associated with the activity evaluates to true. You can specify a timeout value for the until activity.
Validation Activity	Ensure a pipeline only continues execution if a reference dataset exists, meets a specified criteria, or a timeout has been reached.
Wait Activity	When you use a Wait activity in a pipeline, the pipeline waits for the specified time before continuing with execution of subsequent activities.
Web Activity	Web Activity can be used to call a custom REST endpoint from a pipeline. You can pass datasets and linked services to be consumed and accessed by the activity.
Webhook Activity	Using the webhook activity, call an endpoint, and pass a callback URL. The pipeline run waits for the callback to be invoked before proceeding to the next activity.

Creating a pipeline with UI

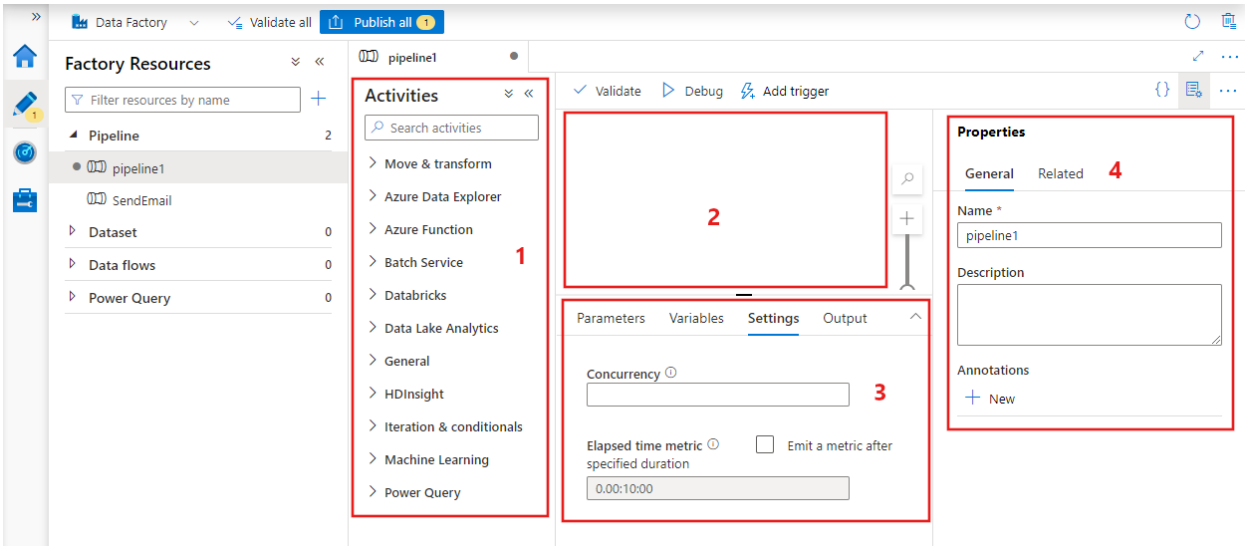
- Azure Data Factory
- Synapse Analytics

To create a new pipeline, navigate to the Author tab in Data Factory Studio (represented by the pencil icon), then click the plus sign and choose Pipeline from the menu, and Pipeline again from the submenu.



Data factory will display the pipeline editor where you can find:

1. All activities that can be used within the pipeline.
2. The pipeline editor canvas, where activities will appear when added to the pipeline.
3. The pipeline configurations pane, including parameters, variables, general settings, and output.
4. The pipeline properties pane, where the pipeline name, optional description, and annotations can be configured. This pane will also show any related items to the pipeline within the data factory.



Pipeline JSON

Here is how a pipeline is defined in JSON format:

```
{
    "name": "PipelineName",
    "properties":
    {
        "description": "pipeline description",
        "activities":
        [
        ],
        "parameters": {
        },
        "concurrency": <your max pipeline concurrency>,
        "annotations": [
        ]
    }
}
```

TAG	DESCRIPTION	TYPE	REQUIRED

TAG	DESCRIPTION	TYPE	REQUIRED
name	Name of the pipeline. Specify a name that represents the action that the pipeline performs. • Maximum number of characters: 140 • Must start with a letter, number, or an underscore (_) • Following characters are not allowed: ".", "+", "?", "/", "<","<","*"," %","&",":"," "	String	Yes
description	Specify the text describing what the pipeline is used for.	String	No
activities	The **activities** section can have one or more activities defined within it. See the Activity JSON section for details about the activities JSON element.	Array	Yes
parameters	The **parameters** section can have one or more parameters defined within the pipeline, making your pipeline flexible for reuse.	List	No
concurrency	The maximum number of concurrent runs the pipeline can have. By default, there is no maximum. If the concurrency limit is reached, additional pipeline runs are queued until earlier ones complete	Number	No
annotations	A list of tags associated with the pipeline	Array	No

Activity JSON

The **activities** section can have one or more activities defined within it. There are two main types of activities: Execution and Control Activities.

Execution activities

Execution activities include data movement and data transformation activities. They have the following top-level structure:

```
{
    "name": "Execution Activity Name",
    "description": "description",
    "type": "<ActivityType>",
    "typeProperties":
    {
    },
    "linkedServiceName": "MyLinkedService",
    "policy":
    {
    },
    "dependsOn":
    {
    }
}
```

Following table describes properties in the activity JSON definition:

TAG	DESCRIPTION	REQUIRED
name	Name of the activity. Specify a name that represents the action that the activity performs. • Maximum number of characters: 55 • Must start with a letter-number, or an underscore (_) • Following characters are not allowed: “.”, "+", "?", "/", "<",">","*"," %"," &","."," "	Yes
description	Text describing what the activity or is used for	Yes
type	Type of the activity. See the Data Movement Activities, Data Transformation Activities, and Control Activities sections for different types of activities.	Yes
linkedServiceName	Name of the linked service used by the activity. An activity may require that you specify the linked service that links to the required compute environment.	Yes for HDInsight Activity, ML Studio (classic) Batch Scoring Activity, Stored Procedure Activity. No for all others
typeProperties	Properties in the typeProperties section depend on each type of activity. To see type properties for an activity, click links to the activity in the previous section.	No
policy	Policies that affect the run-time behavior of the activity. This property includes a timeout and retry behavior. If it isn't specified, default values are used. For more information, see Activity policy section.	No

TAG	DESCRIPTION	REQUIRED
dependsOn	This property is used to define activity dependencies, and how subsequent activities depend on previous activities. For more information, see Activity dependency	No

Activity policy

Policies affect the run-time behavior of an activity, giving configuration options. Activity Policies are only available for execution activities.

Activity policy JSON definition

```
{
    "name": "MyPipelineName",
    "properties": {
      "activities": [
        {
          "name": "MyCopyBlobtoSqlActivity",
          "type": "Copy",
          "typeProperties": {
            ...
          },
         "policy": {
            "timeout": "00:10:00",
            "retry": 1,
            "retryIntervalInSeconds": 60,
            "secureOutput": true
         }
        }
      ],
        "parameters": {
           ...
        }
    }
}
```

JSON NAME	DESCRIPTION	ALLOWED VALUES	REQUIRED
timeout	Specifies the timeout for the activity to run.	Timespan	No. Default timeout is 7 days.
retry	Maximum retry attempts	Integer	No. Default is 0
retryIntervalInSeconds	The delay between retry attempts in seconds	Integer	No. Default is 30 seconds
secureOutput	When set to true, the output from activity is considered as secure and aren't logged for monitoring.	Boolean	No. Default is false.

Control activity

Control activities have the following top-level structure:

```
{
    "name": "Control Activity Name",
    "description": "description",
    "type": "<ActivityType>",
    "typeProperties":
    {
    },
    "dependsOn":
    {
    }
}
```

TAG	DESCRIPTION	REQUIRED
name	Name of the activity. Specify a name that represents the action that the activity performs. • Maximum number of characters: 55 • Must start with a letter number, or an underscore (_) • Following characters are not allowed: ".", "+", "?", "/", "<","<","*"," %"," &",":"," "	Yes
description	Text describing what the activity or is used for	Yes
type	Type of the activity. See the data movement activities, data transformation activities, and control activities sections for different types of activities.	Yes
typeProperties	Properties in the typeProperties section depend on each type of activity. To see type properties for an activity, click links to the activity in the previous section.	No
dependsOn	This property is used to define Activity Dependency, and how subsequent activities depend on previous activities. For more information, see activity dependency.	No

Activity dependency

Activity Dependency defines how subsequent activities depend on previous activities, determining the condition of whether to continue executing the next task. An activity can depend on one or multiple previous activities with different dependency conditions.

The different dependency conditions are: Succeeded, Failed, Skipped, Completed.

For example, if a pipeline has Activity A -> Activity B, the different scenarios that can happen are:

- Activity B has dependency condition on Activity A with **succeeded**: Activity B only runs if Activity A has a final status of succeeded
- Activity B has dependency condition on Activity A with **failed**: Activity B only runs if Activity A has a final

status of failed

- Activity B has dependency condition on Activity A with **completed**: Activity B runs if Activity A has a final status of succeeded or failed
- Activity B has a dependency condition on Activity A with **skipped**: Activity B runs if Activity A has a final status of skipped. Skipped occurs in the scenario of Activity X -> Activity Y -> Activity Z, where each activity runs only if the previous activity succeeds. If Activity X fails, then Activity Y has a status of "Skipped" because it never executes. Similarly, Activity Z has a status of "Skipped" as well.

Example: Activity 2 depends on the Activity 1 succeeding

```
{
    "name": "PipelineName",
    "properties":
    {
        "description": "pipeline description",
        "activities": [
         {
            "name": "MyFirstActivity",
            "type": "Copy",
            "typeProperties": {
            },
            "linkedServiceName": {
            }
        },
        {
            "name": "MySecondActivity",
            "type": "Copy",
            "typeProperties": {
            },
            "linkedServiceName": {
            },
            "dependsOn": [
            {
                "activity": "MyFirstActivity",
                "dependencyConditions": [
                    "Succeeded"
                ]
            }
          ]
        }
      ],
      "parameters": {
       }
    }
}
```

Sample copy pipeline

In the following sample pipeline, there is one activity of type **Copy** in the **activities** section. In this sample, the copy activity copies data from an Azure Blob storage to a database in Azure SQL Database.

```
{
  "name": "CopyPipeline",
  "properties": {
    "description": "Copy data from a blob to Azure SQL table",
    "activities": [
      {
        "name": "CopyFromBlobToSQL",
        "type": "Copy",
        "inputs": [
          {
            "name": "InputDataset"
          }
        ],
        "outputs": [
          {
            "name": "OutputDataset"
          }
        ],
        "typeProperties": {
          "source": {
            "type": "BlobSource"
          },
          "sink": {
            "type": "SqlSink",
            "writeBatchSize": 10000,
            "writeBatchTimeout": "60:00:00"
          }
        },
        "policy": {
          "retry": 2,
          "timeout": "01:00:00"
        }
      }
    ]
  }
}
```

Note the following points:

- In the activities section, there is only one activity whose **type** is set to **Copy**.
- Input for the activity is set to **InputDataset** and output for the activity is set to **OutputDataset**. See Datasets article for defining datasets in JSON.
- In the **typeProperties** section, **BlobSource** is specified as the source type and **SqlSink** is specified as the sink type. In the data movement activities section, click the data store that you want to use as a source or a sink to learn more about moving data to/from that data store.

For a complete walkthrough of creating this pipeline, see Quickstart: create a Data Factory.

Sample transformation pipeline

In the following sample pipeline, there is one activity of type **HDInsightHive** in the **activities** section. In this sample, the HDInsight Hive activity transforms data from an Azure Blob storage by running a Hive script file on an Azure HDInsight Hadoop cluster.

```
{
    "name": "TransformPipeline",
    "properties": {
        "description": "My first Azure Data Factory pipeline",
        "activities": [
            {
                "type": "HDInsightHive",
                "typeProperties": {
                    "scriptPath": "adfgetstarted/script/partitionweblogs.hql",
                    "scriptLinkedService": "AzureStorageLinkedService",
                    "defines": {
                        "inputtable":
"wasb://adfgetstarted@<storageaccountname>.blob.core.windows.net/inputdata",
                        "partitionedtable":
"wasb://adfgetstarted@<storageaccountname>.blob.core.windows.net/partitioneddata"
                    }
                },
                "inputs": [
                    {
                        "name": "AzureBlobInput"
                    }
                ],
                "outputs": [
                    {
                        "name": "AzureBlobOutput"
                    }
                ],
                "policy": {
                    "retry": 3
                },
                "name": "RunSampleHiveActivity",
                "linkedServiceName": "HDInsightOnDemandLinkedService"
            }
        ]
    }
}
```

Note the following points:

- In the activities section, there is only one activity whose **type** is set to **HDInsightHive**.
- The Hive script file, **partitionweblogs.hql**, is stored in the Azure Storage account (specified by the scriptLinkedService, called AzureStorageLinkedService), and in script folder in the container `adfgetstarted`.
- The `defines` section is used to specify the runtime settings that are passed to the hive script as Hive configuration values (for example, $ `{hiveconf:inputtable}`, `${hiveconf:partitionedtable}`).

The **typeProperties** section is different for each transformation activity. To learn about type properties supported for a transformation activity, click the transformation activity in the Data transformation activities.

For a complete walkthrough of creating this pipeline, see Tutorial: transform data using Spark.

Multiple activities in a pipeline

The previous two sample pipelines have only one activity in them. You can have more than one activity in a pipeline. If you have multiple activities in a pipeline and subsequent activities are not dependent on previous activities, the activities may run in parallel.

You can chain two activities by using activity dependency, which defines how subsequent activities depend on previous activities, determining the condition whether to continue executing the next task. An activity can depend on one or more previous activities with different dependency conditions.

Scheduling pipelines

Pipelines are scheduled by triggers. There are different types of triggers (Scheduler trigger, which allows pipelines to be triggered on a wall-clock schedule, as well as the manual trigger, which triggers pipelines on-demand). For more information about triggers, see pipeline execution and triggers article.

To have your trigger kick off a pipeline run, you must include a pipeline reference of the particular pipeline in the trigger definition. Pipelines & triggers have an n-m relationship. Multiple triggers can kick off a single pipeline, and the same trigger can kick off multiple pipelines. Once the trigger is defined, you must start the trigger to have it start triggering the pipeline. For more information about triggers, see pipeline execution and triggers article.

For example, say you have a Scheduler trigger, "Trigger A," that I wish to kick off my pipeline, "MyCopyPipeline." You define the trigger, as shown in the following example:

Trigger A definition

```
{
  "name": "TriggerA",
  "properties": {
    "type": "ScheduleTrigger",
    "typeProperties": {
      ...
      }
    },
    "pipeline": {
      "pipelineReference": {
        "type": "PipelineReference",
        "referenceName": "MyCopyPipeline"
      },
      "parameters": {
        "copySourceName": "FileSource"
      }
    }
  }
}
```

Next steps

See the following tutorials for step-by-step instructions for creating pipelines with activities:

- Build a pipeline with a copy activity

Linked services in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes what linked services are, how they're defined in JSON format, and how they're used in Azure Data Factory and Azure Synapse Analytics.

To learn more read the introductory article for Azure Data Factory or Azure Synapse.

Overview

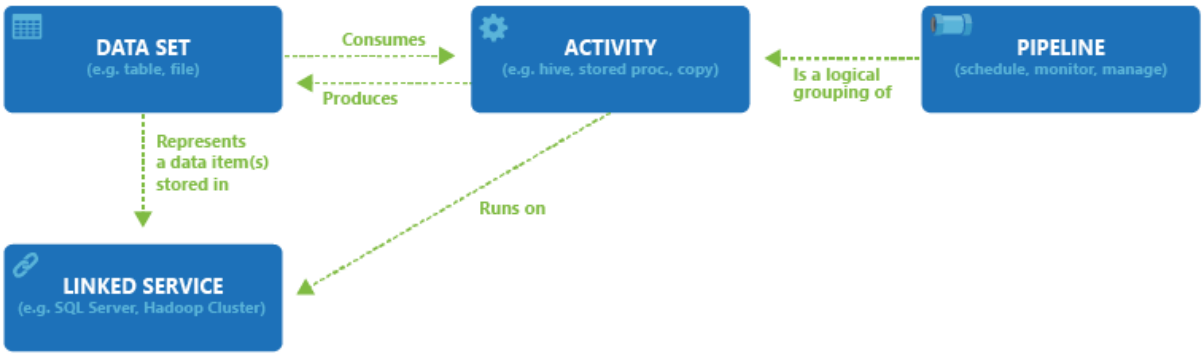
Azure Data Factory and Azure Synapse Analytics can have one or more pipelines. A **pipeline** is a logical grouping of **activities** that together perform a task. The activities in a pipeline define actions to perform on your data. For example, you might use a copy activity to copy data from SQL Server to Azure Blob storage. Then, you might use a Hive activity that runs a Hive script on an Azure HDInsight cluster to process data from Blob storage to produce output data. Finally, you might use a second copy activity to copy the output data to Azure Synapse Analytics, on top of which business intelligence (BI) reporting solutions are built. For more information about pipelines and activities, see Pipelines and activities.

Now, a **dataset** is a named view of data that simply points or references the data you want to use in your **activities** as inputs and outputs.

Before you create a dataset, you must create a **linked service** to link your data store to the Data Factory or Synapse Workspace. Linked services are much like connection strings, which define the connection information needed for the service to connect to external resources. Think of it this way; the dataset represents the structure of the data within the linked data stores, and the linked service defines the connection to the data source. For example, an Azure Storage linked service links a storage account to the service. An Azure Blob dataset represents the blob container and the folder within that Azure Storage account that contains the input blobs to be processed.

Here is a sample scenario. To copy data from Blob storage to a SQL Database, you create two linked services: Azure Storage and Azure SQL Database. Then, create two datasets: Azure Blob dataset (which refers to the Azure Storage linked service) and Azure SQL Table dataset (which refers to the Azure SQL Database linked service). The Azure Storage and Azure SQL Database linked services contain connection strings that the service uses at runtime to connect to your Azure Storage and Azure SQL Database, respectively. The Azure Blob dataset specifies the blob container and blob folder that contains the input blobs in your Blob storage. The Azure SQL Table dataset specifies the SQL table in your SQL Database to which the data is to be copied.

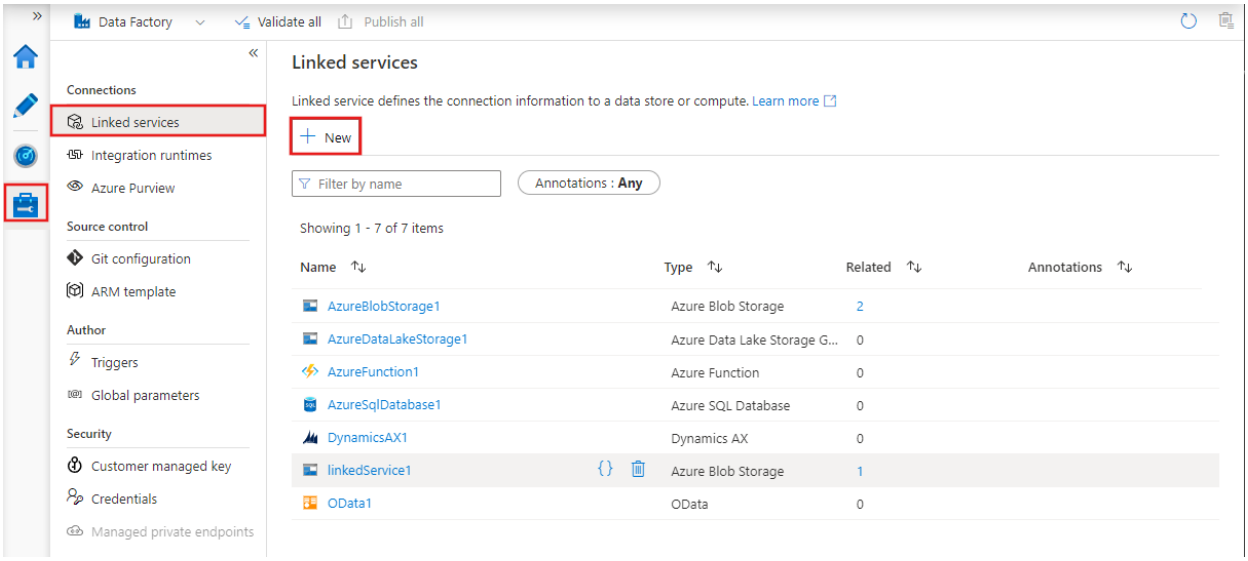
The following diagram shows the relationships among pipeline, activity, dataset, and linked service in the service:



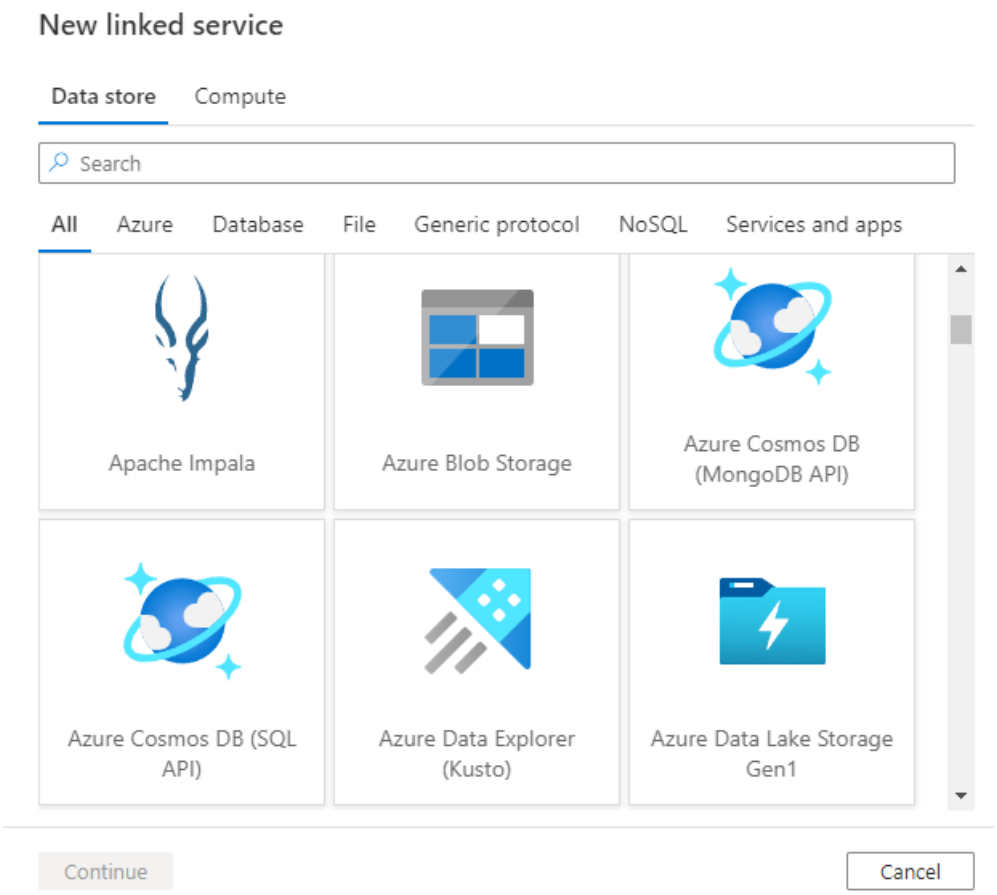
Linked service with UI

- Azure Data Factory
- Synapse Analytics

To create a new linked service in Azure Data Factory Studio, select the **Manage** tab and then **linked services**, where you can see any existing linked services you defined. Select **New** to create a new linked service.



After selecting New to create a new linked service you will be able to choose any of the supported connectors and configure its details accordingly. Thereafter you can use the linked service in any pipelines you create.



Linked service JSON

A linked service is defined in JSON format as follows:

```
{
    "name": "<Name of the linked service>",
    "properties": {
        "type": "<Type of the linked service>",
        "typeProperties": {
              "<data store or compute-specific type properties>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

The following table describes properties in the above JSON:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the linked service. See Naming rules.	Yes
type	Type of the linked service. For example: AzureBlobStorage (data store) or AzureBatch (compute). See the description for typeProperties.	Yes

PROPERTY	DESCRIPTION	REQUIRED
typeProperties	The type properties are different for each data store or compute. For the supported data store types and their type properties, see the connector overview article. Navigate to the data store connector article to learn about type properties specific to a data store. For the supported compute types and their type properties, see Compute linked services.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in a private network). If not specified, it uses the default Azure Integration Runtime.	No

Linked service example

The following linked service is an Azure Blob storage linked service. Notice that the type is set to Azure Blob storage. The type properties for the Azure Blob storage linked service include a connection string. The service uses this connection string to connect to the data store at runtime.

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;AccountKey=
<accountkey>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Create linked services

Linked services can be created in the Azure Data Factory UX via the management hub and any activities, datasets, or data flows that reference them.

You can create linked services by using one of these tools or SDKs: .NET API, PowerShell, REST API, Azure Resource Manager Template, and Azure portal.

Data store linked services

You can find the list of supported data stores in the connector overview article. Click a data store to learn the supported connection properties.

Compute linked services

Reference compute environments supported for details about different compute environments you can connect to from your service as well as the different configurations.

Datasets in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes what datasets are, how they're defined in JSON format, and how they're used in Azure Data Factory and Synapse pipelines.

If you're new to Data Factory, see Introduction to Azure Data Factory for an overview. For more information about Azure Synapse, see What is Azure Synapse

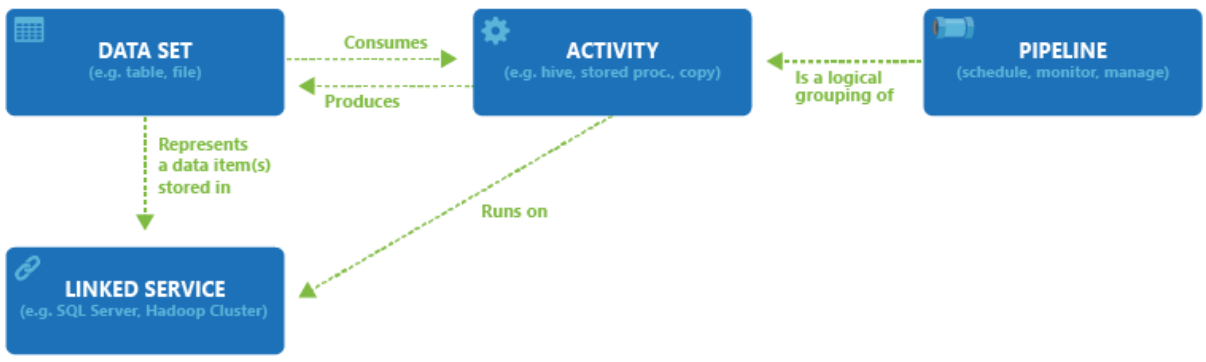
Overview

An Azure Data Factory or Synapse workspace can have one or more pipelines. A **pipeline** is a logical grouping of **activities** that together perform a task. The activities in a pipeline define actions to perform on your data. Now, a **dataset** is a named view of data that simply points or references the data you want to use in your **activities** as inputs and outputs. Datasets identify data within different data stores, such as tables, files, folders, and documents. For example, an Azure Blob dataset specifies the blob container and folder in Blob Storage from which the activity should read the data.

Before you create a dataset, you must create a **linked service** to link your data store to the service. Linked services are much like connection strings, which define the connection information needed for the service to connect to external resources. Think of it this way; the dataset represents the structure of the data within the linked data stores, and the linked service defines the connection to the data source. For example, an Azure Storage linked service links a storage account. An Azure Blob dataset represents the blob container and the folder within that Azure Storage account that contains the input blobs to be processed.

Here's a sample scenario. To copy data from Blob storage to a SQL Database, you create two linked services: Azure Blob Storage and Azure SQL Database. Then, create two datasets: Delimited Text dataset (which refers to the Azure Blob Storage linked service, assuming you have text files as source) and Azure SQL Table dataset (which refers to the Azure SQL Database linked service). The Azure Blob Storage and Azure SQL Database linked services contain connection strings that the service uses at runtime to connect to your Azure Storage and Azure SQL Database, respectively. The Delimited Text dataset specifies the blob container and blob folder that contains the input blobs in your Blob Storage, along with format-related settings. The Azure SQL Table dataset specifies the SQL table in your SQL Database to which the data is to be copied.

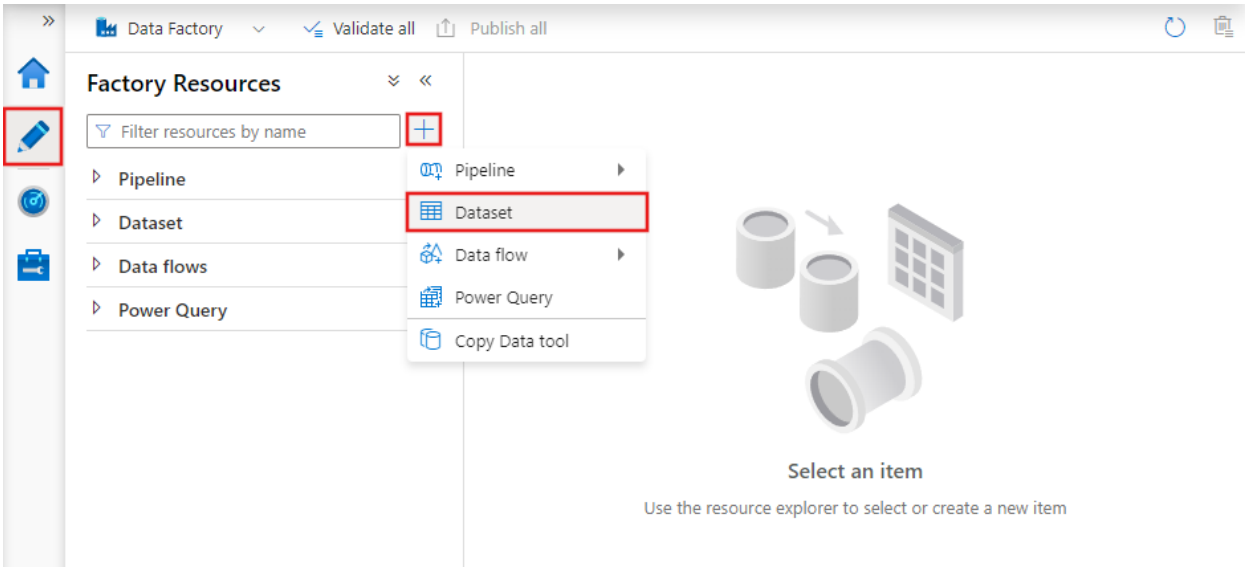
The following diagram shows the relationships among pipeline, activity, dataset, and linked services:



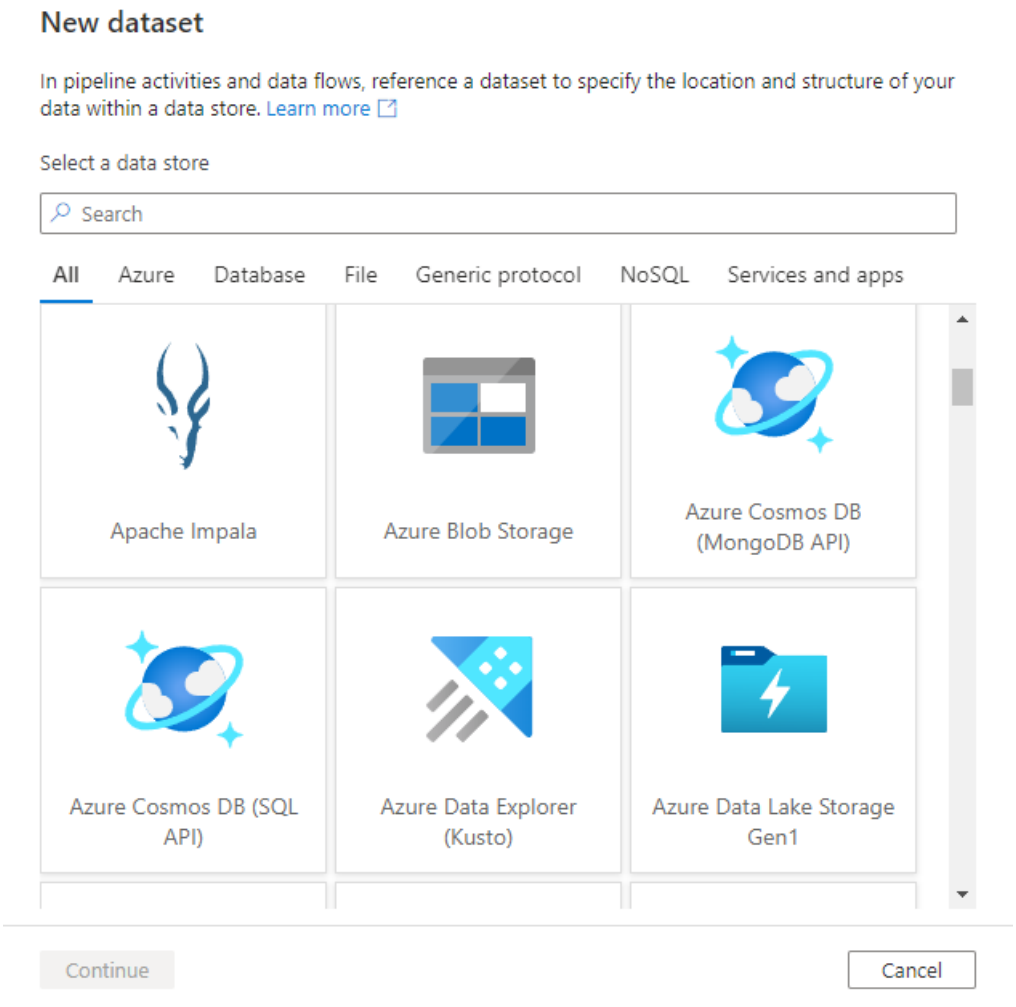
Create a dataset with UI

- Azure Data Factory
- Synapse Analytics

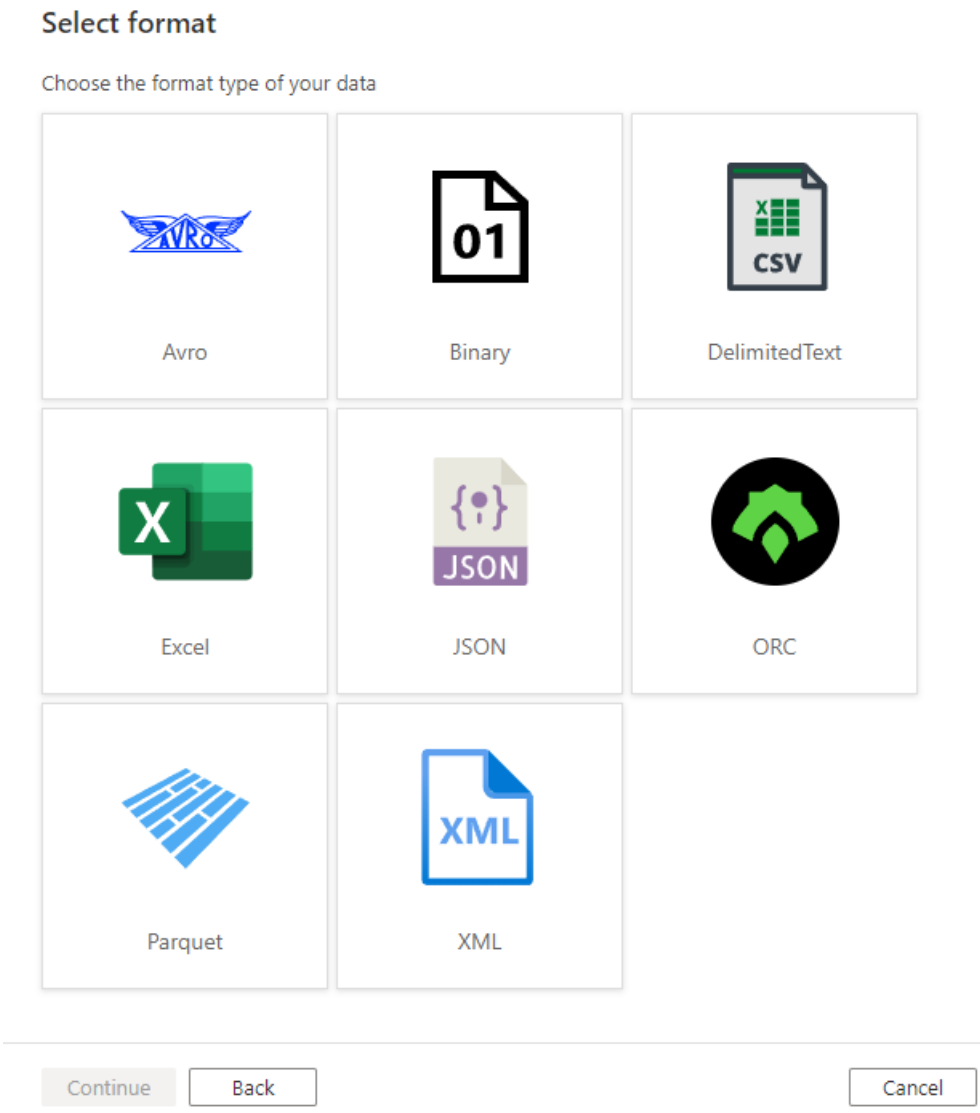
To create a dataset with the Azure Data Factory Studio, select the Author tab (with the pencil icon), and then the plus sign icon, to choose **Dataset**.



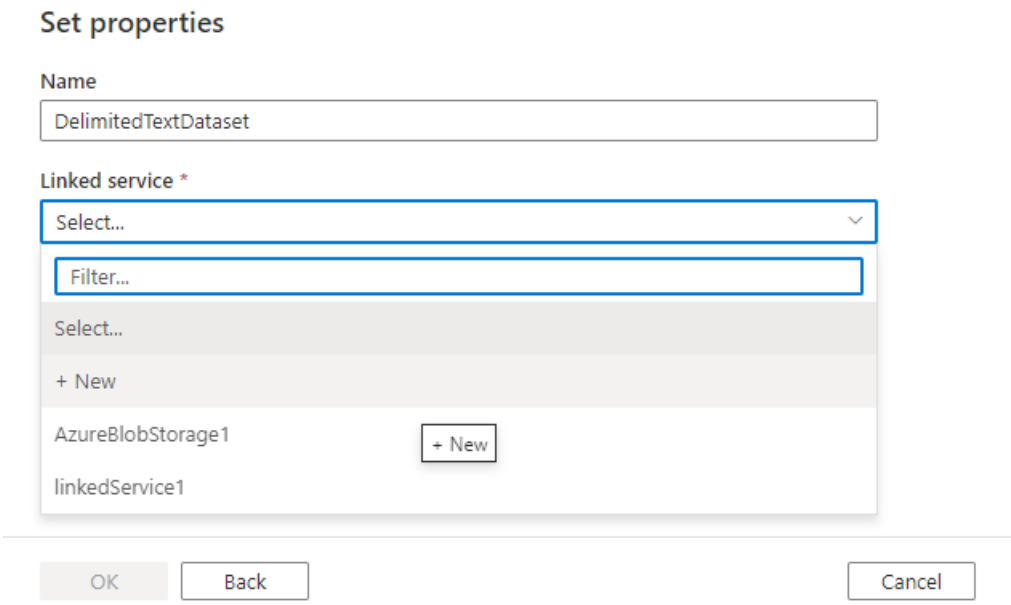
You'll see the new dataset window to choose any of the connectors available in Azure Data Factory, to set up an existing or new linked service.



Next you'll be prompted to choose the dataset format.



Finally, you can choose an existing linked service of the type you selected for the dataset, or create a new one if one isn't already defined.



Once you create the dataset, you can use it within any pipelines in the Azure Data Factory.

Dataset JSON

A dataset is defined in the following JSON format:

```
{
    "name": "<name of dataset>",
    "properties": {
        "type": "<type of dataset: DelimitedText, AzureSqlTable etc...>",
        "linkedServiceName": {
                "referenceName": "<name of linked service>",
                "type": "LinkedServiceReference",
        },
        "schema":[

        ],
        "typeProperties": {
            "<type specific property>": "<value>",
            "<type specific property 2>": "<value 2>",
        }
    }
}
```

The following table describes properties in the above JSON:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the dataset. See Naming rules.	Yes
type	Type of the dataset. Specify one of the types supported by Data Factory (for example: DelimitedText, AzureSqlTable). For details, see Dataset types.	Yes
schema	Schema of the dataset, represents the physical data type and shape.	No
typeProperties	The type properties are different for each type. For details on the supported types and their properties, see Dataset type.	Yes

When you import the schema of dataset, select the **Import Schema** button and choose to import from the source or from a local file. In most cases, you'll import the schema directly from the source. But if you already have a local schema file (a Parquet file or CSV with headers), you can direct the service to base the schema on that file.

In copy activity, datasets are used in source and sink. Schema defined in dataset is optional as reference. If you want to apply column/field mapping between source and sink, refer to Schema and type mapping.

In Data Flow, datasets are used in source and sink transformations. The datasets define the basic data schemas. If your data has no schema, you can use schema drift for your source and sink. Metadata from the datasets appears in your source transformation as the source projection. The projection in the source transformation represents the Data Flow data with defined names and types.

Dataset type

The service supports many different types of datasets, depending on the data stores you use. You can find the list of supported data stores from Connector overview article. Select a data store to learn how to create a linked service and a dataset for it.

For example, for a Delimited Text dataset, the dataset type is set to **DelimitedText** as shown in the following JSON sample:

```
{
    "name": "DelimitedTextInput",
    "properties": {
        "linkedServiceName": {
            "referenceName": "AzureBlobStorage",
            "type": "LinkedServiceReference"
        },
        "annotations": [],
        "type": "DelimitedText",
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "fileName": "input.log",
                "folderPath": "inputdata",
                "container": "adfgetstarted"
            },
            "columnDelimiter": ",",
            "escapeChar": "\\",
            "quoteChar": "\""
        },
        "schema": []
    }
}
```

Create datasets

You can create datasets by using one of these tools or SDKs: .NET API, PowerShell, REST API, Azure Resource Manager Template, and Azure portal

Current version vs. version 1 datasets

Here are some differences between datasets in Data Factory current version (and Azure Synapse), and the legacy Data Factory version 1:

- The external property isn't supported in the current version. It's replaced by a trigger.
- The policy and availability properties aren't supported in the current version. The start time for a pipeline depends on triggers.
- Scoped datasets (datasets defined in a pipeline) aren't supported in the current version.

Next steps

See the following tutorial for step-by-step instructions for creating pipelines and datasets by using one of these tools or SDKs.

- Quickstart: create a data factory using .NET
- Quickstart: create a data factory using PowerShell
- Quickstart: create a data factory using REST API
- Quickstart: create a data factory using Azure portal

Pipeline execution and triggers in Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 16 minutes to read • Edit Online

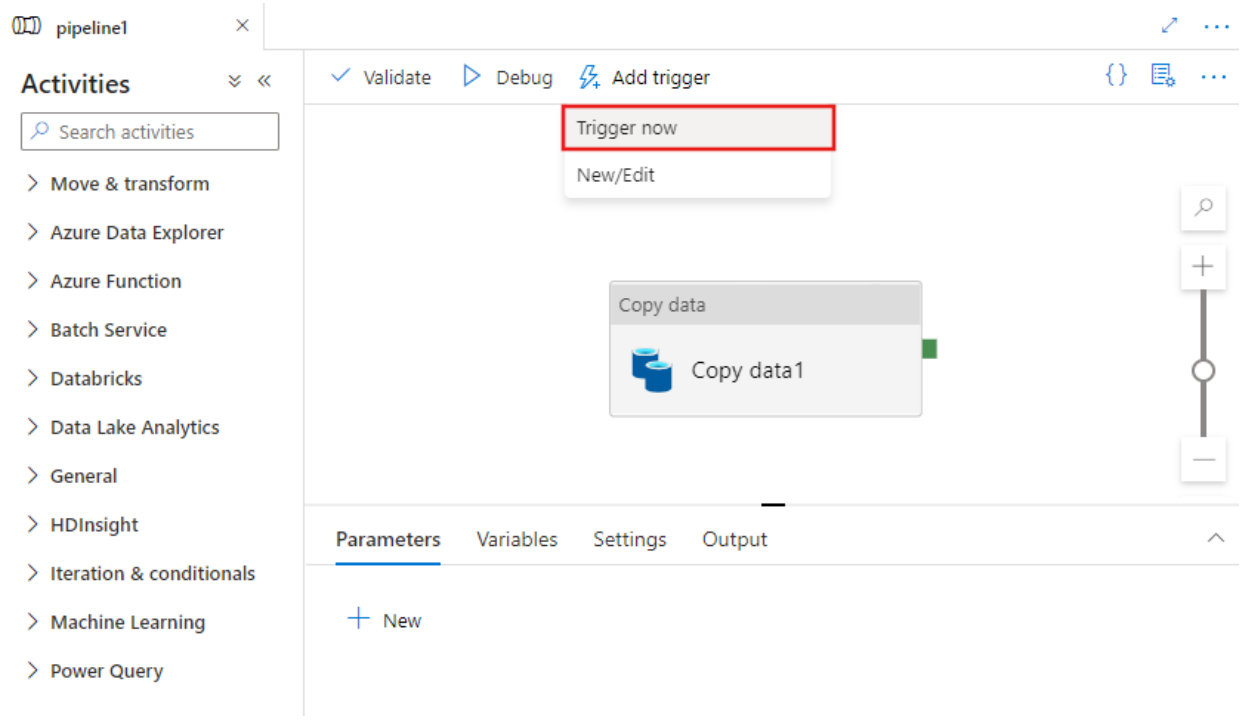
APPLIES TO: Azure Data Factory Azure Synapse Analytics

A *pipeline run* in Azure Data Factory and Azure Synapse defines an instance of a pipeline execution. For example, say you have a pipeline that executes at 8:00 AM, 9:00 AM, and 10:00 AM. In this case, there are three separate runs of the pipeline or pipeline runs. Each pipeline run has a unique pipeline run ID. A run ID is a GUID that uniquely defines that particular pipeline run.

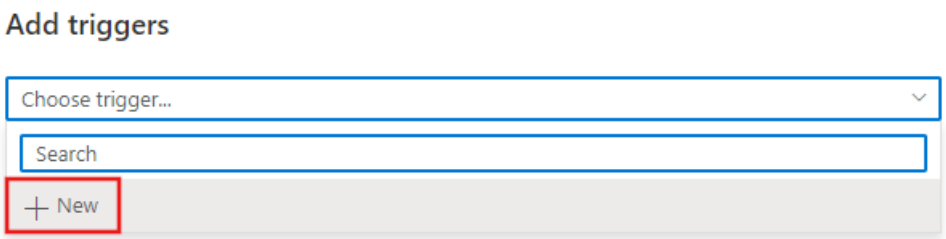
Pipeline runs are typically instantiated by passing arguments to parameters that you define in the pipeline. You can execute a pipeline either manually or by using a *trigger*. This article provides details about both ways of executing a pipeline.

Create triggers with UI

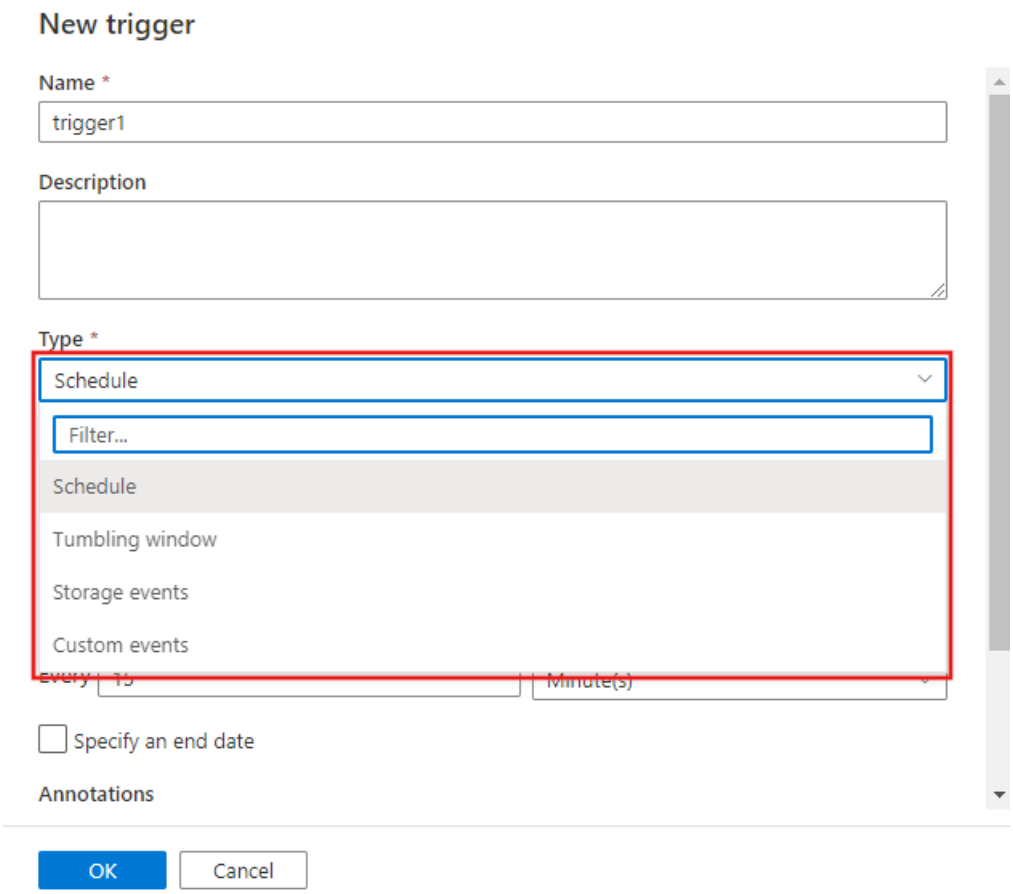
To manually trigger a pipeline or configure a new scheduled, tumbling window, storage event, or custom event trigger, select Add trigger at the top of the pipeline editor.



If you choose to manually trigger the pipeline, it will execute immediately. Otherwise if you choose New/Edit, you will be prompted with the add triggers window to either choose an existing trigger to edit, or create a new trigger.



You will see the trigger configuration window, allowing you to choose the trigger type.



Read more about scheduled, tumbling window, storage event, and custom event triggers below.

Manual execution (on-demand) with JSON

The manual execution of a pipeline is also referred to as *on-demand* execution.

For example, say you have a basic pipeline named **copyPipeline** that you want to execute. The pipeline has a single activity that copies from an Azure Blob storage source folder to a destination folder in the same storage. The following JSON definition shows this sample pipeline:

```
{
    "name": "copyPipeline",
    "properties": {
        "activities": [
            {
                "type": "Copy",
                "typeProperties": {
                    "source": {
                        "type": "BlobSource"
                    },
                    "sink": {
                        "type": "BlobSink"
                    }
                },
                "name": "CopyBlobtoBlob",
                "inputs": [
                    {
                        "referenceName": "sourceBlobDataset",
                        "type": "DatasetReference"
                    }
                ],
                "outputs": [
                    {
                        "referenceName": "sinkBlobDataset",
                        "type": "DatasetReference"
                    }
                ]
            }
        ],
        "parameters": {
            "sourceBlobContainer": {
                "type": "String"
            },
            "sinkBlobContainer": {
                "type": "String"
            }
        }
    }
}
```

In the JSON definition, the pipeline takes two parameters: **sourceBlobContainer** and **sinkBlobContainer**. You pass values to these parameters at runtime.

You can manually run your pipeline by using one of the following methods:

- .NET SDK
- Azure PowerShell module
- REST API
- Python SDK

REST API

The following sample command shows you how to run your pipeline by using the REST API manually:

```
POST
https://management.azure.com/subscriptions/mySubId/resourceGroups/myResourceGroup/providers/Microsoft.DataFa
ctory/factories/myDataFactory/pipelines/copyPipeline/createRun?api-version=2017-03-01-preview
```

For a complete sample, see Quickstart: Create a data factory by using the REST API.

Azure PowerShell

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

The following sample command shows you how to manually run your pipeline by using Azure PowerShell:

```
Invoke-AzDataFactoryV2Pipeline -DataFactory $df -PipelineName "Adfv2QuickStartPipeline" -ParameterFile
.\PipelineParameters.json
```

You pass parameters in the body of the request payload. In the .NET SDK, Azure PowerShell, and the Python SDK, you pass values in a dictionary that's passed as an argument to the call:

```
{
  "sourceBlobContainer": "MySourceFolder",
  "sinkBlobContainer": "MySinkFolder"
}
```

The response payload is a unique ID of the pipeline run:

```
{
  "runId": "0448d45a-a0bd-23f3-90a5-bfeea9264aed"
}
```

For a complete sample, see Quickstart: Create a data factory by using Azure PowerShell.

.NET SDK

The following sample call shows you how to run your pipeline by using the .NET SDK manually:

```
client.Pipelines.CreateRunWithHttpMessagesAsync(resourceGroup, dataFactoryName, pipelineName, parameters)
```

For a complete sample, see Quickstart: Create a data factory by using the .NET SDK.

> **NOTE**
> You can use the .NET SDK to invoke pipelines from Azure Functions, from your web services, and so on.

Trigger execution with JSON

Triggers are another way that you can execute a pipeline run. Triggers represent a unit of processing that determines when a pipeline execution needs to be kicked off. Currently, the service supports three types of triggers:

- Schedule trigger: A trigger that invokes a pipeline on a wall-clock schedule.
- Tumbling window trigger: A trigger that operates on a periodic interval, while also retaining state.
- Event-based trigger: A trigger that responds to an event.

Pipelines and triggers have a many-to-many relationship (except for the tumbling window trigger). Multiple triggers can kick off a single pipeline, or a single trigger can kick off multiple pipelines. In the following trigger definition, the **pipelines** property refers to a list of pipelines that are triggered by the particular trigger. The

property definition includes values for the pipeline parameters.

Basic trigger definition

```
{
    "properties": {
        "name": "MyTrigger",
        "type": "<type of trigger>",
        "typeProperties": {...},
        "pipelines": [
            {
                "pipelineReference": {
                    "type": "PipelineReference",
                    "referenceName": "<Name of your pipeline>"
                },
                "parameters": {
                    "<parameter 1 Name>": {
                        "type": "Expression",
                        "value": "<parameter 1 Value>"
                    },
                    "<parameter 2 Name>": "<parameter 2 Value>"
                }
            }
        ]
    }
}
```

Schedule trigger with JSON

A schedule trigger runs pipelines on a wall-clock schedule. This trigger supports periodic and advanced calendar options. For example, the trigger supports intervals like "weekly" or "Monday at 5:00 PM and Thursday at 9:00 PM." The schedule trigger is flexible because the dataset pattern is agnostic, and the trigger doesn't discern between time-series and non-time-series data.

For more information about schedule triggers and, for examples, see Create a trigger that runs a pipeline on a schedule.

Schedule trigger definition

When you create a schedule trigger, you specify scheduling and recurrence by using a JSON definition.

To have your schedule trigger kick off a pipeline run, include a pipeline reference of the particular pipeline in the trigger definition. Pipelines and triggers have a many-to-many relationship. Multiple triggers can kick off a single pipeline. A single trigger can kick off multiple pipelines.

```
{
  "properties": {
    "type": "ScheduleTrigger",
    "typeProperties": {
      "recurrence": {
        "frequency": <<Minute, Hour, Day, Week, Year>>,
        "interval": <<int>>, // How often to fire
        "startTime": <<datetime>>,
        "endTime": <<datetime>>,
        "timeZone": "UTC",
        "schedule": { // Optional (advanced scheduling specifics)
          "hours": [<<0-24>>],
          "weekDays": [<<Monday-Sunday>>],
          "minutes": [<<0-60>>],
          "monthDays": [<<1-31>>],
          "monthlyOccurrences": [
            {
              "day": <<Monday-Sunday>>,
              "occurrence": <<1-5>>
            }
          ]
        }
      }
    },
  "pipelines": [
    {
      "pipelineReference": {
        "type": "PipelineReference",
        "referenceName": "<Name of your pipeline>"
      },
      "parameters": {
        "<parameter 1 Name>": {
          "type": "Expression",
          "value": "<parameter 1 Value>"
        },
        "<parameter 2 Name>": "<parameter 2 Value>"
      }
    }
  ]}
}
```

IMPORTANT

The **parameters** property is a mandatory property of the **pipelines** element. If your pipeline doesn't take any parameters, you must include an empty JSON definition for the **parameters** property.

Schema overview

The following table provides a high-level overview of the major schema elements that are related to recurrence and scheduling a trigger:

JSON PROPERTY	DESCRIPTION
startTime	A date-time value. For basic schedules, the value of the **startTime** property applies to the first occurrence. For complex schedules, the trigger starts no sooner than the specified **startTime** value.
endTime	The end date and time for the trigger. The trigger doesn't execute after the specified end date and time. The value for the property can't be in the past.

JSON PROPERTY	DESCRIPTION
timeZone	The time zone. For a list of supported time zones, see Create a trigger that runs a pipeline on a schedule.
recurrence	A recurrence object that specifies the recurrence rules for the trigger. The recurrence object supports the **frequency**, **interval**, **endTime**, **count**, and **schedule** elements. When a recurrence object is defined, the **frequency** element is required. The other elements of the recurrence object are optional.
frequency	The unit of frequency at which the trigger recurs. The supported values include "minute", "hour", "day", "week", and "month".
interval	A positive integer that denotes the interval for the **frequency** value. The **frequency** value determines how often the trigger runs. For example, if the **interval** is 3 and the **frequency** is "week", the trigger recurs every three weeks.
schedule	The recurrence schedule for the trigger. A trigger with a specified **frequency** value alters its recurrence based on a recurrence schedule. The **schedule** property contains modifications for the recurrence that are based on minutes, hours, weekdays, month days, and week number.

Schedule trigger example

```
{
  "properties": {
    "name": "MyTrigger",
    "type": "ScheduleTrigger",
    "typeProperties": {
      "recurrence": {
        "frequency": "Hour",
        "interval": 1,
        "startTime": "2017-11-01T09:00:00-08:00",
        "endTime": "2017-11-02T22:00:00-08:00"
      }
    },
    "pipelines": [{
        "pipelineReference": {
          "type": "PipelineReference",
          "referenceName": "SQLServerToBlobPipeline"
        },
        "parameters": {}
      },
      {
        "pipelineReference": {
          "type": "PipelineReference",
          "referenceName": "SQLServerToAzureSQLPipeline"
        },
        "parameters": {}
      }
    ]
  }
}
```

Schema defaults, limits, and examples

JSON PROPERTY	TYPE	REQUIRED	DEFAULT VALUE	VALID VALUES	EXAMPLE
startTime	string	Yes	None	ISO 8601 date-times	`"startTime" : "2013-01-09T09:30:00-08:00"`
recurrence	object	Yes	None	A recurrence object	`"recurrence" : { "frequency" : "monthly", "interval" : 1 }`
interval	number	No	1	1 to 1000	`"interval":10`
endTime	string	Yes	None	A date-time value that represents a time in the future	`"endTime" : "2013-02-09T09:30:00-08:00"`
schedule	object	No	None	A schedule object	`"schedule" : { "minute" : [30], "hour" : [8,17] }`

startTime property

The following table shows you how the **startTime** property controls a trigger run:

STARTTIME VALUE	RECURRENCE WITHOUT SCHEDULE	RECURRENCE WITH SCHEDULE
Start time is in the past	Calculates the first future execution time after the start time, and runs at that time. Runs subsequent executions calculated from the last execution time. See the example that follows this table.	The trigger starts *no sooner than* the specified start time. The first occurrence is based on the schedule, calculated from the start time. Runs subsequent executions based on the recurrence schedule.
Start time is in the future or the current time	Runs once at the specified start time. Runs subsequent executions calculated from the last execution time.	The trigger starts *no sooner* than the specified start time. The first occurrence is based on the schedule, calculated from the start time. Runs subsequent executions based on the recurrence schedule.

Let's look at an example of what happens when the start time is in the past, with a recurrence, but no schedule. Assume that the current time is 2017-04-08 13:00, the start time is 2017-04-07 14:00, and the recurrence is every two days. (The **recurrence** value is defined by setting the **frequency** property to "day" and the **interval** property to 2.) Notice that the **startTime** value is in the past and occurs before the current time.

Under these conditions, the first execution is 2017-04-09 at 14:00. The Scheduler engine calculates execution occurrences from the start time. Any instances in the past are discarded. The engine uses the next instance that occurs in the future. In this scenario, the start time is 2017-04-07 at 2:00 PM. The next instance is two days from that time, which is on 2017-04-09 at 2:00 PM.

The first execution time is the same even whether **startTime** is 2017-04-05 14:00 or 2017-04-01 14:00. After the first execution, subsequent executions are calculated by using the schedule. Therefore, the subsequent

executions are on 2017-04-11 at 2:00 PM, then on 2017-04-13 at 2:00 PM, then on 2017-04-15 at 2:00 PM, and so on.

Finally, when hours or minutes aren't set in the schedule for a trigger, the hours or minutes of the first execution are used as defaults.

schedule property

You can use **schedule** to *limit* the number of trigger executions. For example, if a trigger with a monthly frequency is scheduled to run only on day 31, the trigger runs only in those months that have a thirty-first day.

You can also use **schedule** to *expand* the number of trigger executions. For example, a trigger with a monthly frequency that's scheduled to run on month days 1 and 2, runs on the first and second days of the month, rather than once a month.

If multiple **schedule** elements are specified, the order of evaluation is from the largest to the smallest schedule setting: week number, month day, weekday, hour, minute.

The following table describes the **schedule** elements in detail:

JSON ELEMENT	DESCRIPTION	VALID VALUES
minutes	Minutes of the hour at which the trigger runs.	- Integer - Array of integers
hours	Hours of the day at which the trigger runs.	- Integer - Array of integers
weekDays	Days of the week the trigger runs. The value can be specified only with a weekly frequency.	- Monday - Tuesday - Wednesday - Thursday - Friday - Saturday - Sunday - Array of day values (maximum array size is 7) Day values aren't case-sensitive
monthlyOccurrences	Days of the month on which the trigger runs. The value can be specified with a monthly frequency only.	- Array of **monthlyOccurrence** objects: `{ "day": day, "occurrence": occurrence }` - The **day** attribute is the day of the week on which the trigger runs. For example, a **monthlyOccurrences** property with a **day** value of `{Sunday}` means every Sunday of the month. The **day** attribute is required. - The **occurrence** attribute is the occurrence of the specified **day** during the month. For example, a **monthlyOccurrences** property with **day** and **occurrence** values of `{Sunday, -1}` means the last Sunday of the month. The **occurrence** attribute is optional.

JSON ELEMENT	DESCRIPTION	VALID VALUES
monthDays	Day of the month on which the trigger runs. The value can be specified with a monthly frequency only.	- Any value <= -1 and >= -31 - Any value >= 1 and <= 31 - Array of values

Tumbling window trigger

Tumbling window triggers are a type of trigger that fires at a periodic time interval from a specified start time, while retaining state. Tumbling windows are a series of fixed-sized, non-overlapping, and contiguous time intervals.

For more information about tumbling window triggers and, for examples, see Create a tumbling window trigger.

Examples of trigger recurrence schedules

This section provides examples of recurrence schedules. It focuses on the **schedule** object and its elements.

The examples assume that the **interval** value is 1 and that the **frequency** value is correct according to the schedule definition. For example, you can't have a **frequency** value of "day" and also have a **monthDays** modification in the **schedule** object. These kinds of restrictions are described in the table in the preceding section.

EXAMPLE	DESCRIPTION
`{"hours":[5]}`	Run at 5:00 AM every day.
`{"minutes":[15], "hours":[5]}`	Run at 5:15 AM every day.
`{"minutes":[15], "hours":[5,17]}`	Run at 5:15 AM and 5:15 PM every day.
`{"minutes":[15,45], "hours":[5,17]}`	Run at 5:15 AM, 5:45 AM, 5:15 PM, and 5:45 PM every day.
`{"minutes":[0,15,30,45]}`	Run every 15 minutes.
`{hours":[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23]}`	Run every hour. This trigger runs every hour. The minutes are controlled by the **startTime** value, when a value is specified. If a value isn't specified, the minutes are controlled by the creation time. For example, if the start time or creation time (whichever applies) is 12:25 PM, the trigger runs at 00:25, 01:25, 02:25, ..., and 23:25. This schedule is equivalent to having a trigger with a **frequency** value of "hour", an **interval** value of 1, and no **schedule**. This schedule can be used with different **frequency** and **interval** values to create other triggers. For example, when the **frequency** value is "month", the schedule runs only once a month, rather than every day when the **frequency** value is "day".

EXAMPLE	DESCRIPTION
`{"minutes":[0]}`	Run every hour on the hour. This trigger runs every hour on the hour starting at 12:00 AM, 1:00 AM, 2:00 AM, and so on. This schedule is equivalent to a trigger with a **frequency** value of "hour" and a **startTime** value of zero minutes, and no **schedule** but a **frequency** value of "day". If the **frequency** value is "week" or "month", the schedule executes one day a week or one day a month only, respectively.
`{"minutes":[15]}`	Run at 15 minutes past every hour. This trigger runs every hour at 15 minutes past the hour starting at 00:15 AM, 1:15 AM, 2:15 AM, and so on, and ending at 11:15 PM.
`{"hours":[17], "weekDays":["saturday"]}`	Run at 5:00 PM on Saturdays every week.
`{"hours":[17], "weekDays":["monday", "wednesday", "friday"]}`	Run at 5:00 PM on Monday, Wednesday, and Friday every week.
`{"minutes":[15,45], "hours":[17], "weekDays": ["monday", "wednesday", "friday"]}`	Run at 5:15 PM and 5:45 PM on Monday, Wednesday, and Friday every week.
`{"minutes":[0,15,30,45], "weekDays":["monday", "tuesday", "wednesday", "thursday", "friday"]}`	Run every 15 minutes on weekdays.
`{"minutes":[0,15,30,45], "hours": [9, 10, 11, 12, 13, 14, 15, 16] "weekDays":["monday", "tuesday", "wednesday", "thursday", "friday"]}`	Run every 15 minutes on weekdays between 9:00 AM and 4:45 PM.
`{"weekDays":["tuesday", "thursday"]}`	Run on Tuesdays and Thursdays at the specified start time.
`{"minutes":[0], "hours":[6], "monthDays":[28]}`	Run at 6:00 AM on the twenty-eighth day of every month (assuming a **frequency** value of "month").
`{"minutes":[0], "hours":[6], "monthDays":[-1]}`	Run at 6:00 AM on the last day of the month. To run a trigger on the last day of a month, use -1 instead of day 28, 29, 30, or 31.
`{"minutes":[0], "hours":[6], "monthDays":[1,-1]}`	Run at 6:00 AM on the first and last day of every month.
`{monthDays":[1,14]}`	Run on the first and fourteenth day of every month at the specified start time.
`{"minutes":[0], "hours":[5], "monthlyOccurrences": [{"day":"friday", "occurrence":1}]}`	Run on the first Friday of every month at 5:00 AM.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":1}]}`	Run on the first Friday of every month at the specified start time.

EXAMPLE	DESCRIPTION
`{"monthlyOccurrences":[{"day":"friday", "occurrence":-3}]}`	Run on the third Friday from the end of the month, every month, at the specified start time.
`{"minutes":[15], "hours":[5], "monthlyOccurrences": [{"day":"friday", "occurrence":1},{"day":"friday", "occurrence":-1}]}`	Run on the first and last Friday of every month at 5:15 AM.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":1},{"day":"friday", "occurrence":-1}]}`	Run on the first and last Friday of every month at the specified start time.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":5}]}`	Run on the fifth Friday of every month at the specified start time. When there's no fifth Friday in a month, the pipeline doesn't run. To run the trigger on the last occurring Friday of the month, consider using -1 instead of 5 for the **occurrence** value.
`{"minutes":[0,15,30,45], "monthlyOccurrences": [{"day":"friday", "occurrence":-1}]}`	Run every 15 minutes on the last Friday of the month.
`{"minutes":[15,45], "hours":[5,17], "monthlyOccurrences":[{"day":"wednesday", "occurrence":3}]}`	Run at 5:15 AM, 5:45 AM, 5:15 PM, and 5:45 PM on the third Wednesday of every month.

Trigger type comparison

The tumbling window trigger and the schedule trigger both operate on time heartbeats. How are they different?

> **NOTE**
>
> The tumbling window trigger run *waits for the triggered pipeline run* to finish. Its run state reflects the state of the triggered pipeline run. For example, if a triggered pipeline run is cancelled, the corresponding tumbling window trigger run is marked cancelled. This is different from the "fire and forget" behavior of the schedule trigger, which is marked successful as long as a pipeline run started.

The following table provides a comparison of the tumbling window trigger and schedule trigger:

ITEM	TUMBLING WINDOW TRIGGER	SCHEDULE TRIGGER
Backfill scenarios	Supported. Pipeline runs can be scheduled for windows in the past.	Not supported. Pipeline runs can be executed only on time periods from the current time and the future.
Reliability	100% reliability. Pipeline runs can be scheduled for all windows from a specified start date without gaps.	Less reliable.

ITEM	TUMBLING WINDOW TRIGGER	SCHEDULE TRIGGER
Retry capability	Supported. Failed pipeline runs have a default retry policy of 0, or a policy that's specified by the user in the trigger definition. Automatically retries when the pipeline runs fail due to concurrency/server/throttling limits (that is, status codes 400: User Error, 429: Too many requests, and 500: Internal Server error).	Not supported.
Concurrency	Supported. Users can explicitly set concurrency limits for the trigger. Allows between 1 and 50 concurrent triggered pipeline runs.	Not supported.
System variables	Along with @trigger().scheduledTime and @trigger().startTime, it also supports the use of the **WindowStart** and **WindowEnd** system variables. Users can access `trigger().outputs.windowStartTime` and `trigger().outputs.windowEndTime` as trigger system variables in the trigger definition. The values are used as the window start time and window end time, respectively. For example, for a tumbling window trigger that runs every hour, for the window 1:00 AM to 2:00 AM, the definition is `trigger().outputs.windowStartTime = 2017-09-01T01:00:00Z` and `trigger().outputs.windowEndTime = 2017-09-01T02:00:00Z` .	Only supports default @trigger().scheduledTime and @trigger().startTime variables.
Pipeline-to-trigger relationship	Supports a one-to-one relationship. Only one pipeline can be triggered.	Supports many-to-many relationships. Multiple triggers can kick off a single pipeline. A single trigger can kick off multiple pipelines.

Event-based trigger

An event-based trigger runs pipelines in response to an event. There are two flavors of event-based triggers.

- *Storage event trigger* runs a pipeline against events happening in a Storage account, such as the arrival of a file, or the deletion of a file in Azure Blob Storage account.
- *Custom event trigger* processes and handles custom articles in Event Grid

For more information about event-based triggers, see Storage Event Trigger and Custom Event Trigger.

Integration runtime in Azure Data Factory

8/19/2022 • 14 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Integration Runtime (IR) is the compute infrastructure used by Azure Data Factory and Azure Synapse pipelines to provide the following data integration capabilities across different network environments:

- **Data Flow**: Execute a Data Flow in a managed Azure compute environment.
- **Data movement**: Copy data across data stores in a public or private networks (for both on-premises or virtual private networks). The service provides support for built-in connectors, format conversion, column mapping, and performant and scalable data transfer.
- **Activity dispatch**: Dispatch and monitor transformation activities running on a variety of compute services such as Azure Databricks, Azure HDInsight, ML Studio (classic), Azure SQL Database, SQL Server, and more.
- **SSIS package execution**: Natively execute SQL Server Integration Services (SSIS) packages in a managed Azure compute environment.

In Data Factory and Synapse pipelines, an activity defines the action to be performed. A linked service defines a target data store or a compute service. An integration runtime provides the bridge between activities and linked services. It's referenced by the linked service or activity, and provides the compute environment where the activity is either run directly or dispatched. This allows the activity to be performed in the closest possible region to the target data store or compute service to maximize performance while also allowing flexibility to meet security and compliance requirements.

Integration runtimes can be created in the Azure Data Factory and Azure Synapse UI via the management hub directly, as well as from any activities, datasets, or data flows that reference them.

Integration runtime types

Data Factory offers three types of Integration Runtime (IR), and you should choose the type that best serves your data integration capabilities and network environment requirements. The three types of IR are:

- Azure
- Self-hosted
- Azure-SSIS

> **NOTE**
> Synapse pipelines currently only support Azure or self-hosted integration runtimes.

The following table describes the capabilities and network support for each of the integration runtime types:

IR TYPE	PUBLIC NETWORK SUPPORT	PRIVATE LINK SUPPORT
Azure	Data Flow Data movement Activity dispatch	Data Flow Data movement Activity dispatch
Self-hosted	Data movement Activity dispatch	Data movement Activity dispatch

IR TYPE	PUBLIC NETWORK SUPPORT	PRIVATE LINK SUPPORT
Azure-SSIS	SSIS package execution	SSIS package execution

> **NOTE**
> Outbound controls vary by service for Azure IR. In Synapse, workspaces have options to limit outbound traffic from the managed virtual network when utilizing Azure IR. In Data Factory, all ports are opened for outbound communications when utilizing Azure IR. Azure-SSIS IR can be integrated with your vNET to provide outbound communications controls.

Azure integration runtime

An Azure integration runtime can:

- Run Data Flows in Azure
- Run copy activities between cloud data stores
- Dispatch the following transform activities in a public network: Databricks Notebook/ Jar/ Python activity, HDInsight Hive activity, HDInsight Pig activity, HDInsight MapReduce activity, HDInsight Spark activity, HDInsight Streaming activity, ML Studio (classic) Batch Execution activity, ML Studio (classic) Update Resource activities, Stored Procedure activity, Data Lake Analytics U-SQL activity, .NET custom activity, Web activity, Lookup activity, and Get Metadata activity.

Azure IR network environment

Azure Integration Runtime supports connecting to data stores and computes services with public accessible endpoints. Enabling Managed Virtual Network, Azure Integration Runtime supports connecting to data stores using private link service in private network environment. In Synapse, workspaces have options to limit outbound traffic from the IR managed virtual network. In Data Factory, all ports are opened for outbound communications. The Azure-SSIS IR can be integrated with your vNET to provide outbound communications controls.

Azure IR compute resource and scaling

Azure integration runtime provides a fully managed, serverless compute in Azure. You don't have to worry about infrastructure provision, software installation, patching, or capacity scaling. In addition, you only pay for the duration of the actual utilization.

Azure integration runtime provides the native compute to move data between cloud data stores in a secure, reliable, and high-performance manner. You can set how many data integration units to use on the copy activity, and the compute size of the Azure IR is elastically scaled up accordingly without requiring you to explicitly adjust the size of the Azure Integration Runtime.

Activity dispatch is a lightweight operation to route the activity to the target compute service, so there isn't need to scale up the compute size for this scenario.

For information about creating and configuring an Azure IR, see How to create and configure Azure Integration Runtime.

> **NOTE**
> Azure Integration runtime has properties related to Data Flow runtime, which defines the underlying compute infrastructure that would be used to run the data flows.

Self-hosted integration runtime

A self-hosted IR is capable of:

- Running copy activity between a cloud data stores and a data store in private network.
- Dispatching the following transform activities against compute resources in on-premises or Azure Virtual Network: HDInsight Hive activity (BYOC-Bring Your Own Cluster), HDInsight Pig activity (BYOC), HDInsight MapReduce activity (BYOC), HDInsight Spark activity (BYOC), HDInsight Streaming activity (BYOC), ML Studio (classic) Batch Execution activity, ML Studio (classic) Update Resource activities, Stored Procedure activity, Data Lake Analytics U-SQL activity, Custom activity (runs on Azure Batch), Lookup activity, and Get Metadata activity.

> **NOTE**
> Use self-hosted integration runtime to support data stores that require bring-your-own driver, such as SAP Hana, MySQL, etc. For more information, see supported data stores.

> **NOTE**
> The Java Runtime Environment (JRE) is a dependency of the Self Hosted IR. Please make sure you have the JRE installed on the same host.

Self-hosted IR network environment

If you want to perform data integration securely in a private network environment that doesn't have a direct line-of-sight from the public cloud environment, you can install a self-hosted IR in your on-premises environment behind a firewall, or inside a virtual private network. The self-hosted integration runtime only makes outbound HTTP-based connections to the internet.

Self-hosted IR compute resource and scaling

Install a Self-hosted IR on an on-premises machine or a virtual machine inside a private network. Currently, the self-hosted IR is only supported on a Windows operating system.
For high availability and scalability, you can scale out the self-hosted IR by associating the logical instance with multiple on-premises machines in active-active mode. For more information, see the article on how to create and configure a self-hosted IR for details.

Azure-SSIS integration runtime

To lift and shift existing SSIS workload, you can create an Azure-SSIS IR to natively execute SSIS packages.

Azure-SSIS IR network environment

The Azure-SSIS IR can be provisioned in either public network or private network. On-premises data access is supported by joining Azure-SSIS IR to a virtual network that is connected to your on-premises network.

Azure-SSIS IR compute resource and scaling

The Azure-SSIS IR is a fully managed cluster of Azure VMs dedicated to run your SSIS packages. You can bring your own Azure SQL Database or SQL Managed Instance for the catalog of SSIS projects/packages (SSISDB). You can scale up the power of the compute by specifying node size and scale it out by specifying the number of nodes in the cluster. You can manage the cost of running your Azure-SSIS Integration Runtime by stopping and starting it as your requirements demand.

For more information, see How to create and configure the Azure-SSIS IR. Once created, you can deploy and manage your existing SSIS packages with little to no change using familiar tools such as SQL Server Data Tools (SSDT) and SQL Server Management Studio (SSMS), just like using SSIS on-premises.

For more information about the Azure-SSIS runtime, see the following articles:

- Tutorial: deploy SSIS packages to Azure. This article provides step-by-step instructions to create an Azure-SSIS IR and uses an Azure SQL Database to host the SSIS catalog.
- How to: Create an Azure-SSIS integration runtime. This article expands on the tutorial and provides instructions on using SQL Managed Instance and joining the IR to a virtual network.
- Monitor an Azure-SSIS IR. This article shows you how to retrieve information about an Azure-SSIS IR and provides descriptions of statuses in the returned information.
- Manage an Azure-SSIS IR. This article shows you how to stop, start, or remove an Azure-SSIS IR. It also shows you how to scale out your Azure-SSIS IR by adding more nodes to the IR.
- Join an Azure-SSIS IR to a virtual network. This article provides conceptual information about joining an Azure-SSIS IR to an Azure virtual network. It also provides steps to use the Azure portal to configure a virtual network and join an Azure-SSIS IR to it.

Integration runtime location

Relationship between factory location and IR location

When you create an instance of Data Factory or a Synapse Workspace, you need to specify its location. The metadata for the instance is stored here, and triggering of the pipeline is initiated from here. Metadata is only stored in the chosen region and will not be stored in other regions.

Meanwhile, a pipeline can access data stores and compute services in other Azure regions to move data between data stores or process data using compute services. This behavior is realized through the globally available IR to ensure data compliance, efficiency, and reduced network egress costs.

The IR Location defines the location of its back-end compute, and where the data movement, activity dispatching, and SSIS package execution are performed. The IR location can be different from the location of the Data Factory it belongs to.

Azure IR location

You can set the location region of an Azure IR, in which case the activity execution or dispatch will happen in the selected region.

The default is to auto-resolve the Azure IR in the public network. With this option:

- For copy activity, a best effort is made to automatically detect your sink data store's location, then use the IR in either the same region, if available, or the closest one in the same geography, otherwise; if the sink data store's region is not detectable, the IR in the instance's region is used instead.

  For example, a Data Factory or Synapse Workspace was created in East US,

  - When copying data to an Azure Blob in West US, if the blob is detected to be in the West US region, the copy activity is executed on the IR in West US; if region detection fails, the copy activity is executed on the IR in East US.
  - When copying data to Salesforce, for which the region is not detectable, the copy activity is executed on the IR in East US.

  > **TIP**
  > If you have strict data compliance requirements and need to ensure that data do not leave a certain geography, you can explicitly create an Azure IR in a certain region and point the Linked Service to this IR using the ConnectVia property. For example, if you want to copy data from a blob in UK South to an Azure Synapse workspace in UK South and want to ensure data does not leave the UK, create an Azure IR in UK South and link both Linked Services to this IR.

- For Lookup/GetMetadata/Delete activity execution (Pipeline activities), transformation activity dispatching (External activities), and authoring operations (test connection, browse folder list and table list, and

preview data), the IR in the same region as the Data Factory or Synapse Workspace is used.

- For Data Flow, the IR in the Data Factory or Synapse Workspace region is used.

  > **TIP**
  > A best practice is to ensure data flows run in the same region as your corresponding data stores when possible. You can either achieve this with auto-resolve for the Azure IR (if the data store location is the same as the Data Factory or Synapse Workspace location), or by creating a new Azure IR instance in the same region as your data stores and then executing the data flows on it.

If you enable Managed Virtual Network with auto-resolve for the Azure IR, the IR in the Data Factory or Synapse Workspace region is used.

You can monitor which IR location takes effect during activity execution in pipeline activity monitoring view in the Data Factory Studio or Synapse Studio, or in the activity monitoring payload.

Self-hosted IR location

The self-hosted IR is logically registered to the Data Factory or Synapse Workspace and the compute used to support its functionalities is provided by you. Therefore there is no explicit location property for self-hosted IR.

When used to perform data movement, the self-hosted IR extracts data from the source and writes into the destination.

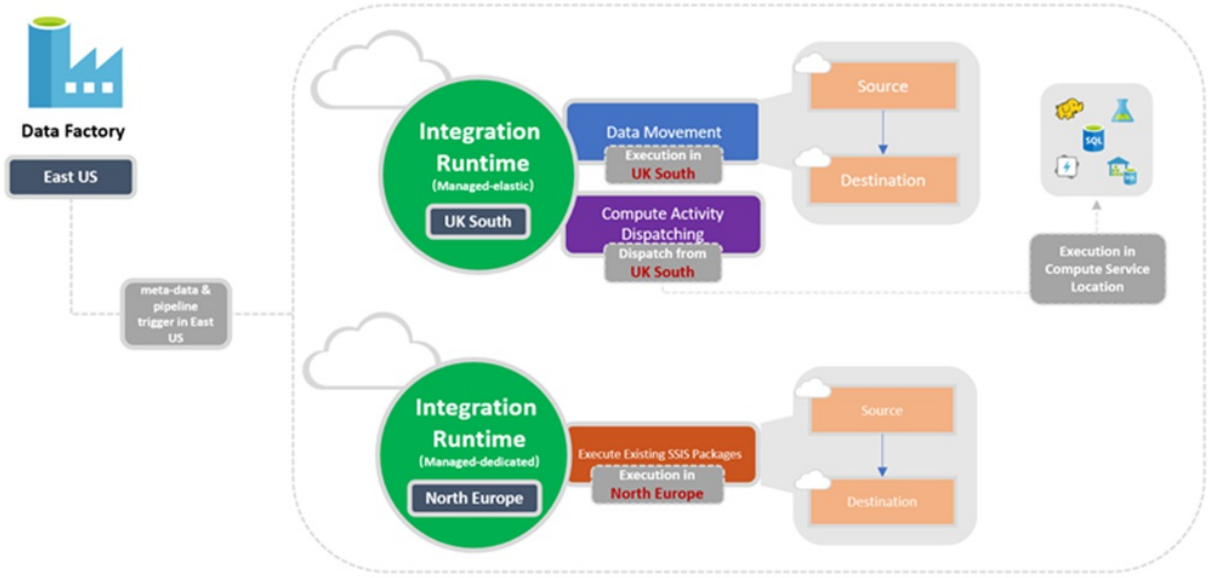
Azure-SSIS IR location

> **NOTE**
> Azure-SSIS integration runtimes are not currently supported in Synapse pipelines.

Selecting the right location for your Azure-SSIS IR is essential to achieve high performance in your extract-transform-load (ETL) workflows.

- The location of your Azure-SSIS IR does not need to be the same as the location of your Data Factory, but it should be the same as the location of your own Azure SQL Database or SQL Managed Instance where SSISDB is located. This way, your Azure-SSIS Integration Runtime can easily access the SSISDB without incurring excessive traffic between different locations.
- If you do not have an existing SQL Database or SQL Managed Instance, but you have on-premises data sources/destinations, you should create a new Azure SQL Database or SQL Managed Instance in the same location of a virtual network connected to your on-premises network. This way, you can create your Azure-SSIS IR using the new Azure SQL Database or SQL Managed Instance, and join that virtual network. Everything will be in the same location, minimizing data movement and associated costs, while maximizing performance.
- If the location of your existing Azure SQL Database or SQL Managed Instance is not the same as the location of a virtual network connected to your on-premises network, first create your Azure-SSIS IR using an existing Azure SQL Database or SQL Managed Instance and join another virtual network in the same location. Then configure a virtual network to virtual network connection between the different locations.

The following diagram shows the location settings for Data Factory and its integration runtimes:



Determining which IR to use

If an activity associates with more than one type of integration runtime, it will resolve to one of them. The self-hosted integration runtime takes precedence over the Azure integration runtime in Azure Data Factory or Synapse Workspace instances using a managed virtual network. And the latter takes precedence over the global Azure integration runtime.

For example, one copy activity is used to copy data from source to sink. The global Azure integration runtime is associated with the linked service to source and an Azure integration runtime in an Azure Data Factory managed virtual network associates with the linked service for sink, then the result is that both source and sink linked services use the Azure integration runtime in the Azure Data Factory managed virtual network. But if a self-hosted integration runtime associates the linked service for source, then both source and sink linked service use the self-hosted integration runtime.

Copy activity

The Copy activity requires both source and sink linked services to define the direction of data flow. The following logic is used to determine which integration runtime instance is used to perform the copy:

- **Copying between two cloud data sources**: if both source and sink linked services are using Azure IR, the regional Azure IR is used if it was specified, or the location of the Azure IR is automatically determined if the auto-resolve IR (default) option was chosen as described in the Integration runtime location section.
- **Copying between a cloud data source and a data source in a private network**: if either the source or sink linked service points to a self-hosted IR, the copy activity is executed on the self-hosted IR.
- **Copying between two data sources in a private network**: both the source and sink linked service must point to the same instance of the integration runtime, and that IR is used to execute the copy activity.

Lookup and GetMetadata activity

The Lookup and GetMetadata activity is executed on the integration runtime associated to the data store linked service.

External transformation activity

Each external transformation activity that utilizes an external compute engine has a target compute linked service, which points to an integration runtime. This IR instance determines the location from where that external hand-coded transformation activity is dispatched.

Data Flow activity

Data Flow activities are executed on their associated Azure integration runtime. The Spark compute utilized by

Data Flows are determined by the data flow properties in your Azure IR, and are fully managed by the service.

Integration Runtime in CI/CD

Integration runtimes don't change often and are similar across all stages in your CI/CD. Data Factory requires you to have the same name and type of integration runtime across all stages of CI/CD. If you want to share integration runtimes across all stages, consider using a dedicated factory just to contain the shared integration runtimes. You can then use this shared factory in all of your environments as a linked integration runtime type.

- Create Azure integration runtime
- Create self-hosted integration runtime
- Create an Azure-SSIS integration runtime. This article expands on the tutorial and provides instructions on using SQL Managed Instance and joining the IR to a virtual network.

Data integration in Azure Synapse Analytics versus Azure Data Factory

8/19/2022 • 2 minutes to read • Edit Online

In Azure Synapse Analytics, the data integration capabilities such as Synapse pipelines and data flows are based upon those of Azure Data Factory. For more information, see what is Azure Data Factory.

Available features in ADF & Azure Synapse Analytics

Check below table for features availability:

CATEGORY	FEATURE	AZURE DATA FACTORY	AZURE SYNAPSE ANALYTICS
Integration Runtime	Using SSIS and SSIS Integration Runtime	✓	✓ *Public preview*
	Support for Cross-region Integration Runtime (Data Flows)	✓	✗
	Integration Runtime Sharing	✓ *Can be shared across different data factories*	✗
Pipelines Activities	SSIS Package Activity	✓	✓ *Public preview*
	Support for Power Query Activity	✓	✗
	Support for global parameters	✓	✗
Template Gallery and Knowledge center	Solution Templates	✓ *Azure Data Factory Template Gallery*	✓ *Synapse Workspace Knowledge center*
GIT Repository Integration	GIT Integration	✓	✓
Monitoring	Monitoring of Spark Jobs for Data Flow	✗	✓ *Leverage the Synapse Spark pools*

Data flows in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

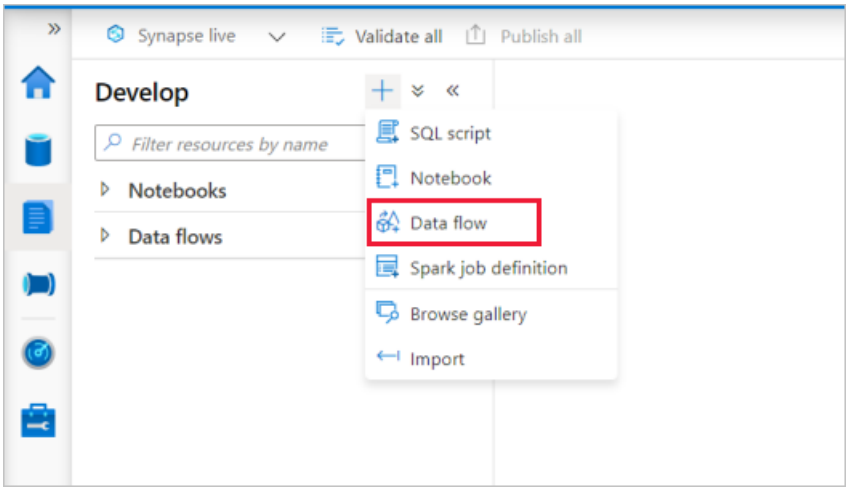
What are data flows?

Data flows are visually designed data transformations in Azure Synapse Analytics. Data flows allow data engineers to develop data transformation logic without writing code. The resulting data flows are executed as activities within Azure Synapse Analytics pipelines that use scaled-out Apache Spark clusters. Data flow activities can be operationalized using existing Azure Synapse Analytics scheduling, control, flow, and monitoring capabilities.

Data flows provide an entirely visual experience with no coding required. Your data flows run on Synapse-managed execution clusters for scaled-out data processing. Azure Synapse Analytics handles all the code translation, path optimization, and execution of your data flow jobs.

Getting started

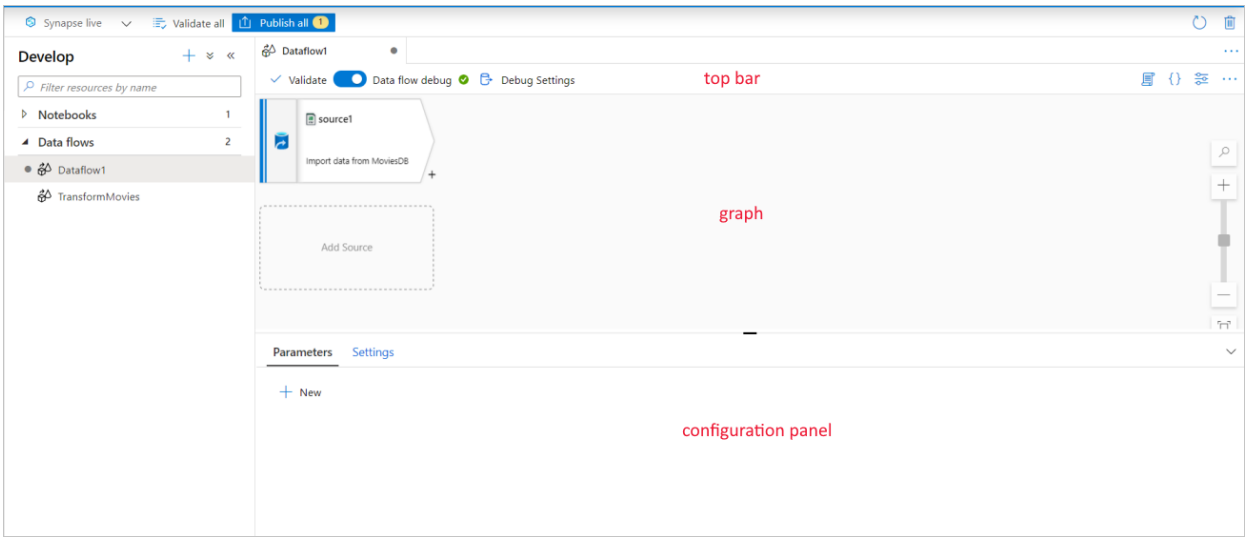
Data flows are created from the Develop pane in Synapse studio. To create a data flow, select the plus sign next to **Develop**, and then select **Data Flow**.



This action takes you to the data flow canvas, where you can create your transformation logic. Select **Add source** to start configuring your source transformation. For more information, see Source transformation.

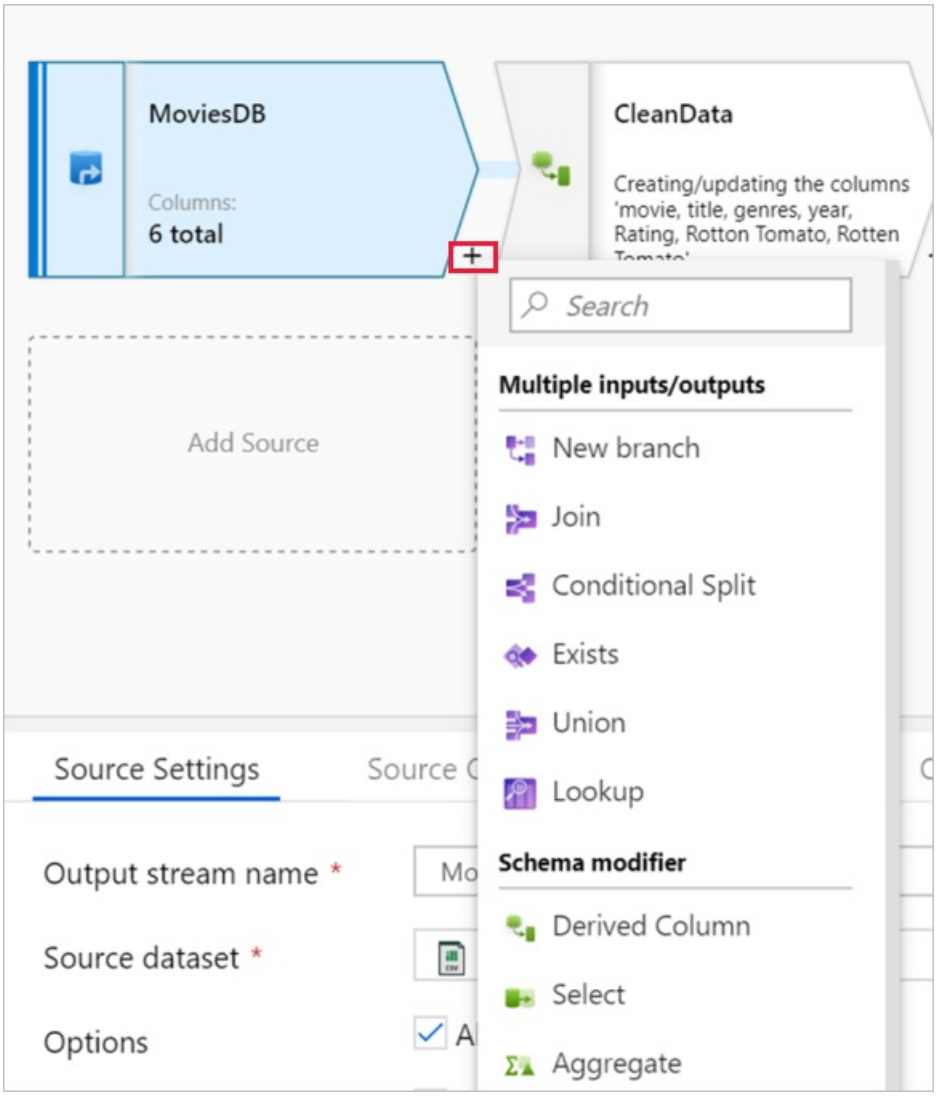
Authoring data flows

Data flow has a unique authoring canvas designed to make building transformation logic easy. The data flow canvas is separated into three parts: the top bar, the graph, and the configuration panel.



Graph

The graph displays the transformation stream. It shows the lineage of source data as it flows into one or more sinks. To add a new source, select **Add source**. To add a new transformation, select the plus sign on the lower right of an existing transformation. Learn more on how to manage the data flow graph.



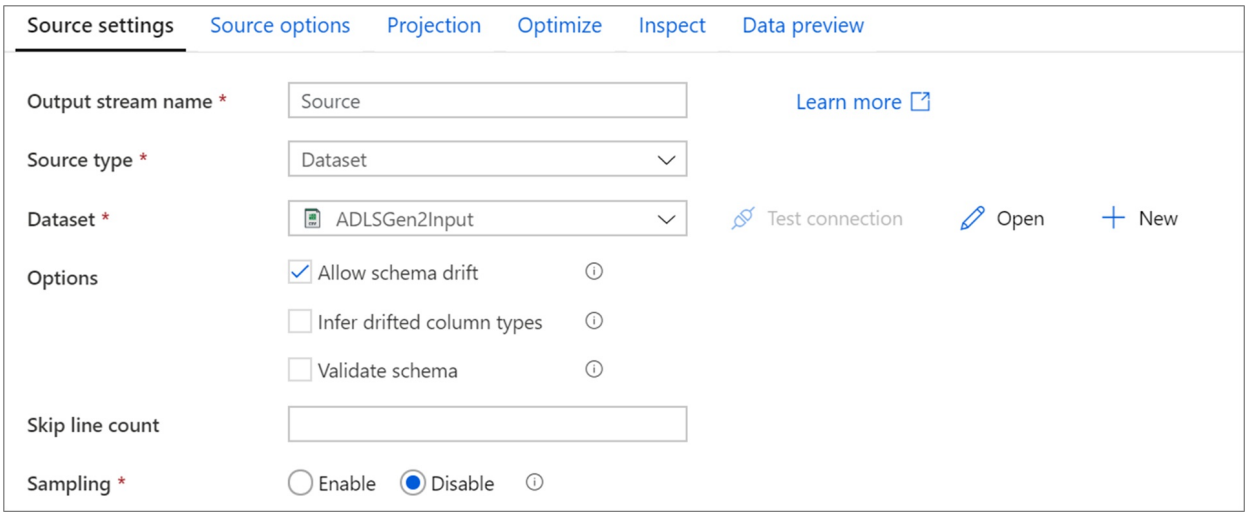
Configuration panel

The configuration panel shows the settings specific to the currently selected transformation. If no transformation is selected, it shows the data flow. In the overall data flow configuration, you can add parameters via the **Parameters** tab. For more information, see Data flow parameters.

Each transformation contains at least four configuration tabs.

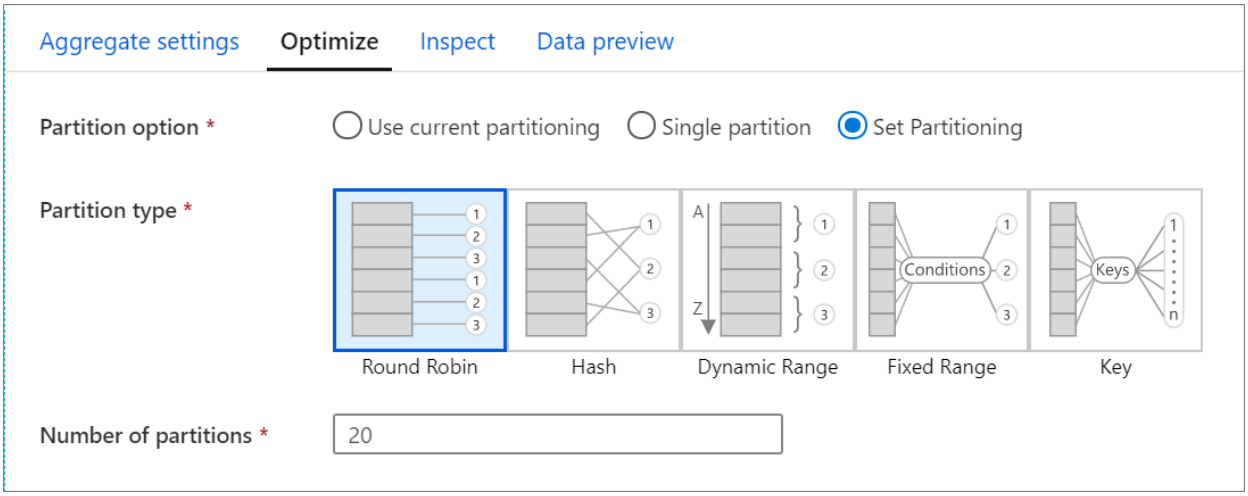
Transformation settings

The first tab in each transformation's configuration pane contains the settings specific to that transformation. For more information, see that transformation's documentation page.



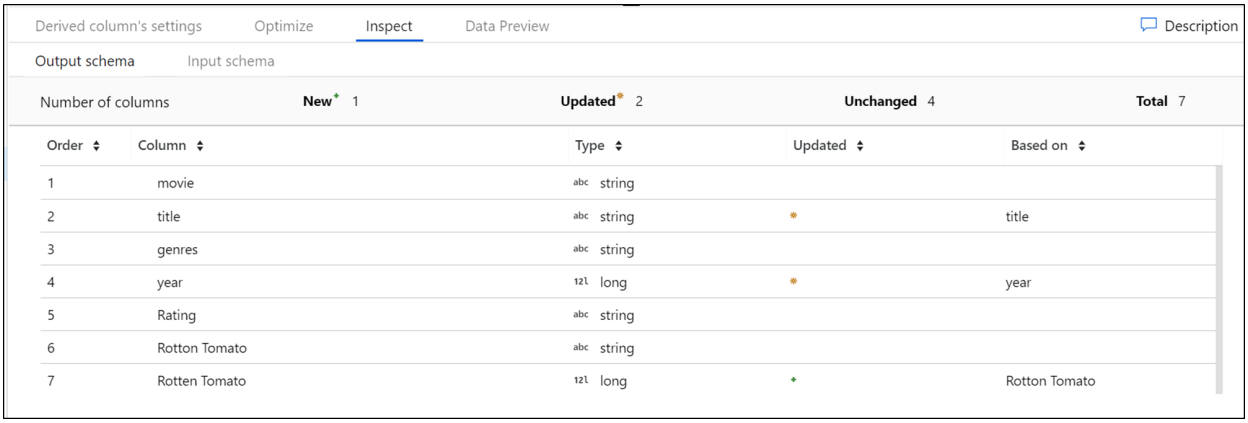
Optimize

The **Optimize** tab contains settings to configure partitioning schemes. To learn more about how to optimize your data flows, see the mapping data flow performance guide.



Inspect

The **Inspect** tab provides a view into the metadata of the data stream that you're transforming. You can see column counts, the columns changed, the columns added, data types, the column order, and column references. **Inspect** is a read-only view of your metadata. You don't need to have debug mode enabled to see metadata in the **Inspect** pane.



As you change the shape of your data through transformations, you'll see the metadata changes flow in the **Inspect** pane. If there isn't a defined schema in your source transformation, then metadata won't be visible in the **Inspect** pane. Lack of metadata is common in schema drift scenarios.

Data preview

If debug mode is on, the **Data Preview** tab gives you an interactive snapshot of the data at each transform. For more information, see Data preview in debug mode.

Top bar

The top bar contains actions that affect the whole data flow, like validation and debug settings. You can view the underlying JSON code and data flow script of your transformation logic as well.

Available transformations

View the mapping data flow transformation overview to get a list of available transformations.

Data flow activity

Data flows are operationalized within Azure Synapse Analytics pipelines using the data flow activity. All a user has to do is specify which integration runtime to use and pass in parameter values. For more information, learn about the Azure integration runtime.

Debug mode

Debug mode allows you to interactively see the results of each transformation step while you build and debug your data flows. The debug session can be used both in when building your data flow logic and running pipeline debug runs with data flow activities. To learn more, see the debug mode documentation.

Monitoring data flows

Data flow integrates with existing Azure Synapse Analytics monitoring capabilities. To learn how to understand data flow monitoring output, see monitoring mapping data flows.

The Azure Synapse Analytics team has created a performance tuning guide to help you optimize the execution time of your data flows after building your business logic.

Next steps

- Learn how to create a source transformation.
- Learn how to build your data flows in debug mode.

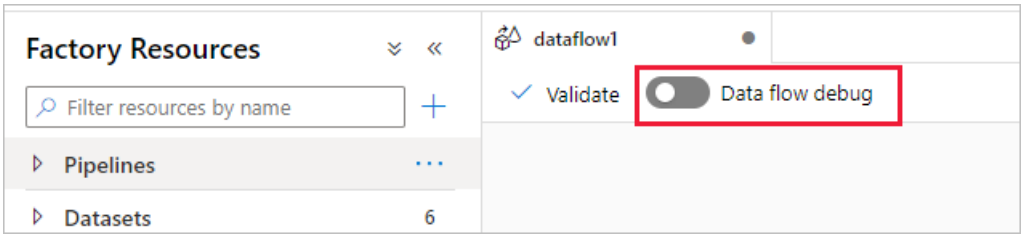
Mapping data flow Debug Mode

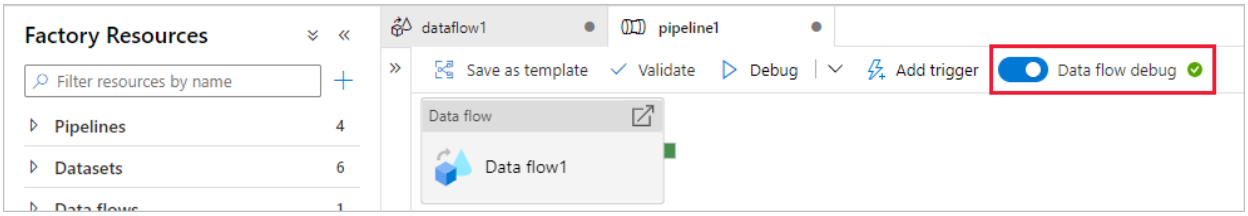
8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

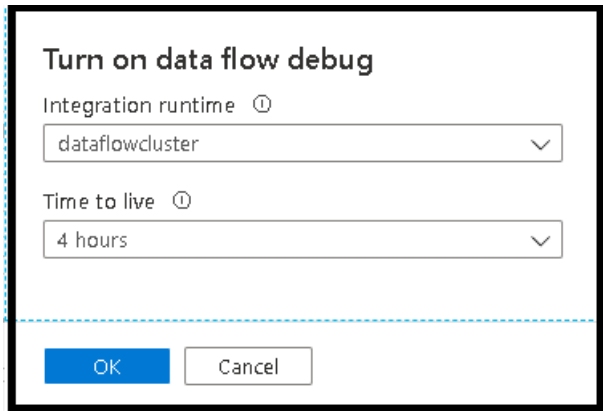
Overview

Azure Data Factory and Synapse Analytics mapping data flow's debug mode allows you to interactively watch the data shape transform while you build and debug your data flows. The debug session can be used both in Data Flow design sessions as well as during pipeline debug execution of data flows. To turn on debug mode, use the **Data Flow Debug** button in the top bar of data flow canvas or pipeline canvas when you have data flow activities.





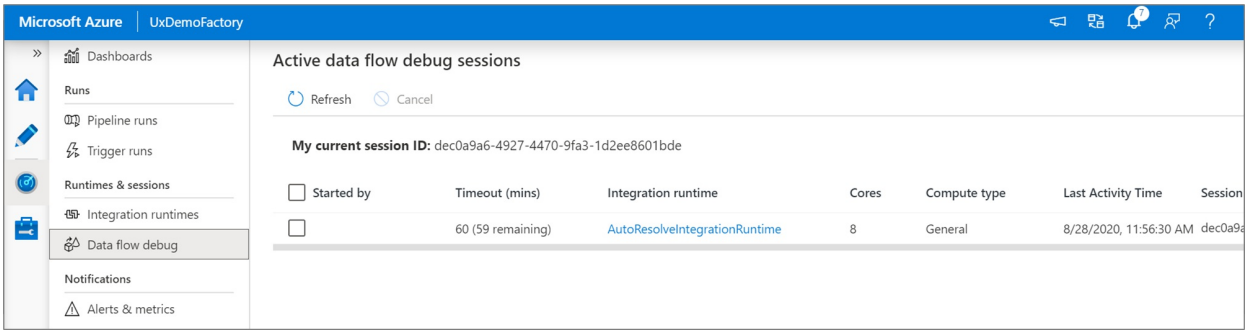
Once you turn on the slider, you will be prompted to select which integration runtime configuration you wish to use. If AutoResolveIntegrationRuntime is chosen, a cluster with eight cores of general compute with a default 60-minute time to live will be spun up. If you'd like to allow for more idle team before your session times out, you can choose a higher TTL setting. For more information on data flow integration runtimes, see Integration Runtime performance.



When Debug mode is on, you'll interactively build your data flow with an active Spark cluster. The session will close once you turn debug off. You should be aware of the hourly charges incurred by Data Factory during the time that you have the debug session turned on.

In most cases, it's a good practice to build your Data Flows in debug mode so that you can validate your business logic and view your data transformations before publishing your work. Use the "Debug" button on the pipeline panel to test your data flow in a pipeline.

- Azure Data Factory
- Synapse Analytics



> **NOTE**
>
> Every debug session that a user starts from their browser UI is a new session with its own Spark cluster. You can use the monitoring view for debug sessions above to view and manage debug sessions. You are charged for every hour that each debug session is executing including the TTL time.

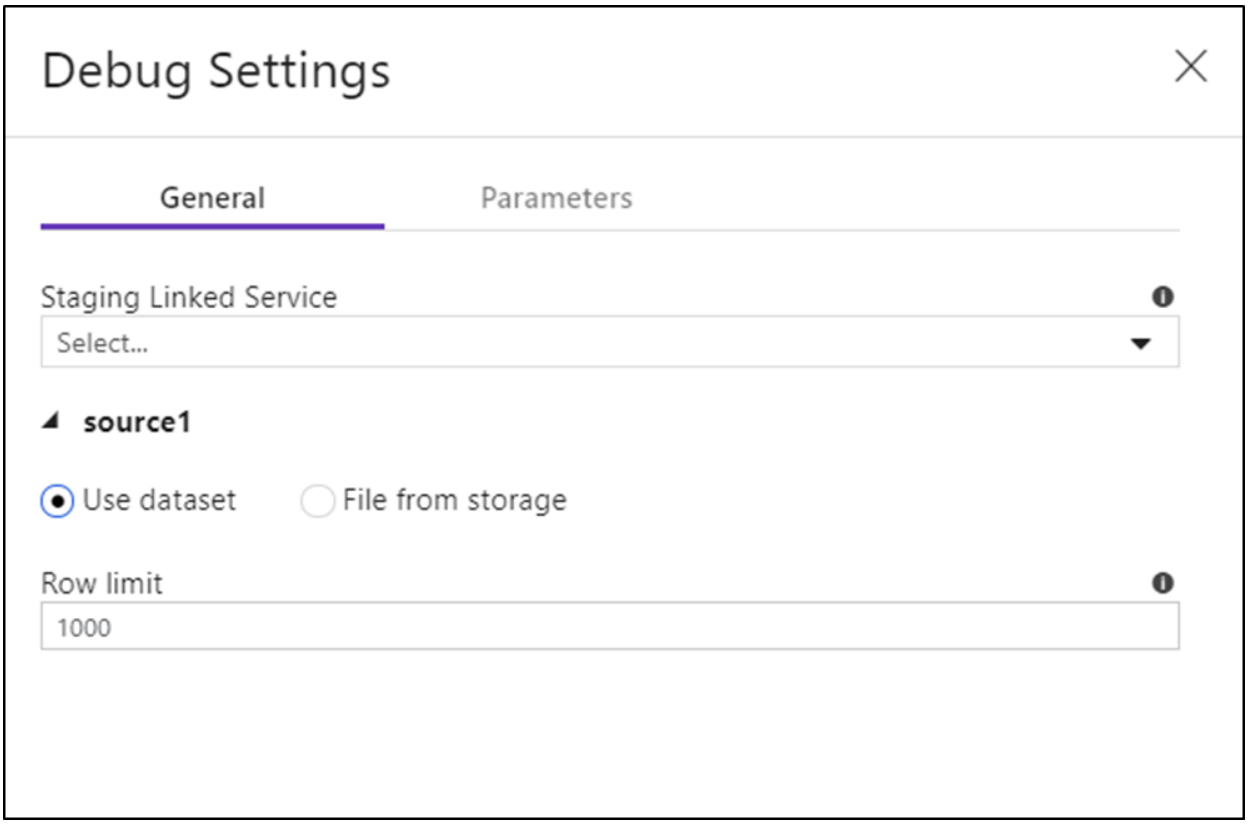
Cluster status

The cluster status indicator at the top of the design surface turns green when the cluster is ready for debug. If your cluster is already warm, then the green indicator will appear almost instantly. If your cluster wasn't already running when you entered debug mode, then the Spark cluster will perform a cold boot. The indicator will spin until the environment is ready for interactive debugging.

When you are finished with your debugging, turn the Debug switch off so that your Spark cluster can terminate and you'll no longer be billed for debug activity.

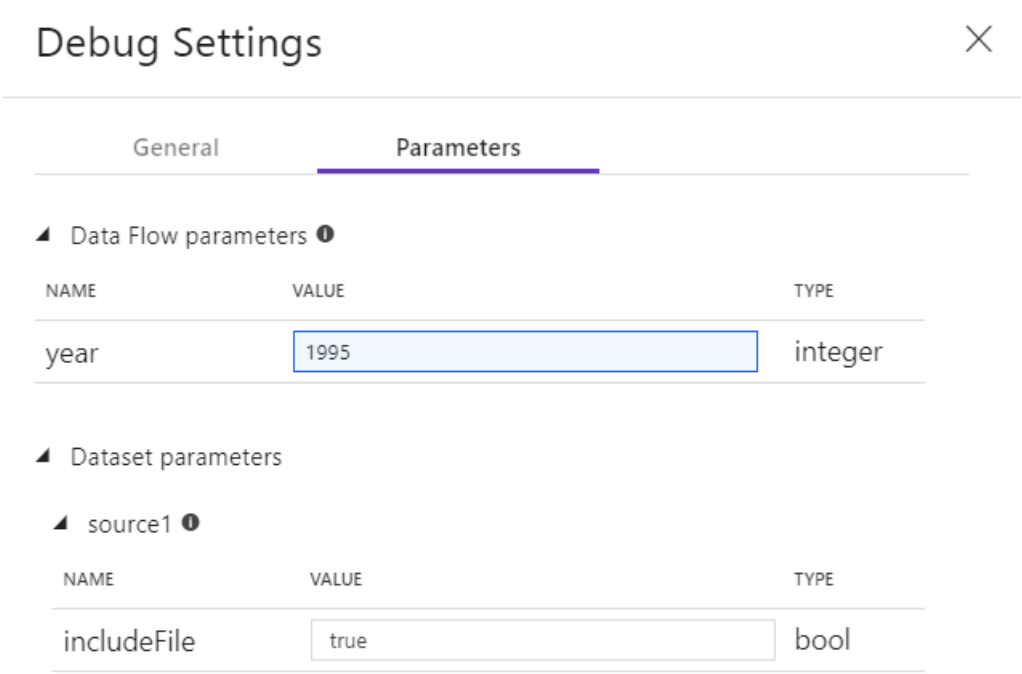
Debug settings

Once you turn on debug mode, you can edit how a data flow previews data. Debug settings can be edited by clicking "Debug Settings" on the Data Flow canvas toolbar. You can select the row limit or file source to use for each of your Source transformations here. The row limits in this setting are only for the current debug session. You can also select the staging linked service to be used for an Azure Synapse Analytics source.



If you have parameters in your Data Flow or any of its referenced datasets, you can specify what values to use during debugging by selecting the **Parameters** tab.

Use the sampling settings here to point to sample files or sample tables of data so that you do not have to change your source datasets. By using a sample file or table here, you can maintain the same logic and property settings in your data flow while testing against a subset of data.

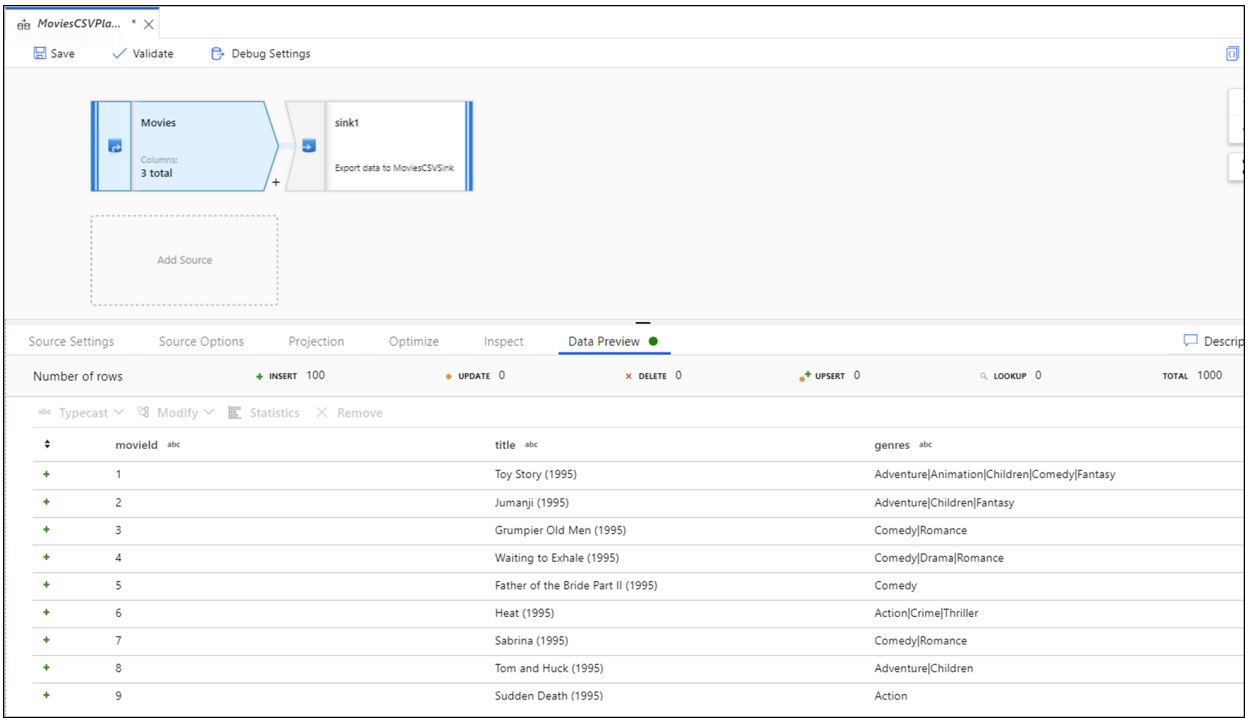


The default IR used for debug mode in data flows is a small 4-core single worker node with a 4-core single driver node. This works fine with smaller samples of data when testing your data flow logic. If you expand the row limits in your debug settings during data preview or set a higher number of sampled rows in your source during pipeline debug, then you may wish to consider setting a larger compute environment in a new Azure

Integration Runtime. Then you can restart your debug session using the larger compute environment.

Data preview

With debug on, the Data Preview tab will light-up on the bottom panel. Without debug mode on, Data Flow will show you only the current metadata in and out of each of your transformations in the Inspect tab. The data preview will only query the number of rows that you have set as your limit in your debug settings. Click **Refresh** to update the data preview based on your current transformations. If your source data has changed, then click the Refresh > Refetch from source.



> **NOTE**
> File sources only limit the rows that you see, not the rows being read. For very large datasets, it is recommended that you take a small portion of that file and use it for your testing. You can select a temporary file in Debug Settings for each source that is a file dataset type.

When running in Debug Mode in Data Flow, your data will not be written to the Sink transform. A Debug session is intended to serve as a test harness for your transformations. Sinks are not required during debug and are ignored in your data flow. If you wish to test writing the data in your Sink, execute the Data Flow from a pipeline and use the Debug execution from a pipeline.

Data Preview is a snapshot of your transformed data using row limits and data sampling from data frames in Spark memory. Therefore, the sink drivers are not utilized or tested in this scenario.

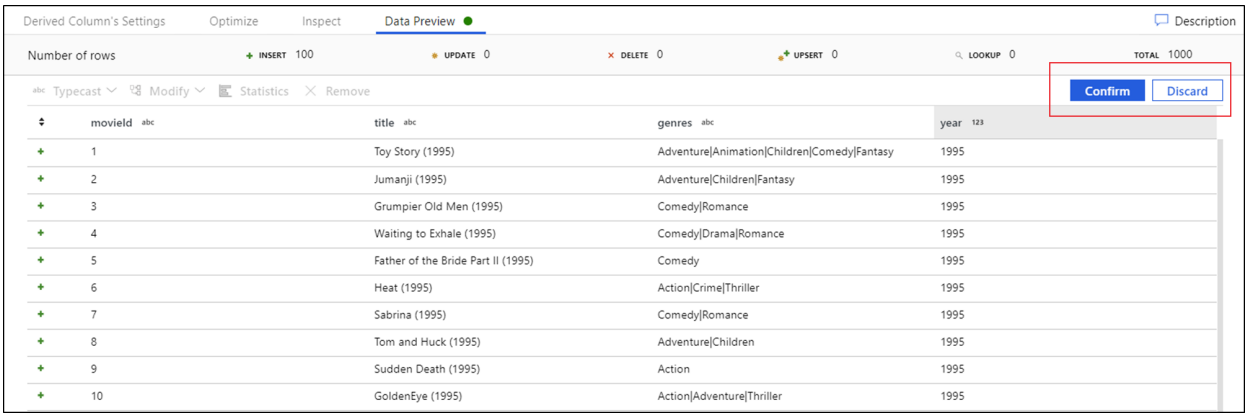
Testing join conditions

When unit testing Joins, Exists, or Lookup transformations, make sure that you use a small set of known data for your test. You can use the Debug Settings option above to set a temporary file to use for your testing. This is needed because when limiting or sampling rows from a large dataset, you cannot predict which rows and which keys will be read into the flow for testing. The result is non-deterministic, meaning that your join conditions may fail.

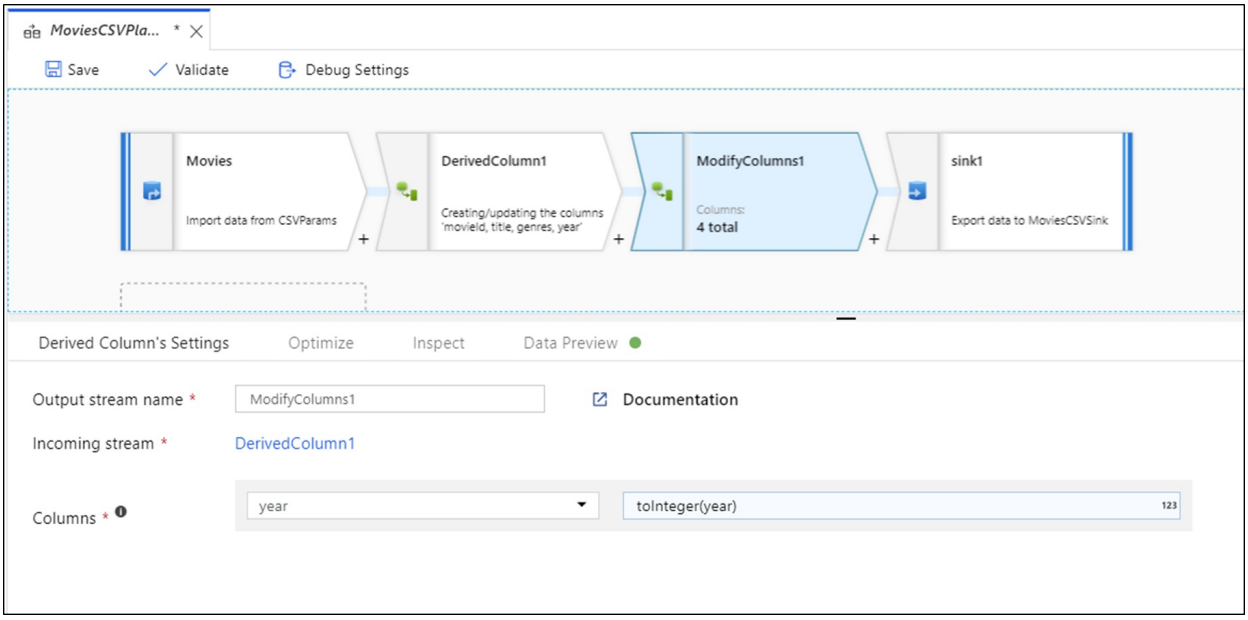
Quick actions

Once you see the data preview, you can generate a quick transformation to typecast, remove, or do a modification on a column. Click on the column header and then select one of the options from the data preview toolbar.

Once you select a modification, the data preview will immediately refresh. Click **Confirm** in the top-right corner to generate a new transformation.



Typecast and **Modify** will generate a Derived Column transformation and **Remove** will generate a Select transformation.

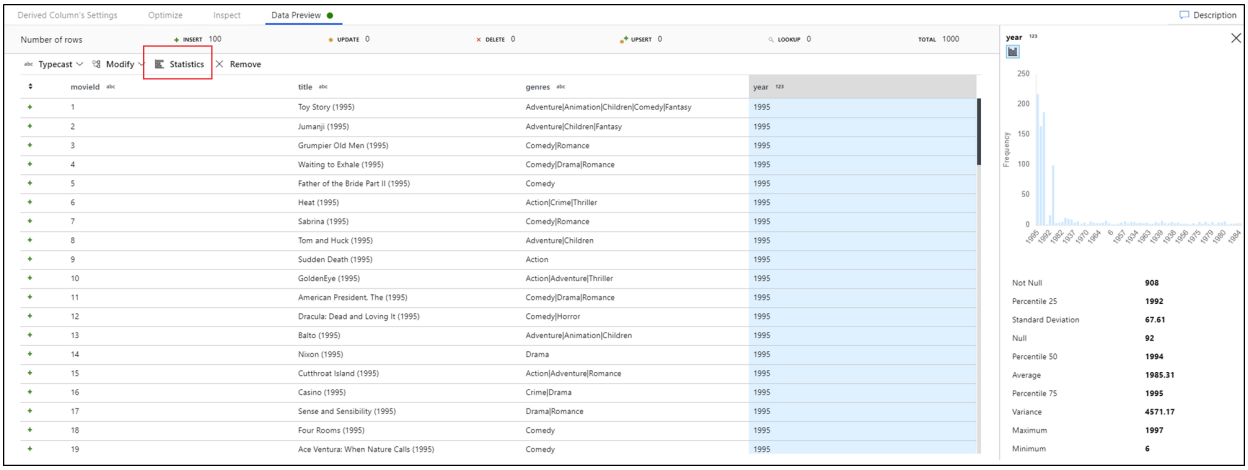


> **NOTE**
>
> If you edit your Data Flow, you need to re-fetch the data preview before adding a quick transformation.

Data profiling

Selecting a column in your data preview tab and clicking **Statistics** in the data preview toolbar will pop up a chart on the far-right of your data grid with detailed statistics about each field. The service will make a determination based upon the data sampling of which type of chart to display. High-cardinality fields will default

to NULL/NOT NULL charts while categorical and numeric data that has low cardinality will display bar charts showing data value frequency. You'll also see max/len length of string fields, min/max values in numeric fields, standard dev, percentiles, counts, and average.



Next steps

- Once you're finished building and debugging your data flow, execute it from a pipeline.
- When testing your pipeline with a data flow, use the pipeline Debug run execution option.

Schema drift in mapping data flow

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Schema drift is the case where your sources often change metadata. Fields, columns, and, types can be added, removed, or changed on the fly. Without handling for schema drift, your data flow becomes vulnerable to upstream data source changes. Typical ETL patterns fail when incoming columns and fields change because they tend to be tied to those source names.

To protect against schema drift, it's important to have the facilities in a data flow tool to allow you, as a Data Engineer, to:

- Define sources that have mutable field names, data types, values, and sizes
- Define transformation parameters that can work with data patterns instead of hard-coded fields and values
- Define expressions that understand patterns to match incoming fields, instead of using named fields

Azure Data Factory natively supports flexible schemas that change from execution to execution so that you can build generic data transformation logic without the need to recompile your data flows.

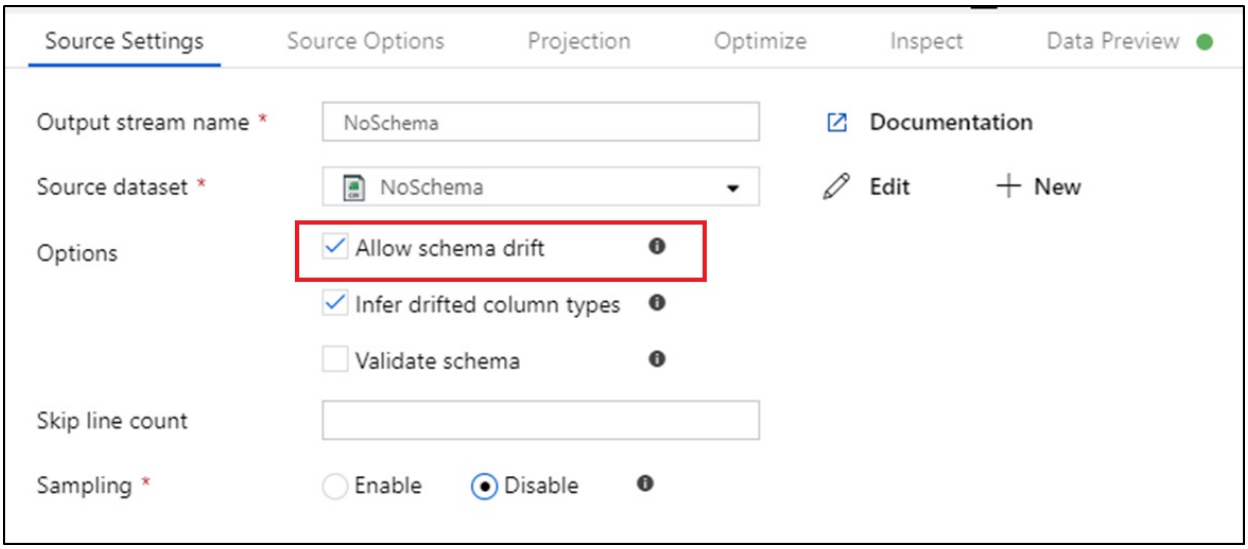
You need to make an architectural decision in your data flow to accept schema drift throughout your flow. When you do this, you can protect against schema changes from the sources. However, you'll lose early-binding of your columns and types throughout your data flow. Azure Data Factory treats schema drift flows as late-binding flows, so when you build your transformations, the drifted column names won't be available to you in the schema views throughout the flow.

This video provides an introduction to some of the complex solutions that you can build easily in Azure Data Factory or Synapse Analytics pipelines with data flow's **schema drift** feature. In this example, we build reusable patterns based on flexible database schemas:

Schema drift in source

Columns coming into your data flow from your source definition are defined as "drifted" when they are not present in your source projection. You can view your source projection from the projection tab in the source transformation. When you select a dataset for your source, the service will automatically take the schema from the dataset and create a projection from that dataset schema definition.

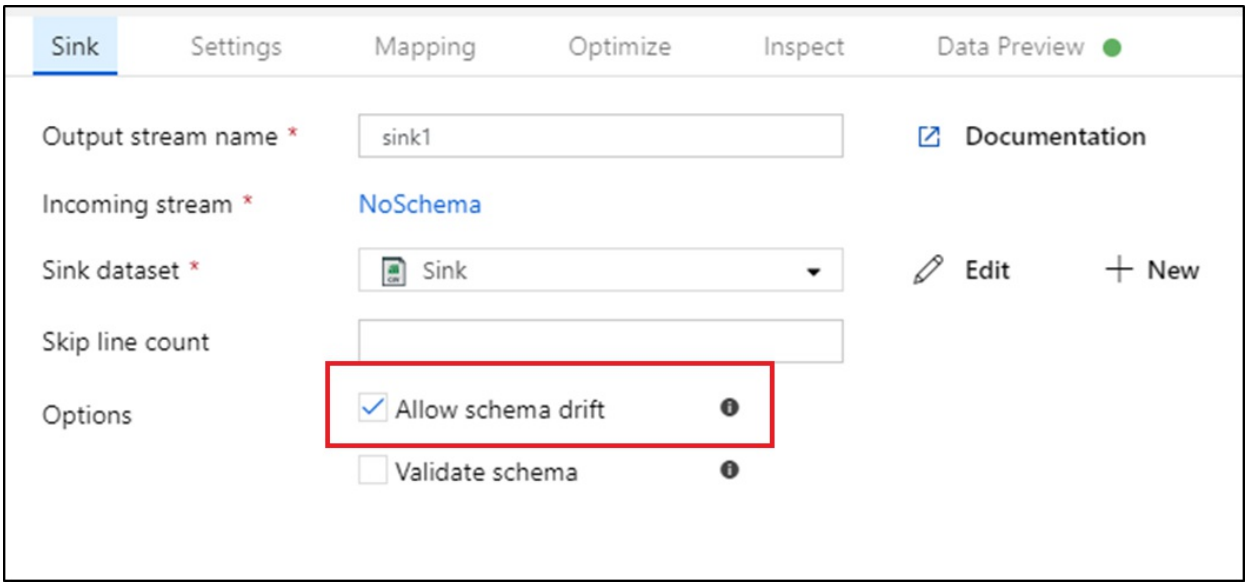
In a source transformation, schema drift is defined as reading columns that aren't defined your dataset schema. To enable schema drift, check **Allow schema drift** in your source transformation.



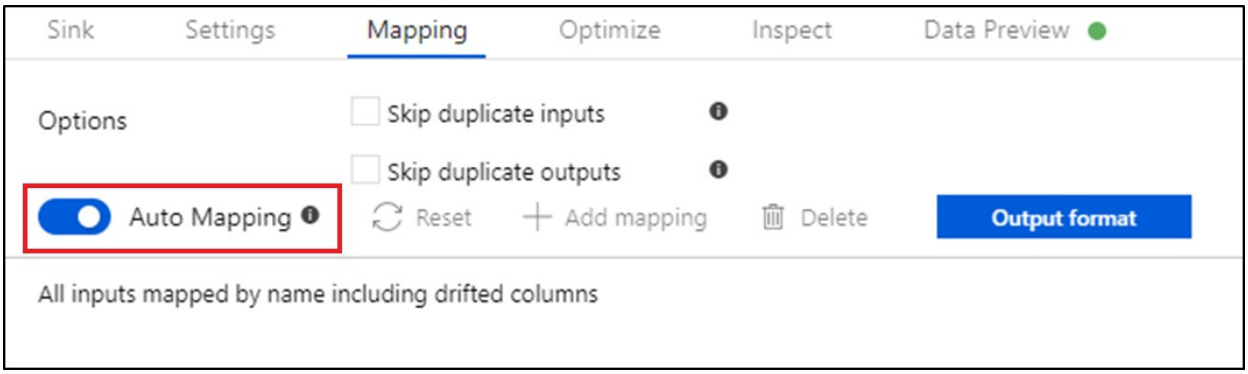
When schema drift is enabled, all incoming fields are read from your source during execution and passed through the entire flow to the Sink. By default, all newly detected columns, known as *drifted columns*, arrive as a string data type. If you wish for your data flow to automatically infer data types of drifted columns, check **Infer drifted column types** in your source settings.

Schema drift in sink

In a sink transformation, schema drift is when you write additional columns on top of what is defined in the sink data schema. To enable schema drift, check **Allow schema drift** in your sink transformation.



If schema drift is enabled, make sure the **Auto-mapping** slider in the Mapping tab is turned on. With this slider on, all incoming columns are written to your destination. Otherwise you must use rule-based mapping to write drifted columns.



Transforming drifted columns

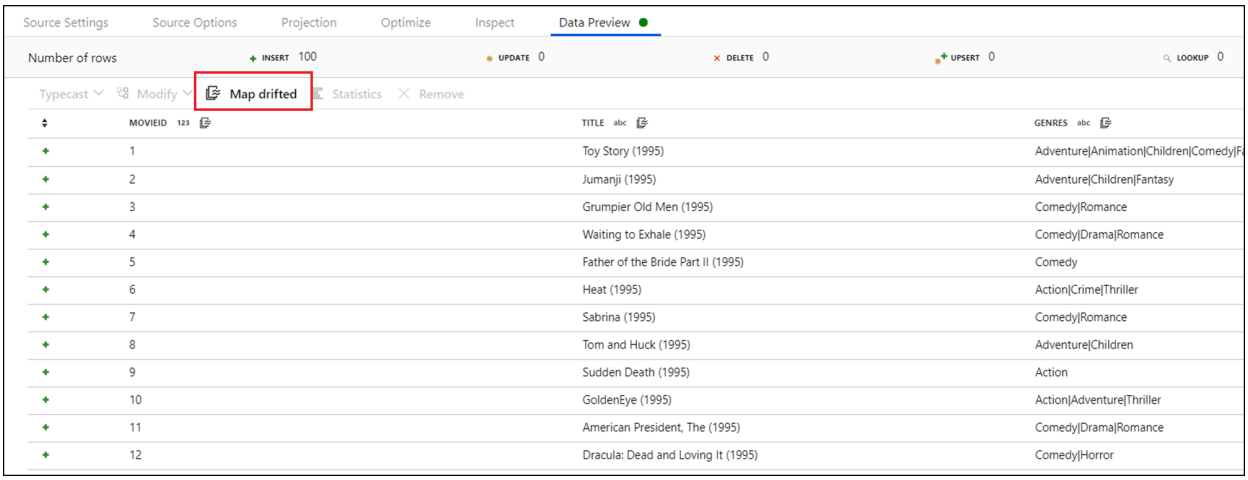
When your data flow has drifted columns, you can access them in your transformations with the following methods:

- Use the `byPosition` and `byName` expressions to explicitly reference a column by name or position number.
- Add a column pattern in a Derived Column or Aggregate transformation to match on any combination of name, stream, position, origin, or type
- Add rule-based mapping in a Select or Sink transformation to match drifted columns to columns aliases via a pattern

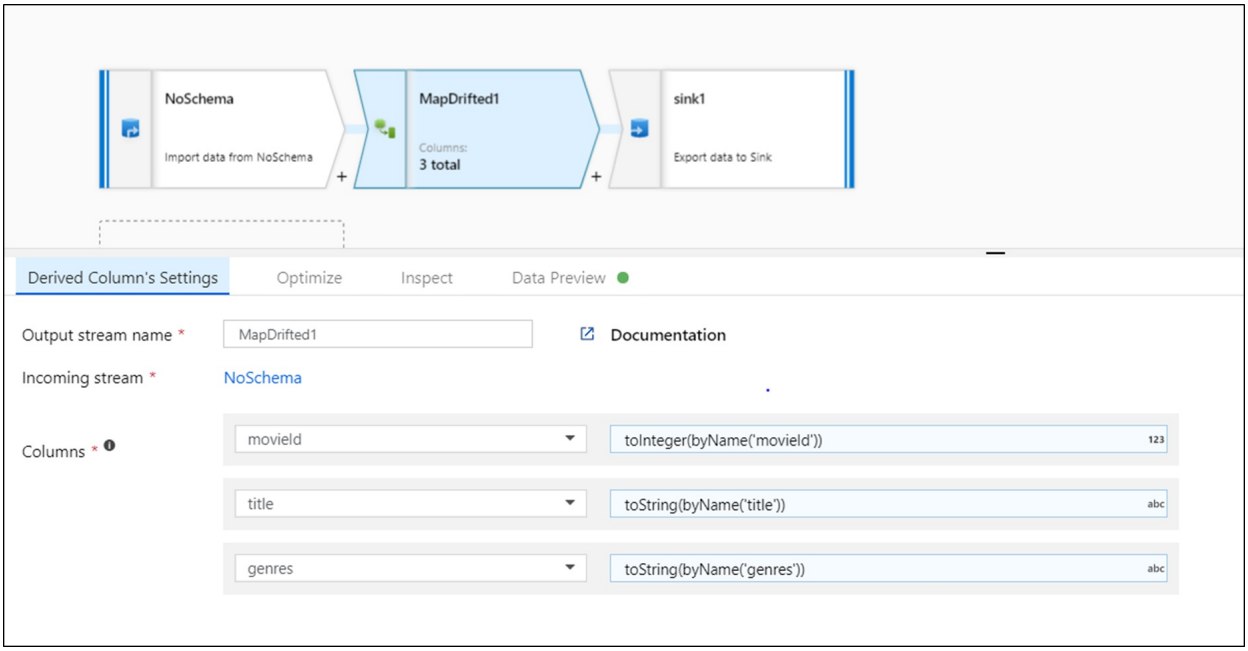
For more information on how to implement column patterns, see Column patterns in mapping data flow.

Map drifted columns quick action

To explicitly reference drifted columns, you can quickly generate mappings for these columns via a data preview quick action. Once debug mode is on, go to the Data Preview tab and click **Refresh** to fetch a data preview. If data factory detects that drifted columns exist, you can click **Map Drifted** and generate a derived column that allows you to reference all drifted columns in schema views downstream.



In the generated Derived Column transformation, each drifted column is mapped to its detected name and data type. In the above data preview, the column 'movieId' is detected as an integer. After **Map Drifted** is clicked, movieId is defined in the Derived Column as `toInteger(byName('movieId'))` and included in schema views in downstream transformations.



Next steps

In the Data Flow Expression Language, you'll find additional facilities for column patterns and schema drift including "byName" and "byPosition".

Using column patterns in mapping data flow

8/19/2022 • 4 minutes to read • Edit Online

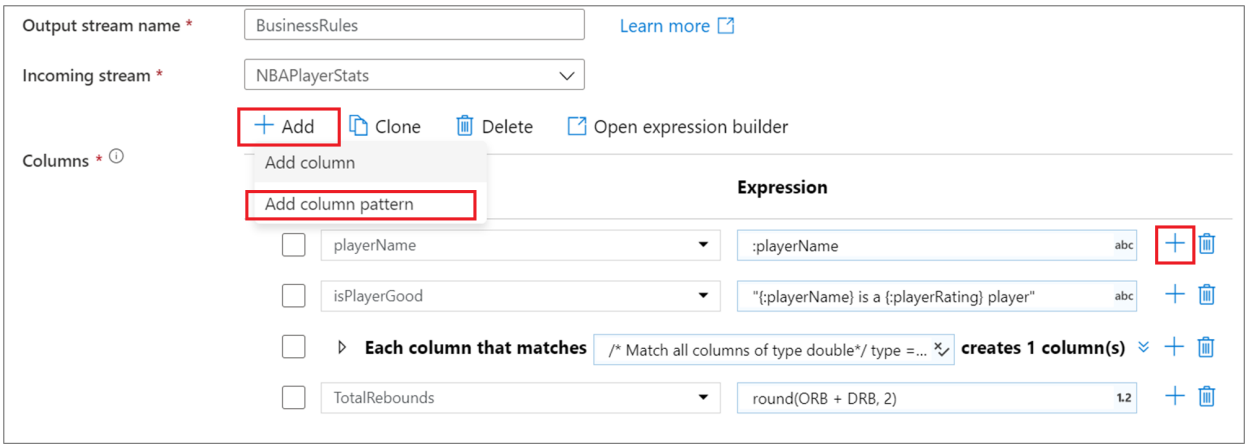
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Several mapping data flow transformations allow you to reference template columns based on patterns instead of hard-coded column names. This matching is known as *column patterns*. You can define patterns to match columns based on name, data type, stream, origin, or position instead of requiring exact field names. There are two scenarios where column patterns are useful:

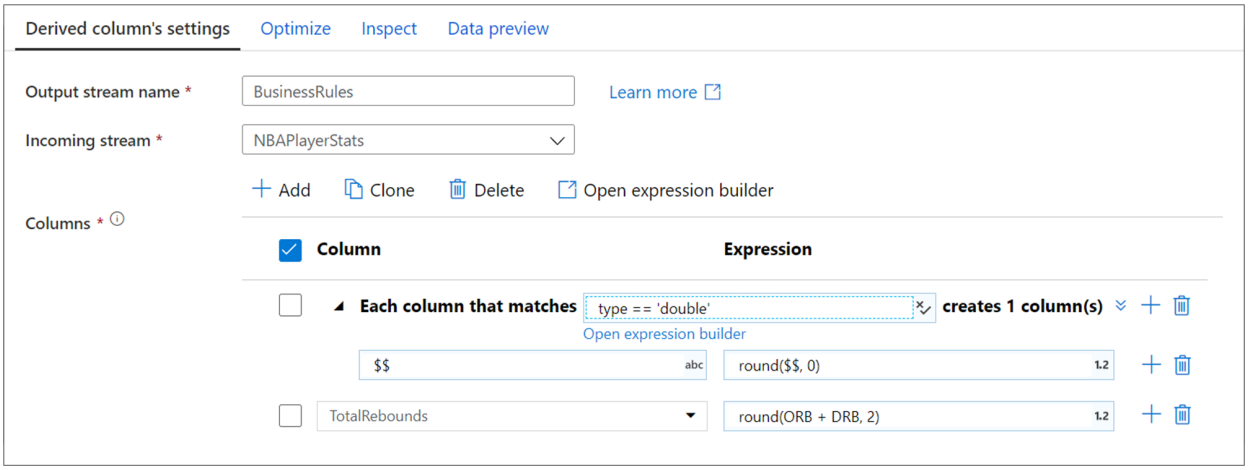
- If incoming source fields change often such as the case of changing columns in text files or NoSQL databases. This scenario is known as schema drift.
- If you wish to do a common operation on a large group of columns. For example, wanting to cast every column that has 'total' in its column name into a double.

Column patterns in derived column and aggregate

To add a column pattern in a derived column, aggregate, or window transformation, click on **Add** above the column list or the plus icon next to an existing derived column. Choose **Add column pattern**.



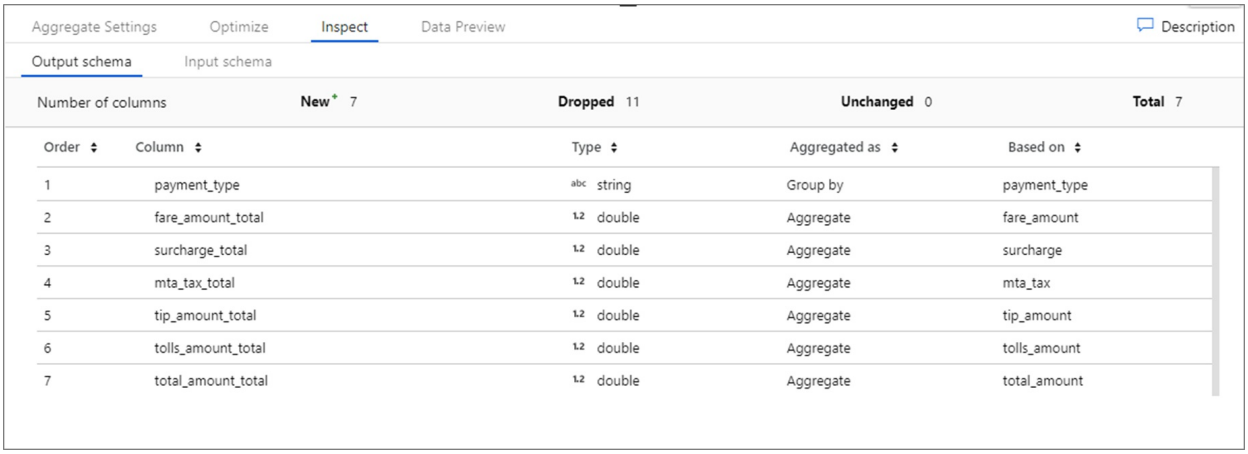
Use the expression builder to enter the match condition. Create a boolean expression that matches columns based on the `name`, `type`, `stream`, `origin`, and `position` of the column. The pattern will affect any column, drifted or defined, where the condition returns true.



The above column pattern matches every column of type double and creates one derived column per match. By

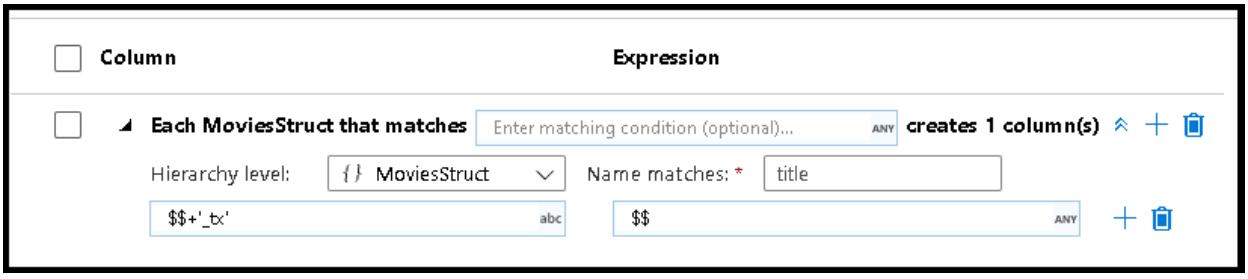
stating `$$` as the column name field, each matched column is updated with the same name. The value of the each column is the existing value rounded to two decimal points.

To verify your matching condition is correct, you can validate the output schema of defined columns in the **Inspect** tab or get a snapshot of the data in the **Data preview** tab.



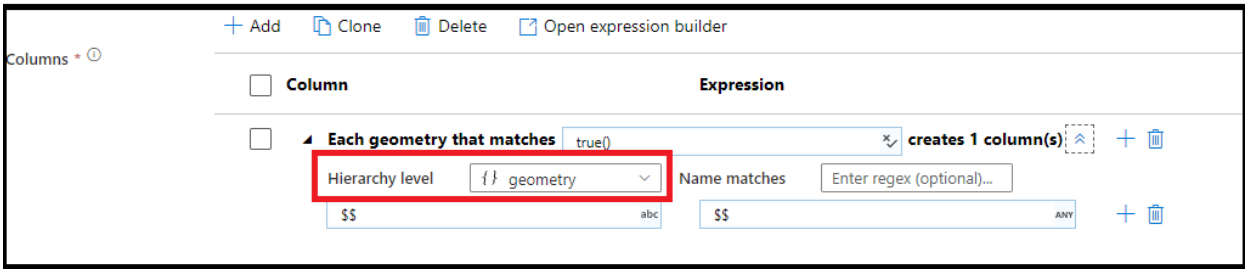
Hierarchical pattern matching

You can build pattern matching inside of complex hierarchical structures as well. Expand the section `Each MoviesStruct that matches` where you will be prompted for each hierarchy in your data stream. You can then build matching patterns for properties within that chosen hierarchy.



Flattening structures

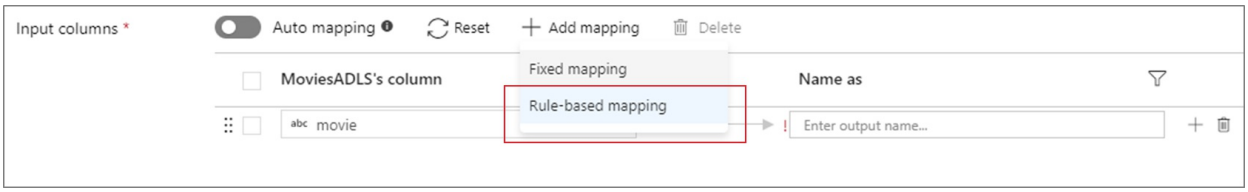
When your data has complex structures like arrays, hierarchical structures, and maps, you can use the Flatten transformation to unroll arrays and denormalize your data. For structures and maps, use the derived column transformation with column patterns to form your flattened relational table from the hierarchies. You can use the column patterns that would look like this sample, which flattens the geography hierarchy into a relational table form:



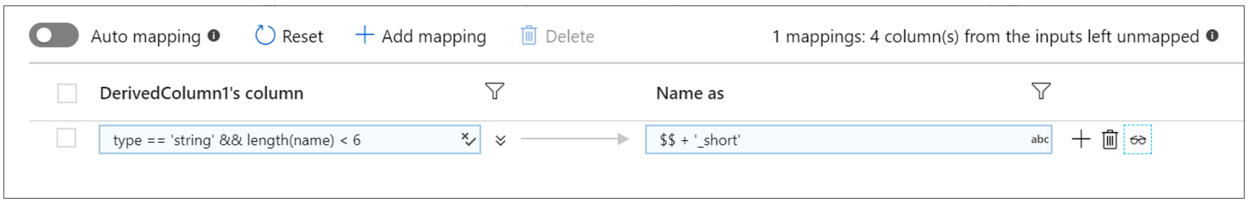
Rule-based mapping in select and sink

When mapping columns in source and select transformations, you can add either fixed mapping or rule-based mappings. Match based on the `name`, `type`, `stream`, `origin`, and `position` of columns. You can have any combination of fixed and rule-based mappings. By default, all projections with greater than 50 columns will default to a rule-based mapping that matches on every column and outputs the inputted name.

To add a rule-based mapping, click **Add mapping** and select **Rule-based mapping**.



Each rule-based mapping requires two inputs: the condition on which to match by and what to name each mapped column. Both values are inputted via the expression builder. In the left expression box, enter your boolean match condition. In the right expression box, specify what the matched column will be mapped to.

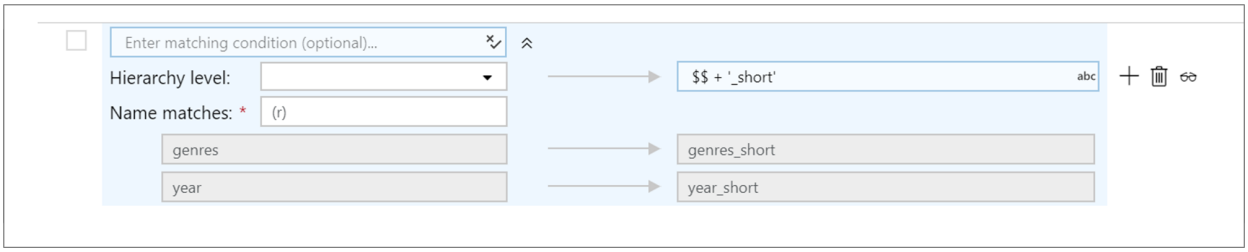


Use `$$` syntax to reference the input name of a matched column. Using the above image as an example, say a user wants to match on all string columns whose names are shorter than six characters. If one incoming column was named `test`, the expression `$$ + '_short'` will rename the column `test_short`. If that's the only mapping that exists, all columns that don't meet the condition will be dropped from the outputted data.

Patterns match both drifted and defined columns. To see which defined columns are mapped by a rule, click the eyeglasses icon next to the rule. Verify your output using data preview.

Regex mapping

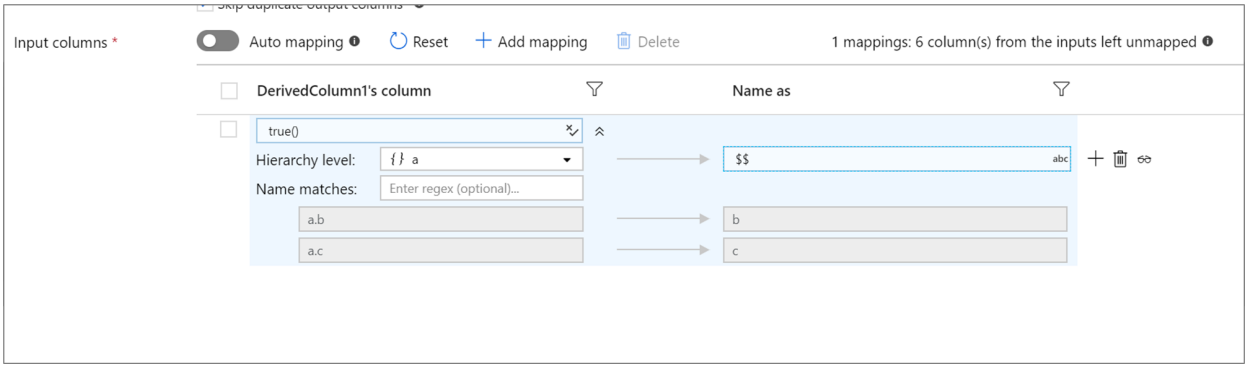
If you click the downward chevron icon, you can specify a regex-mapping condition. A regex-mapping condition matches all column names that match the specified regex condition. This can be used in combination with standard rule-based mappings.



The above example matches on regex pattern `(r)` or any column name that contains a lower case r. Similar to standard rule-based mapping, all matched columns are altered by the condition on the right using `$$` syntax.

Rule-based hierarchies

If your defined projection has a hierarchy, you can use rule-based mapping to map the hierarchies subcolumns. Specify a matching condition and the complex column whose subcolumns you wish to map. Every matched subcolumn will be outputted using the 'Name as' rule specified on the right.



The above example matches on all subcolumns of complex column `a`. `a` contains two subcolumns `b` and `c`.

The output schema will include two columns `b` and `c` as the 'Name as' condition is `$$`.

Pattern matching expression values

- `$$` translates to the name or value of each match at run time. Think of `$$` as equivalent to `this`
- `$0` translates to the current column name match at run time for scalar types. For hierarchical types, `$0` represents the current matched column hierarchy path.
- `name` represents the name of each incoming column
- `type` represents the data type of each incoming column. The list of data types in the data flow type system can be found here.
- `stream` represents the name associated with each stream, or transformation in your flow
- `position` is the ordinal position of columns in your data flow
- `origin` is the transformation where a column originated or was last updated

Next steps

- Learn more about the mapping data flow expression language for data transformations
- Use column patterns in the sink transformation and select transformation with rule-based mapping

Monitor Data Flows

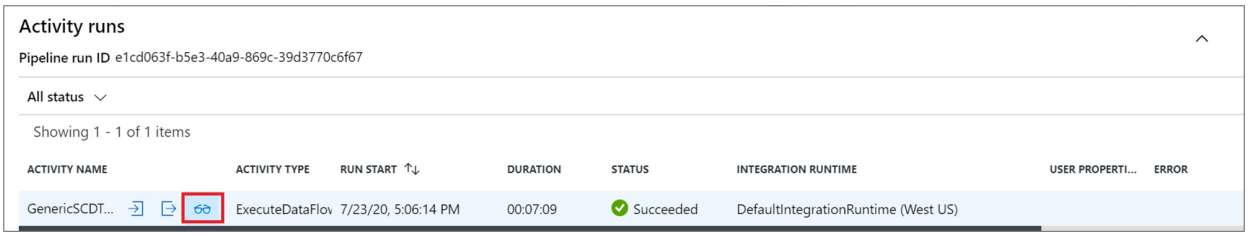
8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

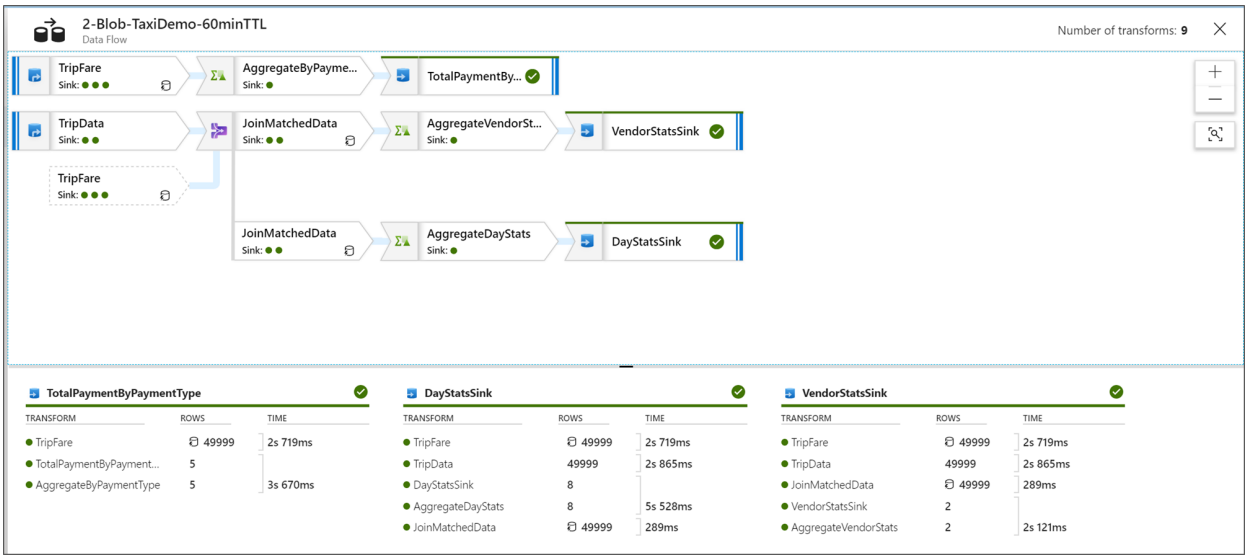
After you have completed building and debugging your data flow, you want to schedule your data flow to execute on a schedule within the context of a pipeline. You can schedule the pipeline using Triggers. For testing and debugging you data flow from a pipeline, you can use the Debug button on the toolbar ribbon or Trigger Now option from the Pipeline Builder to execute a single-run execution to test your data flow within the pipeline context.

When you execute your pipeline, you can monitor the pipeline and all of the activities contained in the pipeline including the Data Flow activity. Click on the monitor icon in the left-hand UI panel. You can see a screen similar to the one below. The highlighted icons allow you to drill into the activities in the pipeline, including the Data Flow activity.

You see statistics at this level as well including the run times and status. The Run ID at the activity level is different than the Run ID at the pipeline level. The Run ID at the previous level is for the pipeline. Selecting the eyeglasses gives you deep details on your data flow execution.

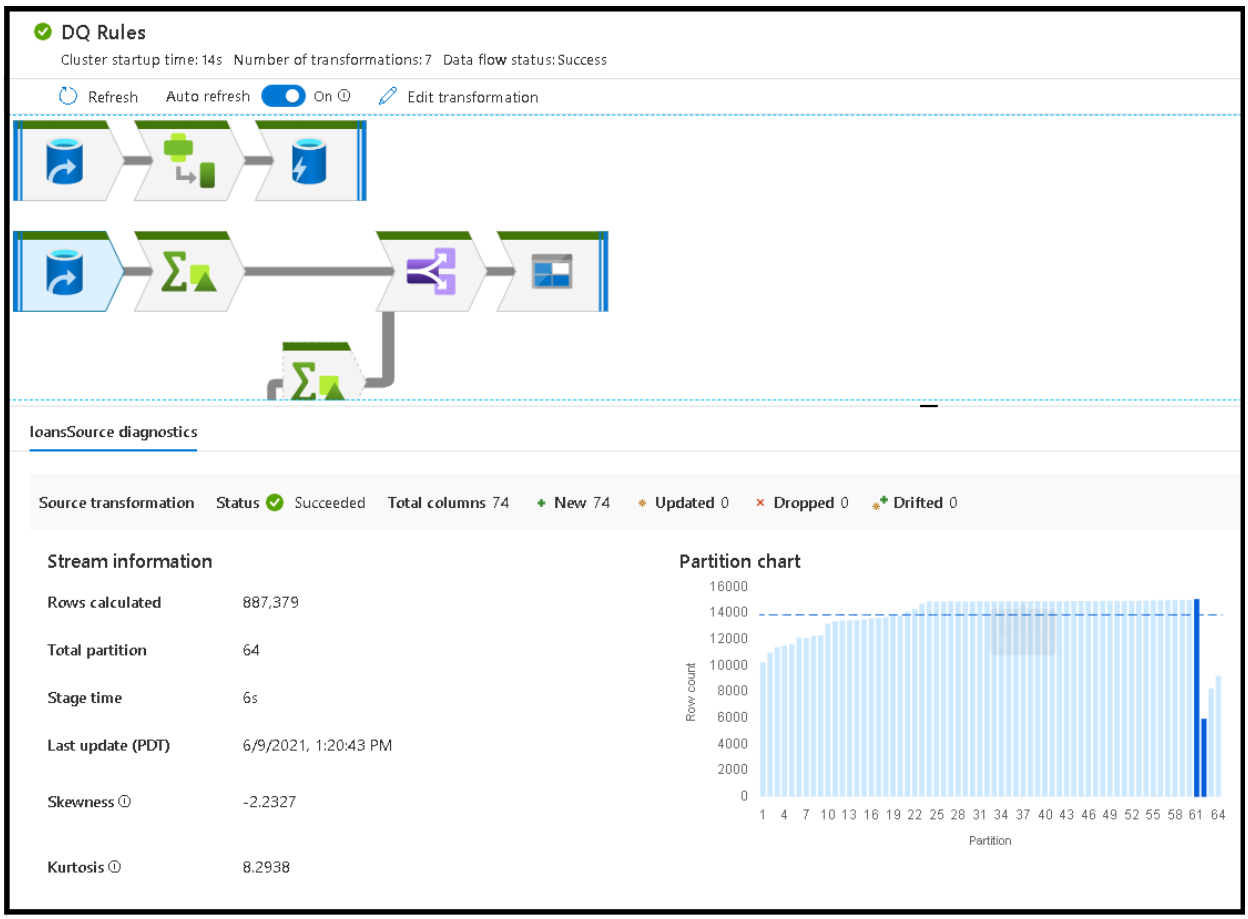


When you're in the graphical node monitoring view, you can see a simplified view-only version of your data flow graph. To see the details view with larger graph nodes that include transformation stage labels, use the zoom slider on the right side of your canvas. You can also use the search button on the right side to find parts of your data flow logic in the graph.



View Data Flow Execution Plans

When your Data Flow is executed in Spark, the service determines optimal code paths based on the entirety of your data flow. Additionally, the execution paths may occur on different scale-out nodes and data partitions. Therefore, the monitoring graph represents the design of your flow, taking into account the execution path of your transformations. When you select individual nodes, you can see "stages" that represent code that was executed together on the cluster. The timings and counts that you see represent those groups or stages as opposed to the individual steps in your design.



- When you select the open space in the monitoring window, the stats in the bottom pane display timing and row counts for each Sink and the transformations that led to the sink data for transformation lineage.
- When you select individual transformations, you receive additional feedback on the right-hand panel that shows partition stats, column counts, skewness (how evenly is the data distributed across partitions), and

kurtosis (how spiky is the data).

- Sorting by *processing time* will help you to identify which stages in your data flow took the most time.
- To find which transformations inside each stage took the most time, sort on *highest processing time*.
- The *rows written* is also sortable as a way to identify which streams inside your data flow are writing the most data.
- When you select the Sink in the node view, you can see column lineage. There are three different methods that columns are accumulated throughout your data flow to land in the Sink. They are:
  - Computed: You use the column for conditional processing or within an expression in your data flow, but don't land it in the Sink
  - Derived: The column is a new column that you generated in your flow, that is, it was not present in the Source
  - Mapped: The column originated from the source and your are mapping it to a sink field
  - Data flow status: The current status of your execution
  - Cluster startup time: Amount of time to acquire the JIT Spark compute environment for your data flow execution
  - Number of transforms: How many transformation steps are being executed in your flow

Total Sink Processing Time vs. Transformation Processing Time

Each transformation stage includes a total time for that stage to complete with each partition execution time totaled together. When you click on the Sink you will see "Sink Processing Time". This time includes the total of the transformation time *plus* the I/O time it took to write your data to your destination store. The difference between the Sink Processing Time and the total of the transformation is the I/O time to write the data.

You can also see detailed timing for each partition transformation step if you open the JSON output from your data flow activity in the pipeline monitoring view. The JSON contains millisecond timing for each partition, whereas the UX monitoring view is an aggregate timing of partitions added together:

```
{
    "stage": 4,
    "partitionTimes": [
         14353,
         14914,
         14246,
         14912,
         ...
        ]
}
```

Sink processing time

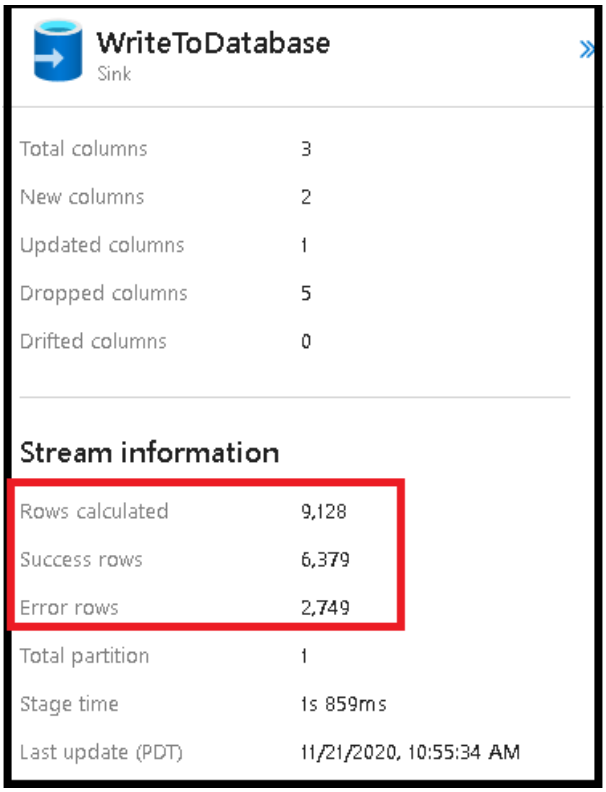
When you select a sink transformation icon in your map, the slide-in panel on the right will show an additional data point called "post processing time" at the bottom. This is the amount time spent executing your job on the Spark cluster *after* your data has been loaded, transformed, and written. This time can include closing connection pools, driver shutdown, deleting files, coalescing files, etc. When you perform actions in your flow like "move files" and "output to single file", you will likely see an increase in the post processing time value.

- Write stage duration: The time to write the data to a staging location for Synapse SQL
- Table operation SQL duration: The time spent moving data from temp tables to target table

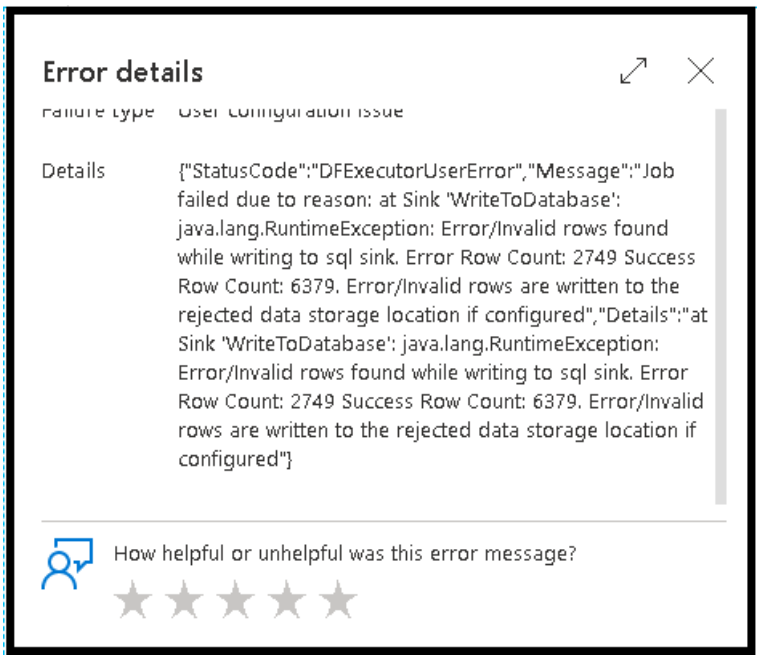
- Pre SQL duration & Post SQL duration: The time spent running pre/post SQL commands
- Pre commands duration & post commands duration: The time spent running any pre/post operations for file based source/sinks. For example move or delete files after processing.
- Merge duration: The time spent merging the file, merge files are used for file based sinks when writing to single file or when "File name as column data" is used. If significant time is spent in this metric, you should avoid using these options.
- Stage time: Total amount of time spent inside of Spark to complete the operation as a stage.
- Temporary staging stable: Name of the temporary table used by data flows to stage data in the database.

Error rows

Enabling error row handling in your data flow sink will be reflected in the monitoring output. When you set the sink to "report success on error", the monitoring output will show the number of success and failed rows when you click on the sink monitoring node.

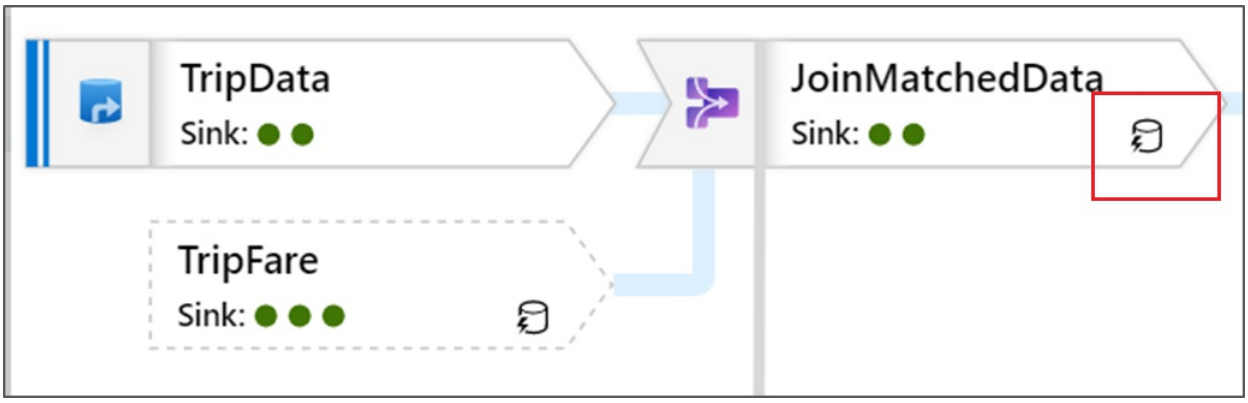


When you select "report failure on error", the same output will be shown only in the activity monitoring output text. This is because the data flow activity will return failure for execution and the detailed monitoring view will be unavailable.



Monitor Icons

This icon means that the transformation data was already cached on the cluster, so the timings and execution path have taken that into account:



You also see green circle icons in the transformation. They represent a count of the number of sinks that data is flowing into.

Mapping data flows performance and tuning guide

8/19/2022 • 5 minutes to read • Edit Online

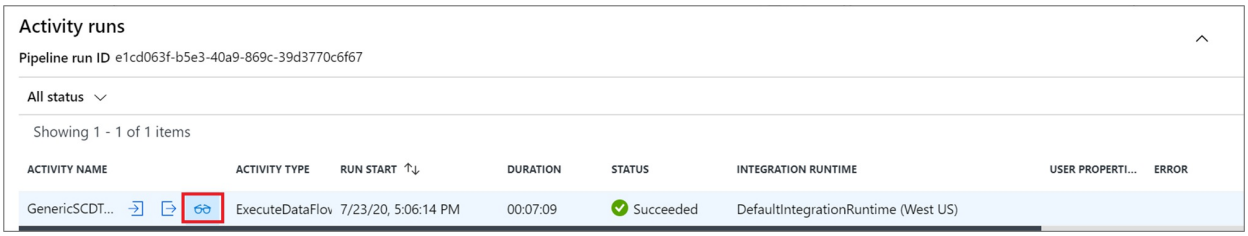
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Mapping data flows in Azure Data Factory and Synapse pipelines provide a code-free interface to design and run data transformations at scale. If you're not familiar with mapping data flows, see the Mapping Data Flow Overview. This article highlights various ways to tune and optimize your data flows so that they meet your performance benchmarks.

Watch the below video to see shows some sample timings transforming data with data flows.

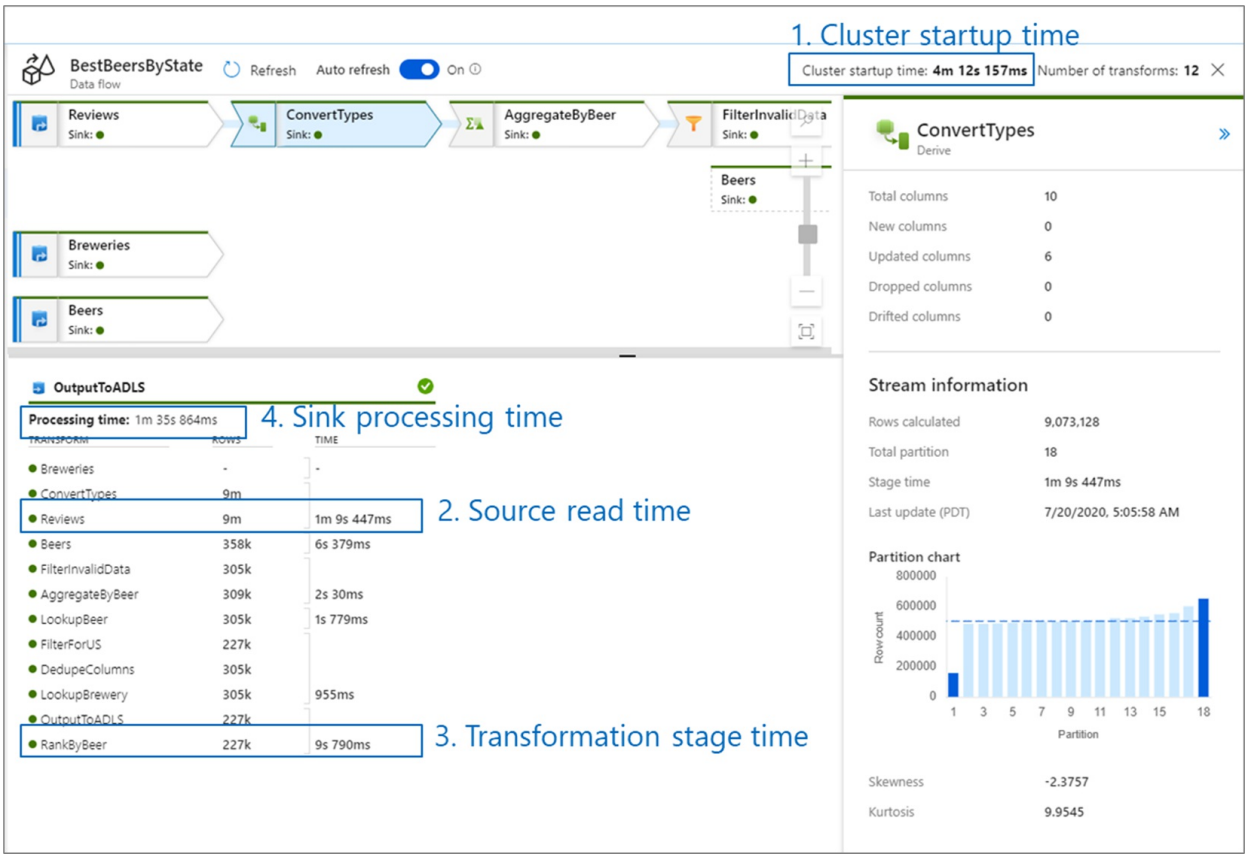
Monitoring data flow performance

Once you verify your transformation logic using debug mode, run your data flow end-to-end as an activity in a pipeline. Data flows are operationalized in a pipeline using the execute data flow activity. The data flow activity has a unique monitoring experience compared to other activities that displays a detailed execution plan and performance profile of the transformation logic. To view detailed monitoring information of a data flow, click on the eyeglasses icon in the activity run output of a pipeline. For more information, see Monitoring mapping data flows.



When monitoring data flow performance, there are four possible bottlenecks to look out for:

- Cluster start-up time
- Reading from a source
- Transformation time
- Writing to a sink



Cluster start-up time is the time it takes to spin up an Apache Spark cluster. This value is located in the top-right corner of the monitoring screen. Data flows run on a just-in-time model where each job uses an isolated cluster. This start-up time generally takes 3-5 minutes. For sequential jobs, this can be reduced by enabling a time to live value. For more information, refer to the **Time to live** section in Integration Runtime performance.

Data flows utilize a Spark optimizer that reorders and runs your business logic in 'stages' to perform as quickly as possible. For each sink that your data flow writes to, the monitoring output lists the duration of each transformation stage, along with the time it takes to write data into the sink. The time that is the largest is likely the bottleneck of your data flow. If the transformation stage that takes the largest contains a source, then you may want to look at further optimizing your read time. If a transformation is taking a long time, then you may need to repartition or increase the size of your integration runtime. If the sink processing time is large, you may need to scale up your database or verify you are not outputting to a single file.

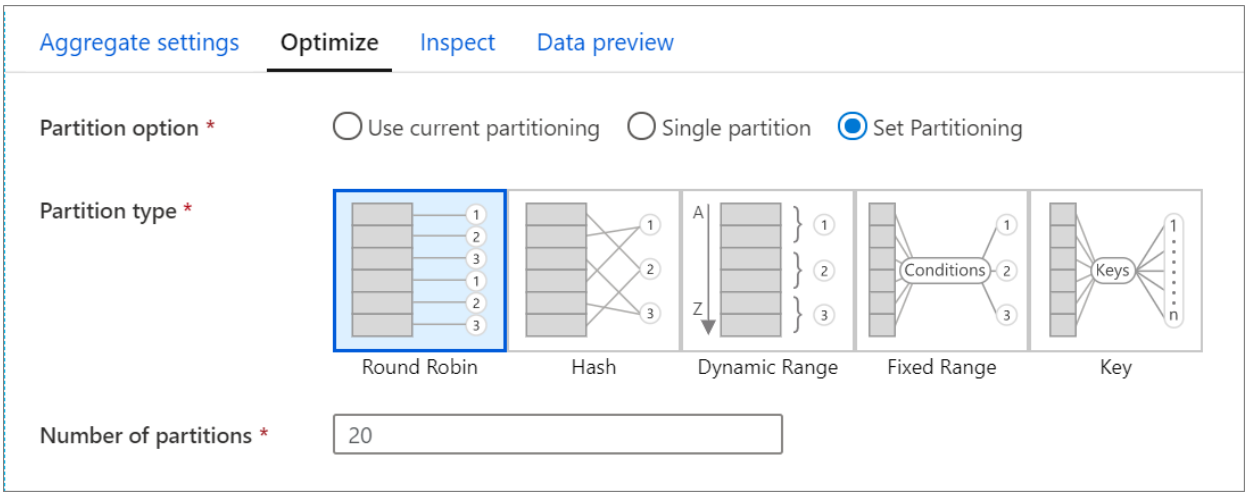
Once you have identified the bottleneck of your data flow, use the below optimizations strategies to improve performance.

Testing data flow logic

When designing and testing data flows from UI, debug mode allows you to interactively test against a live Spark cluster. This allows you to preview data and execute your data flows without waiting for a cluster to warm up. For more information, see Debug Mode.

Optimize tab

The **Optimize** tab contains settings to configure the partitioning scheme of the Spark cluster. This tab exists in every transformation of data flow and specifies whether you want to repartition the data **after** the transformation has completed. Adjusting the partitioning provides control over the distribution of your data across compute nodes and data locality optimizations that can have both positive and negative effects on your overall data flow performance.



By default, *Use current partitioning* is selected which instructs the service keep the current output partitioning of the transformation. As repartitioning data takes time, *Use current partitioning* is recommended in most scenarios. Scenarios where you may want to repartition your data include after aggregates and joins that significantly skew your data or when using Source partitioning on a SQL DB.

To change the partitioning on any transformation, select the **Optimize** tab and select the **Set Partitioning** radio button. You are presented with a series of options for partitioning. The best method of partitioning differs based on your data volumes, candidate keys, null values, and cardinality.

> **IMPORTANT**
> Single partition combines all the distributed data into a single partition. This is a very slow operation that also significantly affects all downstream transformation and writes. This option is strongly discouraged unless there is an explicit business reason to use it.

The following partitioning options are available in every transformation:

Round robin

Round robin distributes data equally across partitions. Use round-robin when you don't have good key candidates to implement a solid, smart partitioning strategy. You can set the number of physical partitions.

Hash

The service produces a hash of columns to produce uniform partitions such that rows with similar values fall in the same partition. When you use the Hash option, test for possible partition skew. You can set the number of physical partitions.

Dynamic range

The dynamic range uses Spark dynamic ranges based on the columns or expressions that you provide. You can set the number of physical partitions.

Fixed range

Build an expression that provides a fixed range for values within your partitioned data columns. To avoid partition skew, you should have a good understanding of your data before you use this option. The values you enter for the expression are used as part of a partition function. You can set the number of physical partitions.

Key

If you have a good understanding of the cardinality of your data, key partitioning might be a good strategy. Key partitioning creates partitions for each unique value in your column. You can't set the number of partitions because the number is based on unique values in the data.

TIP

Manually setting the partitioning scheme reshuffles the data and can offset the benefits of the Spark optimizer. A best practice is to not manually set the partitioning unless you need to.

Logging level

If you do not require every pipeline execution of your data flow activities to fully log all verbose telemetry logs, you can optionally set your logging level to "Basic" or "None". When executing your data flows in "Verbose" mode (default), you are requesting the service to fully log activity at each individual partition level during your data transformation. This can be an expensive operation, so only enabling verbose when troubleshooting can improve your overall data flow and pipeline performance. "Basic" mode will only log transformation durations while "None" will only provide a summary of durations.

Optimizing sources

8/19/2022 • 2 minutes to read • Edit Online

For every source except Azure SQL Database, it is recommended that you keep **Use current partitioning** as the selected value. When reading from all other source systems, data flows automatically partitions data evenly based upon the size of the data. A new partition is created for about every 128 MB of data. As your data size increases, the number of partitions increase.

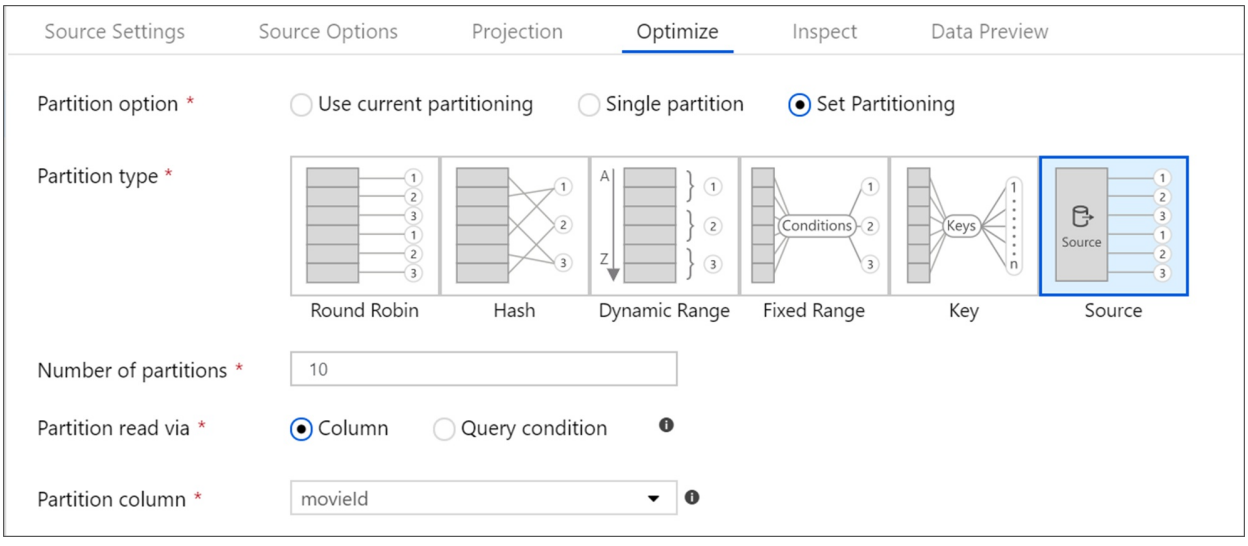
Any custom partitioning happens *after* Spark reads in the data and will negatively impact your data flow performance. As the data is evenly partitioned on read, this is not recommended.

> **NOTE**
> Read speeds can be limited by the throughput of your source system.

Azure SQL Database sources

Azure SQL Database has a unique partitioning option called 'Source' partitioning. Enabling source partitioning can improve your read times from Azure SQL DB by enabling parallel connections on the source system. Specify the number of partitions and how to partition your data. Use a partition column with high cardinality. You can also enter a query that matches the partitioning scheme of your source table.

> **TIP**
> For source partitioning, the I/O of the SQL Server is the bottleneck. Adding too many partitions may saturate your source database. Generally four or five partitions is ideal when using this option.



Isolation level

The isolation level of the read on an Azure SQL source system has an impact on performance. Choosing 'Read uncommitted' will provide the fastest performance and prevent any database locks. To learn more about SQL Isolation levels, please see Understanding isolation levels.

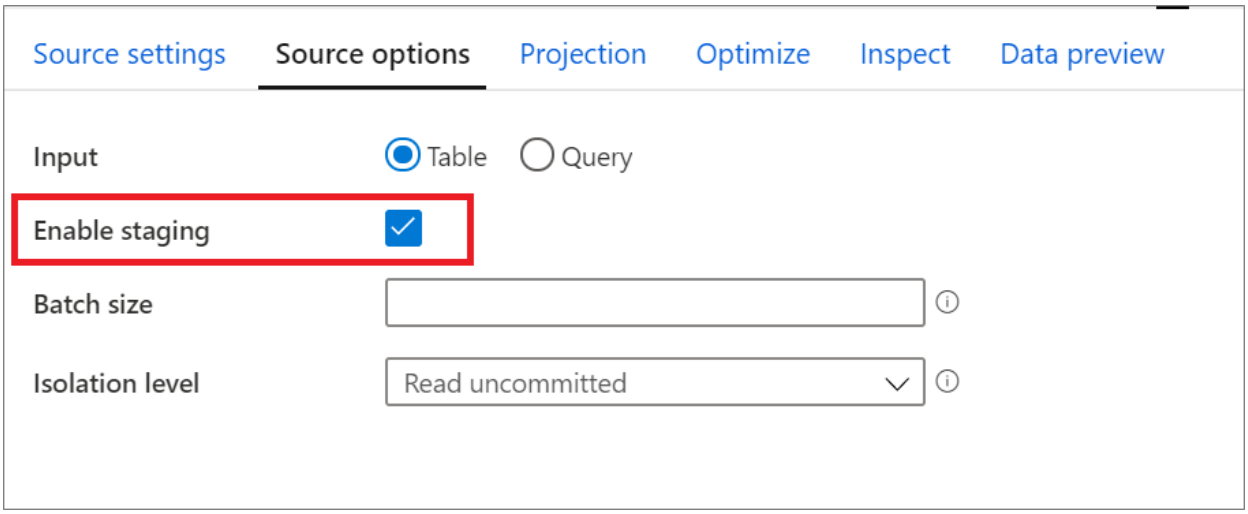
Read using query

You can read from Azure SQL Database using a table or a SQL query. If you are executing a SQL query, the

query must complete before transformation can start. SQL Queries can be useful to push down operations that may execute faster and reduce the amount of data read from a SQL Server such as SELECT, WHERE, and JOIN statements. When pushing down operations, you lose the ability to track lineage and performance of the transformations before the data comes into the data flow.

Azure Synapse Analytics sources

When using Azure Synapse Analytics, a setting called **Enable staging** exists in the source options. This allows the service to read from Synapse using `Staging` which greatly improves read performance by using the most performant bulk loading capability such as CETAS and COPY command. Enabling `Staging` requires you to specify an Azure Blob Storage or Azure Data Lake Storage gen2 staging location in the data flow activity settings.



File-based sources

While data flows support a variety of file types, the Spark-native Parquet format is recommended for optimal read and write times.

If you're running the same data flow on a set of files, we recommend reading from a folder, using wildcard paths or reading from a list of files. A single data flow activity run can process all of your files in batch. More information on how to configure these settings can be found in the **Source transformation** section of the Azure Blob Storage connector documentation.

If possible, avoid using the For-Each activity to run data flows over a set of files. This will cause each iteration of the for-each to spin up its own Spark cluster, which is often not necessary and can be expensive.

Optimizing sinks

8/19/2022 • 4 minutes to read • Edit Online

When data flows write to sinks, any custom partitioning will happen immediately before the write. Like the source, in most cases it is recommended that you keep **Use current partitioning** as the selected partition option. Partitioned data will write significantly quicker than unpartitioned data, even your destination is not partitioned. Below are the individual considerations for various sink types.

Azure SQL Database sinks

With Azure SQL Database, the default partitioning should work in most cases. There is a chance that your sink may have too many partitions for your SQL database to handle. If you are running into this, reduce the number of partitions outputted by your SQL Database sink.

Best practice for deleting rows in sink based on missing rows in source

Here is a video walk through of how to use data flows with exists, alter row, and sink transformations to achieve this common pattern:

Impact of error row handling to performance

When you enable error row handling ("continue on error") in the sink transformation, the service will take an additional step before writing the compatible rows to your destination table. This additional step will have a small performance penalty that can be in the range of 5% added for this step with an additional small performance hit also added if you set the option to also write the incompatible rows to a log file.

Disabling indexes using a SQL Script

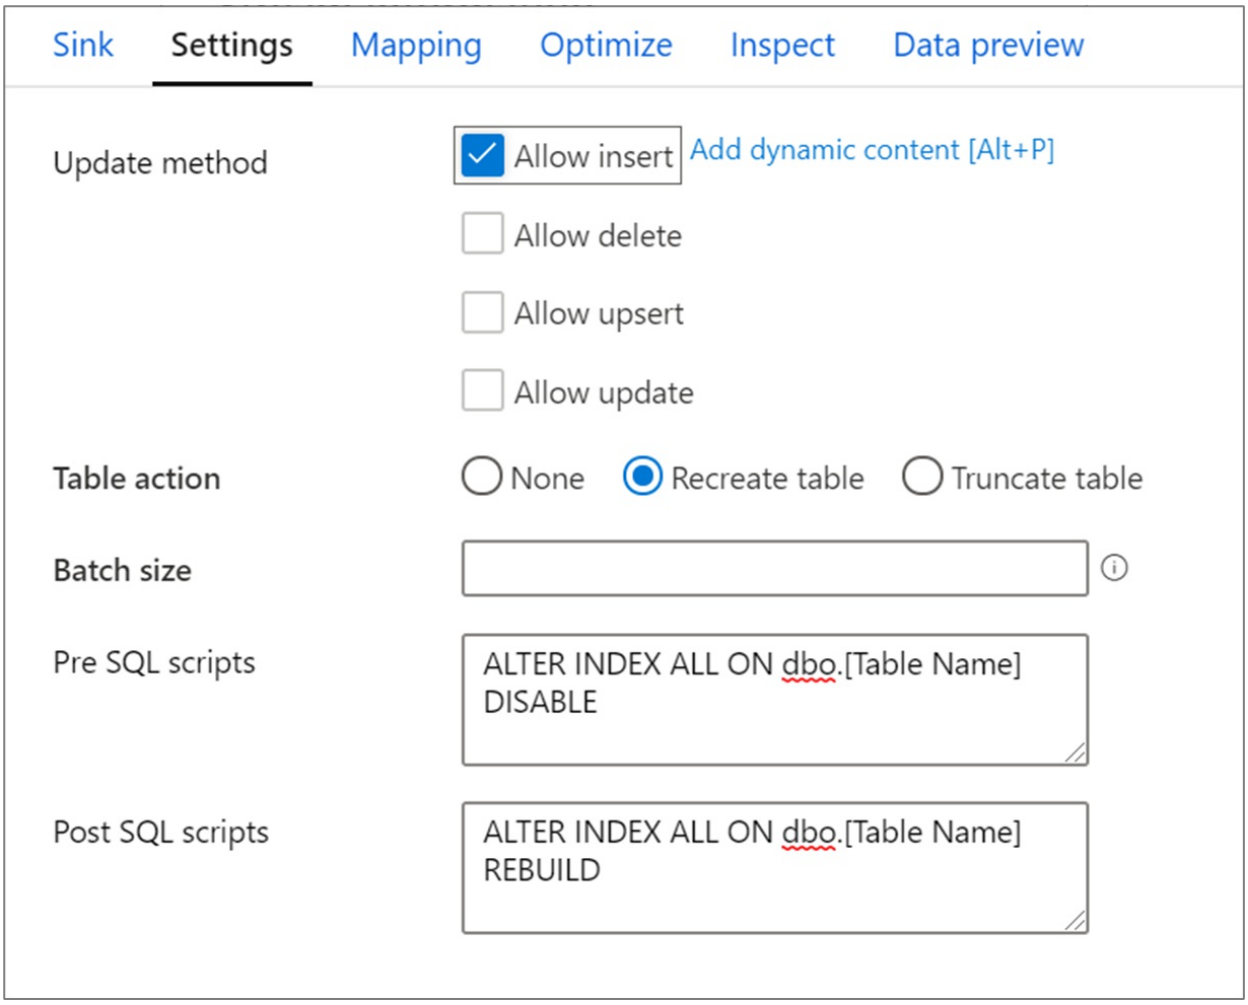
Disabling indexes before a load in a SQL database can greatly improve performance of writing to the table. Run the below command before writing to your SQL sink.

```
ALTER INDEX ALL ON dbo.[Table Name] DISABLE
```

After the write has completed, rebuild the indexes using the following command:

```
ALTER INDEX ALL ON dbo.[Table Name] REBUILD
```

These can both be done natively using Pre and Post-SQL scripts within an Azure SQL DB or Synapse sink in mapping data flows.



WARNING

When disabling indexes, the data flow is effectively taking control of a database and queries are unlikely to succeed at this time. As a result, many ETL jobs are triggered in the middle of the night to avoid this conflict. For more information, learn about the constraints of disabling SQL indexes

Scaling up your database

Schedule a resizing of your source and sink Azure SQL DB and DW before your pipeline run to increase the throughput and minimize Azure throttling once you reach DTU limits. After your pipeline execution is complete, resize your databases back to their normal run rate.

Azure Synapse Analytics sinks

When writing to Azure Synapse Analytics, make sure that **Enable staging** is set to true. This enables the service to write using the SQL COPY Command which effectively loads the data in bulk. You will need to reference an Azure Data Lake Storage gen2 or Azure Blob Storage account for staging of the data when using Staging.

Other than Staging, the same best practices apply to Azure Synapse Analytics as Azure SQL Database.

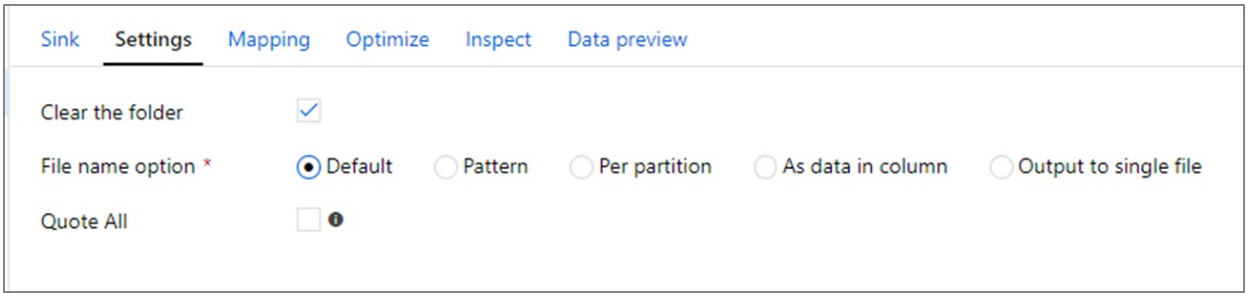
File-based sinks

While data flows support a variety of file types, the Spark-native Parquet format is recommended for optimal read and write times.

If the data is evenly distributed, **Use current partitioning** will be the fastest partitioning option for writing files.

File name options

When writing files, you have a choice of naming options that each have a performance impact.



Selecting the **Default** option will write the fastest. Each partition will equate to a file with the Spark default name. This is useful if you are just reading from the folder of data.

Setting a naming **Pattern** will rename each partition file to a more user-friendly name. This operation happens after write and is slightly slower than choosing the default.

Per partition allows you to name each individual partition manually.

If a column corresponds to how you wish to output the data, you can select **Name file as column data**. This reshuffles the data and can impact performance if the columns are not evenly distributed.

If a column corresponds to how you wish to generate folder names, select **Name folder as column data**.

Output to single file combines all the data into a single partition. This leads to long write times, especially for large datasets. This option is strongly discouraged unless there is an explicit business reason to use it.

Azure Cosmos DB sinks

When writing to Azure Cosmos DB, altering throughput and batch size during data flow execution can improve performance. These changes only take effect during the data flow activity run and will return to the original collection settings after conclusion.

Batch size: Usually, starting with the default batch size is sufficient. To further tune this value, calculate the rough object size of your data, and make sure that object size * batch size is less than 2MB. If it is, you can increase the batch size to get better throughput.

Throughput: Set a higher throughput setting here to allow documents to write faster to Azure Cosmos DB. Keep in mind the higher RU costs based upon a high throughput setting.

Write throughput budget: Use a value which is smaller than total RUs per minute. If you have a data flow with a high number of Spark partitions, setting a budget throughput will allow more balance across those partitions.

Optimizing transformations

8/19/2022 • 4 minutes to read • Edit Online

Use the following strategies to optimize performance of transformations in mapping data flows in Azure Data Factory and Azure Synapse Analytics pipelines.

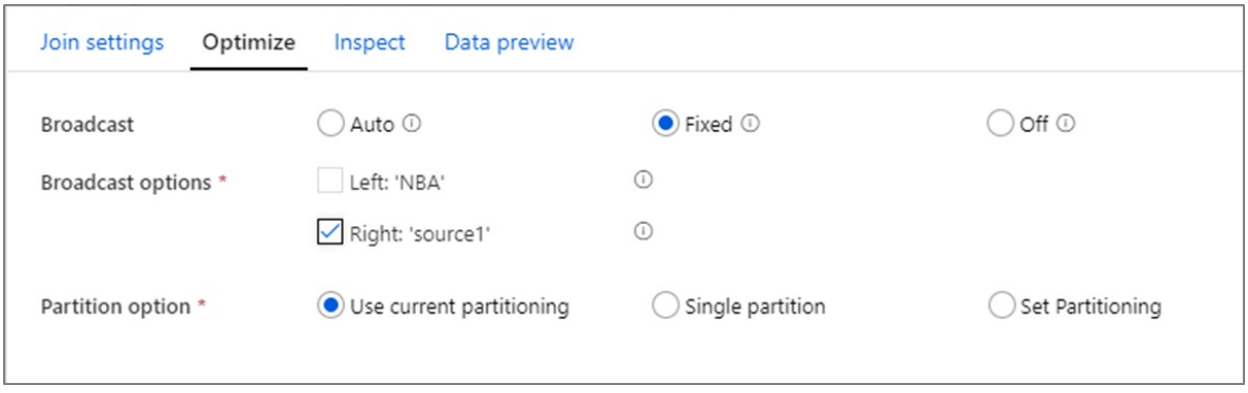
Optimizing Joins, Exists, and Lookups

Broadcasting

In joins, lookups, and exists transformations, if one or both data streams are small enough to fit into worker node memory, you can optimize performance by enabling **Broadcasting**. Broadcasting is when you send small data frames to all nodes in the cluster. This allows for the Spark engine to perform a join without reshuffling the data in the large stream. By default, the Spark engine will automatically decide whether or not to broadcast one side of a join. If you are familiar with your incoming data and know that one stream will be significantly smaller than the other, you can select **Fixed** broadcasting. Fixed broadcasting forces Spark to broadcast the selected stream.

If the size of the broadcasted data is too large for the Spark node, you may get an out of memory error. To avoid out of memory errors, use **memory optimized** clusters. If you experience broadcast timeouts during data flow executions, you can switch off the broadcast optimization. However, this will result in slower performing data flows.

When working with data sources that can take longer to query, like large database queries, it is recommended to turn broadcast off for joins. Source with long query times can cause Spark timeouts when the cluster attempts to broadcast to compute nodes. Another good choice for turning off broadcast is when you have a stream in your data flow that is aggregating values for use in a lookup transformation later. This pattern can confuse the Spark optimizer and cause timeouts.



Cross joins

If you use literal values in your join conditions or have multiple matches on both sides of a join, Spark will run the join as a cross join. A cross join is a full cartesian product that then filters out the joined values. This is significantly slower than other join types. Ensure that you have column references on both sides of your join conditions to avoid the performance impact.

Sorting before joins

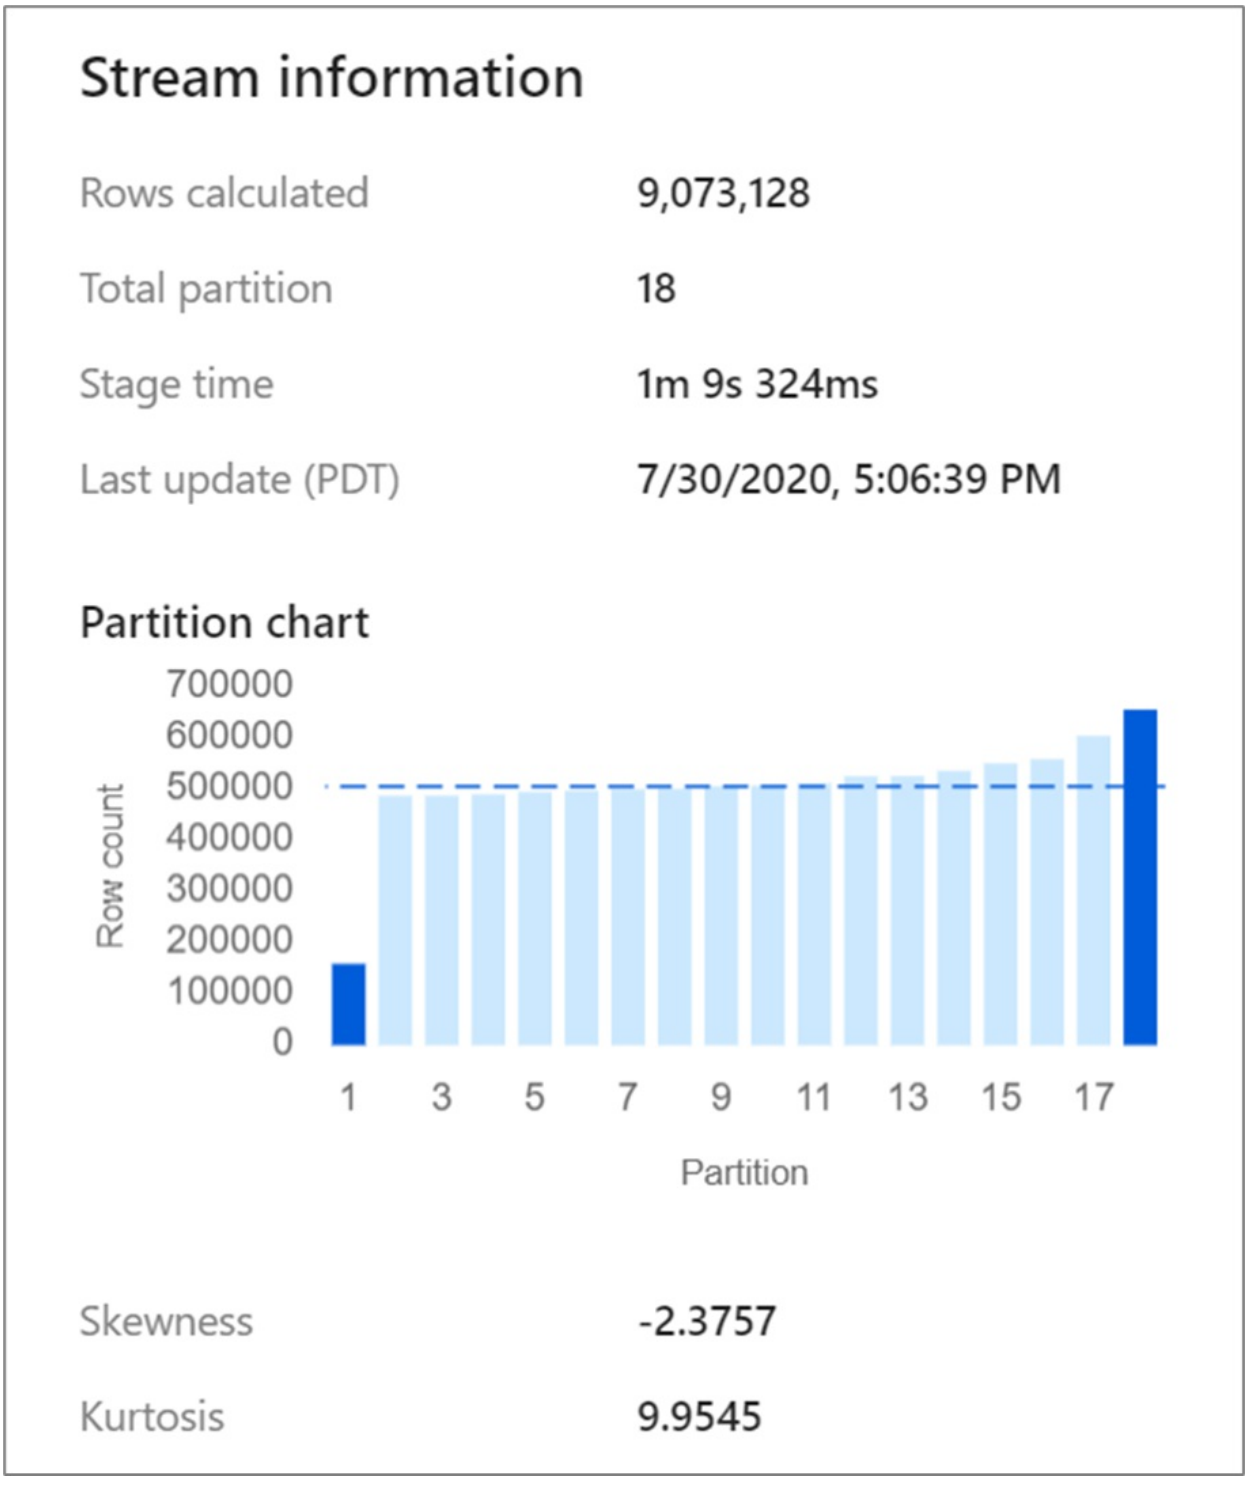
Unlike merge join in tools like SSIS, the join transformation isn't a mandatory merge join operation. The join keys don't require sorting prior to the transformation. Using Sort transformations in mapping data flows is not recommended.

Window transformation performance

The Window transformation in mapping data flow partitions your data by value in columns that you select as part of the `over()` clause in the transformation settings. There are a number of very popular aggregate and analytical functions that are exposed in the Windows transformation. However, if your use case is to generate a window over your entire dataset for the purpose of ranking `rank()` or row number `rowNumber()`, it is recommended that you instead use the Rank transformation and the Surrogate Key transformation. Those transformation will perform better again full dataset operations using those functions.

Repartitioning skewed data

Certain transformations such as joins and aggregates reshuffle your data partitions and can occasionally lead to skewed data. Skewed data means that data is not evenly distributed across the partitions. Heavily skewed data can lead to slower downstream transformations and sink writes. You can check the skewness of your data at any point in a data flow run by clicking on the transformation in the monitoring display.



The monitoring display will show how the data is distributed across each partition along with two metrics, skewness and kurtosis. **Skewness** is a measure of how asymmetrical the data is and can have a positive, zero, negative, or undefined value. Negative skew means the left tail is longer than the right. **Kurtosis** is the measure of whether the data is heavy-tailed or light-tailed. High kurtosis values are not desirable. Ideal ranges of skewness lie between -3 and 3 and ranges of kurtosis are less than 10. An easy way to interpret these numbers is looking at the partition chart and seeing if 1 bar is significantly larger than the rest.

If your data is not evenly partitioned after a transformation, you can use the optimize tab to repartition. Reshuffling data takes time and may not improve your data flow performance.

> **TIP**
> If you repartition your data, but have downstream transformations that reshuffle your data, use hash partitioning on a column used as a join key.

> **NOTE**
> Transformations inside your data flow (with the exception of the Sink transformation) do not modify the file and folder partitioning of data at rest. Partitioning in each transformation repartitions data inside the data frames of the temporary serverless Spark cluster that ADF manages for each of your data flow executions.

Using data flows in pipelines

8/19/2022 • 2 minutes to read • Edit Online

When building complex pipelines with multiple data flows, your logical flow can have a big impact on timing and cost. This section covers the impact of different architecture strategies.

Executing data flows in parallel

If you execute multiple data flows in parallel, the service spins up separate Spark clusters for each activity. This allows for each job to be isolated and run in parallel, but will lead to multiple clusters running at the same time.

If your data flows execute in parallel, we recommend that you don't enable the Azure IR time to the live property because it will lead to multiple unused warm pools.

> **TIP**
> Instead of running the same data flow multiple times in a for each activity, stage your data in a data lake and use wildcard paths to process the data in a single data flow.

Execute data flows sequentially

If you execute your data flow activities in sequence, it is recommended that you set a TTL in the Azure IR configuration. The service will reuse the compute resources, resulting in a faster cluster start-up time. Each activity will still be isolated and receive a new Spark context for each execution.

Overloading a single data flow

If you put all of your logic inside of a single data flow, the service will execute the entire job on a single Spark instance. While this may seem like a way to reduce costs, it mixes together different logical flows and can be difficult to monitor and debug. If one component fails, all other parts of the job will fail as well. Organizing data flows by independent flows of business logic is recommended. If your data flow becomes too large, splitting it into separate components will make monitoring and debugging easier. While there is no hard limit on the number of transformations in a data flow, having too many will make the job complex.

Execute sinks in parallel

The default behavior of data flow sinks is to execute each sink sequentially, in a serial manner, and to fail the data flow when an error is encountered in the sink. Additionally, all sinks are defaulted to the same group unless you go into the data flow properties and set different priorities for the sinks.

Data flows allow you to group sinks together into groups from the data flow properties tab in the UI designer. You can both set the order of execution of your sinks as well as to group sinks together using the same group number. To help manage groups, you can ask the service to run sinks in the same group, to run in parallel.

On the pipeline execute data flow activity under the "Sink Properties" section is an option to turn on parallel sink loading. When you enable "run in parallel", you are instructing data flows write to connected sinks at the same time rather than in a sequential manner. In order to utilize the parallel option, the sinks must be group together and connected to the same stream via a New Branch or Conditional Split.

Memory optimized compute type for Data Flows in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flow activities in Azure Data Factory and Azure Synapse support the Compute type setting to help optimize the cluster configuration for cost and performance of the workload. The default selection for the setting is **General** and will be sufficient for most data flow workloads. General purpose clusters typically provide the best balance of performance and cost. However, the **Memory optimized** setting can significantly improve performance in some scenarios by maximizing the memory available per core for the cluster.

When to use the memory optimized compute type

If your data flow has many joins and lookups, you may want to use a memory optimized cluster. These more memory intensive operations will benefit particularly by additional memory, and any out-of-memory errors encountered with the default compute type will be minimized. **Memory optimized** clusters do incur the highest cost per core, but may avoid pipeline failures for memory intensive operations. If you experience any out of memory errors when executing data flows, switch to a memory optimized Azure IR configuration.

Next steps

Data Flow type properties

Optimizing performance of the Azure Integration Runtime

8/19/2022 • 3 minutes to read • Edit Online

Data flows run on Spark clusters that are spun up at run-time. The configuration for the cluster used is defined in the integration runtime (IR) of the activity. There are three performance considerations to make when defining your integration runtime: cluster type, cluster size, and time to live.

For more information how to create an Integration Runtime, see Integration Runtime.

The easiest way to get started with data flow integration runtimes is to choose small, medium, or large from the compute size picker. See the mappings to cluster configurations for those sizes below.

Cluster type

There are two available options for the type of Spark cluster to utilize: general purpose & memory optimized.

General purpose clusters are the default selection and will be ideal for most data flow workloads. These tend to be the best balance of performance and cost.

If your data flow has many joins and lookups, you may want to use a **memory optimized** cluster. Memory optimized clusters can store more data in memory and will minimize any out-of-memory errors you may get. Memory optimized have the highest price-point per core, but also tend to result in more successful pipelines. If you experience any out of memory errors when executing data flows, switch to a memory optimized Azure IR configuration.

Cluster size

Data flows distribute the data processing over different nodes in a Spark cluster to perform operations in parallel. A Spark cluster with more cores increases the number of nodes in the compute environment. More nodes increase the processing power of the data flow. Increasing the size of the cluster is often an easy way to reduce the processing time.

The default cluster size is four driver nodes and four worker nodes (small). As you process more data, larger clusters are recommended. Below are the possible sizing options:

WORKER CORES	DRIVER CORES	TOTAL CORES	NOTES
4	4	8	Small
8	8	16	Medium
16	16	32	
32	16	48	
64	16	80	Large
128	16	144	

WORKER CORES	DRIVER CORES	TOTAL CORES	NOTES
256	16	272	

Data flows are priced at vcore-hrs meaning that both cluster size and execution-time factor into this. As you scale up, your cluster cost per minute will increase, but your overall time will decrease.

> **TIP**
> There is a ceiling on how much the size of a cluster affects the performance of a data flow. Depending on the size of your data, there is a point where increasing the size of a cluster will stop improving performance. For example, If you have more nodes than partitions of data, adding additional nodes won't help. A best practice is to start small and scale up to meet your performance needs.

Time to live

By default, every data flow activity spins up a new Spark cluster based upon the Azure IR configuration. Cold cluster start-up time takes a few minutes and data processing can't start until it is complete. If your pipelines contain multiple **sequential** data flows, you can enable a time to live (TTL) value. Specifying a time to live value keeps a cluster alive for a certain period of time after its execution completes. If a new job starts using the IR during the TTL time, it will reuse the existing cluster and start up time will greatly reduced. After the second job completes, the cluster will again stay alive for the TTL time.

However, if most of your data flows execute in parallel, it is not recommended that you enable TTL for the IR that you use for those activities. Only one job can run on a single cluster at a time. If there is an available cluster, but two data flows start, only one will use the live cluster. The second job will spin up its own isolated cluster.

> **NOTE**
> Time to live is not available when using the auto-resolve integration runtime (default).

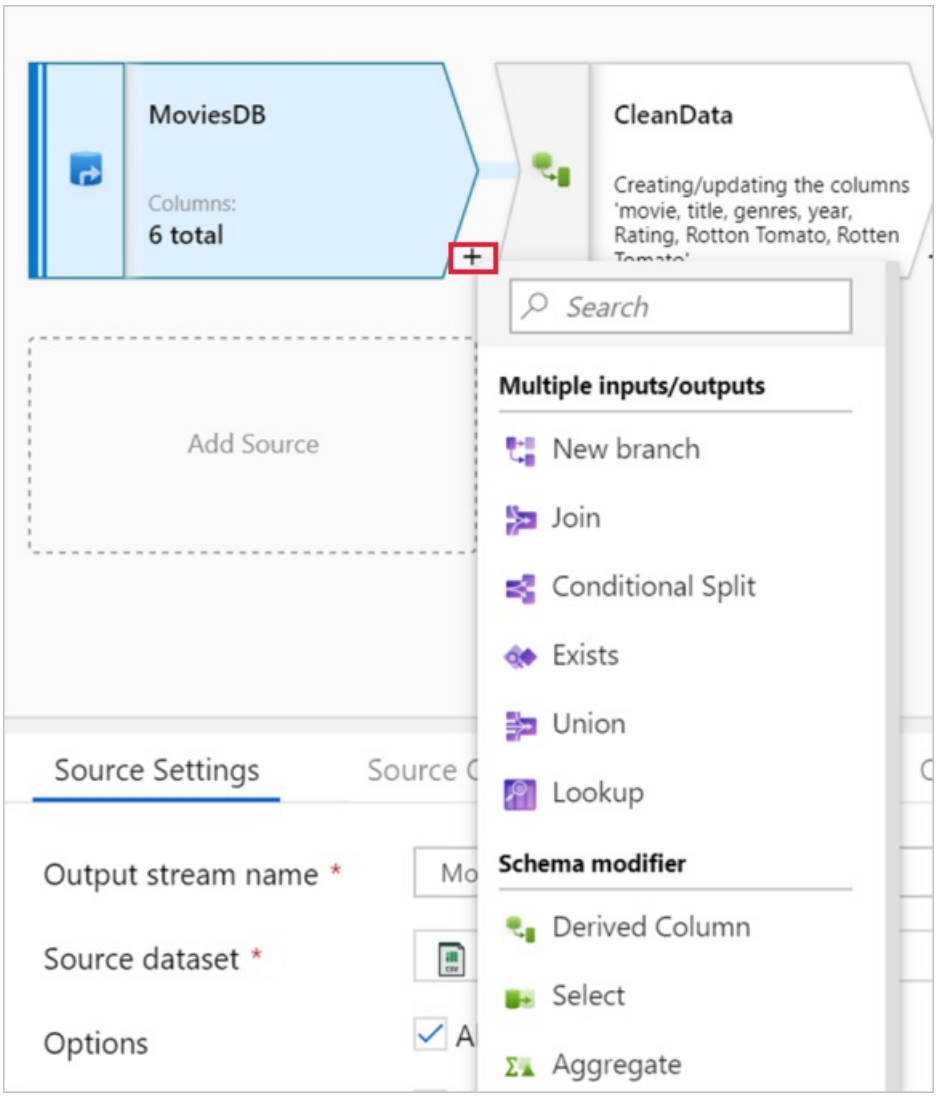
Managing the mapping data flow graph

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

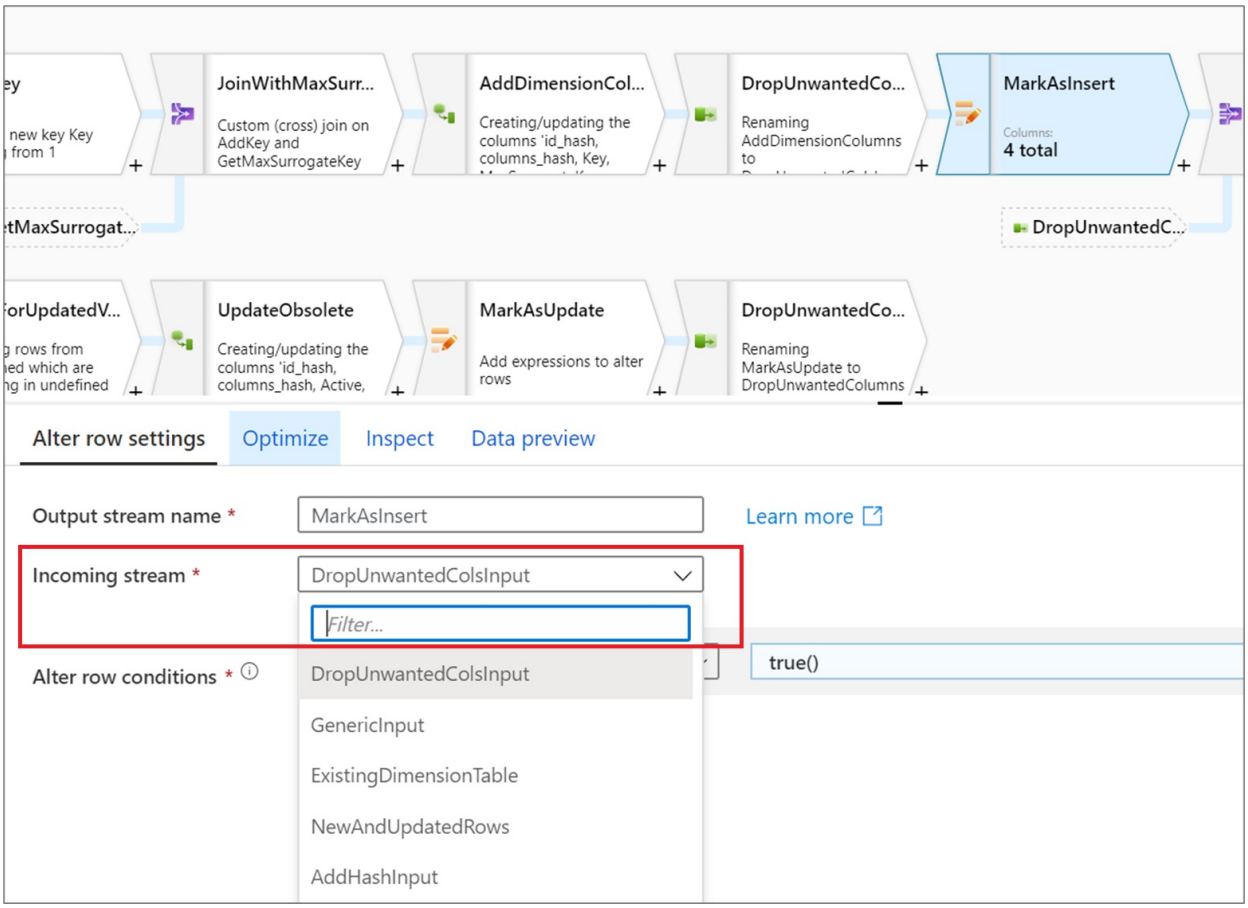
Mapping data flows are authored using a design surface know as the data flow graph. In the graph, transformation logic is built left-to-right and additional data streams are added top-down. To add a new transformation, select the plus sign on the lower right of an existing transformation.



As your data flows get more complex, use the following mechanisms to effectively navigate and manage the data flow graph.

Moving transformations

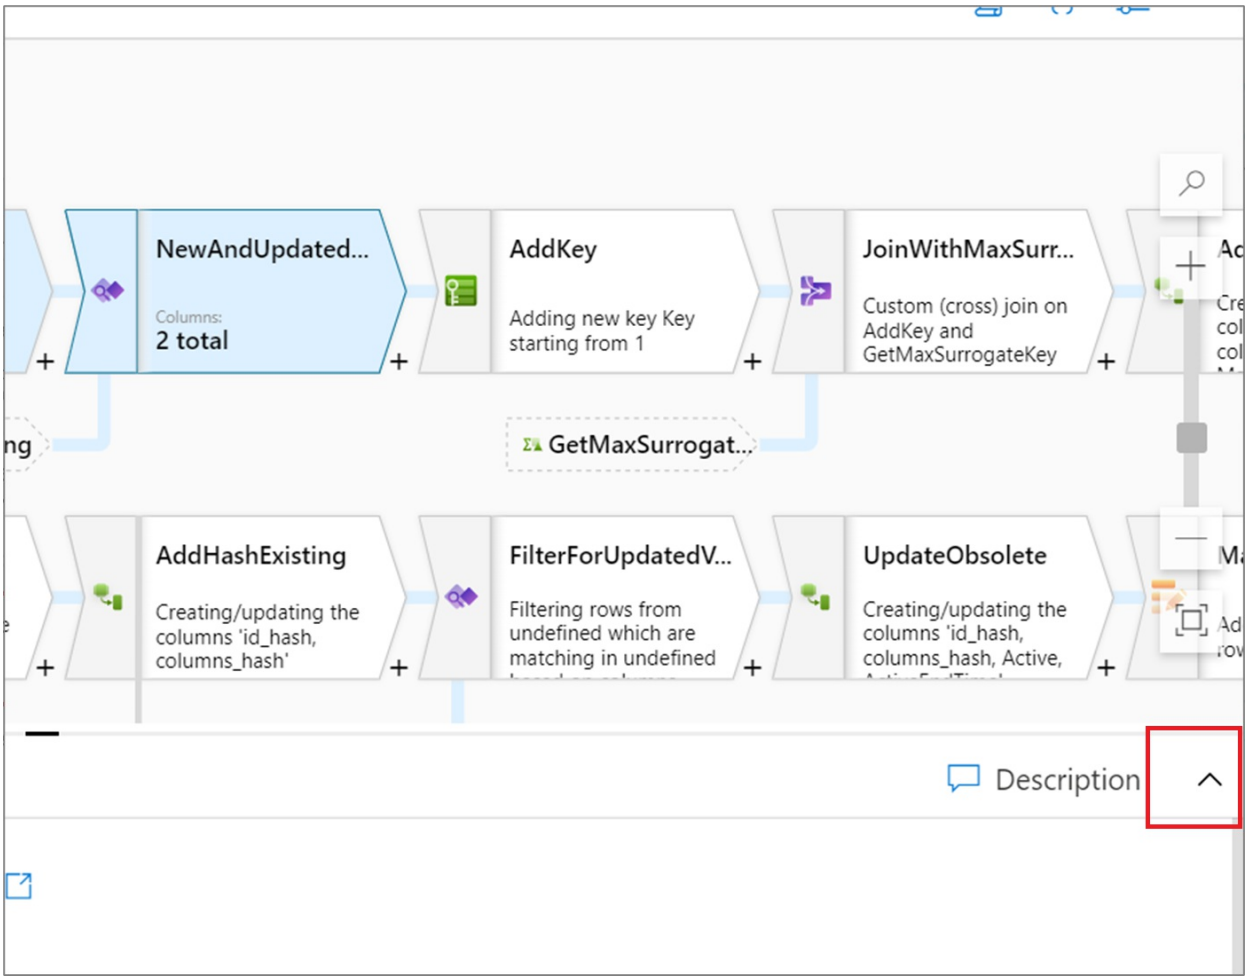
In mapping data flows, a set of connected transformation logic is known as a **stream**. The **Incoming stream** field dictates which data stream is feeding the current transformation. Each transformation has one or two incoming streams depending on its function and represents an output stream. The output schema of the incoming streams determines which column metadata can be referenced by the current transformation.



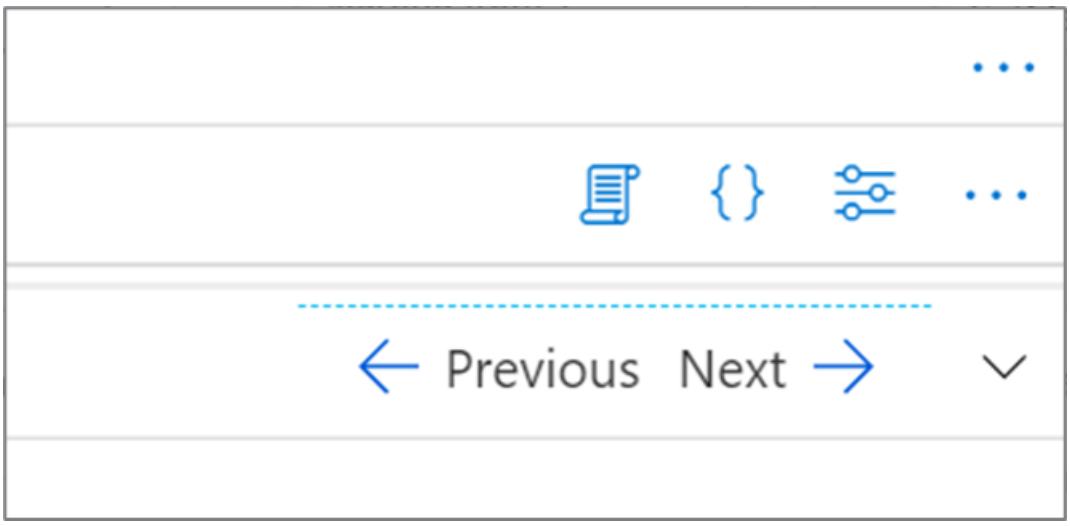
Unlike the pipeline canvas, data flow transformations aren't edited using a drag and drop model. To change the incoming stream of or "move" a transformation, choose a different value from the **Incoming stream** dropdown. When you do this, all downstream transformations will move alongside the edited transformation. The graph will automatically update to show the new logical flow. If you change the incoming stream to a transformation that already has downstream transformation, a new branch or parallel data stream will be created. Learn more about new branches in mapping data flow.

Hide graph and show graph

When editing your transformation, you can expand the configuration panel to take up the entire canvas, hiding the graph. Click on the upward-facing chevron located on the right side of the canvas.

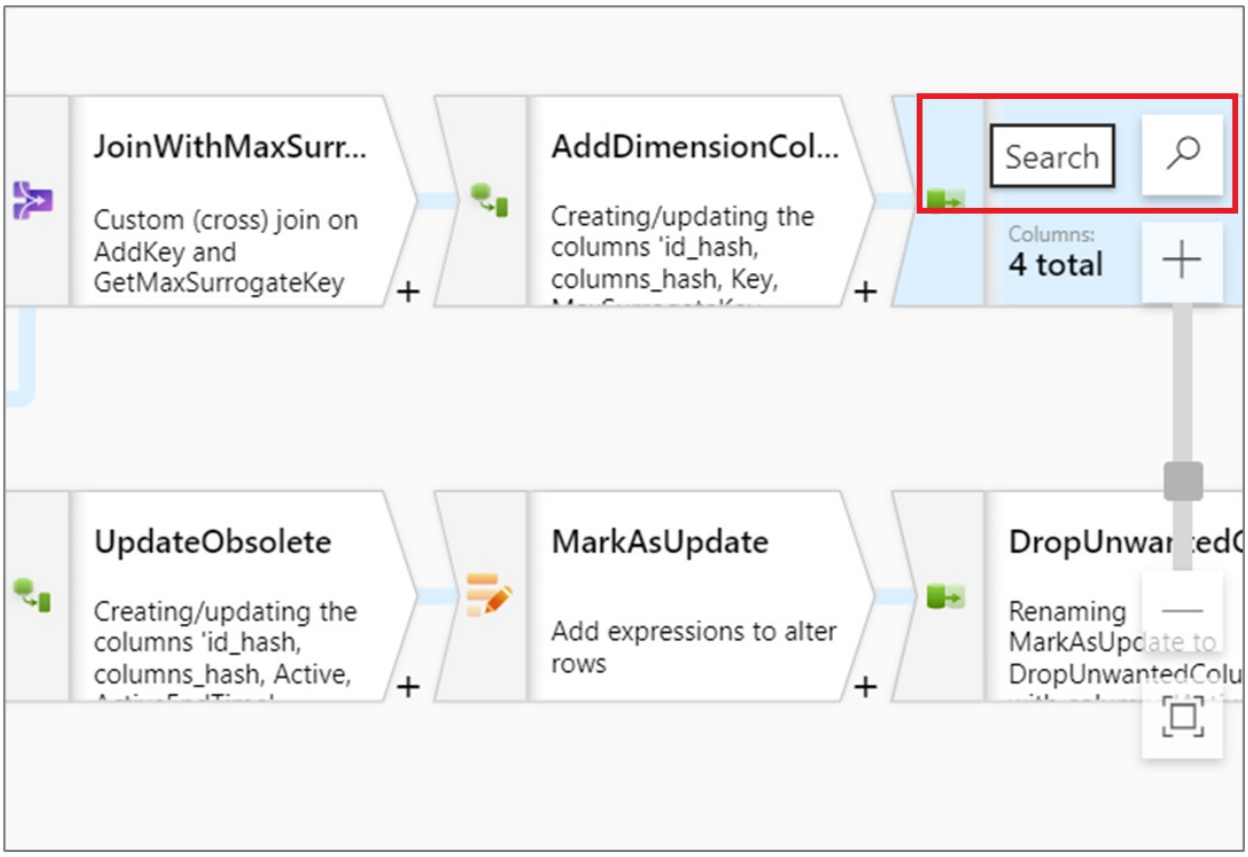


When the graph is hidden, you can move between transformations within a stream by clicking **Next** or **Previous**. Click the downward-facing chevron to show the graph.

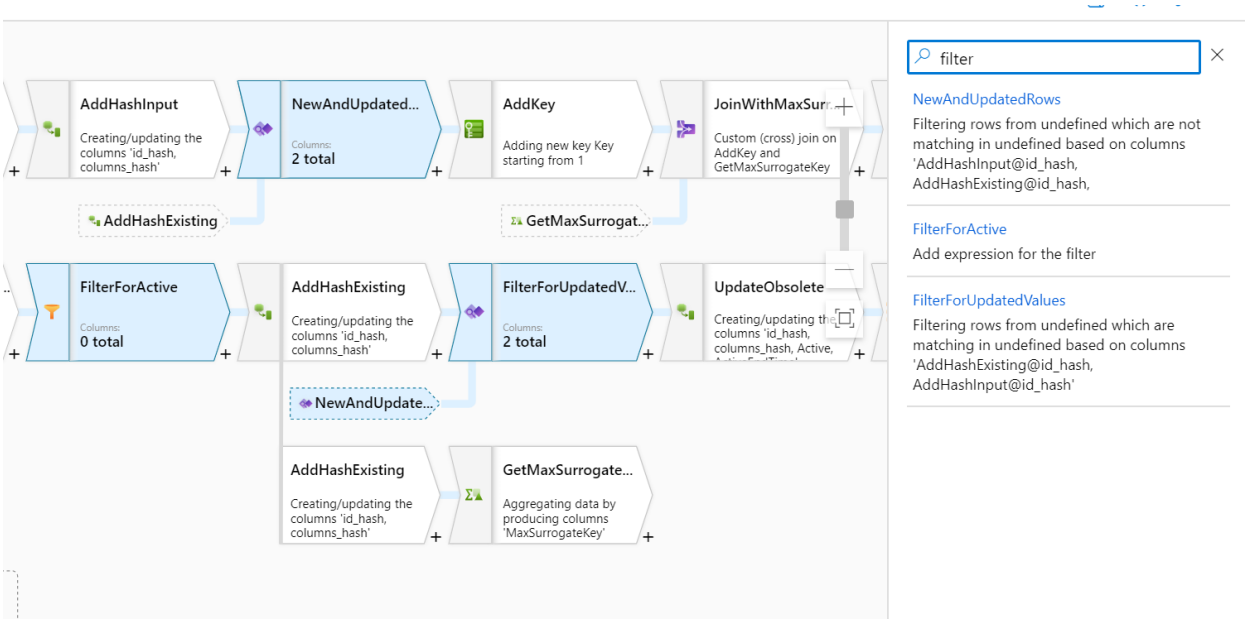


Searching for transformations

To quickly find a transformation in your graph, click on the **Search** icon above the zoom setting.

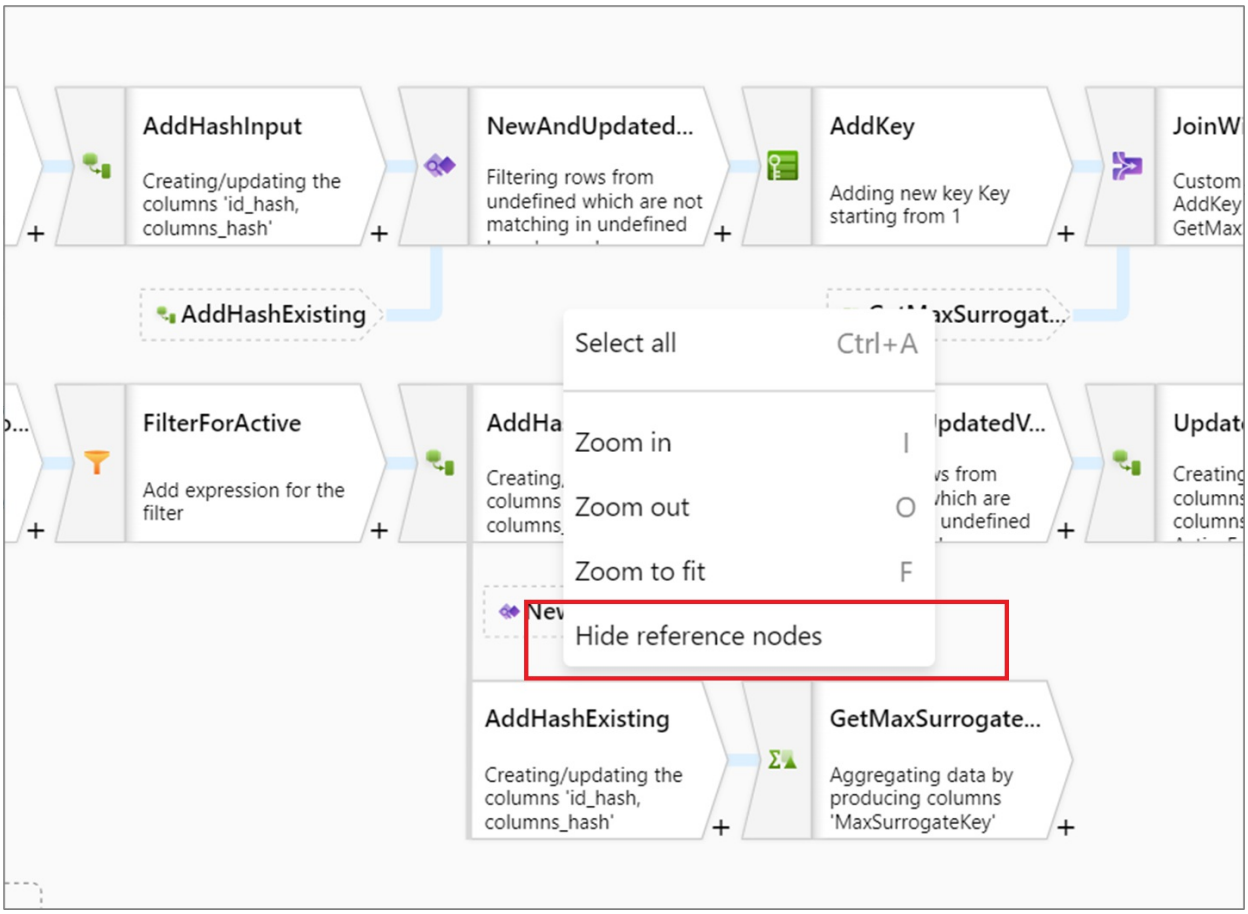


You can search by transformation name or description to locate a transformation.



Hide reference nodes

If your data flow has any join, lookup, exists, or union transformations, data flow shows reference nodes to all incoming streams. If you wish to minimize the amount of vertical space taken, you can minimize your reference nodes. To do so, right click on the canvas and select **Hide reference nodes**.



Next steps

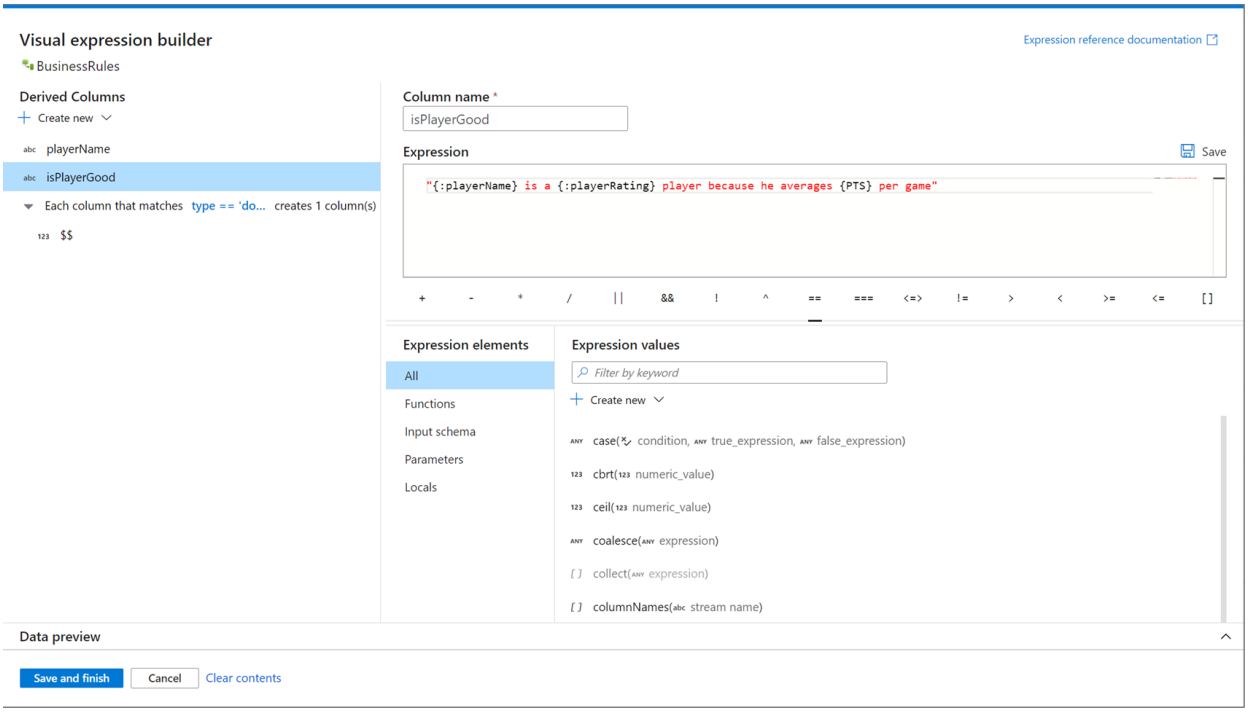
After completing your data flow logic, turn on debug mode and test it out in a data preview.

Build expressions in mapping data flow

8/19/2022 • 7 minutes to read • Edit Online

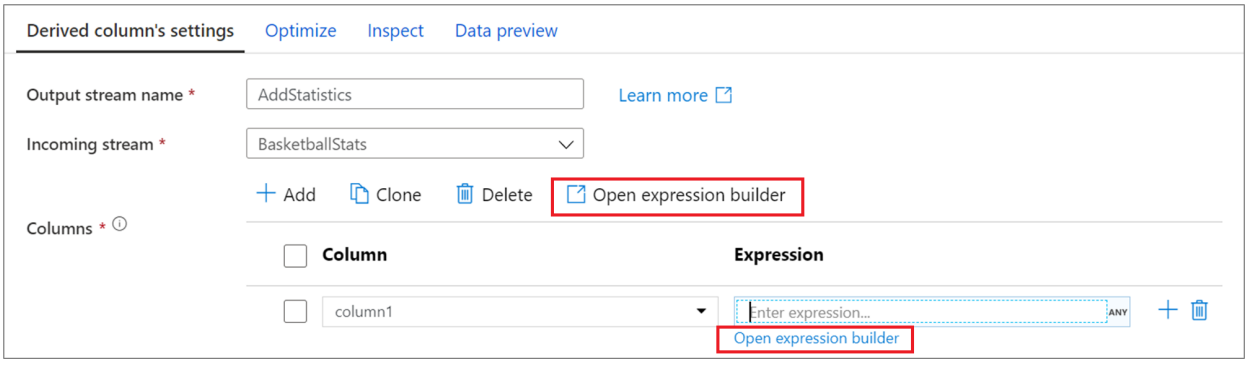
APPLIES TO: Azure Data Factory Azure Synapse Analytics

In mapping data flow, many transformation properties are entered as expressions. These expressions are composed of column values, parameters, functions, operators, and literals that evaluate to a Spark data type at run time. Mapping data flows has a dedicated experience aimed to aid you in building these expressions called the **Expression Builder**. Utilizing IntelliSense code completion for highlighting, syntax checking, and autocompleting, the expression builder is designed to make building data flows easy. This article explains how to use the expression builder to effectively build your business logic.

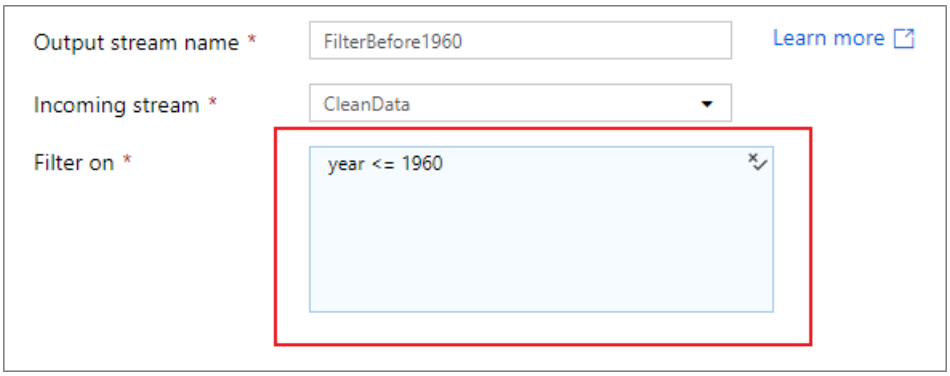


Open Expression Builder

There are multiple entry points to opening the expression builder. These are all dependent on the specific context of the data flow transformation. The most common use case is in transformations like derived column and aggregate where users create or update columns using the data flow expression language. The expression builder can be opened by selecting **Open expression builder** above the list of columns. You can also click on a column context and open the expression builder directly to that expression.

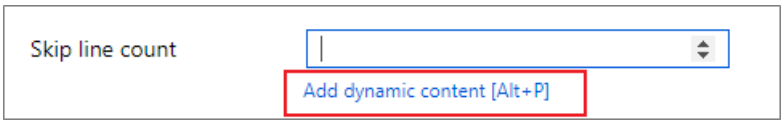


In some transformations like filter, clicking on a blue expression text box will open the expression builder.



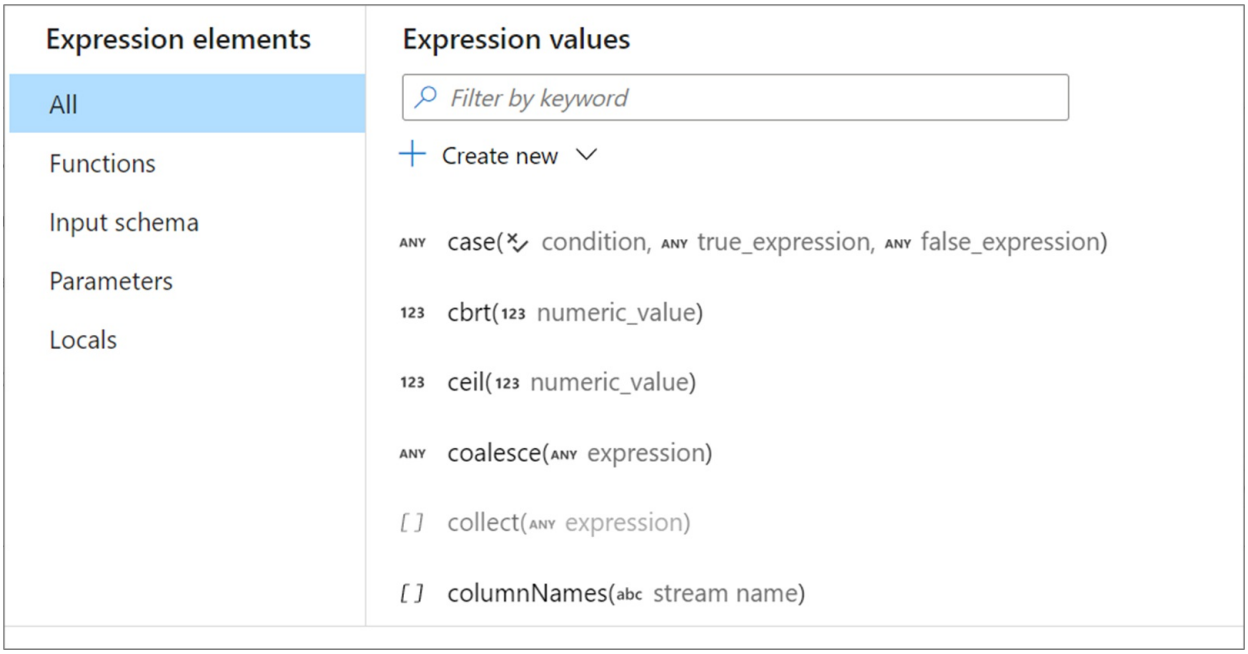
When you reference columns in a matching or group-by condition, an expression can extract values from columns. To create an expression, select **Computed column**.

In cases where an expression or a literal value are valid inputs, select **Add dynamic content** to build an expression that evaluates to a literal value.



Expression elements

In mapping data flows, expressions can be composed of column values, parameters, functions, local variables, operators, and literals. These expressions must evaluate to a Spark data type such as string, boolean, or integer.



Functions

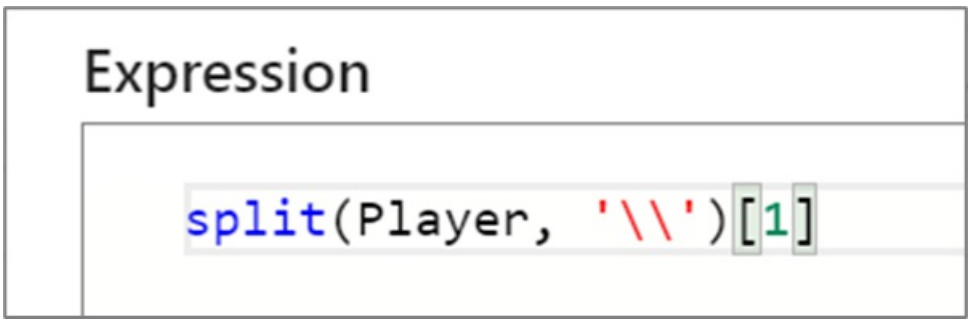
Mapping data flows has built-in functions and operators that can be used in expressions. For a list of available functions, see the mapping data flow language reference.

User Defined Functions (Preview)

Mapping data flows supports the creation and use of user defined functions. To see how to create and use user defined functions see user defined functions.

Address array indexes

When dealing with columns or functions that return array types, use brackets ([]) to access a specific element. If the index doesn't exist, the expression evaluates into NULL.



> **IMPORTANT**
> In mapping data flows, arrays are one-based meaning the first element is referenced by index one. For example, myArray[1] will access the first element of an array called 'myArray'.

Input schema

If your data flow uses a defined schema in any of its sources, you can reference a column by name in many expressions. If you are utilizing schema drift, you can reference columns explicitly using the `byName()` or `byNames()` functions or match using column patterns.

Column names with special characters

When you have column names that include special characters or spaces, surround the name with curly braces to reference them in an expression.

```
{[dbo].this_is my complex name$$$}
```

Parameters

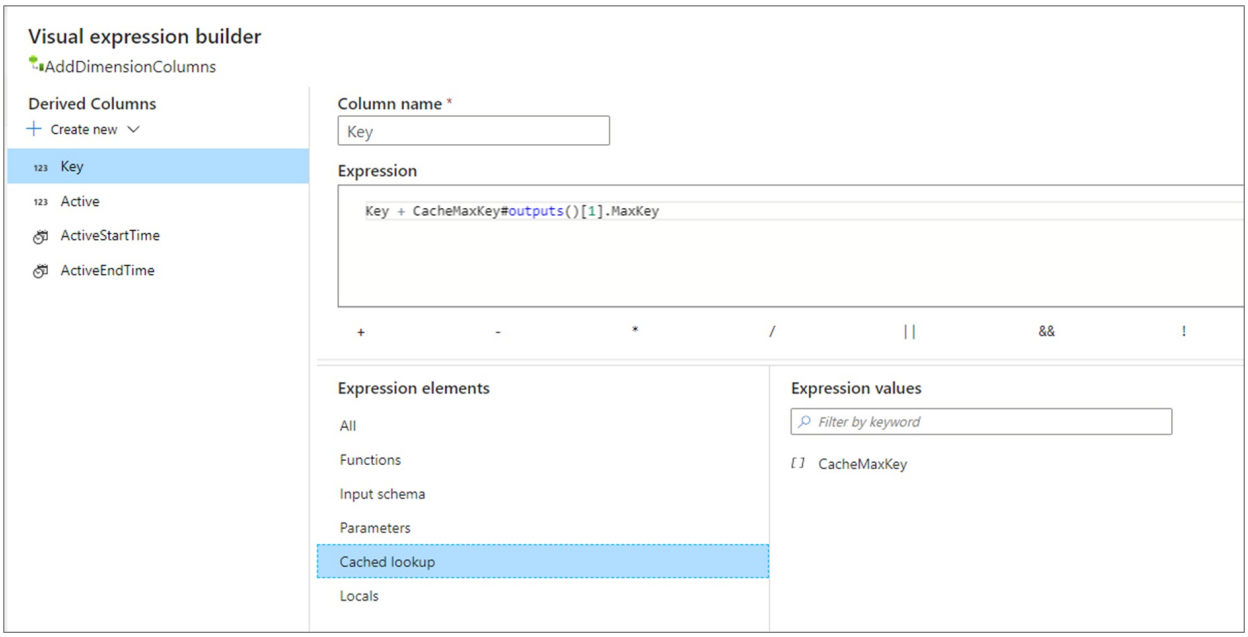
Parameters are values that are passed into a data flow at run time from a pipeline. To reference a parameter, either click on the parameter from the **Expression elements** view or reference it with a dollar sign in front of its name. For example, a parameter called parameter1 would be referenced by `$parameter1`. To learn more, see parameterizing mapping data flows.

Cached lookup

A cached lookup allows you to do an inline lookup of the output of a cached sink. There are two functions available to use on each sink, `lookup()` and `outputs()`. The syntax to reference these functions is `cacheSinkName#functionName()`. For more information, see cache sinks.

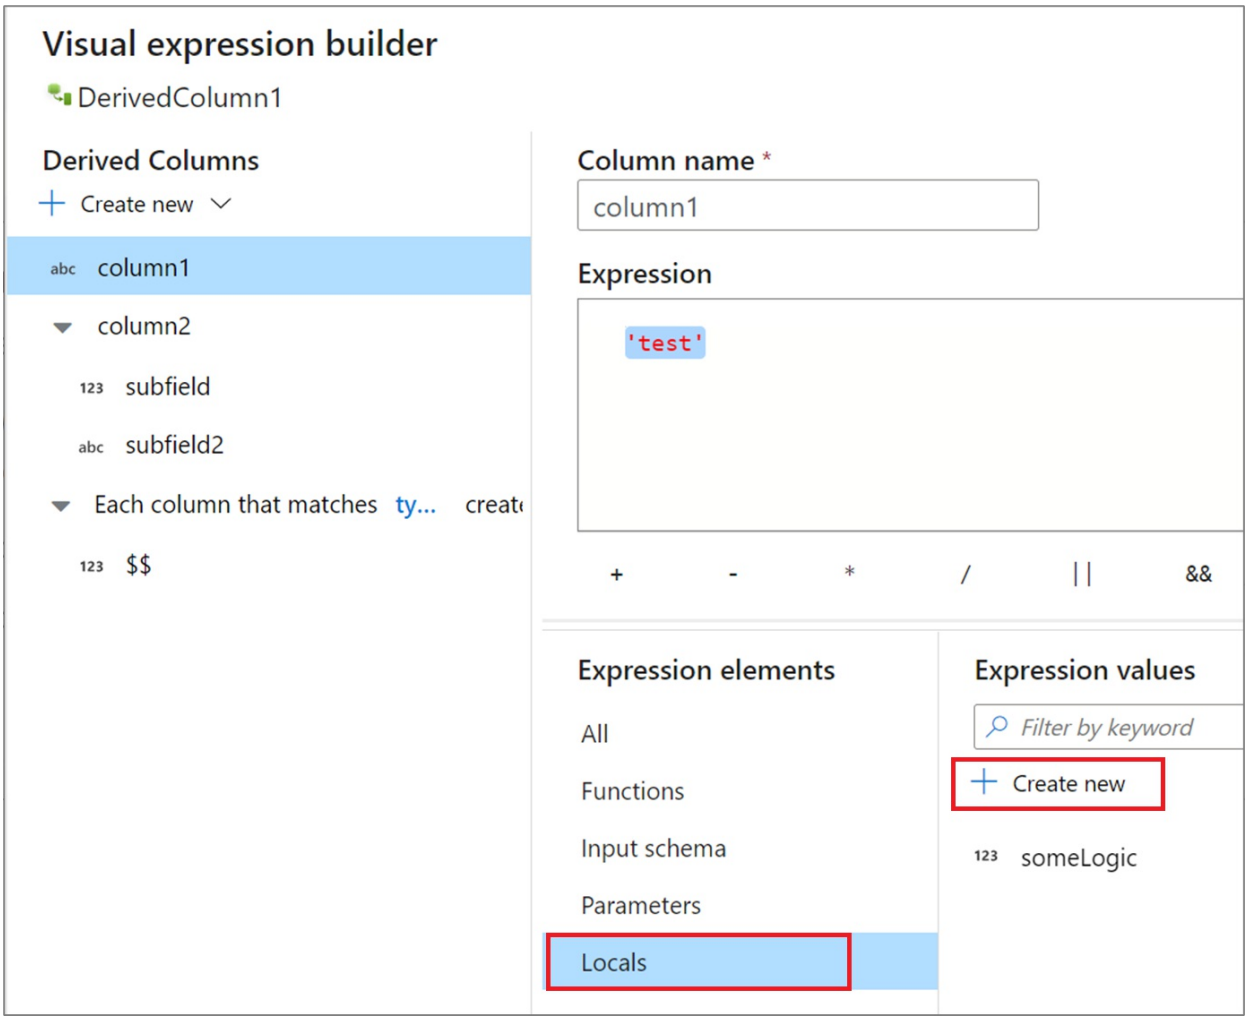
`lookup()` takes in the matching columns in the current transformation as parameters and returns a complex column equal to the row matching the key columns in the cache sink. The complex column returned contains a subcolumn for each column mapped in the cache sink. For example, if you had an error code cache sink `errorCodeCache` that had a key column matching on the code and a column called `Message`. Calling `errorCodeCache#lookup(errorCode).Message` would return the message corresponding with the code passed in.

`outputs()` takes no parameters and returns the entire cache sink as an array of complex columns. This can't be called if key columns are specified in the sink and should only be used if there is a small number of rows in the cache sink. A common use case is appending the max value of an incrementing key. If a cached single aggregated row `CacheMaxKey` contains a column `MaxKey`, you can reference the first value by calling `CacheMaxKey#outputs()[1].MaxKey`.

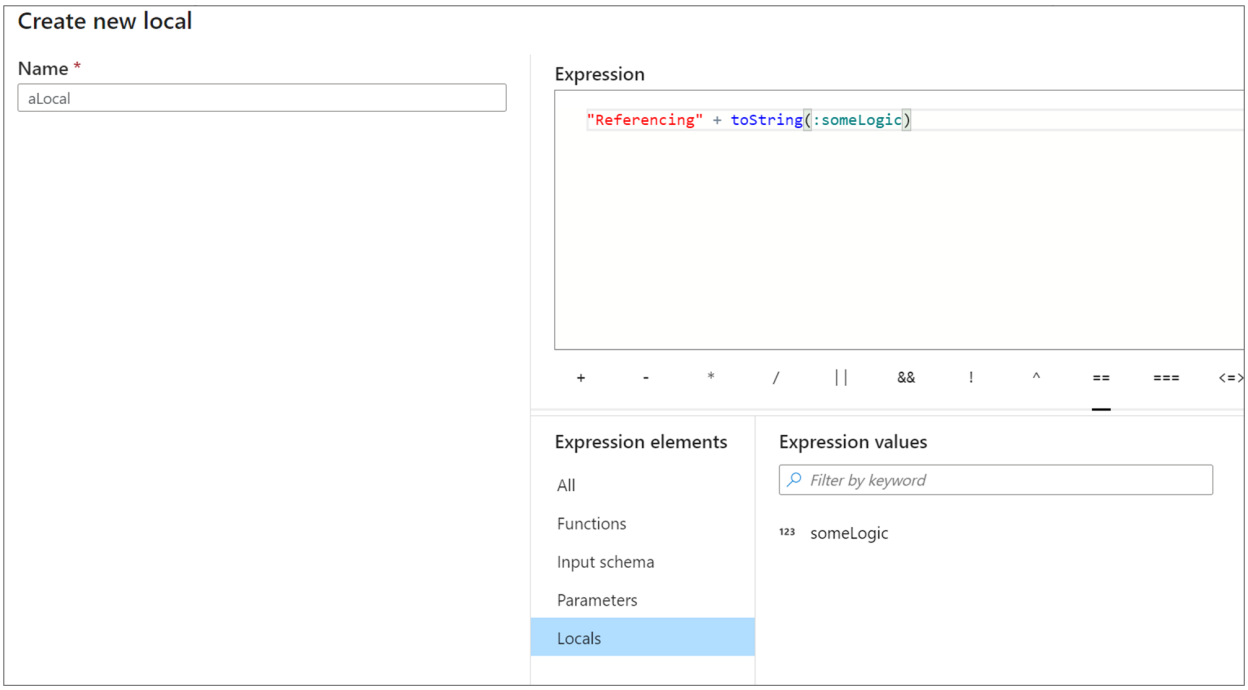


Locals

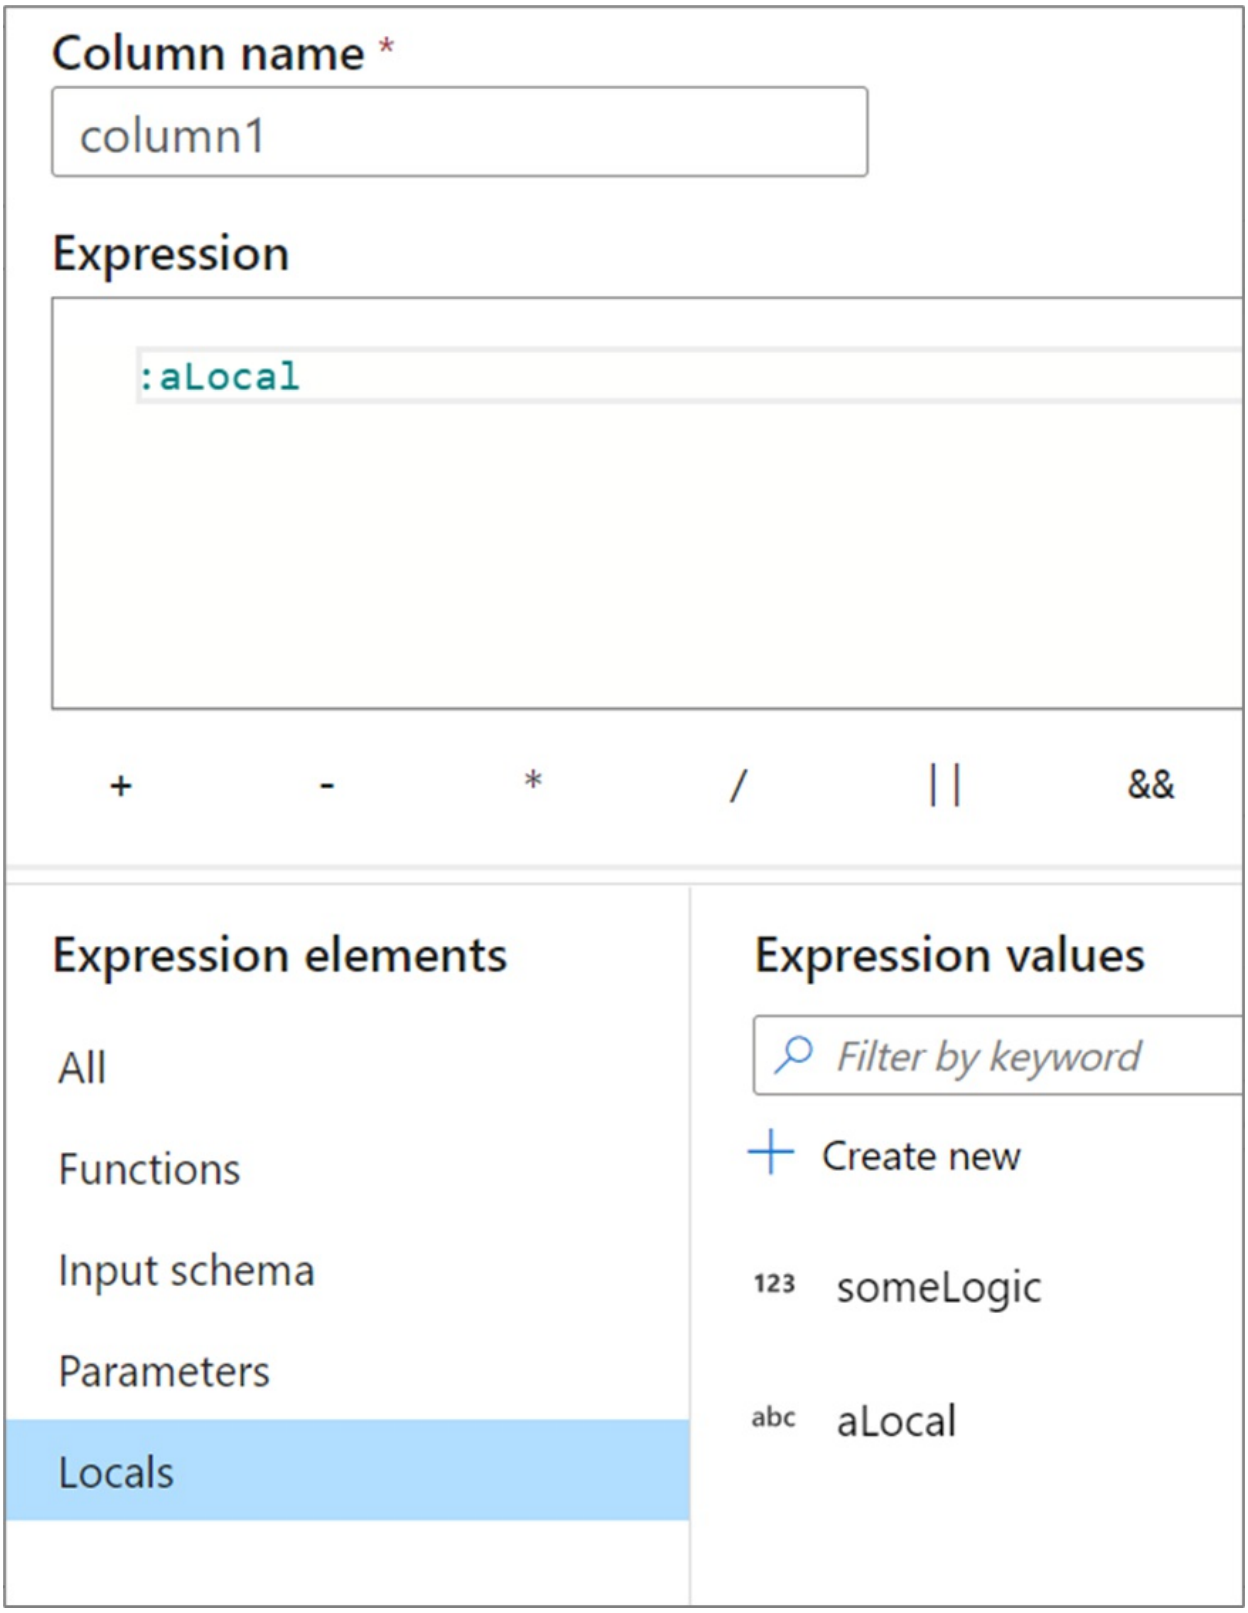
If you are sharing logic across multiple columns or want to compartmentalize your logic, you can create a local variable. A local is a set of logic that doesn't get propagated downstream to the following transformation. Locals can be created within the expression builder by going to **Expression elements** and selecting **Locals**. Create a new one by selecting **Create new**.



Locals can reference any expression element including functions, input schema, parameters, and other locals. When referencing other locals, order does matter as the referenced local needs to be "above" the current one.

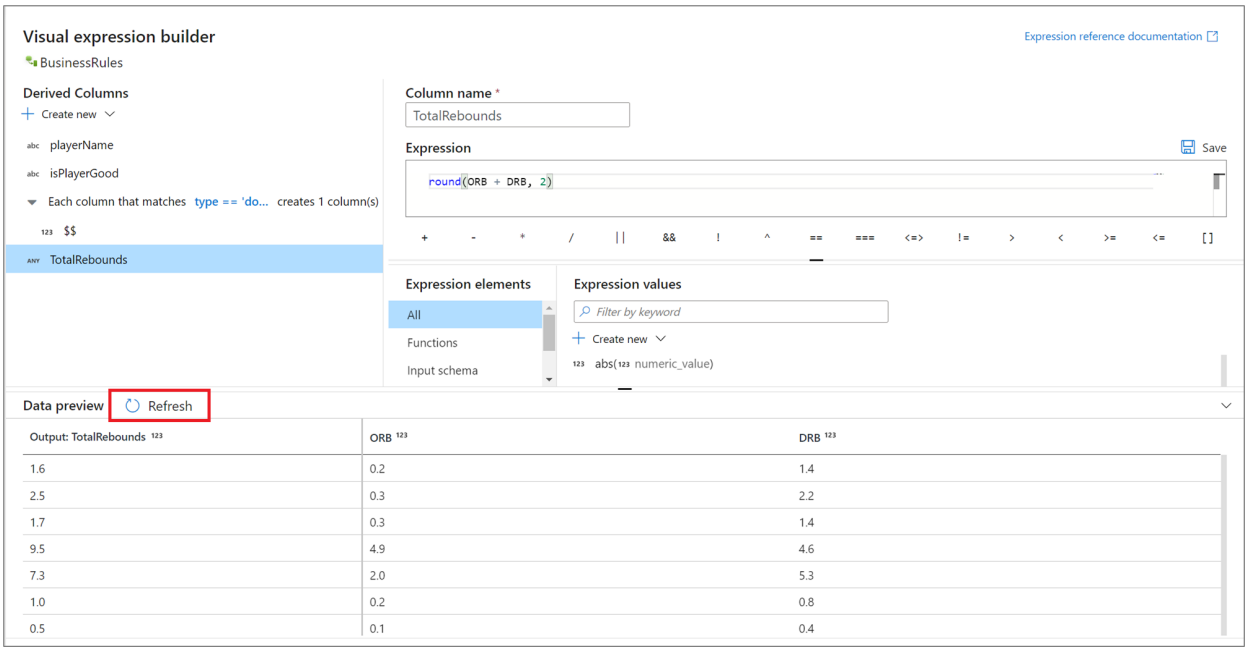


To reference a local in a transformation, either click on the local from the **Expression elements** view or reference it with a colon in front of its name. For example, a local called local1 would be referenced by `:local1`. To edit a local definition, hover over it in the expression elements view and click on the pencil icon.



Preview expression results

If debug mode is switched on, you can interactively use the debug cluster to preview what your expression evaluates to. Select **Refresh** next to data preview to update the results of the data preview. You can see the output of each row given the input columns.



String interpolation

When creating long strings that use expression elements, use string interpolation to easily build up complex string logic. String interpolation avoids extensive use of string concatenation when parameters are included in query strings. Use double quotation marks to enclose literal string text together with expressions. You can include expression functions, columns, and parameters. To use expression syntax, enclose it in curly braces,

Some examples of string interpolation:

- `"My favorite movie is {iif(instr(title,', The')>0,"The {split(title,', The')[1]}",title)}"`
- `"select * from {$tablename} where orderyear > {$year}"`
- `"Total cost with sales tax is {round(totalcost * 1.08,2)}"`
- `"{:playerName} is a {:playerRating} player"`

> **NOTE**
> When using string interpolation syntax in SQL source queries, the query string must be on one single line, without '/n'.

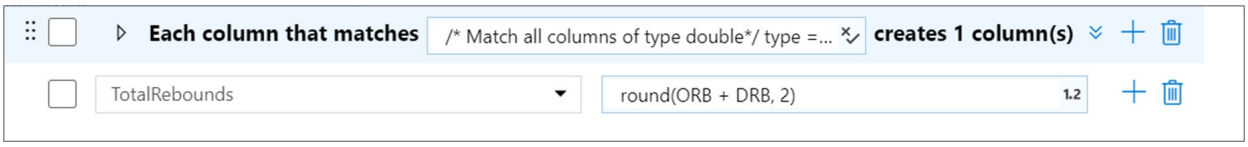
Commenting expressions

Add comments to your expressions by using single-line and multiline comment syntax.

The following examples are valid comments:

- `/* This is my comment */`
- `/* This is a`
- `multi-line comment */`

If you put a comment at the top of your expression, it appears in the transformation text box to document your transformation expressions.



Regular expressions

Many expression language functions use regular expression syntax. When you use regular expression functions, Expression Builder tries to interpret a backslash (\) as an escape character sequence. When you use backslashes in your regular expression, either enclose the entire regex in backticks (`) or use a double backslash.

An example that uses backticks:

```
regex_replace('100 and 200', `(\d+)`, 'digits')
```

An example that uses double slashes:

```
regex_replace('100 and 200', '(\\d+)', 'digits')
```

Keyboard shortcuts

Below are a list of shortcuts available in the expression builder. Most intellisense shortcuts are available when creating expressions.

- Ctrl+K Ctrl+C: Comment entire line.
- Ctrl+K Ctrl+U: Uncomment.
- F1: Provide editor help commands.
- Alt+Down arrow key: Move down current line.
- Alt+Up arrow key: Move up current line.
- Ctrl+Spacebar: Show context help.

Commonly used expressions

Convert to dates or timestamps

To include string literals in your timestamp output, wrap your conversion in `toString()`.

```
toString(toTimestamp('12/31/2016T00:12:00', 'MM/dd/yyyy\'T\'HH:mm:ss'), 'MM/dd /yyyy\'T\'HH:mm:ss')
```

To convert milliseconds from epoch to a date or timestamp, use `toTimestamp(<number of milliseconds>)`. If time is coming in seconds, multiply by 1,000.

```
toTimestamp(1574127407*1000l)
```

The trailing "l" at the end of the previous expression signifies conversion to a long type as inline syntax.

Find time from epoch or Unix Time

toLong(currentTimestamp() - toTimestamp('1970-01-01 00:00:00.000', 'yyyy-MM-dd HH:mm:ss.SSS')) * 1000l

Data flow time evaluation

Dataflow processes till milliseconds. For *2018-07-31T20:00:00.2170000*, you will see *2018-07-31T20:00:00.217* in output. In the portal for the service, timestamp is being shown in the **current browser setting**, which can eliminate 217, but when you will run the data flow end to end, 217 (milliseconds part will be processed as well). You can use toString(myDateTimeColumn) as expression and see full precision data in preview. Process datetime as datetime rather than string for all practical purposes.

Begin building data transformation expressions

Expression functions in mapping data flow

8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The following articles provide details about expression functions supported by Azure Data Factory and Azure Synapse Analytics in mapping data flows.

Expression functions list

In Data Factory and Synapse pipelines, use the expression language of the mapping data flow feature to configure data transformations.

EXPRESSION FUNCTION	TASK
abs	Absolute value of a number.
acos	Calculates a cosine inverse value.
add	Adds a pair of strings or numbers. Adds a date to a number of days. Adds a duration to a timestamp. Appends one array of similar type to another. Same as the + operator.
and	Logical AND operator. Same as &&.
asin	Calculates an inverse sine value.
assertErrorMessages	Returns map of all assert messages.
atan	Calculates an inverse tangent value.
atan2	Returns the angle in radians between the positive x-axis of a plane and the point given by the coordinates.
between	Checks if the first value is in between two other values inclusively. Numeric, string and datetime values can be compared
bitwiseAnd	Bitwise And operator across integral types. Same as & operator.
bitwiseOr	Bitwise Or operator across integral types. Same as | operator.
bitwiseXor	Bitwise Or operator across integral types. Same as | operator.

EXPRESSION FUNCTION	TASK
blake2b	Calculates the Blake2 digest of set of columns of varying primitive datatypes given a bit length. The bit length can only be multiples of 8 between 8 and 512. It can be used to calculate a fingerprint for a row.
blake2bBinary	Calculates the Blake2 digest of set of column of varying primitive datatypes given a bit length, which can only be multiples of 8 between 8 & 512. It can be used to calculate a fingerprint for a row
case	Based on alternating conditions applies one value or the other. If the number of inputs are even, the other is defaulted to NULL for last condition.
cbrt	Calculates the cube root of a number.
ceil	Returns the smallest integer not smaller than the number.
coalesce	Returns the first not null value from a set of inputs. All inputs should be of the same type.
columnNames	Gets the names of all output columns for a stream. You can pass an optional stream name as the first argument and optional second argument to only return schema drift columns.
columns	Gets the values of all output columns for a stream. You can pass an optional stream name as the second argument.
compare	Compares two values of the same type. Returns a negative integer if value1 < value2, 0 if value1 == value2, positive value if value1 > value2.
concat	Concatenates a variable number of strings together. Same as the + operator with strings.
concatWS	Concatenates a variable number of strings together with a separator. The first parameter is the separator.
cos	Calculates a cosine value.
cosh	Calculates a hyperbolic cosine of a value.
crc32	Calculates the CRC32 hash of set of column of varying primitive datatypes given a bit length. The bit length must be of values 0 (256), 224, 256, 384, or 512. It can be used to calculate a fingerprint for a row.
degrees	Converts radians to degrees.
divide	Divides pair of numbers. Same as the `/` operator.

EXPRESSION FUNCTION	TASK
dropLeft	Removes as many characters from the left of the string. If the drop requested exceeds the length of the string, an empty string is returned.
dropRight	Removes as many characters from the right of the string. If the drop requested exceeds the length of the string, an empty string is returned.
endsWith	Checks if the string ends with the supplied string.
equals	Comparison equals operator. Same as == operator.
equalsIgnoreCase	Comparison equals operator, ignoring case. Same as <=> operator.
escape	Escapes a string according to a format. Literal values for acceptable format are 'json', 'xml', 'ecmascript', 'html', 'java'.
expr	Results in an expression from a string. It is equivalent to writing the expression in a non-literal form and can be used to pass parameters as string representations.
factorial	Calculates the factorial of a number.
false	Always returns a false value. Use the function `syntax(false())` if there's a column named 'false'.
floor	Returns the largest integer not greater than the number.
fromBase64	Decodes the given base64-encoded string.
greater	Comparison greater operator. Same as > operator.
greaterOrEqual	Comparison greater than or equal operator. Same as >= operator.
greatest	Returns the greatest value among the list of values as input skipping null values. Returns null if all inputs are null.
hasColumn	Checks for a column value by name in the stream. You can pass an optional stream name as the second argument. Column names known at design time should be addressed just by their name. Computed inputs aren't supported but you can use parameter substitutions.
hasError	Checks if the assert with provided ID is marked as error.
iif	Based on a condition applies one value or the other. If other is unspecified, it's considered NULL. Both the values must be compatible(numeric, string...).
iifNull	Given two or more inputs, returns the first not null item. This function is equivalent to coalesce.

EXPRESSION FUNCTION	TASK
initCap	Converts the first letter of every word to uppercase. Words are identified as separated by whitespace.
instr	Finds the position(1 based) of the substring within a string. 0 is returned if not found.
isDelete	Checks if the row is marked for delete. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isError	Checks if the row is marked as error. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isIgnore	Checks if the row is marked to be ignored. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isInsert	Checks if the row is marked for insert. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isMatch	Checks if the row is matched at lookup. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isNull	Checks if the value is NULL.
isUpdate	Checks if the row is marked for update. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
isUpsert	Checks if the row is marked for insert. For transformations taking more than one input stream you can pass the (1-based) index of the stream. The stream index should be either 1 or 2 and the default value is 1.
jaroWinkler	Gets the JaroWinkler distance between two strings.
least	Comparison lesser than or equal operator. Same as <= operator.
left	Extracts a substring start at index 1 with number of characters. Same as SUBSTRING(str, 1, n).
length	Returns the length of the string.
lesser	Comparison less operator. Same as < operator.

EXPRESSION FUNCTION	TASK
lesserOrEqual	Comparison lesser than or equal operator. Same as <= operator.
levenshtein	Gets the levenshtein distance between two strings.
like	The pattern is a string that is matched literally. The exceptions are the following special symbols: _ matches any one character in the input (similar to. in `posix` regular expressions)
locate	Finds the position(1 based) of the substring within a string starting a certain position. If the position is omitted, it's considered from the beginning of the string. 0 is returned if not found.
log	Calculates log value. An optional base can be supplied else a Euler number if used.
log10	Calculates log value based on 10 base.
lower	Lowercases a string.
lpad	Left pads the string by the supplied padding until it is of a certain length. If the string is equal to or greater than the length, then it's trimmed to the length.
ltrim	Left trims a string of leading characters. If second parameter is unspecified, it trims whitespace. Else it trims any character specified in the second parameter.
md5	Calculates the MD5 digest of set of column of varying primitive datatypes and returns a 32-character hex string. It can be used to calculate a fingerprint for a row.
minus	Subtracts numbers. Subtract number of days from a date. Subtract duration from a timestamp. Subtract two timestamps to get difference in milliseconds. Same as the - operator.
mod	Modulus of pair of numbers. Same as the % operator.
multiply	Multiplies pair of numbers. Same as the * operator.
negate	Negates a number. Turns positive numbers to negative and vice versa.
nextSequence	Returns the next unique sequence. The number is consecutive only within a partition and is prefixed by the partitionId.
normalize	Normalizes the string value to separate accented unicode characters.
not	Logical negation operator.

EXPRESSION FUNCTION	TASK
notEquals	Comparison not equals operator. Same as != operator.
notNull	Checks if the value isn't NULL.
null	Returns a NULL value. Use the function `syntax(null())` if there's a column named 'null'. Any operation that uses will result in a NULL.
or	Logical OR operator. Same as ||.
pMod	Positive Modulus of pair of numbers.
partitionId	Returns the current partition ID the input row is in.
power	Raises one number to the power of another.
radians	Converts degrees to radians
random	Returns a random number given an optional seed within a partition. The seed should be a fixed value and is used with the partitionId to produce random values
regexExtract	Extract a matching substring for a given regex pattern. The last parameter identifies the match group and is defaulted to 1 if omitted. Use `` `<regex>` `` (back quote) to match a string without escaping.
regexMatch	Checks if the string matches the given regex pattern. Use `` `<regex>` `` (back quote) to match a string without escaping.
regexReplace	Replace all occurrences of a regex pattern with another substring in the given string Use `` `<regex>` `` (back quote) to match a string without escaping.
regexSplit	Splits a string based on a delimiter based on regex and returns an array of strings.
replace	Replace all occurrences of a substring with another substring in the given string. If the last parameter is omitted, it's default to empty string.
reverse	Reverses a string.
right	Extracts a substring with number of characters from the right. Same as SUBSTRING(str, LENGTH(str) - n, n).
rlike	Checks if the string matches the given regex pattern.
round	Rounds a number given an optional scale and an optional rounding mode. If the scale is omitted, it's defaulted to 0. If the mode is omitted, it's defaulted to ROUND_HALF_UP(5). The values for rounding include

EXPRESSION FUNCTION	TASK
rpad	Right pads the string by the supplied padding until it is of a certain length. If the string is equal to or greater than the length, then it's trimmed to the length.
rtrim	Right trims a string of trailing characters. If second parameter is unspecified, it trims whitespace. Else it trims any character specified in the second parameter.
sha1	Calculates the SHA-1 digest of set of column of varying primitive datatypes and returns a 40 character hex string. It can be used to calculate a fingerprint for a row.
sha2	Calculates the SHA-2 digest of set of column of varying primitive datatypes given a bit length, which can only be of values 0(256), 224, 256, 384, 512. It can be used to calculate a fingerprint for a row.
sin	Calculates a sine value.
sinh	Calculates a hyperbolic sine value.
soundex	Gets the `soundex` code for the string.
split	Splits a string based on a delimiter and returns an array of strings.
sqrt	Calculates the square root of a number.
startsWith	Checks if the string starts with the supplied string.
substring	Extracts a substring of a certain length from a position. Position is 1 based. If the length is omitted, it's defaulted to end of the string.
substringIndex	Extracts the substring before `count` occurrences of the delimiter. If `count` is positive, everything to the left of the final delimiter (counting from the left) is returned. If `count` is negative, everything to the right of the final delimiter (counting from the right) is returned.
tan	Calculates a tangent value.
tanh	Calculates a hyperbolic tangent value.
translate	Replace one set of characters by another set of characters in the string. Characters have 1 to 1 replacement.
trim	Trims a string of leading and trailing characters. If second parameter is unspecified, it trims whitespace. Else it trims any character specified in the second parameter.
true	Always returns a true value. Use the function `syntax(true())` if there's a column named 'true'.

EXPRESSION FUNCTION	TASK
typeMatch	Matches the type of the column. Can only be used in pattern expressions.number matches short, integer, long, double, float or decimal, integral matches short, integer, long, fractional matches double, float, decimal and datetime matches date or timestamp type.
unescape	Unescapes a string according to a format. Literal values for acceptable format are 'json', 'xml', 'ecmascript', 'html', 'java'.
upper	Uppercases a string.
uuid	Returns the generated UUID.
xor	Logical XOR operator. Same as ^ operator.

Visual authoring in Azure Data Factory

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

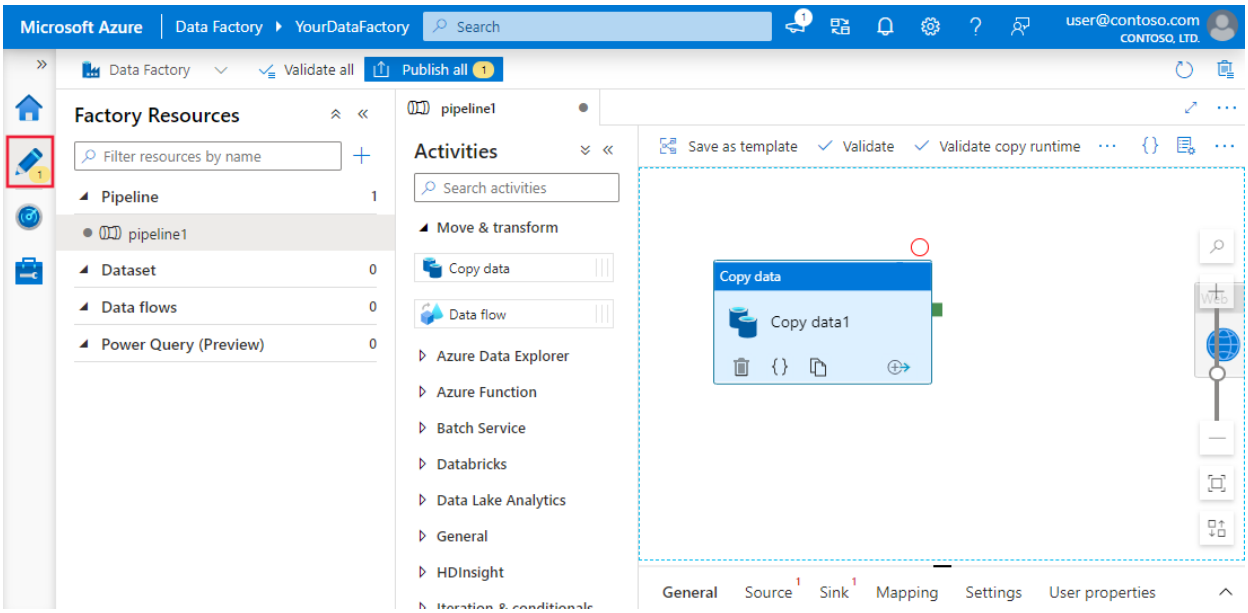
The Azure Data Factory and Synapse Analytics user interface (UI) experience lets you visually author and deploy resources for your data factory or Synapse pipelines without having to write any code. You can drag activities to a pipeline canvas, perform test runs, debug iteratively, and deploy and monitor your pipeline runs.

Currently, the UI is only supported in Microsoft Edge and Google Chrome.

Authoring canvas

- Azure Data Factory
- Synapse Analytics

To open the **authoring canvas**, click on the pencil icon.

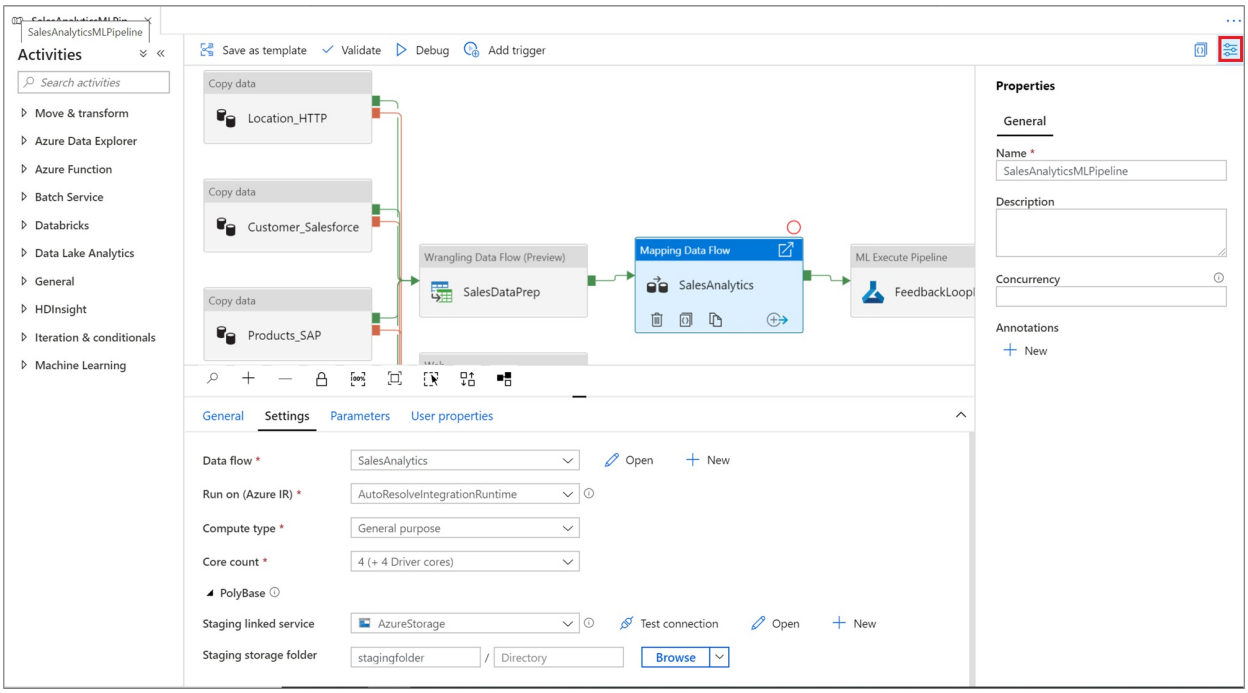


Here, you author the pipelines, activities, datasets, and data flows that comprise your factory. Similarly, linked services, triggers and integration runtimes can be edited on the Manage tab. To get started building a pipeline using the authoring canvas, see Copy data using the copy Activity.

The default visual authoring experience is directly working with the service. Azure Repos Git or GitHub integration is also supported to allow source control and collaboration for work on your pipelines. To learn more about the differences between these authoring experiences, see Source control.

Properties pane

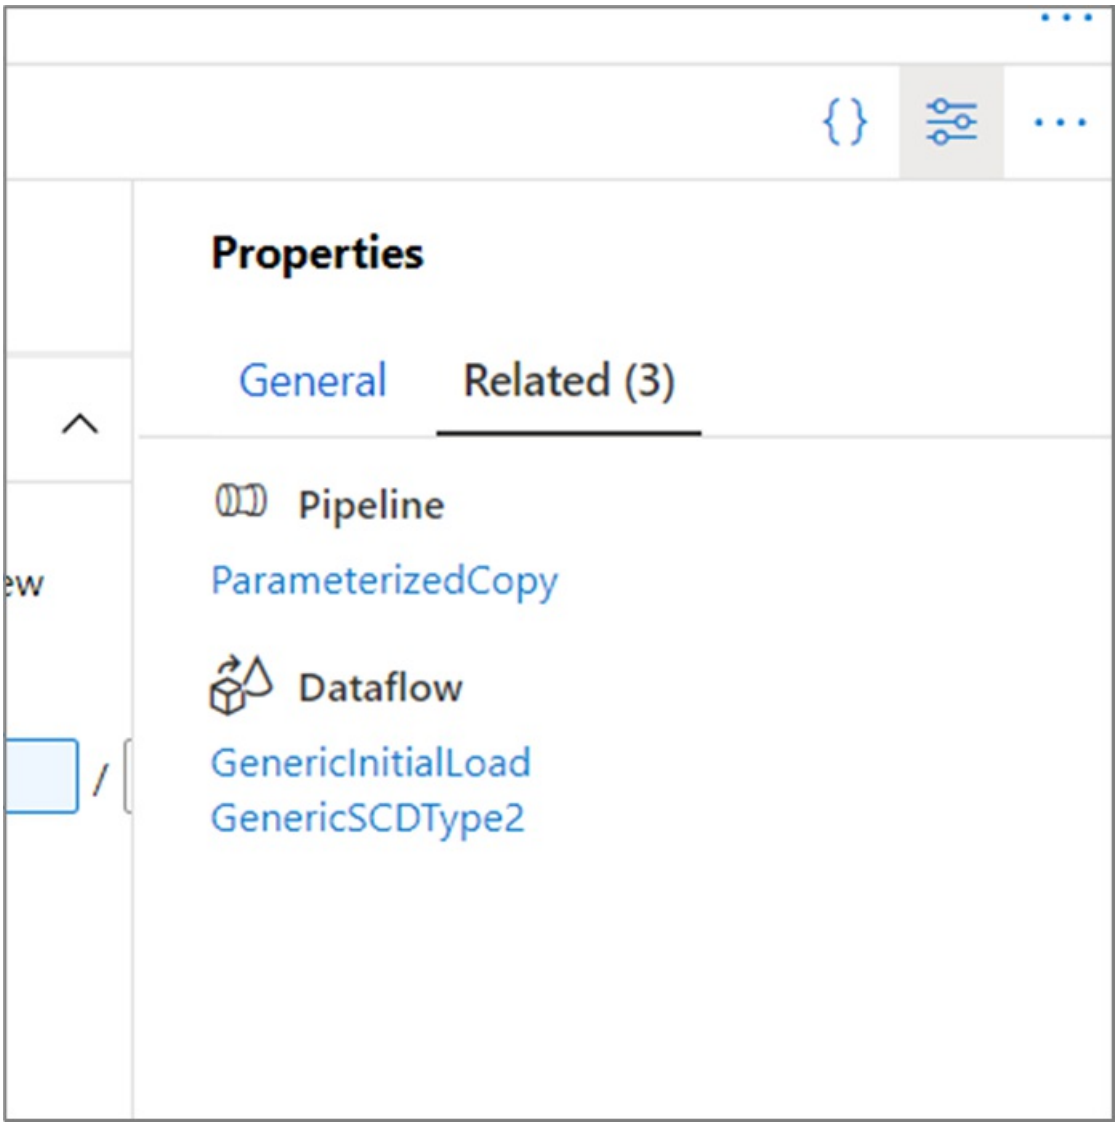
For top-level resources such as pipelines, datasets, and data flows, high-level properties are editable in the properties pane on the right-hand side of the canvas. The properties pane contains properties such as name, description, annotations, and other high-level properties. Subresources such as pipeline activities and data flow transformations are edited using the panel at the bottom of the canvas.



The properties pane only opens by default on resource creation. To edit it, click on the properties pane icon located in the top-right corner of the canvas.

Related resources

In the properties pane, you can see what resources are dependent on the selected resource by selecting the **Related** tab. Any resource that references the current resource will be listed here.

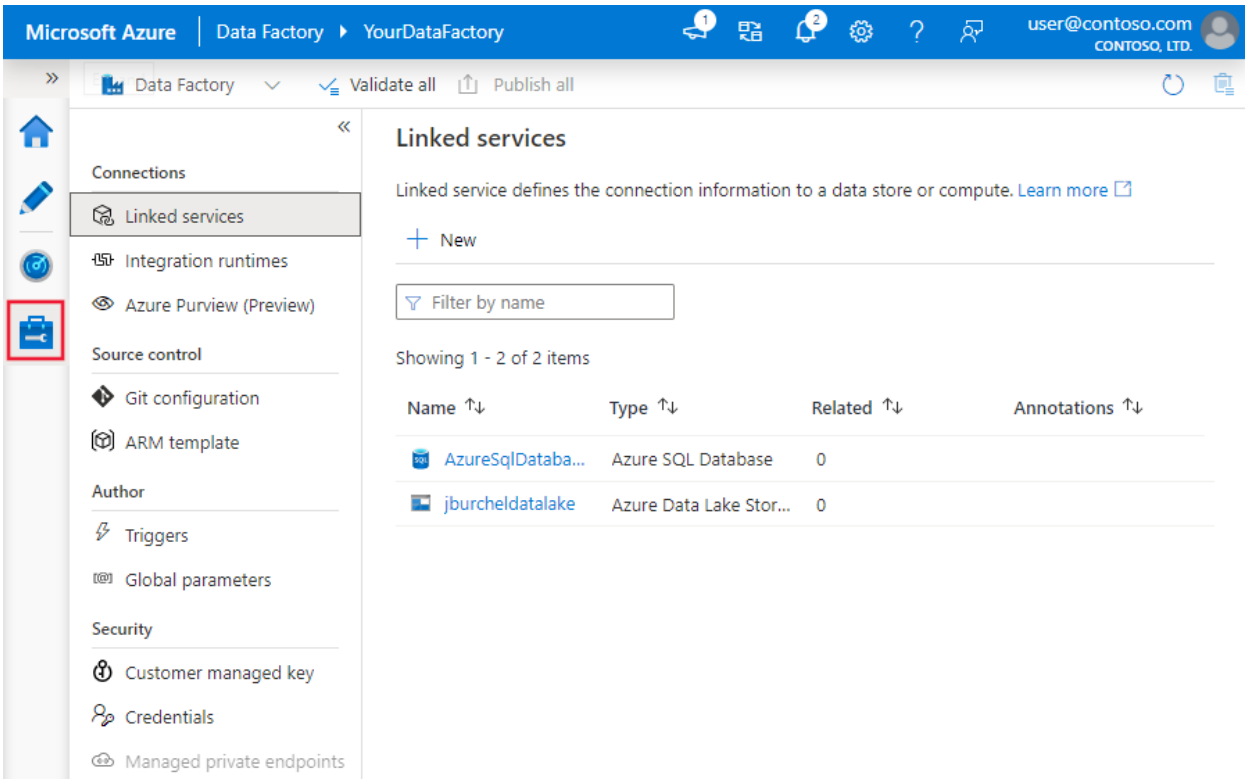


For example, in the above image, one pipeline and two data flows use the dataset currently selected.

Management hub

The management hub, accessed by the *Manage* tab in the UI, is a portal that hosts global management actions for the service. Here, you can manage your connections to data stores and external computes, source control configuration, and trigger settings. For more information, learn about the capabilities of the management hub.

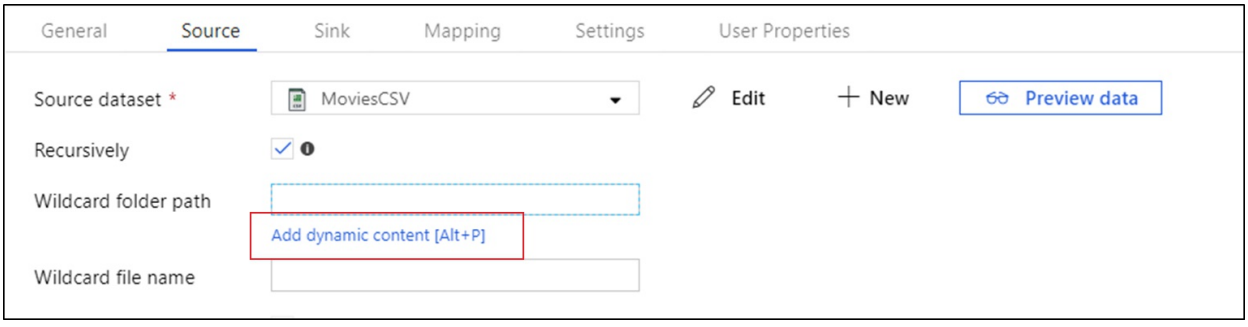
- Azure Data Factory
- Synapse Analytics



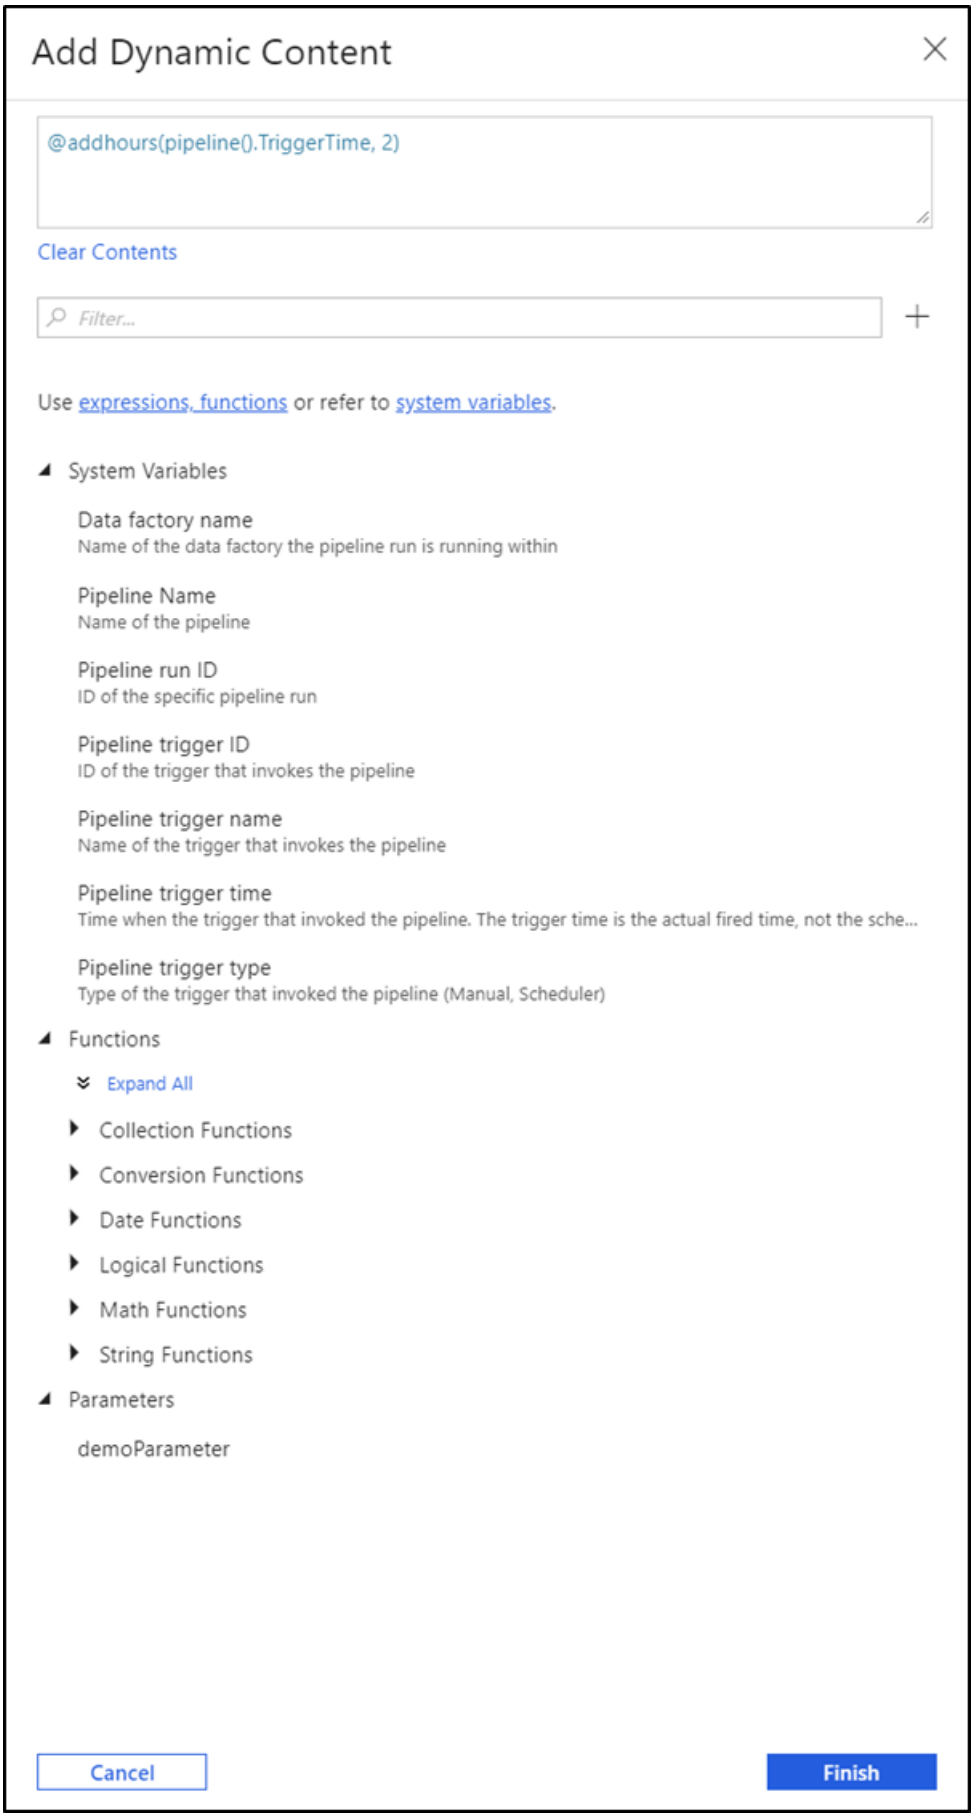
Expressions and functions

Expressions and functions can be used instead of static values to specify many properties within the service.

To specify an expression for a property value, select **Add Dynamic Content** or click **Alt + P** while focusing on the field.



This opens the **Expression Builder** where you can build expressions from supported system variables, activity output, functions, and user-specified variables or parameters.



For information about the expression language, see Expressions and functions.

Provide feedback

Select **Feedback** to comment about features or to notify Microsoft about issues with the tool:

Iterative development and debugging with Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 4 minutes to read • Edit Online

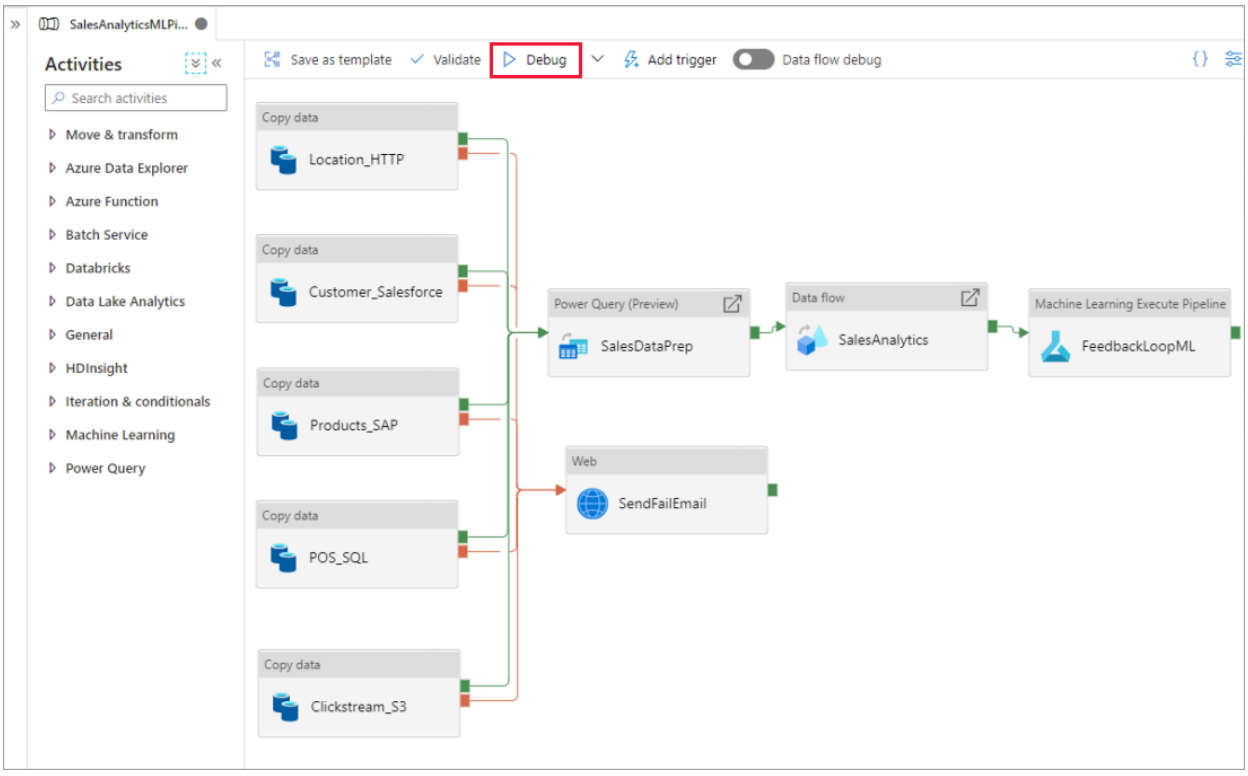
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Azure Data Factory and Synapse Analytics supports iterative development and debugging of pipelines. These features allow you to test your changes before creating a pull request or publishing them to the service.

For an eight-minute introduction and demonstration of this feature, watch the following video:

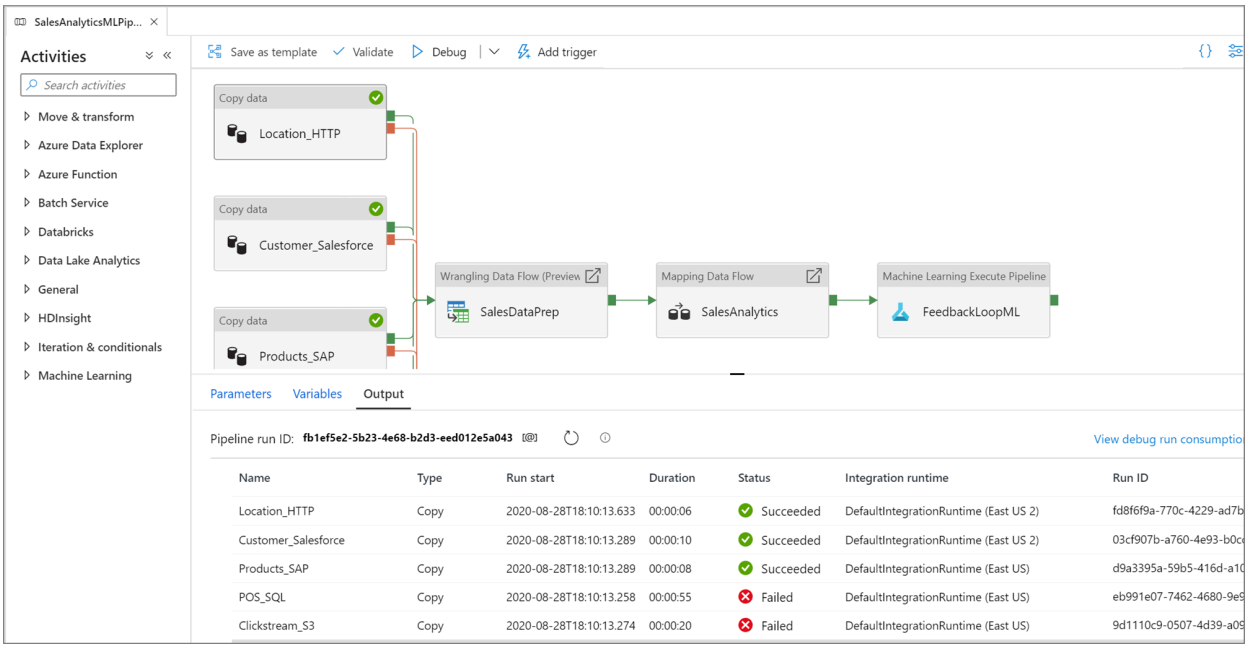
Debugging a pipeline

As you author using the pipeline canvas, you can test your activities using the **Debug** capability. When you do test runs, you don't have to publish your changes to the service before you select **Debug**. This feature is helpful in scenarios where you want to make sure that the changes work as expected before you update the workflow.



As the pipeline is running, you can see the results of each activity in the **Output** tab of the pipeline canvas.

View the results of your test runs in the **Output** window of the pipeline canvas.

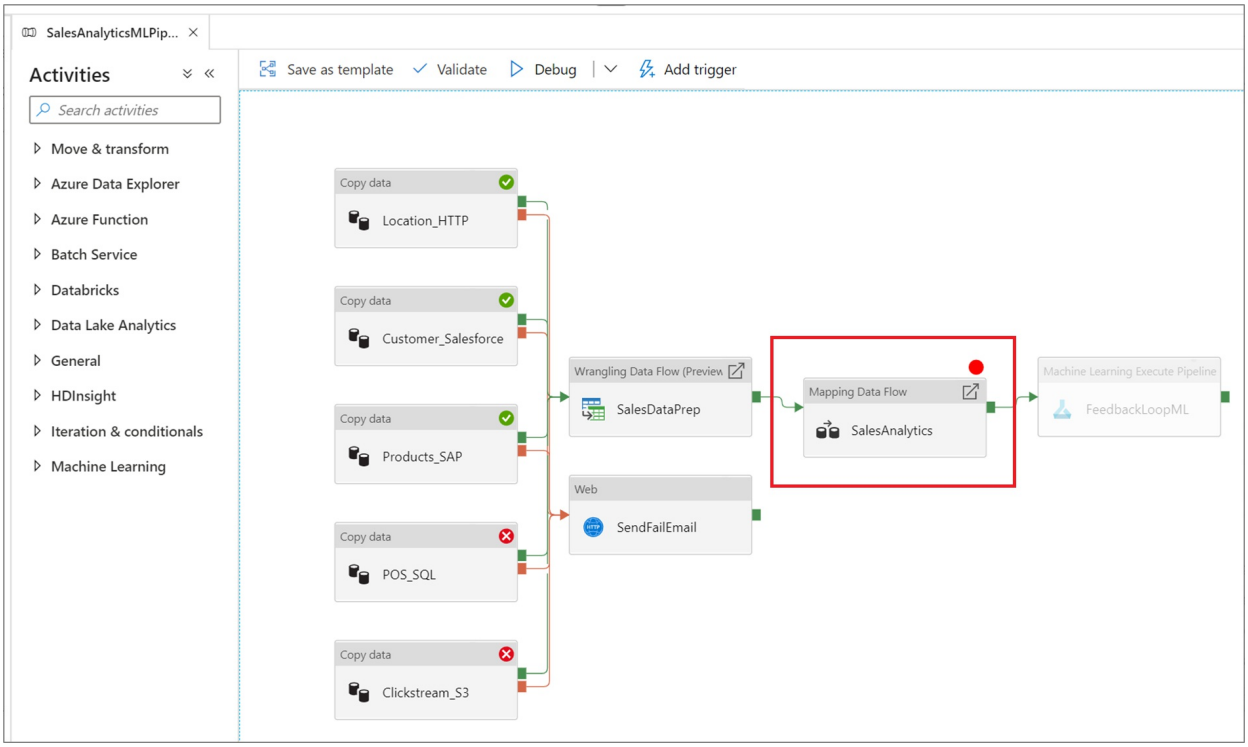


After a test run succeeds, add more activities to your pipeline and continue debugging in an iterative manner. You can also **Cancel** a test run while it is in progress.

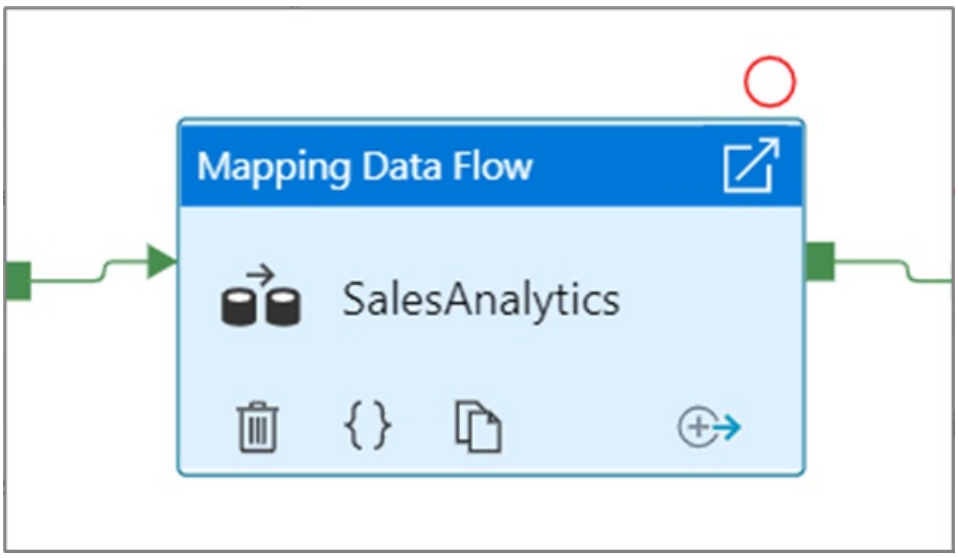
> **IMPORTANT**
>
> Selecting **Debug** actually runs the pipeline. For example, if the pipeline contains copy activity, the test run copies data from source to destination. As a result, we recommend that you use test folders in your copy activities and other activities when debugging. After you've debugged the pipeline, switch to the actual folders that you want to use in normal operations.

Setting breakpoints

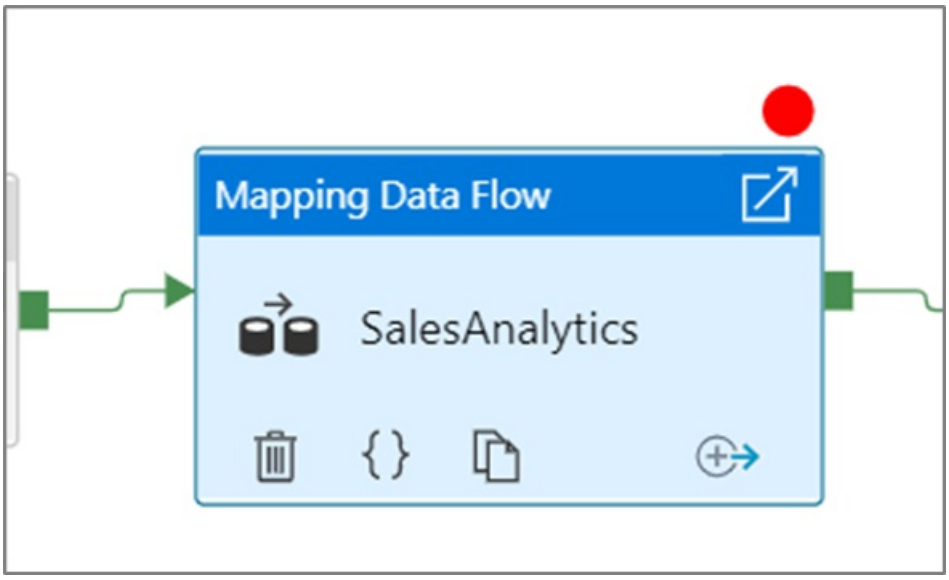
The service allows for you to debug a pipeline until you reach a particular activity on the pipeline canvas. Put a breakpoint on the activity until which you want to test, and select **Debug**. The service ensures that the test runs only until the breakpoint activity on the pipeline canvas. This *Debug Until* feature is useful when you don't want to test the entire pipeline, but only a subset of activities inside the pipeline.



To set a breakpoint, select an element on the pipeline canvas. A *Debug Until* option appears as an empty red circle at the upper right corner of the element.

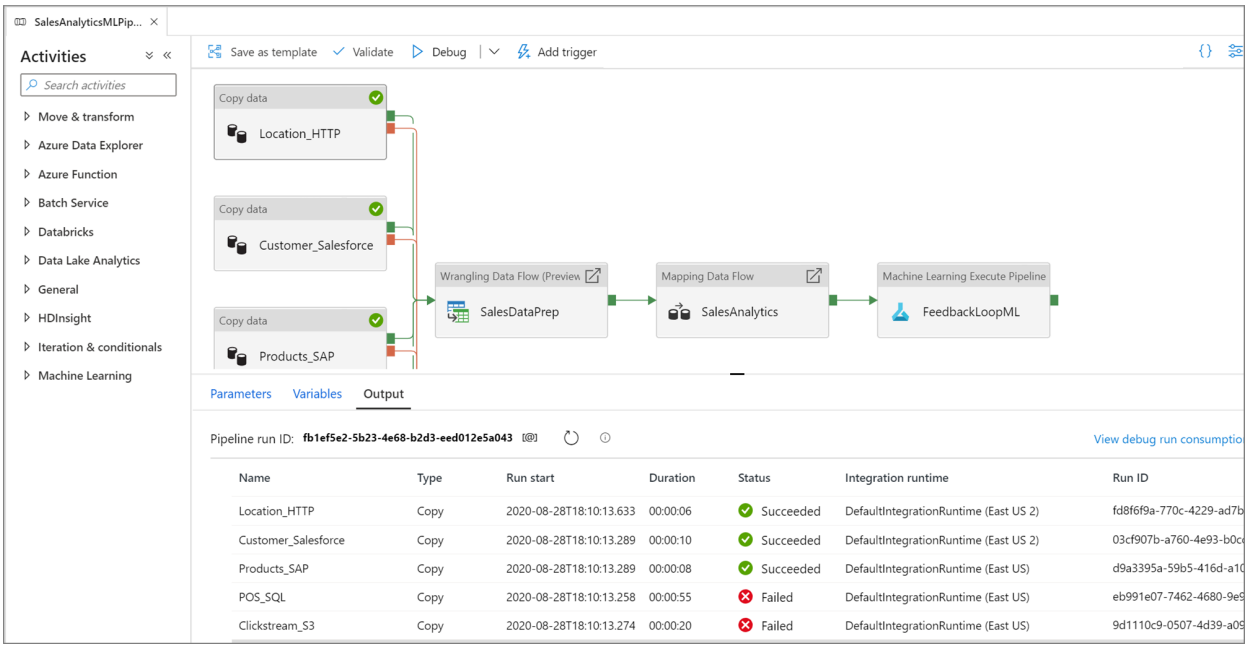


After you select the *Debug Until* option, it changes to a filled red circle to indicate the breakpoint is enabled.



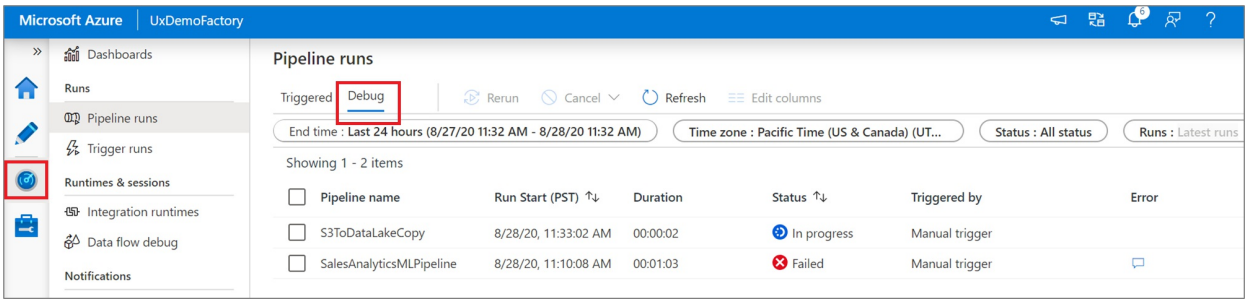
Monitoring debug runs

When you run a pipeline debug run, the results will appear in the **Output** window of the pipeline canvas. The output tab will only contain the most recent run that occurred during the current browser session.



To view a historical view of debug runs or see a list of all active debug runs, you can go into the **Monitor** experience.

- Azure Data Factory
- Synapse Analytics

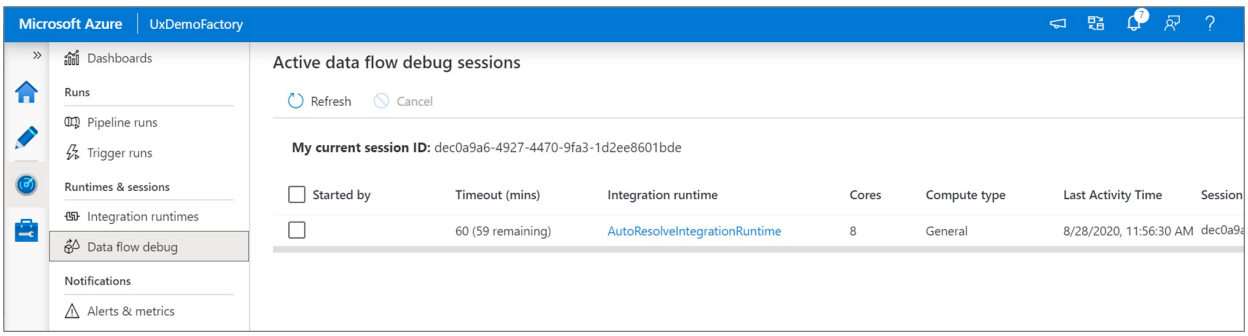


> **NOTE**
> The service only persists debug run history for 15 days.

Debugging mapping data flows

Mapping data flows allow you to build code-free data transformation logic that runs at scale. When building your logic, you can turn on a debug session to interactively work with your data using a live Spark cluster. To learn more, read about mapping data flow debug mode.

You can monitor active data flow debug sessions in the **Monitor** experience.



Data preview in the data flow designer and pipeline debugging of data flows are intended to work best with

small samples of data. However, if you need to test your logic in a pipeline or data flow against large amounts of data, increase the size of the Azure Integration Runtime being used in the debug session with more cores and a minimum of general purpose compute.

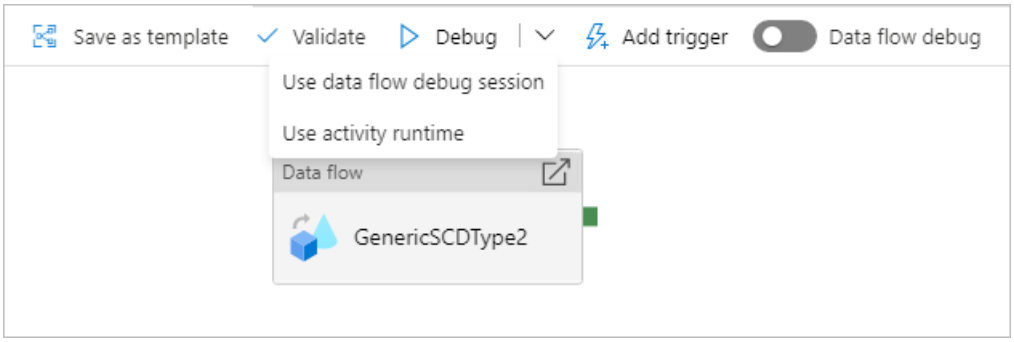
Debugging a pipeline with a data flow activity

When executing a debug pipeline run with a data flow, you have two options on which compute to use. You can either use an existing debug cluster or spin up a new just-in-time cluster for your data flows.

Using an existing debug session will greatly reduce the data flow start up time as the cluster is already running, but is not recommended for complex or parallel workloads as it may fail when multiple jobs are run at once.

Using the activity runtime will create a new cluster using the settings specified in each data flow activity's integration runtime. This allows each job to be isolated and should be used for complex workloads or performance testing. You can also control the TTL in the Azure IR so that the cluster resources used for debugging will still be available for that time period to serve additional job requests.

> **NOTE**
> If you have a pipeline with data flows executing in parallel or data flows that need to be tested with large datasets, choose "Use Activity Runtime" so that the service can use the Integration Runtime that you've selected in your data flow activity. This will allow the data flows to execute on multiple clusters and can accommodate your parallel data flow executions.



Next steps

After testing your changes, promote them to higher environments using continuous integration and deployment.

Azure Data Factory and Azure Synapse Analytics connector overview

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Azure Data Factory and Azure Synapse Analytics pipelines support the following data stores and formats via Copy, Data Flow, Look up, Get Metadata, and Delete activities. Click each data store to learn the supported capabilities and the corresponding configurations in details.

Supported data stores

CATEGORY	DATA STORE	COPY ACTIVITY (SOURCE/SINK)	MAPPING DATA FLOW (SOURCE/SINK)	LOOKUP ACTIVITY	GET METADATA ACTIVITY/VALIDATION ACTIVITY	DELETE ACTIVITY	MANAGED PRIVATE ENDPOINT

NOTE

Any connector marked as *Preview* means that you can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Integrate with more data stores

Azure Data Factory and Synapse pipelines can reach broader set of data stores than the list mentioned above. If you need to move data to/from a data store that is not in the service built-in connector list, here are some extensible options:

- For database and data warehouse, usually you can find a corresponding ODBC driver, with which you can use generic ODBC connector.
- For SaaS applications:
  - If it provides RESTful APIs, you can use generic REST connector.
  - If it has OData feed, you can use generic OData connector.
  - If it provides SOAP APIs, you can use generic HTTP connector.
  - If it has ODBC driver, you can use generic ODBC connector.
- For others, check if you can load data to or expose data as any supported data stores, e.g. Azure Blob/File/FTP/SFTP/etc, then let the service pick up from there. You can invoke custom data loading mechanism via Azure Function, Custom activity, Databricks/HDInsight, Web activity, etc.

Supported file formats

The following file formats are supported. Refer to each article for format-based settings.

- Avro format
- Binary format
- Common Data Model format
- Delimited text format
- Delta format
- Excel format

- JSON format
- ORC format
- Parquet format
- XML format

- Delete Activity

Copy data from Amazon Marketplace Web Service using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Amazon Marketplace Web Service. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Amazon Marketplace Web Service connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

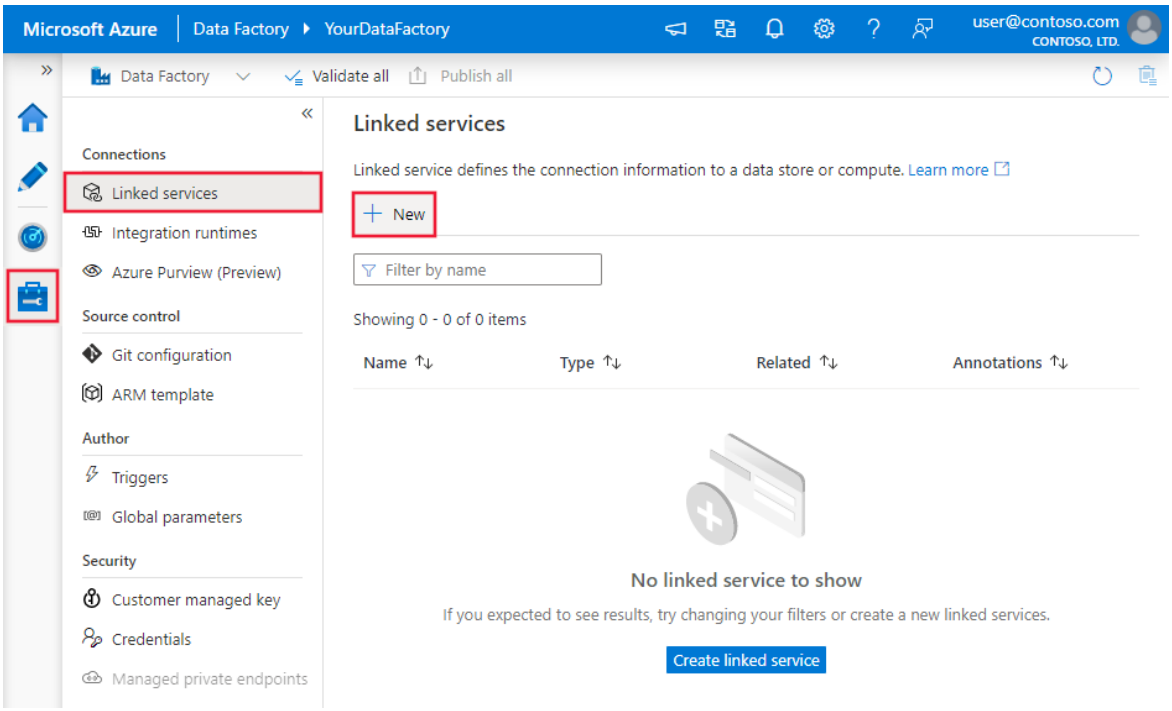
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Amazon Marketplace Web Service using UI

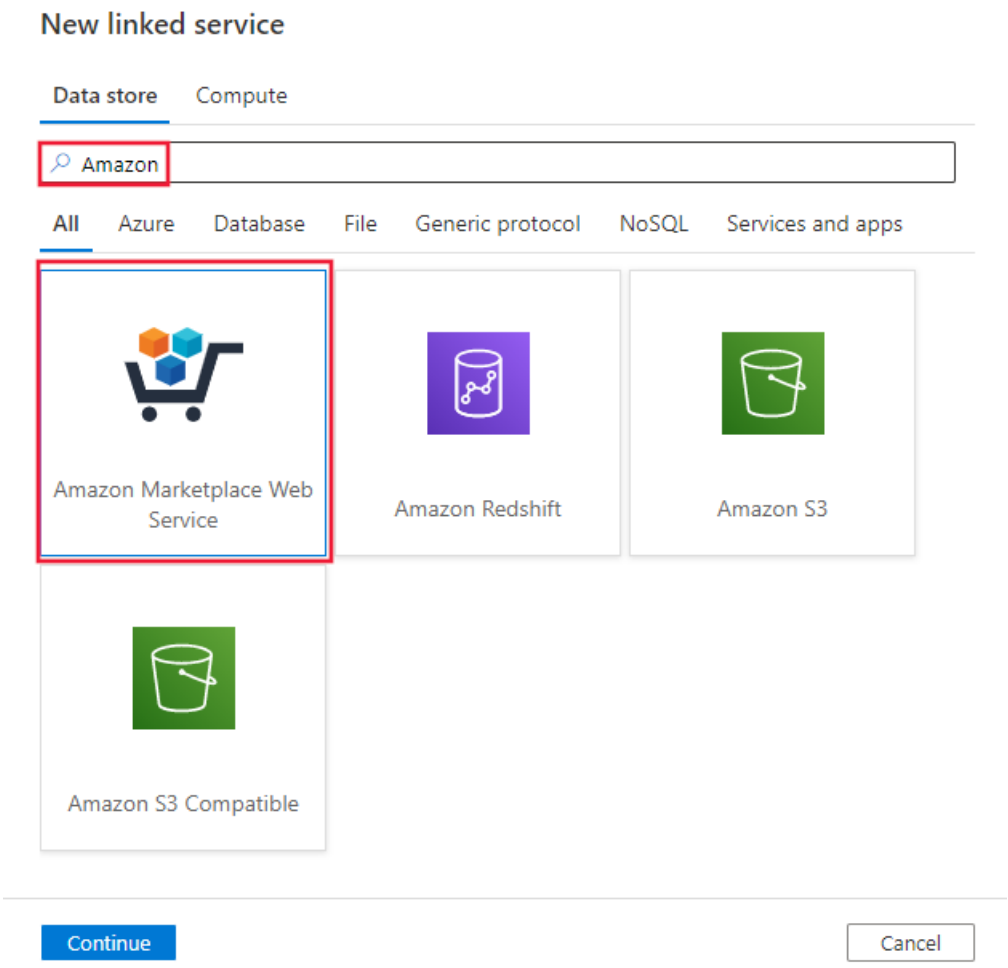
Use the following steps to create a linked service to Amazon Marketplace Web Service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

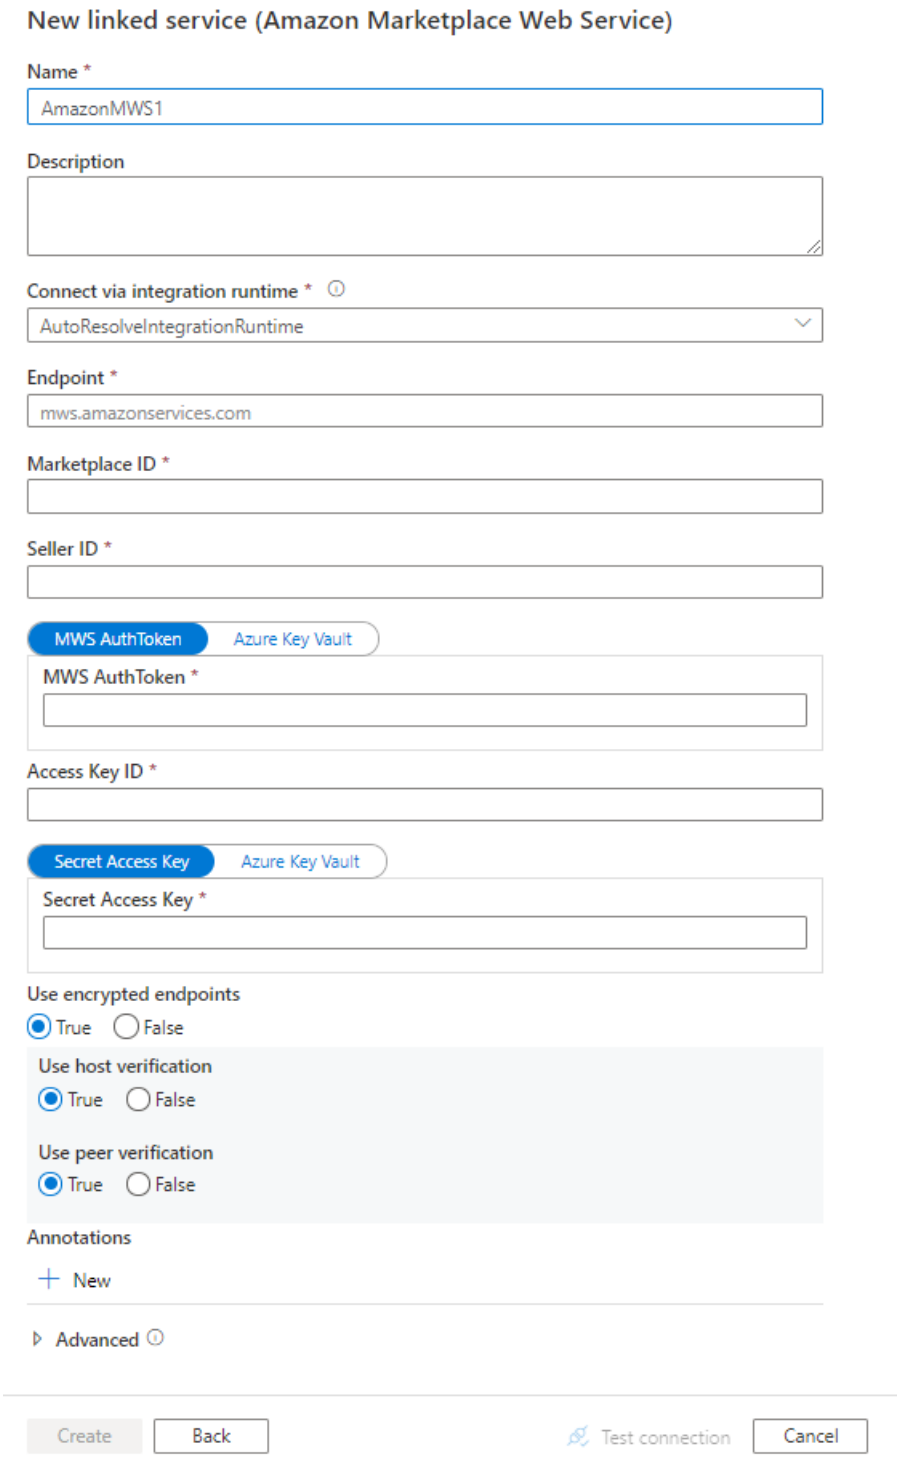
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon and select the Amazon Marketplace Web Service connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Amazon Marketplace Web Service connector.

Linked service properties

The following properties are supported for Amazon Marketplace Web Service linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AmazonMWS**	Yes

PROPERTY	DESCRIPTION	REQUIRED
endpoint	The endpoint of the Amazon MWS server, (that is, mws.amazonservices.com)	Yes
marketplaceID	The Amazon Marketplace ID you want to retrieve data from. To retrieve data from multiple Marketplace IDs, separate them with a comma (`,`). (that is, A2EUQ1WTGCTBG2)	Yes
sellerID	The Amazon seller ID.	Yes
mwsAuthToken	The Amazon MWS authentication token. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
accessKeyId	The access key ID used to access data.	Yes
secretKey	The secret key used to access data. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "AmazonMWSLinkedService",
    "properties": {
        "type": "AmazonMWS",
        "typeProperties": {
            "endpoint" : "mws.amazonservices.com",
            "marketplaceID" : "A2EUQ1WTGCTBG2",
            "sellerID" : "<sellerID>",
            "mwsAuthToken": {
                 "type": "SecureString",
                 "value": "<mwsAuthToken>"
            },
            "accessKeyId" : "<accessKeyId>",
            "secretKey": {
                 "type": "SecureString",
                 "value": "<secretKey>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Amazon Marketplace Web Service dataset.

To copy data from Amazon Marketplace Web Service, set the type property of the dataset to **AmazonMWSObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **AmazonMWSObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "AmazonMWSDataset",
    "properties": {
        "type": "AmazonMWSObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<AmazonMWS linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Amazon Marketplace Web Service source.

Amazon MWS as source

To copy data from Amazon Marketplace Web Service, set the source type in the copy activity to **AmazonMWSSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **AmazonMWSSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Orders where Amazon_Order_Id = 'xx'"` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromAmazonMWS",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<AmazonMWS input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AmazonMWSSource",
                "query": "SELECT * FROM Orders where Amazon_Order_Id = 'xx'"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Copy data from Amazon RDS for Oracle by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 12 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory to copy data from an Amazon RDS for Oracle database. It builds on the copy activity overview.

Supported capabilities

This Amazon RDS for Oracle connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this Amazon RDS for Oracle connector supports:

- The following versions of an Amazon RDS for Oracle database:
  - Amazon RDS for Oracle 19c R1 (19.1) and higher
  - Amazon RDS for Oracle 18c R1 (18.1) and higher
  - Amazon RDS for Oracle 12c R1 (12.1) and higher
  - Amazon RDS for Oracle 11g R1 (11.1) and higher
- Parallel copying from an Amazon RDS for Oracle source. See the Parallel copy from Amazon RDS for Oracle section for details.

> **NOTE**
> Amazon RDS for Oracle proxy server isn't supported.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The integration runtime provides a built-in Amazon RDS for Oracle driver. Therefore, you don't need to manually install a driver when you copy data from Amazon RDS for Oracle.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

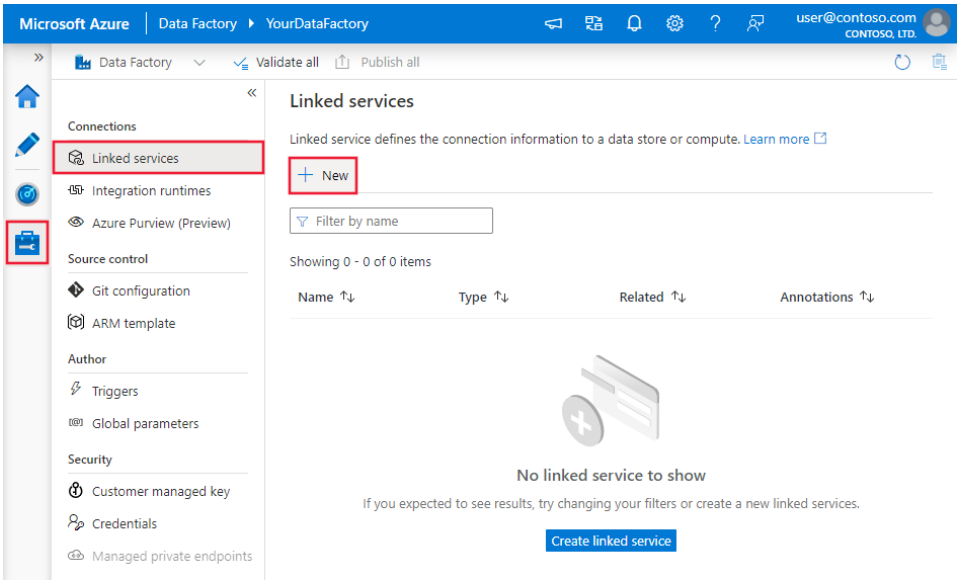
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Amazon RDS for Oracle using UI

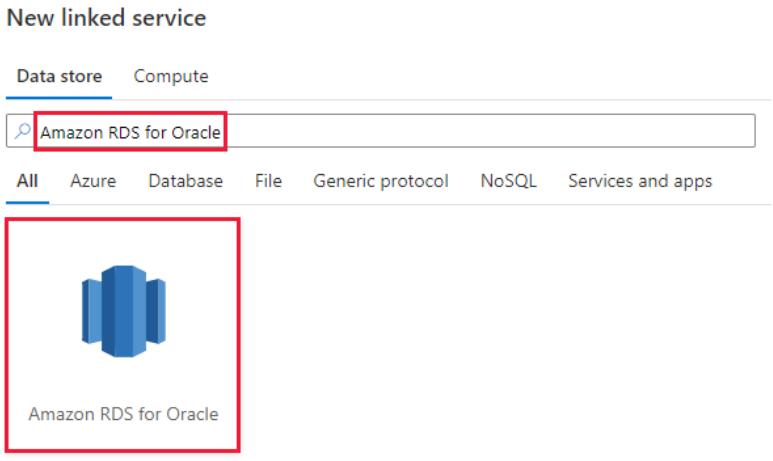
Use the following steps to create a linked service to Amazon RDS for Oracle in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

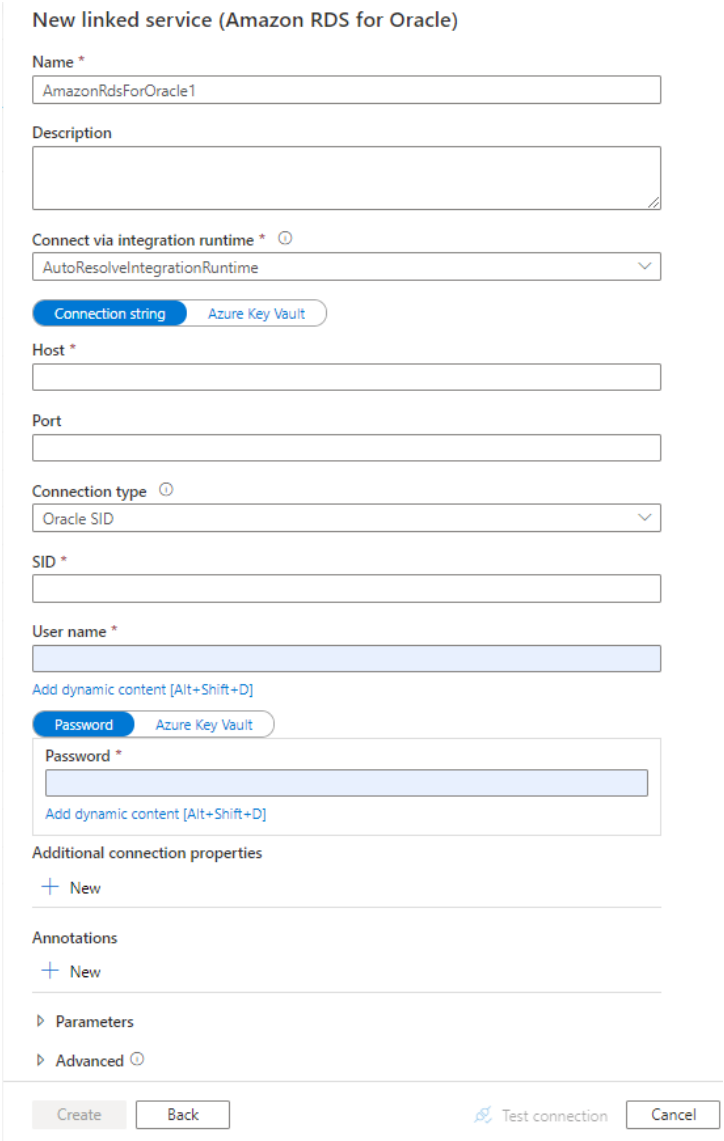
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon RDS for Oracle and select the Amazon RDS for Oracle connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to the Amazon RDS for Oracle connector.

Linked service properties

The Amazon RDS for Oracle linked service supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AmazonRdsForOracle**.	Yes

PROPERTY	DESCRIPTION	REQUIRED

connectionString	Specifies the information needed to connect to the Amazon RDS for Oracle Database instance.
	You can also put a password in Azure Key Vault, and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault with more details.
	
	Supported connection type: You can use **Amazon RDS for Oracle SID** or **Amazon RDS for Oracle Service Name** to identify your database:
	- If you use SID:
	`Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;`
	- If you use Service Name:
	`Host=<host>;Port=<port>;ServiceName=<servicename>;User Id=<username>;Password=<password>;`
	For advanced Amazon RDS for Oracle native connection options, you can choose to add an entry in TNSNAMES.ORA file on the Amazon RDS for Oracle server, and in Amazon RDS for Oracle linked service, choose to use Amazon RDS for Oracle Service Name connection type and configure the corresponding service name.
		Yes

connectVia	The integration runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure Integration Runtime is used.	No

If you have multiple Amazon RDS for Oracle instances for failover scenario, you can create Amazon RDS for Oracle linked service and fill in the primary host, port, user name, password, etc., and add a new "**Additional connection properties**" with property name as `AlternateServers` and value as `(HostName=<secondary host>:PortNumber=<secondary port>:ServiceName=<secondary service name>)` - do not miss the brackets and pay attention to the colons (`:`) as separator. As an example, the following value of alternate servers defines two alternate database servers for connection failover:

```
(HostName=AccountingAmazonRdsForOracleServer:PortNumber=1521:SID=Accounting,HostName=255.201.11.24:PortNumber=1522:ServiceName=ABackup.
```

.

More connection properties you can set in connection string per your case:

PROPERTY	DESCRIPTION	ALLOWED VALUES
ArraySize	The number of bytes the connector can fetch in a single network round trip. For example, `ArraySize=10485760`. Larger values increase throughput by reducing the number of times to fetch data across the network. Smaller values increase response time, as there is less of a delay waiting for the server to transmit data.	An integer from 1 to 4294967296 (4 GB). Default value is `60000`. The value 1 does not define the number of bytes, but indicates allocating space for exactly one row of data.

To enable encryption on Amazon RDS for Oracle connection, you have two options:

- To use **Triple-DES Encryption (3DES) and Advanced Encryption Standard (AES)**, on the Amazon RDS for Oracle server side, go to Oracle Advanced Security (OAS) and configure the encryption settings. For details, see this Oracle documentation. The Amazon RDS for Oracle Application Development Framework (ADF) connector automatically negotiates the encryption method to use the one you configure in OAS when establishing a connection to Amazon RDS for Oracle.

- To use **TLS**:

  1. Get the TLS/SSL certificate info. Get the Distinguished Encoding Rules (DER)-encoded certificate information of your TLS/SSL cert, and save the output (----- Begin Certificate ... End Certificate -----) as a text file.

     ```
     openssl x509 -inform DER -in [Full Path to the DER Certificate including the name of the DER Certificate] -text
     ```

     Example: Extract cert info from DERcert.cer, and then save the output to cert.txt.

     ```
     openssl x509 -inform DER -in DERcert.cer -text
     Output:
     -----BEGIN CERTIFICATE-----
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXX
     -----END CERTIFICATE-----
     ```

  2. Build the `keystore` or `truststore`. The following command creates the `truststore` file, with or without a password, in PKCS-12 format.

     ```
     openssl pkcs12 -in [Path to the file created in the previous step] -out [Path and name of TrustStore] -passout pass:[Keystore PWD] -nokeys -export
     ```

     Example: Create a PKCS12 `truststore` file, named MyTrustStoreFile, with a password.

     ```
     openssl pkcs12 -in cert.txt -out MyTrustStoreFile -passout pass:ThePWD -nokeys -export
     ```

  3. Place the `truststore` file on the self-hosted IR machine. For example, place the file at C:\MyTrustStoreFile.

  4. In the service, configure the Amazon RDS for Oracle connection string with `EncryptionMethod=1` and the corresponding `TrustStore` / `TrustStorePassword` value. For example, `Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;EncryptionMethod=1;TrustStore=C:\\MyTrustStoreFile;TrustStorePassword=<trust_store_password>`.

Example:

```
{
    "name": "AmazonRdsForOracleLinkedService",
    "properties": {
        "type": "AmazonRdsForOracle",
        "typeProperties": {
            "connectionString": "Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "AmazonRdsForOracleLinkedService",
    "properties": {
        "type": "AmazonRdsForOracle",
        "typeProperties": {
            "connectionString": "Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties supported by the Amazon RDS for Oracle dataset. For a full list of sections and properties available for defining datasets, see Datasets.

To copy data from Amazon RDS for Oracle, set the type property of the dataset to `AmazonRdsForOracleTable`. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to `AmazonRdsForOracleTable`.	Yes
schema	Name of the schema.	No
table	Name of the table/view.	No
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No

Example:

```
{
    "name": "AmazonRdsForOracleDataset",
    "properties":
    {
        "type": "AmazonRdsForOracleTable",
        "schema": [],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        },
        "linkedServiceName": {
            "referenceName": "<Amazon RDS for Oracle linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

This section provides a list of properties supported by the Amazon RDS for Oracle source. For a full list of sections and properties available for defining activities, see Pipelines.

Amazon RDS for Oracle as source

TIP

To load data from Amazon RDS for Oracle efficiently by using data partitioning, learn more from Parallel copy from Amazon RDS for Oracle.

To copy data from Amazon RDS for Oracle, set the source type in the copy activity to `AmazonRdsForOracleSource`. The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to `AmazonRdsForOracleSource`.	Yes
oracleReaderQuery	Use the custom SQL query to read data. An example is `"SELECT * FROM MyTable"`. When you enable partitioned load, you need to hook any corresponding built-in partition parameters in your query. For examples, see the Parallel copy from Amazon RDS for Oracle section.	No
partitionOptions	Specifies the data partitioning options used to load data from Amazon RDS for Oracle. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from an Amazon RDS for Oracle database is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
partitionNames	The list of physical partitions that needs to be copied. Apply when the partition option is `PhysicalPartitionsOfTable`. If you use a query to retrieve the source data, hook `?AdfTabularPartitionName` in the WHERE clause. For an example, see the Parallel copy from Amazon RDS for Oracle section.	No
partitionColumnName	Specify the name of the source column **in integer type** that will be used by range partitioning for parallel copy. If not specified, the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionColumnName` in the WHERE clause. For an example, see the Parallel copy from Amazon RDS for Oracle section.	No

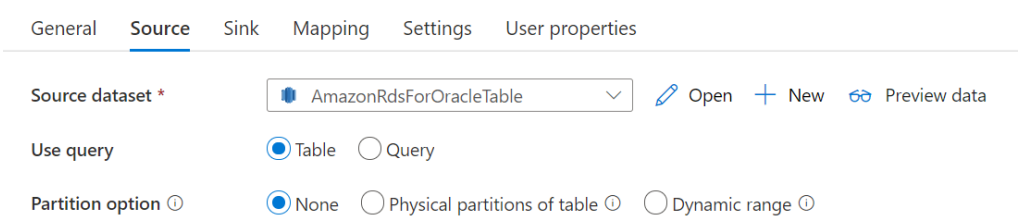
PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionUpbound` in the WHERE clause. For an example, see the Parallel copy from Amazon RDS for Oracle section.	No
partitionLowerBound	The minimum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionLowbound` in the WHERE clause. For an example, see the Parallel copy from Amazon RDS for Oracle section.	No

Example: copy data by using a basic query without partition

```
"activities":[
    {
        "name": "CopyFromAmazonRdsForOracle",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Amazon RDS for Oracle input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AmazonRdsForOracleSource",
                "oracleReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Parallel copy from Amazon RDS for Oracle

The Amazon RDS for Oracle connector provides built-in data partitioning to copy data from Amazon RDS for Oracle in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, the service runs parallel queries against your Amazon RDS for Oracle source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Amazon RDS for Oracle database.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Amazon RDS for Oracle database. The following are suggested configurations for different scenarios.

When copying data into file-based data store, it's recommanded to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions.
Full load from large table, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column**: Specify the column used to partition data. If not specified, the primary key column is used.
Load a large amount of data by using a custom query, with physical partitions.	**Partition option**: Physical partitions of table. **Query**: `SELECT * FROM <TABLENAME> PARTITION("?AdfTabularPartitionName") WHERE <your_additional_where_clause>` . **Partition name**: Specify the partition name(s) to copy data from. If not specified, the service automatically detects the physical partitions on the table you specified in the Amazon RDS for Oracle dataset. During execution, the service replaces `?AdfTabularPartitionName` with the actual partition name, and sends to Amazon RDS for Oracle.
Load a large amount of data by using a custom query, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Query**: `SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ? AdfRangePartitionUpbound AND ?AdfRangePartitionColumnName >= ? AdfRangePartitionLowbound AND <your_additional_where_clause>` . **Partition column**: Specify the column used to partition data. You can partition against the column with integer data type. **Partition upper bound** and **partition lower bound**: Specify if you want to filter against partition column to retrieve data only between the lower and upper range. During execution, the service replaces `?AdfRangePartitionColumnName`, `?AdfRangePartitionUpbound`, and `?AdfRangePartitionLowbound` with the actual column name and value ranges for each partition, and sends to Amazon RDS for Oracle. For example, if your partition column "ID" is set with the lower bound as 1 and the upper bound as 80, with parallel copy set as 4, the service retrieves data by 4 partitions. Their IDs are between [1, 20], [21, 40], [41, 60], and [61, 80], respectively.

TIP

When copying data from a non-partitioned table, you can use "Dynamic range" partition option to partition against an integer column. If your source data doesn't have such type of column, you can leverage ORA_HASH function in source query to generate a column and use it as partition column.

Example: query with physical partition

```
"source": {
    "type": "AmazonRdsForOracleSource",
    "query":"SELECT * FROM <TABLENAME> PARTITION(\"?AdfTabularPartitionName\") WHERE
<your_additional_where_clause>",
    "partitionOption": "PhysicalPartitionsOfTable",
    "partitionSettings": {
        "partitionNames": [
            "<partitionA_name>",
            "<partitionB_name>"
        ]
    }
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "AmazonRdsForOracleSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ?AdfRangePartitionUpbound AND ?
AdfRangePartitionColumnName >= ?AdfRangePartitionLowbound AND <your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column>",
        "partitionLowerBound": "<lower_value_of_partition_column>"
    }
}
```

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Amazon RDS for SQL Server by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 15 minutes to read • Edit Online

This article outlines how to use the copy activity in Azure Data Factory and Azure Synapse pipelines to copy data from Amazon RDS for SQL Server database. To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This Amazon RDS for SQL Server connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Stored procedure activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this Amazon RDS for SQL Server connector supports:

- SQL Server version 2005 and above.
- Copying data by using SQL or Windows authentication.
- As a source, retrieving data by using a SQL query or a stored procedure. You can also choose to parallel copy from Amazon RDS for SQL Server source, see the Parallel copy from SQL database section for details.

SQL Server Express LocalDB is not supported.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data

access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

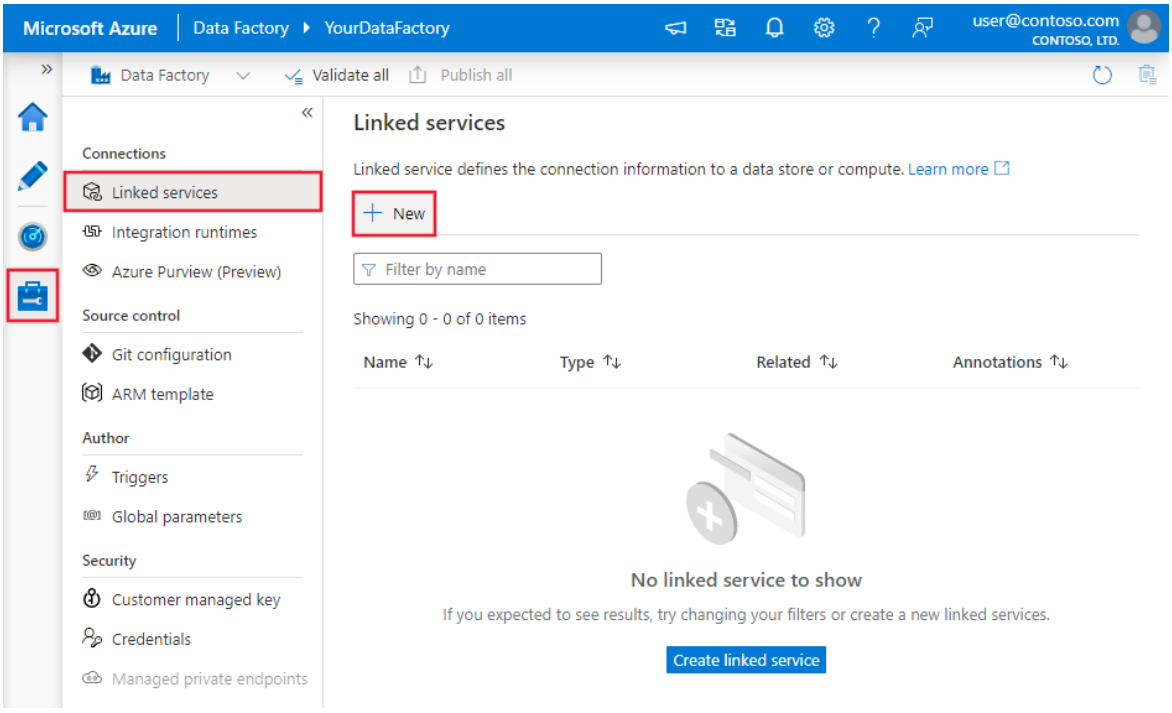
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Amazon RDS for SQL Server linked service using UI

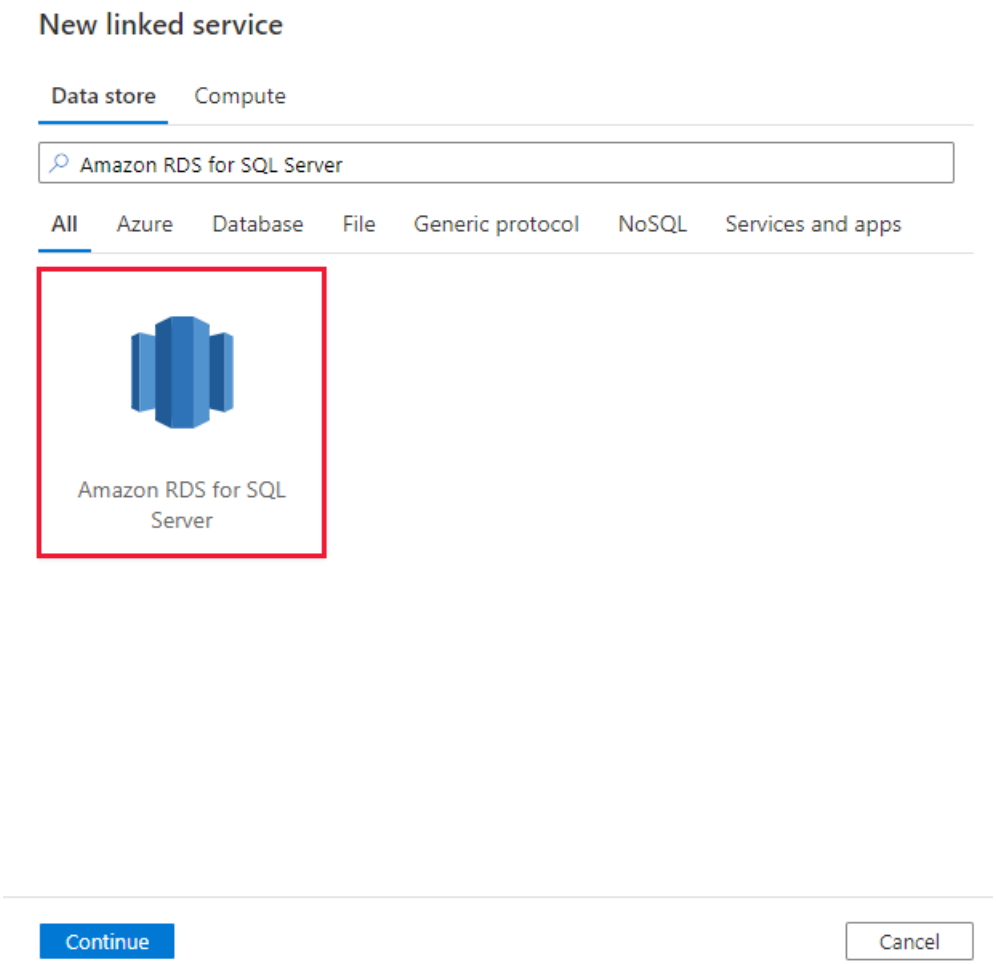
Use the following steps to create an Amazon RDS for SQL Server linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

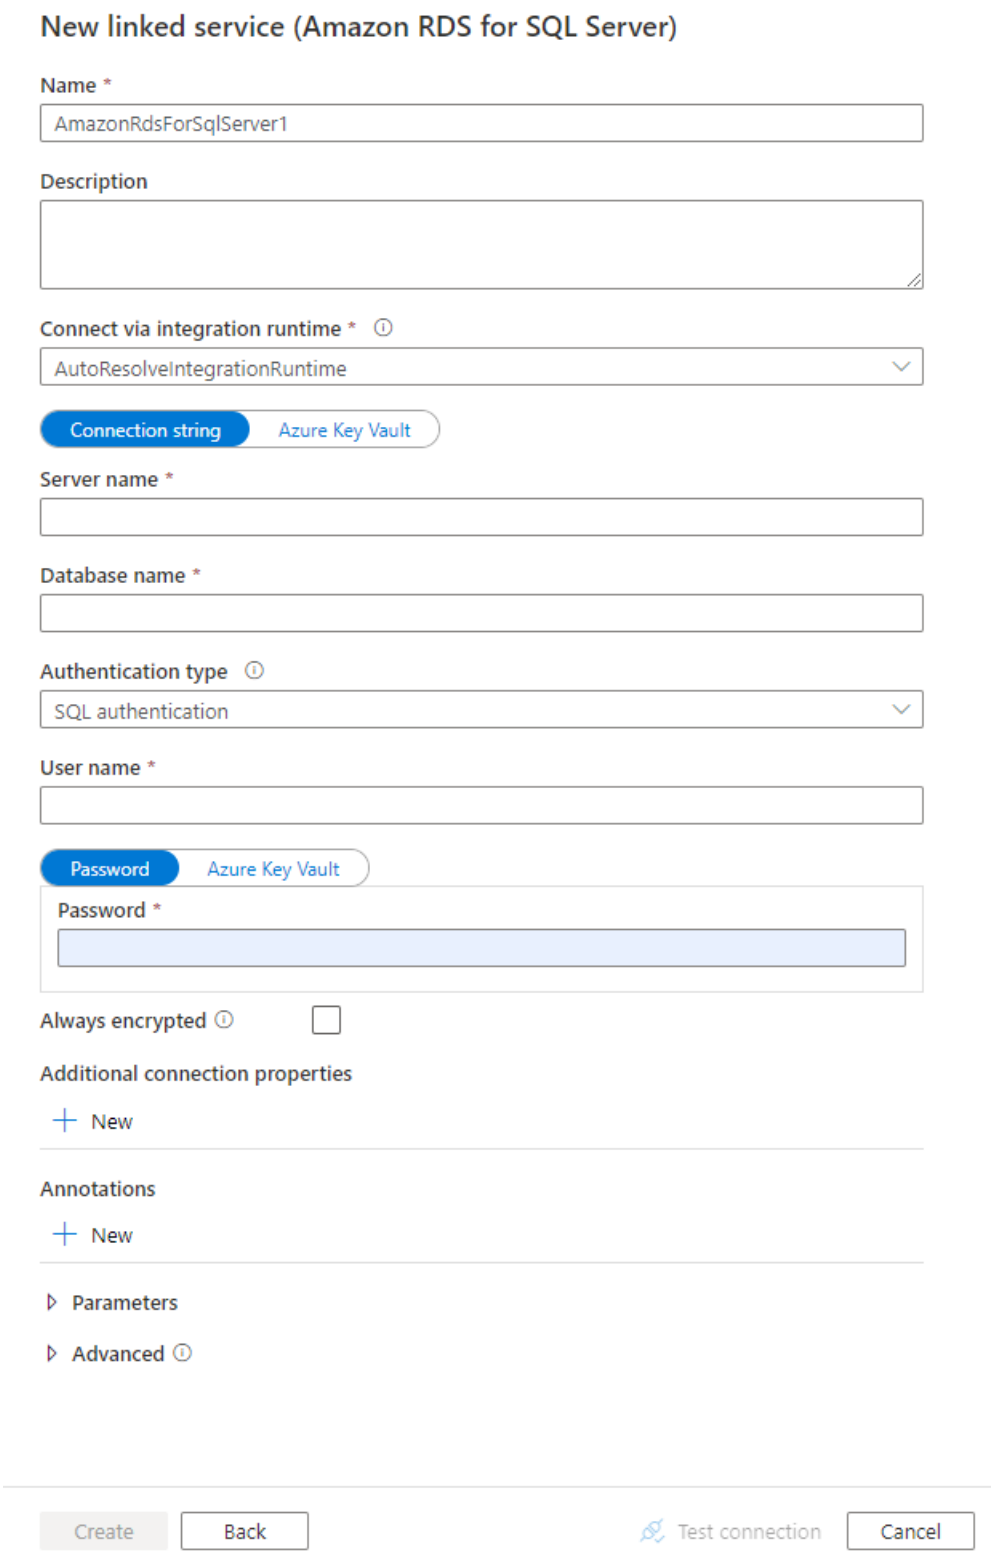
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon RDS for SQL server and select the Amazon RDS for SQL Server connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory and Synapse pipeline entities specific to the Amazon RDS for SQL Server database connector.

Linked service properties

The following properties are supported for the Amazon RDS for SQL Server linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AmazonRdsForSqlServer**.	Yes
connectionString	Specify **connectionString** information that's needed to connect to the Amazon RDS for SQL Server database by using either SQL authentication or Windows authentication. Refer to the following samples. You also can put a password in Azure Key Vault. If it's SQL authentication, pull the `password` configuration out of the connection string. For more information, see the JSON example following the table and Store credentials in Azure Key Vault.	Yes
userName	Specify a user name if you use Windows authentication. An example is **domainname\username**.	No
password	Specify a password for the user account you specified for the user name. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	No
alwaysEncryptedSettings	Specify **alwaysencryptedsettings** information that's needed to enable Always Encrypted to protect sensitive data stored in Amazon RDS for SQL Server by using either managed identity or service principal. For more information, see the JSON example following the table and Using Always Encrypted section. If not specified, the default always encrypted setting is disabled.	No
connectVia	This integration runtime is used to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure integration runtime is used.	No

NOTE

Amazon RDS for SQL Server **Always Encrypted** is not supported in data flow.

TIP

If you hit an error with the error code "UserErrorFailedToConnectToSqlServer" and a message like "The session limit for the database is XXX and has been reached," add `Pooling=false` to your connection string and try again.

Example 1: Use SQL authentication

```
{
    "name": "AmazonSqlLinkedService",
    "properties": {
        "type": "AmazonRdsForSqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;Password=<password>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: Use SQL authentication with a password in Azure Key Vault

```
{
    "name": "AmazonSqlLinkedService",
    "properties": {
        "type": "AmazonRdsForSqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 3: Use Windows authentication

```
{
    "name": "AmazonSqlLinkedService",
    "properties": {
        "type": "AmazonRdsForSqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=True;",
            "userName": "<domain\\username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 4: Use Always Encrypted

```
{
    "name": "AmazonSqlLinkedService",
    "properties": {
        "type": "AmazonRdsForSqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;Password=<password>;"
        },
        "alwaysEncryptedSettings": {
            "alwaysEncryptedAkvAuthType": "ServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by the Amazon RDS for SQL Server dataset.

To copy data from an Amazon RDS for SQL Server database, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AmazonRdsForSqlServerTable**.	Yes
schema	Name of the schema.	No
table	Name of the table/view.	No
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No

Example

```
{
    "name": "AmazonRdsForSQLServerDataset",
    "properties":
    {
        "type": "AmazonRdsForSqlServerTable",
        "linkedServiceName": {
            "referenceName": "<Amazon RDS for SQL Server linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for use to define activities, see the Pipelines article. This section provides a list of properties supported by the Amazon RDS for SQL Server source.

Amazon RDS for SQL Server as a source

> **TIP**
> To load data from Amazon RDS for SQL Server efficiently by using data partitioning, learn more from Parallel copy from SQL database.

To copy data from Amazon RDS for SQL Server, set the source type in the copy activity to **AmazonRdsForSqlServerSource**. The following properties are supported in the copy activity source section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AmazonRdsForSqlServerSource**.	Yes
sqlReaderQuery	Use the custom SQL query to read data. An example is `select * from MyTable`.	No
sqlReaderStoredProcedureName	This property is the name of the stored procedure that reads data from the source table. The last SQL statement must be a SELECT statement in the stored procedure.	No
storedProcedureParameters	These parameters are for the stored procedure. Allowed values are name or value pairs. The names and casing of parameters must match the names and casing of the stored procedure parameters.	No

PROPERTY	DESCRIPTION	REQUIRED
isolationLevel	Specifies the transaction locking behavior for the SQL source. The allowed values are: **ReadCommitted**, **ReadUncommitted**, **RepeatableRead**, **Serializable**, **Snapshot**. If not specified, the database's default isolation level is used. Refer to this doc for more details.	No
partitionOptions	Specifies the data partitioning options used to load data from Amazon RDS for SQL Server. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from Amazon RDS for SQL Server is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`***:***		
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int`, `smallint`, `bigint`, `date`, `smalldatetime`, `datetime`, `datetime2`, or `datetimeoffset`) that will be used by range partitioning for parallel copy. If not specified, the index or the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfDynamicRangePartitionCondition` in the WHERE clause. For an example, see the Parallel copy from SQL database section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No
partitionLowerBound	The minimum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No

Note the following points:

- If **sqlReaderQuery** is specified for **AmazonRdsForSqlServerSource**, the copy activity runs this query against the Amazon RDS for SQL Server source to get the data. You also can specify a stored procedure by specifying **sqlReaderStoredProcedureName** and **storedProcedureParameters** if the stored procedure takes parameters.
- When using stored procedure in source to retrieve data, note if your stored procedure is designed as returning different schema when different parameter value is passed in, you may encounter failure or see unexpected result when importing schema from UI or when copying data to SQL database with auto table creation.

Example: Use SQL query

```
"activities":[
    {
        "name": "CopyFromAmazonRdsForSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Amazon RDS for SQL Server input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AmazonRdsForSqlServerSource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Example: Use a stored procedure

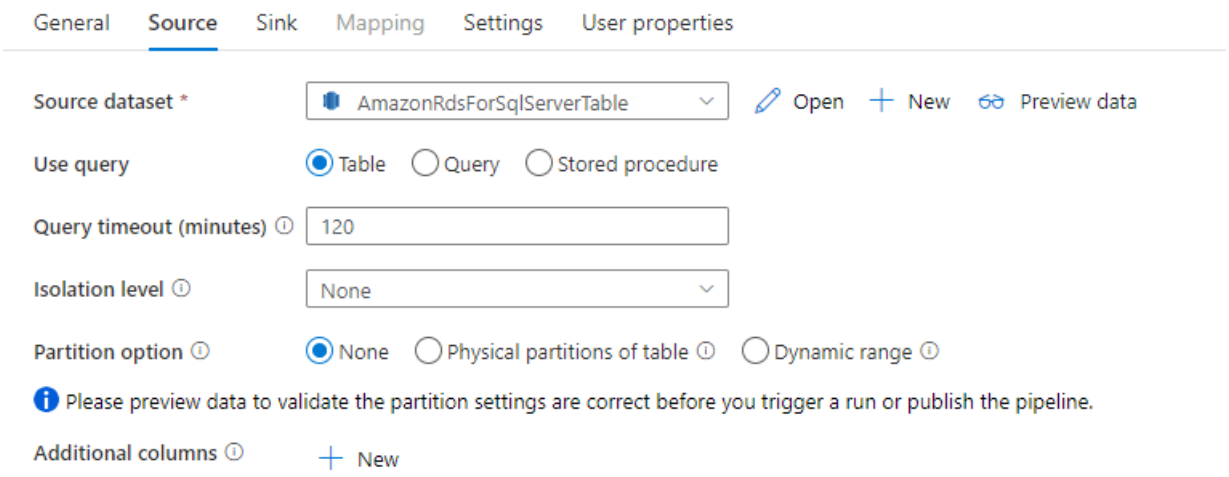
```
"activities":[
    {
        "name": "CopyFromAmazonRdsForSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Amazon RDS for SQL Server input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AmazonRdsForSqlServerSource",
                "sqlReaderStoredProcedureName": "CopyTestSrcStoredProcedureWithParameters",
                "storedProcedureParameters": {
                    "stringData": { "value": "str3" },
                    "identifier": { "value": "$$Text.Format('{0:yyyy}', <datetime parameter>)", "type":
"Int"}
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

The stored procedure definition

```
CREATE PROCEDURE CopyTestSrcStoredProcedureWithParameters
(
    @stringData varchar(20),
    @identifier int
)
AS
SET NOCOUNT ON;
BEGIN
    select *
    from dbo.UnitTestSrcTable
    where dbo.UnitTestSrcTable.stringData != stringData
    and dbo.UnitTestSrcTable.identifier != identifier
END
GO
```

Parallel copy from SQL database

The Amazon RDS for SQL Server connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your Amazon RDS for SQL Server source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Amazon RDS for SQL Server.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Amazon RDS for SQL Server. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions. To check if your table has physical partition or not, you can refer to this query.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, without physical partitions, while with an integer or datetime column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column** (optional): Specify the column used to partition data. If not specified, the primary key column is used. **Partition upper bound** and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the table will be partitioned and copied. If not specified, copy activity auto detects the values and it can take long time depending on MIN and MAX values. It is recommended to provide upper bound and lower bound. For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions - IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.

Load a large amount of data by using a custom query, without physical partitions, while with an integer or date/datetime column for data partitioning.	**Partition options**: Dynamic range partition.
	Query:
	`SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to partition data.
	Partition upper bound and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the query result will be partitioned and copied. If not specified, copy activity auto detect the value.
	
	During execution, the service replaces `?AdfRangePartitionColumnName` with the actual column name and value ranges for each partition, and sends to Amazon RDS for SQL Server.
	For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions- IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.
	
	Here are more sample queries for different scenarios:
	1. Query the whole table:
	`SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition`
	2. Query from a table with column selection and additional where-clause filters:
	`SELECT <column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	3. Query with subqueries:
	`SELECT <column_list> FROM (<your_sub_query>) AS T WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	4. Query with partition in subquery:
	`SELECT <column_list> FROM (SELECT <your_sub_query_column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition) AS T`

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.
3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).

Example: full load from large table with physical partitions

```
"source": {
    "type": "AmazonRdsForSqlServerSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "AmazonRdsForSqlServerSource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Sample query to check physical partition

```
SELECT DISTINCT s.name AS SchemaName, t.name AS TableName, pf.name AS PartitionFunctionName, c.name AS
ColumnName, iif(pf.name is null, 'no', 'yes') AS HasPartition
FROM sys.tables AS t
LEFT JOIN sys.objects AS o ON t.object_id = o.object_id
LEFT JOIN sys.schemas AS s ON o.schema_id = s.schema_id
LEFT JOIN sys.indexes AS i ON t.object_id = i.object_id
LEFT JOIN sys.index_columns AS ic ON ic.partition_ordinal > 0 AND ic.index_id = i.index_id AND ic.object_id
= t.object_id
LEFT JOIN sys.columns AS c ON c.object_id = ic.object_id AND c.column_id = ic.column_id
LEFT JOIN sys.partition_schemes ps ON i.data_space_id = ps.data_space_id
LEFT JOIN sys.partition_functions pf ON pf.function_id = ps.function_id
WHERE s.name='[your schema]' AND t.name = '[your table name]'
```

If the table has physical partition, you would see "HasPartition" as "yes" like the following.

SchemaName	TableName	PartitionFunctionName	ColumnName	HasPartition
dbo	PerfWithPartition	RangePF1	Id	yes

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

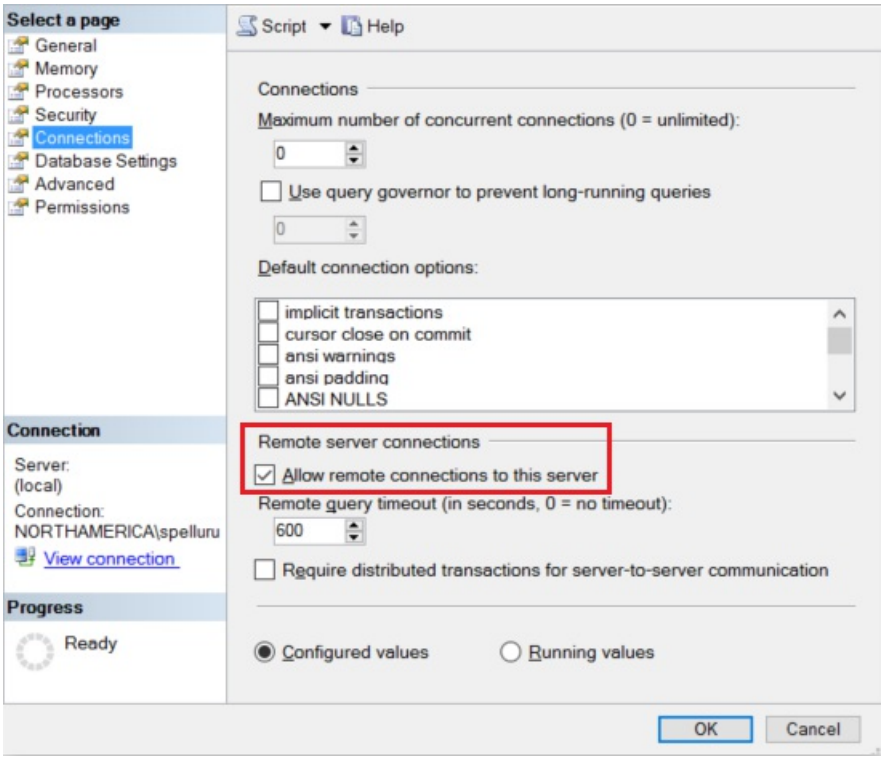
Using Always Encrypted

When you copy data from/to Amazon RDS for SQL Server with Always Encrypted, follow below steps:

1. Store the Column Master Key (CMK) in an Azure Key Vault. Learn more on how to configure Always Encrypted by using Azure Key Vault
2. Make sure to grant access to the key vault where the Column Master Key (CMK) is stored. Refer to this article for required permissions.
3. Create linked service to connect to your SQL database and enable 'Always Encrypted' function by using either managed identity or service principal.

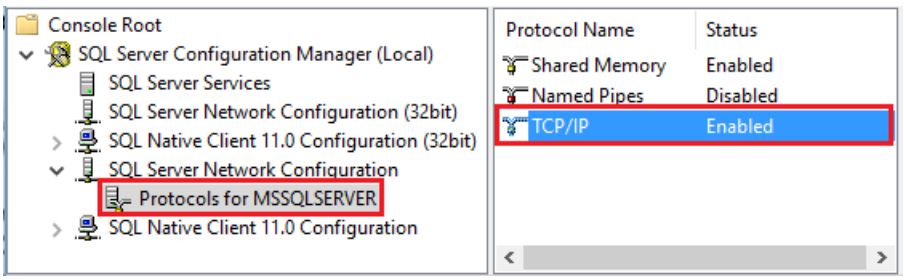
Troubleshoot connection issues

1. Configure your Amazon RDS for SQL Server instance to accept remote connections. Start **Amazon RDS for SQL Server Management Studio**, right-click **server**, and select **Properties**. Select **Connections** from the list, and select the **Allow remote connections to this server** check box.



For detailed steps, see Configure the remote access server configuration option.

2. Start **Amazon RDS for SQL Server Configuration Manager**. Expand **Amazon RDS for SQL Server Network Configuration** for the instance you want, and select **Protocols for MSSQLSERVER**. Protocols appear in the right pane. Enable TCP/IP by right-clicking **TCP/IP** and selecting **Enable**.



For more information and alternate ways of enabling TCP/IP protocol, see Enable or disable a server network protocol.

3. In the same window, double-click **TCP/IP** to launch the **TCP/IP Properties** window.
4. Switch to the **IP Addresses** tab. Scroll down to see the **IPAll** section. Write down the **TCP Port**. The default is **1433**.
5. Create a **rule for the Windows Firewall** on the machine to allow incoming traffic through this port.
6. **Verify connection**: To connect to Amazon RDS for SQL Server by using a fully qualified name, use Amazon RDS for SQL Server Management Studio from a different machine. An example is `"<machine>.<domain>.corp.<company>.com,1433"`.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Amazon Redshift using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from an Amazon Redshift. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Amazon Redshift connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this Amazon Redshift connector supports retrieving data from Redshift using query or built-in Redshift UNLOAD support.

> **TIP**
> To achieve the best performance when copying large amounts of data from Redshift, consider using the built-in Redshift UNLOAD through Amazon S3. See Use UNLOAD to copy data from Amazon Redshift section for details.

Prerequisites

- If you are copying data to an on-premises data store using Self-hosted Integration Runtime, grant Integration Runtime (use IP address of the machine) the access to Amazon Redshift cluster. See Authorize access to the cluster for instructions.
- If you are copying data to an Azure data store, see Azure Data Center IP Ranges for the Compute IP address and SQL ranges used by the Azure data centers.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK

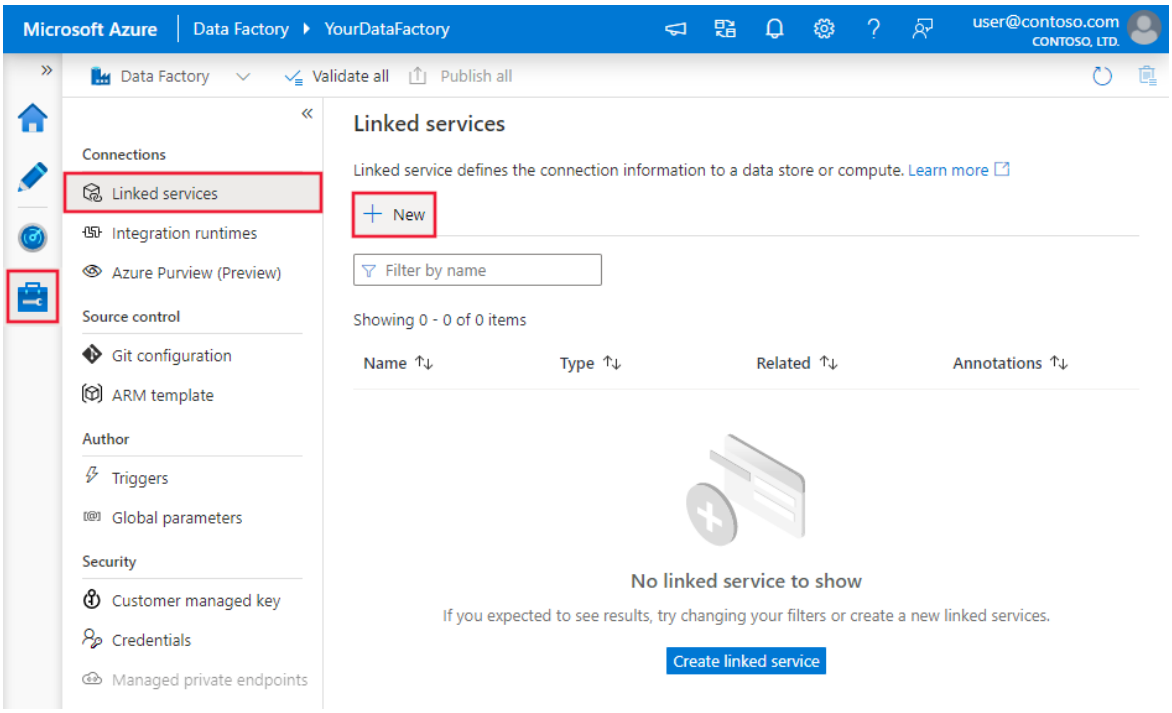
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Amazon Redshift using UI

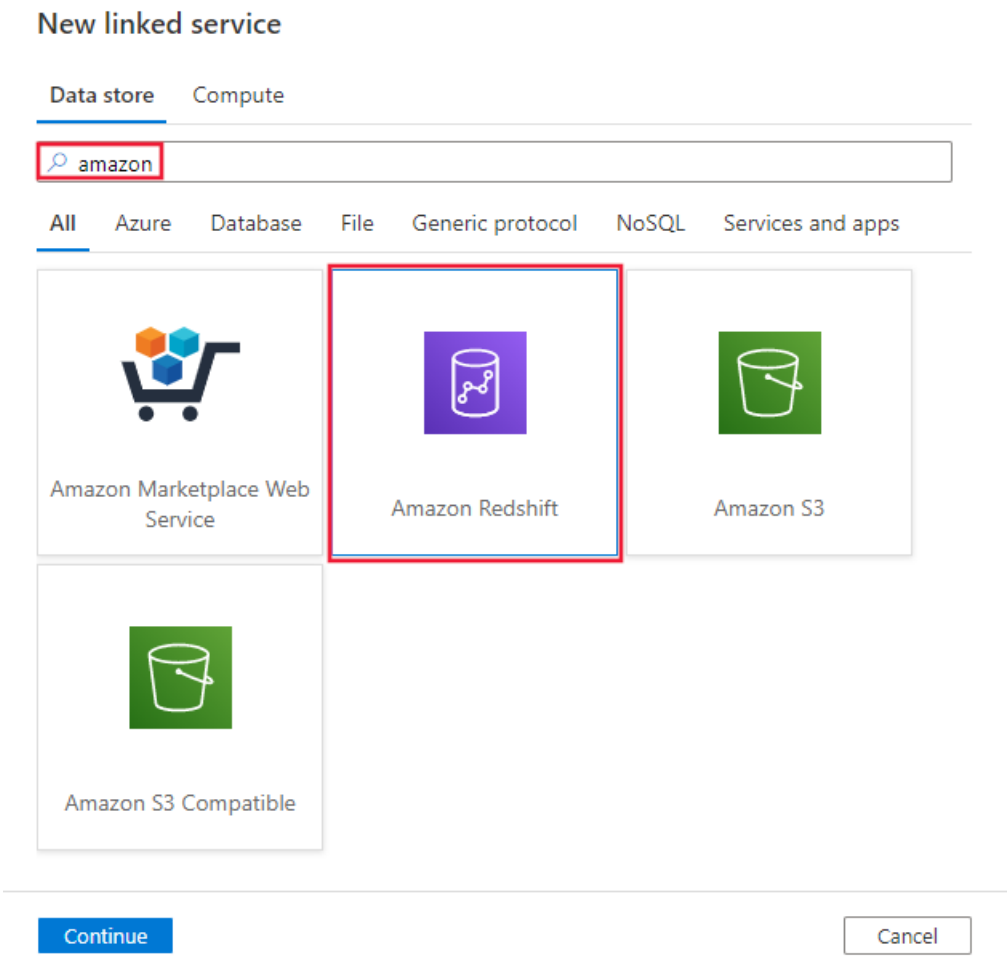
Use the following steps to create a linked service to Amazon Redshift in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

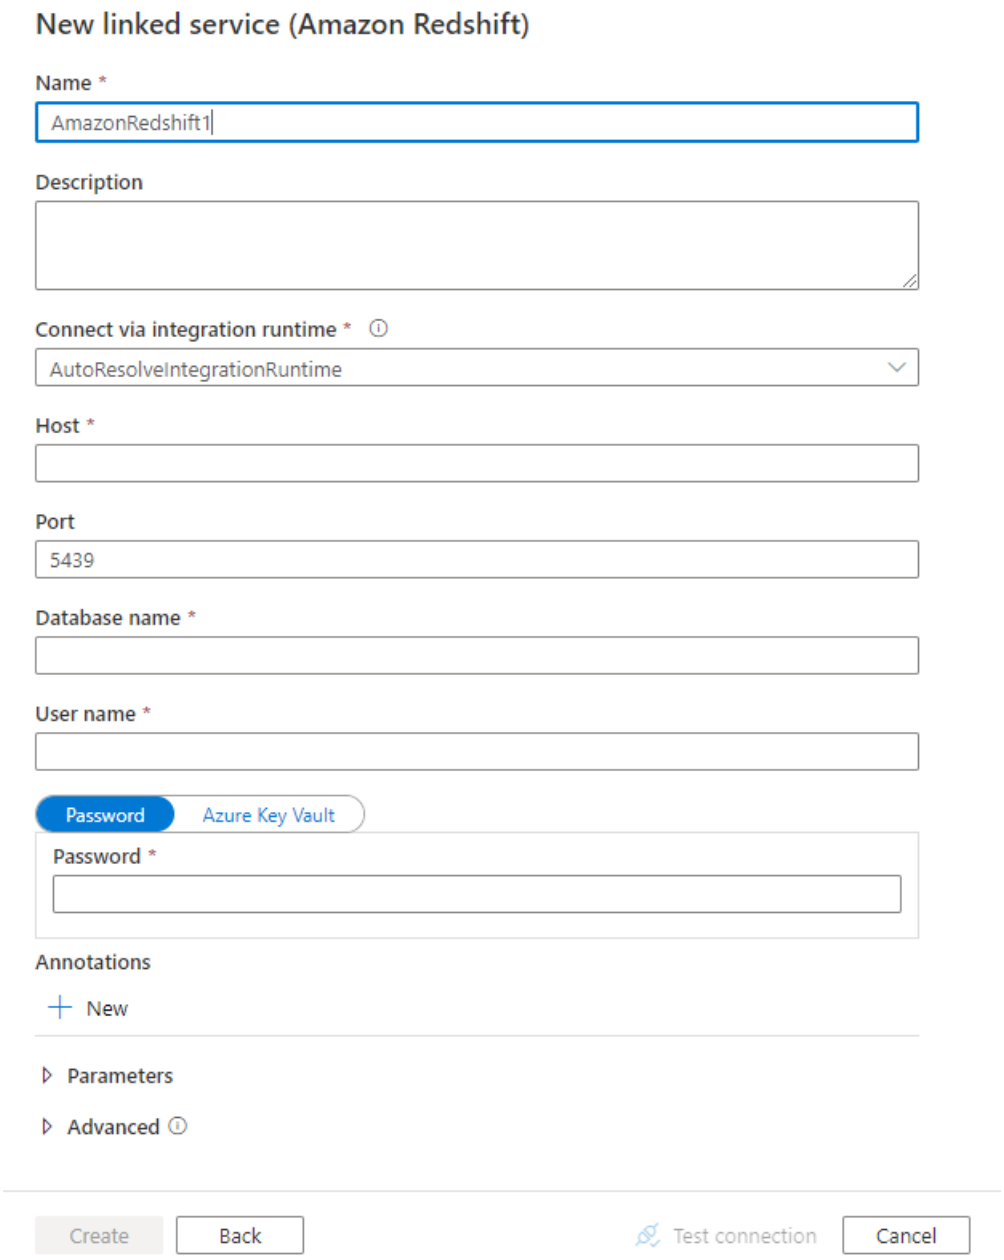
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon and select the Amazon Redshift connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Amazon Redshift connector.

Linked service properties

The following properties are supported for Amazon Redshift linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AmazonRedshift**	Yes
server	IP address or host name of the Amazon Redshift server.	Yes
port	The number of the TCP port that the Amazon Redshift server uses to listen for client connections.	No, default is 5439

PROPERTY	DESCRIPTION	REQUIRED
database	Name of the Amazon Redshift database.	Yes
username	Name of user who has access to the database.	Yes
password	Password for the user account. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "AmazonRedshiftLinkedService",
    "properties":
    {
        "type": "AmazonRedshift",
        "typeProperties":
        {
            "server": "<server name>",
            "database": "<database name>",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Amazon Redshift dataset.

To copy data from Amazon Redshift, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **AmazonRedshiftTable**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)

PROPERTY	DESCRIPTION	REQUIRED
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "AmazonRedshiftDataset",
    "properties":
    {
        "type": "AmazonRedshiftTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Amazon Redshift linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Amazon Redshift source.

Amazon Redshift as source

To copy data from Amazon Redshift, set the source type in the copy activity to **AmazonRedshiftSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **AmazonRedshiftSource**	Yes
query	Use the custom query to read data. For example: select * from MyTable.	No (if "tableName" in dataset is specified)
redshiftUnloadSettings	Property group when using Amazon Redshift UNLOAD.	No
s3LinkedServiceName	Refers to an Amazon S3 to-be-used as an interim store by specifying a linked service name of "AmazonS3" type.	Yes if using UNLOAD
bucketName	Indicate the S3 bucket to store the interim data. If not provided, the service generates it automatically.	Yes if using UNLOAD

Example: Amazon Redshift source in copy activity using UNLOAD

```
"source": {
    "type": "AmazonRedshiftSource",
    "query": "<SQL query>",
    "redshiftUnloadSettings": {
        "s3LinkedServiceName": {
            "referenceName": "<Amazon S3 linked service>",
            "type": "LinkedServiceReference"
        },
        "bucketName": "bucketForUnload"
    }
}
```

Learn more on how to use UNLOAD to copy data from Amazon Redshift efficiently from next section.

Use UNLOAD to copy data from Amazon Redshift

UNLOAD is a mechanism provided by Amazon Redshift, which can unload the results of a query to one or more files on Amazon Simple Storage Service (Amazon S3). It is the way recommended by Amazon for copying large data set from Redshift.

Example: copy data from Amazon Redshift to Azure Synapse Analytics using UNLOAD, staged copy and PolyBase

For this sample use case, copy activity unloads data from Amazon Redshift to Amazon S3 as configured in "redshiftUnloadSettings", and then copy data from Amazon S3 to Azure Blob as specified in "stagingSettings", lastly use PolyBase to load data into Azure Synapse Analytics. All the interim format is handled by copy activity properly.

```
"activities":[
    {
        "name": "CopyFromAmazonRedshiftToSQLDW",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "AmazonRedshiftDataset",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "AzureSQLDWDataset",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AmazonRedshiftSource",
                "query": "select * from MyTable",
                "redshiftUnloadSettings": {
                    "s3LinkedServiceName": {
                        "referenceName": "AmazonS3LinkedService",
                        "type": "LinkedServiceReference"
                    },
                    "bucketName": "bucketForUnload"
                }
            },
            "sink": {
                "type": "SqlDWSink",
                "allowPolyBase": true
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": "AzureStorageLinkedService",
                "path": "adfstagingcopydata"
            },
            "dataIntegrationUnits": 32
        }
    }
]
```

Data type mapping for Amazon Redshift

When copying data from Amazon Redshift, the following mappings are used from Amazon Redshift data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

AMAZON REDSHIFT DATA TYPE	INTERIM SERVICE DATA TYPE
BIGINT	Int64
BOOLEAN	String
CHAR	String
DATE	DateTime
DECIMAL	Decimal

AMAZON REDSHIFT DATA TYPE	INTERIM SERVICE DATA TYPE
DOUBLE PRECISION	Double
INTEGER	Int32
REAL	Single
SMALLINT	Int16
TEXT	String
TIMESTAMP	DateTime
VARCHAR	String

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Amazon Simple Storage Service using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 18 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity to copy data from Amazon Simple Storage Service (Amazon S3), and use Data Flow to transform data in Amazon S3. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

> **TIP**
> To learn more about the data migration scenario from Amazon S3 to Azure Storage, see Migrate data from Amazon S3 to Azure Storage.

Supported capabilities

This Amazon S3 connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Mapping data flow (source/-)	①
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, this Amazon S3 connector supports copying files as is or parsing files with the supported file formats and compression codecs. You can also choose to preserve file metadata during copy. The connector uses AWS Signature Version 4 to authenticate requests to S3.

> **TIP**
> If you want to copy data from *any S3-compatible storage provider*, see Amazon S3 Compatible Storage.

Required permissions

To copy data from Amazon S3, make sure you've been granted the following permissions for Amazon S3 object operations: `s3:GetObject` and `s3:GetObjectVersion`.

If you use Data Factory UI to author, additional `s3:ListAllMyBuckets` and `s3:ListBucket` / `s3:GetBucketLocation`

permissions are required for operations like testing connection to linked service and browsing from root. If you don't want to grant these permissions, you can choose "Test connection to file path" or "Browse from specified path" options from the UI.

For the full list of Amazon S3 permissions, see Specifying Permissions in a Policy on the AWS site.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

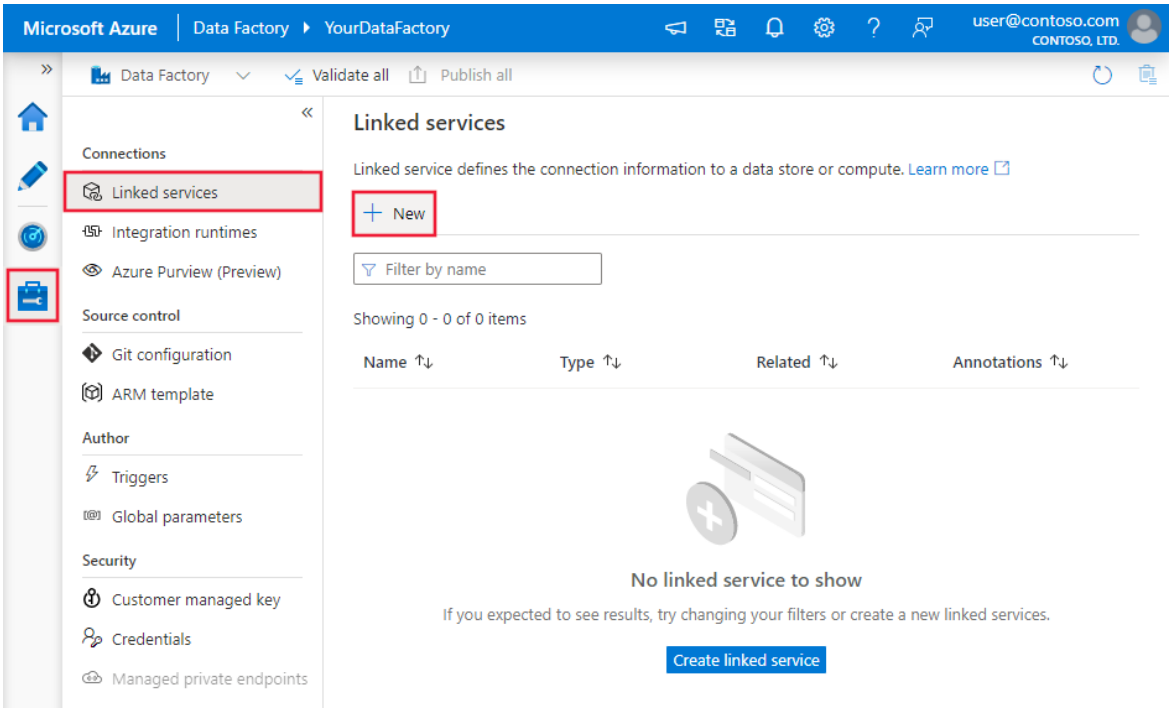
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Amazon Simple Storage Service (S3) linked service using UI

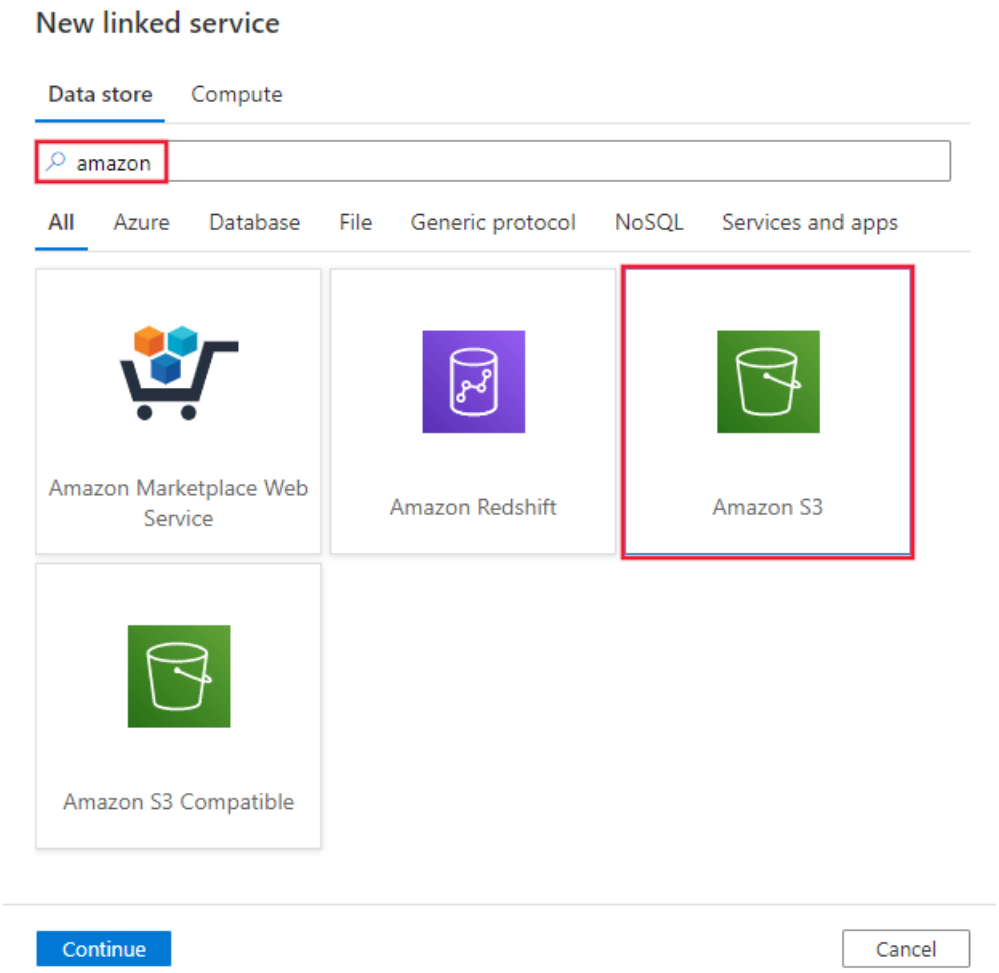
Use the following steps to create an Amazon S3 linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

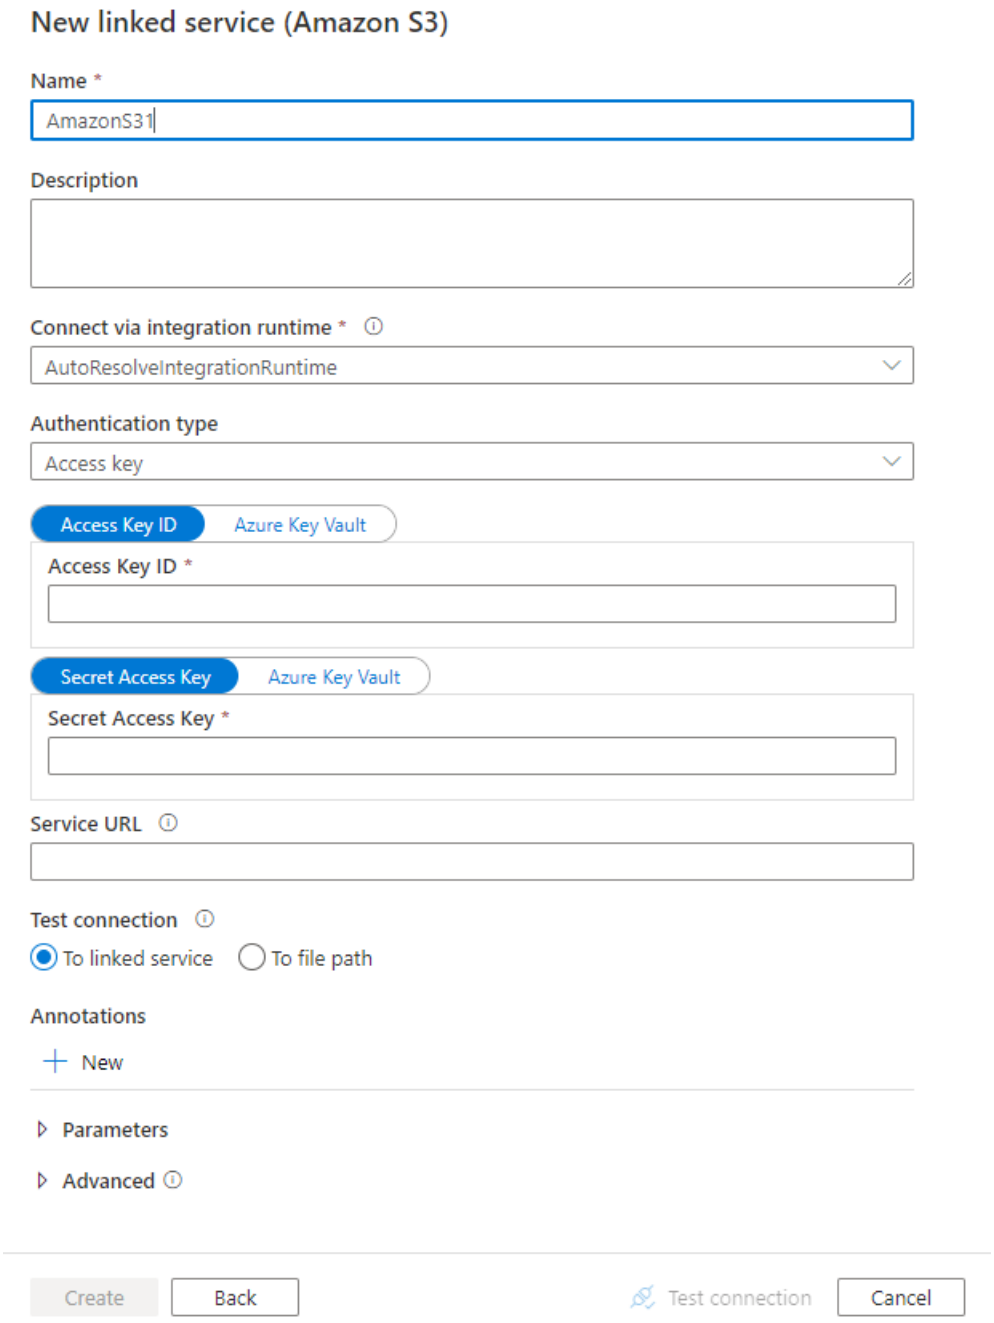
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon and select the Amazon S3 connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Amazon S3.

Linked service properties

The following properties are supported for an Amazon S3 linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AmazonS3**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
authenticationType	Specify the authentication type used to connect to Amazon S3. You can choose to use access keys for an AWS Identity and Access Management (IAM) account, or temporary security credentials. Allowed values are: `AccessKey` (default) and `TemporarySecurityCredentials`.	No
accessKeyId	ID of the secret access key.	Yes
secretAccessKey	The secret access key itself. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes
sessionToken	Applicable when using temporary security credentials authentication. Learn how to request temporary security credentials from AWS. Note AWS temporary credential expires between 15 minutes to 36 hours based on settings. Make sure your credential is valid when activity executes, especially for operationalized workload - for example, you can refresh it periodically and store it in Azure Key Vault. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	No
serviceUrl	Specify the custom S3 endpoint `https://<service url>`. Change it only if you want to try a different service endpoint or want to switch between https and http.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Example: using access key authentication

```
{
    "name": "AmazonS3LinkedService",
    "properties": {
        "type": "AmazonS3",
        "typeProperties": {
            "accessKeyId": "<access key id>",
            "secretAccessKey": {
                "type": "SecureString",
                "value": "<secret access key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: using temporary security credential authentication

```
{
    "name": "AmazonS3LinkedService",
    "properties": {
        "type": "AmazonS3",
        "typeProperties": {
            "authenticationType": "TemporarySecurityCredentials",
            "accessKeyId": "<access key id>",
            "secretAccessKey": {
                "type": "SecureString",
                "value": "<secret access key>"
            },
            "sessionToken": {
                "type": "SecureString",
                "value": "<session token>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Amazon S3 under `location` settings in a format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `location` in a dataset must be set to **AmazonS3Location**.	Yes
bucketName	The S3 bucket name.	Yes
folderPath	The path to the folder under the given bucket. If you want to use a wildcard to filter the folder, skip this setting and specify that in the activity source settings.	No
fileName	The file name under the given bucket and folder path. If you want to use a wildcard to filter files, skip this setting and specify that in the activity source settings.	No
version	The version of the S3 object, if S3 versioning is enabled. If it's not specified, the latest version will be fetched.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Amazon S3 linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AmazonS3Location",
                "bucketName": "bucketname",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties that the Amazon S3 source supports.

Amazon S3 as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format

- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Amazon S3 under `storeSettings` settings in a format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `storeSettings` must be set to **AmazonS3ReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given bucket or folder/file path specified in the dataset. If you want to copy all files from a bucket or folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: S3 prefix - prefix	Prefix for the S3 key name under the given bucket configured in a dataset to filter source S3 files. S3 keys whose names start with `bucket_in_dataset/this_prefix` are selected. It utilizes S3's service-side filter, which provides better performance than a wildcard filter. When you use prefix and choose to copy to file-based sink with preserving hierarchy, note the sub-path after the last "/" in prefix will be preserved. For example, you have source `bucket/folder/subfolder/file.txt`, and configure prefix as `folder/sub`, then the preserved file path is `subfolder/file.txt`.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given bucket configured in a dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	No

PROPERTY	DESCRIPTION	REQUIRED
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given bucket and folder path (or wildcard folder path) to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your file name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	Yes
OPTION 4: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When you're using this option, do not specify a file name in the dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to a UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. - When you use prefix, partition root path is sub-path before the last "/". For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAmazonS3",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AmazonS3ReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	false	bucket FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	true	bucket FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	false	bucket FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	true	bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using a file list path in a Copy activity source.

Assume that you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Bucket: `bucket` - Folder path: `FolderA` **In Copy activity source:** - File list path: `bucket/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line, with the relative path to the path configured in the dataset.

Preserve metadata during copy

When you copy files from Amazon S3 to Azure Data Lake Storage Gen2 or Azure Blob storage, you can choose to preserve the file metadata along with data. Learn more from Preserve metadata.

Mapping data flow properties

When you're transforming data in mapping data flows, you can read files from Amazon S3 in the following formats:

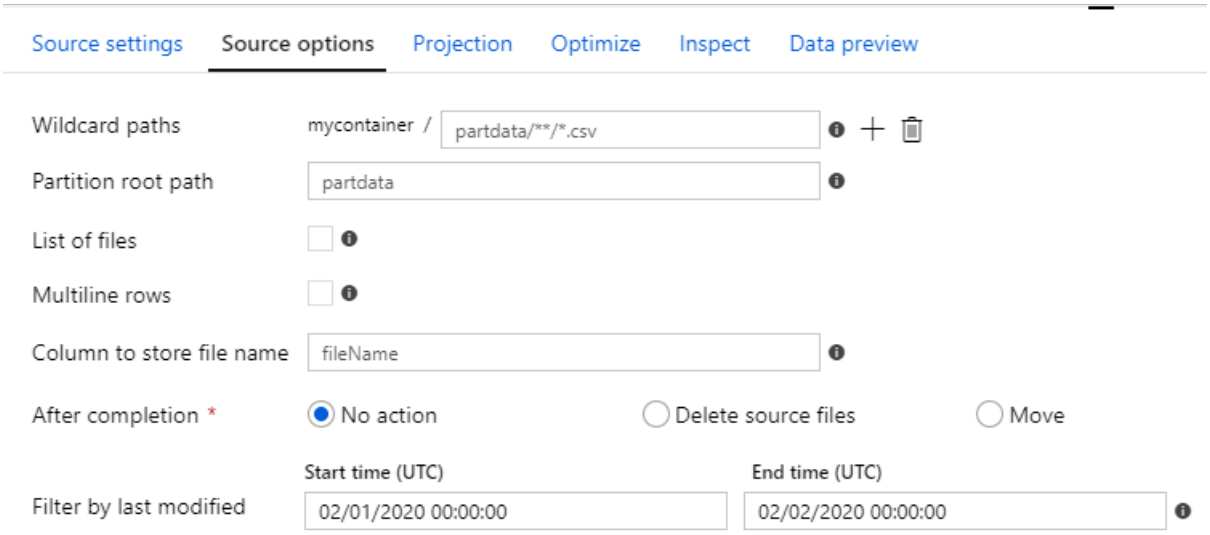
- Avro
- Delimited text
- Delta
- Excel
- JSON
- Parquet

Format specific settings are located in the documentation for that format. For more information, see Source transformation in mapping data flow.

> **NOTE**
> The Amazon S3 source transformation is only supported in the **Azure Synapse Analytics** workspace now.

Source transformation

In source transformation, you can read from a container, folder, or individual file in Amazon S3. Use the **Source options** tab to manage how the files are read.



Wildcard paths: Using a wildcard pattern will instruct the service to loop through each matching folder and file in a single source transformation. This is an effective way to process multiple files within a single flow. Add multiple wildcard matching patterns with the plus sign that appears when you hover over your existing wildcard pattern.

From your source container, choose a series of files that match a pattern. Only a container can be specified in the dataset. Your wildcard path must therefore also include your folder path from the root folder.

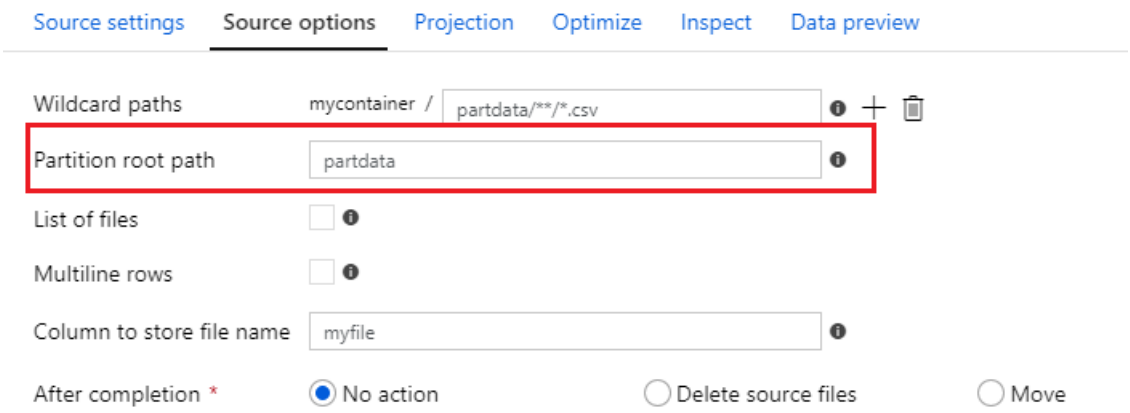
Wildcard examples:

- `*` Represents any set of characters.
- `**` Represents recursive directory nesting.

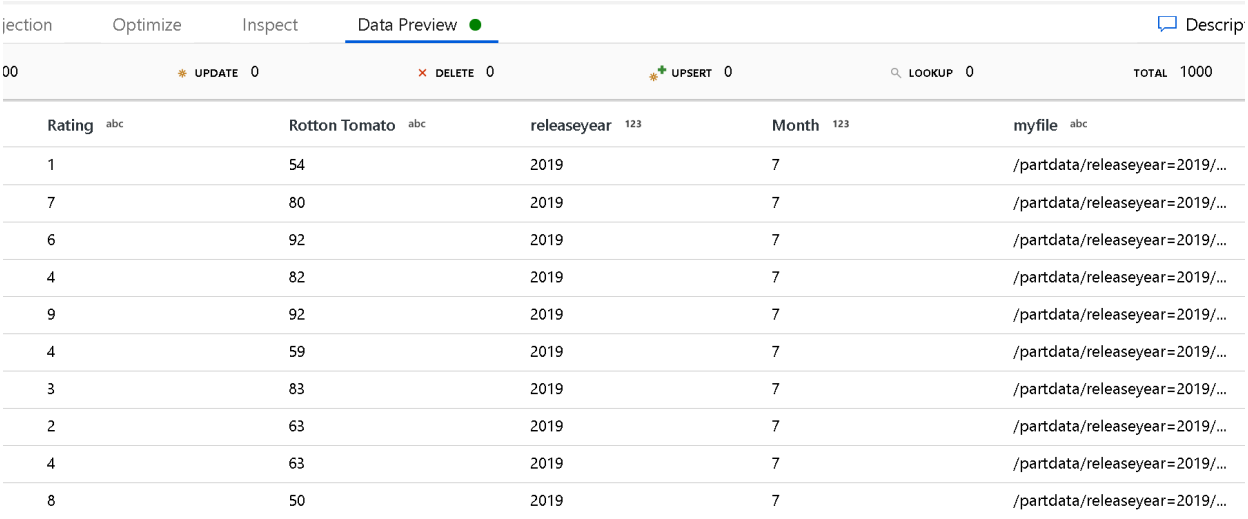
- `?` Replaces one character.
- `[]` Matches one or more characters in the brackets.
- `/data/sales/**/*.csv` Gets all .csv files under /data/sales.
- `/data/sales/20??/**/` Gets all files in the 20th century.
- `/data/sales/*/*/*.csv` Gets .csv files two levels under /data/sales.
- `/data/sales/2004/*/12/[XY]1?.csv` Gets all .csv files in December 2004 starting with X or Y prefixed by a two-digit number.

Partition root path: If you have partitioned folders in your file source with a `key=value` format (for example, `year=2019`), then you can assign the top level of that partition folder tree to a column name in your data flow's data stream.

First, set a wildcard to include all paths that are the partitioned folders plus the leaf files that you want to read.



Use the **Partition root path** setting to define what the top level of the folder structure is. When you view the contents of your data via a data preview, you'll see that the service will add the resolved partitions found in each of your folder levels.



Rating abc	Rotton Tomato abc	releaseyear 123	Month 123	myfile abc
1	54	2019	7	/partdata/releaseyear=2019/...
7	80	2019	7	/partdata/releaseyear=2019/...
6	92	2019	7	/partdata/releaseyear=2019/...
4	82	2019	7	/partdata/releaseyear=2019/...
9	92	2019	7	/partdata/releaseyear=2019/...
4	59	2019	7	/partdata/releaseyear=2019/...
3	83	2019	7	/partdata/releaseyear=2019/...
2	63	2019	7	/partdata/releaseyear=2019/...
4	63	2019	7	/partdata/releaseyear=2019/...
8	50	2019	7	/partdata/releaseyear=2019/...

List of files: This is a file set. Create a text file that includes a list of relative path files to process. Point to this text file.

Column to store file name: Store the name of the source file in a column in your data. Enter a new column name here to store the file name string.

After completion: Choose to do nothing with the source file after the data flow runs, delete the source file, or move the source file. The paths for the move are relative.

To move source files to another location post-processing, first select "Move" for file operation. Then, set the "from" directory. If you're not using any wildcards for your path, then the "from" setting will be the same folder as your source folder.

If you have a source path with wildcard, your syntax will look like this:

`/data/sales/20??/**/*.csv`

You can specify "from" as:

`/data/sales`

And you can specify "to" as:

`/backup/priorSales`

In this case, all files that were sourced under `/data/sales` are moved to `/backup/priorSales`.

> **NOTE**
> File operations run only when you start the data flow from a pipeline run (a pipeline debug or execution run) that uses the Execute Data Flow activity in a pipeline. File operations *do not* run in Data Flow debug mode.

Filter by last modified: You can filter which files you process by specifying a date range of when they were last modified. All datetimes are in UTC.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity.

Delete activity properties

To learn details about the properties, check Delete activity.

Legacy models

> **NOTE**
> The following models are still supported as is for backward compatibility. We suggest that you use the new model mentioned earlier. The authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **AmazonS3Object**.	Yes
bucketName	The S3 bucket name. The wildcard filter is not supported.	Yes for the Copy or Lookup activity, no for the GetMetadata activity

PROPERTY	DESCRIPTION	REQUIRED

key	The name or wildcard filter of the S3 object key under the specified bucket. Applies only when the **prefix** property is not specified.
	
	The wildcard filter is supported for both the folder part and the file name part. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character).
	- Example 1:
	`"key": "rootfolder/subfolder/*.csv"`
	- Example 2:
	`"key": "rootfolder/subfolder/???20180427.txt"`
	See more example in Folder and file filter examples. Use `^` to escape if your actual folder or file name has a wildcard or this escape character inside.
		No

prefix	Prefix for the S3 object key. Objects whose keys start with this prefix are selected. Applies only when the **key** property is not specified.	No
version	The version of the S3 object, if S3 versioning is enabled. If a version is not specified, the latest version will be fetched.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware that enabling this setting will affect the overall performance of data movement when you want to filter huge amounts of files. The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, the files whose last modified attribute is less than the datetime value will be selected.	No
modifiedDatetimeEnd	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware that enabling this setting will affect the overall performance of data movement when you want to filter huge amounts of files. The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected.	No

PROPERTY	DESCRIPTION	REQUIRED
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, **ParquetFormat**. Set the **type** property under **format** to one of these values. For more information, see the Text format, JSON format, Avro format, Orc format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are **Optimal** and **Fastest**.	No

TIP

To copy all files under a folder, specify **bucketName** for the bucket and **prefix** for the folder part.

To copy a single file with a given name, specify **bucketName** for the bucket and **key** for the folder part plus file name.

To copy a subset of files under a folder, specify **bucketName** for the bucket and **key** for the folder part plus wildcard filter.

Example: using prefix

```
{
    "name": "AmazonS3Dataset",
    "properties": {
        "type": "AmazonS3Object",
        "linkedServiceName": {
            "referenceName": "<Amazon S3 linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "bucketName": "testbucket",
            "prefix": "testFolder/test",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Example: using key and version (optional)

```
{
    "name": "AmazonS3Dataset",
    "properties": {
        "type": "AmazonS3",
        "linkedServiceName": {
            "referenceName": "<Amazon S3 linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "bucketName": "testbucket",
            "key": "testFolder/testfile.csv.gz",
            "version": "XXXXXXXXXczm0CJajYkHf0_k6LhBmkcL",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy source model for the Copy activity

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy activity source must be set to **FileSystemSource**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder will not be copied or created at the sink. Allowed values are **true** (default) and **false**.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAmazonS3",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Amazon S3 input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "FileSystemSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

For a list of data stores that the Copy activity supports as sources and sinks, see Supported data stores.

Copy data from Amazon S3 Compatible Storage by using Azure Data Factory or Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data from Amazon Simple Storage Service (Amazon S3) Compatible Storage. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This Amazon S3 Compatible Storage connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, this Amazon S3 Compatible Storage connector supports copying files as is or parsing files with the supported file formats and compression codecs. The connector uses AWS Signature Version 4 to authenticate requests to S3. You can use this Amazon S3 Compatible Storage connector to copy data from any S3-compatible storage provider. Specify the corresponding service URL in the linked service configuration.

Required permissions

To copy data from Amazon S3 Compatible Storage, make sure you've been granted the following permissions for Amazon S3 object operations: `s3:GetObject` and `s3:GetObjectVersion`.

If you use UI to author, additional `s3:ListAllMyBuckets` and `s3:ListBucket` / `s3:GetBucketLocation` permissions are required for operations like testing connection to linked service and browsing from root. If you don't want to grant these permissions, you can choose "Test connection to file path" or "Browse from specified path" options from the UI.

For the full list of Amazon S3 permissions, see Specifying Permissions in a Policy on the AWS site.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK

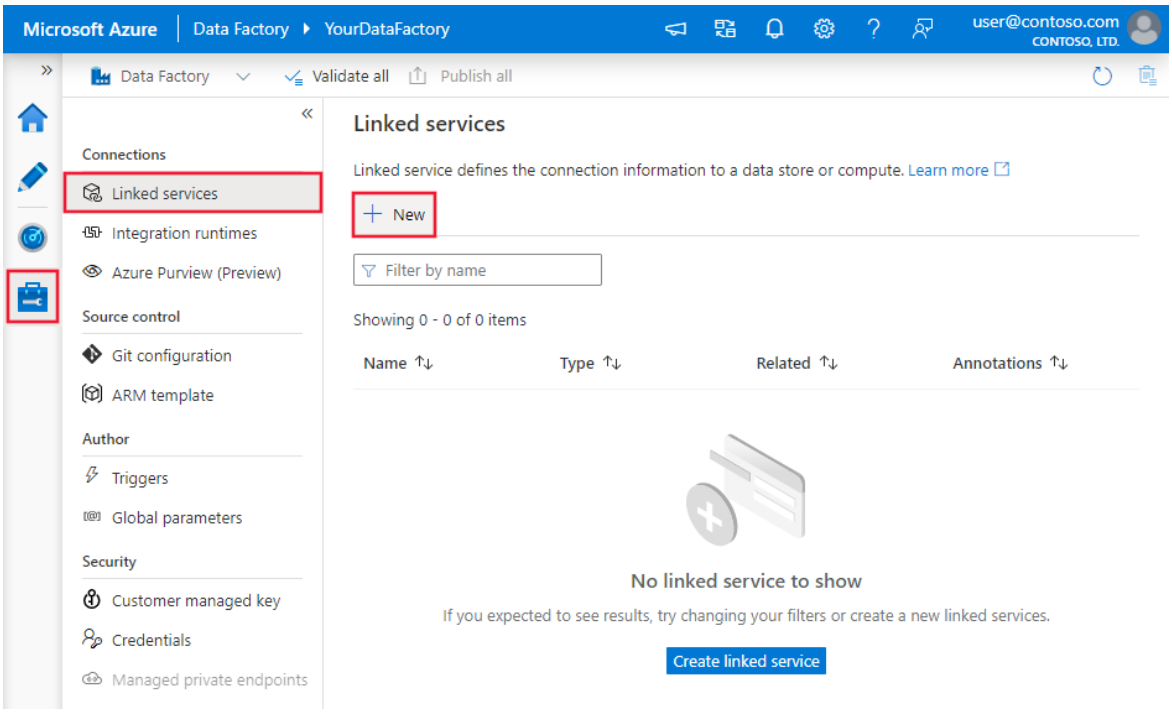
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Amazon S3 Compatible Storage using UI

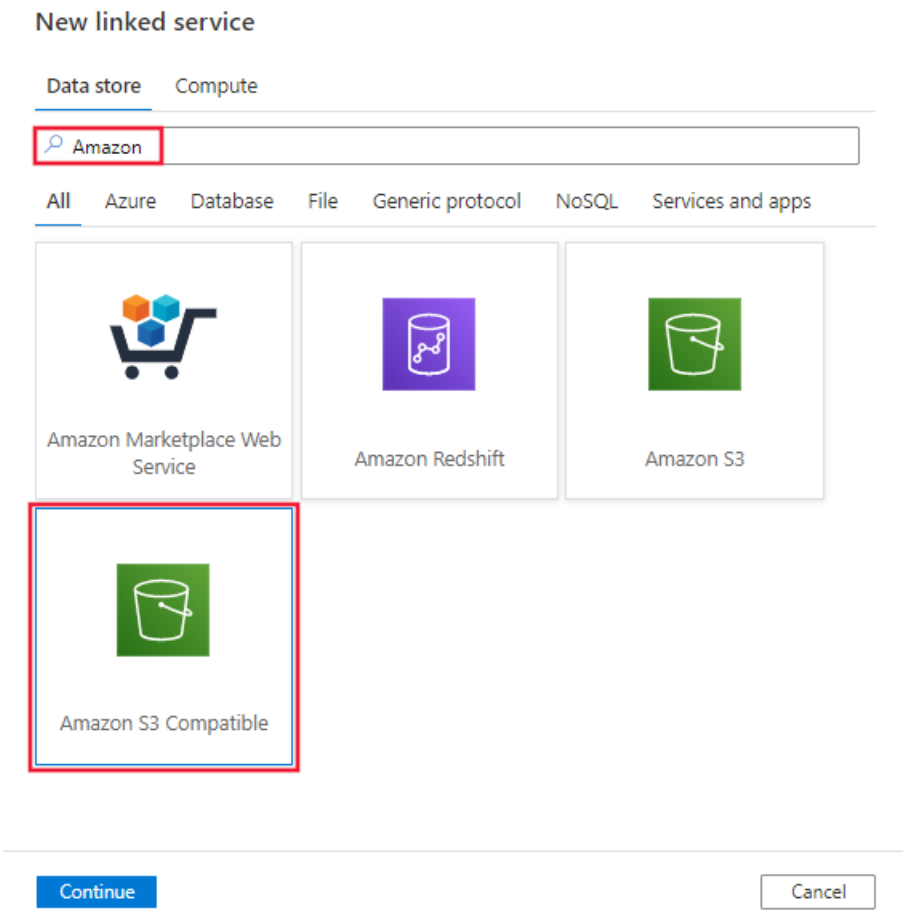
Use the following steps to create a linked service to Amazon S3 Compatible Storage in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

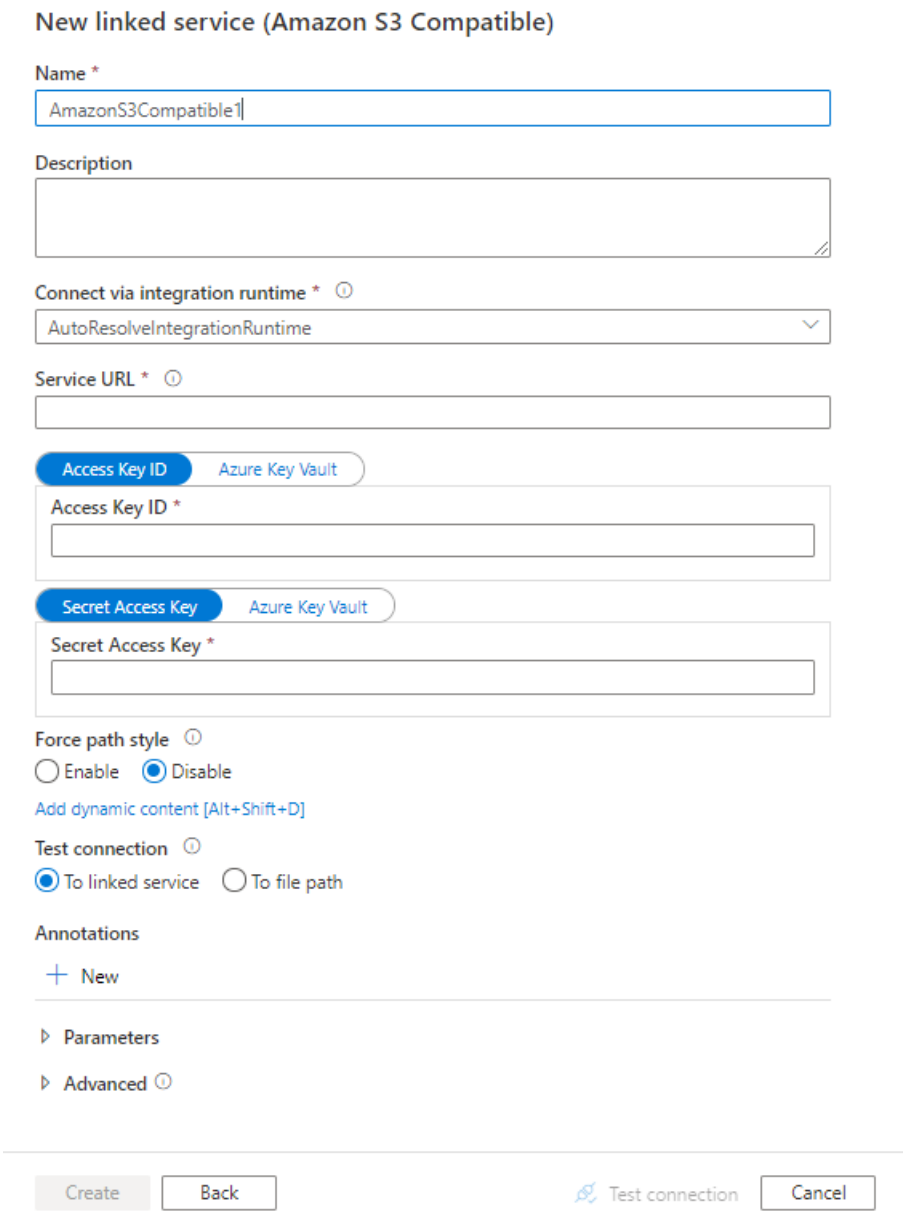
   - Azure Data Factory
   - Azure Synapse



2. Search for Amazon and select the Amazon S3 Compatible Storage connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Amazon S3 Compatible Storage.

Linked service properties

The following properties are supported for an Amazon S3 Compatible linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AmazonS3Compatible**.	Yes
accessKeyId	ID of the secret access key.	Yes
secretAccessKey	The secret access key itself. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes

PROPERTY	DESCRIPTION	REQUIRED
serviceUrl	Specify the custom S3 endpoint `https://<service url>`.	No
forcePathStyle	Indicates whether to use S3 path-style access instead of virtual hosted-style access. Allowed values are: **false** (default), **true**. Check each data store's documentation on if path-style access is needed or not.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AmazonS3CompatibleLinkedService",
    "properties": {
        "type": "AmazonS3Compatible",
        "typeProperties": {
            "accessKeyId": "<access key id>",
            "secretAccessKey": {
                "type": "SecureString",
                "value": "<secret access key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Amazon S3 Compatible under `location` settings in a format-based

dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `location` in a dataset must be set to **AmazonS3CompatibleLocation**.	Yes
bucketName	The S3 Compatible Storage bucket name.	Yes
folderPath	The path to the folder under the given bucket. If you want to use a wildcard to filter the folder, skip this setting and specify that in the activity source settings.	No
fileName	The file name under the given bucket and folder path. If you want to use a wildcard to filter files, skip this setting and specify that in the activity source settings.	No
version	The version of the S3 Compatible Storage object, if S3 Compatible Storage versioning is enabled. If it's not specified, the latest version will be fetched.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Amazon S3 Compatible Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AmazonS3CompatibleLocation",
                "bucketName": "bucketname",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties that the Amazon S3 Compatible Storage source supports.

Amazon S3 Compatible Storage as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Amazon S3 Compatible Storage under `storeSettings` settings in a format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `storeSettings` must be set to **AmazonS3CompatibleReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given bucket or folder/file path specified in the dataset. If you want to copy all files from a bucket or folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: S3 Compatible Storage prefix - prefix	Prefix for the S3 Compatible Storage key name under the given bucket configured in a dataset to filter source S3 Compatible Storage files. S3 Compatible Storage keys whose names start with `bucket_in_dataset/this_prefix` are selected. It utilizes S3 Compatible Storage's service-side filter, which provides better performance than a wildcard filter. When you use prefix and choose to copy to file-based sink with preserving hierarchy, note the sub-path after the last "/" in prefix will be preserved. For example, you have source `bucket/folder/subfolder/file.txt`, and configure prefix as `folder/sub`, then the preserved file path is `subfolder/file.txt`.	No

PROPERTY	DESCRIPTION	REQUIRED
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given bucket configured in a dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	No
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given bucket and folder path (or wildcard folder path) to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your file name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	Yes
OPTION 4: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When you're using this option, do not specify a file name in the dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No

PROPERTY	DESCRIPTION	REQUIRED
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to a UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. - When you use prefix, partition root path is sub-path before the last "/". For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAmazonS3CompatibleStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AmazonS3CompatibleReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	false	bucket FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	true	bucket FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	false	bucket FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	true	bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using a file list path in a Copy activity source.

Assume that you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Bucket: `bucket` - Folder path: `FolderA` **In Copy activity source:** - File list path: `bucket/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line, with the relative path to the path configured in the dataset.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity.

Delete activity properties

To learn details about the properties, check Delete activity.

Next steps

For a list of data stores that the Copy activity supports as sources and sinks, see Supported data stores.

Transform data in Asana (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in Asana (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Asana connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

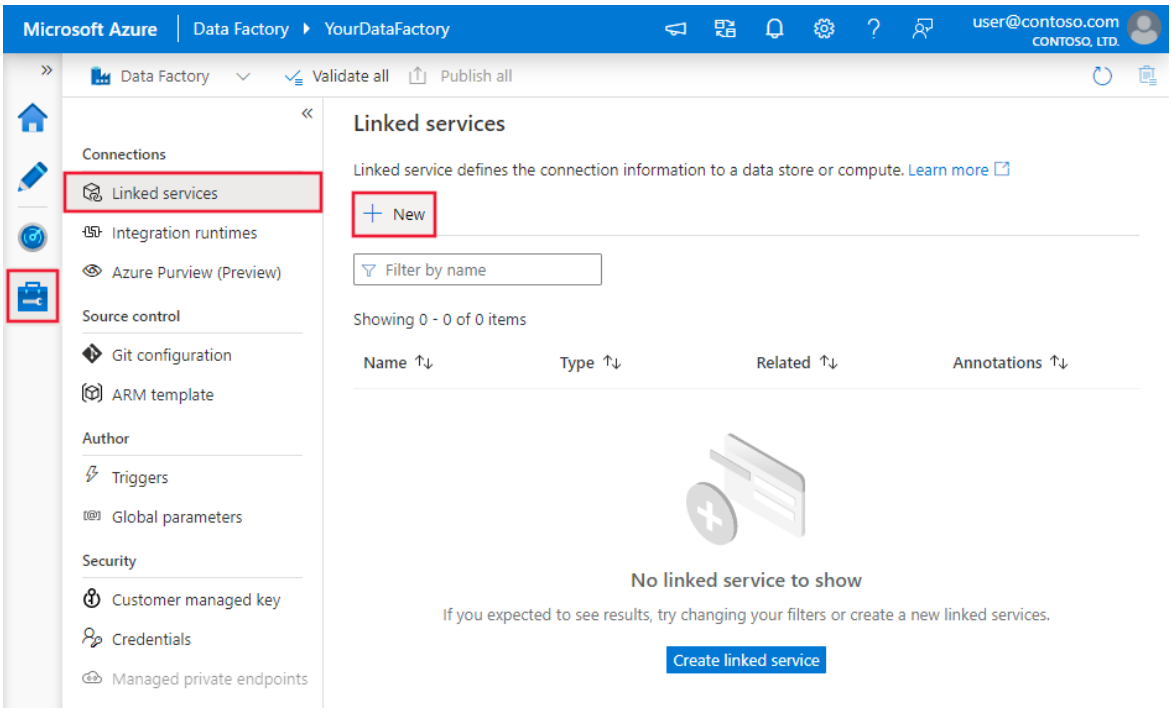
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create an Asana linked service using UI

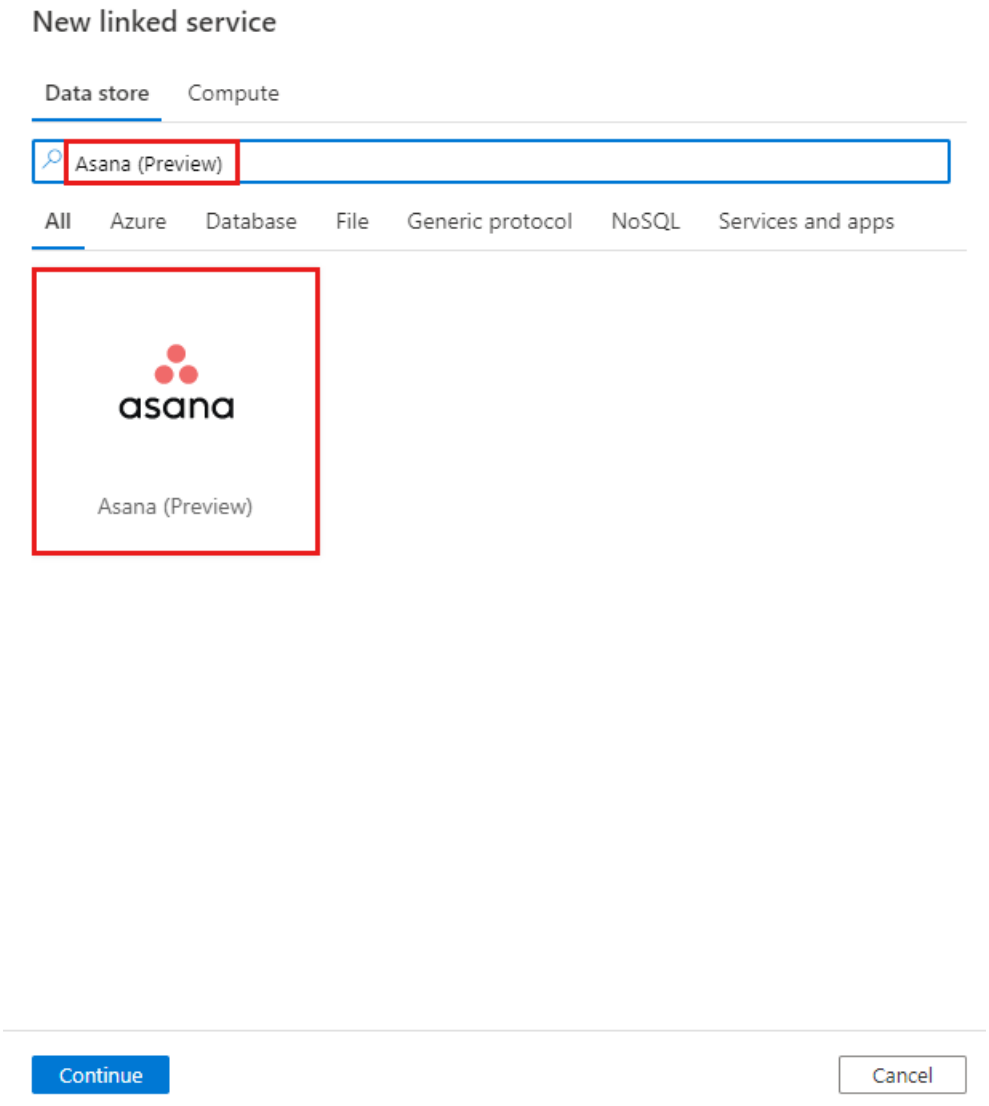
Use the following steps to create an Asana linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

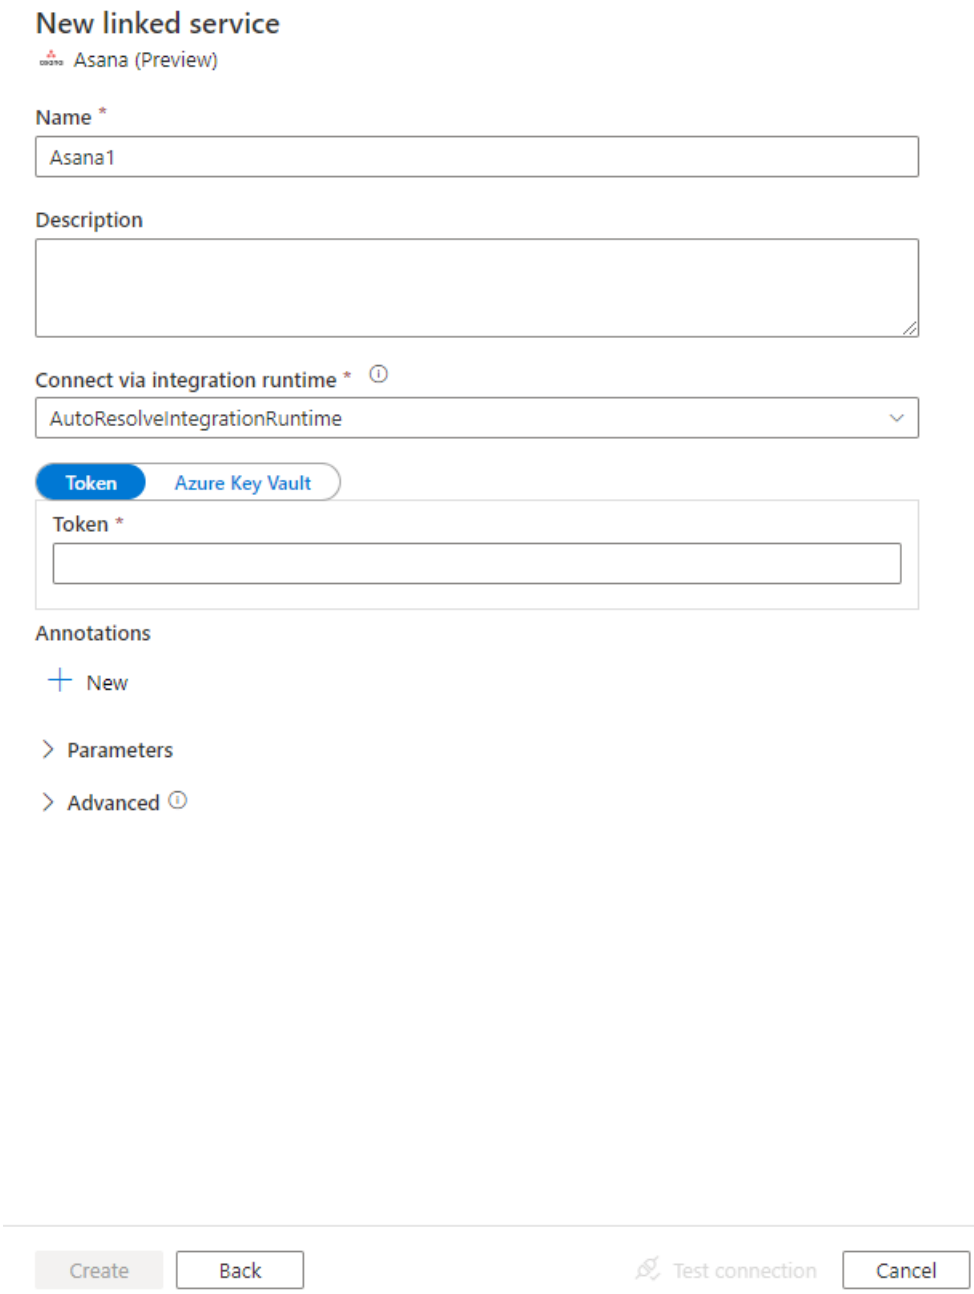
   - Azure Data Factory
   - Azure Synapse



2. Search for Asana (Preview) and select the Asana (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Asana.

Linked service properties

The following properties are supported for the Asana linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Asana**.	Yes
apiToken	Specify an API token for the Asana. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "AsanaLinkedService",
    "properties": {
        "type": "Asana",
        "typeProperties": {
            "apiToken": {
                "type": "SecureString",
                "value": "<API token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from Asana. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by Asana source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Workspace	The ID of the workspace in Asana.	Yes	String	workspaceId
Entity	The ID of the entity in Asana.	Yes	String	entityId

Entity Type	The type of the entity in Asana.	Yes	`teams`
			`portfolios`
			`projects`
				entityType

Asana source script examples

When you use Asana as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    store: 'asana',
    format: 'rest',
    workspaceId: '9876543210',
    entityId: '1234567890',
    entityType: 'teams') ~> AsanaSource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Avro format in Azure Data Factory and Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse Avro files or write the data into Avro format**.

Avro format is supported for the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Avro dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Avro**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section**.	Yes
avroCompressionCodec	The compression codec to use when writing to Avro files. When reading from Avro files, the service automatically determines the compression codec based on the file metadata. Supported types are "**none**" (default), "**deflate**", "**snappy**". Note currently Copy activity doesn't support Snappy when read/write Avro files.	No

NOTE

White space in column name is not supported for Avro files.

Below is an example of Avro dataset on Azure Blob Storage:

```
{
    "name": "AvroDataset",
    "properties": {
        "type": "Avro",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "avroCompressionCodec": "snappy"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Avro source and sink.

Avro as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AvroSource**.	Yes
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Avro as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AvroSink**.	Yes
formatSettings	A group of properties. Refer to **Avro write settings** table below.	No
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **Avro write settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **AvroWriteSettings**.	Yes
maxRowsPerFile	When writing data into a folder, you can choose to write to multiple files and specify the max rows per file.	No
fileNamePrefix	Applicable when `maxRowsPerFile` is configured. Specify the file name prefix when writing data to multiple files, resulted in this pattern: `<fileNamePrefix>_00000.<fileExtension>`. If not specified, file name prefix will be auto generated. This property does not apply when source is file-based store or partition-option-enabled data store.	No

Mapping data flow properties

In mapping data flows, you can read and write to avro format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and SFTP, and you can read avro format in Amazon S3.

Source properties

The below table lists the properties supported by an avro source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

Sink properties

The below table lists the properties supported by an avro sink. You can edit these properties in the **Settings** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>`	no	Pattern: String Per partition: String[] As data in column: String Output to single file: `['<fileName>']`	filePattern partitionFileNames rowUrlColumn partitionFileNames
Quote all	Enclose all values in quotes	no	`true` or `false`	quoteAll

Data type support

Copy activity

Avro complex data types are not supported (records, enums, arrays, maps, unions, and fixed) in Copy Activity.

Data flows

When working with Avro files in data flows, you can read and write complex data types, but be sure to clear the physical schema from the dataset first. In data flows, you can set your logical projection and derive columns that are complex structures, then auto-map those fields to an Avro file.

Next steps

- Copy activity overview
- Lookup activity

- GetMetadata activity

Copy and transform data in Azure Blob storage by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 36 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy activity in Azure Data Factory and Azure Synapse pipelines to copy data from and to Azure Blob storage. It also describes how to use the Data Flow activity to transform data in Azure Blob storage. To learn more read the Azure Data Factory and the Azure Synapse Analytics introduction articles.

> **TIP**
> To learn about a migration scenario for a data lake or a data warehouse, see the article Migrate data from your data lake or data warehouse to Azure.

Supported capabilities

This Azure Blob storage connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓ Exclude storage account V1
Mapping data flow (source/sink)	①	✓ Exclude storage account V1
Lookup activity	① ②	✓ Exclude storage account V1
GetMetadata activity	① ②	✓ Exclude storage account V1
Delete activity	① ②	✓ Exclude storage account V1

① Azure integration runtime ② Self-hosted integration runtime

For the Copy activity, this Blob storage connector supports:

- Copying blobs to and from general-purpose Azure storage accounts and hot/cool blob storage.
- Copying blobs by using an account key, a service shared access signature (SAS), a service principal, or managed identities for Azure resource authentications.
- Copying blobs from block, append, or page blobs and copying data to only block blobs.
- Copying blobs as is, or parsing or generating blobs with supported file formats and compression codecs.
- Preserving file metadata during copy.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

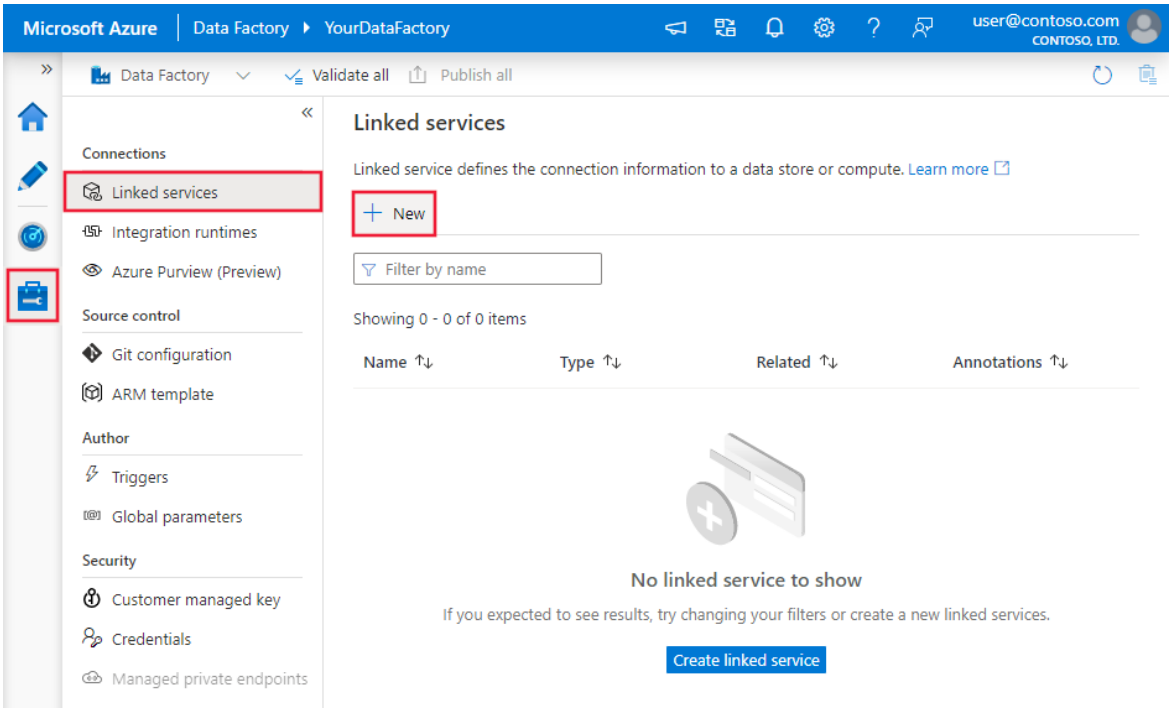
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Azure Blob Storage linked service using UI

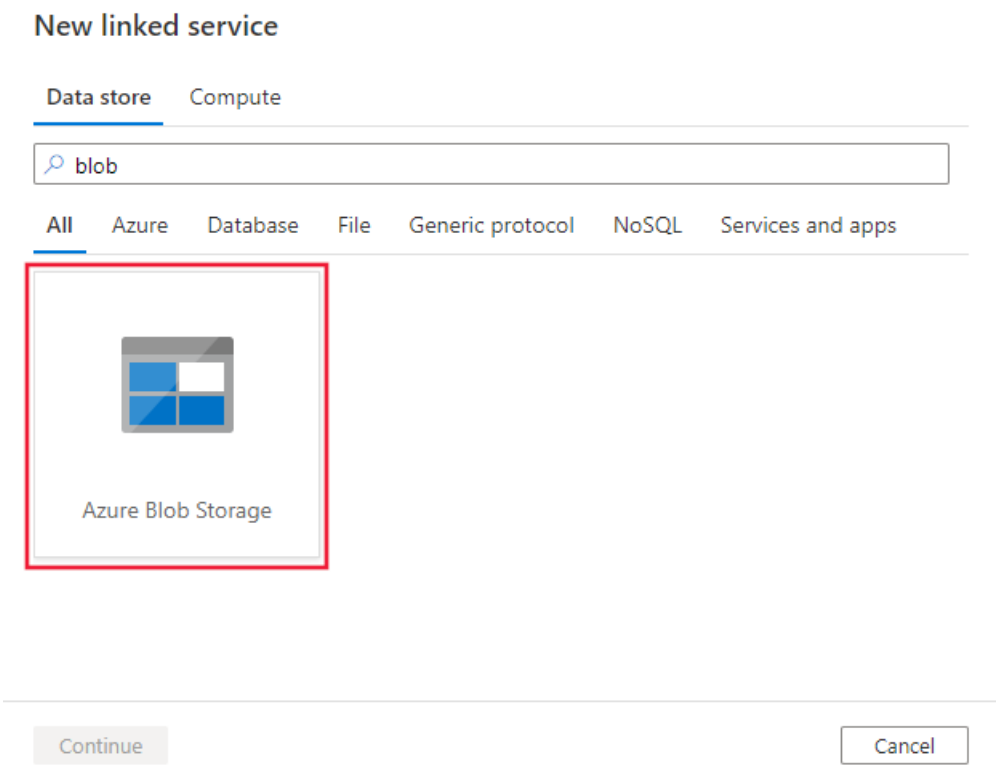
Use the following steps to create an Azure Blob Storage linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

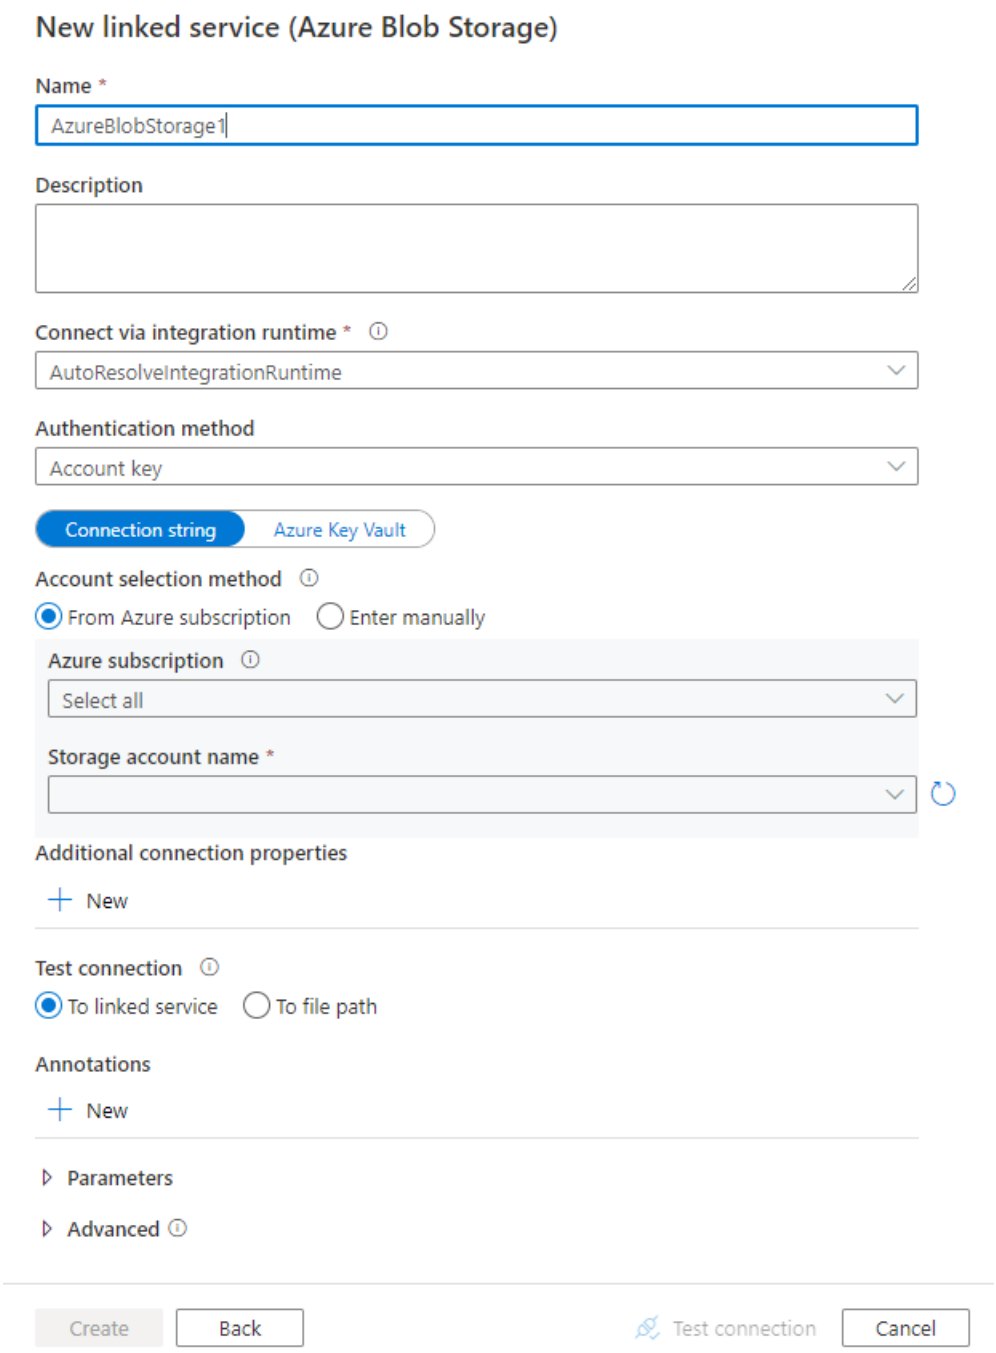
   - Azure Data Factory
   - Azure Synapse



2. Search for blob and select the Azure Blob Storage connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory and Synapse pipeline entities specific to Blob storage.

Linked service properties

This Blob storage connector supports the following authentication types. See the corresponding sections for details.

- Account key authentication
- Shared access signature authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

NOTE

- If want to use the public Azure integration runtime to connect to your Blob storage by leveraging the **Allow trusted Microsoft services to access this storage account** option enabled on Azure Storage firewall, you must use managed identity authentication. For more information about the Azure Storage firewalls settings, see Configure Azure Storage firewalls and virtual networks.
- When you use PolyBase or COPY statement to load data into Azure Synapse Analytics, if your source or staging Blob storage is configured with an Azure Virtual Network endpoint, you must use managed identity authentication as required by Azure Synapse. See the Managed identity authentication section for more configuration prerequisites.

NOTE

Azure HDInsight and Azure Machine Learning activities only support authentication that uses Azure Blob storage account keys.

Account key authentication

The following properties are supported for storage account key authentication in Azure Data Factory or Synapse pipelines:

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property must be set to `AzureBlobStorage` (suggested) or `AzureStorage` (see the following notes).	Yes
connectionString	Specify the information needed to connect to Storage for the `connectionString` property. You can also put the account key in Azure Key Vault and pull the `accountKey` configuration out of the connection string. For more information, see the following samples and the Store credentials in Azure Key Vault article.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

NOTE

A secondary Blob service endpoint is not supported when you're using account key authentication. You can use other authentication types.

> **NOTE**
>
> If you're using the `AzureStorage` type linked service, it's still supported as is. But we suggest that you use the new `AzureBlobStorage` linked service type going forward.

Example:

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
          "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;AccountKey=
<accountkey>"
        },
        "connectVia": {
          "referenceName": "<name of Integration Runtime>",
          "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store the account key in Azure Key Vault

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;",
            "accountKey": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Shared access signature authentication

A shared access signature provides delegated access to resources in your storage account. You can use a shared access signature to grant a client limited permissions to objects in your storage account for a specified time.

You don't have to share your account access keys. The shared access signature is a URI that encompasses in its query parameters all the information necessary for authenticated access to a storage resource. To access storage resources with the shared access signature, the client only needs to pass in the shared access signature to the appropriate constructor or method.

For more information about shared access signatures, see Shared access signatures: Understand the shared access signature model.

NOTE

- The service now supports both *service shared access signatures* and *account shared access signatures*. For more information about shared access signatures, see Grant limited access to Azure Storage resources using shared access signatures.
- In later dataset configurations, the folder path is the absolute path starting from the container level. You need to configure one aligned with the path in your SAS URI.

The following properties are supported for using shared access signature authentication:

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property must be set to `AzureBlobStorage` (suggested) or `AzureStorage` (see the following note).	Yes
sasUri	Specify the shared access signature URI to the Storage resources such as blob or container. Mark this field as `SecureString` to store it securely. You can also put the SAS token in Azure Key Vault to use auto-rotation and remove the token portion. For more information, see the following samples and Store credentials in Azure Key Vault.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

NOTE

If you're using the `AzureStorage` type linked service, it's still supported as is. But we suggest that you use the new `AzureBlobStorage` linked service type going forward.

Example:

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the Azure Storage resource e.g.
https://<accountname>.blob.core.windows.net/?sv=<storage version>&st=<start time>&se=<expire time>&sr=
<resource>&sp=<permissions>&sip=<ip range>&spr=<protocol>&sig=<signature>>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store the account key in Azure Key Vault

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the Azure Storage resource without token e.g.
https://<accountname>.blob.core.windows.net/>"
            },
            "sasToken": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName with value of SAS token e.g. ?sv=<storage version>&st=<start
time>&se=<expire time>&sr=<resource>&sp=<permissions>&sip=<ip range>&spr=<protocol>&sig=<signature>>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

When you create a shared access signature URI, consider the following points:

- Set appropriate read/write permissions on objects based on how the linked service (read, write, read/write) is used.
- Set **Expiry time** appropriately. Make sure that the access to Storage objects doesn't expire within the active period of the pipeline.
- The URI should be created at the right container or blob based on the need. A shared access signature URI to a blob allows the data factory or Synapse pipeline to access that particular blob. A shared access signature URI to a Blob storage container allows the data factory or Synapse pipeline to iterate through blobs in that container. To provide access to more or fewer objects later, or to update the shared access signature URI, remember to update the linked service with the new URI.

Service principal authentication

For general information about Azure Storage service principal authentication, see Authenticate access to Azure Storage using Azure Active Directory.

To use service principal authentication, follow these steps:

1. Register an application entity in Azure Active Directory (Azure AD) by following Register your application with an Azure AD tenant. Make note of these values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant the service principal proper permission in Azure Blob storage. For more information on the roles, see Use the Azure portal to assign an Azure role for access to blob and queue data.
   - **As source**, in **Access control (IAM)**, grant at least the **Storage Blob Data Reader** role.
   - **As sink**, in **Access control (IAM)**, grant at least the **Storage Blob Data Contributor** role.

These properties are supported for an Azure Blob storage linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureBlobStorage**.	Yes
serviceEndpoint	Specify the Azure Blob storage service endpoint with the pattern of `https://<accountName>.blob.core.windows.net/`.	Yes
accountKind	Specify the kind of your storage account. Allowed values are: **Storage** (general purpose v1), **StorageV2** (general purpose v2), **BlobStorage**, or **BlockBlobStorage**. When using Azure Blob linked service in data flow, managed identity or service principal authentication is not supported when account kind as empty or "Storage". Specify the proper account kind, choose a different authentication, or upgrade your storage account to general purpose v2.	No
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as **SecureString** to store it securelyFactory, or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering over the upper-right corner of the Azure portal.	Yes

PROPERTY	DESCRIPTION	REQUIRED
azureCloudType	For service principal authentication, specify the type of Azure cloud environment, to which your Azure Active Directory application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the data factory or Synapse pipeline's cloud environment is used.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

NOTE

- If your blob account enables soft delete, service principal authentication is not supported in Data Flow.
- If you access the blob storage through private endpoint using Data Flow, note when service principal authentication is used Data Flow connects to the ADLS Gen2 endpoint instead of Blob endpoint. Make sure you create the corresponding private endpoint in your data factory or Synapse workspace to enable access.

NOTE

Service principal authentication is supported only by the "AzureBlobStorage" type linked service, not the previous "AzureStorage" type linked service.

Example:

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "serviceEndpoint": "https://<accountName>.blob.core.windows.net/",
            "accountKind": "StorageV2",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identity authentication

A data factory or Synapse pipeline can be associated with a system-assigned managed identity for Azure resources, which represents that resource for authentication to other Azure services. You can directly use this system-assigned managed identity for Blob storage authentication, which is similar to using your own service principal. It allows this designated resource to access and copy data from or to Blob storage. To learn more about managed identities for Azure resources, see Managed identities for Azure resources

For general information about Azure Storage authentication, see Authenticate access to Azure Storage using Azure Active Directory. To use managed identities for Azure resource authentication, follow these steps:

1. Retrieve system-assigned managed identity information by copying the value of the system-assigned managed identity object ID generated along with your factory or Synapse workspace.
2. Grant the managed identity permission in Azure Blob storage. For more information on the roles, see Use the Azure portal to assign an Azure role for access to blob and queue data.
   - **As source**, in **Access control (IAM)**, grant at least the **Storage Blob Data Reader** role.
   - **As sink**, in **Access control (IAM)**, grant at least the **Storage Blob Data Contributor** role.

These properties are supported for an Azure Blob storage linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureBlobStorage**.	Yes
serviceEndpoint	Specify the Azure Blob storage service endpoint with the pattern of `https://<accountName>.blob.core.windows.net/`.	Yes
accountKind	Specify the kind of your storage account. Allowed values are: **Storage** (general purpose v1), **StorageV2** (general purpose v2), **BlobStorage**, or **BlockBlobStorage**. When using Azure Blob linked service in data flow, managed identity or service principal authentication is not supported when account kind as empty or "Storage". Specify the proper account kind, choose a different authentication, or upgrade your storage account to general purpose v2.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "serviceEndpoint": "https://<accountName>.blob.core.windows.net/",
            "accountKind": "StorageV2"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

A data factory can be assigned with one or multiple user-assigned managed identities. You can use this user-assigned managed identity for Blob storage authentication, which allows to access and copy data from or to Blob storage. To learn more about managed identities for Azure resources, see Managed identities for Azure resources

For general information about Azure storage authentication, see Authenticate access to Azure Storage using Azure Active Directory. To use user-assigned managed identity authentication, follow these steps:

1. Create one or multiple user-assigned managed identities and grant permission in Azure Blob storage. For more information on the roles, see Use the Azure portal to assign an Azure role for access to blob and queue data.
    - **As source**, in **Access control (IAM)**, grant at least the **Storage Blob Data Reader** role.
    - **As sink**, in **Access control (IAM)**, grant at least the **Storage Blob Data Contributor** role.
2. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

These properties are supported for an Azure Blob storage linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureBlobStorage**.	Yes
serviceEndpoint	Specify the Azure Blob storage service endpoint with the pattern of `https://<accountName>.blob.core.windows.net/`.	Yes

PROPERTY	DESCRIPTION	REQUIRED
accountKind	Specify the kind of your storage account. Allowed values are: **Storage** (general purpose v1), **StorageV2** (general purpose v2), **BlobStorage**, or **BlockBlobStorage**. When using Azure Blob linked service in data flow, managed identity or service principal authentication is not supported when account kind as empty or "Storage". Specify the proper account kind, choose a different authentication, or upgrade your storage account to general purpose v2.	No
credentials	Specify the user-assigned managed identity as the credential object.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AzureBlobStorageLinkedService",
    "properties": {
        "type": "AzureBlobStorage",
        "typeProperties": {
            "serviceEndpoint": "https://<accountName>.blob.core.windows.net/",
            "accountKind": "StorageV2",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

IMPORTANT

If you use PolyBase or COPY statement to load data from Blob storage (as a source or as staging) into Azure Synapse Analytics, when you use managed identity authentication for Blob storage, make sure you also follow steps 1 to 3 in this guidance. Those steps will register your server with Azure AD and assign the Storage Blob Data Contributor role to your server. Data Factory handles the rest. If you configure Blob storage with an Azure Virtual Network endpoint, you also need to have **Allow trusted Microsoft services to access this storage account** turned on under Azure Storage account **Firewalls and Virtual networks** settings menu as required by Azure Synapse.

NOTE

- If your blob account enables soft delete, system-assigned/user-assigned managed identity authentication is not supported in Data Flow.
- If you access the blob storage through private endpoint using Data Flow, note when system-assigned/user-assigned managed identity authentication is used Data Flow connects to the ADLS Gen2 endpoint instead of Blob endpoint. Make sure you create the corresponding private endpoint in ADF to enable access.

NOTE

System-assigned/user-assigned managed identity authentication is supported only by the "AzureBlobStorage" type linked service, not the previous "AzureStorage" type linked service.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Blob storage under `location` settings in a format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the location in the dataset must be set to **AzureBlobStorageLocation**.	Yes
container	The blob container.	Yes
folderPath	The path to the folder under the given container. If you want to use a wildcard to filter the folder, skip this setting and specify that in activity source settings.	No
fileName	The file name under the given container and folder path. If you want to use wildcard to filter files, skip this setting and specify that in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties that the Blob storage source and sink support.

Blob storage as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Blob storage under `storeSettings` settings in a format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `storeSettings` must be set to **AzureBlobStorageReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given container or folder/file path specified in the dataset. If you want to copy all blobs from a container or folder, additionally specify `wildcardFileName` as `*`.	

PROPERTY	DESCRIPTION	REQUIRED
OPTION 2: blob prefix - prefix	Prefix for the blob name under the given container configured in a dataset to filter source blobs. Blobs whose names start with `container_in_dataset/this_prefix` are selected. It utilizes the service-side filter for Blob storage, which provides better performance than a wildcard filter. When you use prefix and choose to copy to file-based sink with preserving hierarchy, note the sub-path after the last "/" in prefix will be preserved. For example, you have source `container/folder/subfolder/file.txt`, and configure prefix as `folder/sub`, then the preserved file path is `subfolder/file.txt`.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given container configured in a dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has wildcard or this escape character inside. See more examples in Folder and file filter examples.	No
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given container and folder path (or wildcard folder path) to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your file name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	Yes
OPTION 4: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When you're using this option, do not specify a file name in the dataset. See more examples in File list examples.	No
Additional settings:		

PROPERTY	DESCRIPTION	REQUIRED
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to a UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. - When you use prefix, partition root path is sub-path before the last "/". For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

NOTE

For Parquet/delimited text format, the **BlobSource** type for the Copy activity source mentioned in the next section is still supported as is for backward compatibility. We suggest that you use the new model until the authoring UI has switched to generating these new types.

Example:

```
"activities":[
    {
        "name": "CopyFromBlob",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AzureBlobStorageReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

NOTE

The `$logs` container, which is automatically created when Storage Analytics is enabled for a storage account, isn't shown when a container listing operation is performed via the UI. The file path must be provided directly for your data factory or Synapse pipeline to consume files from the `$logs` container.

Blob storage as a sink type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for Azure Blob storage under `storeSettings` settings in a format-based copy sink:

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property under `storeSettings` must be set to `AzureBlobStorageWriteSettings`.	Yes
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file or blob name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
blockSizeInMB	Specify the block size, in megabytes, used to write data to block blobs. Learn more about Block Blobs. Allowed value is *between 4 MB and 100 MB*. By default, the service automatically determines the block size based on your source store type and data. For nonbinary copy into Blob storage, the default block size is 100 MB so it can fit in (at most) 4.95 TB of data. It might be not optimal when your data is not large, especially when you use the self-hosted integration runtime with poor network connections that result in operation timeout or performance issues. You can explicitly specify a block size, while ensuring that `blockSizeInMB*50000` is big enough to store the data. Otherwise, the Copy activity run will fail.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

PROPERTY	DESCRIPTION	REQUIRED
metadata	Set custom metadata when copy to sink. Each object under the `metadata` array represents an extra column. The `name` defines the metadata key name, and the `value` indicates the data value of that key. If preserve attributes feature is used, the specified metadata will union/overwrite with the source file metadata. Allowed data values are: - `$$LASTMODIFIED`: a reserved variable indicates to store the source files' last modified time. Apply to file-based source with binary format only. - **Expression** - **Static value**	No

Example:

```
"activities":[
    {
        "name": "CopyFromBlob",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Parquet output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "ParquetSink",
                "storeSettings":{
                    "type": "AzureBlobStorageWriteSettings",
                    "copyBehavior": "PreserveHierarchy",
                    "metadata": [
                        {
                            "name": "testKey1",
                            "value": "value1"
                        },
                        {
                            "name": "testKey2",
                            "value": "value2"
                        },
                        {
                            "name": "lastModifiedKey",
                            "value": "$$LASTMODIFIED"
                        }
                    ]
                }
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`container/Folder*`	(empty, use default)	false	container FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`container/Folder*`	(empty, use default)	true	container FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`container/Folder*`	`*.csv`	false	container FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`container/Folder*`	`*.csv`	true	container FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using a file list path in the Copy activity source.

Assume that you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
container FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Container: `container` - Folder path: `FolderA` **In Copy activity source:** - File list path: `container/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line, with the relative path to the path configured in the dataset.

Some recursive and copyBehavior examples

This section describes the resulting behavior of the Copy operation for different combinations of **recursive** and

copyBehavior values.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET
true	preserveHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder, Folder1, is created with the same structure as the source: Folder1 File1 File2 Subfolder1 File3 File4 File5
true	flattenHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder, Folder1, is created with the following structure: Folder1 autogenerated name for File1 autogenerated name for File2 autogenerated name for File3 autogenerated name for File4 autogenerated name for File5
true	mergeFiles	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder, Folder1, is created with the following structure: Folder1 File1 + File2 + File3 + File4 + File5 contents are merged into one file with an autogenerated file name.
false	preserveHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder, Folder1, is created with the following structure: Folder1 File1 File2 Subfolder1 with File3, File4, and File5 is not picked up.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

false	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder, Folder1, is created with the following structure:
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			
			Subfolder1 with File3, File4, and File5 is not picked up.

false	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder, Folder1, is created with the following structure:
			
			Folder1
			  File1 + File2 contents are merged into one file with an autogenerated file name. autogenerated name for File1
			
			Subfolder1 with File3, File4, and File5 is not picked up.

Preserving metadata during copy

When you copy files from Amazon S3, Azure Blob storage, or Azure Data Lake Storage Gen2 to Azure Data Lake Storage Gen2 or Azure Blob storage, you can choose to preserve the file metadata along with data. Learn more from Preserve metadata.

Mapping data flow properties

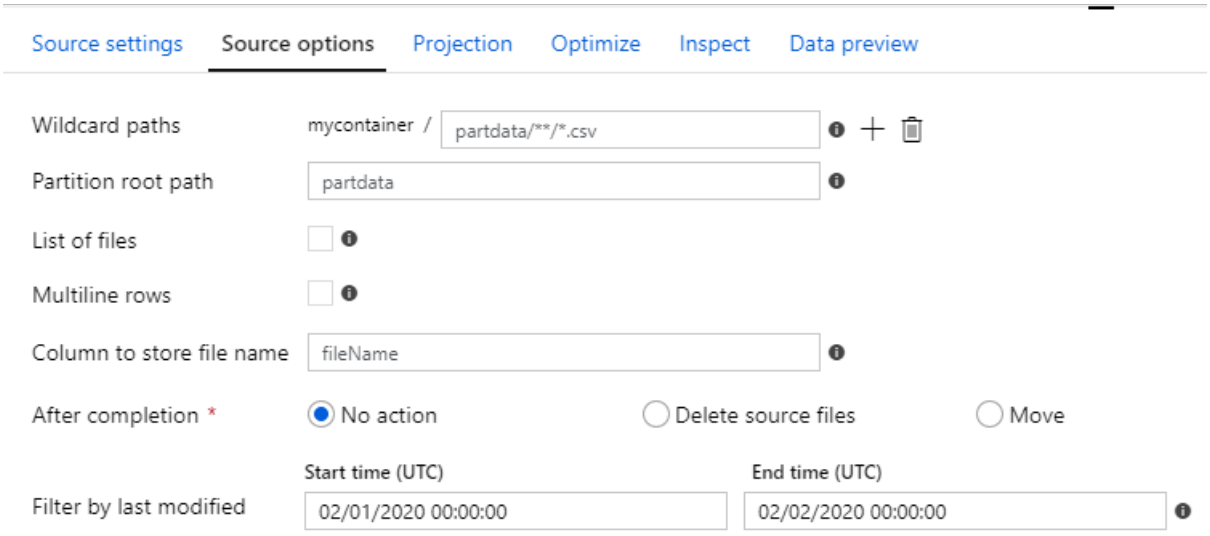
When you're transforming data in mapping data flows, you can read and write files from Azure Blob storage in the following formats:

- Avro
- Delimited text
- Delta
- Excel
- JSON
- Parquet

Format specific settings are located in the documentation for that format. For more information, see Source transformation in mapping data flow and Sink transformation in mapping data flow.

Source transformation

In source transformation, you can read from a container, folder, or individual file in Azure Blob storage. Use the **Source options** tab to manage how the files are read.



Wildcard paths: Using a wildcard pattern will instruct the service to loop through each matching folder and file in a single source transformation. This is an effective way to process multiple files within a single flow. Add multiple wildcard matching patterns with the plus sign that appears when you hover over your existing wildcard pattern.

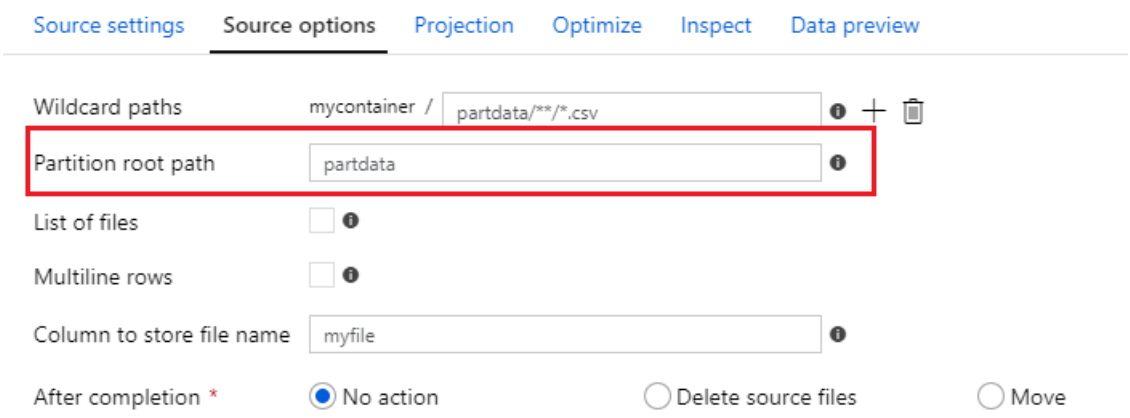
From your source container, choose a series of files that match a pattern. Only a container can be specified in the dataset. Your wildcard path must therefore also include your folder path from the root folder.

Wildcard examples:

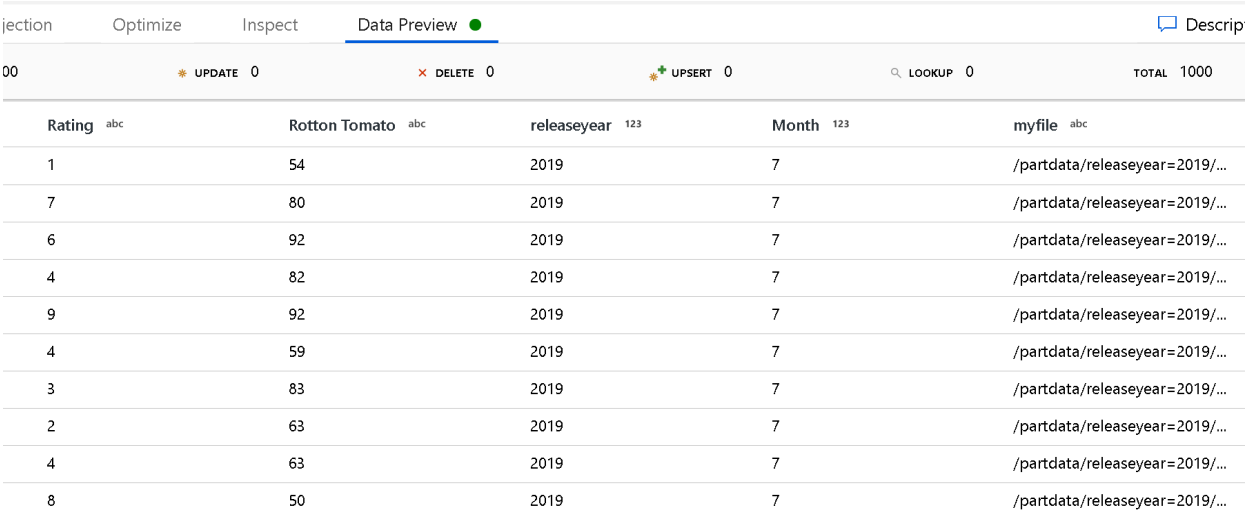
- `*` Represents any set of characters.
- `**` Represents recursive directory nesting.
- `?` Replaces one character.
- `[]` Matches one or more characters in the brackets.
- `/data/sales/**/*.csv` Gets all .csv files under /data/sales.
- `/data/sales/20??/**/` Gets all files in the 20th century.
- `/data/sales/*/*/*.csv` Gets .csv files two levels under /data/sales.
- `/data/sales/2004/*/12/[XY]1?.csv` Gets all .csv files in December 2004 starting with X or Y prefixed by a two-digit number.

Partition root path: If you have partitioned folders in your file source with a `key=value` format (for example, `year=2019`), then you can assign the top level of that partition folder tree to a column name in your data flow's data stream.

First, set a wildcard to include all paths that are the partitioned folders plus the leaf files that you want to read.



Use the **Partition root path** setting to define what the top level of the folder structure is. When you view the contents of your data via a data preview, you'll see that the service will add the resolved partitions found in each of your folder levels.



Rating abc	Rotton Tomato abc	releaseyear 123	Month 123	myfile abc
1	54	2019	7	/partdata/releaseyear=2019/...
7	80	2019	7	/partdata/releaseyear=2019/...
6	92	2019	7	/partdata/releaseyear=2019/...
4	82	2019	7	/partdata/releaseyear=2019/...
9	92	2019	7	/partdata/releaseyear=2019/...
4	59	2019	7	/partdata/releaseyear=2019/...
3	83	2019	7	/partdata/releaseyear=2019/...
2	63	2019	7	/partdata/releaseyear=2019/...
4	63	2019	7	/partdata/releaseyear=2019/...
8	50	2019	7	/partdata/releaseyear=2019/...

List of files: This is a file set. Create a text file that includes a list of relative path files to process. Point to this text file.

Column to store file name: Store the name of the source file in a column in your data. Enter a new column name here to store the file name string.

After completion: Choose to do nothing with the source file after the data flow runs, delete the source file, or move the source file. The paths for the move are relative.

To move source files to another location post-processing, first select "Move" for file operation. Then, set the "from" directory. If you're not using any wildcards for your path, then the "from" setting will be the same folder as your source folder.

If you have a source path with wildcard, your syntax will look like this:

`/data/sales/20??/**/*.csv`

You can specify "from" as:

`/data/sales`

And you can specify "to" as:

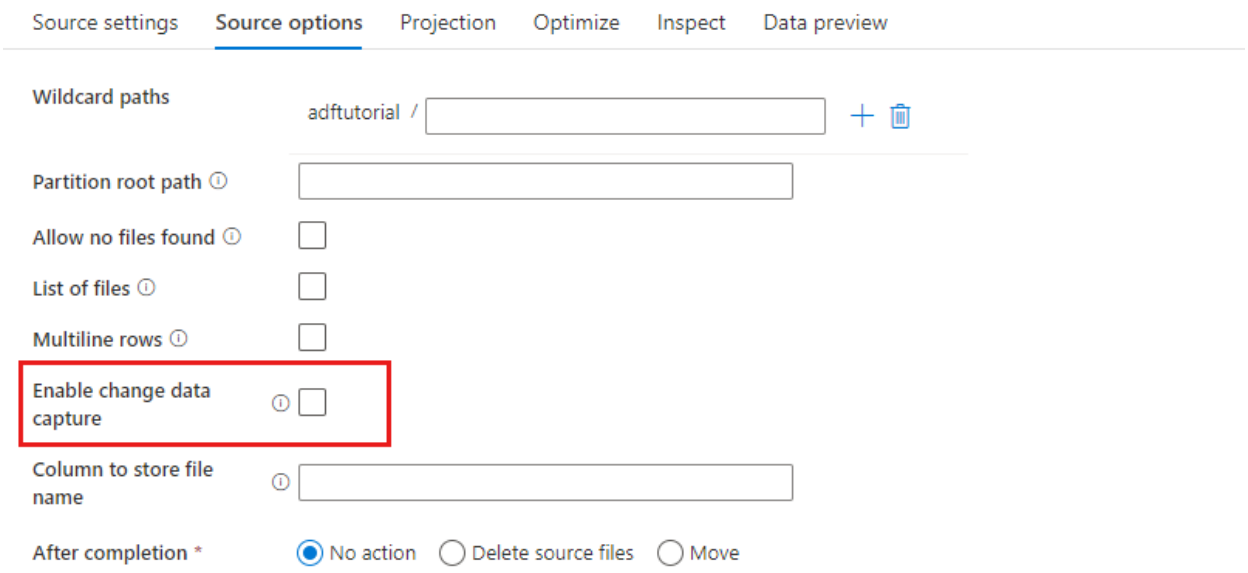
`/backup/priorSales`

In this case, all files that were sourced under `/data/sales` are moved to `/backup/priorSales`.

> **NOTE**
>
> File operations run only when you start the data flow from a pipeline run (a pipeline debug or execution run) that uses the Execute Data Flow activity in a pipeline. File operations *do not* run in Data Flow debug mode.

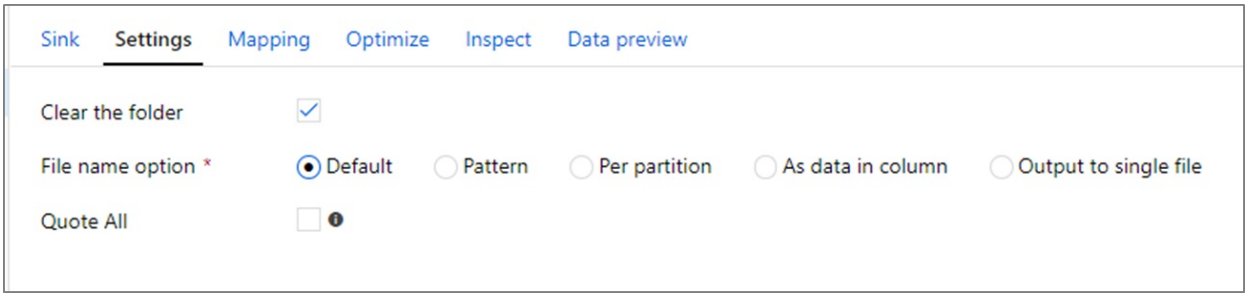
Filter by last modified: You can filter which files you process by specifying a date range of when they were last modified. All datetimes are in UTC.

Enable change data capture: If true, you will get new or changed files only from the last run. Initial load of full snapshot data will always be gotten in the first run, followed by capturing new or changed files only in next runs. For more details, see Change data capture.



Sink properties

In the sink transformation, you can write to either a container or a folder in Azure Blob storage. Use the **Settings** tab to manage how the files get written.



Clear the folder: Determines whether or not the destination folder gets cleared before the data is written.

File name option: Determines how the destination files are named in the destination folder. The file name options are:

- **Default**: Allow Spark to name files based on PART defaults.
- **Pattern**: Enter a pattern that enumerates your output files per partition. For example, `loans[n].csv` will create `loans1.csv`, `loans2.csv`, and so on.
- **Per partition**: Enter one file name per partition.
- **As data in column**: Set the output file to the value of a column. The path is relative to the dataset container, not the destination folder. If you have a folder path in your dataset, it will be overridden.
- **Output to a single file**: Combine the partitioned output files into a single named file. The path is relative to the dataset folder. Be aware that the merge operation can possibly fail based on node size. We don't

recommend this option for large datasets.

Quote all: Determines whether to enclose all values in quotation marks.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity.

Delete activity properties

To learn details about the properties, check Delete activity.

Legacy models

> **NOTE**
> The following models are still supported as is for backward compatibility. We suggest that you use the new model mentioned earlier. The authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property of the dataset must be set to `AzureBlob`.	Yes
folderPath	Path to the container and folder in Blob storage. A wildcard filter is supported for the path, excluding container name. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has a wildcard or this escape character inside. An example is: `myblobcontainer/myblobfolder/`. See more examples in Folder and file filter examples.	Yes for the Copy or Lookup activity, No for the GetMetadata activity

PROPERTY	DESCRIPTION	REQUIRED
fileName	Name or wildcard filter for the blobs under the specified `folderPath` value. If you don't specify a value for this property, the dataset points to all blobs in the folder. For the filter, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your file name has a wildcard or this escape character inside. When `fileName` isn't specified for an output dataset and `preserveHierarchy` isn't specified in the activity sink, the Copy activity automatically generates the blob name with the following pattern: "*Data.[activity run ID GUID].[GUID if FlattenHierarchy].[format if configured].[compression if configured]*". For example: "Data.0a405f8a-93ff-4c6f-b3be-f69616f1df7a.txt.gz". If you copy from a tabular source by using a table name instead of a query, the name pattern is `[table name].[format].[compression if configured]`. For example: "MyTable.csv".	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware that enabling this setting will affect the overall performance of data movement when you want to filter huge amounts of files. The properties can be `NULL`, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is `NULL`, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is `NULL`, the files whose last modified attribute is less than the datetime value will be selected.	No
modifiedDatetimeEnd	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware that enabling this setting will affect the overall performance of data movement when you want to filter huge amounts of files. The properties can be `NULL`, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is `NULL`, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is `NULL`, the files whose last modified attribute is less than the datetime value will be selected.	No

PROPERTY	DESCRIPTION	REQUIRED
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both the input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, and **ParquetFormat**. Set the **type** property under **format** to one of these values. For more information, see the Text format, JSON format, Avro format, Orc format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are **Optimal** and **Fastest**.	No

TIP

To copy all blobs under a folder, specify **folderPath** only.
To copy a single blob with a given name, specify **folderPath** for the folder part and **fileName** for the file name.
To copy a subset of blobs under a folder, specify **folderPath** for the folder part and **fileName** with a wildcard filter.

Example:

```
{
    "name": "AzureBlobDataset",
    "properties": {
        "type": "AzureBlob",
        "linkedServiceName": {
            "referenceName": "<Azure Blob storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "mycontainer/myfolder",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy source model for the Copy activity

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property of the Copy activity source must be set to `BlobSource`.	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when `recursive` is set to `true` and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are `true` (default) and `false`.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromBlob",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure Blob input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "BlobSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Legacy sink model for the Copy activity

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property of the Copy activity sink must be set to `BlobSink`.	Yes
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of source file to source folder is identical to the relative path of target file to target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file or blob name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToBlob",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure Blob output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "BlobSink",
                "copyBehavior": "PreserveHierarchy"
            }
        }
    }
]
```

Change data capture (preview)

Azure Data Factory can get new or changed files only from Azure Blob Storage by enabling **Enable change data capture (Preview)** in the mapping data flow source transformation. With this connector option, you can read new or updated files only and apply transformations before loading transformed data into destination datasets of your choice.

Make sure you keep the pipeline and activity name unchanged, so that the checkpoint can always be recorded from the last run to get changes from there. If you change your pipeline name or activity name, the checkpoint will be reset, and you will start from the beginning in the next run.

When you debug the pipeline, the **Enable change data capture (Preview)** works as well. Be aware that the checkpoint will be reset when you refresh your browser during the debug run. After you are satisfied with the result from debug run, you can publish and trigger the pipeline. It will always start from the beginning regardless of the previous checkpoint recorded by debug run.

In the monitoring section, you always have the chance to rerun a pipeline. When you are doing so, the changes are always gotten from the checkpoint record in your selected pipeline run.

Next steps

For a list of data stores that the Copy activity supports as sources and sinks, see Supported data stores.

Copy data to an Azure Cognitive Search index using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data into Azure Cognitive Search index. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Azure Cognitive Search connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (-/sink)	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from any supported source data store into search index. For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

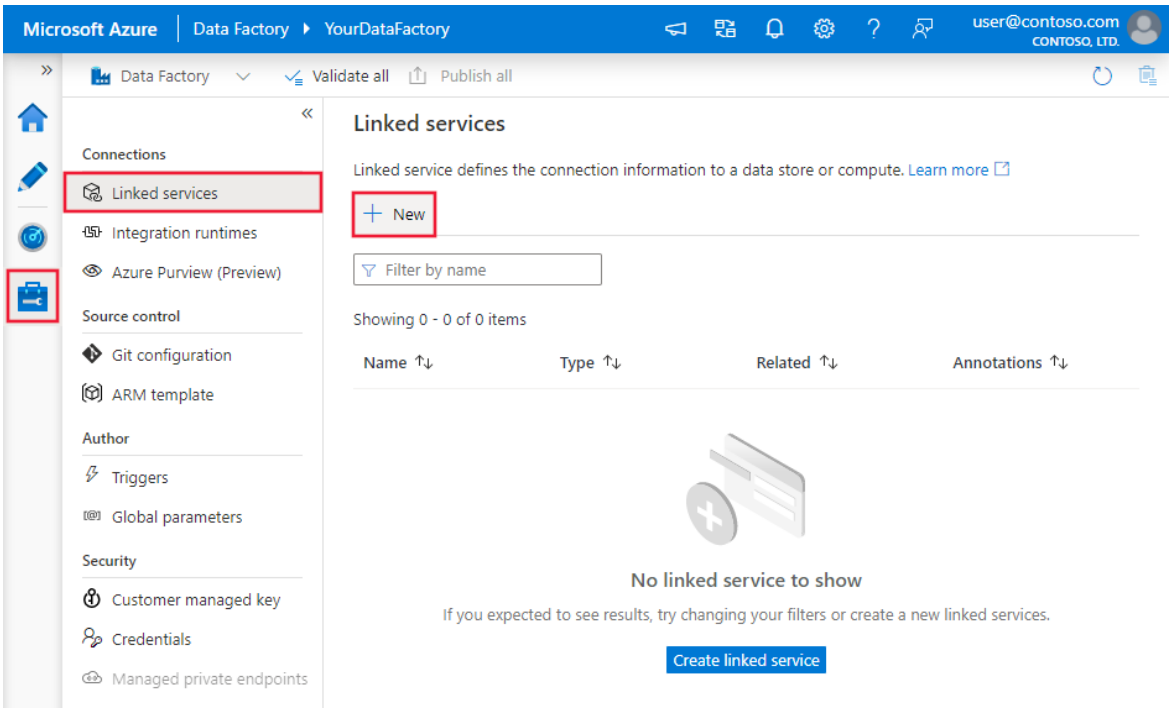
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Search using UI

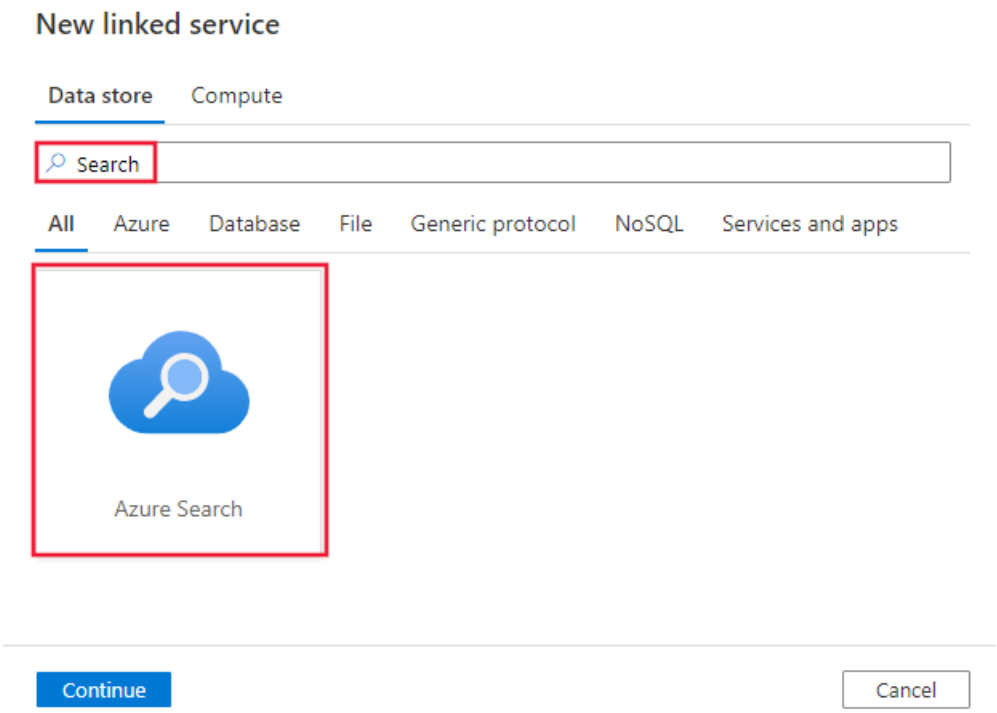
Use the following steps to create a linked service to Azure Search in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

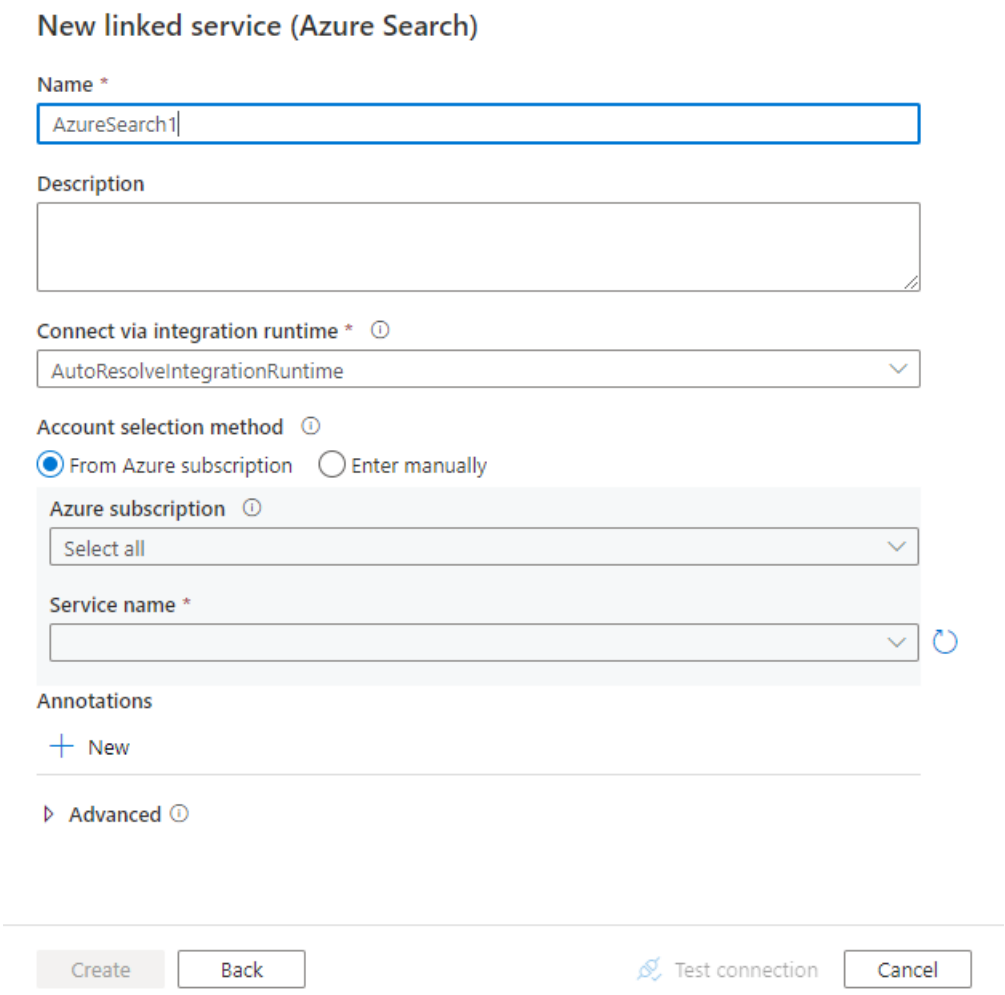
   - Azure Data Factory
   - Azure Synapse



2. Search for Search and select the Azure Search connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Azure Cognitive Search connector.

Linked service properties

The following properties are supported for Azure Cognitive Search linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureSearch**	Yes
url	URL for the search service.	Yes
key	Admin key for the search service. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

> **IMPORTANT**
>
> When copying data from a cloud data store into search index, in Azure Cognitive Search linked service, you need to refer an Azure Integration Runtime with explicit region in connactVia. Set the region as the one where your search service resides. Learn more from Azure Integration Runtime.

Example:

```
{
    "name": "AzureSearchLinkedService",
    "properties": {
        "type": "AzureSearch",
        "typeProperties": {
            "url": "https://<service>.search.windows.net",
            "key": {
                "type": "SecureString",
                "value": "<AdminKey>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Azure Cognitive Search dataset.

To copy data into Azure Cognitive Search, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **AzureSearchIndex**	Yes
indexName	Name of the search index. The service does not create the index. The index must exist in Azure Cognitive Search.	Yes

Example:

```
{
    "name": "AzureSearchIndexDataset",
    "properties": {
        "type": "AzureSearchIndex",
        "typeProperties" : {
            "indexName": "products"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Azure Cognitive Search linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Azure Cognitive Search source.

Azure Cognitive Search as sink

To copy data into Azure Cognitive Search, set the source type in the copy activity to **AzureSearchIndexSink**. The following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **AzureSearchIndexSink**	Yes
writeBehavior	Specifies whether to merge or replace when a document already exists in the index. See the WriteBehavior property. Allowed values are: **Merge** (default), and **Upload**.	No
writeBatchSize	Uploads data into the search index when the buffer size reaches writeBatchSize. See the WriteBatchSize property for details. Allowed values are: integer 1 to 1,000; default is 1000.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

WriteBehavior property

AzureSearchSink upserts when writing data. In other words, when writing a document, if the document key already exists in the search index, Azure Cognitive Search updates the existing document rather than throwing a conflict exception.

The AzureSearchSink provides the following two upsert behaviors (by using AzureSearch SDK):

- **Merge**: combine all the columns in the new document with the existing one. For columns with null value in the new document, the value in the existing one is preserved.
- **Upload**: The new document replaces the existing one. For columns not specified in the new document, the value is set to null whether there is a non-null value in the existing document or not.

The default behavior is **Merge**.

WriteBatchSize Property

Azure Cognitive Search service supports writing documents as a batch. A batch can contain 1 to 1,000 Actions. An action handles one document to perform the upload/merge operation.

Example:

```
"activities":[
    {
        "name": "CopyToAzureSearch",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure Cognitive Search output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureSearchIndexSink",
                "writeBehavior": "Merge"
            }
        }
    }
]
```

Data type support

The following table specifies whether an Azure Cognitive Search data type is supported or not.

AZURE COGNITIVE SEARCH DATA TYPE	SUPPORTED IN AZURE COGNITIVE SEARCH SINK
String	Y
Int32	Y
Int64	Y
Double	Y
Boolean	Y
DataTimeOffset	Y
String Array	N
GeographyPoint	N

Currently other data types e.g. ComplexType are not supported. For a full list of Azure Cognitive Search supported data types, see Supported data types (Azure Cognitive Search).

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Azure Cosmos DB (SQL API) by using Azure Data Factory

8/19/2022 • 18 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory to copy data from and to Azure Cosmos DB (SQL API), and use Data Flow to transform data in Azure Cosmos DB (SQL API). To learn more, read the introductory articles for Azure Data Factory and Azure Synapse Analytics.

> **NOTE**
> This connector only support Cosmos DB SQL API. For MongoDB API, refer to connector for Azure Cosmos DB's API for MongoDB. Other API types are not supported now.

Supported capabilities

This Azure Cosmos DB (SQL API) connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

For Copy activity, this Azure Cosmos DB (SQL API) connector supports:

- Copy data from and to the Azure Cosmos DB SQL API using key, service principal, or managed identities for Azure resources authentications.
- Write to Azure Cosmos DB as **insert** or **upsert**.
- Import and export JSON documents as-is, or copy data from or to a tabular dataset. Examples include a SQL database and a CSV file. To copy documents as-is to or from JSON files or to or from another Azure Cosmos DB collection, see Import and export JSON documents.

Data Factory and Synapse pipelines integrate with the Azure Cosmos DB bulk executor library to provide the best performance when you write to Azure Cosmos DB.

> **TIP**
> The Data Migration video walks you through the steps of copying data from Azure Blob storage to Azure Cosmos DB. The video also describes performance-tuning considerations for ingesting data to Azure Cosmos DB in general.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

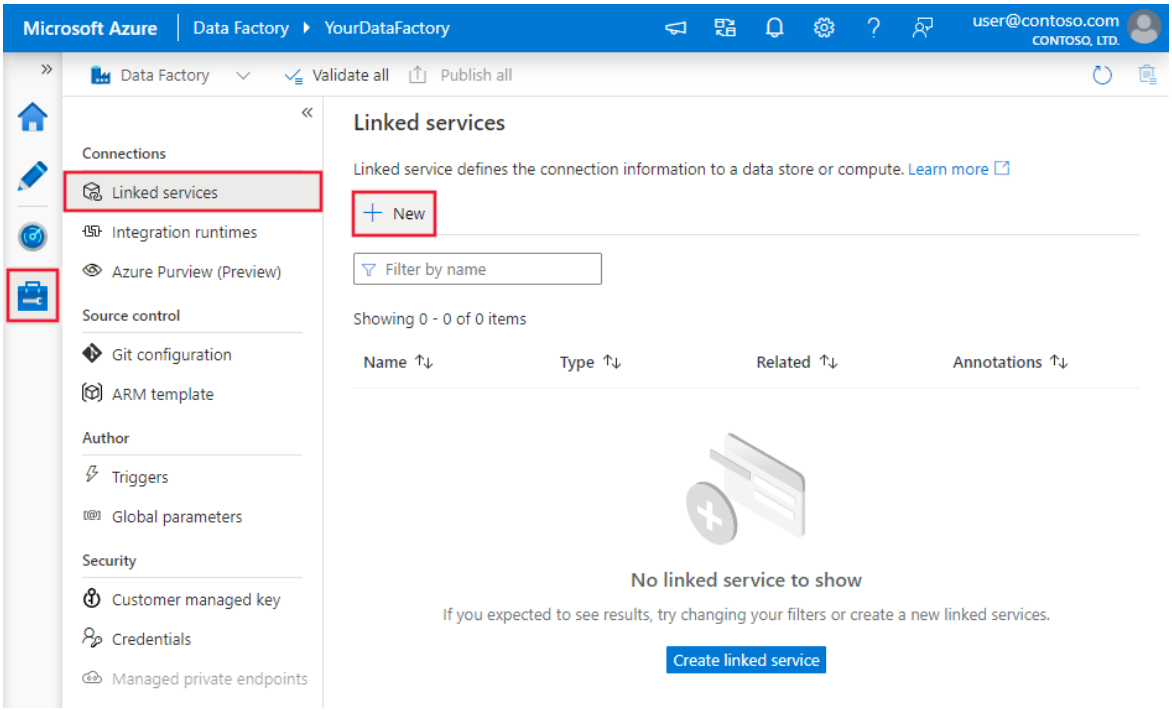
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Cosmos DB using UI

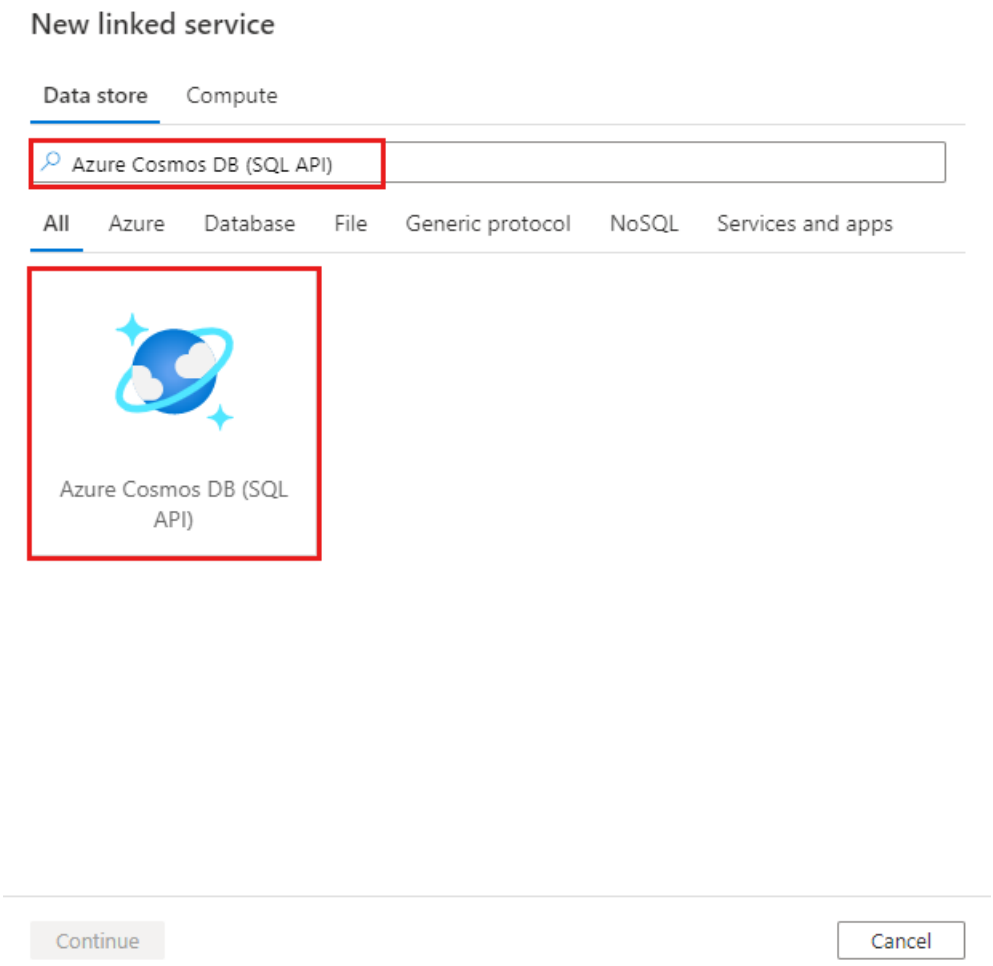
Use the following steps to create a linked service to Azure Cosmos DB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

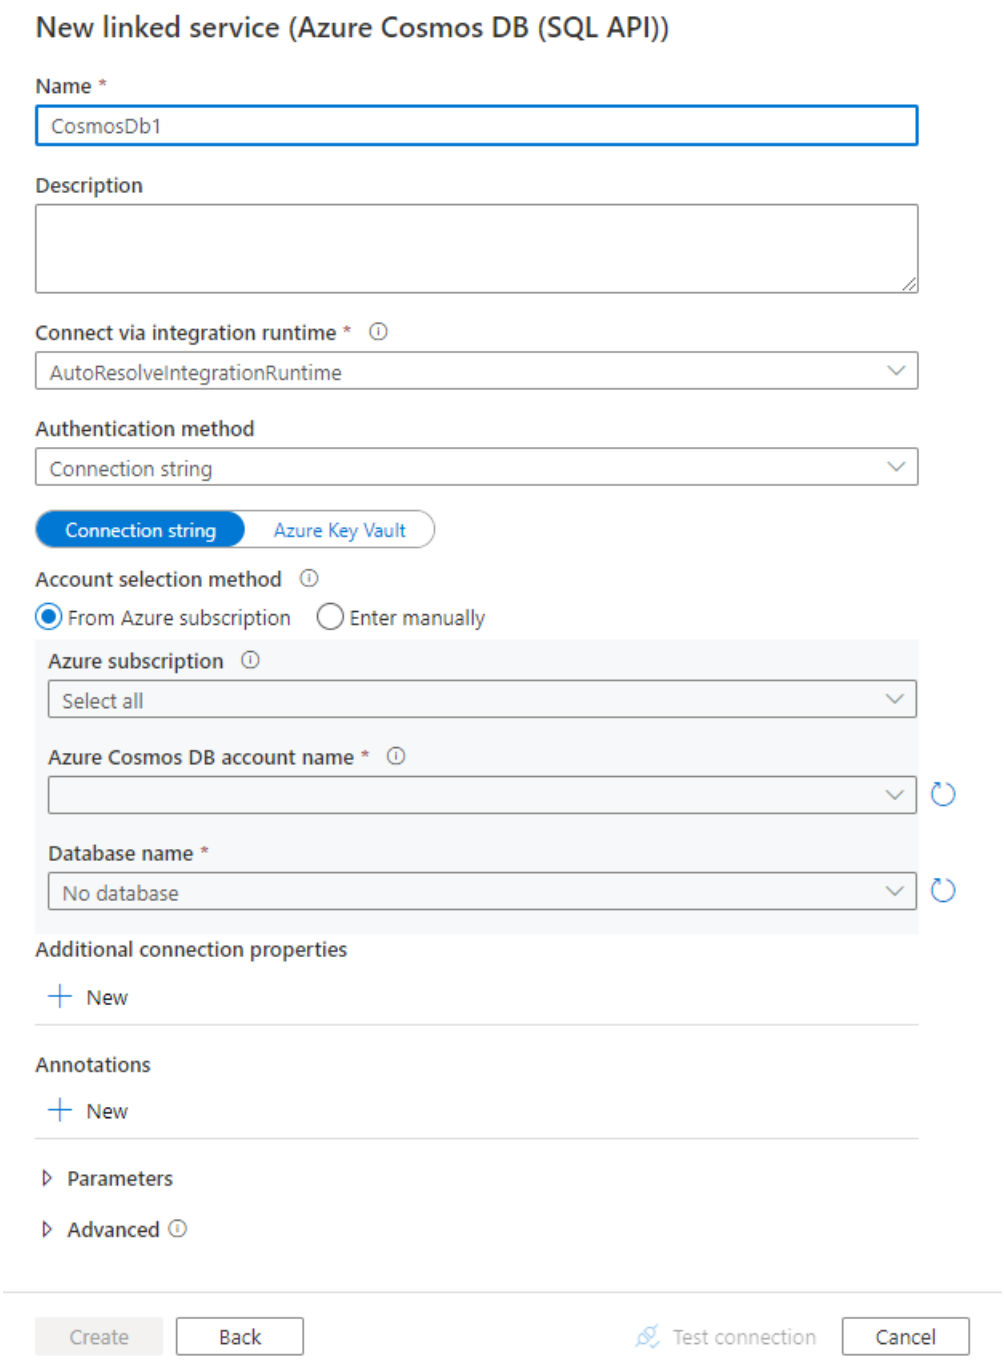
   - Azure Data Factory
   - Azure Synapse



2. Search for Azure Cosmos DB (SQL API) and select the Azure Cosmos DB (SQL API) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define entities that are specific to Azure Cosmos DB (SQL API).

Linked service properties

The Azure Cosmos DB (SQL API) connector supports the following authentication types. See the corresponding sections for details:

- Key authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

Key authentication

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **CosmosDb**.	Yes
connectionString	Specify information that's required to connect to the Azure Cosmos DB database. **Note**: You must specify database information in the connection string as shown in the examples that follow. You can also put account key in Azure Key Vault and pull the `accountKey` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to use to connect to the data store. You can use the Azure Integration Runtime or a self-hosted integration runtime (if your data store is located in a private network). If this property isn't specified, the default Azure Integration Runtime is used.	No

Example

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "connectionString": "AccountEndpoint=<EndpointUrl>;AccountKey=<AccessKey>;Database=<Database>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store account key in Azure Key Vault

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "connectionString": "AccountEndpoint=<EndpointUrl>;Database=<Database>",
            "accountKey": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Service principal authentication

> **NOTE**
> Currently, the service principal authentication is not supported in data flow.

To use service principal authentication, follow these steps.

1. Register an application entity in Azure Active Directory (Azure AD) by following the steps in Register your application with an Azure AD tenant. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant the service principal proper permission. See examples on how permission works in Cosmos DB from Access control lists on files and directories. More specifically, create a role definition, and assign the role to the service principle via service principle object ID.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **CosmosDb**.	Yes
accountEndpoint	Specify the account endpoint URL for the Azure Cosmos DB.	Yes
database	Specify the name of the database.	Yes
servicePrincipalId	Specify the application's client ID.	Yes

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalCredentialType	The credential type to use for service principal authentication. Allowed values are **ServicePrincipalKey** and **ServicePrincipalCert**.	Yes
servicePrincipalCredential	The service principal credential. When you use **ServicePrincipalKey** as the credential type, specify the application's key. Mark this field as **SecureString** to store it securely, or reference a secret stored in Azure Key Vault. When you use **ServicePrincipalCert** as the credential, reference a certificate in Azure Key Vault, and ensure the certificate content type is **PKCS #12**.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure Active Directory application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the service's cloud environment is used.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example: using service principal key authentication

You can also store service principal key in Azure Key Vault.

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "accountEndpoint": "<account endpoint>",
            "database": "<database name>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalCredential": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: using service principal certificate authentication

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "accountEndpoint": "<account endpoint>",
            "database": "<database name>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalCredential": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<AKV reference>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<certificate name in AKV>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identity authentication

> **NOTE**
> Currently, the system-assigned managed identity authentication is not supported in data flow.

A data factory or Synapse pipeline can be associated with a system-assigned managed identity for Azure resources, which represents this specific service instance. You can directly use this managed identity for Cosmos DB authentication, similar to using your own service principal. It allows this designated resource to access and copy data to or from your Cosmos DB.

To use system-assigned managed identities for Azure resource authentication, follow these steps.

1. Retrieve the system-assigned managed identity information by copying the value of the **managed identity object ID** generated along with your service.

2. Grant the system-assigned managed identity proper permission. See examples on how permission works in Cosmos DB from Access control lists on files and directories. More specifically, create a role definition, and assign the role to the system-assigned managed identity.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **CosmosDb**.	Yes
accountEndpoint	Specify the account endpoint URL for the Azure Cosmos DB.	Yes
database	Specify the name of the database.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example:

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "accountEndpoint": "<account endpoint>",
            "database": "<database name>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

> **NOTE**
> Currently, the user-assigned managed identity authentication is not supported in data flow.

A data factory or Synapse pipeline can be associated with a user-assigned managed identities, which represents this specific service instance. You can directly use this managed identity for Cosmos DB authentication, similar to using your own service principal. It allows this designated resource to access and copy data to or from your Cosmos DB.

To use user-assigned managed identities for Azure resource authentication, follow these steps.

1. Create one or multiple user-assigned managed identities and grant the user-assigned managed identity

proper permission. See examples on how permission works in Cosmos DB from Access control lists on files and directories. More specifically, create a role definition, and assign the role to the user-assigned managed identity.

2. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **CosmosDb**.	Yes
accountEndpoint	Specify the account endpoint URL for the Azure Cosmos DB.	Yes
database	Specify the name of the database.	Yes
credentials	Specify the user-assigned managed identity as the credential object.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example:

```
{
    "name": "CosmosDbSQLAPILinkedService",
    "properties": {
        "type": "CosmosDb",
        "typeProperties": {
            "accountEndpoint": "<account endpoint>",
            "database": "<database name>",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services.

The following properties are supported for Azure Cosmos DB (SQL API) dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **CosmosDbSqlApiCollection**.	Yes
collectionName	The name of the Azure Cosmos DB document collection.	Yes

If you use "DocumentDbCollection" type dataset, it is still supported as-is for backward compatibility for Copy and Lookup activity, it's not supported for Data Flow. You are suggested to use the new model going forward.

Example

```
{
    "name": "CosmosDbSQLAPIDataset",
    "properties": {
        "type": "CosmosDbSqlApiCollection",
        "linkedServiceName":{
            "referenceName": "<Azure Cosmos DB linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [],
        "typeProperties": {
            "collectionName": "<collection name>"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties that the Azure Cosmos DB (SQL API) source and sink support. For a full list of sections and properties that are available for defining activities, see Pipelines.

Azure Cosmos DB (SQL API) as source

To copy data from Azure Cosmos DB (SQL API), set the **source** type in Copy Activity to **DocumentDbCollectionSource**.

The following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **CosmosDbSqlApiSource**.	Yes
query	Specify the Azure Cosmos DB query to read data. Example: `SELECT c.BusinessEntityID, c.Name.First AS FirstName, c.Name.Middle AS MiddleName, c.Name.Last AS LastName, c.Suffix, c.EmailPromotion FROM c WHERE c.ModifiedDate > \"2009-01-01T00:00:00\"`	No If not specified, this SQL statement is executed: `select <columns defined in structure> from mycollection`

PROPERTY	DESCRIPTION	REQUIRED
preferredRegions	The preferred list of regions to connect to when retrieving data from Cosmos DB.	No
pageSize	The number of documents per page of the query result. Default is "-1" which means uses the service side dynamic page size up to 1000.	No
detectDatetime	Whether to detect datetime from the string values in the documents. Allowed values are: **true** (default), **false**.	No

If you use "DocumentDbCollectionSource" type source, it is still supported as-is for backward compatibility. You are suggested to use the new model going forward which provide richer capabilities to copy data from Cosmos DB.

Example

```
"activities":[
    {
        "name": "CopyFromCosmosDBSQLAPI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Cosmos DB SQL API input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "CosmosDbSqlApiSource",
                "query": "SELECT c.BusinessEntityID, c.Name.First AS FirstName, c.Name.Middle AS MiddleName,
c.Name.Last AS LastName, c.Suffix, c.EmailPromotion FROM c WHERE c.ModifiedDate > \"2009-01-01T00:00:00\"",
                "preferredRegions": [
                    "East US"
                ]
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

When copying data from Cosmos DB, unless you want to export JSON documents as-is, the best practice is to specify the mapping in copy activity. The service honors the mapping you specified on the activity - if a row doesn't contain a value for a column, a null value is provided for the column value. If you don't specify a mapping, the service infers the schema by using the first row in the data. If the first row doesn't contain the full schema, some columns will be missing in the result of the activity operation.

Azure Cosmos DB (SQL API) as sink

To copy data to Azure Cosmos DB (SQL API), set the **sink** type in Copy Activity to **DocumentDbCollectionSink**.

The following properties are supported in the Copy Activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity sink must be set to **CosmosDbSqlApiSink**.	Yes
writeBehavior	Describes how to write data to Azure Cosmos DB. Allowed values: **insert** and **upsert**. The behavior of **upsert** is to replace the document if a document with the same ID already exists; otherwise, insert the document. **Note**: The service automatically generates an ID for a document if an ID isn't specified either in the original document or by column mapping. This means that you must ensure that, for **upsert** to work as expected, your document has an ID.	No (the default is **insert**)
writeBatchSize	The service uses the Azure Cosmos DB bulk executor library to write data to Azure Cosmos DB. The **writeBatchSize** property controls the size of documents the service provides to the library. You can try increasing the value for **writeBatchSize** to improve performance and decreasing the value if your document size being large - see below tips.	No (the default is **10,000**)
disableMetricsCollection	The service collects metrics such as Cosmos DB RUs for copy performance optimization and recommendations. If you are concerned with this behavior, specify `true` to turn it off.	No (default is `false`)
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

TIP

To import JSON documents as-is, refer to Import or export JSON documents section; to copy from tabular-shaped data, refer to Migrate from relational database to Cosmos DB.

> **TIP**
> Cosmos DB limits single request's size to 2MB. The formula is Request Size = Single Document Size * Write Batch Size. If you hit error saying **"Request size is too large."**, **reduce the** `writeBatchSize` **value** in copy sink configuration.

If you use "DocumentDbCollectionSink" type source, it is still supported as-is for backward compatibility. You are suggested to use the new model going forward which provide richer capabilities to copy data from Cosmos DB.

Example

```
"activities":[
    {
        "name": "CopyToCosmosDBSQLAPI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Document DB output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "CosmosDbSqlApiSink",
                "writeBehavior": "upsert"
            }
        }
    }
]
```

Schema mapping

To copy data from Azure Cosmos DB to tabular sink or reversed, refer to schema mapping.

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to collections in Cosmos DB. For more information, see the source transformation and sink transformation in mapping data flows.

> **NOTE**
> The Azure Cosmos DB serverless is not supported in mapping data flow.

Source transformation

Settings specific to Azure Cosmos DB are available in the **Source Options** tab of the source transformation.

Include system columns: If true, `id`, `_ts`, and other system columns will be included in your data flow metadata from CosmosDB. When updating collections, it is important to include this so that you can grab the existing row ID.

Page size: The number of documents per page of the query result. Default is "-1" which uses the service

dynamic page up to 1000.

Throughput: Set an optional value for the number of RUs you'd like to apply to your CosmosDB collection for each execution of this data flow during the read operation. Minimum is 400.

Preferred regions: Choose the preferred read regions for this process.

Change feed: If true, you will get data from Azure Cosmos DB change feed which is a persistent record of changes to a container in the order they occur from last run automatically. When you set it true, do not set both **Infer drifted column types** and **Allow schema drift** as true at the same time. For more details, see Azure Cosmos DB change feed).

Start from beginning: If true, you will get initial load of full snapshot data in the first run, followed by capturing changed data in next runs. If false, the initial load will be skipped in the first run, followed by capturing changed data in next runs. The setting is aligned with the same setting name in Cosmos DB reference. For more details, see Azure Cosmos DB change feed.

Sink transformation

Settings specific to Azure Cosmos DB are available in the **Settings** tab of the sink transformation.

Update method: Determines what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an alter-row transformation is required to tag rows for those actions. For updates, upserts and deletes, a key column or columns must be set to determine which row to alter.

Collection action: Determines whether to recreate the destination collection prior to writing.

- None: No action will be done to the collection.
- Recreate: The collection will get dropped and recreated

Batch size: An integer that represents how many objects are being written to Cosmos DB collection in each batch. Usually, starting with the default batch size is sufficient. To further tune this value, note:

- Cosmos DB limits single request's size to 2MB. The formula is "Request Size = Single Document Size * Batch Size". If you hit error saying "Request size is too large", reduce the batch size value.
- The larger the batch size, the better throughput the service can achieve, while make sure you allocate enough RUs to empower your workload.

Partition key: Enter a string that represents the partition key for your collection. Example: `/movies/title`

Throughput: Set an optional value for the number of RUs you'd like to apply to your CosmosDB collection for each execution of this data flow. Minimum is 400.

Write throughput budget: An integer that represents the RUs you want to allocate for this Data Flow write operation, out of the total throughput allocated to the collection.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Import and export JSON documents

You can use this Azure Cosmos DB (SQL API) connector to easily:

- Copy documents between two Azure Cosmos DB collections as-is.
- Import JSON documents from various sources to Azure Cosmos DB, including from Azure Blob storage, Azure Data Lake Store, and other file-based stores that the service supports.
- Export JSON documents from an Azure Cosmos DB collection to various file-based stores.

To achieve schema-agnostic copy:

- When you use the Copy Data tool, select the **Export as-is to JSON files or Cosmos DB collection** option.
- When you use activity authoring, choose JSON format with the corresponding file store for source or sink.

Migrate from relational database to Cosmos DB

When migrating from a relational database e.g. SQL Server to Azure Cosmos DB, copy activity can easily map tabular data from source to flatten JSON documents in Cosmos DB. In some cases, you may want to redesign the data model to optimize it for the NoSQL use-cases according to Data modeling in Azure Cosmos DB, for example, to de-normalize the data by embedding all of the related sub-items within one JSON document. For such case, refer to this article with a walk-through on how to achieve it using the copy activity.

Azure Cosmos DB change feed

Azure Data Factory can get data from Azure Cosmos DB change feed by enabling it in the mapping data flow source transformation. With this connector option, you can read change feeds and apply transformations before loading transformed data into destination datasets of your choice. You do not have to use Azure functions to read the change feed and then write custom transformations. You can use this option to move data from one container to another, prepare change feed driven material views for fit purpose or automate container backup or recovery based on change feed, and enable many more such use cases using visual drag and drop capability of Azure Data Factory.

Make sure you keep the pipeline and activity name unchanged, so that the checkpoint can be recorded by ADF for you to get changed data from the last run automatically. If you change your pipeline name or activity name, the checkpoint will be reset, which leads you to start from beginning or get changes from now in the next run.

When you debug the pipeline, this feature works the same. Be aware that the checkpoint will be reset when you refresh your browser during the debug run. After you are satisfied with the pipeline result from debug run, you can go ahead to publish and trigger the pipeline. At the moment when you first time trigger your published pipeline, it automatically restarts from the beginning or gets changes from now on.

In the monitoring section, you always have the chance to rerun a pipeline. When you are doing so, the changed data is always captured from the previous checkpoint of your selected pipeline run.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see supported data stores.

Copy data to or from Azure Cosmos DB's API for MongoDB using Azure Data Factory or Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from and to Azure Cosmos DB's API for MongoDB. The article builds on Copy Activity, which presents a general overview of Copy Activity.

> **NOTE**
> This connector only supports copy data to/from Azure Cosmos DB's API for MongoDB. For SQL API, refer to Cosmos DB SQL API connector. Other API types are not supported now.

Supported capabilities

This Azure Cosmos DB's API for MongoDB connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from Azure Cosmos DB's API for MongoDB to any supported sink data store, or copy data from any supported source data store to Azure Cosmos DB's API for MongoDB. For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

You can use the Azure Cosmos DB's API for MongoDB connector to:

- Copy data from and to the Azure Cosmos DB's API for MongoDB.
- Write to Azure Cosmos DB as **insert** or **upsert**.
- Import and export JSON documents as-is, or copy data from or to a tabular dataset. Examples include a SQL database and a CSV file. To copy documents as-is to or from JSON files or to or from another Azure Cosmos DB collection, see Import or export JSON documents.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

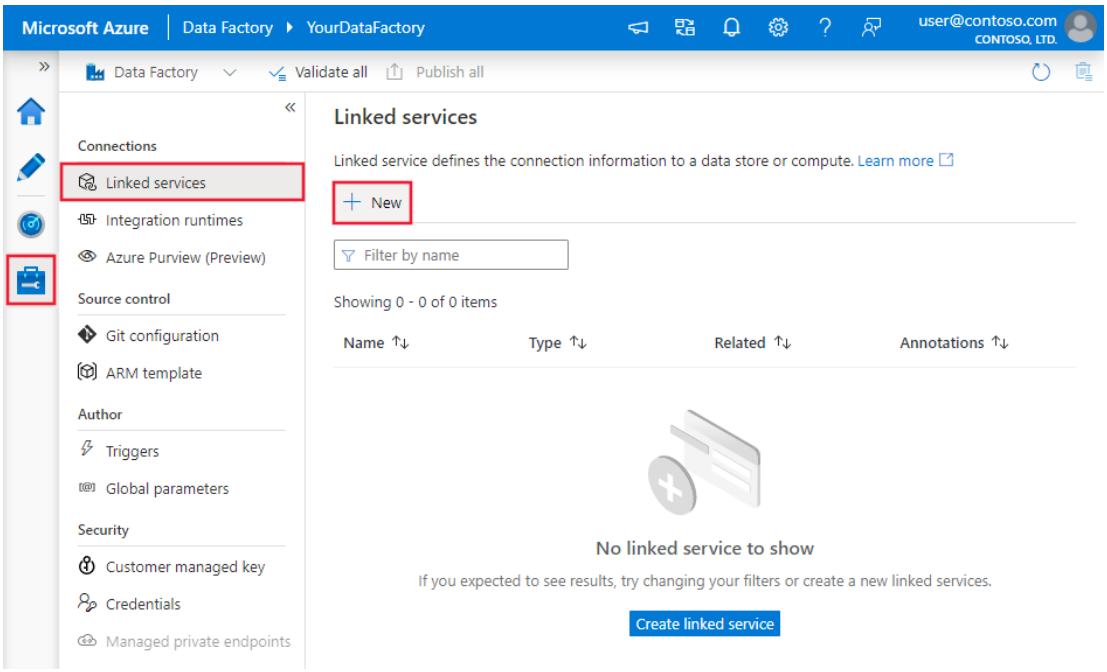
Create a linked service to Azure Cosmos DB's API for MongoDB using

UI

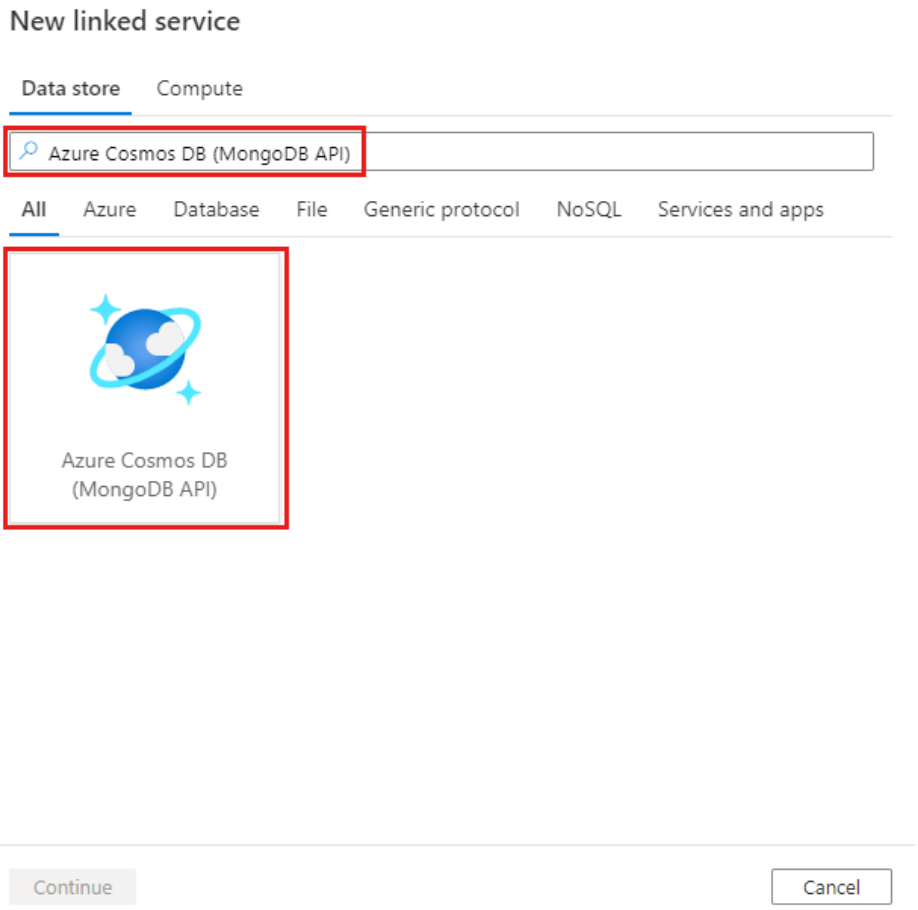
Use the following steps to create a linked service to Azure Cosmos DB's API for MongoDB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

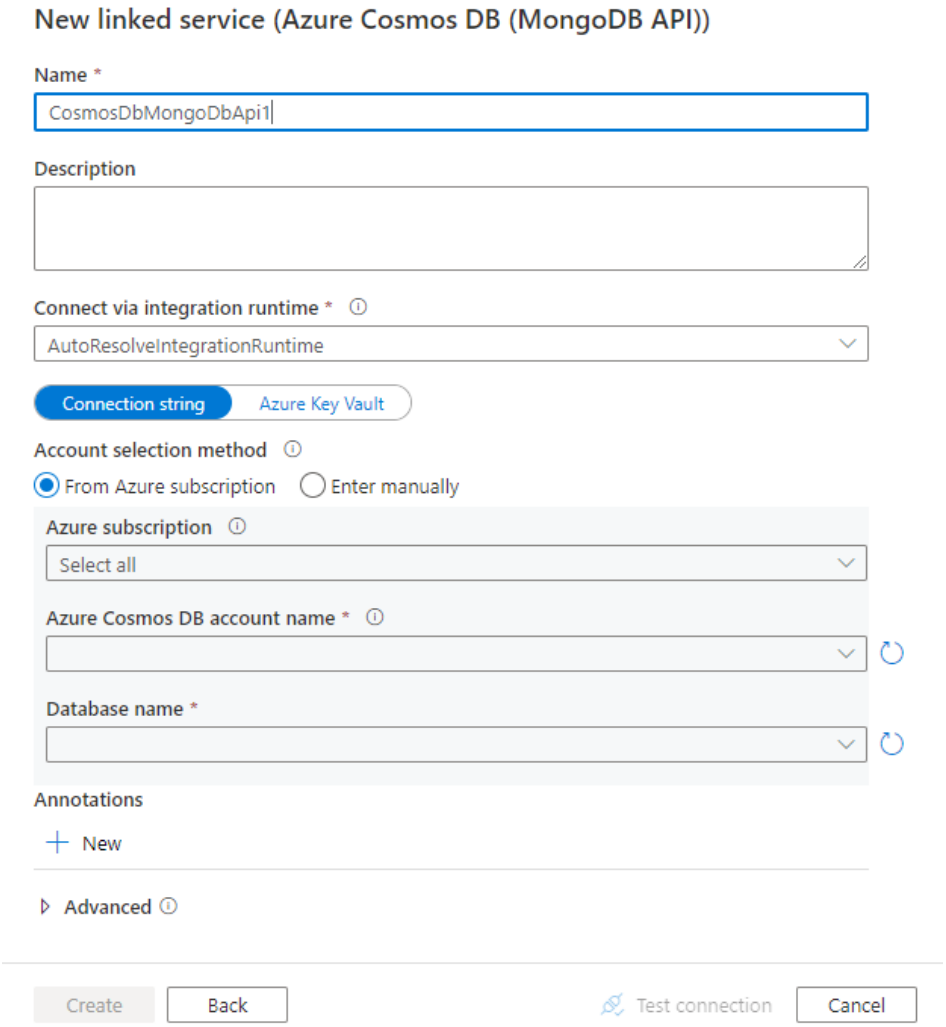
   - Azure Data Factory
   - Azure Synapse



2. Search for Azure Cosmos DB (MongoDB API) and select the Azure Cosmos DB's API for MongoDB connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define Data Factory entities that are specific to Azure Cosmos DB's API for MongoDB.

Linked service properties

The following properties are supported for the Azure Cosmos DB's API for MongoDB linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **CosmosDbMongoDbApi**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify the connection string for your Azure Cosmos DB's API for MongoDB. You can find it in the Azure portal -> your Cosmos DB blade -> primary or secondary connection string. For 3.2 server version, the string pattern is `mongodb://<cosmosdb-name>:<password>@<cosmosdb-name>.documents.azure.com:10255/?ssl=true&replicaSet=globaldb`. For 3.6+ server versions, the string pattern is `mongodb://<cosmosdb-name>:<password>@<cosmosdb-name>.mongo.cosmos.azure.com:10255/?ssl=true&replicaSet=globaldb&retrywrites=false&maxIdleTimeMS=120000&appName=@<cosmos name>@`. You can also put a password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to Store credentials in Azure Key Vault with more details.	Yes
database	Name of the database that you want to access.	Yes
isServerVersionAbove32	Specify whether the server version is above 3.2. Allowed values are **true** and **false**(default). This will determine the driver to use in the service.	Yes
connectVia	The Integration Runtime to use to connect to the data store. You can use the Azure Integration Runtime or a self-hosted integration runtime (if your data store is located in a private network). If this property isn't specified, the default Azure Integration Runtime is used.	No

Example

```
{
    "name": "CosmosDbMongoDBAPILinkedService",
    "properties": {
        "type": "CosmosDbMongoDbApi",
        "typeProperties": {
            "connectionString": "mongodb://<cosmosdb-name>:<password>@<cosmosdb-
name>.documents.azure.com:10255/?ssl=true&replicaSet=globaldb",
            "database": "myDatabase",
            "isServerVersionAbove32": "false"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services. The following properties are supported for Azure Cosmos DB's API for MongoDB dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **CosmosDbMongoDbApiCollection**.	Yes
collectionName	The name of the Azure Cosmos DB collection.	Yes

Example

```
{
    "name": "CosmosDbMongoDBAPIDataset",
    "properties": {
        "type": "CosmosDbMongoDbApiCollection",
        "typeProperties": {
            "collectionName": "<collection name>"
        },
        "schema": [],
        "linkedServiceName":{
            "referenceName": "<Azure Cosmos DB's API for MongoDB linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties that the Azure Cosmos DB's API for MongoDB source and sink support.

For a full list of sections and properties that are available for defining activities, see Pipelines.

Azure Cosmos DB's API for MongoDB as source

The following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **CosmosDbMongoDbApiSource**.	Yes
filter	Specifies selection filter using query operators. To return all documents in a collection, omit this parameter or pass an empty document ({}).	No
cursorMethods.project	Specifies the fields to return in the documents for projection. To return all fields in the matching documents, omit this parameter.	No
cursorMethods.sort	Specifies the order in which the query returns matching documents. Refer to cursor.sort().	No

PROPERTY	DESCRIPTION	REQUIRED
cursorMethods.limit	Specifies the maximum number of documents the server returns. Refer to cursor.limit().	No
cursorMethods.skip	Specifies the number of documents to skip and from where MongoDB begins to return results. Refer to cursor.skip().	No
batchSize	Specifies the number of documents to return in each batch of the response from MongoDB instance. In most cases, modifying the batch size will not affect the user or the application. Cosmos DB limits each batch cannot exceed 40MB in size, which is the sum of the batchSize number of documents' size, so decrease this value if your document size being large.	No (the default is **100**)

TIP

ADF support consuming BSON document in **Strict mode**. Make sure your filter query is in Strict mode instead of Shell mode. More description can be found at MongoDB manual.

Example

```
"activities":[
    {
        "name": "CopyFromCosmosDBMongoDBAPI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure Cosmos DB's API for MongoDB input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "CosmosDbMongoDbApiSource",
                "filter": "{datetimeData: {$gte: ISODate(\"2018-12-11T00:00:00.000Z\"),$lt: ISODate(\"2018-
12-12T00:00:00.000Z\")}, _id: ObjectId(\"5acd7c3d0000000000000000\") }",
                "cursorMethods": {
                    "project": "{ _id : 1, name : 1, age: 1, datetimeData: 1 }",
                    "sort": "{ age : 1 }",
                    "skip": 3,
                    "limit": 3
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Cosmos DB's API for MongoDB as sink

The following properties are supported in the Copy Activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity sink must be set to **CosmosDbMongoDbApiSink**.	Yes
writeBehavior	Describes how to write data to Azure Cosmos DB. Allowed values: **insert** and **upsert**. The behavior of **upsert** is to replace the document if a document with the same `_id` already exists; otherwise, insert the document. **Note**: The service automatically generates an `_id` for a document if an `_id` isn't specified either in the original document or by column mapping. This means that you must ensure that, for **upsert** to work as expected, your document has an ID.	No (the default is **insert**)
writeBatchSize	The **writeBatchSize** property controls the size of documents to write in each batch. You can try increasing the value for **writeBatchSize** to improve performance and decreasing the value if your document size being large.	No (the default is **10,000**)
writeBatchTimeout	The wait time for the batch insert operation to finish before it times out. The allowed value is timespan.	No (the default is **00:30:00** - 30 minutes)

TIP

To import JSON documents as-is, refer to Import or export JSON documents section; to copy from tabular-shaped data, refer to Schema mapping.

Example

```
"activities":[
    {
        "name": "CopyToCosmosDBMongoDBAPI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Document DB output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "CosmosDbMongoDbApiSink",
                "writeBehavior": "upsert"
            }
        }
    }
]
```

Import and export JSON documents

You can use this Azure Cosmos DB connector to easily:

- Copy documents between two Azure Cosmos DB collections as-is.
- Import JSON documents from various sources to Azure Cosmos DB, including from MongoDB, Azure Blob storage, Azure Data Lake Store, and other file-based stores that the service supports.
- Export JSON documents from an Azure Cosmos DB collection to various file-based stores.

To achieve schema-agnostic copy:

- When you use the Copy Data tool, select the **Export as-is to JSON files or Cosmos DB collection** option.
- When you use activity authoring, choose JSON format with the corresponding file store for source or sink.

Schema mapping

To copy data from Azure Cosmos DB's API for MongoDB to tabular sink or reversed, refer to schema mapping.

Specifically for writing into Cosmos DB, to make sure you populate Cosmos DB with the right object ID from your source data, for example, you have an "id" column in SQL database table and want to use the value of that as the document ID in MongoDB for insert/upsert, you need to set the proper schema mapping according to MongoDB strict mode definition (`_id.$oid`) as the following:

After copy activity execution, below BSON ObjectId is generated in sink:

```
{
    "_id": ObjectId("592e07800000000000000000")
}
```

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see supported data stores.

Copy data to or from Azure Data Explorer using Azure Data Factory or Synapse Analytics

8/19/2022 • 12 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes how to use the copy activity in Azure Data Factory and Synapse Analytics pipelines to copy data to or from Azure Data Explorer. It builds on the copy activity overview article, which offers a general overview of copy activity.

> **TIP**
> To learn more about Azure Data Explorer integration with the service generally read Integrate Azure Data Explorer.

Supported capabilities

This Azure Data Explorer connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from any supported source data store to Azure Data Explorer. You can also copy data from Azure Data Explorer to any supported sink data store. For a list of data stores that the copy activity supports as sources or sinks, see the Supported data stores table.

> **NOTE**
> Copying data to or from Azure Data Explorer through an on-premises data store by using self-hosted integration runtime is supported in version 3.14 and later.

With the Azure Data Explorer connector, you can do the following:

- Copy data by using Azure Active Directory (Azure AD) application token authentication with a **service principal**.
- As a source, retrieve data by using a KQL (Kusto) query.
- As a sink, append data to a destination table.

Getting started

TIP

For a walkthrough of Azure Data Explorer connector, see Copy data to/from Azure Data Explorer and Bulk copy from a database to Azure Data Explorer.

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

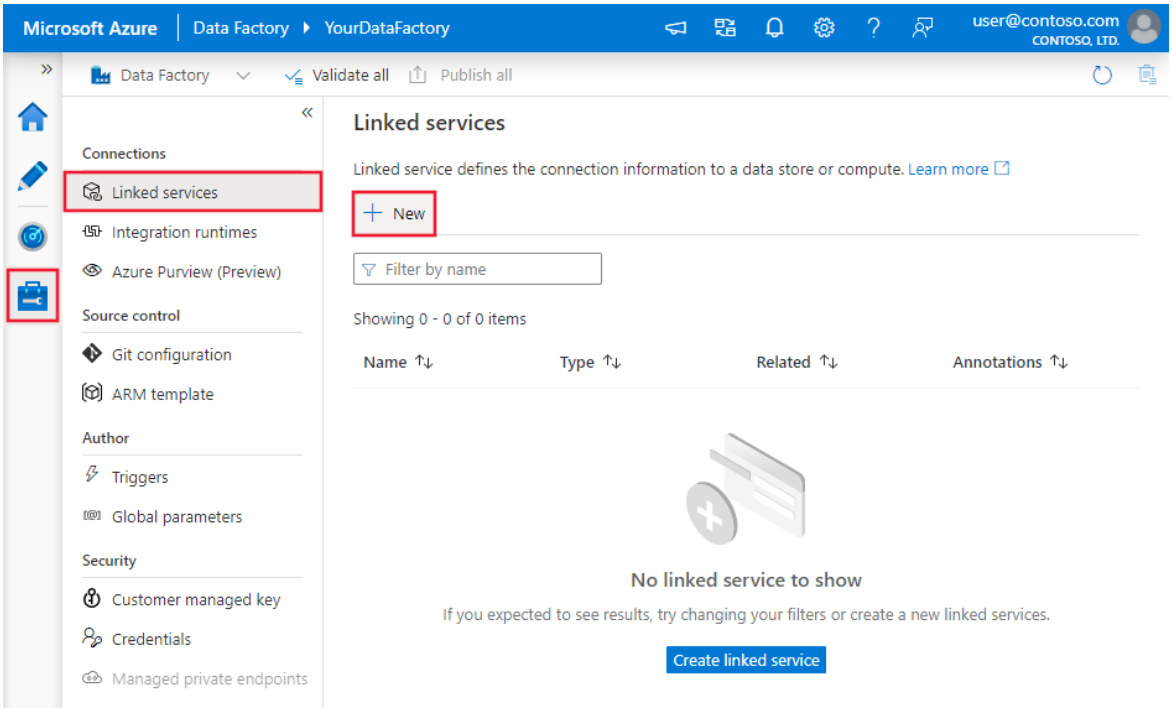
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Data Explorer using UI

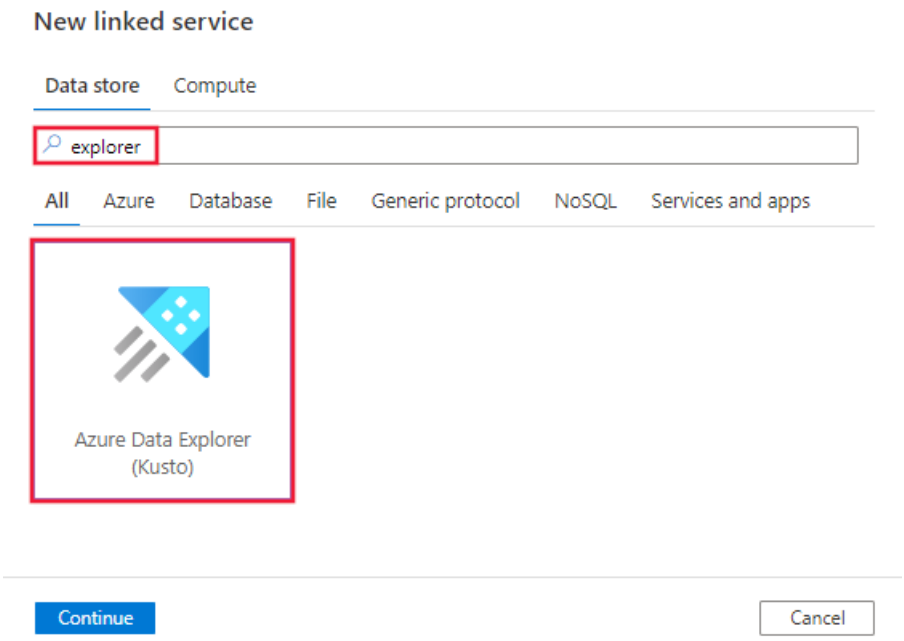
Use the following steps to create a linked service to Azure Data Explorer in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

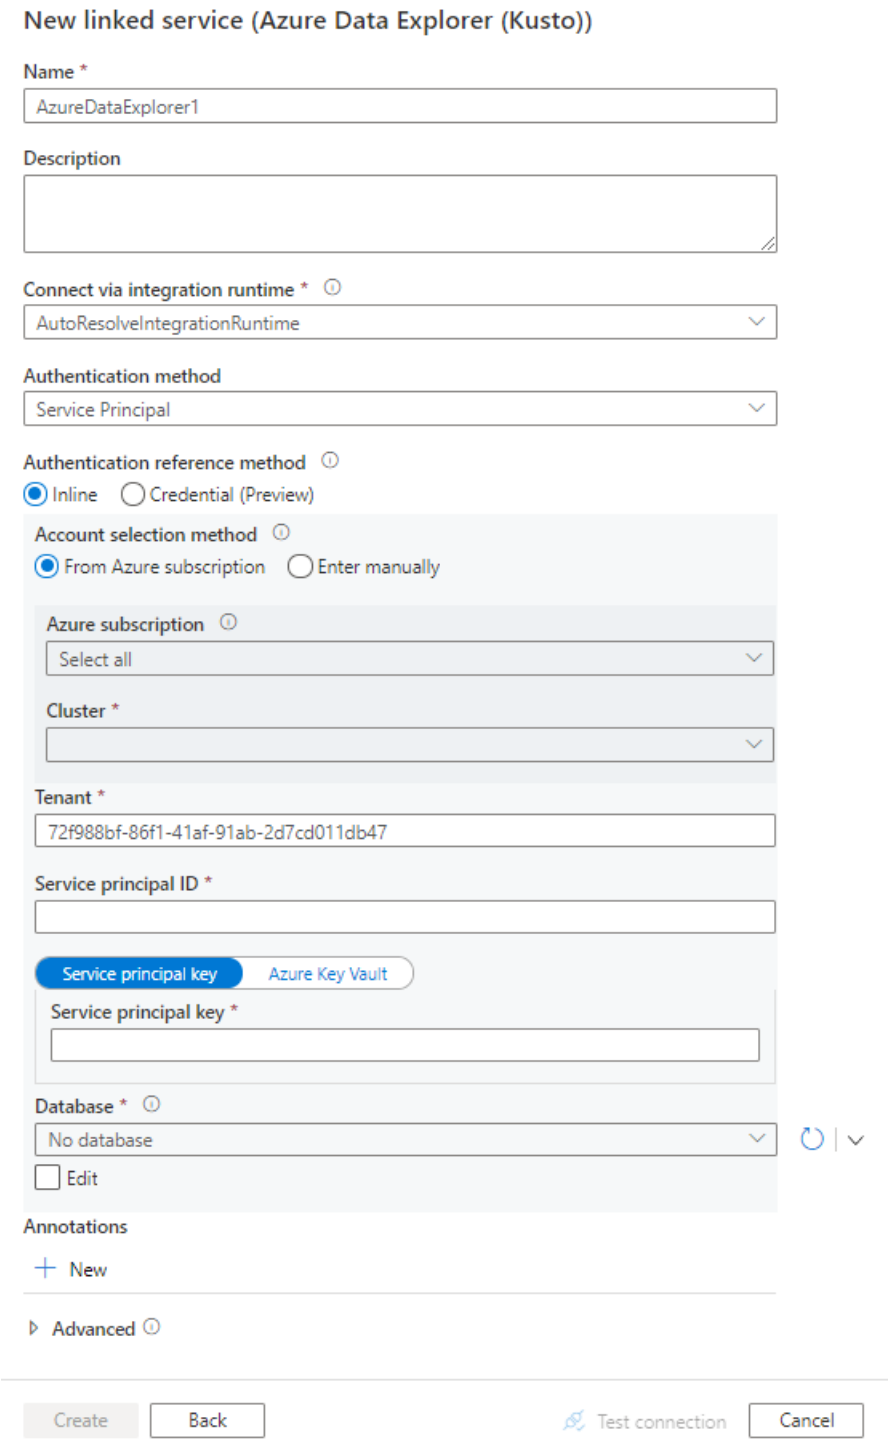
   - Azure Data Factory
   - Azure Synapse



2. Search for Explorer and select the Azure Data Explorer (Kusto) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Azure Data Explorer connector.

Linked service properties

The Azure Data Explorer connector supports the following authentication types. See the corresponding sections for details:

- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

Service principal authentication

To use service principal authentication, follow these steps to get a service principal and to grant permissions:

1. Register an application entity in Azure Active Directory by following the steps in Register your application with an Azure AD tenant. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant the service principal the correct permissions in Azure Data Explorer. See Manage Azure Data Explorer database permissions for detailed information about roles and permissions and about managing permissions. In general, you must:
   - **As source**, grant at least the **Database viewer** role to your database
   - **As sink**, grant at least the **Database ingestor** role to your database

> **NOTE**
> When you use the UI to author, by default your login user account is used to list Azure Data Explorer clusters, databases, and tables. You can choose to list the objects using the service principal by clicking the dropdown next to the refresh button, or manually enter the name if you don't have permission for these operations.

The following properties are supported for the Azure Data Explorer linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureDataExplorer**.	Yes
endpoint	Endpoint URL of the Azure Data Explorer cluster, with the format as `https://<clusterName>.<regionName>.kusto.windows.net`.	Yes
database	Name of database.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. This is known as "Authority ID" in Kusto connection string. Retrieve it by hovering the mouse pointer in the upper-right corner of the Azure portal.	Yes
servicePrincipalId	Specify the application's client ID. This is known as "AAD application client ID" in Kusto connection string.	Yes
servicePrincipalKey	Specify the application's key. This is known as "AAD application key" in Kusto connection string. Mark this field as a **SecureString** to store it securely, or reference secure data stored in Azure Key Vault.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example: using service principal key authentication

```
{
    "name": "AzureDataExplorerLinkedService",
    "properties": {
        "type": "AzureDataExplorer",
        "typeProperties": {
            "endpoint": "https://<clusterName>.<regionName>.kusto.windows.net ",
            "database": "<database name>",
            "tenant": "<tenant name/id e.g. microsoft.onmicrosoft.com>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            }
        }
    }
}
```

System-assigned managed identity authentication

To learn more about managed identities for Azure resources, see Managed identities for Azure resources.

To use system-assigned managed identity authentication, follow these steps to grant permissions:

1. Retrieve the managed identity information by copying the value of the **managed identity object ID** generated along with your factory or Synapse workspace.
2. Grant the managed identity the correct permissions in Azure Data Explorer. See Manage Azure Data Explorer database permissions for detailed information about roles and permissions and about managing permissions. In general, you must:
   - **As source**, grant at least the **Database viewer** role to your database
   - **As sink**, grant at least the **Database ingestor** role to your database

> **NOTE**
> When you use the UI to author, your login user account is used to list Azure Data Explorer clusters, databases, and tables. Manually enter the name if you don't have permission for these operations.

The following properties are supported for the Azure Data Explorer linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureDataExplorer**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
endpoint	Endpoint URL of the Azure Data Explorer cluster, with the format as `https://<clusterName>.<regionName>.kusto.windows.net`.	Yes
database	Name of database.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example: using system-assigned managed identity authentication

```
{
    "name": "AzureDataExplorerLinkedService",
    "properties": {
        "type": "AzureDataExplorer",
        "typeProperties": {
            "endpoint": "https://<clusterName>.<regionName>.kusto.windows.net ",
            "database": "<database name>",
        }
    }
}
```

User-assigned managed identity authentication

To learn more about managed identities for Azure resources, see Managed identities for Azure resources

To use user-assigned managed identity authentication, follow these steps:

1. Create one or multiple user-assigned managed identities and grant permission in Azure Data Explorer. See Manage Azure Data Explorer database permissions for detailed information about roles and permissions and about managing permissions. In general, you must:
   - **As source**, grant at least the **Database viewer** role to your database
   - **As sink**, grant at least the **Database ingestor** role to your database
2. Assign one or multiple user-assigned managed identities to your data factory or Synapse workspace, and create credentials for each user-assigned managed identity.

The following properties are supported for the Azure Data Explorer linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureDataExplorer**.	Yes
endpoint	Endpoint URL of the Azure Data Explorer cluster, with the format as `https://<clusterName>.<regionName>.kusto.windows.net`.	Yes

PROPERTY	DESCRIPTION	REQUIRED
database	Name of database.	Yes
credentials	Specify the user-assigned managed identity as the credential object.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example: using user-assigned managed identity authentication

```
{
    "name": "AzureDataExplorerLinkedService",
    "properties": {
        "type": "AzureDataExplorer",
        "typeProperties": {
            "endpoint": "https://<clusterName>.<regionName>.kusto.windows.net ",
            "database": "<database name>",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see Datasets. This section lists properties that the Azure Data Explorer dataset supports.

To copy data to Azure Data Explorer, set the type property of the dataset to **AzureDataExplorerTable**.

The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureDataExplorerTable**.	Yes
table	The name of the table that the linked service refers to.	Yes for sink; No for source

Dataset properties example:

```
{
   "name": "AzureDataExplorerDataset",
    "properties": {
        "type": "AzureDataExplorerTable",
        "typeProperties": {
            "table": "<table name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Azure Data Explorer linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see Pipelines and activities. This section provides a list of properties that Azure Data Explorer sources and sinks support.

Azure Data Explorer as source

To copy data from Azure Data Explorer, set the **type** property in the Copy activity source to **AzureDataExplorerSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to: **AzureDataExplorerSource**	Yes
query	A read-only request given in a KQL format. Use the custom KQL query as a reference.	Yes
queryTimeout	The wait time before the query request times out. Default value is 10 min (00:10:00); allowed max value is 1 hour (01:00:00).	No
noTruncation	Indicates whether to truncate the returned result set. By default, result is truncated after 500,000 records or 64 megabytes (MB). Truncation is strongly recommended to ensure the correct behavior of the activity.	No

> **NOTE**
>
> By default, Azure Data Explorer source has a size limit of 500,000 records or 64 MB. To retrieve all the records without truncation, you can specify `set notruncation;` at the beginning of your query. For more information, see Query limits.

Example:

```
"activities":[
    {
        "name": "CopyFromAzureDataExplorer",
        "type": "Copy",
        "typeProperties": {

                "query": "TestTable1 | take 10",
                "queryTimeout": "00:10:00"
            },
            "sink": {
                "type": "<sink type>"
            }
        },
        "inputs": [
            {
                "referenceName": "<Azure Data Explorer input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ]
    }
]
```

Azure Data Explorer as sink

To copy data to Azure Data Explorer, set the type property in the copy activity sink to **AzureDataExplorerSink**. The following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity sink must be set to: **AzureDataExplorerSink**.	Yes
ingestionMappingName	Name of a pre-created mapping on a Kusto table. To map the columns from source to Azure Data Explorer (which applies to all supported source stores and formats, including CSV/JSON/Avro formats), you can use the copy activity column mapping (implicitly by name or explicitly as configured) and/or Azure Data Explorer mappings.	No
additionalProperties	A property bag which can be used for specifying any of the ingestion properties which aren't being set already by the Azure Data Explorer Sink. Specifically, it can be useful for specifying ingestion tags. Learn more from Azure Data Explore data ingestion doc.	No

Example:

```
"activities":[
    {
        "name": "CopyToAzureDataExplorer",
        "type": "Copy",
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureDataExplorerSink",
                "ingestionMappingName": "<optional Azure Data Explorer mapping name>",
                "additionalProperties": {<additional settings for data ingestion>}
            }
        },
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure Data Explorer output dataset name>",
                "type": "DatasetReference"
            }
        ]
    }
]
```

Mapping data flow properties

When transforming data in mapping data flow, you can read from and write to tables in Azure Data Explorer. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use an Azure Data Explorer dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Azure Data Explorer source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow will fetch all the data from the table specified in the Azure Data Explorer dataset or in the source options when using inline dataset.	No	String	*(for inline dataset only)* tableName
Query	A read-only request given in a KQL format. Use the custom KQL query as a reference.	No	String	query

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Timeout	The wait time before the query request times out. Default is '172000' (2 days)	No	Integer	timeout

Azure Data Explorer source script examples

When you use Azure Data Explorer dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 query: 'table | take 10',
 format: 'query') ~> AzureDataExplorerSource
```

If you use inline dataset, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    format: 'query',
    query: 'table | take 10',
    store: 'azuredataexplorer') ~> AzureDataExplorerSource
```

Sink transformation

The below table lists the properties supported by Azure Data Explorer sink. You can edit these properties in the **Settings** tab. When using inline dataset, you will see additional settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Pre and Post SQL scripts	Specify multiple Kusto control commands scripts that will execute before (pre-processing) and after (post-processing) data is written to your sink database.	No	String	preSQLs; postSQLs
Timeout	The wait time before the query request times out. Default is '172000' (2 days)	No	Integer	timeout

Azure Data Explorer sink script examples

When you use Azure Data Explorer dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
 validateSchema: false,
 format: 'table',
 preSQLs:['pre SQL scripts'],
 postSQLs:['post SQL script'],
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true) ~> AzureDataExplorerSink
```

If you use inline dataset, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    format: 'table',
    store: 'azuredataexplorer',
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> AzureDataExplorerSink
```

Lookup activity properties

For more information about the properties, see Lookup activity.

Next steps

- For a list of data stores that the copy activity supports as sources and sinks, see supported data stores.
- Learn more about how to copy data from Azure Data Factory and Synapse Analytics to Azure Data Explorer.

Copy data to or from Azure Data Lake Storage Gen1 using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 28 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data to and from Azure Data Lake Storage Gen1. To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This Azure Data Lake Storage Gen1 connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, with this connector you can:

- Copy files by using one of the following methods of authentication: service principal or managed identities for Azure resources.
- Copy files as is or parse or generate files with the supported file formats and compression codecs.
- Preserve ACLs when copying into Azure Data Lake Storage Gen2.

> **IMPORTANT**
> If you copy data by using the self-hosted integration runtime, configure the corporate firewall to allow outbound traffic to `<ADLS account name>.azuredatalakestore.net` and `login.microsoftonline.com/<tenant>/oauth2/token` on port 443. The latter is the Azure Security Token Service that the integration runtime needs to communicate with to get the access token.

Get started

> **TIP**
> For a walk-through of how to use the Azure Data Lake Store connector, see Load data into Azure Data Lake Store.

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

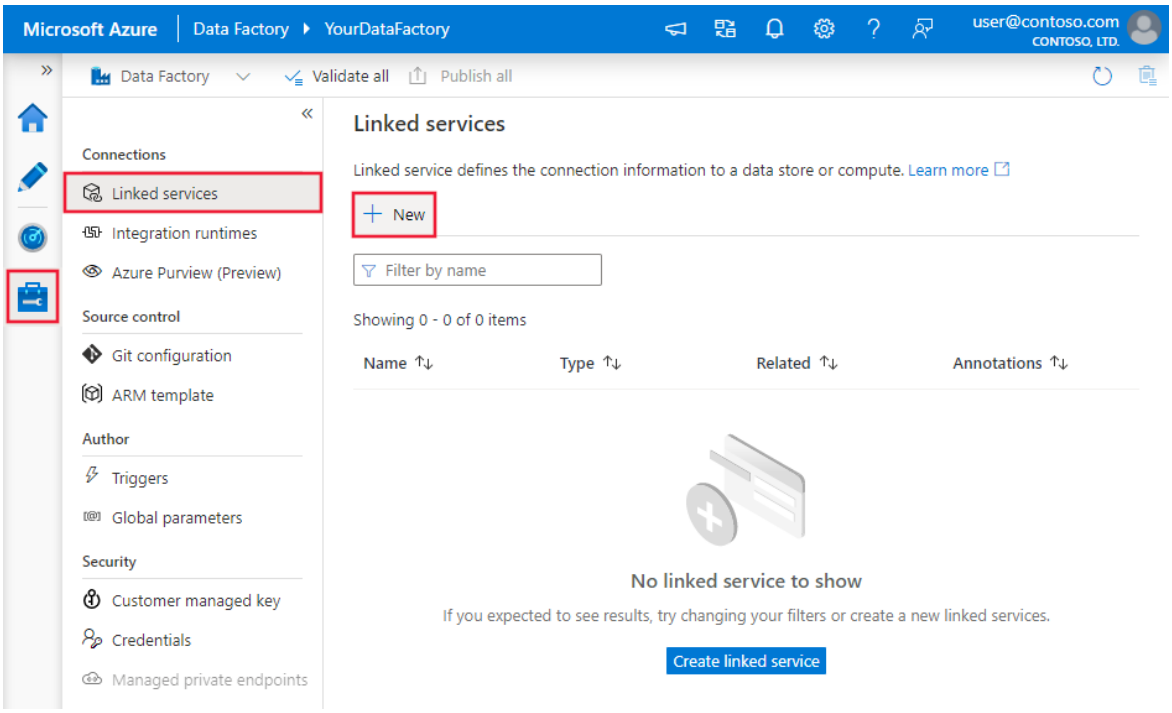
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Data Lake Storage Gen1 using UI

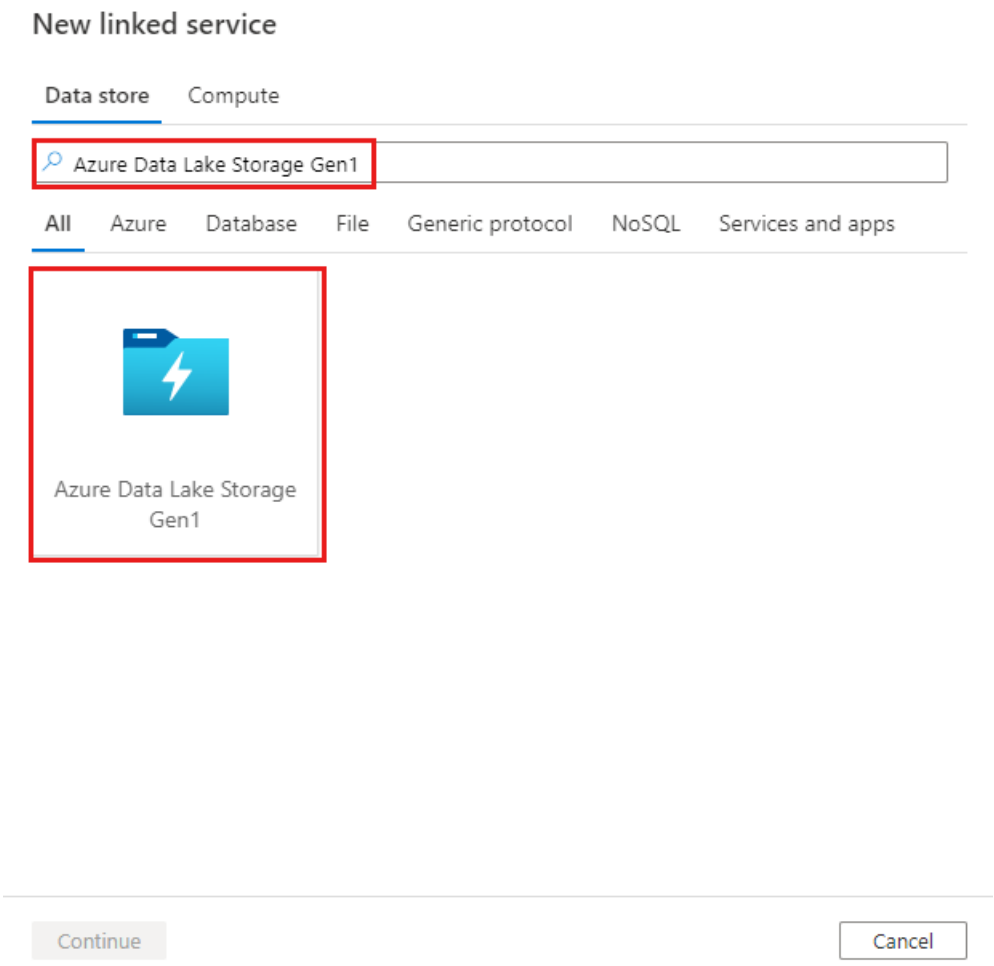
Use the following steps to create a linked service to Azure Data Lake Storage Gen1 in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

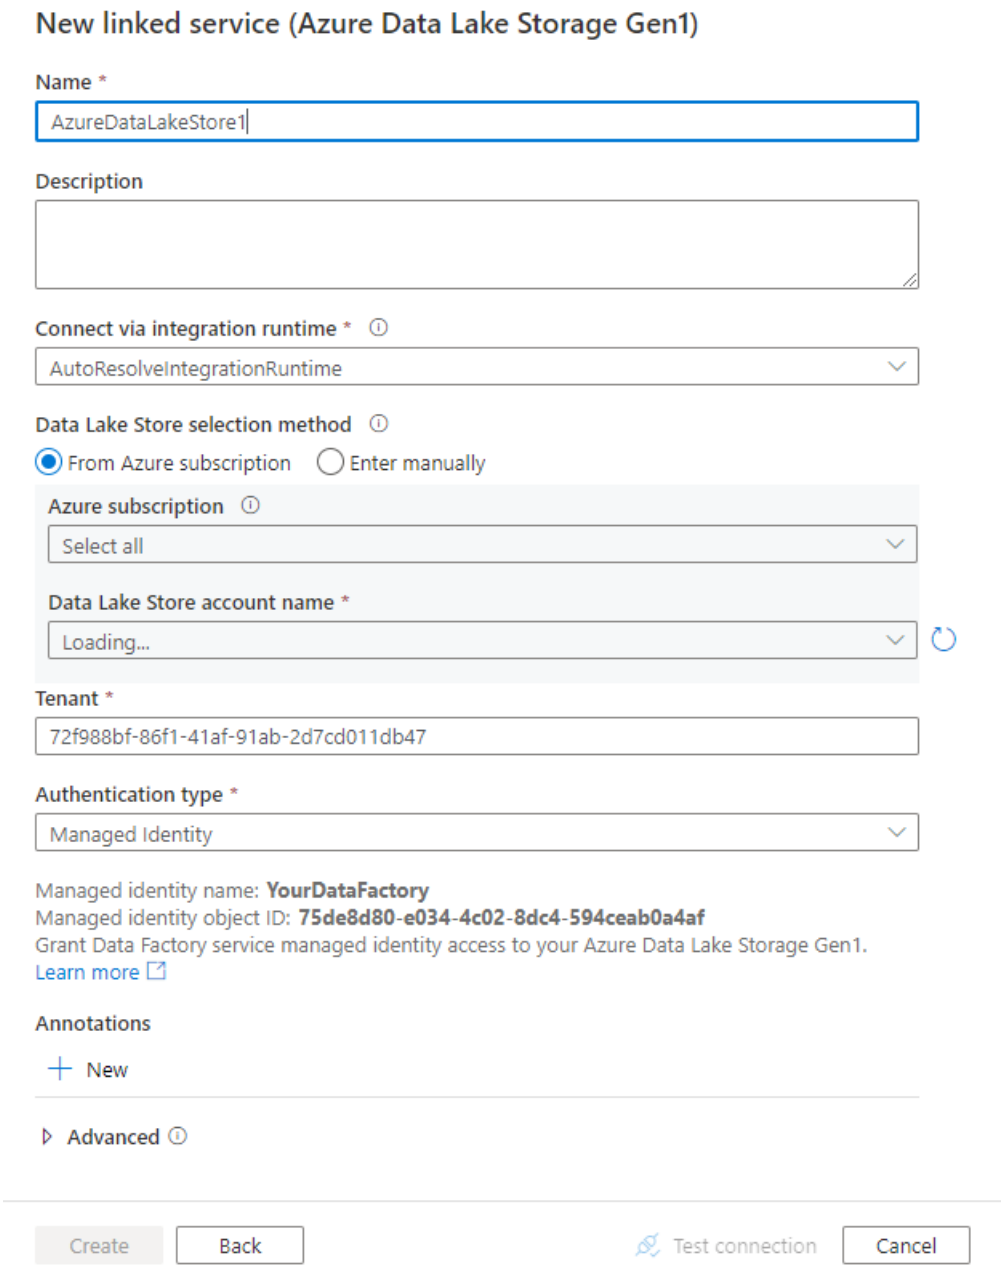
   - Azure Data Factory
   - Azure Synapse



2. Search for Azure Data Lake Storage Gen1 and select the Azure Data Lake Storage Gen1 connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define entities specific to Azure Data Lake Store Gen1.

Linked service properties

The following properties are supported for the Azure Data Lake Store linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property must be set to **AzureDataLakeStore**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
dataLakeStoreUri	Information about the Azure Data Lake Store account. This information takes one of the following formats: `https://[accountname].azuredatalakestore.net/webhdfs/v1` or `adl://[accountname].azuredatalakestore.net/`.	Yes
subscriptionId	The Azure subscription ID to which the Data Lake Store account belongs.	Required for sink
resourceGroupName	The Azure resource group name to which the Data Lake Store account belongs.	Required for sink
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is located in a private network. If this property isn't specified, the default Azure integration runtime is used.	No

Use service principal authentication

To use service principal authentication, follow these steps.

1. Register an application entity in Azure Active Directory and grant it access to Data Lake Store. For detailed steps, see Service-to-service authentication. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant the service principal proper permission. See examples on how permission works in Data Lake Storage Gen1 from Access control in Azure Data Lake Storage Gen1.
   - **As source**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Read** permission for the files to copy. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**. There's no requirement on account-level access control (IAM).
   - **As sink**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Write** permission for the sink folder. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**.

The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalKey	Specify the application's key. Mark this field as a `SecureString` to store it securely, or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information, such as domain name or tenant ID, under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure Active Directory application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the service's cloud environment is used.	No

Example:

```
{
    "name": "AzureDataLakeStoreLinkedService",
    "properties": {
        "type": "AzureDataLakeStore",
        "typeProperties": {
            "dataLakeStoreUri": "https://<accountname>.azuredatalakestore.net/webhdfs/v1",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "subscriptionId": "<subscription of ADLS>",
            "resourceGroupName": "<resource group of ADLS>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use system-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a system-assigned managed identity, which represents the service for authentication. You can directly use this system-assigned managed identity for Data Lake Store authentication, similar to using your own service principal. It allows this designated resource to access and copy data to or from Data Lake Store.

To use system-assigned managed identity authentication, follow these steps.

1. Retrieve the system-assigned managed identity information by copying the value of the "Service Identity Application ID" generated along with your factory or Synapse workspace.
2. Grant the system-assigned managed identity access to Data Lake Store. See examples on how permission

works in Data Lake Storage Gen1 from Access control in Azure Data Lake Storage Gen1.

- **As source**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Read** permission for the files to copy. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**. There's no requirement on account-level access control (IAM).
- **As sink**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Write** permission for the sink folder. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**.

You don't need to specify any properties other than the general Data Lake Store information in the linked service.

Example:

```
{
    "name": "AzureDataLakeStoreLinkedService",
    "properties": {
        "type": "AzureDataLakeStore",
        "typeProperties": {
            "dataLakeStoreUri": "https://<accountname>.azuredatalakestore.net/webhdfs/v1",
            "subscriptionId": "<subscription of ADLS>",
            "resourceGroupName": "<resource group of ADLS>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use user-assigned managed identity authentication

A data factory can be assigned with one or multiple user-assigned managed identities. You can use this user-assigned managed identity for Blob storage authentication, which allows to access and copy data from or to Data Lake Store. To learn more about managed identities for Azure resources, see Managed identities for Azure resources

To use user-assigned managed identity authentication, follow these steps:

1. Create one or multiple user-assigned managed identities and grant access to Azure Data Lake. See examples on how permission works in Data Lake Storage Gen1 from Access control in Azure Data Lake Storage Gen1.

   - **As source**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Read** permission for the files to copy. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**. There's no requirement on account-level access control (IAM).
   - **As sink**: In **Data explorer** > **Access**, grant at least **Execute** permission for ALL upstream folders including the root, along with **Write** permission for the sink folder. You can choose to add to **This folder and all children** for recursive, and add as **an access permission and a default permission entry**.
2. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

The following property is supported:

PROPERTY	DESCRIPTION	REQUIRED
credentials	Specify the user-assigned managed identity as the credential object.	Yes

Example:

```
{
    "name": "AzureDataLakeStoreLinkedService",
    "properties": {
        "type": "AzureDataLakeStore",
        "typeProperties": {
            "dataLakeStoreUri": "https://<accountname>.azuredatalakestore.net/webhdfs/v1",
            "subscriptionId": "<subscription of ADLS>",
            "resourceGroupName": "<resource group of ADLS>",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Data Lake Store Gen1 under `location` settings in the format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in the dataset must be set to **AzureDataLakeStoreLocation**.	Yes
folderPath	The path to a folder. If you want to use a wildcard to filter folders, skip this setting and specify it in activity source settings.	No

PROPERTY	DESCRIPTION	REQUIRED
fileName	The file name under the given folderPath. If you want to use a wildcard to filter files, skip this setting and specify it in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<ADLS Gen1 linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureDataLakeStoreLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see Pipelines. This section provides a list of properties supported by Azure Data Lake Store source and sink.

Azure Data Lake Store as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Data Lake Store Gen1 under `storeSettings` settings in the format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureDataLakeStoreReadSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
Locate the files to copy:		
OPTION 1: static path	Copy from the given folder/file path specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: name range - listAfter	Retrieve the folders/files whose name is after this value alphabetically (exclusive). It utilizes the service-side filter for ADLS Gen1, which provides better performance than a wildcard filter. The service applies this filter to the path defined in dataset, and only one entity level is supported. See more examples in Name range filter examples.	No
OPTION 2: name range - listBefore	Retrieve the folders/files whose name is before this value alphabetically (inclusive). It utilizes the service-side filter for ADLS Gen1, which provides better performance than a wildcard filter. The service applies this filter to the path defined in dataset, and only one entity level is supported. See more examples in Name range filter examples.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	No
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given folderPath/wildcardFolderPath to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	Yes

PROPERTY	DESCRIPTION	REQUIRED
OPTION 4: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When using this option, do not specify file name in dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromADLSGen1",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AzureDataLakeStoreReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Data Lake Store as sink

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for Azure Data Lake Store Gen1 under `storeSettings` settings in the format-based copy sink:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureDataLakeStoreWriteSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
expiryDateTime	Specifies the expiry time of the written files. The time is applied to the UTC time in the format of "2020-03-01T08:00:00Z". By default it is NULL, which means the written files are never expired.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToADLSGen1",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Parquet output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "ParquetSink",
                "storeSettings":{
                    "type": "AzureDataLakeStoreWriteSettings",
                    "copyBehavior": "PreserveHierarchy"
                }
            }
        }
    }
]
```

Name range filter examples

This section describes the resulting behavior of name range filters.

SAMPLE SOURCE STRUCTURE	CONFIGURATION	RESULT

root
  a
  file.csv
  ax
  file2.csv
  ax.csv
  b
  file3.csv
  bx.csv
  c
  file4.csv
  cx.csv
	In dataset:
	- Folder path: `root`
	
	In copy activity source:
	- List after: `a`
	- List before: `b`
		Then the following files will be copied:
		
		root
		  ax
		  file2.csv
		  ax.csv
		  b
		  file3.csv

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(Empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	(Empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using file list path in copy activity source.

Assuming you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Folder path: `root/FolderA` **In copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line with the relative path to the path configured in the dataset.

Examples of behavior of the copy operation

This section describes the resulting behavior of the copy operation for different combinations of `recursive` and `copyBehavior` values.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET
true	preserveHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the same structure as the source: Folder1 File1 File2 Subfolder1 File3 File4 File5.
true	flattenHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 autogenerated name for File1 autogenerated name for File2 autogenerated name for File3 autogenerated name for File4 autogenerated name for File5
true	mergeFiles	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 File1 + File2 + File3 + File4 + File5 contents are merged into one file, with an autogenerated file name.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

false	preserveHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  File1
			  File2
			
			Subfolder1 with File3, File4, and File5 aren't picked up.

false	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			
			Subfolder1 with File3, File4, and File5 aren't picked up.

false	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  File1 + File2 contents are merged into one file with autogenerated file name. autogenerated name for File1
			
			Subfolder1 with File3, File4, and File5 aren't picked up.

Preserve ACLs to Data Lake Storage Gen2

> **TIP**
> To copy data from Azure Data Lake Storage Gen1 into Gen2 in general, see Copy data from Azure Data Lake Storage Gen1 to Gen2 for a walk-through and best practices.

If you want to replicate the access control lists (ACLs) along with data files when you upgrade from Data Lake Storage Gen1 to Data Lake Storage Gen2, see Preserve ACLs from Data Lake Storage Gen1.

Mapping data flow properties

When you're transforming data in mapping data flows, you can read and write files from Azure Data Lake Storage Gen1 in the following formats:

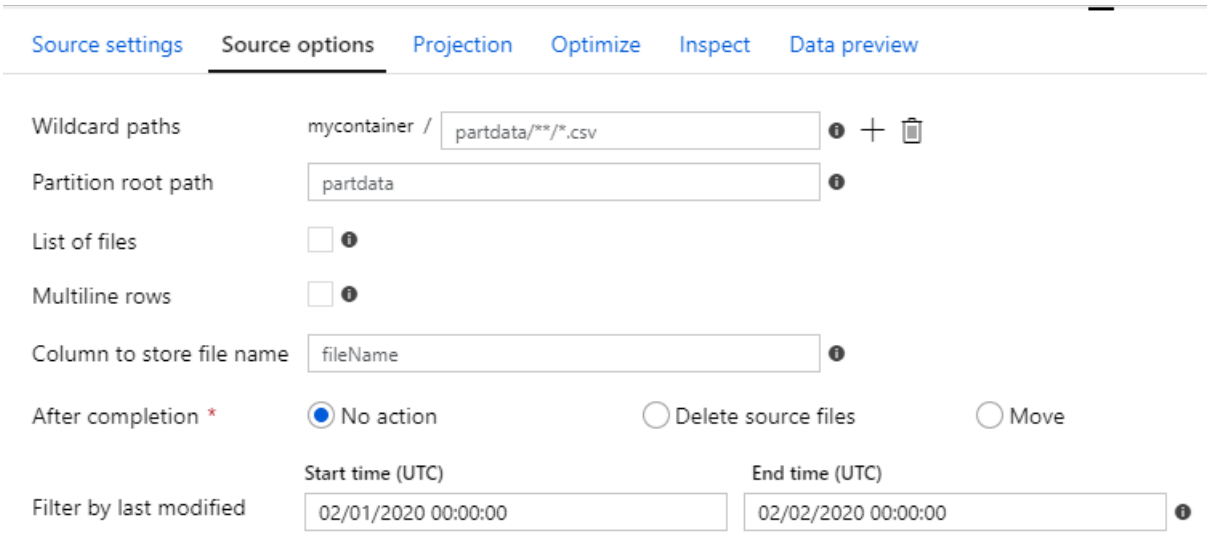
- Avro
- Delimited text

- Excel
- JSON
- ORC format
- Parquet

Format-specific settings are located in the documentation for that format. For more information, see Source transformation in mapping data flow and Sink transformation in mapping data flow.

Source transformation

In the source transformation, you can read from a container, folder, or individual file in Azure Data Lake Storage Gen1. The **Source options** tab lets you manage how the files get read.



Wildcard path: Using a wildcard pattern will instruct the service to loop through each matching folder and file in a single Source transformation. This is an effective way to process multiple files within a single flow. Add multiple wildcard matching patterns with the + sign that appears when hovering over your existing wildcard pattern.

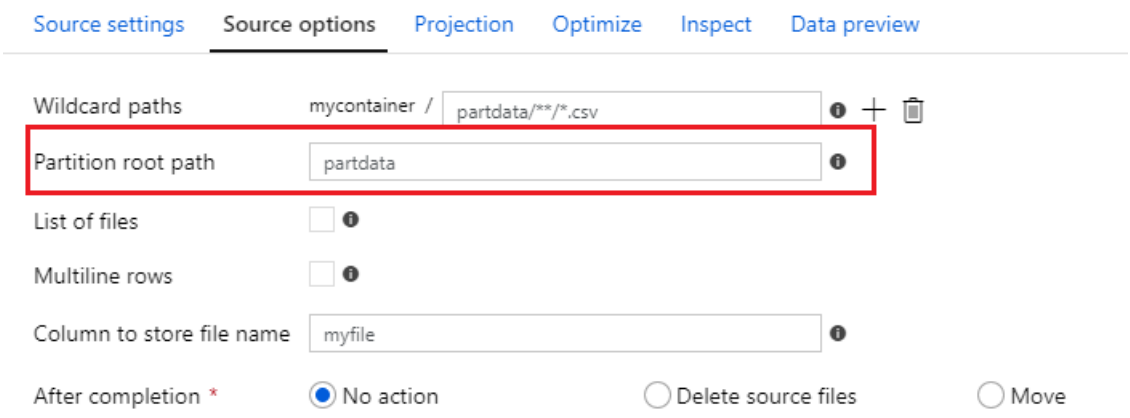
From your source container, choose a series of files that match a pattern. Only container can be specified in the dataset. Your wildcard path must therefore also include your folder path from the root folder.

Wildcard examples:

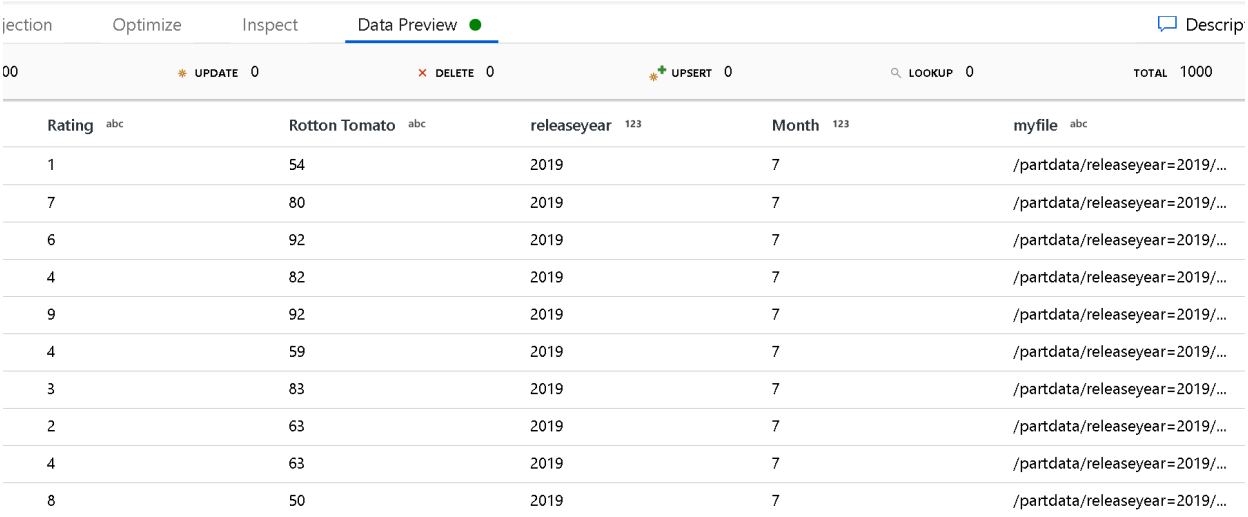
- `*` Represents any set of characters
- `**` Represents recursive directory nesting
- `?` Replaces one character
- `[]` Matches one of more characters in the brackets
- `/data/sales/**/*.csv` Gets all csv files under /data/sales
- `/data/sales/20??/**/` Gets all files in the 20th century
- `/data/sales/*/*/*.csv` Gets csv files two levels under /data/sales
- `/data/sales/2004/*/12/[XY]1?.csv` Gets all csv files in 2004 in December starting with X or Y prefixed by a two-digit number

Partition Root Path: If you have partitioned folders in your file source with a `key=value` format (for example, year=2019), then you can assign the top level of that partition folder tree to a column name in your data flow data stream.

First, set a wildcard to include all paths that are the partitioned folders plus the leaf files that you wish to read.



Use the Partition Root Path setting to define what the top level of the folder structure is. When you view the contents of your data via a data preview, you'll see that the service will add the resolved partitions found in each of your folder levels.



Rating abc	Rotton Tomato abc	releaseyear 123	Month 123	myfile abc
1	54	2019	7	/partdata/releaseyear=2019/...
7	80	2019	7	/partdata/releaseyear=2019/...
6	92	2019	7	/partdata/releaseyear=2019/...
4	82	2019	7	/partdata/releaseyear=2019/...
9	92	2019	7	/partdata/releaseyear=2019/...
4	59	2019	7	/partdata/releaseyear=2019/...
3	83	2019	7	/partdata/releaseyear=2019/...
2	63	2019	7	/partdata/releaseyear=2019/...
4	63	2019	7	/partdata/releaseyear=2019/...
8	50	2019	7	/partdata/releaseyear=2019/...

List of files: This is a file set. Create a text file that includes a list of relative path files to process. Point to this text file.

Column to store file name: Store the name of the source file in a column in your data. Enter a new column name here to store the file name string.

After completion: Choose to do nothing with the source file after the data flow runs, delete the source file, or move the source file. The paths for the move are relative.

To move source files to another location post-processing, first select "Move" for file operation. Then, set the "from" directory. If you're not using any wildcards for your path, then the "from" setting will be the same folder as your source folder.

If you have a source path with wildcard, your syntax will look like this below:

```
/data/sales/20??/**/*.csv
```

You can specify "from" as

```
/data/sales
```

And "to" as

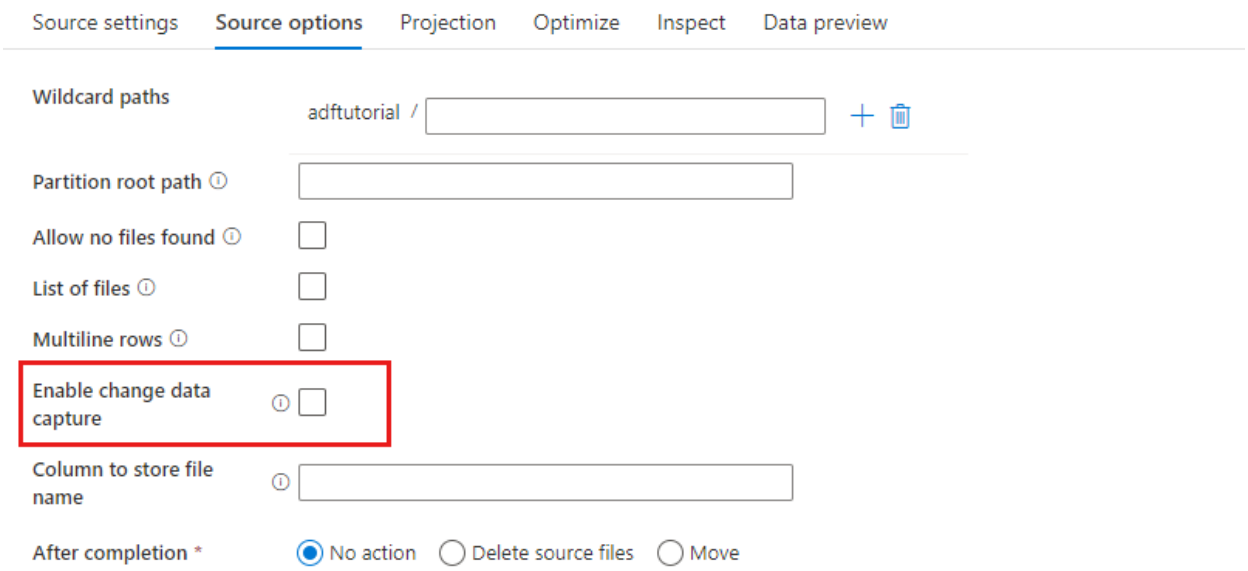
```
/backup/priorSales
```

In this case, all files that were sourced under /data/sales are moved to /backup/priorSales.

> **NOTE**
> File operations run only when you start the data flow from a pipeline run (a pipeline debug or execution run) that uses the Execute Data Flow activity in a pipeline. File operations *do not* run in Data Flow debug mode.

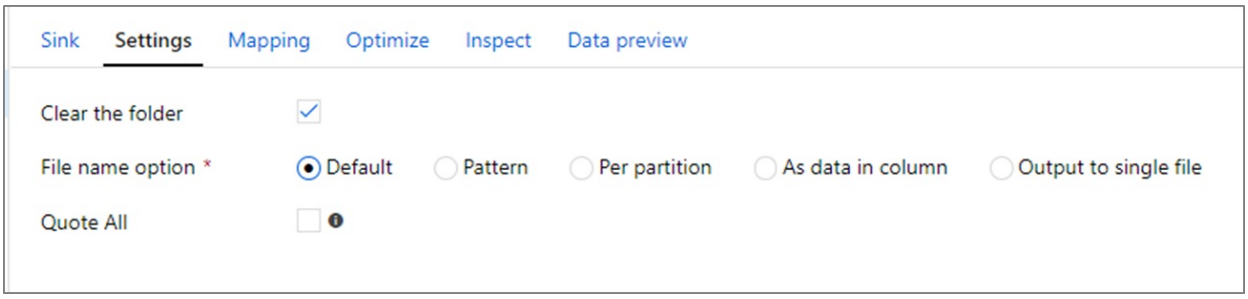
Filter by last modified: You can filter which files you process by specifying a date range of when they were last modified. All date-times are in UTC.

Enable change data capture: If true, you will get new or changed files only from the last run. Initial load of full snapshot data will always be gotten in the first run, followed by capturing new or changed files only in next runs. For more details, see Change data capture.



Sink properties

In the sink transformation, you can write to either a container or folder in Azure Data Lake Storage Gen1. the **Settings** tab lets you manage how the files get written.



Clear the folder: Determines whether or not the destination folder gets cleared before the data is written.

File name option: Determines how the destination files are named in the destination folder. The file name options are:

- **Default**: Allow Spark to name files based on PART defaults.
- **Pattern**: Enter a pattern that enumerates your output files per partition. For example, **loans[n].csv** will create loans1.csv, loans2.csv, and so on.
- **Per partition**: Enter one file name per partition.
- **As data in column**: Set the output file to the value of a column. The path is relative to the dataset container, not the destination folder. If you have a folder path in your dataset, it will be overridden.
- **Output to a single file**: Combine the partitioned output files into a single named file. The path is relative to the dataset folder. Please be aware that the merge operation can possibly fail based upon node size. This

option is not recommended for large datasets.

Quote all: Determines whether to enclose all values in quotes

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Delete activity properties

To learn details about the properties, check Delete activity

Legacy models

> **NOTE**
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzureDataLakeStoreFile**.	Yes
folderPath	Path to the folder in Data Lake Store. If not specified, it points to the root. Wildcard filter is supported. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your actual folder name has a wildcard or this escape char inside. For example: rootfolder/subfolder/. See more examples in Folder and file filter examples.	No

PROPERTY	DESCRIPTION	REQUIRED
fileName	Name or wildcard filter for the files under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, the wildcards allowed are `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual file name has a wildcard or this escape char inside. When fileName isn't specified for an output dataset and **preserveHierarchy** isn't specified in the activity sink, the copy activity automatically generates the file name with the following pattern: "*Data.[activity run ID GUID].[GUID if FlattenHierarchy].[format if configured].[compression if configured]*", for example, "Data.0a405f8a-93ff-4c6f-b3be-f69616f1df7a.txt.gz". If you copy from a tabular source by using a table name instead of a query, the name pattern is "*[table name].[format].[compression if configured]*", for example, "MyTable.csv".	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute Last Modified. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The overall performance of data movement is affected by enabling this setting when you want to do file filter with huge amounts of files. The properties can be NULL, which means no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value are selected.	No
modifiedDatetimeEnd	Files filter based on the attribute Last Modified. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The overall performance of data movement is affected by enabling this setting when you want to do file filter with huge amounts of files. The properties can be NULL, which means no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value are selected.	No

PROPERTY	DESCRIPTION	REQUIRED
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, and **ParquetFormat**. Set the **type** property under **format** to one of these values. For more information, see the Text format, JSON format, Avro format, Orc format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are **Optimal** and **Fastest**.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a particular name, specify **folderPath** with a folder part and **fileName** with a file name.
To copy a subset of files under a folder, specify **folderPath** with a folder part and **fileName** with a wildcard filter.

Example:

```
{
    "name": "ADLSDataset",
    "properties": {
        "type": "AzureDataLakeStoreFile",
        "linkedServiceName":{
            "referenceName": "<ADLS linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "datalake/myfolder/",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property of the copy activity source must be set to **AzureDataLakeStoreSource**.	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When `recursive` is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromADLSGen1",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<ADLS Gen1 input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureDataLakeStoreSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Legacy copy activity sink model

PROPERTY	DESCRIPTION	REQUIRED
type	The `type` property of the copy activity sink must be set to **AzureDataLakeStoreSink**.	Yes
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, the file name is autogenerated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToADLSGen1",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<ADLS Gen1 output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureDataLakeStoreSink",
                "copyBehavior": "PreserveHierarchy"
            }
        }
    }
]
```

Change data capture (preview)

Azure Data Factory can get new or changed files only from Azure Data Lake Storage Gen1 by enabling **Enable change data capture (Preview)** in the mapping data flow source transformation. With this connector option, you can read new or updated files only and apply transformations before loading transformed data into destination datasets of your choice.

Make sure you keep the pipeline and activity name unchanged, so that the checkpoint can always be recorded from the last run to get changes from there. If you change your pipeline name or activity name, the checkpoint will be reset, and you will start from the beginning in the next run.

When you debug the pipeline, the **Enable change data capture (Preview)** works as well. Be aware that the checkpoint will be reset when you refresh your browser during the debug run. After you are satisfied with the result from debug run, you can publish and trigger the pipeline. It will always start from the beginning regardless of the previous checkpoint recorded by debug run.

In the monitoring section, you always have the chance to rerun a pipeline. When you are doing so, the changes are always gotten from the checkpoint record in your selected pipeline run.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Azure Data Lake Storage Gen2 using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 33 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Azure Data Lake Storage Gen2 (ADLS Gen2) is a set of capabilities dedicated to big data analytics built into Azure Blob storage. You can use it to interface with your data by using both file system and object storage paradigms.

This article outlines how to use Copy Activity to copy data from and to Azure Data Lake Storage Gen2, and use Data Flow to transform data in Azure Data Lake Storage Gen2. To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **TIP**
> For data lake or data warehouse migration scenario, learn more in Migrate data from your data lake or data warehouse to Azure.

Supported capabilities

This Azure Data Lake Storage Gen2 connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓
GetMetadata activity	① ②	✓
Delete activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

For Copy activity, with this connector you can:

- Copy data from/to Azure Data Lake Storage Gen2 by using account key, service principal, or managed identities for Azure resources authentications.
- Copy files as-is or parse or generate files with supported file formats and compression codecs.
- Preserve file metadata during copy.
- Preserve ACLs when copying from Azure Data Lake Storage Gen1/Gen2.

Get started

TIP

For a walk-through of how to use the Data Lake Storage Gen2 connector, see Load data into Azure Data Lake Storage Gen2.

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

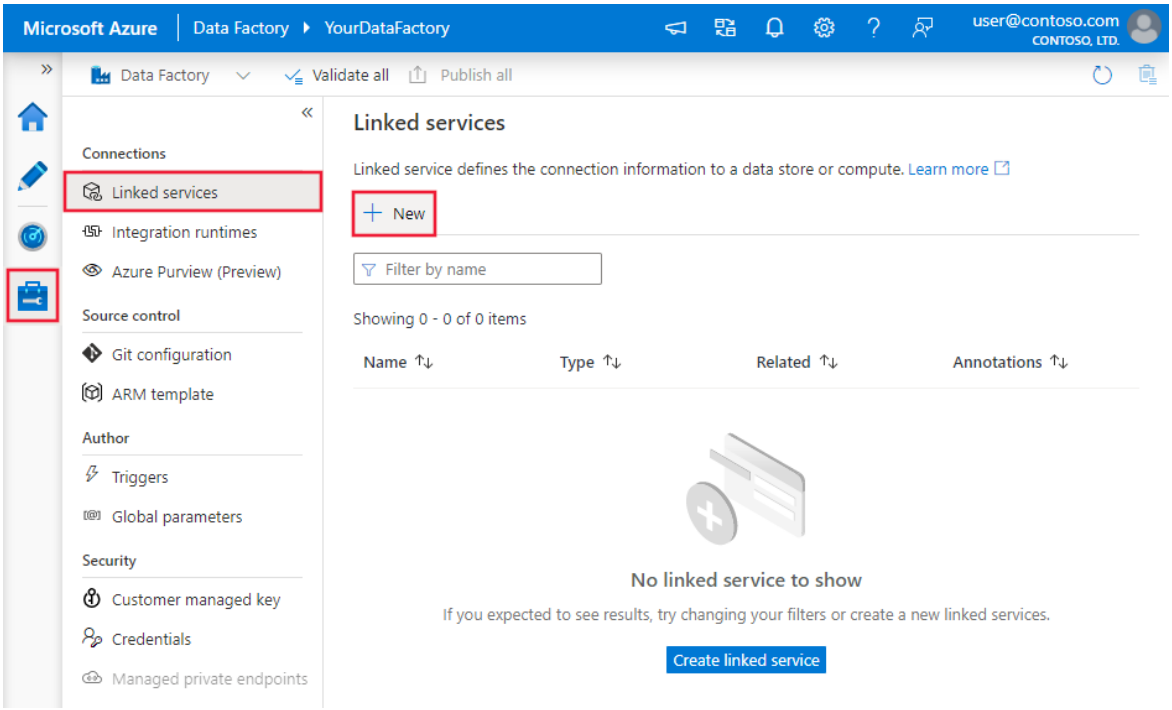
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Azure Data Lake Storage Gen2 linked service using UI

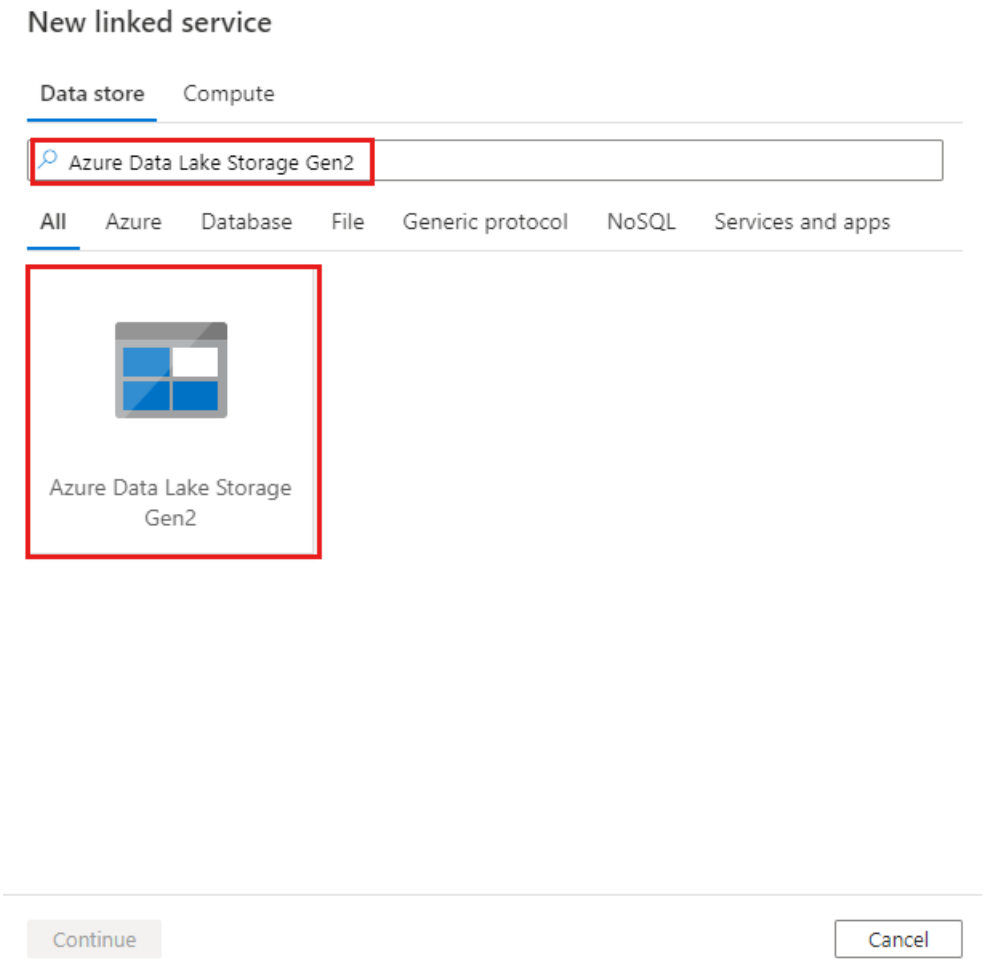
Use the following steps to create an Azure Data Lake Storage Gen2 linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

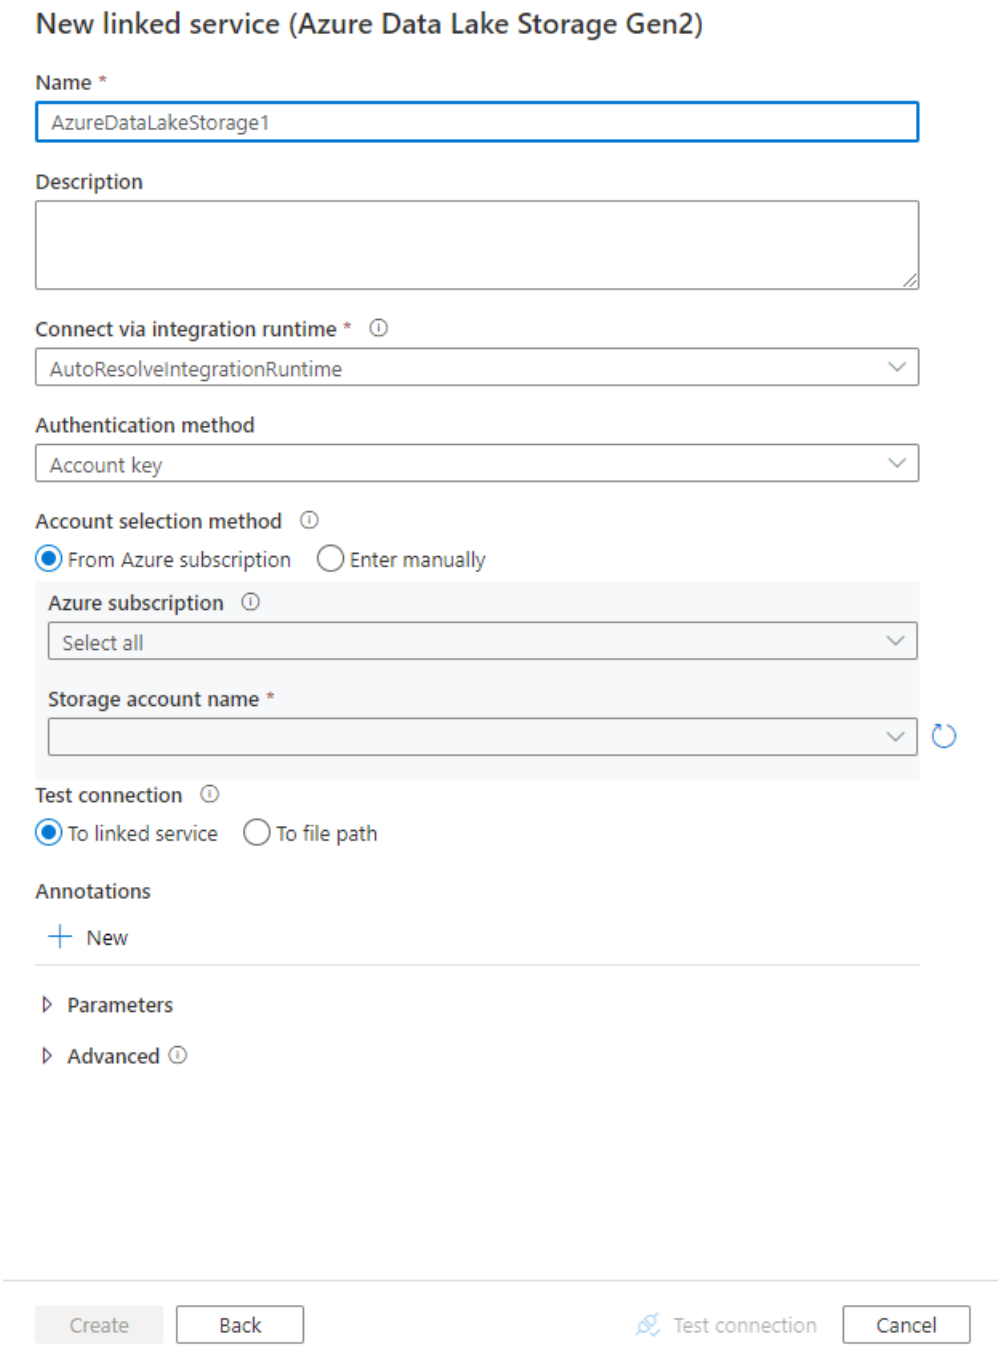
   - Azure Data Factory
   - Azure Synapse



2. Search for Azure Data Lake Storage Gen2 and select the Azure Data Lake Storage Gen2 connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Data Lake Storage Gen2.

Linked service properties

The Azure Data Lake Storage Gen2 connector supports the following authentication types. See the corresponding sections for details:

- Account key authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

NOTE

- If want to use the public Azure integration runtime to connect to the Data Lake Storage Gen2 by leveraging the **Allow trusted Microsoft services to access this storage account** option enabled on Azure Storage firewall, you must use managed identity authentication. For more information about the Azure Storage firewalls settings, see Configure Azure Storage firewalls and virtual networks.
- When you use PolyBase or COPY statement to load data into Azure Synapse Analytics, if your source or staging Data Lake Storage Gen2 is configured with an Azure Virtual Network endpoint, you must use managed identity authentication as required by Azure Synapse. See the managed identity authentication section with more configuration prerequisites.

Account key authentication

To use storage account key authentication, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureBlobFS**.	Yes
url	Endpoint for Data Lake Storage Gen2 with the pattern of `https://<accountname>.dfs.core.windows.net`.	Yes
accountKey	Account key for Data Lake Storage Gen2. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If this property isn't specified, the default Azure integration runtime is used.	No

NOTE

Secondary ADLS file system endpoint is not supported when using account key authentication. You can use other authentication types.

Example:

```
{
    "name": "AzureDataLakeStorageGen2LinkedService",
    "properties": {
        "type": "AzureBlobFS",
        "typeProperties": {
            "url": "https://<accountname>.dfs.core.windows.net",
            "accountkey": {
                "type": "SecureString",
                "value": "<accountkey>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Service principal authentication

To use service principal authentication, follow these steps.

1. Register an application entity in Azure Active Directory (Azure AD) by following the steps in Register your application with an Azure AD tenant. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant the service principal proper permission. See examples on how permission works in Data Lake Storage Gen2 from Access control lists on files and directories
   - **As source**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Read** permission for the files to copy. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Reader** role.
   - **As sink**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Write** permission for the sink folder. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Contributor** role.

> **NOTE**
> If you use UI to author and the service principal is not set with "Storage Blob Data Reader/Contributor" role in IAM, when doing test connection or browsing/navigating folders, choose "Test connection to file path" or "Browse from specified path", and specify a path with **Read + Execute** permission to continue.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureBlobFS**.	Yes
url	Endpoint for Data Lake Storage Gen2 with the pattern of `https://<accountname>.dfs.core.windows.net`.	Yes

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalCredentialType	The credential type to use for service principal authentication. Allowed values are **ServicePrincipalKey** and **ServicePrincipalCert**.	Yes
servicePrincipalCredential	The service principal credential. When you use **ServicePrincipalKey** as the credential type, specify the application's key. Mark this field as **SecureString** to store it securely, or reference a secret stored in Azure Key Vault. When you use **ServicePrincipalCert** as the credential, reference a certificate in Azure Key Vault, and ensure the certificate content type is **PKCS #12**.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as **SecureString** to store it securely, or reference a secret stored in Azure Key Vault. This property is still supported as-is for `servicePrincipalId` + `servicePrincipalKey`. As ADF adds new service principal certificate authentication, the new model for service principal authentication is `servicePrincipalId` + `servicePrincipalCredentialType` + `servicePrincipalCredential`.	No
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure Active Directory application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the data factory or Synapse pipeline's cloud environment is used.	No
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example: using service principal key authentication

You can also store service principal key in Azure Key Vault.

```
{
    "name": "AzureDataLakeStorageGen2LinkedService",
    "properties": {
        "type": "AzureBlobFS",
        "typeProperties": {
            "url": "https://<accountname>.dfs.core.windows.net",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalCredential": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: using service principal certificate authentication

```
{
    "name": "AzureDataLakeStorageGen2LinkedService",
    "properties": {
        "type": "AzureBlobFS",
        "typeProperties": {
            "url": "https://<accountname>.dfs.core.windows.net",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalCredential": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<AKV reference>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<certificate name in AKV>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a system-assigned managed identity. You can directly use this system-assigned managed identity for Data Lake Storage Gen2 authentication, similar to using your own service principal. It allows this designated factory or workspace to access and copy data to or from your Data Lake Storage Gen2.

To use system-assigned managed identity authentication, follow these steps.

1. Retrieve the system-assigned managed identity information by copying the value of the **managed identity object ID** generated along with your data factory or Synapse workspace.

2. Grant the system-assigned managed identity proper permission. See examples on how permission works in Data Lake Storage Gen2 from Access control lists on files and directories.

   - **As source**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Read** permission for the files to copy. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Reader** role.
   - **As sink**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Write** permission for the sink folder. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Contributor** role.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureBlobFS**.	Yes
url	Endpoint for Data Lake Storage Gen2 with the pattern of `https://<accountname>.dfs.core.windows.net`.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example:

```
{
    "name": "AzureDataLakeStorageGen2LinkedService",
    "properties": {
        "type": "AzureBlobFS",
        "typeProperties": {
            "url": "https://<accountname>.dfs.core.windows.net",
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

A data factory can be assigned with one or multiple user-assigned managed identities. You can use this user-assigned managed identity for Blob storage authentication, which allows to access and copy data from or to Data Lake Storage Gen2. To learn more about managed identities for Azure resources, see Managed identities for Azure resources

To use user-assigned managed identity authentication, follow these steps:

1. Create one or multiple user-assigned managed identities and grant access to Azure Data Lake Storage Gen2. See examples on how permission works in Data Lake Storage Gen2 from Access control lists on files and directories.

- **As source**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Read** permission for the files to copy. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Reader** role.
- **As sink**: In Storage Explorer, grant at least **Execute** permission for ALL upstream folders and the file system, along with **Write** permission for the sink folder. Alternatively, in Access control (IAM), grant at least the **Storage Blob Data Contributor** role.

2. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

These properties are supported for the linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureBlobFS**.	Yes
url	Endpoint for Data Lake Storage Gen2 with the pattern of `https://<accountname>.dfs.core.windows.net`.	Yes
credentials	Specify the user-assigned managed identity as the credential object.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is in a private network. If not specified, the default Azure integration runtime is used.	No

Example:

```
{
    "name": "AzureDataLakeStorageGen2LinkedService",
    "properties": {
        "type": "AzureBlobFS",
        "typeProperties": {
            "url": "https://<accountname>.dfs.core.windows.net",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
                }
            },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

NOTE

If you use Data Factory UI to author and the managed identity is not set with "Storage Blob Data Reader/Contributor" role in IAM, when doing test connection or browsing/navigating folders, choose "Test connection to file path" or "Browse from specified path", and specify a path with **Read + Execute** permission to continue.

IMPORTANT

If you use PolyBase or COPY statement to load data from Data Lake Storage Gen2 into Azure Synapse Analytics, when you use managed identity authentication for Data Lake Storage Gen2, make sure you also follow steps 1 to 3 in this guidance. Those steps will register your server with Azure AD and assign the Storage Blob Data Contributor role to your server. Data Factory handles the rest. If you configure Blob storage with an Azure Virtual Network endpoint, you also need to have **Allow trusted Microsoft services to access this storage account** turned on under Azure Storage account **Firewalls and Virtual networks** settings menu as required by Azure Synapse.

Dataset properties

For a full list of sections and properties available for defining datasets, see Datasets.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Data Lake Storage Gen2 under `location` settings in the format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in the dataset must be set to **AzureBlobFSLocation**.	Yes
fileSystem	The Data Lake Storage Gen2 file system name.	No
folderPath	The path to a folder under the given file system. If you want to use a wildcard to filter folders, skip this setting and specify it in activity source settings.	No
fileName	The file name under the given fileSystem + folderPath. If you want to use a wildcard to filter files, skip this setting and specify it in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Data Lake Storage Gen2 linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobFSLocation",
                "fileSystem": "filesystemname",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see Copy activity configurations and Pipelines and activities. This section provides a list of properties supported by the Data Lake Storage Gen2 source and sink.

Azure Data Lake Storage Gen2 as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

You have several options to copy data from ADLS Gen2:

- Copy from the given path specified in the dataset.
- Wildcard filter against folder path or file name, see `wildcardFolderPath` and `wildcardFileName`.
- Copy the files defined in a given text file as file set, see `fileListPath`.

The following properties are supported for Data Lake Storage Gen2 under `storeSettings` settings in format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureBlobFSReadSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
Locate the files to copy:		
OPTION 1: static path	Copy from the given file system or folder/file path specified in the dataset. If you want to copy all files from a file system/folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given file system configured in dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	No
OPTION 2: wildcard - wildcardFileName	The file name with wildcard characters under the given file system + folderPath/wildcardFolderPath to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When using this option, do not specify file name in dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No

PROPERTY	DESCRIPTION	REQUIRED
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromADLSGen2",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AzureBlobFSReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Data Lake Storage Gen2 as a sink type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for Data Lake Storage Gen2 under `storeSettings` settings in format-based copy sink:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureBlobFSWriteSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
blockSizeInMB	Specify the block size in MB used to write data to ADLS Gen2. Learn more about Block Blobs. Allowed value is **between 4 MB and 100 MB**. By default, ADF automatically determines the block size based on your source store type and data. For non-binary copy into ADLS Gen2, the default block size is 100 MB so as to fit in at most approximately 4.75-TB data. It may be not optimal when your data is not large, especially when you use Self-hosted Integration Runtime with poor network resulting in operation timeout or performance issue. You can explicitly specify a block size, while ensure blockSizeInMB*50000 is big enough to store the data, otherwise copy activity run will fail.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

PROPERTY	DESCRIPTION	REQUIRED
metadata	Set custom metadata when copy to sink. Each object under the `metadata` array represents an extra column. The `name` defines the metadata key name, and the `value` indicates the data value of that key. If preserve attributes feature is used, the specified metadata will union/overwrite with the source file metadata. Allowed data values are: - `$$LASTMODIFIED`: a reserved variable indicates to store the source files' last modified time. Apply to file-based source with binary format only. - **Expression** - **Static value**	No

Example:

```
"activities":[
    {
        "name": "CopyToADLSGen2",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Parquet output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "ParquetSink",
                "storeSettings":{
                    "type": "AzureBlobFSWriteSettings",
                    "copyBehavior": "PreserveHierarchy",
                    "metadata": [
                        {
                            "name": "testKey1",
                            "value": "value1"
                        },
                        {
                            "name": "testKey2",
                            "value": "value2"
                        },
                        {
                            "name": "lastModifiedKey",
                            "value": "$$LASTMODIFIED"
                        }
                    ]
                }
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(Empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(Empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using file list path in copy activity source.

Assuming you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	ADF CONFIGURATION
filesystem FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - File system: `filesystem` - Folder path: `FolderA` **In copy activity source:** - File list path: `filesystem/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line with the relative path to the path configured in the dataset.

Some recursive and copyBehavior examples

This section describes the resulting behavior of the copy operation for different combinations of recursive and copyBehavior values.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

true	preserveHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the same structure as the source:
			
			Folder1
			  File1
			  File2
			  Subfolder1
			  File3
			  File4
			  File5

true	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			  autogenerated name for File3
			  autogenerated name for File4
			  autogenerated name for File5

true	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  File1 + File2 + File3 + File4 + File5 contents are merged into one file with an autogenerated file name.

false	preserveHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  File1
			  File2
			
			Subfolder1 with File3, File4, and File5 isn't picked up.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

false	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			
			Subfolder1 with File3, File4, and File5 isn't picked up.

false	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target Folder1 is created with the following structure:
			
			Folder1
			  File1 + File2 contents are merged into one file with an autogenerated file name. autogenerated name for File1
			
			Subfolder1 with File3, File4, and File5 isn't picked up.

Preserve metadata during copy

When you copy files from Amazon S3/Azure Blob/Azure Data Lake Storage Gen2 to Azure Data Lake Storage Gen2/Azure Blob, you can choose to preserve the file metadata along with data. Learn more from Preserve metadata.

Preserve ACLs from Data Lake Storage Gen1/Gen2

When you copy files from Azure Data Lake Storage Gen1/Gen2 to Gen2, you can choose to preserve the POSIX access control lists (ACLs) along with data. Learn more from Preserve ACLs from Data Lake Storage Gen1/Gen2 to Gen2.

> **TIP**
> To copy data from Azure Data Lake Storage Gen1 into Gen2 in general, see Copy data from Azure Data Lake Storage Gen1 to Gen2 for a walk-through and best practices.

Mapping data flow properties

When you're transforming data in mapping data flows, you can read and write files from Azure Data Lake Storage Gen2 in the following formats:

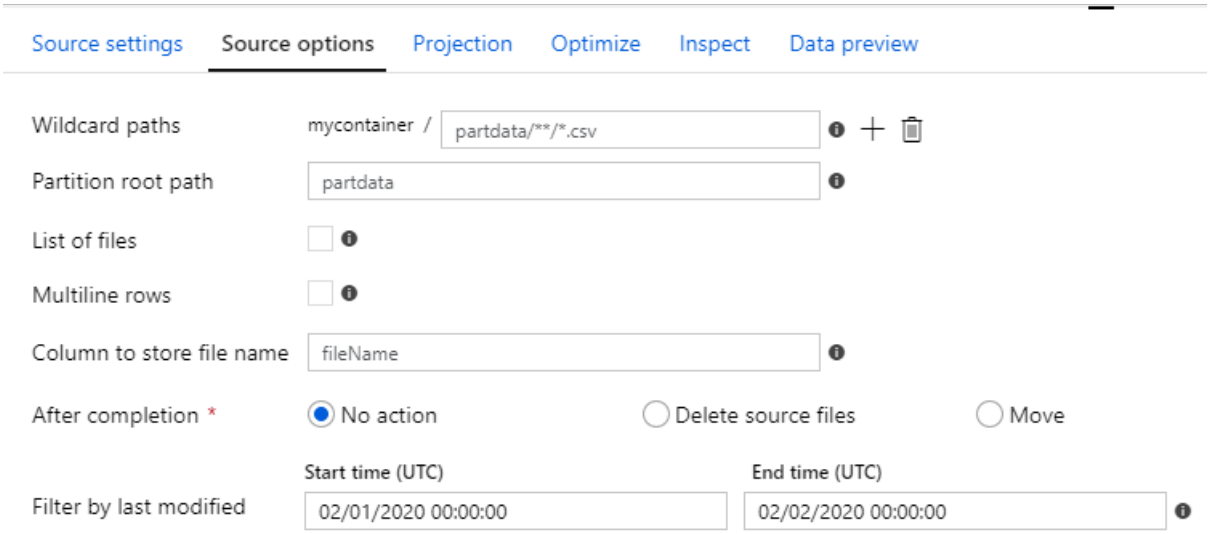
- Avro
- Common Data Model
- Delimited text
- Delta

- Excel
- JSON
- Parquet

Format specific settings are located in the documentation for that format. For more information, see Source transformation in mapping data flow and Sink transformation in mapping data flow.

Source transformation

In the source transformation, you can read from a container, folder, or individual file in Azure Data Lake Storage Gen2. The **Source options** tab lets you manage how the files get read.



Wildcard path: Using a wildcard pattern will instruct ADF to loop through each matching folder and file in a single Source transformation. This is an effective way to process multiple files within a single flow. Add multiple wildcard matching patterns with the + sign that appears when hovering over your existing wildcard pattern.

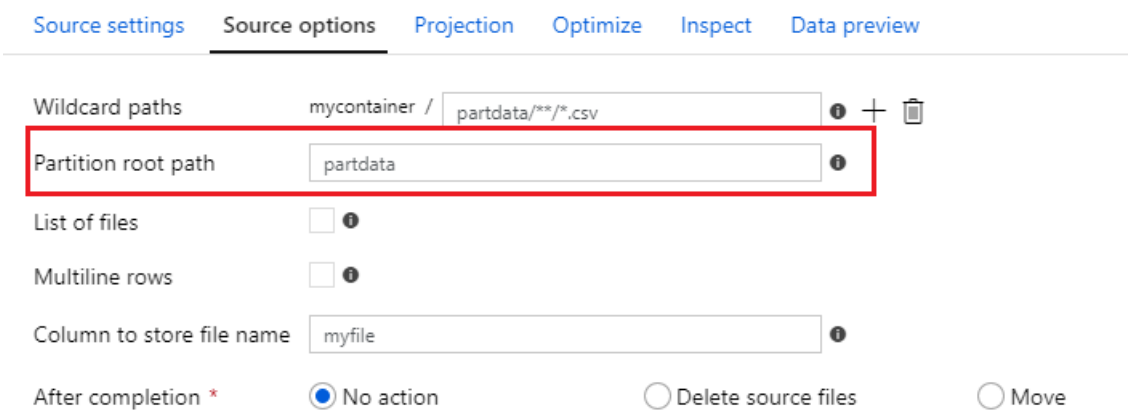
From your source container, choose a series of files that match a pattern. Only container can be specified in the dataset. Your wildcard path must therefore also include your folder path from the root folder.

Wildcard examples:

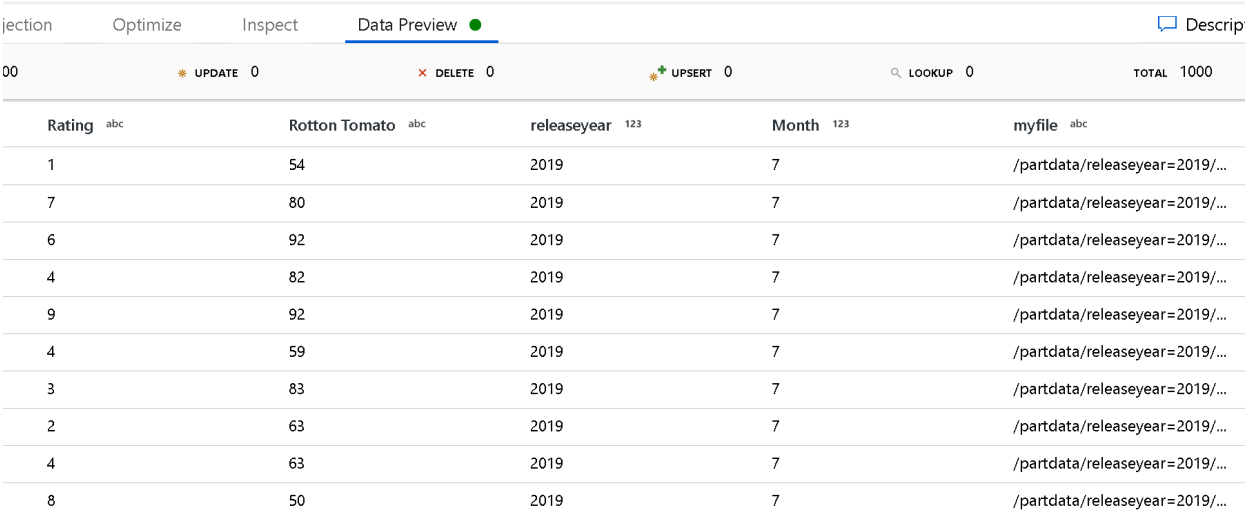
- `*` Represents any set of characters
- `**` Represents recursive directory nesting
- `?` Replaces one character
- `[]` Matches one of more characters in the brackets
- `/data/sales/**/*.csv` Gets all csv files under /data/sales
- `/data/sales/20??/**/` Gets all files in the 20th century
- `/data/sales/*/*/*.csv` Gets csv files two levels under /data/sales
- `/data/sales/2004/*/12/[XY]1?.csv` Gets all csv files in 2004 in December starting with X or Y prefixed by a two-digit number

Partition Root Path: If you have partitioned folders in your file source with a `key=value` format (for example, year=2019), then you can assign the top level of that partition folder tree to a column name in your data flow data stream.

First, set a wildcard to include all paths that are the partitioned folders plus the leaf files that you wish to read.



Use the Partition Root Path setting to define what the top level of the folder structure is. When you view the contents of your data via a data preview, you'll see that ADF will add the resolved partitions found in each of your folder levels.



Rating abc	Rotton Tomato abc	releaseyear 123	Month 123	myfile abc
1	54	2019	7	/partdata/releaseyear=2019/...
7	80	2019	7	/partdata/releaseyear=2019/...
6	92	2019	7	/partdata/releaseyear=2019/...
4	82	2019	7	/partdata/releaseyear=2019/...
9	92	2019	7	/partdata/releaseyear=2019/...
4	59	2019	7	/partdata/releaseyear=2019/...
3	83	2019	7	/partdata/releaseyear=2019/...
2	63	2019	7	/partdata/releaseyear=2019/...
4	63	2019	7	/partdata/releaseyear=2019/...
8	50	2019	7	/partdata/releaseyear=2019/...

List of files: This is a file set. Create a text file that includes a list of relative path files to process. Point to this text file.

Column to store file name: Store the name of the source file in a column in your data. Enter a new column name here to store the file name string.

After completion: Choose to do nothing with the source file after the data flow runs, delete the source file, or move the source file. The paths for the move are relative.

To move source files to another location post-processing, first select "Move" for file operation. Then, set the "from" directory. If you're not using any wildcards for your path, then the "from" setting will be the same folder as your source folder.

If you have a source path with wildcard, your syntax will look like this below:

```
/data/sales/20??/**/*.csv
```

You can specify "from" as

```
/data/sales
```

And "to" as

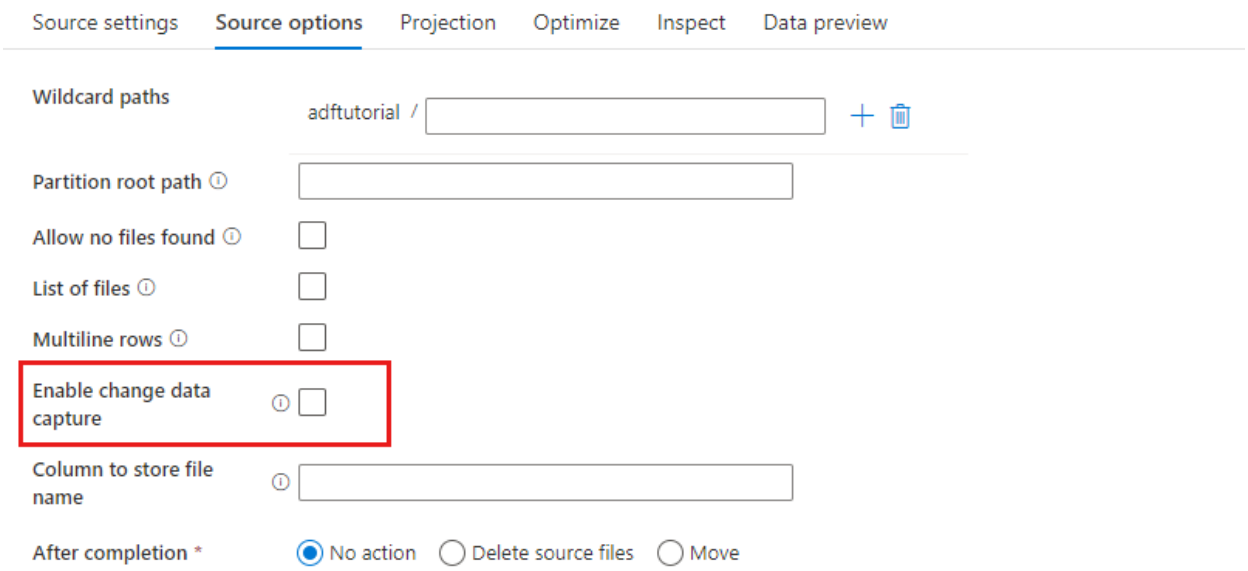
```
/backup/priorSales
```

In this case, all files that were sourced under /data/sales are moved to /backup/priorSales.

> **NOTE**
>
> File operations run only when you start the data flow from a pipeline run (a pipeline debug or execution run) that uses the Execute Data Flow activity in a pipeline. File operations *do not* run in Data Flow debug mode.

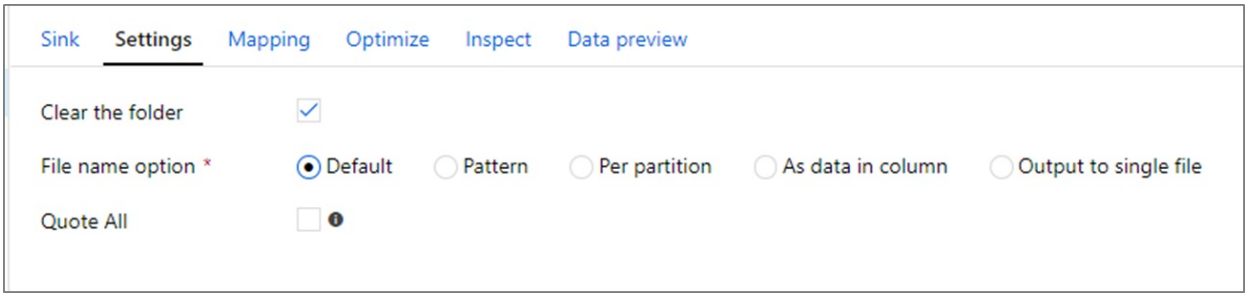
Filter by last modified: You can filter which files you process by specifying a date range of when they were last modified. All date-times are in UTC.

Enable change data capture: If true, you will get new or changed files only from the last run. Initial load of full snapshot data will always be gotten in the first run, followed by capturing new or changed files only in next runs. For more details, see Change data capture.



Sink properties

In the sink transformation, you can write to either a container or folder in Azure Data Lake Storage Gen2. the **Settings** tab lets you manage how the files get written.



Clear the folder: Determines whether or not the destination folder gets cleared before the data is written.

File name option: Determines how the destination files are named in the destination folder. The file name options are:

- **Default**: Allow Spark to name files based on PART defaults.
- **Pattern**: Enter a pattern that enumerates your output files per partition. For example, **loans[n].csv** will create loans1.csv, loans2.csv, and so on.
- **Per partition**: Enter one file name per partition.
- **As data in column**: Set the output file to the value of a column. The path is relative to the dataset container, not the destination folder. If you have a folder path in your dataset, it will be overridden.
- **Output to a single file**: Combine the partitioned output files into a single named file. The path is relative to the dataset folder. Please be aware that the merge operation can possibly fail based upon node size. This

option is not recommended for large datasets.

Quote all: Determines whether to enclose all values in quotes

`umask`

You can optionally set the `umask` for files using POSIX read, write, execute flags for owner, user and group.

Pre-processing and post-processing commands

You can optionally execute Hadoop filesystem commands before or after writing to an ADLS Gen2 sink. The following commands are supported:

- `cp`
- `mv`
- `rm`
- `mkdir`

Examples:

- `mkdir /folder1`
- `mkdir -p folder1`
- `mv /folder1/*.* /folder2/`
- `cp /folder1/file1.txt /folder2`
- `rm -r /folder1`

Parameters are also supported through expression builder, for example:

`mkdir -p {$tempPath}/commands/c1/c2` `mv {$tempPath}/commands/*.* {$tempPath}/commands/c1/c2`

By default, folders are created as user/root. Refer to the top level container with '/'.

Lookup activity properties

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Delete activity properties

To learn details about the properties, check Delete activity

Legacy models

> **NOTE**
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the ADF authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzureBlobFSFile**.	Yes
folderPath	Path to the folder in Data Lake Storage Gen2. If not specified, it points to the root. Wildcard filter is supported. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your actual folder name has a wildcard or this escape char is inside. Examples: filesystem/folder/. See more examples in Folder and file filter examples.	No
fileName	Name or wildcard filter for the files under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, the wildcards allowed are `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual file name has a wildcard or this escape char is inside. When fileName isn't specified for an output dataset and **preserveHierarchy** isn't specified in the activity sink, the copy activity automatically generates the file name with the following pattern: "*Data.[activity run ID GUID].[GUID if FlattenHierarchy].[format if configured].[compression if configured]*", for example, "Data.0a405f8a-93ff-4c6f-b3be-f69616f1df7a.txt.gz". If you copy from a tabular source using a table name instead of a query, the name pattern is "*[table name].[format].[compression if configured]*", for example, "MyTable.csv".	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute Last Modified. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The overall performance of data movement is affected by enabling this setting when you want to do file filter with huge amounts of files. The properties can be NULL, which means no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value are selected.	No
modifiedDatetimeEnd	Files filter based on the attribute Last Modified. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The overall performance of data movement is affected by enabling this setting when you want to do file filter with huge amounts of files. The properties can be NULL, which means no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value are selected.	No

PROPERTY	DESCRIPTION	REQUIRED
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both the input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, and **ParquetFormat**. Set the **type** property under **format** to one of these values. For more information, see the Text format, JSON format, Avro format, ORC format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are `**GZip**, **Deflate**, **BZip2**, and **ZipDeflate**`. Supported levels are **Optimal** and **Fastest**.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a given name, specify **folderPath** with a folder part and **fileName** with a file name.
To copy a subset of files under a folder, specify **folderPath** with a folder part and **fileName** with a wildcard filter.

Example:

```
{
    "name": "ADLSGen2Dataset",
    "properties": {
        "type": "AzureBlobFSFile",
        "linkedServiceName": {
            "referenceName": "<Azure Data Lake Storage Gen2 linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "myfilesystem/myfolder",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AzureBlobFSSource**.	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromADLSGen2",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<ADLS Gen2 input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureBlobFSSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Legacy copy activity sink model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **AzureBlobFSSink**.	Yes
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToADLSGen2",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<ADLS Gen2 output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureBlobFSSink",
                "copyBehavior": "PreserveHierarchy"
            }
        }
    }
]
```

Change data capture

Azure Data Factory can get new or changed files only from Azure Data Lake Storage Gen2 by enabling **Enable change data capture** in the mapping data flow source transformation. With this connector option, you can read new or updated files only and apply transformations before loading transformed data into destination datasets of your choice.

Make sure you keep the pipeline and activity name unchanged, so that the checkpoint can always be recorded from the last run to get changes from there. If you change your pipeline name or activity name, the checkpoint will be reset, and you will start from the beginning in the next run.

When you debug the pipeline, the **Enable change data capture** works as well. Be aware that the checkpoint will be reset when you refresh your browser during the debug run. After you are satisfied with the result from debug run, you can publish and trigger the pipeline. It will always start from the beginning regardless of the previous checkpoint recorded by debug run.

In the monitoring section, you always have the chance to rerun a pipeline. When you are doing so, the changes are always gotten from the checkpoint record in your selected pipeline run.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Azure Database for MariaDB using Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Azure Database for MariaDB. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Azure Database for MariaDB connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/-)	① ②	✓
Lookup activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from Azure Database for MariaDB to any supported sink data store. For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

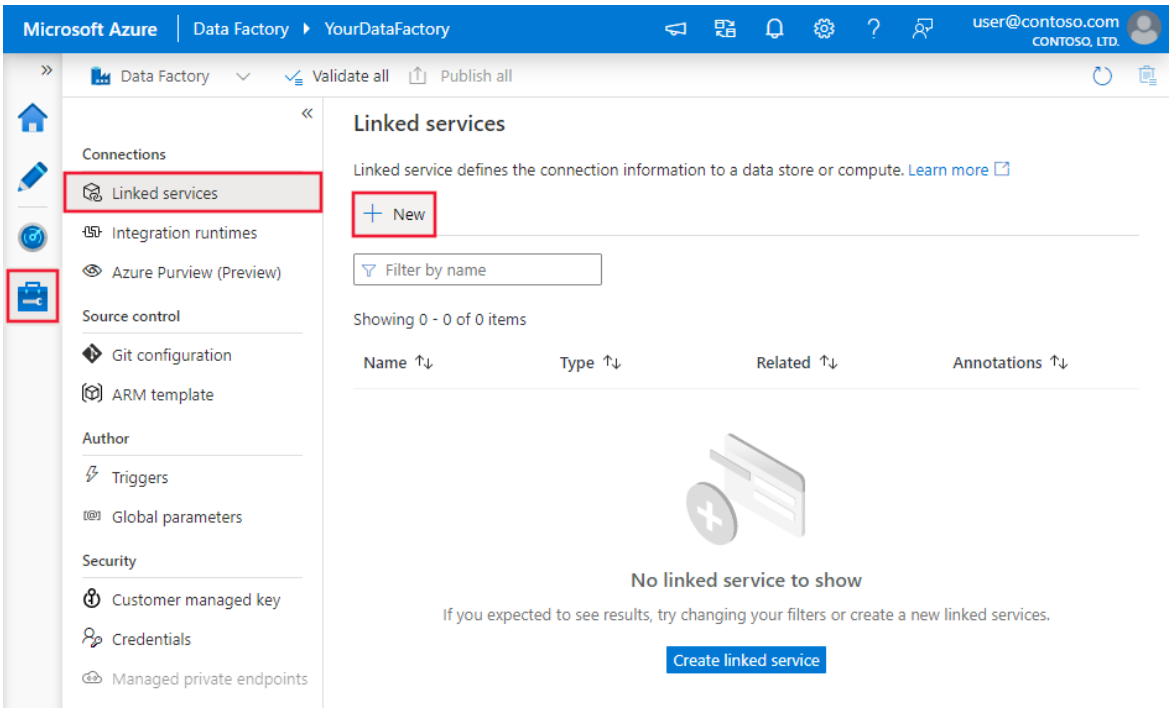
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Database for MariaDB using UI

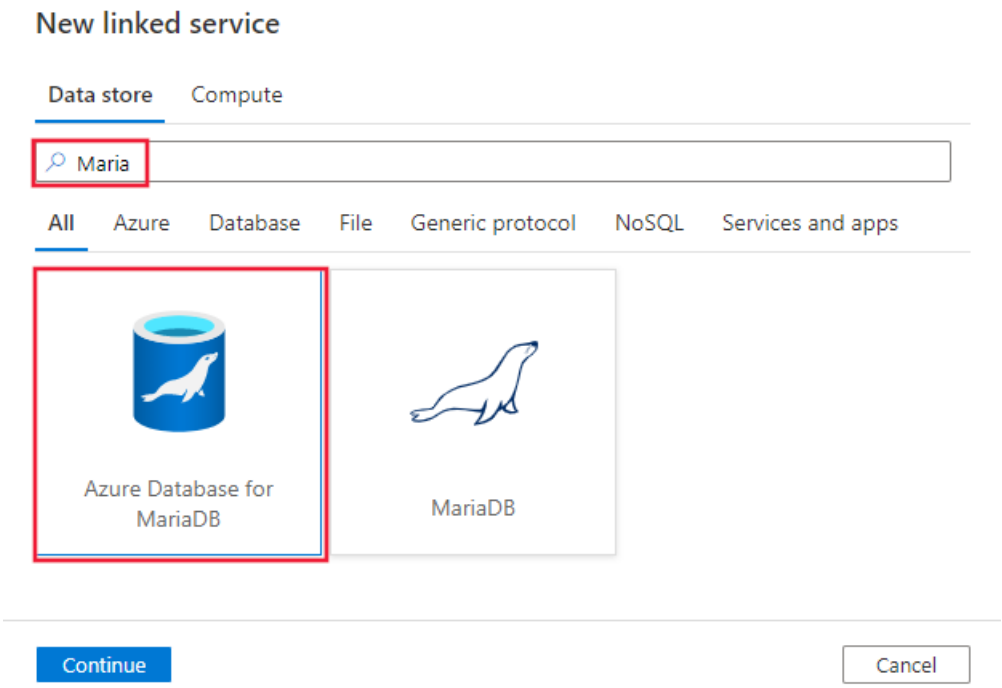
Use the following steps to create a linked service to Azure Database for MariaDB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

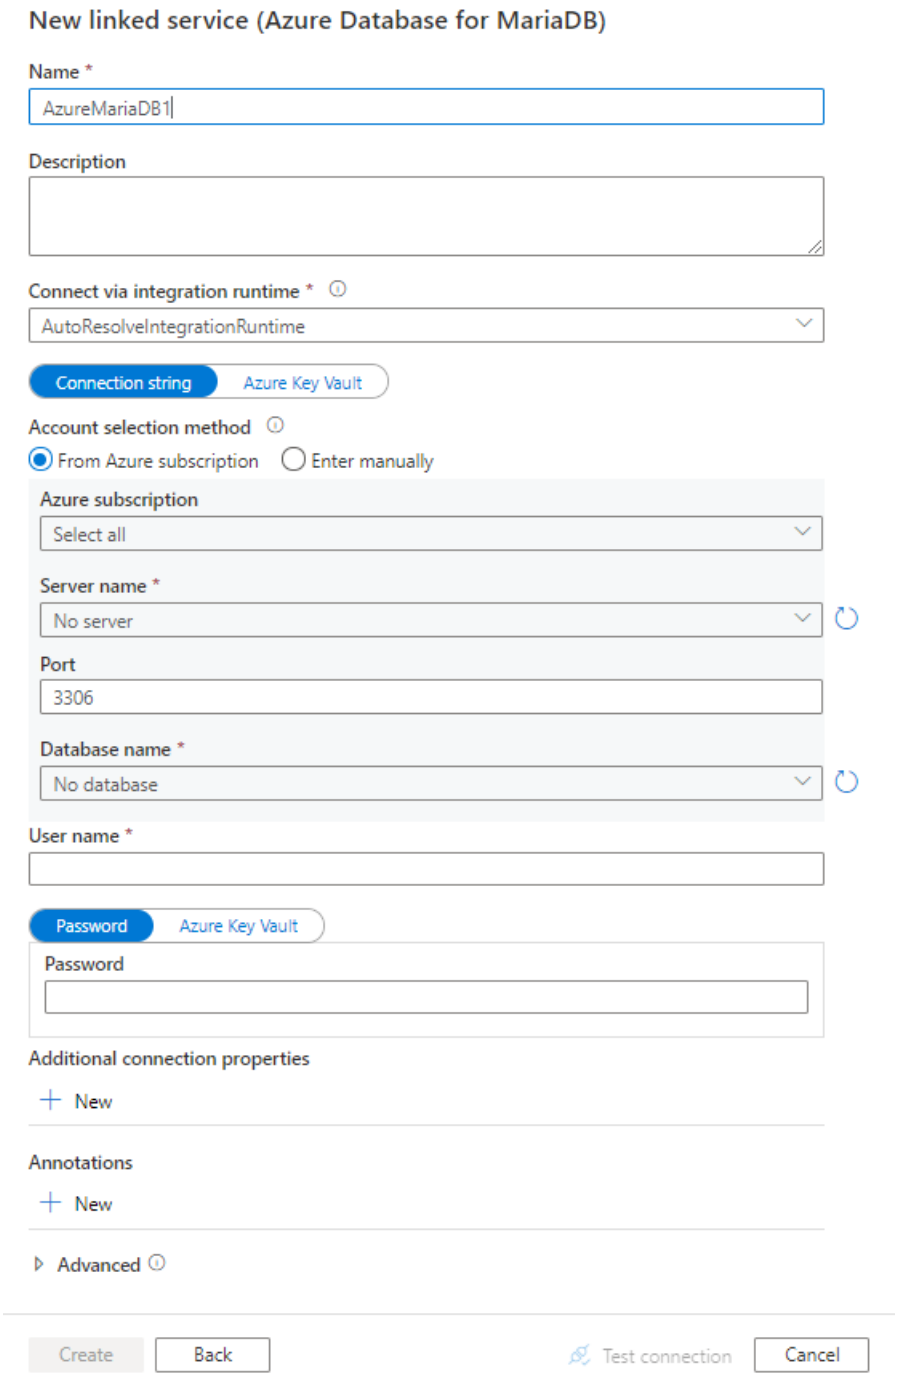
   - Azure Data Factory
   - Azure Synapse



2. Search for Maria and select the Azure Database for MariaDB connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Azure Database for MariaDB connector.

Linked service properties

The following properties are supported for Azure Database for MariaDB linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureMariaDB**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	A connection string to connect to Azure Database for MariaDB. You can find it from the Azure portal -> your Azure Database for MariaDB -> Connection strings -> ADO.NET one. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "AzureDatabaseForMariaDBLinkedService",
    "properties": {
        "type": "AzureMariaDB",
        "typeProperties": {
            "connectionString": "Server={your_server}.mariadb.database.azure.com; Port=3306; Database=
{your_database}; Uid={your_user}@{your_server}; Pwd={your_password}; SslMode=Preferred;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "AzureDatabaseForMariaDBLinkedService",
    "properties": {
        "type": "AzureMariaDB",
        "typeProperties": {
            "connectionString": "Server={your_server}.mariadb.database.azure.com; Port=3306; Database=
{your_database}; Uid={your_user}@{your_server}; SslMode=Preferred;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Azure Database for MariaDB dataset.

To copy data from Azure Database for MariaDB, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **AzureMariaDBTable**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "AzureDatabaseForMariaDBDataset",
    "properties": {
        "type": "AzureMariaDBTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Azure Database for MariaDB linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Azure Database for MariaDB source.

Azure Database for MariaDB as source

To copy data from Azure Database for MariaDB, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **AzureMariaDBSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromAzureDatabaseForMariaDB",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure Database for MariaDB input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureMariaDBSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Azure Database for MySQL using Azure Data Factory or Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory or Synapse Analytics pipelines to copy data from and to Azure Database for MySQL, and use Data Flow to transform data in Azure Database for MySQL. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

This connector is specialized for

- Azure Database for MySQL Single Server
- Azure Database for MySQL Flexible Server (Currently public access is only supported)

To copy data from generic MySQL database located on-premises or in the cloud, use MySQL connector.

Prerequisites

This quickstart requires the following resources and configuration mentioned below as a starting point:

- An existing Azure database for MySQL Single server or MySQL Flexible Server.
- Enable **Allow public access from any Azure service within Azure to this server** in networking page of the MySQL server . This will allow you to use Data factory studio.

Supported capabilities

This Azure Database for MySQL connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell

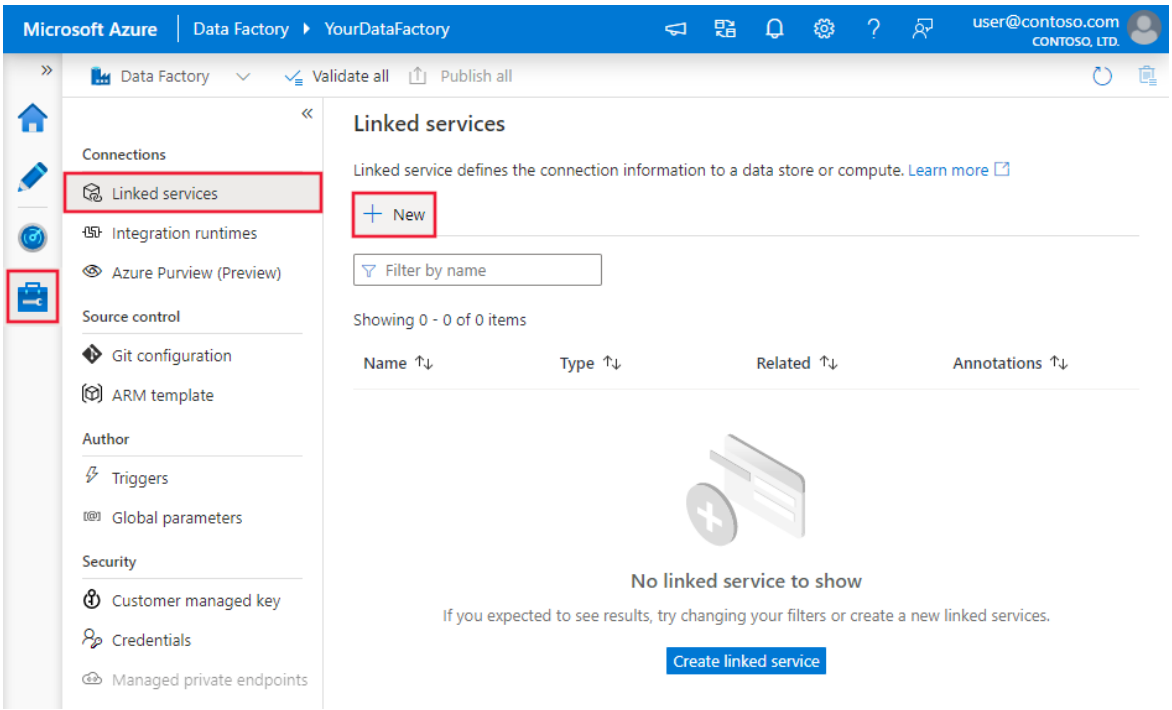
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Database for MySQL using UI

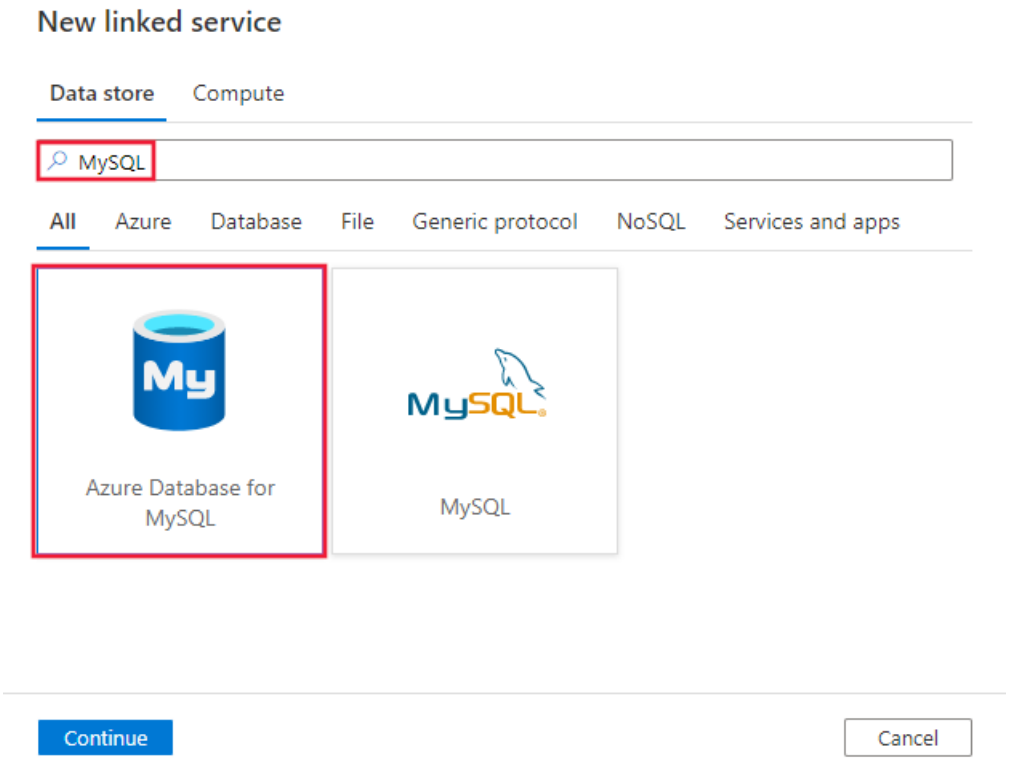
Use the following steps to create a linked service to Azure Database for MySQL in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

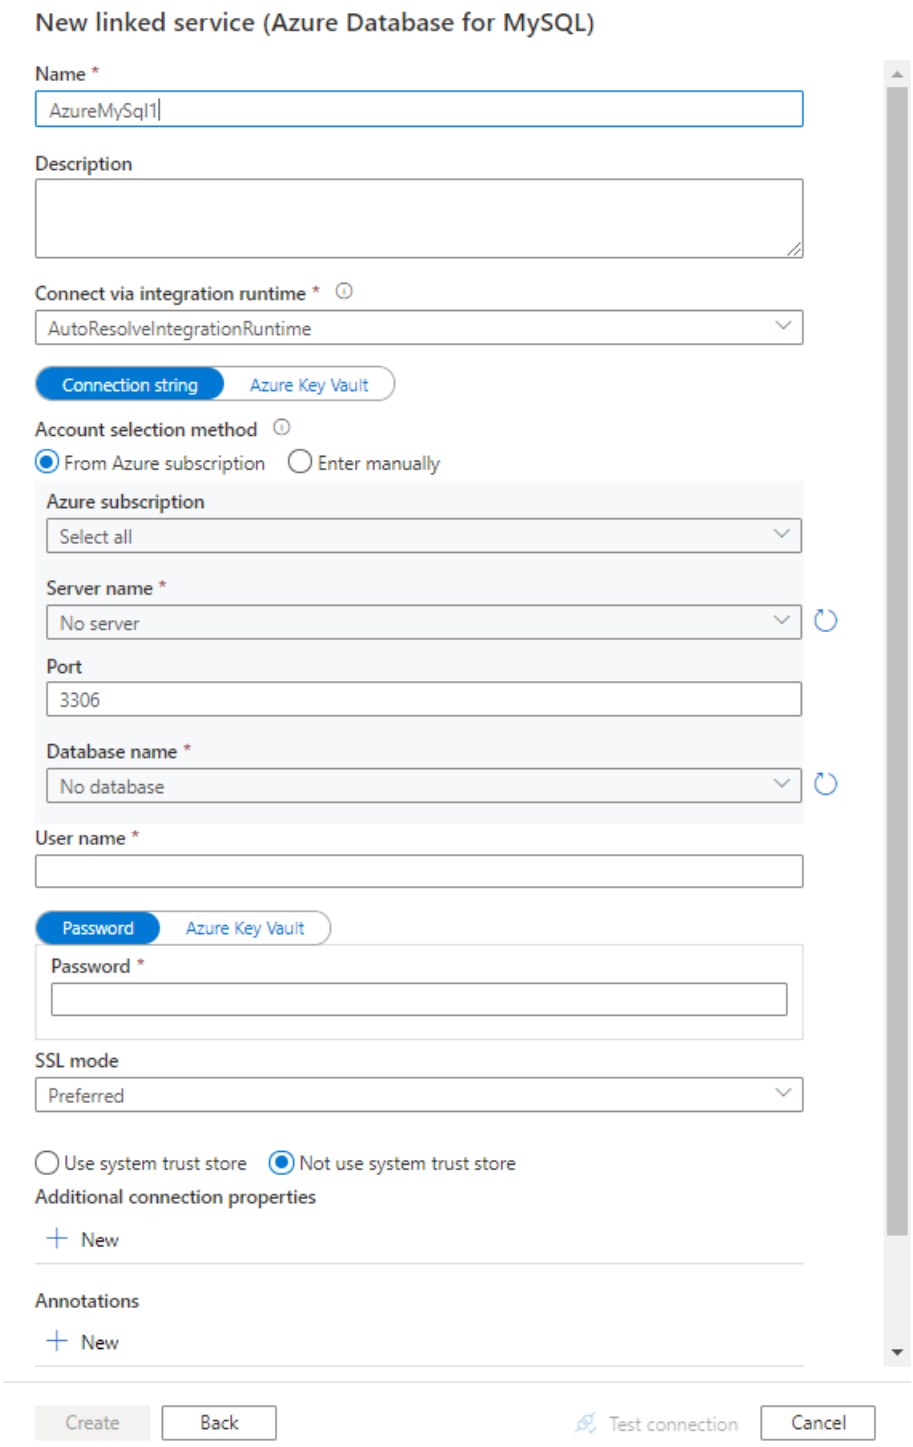
   - Azure Data Factory
   - Azure Synapse



2. Search for MySQL and select the Azure Database for MySQL connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Azure Database for MySQL connector.

Linked service properties

The following properties are supported for Azure Database for MySQL linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureMySql**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify information needed to connect to the Azure Database for MySQL instance. You can also put password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

A typical connection string is `Server=<server>.mysql.database.azure.com;Port=<port>;Database=<database>;UID=<username>;PWD=<password>`. More properties you can set per your case:

PROPERTY	DESCRIPTION	OPTIONS	REQUIRED
SSLMode	This option specifies whether the driver uses TLS encryption and verification when connecting to MySQL. E.g. `SSLMode=<0/1/2/3/4>`	DISABLED (0) / PREFERRED (1) **(Default)** / REQUIRED (2) / VERIFY_CA (3) / VERIFY_IDENTITY (4)	No
UseSystemTrustStore	This option specifies whether to use a CA certificate from the system trust store, or from a specified PEM file. E.g. `UseSystemTrustStore=<0/1>;`	Enabled (1) / Disabled (0) **(Default)**	No

Example:

```
{
    "name": "AzureDatabaseForMySQLLinkedService",
    "properties": {
        "type": "AzureMySql",
        "typeProperties": {
            "connectionString": "Server=<server>.mysql.database.azure.com;Port=<port>;Database=
<database>;UID=<username>;PWD=<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "AzureDatabaseForMySQLLinkedService",
    "properties": {
        "type": "AzureMySql",
        "typeProperties": {
            "connectionString": "Server=<server>.mysql.database.azure.com;Port=<port>;Database=
<database>;UID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Azure Database for MySQL dataset.

To copy data from Azure Database for MySQL, set the type property of the dataset to **AzureMySqlTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **AzureMySqlTable**	Yes
tableName	Name of the table in the MySQL database.	No (if "query" in activity source is specified)

Example

```
{
    "name": "AzureMySQLDataset",
    "properties": {
        "type": "AzureMySqlTable",
        "linkedServiceName": {
            "referenceName": "<Azure MySQL linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "<table name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Azure Database for MySQL source and sink.

Azure Database for MySQL as source

To copy data from Azure Database for MySQL, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **AzureMySqlSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)
queryCommandTimeout	The wait time before the query request times out. Default is 120 minutes (02:00:00)	No

Example:

```
"activities":[
    {
        "name": "CopyFromAzureDatabaseForMySQL",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure MySQL input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureMySqlSource",
                "query": "<custom query e.g. SELECT * FROM MyTable>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Database for MySQL as sink

To copy data to Azure Database for MySQL, the following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **AzureMySqlSink**	Yes

PROPERTY	DESCRIPTION	REQUIRED
preCopyScript	Specify a SQL query for the copy activity to execute before writing data into Azure Database for MySQL in each run. You can use this property to clean up the preloaded data.	No
writeBatchSize	Inserts data into the Azure Database for MySQL table when the buffer size reaches writeBatchSize. Allowed value is integer representing number of rows.	No (default is 10,000)
writeBatchTimeout	Wait time for the batch insert operation to complete before it times out. Allowed values are Timespan. An example is 00:30:00 (30 minutes).	No (default is 00:00:30)

Example:

```
"activities":[
    {
        "name": "CopyToAzureDatabaseForMySQL",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure MySQL output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureMySqlSink",
                "preCopyScript": "<custom SQL script>",
                "writeBatchSize": 100000
            }
        }
    }
]
```

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from Azure Database for MySQL. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use an Azure Database for MySQL dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Azure Database for MySQL source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow fetches all the data from the table specified in the dataset.	No	-	*(for inline dataset only)* tableName

Query	If you select Query as input, specify a SQL query to fetch data from source, which overrides any table you specify in dataset. Using queries is a great way to reduce rows for testing or lookups.
	
	Order By clause is not supported, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table that you can use in data flow.
	Query example:
	`select * from mytable where customerId > 1000 and customerId < 2000`
	or
	`select * from "MyTable"`
	.
		No	String	query

Stored procedure	If you select Stored procedure as input, specify a name of the stored procedure to read data from the source table, or select Refresh to ask the service to discover the procedure names.	Yes (if you select Stored procedure as input)	String	procedureName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Procedure parameters	If you select Stored procedure as input, specify any input parameters for the stored procedure in the order set in the procedure, or select Import to import all procedure parameters using the form `@paraName`.	No	Array	inputs
Batch size	Specify a batch size to chunk large data into batches.	No	Integer	batchSize
Isolation Level	Choose one of the following isolation levels: - Read Committed - Read Uncommitted (default) - Repeatable Read - Serializable - None (ignore isolation level)	No	READ_COMMITTED READ_UNCOMMITTED REPEATABLE_READ SERIALIZABLE NONE	isolationLevel

Azure Database for MySQL source script example

When you use Azure Database for MySQL as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    isolationLevel: 'READ_UNCOMMITTED',
    query: 'select * from mytable',
    format: 'query') ~> AzureMySQLSource
```

Sink transformation

The below table lists the properties supported by Azure Database for MySQL sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	deletable insertable updateable upsertable

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Key columns	For updates, upserts and deletes, key column(s) must be set to determine which row to alter. The column name that you pick as the key will be used as part of the subsequent update, upsert, delete. Therefore, you must pick a column that exists in the Sink mapping.	No	Array	keys
Skip writing key columns	If you wish to not write the value to the key column, select "Skip writing key columns".	No	`true` or `false`	skipKeyWrites
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate
Batch size	Specify how many rows are being written in each batch. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.	No	Integer	batchSize
Pre and Post SQL scripts	Specify multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database.	No	String	preSQLs postSQLs

TIP

1. It's recommended to break single batch scripts with multiple commands into multiple batches.
2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

- Enable incremental extract: Use this option to tell ADF to only process rows that have changed since the last time that the pipeline executed.
- Incremental date column: When using the incremental extract feature, you must choose the date/time column that you wish to use as the watermark in your source table.
- Start reading from beginning: Setting this option with incremental extract will instruct ADF to read all rows on first execution of a pipeline with incremental extract turned on.

Azure Database for MySQL sink script example

When you use Azure Database for MySQL as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:false,
    insertable:true,
    updateable:true,
    upsertable:true,
    keys:['keyColumn'],
    format: 'table',
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> AzureMySQLSink
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Data type mapping for Azure Database for MySQL

When copying data from Azure Database for MySQL, the following mappings are used from MySQL data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

AZURE DATABASE FOR MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`bigint`	`Int64`
`bigint unsigned`	`Decimal`
`bit`	`Boolean`
`bit(M), M>1`	`Byte[]`
`blob`	`Byte[]`
`bool`	`Int16`
`char`	`String`

AZURE DATABASE FOR MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`date`	`Datetime`
`datetime`	`Datetime`
`decimal`	`Decimal, String`
`double`	`Double`
`double precision`	`Double`
`enum`	`String`
`float`	`Single`
`int`	`Int32`
`int unsigned`	`Int64`
`integer`	`Int32`
`integer unsigned`	`Int64`
`long varbinary`	`Byte[]`
`long varchar`	`String`
`longblob`	`Byte[]`
`longtext`	`String`
`mediumblob`	`Byte[]`
`mediumint`	`Int32`
`mediumint unsigned`	`Int64`
`mediumtext`	`String`
`numeric`	`Decimal`
`real`	`Double`
`set`	`String`
`smallint`	`Int16`
`smallint unsigned`	`Int32`

AZURE DATABASE FOR MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`text`	`String`
`time`	`TimeSpan`
`timestamp`	`Datetime`
`tinyblob`	`Byte[]`
`tinyint`	`Int16`
`tinyint unsigned`	`Int16`
`tinytext`	`String`
`varchar`	`String`
`year`	`Int32`

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Azure Database for PostgreSQL using Azure Data Factory or Synapse Analytics

8/19/2022 • 15 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from and to Azure Database for PostgreSQL, and use Data Flow to transform data in Azure Database for PostgreSQL. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

This connector is specialized for the Azure Database for PostgreSQL service. To copy data from a generic PostgreSQL database located on-premises or in the cloud, use the PostgreSQL connector.

Supported capabilities

This Azure Database for PostgreSQL connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

The three activities work on all Azure Database for PostgreSQL deployment options:

- Single Server
- Flexible Server
- Hyperscale (Citus)

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

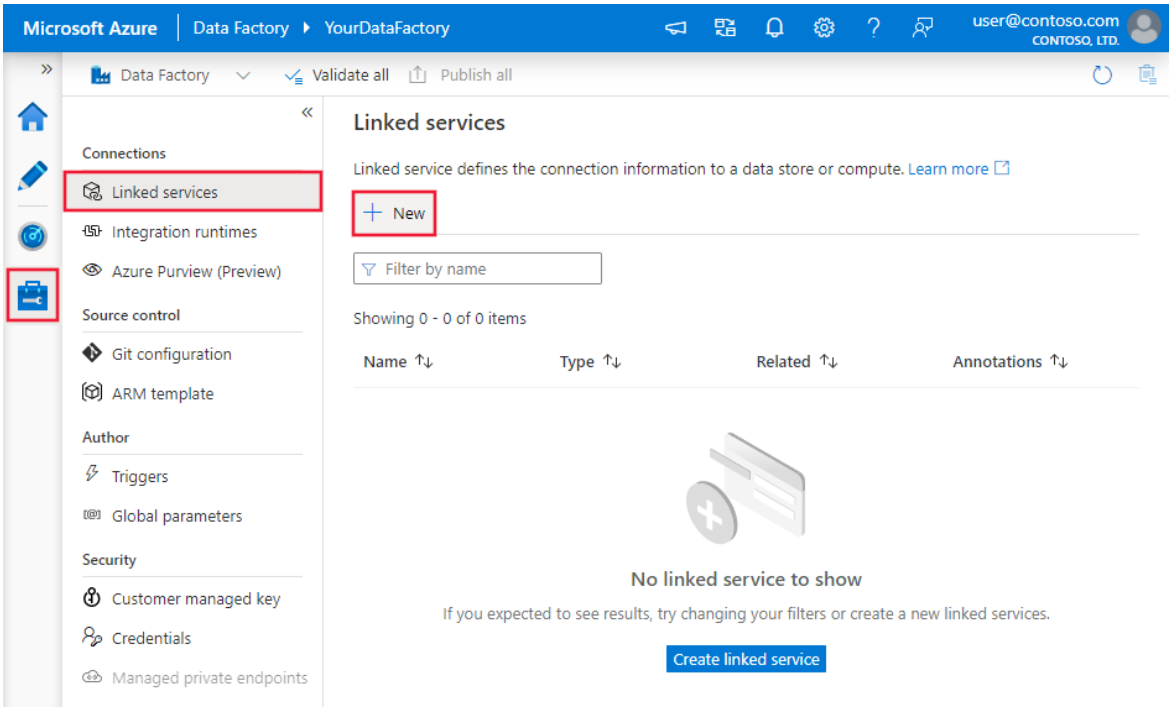
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure database for PostgreSQL using UI

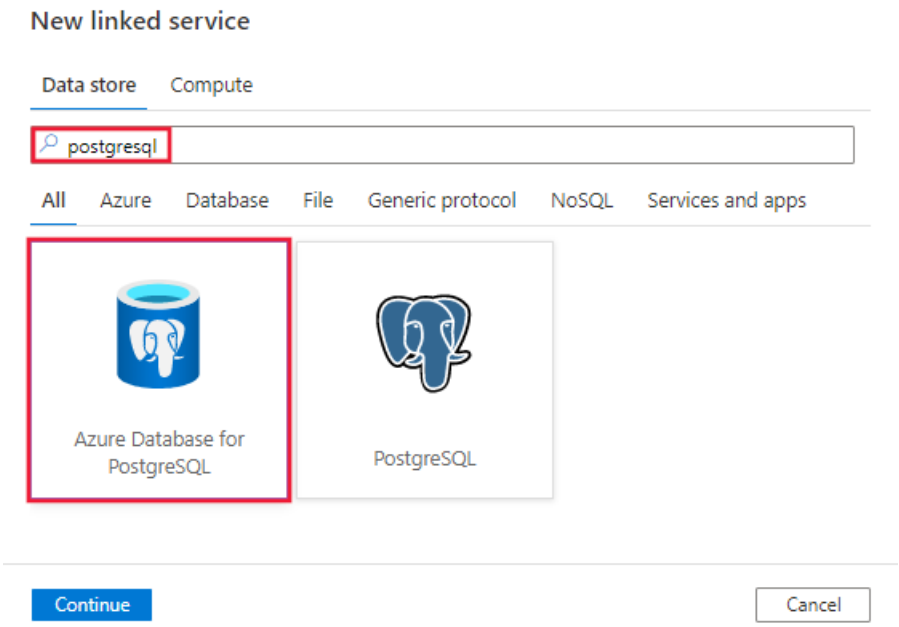
Use the following steps to create a linked service to Azure database for PostgreSQL in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

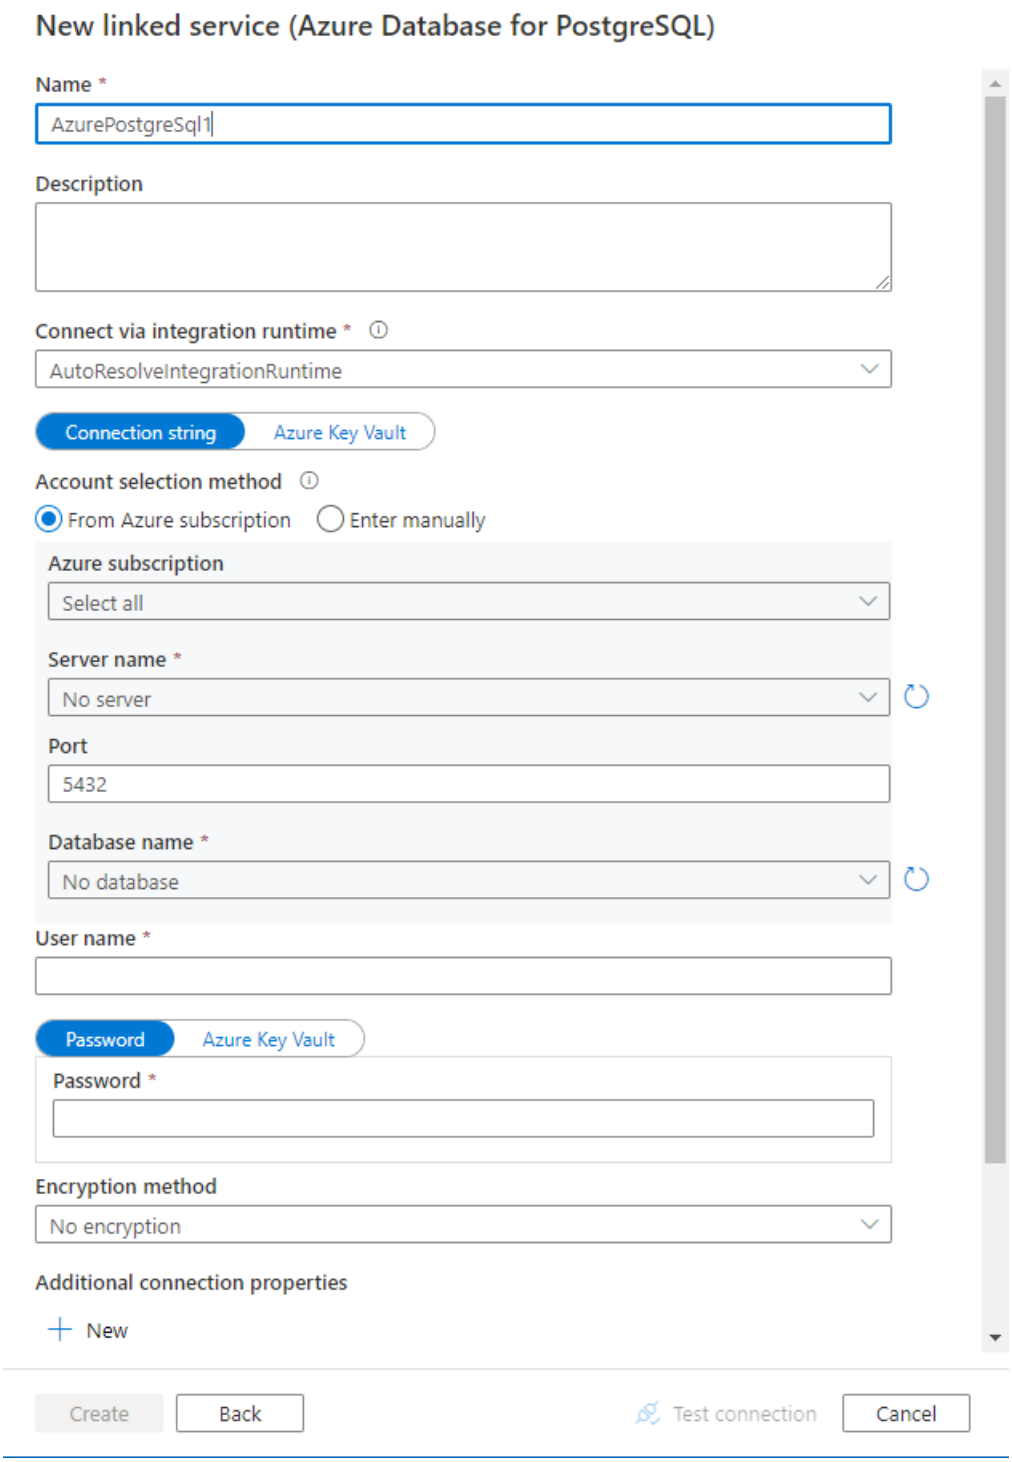
   - Azure Data Factory
   - Azure Synapse



2. Search for PostgreSQL and select the Azure database for PostgreSQL connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections offer details about properties that are used to define Data Factory entities specific to Azure Database for PostgreSQL connector.

Linked service properties

The following properties are supported for the Azure Database for PostgreSQL linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzurePostgreSql**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to Azure Database for PostgreSQL. You can also put a password in Azure Key Vault and pull the `password` configuration out of the connection string. See the following samples and Store credentials in Azure Key Vault for more details.	Yes
connectVia	This property represents the integration runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

A typical connection string is `Server=<server>.postgres.database.azure.com;Database=<database>;Port=<port>;UID=<username>;Password=<Password>`. Here are more properties you can set per your case:

PROPERTY	DESCRIPTION	OPTIONS	REQUIRED
EncryptionMethod (EM)	The method the driver uses to encrypt data sent between the driver and the database server. For example, `EncryptionMethod=<0/1/6>;`	0 (No Encryption) **(Default)** / 1 (SSL) / 6 (RequestSSL)	No
ValidateServerCertificate (VSC)	Determines whether the driver validates the certificate that's sent by the database server when SSL encryption is enabled (Encryption Method=1). For example, `ValidateServerCertificate=<0/1>;`	0 (Disabled) **(Default)** / 1 (Enabled)	No

Example:

```
{
    "name": "AzurePostgreSqlLinkedService",
    "properties": {
        "type": "AzurePostgreSql",
        "typeProperties": {
            "connectionString": "Server=<server>.postgres.database.azure.com;Database=<database>;Port=
<port>;UID=<username>;Password=<Password>"
        }
    }
}
```

Example:

Store password in Azure Key Vault

```
{
    "name": "AzurePostgreSqlLinkedService",
    "properties": {
        "type": "AzurePostgreSql",
        "typeProperties": {
            "connectionString": "Server=<server>.postgres.database.azure.com;Database=<database>;Port=
<port>;UID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see Datasets. This section provides a list of properties that Azure Database for PostgreSQL supports in datasets.

To copy data from Azure Database for PostgreSQL, set the type property of the dataset to **AzurePostgreSqlTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzurePostgreSqlTable**	Yes
tableName	Name of the table	No (if "query" in activity source is specified)

Example:

```
{
    "name": "AzurePostgreSqlDataset",
    "properties": {
        "type": "AzurePostgreSqlTable",
        "linkedServiceName": {
            "referenceName": "<AzurePostgreSql linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {}
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see Pipelines and activities. This section provides a list of properties supported by an Azure Database for PostgreSQL source.

Azure Database for PostgreSql as source

To copy data from Azure Database for PostgreSQL, set the source type in the copy activity to

AzurePostgreSqlSource. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AzurePostgreSqlSource**	Yes
query	Use the custom SQL query to read data. For example: `SELECT * FROM mytable` or `SELECT * FROM "MyTable"`. Note in PostgreSQL, the entity name is treated as case-insensitive if not quoted.	No (if the tableName property in the dataset is specified)
partitionOptions	Specifies the data partitioning options used to load data from Azure SQL Database. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from an Azure SQL Database is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`:		
partitionNames	The list of physical partitions that needs to be copied. Apply when the partition option is `PhysicalPartitionsOfTable`. If you use a query to retrieve the source data, hook `?AdfTabularPartitionName` in the WHERE clause. For an example, see the Parallel copy from Azure Database for PostgreSQL section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int` , `smallint` , `bigint` , `date` , `timestamp without time zone` , `timestamp with time zone` or `time without time zone`) that will be used by range partitioning for parallel copy. If not specified, the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange` . If you use a query to retrieve the source data, hook `?AdfRangePartitionColumnName` in the WHERE clause. For an example, see the Parallel copy from Azure Database for PostgreSQL section.	No
partitionUpperBound	The maximum value of the partition column to copy data out. Apply when the partition option is `DynamicRange` . If you use a query to retrieve the source data, hook `?AdfRangePartitionUpbound` in the WHERE clause. For an example, see the Parallel copy from Azure Database for PostgreSQL section.	No
partitionLowerBound	The minimum value of the partition column to copy data out. Apply when the partition option is `DynamicRange` . If you use a query to retrieve the source data, hook `?AdfRangePartitionLowbound` in the WHERE clause. For an example, see the Parallel copy from Azure Database for PostgreSQL section.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAzurePostgreSql",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<AzurePostgreSql input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzurePostgreSqlSource",
                "query": "<custom query e.g. SELECT * FROM mytable>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Database for PostgreSQL as sink

To copy data to Azure Database for PostgreSQL, the following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **AzurePostgreSQLSink**.	Yes
preCopyScript	Specify a SQL query for the copy activity to execute before you write data into Azure Database for PostgreSQL in each run. You can use this property to clean up the preloaded data.	No
writeMethod	The method used to write data into Azure Database for PostgreSQL. Allowed values are: **CopyCommand** (default, which is more performant), **BulkInsert**.	No
writeBatchSize	The number of rows loaded into Azure Database for PostgreSQL per batch. Allowed value is an integer that represents the number of rows.	No (default is 1,000,000)

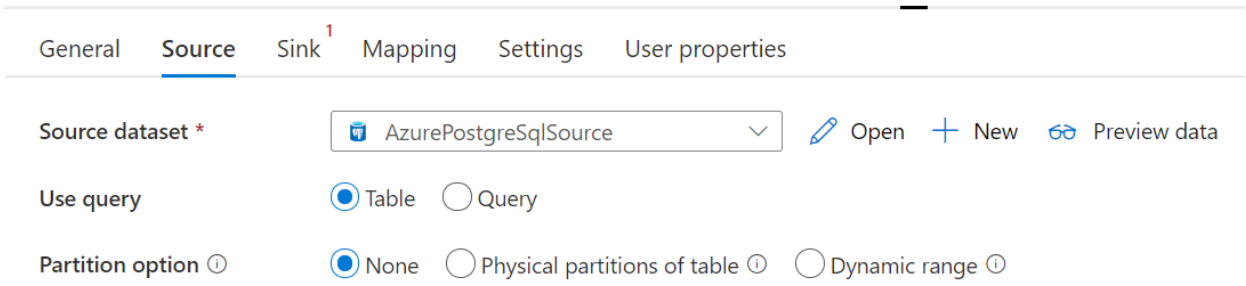
PROPERTY	DESCRIPTION	REQUIRED
writeBatchTimeout	Wait time for the batch insert operation to complete before it times out. Allowed values are Timespan strings. An example is 00:30:00 (30 minutes).	No (default is 00:30:00)

Example:

```
"activities":[
    {
        "name": "CopyToAzureDatabaseForPostgreSQL",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure PostgreSQL output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzurePostgreSQLSink",
                "preCopyScript": "<custom SQL script>",
                "writeMethod": "CopyCommand",
                "writeBatchSize": 1000000
            }
        }
    }
]
```

Parallel copy from Azure Database for PostgreSQL

The Azure Database for PostgreSQL connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your Azure Database for PostgreSQL source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Azure Database for PostgreSQL.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Azure Database for PostgreSQL. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions.
Full load from large table, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column**: Specify the column used to partition data. If not specified, the primary key column is used.
Load a large amount of data by using a custom query, with physical partitions.	**Partition option**: Physical partitions of table. **Query**: `SELECT * FROM ?AdfTabularPartitionName WHERE <your_additional_where_clause>` . **Partition name**: Specify the partition name(s) to copy data from. If not specified, the service automatically detects the physical partitions on the table you specified in the PostgreSQL dataset. During execution, the service replaces `?AdfTabularPartitionName` with the actual partition name, and sends to Azure Database for PostgreSQL.
Load a large amount of data by using a custom query, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Query**: `SELECT * FROM ?AdfTabularPartitionName WHERE ? AdfRangePartitionColumnName <= ? AdfRangePartitionUpbound AND ? AdfRangePartitionColumnName >= ? AdfRangePartitionLowbound AND <your_additional_where_clause>` . **Partition column**: Specify the column used to partition data. You can partition against the column with integer or date/datetime data type. **Partition upper bound** and **partition lower bound**: Specify if you want to filter against partition column to retrieve data only between the lower and upper range. During execution, the service replaces `?AdfRangePartitionColumnName`, `?AdfRangePartitionUpbound`, and `?AdfRangePartitionLowbound` with the actual column name and value ranges for each partition, and sends to Azure Database for PostgreSQL. For example, if your partition column "ID" is set with the lower bound as 1 and the upper bound as 80, with parallel copy set as 4, the service retrieves data by 4 partitions. Their IDs are between [1,20], [21, 40], [41, 60], and [61, 80], respectively.

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.

3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).

Example: full load from large table with physical partitions

```
"source": {
    "type": "AzurePostgreSqlSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "AzurePostgreSqlSource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from Azure Database for PostgreSQL. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use an Azure Database for PostgreSQL dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Azure Database for PostgreSQL source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow fetches all the data from the table specified in the dataset.	No	-	*(for inline dataset only)* tableName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Query	If you select Query as input, specify a SQL query to fetch data from source, which overrides any table you specify in dataset. Using queries is a great way to reduce rows for testing or lookups. **Order By** clause is not supported, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table that you can use in data flow. Query example: `select * from mytable where customerId > 1000 and customerId < 2000` or `select * from "MyTable"`. Note in PostgreSQL, the entity name is treated as case-insensitive if not quoted.	No	String	query
Schema name	If you select Stored procedure as input, specify a schema name of the stored procedure, or select Refresh to ask the service to discover the schema names.	No	String	schemaName
Stored procedure	If you select Stored procedure as input, specify a name of the stored procedure to read data from the source table, or select Refresh to ask the service to discover the procedure names.	Yes (if you select Stored procedure as input)	String	procedureName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Procedure parameters	If you select Stored procedure as input, specify any input parameters for the stored procedure in the order set in the procedure, or select Import to import all procedure parameters using the form `@paraName`.	No	Array	inputs
Batch size	Specify a batch size to chunk large data into batches.	No	Integer	batchSize
Isolation Level	Choose one of the following isolation levels: - Read Committed - Read Uncommitted (default) - Repeatable Read - Serializable - None (ignore isolation level)	No	READ_COMMITTED READ_UNCOMMITTED REPEATABLE_READ SERIALIZABLE NONE	isolationLevel

Azure Database for PostgreSQL source script example

When you use Azure Database for PostgreSQL as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    isolationLevel: 'READ_UNCOMMITTED',
    query: 'select * from mytable',
    format: 'query') ~> AzurePostgreSQLSource
```

Sink transformation

The below table lists the properties supported by Azure Database for PostgreSQL sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	deletable insertable updateable upsertable

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Key columns	For updates, upserts and deletes, key column(s) must be set to determine which row to alter. The column name that you pick as the key will be used as part of the subsequent update, upsert, delete. Therefore, you must pick a column that exists in the Sink mapping.	No	Array	keys
Skip writing key columns	If you wish to not write the value to the key column, select "Skip writing key columns".	No	`true` or `false`	skipKeyWrites
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate
Batch size	Specify how many rows are being written in each batch. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.	No	Integer	batchSize

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Select user DB schema	By default, a temporary table will be created under the sink schema as staging. You can alternatively uncheck the **Use sink schema** option and instead, specify a schema name under which Data Factory will create a staging table to load upstream data and automatically clean them up upon completion. Make sure you have create table permission in the database and alter permission on the schema.	No	String	stagingSchemaName
Pre and Post SQL scripts	Specify multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database.	No	String	preSQLs postSQLs

TIP

1. It's recommended to break single batch scripts with multiple commands into multiple batches.
2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

- Enable incremental extract: Use this option to tell ADF to only process rows that have changed since the last time that the pipeline executed.
- Incremental date column: When using the incremental extract feature, you must choose the date/time column that you wish to use as the watermark in your source table.
- Start reading from beginning: Setting this option with incremental extract will instruct ADF to read all rows on first execution of a pipeline with incremental extract turned on.

Azure Database for PostgreSQL sink script example

When you use Azure Database for PostgreSQL as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:false,
    insertable:true,
    updateable:true,
    upsertable:true,
    keys:['keyColumn'],
    format: 'table',
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> AzurePostgreSQLSink
```

Lookup activity properties

For more information about the properties, see Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data to and from Azure Databricks Delta Lake using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 14 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy activity in Azure Data Factory and Azure Synapse to copy data to and from Azure Databricks Delta Lake. It builds on the Copy activity article, which presents a general overview of copy activity.

Supported capabilities

This Azure Databricks Delta Lake connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

In general, the service supports Delta Lake with the following capabilities to meet your various needs.

- Copy activity supports Azure Databricks Delta Lake connector to copy data from any supported source data store to Azure Databricks delta lake table, and from delta lake table to any supported sink data store. It leverages your Databricks cluster to perform the data movement, see details in Prerequisites section.
- Mapping Data Flow supports generic Delta format on Azure Storage as source and sink to read and write Delta files for code-free ETL, and runs on managed Azure Integration Runtime.
- Databricks activities supports orchestrating your code-centric ETL or machine learning workload on top of delta lake.

Prerequisites

To use this Azure Databricks Delta Lake connector, you need to set up a cluster in Azure Databricks.

- To copy data to delta lake, Copy activity invokes Azure Databricks cluster to read data from an Azure Storage, which is either your original source or a staging area to where the service firstly writes the source data via built-in staged copy. Learn more from Delta lake as the sink.
- Similarly, to copy data from delta lake, Copy activity invokes Azure Databricks cluster to write data to an Azure Storage, which is either your original sink or a staging area from where the service continues to write data to final sink via built-in staged copy. Learn more from Delta lake as the source.

The Databricks cluster needs to have access to Azure Blob or Azure Data Lake Storage Gen2 account, both the storage container/file system used for source/sink/staging and the container/file system where you want to write the Delta Lake tables.

- To use **Azure Data Lake Storage Gen2**, you can configure a **service principal** on the Databricks cluster as part of the Apache Spark configuration. Follow the steps in Access directly with service principal.
- To use **Azure Blob storage**, you can configure a **storage account access key** or **SAS token** on the Databricks cluster as part of the Apache Spark configuration. Follow the steps in Access Azure Blob storage using the RDD API.

During copy activity execution, if the cluster you configured has been terminated, the service automatically starts it. If you author pipeline using authoring UI, for operations like data preview, you need to have a live cluster, the service won't start the cluster on your behalf.

Specify the cluster configuration

1. In the **Cluster Mode** drop-down, select **Standard**.
2. In the **Databricks Runtime Version** drop-down, select a Databricks runtime version.
3. Turn on Auto Optimize by adding the following properties to your Spark configuration:

   ```
   spark.databricks.delta.optimizeWrite.enabled true
   spark.databricks.delta.autoCompact.enabled true
   ```

4. Configure your cluster depending on your integration and scaling needs.

For cluster configuration details, see Configure clusters.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

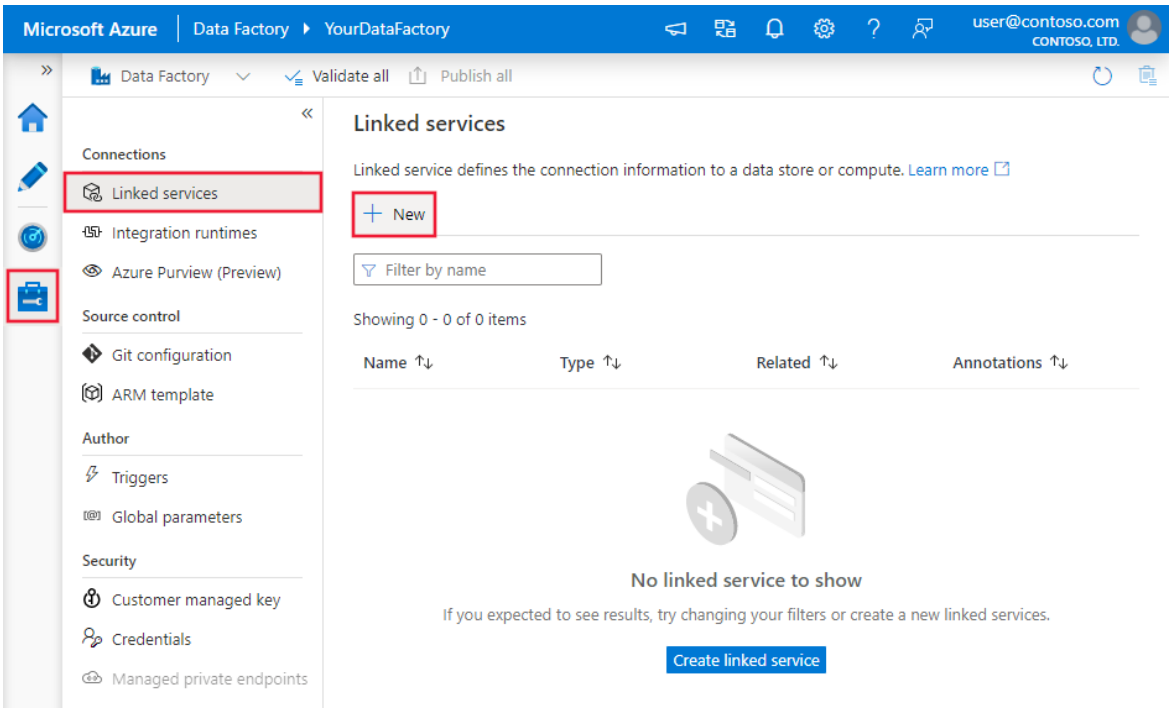
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Databricks Delta Lake using UI

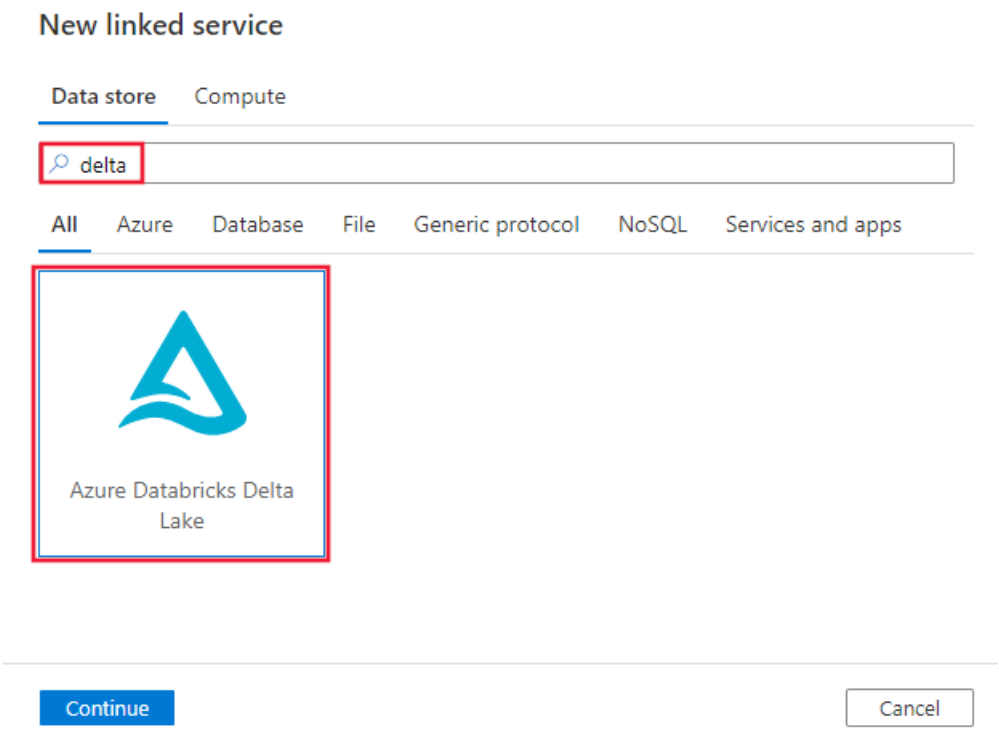
Use the following steps to create a linked service to Azure Databricks Delta Lake in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

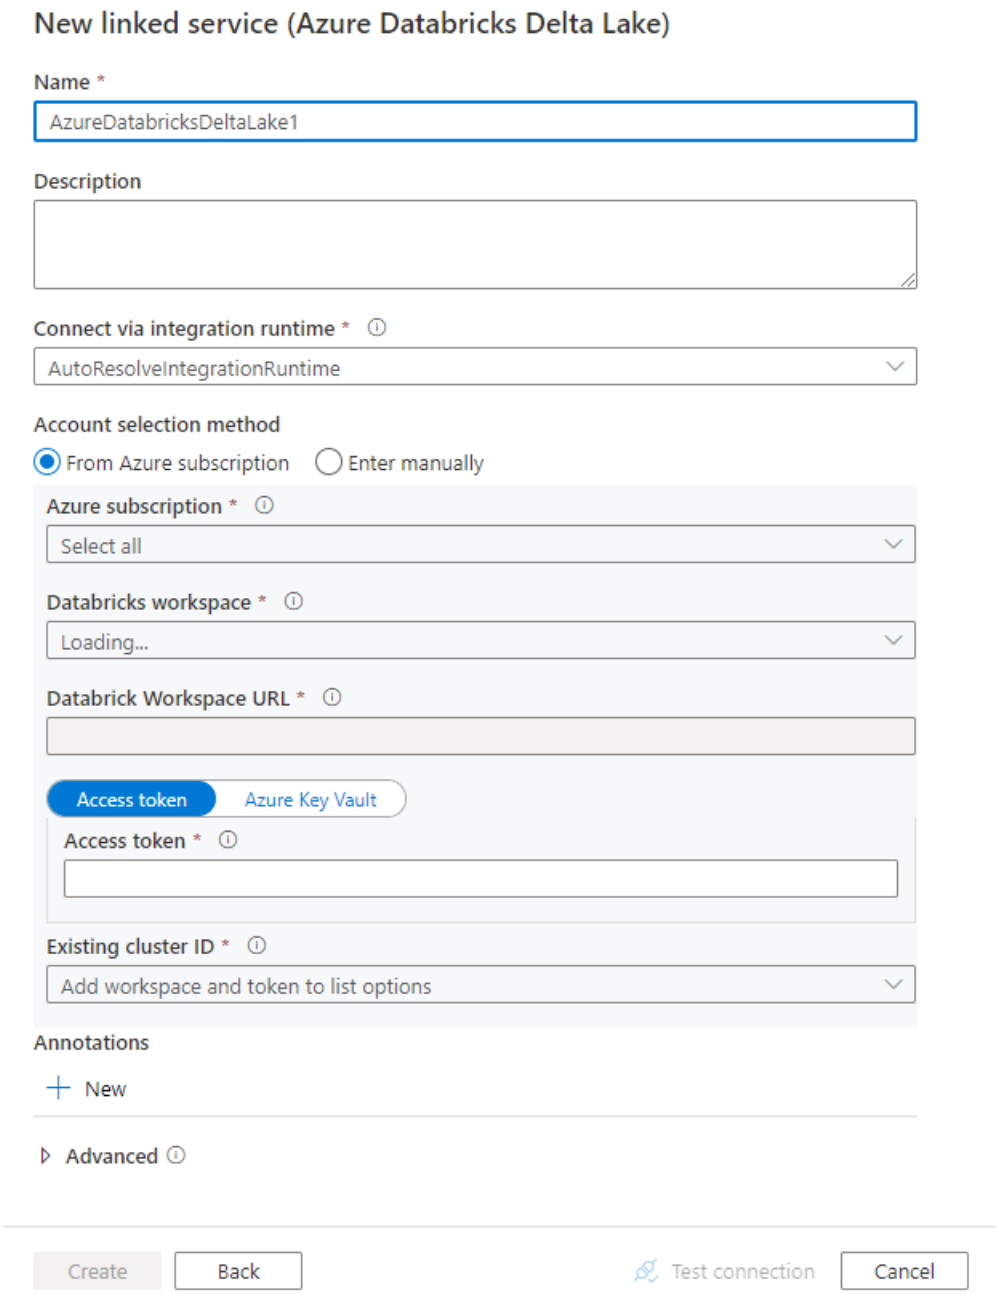
   - Azure Data Factory
   - Azure Synapse



2. Search for delta and select the Azure Databricks Delta Lake connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that define entities specific to an Azure Databricks Delta Lake connector.

Linked service properties

This Azure Databricks Delta Lake connector supports the following authentication types. See the corresponding sections for details.

- Access token
- System-assigned managed identity authentication
- User-assigned managed identity authentication

Access token

The following properties are supported for the Azure Databricks Delta Lake linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureDatabricksDeltaLake**.	Yes
domain	Specify the Azure Databricks workspace URL, e.g. `https://adb-xxxxxxxxx.xx.azuredatabricks.net`.	
clusterId	Specify the cluster ID of an existing cluster. It should be an already created Interactive Cluster. You can find the Cluster ID of an Interactive Cluster on Databricks workspace -> Clusters -> Interactive Cluster Name -> Configuration -> Tags. Learn more.	
accessToken	Access token is required for the service to authenticate to Azure Databricks. Access token needs to be generated from the databricks workspace. More detailed steps to find the access token can be found here.	
connectVia	The integration runtime that is used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime (if your data store is located in a private network). If not specified, it uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AzureDatabricksDeltaLakeLinkedService",
    "properties": {
        "type": "AzureDatabricksDeltaLake",
        "typeProperties": {
            "domain": "https://adb-xxxxxxxxx.xx.azuredatabricks.net",
            "clusterId": "<cluster id>",
            "accessToken": {
                "type": "SecureString",
                "value": "<access token>"
           }
        }
    }
}
```

System-assigned managed identity authentication

To learn more about system-assigned managed identities for Azure resources, see system-assigned managed identity for Azure resources.

To use system-assigned managed identity authentication, follow these steps to grant permissions:

1. Retrieve the managed identity information by copying the value of the **managed identity object ID** generated along with your data factory or Synapse workspace.

2. Grant the managed identity the correct permissions in Azure Databricks. In general, you must grant at least the **Contributor** role to your system-assigned managed identity in **Access control (IAM)** of Azure Databricks.

The following properties are supported for the Azure Databricks Delta Lake linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureDatabricksDeltaLake**.	Yes
domain	Specify the Azure Databricks workspace URL, e.g. `https://adb-xxxxxxxxx.xx.azuredatabricks.net`.	Yes
clusterId	Specify the cluster ID of an existing cluster. It should be an already created Interactive Cluster. You can find the Cluster ID of an Interactive Cluster on Databricks workspace -> Clusters -> Interactive Cluster Name -> Configuration -> Tags. Learn more.	Yes
workspaceResourceId	Specify the workspace resource ID of your Azure Databricks.	Yes
connectVia	The integration runtime that is used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime (if your data store is located in a private network). If not specified, it uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AzureDatabricksDeltaLakeLinkedService",
    "properties": {
        "type": "AzureDatabricksDeltaLake",
        "typeProperties": {
            "domain": "https://adb-xxxxxxxxx.xx.azuredatabricks.net",
            "clusterId": "<cluster id>",
            "workspaceResourceId": "<workspace resource id>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

To learn more about user-assigned managed identities for Azure resources, see user-assigned managed identities

To use user-assigned managed identity authentication, follow these steps:

1. Create one or multiple user-assigned managed identities and grant permission in your Azure Databricks. In general, you must grant at least the **Contributor** role to your user-assigned managed identity in **Access control (IAM)** of Azure Databricks.
2. Assign one or multiple user-assigned managed identities to your data factory or Synapse workspace, and create credentials for each user-assigned managed identity.

The following properties are supported for the Azure Databricks Delta Lake linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureDatabricksDeltaLake**.	Yes
domain	Specify the Azure Databricks workspace URL, e.g. `https://adb-xxxxxxxxx.xx.azuredatabricks.net`.	Yes
clusterId	Specify the cluster ID of an existing cluster. It should be an already created Interactive Cluster. You can find the Cluster ID of an Interactive Cluster on Databricks workspace -> Clusters -> Interactive Cluster Name -> Configuration -> Tags. Learn more.	Yes
credentials	Specify the user-assigned managed identity as the credential object.	Yes
workspaceResourceId	Specify the workspace resource ID of your Azure Databricks.	Yes
connectVia	The integration runtime that is used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime (if your data store is located in a private network). If not specified, it uses the default Azure integration runtime.	No

Example:

```
{
    "name": "AzureDatabricksDeltaLakeLinkedService",
    "properties": {
        "type": "AzureDatabricksDeltaLake",
        "typeProperties": {
            "domain": "https://adb-xxxxxxxxx.xx.azuredatabricks.net",
            "clusterId": "<cluster id>",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            },
            "workspaceResourceId": "<workspace resource id>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

The following properties are supported for the Azure Databricks Delta Lake dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzureDatabricksDeltaLakeDataset**.	Yes
database	Name of the database.	No for source, yes for sink
table	Name of the delta table.	No for source, yes for sink

Example:

```
{
    "name": "AzureDatabricksDeltaLakeDataset",
    "properties": {
        "type": "AzureDatabricksDeltaLakeDataset",
        "typeProperties": {
            "database": "<database name>",
            "table": "<delta table name>"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "linkedServiceName": {
            "referenceName": "<name of linked service>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Azure Databricks Delta Lake source and sink.

Delta lake as source

To copy data from Azure Databricks Delta Lake, the following properties are supported in the Copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the Copy activity source must be set to **AzureDatabricksDeltaLakeSource**.	Yes

query	Specify the SQL query to read data. For the time travel control, follow the below pattern:
	-
	`SELECT * FROM events TIMESTAMP AS OF timestamp_expression`
	-
	`SELECT * FROM events VERSION AS OF version`
		No

exportSettings	Advanced settings used to retrieve data from delta table.	No
Under `exportSettings`*:*		
type	The type of export command, set to **AzureDatabricksDeltaLakeExportCommand**.	Yes
dateFormat	Format date type to string with a date format. Custom date formats follow the formats at datetime pattern. If not specified, it uses the default value `yyyy-MM-dd`.	No
timestampFormat	Format timestamp type to string with a timestamp format. Custom date formats follow the formats at datetime pattern. If not specified, it uses the default value `yyyy-MM-dd'T'HH:mm:ss[.SSS][XXX]`.	No

Direct copy from delta lake

If your sink data store and format meet the criteria described in this section, you can use the Copy activity to directly copy from Azure Databricks Delta table to sink. The service checks the settings and fails the Copy activity run if the following criteria is not met:

- The **sink linked service** is Azure Blob storage or Azure Data Lake Storage Gen2. The account credential should be pre-configured in Azure Databricks cluster configuration, learn more from Prerequisites.
- The **sink data format** is of **Parquet**, **delimited text**, or **Avro** with the following configurations, and points to a folder instead of file.
  - For **Parquet** format, the compression codec is **none**, **snappy**, or **gzip**.
  - For **delimited text** format:
    - `rowDelimiter` is any single character.
    - `compression` can be **none**, **bzip2**, **gzip**.

    - `encodingName` UTF-7 is not supported.
  - For **Avro** format, the compression codec is **none**, **deflate**, or **snappy**.
- In the Copy activity source, `additionalColumns` is not specified.
- If copying data to delimited text, in copy activity sink, `fileExtension` need to be ".csv".
- In the Copy activity mapping, type conversion is not enabled.

Example:

```
"activities":[
    {
        "name": "CopyFromDeltaLake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delta lake input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureDatabricksDeltaLakeSource",
                "sqlReaderQuery": "SELECT * FROM events TIMESTAMP AS OF timestamp_expression"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Staged copy from delta lake

When your sink data store or format does not match the direct copy criteria, as mentioned in the last section, enable the built-in staged copy using an interim Azure storage instance. The staged copy feature also provides you better throughput. The service exports data from Azure Databricks Delta Lake into staging storage, then copies the data to sink, and finally cleans up your temporary data from the staging storage. See Staged copy for details about copying data by using staging.

To use this feature, create an Azure Blob storage linked service or Azure Data Lake Storage Gen2 linked service that refers to the storage account as the interim staging. Then specify the `enableStaging` and `stagingSettings` properties in the Copy activity.

> **NOTE**
> The staging storage account credential should be pre-configured in Azure Databricks cluster configuration, learn more from Prerequisites.

Example:

```
"activities":[
    {
        "name": "CopyFromDeltaLake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delta lake input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureDatabricksDeltaLakeSource",
                "sqlReaderQuery": "SELECT * FROM events TIMESTAMP AS OF timestamp_expression"
            },
            "sink": {
                "type": "<sink type>"
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingStorage",
                    "type": "LinkedServiceReference"
                },
                "path": "mystagingpath"
            }
        }
    }
]
```

Delta lake as sink

To copy data to Azure Databricks Delta Lake, the following properties are supported in the Copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the Copy activity sink, set to **AzureDatabricksDeltaLakeSink**.	Yes
preCopyScript	Specify a SQL query for the Copy activity to run before writing data into Databricks delta table in each run. Example : `VACUUM eventsTable DRY RUN` You can use this property to clean up the preloaded data, or add a truncate table or Vacuum statement.	No
importSettings	Advanced settings used to write data into delta table.	No
Under `importSettings`*:*		

PROPERTY	DESCRIPTION	REQUIRED
type	The type of import command, set to **AzureDatabricksDeltaLakeImport Command**.	Yes
dateFormat	Format string to date type with a date format. Custom date formats follow the formats at datetime pattern. If not specified, it uses the default value `yyyy-MM-dd`.	No
timestampFormat	Format string to timestamp type with a timestamp format. Custom date formats follow the formats at datetime pattern. If not specified, it uses the default value `yyyy-MM-dd'T'HH:mm:ss[.SSS][XXX]`.	No

Direct copy to delta lake

If your source data store and format meet the criteria described in this section, you can use the Copy activity to directly copy from source to Azure Databricks Delta Lake. The service checks the settings and fails the Copy activity run if the following criteria is not met:

- The **source linked service** is Azure Blob storage or Azure Data Lake Storage Gen2. The account credential should be pre-configured in Azure Databricks cluster configuration, learn more from Prerequisites.
- The **source data format** is of **Parquet**, **delimited text**, or **Avro** with the following configurations, and points to a folder instead of file.
  - For **Parquet** format, the compression codec is **none**, **snappy**, or **gzip**.
  - For **delimited text** format:
    - `rowDelimiter` is default, or any single character.
    - `compression` can be **none**, **bzip2**, **gzip**.
    - `encodingName` UTF-7 is not supported.
  - For **Avro** format, the compression codec is **none**, **deflate**, or **snappy**.
- In the Copy activity source:
  - `wildcardFileName` only contains wildcard `*` but not `?`, and `wildcardFolderName` is not specified.
  - `prefix`, `modifiedDateTimeStart`, `modifiedDateTimeEnd`, and `enablePartitionDiscovery` are not specified.
  - `additionalColumns` is not specified.
- In the Copy activity mapping, type conversion is not enabled.

Example:

```
"activities":[
    {
        "name": "CopyToDeltaLake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Delta lake output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureDatabricksDeltaLakeSink",
                "sqlReadrQuery": "VACUUM eventsTable DRY RUN"
            }
        }
    }
]
```

Staged copy to delta lake

When your source data store or format does not match the direct copy criteria, as mentioned in the last section, enable the built-in staged copy using an interim Azure storage instance. The staged copy feature also provides you better throughput. The service automatically converts the data to meet the data format requirements into staging storage, then load data into delta lake from there. Finally, it cleans up your temporary data from the storage. See Staged copy for details about copying data using staging.

To use this feature, create an Azure Blob storage linked service or Azure Data Lake Storage Gen2 linked service that refers to the storage account as the interim staging. Then specify the `enableStaging` and `stagingSettings` properties in the Copy activity.

> **NOTE**
>
> The staging storage account credential should be pre-configured in Azure Databricks cluster configuration, learn more from Prerequisites.

Example:

```
"activities":[
    {
        "name": "CopyToDeltaLake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Delta lake output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureDatabricksDeltaLakeSink"
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingBlob",
                    "type": "LinkedServiceReference"
                },
                "path": "mystagingpath"
            }
        }
    }
]
```

Monitoring

The same copy activity monitoring experience is provided as for other connectors. In addition, because loading data from/to delta lake is running on your Azure Databricks cluster, you can further view detailed cluster logs and monitor performance.

Lookup activity properties

For more information about the properties, see Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by Copy activity, see supported data stores and formats.

Copy data from or to Azure Files by using Azure Data Factory

8/19/2022 • 20 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data to and from Azure Files. To learn about Azure Data Factory, read the introductory article.

Supported capabilities

This Azure Files connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓ Exclude storage account V1
Lookup activity	① ②	✓ Exclude storage account V1
GetMetadata activity	① ②	✓ Exclude storage account V1
Delete activity	① ②	✓ Exclude storage account V1

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from Azure Files to any supported sink data store, or copy data from any supported source data store to Azure Files. For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Specifically, this Azure Files connector supports:

- Copying files by using account key or service shared access signature (SAS) authentications.
- Copying files as-is or parsing/generating files with the supported file formats and compression codecs.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

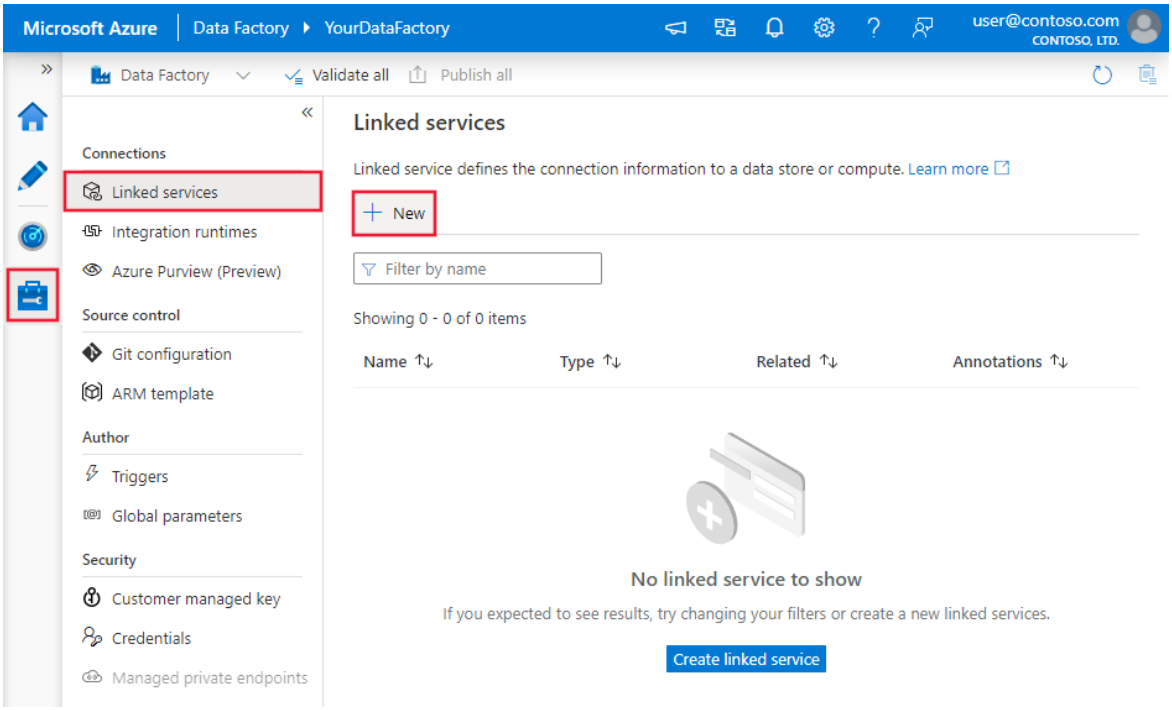
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Azure Files using UI

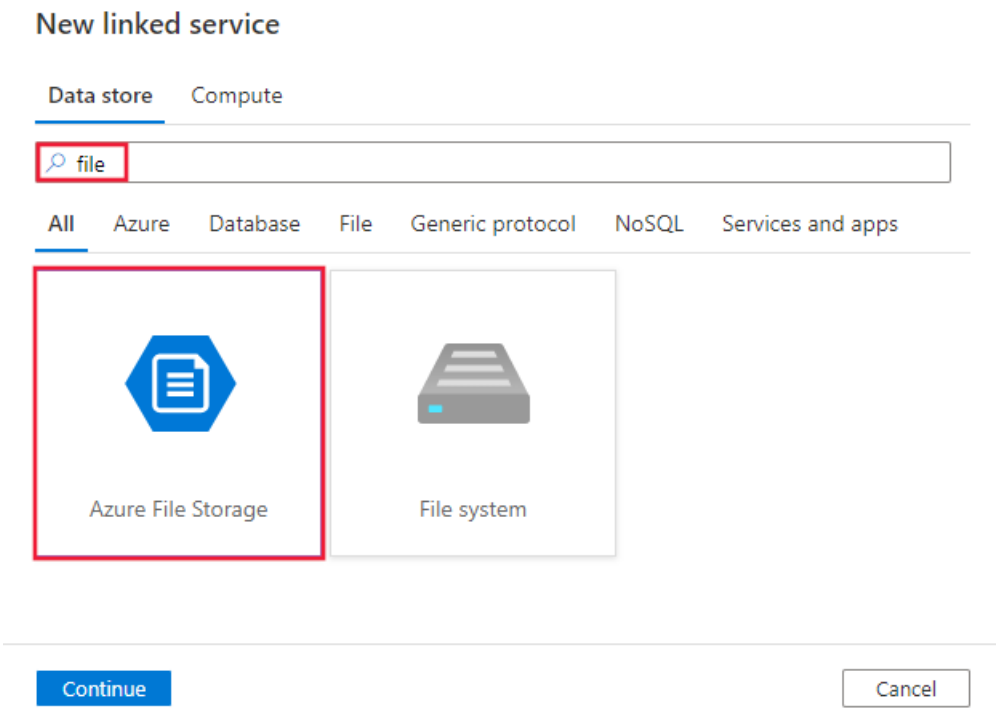
Use the following steps to create a linked service to Azure Files in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

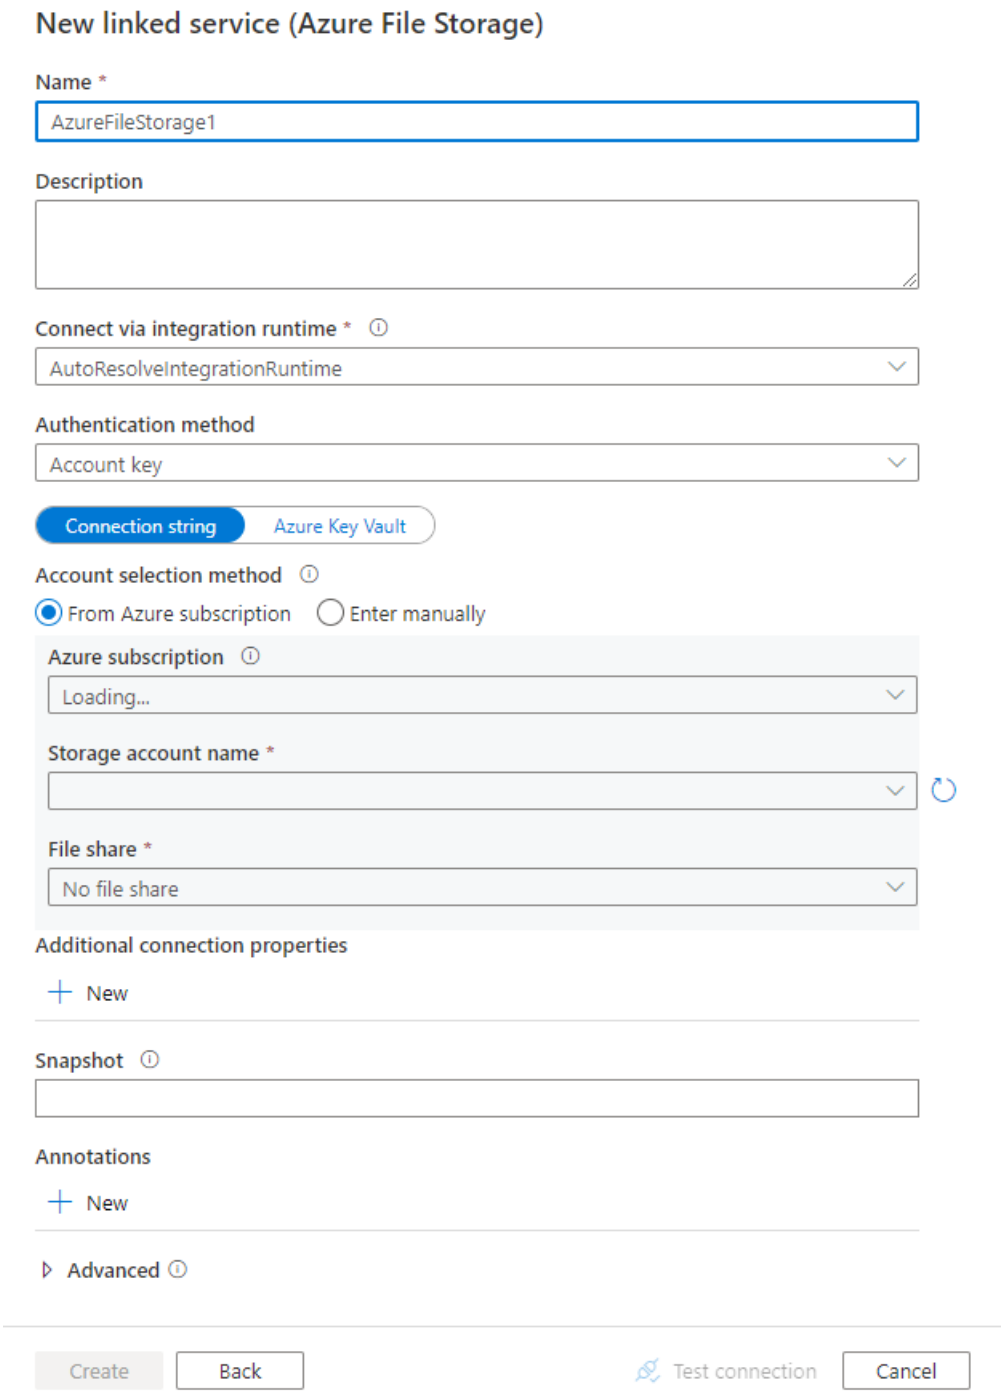
   - Azure Data Factory
   - Azure Synapse



2. Search for file and select the connector for Azure Files labeled *Azure File Storage*.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Azure Files.

Linked service properties

The Azure Files connector supports the following authentication types. See the corresponding sections for details.

- Account key authentication
- Shared access signature authentication

> **NOTE**
>
> If you were using Azure Files linked service with legacy model, where on ADF authoring UI shown as "Basic authentication", it is still supported as-is, while you are suggested to use the new model going forward. The legacy model transfers data from/to storage over Server Message Block (SMB), while the new model utilizes the storage SDK which has better throughput. To upgrade, you can edit your linked service to switch the authentication method to "Account key" or "SAS URI"; no change needed on dataset or copy activity.

Account key authentication

Data Factory supports the following properties for Azure Files account key authentication:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureFileStorage**.	Yes
connectionString	Specify the information needed to connect to Azure Files. You can also put the account key in Azure Key Vault and pull the `accountKey` configuration out of the connection string. For more information, see the following samples and the Store credentials in Azure Key Vault article.	Yes
fileShare	Specify the file share.	Yes
snapshot	Specify the date of the file share snapshot if you want to copy from a snapshot.	No
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "AzureFileStorageLinkedService",
    "properties": {
        "type": "AzureFileStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountName>;AccountKey=
<accountKey>;EndpointSuffix=core.windows.net;",
            "fileShare": "<file share name>"
        },
        "connectVia": {
          "referenceName": "<name of Integration Runtime>",
          "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store the account key in Azure Key Vault

```
{
    "name": "AzureFileStorageLinkedService",
    "properties": {
        "type": "AzureFileStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;",
            "fileShare": "<file share name>",
            "accountKey": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Shared access signature authentication

A shared access signature provides delegated access to resources in your storage account. You can use a shared access signature to grant a client limited permissions to objects in your storage account for a specified time. For more information about shared access signatures, see Shared access signatures: Understand the shared access signature model.

The service supports the following properties for using shared access signature authentication:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureFileStorage**.	Yes
sasUri	Specify the shared access signature URI to the resources. Mark this field as **SecureString** to store it securely. You can also put the SAS token in Azure Key Vault to use auto-rotation and remove the token portion. For more information, see the following samples and Store credentials in Azure Key Vault.	Yes
fileShare	Specify the file share.	Yes
snapshot	Specify the date of the file share snapshot if you want to copy from a snapshot.	No

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "AzureFileStorageLinkedService",
    "properties": {
        "type": "AzureFileStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the resource e.g. https://<accountname>.file.core.windows.net/?sv=
<storage version>&st=<start time>&se=<expire time>&sr=<resource>&sp=<permissions>&sip=<ip range>&spr=
<protocol>&sig=<signature>>"
            },
            "fileShare": "<file share name>",
            "snapshot": "<snapshot version>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store the SAS token in Azure Key Vault

```
{
    "name": "AzureFileStorageLinkedService",
    "properties": {
        "type": "AzureFileStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the Azure Storage resource without token e.g.
https://<accountname>.file.core.windows.net/>"
            },
            "sasToken": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName with value of SAS token e.g. ?sv=<storage version>&st=<start
time>&se=<expire time>&sr=<resource>&sp=<permissions>&sip=<ip range>&spr=<protocol>&sig=<signature>>"
            },
            "fileShare": "<file share name>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Legacy model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureFileStorage**.	Yes

host	Specifies the Azure Files endpoint as:
	-Using UI: specify
	`\\<storage name>.file.core.windows.net\<file service name>`
	- Using JSON:
	`"host": "\\\\<storage name>.file.core.windows.net\\<file service name>"`
	.
		Yes

userid	Specify the user to access the Azure Files as:
	-Using UI: specify
	`AZURE\<storage name>`
	-Using JSON:
	`"userid": "AZURE\\<storage name>"`
	.
		Yes

password	Specify the storage access key. Mark this field as a SecureString to store it securely in Data Factory, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in private network). If not specified, it uses the default Azure Integration Runtime.	No for source, Yes for sink

Example:

```
{
    "name": "AzureFileStorageLinkedService",
    "properties": {
        "type": "AzureFileStorage",
        "typeProperties": {
            "host": "\\\\<storage name>.file.core.windows.net\\<file service name>",
            "userid": "AZURE\\<storage name>",
            "password": {
                "type": "SecureString",
                "value": "<storage access key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Files under `location` settings in format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in dataset must be set to **AzureFileStorageLocation**.	Yes
folderPath	The path to folder. If you want to use wildcard to filter folder, skip this setting and specify in activity source settings.	No
fileName	The file name under the given folderPath. If you want to use wildcard to filter files, skip this setting and specify in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Azure File Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureFileStorageLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Azure Files source and sink.

Azure Files as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Azure Files under `storeSettings` settings in format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureFileStorageReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given folder/file path specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: file prefix - prefix	Prefix for the file name under the given file share configured in a dataset to filter source files. Files with name starting with `fileshare_in_linked_service/this_prefix` are selected. It utilizes the service-side filter for Azure Files, which provides better performance than a wildcard filter. This feature is not supported when using a legacy linked service model.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	No

PROPERTY	DESCRIPTION	REQUIRED
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given folderPath/wildcardFolderPath to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	Yes
OPTION 4: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When using this option, do not specify file name in dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAzureFileStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "AzureFileStorageReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Azure Files as sink

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for Azure Files under `storeSettings` settings in format-based copy sink:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **AzureFileStorageWriteSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of source file to source folder is identical to the relative path of target file to target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToAzureFileStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Parquet output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "ParquetSink",
                "storeSettings":{
                    "type": "AzureFileStorageWriteSettings",
                    "copyBehavior": "PreserveHierarchy"
                }
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	(empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using file list path in copy activity source.

Assuming you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Folder path: `root/FolderA` **In copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line with the relative path to the path configured in the dataset.

recursive and copyBehavior examples

This section describes the resulting behavior of the Copy operation for different combinations of recursive and copyBehavior values.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET
true	preserveHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder Folder1 is created with the same structure as the source: Folder1 File1 File2 Subfolder1 File3 File4 File5.
true	flattenHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 autogenerated name for File1 autogenerated name for File2 autogenerated name for File3 autogenerated name for File4 autogenerated name for File5
true	mergeFiles	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 File1 + File2 + File3 + File4 + File 5 contents are merged into one file with autogenerated file name

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

false	preserveHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  File1
			  File2
			
			Subfolder1 with File3, File4, and File5 are not picked up.

false	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			
			Subfolder1 with File3, File4, and File5 are not picked up.

false	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  File1 + File2 contents are merged into one file with autogenerated file name. autogenerated name for File1
			
			Subfolder1 with File3, File4, and File5 are not picked up.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Delete activity properties

To learn details about the properties, check Delete activity

Legacy models

> **NOTE**
>
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **FileShare**	Yes
folderPath	Path to the folder. Wildcard filter is supported, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. Examples: rootfolder/subfolder/, see more examples in Folder and file filter examples.	Yes
fileName	**Name or wildcard filter** for the file(s) under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual file name has wildcard or this escape char inside. When fileName isn't specified for an output dataset and **preserveHierarchy** isn't specified in the activity sink, the copy activity automatically generates the file name with the following pattern: "*Data.[activity run ID GUID].[GUID if FlattenHierarchy].[format if configured].[compression if configured]*", for example "Data.0a405f8a-93ff-4c6f-b3be-f69616f1df7a.txt.gz"; if you copy from tabular source using table name instead of query, the name pattern is "*[table name].[format].[compression if configured]*", for example "MyTable.csv".	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware the overall performance of data movement will be impacted by enabling this setting when you want to do file filter from huge amounts of files. The properties can be NULL that means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeEnd	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware the overall performance of data movement will be impacted by enabling this setting when you want to do file filter from huge amounts of files. The properties can be NULL that means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected.	No
format	If you want to **copy files as-is** between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, **ParquetFormat**. Set the **type** property under format to one of these values. For more information, see Text Format, Json Format, Avro Format, Orc Format, and Parquet Format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are: **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are: **Optimal** and **Fastest**.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a given name, specify **folderPath** with folder part and **fileName** with file name.
To copy a subset of files under a folder, specify **folderPath** with folder part and **fileName** with wildcard filter.

NOTE

If you were using "fileFilter" property for file filter, it is still supported as-is, while you are suggested to use the new filter capability added to "fileName" going forward.

Example:

```
{
    "name": "AzureFileStorageDataset",
    "properties": {
        "type": "FileShare",
        "linkedServiceName":{
            "referenceName": "<Azure File Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "folder/subfolder/",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **FileSystemSource**	Yes
recursive	Indicates whether the data is read recursively from the sub folders or only from the specified folder. Note when recursive is set to true and sink is file-based store, empty folder/sub-folder will not be copied/created at sink. Allowed values are: **true** (default), **false**	No

PROPERTY	DESCRIPTION	REQUIRED
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromAzureFileStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure File Storage input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "FileSystemSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Legacy copy activity sink model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **FileSystemSink**	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from file-based data store. Allowed values are: - **PreserveHierarchy (default)**: preserves the file hierarchy in the target folder. The relative path of source file to source folder is identical to the relative path of target file to target folder. - **FlattenHierarchy**: all files from the source folder are in the first level of target folder. The target files have autogenerated name. - **MergeFiles**: merges all files from the source folder to one file. If the File Name is specified, the merged file name would be the specified name; otherwise, would be autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToAzureFileStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure File Storage output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "FileSystemSink",
                "copyBehavior": "PreserveHierarchy"
            }
        }
    }
]
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Azure SQL Database by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 32 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory or Azure Synapse pipelines to copy data from and to Azure SQL Database, and use Data Flow to transform data in Azure SQL Database. To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This Azure SQL Database connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓
GetMetadata activity	① ②	✓
Script activity	① ②	✓
Stored procedure activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

For Copy activity, this Azure SQL Database connector supports these functions:

- Copying data by using SQL authentication and Azure Active Directory (Azure AD) Application token authentication with a service principal or managed identities for Azure resources.
- As a source, retrieving data by using a SQL query or a stored procedure. You can also choose to parallel copy from an Azure SQL Database source, see the Parallel copy from SQL database section for details.
- As a sink, automatically creating destination table if not exists based on the source schema; appending data to a table or invoking a stored procedure with custom logic during the copy.

If you use Azure SQL Database serverless tier, note when the server is paused, activity run fails instead of waiting for the auto resume to be ready. You can add activity retry or chain additional activities to make sure the server is live upon the actual execution.

IMPORTANT

If you copy data by using the Azure integration runtime, configure a server-level firewall rule so that Azure services can access the server. If you copy data by using a self-hosted integration runtime, configure the firewall to allow the appropriate IP range. This range includes the machine's IP that's used to connect to Azure SQL Database.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

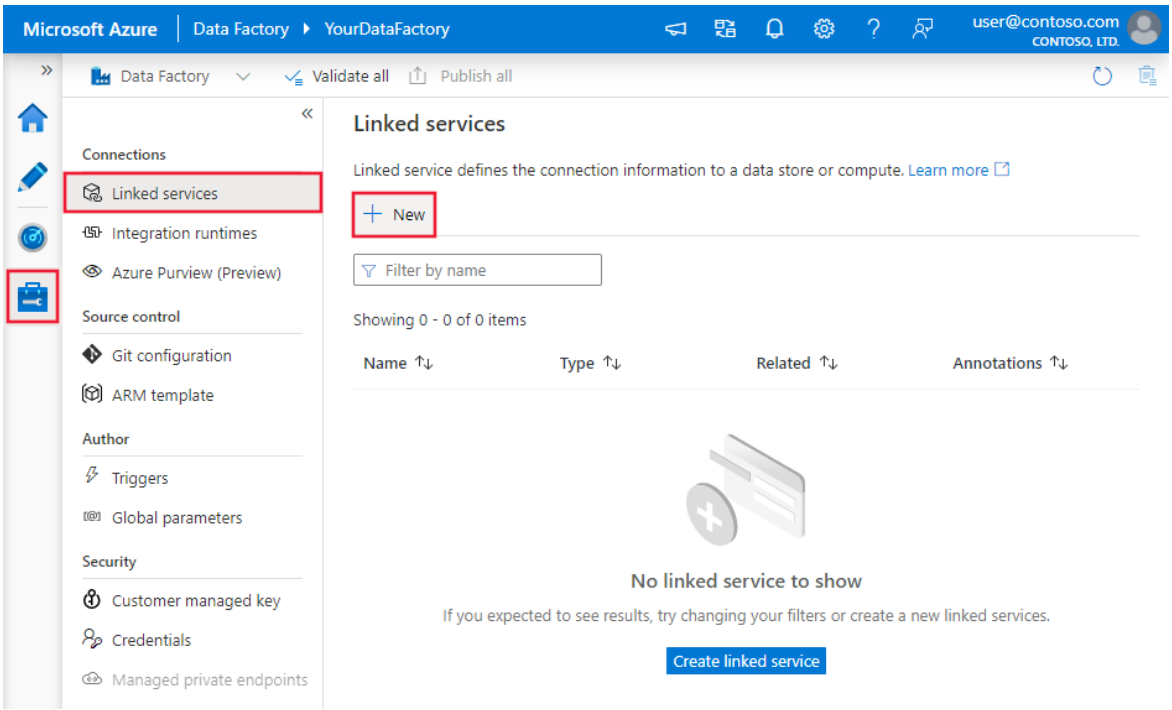
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Azure SQL Database linked service using UI

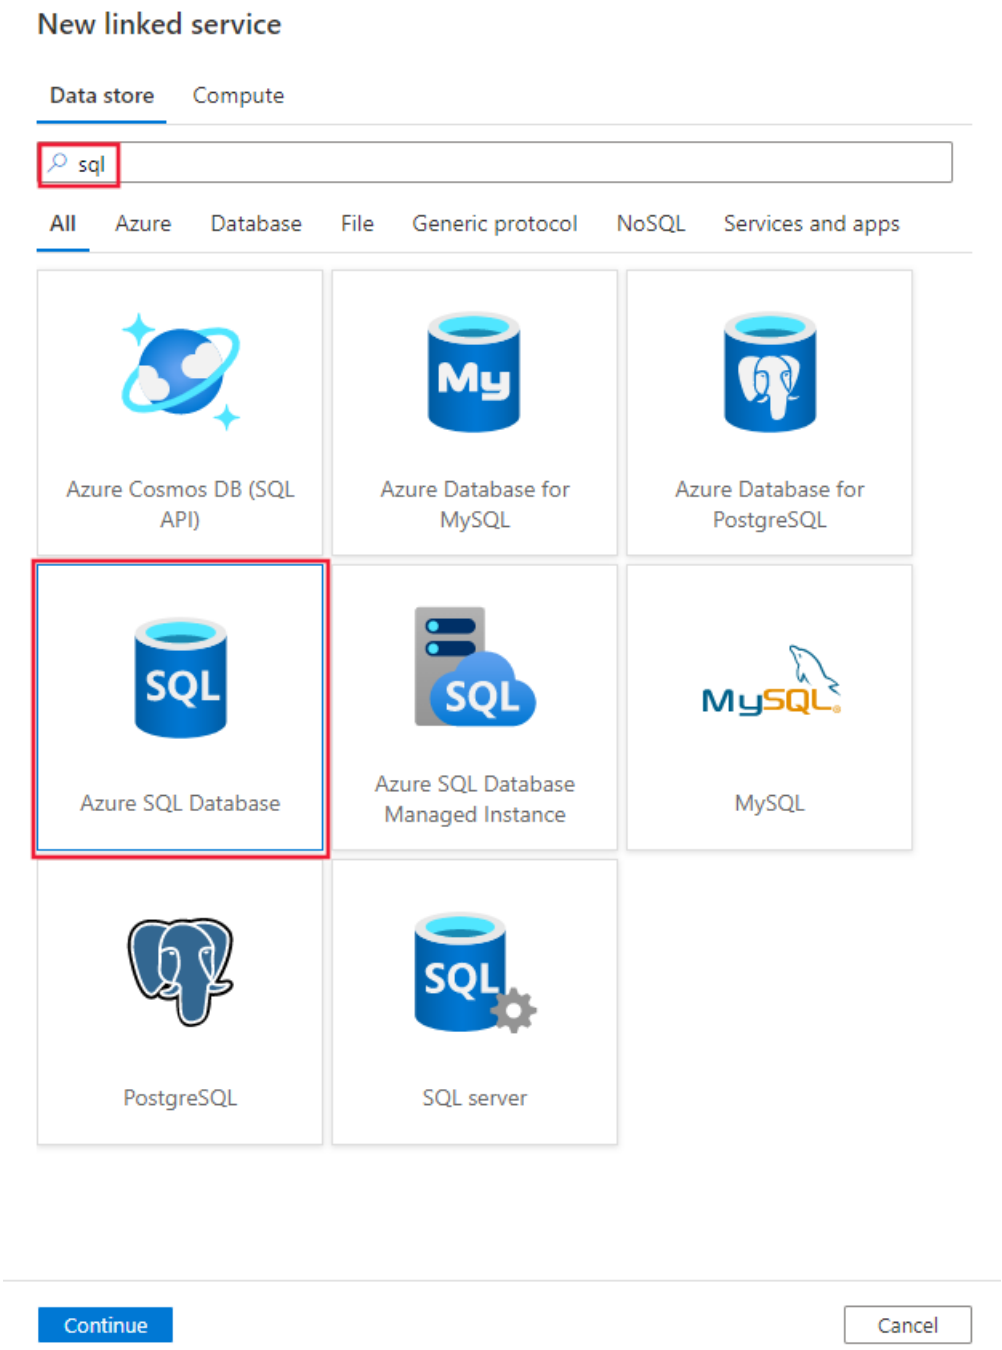
Use the following steps to create an Azure SQL Database linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

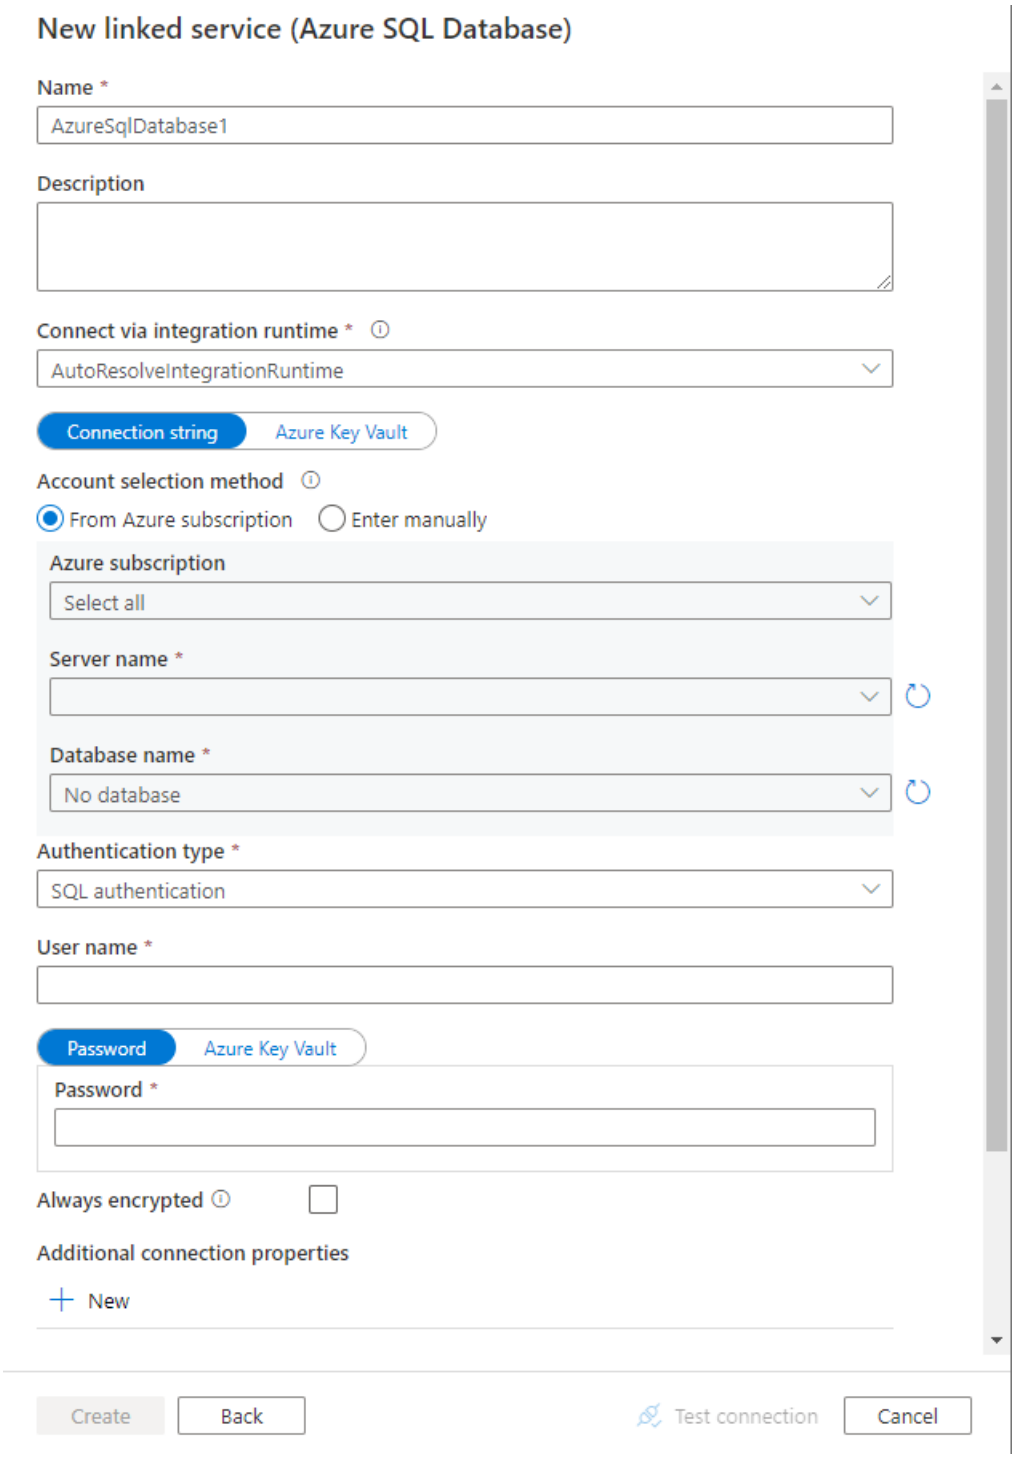
   - Azure Data Factory
   - Azure Synapse



2. Search for SQL and select the Azure SQL Database connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Azure Data Factory or Synapse pipeline entities specific to an Azure SQL Database connector.

Linked service properties

These generic properties are supported for an Azure SQL Database linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **AzureSqlDatabase**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify information needed to connect to the Azure SQL Database instance for the **connectionString** property. You also can put a password or service principal key in Azure Key Vault. If it's SQL authentication, pull the `password` configuration out of the connection string. For more information, see the JSON example following the table and Store credentials in Azure Key Vault.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure AD application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the data factory or Synapse pipeline's cloud environment is used.	No
alwaysEncryptedSettings	Specify **alwaysencryptedsettings** information that's needed to enable Always Encrypted to protect sensitive data stored in SQL server by using either managed identity or service principal. For more information, see the JSON example following the table and Using Always Encrypted section. If not specified, the default always encrypted setting is disabled.	No
connectVia	This integration runtime is used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime if your data store is located in a private network. If not specified, the default Azure integration runtime is used.	No

For different authentication types, refer to the following sections on specific properties, prerequisites and JSON samples, respectively:

- SQL authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

TIP

If you hit an error with the error code "UserErrorFailedToConnectToSqlServer" and a message like "The session limit for the database is XXX and has been reached," add `Pooling=false` to your connection string and try again. `Pooling=false` is also recommended for **SHIR(Self Hosted Integration Runtime)** type linked service setup. Pooling and other connection parameters can be added as new parameter names and values in **Additional connection properties** section of linked service creation form.

SQL authentication

To use SQL authentication authentication type, specify the generic properties that are described in the preceding section.

Example: using SQL authentication

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;User ID=<username>@<servername>;Password=
<password>;Trusted_Connection=False;Encrypt=True;Connection Timeout=30"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: password in Azure Key Vault

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;User ID=<username>@<servername>;Trusted_Connection=False;Encrypt=True;Connection Timeout=30",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Use Always Encrypted

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;User ID=<username>@<servername>;Password=
<password>;Trusted_Connection=False;Encrypt=True;Connection Timeout=30"
        },
        "alwaysEncryptedSettings": {
            "alwaysEncryptedAkvAuthType": "ServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Service principal authentication

To use service principal authentication, in addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as **SecureString** to store it securely or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information, like the domain name or tenant ID, under which your application resides. Retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes

You also need to follow the steps below:

1. Create an Azure Active Directory application from the Azure portal. Make note of the application name and the following values that define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Provision an Azure Active Directory administrator for your server on the Azure portal if you haven't already done so. The Azure AD administrator must be an Azure AD user or Azure AD group, but it can't be a service principal. This step is done so that, in the next step, you can use an Azure AD identity to create a contained database user for the service principal.
3. Create contained database users for the service principal. Connect to the database from or to which you want to copy data by using tools like SQL Server Management Studio, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL:

```
CREATE USER [your application name] FROM EXTERNAL PROVIDER;
```

4. Grant the service principal needed permissions as you normally do for SQL users or others. Run the following code. For more options, see this document.

```
ALTER ROLE [role name] ADD MEMBER [your application name];
```

5. Configure an Azure SQL Database linked service in an Azure Data Factory or Synapse workspace.

Linked service example that uses service principal authentication

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;Connection Timeout=30",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a system-assigned managed identity for Azure resources that represents the service when authenticating to other resources in Azure. You can use this managed identity for Azure SQL Database authentication. The designated factory or Synapse workspace can access and copy data from or to your database by using this identity.

To use system-assigned managed identity authentication, specify the generic properties that are described in the preceding section, and follow these steps.

1. Provision an Azure Active Directory administrator for your server on the Azure portal if you haven't already done so. The Azure AD administrator can be an Azure AD user or an Azure AD group. If you grant the group with managed identity an admin role, skip steps 3 and 4. The administrator has full access to the database.

2. Create contained database users for the managed identity. Connect to the database from or to which you want to copy data by using tools like SQL Server Management Studio, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL:

```
CREATE USER [your_resource_name] FROM EXTERNAL PROVIDER;
```

3. Grant the managed identity needed permissions as you normally do for SQL users and others. Run the following code. For more options, see this document.

```
ALTER ROLE [role name] ADD MEMBER [your_resource_name];
```

4. Configure an Azure SQL Database linked service.

Example

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;Connection Timeout=30"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a user-assigned managed identities that represents the service when authenticating to other resources in Azure. You can use this managed identity for Azure SQL Database authentication. The designated factory or Synapse workspace can access and copy data from or to your database by using this identity.

To use user-assigned managed identity authentication, in addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
credentials	Specify the user-assigned managed identity as the credential object.	Yes

You also need to follow the steps below:

1. Provision an Azure Active Directory administrator for your server on the Azure portal if you haven't already done so. The Azure AD administrator can be an Azure AD user or an Azure AD group. If you grant the group with user-assigned managed identity an admin role, skip steps 3. The administrator has full access to the database.

2. Create contained database users for the user-assigned managed identity. Connect to the database from or to which you want to copy data by using tools like SQL Server Management Studio, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL:

   ```
   CREATE USER [your_resource_name] FROM EXTERNAL PROVIDER;
   ```

3. Create one or multiple user-assigned managed identities and grant the user-assigned managed identity needed permissions as you normally do for SQL users and others. Run the following code. For more options, see this document.

   ```
   ALTER ROLE [role name] ADD MEMBER [your_resource_name];
   ```

4. Assign one or multiple user-assigned managed identities to your data factory and create credentials for

each user-assigned managed identity.

5. Configure an Azure SQL Database linked service.

Example:

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlDatabase",
        "typeProperties": {
            "connectionString": "Data Source=tcp:<servername>.database.windows.net,1433;Initial Catalog=
<databasename>;Connection Timeout=30",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available to define datasets, see Datasets.

The following properties are supported for Azure SQL Database dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **AzureSqlTable**.	Yes
schema	Name of the schema.	No for source, Yes for sink
table	Name of the table/view.	No for source, Yes for sink
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No for source, Yes for sink

Dataset properties example

```
{
    "name": "AzureSQLDbDataset",
    "properties":
    {
        "type": "AzureSqlTable",
        "linkedServiceName": {
            "referenceName": "<Azure SQL Database linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see Pipelines. This section provides a list of properties supported by the Azure SQL Database source and sink.

Azure SQL Database as the source

> **TIP**
> To load data from Azure SQL Database efficiently by using data partitioning, learn more from Parallel copy from SQL database.

To copy data from Azure SQL Database, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **AzureSqlSource**. "SqlSource" type is still supported for backward compatibility.	Yes
sqlReaderQuery	This property uses the custom SQL query to read data. An example is `select * from MyTable`.	No
sqlReaderStoredProcedureName	The name of the stored procedure that reads data from the source table. The last SQL statement must be a SELECT statement in the stored procedure.	No
storedProcedureParameters	Parameters for the stored procedure. Allowed values are name or value pairs. The names and casing of parameters must match the names and casing of the stored procedure parameters.	No

PROPERTY	DESCRIPTION	REQUIRED
isolationLevel	Specifies the transaction locking behavior for the SQL source. The allowed values are: **ReadCommitted**, **ReadUncommitted**, **RepeatableRead**, **Serializable**, **Snapshot**. If not specified, the database's default isolation level is used. Refer to this doc for more details.	No
partitionOptions	Specifies the data partitioning options used to load data from Azure SQL Database. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from an Azure SQL Database is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`***:***		
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int`, `smallint`, `bigint`, `date`, `smalldatetime`, `datetime`, `datetime2`, or `datetimeoffset`) that will be used by range partitioning for parallel copy. If not specified, the index or the primary key of the table is autodetected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfDynamicRangePartitionCondition` in the WHERE clause. For an example, see the Parallel copy from SQL database section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No
partitionLowerBound	The minimum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No

Note the following points:

- If **sqlReaderQuery** is specified for **AzureSqlSource**, the copy activity runs this query against the Azure SQL Database source to get the data. You also can specify a stored procedure by specifying **sqlReaderStoredProcedureName** and **storedProcedureParameters** if the stored procedure takes parameters.
- When using stored procedure in source to retrieve data, note if your stored procedure is designed as returning different schema when different parameter value is passed in, you may encounter failure or see unexpected result when importing schema from UI or when copying data to SQL database with auto table creation.

SQL query example

```
"activities":[
    {
        "name": "CopyFromAzureSQLDatabase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure SQL Database input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureSqlSource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Stored procedure example

```
"activities":[
    {
        "name": "CopyFromAzureSQLDatabase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure SQL Database input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "AzureSqlSource",
                "sqlReaderStoredProcedureName": "CopyTestSrcStoredProcedureWithParameters",
                "storedProcedureParameters": {
                    "stringData": { "value": "str3" },
                    "identifier": { "value": "$$Text.Format('{0:yyyy}', <datetime parameter>)", "type":
"Int"}
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Stored procedure definition

```
CREATE PROCEDURE CopyTestSrcStoredProcedureWithParameters
(
    @stringData varchar(20),
    @identifier int
)
AS
SET NOCOUNT ON;
BEGIN
     select *
     from dbo.UnitTestSrcTable
     where dbo.UnitTestSrcTable.stringData != stringData
    and dbo.UnitTestSrcTable.identifier != identifier
END
GO
```

Azure SQL Database as the sink

> **TIP**
> Learn more about the supported write behaviors, configurations, and best practices from Best practice for loading data into Azure SQL Database.

To copy data to Azure SQL Database, the following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity sink must be set to **AzureSqlSink**. "SqlSink" type is still supported for backward compatibility.	Yes
preCopyScript	Specify a SQL query for the copy activity to run before writing data into Azure SQL Database. It's invoked only once per copy run. Use this property to clean up the preloaded data.	No
tableOption	Specifies whether to automatically create the sink table if not exists based on the source schema. Auto table creation is not supported when sink specifies stored procedure. Allowed values are: `none` (default), `autoCreate`.	No
sqlWriterStoredProcedureName	The name of the stored procedure that defines how to apply source data into a target table. This stored procedure is *invoked per batch*. For operations that run only once and have nothing to do with source data, for example, delete or truncate, use the `preCopyScript` property. See example from Invoke a stored procedure from a SQL sink.	No
storedProcedureTableTypeParameterName	The parameter name of the table type specified in the stored procedure.	No

PROPERTY	DESCRIPTION	REQUIRED
sqlWriterTableType	The table type name to be used in the stored procedure. The copy activity makes the data being moved available in a temp table with this table type. Stored procedure code can then merge the data that's being copied with existing data.	No
storedProcedureParameters	Parameters for the stored procedure. Allowed values are name and value pairs. Names and casing of parameters must match the names and casing of the stored procedure parameters.	No
writeBatchSize	Number of rows to insert into the SQL table *per batch*. The allowed value is **integer** (number of rows). By default, the service dynamically determines the appropriate batch size based on the row size.	No
writeBatchTimeout	The wait time for the batch insert operation to finish before it times out. The allowed value is **timespan**. An example is "00:30:00" (30 minutes).	No
disableMetricsCollection	The service collects metrics such as Azure SQL Database DTUs for copy performance optimization and recommendations, which introduces additional master DB access. If you are concerned with this behavior, specify `true` to turn it off.	No (default is `false`)
maxConcurrentConnections	The upper limit of concurrent connecti ons established to the data store durin g the activity run. Specify a value only when you want to limit concurrent con nections.	No
WriteBehavior	Specify the write behavior for copy activity to load data into Azure SQL Database. The allowed value is **Insert** and **Upsert**. By default, the service uses insert to load data.	No
upsertSettings	Specify the group of the settings for write behavior. Apply when the WriteBehavior option is `Upsert`.	No
Under `upsertSettings`:		

PROPERTY	DESCRIPTION	REQUIRED
useTempDB	Specify whether to use the a global temporary table or physical table as the interim table for upsert. By default, the service uses global temporary table as the interim table. value is `true`.	No
interimSchemaName	Specify the interim schema for creating interim table if physical table is used. Note: user need to have the permission for creating and deleting table. By default, interim table will share the same schema as sink table. Apply when the useTempDB option is `False`.	No
keys	Specify the column names for unique row identification. Either a single key or a series of keys can be used. If not specified, the primary key is used.	No

Example 1: Append data

```
"activities":[
    {
        "name": "CopyToAzureSQLDatabase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure SQL Database output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureSqlSink",
                "tableOption": "autoCreate",
                "writeBatchSize": 100000
            }
        }
    }
]
```

Example 2: Invoke a stored procedure during copy

Learn more details from Invoke a stored procedure from a SQL sink.

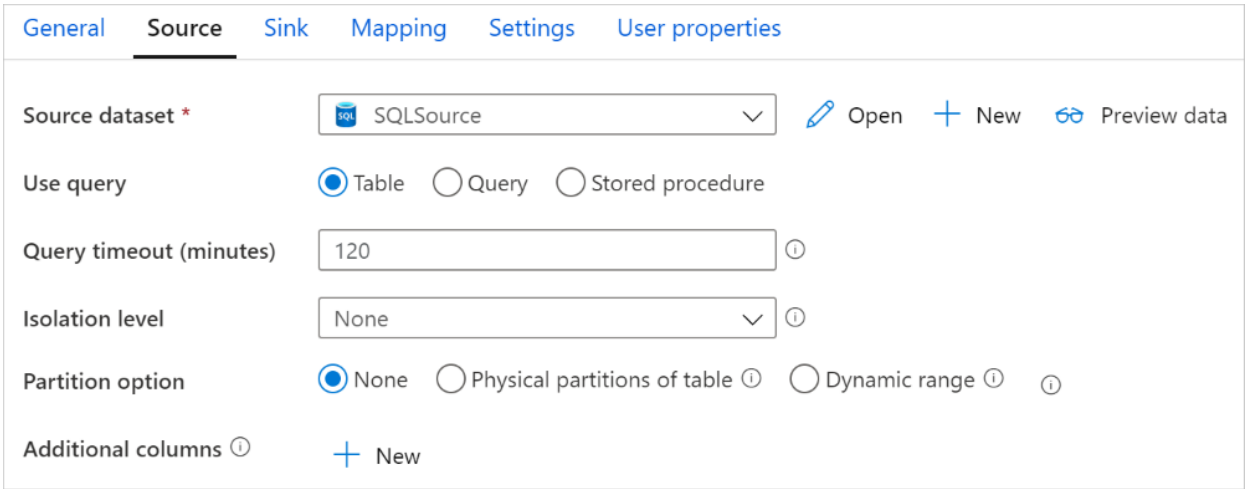
```
"activities":[
    {
        "name": "CopyToAzureSQLDatabase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure SQL Database output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureSqlSink",
                "sqlWriterStoredProcedureName": "CopyTestStoredProcedureWithParameters",
                "storedProcedureTableTypeParameterName": "MyTable",
                "sqlWriterTableType": "MyTableType",
                "storedProcedureParameters": {
                    "identifier": { "value": "1", "type": "Int" },
                    "stringData": { "value": "str1" }
                }
            }
        }
    }
]
```

Example 3: Upsert data

```
"activities":[
    {
        "name": "CopyToAzureSQLDatabase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure SQL Database output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureSqlSink",
                "tableOption": "autoCreate",
                "writeBehavior": "upsert",
                "upsertSettings": {
                    "useTempDB": true,
                    "keys": [
                        "<column name>"
                    ]
                },
            }
        }
    }
]
```

Parallel copy from SQL database

The Azure SQL Database connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your Azure SQL Database source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Azure SQL Database.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data

from your Azure SQL Database. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions. To check if your table has physical partition or not, you can refer to this query.
Full load from large table, without physical partitions, while with an integer or datetime column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column** (optional): Specify the column used to partition data. If not specified, the index or primary key column is used. **Partition upper bound** and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the table will be partitioned and copied. If not specified, copy activity auto detect the values. For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions - IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.

SCENARIO	SUGGESTED SETTINGS

Load a large amount of data by using a custom query, without physical partitions, while with an integer or date/datetime column for data partitioning.	**Partition options**: Dynamic range partition.
	Query:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to partition data.
	Partition upper bound and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the query result will be partitioned and copied. If not specified, copy activity auto detect the value.
	
	During execution, the service replaces `?AdfRangePartitionColumnName` with the actual column name and value ranges for each partition, and sends to Azure SQL Database.
	For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions- IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.
	
	Here are more sample queries for different scenarios:
	1. Query the whole table:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition`
	2. Query from a table with column selection and additional where-clause filters:
	`SELECT <column_list> FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	3. Query with subqueries:
	`SELECT <column_list> FROM (<your_sub_query>) AS T WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	4. Query with partition in subquery:
	`SELECT <column_list> FROM (SELECT <your_sub_query_column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition) AS T`

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.
3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).

Example: full load from large table with physical partitions

```
"source": {
    "type": "AzureSqlSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "AzureSqlSource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Sample query to check physical partition

```
SELECT DISTINCT s.name AS SchemaName, t.name AS TableName, pf.name AS PartitionFunctionName, c.name AS
ColumnName, iif(pf.name is null, 'no', 'yes') AS HasPartition
FROM sys.tables AS t
LEFT JOIN sys.objects AS o ON t.object_id = o.object_id
LEFT JOIN sys.schemas AS s ON o.schema_id = s.schema_id
LEFT JOIN sys.indexes AS i ON t.object_id = i.object_id
LEFT JOIN sys.index_columns AS ic ON ic.partition_ordinal > 0 AND ic.index_id = i.index_id AND ic.object_id
= t.object_id
LEFT JOIN sys.columns AS c ON c.object_id = ic.object_id AND c.column_id = ic.column_id
LEFT JOIN sys.partition_schemes ps ON i.data_space_id = ps.data_space_id
LEFT JOIN sys.partition_functions pf ON pf.function_id = ps.function_id
WHERE s.name='[your schema]' AND t.name = '[your table name]'
```

If the table has physical partition, you would see "HasPartition" as "yes" like the following.

SchemaName	TableName	PartitionFunctionName	ColumnName	HasPartition
dbo	PerfWithPartition	RangePF1	Id	yes

Best practice for loading data into Azure SQL Database

When you copy data into Azure SQL Database, you might require different write behavior:

- Append: My source data has only new records.
- Upsert: My source data has both inserts and updates.
- Overwrite: I want to reload an entire dimension table each time.
- Write with custom logic: I need extra processing before the final insertion into the destination table.

Refer to the respective sections about how to configure in the service and best practices.

Append data

Appending data is the default behavior of this Azure SQL Database sink connector. the service does a bulk insert to write to your table efficiently. You can configure the source and sink accordingly in the copy activity.

Upsert data

Copy activity now supports natively loading data into a database temporary table and then update the data in sink table if key exists and otherwise insert new data. To learn more about upsert settings in copy activities, see Azure SQL Database as the sink.

Overwrite the entire table

You can configure the **preCopyScript** property in the copy activity sink. In this case, for each copy activity that runs, the service runs the script first. Then it runs the copy to insert the data. For example, to overwrite the entire table with the latest data, specify a script to first delete all the records before you bulk load the new data from

the source.

Write data with custom logic

The steps to write data with custom logic are similar to those described in the Upsert data section. When you need to apply extra processing before the final insertion of source data into the destination table, you can load to a staging table then invoke stored procedure activity, or invoke a stored procedure in copy activity sink to apply data, or use Mapping Data Flow.

Invoke a stored procedure from a SQL sink

When you copy data into Azure SQL Database, you also can configure and invoke a user-specified stored procedure with additional parameters on each batch of the source table. The stored procedure feature takes advantage of table-valued parameters.

You can use a stored procedure when built-in copy mechanisms don't serve the purpose. An example is when you want to apply extra processing before the final insertion of source data into the destination table. Some extra processing examples are when you want to merge columns, look up additional values, and insert into more than one table.

The following sample shows how to use a stored procedure to do an upsert into a table in Azure SQL Database. Assume that the input data and the sink **Marketing** table each have three columns: **ProfileID**, **State**, and **Category**. Do the upsert based on the **ProfileID** column, and only apply it for a specific category called "ProductA".

1. In your database, define the table type with the same name as **sqlWriterTableType**. The schema of the table type is the same as the schema returned by your input data.

   ```
   CREATE TYPE [dbo].[MarketingType] AS TABLE(
       [ProfileID] [varchar](256) NOT NULL,
       [State] [varchar](256) NOT NULL,
       [Category] [varchar](256) NOT NULL
   )
   ```

2. In your database, define the stored procedure with the same name as **sqlWriterStoredProcedureName**. It handles input data from your specified source and merges into the output table. The parameter name of the table type in the stored procedure is the same as **tableName** defined in the dataset.

   ```
   CREATE PROCEDURE spOverwriteMarketing @Marketing [dbo].[MarketingType] READONLY, @category
   varchar(256)
   AS
   BEGIN
   MERGE [dbo].[Marketing] AS target
   USING @Marketing AS source
   ON (target.ProfileID = source.ProfileID and target.Category = @category)
   WHEN MATCHED THEN
       UPDATE SET State = source.State
   WHEN NOT MATCHED THEN
       INSERT (ProfileID, State, Category)
       VALUES (source.ProfileID, source.State, source.Category);
   END
   ```

3. In your Azure Data Factory or Synapse pipeline, define the **SQL sink** section in the copy activity as follows:

```
"sink": {
    "type": "AzureSqlSink",
    "sqlWriterStoredProcedureName": "spOverwriteMarketing",
    "storedProcedureTableTypeParameterName": "Marketing",
    "sqlWriterTableType": "MarketingType",
    "storedProcedureParameters": {
        "category": {
            "value": "ProductA"
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from Azure SQL Database. For more information, see the source transformation and sink transformation in mapping data flows.

Source transformation

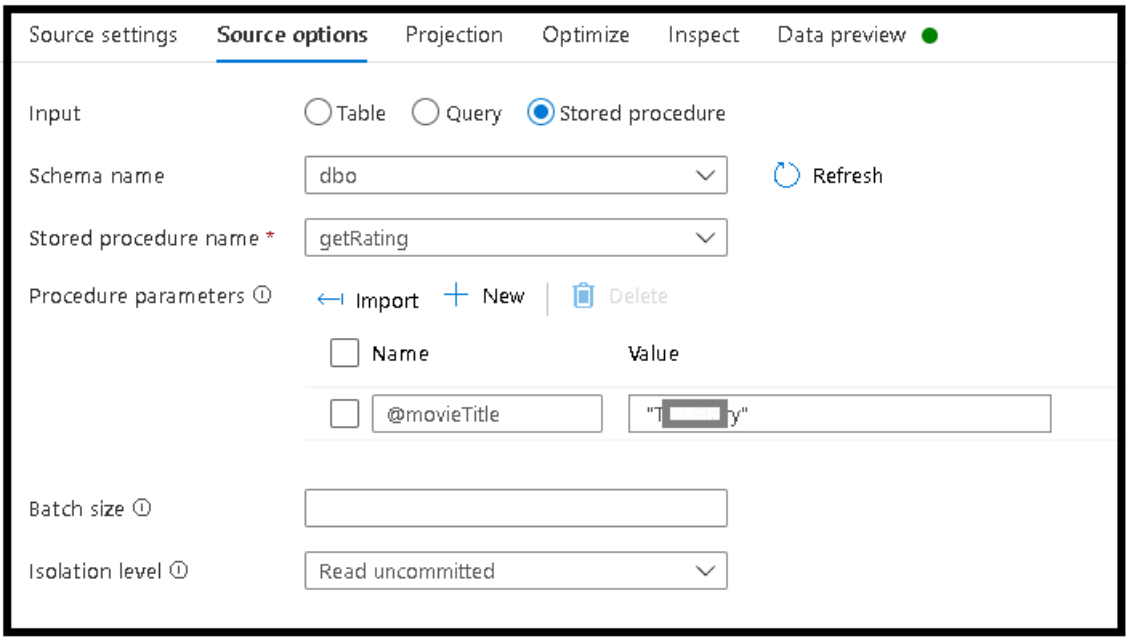
Settings specific to Azure SQL Database are available in the **Source Options** tab of the source transformation.

Input: Select whether you point your source at a table (equivalent of `Select * from <table-name>`) or enter a custom SQL query.

Query: If you select Query in the input field, enter a SQL query for your source. This setting overrides any table that you've chosen in the dataset. **Order By** clauses aren't supported here, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table. This query will produce a source table that you can use in your data flow. Using queries is also a great way to reduce rows for testing or for lookups.

> **TIP**
>
> The common table expression (CTE) in SQL is not supported in the mapping data flow **Query** mode, because the prerequisite of using this mode is that queries can be used in the SQL query FROM clause but CTEs cannot do this. To use CTEs, you need to create a stored procedure using the following query:
>
> ```
> CREATE PROC CTESP @query nvarchar(max)
> AS
> BEGIN
> EXECUTE sp_executesql @query;
> END
> ```
>
> Then use the **Stored procedure** mode in the source transformation of the mapping data flow and set the `@query` like example `with CTE as (select 'test' as a) select * from CTE`. Then you can use CTEs as expected.

Stored procedure: Choose this option if you wish to generate a projection and source data from a stored procedure that is executed from your source database. You can type in the schema, procedure name, and parameters, or click on Refresh to ask the service to discover the schemas and procedure names. Then you can click on Import to import all procedure parameters using the form `@paraName`.

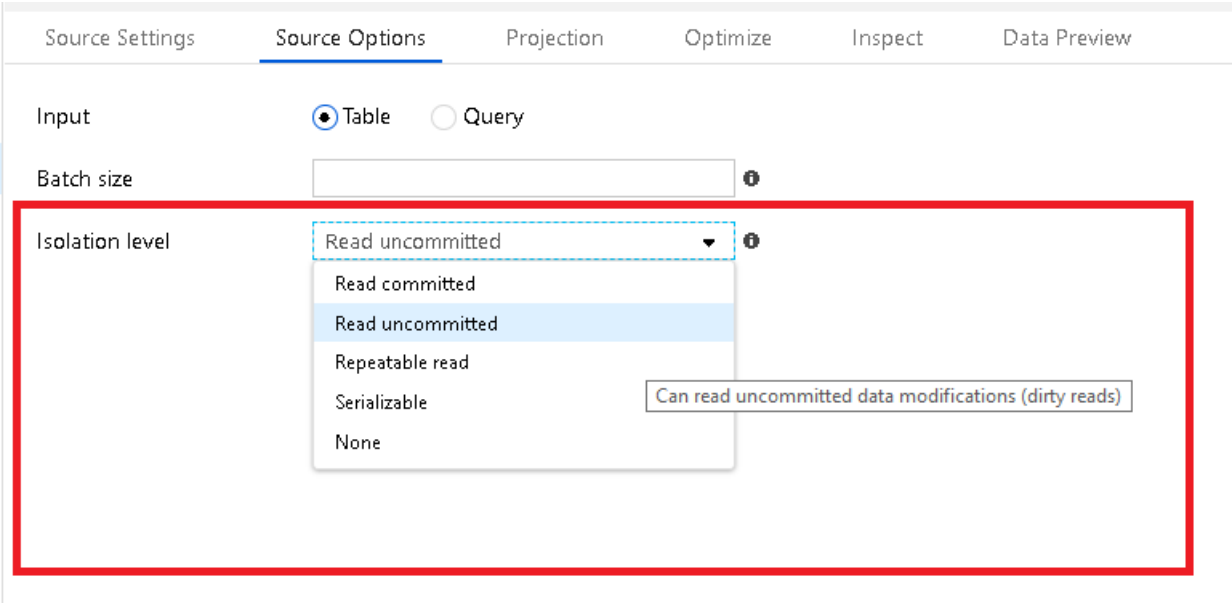


- SQL Example: `Select * from MyTable where customerId > 1000 and customerId < 2000`
- Parameterized SQL Example: `"select * from {$tablename} where orderyear > {$year}"`

Batch size: Enter a batch size to chunk large data into reads.

Isolation Level: The default for SQL sources in mapping data flow is read uncommitted. You can change the isolation level here to one of these values:

- Read Committed
- Read Uncommitted
- Repeatable Read
- Serializable
- None (ignore isolation level)



Enable incremental extract: Use this option to tell ADF to only process rows that have changed since the last time that the pipeline executed.

Incremental date column: When using the incremental extract feature, you must choose the date/time column that you wish to use as the watermark in your source table.

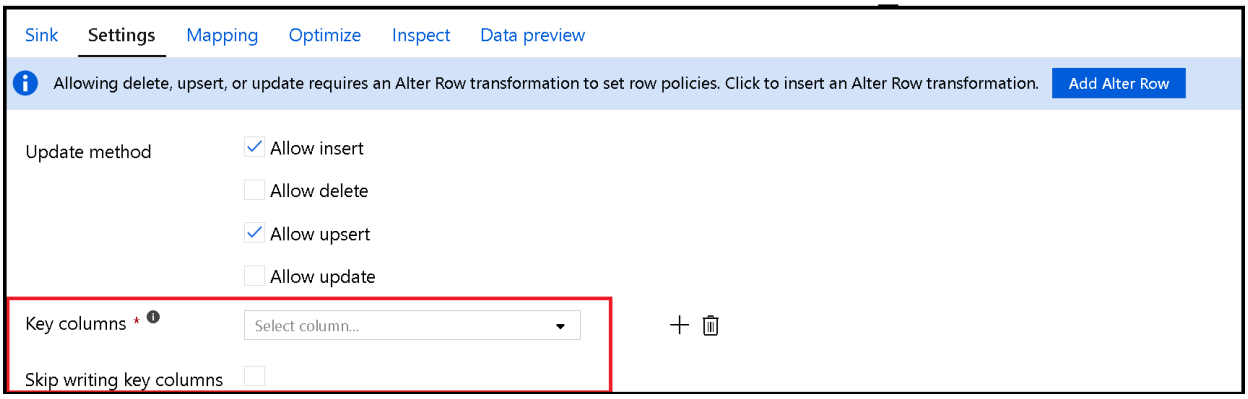
Start reading from beginning: Setting this option with incremental extract will instruct ADF to read all rows

on first execution of a pipeline with incremental extract turned on.

Sink transformation

Settings specific to Azure SQL Database are available in the **Settings** tab of the sink transformation.

Update method: Determines what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an alter-row transformation is required to tag rows for those actions. For updates, upserts and deletes, a key column or columns must be set to determine which row to alter.



The column name that you pick as the key here will be used by the service as part of the subsequent update, upsert, delete. Therefore, you must pick a column that exists in the Sink mapping. If you wish to not write the value to this key column, then click "Skip writing key columns".

You can parameterize the key column used here for updating your target Azure SQL Database table. If you have multiple columns for a composite key, the click on "Custom Expression" and you will be able to add dynamic content using the data flow expression language, which can include an array of strings with column names for a composite key.

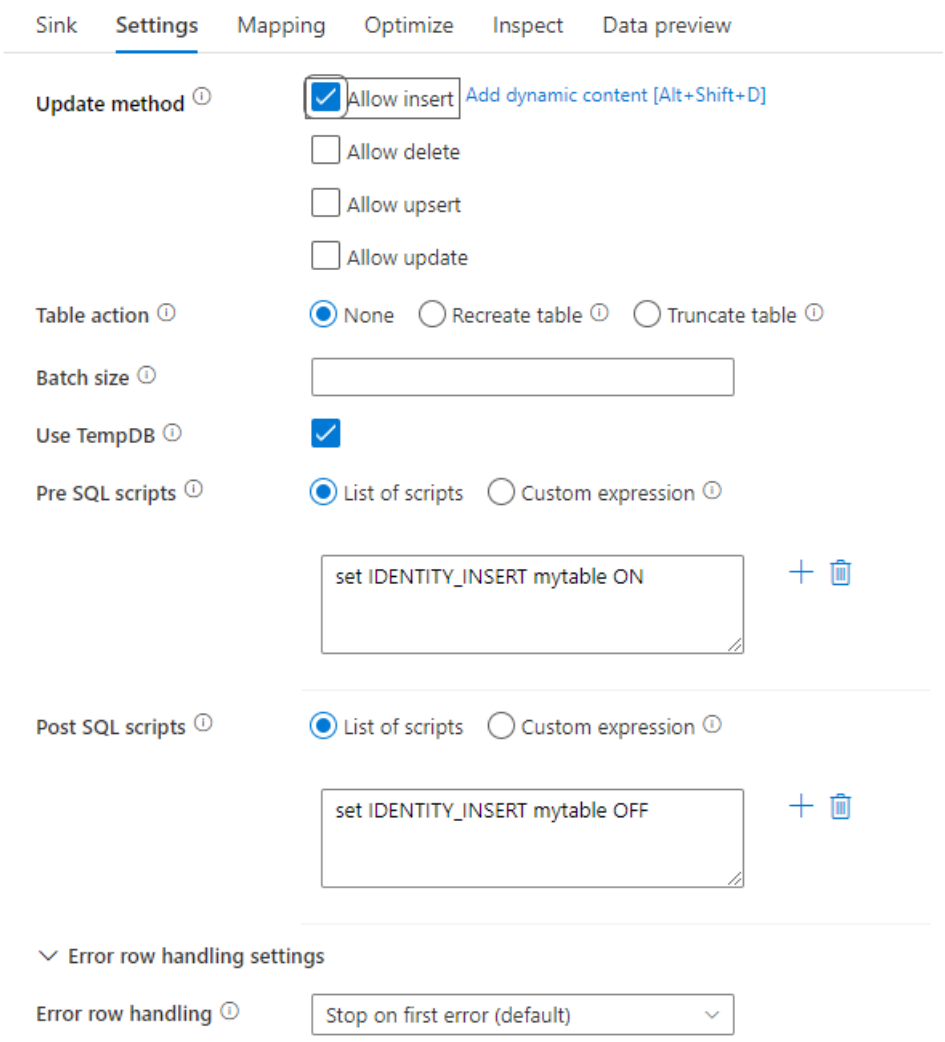
Table action: Determines whether to recreate or remove all rows from the destination table prior to writing.

- None: No action will be done to the table.
- Recreate: The table will get dropped and recreated. Required if creating a new table dynamically.
- Truncate: All rows from the target table will get removed.

Batch size: Controls how many rows are being written in each bucket. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.

Use TempDB: By default, the service will use a global temporary table to store data as part of the loading process. You can alternatively uncheck the "Use TempDB" option and instead, ask the service to store the temporary holding table in a user database that is located in the database that is being used for this Sink.

Pre and Post SQL scripts: Enter multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database



TIP

1. It's recommended to break single batch scripts with multiple commands into multiple batches.
2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

Error row handling

When writing to Azure SQL DB, certain rows of data may fail due to constraints set by the destination. Some common errors include:

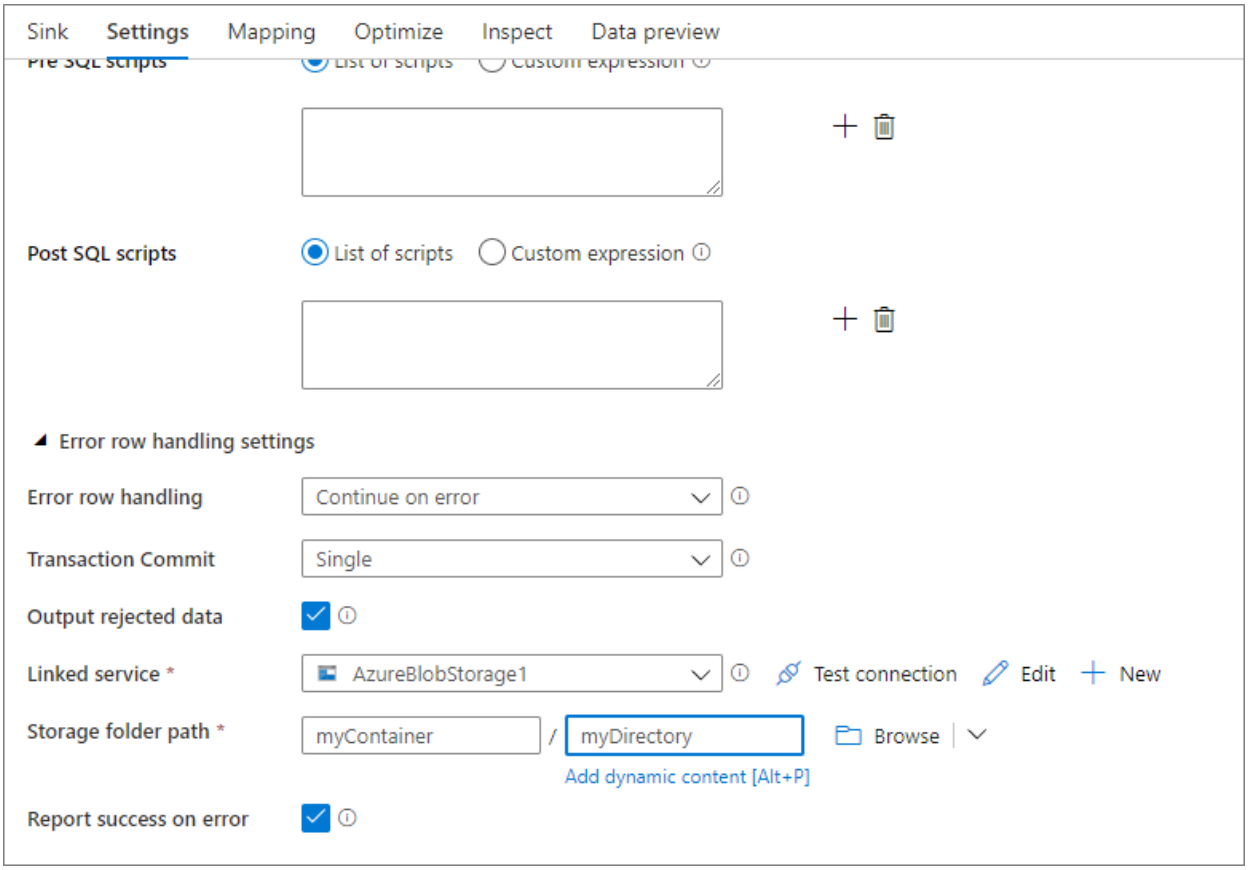
- String or binary data would be truncated in table
- Cannot insert the value NULL into column
- The INSERT statement conflicted with the CHECK constraint

By default, a data flow run will fail on the first error it gets. You can choose to **Continue on error** that allows your data flow to complete even if individual rows have errors. The service provides different options for you to handle these error rows.

Transaction Commit: Choose whether your data gets written in a single transaction or in batches. Single transaction will provide worse performance but no data written will be visible to others until the transaction completes.

Output rejected data: If enabled, you can output the error rows into a csv file in Azure Blob Storage or an Azure Data Lake Storage Gen2 account of your choosing. This will write the error rows with three additional columns: the SQL operation like INSERT or UPDATE, the data flow error code, and the error message on the row.

Report success on error: If enabled, the data flow will be marked as a success even if error rows are found.



Data type mapping for Azure SQL Database

When data is copied from or to Azure SQL Database, the following mappings are used from Azure SQL Database data types to Azure Data Factory interim data types. The same mappings are used by the Synapse pipeline feature, which implements Azure Data Factory directly. To learn how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

AZURE SQL DATABASE DATA TYPE	DATA FACTORY INTERIM DATA TYPE
bigint	Int64
binary	Byte[]
bit	Boolean
char	String, Char[]
date	DateTime
Datetime	DateTime
datetime2	DateTime
Datetimeoffset	DateTimeOffset
Decimal	Decimal
FILESTREAM attribute (varbinary(max))	Byte[]

AZURE SQL DATABASE DATA TYPE	DATA FACTORY INTERIM DATA TYPE
Float	Double
image	Byte[]
int	Int32
money	Decimal
nchar	String, Char[]
ntext	String, Char[]
numeric	Decimal
nvarchar	String, Char[]
real	Single
rowversion	Byte[]
smalldatetime	DateTime
smallint	Int16
smallmoney	Decimal
sql_variant	Object
text	String, Char[]
time	TimeSpan
timestamp	Byte[]
tinyint	Byte
uniqueidentifier	Guid
varbinary	Byte[]
varchar	String, Char[]
xml	String

NOTE

For data types that map to the Decimal interim type, currently Copy activity supports precision up to 28. If you have data with precision larger than 28, consider converting to a string in SQL query.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Using Always Encrypted

When you copy data from/to Azure SQL Database with Always Encrypted, follow below steps:

1. Store the Column Master Key (CMK) in an Azure Key Vault. Learn more on how to configure Always Encrypted by using Azure Key Vault
2. Make sure to great access to the key vault where the Column Master Key (CMK) is stored. Refer to this article for required permissions.
3. Create linked service to connect to your SQL database and enable 'Always Encrypted' function by using either managed identity or service principal.

> **NOTE**
>
> Azure SQL Database Always Encrypted supports below scenarios:
>
> 1. Either source or sink data stores is using managed identity or service principal as key provider authentication type.
> 2. Both source and sink data stores are using managed identity as key provider authentication type.
> 3. Both source and sink data stores are using the same service principal as key provider authentication type.

> **NOTE**
>
> Currently, Azure SQL Database **Always Encrypted** is only supported for source transformation in mapping data flows.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores and formats.

Copy and transform data in Azure SQL Managed Instance using Azure Data Factory or Synapse Analytics

8/19/2022 • 30 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity to copy data from and to Azure SQL Managed Instance, and use Data Flow to transform data in Azure SQL Managed Instance. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This Azure SQL Managed Instance connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓ Public preview
Mapping data flow (source/sink)	①	✓ Public preview
Lookup activity	① ②	✓ Public preview
GetMetadata activity	① ②	✓ Public preview
Script activity	① ②	✓ Public preview
Stored procedure activity	① ②	✓ Public preview

① Azure integration runtime ② Self-hosted integration runtime

For Copy activity, this Azure SQL Database connector supports these functions:

- Copying data by using SQL authentication and Azure Active Directory (Azure AD) Application token authentication with a service principal or managed identities for Azure resources.
- As a source, retrieving data by using a SQL query or a stored procedure. You can also choose to parallel copy from SQL MI source, see the Parallel copy from SQL MI section for details.
- As a sink, automatically creating destination table if not exists based on the source schema; appending data to a table or invoking a stored procedure with custom logic during copy.

Prerequisites

To access the SQL Managed Instance public endpoint, you can use a managed Azure integration runtime. Make sure that you enable the public endpoint and also allow public endpoint traffic on the network security group so that the service can connect to your database. For more information, see this guidance.

To access the SQL Managed Instance private endpoint, set up a self-hosted integration runtime that can access the database. If you provision the self-hosted integration runtime in the same virtual network as your managed instance, make sure that your integration runtime machine is in a different subnet than your managed instance.

If you provision your self-hosted integration runtime in a different virtual network than your managed instance, you can use either a virtual network peering or a virtual network to virtual network connection. For more information, see Connect your application to SQL Managed Instance.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

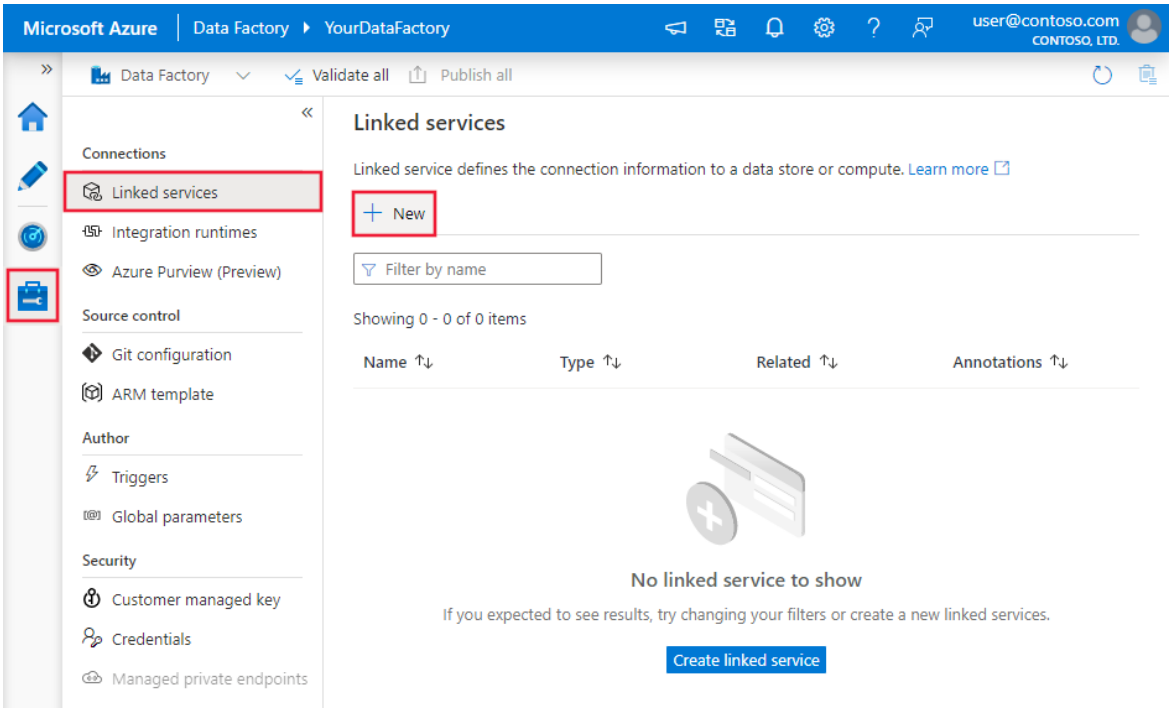
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an Azure SQL Managed instance using UI

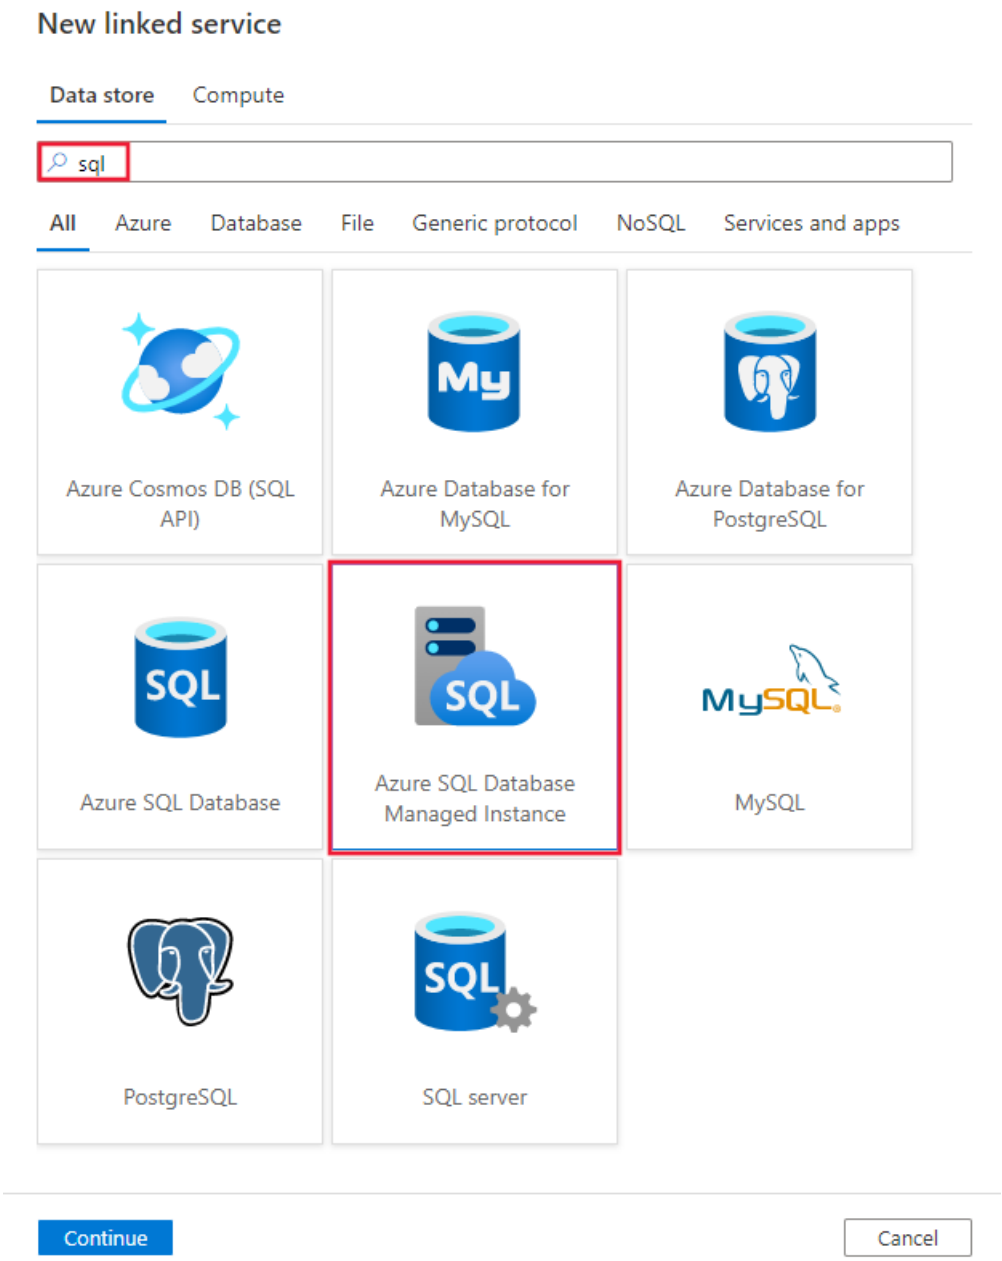
Use the following steps to create a linked service to an SQL Managed instance in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

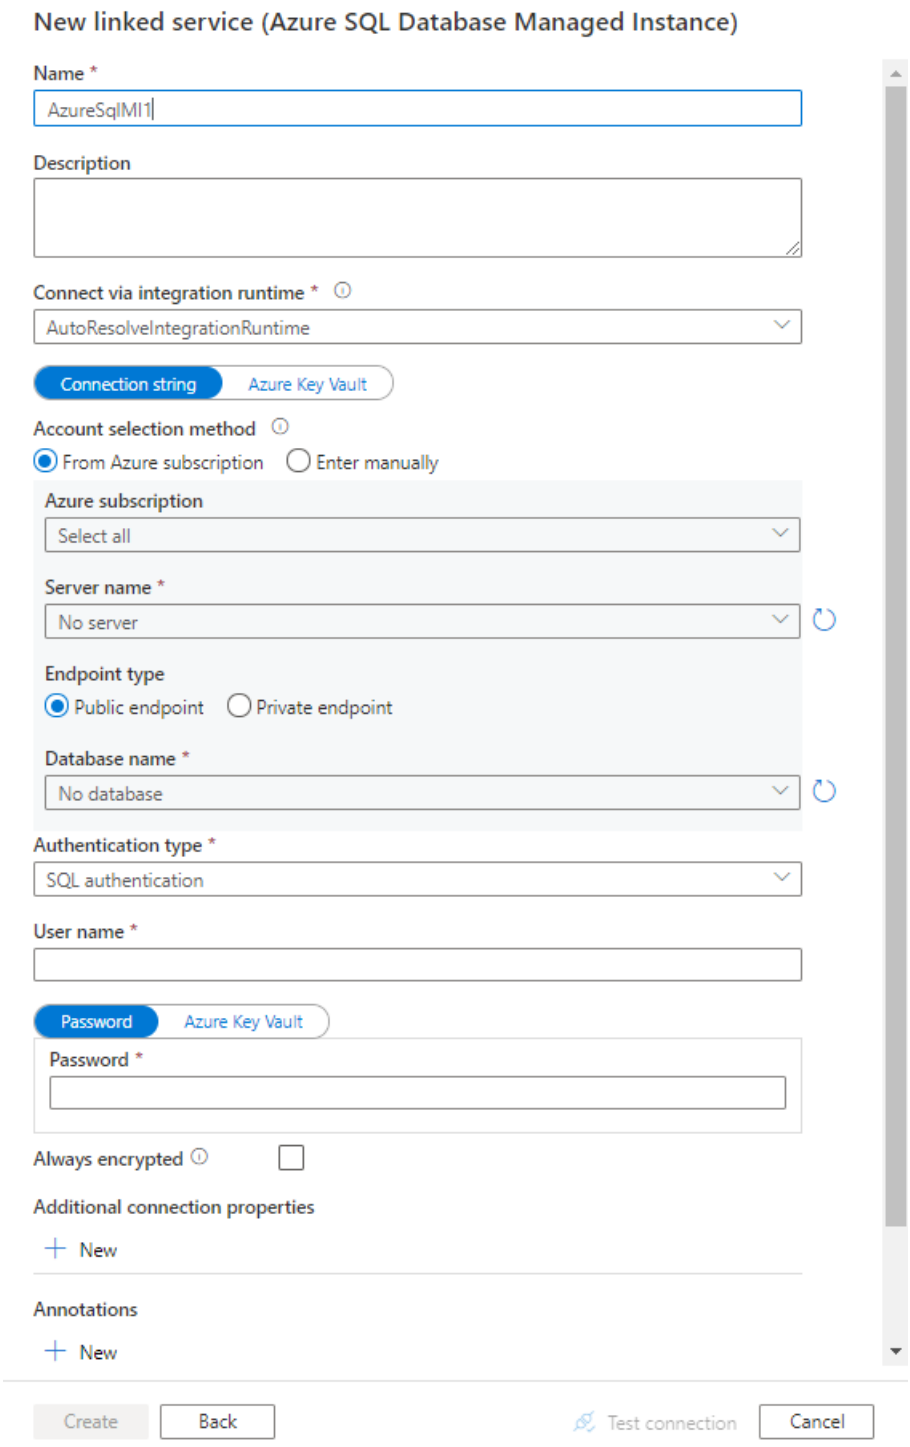
   - Azure Data Factory
   - Azure Synapse



2. Search for SQL and select the Azure SQL Server Managed Instance connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Azure Data Factory entities specific to the SQL Managed Instance connector.

Linked service properties

These generic properties are supported for an SQL Managed Instance linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureSqlMI**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	This property specifies the **connectionString** information that's needed to connect to SQL Managed Instance by using SQL authentication. For more information, see the following examples. The default port is 1433. If you're using SQL Managed Instance with a public endpoint, explicitly specify port 3342. You also can put a password in Azure Key Vault. If it's SQL authentication, pull the `password` configuration out of the connection string. For more information, see the JSON example following the table and Store credentials in Azure Key Vault.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure AD application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the service's cloud environment is used.	No
alwaysEncryptedSettings	Specify **alwaysencryptedsettings** information that's needed to enable Always Encrypted to protect sensitive data stored in SQL server by using either managed identity or service principal. For more information, see the JSON example following the table and Using Always Encrypted section. If not specified, the default always encrypted setting is disabled.	No
connectVia	This integration runtime is used to connect to the data store. You can use a self-hosted integration runtime or an Azure integration runtime if your managed instance has a public endpoint and allows the service to access it. If not specified, the default Azure integration runtime is used.	Yes

For different authentication types, refer to the following sections on specific properties, prerequisites and JSON samples, respectively:

- SQL authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

SQL authentication

To use SQL authentication authentication type, specify the generic properties that are described in the preceding section.

Example 1: use SQL authentication

```
{
    "name": "AzureSqlMILinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;Integrated
Security=False;User ID=<username>;Password=<password>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: use SQL authentication with a password in Azure Key Vault

```
{
    "name": "AzureSqlMILinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;Integrated
Security=False;User ID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 3: use SQL authentication with Always Encrypted

```
{
    "name": "AzureSqlMILinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;Integrated
Security=False;User ID=<username>;Password=<password>;"
        },
        "alwaysEncryptedSettings": {
            "alwaysEncryptedAkvAuthType": "ServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Service principal authentication

To use service principal authentication, in addition to the generic properties that are described in the preceding section, specify the following properties

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as **SecureString** to store it securely or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information, like the domain name or tenant ID, under which your application resides. Retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes

You also need to follow the steps below:

1. Follow the steps to Provision an Azure Active Directory administrator for your Managed Instance.
2. Create an Azure Active Directory application from the Azure portal. Make note of the application name and the following values that define the linked service:
   - Application ID
   - Application key
   - Tenant ID
3. Create logins for the service principal. In SQL Server Management Studio (SSMS), connect to your managed instance using a SQL Server account that is a **sysadmin**. In **master** database, run the following T-SQL:

   ```
   CREATE LOGIN [your application name] FROM EXTERNAL PROVIDER
   ```

4. Create contained database users for the service principal. Connect to the database from or to which you want to copy data, run the following T-SQL:

```
CREATE USER [your application name] FROM EXTERNAL PROVIDER
```

5. Grant the service principal needed permissions as you normally do for SQL users and others. Run the following code. For more options, see this document.

```
ALTER ROLE [role name e.g. db_owner] ADD MEMBER [your application name]
```

6. Configure a SQL Managed Instance linked service.

Example: use service principal authentication

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a system-assigned managed identity for Azure resources that represents the service for authentication to other Azure services. You can use this managed identity for SQL Managed Instance authentication. The designated service can access and copy data from or to your database by using this identity.

To use system-assigned managed identity authentication, specify the generic properties that are described in the preceding section, and follow these steps.

1. Follow the steps to Provision an Azure Active Directory administrator for your Managed Instance.

2. Create logins for the system-assigned managed identity. In SQL Server Management Studio (SSMS), connect to your managed instance using a SQL Server account that is a **sysadmin**. In **master** database, run the following T-SQL:

```
CREATE LOGIN [your_factory_or_workspace_ name] FROM EXTERNAL PROVIDER
```

3. Create contained database users for the system-assigned managed identity. Connect to the database from or to which you want to copy data, run the following T-SQL:

```
CREATE USER [your_factory_or_workspace_name] FROM EXTERNAL PROVIDER
```

4. Grant the system-assigned managed identity needed permissions as you normally do for SQL users and others. Run the following code. For more options, see this document.

```
ALTER ROLE [role name e.g. db_owner] ADD MEMBER [your_factory_or_workspace_name]
```

5. Configure a SQL Managed Instance linked service.

Example: uses system-assigned managed identity authentication

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a user-assigned managed identities that represents the service for authentication to other Azure services. You can use this managed identity for SQL Managed Instance authentication. The designated service can access and copy data from or to your database by using this identity.

To use user-assigned managed identity authentication, in addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
credentials	Specify the user-assigned managed identity as the credential object.	Yes

You also need to follow the steps below:

1. Follow the steps to Provision an Azure Active Directory administrator for your Managed Instance.

2. Create logins for the user-assigned managed identity. In SQL Server Management Studio (SSMS), connect to your managed instance using a SQL Server account that is a **sysadmin**. In **master** database, run the following T-SQL:

```
CREATE LOGIN [your_factory_or_workspace_ name] FROM EXTERNAL PROVIDER
```

3. Create contained database users for the user-assigned managed identity. Connect to the database from or to which you want to copy data, run the following T-SQL:

```
CREATE USER [your_factory_or_workspace_name] FROM EXTERNAL PROVIDER
```

4. Create one or multiple user-assigned managed identities and grant the user-assigned managed identity needed permissions as you normally do for SQL users and others. Run the following code. For more options, see this document.

```
ALTER ROLE [role name e.g. db_owner] ADD MEMBER [your_factory_or_workspace_name]
```

5. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

6. Configure a SQL Managed Instance linked service.

Example: uses user-assigned managed identity authentication

```
{
    "name": "AzureSqlDbLinkedService",
    "properties": {
        "type": "AzureSqlMI",
        "typeProperties": {
            "connectionString": "Data Source=<hostname,port>;Initial Catalog=<databasename>;",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for use to define datasets, see the datasets article. This section provides a list of properties supported by the SQL Managed Instance dataset.

To copy data to and from SQL Managed Instance, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzureSqlMITable**.	Yes
schema	Name of the schema.	No for source, Yes for sink
table	Name of the table/view.	No for source, Yes for sink
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No for source, Yes for sink

Example

```
{
    "name": "AzureSqlMIDataset",
    "properties":
    {
        "type": "AzureSqlMITable",
        "linkedServiceName": {
            "referenceName": "<SQL Managed Instance linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for use to define activities, see the Pipelines article. This section provides a list of properties supported by the SQL Managed Instance source and sink.

SQL Managed Instance as a source

> **TIP**
> To load data from SQL MI efficiently by using data partitioning, learn more from Parallel copy from SQL MI.

To copy data from SQL Managed Instance, the following properties are supported in the copy activity source section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **SqlMISource**.	Yes
sqlReaderQuery	This property uses the custom SQL query to read data. An example is `select * from MyTable`.	No
sqlReaderStoredProcedureName	This property is the name of the stored procedure that reads data from the source table. The last SQL statement must be a SELECT statement in the stored procedure.	No
storedProcedureParameters	These parameters are for the stored procedure. Allowed values are name or value pairs. The names and casing of the parameters must match the names and casing of the stored procedure parameters.	No

PROPERTY	DESCRIPTION	REQUIRED
isolationLevel	Specifies the transaction locking behavior for the SQL source. The allowed values are: **ReadCommitted**, **ReadUncommitted**, **RepeatableRead**, **Serializable**, **Snapshot**. If not specified, the database's default isolation level is used. Refer to this doc for more details.	No
partitionOptions	Specifies the data partitioning options used to load data from SQL MI. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from SQL MI is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`***:***		
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int`, `smallint`, `bigint`, `date`, `smalldatetime`, `datetime`, `datetime2`, or `datetimeoffset`) that will be used by range partitioning for parallel copy. If not specified, the index or the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfDynamicRangePartitionCondition` in the WHERE clause. For an example, see the Parallel copy from SQL database section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No
partitionLowerBound	The minimum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No

Note the following points:

- If **sqlReaderQuery** is specified for **SqlMISource**, the copy activity runs this query against the SQL Managed Instance source to get the data. You also can specify a stored procedure by specifying **sqlReaderStoredProcedureName** and **storedProcedureParameters** if the stored procedure takes parameters.
- When using stored procedure in source to retrieve data, note if your stored procedure is designed as returning different schema when different parameter value is passed in, you may encounter failure or see unexpected result when importing schema from UI or when copying data to SQL database with auto table creation.

Example: Use a SQL query

```
"activities":[
    {
        "name": "CopyFromAzureSqlMI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SQL Managed Instance input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlMISource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Example: Use a stored procedure

```
"activities":[
    {
        "name": "CopyFromAzureSqlMI",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SQL Managed Instance input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlMISource",
                "sqlReaderStoredProcedureName": "CopyTestSrcStoredProcedureWithParameters",
                "storedProcedureParameters": {
                    "stringData": { "value": "str3" },
                    "identifier": { "value": "$$Text.Format('{0:yyyy}', <datetime parameter>)", "type":
"Int"}
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

The stored procedure definition

```
CREATE PROCEDURE CopyTestSrcStoredProcedureWithParameters
(
    @stringData varchar(20),
    @identifier int
)
AS
SET NOCOUNT ON;
BEGIN
    select *
    from dbo.UnitTestSrcTable
    where dbo.UnitTestSrcTable.stringData != stringData
    and dbo.UnitTestSrcTable.identifier != identifier
END
GO
```

SQL Managed Instance as a sink

> **TIP**
> Learn more about the supported write behaviors, configurations, and best practices from Best practice for loading data into SQL Managed Instance.

To copy data to SQL Managed Instance, the following properties are supported in the copy activity sink section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **SqlMISink**.	Yes
preCopyScript	This property specifies a SQL query for the copy activity to run before writing data into SQL Managed Instance. It's invoked only once per copy run. You can use this property to clean up preloaded data.	No
tableOption	Specifies whether to automatically create the sink table if not exists based on the source schema. Auto table creation is not supported when sink specifies stored procedure. Allowed values are: `none` (default), `autoCreate`.	No
sqlWriterStoredProcedureName	The name of the stored procedure that defines how to apply source data into a target table. This stored procedure is *invoked per batch*. For operations that run only once and have nothing to do with source data, for example, delete or truncate, use the `preCopyScript` property. See example from Invoke a stored procedure from a SQL sink.	No
storedProcedureTableTypeParameterName	The parameter name of the table type specified in the stored procedure.	No

PROPERTY	DESCRIPTION	REQUIRED
sqlWriterTableType	The table type name to be used in the stored procedure. The copy activity makes the data being moved available in a temp table with this table type. Stored procedure code can then merge the data that's being copied with existing data.	No
storedProcedureParameters	Parameters for the stored procedure. Allowed values are name and value pairs. Names and casing of parameters must match the names and casing of the stored procedure parameters.	No
writeBatchSize	Number of rows to insert into the SQL table *per batch*. Allowed values are integers for the number of rows. By default, the service dynamically determines the appropriate batch size based on the row size.	No
writeBatchTimeout	This property specifies the wait time for the batch insert operation to complete before it times out. Allowed values are for the timespan. An example is "00:30:00," which is 30 minutes.	No
maxConcurrentConnections	The upper limit of concurrent connecti ons established to the data store durin g the activity run. Specify a value only when you want to limit concurrent con nections.	No
WriteBehavior	Specify the write behavior for copy activity to load data into Azure SQL MI. The allowed value is **Insert** and **Upsert**. By default, the service uses insert to load data.	No
upsertSettings	Specify the group of the settings for write behavior. Apply when the WriteBehavior option is `Upert`.	No
Under `upsertSettings`:		
useTempDB	Specify whether to use the a global temporary table or physical table as the interim table for upsert. By default, the service uses global temporary table as the interim table. value is `true`.	No

PROPERTY	DESCRIPTION	REQUIRED
interimSchemaName	Specify the interim schema for creating interim table if physical table is used. Note: user need to have the permission for creating and deleting table. By default, interim table will share the same schema as sink table. Apply when the useTempDB option is `False`.	No
keys	Specify the column names for unique row identification. Either a single key or a series of keys can be used. If not specified, the primary key is used.	No

Example 1: Append data

```
"activities":[
    {

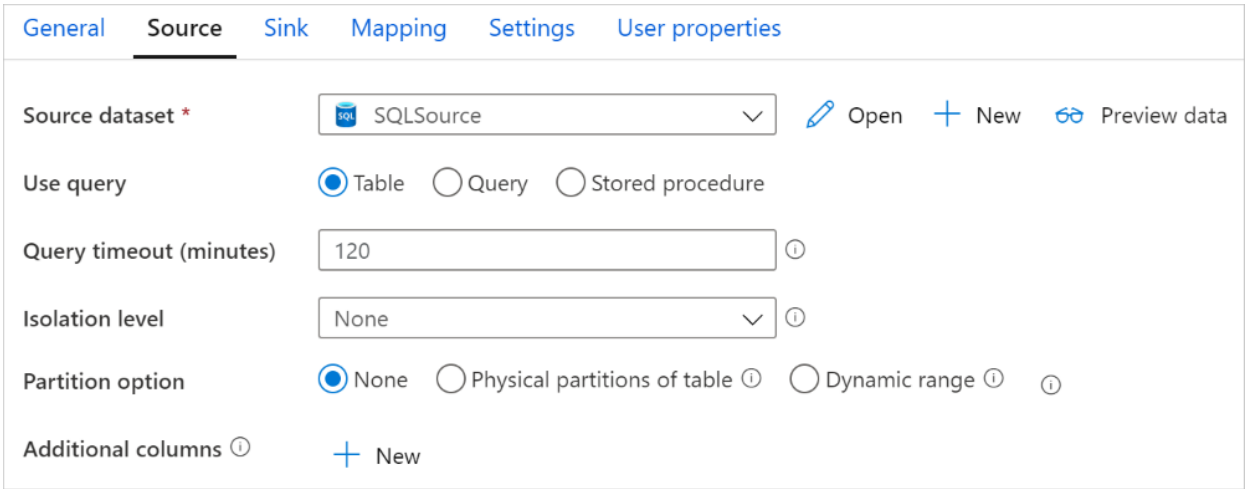
                "upsertSettings": {
                    "useTempDB": true,
                    "keys": [
                        "<column name>"
                    ]
                },
            }
        }
    }
]
```

Parallel copy from SQL MI

The Azure SQL Managed Instance connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your SQL MI source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your SQL MI.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your SQL MI. The following are suggested configurations for different scenarios. When copying data into

file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions. To check if your table has physical partition or not, you can refer to this query.
Full load from large table, without physical partitions, while with an integer or datetime column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column** (optional): Specify the column used to partition data. If not specified, the index or primary key column is used. **Partition upper bound** and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the table will be partitioned and copied. If not specified, copy activity auto detect the values. For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions - IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.

SCENARIO	SUGGESTED SETTINGS

Load a large amount of data by using a custom query, without physical partitions, while with an integer or date/datetime column for data partitioning.	**Partition options**: Dynamic range partition.
	Query:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to partition data.
	Partition upper bound and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the query result will be partitioned and copied. If not specified, copy activity auto detect the value.
	
	During execution, the service replaces `?AdfRangePartitionColumnName` with the actual column name and value ranges for each partition, and sends to SQL MI.
	For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions- IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.
	
	Here are more sample queries for different scenarios:
	1. Query the whole table:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition`
	2. Query from a table with column selection and additional where-clause filters:
	`SELECT <column_list> FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	3. Query with subqueries:
	`SELECT <column_list> FROM (<your_sub_query>) AS T WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	4. Query with partition in subquery:
	`SELECT <column_list> FROM (SELECT <your_sub_query_column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition) AS T`

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.
3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).

Example: full load from large table with physical partitions

```
"source": {
    "type": "SqlMISource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "SqlMISource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Sample query to check physical partition

```
SELECT DISTINCT s.name AS SchemaName, t.name AS TableName, pf.name AS PartitionFunctionName, c.name AS
ColumnName, iif(pf.name is null, 'no', 'yes') AS HasPartition
FROM sys.tables AS t
LEFT JOIN sys.objects AS o ON t.object_id = o.object_id
LEFT JOIN sys.schemas AS s ON o.schema_id = s.schema_id
LEFT JOIN sys.indexes AS i ON t.object_id = i.object_id
LEFT JOIN sys.index_columns AS ic ON ic.partition_ordinal > 0 AND ic.index_id = i.index_id AND ic.object_id
= t.object_id
LEFT JOIN sys.columns AS c ON c.object_id = ic.object_id AND c.column_id = ic.column_id
LEFT JOIN sys.partition_schemes ps ON i.data_space_id = ps.data_space_id
LEFT JOIN sys.partition_functions pf ON pf.function_id = ps.function_id
WHERE s.name='[your schema]' AND t.name = '[your table name]'
```

If the table has physical partition, you would see "HasPartition" as "yes" like the following.

SchemaName	TableName	PartitionFunctionName	ColumnName	HasPartition
dbo	PerfWithPartition	RangePF1	Id	yes

Best practice for loading data into SQL Managed Instance

When you copy data into SQL Managed Instance, you might require different write behavior:

- Append: My source data has only new records.
- Upsert: My source data has both inserts and updates.
- Overwrite: I want to reload the entire dimension table each time.
- Write with custom logic: I need extra processing before the final insertion into the destination table.

See the respective sections for how to configure and best practices.

Append data

Appending data is the default behavior of the SQL Managed Instance sink connector. The service does a bulk insert to write to your table efficiently. You can configure the source and sink accordingly in the copy activity.

Upsert data

Copy activity now supports natively loading data into a database temporary table and then update the data in sink table if key exists and otherwise insert new data. To learn more about upsert settings in copy activities, see SQL Managed Instance as a sink.

Overwrite the entire table

You can configure the **preCopyScript** property in a copy activity sink. In this case, for each copy activity that runs, the service runs the script first. Then it runs the copy to insert the data. For example, to overwrite the entire table with the latest data, specify a script to first delete all the records before you bulk load the new data from

the source.

Write data with custom logic

The steps to write data with custom logic are similar to those described in the Upsert data section. When you need to apply extra processing before the final insertion of source data into the destination table, you can load to a staging table then invoke stored procedure activity, or invoke a stored procedure in copy activity sink to apply data.

Invoke a stored procedure from a SQL sink

When you copy data into SQL Managed Instance, you also can configure and invoke a user-specified stored procedure with additional parameters on each batch of the source table. The stored procedure feature takes advantage of table-valued parameters.

You can use a stored procedure when built-in copy mechanisms don't serve the purpose. An example is when you want to apply extra processing before the final insertion of source data into the destination table. Some extra processing examples are when you want to merge columns, look up additional values, and insert into more than one table.

The following sample shows how to use a stored procedure to do an upsert into a table in the SQL Server database. Assume that the input data and the sink **Marketing** table each have three columns: **ProfileID**, **State**, and **Category**. Do the upsert based on the **ProfileID** column, and only apply it for a specific category called "ProductA".

1. In your database, define the table type with the same name as **sqlWriterTableType**. The schema of the table type is the same as the schema returned by your input data.

   ```
   CREATE TYPE [dbo].[MarketingType] AS TABLE(
       [ProfileID] [varchar](256) NOT NULL,
       [State] [varchar](256) NOT NULL,
       [Category] [varchar](256) NOT NULL
   )
   ```

2. In your database, define the stored procedure with the same name as **sqlWriterStoredProcedureName**. It handles input data from your specified source and merges into the output table. The parameter name of the table type in the stored procedure is the same as **tableName** defined in the dataset.

   ```
   CREATE PROCEDURE spOverwriteMarketing @Marketing [dbo].[MarketingType] READONLY, @category
   varchar(256)
   AS
   BEGIN
   MERGE [dbo].[Marketing] AS target
   USING @Marketing AS source
   ON (target.ProfileID = source.ProfileID and target.Category = @category)
   WHEN MATCHED THEN
       UPDATE SET State = source.State
   WHEN NOT MATCHED THEN
       INSERT (ProfileID, State, Category)
       VALUES (source.ProfileID, source.State, source.Category);
   END
   ```

3. In your pipeline, define the **SQL MI sink** section in the copy activity as follows:

```
"sink": {
    "type": "SqlMISink",
    "sqlWriterStoredProcedureName": "spOverwriteMarketing",
    "storedProcedureTableTypeParameterName": "Marketing",
    "sqlWriterTableType": "MarketingType",
    "storedProcedureParameters": {
        "category": {
            "value": "ProductA"
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from Azure SQL Managed Instance. For more information, see the source transformation and sink transformation in mapping data flows.

Source transformation

The below table lists the properties supported by Azure SQL Managed Instance source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow fetches all the data from the table specified in the dataset.	No	-	-
Query	If you select Query as input, specify a SQL query to fetch data from source, which overrides any table you specify in dataset. Using queries is a great way to reduce rows for testing or lookups. **Order By** clause is not supported, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table that you can use in data flow. Query example: `Select * from MyTable where customerId > 1000 and customerId < 2000`	No	String	query

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Batch size	Specify a batch size to chunk large data into reads.	No	Integer	batchSize
Isolation Level	Choose one of the following isolation levels: - Read Committed - Read Uncommitted (default) - Repeatable Read - Serializable - None (ignore isolation level)	No	READ_COMMITTED READ_UNCOMMITTED REPEATABLE_READ SERIALIZABLE NONE	isolationLevel

TIP

The common table expression (CTE) in SQL is not supported in the mapping data flow **Query** mode, because the prerequisite of using this mode is that queries can be used in the SQL query FROM clause but CTEs cannot do this. To use CTEs, you need to create a stored procedure using the following query:

```
CREATE PROC CTESP @query nvarchar(max)
AS
BEGIN
EXECUTE sp_executesql @query;
END
```

Then use the **Stored procedure** mode in the source transformation of the mapping data flow and set the `@query` like example `with CTE as (select 'test' as a) select * from CTE`. Then you can use CTEs as expected.

Azure SQL Managed Instance source script example

When you use Azure SQL Managed Instance as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    isolationLevel: 'READ_UNCOMMITTED',
    query: 'select * from MYTABLE',
    format: 'query') ~> SQLMISource
```

Sink transformation

The below table lists the properties supported by Azure SQL Managed Instance sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	deletable insertable updateable upsertable
Key columns	For updates, upserts and deletes, key column(s) must be set to determine which row to alter. The column name that you pick as the key will be used as part of the subsequent update, upsert, delete. Therefore, you must pick a column that exists in the Sink mapping.	No	Array	keys
Skip writing key columns	If you wish to not write the value to the key column, select "Skip writing key columns".	No	`true` or `false`	skipKeyWrites
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Batch size	Specify how many rows are being written in each batch. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.	No	Integer	batchSize
Pre and Post SQL scripts	Specify multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database.	No	String	preSQLs postSQLs

TIP

1. It's recommended to break single batch scripts with multiple commands into multiple batches.
2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

Azure SQL Managed Instance sink script example

When you use Azure SQL Managed Instance as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:false,
    insertable:true,
    updateable:true,
    upsertable:true,
    keys:['keyColumn'],
    format: 'table',
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> SQLMISink
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Data type mapping for SQL Managed Instance

When data is copied to and from SQL Managed Instance using copy activity, the following mappings are used from SQL Managed Instance data types to interim data types used internally within the service. To learn how the copy activity maps from the source schema and data type to the sink, see Schema and data type mappings.

SQL MANAGED INSTANCE DATA TYPE	INTERIM SERVICE DATA TYPE
bigint	Int64
binary	Byte[]
bit	Boolean
char	String, Char[]
date	DateTime
Datetime	DateTime
datetime2	DateTime
Datetimeoffset	DateTimeOffset
Decimal	Decimal
FILESTREAM attribute (varbinary(max))	Byte[]
Float	Double
image	Byte[]
int	Int32
money	Decimal
nchar	String, Char[]
ntext	String, Char[]
numeric	Decimal
nvarchar	String, Char[]
real	Single
rowversion	Byte[]
smalldatetime	DateTime
smallint	Int16
smallmoney	Decimal
sql_variant	Object
text	String, Char[]

SQL MANAGED INSTANCE DATA TYPE	INTERIM SERVICE DATA TYPE
time	TimeSpan
timestamp	Byte[]
tinyint	Int16
uniqueidentifier	Guid
varbinary	Byte[]
varchar	String, Char[]
xml	String

> **NOTE**
> For data types that map to the Decimal interim type, currently Copy activity supports precision up to 28. If you have data that requires precision larger than 28, consider converting to a string in a SQL query.

Using Always Encrypted

When you copy data from/to SQL Managed Instance with Always Encrypted, follow below steps:

1. Store the Column Master Key (CMK) in an Azure Key Vault. Learn more on how to configure Always Encrypted by using Azure Key Vault
2. Make sure to great access to the key vault where the Column Master Key (CMK) is stored. Refer to this article for required permissions.
3. Create linked service to connect to your SQL database and enable 'Always Encrypted' function by using either managed identity or service principal.

> **NOTE**
> SQL Managed Instance Always Encrypted supports below scenarios:
>
> 1. Either source or sink data stores is using managed identity or service principal as key provider authentication type.
> 2. Both source and sink data stores are using managed identity as key provider authentication type.
> 3. Both source and sink data stores are using the same service principal as key provider authentication type.

> **NOTE**
> Currently, SQL Managed Instance **Always Encrypted** is only supported for source transformation in mapping data flows.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy and transform data in Azure Synapse Analytics by using Azure Data Factory or Synapse pipelines

8/19/2022 • 40 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory or Synapse pipelines to copy data from and to Azure Synapse Analytics, and use Data Flow to transform data in Azure Data Lake Storage Gen2. To learn about Azure Data Factory, read the introductory article.

Supported capabilities

This Azure Synapse Analytics connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓
Mapping data flow (source/sink)	①	✓
Lookup activity	① ②	✓
GetMetadata activity	① ②	✓
Script activity	① ②	✓
Stored procedure activity	① ②	✓

① Azure integration runtime ② Self-hosted integration runtime

For Copy activity, this Azure Synapse Analytics connector supports these functions:

- Copy data by using SQL authentication and Azure Active Directory (Azure AD) Application token authentication with a service principal or managed identities for Azure resources.
- As a source, retrieve data by using a SQL query or stored procedure. You can also choose to parallel copy from an Azure Synapse Analytics source, see the Parallel copy from Azure Synapse Analytics section for details.
- As a sink, load data by using COPY statement or PolyBase or bulk insert. We recommend COPY statement or PolyBase for better copy performance. The connector also supports automatically creating destination table with DISTRIBUTION = ROUND_ROBIN if not exists based on the source schema.

> **IMPORTANT**
> If you copy data by using an Azure Integration Runtime, configure a server-level firewall rule so that Azure services can access the logical SQL server. If you copy data by using a self-hosted integration runtime, configure the firewall to allow the appropriate IP range. This range includes the machine's IP that is used to connect to Azure Synapse Analytics.

Get started

> **TIP**
>
> To achieve best performance, use PolyBase or COPY statement to load data into Azure Synapse Analytics. The Use PolyBase to load data into Azure Synapse Analytics and Use COPY statement to load data into Azure Synapse Analytics sections have details. For a walkthrough with a use case, see Load 1 TB into Azure Synapse Analytics under 15 minutes with Azure Data Factory.

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

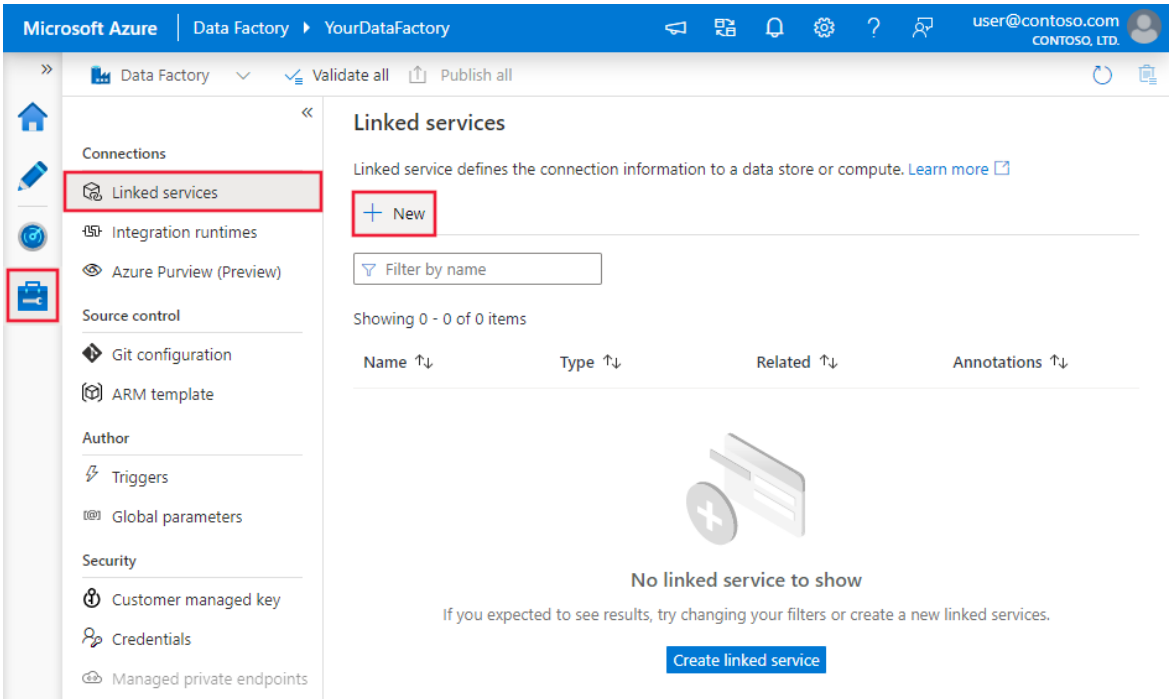
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Azure Synapse Analytics linked service using UI

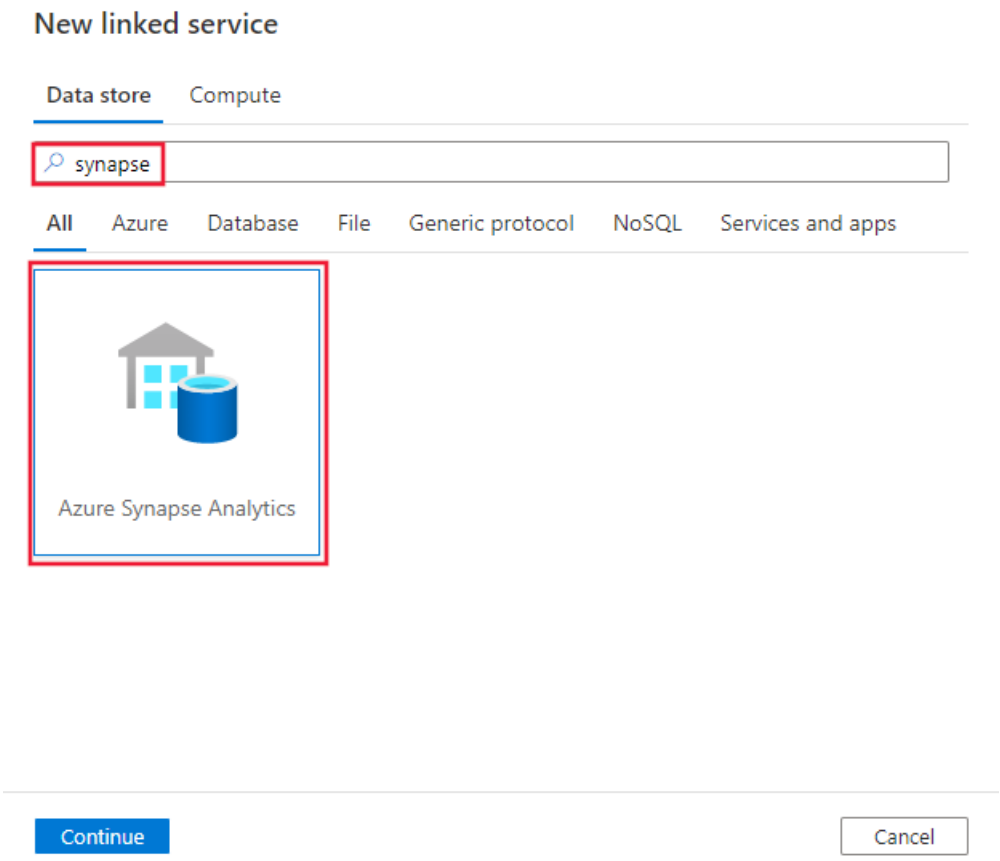
Use the following steps to create an Azure Synapse Analytics linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

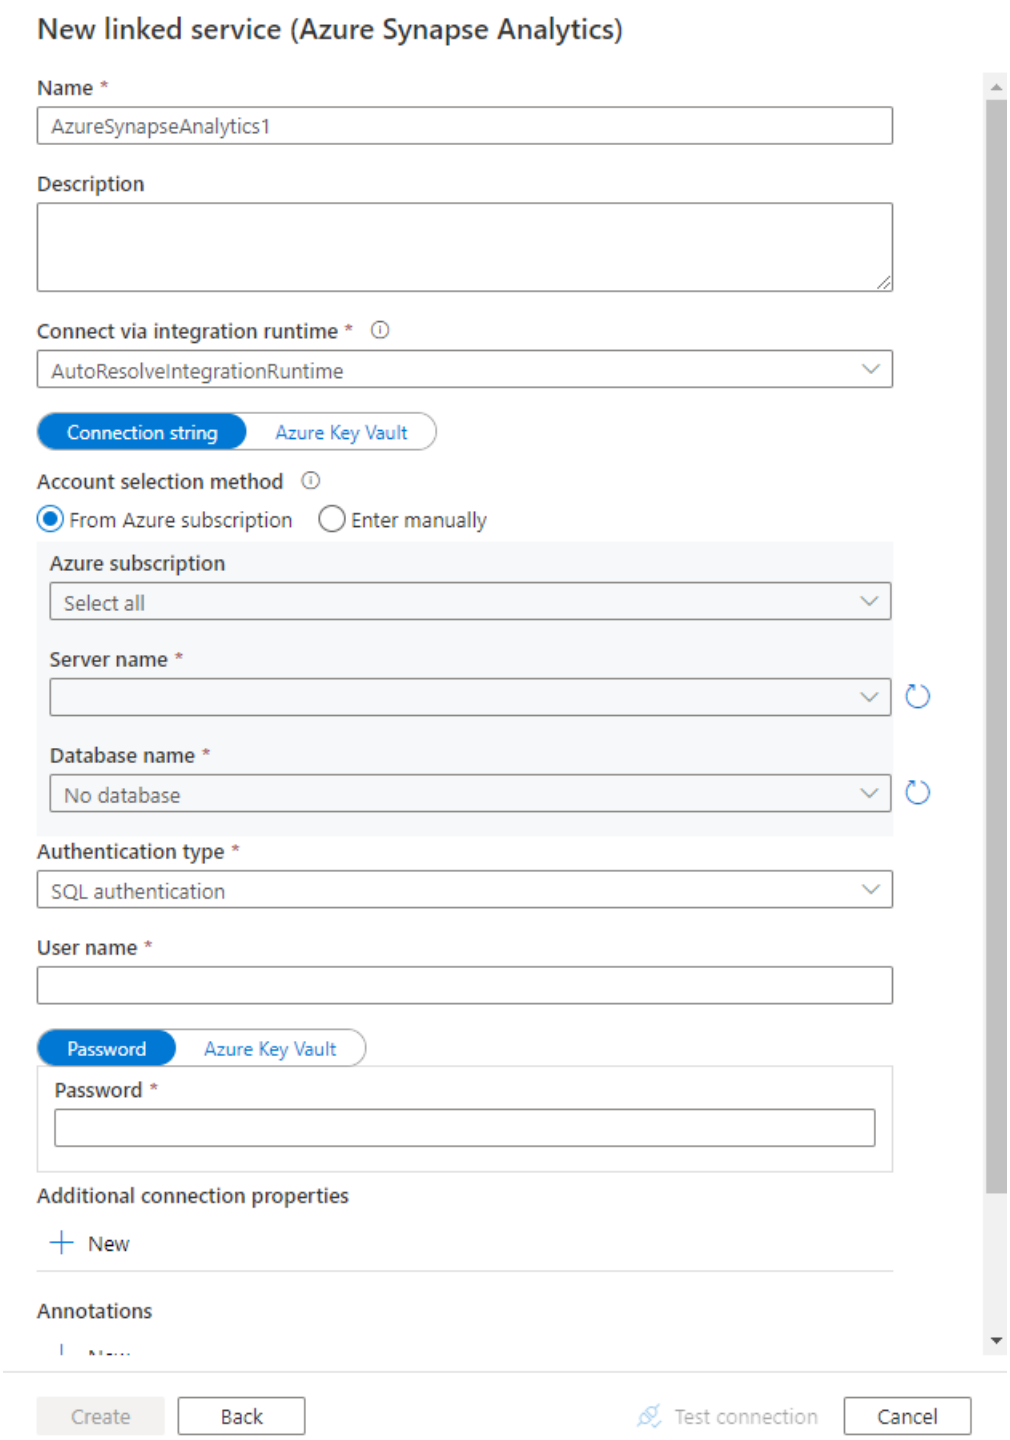
   - Azure Data Factory
   - Azure Synapse



2. Search for Synapse and select the Azure Synapse Analytics connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that define Data Factory and Synapse pipeline entities specific to an Azure Synapse Analytics connector.

Linked service properties

These generic properties are supported for an Azure Synapse Analytics linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureSqlDW**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify the information needed to connect to the Azure Synapse Analytics instance for the **connectionString** property. Mark this field as a SecureString to store it securely. You can also put password/service principal key in Azure Key Vault, and if it's SQL authentication pull the `password` configuration out of the connection string. See the JSON example below the table and Store credentials in Azure Key Vault article with more details.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure AD application is registered. Allowed values are `AzurePublic`, `AzureChina`, `AzureUsGovernment`, and `AzureGermany`. By default, the data factory or Synapse pipeline's cloud environment is used.	No
connectVia	The integration runtime to be used to connect to the data store. You can use Azure Integration Runtime or a self-hosted integration runtime (if your data store is located in a private network). If not specified, it uses the default Azure Integration Runtime.	No

For different authentication types, refer to the following sections on specific properties, prerequisites and JSON samples, respectively:

- SQL authentication
- Service principal authentication
- System-assigned managed identity authentication
- User-assigned managed identity authentication

> **TIP**
> When creating linked service for Azure Synapse **serverless** SQL pool from UI, choose "enter manually" instead of browsing from subscription.

> **TIP**
> If you hit error with error code as "UserErrorFailedToConnectToSqlServer" and message like "The session limit for the database is XXX and has been reached.", add `Pooling=false` to your connection string and try again.

SQL authentication

To use SQL authentication authentication type, specify the generic properties that are described in the preceding section.

Linked service example that uses SQL authentication

```
{
    "name": "AzureSqlDWLinkedService",
    "properties": {
        "type": "AzureSqlDW",
        "typeProperties": {
            "connectionString": "Server=tcp:<servername>.database.windows.net,1433;Database=
<databasename>;User ID=<username>@<servername>;Password=
<password>;Trusted_Connection=False;Encrypt=True;Connection Timeout=30"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Password in Azure Key Vault:

```
{
    "name": "AzureSqlDWLinkedService",
    "properties": {
        "type": "AzureSqlDW",
        "typeProperties": {
            "connectionString": "Server=tcp:<servername>.database.windows.net,1433;Database=
<databasename>;User ID=<username>@<servername>;Trusted_Connection=False;Encrypt=True;Connection Timeout=30",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Service principal authentication

To use service principal authentication, in addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the top-right corner of the Azure portal.	Yes

You also need to follow the steps below:

1. **Create an Azure Active Directory application** from the Azure portal. Make note of the application name and the following values that define the linked service:

   - Application ID
   - Application key
   - Tenant ID

2. **Provision an Azure Active Directory administrator** for your server in the Azure portal if you haven't already done so. The Azure AD administrator can be an Azure AD user or Azure AD group. If you grant the group with managed identity an admin role, skip steps 3 and 4. The administrator will have full access to the database.

3. **Create contained database users** for the service principal. Connect to the data warehouse from or to which you want to copy data by using tools like SSMS, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL:

   ```
   CREATE USER [your_application_name] FROM EXTERNAL PROVIDER;
   ```

4. **Grant the service principal needed permissions** as you normally do for SQL users or others. Run the following code, or refer to more options here. If you want to use PolyBase to load the data, learn the required database permission.

   ```
   EXEC sp_addrolemember db_owner, [your application name];
   ```

5. **Configure an Azure Synapse Analytics linked service** in an Azure Data Factory or Synapse workspace.

Linked service example that uses service principal authentication

```
{
    "name": "AzureSqlDWLinkedService",
    "properties": {
        "type": "AzureSqlDW",
        "typeProperties": {
            "connectionString": "Server=tcp:<servername>.database.windows.net,1433;Database=
<databasename>;Connection Timeout=30",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

System-assigned managed identities for Azure resources authentication

A data factory or Synapse workspace can be associated with a system-assigned managed identity for Azure resources that represents the resource. You can use this managed identity for Azure Synapse Analytics authentication. The designated resource can access and copy data from or to your data warehouse by using this identity.

To use system-assigned managed identity authentication, specify the generic properties that are described in the

preceding section, and follow these steps.

1. Provision an Azure Active Directory administrator for your server on the Azure portal if you haven't already done so. The Azure AD administrator can be an Azure AD user or Azure AD group. If you grant the group with system-assigned managed identity an admin role, skip steps 3 and 4. The administrator will have full access to the database.
2. Create contained database users for the system-assigned managed identity. Connect to the data warehouse from or to which you want to copy data by using tools like SSMS, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL.

   ```
   CREATE USER [your_resource_name] FROM EXTERNAL PROVIDER;
   ```

3. **Grant the system-assigned managed identity needed permissions** as you normally do for SQL users and others. Run the following code, or refer to more options here. If you want to use PolyBase to load the data, learn the required database permission.

   ```
   EXEC sp_addrolemember db_owner, [your_resource_name];
   ```

4. **Configure an Azure Synapse Analytics linked service**.

Example:

```
{
    "name": "AzureSqlDWLinkedService",
    "properties": {
        "type": "AzureSqlDW",
        "typeProperties": {
            "connectionString": "Server=tcp:<servername>.database.windows.net,1433;Database=
<databasename>;Connection Timeout=30"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

User-assigned managed identity authentication

A data factory or Synapse workspace can be associated with a user-assigned managed identities that represents the resource. You can use this managed identity for Azure Synapse Analytics authentication. The designated resource can access and copy data from or to your data warehouse by using this identity.

To use user-assigned managed identity authentication, in addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
credentials	Specify the user-assigned managed identity as the credential object.	Yes

You also need to follow the steps below:

1. Provision an Azure Active Directory administrator for your server on the Azure portal if you haven't already done so. The Azure AD administrator can be an Azure AD user or Azure AD group. If you grant the group with user-assigned managed identity an admin role, skip steps 3. The administrator will

have full access to the database.

2. **Create contained database users** for the user-assigned managed identity. Connect to the data warehouse from or to which you want to copy data by using tools like SSMS, with an Azure AD identity that has at least ALTER ANY USER permission. Run the following T-SQL.

   ```
   CREATE USER [your_resource_name] FROM EXTERNAL PROVIDER;
   ```

3. Create one or multiple user-assigned managed identities and **grant the user-assigned managed identity needed permissions** as you normally do for SQL users and others. Run the following code, or refer to more options here. If you want to use PolyBase to load the data, learn the required database permission.

   ```
   EXEC sp_addrolemember db_owner, [your_resource_name];
   ```

4. Assign one or multiple user-assigned managed identities to your data factory and create credentials for each user-assigned managed identity.

5. **Configure an Azure Synapse Analytics linked service**.

Example:

```
{
    "name": "AzureSqlDWLinkedService",
    "properties": {
        "type": "AzureSqlDW",
        "typeProperties": {
            "connectionString": "Server=tcp:<servername>.database.windows.net,1433;Database=
<databasename>;Connection Timeout=30",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

The following properties are supported for Azure Synapse Analytics dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **AzureSqlDWTable**.	Yes
schema	Name of the schema.	No for source, Yes for sink
table	Name of the table/view.	No for source, Yes for sink

PROPERTY	DESCRIPTION	REQUIRED
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No for source, Yes for sink

Dataset properties example

```
{
    "name": "AzureSQLDWDataset",
    "properties":
    {
        "type": "AzureSqlDWTable",
        "linkedServiceName": {
            "referenceName": "<Azure Synapse Analytics linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        }
    }
}
```

Copy Activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Azure Synapse Analytics source and sink.

Azure Synapse Analytics as the source

> **TIP**
> To load data from Azure Synapse Analytics efficiently by using data partitioning, learn more from Parallel copy from Azure Synapse Analytics.

To copy data from Azure Synapse Analytics, set the **type** property in the Copy Activity source to **SqlDWSource**. The following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity source must be set to **SqlDWSource**.	Yes
sqlReaderQuery	Use the custom SQL query to read data. Example: `select * from MyTable`.	No
sqlReaderStoredProcedureName	The name of the stored procedure that reads data from the source table. The last SQL statement must be a SELECT statement in the stored procedure.	No

PROPERTY	DESCRIPTION	REQUIRED
storedProcedureParameters	Parameters for the stored procedure. Allowed values are name or value pairs. Names and casing of parameters must match the names and casing of the stored procedure parameters.	No
isolationLevel	Specifies the transaction locking behavior for the SQL source. The allowed values are: **ReadCommitted**, **ReadUncommitted**, **RepeatableRead**, **Serializable**, **Snapshot**. If not specified, the database's default isolation level is used. For more information, see system.data.isolationlevel.	No
partitionOptions	Specifies the data partitioning options used to load data from Azure Synapse Analytics. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from an Azure Synapse Analytics is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`***:***		
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int`, `smallint`, `bigint`, `date`, `smalldatetime`, `datetime`, `datetime2`, or `datetimeoffset`) that will be used by range partitioning for parallel copy. If not specified, the index or the primary key of the table is detected automatically and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfDynamicRangePartitionCondition` in the WHERE clause. For an example, see the Parallel copy from SQL database section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No
partitionLowerBound	The minimum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No

Note the following point:

- When using stored procedure in source to retrieve data, note if your stored procedure is designed as returning different schema when different parameter value is passed in, you may encounter failure or see unexpected result when importing schema from UI or when copying data to SQL database with auto table creation.

Example: using SQL query

```
"activities":[
    {
        "name": "CopyFromAzureSQLDW",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure Synapse Analytics input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlDWSource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Example: using stored procedure

```
"activities":[
    {
        "name": "CopyFromAzureSQLDW",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Azure Synapse Analytics input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlDWSource",
                "sqlReaderStoredProcedureName": "CopyTestSrcStoredProcedureWithParameters",
                "storedProcedureParameters": {
                    "stringData": { "value": "str3" },
                    "identifier": { "value": "$$Text.Format('{0:yyyy}', <datetime parameter>)", "type":
"Int"}
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Sample stored procedure:

```
CREATE PROCEDURE CopyTestSrcStoredProcedureWithParameters
(
    @stringData varchar(20),
    @identifier int
)
AS
SET NOCOUNT ON;
BEGIN
    select *
    from dbo.UnitTestSrcTable
    where dbo.UnitTestSrcTable.stringData != stringData
    and dbo.UnitTestSrcTable.identifier != identifier
END
GO
```

Azure Synapse Analytics as sink

Azure Data Factory and Synapse pipelines support three ways to load data into Azure Synapse Analytics.

- Use COPY statement
- Use PolyBase
- Use bulk insert

The fastest and most scalable way to load data is through the COPY statement or the PolyBase.

To copy data to Azure Synapse Analytics, set the sink type in Copy Activity to **SqlDWSink**. The following properties are supported in the Copy Activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity sink must be set to **SqlDWSink**.	Yes
allowPolyBase	Indicates whether to use PolyBase to load data into Azure Synapse Analytics. `allowCopyCommand` and `allowPolyBase` cannot be both true. See Use PolyBase to load data into Azure Synapse Analytics section for constraints and details. Allowed values are **True** and **False** (default).	No. Apply when using PolyBase.
polyBaseSettings	A group of properties that can be specified when the `allowPolybase` property is set to **true**.	No. Apply when using PolyBase.

PROPERTY	DESCRIPTION	REQUIRED
allowCopyCommand	Indicates whether to use COPY statement to load data into Azure Synapse Analytics. `allowCopyCommand` and `allowPolyBase` cannot be both true. See Use COPY statement to load data into Azure Synapse Analytics section for constraints and details. Allowed values are **True** and **False** (default).	No. Apply when using COPY.
copyCommandSettings	A group of properties that can be specified when `allowCopyCommand` property is set to TRUE.	No. Apply when using COPY.
writeBatchSize	Number of rows to inserts into the SQL table **per batch**. The allowed value is **integer** (number of rows). By default, the service dynamically determines the appropriate batch size based on the row size.	No. Apply when using bulk insert.
writeBatchTimeout	Wait time for the batch insert operation to finish before it times out. The allowed value is **timespan**. Example: "00:30:00" (30 minutes).	No. Apply when using bulk insert.
preCopyScript	Specify a SQL query for Copy Activity to run before writing data into Azure Synapse Analytics in each run. Use this property to clean up the preloaded data.	No
tableOption	Specifies whether to automatically create the sink table if not exists based on the source schema. Allowed values are: `none` (default), `autoCreate`.	No
disableMetricsCollection	The service collects metrics such as Azure Synapse Analytics DWUs for copy performance optimization and recommendations, which introduce additional master DB access. If you are concerned with this behavior, specify `true` to turn it off.	No (default is `false`)
maxConcurrentConnections	The upper limit of concurrent connecti ons established to the data store durin g the activity run. Specify a value only when you want to limit concurrent con nections.	No

PROPERTY	DESCRIPTION	REQUIRED
WriteBehavior	Specify the write behavior for copy activity to load data into Azure SQL Database. The allowed value is **Insert** and **Upsert**. By default, the service uses insert to load data.	No
upsertSettings	Specify the group of the settings for write behavior. Apply when the WriteBehavior option is `Upert`.	No
Under `upsertSettings`***:***		
keys	Specify the column names for unique row identification. Either a single key or a series of keys can be used. If not specified, the primary key is used.	No
interimSchemaName	Specify the interim schema for creating interim table. Note: user need to have the permission for creating and deleting table. By default, interim table will share the same schema as sink table.	No

Example 1: Azure Synapse Analytics sink

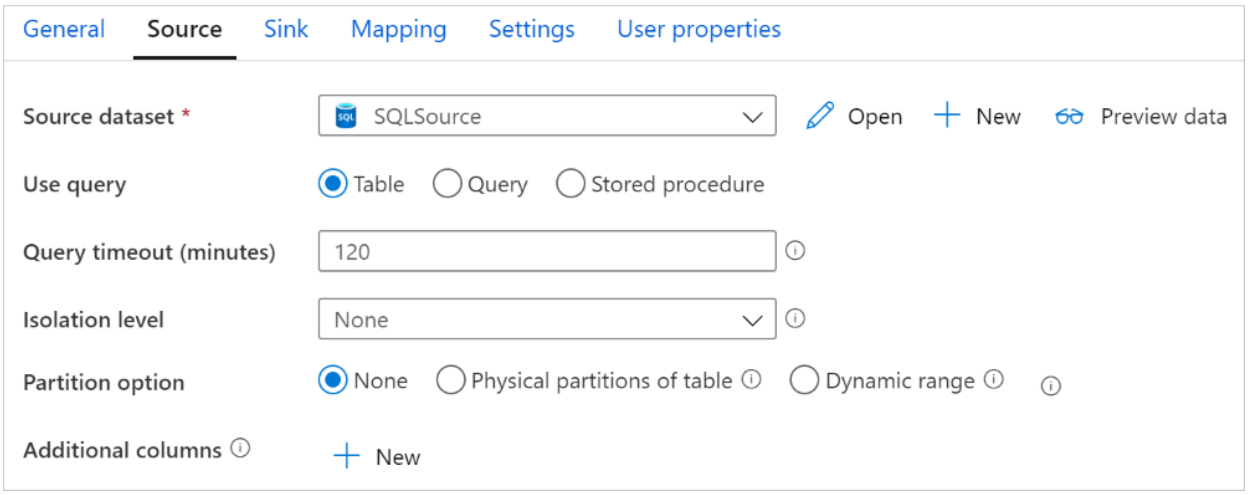
```
"sink": {
    "type": "SqlDWSink",
    "allowPolyBase": true,
    "polyBaseSettings":
    {
        "rejectType": "percentage",
        "rejectValue": 10.0,
        "rejectSampleValue": 100,
        "useTypeDefault": true
    }
}
```

Example 2: Upsert data

```
"sink": {
    "type": "SqlDWSink",
    "writeBehavior": "Upsert",
    "upsertSettings": {
        "keys": [
             "<column name>"
        ],
        "interimSchemaName": "<interim schema name>"
    },
}
```

Parallel copy from Azure Synapse Analytics

The Azure Synapse Analytics connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your Azure Synapse Analytics source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Azure Synapse Analytics.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Azure Synapse Analytics. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions. To check if your table has physical partition or not, you can refer to this query.
Full load from large table, without physical partitions, while with an integer or datetime column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column** (optional): Specify the column used to partition data. If not specified, the index or primary key column is used. **Partition upper bound** and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the table will be partitioned and copied. If not specified, copy activity auto detect the values. For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions - IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.

SCENARIO	SUGGESTED SETTINGS

Load a large amount of data by using a custom query, without physical partitions, while with an integer or date/datetime column for data partitioning.	**Partition options**: Dynamic range partition.
	Query:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to partition data.
	Partition upper bound and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the query result will be partitioned and copied. If not specified, copy activity auto detect the value.
	
	During execution, the service replaces `?AdfRangePartitionColumnName` with the actual column name and value ranges for each partition, and sends to Azure Synapse Analytics.
	For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions- IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.
	
	Here are more sample queries for different scenarios:
	1. Query the whole table:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition`
	2. Query from a table with column selection and additional where-clause filters:
	`SELECT <column_list> FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	3. Query with subqueries:
	`SELECT <column_list> FROM (<your_sub_query>) AS T WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	4. Query with partition in subquery:
	`SELECT <column_list> FROM (SELECT <your_sub_query_column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition) AS T`

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.
3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).
5. Note Azure Synapse Analytics can execute a maximum of 32 queries at a moment, setting "Degree of copy parallelism" too large may cause a Synapse throttling issue.

Example: full load from large table with physical partitions

```
"source": {
    "type": "SqlDWSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "SqlDWSource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Sample query to check physical partition

```
SELECT DISTINCT s.name AS SchemaName, t.name AS TableName, c.name AS ColumnName, CASE WHEN c.name IS NULL
THEN 'no' ELSE 'yes' END AS HasPartition
FROM sys.tables AS t
LEFT JOIN sys.objects AS o ON t.object_id = o.object_id
LEFT JOIN sys.schemas AS s ON o.schema_id = s.schema_id
LEFT JOIN sys.indexes AS i ON t.object_id = i.object_id
LEFT JOIN sys.index_columns AS ic ON ic.partition_ordinal > 0 AND ic.index_id = i.index_id AND ic.object_id
= t.object_id
LEFT JOIN sys.columns AS c ON c.object_id = ic.object_id AND c.column_id = ic.column_id
LEFT JOIN sys.types AS y ON c.system_type_id = y.system_type_id
WHERE s.name='[your schema]' AND t.name = '[your table name]'
```

If the table has physical partition, you would see "HasPartition" as "yes".

Use COPY statement to load data into Azure Synapse Analytics

Using COPY statement is a simple and flexible way to load data into Azure Synapse Analytics with high throughput. To learn more details, check Bulk load data using the COPY statement

- If your source data is in **Azure Blob or Azure Data Lake Storage Gen2**, and the **format is COPY statement compatible**, you can use copy activity to directly invoke COPY statement to let Azure Synapse Analytics pull the data from source. For details, see **Direct copy by using COPY statement**.
- If your source data store and format isn't originally supported by COPY statement, use the **Staged copy by using COPY statement** feature instead. The staged copy feature also provides you better throughput. It automatically converts the data into COPY statement compatible format, stores the data in Azure Blob storage, then calls COPY statement to load data into Azure Synapse Analytics.

> **TIP**
> When using COPY statement with Azure Integration Runtime, effective Data Integration Units (DIU) is always 2. Tuning the DIU doesn't impact the performance, as loading data from storage is powered by the Azure Synapse engine.

Direct copy by using COPY statement

Azure Synapse Analytics COPY statement directly supports Azure Blob, Azure Data Lake Storage Gen1 and

Azure Data Lake Storage Gen2. If your source data meets the criteria described in this section, use COPY statement to copy directly from the source data store to Azure Synapse Analytics. Otherwise, use Staged copy by using COPY statement. the service checks the settings and fails the copy activity run if the criteria is not met.

1. The **source linked service and format** are with the following types and authentication methods:

SUPPORTED SOURCE DATA STORE TYPE	SUPPORTED FORMAT	SUPPORTED SOURCE AUTHENTICATION TYPE
Azure Blob	Delimited text	Account key authentication, shared access signature authentication, service principal authentication, managed identity authentication
	Parquet	Account key authentication, shared access signature authentication
	ORC	Account key authentication, shared access signature authentication
Azure Data Lake Storage Gen2	Delimited text Parquet ORC	Account key authentication, service principal authentication, managed identity authentication

> **IMPORTANT**
> - When you use managed identity authentication for your storage linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
> - If your Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.

2. Format settings are with the following:
   a. For **Parquet**: `compression` can be **no compression**, **Snappy**, or `GZip`.
   b. For **ORC**: `compression` can be **no compression**, `zlib`, or **Snappy**.
   c. For **Delimited text**:
      a. `rowDelimiter` is explicitly set as **single character** or "**\r\n**", the default value is not supported.
      b. `nullValue` is left as default or set to **empty string** ("").
      c. `encodingName` is left as default or set to **utf-8 or utf-16**.
      d. `escapeChar` must be same as `quoteChar`, and is not empty.
      e. `skipLineCount` is left as default or set to 0.
      f. `compression` can be **no compression** or `GZip`.
3. If your source is a folder, `recursive` in copy activity must be set to true, and `wildcardFilename` need to be `*` or `*.*`.
4. `wildcardFolderPath`, `wildcardFilename` (other than `*` or `*.*`), `modifiedDateTimeStart`, `modifiedDateTimeEnd`, `prefix`, `enablePartitionDiscovery` and `additionalColumns` are not specified.

The following COPY statement settings are supported under `allowCopyCommand` in copy activity:

PROPERTY	DESCRIPTION	REQUIRED
defaultValues	Specifies the default values for each target column in Azure Synapse Analytics. The default values in the property overwrite the DEFAULT constraint set in the data warehouse, and identity column cannot have a default value.	No
additionalOptions	Additional options that will be passed to an Azure Synapse Analytics COPY statement directly in "With" clause in COPY statement. Quote the value as needed to align with the COPY statement requirements.	No

```
"activities":[
    {
        "name": "CopyFromAzureBlobToSQLDataWarehouseViaCOPY",
        "type": "Copy",

                        "MAXERRORS":"10000",
                        "DATEFORMAT":"'ymd'"
                    }
                }
            },
            "enableSkipIncompatibleRow": true
        }
    }
]
```

Staged copy by using COPY statement

When your source data is not natively compatible with COPY statement, enable data copying via an interim staging Azure Blob or Azure Data Lake Storage Gen2 (it can't be Azure Premium Storage). In this case, the service automatically converts the data to meet the data format requirements of COPY statement. Then it invokes COPY statement to load data into Azure Synapse Analytics. Finally, it cleans up your temporary data from the storage. See Staged copy for details about copying data via a staging.

To use this feature, create an Azure Blob Storage linked service or Azure Data Lake Storage Gen2 linked service with **account key or system-managed identity authentication** that refers to the Azure storage account as the interim storage.

> **IMPORTANT**
>
> - When you use managed identity authentication for your staging linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
> - If your staging Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.

> **IMPORTANT**
>
> If your staging Azure Storage is configured with Managed Private Endpoint and has the storage firewall enabled, you must use managed identity authentication and grant Storage Blob Data Reader permissions to the Synapse SQL Server to ensure it can access the staged files during the COPY statement load.

```
"activities":[
    {
        "name": "CopyFromSQLServerToSQLDataWarehouseViaCOPYstatement",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "SQLServerDataset",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "AzureSQLDWDataset",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlSource",
            },
            "sink": {
                "type": "SqlDWSink",
                "allowCopyCommand": true
            },
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingStorage",
                    "type": "LinkedServiceReference"
                }
            }
        }
    }
]
```

Use PolyBase to load data into Azure Synapse Analytics

Using PolyBase is an efficient way to load a large amount of data into Azure Synapse Analytics with high throughput. You'll see a large gain in the throughput by using PolyBase instead of the default BULKINSERT mechanism. For a walkthrough with a use case, see Load 1 TB into Azure Synapse Analytics.

- If your source data is in **Azure Blob, Azure Data Lake Storage Gen1 or Azure Data Lake Storage Gen2**, and the **format is PolyBase compatible**, you can use copy activity to directly invoke PolyBase to let Azure Synapse Analytics pull the data from source. For details, see **Direct copy by using PolyBase**.
- If your source data store and format isn't originally supported by PolyBase, use the **Staged copy by using PolyBase** feature instead. The staged copy feature also provides you better throughput. It automatically converts the data into PolyBase-compatible format, stores the data in Azure Blob storage, then calls PolyBase to load data into Azure Synapse Analytics.

> **TIP**
> Learn more on Best practices for using PolyBase. When using PolyBase with Azure Integration Runtime, effective Data Integration Units (DIU) for direct or staged storage-to-Synapse is always 2. Tuning the DIU doesn't impact the performance, as loading data from storage is powered by Synapse engine.

The following PolyBase settings are supported under `polyBaseSettings` in copy activity:

PROPERTY	DESCRIPTION	REQUIRED
rejectValue	Specifies the number or percentage of rows that can be rejected before the query fails. Learn more about PolyBase's reject options in the Arguments section of CREATE EXTERNAL TABLE (Transact-SQL). Allowed values are 0 (default), 1, 2, etc.	No
rejectType	Specifies whether the **rejectValue** option is a literal value or a percentage. Allowed values are **Value** (default) and **Percentage**.	No
rejectSampleValue	Determines the number of rows to retrieve before PolyBase recalculates the percentage of rejected rows. Allowed values are 1, 2, etc.	Yes, if the **rejectType** is **percentage**.

PROPERTY	DESCRIPTION	REQUIRED
useTypeDefault	Specifies how to handle missing values in delimited text files when PolyBase retrieves data from the text file. Learn more about this property from the Arguments section in CREATE EXTERNAL FILE FORMAT (Transact-SQL). Allowed values are **True** and **False** (default).	No

Direct copy by using PolyBase

Azure Synapse Analytics PolyBase directly supports Azure Blob, Azure Data Lake Storage Gen1 and Azure Data Lake Storage Gen2. If your source data meets the criteria described in this section, use PolyBase to copy directly from the source data store to Azure Synapse Analytics. Otherwise, use Staged copy by using PolyBase.

> **TIP**
> To copy data efficiently to Azure Synapse Analytics, learn more from Azure Data Factory makes it even easier and convenient to uncover insights from data when using Data Lake Store with Azure Synapse Analytics.

If the requirements aren't met, the service checks the settings and automatically falls back to the BULKINSERT mechanism for the data movement.

1. The **source linked service** is with the following types and authentication methods:

SUPPORTED SOURCE DATA STORE TYPE	SUPPORTED SOURCE AUTHENTICATION TYPE
Azure Blob	Account key authentication, managed identity authentication
Azure Data Lake Storage Gen1	Service principal authentication
Azure Data Lake Storage Gen2	Account key authentication, managed identity authentication

> **IMPORTANT**
> - When you use managed identity authentication for your storage linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
> - If your Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.

2. The **source data format** is of **Parquet**, **ORC**, or **Delimited text**, with the following configurations:

   a. Folder path doesn't contain wildcard filter.

   b. File name is empty, or points to a single file. If you specify wildcard file name in copy activity, it can only be `*` or `*.*`.

   c. `rowDelimiter` is **default**, **\n**, **\r\n**, or **\r**.

d. `nullValue` is left as default or set to **empty string** (""), and `treatEmptyAsNull` is left as default or set to true.

e. `encodingName` is left as default or set to **utf-8**.

f. `quoteChar`, `escapeChar`, and `skipLineCount` aren't specified. PolyBase support skip header row, which can be configured as `firstRowAsHeader`.

g. `compression` can be **no compression**, `GZip`, or **Deflate**.

3. If your source is a folder, `recursive` in copy activity must be set to true.

4. `wildcardFolderPath`, `wildcardFilename`, `modifiedDateTimeStart`, `modifiedDateTimeEnd`, `prefix`, `enablePartitionDiscovery`, and `additionalColumns` are not specified.

> **NOTE**
> If your source is a folder, note PolyBase retrieves files from the folder and all of its subfolders, and it doesn't retrieve data from files for which the file name begins with an underline (_) or a period (.), as documented here - LOCATION argument.

```
"activities":[
    {
        "name": "CopyFromAzureBlobToSQLDataWarehouseViaPolyBase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "ParquetDataset",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "AzureSQLDWDataset",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ParquetSource",
                "storeSettings":{
                    "type": "AzureBlobStorageReadSettings",
                    "recursive": true
                }
            },
            "sink": {
                "type": "SqlDWSink",
                "allowPolyBase": true
            }
        }
    }
]
```

Staged copy by using PolyBase

When your source data is not natively compatible with PolyBase, enable data copying via an interim staging Azure Blob or Azure Data Lake Storage Gen2 (it can't be Azure Premium Storage). In this case, the service automatically converts the data to meet the data format requirements of PolyBase. Then it invokes PolyBase to load data into Azure Synapse Analytics. Finally, it cleans up your temporary data from the storage. See Staged copy for details about copying data via a staging.

To use this feature, create an Azure Blob Storage linked service or Azure Data Lake Storage Gen2 linked service with **account key or managed identity authentication** that refers to the Azure storage account as the interim storage.

IMPORTANT

- When you use managed identity authentication for your staging linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
- If your staging Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.

IMPORTANT

If your staging Azure Storage is configured with Managed Private Endpoint and has the storage firewall enabled, you must use managed identity authentication and grant Storage Blob Data Reader permissions to the Synapse SQL Server to ensure it can access the staged files during the PolyBase load.

```
"activities":[
    {
        "name": "CopyFromSQLServerToSQLDataWarehouseViaPolyBase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "SQLServerDataset",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "AzureSQLDWDataset",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlSource",
            },
            "sink": {
                "type": "SqlDWSink",
                "allowPolyBase": true
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingStorage",
                    "type": "LinkedServiceReference"
                }
            }
        }
    }
]
```

Best practices for using PolyBase

The following sections provide best practices in addition to those practices mentioned in Best practices for Azure Synapse Analytics.

Required database permission

To use PolyBase, the user that loads data into Azure Synapse Analytics must have "CONTROL" permission on the target database. One way to achieve that is to add the user as a member of the **db_owner** role. Learn how to do that in the Azure Synapse Analytics overview.

Row size and data type limits

PolyBase loads are limited to rows smaller than 1 MB. It cannot be used to load to VARCHR(MAX), NVARCHAR(MAX), or VARBINARY(MAX). For more information, see Azure Synapse Analytics service capacity limits.

When your source data has rows greater than 1 MB, you might want to vertically split the source tables into several small ones. Make sure that the largest size of each row doesn't exceed the limit. The smaller tables can then be loaded by using PolyBase and merged together in Azure Synapse Analytics.

Alternatively, for data with such wide columns, you can use non-PolyBase to load the data by turning off "allow PolyBase" setting.

Azure Synapse Analytics resource class

To achieve the best possible throughput, assign a larger resource class to the user that loads data into Azure Synapse Analytics via PolyBase.

PolyBase troubleshooting

Loading to Decimal column

If your source data is in text format or other non-PolyBase compatible stores (using staged copy and PolyBase), and it contains empty value to be loaded into Azure Synapse Analytics Decimal column, you may get the following error:

```
ErrorCode=FailedDbOperation, ......HadoopSqlException: Error converting data type VARCHAR to
DECIMAL.....Detailed Message=Empty string can't be converted to DECIMAL.....
```

The solution is to unselect "**Use type default**" option (as false) in copy activity sink -> PolyBase settings. "USE_TYPE_DEFAULT" is a PolyBase native configuration, which specifies how to handle missing values in delimited text files when PolyBase retrieves data from the text file.

Check the tableName property in Azure Synapse Analytics

The following table gives examples of how to specify the **tableName** property in the JSON dataset. It shows several combinations of schema and table names.

DB SCHEMA	TABLE NAME	TABLENAME JSON PROPERTY
dbo	MyTable	MyTable or dbo.MyTable or [dbo].[MyTable]
dbo1	MyTable	dbo1.MyTable or [dbo1].[MyTable]
dbo	My.Table	[My.Table] or [dbo].[My.Table]
dbo1	My.Table	[dbo1].[My.Table]

If you see the following error, the problem might be the value you specified for the **tableName** property. See the preceding table for the correct way to specify values for the **tableName** JSON property.

```
Type=System.Data.SqlClient.SqlException,Message=Invalid object name 'stg.Account_test'.,Source=.Net
SqlClient Data Provider
```

Columns with default values

Currently, the PolyBase feature accepts only the same number of columns as in the target table. An example is a table with four columns where one of them is defined with a default value. The input data still needs to have four columns. A three-column input dataset yields an error similar to the following message:

```
All columns of the table must be specified in the INSERT BULK statement.
```

The NULL value is a special form of the default value. If the column is nullable, the input data in the blob for that column might be empty. But it can't be missing from the input dataset. PolyBase inserts NULL for missing values in Azure Synapse Analytics.

External file access failed

If you receive the following error, ensure that you are using managed identity authentication and have granted Storage Blob Data Reader permissions to the Azure Synapse workspace's managed identity.

```
Job failed due to reason: at Sink '[SinkName]':
shaded.msdataflow.com.microsoft.sqlserver.jdbc.SQLServerException: External file access failed due to
internal error: 'Error occurred while accessing HDFS: Java exception raised on call to
HdfsBridge_IsDirExist. Java exception message:\r\nHdfsBridge::isDirExist
```

For more information, see Grant permissions to managed identity after workspace creation.

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from Azure Synapse Analytics. For more information, see the source transformation and sink transformation in mapping data flows.

Source transformation

Settings specific to Azure Synapse Analytics are available in the **Source Options** tab of the source transformation.

Input Select whether you point your source at a table (equivalent of `Select * from <table-name>`) or enter a custom SQL query.

Enable Staging It is highly recommended that you use this option in production workloads with Azure Synapse Analytics sources. When you execute a data flow activity with Azure Synapse Analytics sources from a pipeline, you will be prompted for a staging location storage account and will use that for staged data loading. It is the fastest mechanism to load data from Azure Synapse Analytics.

- When you use managed identity authentication for your storage linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
- If your Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.
- When you use Azure Synapse **serverless** SQL pool as source, enable staging is not supported.

Query: If you select Query in the input field, enter a SQL query for your source. This setting overrides any table that you've chosen in the dataset. **Order By** clauses aren't supported here, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table. This query will produce a source table that you can use in your data flow. Using queries is also a great way to reduce rows for testing or for lookups.

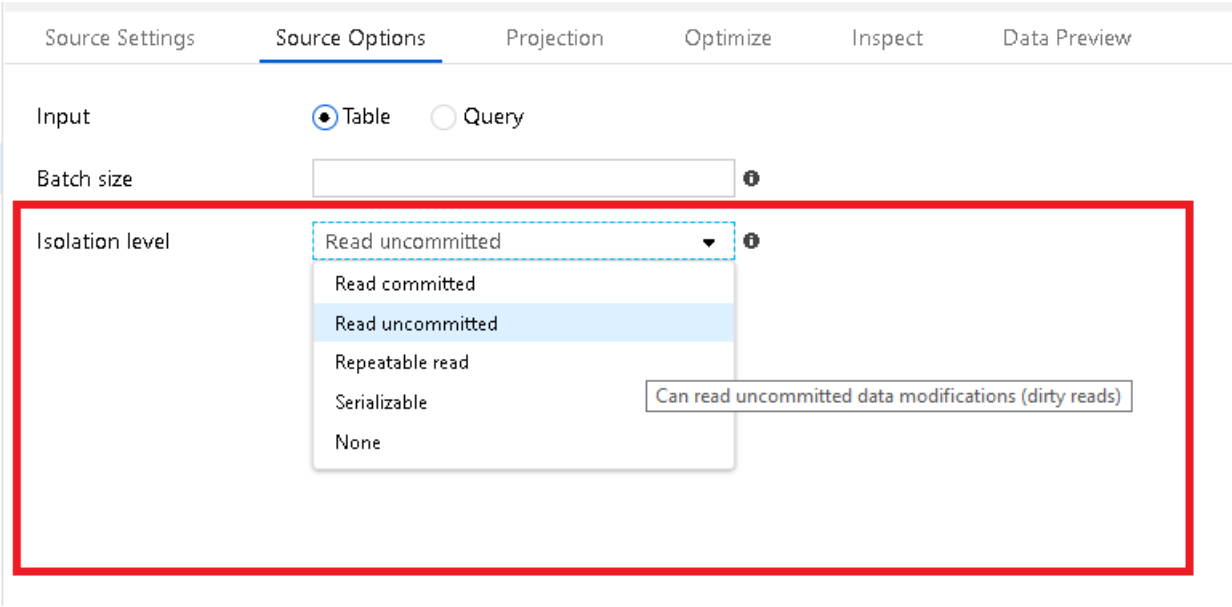
SQL Example: `Select * from MyTable where customerId > 1000 and customerId < 2000`

Batch size: Enter a batch size to chunk large data into reads. In data flows, this setting will be used to set Spark columnar caching. This is an option field, which will use Spark defaults if it is left blank.

Isolation Level: The default for SQL sources in mapping data flow is read uncommitted. You can change the isolation level here to one of these values:

- Read Committed

- Read Uncommitted
- Repeatable Read
- Serializable
- None (ignore isolation level)



Sink transformation

Settings specific to Azure Synapse Analytics are available in the **Settings** tab of the sink transformation.

Update method: Determines what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an alter-row transformation is required to tag rows for those actions. For updates, upserts and deletes, a key column or columns must be set to determine which row to alter.

Table action: Determines whether to recreate or remove all rows from the destination table prior to writing.

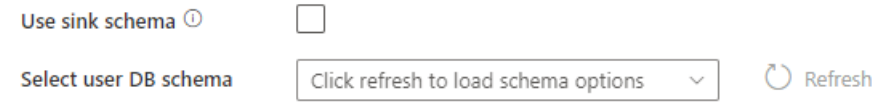
- None: No action will be done to the table.
- Recreate: The table will get dropped and recreated. Required if creating a new table dynamically.
- Truncate: All rows from the target table will get removed.

Enable staging: This enables loading into Azure Synapse Analytics SQL Pools using the copy command and is recommended for most Synapse sinks. The staging storage is configured in Execute Data Flow activity.

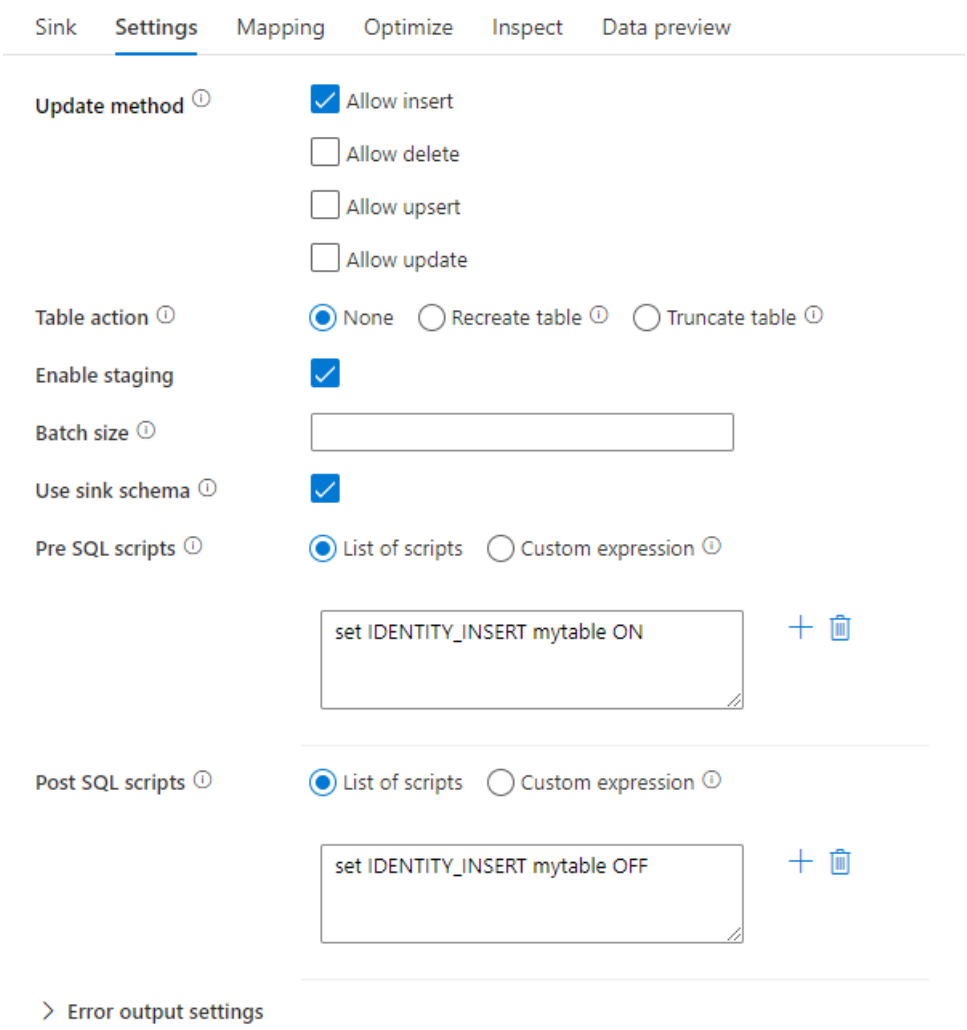
- When you use managed identity authentication for your storage linked service, learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.
- If your Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage.

Batch size: Controls how many rows are being written in each bucket. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.

Use sink schema: By default, a temporary table will be created under the sink schema as staging. You can alternatively uncheck the **Use sink schema** option and instead, in **Select user DB schema**, specify a schema name under which Data Factory will create a staging table to load upstream data and automatically clean them up upon completion. Make sure you have create table permission in the database and alter permission on the schema.



Pre and Post SQL scripts: Enter multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database



> **TIP**
>
> 1. It's recommended to break single batch scripts with multiple commands into multiple batches.
> 2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

Error row handling

When writing to Azure Synapse Analytics, certain rows of data may fail due to constraints set by the destination. Some common errors include:

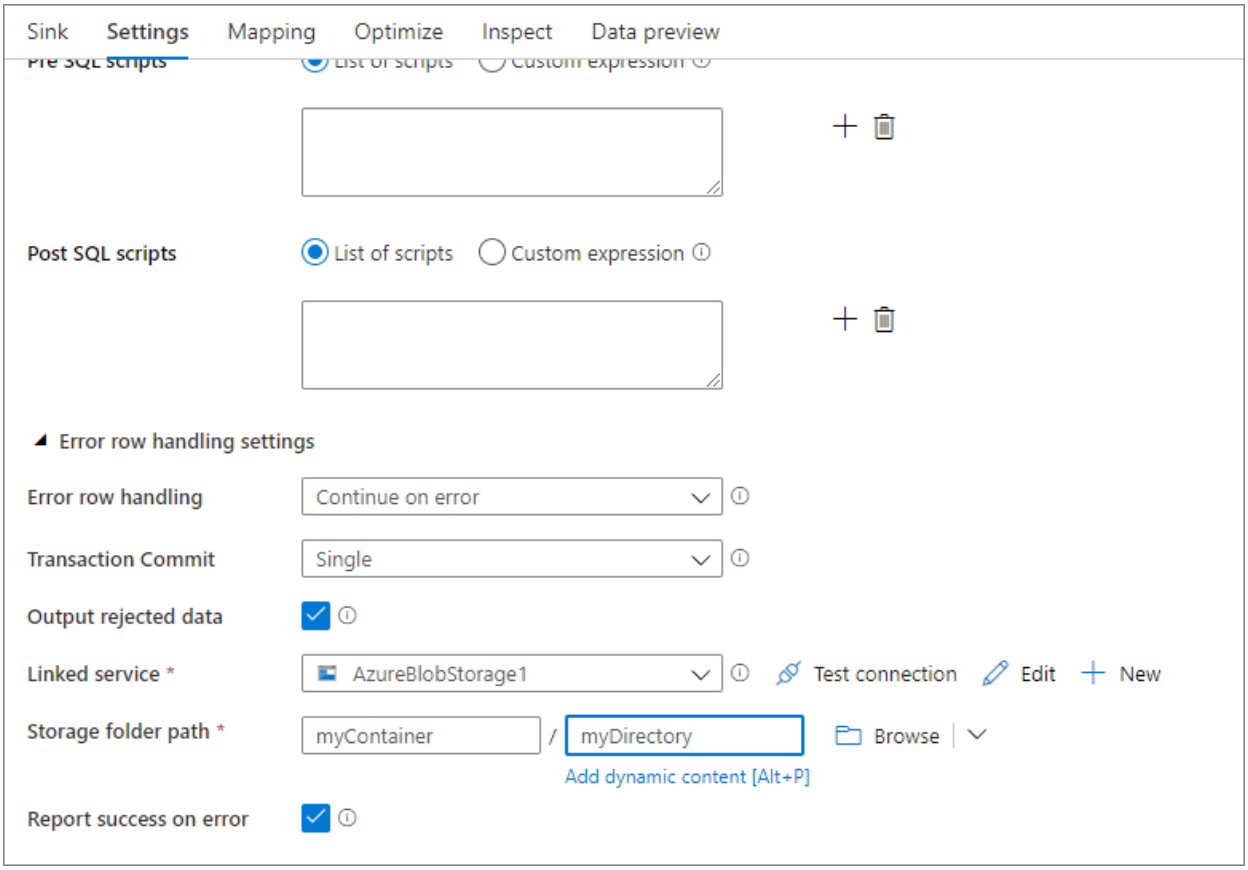
- String or binary data would be truncated in table
- Cannot insert the value NULL into column
- Conversion failed when converting the value to data type

By default, a data flow run will fail on the first error it gets. You can choose to **Continue on error** that allows your data flow to complete even if individual rows have errors. The service provides different options for you to handle these error rows.

Transaction Commit: Choose whether your data gets written in a single transaction or in batches. Single transaction will provide better performance and no data written will be visible to others until the transaction completes. Batch transactions have worse performance but can work for large datasets.

Output rejected data: If enabled, you can output the error rows into a csv file in Azure Blob Storage or an Azure Data Lake Storage Gen2 account of your choosing. This will write the error rows with three additional columns: the SQL operation like INSERT or UPDATE, the data flow error code, and the error message on the row.

Report success on error: If enabled, the data flow will be marked as a success even if error rows are found.



Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Data type mapping for Azure Synapse Analytics

When you copy data from or to Azure Synapse Analytics, the following mappings are used from Azure Synapse Analytics data types to Azure Data Factory interim data types. These mappings are also used when copying data from or to Azure Synapse Analytics using Synapse pipelines, since pipelines also implement Azure Data Factory within Azure Synapse. See schema and data type mappings to learn how Copy Activity maps the source schema and data type to the sink.

> **TIP**
> Refer to Table data types in Azure Synapse Analytics article on Azure Synapse Analytics supported data types and the workarounds for unsupported ones.

AZURE SYNAPSE ANALYTICS DATA TYPE	DATA FACTORY INTERIM DATA TYPE

Copy data to and from Azure Table storage using Azure Data Factory or Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data to and from Azure Table storage. It builds on the Copy Activity overview article that presents a general overview of Copy Activity.

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Supported capabilities

This Azure Table storage connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR	MANAGED PRIVATE ENDPOINT
Copy activity (source/sink)	① ②	✓ Exclude storage account V1
Lookup activity	① ②	✓ Exclude storage account V1

① Azure integration runtime ② Self-hosted integration runtime

You can copy data from any supported source data store to Table storage. You also can copy data from Table storage to any supported sink data store. For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this Azure Table connector supports copying data by using account key and service shared access signature authentications.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

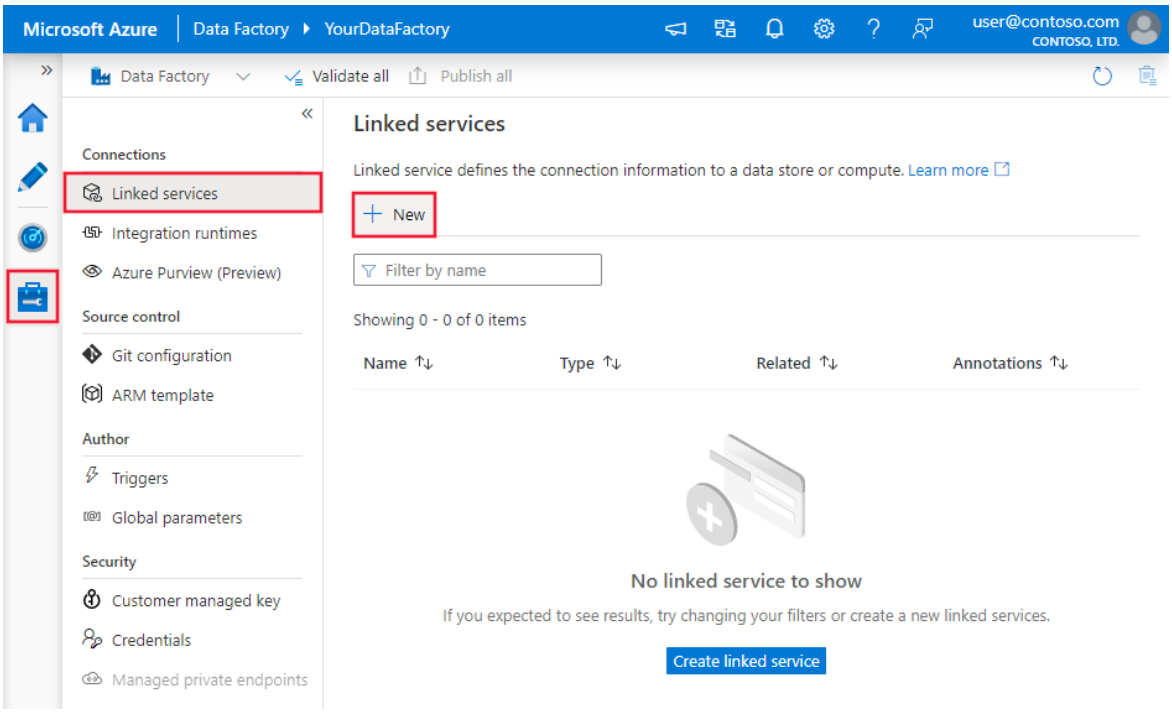
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an Azure Table storage linked service using UI

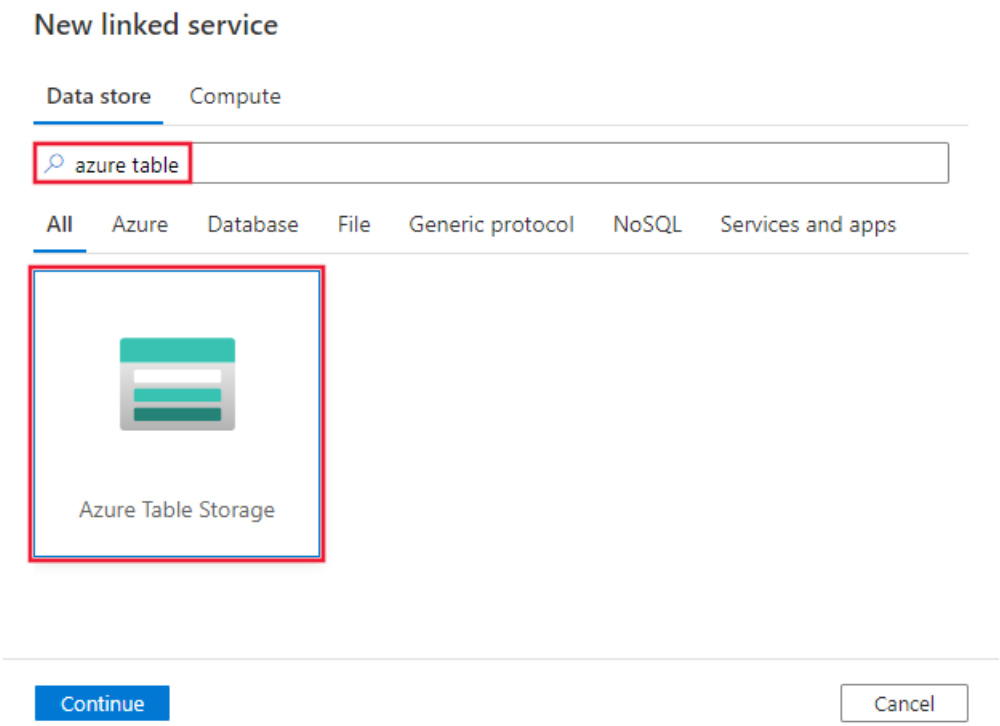
Use the following steps to create an Azure Table storage linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

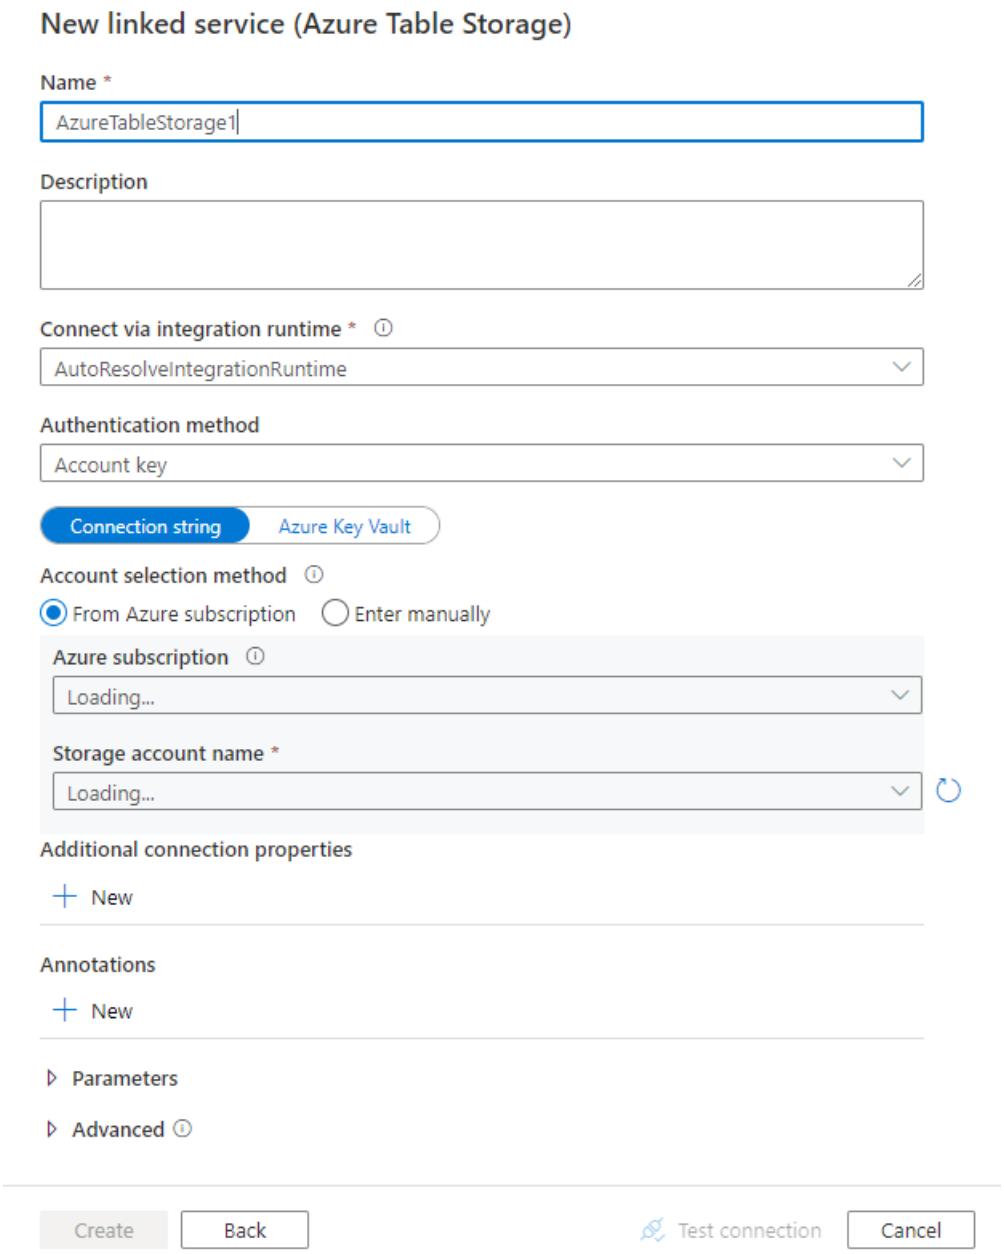
   - Azure Data Factory
   - Azure Synapse



2. Search for Azure Table and select the Azure Table storage connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Azure Table storage.

Linked service properties

Use an account key

You can create an Azure Storage linked service by using the account key. It provides the the service with global access to Storage. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureTableStorage**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify the information needed to connect to Storage for the connectionString property. You can also put account key in Azure Key Vault and pull the `accountKey` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use Azure Integration Runtime or Self-hosted Integration Runtime (if your data store is located in a private network). If not specified, it uses the default Azure Integration Runtime.	No

> **NOTE**
> If you were using "AzureStorage" type linked service, it is still supported as-is, while you are suggested to use this new "AzureTableStorage" linked service type going forward.

Example:

```
{
    "name": "AzureTableStorageLinkedService",
    "properties": {
        "type": "AzureTableStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;AccountKey=
<accountkey>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store account key in Azure Key Vault

```
{
    "name": "AzureTableStorageLinkedService",
    "properties": {
        "type": "AzureTableStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<accountname>;",
            "accountKey": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use shared access signature authentication

You also can create a Storage linked service by using a shared access signature. It provides the service with restricted/time-bound access to all/specific resources in the storage.

A shared access signature provides delegated access to resources in your storage account. You can use it to grant a client limited permissions to objects in your storage account for a specified time and with a specified set of permissions. You don't have to share your account access keys. The shared access signature is a URI that encompasses in its query parameters all the information necessary for authenticated access to a storage resource. To access storage resources with the shared access signature, the client only needs to pass in the shared access signature to the appropriate constructor or method. For more information about shared access signatures, see Shared access signatures: Understand the shared access signature model.

> **NOTE**
>
> Both **service shared access signatures** and **account shared access signatures** are now supported. For more information about shared access signatures, see Grant limited access to Azure Storage resources using shared access signatures (SAS).

> **TIP**
>
> To generate a service shared access signature for your storage account, you can execute the following PowerShell commands. Replace the placeholders and grant the needed permission.
>
> ```
> $context = New-AzStorageContext -StorageAccountName <accountName> -StorageAccountKey <accountKey>
> New-AzStorageContainerSASToken -Name <containerName> -Context $context -Permission rwdl -StartTime <startTime> -ExpiryTime <endTime> -FullUri
> ```

To use shared access signature authentication, the following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **AzureTableStorage**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
sasUri	Specify SAS URI of the shared access signature URI to the table. Mark this field as a SecureString to store it securely. You can also put SAS token in Azure Key Vault to leverage auto rotation and remove the token portion. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure Integration Runtime or the Self-hosted Integration Runtime (if your data store is located in a private network). If not specified, it uses the default Azure Integration Runtime.	No

NOTE

If you were using "AzureStorage" type linked service, it is still supported as-is, while you are suggested to use this new "AzureTableStorage" linked service type going forward.

Example:

```
{
    "name": "AzureTableStorageLinkedService",
    "properties": {
        "type": "AzureTableStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the Azure Storage resource e.g.
https://<account>.table.core.windows.net/<table>?sv=<storage version>&amp;st=<start time>&amp;se=<expire
time>&amp;sr=<resource>&amp;sp=<permissions>&amp;sip=<ip range>&amp;spr=<protocol>&amp;sig=<signature>>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store account key in Azure Key Vault

```
{
    "name": "AzureTableStorageLinkedService",
    "properties": {
        "type": "AzureTableStorage",
        "typeProperties": {
            "sasUri": {
                "type": "SecureString",
                "value": "<SAS URI of the Azure Storage resource without token e.g.
https://<account>.table.core.windows.net/<table>>"
            },
            "sasToken": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

When you create a shared access signature URI, consider the following points:

- Set appropriate read/write permissions on objects based on how the linked service (read, write, read/write) is used.
- Set **Expiry time** appropriately. Make sure that the access to Storage objects doesn't expire within the active period of the pipeline.
- The URI should be created at the right table level based on the need.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Azure Table dataset.

To copy data to and from Azure Table, set the type property of the dataset to **AzureTable**. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **AzureTable**.	Yes
tableName	The name of the table in the Table storage database instance that the linked service refers to.	Yes

Example:

```
{
    "name": "AzureTableDataset",
    "properties":
    {
        "type": "AzureTable",
        "typeProperties": {
            "tableName": "MyTable"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Azure Table storage linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Schema inference by the service

For schema-free data stores such as Azure Table, the service infers the schema in one of the following ways:

- If you specify the column mapping in copy activity, the service uses the source side column list to retrieve data. In this case, if a row doesn't contain a value for a column, a null value is provided for it.
- If you don't specify the column mapping in copy activity, the service infers the schema by using the first row in the data. In this case, if the first row doesn't contain the full schema (e.g. some columns have null value), some columns are missed in the result of the copy operation.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Azure Table source and sink.

Azure Table as a source type

To copy data from Azure Table, set the source type in the copy activity to **AzureTableSource**. The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **AzureTableSource**.	Yes
azureTableSourceQuery	Use the custom Table storage query to read data. The source query is a direct map from the `$filter` query option supported by Azure Table Storage, learn more about the syntax from this doc, and see the examples in the following azureTableSourceQuery examples section.	No
azureTableSourceIgnoreTableNotFound	Indicates whether to allow the exception of the table to not exist. Allowed values are **True** and **False** (default).	No

azureTableSourceQuery examples

> **NOTE**
>
> Azure Table query operation times out in 30 seconds as enforced by Azure Table service. Learn how to optimize the query from Design for querying article.

If you want to filter the data against a datetime type column, refer to this example:

```
"azureTableSourceQuery": "LastModifiedTime gt datetime'2017-10-01T00:00:00' and LastModifiedTime le
datetime'2017-10-02T00:00:00'"
```

If you want to filter the data against a string type column, refer to this example:

```
"azureTableSourceQuery": "LastModifiedTime ge '201710010000_0000' and LastModifiedTime le
'201710010000_9999'"
```

If you use the pipeline parameter, cast the datetime value to proper format according to the previous samples.

Azure Table as a sink type

To copy data to Azure Table, set the sink type in the copy activity to **AzureTableSink**. The following properties are supported in the copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **AzureTableSink**.	Yes
azureTableDefaultPartitionKeyValue	The default partition key value that can be used by the sink.	No
azureTablePartitionKeyName	Specify the name of the column whose values are used as partition keys. If not specified, "AzureTableDefaultPartitionKeyValue" is used as the partition key.	No
azureTableRowKeyName	Specify the name of the column whose column values are used as the row key. If not specified, use a GUID for each row.	No
azureTableInsertType	The mode to insert data into Azure Table. This property controls whether existing rows in the output table with matching partition and row keys have their values replaced or merged. Allowed values are **merge** (default) and **replace**. This setting applies at the row level not the table level. Neither option deletes rows in the output table that do not exist in the input. To learn about how the merge and replace settings work, see Insert or merge entity and Insert or replace entity.	No

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	Inserts data into Azure Table when writeBatchSize or writeBatchTimeout is hit. Allowed values are integer (number of rows).	No (default is 10,000)
writeBatchTimeout	Inserts data into Azure Table when writeBatchSize or writeBatchTimeout is hit. Allowed values are timespan. An example is "00:20:00" (20 minutes).	No (default is 90 seconds, storage client's default timeout)
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToAzureTable",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Azure Table output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "AzureTableSink",
                "azureTablePartitionKeyName": "<column name>",
                "azureTableRowKeyName": "<column name>"
            }
        }
    }
]
```

azureTablePartitionKeyName

Map a source column to a destination column by using the **"translator"** property before you can use the destination column as azureTablePartitionKeyName.

In the following example, source column DivisionID is mapped to the destination column DivisionID:

```
"translator": {
    "type": "TabularTranslator",
    "columnMappings": "DivisionID: DivisionID, FirstName: FirstName, LastName: LastName"
}
```

"DivisionID" is specified as the partition key.

```
"sink": {
    "type": "AzureTableSink",
    "azureTablePartitionKeyName": "DivisionID"
}
```

Data type mapping for Azure Table

When you copy data from and to Azure Table, the following mappings are used from Azure Table data types to interim data types used internally within the service. To learn about how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

When you move data to and from Azure Table, the following mappings defined by Azure Table are used from Azure Table OData types to .NET type and vice versa.

AZURE TABLE DATA TYPE	INTERIM SERVICE DATA TYPE	DETAILS
Edm.Binary	byte[]	An array of bytes up to 64 KB.
Edm.Boolean	bool	A Boolean value.
Edm.DateTime	DateTime	A 64-bit value expressed as Coordinated Universal Time (UTC). The supported DateTime range begins midnight, January 1, 1601 A.D. (C.E.), UTC. The range ends December 31, 9999.
Edm.Double	double	A 64-bit floating point value.
Edm.Guid	Guid	A 128-bit globally unique identifier.
Edm.Int32	Int32	A 32-bit integer.
Edm.Int64	Int64	A 64-bit integer.
Edm.String	String	A UTF-16-encoded value. String values can be up to 64 KB.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Binary format in Azure Data Factory and Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Binary format is supported for the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP.

You can use Binary dataset in Copy activity, GetMetadata activity, or Delete activity. When using Binary dataset, the service does not parse file content but treat it as-is.

> **NOTE**
> When using Binary dataset in copy activity, you can only copy from Binary dataset to Binary dataset.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Binary dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Binary**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section**.	Yes
compression	Group of properties to configure file compression. Configure this section when you want to do compression/decompression during activity execution.	No

PROPERTY	DESCRIPTION	REQUIRED
type	The compression codec used to read/write binary files. Allowed values are **bzip2**, **gzip**, **deflate**, **ZipDeflate**, **Tar**, or **TarGzip**. **Note** when using copy activity to decompress **ZipDeflate/TarGzip/Tar** file(s) and write to file-based sink data store, by default files are extracted to the folder: `<path specified in dataset>/<folder named as source compressed file>/`, use `preserveZipFileNameAsFolder` / `preserveCompressionFileNameAsFolder` on copy activity source to control whether to preserve the name of the compressed file(s) as folder structure.	No
level	The compression ratio. Apply when dataset is used in Copy activity sink. Allowed values are **Optimal** or **Fastest**. - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed. - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete. For more information, see Compression Level topic.	No

Below is an example of Binary dataset on Azure Blob Storage:

```
{
    "name": "BinaryDataset",
    "properties": {
        "type": "Binary",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "compression": {
                "type": "ZipDeflate"
            }
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Binary source and sink.

> **NOTE**
>
> When using Binary dataset in copy activity, you can only copy from Binary dataset to Binary dataset.

Binary as source

The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **BinarySource**.	Yes
formatSettings	A group of properties. Refer to **Binary read settings** table below.	No
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **binary read settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **BinaryReadSettings**.	Yes
compressionProperties	A group of properties on how to decompress data for a given compression codec.	No
preserveZipFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `ZipDeflateReadSettings`)	Applies when input dataset is configured with **ZipDeflate** compression. Indicates whether to preserve the source zip file name as folder structure during copy. - When set to **true (default)**, The service writes unzipped files to `<path specified in dataset>/<folder named as source zip file>/`. - When set to **false**, the service writes unzipped files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source zip files to avoid racing or unexpected behavior.	No

PROPERTY	DESCRIPTION	REQUIRED
preserveCompressionFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `TarGZipReadSettings` *or* `TarReadSettings`)	Applies when input dataset is configured with **TarGzip/Tar** compression. Indicates whether to preserve the source compressed file name as folder structure during copy. - When set to **true (default)**, the service writes decompressed files to `<path specified in dataset>/<folder named as source compressed file>/`. - When set to **false**, the service writes decompressed files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source files to avoid racing or unexpected behavior.	No

```
"activities": [
    {
        "name": "CopyFromBinary",
        "type": "Copy",
        "typeProperties": {
            "source": {
                "type": "BinarySource",
                "storeSettings": {
                    "type": "AzureBlobStorageReadSettings",
                    "recursive": true,
                    "deleteFilesAfterCompletion": true
                },
                "formatSettings": {
                    "type": "BinaryReadSettings",
                    "compressionProperties": {
                        "type": "ZipDeflateReadSettings",
                        "preserveZipFileNameAsFolder": false
                    }
                }
            },
            ...
        }
        ...
    }
]
```

Binary as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **BinarySink**.	Yes
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Copy data from Cassandra using Azure Data Factory or Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from a Cassandra database. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Cassandra connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this Cassandra connector supports:

- Cassandra **versions 2.x and 3.x**.
- Copying data using **Basic** or **Anonymous** authentication.

> **NOTE**
> For activity running on Self-hosted Integration Runtime, Cassandra 3.x is supported since IR version 3.7 and above.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The Integration Runtime provides a built-in Cassandra driver, therefore you don't need to manually install any driver when copying data from/to Cassandra.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

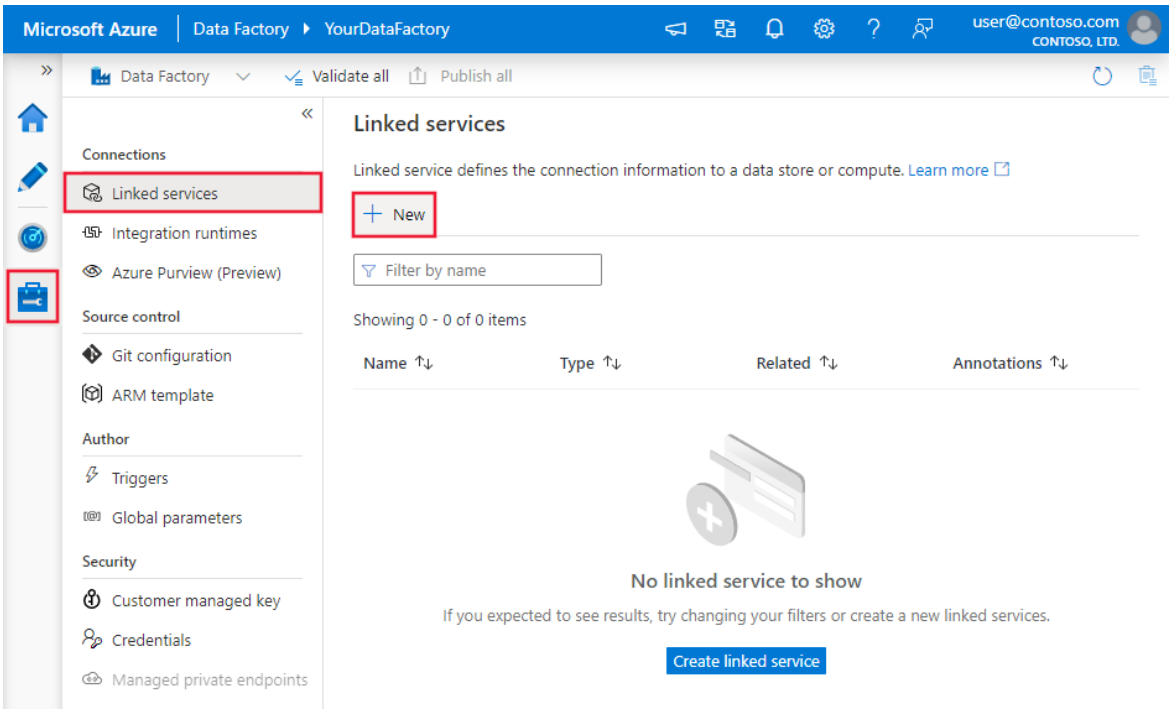
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Cassandra using UI

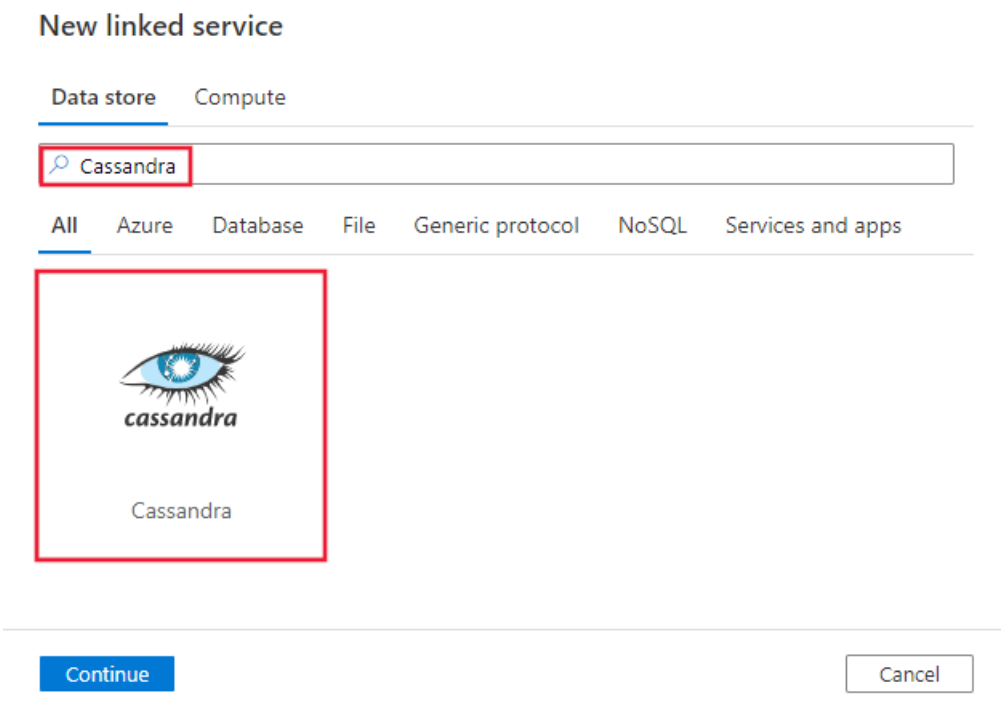
Use the following steps to create a linked service to Cassandra in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

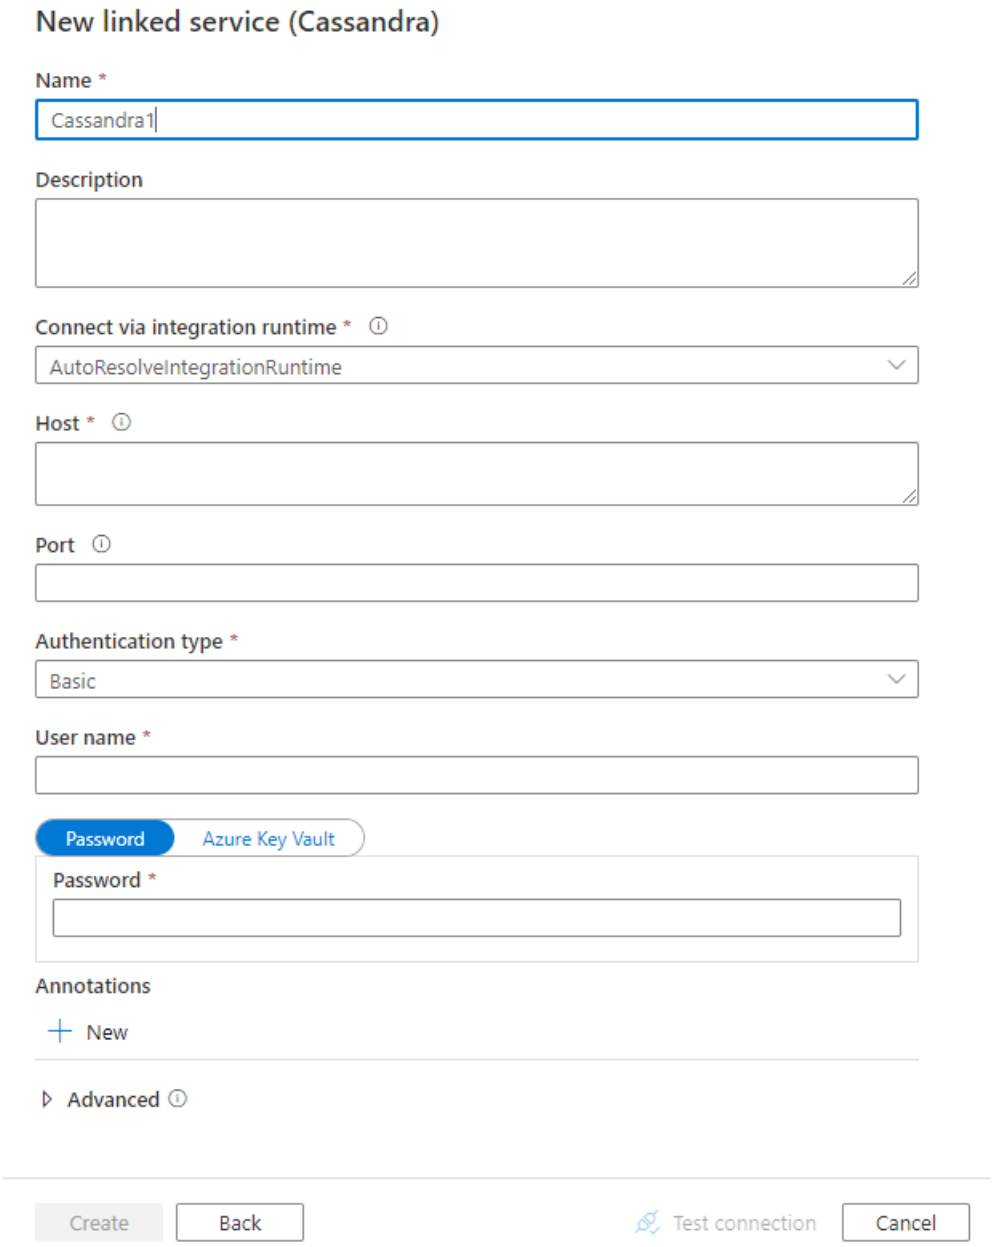
   - Azure Data Factory
   - Azure Synapse



2. Search for Cassandra and select the Cassandra connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Cassandra connector.

Linked service properties

The following properties are supported for Cassandra linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Cassandra**	Yes
host	One or more IP addresses or host names of Cassandra servers. Specify a comma-separated list of IP addresses or host names to connect to all servers concurrently.	Yes
port	The TCP port that the Cassandra server uses to listen for client connections.	No (default is 9042)
authenticationType	Type of authentication used to connect to the Cassandra database. Allowed values are: **Basic**, and **Anonymous**.	Yes
username	Specify user name for the user account.	Yes, if authenticationType is set to Basic.
password	Specify password for the user account. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes, if authenticationType is set to Basic.
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

> **NOTE**
> Currently connection to Cassandra using TLS is not supported.

Example:

```
{
    "name": "CassandraLinkedService",
    "properties": {
        "type": "Cassandra",
        "typeProperties": {
            "host": "<host>",
            "authenticationType": "Basic",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Cassandra dataset.

To copy data from Cassandra, set the type property of the dataset to **CassandraTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **CassandraTable**	Yes
keyspace	Name of the keyspace or schema in Cassandra database.	No (if "query" for "CassandraSource" is specified)
tableName	Name of the table in Cassandra database.	No (if "query" for "CassandraSource" is specified)

Example:

```
{
    "name": "CassandraDataset",
    "properties": {
        "type": "CassandraTable",
        "typeProperties": {
            "keySpace": "<keyspace name>",
            "tableName": "<table name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Cassandra linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Cassandra source.

Cassandra as source

To copy data from Cassandra, set the source type in the copy activity to **CassandraSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **CassandraSource**	Yes
query	Use the custom query to read data. SQL-92 query or CQL query. See CQL reference. When using SQL query, specify **keyspace name.table name** to represent the table you want to query.	No (if "tableName" and "keyspace" in dataset are specified).
consistencyLevel	The consistency level specifies how many replicas must respond to a read request before returning data to the client application. Cassandra checks the specified number of replicas for data to satisfy the read request. See Configuring data consistency for details. Allowed values are: **ONE**, **TWO**, **THREE**, **QUORUM**, **ALL**, **LOCAL_QUORUM**, **EACH_QUORUM**, and **LOCAL_ONE**.	No (default is `ONE`)

Example:

```
"activities":[
    {
        "name": "CopyFromCassandra",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Cassandra input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "CassandraSource",
                "query": "select id, firstname, lastname from mykeyspace.mytable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Data type mapping for Cassandra

When copying data from Cassandra, the following mappings are used from Cassandra data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

CASSANDRA DATA TYPE	INTERIM SERVICE DATA TYPE
ASCII	String
BIGINT	Int64
BLOB	Byte[]
BOOLEAN	Boolean
DECIMAL	Decimal
DOUBLE	Double
FLOAT	Single
INET	String
INT	Int32
TEXT	String
TIMESTAMP	DateTime

CASSANDRA DATA TYPE	INTERIM SERVICE DATA TYPE
TIMEUUID	Guid
UUID	Guid
VARCHAR	String
VARINT	Decimal

> **NOTE**
>
> For collection types (map, set, list, etc.), refer to Work with Cassandra collection types using virtual table section.
>
> User-defined types are not supported.
>
> The length of Binary Column and String Column lengths cannot be greater than 4000.

Work with collections using virtual table

The service uses a built-in ODBC driver to connect to and copy data from your Cassandra database. For collection types including map, set and list, the driver renormalizes the data into corresponding virtual tables. Specifically, if a table contains any collection columns, the driver generates the following virtual tables:

- A **base table**, which contains the same data as the real table except for the collection columns. The base table uses the same name as the real table that it represents.
- A **virtual table** for each collection column, which expands the nested data. The virtual tables that represent collections are named using the name of the real table, a separator "*vt*" and the name of the column.

Virtual tables refer to the data in the real table, enabling the driver to access the de-normalized data. See Example section for details. You can access the content of Cassandra collections by querying and joining the virtual tables.

Example

For example, the following "ExampleTable" is a Cassandra database table that contains an integer primary key column named "pk_int", a text column named value, a list column, a map column, and a set column (named "StringSet").

PK_INT	VALUE	LIST	MAP	STRINGSET
1	"sample value 1"	["1", "2", "3"]	{"S1": "a", "S2": "b"}	{"A", "B", "C"}
3	"sample value 3"	["100", "101", "102", "105"]	{"S1": "t"}	{"A", "E"}

The driver would generate multiple virtual tables to represent this single table. The foreign key columns in the virtual tables reference the primary key columns in the real table, and indicate which real table row the virtual table row corresponds to.

The first virtual table is the base table named "ExampleTable" is shown in the following table:

PK_INT	VALUE
1	"sample value 1"

PK_INT	VALUE
3	"sample value 3"

The base table contains the same data as the original database table except for the collections, which are omitted from this table and expanded in other virtual tables.

The following tables show the virtual tables that renormalize the data from the List, Map, and StringSet columns. The columns with names that end with "_index" or "_key" indicate the position of the data within the original list or map. The columns with names that end with "_value" contain the expanded data from the collection.

Table "ExampleTable_vt_List":

PK_INT	LIST_INDEX	LIST_VALUE
1	0	1
1	1	2
1	2	3
3	0	100
3	1	101
3	2	102
3	3	103

Table "ExampleTable_vt_Map":

PK_INT	MAP_KEY	MAP_VALUE
1	S1	A
1	S2	b
3	S1	t

Table "ExampleTable_vt_StringSet":

PK_INT	STRINGSET_VALUE
1	A
1	B
1	C
3	A
3	E

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Common Data Model format in Azure Data Factory and Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Common Data Model (CDM) metadata system makes it possible for data and its meaning to be easily shared across applications and business processes. To learn more, see the Common Data Model overview.

In Azure Data Factory and Synapse pipelines, users can transform data from CDM entities in both model.json and manifest form stored in Azure Data Lake Store Gen2 (ADLS Gen2) using mapping data flows. You can also sink data in CDM format using CDM entity references that will land your data in CSV or Parquet format in partitioned folders.

Mapping data flow properties

The Common Data Model is available as an inline dataset in mapping data flows as both a source and a sink.

> **NOTE**
> When writing CDM entities, you must have an existing CDM entity definition (metadata schema) already defined to use as a reference. The data flow sink will read that CDM entity file and import the schema into your sink for field mapping.

Source properties

The below table lists the properties supported by a CDM source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `cdm`	yes	`cdm`	format
Metadata format	Where the entity reference to the data is located. If using CDM version 1.0, choose manifest. If using a CDM version before 1.0, choose model.json.	Yes	`'manifest'` or `'model'`	manifestType
Root location: container	Container name of the CDM folder	yes	String	fileSystem
Root location: folder path	Root folder location of CDM folder	yes	String	folderPath
Manifest file: Entity path	Folder path of the entity within the root folder	no	String	entityPath

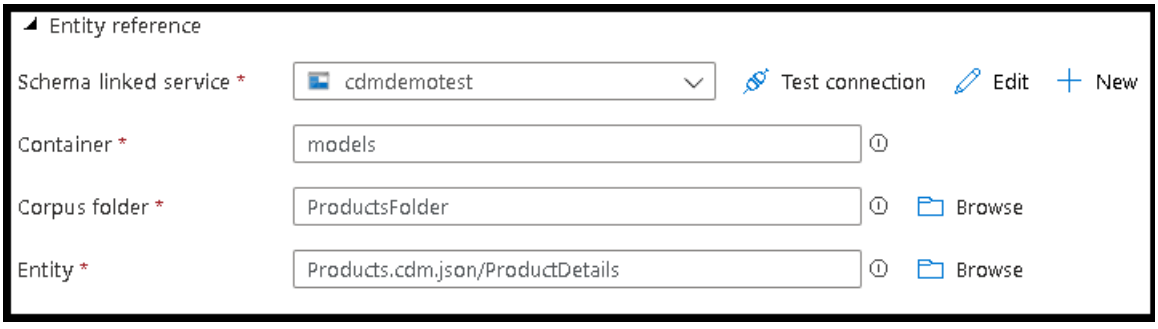
NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Manifest file: Manifest name	Name of the manifest file. Default value is 'default'	No	String	manifestName
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Schema linked service	The linked service where the corpus is located	yes, if using manifest	`'adlsgen2'` or `'github'`	corpusStore
Entity reference container	Container corpus is in	yes, if using manifest and corpus in ADLS Gen2	String	adlsgen2_fileSystem
Entity reference Repository	GitHub repository name	yes, if using manifest and corpus in GitHub	String	github_repository
Entity reference Branch	GitHub repository branch	yes, if using manifest and corpus in GitHub	String	github_branch
Corpus folder	the root location of the corpus	yes, if using manifest	String	corpusPath
Corpus entity	Path to entity reference	yes	String	entity
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

When selecting "Entity Reference" both in the Source and Sink transformations, you can select from these three options for the location of your entity reference:

- Local uses the entity defined in the manifest file already being used by the service
- Custom will ask you to point to an entity manifest file that is different from the manifest file the service is using
- Standard will use an entity reference from the standard library of CDM entities maintained in `GitHub`.

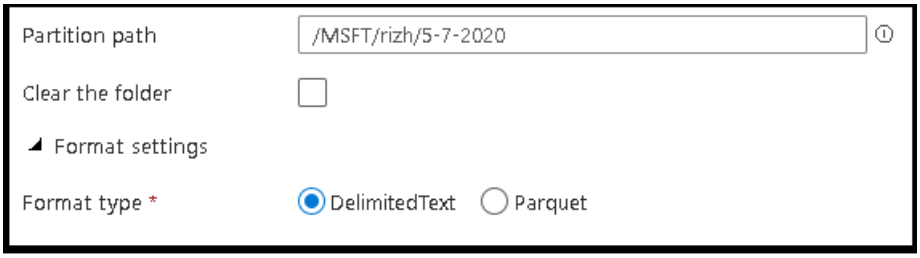
Sink settings

- Point to the CDM entity reference file that contains the definition of the entity you would like to write.



- Define the partition path and format of the output files that you want the service to use for writing your

entities.

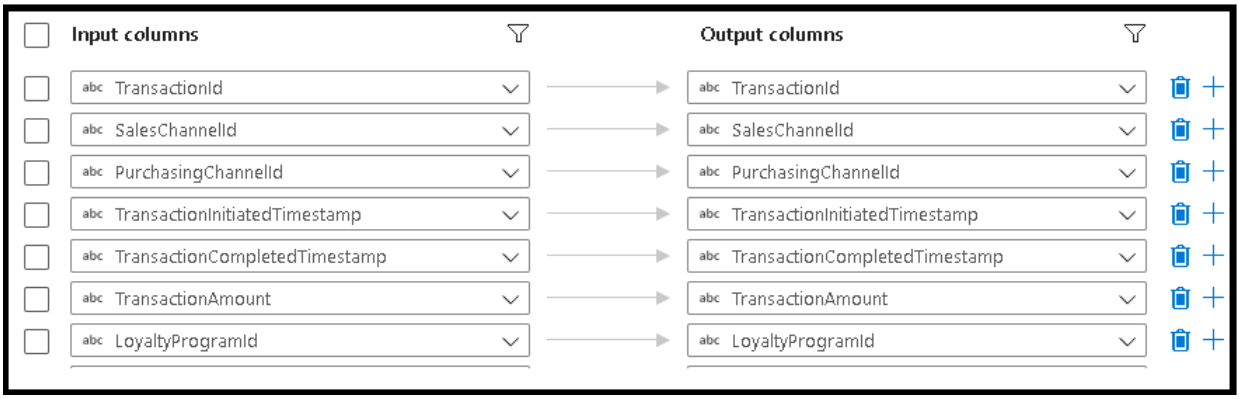


- Set the output file location and the location and name for the manifest file.

Import schema

CDM is only available as an inline dataset and, by default, doesn't have an associated schema. To get column metadata, click the **Import schema** button in the **Projection** tab. This will allow you to reference the column names and data types specified by the corpus. To import the schema, a data flow debug session must be active and you must have an existing CDM entity definition file to point to.

When mapping data flow columns to entity properties in the Sink transformation, click on the "Mapping" tab and select "Import Schema". The service will read the entity reference that you pointed to in your Sink options, allowing you to map to the target CDM schema.



> **NOTE**
> When using model.json source type that originates from Power BI or Power Platform dataflows, you may encounter "corpus path is null or empty" errors from the source transformation. This is likely due to formatting issues of the partition location path in the model.json file. To fix this, follow these steps:

1. Open the model.json file in a text editor
2. Find the partitions.Location property
3. Change "blob.core.windows.net" to "dfs.core.windows.net"
4. Fix any "%2F" encoding in the URL to "/"
5. If using ADF Data Flows, Special characters in the partition file path must be replaced with alpha-numeric values, or switch to Azure Synapse Data Flows

CDM source data flow script example

```
source(output(
        ProductSizeId as integer,
        ProductColor as integer,
        CustomerId as string,
        Note as string,
        LastModifiedDate as timestamp
    ),
    allowSchemaDrift: true,
    validateSchema: false,
    entity: 'Product.cdm.json/Product',
    format: 'cdm',
    manifestType: 'manifest',
    manifestName: 'ProductManifest',
    entityPath: 'Product',
    corpusPath: 'Products',
    corpusStore: 'adlsgen2',
    adlsgen2_fileSystem: 'models',
    folderPath: 'ProductData',
    fileSystem: 'data') ~> CDMSource
```

Sink properties

The below table lists the properties supported by a CDM sink. You can edit these properties in the **Settings** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `cdm`	yes	`cdm`	format
Root location: container	Container name of the CDM folder	yes	String	fileSystem
Root location: folder path	Root folder location of CDM folder	yes	String	folderPath
Manifest file: Entity path	Folder path of the entity within the root folder	no	String	entityPath
Manifest file: Manifest name	Name of the manifest file. Default value is 'default'	No	String	manifestName
Schema linked service	The linked service where the corpus is located	yes	`'adlsgen2'` or `'github'`	corpusStore
Entity reference container	Container corpus is in	yes, if corpus in ADLS Gen2	String	adlsgen2_fileSystem
Entity reference Repository	GitHub repository name	yes, if corpus in GitHub	String	github_repository
Entity reference Branch	GitHub repository branch	yes, if corpus in GitHub	String	github_branch
Corpus folder	the root location of the corpus	yes	String	corpusPath

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Corpus entity	Path to entity reference	yes	String	entity
Partition path	Location where the partition will be written	no	String	partitionPath
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate
Format type	Choose to specify parquet format	no	`parquet` if specified	subformat
Column delimiter	If writing to DelimitedText, how to delimit columns	yes, if writing to DelimitedText	String	columnDelimiter
First row as header	If using DelimitedText, whether the column names are added as a header	no	`true` or `false`	columnNamesAsHeader

CDM sink data flow script example

The associated data flow script is:

```
CDMSource sink(allowSchemaDrift: true,
    validateSchema: false,
    entity: 'Product.cdm.json/Product',
    format: 'cdm',
    entityPath: 'ProductSize',
    manifestName: 'ProductSizeManifest',
    corpusPath: 'Products',
    partitionPath: 'adf',
    folderPath: 'ProductSizeData',
    fileSystem: 'cdm',
    subformat: 'parquet',
    corpusStore: 'adlsgen2',
    adlsgen2_fileSystem: 'models',
    truncate: true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> CDMSink
```

Next steps

Create a source transformation in mapping data flow.

Copy data from Concur using Azure Data Factory or Synapse Analytics(Preview)

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Concur. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Concur connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

> **NOTE**
> Partner account is currently not supported.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

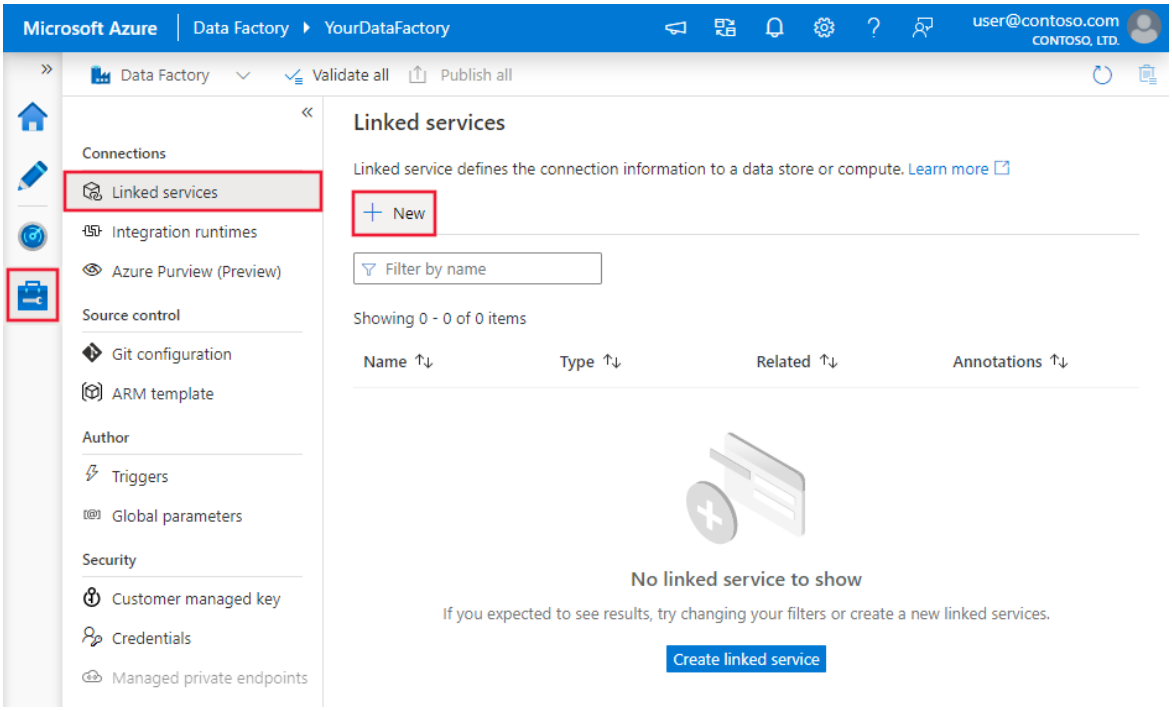
Create a linked service to Concur using UI

Use the following steps to create a linked service to Concur in the Azure portal UI.

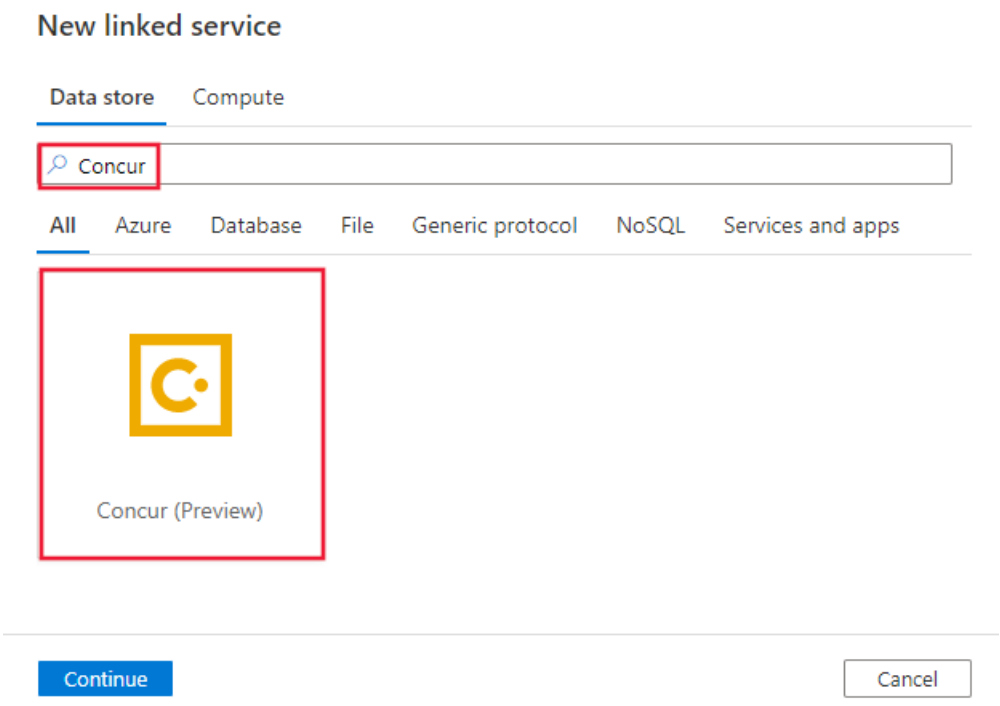
1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services,

then click New:

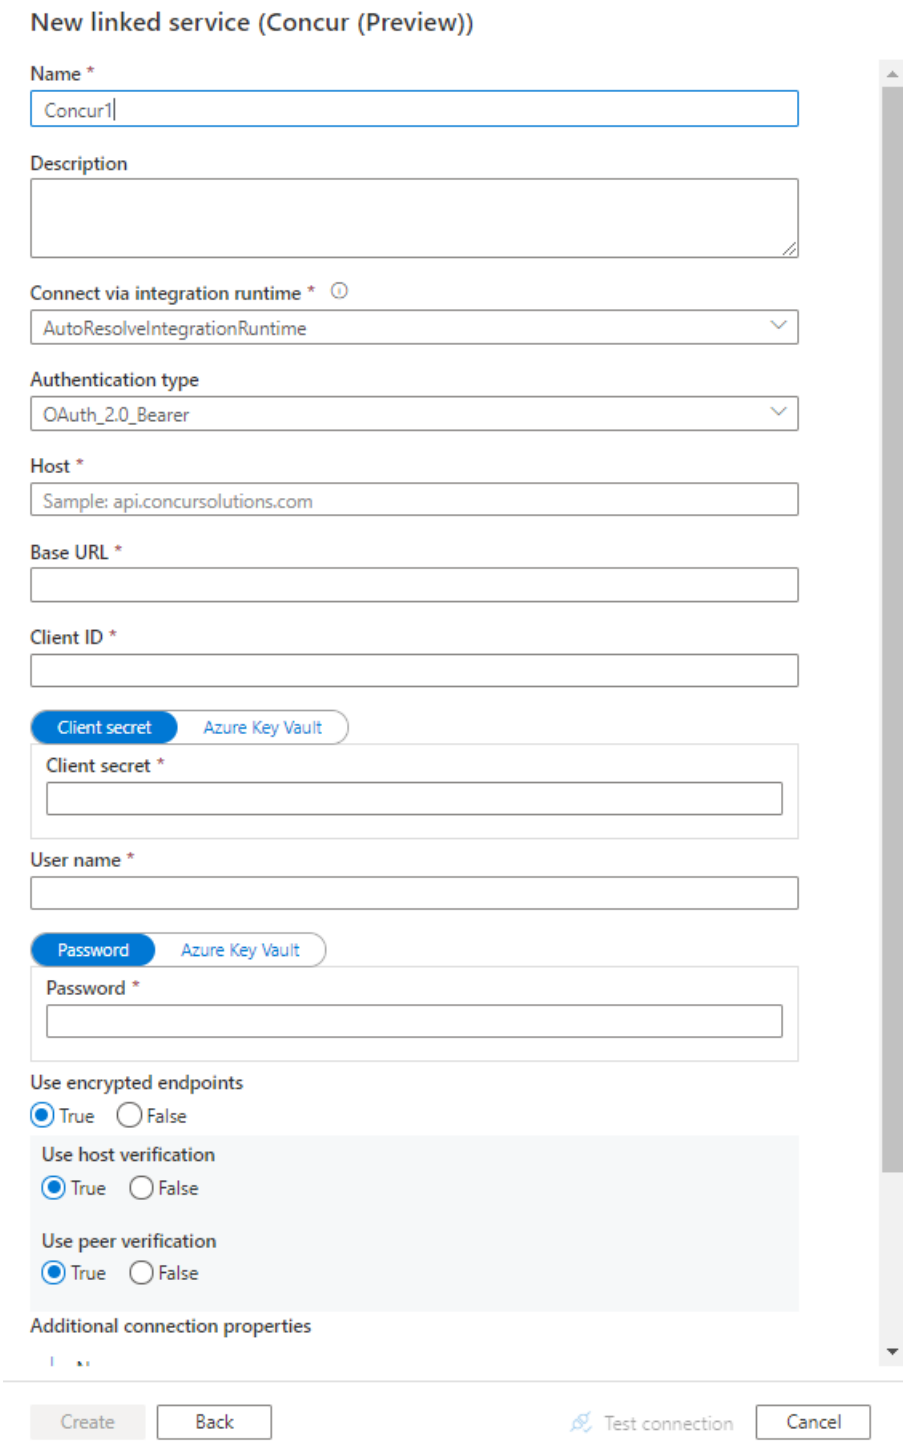
- Azure Data Factory
- Azure Synapse



2. Search for Concur and select the Concur connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Concur connector.

Linked service properties

The following properties are supported for Concur linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Concur**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionProperties	A group of properties that defines how to connect to Concur.	Yes
Under `connectionProperties`*:*		
authenticationType	Allowed values are `OAuth_2.0_Bearer` and `OAuth_2.0` (legacy). The OAuth 2.0 authentication option works with the old Concur API which was deprecated since Feb 2017.	Yes
host	The endpoint of the Concur server, e.g. `implementation.concursolutions.com`.	Yes
baseUrl	The base URL of your Concur's authorization URL.	Yes for `OAuth_2.0_Bearer` authentication
clientId	Application client ID supplied by Concur App Management.	Yes
clientSecret	The client secret corresponding to the client ID. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes for `OAuth_2.0_Bearer` authentication
username	The user name that you use to access Concur service.	Yes
password	The password corresponding to the user name that you provided in the username field. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
"name":"ConcurLinkedService",
"properties":{
"type":"Concur",
"typeProperties":{
"connectionProperties":{
"host":"<host e.g. implementation.concursolutions.com>",
"baseUrl":"<base URL for authorization e.g. us-impl.api.concursolutions.com>",
"authenticationType":"OAuth_2.0_Bearer",
"clientId":"<client id>",
"clientSecret":{
                    "type": "SecureString",
                    "value": "<client secret>"
                },
"username":"fakeUserName",
"password":{
                    "type": "SecureString",
                    "value": "<password>"
                },
"useEncryptedEndpoints":true,
"useHostVerification":true,
"usePeerVerification":true
}
}
}
}
```

Example (legacy):

Note the following is a legacy linked service model without `connectionProperties` and using `OAuth_2.0` authentication.

```
{
    "name": "ConcurLinkedService",
    "properties": {
        "type": "Concur",
        "typeProperties": {
            "clientId" : "<clientId>",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Concur dataset.

To copy data from Concur, set the type property of the dataset to **ConcurObject**. There is no additional type-specific property in this type of dataset. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ConcurObject**	Yes

PROPERTY	DESCRIPTION	REQUIRED
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "ConcurDataset",
    "properties": {
        "type": "ConcurObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Concur linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Concur source.

ConcurSource as source

To copy data from Concur, set the source type in the copy activity to **ConcurSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **ConcurSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Opportunities where Id = xxx "`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromConcur",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Concur input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ConcurSource",
                "query": "SELECT * FROM Opportunities where Id = xxx"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Couchbase using Azure Data Factory (Preview)

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Couchbase. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Couchbase connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

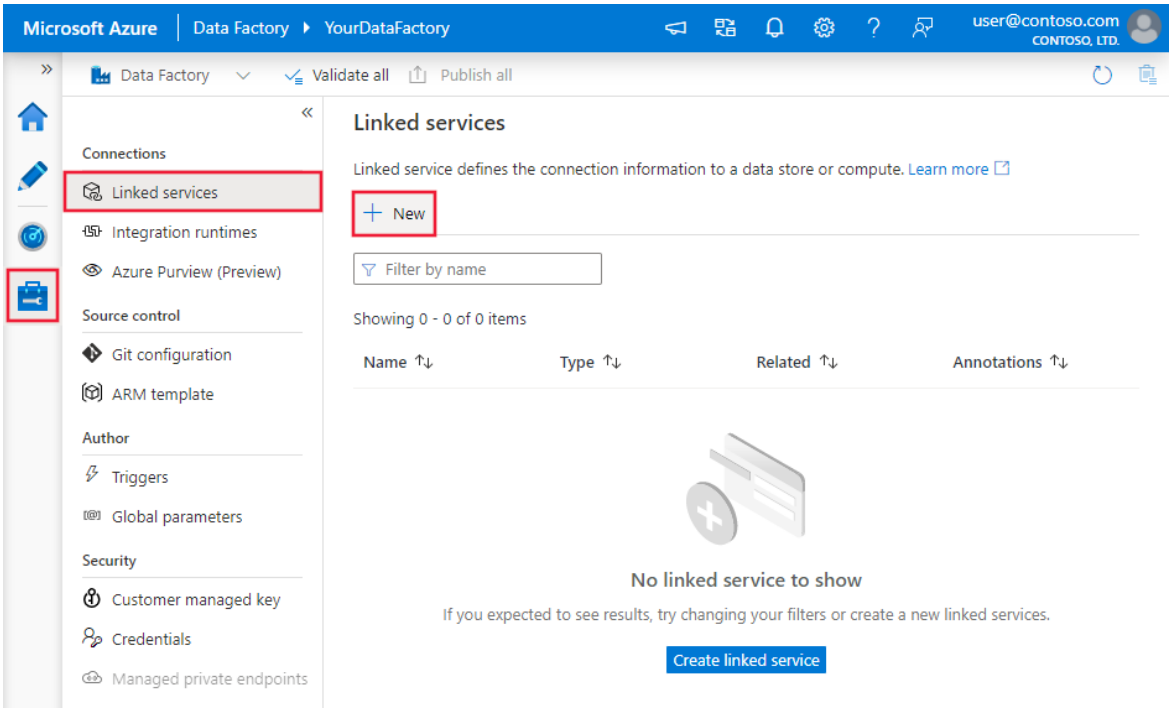
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Couchbase using UI

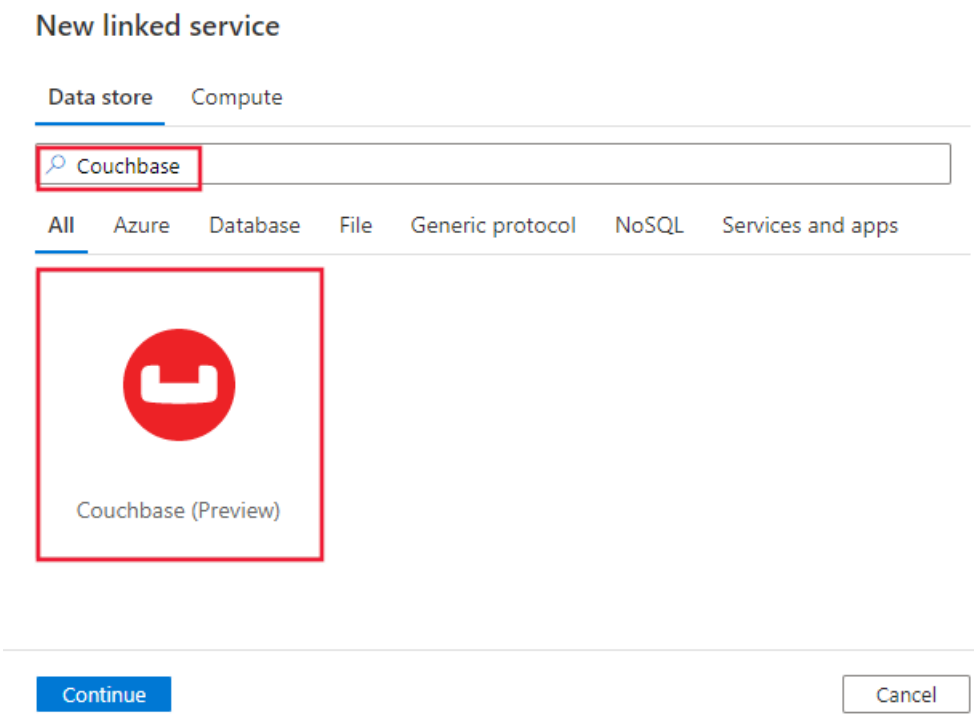
Use the following steps to create a linked service to Couchbase in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

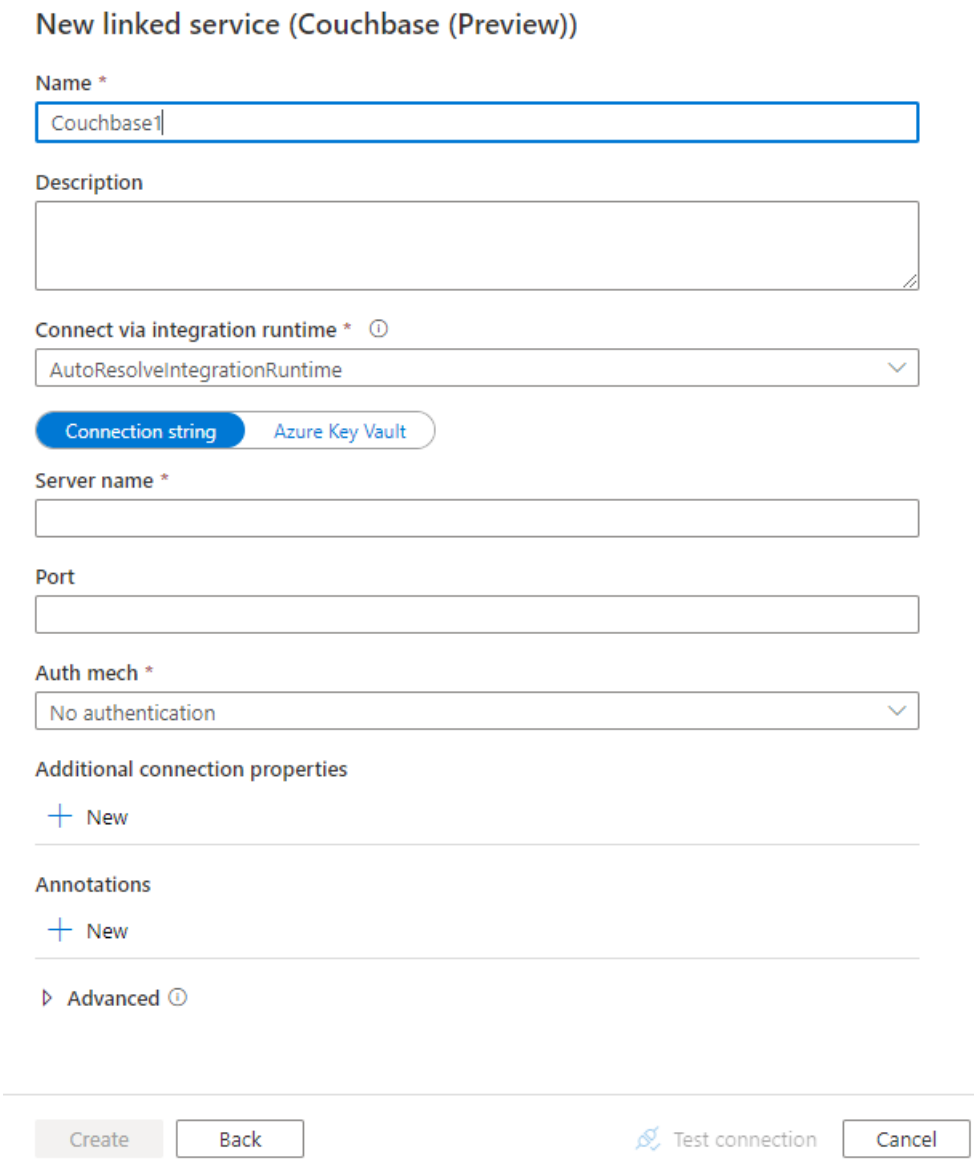
   - Azure Data Factory
   - Azure Synapse



2. Search for Couchbase and select the Couchbase connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Couchbase connector.

Linked service properties

The following properties are supported for Couchbase linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Couchbase**	Yes
connectionString	An ODBC connection string to connect to Couchbase. You can also put credential string in Azure Key Vault and pull the `credString` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "CouchbaseLinkedService",
    "properties": {
        "type": "Couchbase",
        "typeProperties": {
            "connectionString": "Server=<server>; Port=<port>;AuthMech=1;CredString=[{\"user\": \"JSmith\",
\"pass\":\"access123\"}, {\"user\": \"Admin\", \"pass\":\"simba123\"}];"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store credential string in Azure Key Vault

```
{
    "name": "CouchbaseLinkedService",
    "properties": {
        "type": "Couchbase",
        "typeProperties": {
            "connectionString": "Server=<server>; Port=<port>;AuthMech=1;",
            "credString": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Couchbase dataset.

To copy data from Couchbase, set the type property of the dataset to **CouchbaseTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **CouchbaseTable**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "CouchbaseDataset",
    "properties": {
        "type": "CouchbaseTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Couchbase linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Couchbase source.

CouchbaseSource as source

To copy data from Couchbase, set the source type in the copy activity to **CouchbaseSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **CouchbaseSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromCouchbase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Couchbase input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "CouchbaseSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Transform data in data.world (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in data.world (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This data.world connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

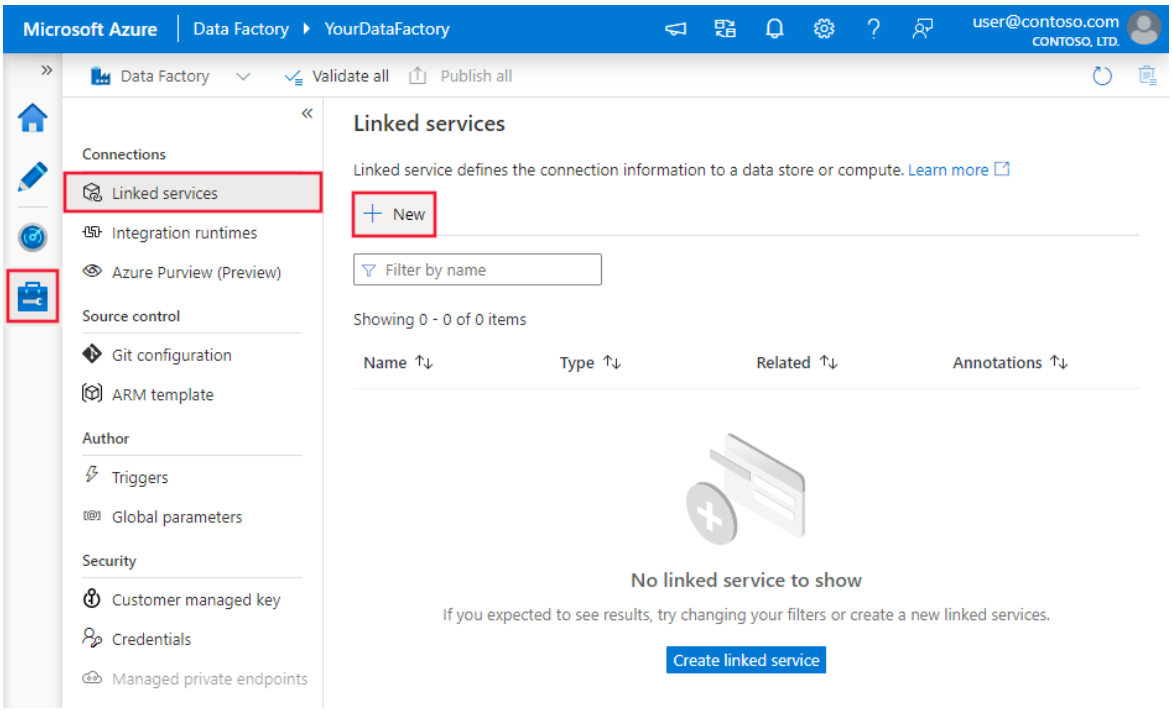
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a data.world linked service using UI

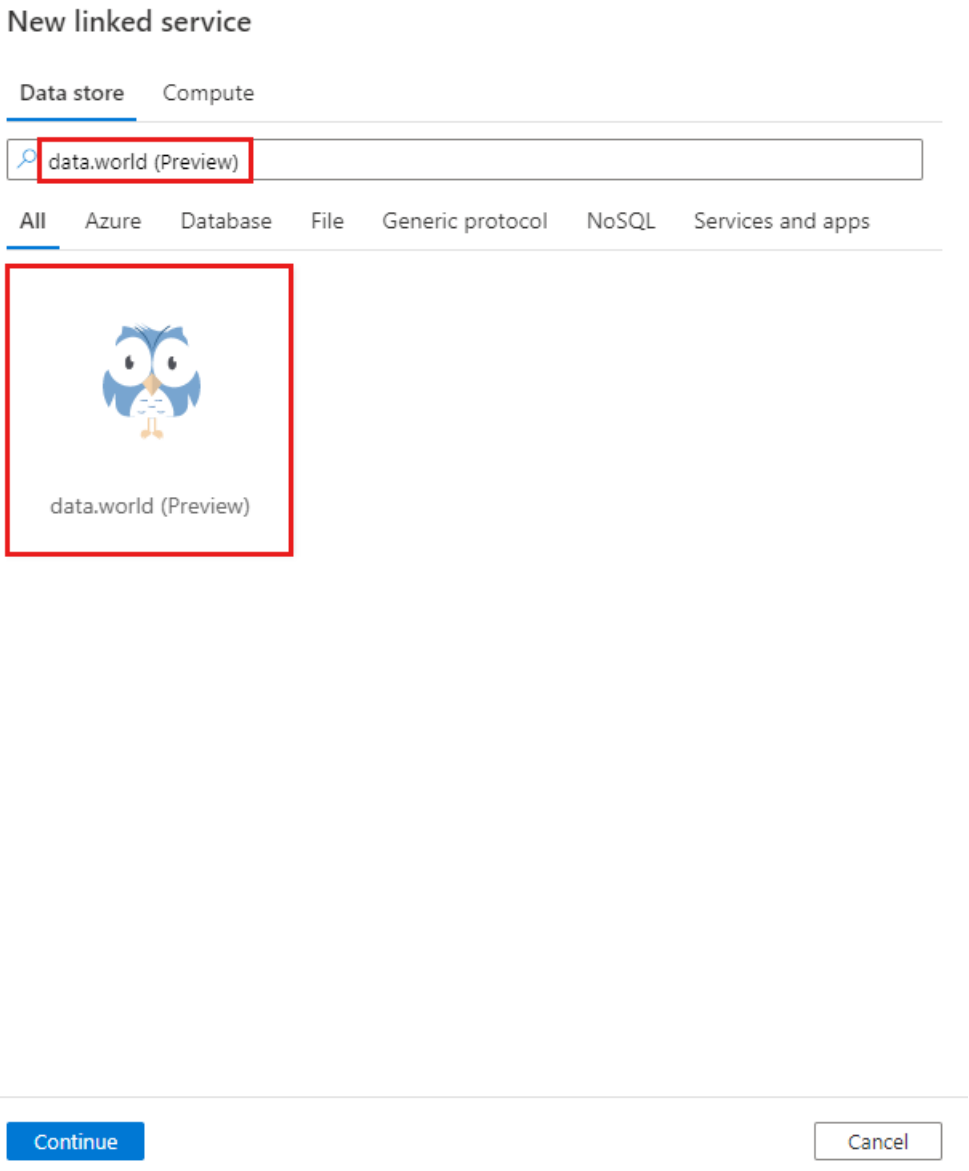
Use the following steps to create a data.world linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

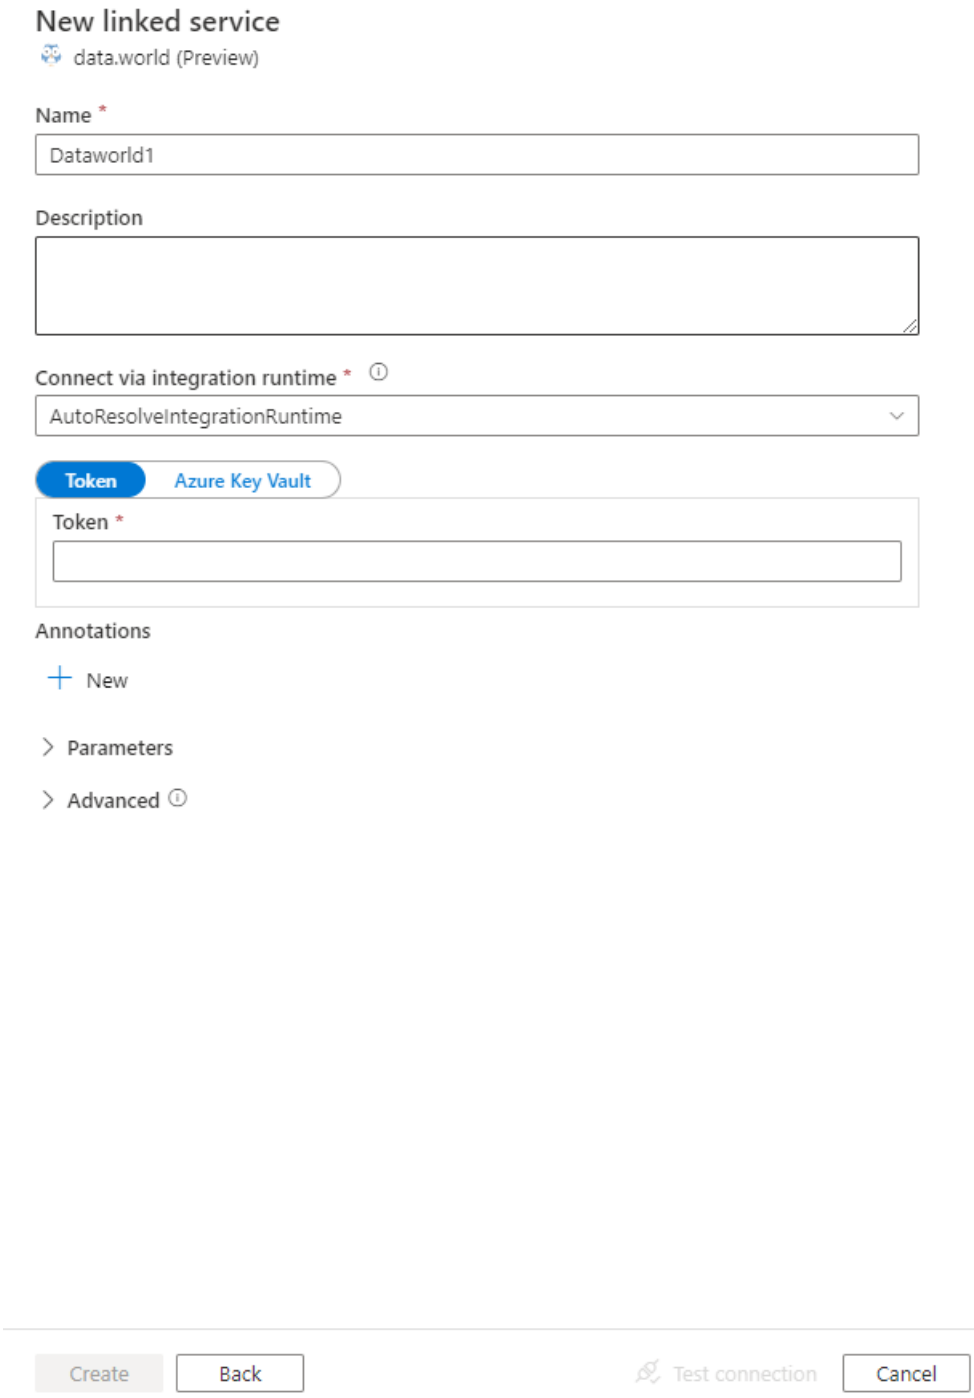
   - Azure Data Factory
   - Azure Synapse



2. Search for data.world (Preview) and select the data.world (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to data.world.

Linked service properties

The following properties are supported for the data.world linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Dataworld**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
apiToken	Specify an API token for the data.world. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "DataworldLinkedService",
    "properties": {
        "type": "Dataworld",
        "typeProperties": {
            "apiToken": {
                "type": "SecureString",
                "value": "<API token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from data.world. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by data.world source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Dataset name	The ID of the dataset in data.world.	Yes	String	datasetId
Table name	The ID of the table within the dataset in data.world.	No (if `query` is specified)	String	tableId
Query	Enter a SQL query to fetch data from data.world. An example is `select * from MyTable`.	No (if `tableId` is specified)	String	query
Owner	The owner of the dataset in data.world.	Yes	String	owner

data.world source script example

When you use data.world as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'dataworld',
 format: 'rest',
 owner: 'owner1',
 datasetId: 'dataset1',
 tableId: 'MyTable') ~> DataworldSource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy and transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 17 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use a copy activity in Azure Data Factory or Synapse pipelines to copy data from and to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM, and use a data flow to transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM. To learn more, read the Azure Data Factory and the Azure Synapse Analytics introduction articles.

Supported capabilities

This connector is supported for the following activities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that a copy activity supports as sources and sinks, see the Supported data stores table.

> **NOTE**
> Effective November 2020, Common Data Service has been renamed to Microsoft Dataverse. This article is updated to reflect the latest terminology.

This Dynamics connector supports Dynamics versions 7 through 9 for both online and on-premises. More specifically:

- Version 7 maps to Dynamics CRM 2015.
- Version 8 maps to Dynamics CRM 2016 and the early version of Dynamics 365.
- Version 9 maps to the later version of Dynamics 365.

Refer to the following table of supported authentication types and configurations for Dynamics versions and products.

DYNAMICS VERSIONS	AUTHENTICATION TYPES	LINKED SERVICE SAMPLES
Dataverse Dynamics 365 online Dynamics CRM online	Azure Active Directory (Azure AD) service principal Office 365	Dynamics online and Azure AD service-principal or Office 365 authentication
Dynamics 365 on-premises with internet-facing deployment (IFD) Dynamics CRM 2016 on-premises with IFD Dynamics CRM 2015 on-premises with IFD	IFD	Dynamics on-premises with IFD and IFD authentication

NOTE

With the deprecation of regional Discovery Service, the service has upgraded to leverage global Discovery Service while using Office 365 Authentication.

IMPORTANT

If your tenant and user is configured in Azure Active Directory for conditional access and/or Multi-Factor Authentication is required, you will not be able to use Office 365 Authentication type. For those situations, you must use an Azure Active Directory (Azure AD) service principal authentication.

For Dynamics 365 specifically, the following application types are supported:

- Dynamics 365 for Sales
- Dynamics 365 for Customer Service
- Dynamics 365 for Field Service
- Dynamics 365 for Project Service Automation
- Dynamics 365 for Marketing This connector doesn't support other application types like Finance, Operations, and Talent.

TIP

To copy data from Dynamics 365 Finance and Operations, you can use the Dynamics AX connector.

This Dynamics connector is built on top of Dynamics XRM tooling.

Prerequisites

To use this connector with Azure AD service-principal authentication, you must set up server-to-server (S2S) authentication in Dataverse or Dynamics. First register the application user (Service Principal) in Azure Active Directory. You can find out how to do this here. During application registration you will need to create that user in Dataverse or Dynamics and grant permissions. Those permissions can either be granted directly or indirectly by adding the application user to a team which has been granted permissions in Dataverse or Dynamics. You can find more information on how to set up an application user to authenticate with Dataverse here.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

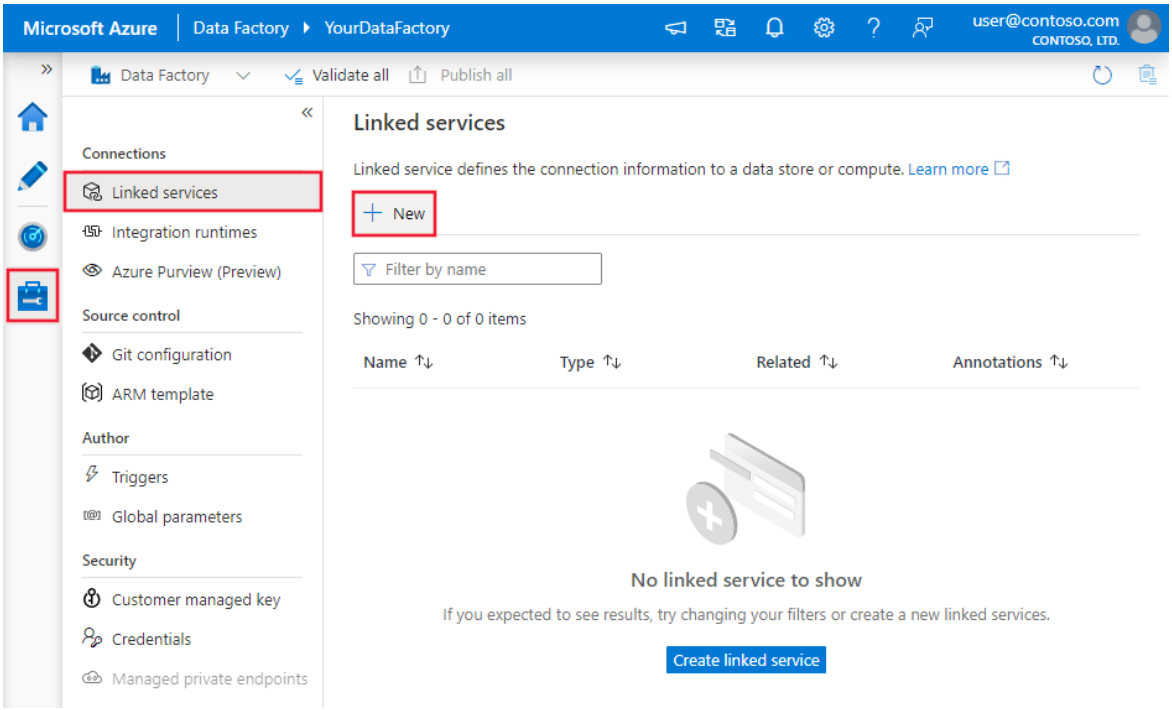
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using UI

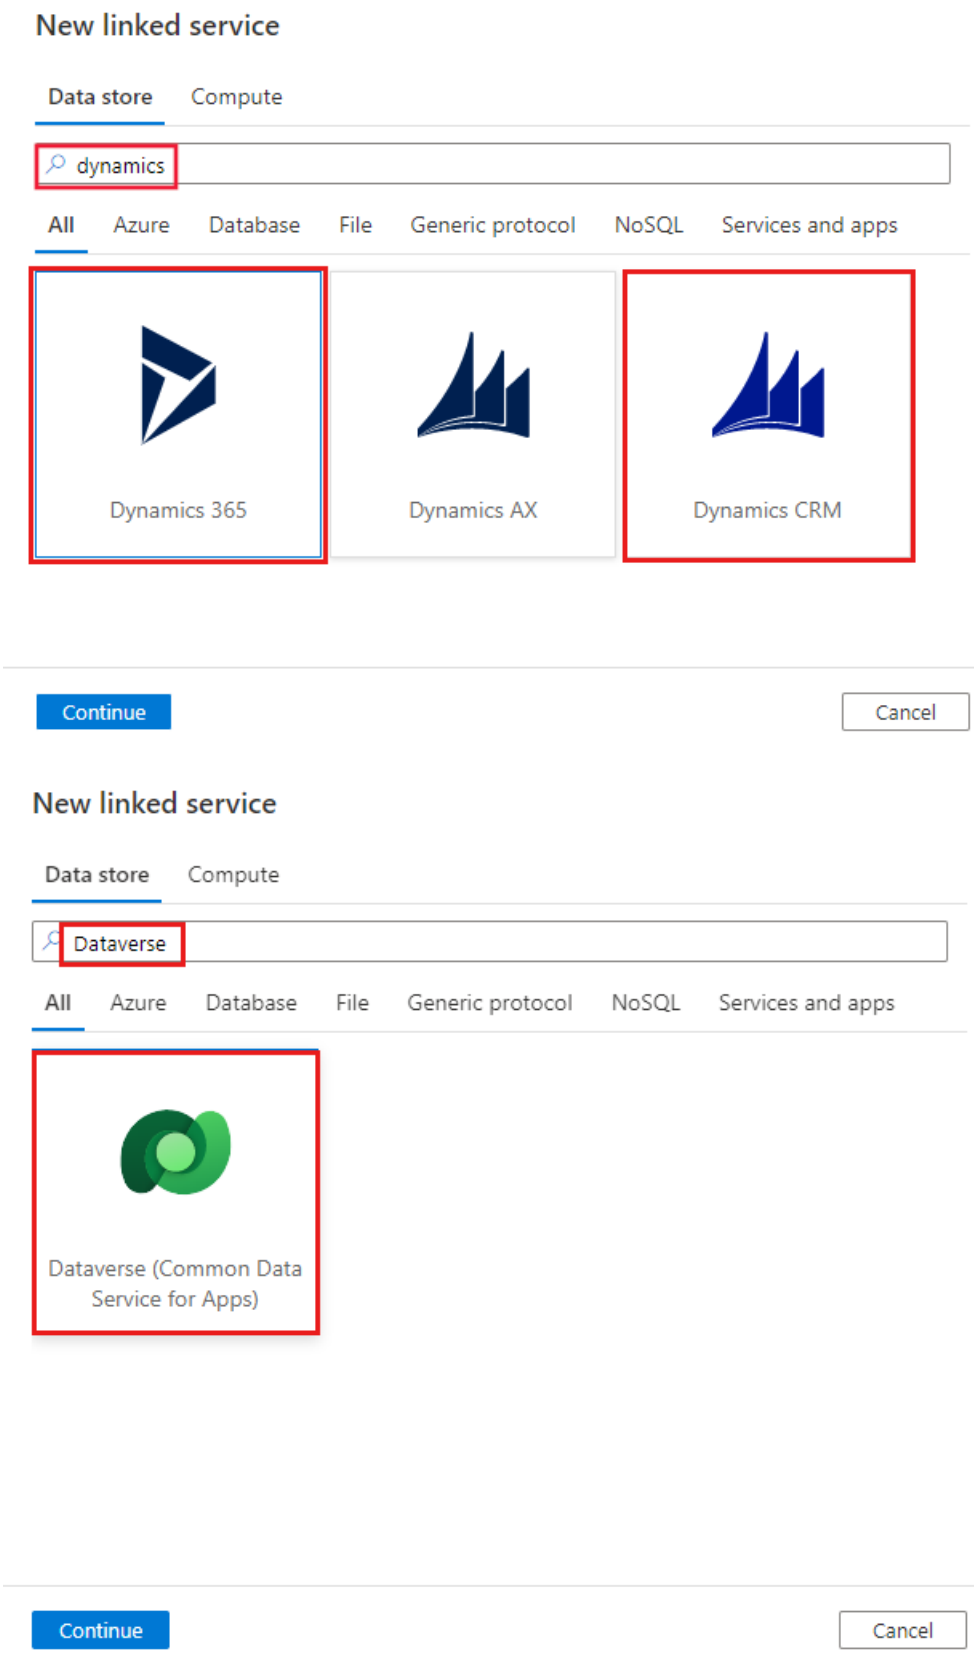
Use the following steps to create a linked service to Dynamics 365 in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

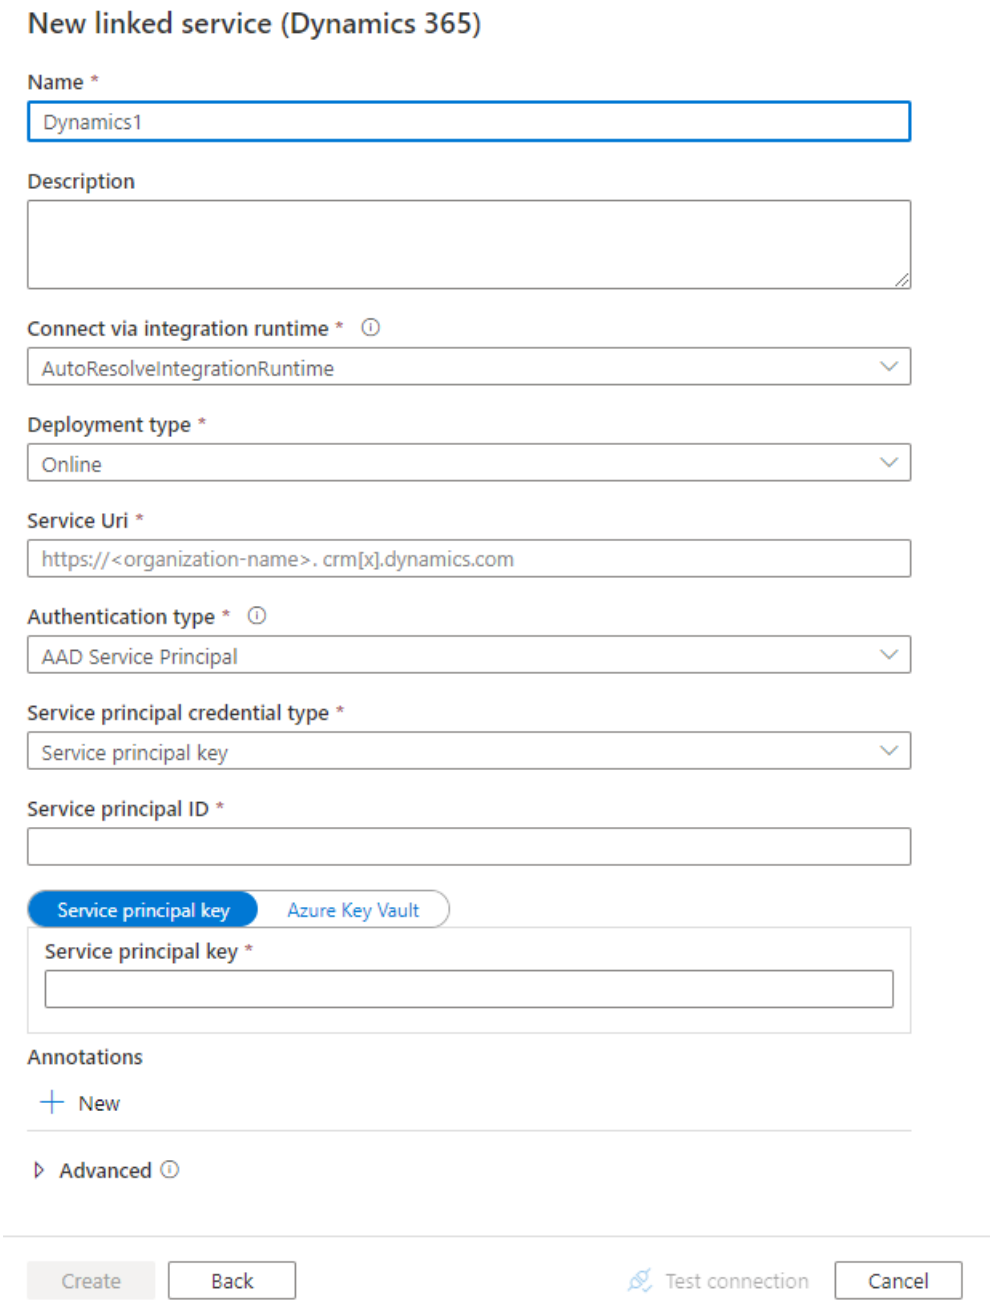
   - Azure Data Factory
   - Azure Synapse



2. Search for Dynamics or Dataverse and select the Dynamics 365 (Microsoft Dataverse) or Dynamics CRM connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Dynamics.

Linked service properties

The following properties are supported for the Dynamics linked service.

Dynamics 365 and Dynamics CRM online

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes
deploymentType	The deployment type of the Dynamics instance. The value must be "Online" for Dynamics online.	Yes

PROPERTY	DESCRIPTION	REQUIRED
serviceUri	The service URL of your Dynamics instance, the same one you access from browser. An example is "https://<organization-name>.crm[x].dynamics.com".	Yes
authenticationType	The authentication type to connect to a Dynamics server. Valid values are "AADServicePrincipal", "Office365" and "ManagedIdentity".	Yes
servicePrincipalId	The client ID of the Azure AD application.	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredentialType	The credential type to use for service-principal authentication. Valid values are "ServicePrincipalKey" and "ServicePrincipalCert".	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredential	The service-principal credential. When you use "ServicePrincipalKey" as the credential type, `servicePrincipalCredential` can be a string that the service encrypts upon linked service deployment. Or it can be a reference to a secret in Azure Key Vault. When you use "ServicePrincipalCert" as the credential, `servicePrincipalCredential` must be a reference to a certificate in Azure Key Vault, and ensure the certificate content type is **PKCS #12**.	Yes when authentication is "AADServicePrincipal"
username	The username to connect to Dynamics.	Yes when authentication is "Office365"
password	The password for the user account you specified as the username. Mark this field with "SecureString" to store it securely, or reference a secret stored in Azure Key Vault.	Yes when authentication is "Office365"
credentials	Specify the user-assigned managed identity as the credential object. Create one or multiple user-assigned managed identities, assign them to your data factory and create credentials for each user-assigned managed identity.	Yes when authentication is "ManagedIdentity"
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

NOTE

The Dynamics connector formerly used the optional **organizationName** property to identify your Dynamics CRM or Dynamics 365 online instance. While that property still works, we suggest you specify the new **serviceUri** property instead to gain better performance for instance discovery.

Example: Dynamics online using Azure AD service-principal and key authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalCredential": "<service principal key>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Azure AD service-principal and certificate authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalCredential": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<AKV reference>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<certificate name in AKV>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Office 365 authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "Office365",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using user-assigned managed identity authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "ManagedIdentity",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dynamics 365 and Dynamics CRM on-premises with IFD

Additional properties that compare to Dynamics online are **hostName** and **port**.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes.
deploymentType	The deployment type of the Dynamics instance. The value must be "OnPremisesWithIfd" for Dynamics on-premises with IFD.	Yes.
hostName	The host name of the on-premises Dynamics server.	Yes.

PROPERTY	DESCRIPTION	REQUIRED
port	The port of the on-premises Dynamics server.	No. The default value is 443.
organizationName	The organization name of the Dynamics instance.	Yes.
authenticationType	The authentication type to connect to the Dynamics server. Specify "Ifd" for Dynamics on-premises with IFD.	Yes.
username	The username to connect to Dynamics.	Yes.
password	The password for the user account you specified for the username. You can mark this field with "SecureString" to store it securely. Or you can store a password in Key Vault and let the copy activity pull from there when it does data copy. Learn more from Store credentials in Key Vault.	Yes.
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

Example: Dynamics on-premises with IFD using IFD authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "description": "Dynamics on-premises with IFD linked service using IFD authentication",
        "typeProperties": {
            "deploymentType": "OnPremisesWithIFD",
            "hostName": "contosodynamicsserver.contoso.com",
            "port": 443,
            "organizationName": "admsDynamicsTest",
            "authenticationType": "Ifd",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by Dynamics dataset.

To copy data from and to Dynamics, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to "DynamicsEntity", "DynamicsCrmEntity", or "CommonDataServiceForAppsEntity".	Yes
entityName	The logical name of the entity to retrieve.	No for source if the activity source is specified as "query" and yes for sink

Example

```
{
    "name": "DynamicsDataset",
    "properties": {
        "type": "DynamicsEntity",
        "schema": [],
        "typeProperties": {
            "entityName": "account"
        },
        "linkedServiceName": {
            "referenceName": "<Dynamics linked service name>",
            "type": "linkedservicereference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Dynamics source and sink types.

Dynamics as a source type

To copy data from Dynamics, the copy activity **source** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to "DynamicsSource", "DynamicsCrmSource", or "CommonDataServiceForAppsSource".	Yes
query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No if `entityName` in the dataset is specified

> **NOTE**
> The PK column will always be copied out even if the column projection you configure in the FetchXML query doesn't contain it.

IMPORTANT

- When you copy data from Dynamics, explicit column mapping from Dynamics to sink is optional. But we highly recommend the mapping to ensure a deterministic copy result.
- When the service imports a schema in the authoring UI, it infers the schema. It does so by sampling the top rows from the Dynamics query result to initialize the source column list. In that case, columns with no values in the top rows are omitted. The same behavior also applies to data preview and copy executions if there is no explicit mapping. You can review and add more columns into the mapping, which are honored during copy runtime.

Example

```
"activities":[
    {
        "name": "CopyFromDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Dynamics input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DynamicsSource",
                "query": "<FetchXML Query>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Sample FetchXML query

```
<fetch>
  <entity name="account">
    <attribute name="accountid" />
    <attribute name="name" />
    <attribute name="marketingonly" />
    <attribute name="modifiedon" />
    <order attribute="modifiedon" descending="false" />
    <filter type="and">
      <condition attribute ="modifiedon" operator="between">
        <value>2017-03-10 18:40:00z</value>
        <value>2017-03-12 20:40:00z</value>
      </condition>
    </filter>
  </entity>
</fetch>
```

Dynamics as a sink type

To copy data to Dynamics, the copy activity **sink** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to "DynamicsSink", "DynamicsCrmSink", or "CommonDataServiceForAppsSink".	Yes.
writeBehavior	The write behavior of the operation. The value must be "Upsert".	Yes
alternateKeyName	The alternate key name defined on your entity to do an upsert.	No.
writeBatchSize	The row count of data written to Dynamics in each batch.	No. The default value is 10.
ignoreNullValues	Whether to ignore null values from input data other than key fields during a write operation. Valid values are **TRUE** and **FALSE**: • **TRUE**: Leave the data in the destination object unchanged when you do an upsert or update operation. Insert a defined default value when you do an insert operation. • **FALSE**: Update the data in the destination object to a null value when you do an upsert or update operation. Insert a null value when you do an insert operation.	No. The default value is **FALSE**.
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

NOTE

The default value for both the sink **writeBatchSize** and the copy activity **parallelCopies** for the Dynamics sink is 10. Therefore, 100 records are concurrently submitted by default to Dynamics.

For Dynamics 365 online, there's a limit of two concurrent batch calls per organization. If that limit is exceeded, a "Server Busy" exception is thrown before the first request is ever run. Keep **writeBatchSize** at 10 or less to avoid such throttling of concurrent calls.

The optimal combination of **writeBatchSize** and **parallelCopies** depends on the schema of your entity. Schema elements include the number of columns, row size, and number of plug-ins, workflows, or workflow activities hooked up to those calls. The default setting of **writeBatchSize** (10) × **parallelCopies** (10) is the recommendation according to the Dynamics service. This value works for most Dynamics entities, although it might not give the best performance. You can tune the performance by adjusting the combination in your copy activity settings.

Example

```
"activities":[
    {
        "name": "CopyToDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Dynamics output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "DynamicsSink",
                "writeBehavior": "Upsert",
                "writeBatchSize": 10,
                "ignoreNullValues": true
            }
        }
    }
]
```

Retrieving data from views

To retrieve data from Dynamics views, you need to get the saved query of the view, and use the query to get the data.

There are two entities which store different types of view: "saved query" stores system view and "user query" stores user view. To get the information of the views, refer to the following FetchXML query and replace the "TARGETENTITY" with `savedquery` or `userquery`. Each entity type has more available attributes that you can add to the query based on your need. Learn more about savedquery entity and userquery entity.

```
<fetch top="5000" >
  <entity name="<TARGETENTITY>">
    <attribute name="name" />
    <attribute name="fetchxml" />
    <attribute name="returnedtypecode" />
    <attribute name="querytype" />
  </entity>
</fetch>
```

You can also add filters to filter the views. For example, add the following filter to get a view named "My Active Accounts" in account entity.

```
<filter type="and" >
    <condition attribute="returnedtypecode" operator="eq" value="1" />
    <condition attribute="name" operator="eq" value="My Active Accounts" />
</filter>
```

Data type mapping for Dynamics

When you copy data from Dynamics, the following table shows mappings from Dynamics data types to interim data types within the service. To learn how a copy activity maps to a source schema and a data type maps to a sink, see Schema and data type mappings.

Configure the corresponding interim data type in a dataset structure that is based on your source Dynamics data type by using the following mapping table:

DYNAMICS DATA TYPE	SERVICE INTERIM DATA TYPE	SUPPORTED AS SOURCE	SUPPORTED AS SINK
AttributeTypeCode.BigInt	Long	✓	✓
AttributeTypeCode.Boolean	Boolean	✓	✓
AttributeType.Customer	GUID	✓	✓ (See guidance)
AttributeType.DateTime	Datetime	✓	✓
AttributeType.Decimal	Decimal	✓	✓
AttributeType.Double	Double	✓	✓
AttributeType.EntityName	String	✓	✓
AttributeType.Integer	Int32	✓	✓
AttributeType.Lookup	GUID	✓	✓ (See guidance)
AttributeType.ManagedProperty	Boolean	✓	
AttributeType.Memo	String	✓	✓
AttributeType.Money	Decimal	✓	✓
AttributeType.Owner	GUID	✓	✓ (See guidance)
AttributeType.Picklist	Int32	✓	✓
AttributeType.Uniqueidentifier	GUID	✓	✓
AttributeType.String	String	✓	✓
AttributeType.State	Int32	✓	✓
AttributeType.Status	Int32	✓	✓

NOTE

The Dynamics data types **AttributeType.CalendarRules**, **AttributeType.MultiSelectPicklist**, and **AttributeType.PartyList** aren't supported.

Writing data to a lookup field

To write data into a lookup field with multiple targets like Customer and Owner, follow this guidance and example:

1. Make your source contains both the field value and the corresponding target entity name.
   - If all records map to the same target entity, ensure one of the following conditions:
     - Your source data has a column that stores the target entity name.
     - You've added an additional column in the copy activity source to define the target entity.
   - If different records map to different target entities, make sure your source data has a column that stores the corresponding target entity name.
2. Map both the value and entity-reference columns from source to sink. The entity-reference column must be mapped to a virtual column with the special naming pattern `{lookup_field_name}@EntityReference`. The column doesn't actually exist in Dynamics. It's used to indicate this column is the metadata column of the given multitarget lookup field.

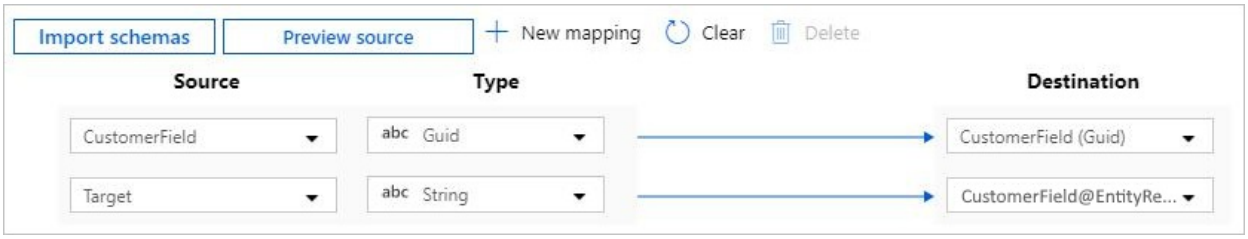
For example, assume the source has these two columns:

- **CustomerField** column of type **GUID**, which is the primary key value of the target entity in Dynamics.
- **Target** column of type **String**, which is the logical name of the target entity.

Also assume you want to copy such data to the sink Dynamics entity field **CustomerField** of type **Customer**.

In copy-activity column mapping, map the two columns as follows:

- **CustomerField** to **CustomerField**. This mapping is the normal field mapping.
- **Target** to **CustomerField@EntityReference**. The sink column is a virtual column representing the entity reference. Input such field names in a mapping, as they won't show up by importing schemas.



If all of your source records map to the same target entity and your source data doesn't contain the target entity name, here is a shortcut: in the copy activity source, add an additional column. Name the new column by using the pattern `{lookup_field_name}@EntityReference`, set the value to the target entity name, then proceed with column mapping as usual. If your source and sink column names are identical, you can also skip explicit column mapping because copy activity by default maps columns by name.

Mapping data flow properties

When transforming data in mapping data flow, you can read from and write to tables in Dynamics. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use a Dynamics dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Dynamics. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Entity name	The logical name of the entity to retrieve.	Yes when use inline dataset	-	*(for inline dataset only)* entity
Query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No	String	query

> **NOTE**
> If you select **Query** as input type, the column type from tables can not be retrieved. It will be treated as string by default.

Dynamics source script example

When you use Dynamics dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

If you use inline dataset, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'dynamics',
 format: 'dynamicsformat',
 entity: 'Entity1',
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

Sink transformation

The below table lists the properties supported by Dynamics sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Alternate key name	The alternate key name defined on your entity to do an update, upsert or delete.	No	-	alternateKeyName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	insertable updateable upsertable deletable
Entity name	The logical name of the entity to write.	Yes when use inline dataset	-	*(for inline dataset only)* entity

Dynamics sink script example

When you use Dynamics dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:true,
    insertable:true,
    updateable:true,
    upsertable:true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

If you use inline dataset, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    store: 'dynamics',
    format: 'dynamicsformat',
    entity: 'Entity1',
    deletable: true,
    insertable: true,
    updateable: true,
    upsertable: true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

Lookup activity properties

To learn details about the properties, see Lookup activity.

Next steps

For a list of supported data stores the copy activity as sources and sinks, see Supported data stores.

Copy data from DB2 using Azure Data Factory or Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from a DB2 database. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This DB2 connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this DB2 connector supports the following IBM DB2 platforms and versions with Distributed Relational Database Architecture (DRDA) SQL Access Manager (SQLAM) version 9, 10 and 11. It utilizes the DDM/DRDA protocol.

- IBM DB2 for z/OS 12.1
- IBM DB2 for z/OS 11.1
- IBM DB2 for z/OS 10.1
- IBM DB2 for i 7.3
- IBM DB2 for i 7.2
- IBM DB2 for i 7.1
- IBM DB2 for LUW 11
- IBM DB2 for LUW 10.5
- IBM DB2 for LUW 10.1

TIP

DB2 connector is built on top of Microsoft OLE DB Provider for DB2. To troubleshoot DB2 connector errors, refer to Data Provider Error Codes.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The Integration Runtime provides a built-in DB2 driver, therefore you don't need to manually install any driver when copying data from DB2.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

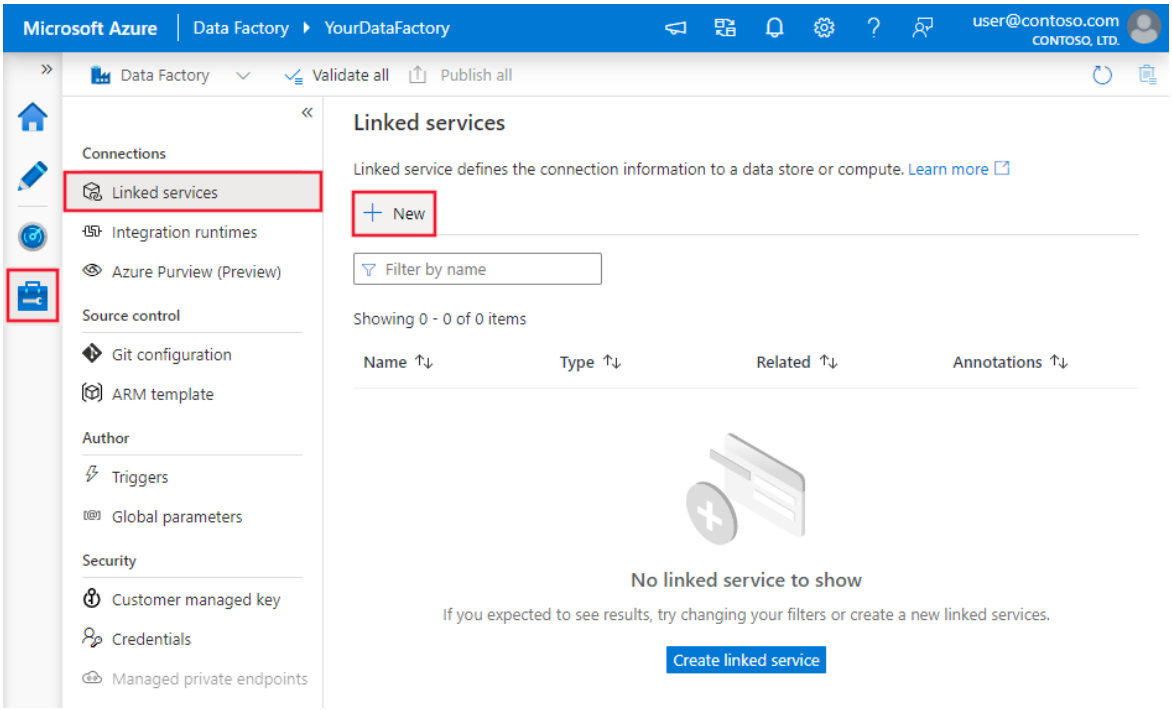
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to DB2 using UI

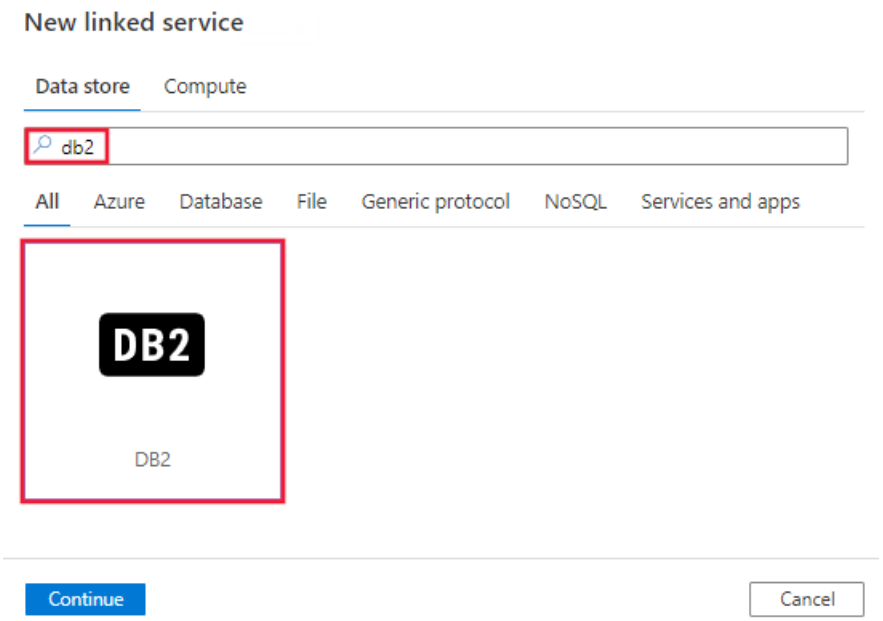
Use the following steps to create a linked service to DB2 in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

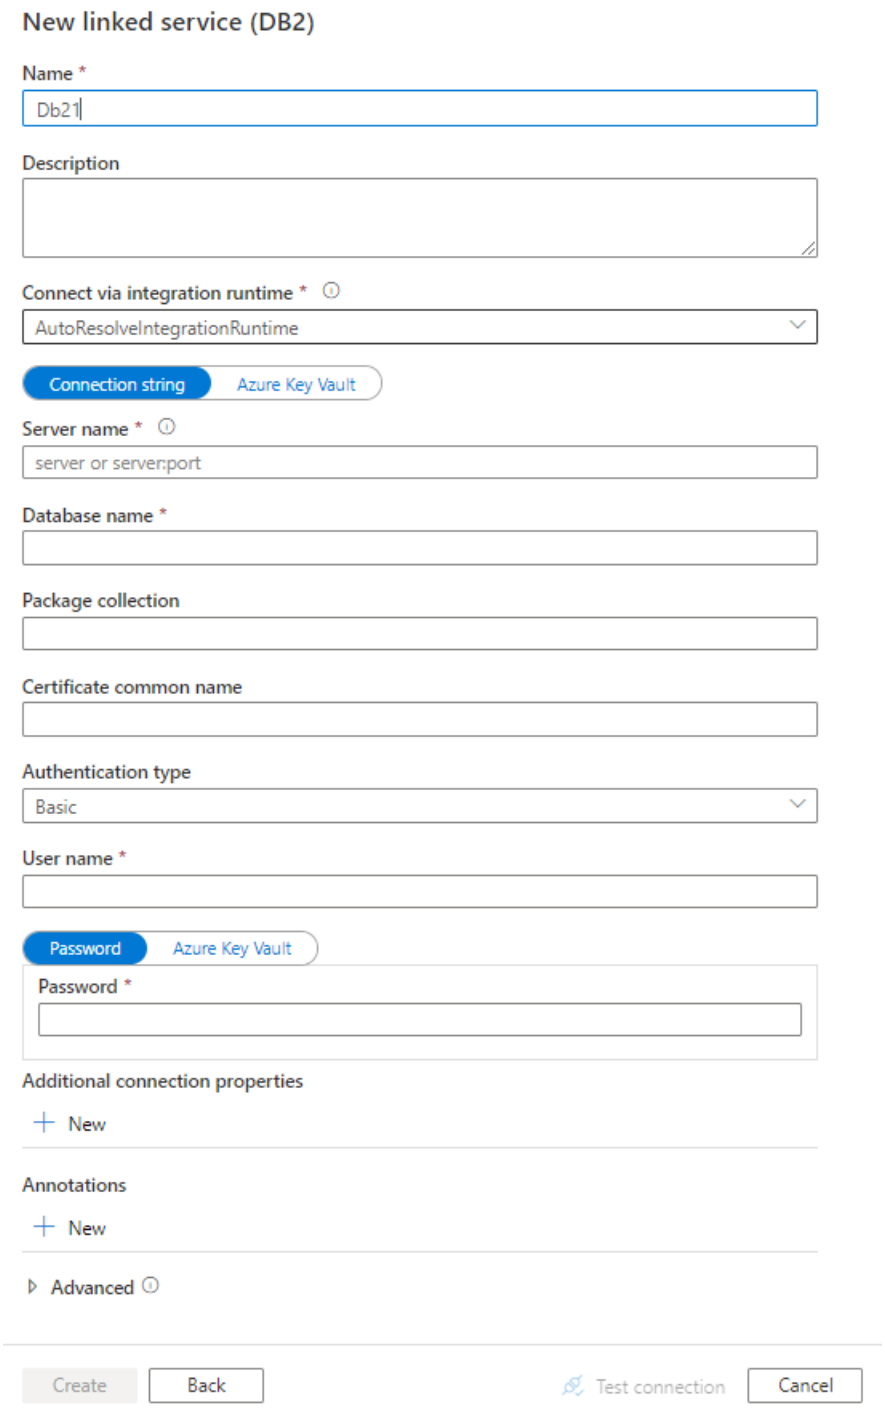
   - Azure Data Factory
   - Azure Synapse



2. Search for DB2 and select the DB2 connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to DB2 connector.

Linked service properties

The following properties are supported for DB2 linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Db2**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify information needed to connect to the DB2 instance. You can also put password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Typical properties inside the connection string:

PROPERTY	DESCRIPTION	REQUIRED
server	Name of the DB2 server. You can specify the port number following the server name delimited by colon e.g. `server:port`. The DB2 connector utilizes the DDM/DRDA protocol, and by default uses port 50000 if not specified. The port your specific DB2 database uses might be different based on the version and your settings, e.g. for DB2 LUW the default port is 50000, for AS400 the default port is 446 or 448 when TLS enabled. Refer to the following DB2 documents on how the port is configured typically: DB2 z/OS, DB2 iSeries, and DB2 LUW.	Yes
database	Name of the DB2 database.	Yes
authenticationType	Type of authentication used to connect to the DB2 database. Allowed value is: **Basic**.	Yes
username	Specify user name to connect to the DB2 database.	Yes
password	Specify password for the user account you specified for the username. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
packageCollection	Specify under where the needed packages are auto created by the service when querying the database. If this is not set, the service uses the {username} as the default value.	No

PROPERTY	DESCRIPTION	REQUIRED
certificateCommonName	When you use Secure Sockets Layer (SSL) or Transport Layer Security (TLS) encryption, you must enter a value for Certificate common name.	No

TIP

If you receive an error message that states `The package corresponding to an SQL statement execution request was not found. SQLSTATE=51002 SQLCODE=-805`, the reason is a needed package is not created for the user. By default, the service will try to create the package under the collection named as the user you used to connect to the DB2. Specify the package collection property to indicate under where you want the service to create the needed packages when querying the database. If you can't determine the package collection name, try to set `packageCollection=NULLID`.

Example:

```
{
    "name": "Db2LinkedService",
    "properties": {
        "type": "Db2",
        "typeProperties": {
            "connectionString":"server=<server:port>;database=<database>;authenticationType=Basic;username=
<username>;password=<password>;packageCollection=<packagecollection>;certificateCommonName=<certname>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "Db2LinkedService",
    "properties": {
        "type": "Db2",
        "typeProperties": {
            "connectionString": "server=<server:port>;database=<database>;authenticationType=Basic;username=
<username>;packageCollection=<packagecollection>;certificateCommonName=<certname>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

If you were using DB2 linked service with the following payload, it is still supported as-is, while you are

suggested to use the new one going forward.

Previous payload:

```
{
    "name": "Db2LinkedService",
    "properties": {
        "type": "Db2",
        "typeProperties": {
            "server": "<servername:port>",
            "database": "<dbname>",
            "authenticationType": "Basic",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by DB2 dataset.

To copy data from DB2, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **Db2Table**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "DB2Dataset",
    "properties":
    {
        "type": "Db2Table",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<DB2 linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by DB2 source.

DB2 as source

To copy data from DB2, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **Db2Source**	Yes
query	Use the custom SQL query to read data. For example: `"query": "SELECT * FROM \"DB2ADMIN\".\"Customers\""` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromDB2",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<DB2 input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "Db2Source",
                "query": "SELECT * FROM \"DB2ADMIN\".\"Customers\""
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Data type mapping for DB2

When copying data from DB2, the following mappings are used from DB2 data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

DB2 DATABASE TYPE	INTERIM SERVICE DATA TYPE
BigInt	Int64
Binary	Byte[]
Blob	Byte[]
Char	String
Clob	String
Date	Datetime
DB2DynArray	String
DbClob	String
Decimal	Decimal

DB2 DATABASE TYPE	INTERIM SERVICE DATA TYPE
DecimalFloat	Decimal
Double	Double
Float	Double
Graphic	String
Integer	Int32
LongVarBinary	Byte[]
LongVarChar	String
LongVarGraphic	String
Numeric	Decimal
Real	Single
SmallInt	Int16
Time	TimeSpan
Timestamp	DateTime
VarBinary	Byte[]
VarChar	String
VarGraphic	String
Xml	Byte[]

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Delimited text format in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the delimited text files or write the data into delimited text format**.

Delimited text format is supported for the following connectors:

- Amazon S3
- Amazon S3 Compatible Storage
- Azure Blob
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Files
- File System
- FTP
- Google Cloud Storage
- HDFS
- HTTP
- Oracle Cloud Storage
- SFTP

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the delimited text dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **DelimitedText**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`.	Yes
columnDelimiter	The character(s) used to separate columns in a file. The default value is **comma** `,`. When the column delimiter is defined as empty string, which means no delimiter, the whole line is taken as a single column. Currently, column delimiter as empty string is only supported for mapping data flow but not Copy activity.	No

PROPERTY	DESCRIPTION	REQUIRED
rowDelimiter	For Copy activity, the single character or "\r\n" used to separate rows in a file. The default value is any of the following values **on read: ["\r\n", "\r", "\n"]**; **on write: "\r\n"**. "\r\n" is only supported in copy command. For Mapping data flow, the single or two characters used to separate rows in a file. The default value is any of the following values **on read: ["\r\n", "\r", "\n"]**; **on write: "\n"**. When the row delimiter is set to no delimiter (empty string), the column delimiter must be set as no delimiter (empty string) as well, which means to treat the entire content as a single value. Currently, row delimiter as empty string is only supported for mapping data flow but not Copy activity.	No
quoteChar	The single character to quote column values if it contains column delimiter. The default value is **double quotes** `"`. When `quoteChar` is defined as empty string, it means there is no quote char and column value is not quoted, and `escapeChar` is used to escape the column delimiter and itself.	No
escapeChar	The single character to escape quotes inside a quoted value. The default value is **backslash** `\`. When `escapeChar` is defined as empty string, the `quoteChar` must be set as empty string as well, in which case make sure all column values don't contain delimiters.	No
firstRowAsHeader	Specifies whether to treat/make the first row as a header line with names of columns. Allowed values are **true** and **false** (default). When first row as header is false, note UI data preview and lookup activity output auto generate column names as Prop_{n} (starting from 0), copy activity requires explicit mapping from source to sink and locates columns by ordinal (starting from 1), and mapping data flow lists and locates columns with name as Column_{n} (starting from 1).	No
nullValue	Specifies the string representation of null value. The default value is **empty string**.	No

PROPERTY	DESCRIPTION	REQUIRED
encodingName	The encoding type used to read/write test files. Allowed values are as follows: "UTF-8","UTF-8 without BOM", "UTF-16", "UTF-16BE", "UTF-32", "UTF-32BE", "US-ASCII", "UTF-7", "BIG5", "EUC-JP", "EUC-KR", "GB2312", "GB18030", "JOHAB", "SHIFT-JIS", "CP875", "CP866", "IBM00858", "IBM037", "IBM273", "IBM437", "IBM500", "IBM737", "IBM775", "IBM850", "IBM852", "IBM855", "IBM857", "IBM860", "IBM861", "IBM863", "IBM864", "IBM865", "IBM869", "IBM870", "IBM01140", "IBM01141", "IBM01142", "IBM01143", "IBM01144", "IBM01145", "IBM01146", "IBM01147", "IBM01148", "IBM01149", "ISO-2022-JP", "ISO-2022-KR", "ISO-8859-1", "ISO-8859-2", "ISO-8859-3", "ISO-8859-4", "ISO-8859-5", "ISO-8859-6", "ISO-8859-7", "ISO-8859-8", "ISO-8859-9", "ISO-8859-13", "ISO-8859-15", "WINDOWS-874", "WINDOWS-1250", "WINDOWS-1251", "WINDOWS-1252", "WINDOWS-1253", "WINDOWS-1254", "WINDOWS-1255", "WINDOWS-1256", "WINDOWS-1257", "WINDOWS-1258". Note mapping data flow doesn't support UTF-7 encoding.	No
compressionCodec	The compression codec used to read/write text files. Allowed values are **bzip2**, **gzip**, **deflate**, **ZipDeflate**, **TarGzip**, **Tar**, **snappy**, or **lz4**. Default is not compressed. **Note** currently Copy activity doesn't support "snappy" & "lz4", and mapping data flow doesn't support "ZipDeflate", "TarGzip" and "Tar". **Note** when using copy activity to decompress **ZipDeflate/TarGzip/Tar** file(s) and write to file-based sink data store, by default files are extracted to the folder: `<path specified in dataset>/<folder named as source compressed file>/`, use `preserveZipFileNameAsFolder` / `preserveCompressionFileNameAsFolder` on copy activity source to control whether to preserve the name of the compressed file(s) as folder structure.	No

PROPERTY	DESCRIPTION	REQUIRED
compressionLevel	The compression ratio. Allowed values are **Optimal** or **Fastest**. - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed. - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete. For more information, see Compression Level topic.	No

Below is an example of delimited text dataset on Azure Blob Storage:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "escapeChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the delimited text source and sink.

Delimited text as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **DelimitedTextSource**.	Yes
formatSettings	A group of properties. Refer to **Delimited text read settings** table below.	No

PROPERTY	DESCRIPTION	REQUIRED
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`.	No

Supported **delimited text read settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **DelimitedTextReadSettings**.	Yes
skipLineCount	Indicates the number of **non-empty** rows to skip when reading data from input files. If both skipLineCount and firstRowAsHeader are specified, the lines are skipped first and then the header information is read from the input file.	No
compressionProperties	A group of properties on how to decompress data for a given compression codec.	No
preserveZipFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `ZipDeflateReadSettings`)	Applies when input dataset is configured with **ZipDeflate** compression. Indicates whether to preserve the source zip file name as folder structure during copy. - When set to **true (default)**, the service writes unzipped files to `<path specified in dataset>/<folder named as source zip file>/`. - When set to **false**, the service writes unzipped files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source zip files to avoid racing or unexpected behavior.	No

PROPERTY	DESCRIPTION	REQUIRED
preserveCompressionFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `TarGZipReadSettings` *or* `TarReadSettings`)	Applies when input dataset is configured with **TarGzip/Tar** compression. Indicates whether to preserve the source compressed file name as folder structure during copy. - When set to **true (default)**, the service writes decompressed files to `<path specified in dataset>/<folder named as source compressed file>/`. - When set to **false**, the service writes decompressed files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source files to avoid racing or unexpected behavior.	No

```

```

Delimited text as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **DelimitedTextSink**.	Yes
formatSettings	A group of properties. Refer to **Delimited text write settings** table below.	No

PROPERTY	DESCRIPTION	REQUIRED
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`.	No

Supported **delimited text write settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **DelimitedTextWriteSettings**.	Yes
fileExtension	The file extension used to name the output files, for example, `.csv`, `.txt`. It must be specified when the `fileName` is not specified in the output DelimitedText dataset. When file name is configured in the output dataset, it will be used as the sink file name and the file extension setting will be ignored.	Yes when file name is not specified in output dataset
maxRowsPerFile	When writing data into a folder, you can choose to write to multiple files and specify the max rows per file.	No
fileNamePrefix	Applicable when `maxRowsPerFile` is configured. Specify the file name prefix when writing data to multiple files, resulted in this pattern: `<fileNamePrefix>_00000.<fileExtension>`. If not specified, file name prefix will be auto generated. This property does not apply when source is file-based store or partition-option-enabled data store.	No

Mapping data flow properties

In mapping data flows, you can read and write to delimited text format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and SFTP, and you can read delimited text format in Amazon S3.

Source properties

The below table lists the properties supported by a delimited text source. You can edit these properties in the **Source options** tab.

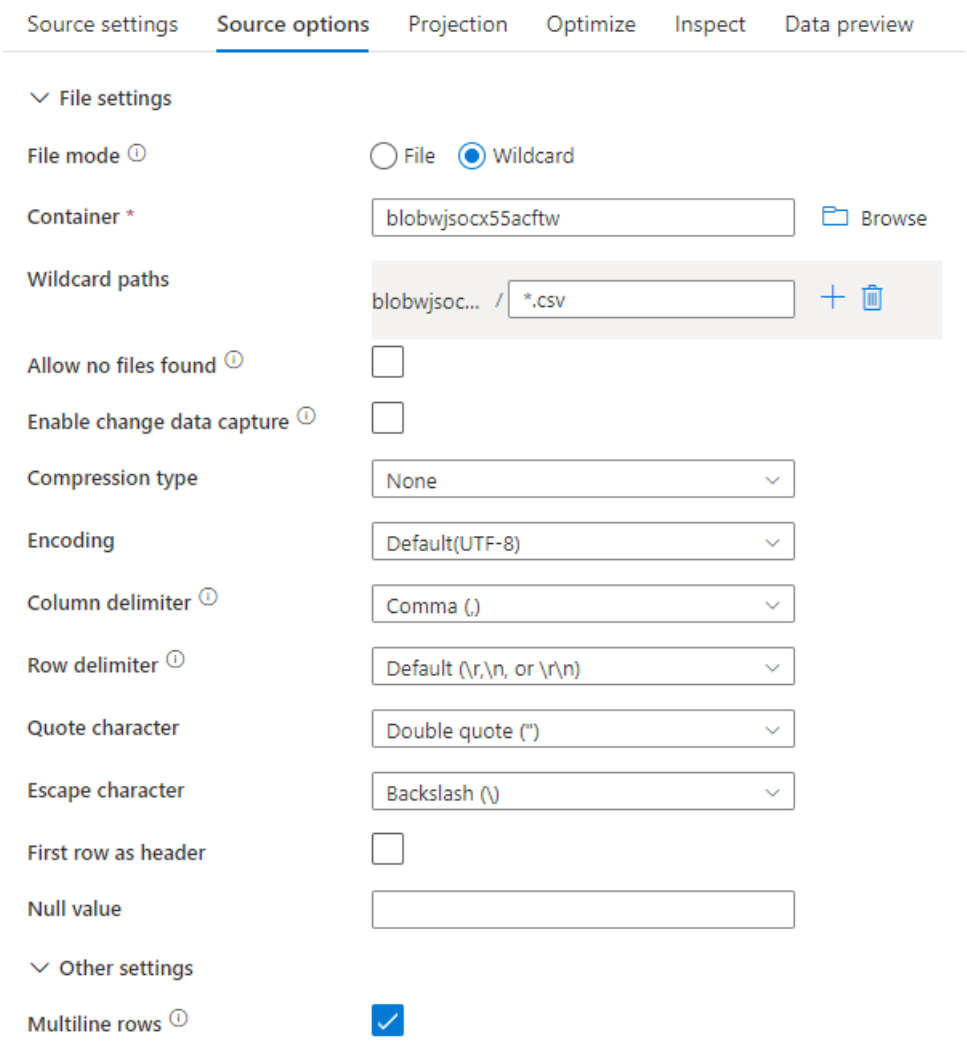
NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList
Multiline rows	Does the source file contain rows that span multiple lines. Multiline values must be in quotes.	no `true` or `false`	multiLineRow	
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

> **NOTE**
> Data flow sources support for list of files is limited to 1024 entries in your file. To include more files, use wildcards in your file list.

Source example

The below image is an example of a delimited text source configuration in mapping data flows.



The associated data flow script is:

```
source(
    allowSchemaDrift: true,
    validateSchema: false,
    multiLineRow: true,
    wildcardPaths:['*.csv']) ~> CSVSource
```

> **NOTE**
> Data flow sources support a limited set of Linux globbing that is support by Hadoop file systems

Sink properties

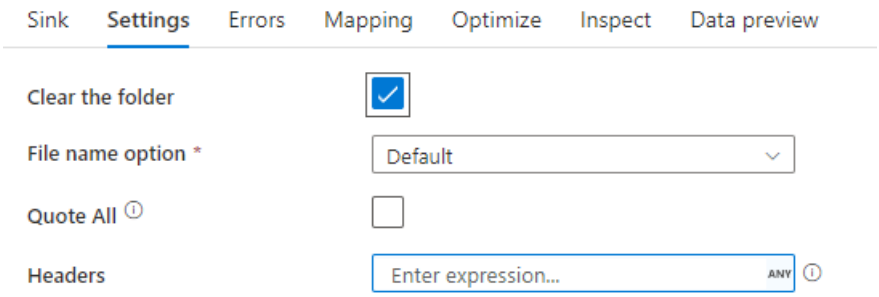
The below table lists the properties supported by a delimited text sink. You can edit these properties in the **Settings** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>`	no	Pattern: String Per partition: String[] Name file as column data: String Output to single file: `['<fileName>']` Name folder as column data: String	filePattern partitionFileNames rowUrlColumn partitionFileNames rowFolderUrlColumn
Quote all	Enclose all values in quotes	no	`true` or `false`	quoteAll
Header	Add customer headers to output files	no	`[<string array>]`	header

Sink example

The below image is an example of a delimited text sink configuration in mapping data flows.



The associated data flow script is:

```
CSVSource sink(allowSchemaDrift: true,
    validateSchema: false,
    truncate: true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> CSVSink
```

Related connectors and formats

Here are some common connectors and formats related to the delimited text format:

- Azure Blob Storage (connector-azure-blob-storage.md)
- Binary format (format-binary.md)
- Dataverse(connector-dynamics-crm-office-365.md)
- Delta format(format-delta.md)
- Excel format(format-excel.md)
- File System(connector-file-system.md)
- FTP(connector-ftp.md)
- HTTP(connector-http.md)
- JSON format(format-json.md)
- Parquet format(format-parquet.md)

Copy data from Drill using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Drill. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Drill connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell

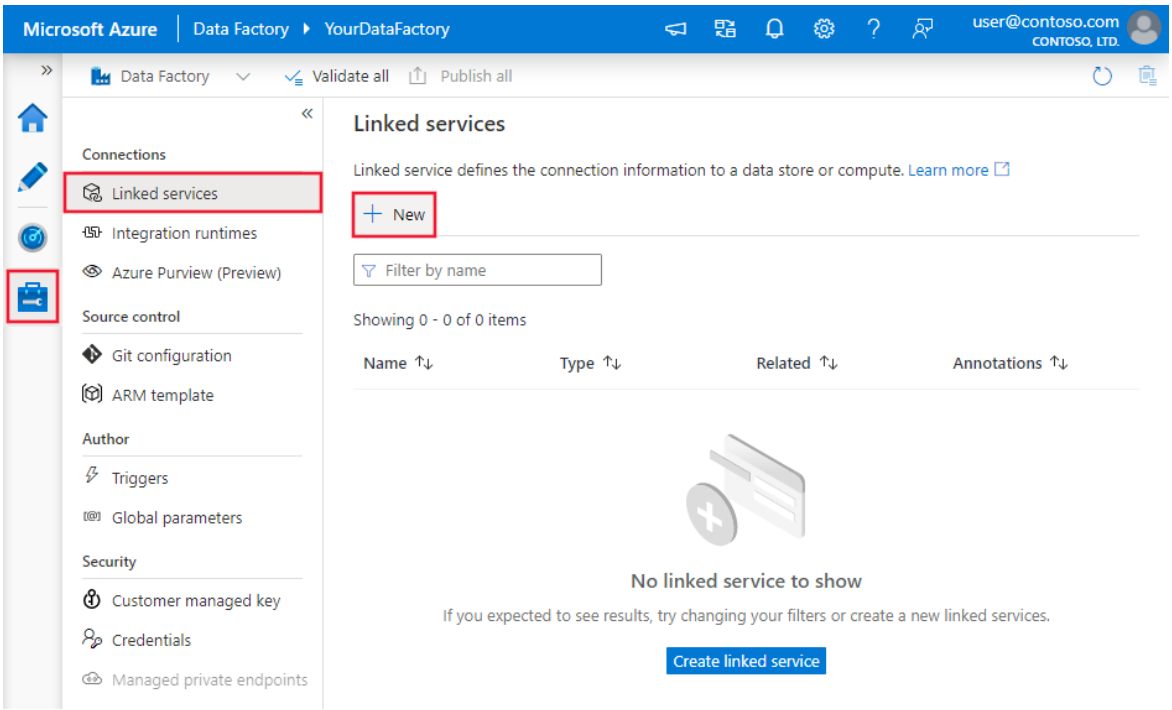
- The REST API
- The Azure Resource Manager template

Create a linked service to Drill using UI

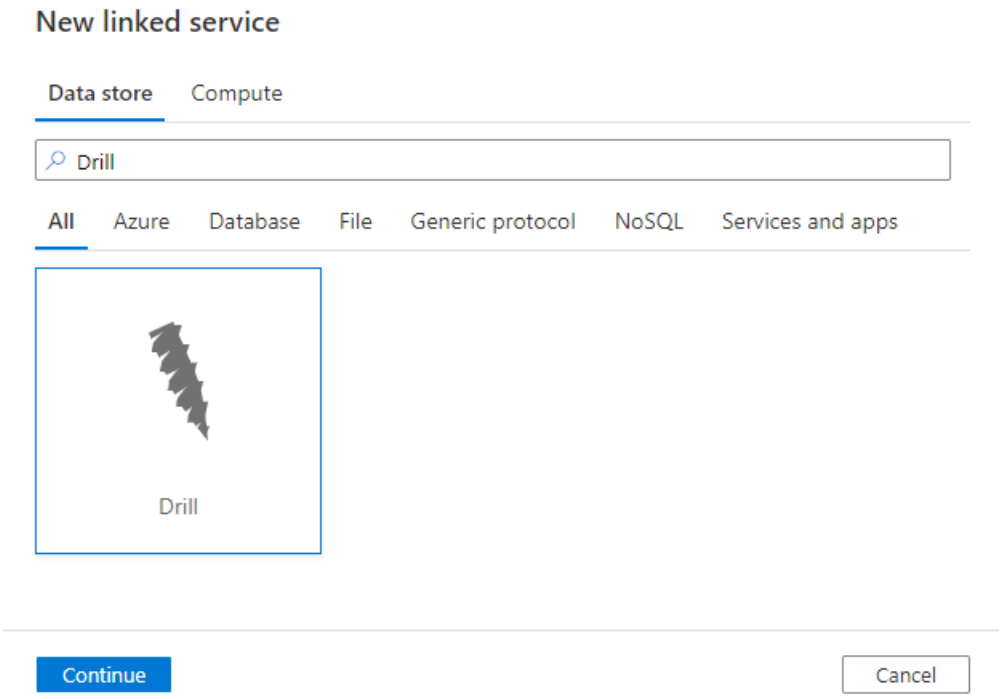
Use the following steps to create a linked service to Drill in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

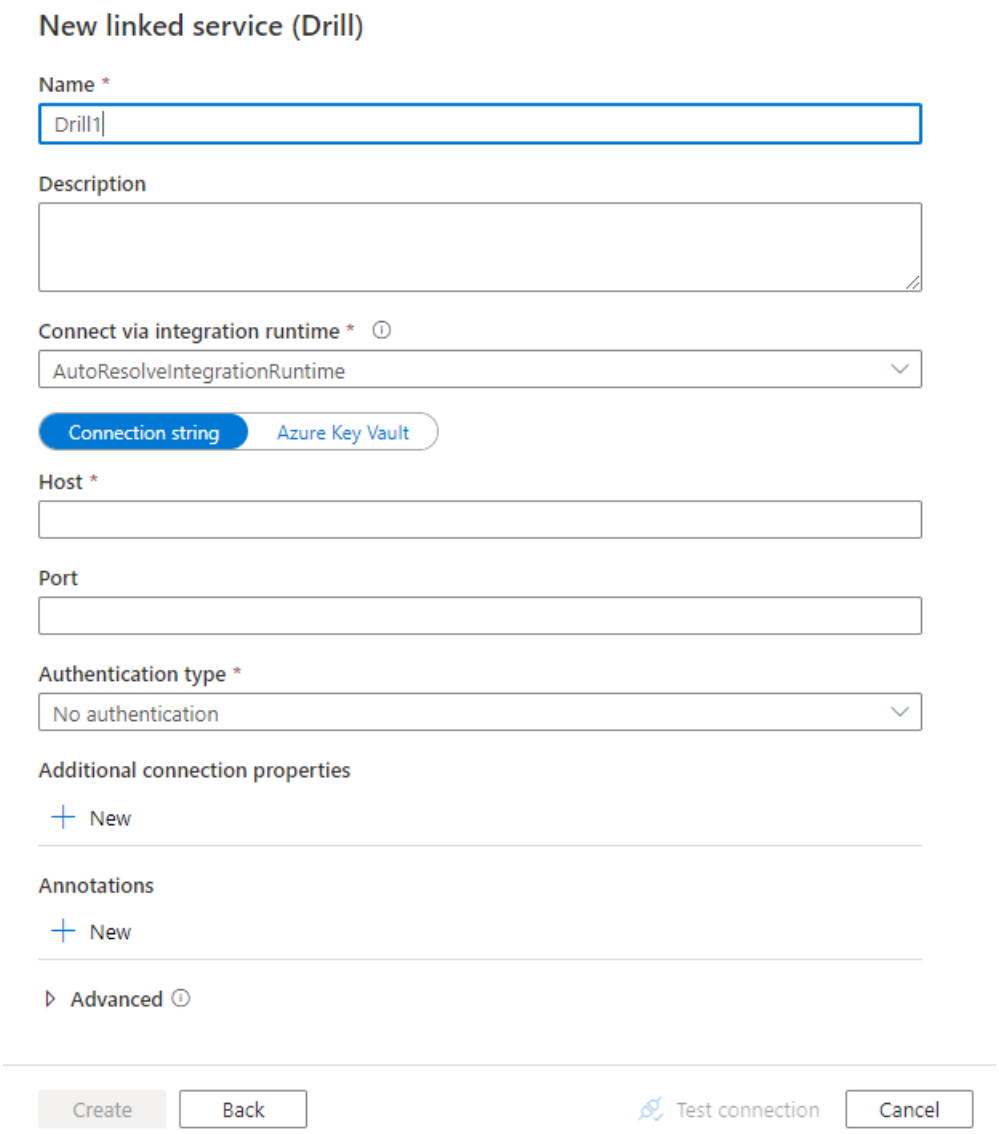
   - Azure Data Factory
   - Azure Synapse



2. Search for Drill and select the Drill connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Drill connector.

Linked service properties

The following properties are supported for Drill linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Drill**	Yes
connectionString	An ODBC connection string to connect to Drill. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "DrillLinkedService",
    "properties": {
        "type": "Drill",
        "typeProperties": {
            "connectionString": "ConnectionType=Direct;Host=<host>;Port=<port>;AuthenticationType=Plain;UID=
<user name>;PWD=<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "DrillLinkedService",
    "properties": {
        "type": "Drill",
        "typeProperties": {
            "connectionString": "ConnectionType=Direct;Host=<host>;Port=<port>;AuthenticationType=Plain;UID=
<user name>;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Drill dataset.

To copy data from Drill, set the type property of the dataset to **DrillTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **DrillTable**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "DrillDataset",
    "properties": {
        "type": "DrillTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Drill linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Drill source.

DrillSource as source

To copy data from Drill, set the source type in the copy activity to **DrillSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **DrillSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromDrill",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Drill input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DrillSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 17 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use a copy activity in Azure Data Factory or Synapse pipelines to copy data from and to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM, and use a data flow to transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM. To learn more, read the Azure Data Factory and the Azure Synapse Analytics introduction articles.

Supported capabilities

This connector is supported for the following activities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that a copy activity supports as sources and sinks, see the Supported data stores table.

> **NOTE**
> Effective November 2020, Common Data Service has been renamed to Microsoft Dataverse. This article is updated to reflect the latest terminology.

This Dynamics connector supports Dynamics versions 7 through 9 for both online and on-premises. More specifically:

- Version 7 maps to Dynamics CRM 2015.
- Version 8 maps to Dynamics CRM 2016 and the early version of Dynamics 365.
- Version 9 maps to the later version of Dynamics 365.

Refer to the following table of supported authentication types and configurations for Dynamics versions and products.

DYNAMICS VERSIONS	AUTHENTICATION TYPES	LINKED SERVICE SAMPLES
Dataverse Dynamics 365 online Dynamics CRM online	Azure Active Directory (Azure AD) service principal Office 365	Dynamics online and Azure AD service-principal or Office 365 authentication
Dynamics 365 on-premises with internet-facing deployment (IFD) Dynamics CRM 2016 on-premises with IFD Dynamics CRM 2015 on-premises with IFD	IFD	Dynamics on-premises with IFD and IFD authentication

NOTE

With the deprecation of regional Discovery Service, the service has upgraded to leverage global Discovery Service while using Office 365 Authentication.

IMPORTANT

If your tenant and user is configured in Azure Active Directory for conditional access and/or Multi-Factor Authentication is required, you will not be able to use Office 365 Authentication type. For those situations, you must use an Azure Active Directory (Azure AD) service principal authentication.

For Dynamics 365 specifically, the following application types are supported:

- Dynamics 365 for Sales
- Dynamics 365 for Customer Service
- Dynamics 365 for Field Service
- Dynamics 365 for Project Service Automation
- Dynamics 365 for Marketing This connector doesn't support other application types like Finance, Operations, and Talent.

TIP

To copy data from Dynamics 365 Finance and Operations, you can use the Dynamics AX connector.

This Dynamics connector is built on top of Dynamics XRM tooling.

Prerequisites

To use this connector with Azure AD service-principal authentication, you must set up server-to-server (S2S) authentication in Dataverse or Dynamics. First register the application user (Service Principal) in Azure Active Directory. You can find out how to do this here. During application registration you will need to create that user in Dataverse or Dynamics and grant permissions. Those permissions can either be granted directly or indirectly by adding the application user to a team which has been granted permissions in Dataverse or Dynamics. You can find more information on how to set up an application user to authenticate with Dataverse here.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

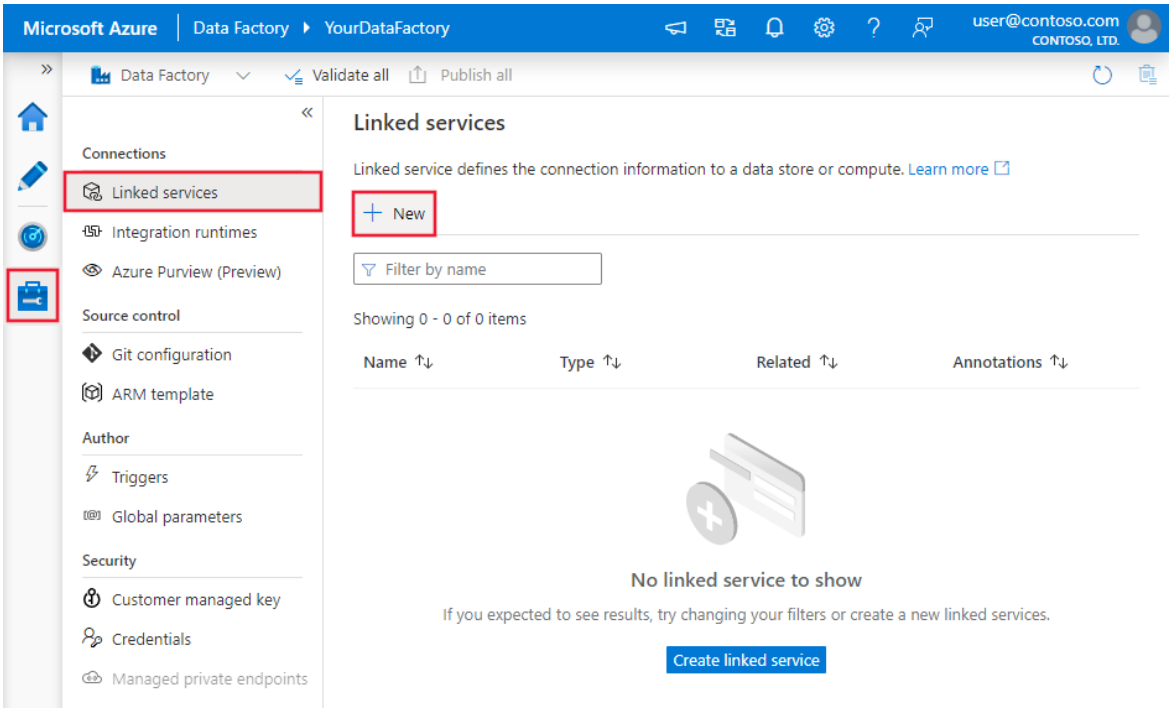
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using UI

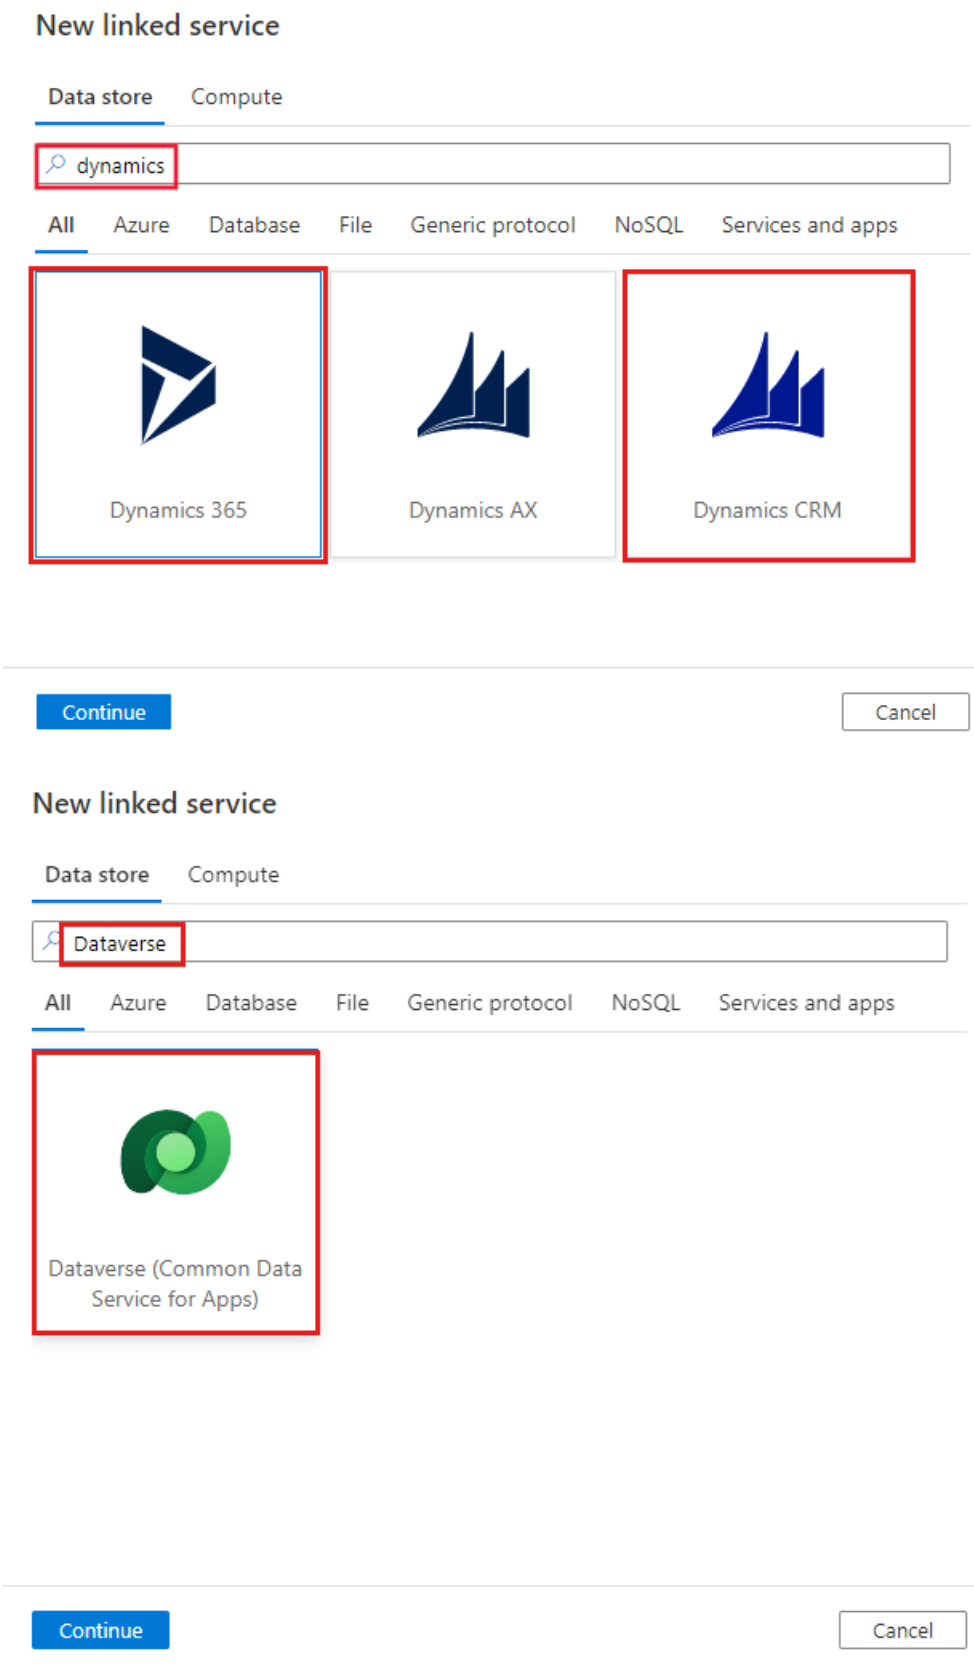
Use the following steps to create a linked service to Dynamics 365 in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

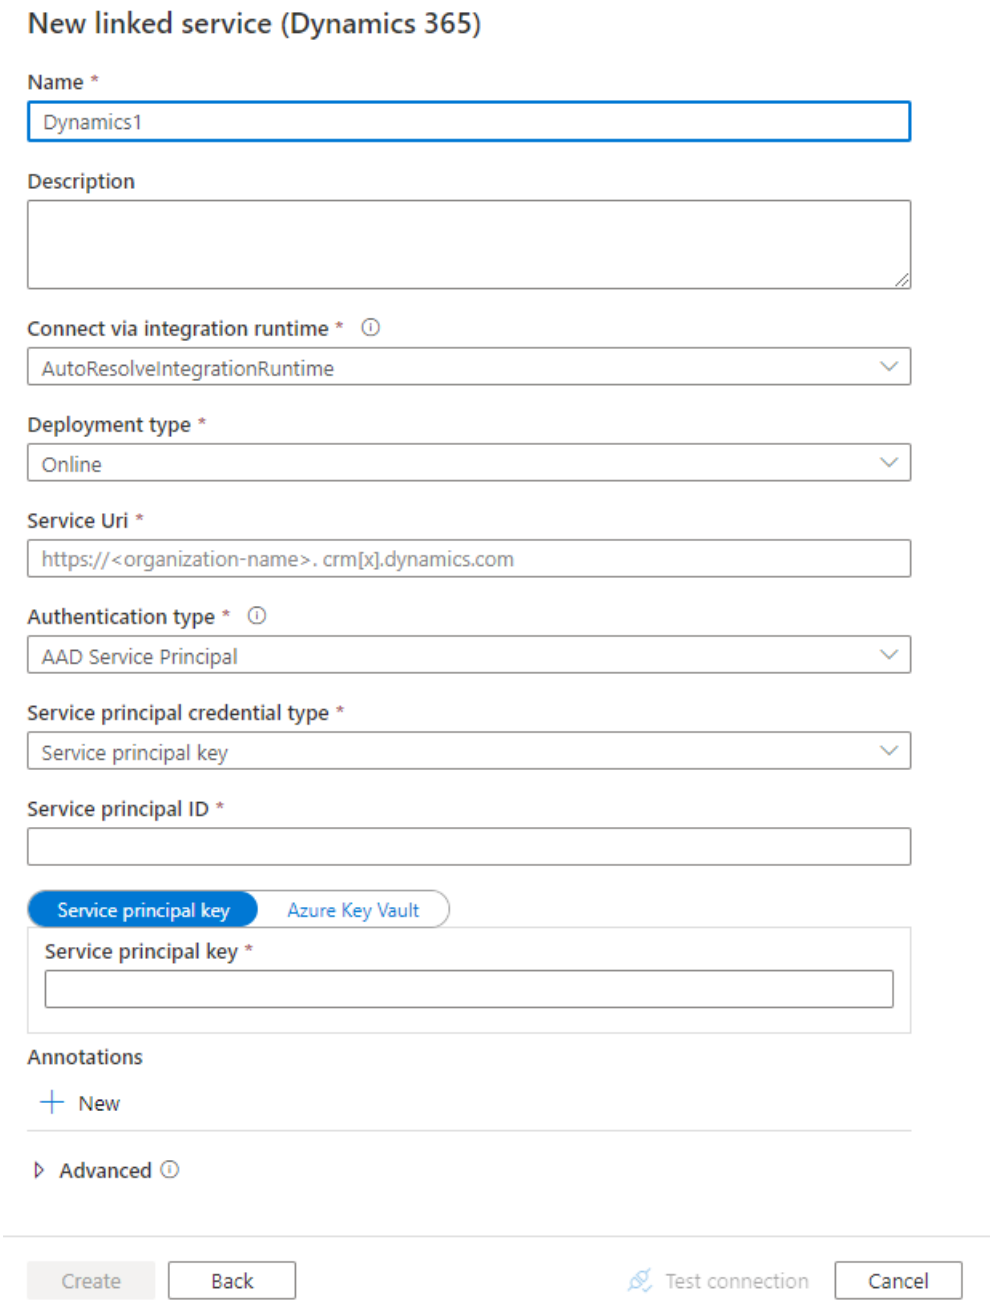
   - Azure Data Factory
   - Azure Synapse



2. Search for Dynamics or Dataverse and select the Dynamics 365 (Microsoft Dataverse) or Dynamics CRM connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Dynamics.

Linked service properties

The following properties are supported for the Dynamics linked service.

Dynamics 365 and Dynamics CRM online

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes
deploymentType	The deployment type of the Dynamics instance. The value must be "Online" for Dynamics online.	Yes

PROPERTY	DESCRIPTION	REQUIRED
serviceUri	The service URL of your Dynamics instance, the same one you access from browser. An example is "https://<organization-name>.crm[x].dynamics.com".	Yes
authenticationType	The authentication type to connect to a Dynamics server. Valid values are "AADServicePrincipal", "Office365" and "ManagedIdentity".	Yes
servicePrincipalId	The client ID of the Azure AD application.	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredentialType	The credential type to use for service-principal authentication. Valid values are "ServicePrincipalKey" and "ServicePrincipalCert".	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredential	The service-principal credential. When you use "ServicePrincipalKey" as the credential type, `servicePrincipalCredential` can be a string that the service encrypts upon linked service deployment. Or it can be a reference to a secret in Azure Key Vault. When you use "ServicePrincipalCert" as the credential, `servicePrincipalCredential` must be a reference to a certificate in Azure Key Vault, and ensure the certificate content type is **PKCS #12**.	Yes when authentication is "AADServicePrincipal"
username	The username to connect to Dynamics.	Yes when authentication is "Office365"
password	The password for the user account you specified as the username. Mark this field with "SecureString" to store it securely, or reference a secret stored in Azure Key Vault.	Yes when authentication is "Office365"
credentials	Specify the user-assigned managed identity as the credential object. Create one or multiple user-assigned managed identities, assign them to your data factory and create credentials for each user-assigned managed identity.	Yes when authentication is "ManagedIdentity"
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

NOTE

The Dynamics connector formerly used the optional **organizationName** property to identify your Dynamics CRM or Dynamics 365 online instance. While that property still works, we suggest you specify the new **serviceUri** property instead to gain better performance for instance discovery.

Example: Dynamics online using Azure AD service-principal and key authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalCredential": "<service principal key>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Azure AD service-principal and certificate authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalCredential": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<AKV reference>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<certificate name in AKV>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Office 365 authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "Office365",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using user-assigned managed identity authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "ManagedIdentity",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dynamics 365 and Dynamics CRM on-premises with IFD

Additional properties that compare to Dynamics online are **hostName** and **port**.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes.
deploymentType	The deployment type of the Dynamics instance. The value must be "OnPremisesWithIfd" for Dynamics on-premises with IFD.	Yes.
hostName	The host name of the on-premises Dynamics server.	Yes.

PROPERTY	DESCRIPTION	REQUIRED
port	The port of the on-premises Dynamics server.	No. The default value is 443.
organizationName	The organization name of the Dynamics instance.	Yes.
authenticationType	The authentication type to connect to the Dynamics server. Specify "Ifd" for Dynamics on-premises with IFD.	Yes.
username	The username to connect to Dynamics.	Yes.
password	The password for the user account you specified for the username. You can mark this field with "SecureString" to store it securely. Or you can store a password in Key Vault and let the copy activity pull from there when it does data copy. Learn more from Store credentials in Key Vault.	Yes.
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

Example: Dynamics on-premises with IFD using IFD authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "description": "Dynamics on-premises with IFD linked service using IFD authentication",
        "typeProperties": {
            "deploymentType": "OnPremisesWithIFD",
            "hostName": "contosodynamicsserver.contoso.com",
            "port": 443,
            "organizationName": "admsDynamicsTest",
            "authenticationType": "Ifd",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by Dynamics dataset.

To copy data from and to Dynamics, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to "DynamicsEntity", "DynamicsCrmEntity", or "CommonDataServiceForAppsEntity".	Yes
entityName	The logical name of the entity to retrieve.	No for source if the activity source is specified as "query" and yes for sink

Example

```
{
    "name": "DynamicsDataset",
    "properties": {
        "type": "DynamicsEntity",
        "schema": [],
        "typeProperties": {
            "entityName": "account"
        },
        "linkedServiceName": {
            "referenceName": "<Dynamics linked service name>",
            "type": "linkedservicereference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Dynamics source and sink types.

Dynamics as a source type

To copy data from Dynamics, the copy activity **source** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to "DynamicsSource", "DynamicsCrmSource", or "CommonDataServiceForAppsSource".	Yes
query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No if `entityName` in the dataset is specified

> **NOTE**
> The PK column will always be copied out even if the column projection you configure in the FetchXML query doesn't contain it.

IMPORTANT

- When you copy data from Dynamics, explicit column mapping from Dynamics to sink is optional. But we highly recommend the mapping to ensure a deterministic copy result.
- When the service imports a schema in the authoring UI, it infers the schema. It does so by sampling the top rows from the Dynamics query result to initialize the source column list. In that case, columns with no values in the top rows are omitted. The same behavior also applies to data preview and copy executions if there is no explicit mapping. You can review and add more columns into the mapping, which are honored during copy runtime.

Example

```
"activities":[
    {
        "name": "CopyFromDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Dynamics input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DynamicsSource",
                "query": "<FetchXML Query>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Sample FetchXML query

```
<fetch>
  <entity name="account">
    <attribute name="accountid" />
    <attribute name="name" />
    <attribute name="marketingonly" />
    <attribute name="modifiedon" />
    <order attribute="modifiedon" descending="false" />
    <filter type="and">
      <condition attribute ="modifiedon" operator="between">
        <value>2017-03-10 18:40:00z</value>
        <value>2017-03-12 20:40:00z</value>
      </condition>
    </filter>
  </entity>
</fetch>
```

Dynamics as a sink type

To copy data to Dynamics, the copy activity **sink** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to "DynamicsSink", "DynamicsCrmSink", or "CommonDataServiceForAppsSink".	Yes.
writeBehavior	The write behavior of the operation. The value must be "Upsert".	Yes
alternateKeyName	The alternate key name defined on your entity to do an upsert.	No.
writeBatchSize	The row count of data written to Dynamics in each batch.	No. The default value is 10.
ignoreNullValues	Whether to ignore null values from input data other than key fields during a write operation. Valid values are **TRUE** and **FALSE**: • **TRUE**: Leave the data in the destination object unchanged when you do an upsert or update operation. Insert a defined default value when you do an insert operation. • **FALSE**: Update the data in the destination object to a null value when you do an upsert or update operation. Insert a null value when you do an insert operation.	No. The default value is **FALSE**.
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

NOTE

The default value for both the sink **writeBatchSize** and the copy activity **parallelCopies** for the Dynamics sink is 10. Therefore, 100 records are concurrently submitted by default to Dynamics.

For Dynamics 365 online, there's a limit of two concurrent batch calls per organization. If that limit is exceeded, a "Server Busy" exception is thrown before the first request is ever run. Keep **writeBatchSize** at 10 or less to avoid such throttling of concurrent calls.

The optimal combination of **writeBatchSize** and **parallelCopies** depends on the schema of your entity. Schema elements include the number of columns, row size, and number of plug-ins, workflows, or workflow activities hooked up to those calls. The default setting of **writeBatchSize** (10) × **parallelCopies** (10) is the recommendation according to the Dynamics service. This value works for most Dynamics entities, although it might not give the best performance. You can tune the performance by adjusting the combination in your copy activity settings.

Example

```
"activities":[
    {
        "name": "CopyToDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Dynamics output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "DynamicsSink",
                "writeBehavior": "Upsert",
                "writeBatchSize": 10,
                "ignoreNullValues": true
            }
        }
    }
]
```

Retrieving data from views

To retrieve data from Dynamics views, you need to get the saved query of the view, and use the query to get the data.

There are two entities which store different types of view: "saved query" stores system view and "user query" stores user view. To get the information of the views, refer to the following FetchXML query and replace the "TARGETENTITY" with `savedquery` or `userquery`. Each entity type has more available attributes that you can add to the query based on your need. Learn more about savedquery entity and userquery entity.

```
<fetch top="5000" >
  <entity name="<TARGETENTITY>">
    <attribute name="name" />
    <attribute name="fetchxml" />
    <attribute name="returnedtypecode" />
    <attribute name="querytype" />
  </entity>
</fetch>
```

You can also add filters to filter the views. For example, add the following filter to get a view named "My Active Accounts" in account entity.

```
<filter type="and" >
    <condition attribute="returnedtypecode" operator="eq" value="1" />
    <condition attribute="name" operator="eq" value="My Active Accounts" />
</filter>
```

Data type mapping for Dynamics

When you copy data from Dynamics, the following table shows mappings from Dynamics data types to interim data types within the service. To learn how a copy activity maps to a source schema and a data type maps to a sink, see Schema and data type mappings.

Configure the corresponding interim data type in a dataset structure that is based on your source Dynamics data type by using the following mapping table:

DYNAMICS DATA TYPE	SERVICE INTERIM DATA TYPE	SUPPORTED AS SOURCE	SUPPORTED AS SINK
AttributeTypeCode.BigInt	Long	✓	✓
AttributeTypeCode.Boolean	Boolean	✓	✓
AttributeType.Customer	GUID	✓	✓ (See guidance)
AttributeType.DateTime	Datetime	✓	✓
AttributeType.Decimal	Decimal	✓	✓
AttributeType.Double	Double	✓	✓
AttributeType.EntityName	String	✓	✓
AttributeType.Integer	Int32	✓	✓
AttributeType.Lookup	GUID	✓	✓ (See guidance)
AttributeType.ManagedProperty	Boolean	✓	
AttributeType.Memo	String	✓	✓
AttributeType.Money	Decimal	✓	✓
AttributeType.Owner	GUID	✓	✓ (See guidance)
AttributeType.Picklist	Int32	✓	✓
AttributeType.Uniqueidentifier	GUID	✓	✓
AttributeType.String	String	✓	✓
AttributeType.State	Int32	✓	✓
AttributeType.Status	Int32	✓	✓

NOTE

The Dynamics data types **AttributeType.CalendarRules**, **AttributeType.MultiSelectPicklist**, and **AttributeType.PartyList** aren't supported.

Writing data to a lookup field

To write data into a lookup field with multiple targets like Customer and Owner, follow this guidance and example:

1. Make your source contains both the field value and the corresponding target entity name.
   - If all records map to the same target entity, ensure one of the following conditions:
     - Your source data has a column that stores the target entity name.
     - You've added an additional column in the copy activity source to define the target entity.
   - If different records map to different target entities, make sure your source data has a column that stores the corresponding target entity name.
2. Map both the value and entity-reference columns from source to sink. The entity-reference column must be mapped to a virtual column with the special naming pattern `{lookup_field_name}@EntityReference`. The column doesn't actually exist in Dynamics. It's used to indicate this column is the metadata column of the given multitarget lookup field.

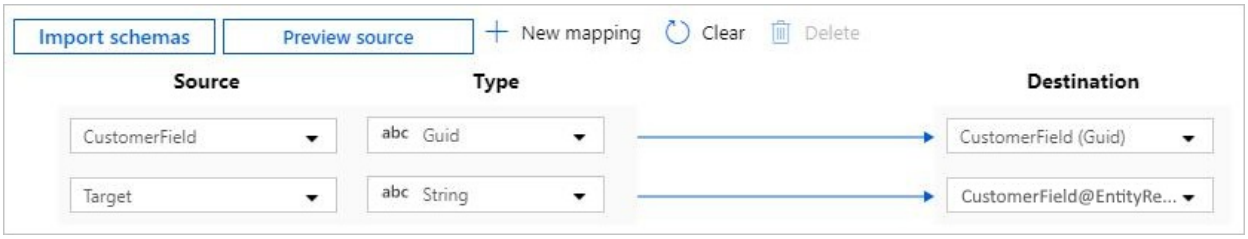
For example, assume the source has these two columns:

- **CustomerField** column of type **GUID**, which is the primary key value of the target entity in Dynamics.
- **Target** column of type **String**, which is the logical name of the target entity.

Also assume you want to copy such data to the sink Dynamics entity field **CustomerField** of type **Customer**.

In copy-activity column mapping, map the two columns as follows:

- **CustomerField** to **CustomerField**. This mapping is the normal field mapping.
- **Target** to **CustomerField@EntityReference**. The sink column is a virtual column representing the entity reference. Input such field names in a mapping, as they won't show up by importing schemas.



If all of your source records map to the same target entity and your source data doesn't contain the target entity name, here is a shortcut: in the copy activity source, add an additional column. Name the new column by using the pattern `{lookup_field_name}@EntityReference`, set the value to the target entity name, then proceed with column mapping as usual. If your source and sink column names are identical, you can also skip explicit column mapping because copy activity by default maps columns by name.

Mapping data flow properties

When transforming data in mapping data flow, you can read from and write to tables in Dynamics. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use a Dynamics dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Dynamics. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Entity name	The logical name of the entity to retrieve.	Yes when use inline dataset	-	*(for inline dataset only)* entity
Query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No	String	query

> **NOTE**
> If you select **Query** as input type, the column type from tables can not be retrieved. It will be treated as string by default.

Dynamics source script example

When you use Dynamics dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

If you use inline dataset, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'dynamics',
 format: 'dynamicsformat',
 entity: 'Entity1',
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

Sink transformation

The below table lists the properties supported by Dynamics sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Alternate key name	The alternate key name defined on your entity to do an update, upsert or delete.	No	-	alternateKeyName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	insertable updateable upsertable deletable
Entity name	The logical name of the entity to write.	Yes when use inline dataset	-	*(for inline dataset only)* entity

Dynamics sink script example

When you use Dynamics dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:true,
    insertable:true,
    updateable:true,
    upsertable:true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

If you use inline dataset, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    store: 'dynamics',
    format: 'dynamicsformat',
    entity: 'Entity1',
    deletable: true,
    insertable: true,
    updateable: true,
    upsertable: true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

Lookup activity properties

To learn details about the properties, see Lookup activity.

Next steps

For a list of supported data stores the copy activity as sources and sinks, see Supported data stores.

Copy data from Dynamics AX using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from Dynamics AX source. The article builds on Copy Activity, which presents a general overview of Copy Activity.

Supported capabilities

This Dynamics AX connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that supports as sources and sinks, see Supported data stores.

Specifically, this Dynamics AX connector supports copying data from Dynamics AX using **OData protocol** with **Service Principal authentication**.

> **TIP**
> You can also use this connector to copy data from **Dynamics 365 Finance and Operations**. Refer to Dynamics 365's OData support and Authentication method.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

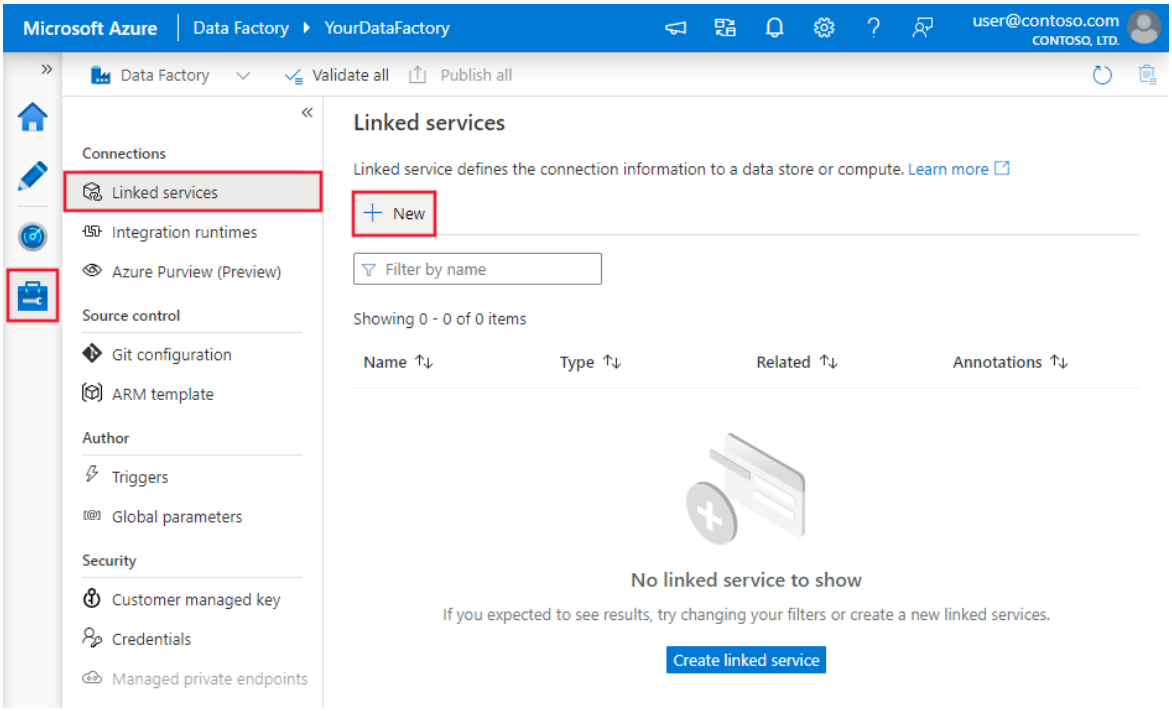
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Dynamics AX using UI

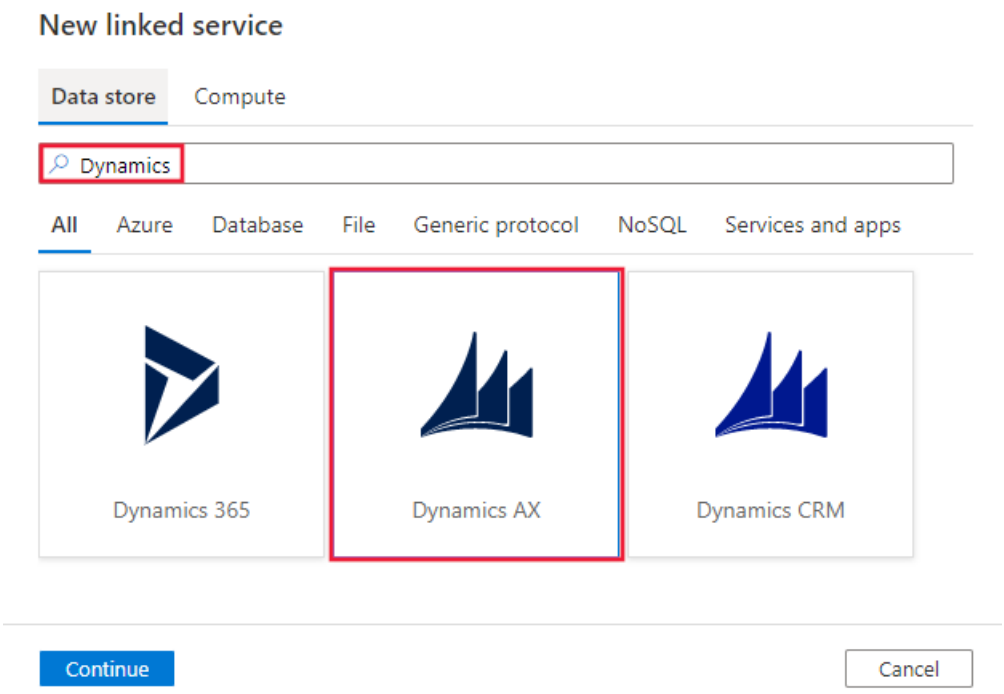
Use the following steps to create a linked service to Dynamics AX in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

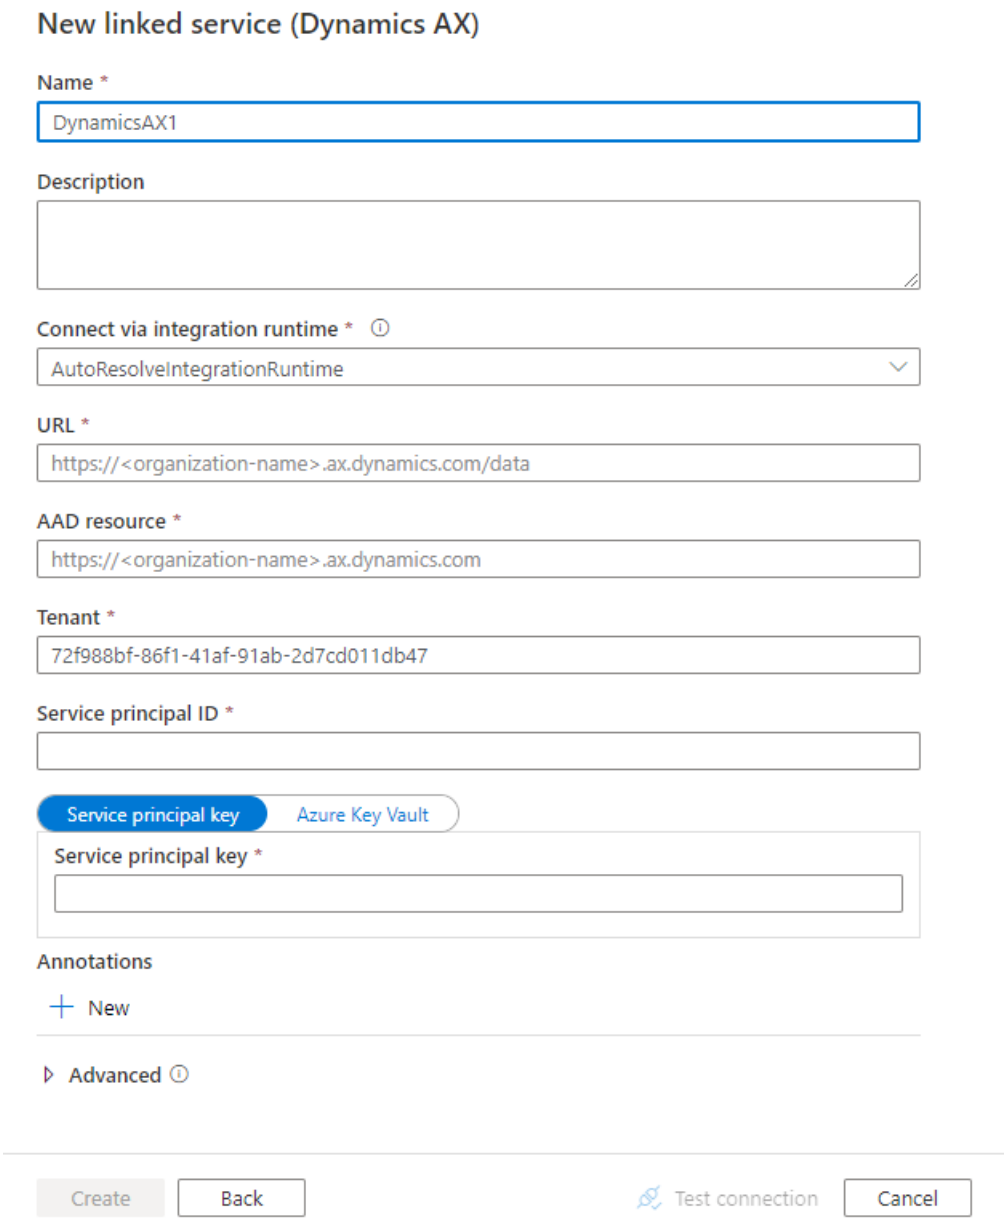
- Azure Data Factory
- Azure Synapse



2. Search for Dynamics and select the Dynamics AX connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define Data Factory entities that are specific to Dynamics AX connector.

Prerequisites

To use service principal authentication, follow these steps:

1. Register an application entity in Azure Active Directory (Azure AD) by following Register your application with an Azure AD tenant. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Go to Dynamics AX, and grant this service principal proper permission to access your Dynamics AX.

Linked service properties

The following properties are supported for Dynamics AX linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **DynamicsAX**.	Yes
url	The Dynamics AX (or Dynamics 365 Finance and Operations) instance OData endpoint.	Yes
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering the mouse in the top-right corner of the Azure portal.	Yes
aadResourceId	Specify the AAD resource you are requesting for authorization. For example, if your Dynamics URL is `https://sampledynamics.sandbox.operations.dynamics.com/data/`, the corresponding AAD resource is usually `https://sampledynamics.sandbox.operations.dynamics.com`.	Yes
connectVia	The Integration Runtime to use to connect to the data store. You can choose Azure Integration Runtime or a self-hosted Integration Runtime (if your data store is located in a private network). If not specified, the default Azure Integration Runtime is used.	No

Example

```
{
    "name": "DynamicsAXLinkedService",
    "properties": {
        "type": "DynamicsAX",
        "typeProperties": {
            "url": "<Dynamics AX instance OData endpoint>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "aadResourceId": "<AAD resource, e.g. https://sampledynamics.sandbox.operations.dynamics.com>"
        }
    },
    "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
    }
}
```

Dataset properties

This section provides a list of properties that the Dynamics AX dataset supports.

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services.

To copy data from Dynamics AX, set the **type** property of the dataset to **DynamicsAXResource**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **DynamicsAXResource**.	Yes
path	The path to the Dynamics AX OData entity.	Yes

Example

```
{
    "name": "DynamicsAXResourceDataset",
    "properties": {
        "type": "DynamicsAXResource",
        "typeProperties": {
            "path": "<entity path e.g. dd04tentitySet>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Dynamics AX linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties that the Dynamics AX source supports.

For a full list of sections and properties that are available for defining activities, see Pipelines.

Dynamics AX as source

To copy data from Dynamics AX, set the **source** type in Copy Activity to **DynamicsAXSource**. The following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity source must be set to **DynamicsAXSource**.	Yes
query	OData query options for filtering data. Example: `"?$select=Name,Description&$top=5"`. **Note**: The connector copies data from the combined URL: `[URL specified in linked service]/[path specified in dataset][query specified in copy activity source]`. For more information, see OData URL components.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. If not specified, the default value is **00:30:00** (30 minutes).	No

Example

```
"activities":[
    {
        "name": "CopyFromDynamicsAX",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Dynamics AX input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DynamicsAXSource",
                "query": "$top=10"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Copy and transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 17 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use a copy activity in Azure Data Factory or Synapse pipelines to copy data from and to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM, and use a data flow to transform data in Dynamics 365 (Microsoft Dataverse) or Dynamics CRM. To learn more, read the Azure Data Factory and the Azure Synapse Analytics introduction articles.

Supported capabilities

This connector is supported for the following activities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that a copy activity supports as sources and sinks, see the Supported data stores table.

> **NOTE**
> Effective November 2020, Common Data Service has been renamed to Microsoft Dataverse. This article is updated to reflect the latest terminology.

This Dynamics connector supports Dynamics versions 7 through 9 for both online and on-premises. More specifically:

- Version 7 maps to Dynamics CRM 2015.
- Version 8 maps to Dynamics CRM 2016 and the early version of Dynamics 365.
- Version 9 maps to the later version of Dynamics 365.

Refer to the following table of supported authentication types and configurations for Dynamics versions and products.

DYNAMICS VERSIONS	AUTHENTICATION TYPES	LINKED SERVICE SAMPLES
Dataverse Dynamics 365 online Dynamics CRM online	Azure Active Directory (Azure AD) service principal Office 365	Dynamics online and Azure AD service-principal or Office 365 authentication
Dynamics 365 on-premises with internet-facing deployment (IFD) Dynamics CRM 2016 on-premises with IFD Dynamics CRM 2015 on-premises with IFD	IFD	Dynamics on-premises with IFD and IFD authentication

NOTE

With the deprecation of regional Discovery Service, the service has upgraded to leverage global Discovery Service while using Office 365 Authentication.

IMPORTANT

If your tenant and user is configured in Azure Active Directory for conditional access and/or Multi-Factor Authentication is required, you will not be able to use Office 365 Authentication type. For those situations, you must use an Azure Active Directory (Azure AD) service principal authentication.

For Dynamics 365 specifically, the following application types are supported:

- Dynamics 365 for Sales
- Dynamics 365 for Customer Service
- Dynamics 365 for Field Service
- Dynamics 365 for Project Service Automation
- Dynamics 365 for Marketing This connector doesn't support other application types like Finance, Operations, and Talent.

TIP

To copy data from Dynamics 365 Finance and Operations, you can use the Dynamics AX connector.

This Dynamics connector is built on top of Dynamics XRM tooling.

Prerequisites

To use this connector with Azure AD service-principal authentication, you must set up server-to-server (S2S) authentication in Dataverse or Dynamics. First register the application user (Service Principal) in Azure Active Directory. You can find out how to do this here. During application registration you will need to create that user in Dataverse or Dynamics and grant permissions. Those permissions can either be granted directly or indirectly by adding the application user to a team which has been granted permissions in Dataverse or Dynamics. You can find more information on how to set up an application user to authenticate with Dataverse here.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

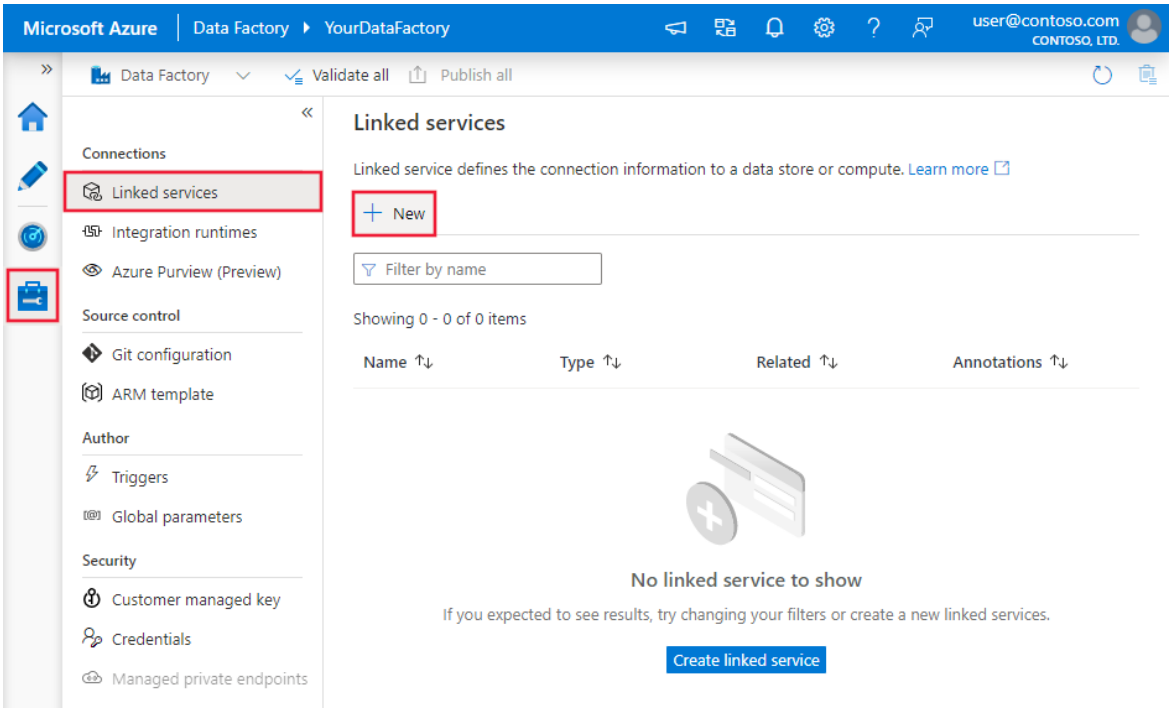
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Dynamics 365 (Microsoft Dataverse) or Dynamics CRM using UI

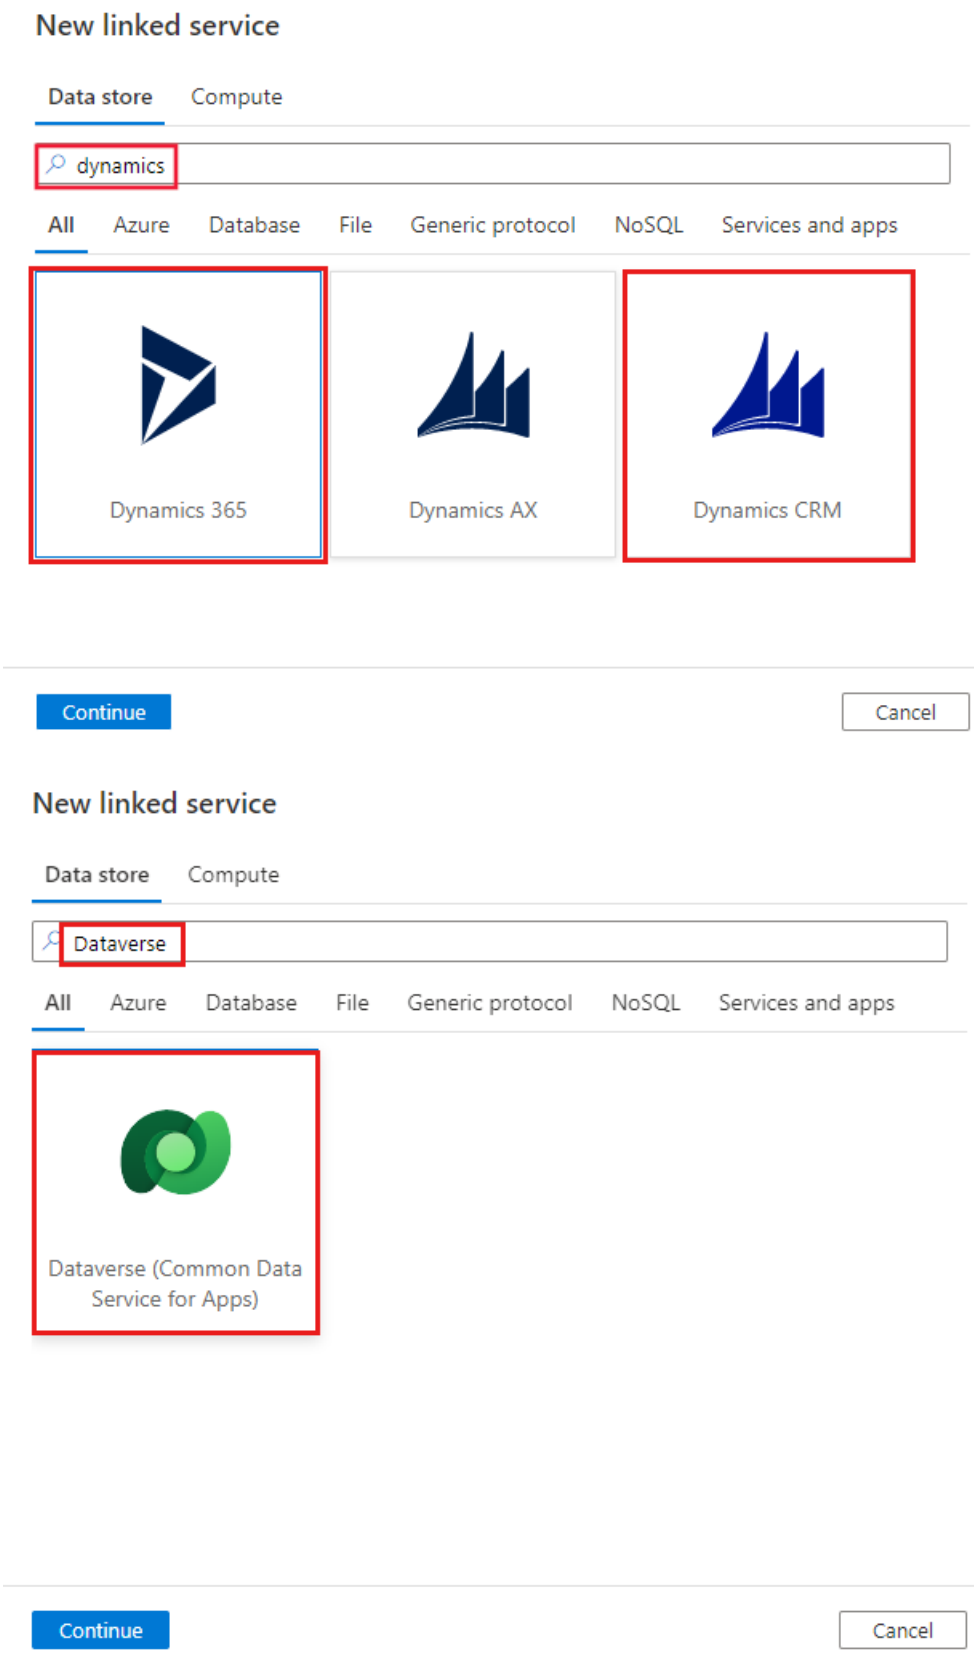
Use the following steps to create a linked service to Dynamics 365 in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

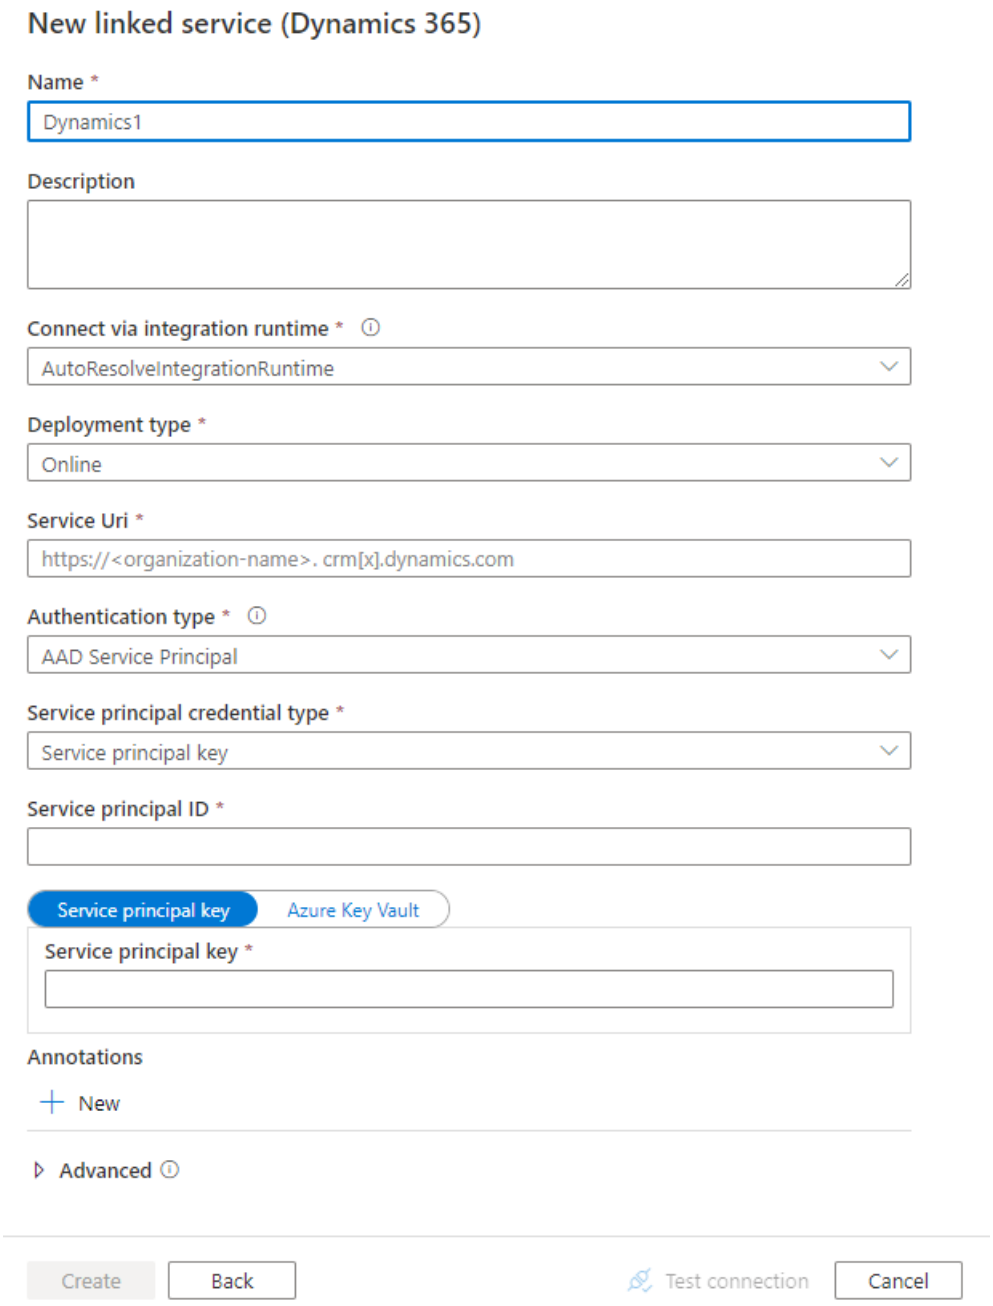
   - Azure Data Factory
   - Azure Synapse



2. Search for Dynamics or Dataverse and select the Dynamics 365 (Microsoft Dataverse) or Dynamics CRM connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Dynamics.

Linked service properties

The following properties are supported for the Dynamics linked service.

Dynamics 365 and Dynamics CRM online

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes
deploymentType	The deployment type of the Dynamics instance. The value must be "Online" for Dynamics online.	Yes

PROPERTY	DESCRIPTION	REQUIRED
serviceUri	The service URL of your Dynamics instance, the same one you access from browser. An example is "https://<organization-name>.crm[x].dynamics.com".	Yes
authenticationType	The authentication type to connect to a Dynamics server. Valid values are "AADServicePrincipal", "Office365" and "ManagedIdentity".	Yes
servicePrincipalId	The client ID of the Azure AD application.	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredentialType	The credential type to use for service-principal authentication. Valid values are "ServicePrincipalKey" and "ServicePrincipalCert".	Yes when authentication is "AADServicePrincipal"
servicePrincipalCredential	The service-principal credential. When you use "ServicePrincipalKey" as the credential type, `servicePrincipalCredential` can be a string that the service encrypts upon linked service deployment. Or it can be a reference to a secret in Azure Key Vault. When you use "ServicePrincipalCert" as the credential, `servicePrincipalCredential` must be a reference to a certificate in Azure Key Vault, and ensure the certificate content type is **PKCS #12**.	Yes when authentication is "AADServicePrincipal"
username	The username to connect to Dynamics.	Yes when authentication is "Office365"
password	The password for the user account you specified as the username. Mark this field with "SecureString" to store it securely, or reference a secret stored in Azure Key Vault.	Yes when authentication is "Office365"
credentials	Specify the user-assigned managed identity as the credential object. Create one or multiple user-assigned managed identities, assign them to your data factory and create credentials for each user-assigned managed identity.	Yes when authentication is "ManagedIdentity"
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

NOTE

The Dynamics connector formerly used the optional **organizationName** property to identify your Dynamics CRM or Dynamics 365 online instance. While that property still works, we suggest you specify the new **serviceUri** property instead to gain better performance for instance discovery.

Example: Dynamics online using Azure AD service-principal and key authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalCredential": "<service principal key>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Azure AD service-principal and certificate authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "AADServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalCredential": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<AKV reference>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<certificate name in AKV>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using Office 365 authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "Office365",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Dynamics online using user-assigned managed identity authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "typeProperties": {
            "deploymentType": "Online",
            "serviceUri": "https://<organization-name>.crm[x].dynamics.com",
            "authenticationType": "ManagedIdentity",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dynamics 365 and Dynamics CRM on-premises with IFD

Additional properties that compare to Dynamics online are **hostName** and **port**.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to "Dynamics", "DynamicsCrm", or "CommonDataServiceForApps".	Yes.
deploymentType	The deployment type of the Dynamics instance. The value must be "OnPremisesWithIfd" for Dynamics on-premises with IFD.	Yes.
hostName	The host name of the on-premises Dynamics server.	Yes.

PROPERTY	DESCRIPTION	REQUIRED
port	The port of the on-premises Dynamics server.	No. The default value is 443.
organizationName	The organization name of the Dynamics instance.	Yes.
authenticationType	The authentication type to connect to the Dynamics server. Specify "Ifd" for Dynamics on-premises with IFD.	Yes.
username	The username to connect to Dynamics.	Yes.
password	The password for the user account you specified for the username. You can mark this field with "SecureString" to store it securely. Or you can store a password in Key Vault and let the copy activity pull from there when it does data copy. Learn more from Store credentials in Key Vault.	Yes.
connectVia	The integration runtime to be used to connect to the data store. If no value is specified, the property uses the default Azure integration runtime.	No

Example: Dynamics on-premises with IFD using IFD authentication

```
{
    "name": "DynamicsLinkedService",
    "properties": {
        "type": "Dynamics",
        "description": "Dynamics on-premises with IFD linked service using IFD authentication",
        "typeProperties": {
            "deploymentType": "OnPremisesWithIFD",
            "hostName": "contosodynamicsserver.contoso.com",
            "port": 443,
            "organizationName": "admsDynamicsTest",
            "authenticationType": "Ifd",
            "username": "test@contoso.onmicrosoft.com",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by Dynamics dataset.

To copy data from and to Dynamics, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to "DynamicsEntity", "DynamicsCrmEntity", or "CommonDataServiceForAppsEntity".	Yes
entityName	The logical name of the entity to retrieve.	No for source if the activity source is specified as "query" and yes for sink

Example

```
{
    "name": "DynamicsDataset",
    "properties": {
        "type": "DynamicsEntity",
        "schema": [],
        "typeProperties": {
            "entityName": "account"
        },
        "linkedServiceName": {
            "referenceName": "<Dynamics linked service name>",
            "type": "linkedservicereference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Dynamics source and sink types.

Dynamics as a source type

To copy data from Dynamics, the copy activity **source** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to "DynamicsSource", "DynamicsCrmSource", or "CommonDataServiceForAppsSource".	Yes
query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No if `entityName` in the dataset is specified

> **NOTE**
> The PK column will always be copied out even if the column projection you configure in the FetchXML query doesn't contain it.

IMPORTANT

- When you copy data from Dynamics, explicit column mapping from Dynamics to sink is optional. But we highly recommend the mapping to ensure a deterministic copy result.
- When the service imports a schema in the authoring UI, it infers the schema. It does so by sampling the top rows from the Dynamics query result to initialize the source column list. In that case, columns with no values in the top rows are omitted. The same behavior also applies to data preview and copy executions if there is no explicit mapping. You can review and add more columns into the mapping, which are honored during copy runtime.

Example

```
"activities":[
    {
        "name": "CopyFromDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Dynamics input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DynamicsSource",
                "query": "<FetchXML Query>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Sample FetchXML query

```
<fetch>
  <entity name="account">
    <attribute name="accountid" />
    <attribute name="name" />
    <attribute name="marketingonly" />
    <attribute name="modifiedon" />
    <order attribute="modifiedon" descending="false" />
    <filter type="and">
      <condition attribute ="modifiedon" operator="between">
        <value>2017-03-10 18:40:00z</value>
        <value>2017-03-12 20:40:00z</value>
      </condition>
    </filter>
  </entity>
</fetch>
```

Dynamics as a sink type

To copy data to Dynamics, the copy activity **sink** section supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to "DynamicsSink", "DynamicsCrmSink", or "CommonDataServiceForAppsSink".	Yes.
writeBehavior	The write behavior of the operation. The value must be "Upsert".	Yes
alternateKeyName	The alternate key name defined on your entity to do an upsert.	No.
writeBatchSize	The row count of data written to Dynamics in each batch.	No. The default value is 10.
ignoreNullValues	Whether to ignore null values from input data other than key fields during a write operation. Valid values are **TRUE** and **FALSE**: • **TRUE**: Leave the data in the destination object unchanged when you do an upsert or update operation. Insert a defined default value when you do an insert operation. • **FALSE**: Update the data in the destination object to a null value when you do an upsert or update operation. Insert a null value when you do an insert operation.	No. The default value is **FALSE**.
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

NOTE

The default value for both the sink **writeBatchSize** and the copy activity **parallelCopies** for the Dynamics sink is 10. Therefore, 100 records are concurrently submitted by default to Dynamics.

For Dynamics 365 online, there's a limit of two concurrent batch calls per organization. If that limit is exceeded, a "Server Busy" exception is thrown before the first request is ever run. Keep **writeBatchSize** at 10 or less to avoid such throttling of concurrent calls.

The optimal combination of **writeBatchSize** and **parallelCopies** depends on the schema of your entity. Schema elements include the number of columns, row size, and number of plug-ins, workflows, or workflow activities hooked up to those calls. The default setting of **writeBatchSize** (10) × **parallelCopies** (10) is the recommendation according to the Dynamics service. This value works for most Dynamics entities, although it might not give the best performance. You can tune the performance by adjusting the combination in your copy activity settings.

Example

```
"activities":[
    {
        "name": "CopyToDynamics",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Dynamics output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "DynamicsSink",
                "writeBehavior": "Upsert",
                "writeBatchSize": 10,
                "ignoreNullValues": true
            }
        }
    }
]
```

Retrieving data from views

To retrieve data from Dynamics views, you need to get the saved query of the view, and use the query to get the data.

There are two entities which store different types of view: "saved query" stores system view and "user query" stores user view. To get the information of the views, refer to the following FetchXML query and replace the "TARGETENTITY" with `savedquery` or `userquery`. Each entity type has more available attributes that you can add to the query based on your need. Learn more about savedquery entity and userquery entity.

```
<fetch top="5000" >
  <entity name="<TARGETENTITY>">
    <attribute name="name" />
    <attribute name="fetchxml" />
    <attribute name="returnedtypecode" />
    <attribute name="querytype" />
  </entity>
</fetch>
```

You can also add filters to filter the views. For example, add the following filter to get a view named "My Active Accounts" in account entity.

```
<filter type="and" >
    <condition attribute="returnedtypecode" operator="eq" value="1" />
    <condition attribute="name" operator="eq" value="My Active Accounts" />
</filter>
```

Data type mapping for Dynamics

When you copy data from Dynamics, the following table shows mappings from Dynamics data types to interim data types within the service. To learn how a copy activity maps to a source schema and a data type maps to a sink, see Schema and data type mappings.

Configure the corresponding interim data type in a dataset structure that is based on your source Dynamics data type by using the following mapping table:

DYNAMICS DATA TYPE	SERVICE INTERIM DATA TYPE	SUPPORTED AS SOURCE	SUPPORTED AS SINK
AttributeTypeCode.BigInt	Long	✓	✓
AttributeTypeCode.Boolean	Boolean	✓	✓
AttributeType.Customer	GUID	✓	✓ (See guidance)
AttributeType.DateTime	Datetime	✓	✓
AttributeType.Decimal	Decimal	✓	✓
AttributeType.Double	Double	✓	✓
AttributeType.EntityName	String	✓	✓
AttributeType.Integer	Int32	✓	✓
AttributeType.Lookup	GUID	✓	✓ (See guidance)
AttributeType.ManagedProperty	Boolean	✓	
AttributeType.Memo	String	✓	✓
AttributeType.Money	Decimal	✓	✓
AttributeType.Owner	GUID	✓	✓ (See guidance)
AttributeType.Picklist	Int32	✓	✓
AttributeType.Uniqueidentifier	GUID	✓	✓
AttributeType.String	String	✓	✓
AttributeType.State	Int32	✓	✓
AttributeType.Status	Int32	✓	✓

NOTE

The Dynamics data types **AttributeType.CalendarRules**, **AttributeType.MultiSelectPicklist**, and **AttributeType.PartyList** aren't supported.

Writing data to a lookup field

To write data into a lookup field with multiple targets like Customer and Owner, follow this guidance and example:

1. Make your source contains both the field value and the corresponding target entity name.
   - If all records map to the same target entity, ensure one of the following conditions:
     - Your source data has a column that stores the target entity name.
     - You've added an additional column in the copy activity source to define the target entity.
   - If different records map to different target entities, make sure your source data has a column that stores the corresponding target entity name.
2. Map both the value and entity-reference columns from source to sink. The entity-reference column must be mapped to a virtual column with the special naming pattern `{lookup_field_name}@EntityReference`. The column doesn't actually exist in Dynamics. It's used to indicate this column is the metadata column of the given multitarget lookup field.

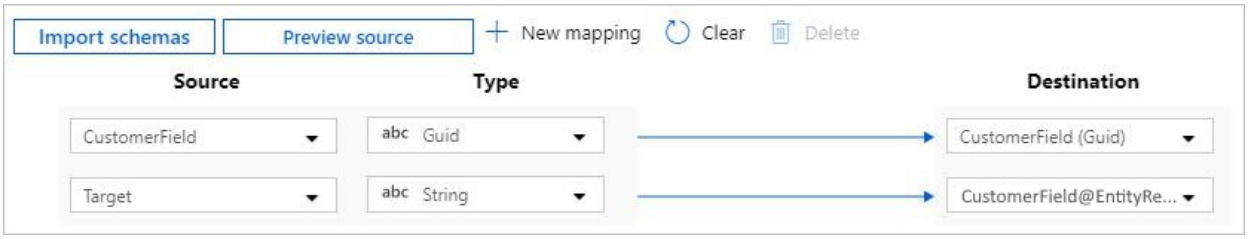
For example, assume the source has these two columns:

- **CustomerField** column of type **GUID**, which is the primary key value of the target entity in Dynamics.
- **Target** column of type **String**, which is the logical name of the target entity.

Also assume you want to copy such data to the sink Dynamics entity field **CustomerField** of type **Customer**.

In copy-activity column mapping, map the two columns as follows:

- **CustomerField** to **CustomerField**. This mapping is the normal field mapping.
- **Target** to **CustomerField@EntityReference**. The sink column is a virtual column representing the entity reference. Input such field names in a mapping, as they won't show up by importing schemas.



If all of your source records map to the same target entity and your source data doesn't contain the target entity name, here is a shortcut: in the copy activity source, add an additional column. Name the new column by using the pattern `{lookup_field_name}@EntityReference`, set the value to the target entity name, then proceed with column mapping as usual. If your source and sink column names are identical, you can also skip explicit column mapping because copy activity by default maps columns by name.

Mapping data flow properties

When transforming data in mapping data flow, you can read from and write to tables in Dynamics. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use a Dynamics dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Dynamics. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Entity name	The logical name of the entity to retrieve.	Yes when use inline dataset	-	*(for inline dataset only)* entity
Query	FetchXML is a proprietary query language that is used in Dynamics online and on-premises. See the following example. To learn more, see Build queries with FetchXML.	No	String	query

> **NOTE**
> If you select **Query** as input type, the column type from tables can not be retrieved. It will be treated as string by default.

Dynamics source script example

When you use Dynamics dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

If you use inline dataset, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'dynamics',
 format: 'dynamicsformat',
 entity: 'Entity1',
 query: '<fetch mapping='logical' count='3 paging-cookie=''><entity name='new_dataflow_crud_test'><attribute
name='new_name'/><attribute name='new_releasedate'/></entity></fetch>') ~> DynamicsSource
```

Sink transformation

The below table lists the properties supported by Dynamics sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Alternate key name	The alternate key name defined on your entity to do an update, upsert or delete.	No	-	alternateKeyName

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	insertable updateable upsertable deletable
Entity name	The logical name of the entity to write.	Yes when use inline dataset	-	*(for inline dataset only)* entity

Dynamics sink script example

When you use Dynamics dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:true,
    insertable:true,
    updateable:true,
    upsertable:true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

If you use inline dataset, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    store: 'dynamics',
    format: 'dynamicsformat',
    entity: 'Entity1',
    deletable: true,
    insertable: true,
    updateable: true,
    upsertable: true,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> DynamicsSink
```

Lookup activity properties

To learn details about the properties, see Lookup activity.

Next steps

For a list of supported data stores the copy activity as sources and sinks, see Supported data stores.

Excel file format in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the Excel files**. The service supports both ".xls" and ".xlsx".

Excel format is supported for the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP. It is supported as source but not sink.

> **NOTE**
> ".xls" format is not supported while using HTTP.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Excel dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Excel**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`.	Yes
sheetName	The Excel worksheet name to read data.	Specify `sheetName` or `sheetIndex`
sheetIndex	The Excel worksheet index to read data, starting from 0.	Specify `sheetName` or `sheetIndex`
range	The cell range in the given worksheet to locate the selective data, e.g.: - Not specified: reads the whole worksheet as a table from the first non-empty row and column - `A3`: reads a table starting from the given cell, dynamically detects all the rows below and all the columns to the right - `A3:H5`: reads this fixed range as a table - `A3:A3`: reads this single cell	No

PROPERTY	DESCRIPTION	REQUIRED
firstRowAsHeader	Specifies whether to treat the first row in the given worksheet/range as a header line with names of columns. Allowed values are **true** and **false** (default).	No
nullValue	Specifies the string representation of null value. The default value is **empty string**.	No
compression	Group of properties to configure file compression. Configure this section when you want to do compression/decompression during activity execution.	No
type (*under* `compression`)	The compression codec used to read/write JSON files. Allowed values are **bzip2**, **gzip**, **deflate**, **ZipDeflate**, **TarGzip**, **Tar**, **snappy**, or **lz4**. Default is not compressed. **Note** currently Copy activity doesn't support "snappy" & "lz4", and mapping data flow doesn't support "ZipDeflate", "TarGzip" and "Tar". **Note** when using copy activity to decompress **ZipDeflate** file(s) and write to file-based sink data store, files are extracted to the folder: `<path specified in dataset>/<folder named as source zip file>/` .	No.
level (*under* `compression`)	The compression ratio. Allowed values are **Optimal** or **Fastest**. - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed. - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete. For more information, see Compression Level topic.	No

Below is an example of Excel dataset on Azure Blob Storage:

```
{
    "name": "ExcelDataset",
    "properties": {
        "type": "Excel",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "sheetName": "MyWorksheet",
            "range": "A3:H5",
            "firstRowAsHeader": true
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Excel source.

Excel as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **ExcelSource**.	Yes
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`.	No

```
"activities": [
    {
        "name": "CopyFromExcel",
        "type": "Copy",
        "typeProperties": {
            "source": {
                "type": "ExcelSource",
                "storeSettings": {
                    "type": "AzureBlobStorageReadSettings",
                    "recursive": true
                }
            },
            ...
        }
        ...
    }
]
```

Mapping data flow properties

In mapping data flows, you can read Excel format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Amazon S3 and SFTP. You can point to Excel files either using Excel dataset or using an inline dataset.

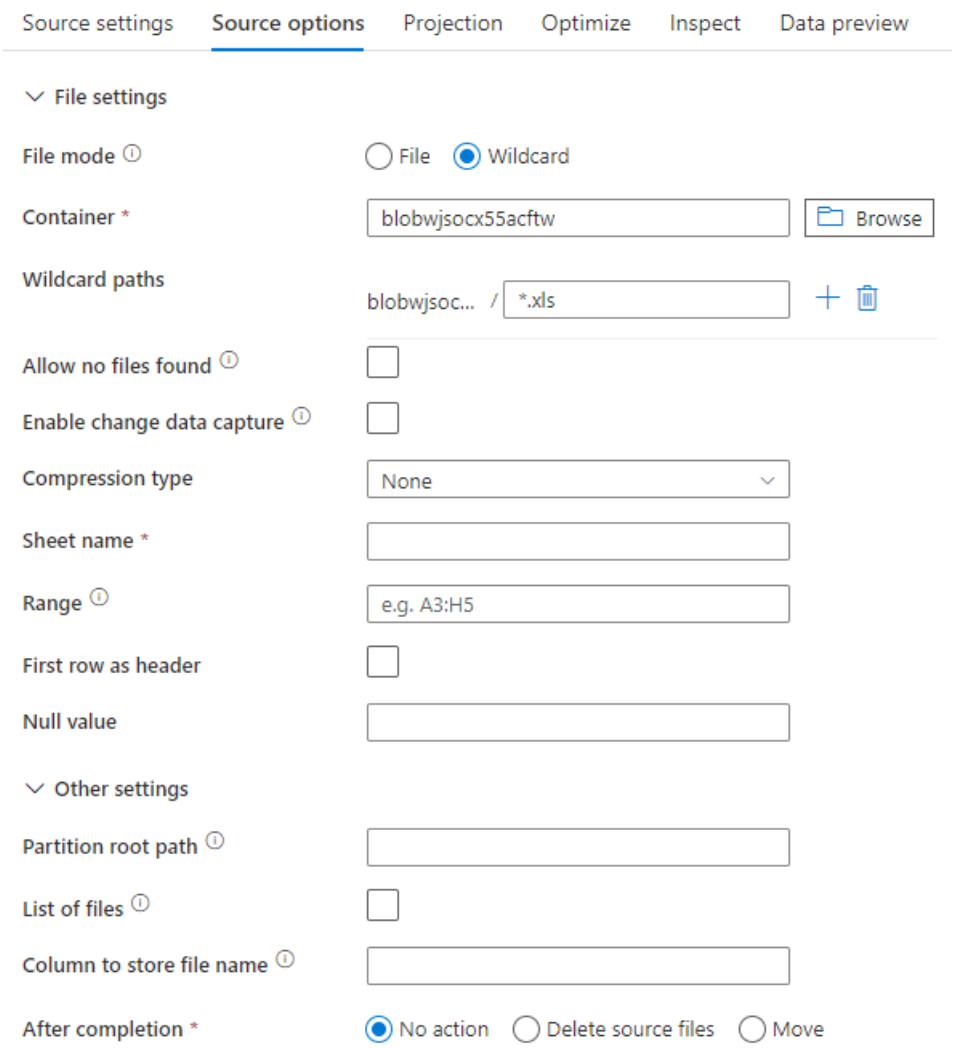
Source properties

The below table lists the properties supported by an Excel source. You can edit these properties in the **Source options** tab. When using inline dataset, you will see additional file settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

Source example

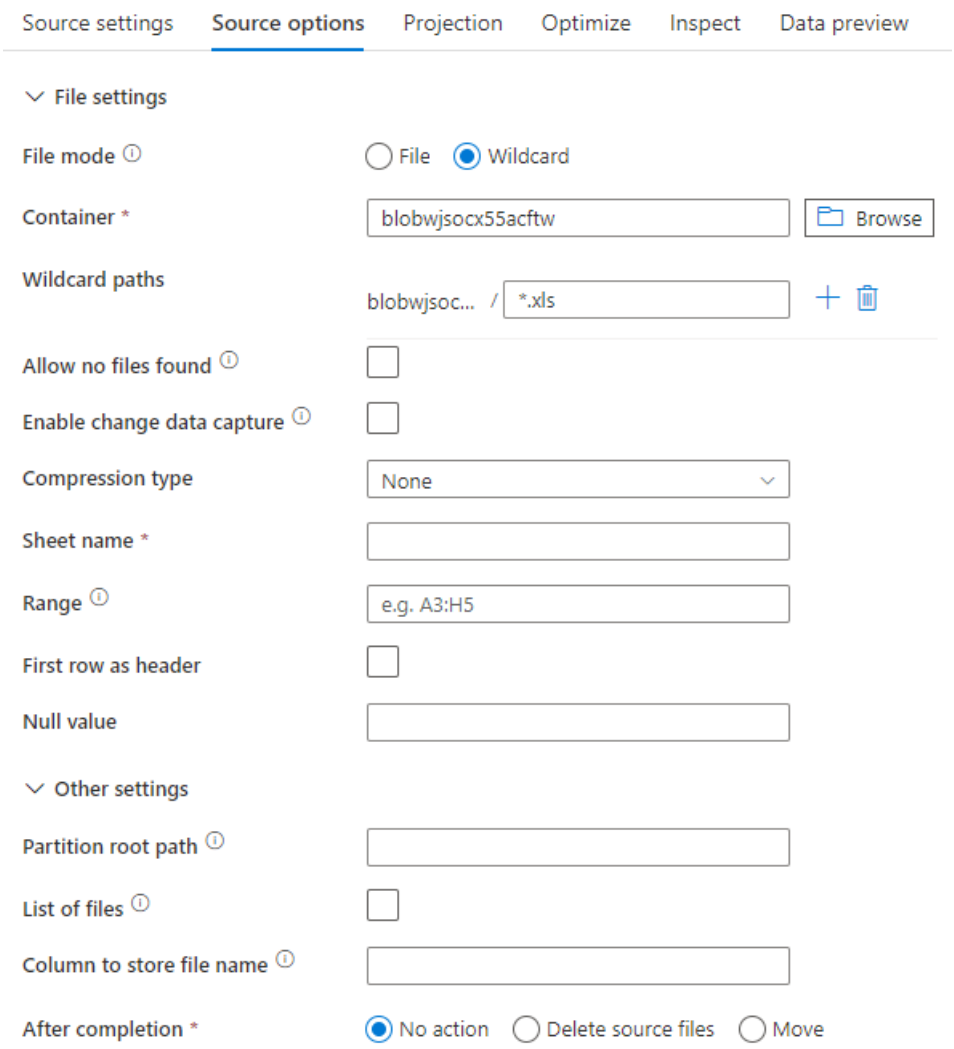
The below image is an example of an Excel source configuration in mapping data flows using dataset mode.



The associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    wildcardPaths:['*.xls']) ~> ExcelSource
```

If you use inline dataset, you see the following source options in mapping data flow.



The associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    format: 'excel',
    fileSystem: 'container',
    folderPath: 'path',
    fileName: 'sample.xls',
    sheetName: 'worksheet',
    firstRowAsHeader: true) ~> ExcelSourceInlineDataset
```

Handling very large Excel files

The Excel connector does not support streaming read for the Copy activity and must load the entire file into memory before data can be read. To import schema, preview data, or refresh an Excel dataset, the data must be returned before the http request timeout (100s). For large Excel files, these operations may not finish within that timeframe, causing a timeout error. If you want to move large Excel files (>100MB) into another data store, you can use one of following options to work around this limitation:

- Use the self-hosted integration runtime (SHIR), then use the Copy activity to move the large Excel file into another data store with the SHIR.
- Split the large Excel file into several smaller ones, then use the Copy activity to move the folder containing the files.
- Use a dataflow activity to move the large Excel file into another data store. Dataflow supports streaming read for Excel and can move/transfer large files quickly.
- Manually convert the large Excel file to CSV format, then use a Copy activity to move the file.

Next steps

- Lookup activity
- GetMetadata activity

Copy data to or from a file system by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 18 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data to and from file system. To learn more read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This file system connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, this file system connector supports:

- Copying files from/to local machine or network file share. To use a Linux file share, install Samba on your Linux server.
- Copying files using **Windows** authentication.
- Copying files as-is or parsing/generating files with the supported file formats and compression codecs.

> **NOTE**
> Mapped network drive is not supported when loading data from a network file share. Use the actual path instead e.g. `\\server\share`.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data

access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

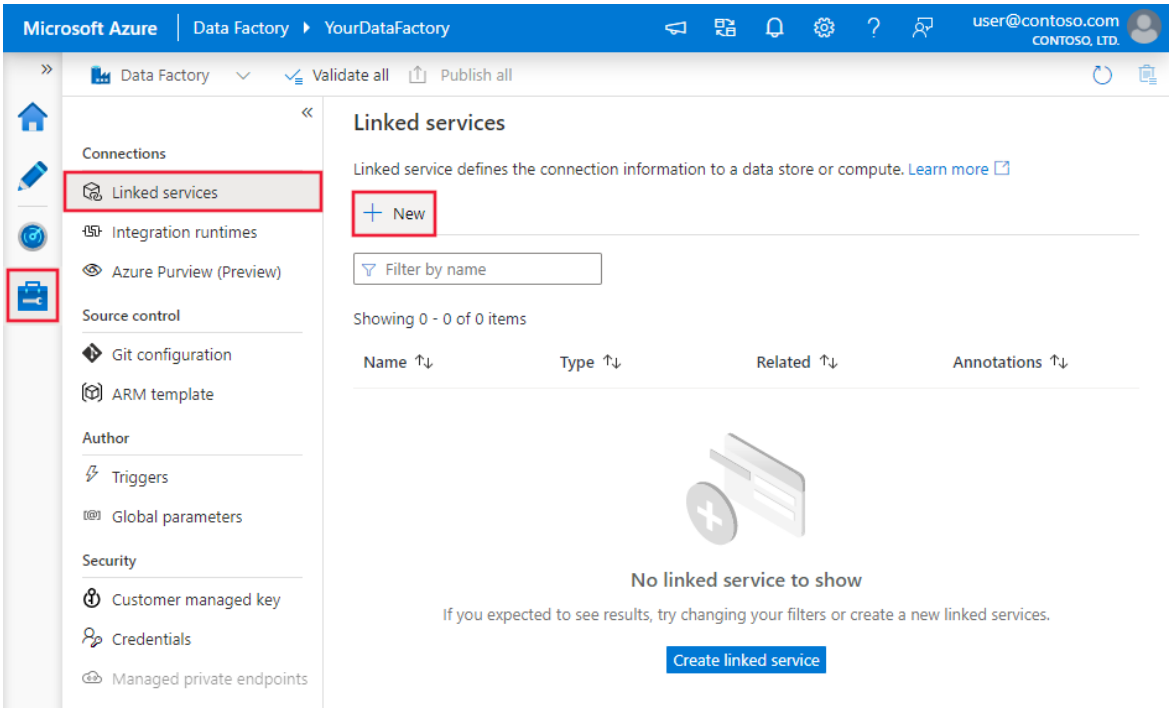
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a file system linked service using UI

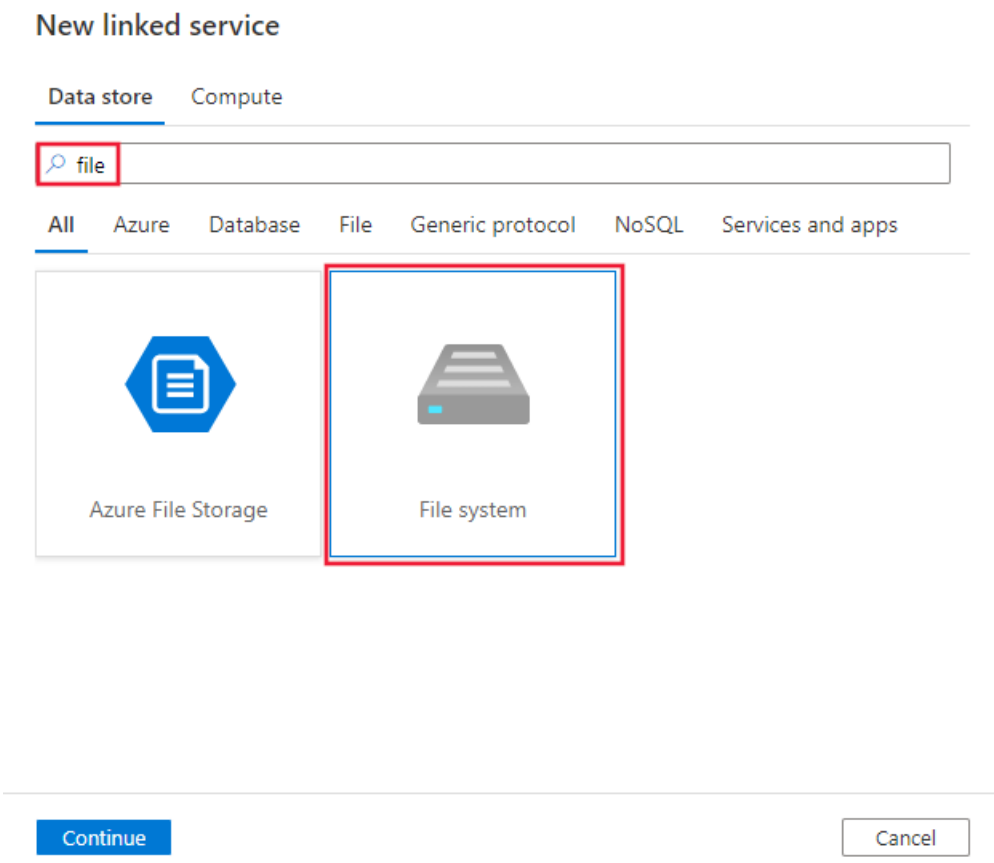
Use the following steps to create a file system linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

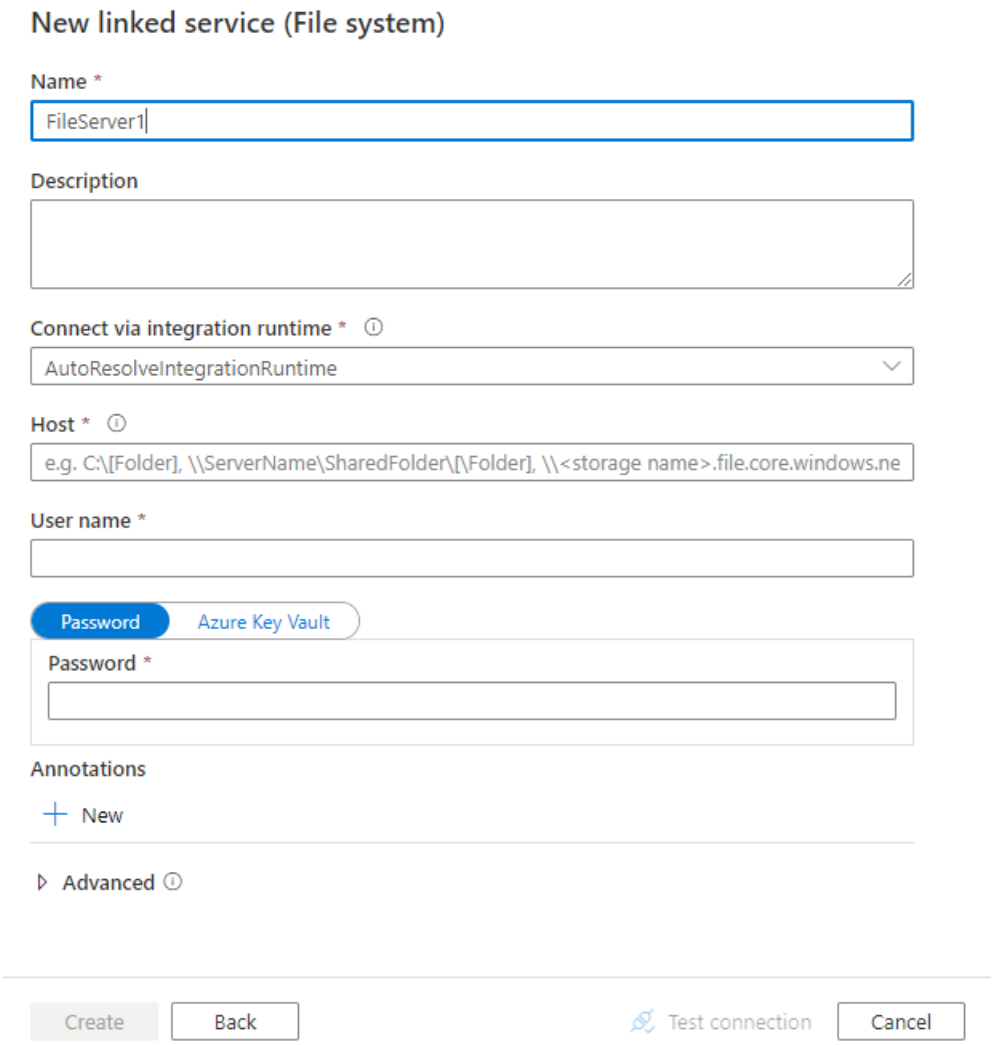
   - Azure Data Factory
   - Azure Synapse



2. Search for file and select the File System connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory and Synapse pipeline entities specific to file system.

Linked service properties

The following properties are supported for file system linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **FileServer**.	Yes
host	Specifies the root path of the folder that you want to copy. Use the escape character "" for special characters in the string. See Sample linked service and dataset definitions for examples.	Yes
userId	Specify the ID of the user who has access to the server.	Yes
password	Specify the password for the user (userId). Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Sample linked service and dataset definitions

SCENARIO	"HOST" IN LINKED SERVICE DEFINITION	"FOLDERPATH" IN DATASET DEFINITION
Local folder on Integration Runtime machine: Examples: D:* or D:\folder\subfolder*	In JSON: `D:\\` On UI: `D:\`	In JSON: `.\\` or `folder\\subfolder` On UI: `.\` or `folder\subfolder`
Remote shared folder: Examples: \\myserver\share* or \\myserver\share\folder\subfolder*	In JSON: `\\\\myserver\\share` On UI: `\\myserver\share`	In JSON: `.\\` or `folder\\subfolder` On UI: `.\` or `folder\subfolder`

> **NOTE**
>
> When authoring via UI, you don't need to input double backslash (`\\`) to escape like you do via JSON, specify single backslash.

Example:

```
{
    "name": "FileLinkedService",
    "properties": {
        "type": "FileServer",
        "typeProperties": {
            "host": "<host>",
            "userId": "<domain>\\<user>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for file system under `location` settings in format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in dataset must be set to **FileServerLocation**.	Yes
folderPath	The path to folder. If you want to use wildcard to filter folder, skip this setting and specify in activity source settings. Note that you will need to setup the file share location in your Windows or Linux environment to expose the folder for sharing.	No
fileName	The file name under the given folderPath. If you want to use wildcard to filter files, skip this setting and specify in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<File system linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "FileServerLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by file system source and sink.

File system as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for file system under `storeSettings` settings in format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **FileServerReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given folder/file path specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	

PROPERTY	DESCRIPTION	REQUIRED
OPTION 2: server side filter - fileFilter	File server side native filter, which provides better performance than OPTION 3 wildcard filter. Use `*` to match zero or more characters and `?` to match zero or single character. Learn more about the syntax and notes from the **Remarks** under this section.	No
OPTION 3: client side filter - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Such filter happens within the service, which enumerate the folders/files under the given path then apply the wildcard filter. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	No
OPTION 3: client side filter - wildcardFileName	The file name with wildcard characters under the given folderPath/wildcardFolderPath to filter source files. Such filter happens within the service, which enumerates the files under the given path then apply the wildcard filter. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When using this option, do not specify file name in dataset. See more examples in File list examples.	No
Additional settings:		

PROPERTY	DESCRIPTION	REQUIRED
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromFileSystem",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "FileServerReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

File system as sink

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for file system under `storeSettings` settings in format-based copy sink:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **FileServerWriteSettings**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of source file to source folder is identical to the relative path of target file to target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToFileSystem",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Parquet output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "ParquetSink",
                "storeSettings":{
                    "type": "FileServerWriteSettings",
                    "copyBehavior": "PreserveHierarchy"
                }
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	(empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using file list path in copy activity source.

Assuming you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	PIPELINE CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Folder path: `root/FolderA` **In copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line with the relative path to the path configured in the dataset.

recursive and copyBehavior examples

This section describes the resulting behavior of the Copy operation for different combinations of recursive and copyBehavior values.

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET
true	preserveHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target folder Folder1 is created with the same structure as the source: Folder1 File1 File2 Subfolder1 File3 File4 File5.
true	flattenHierarchy	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 autogenerated name for File1 autogenerated name for File2 autogenerated name for File3 autogenerated name for File4 autogenerated name for File5
true	mergeFiles	Folder1 File1 File2 Subfolder1 File3 File4 File5	The target Folder1 is created with the following structure: Folder1 File1 + File2 + File3 + File4 + File 5 contents are merged into one file with autogenerated file name

RECURSIVE	COPYBEHAVIOR	SOURCE FOLDER STRUCTURE	RESULTING TARGET

false	preserveHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  File1
			  File2
			
			Subfolder1 with File3, File4, and File5 are not picked up.

false	flattenHierarchy	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  autogenerated name for File1
			  autogenerated name for File2
			
			Subfolder1 with File3, File4, and File5 are not picked up.

false	mergeFiles	Folder1
		  File1
		  File2
		  Subfolder1
		  File3
		  File4
		  File5
			The target folder Folder1 is created with the following structure
			
			Folder1
			  File1 + File2 contents are merged into one file with autogenerated file name. autogenerated name for File1
			
			Subfolder1 with File3, File4, and File5 are not picked up.

Delete activity properties

To learn details about the properties, check Delete activity

Legacy models

> **NOTE**
>
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **FileShare**	Yes
folderPath	Path to the folder. Wildcard filter is supported, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. Examples: rootfolder/subfolder/, see more examples in Sample linked service and dataset definitions and Folder and file filter examples.	No
fileName	**Name or wildcard filter** for the file(s) under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual file name has wildcard or this escape char inside. When fileName isn't specified for an output dataset and **preserveHierarchy** isn't specified in the activity sink, the copy activity automatically generates the file name with the following pattern: "*Data.[activity run ID GUID].[GUID if FlattenHierarchy].[format if configured].[compression if configured]*", for example "Data.0a405f8a-93ff-4c6f-b3be-f69616f1df7a.txt.gz"; if you copy from tabular source using table name instead of query, the name pattern is "*[table name].[format].[compression if configured]*", for example "MyTable.csv".	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware the overall performance of data movement will be impacted by enabling this setting when you want to do file filter from huge amounts of files. The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeEnd	Files filter based on the attribute: Last Modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of "2018-12-01T05:00:00Z". Be aware the overall performance of data movement will be impacted by enabling this setting when you want to do file filter from huge amounts of files. The properties can be NULL, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has datetime value but `modifiedDatetimeEnd` is NULL, it means the files whose last modified attribute is greater than or equal with the datetime value will be selected. When `modifiedDatetimeEnd` has datetime value but `modifiedDatetimeStart` is NULL, it means the files whose last modified attribute is less than the datetime value will be selected.	No
format	If you want to **copy files as-is** between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse or generate files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, **ParquetFormat**. Set the **type** property under format to one of these values. For more information, see Text Format, Json Format, Avro Format, Orc Format, and Parquet Format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are: **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are: **Optimal** and **Fastest**.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a given name, specify **folderPath** with folder part and **fileName** with file name.
To copy a subset of files under a folder, specify **folderPath** with folder part and **fileName** with wildcard filter.

NOTE

If you were using "fileFilter" property for file filter, it is still supported as-is, while you are suggested to use the new filter capability added to "fileName" going forward.

Example:

```
{
    "name": "FileSystemDataset",
    "properties": {
        "type": "FileShare",
        "linkedServiceName":{
            "referenceName": "<file system linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "folder/subfolder/",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **FileSystemSource**	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note when recursive is set to true and sink is file-based store, empty folder/sub-folder will not be copied/created at sink. Allowed values are: **true** (default), **false**	No

PROPERTY	DESCRIPTION	REQUIRED
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromFileSystem",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<file system input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "FileSystemSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Legacy copy activity sink model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **FileSystemSink**	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from file-based data store. Allowed values are: - **PreserveHierarchy (default)**: preserves the file hierarchy in the target folder. The relative path of source file to source folder is identical to the relative path of target file to target folder. - **FlattenHierarchy**: all files from the source folder are in the first level of target folder. The target files have autogenerated name. - **MergeFiles**: merges all files from the source folder to one file. No record deduplication is performed during the merge. If the File Name is specified, the merged file name would be the specified name; otherwise, would be autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToFileSystem",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<file system output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "FileSystemSink",
                "copyBehavior": "PreserveHierarchy"
            }
        }
    }
]
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from FTP server using Azure Data Factory or Synapse Analytics

8/19/2022 • 12 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data from FTP server. To learn about more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This FTP connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, this FTP connector supports:

- Copying files using **Basic** or **Anonymous** authentication.
- Copying files as-is or parsing files with the supported file formats and compression codecs.

The FTP connector support FTP server running in passive mode. Active mode is not supported.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool

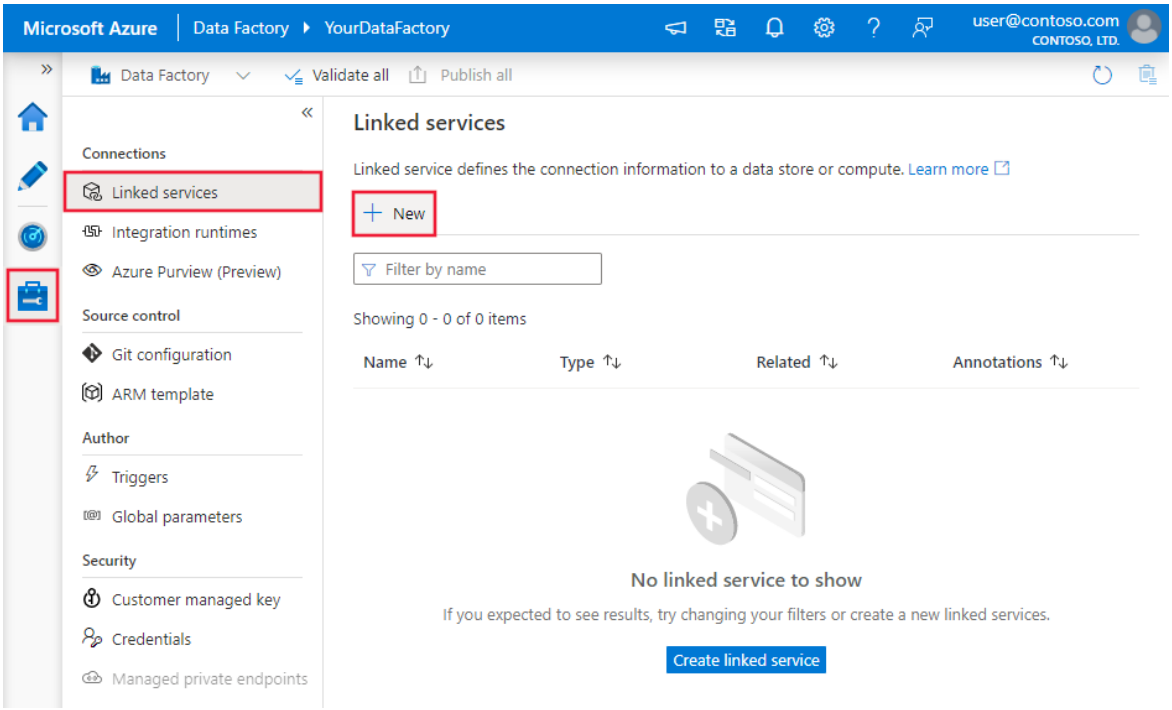
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an FTP server using UI

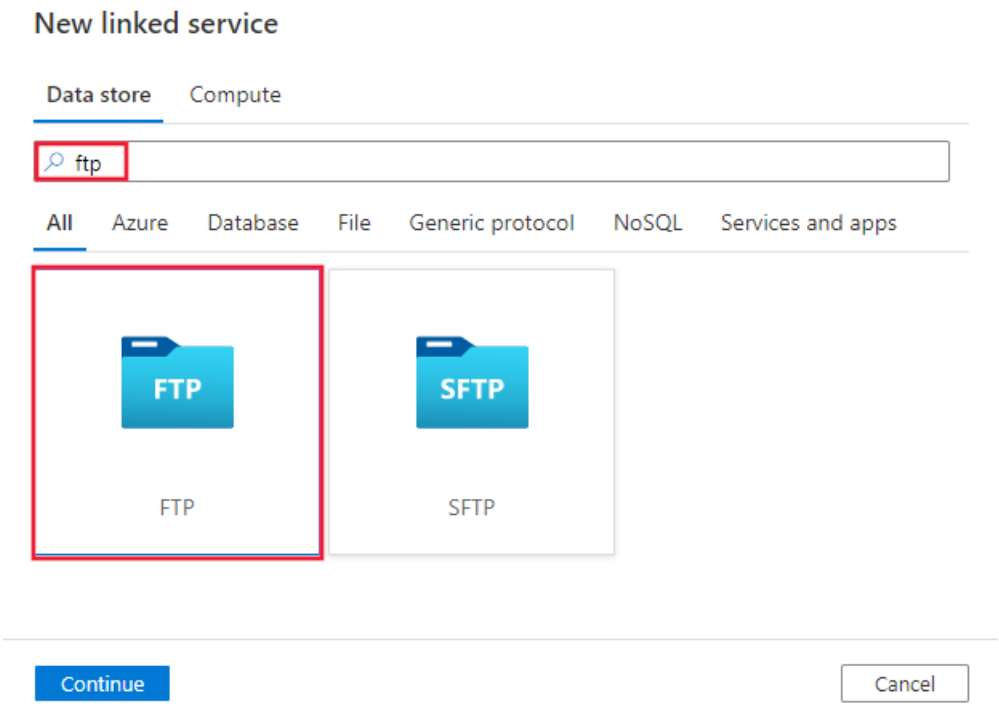
Use the following steps to create a linked service to an FTP server in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

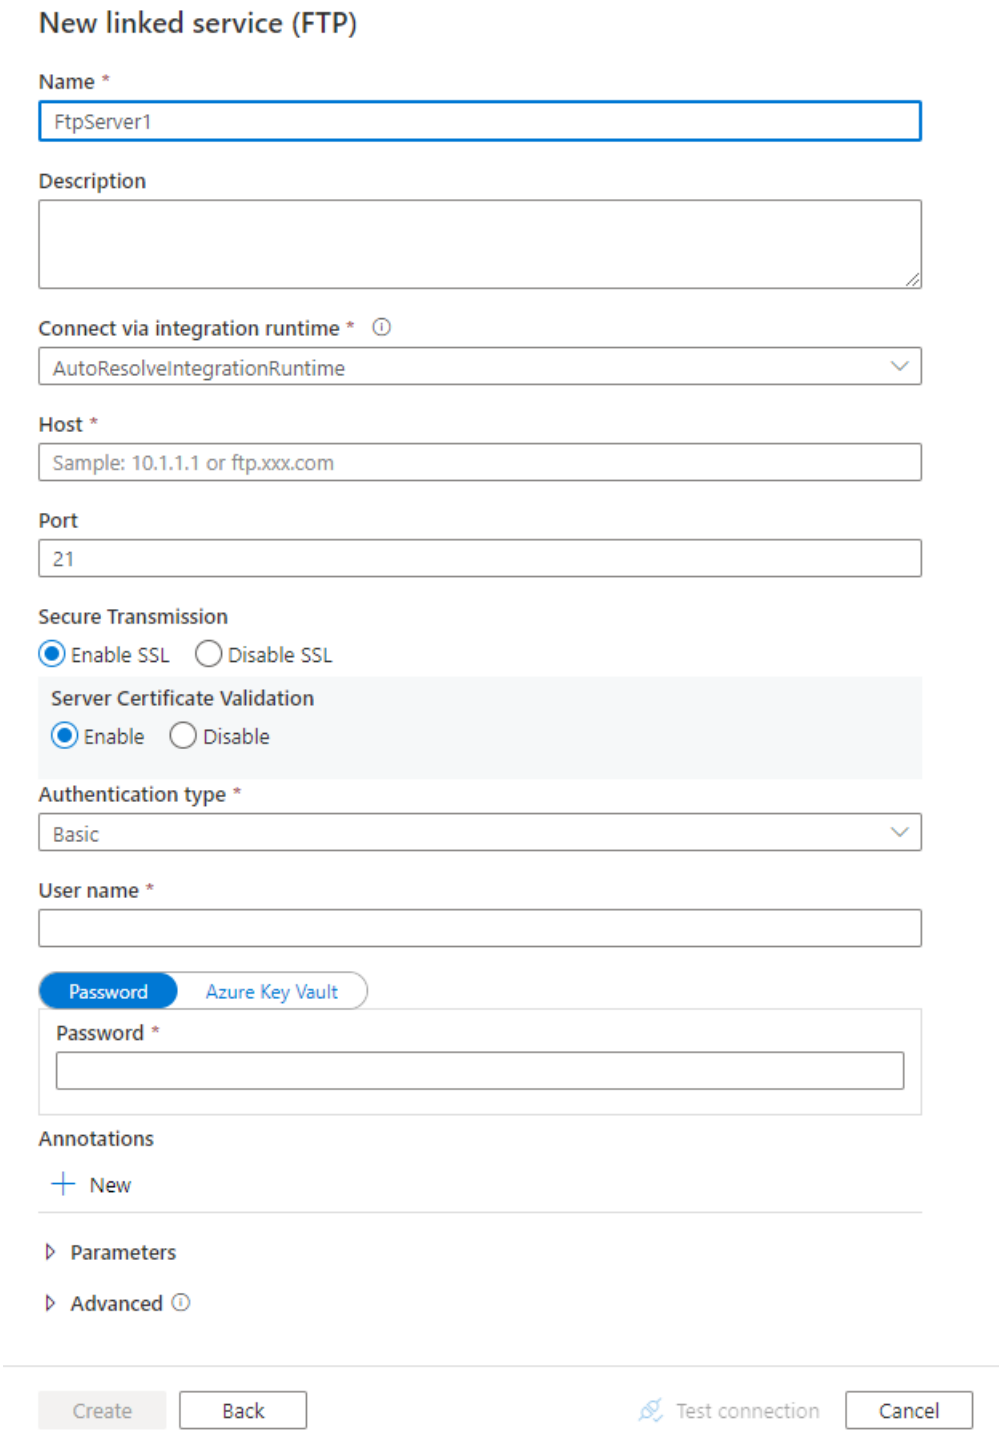
   - Azure Data Factory
   - Azure Synapse



2. Search for FTP and select the FTP connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to FTP.

Linked service properties

The following properties are supported for FTP linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **FtpServer**.	Yes
host	Specify the name or IP address of the FTP server.	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	Specify the port on which the FTP server is listening. Allowed values are: integer, default value is **21**.	No
enableSsl	Specify whether to use FTP over an SSL/TLS channel. Allowed values are: **true** (default), **false**.	No
enableServerCertificateValidation	Specify whether to enable server TLS/SSL certificate validation when you are using FTP over SSL/TLS channel. Allowed values are: **true** (default), **false**.	No
authenticationType	Specify the authentication type. Allowed values are: **Basic**, **Anonymous**	Yes
userName	Specify the user who has access to the FTP server.	No
password	Specify the password for the user (userName). Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

NOTE

The FTP connector supports accessing FTP server with either no encryption or explicit SSL/TLS encryption; it doesn't support implicit SSL/TLS encryption.

Example 1: using Anonymous authentication

```
{
    "name": "FTPLinkedService",
    "properties": {
        "type": "FtpServer",
        "typeProperties": {
            "host": "<ftp server>",
            "port": 21,
            "enableSsl": true,
            "enableServerCertificateValidation": true,
            "authenticationType": "Anonymous"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: using Basic authentication

```
{
    "name": "FTPLinkedService",
    "properties": {
        "type": "FtpServer",
        "typeProperties": {
            "host": "<ftp server>",
            "port": 21,
            "enableSsl": true,
            "enableServerCertificateValidation": true,
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for FTP under `location` settings in format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in dataset must be set to **FtpServerLocation**.	Yes
folderPath	The path to folder. If you want to use wildcard to filter folder, skip this setting and specify in activity source settings.	No
fileName	The file name under the given folderPath. If you want to use wildcard to filter files, skip this setting and specify in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<FTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "FtpServerLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by FTP source.

FTP as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for FTP under `storeSettings` settings in format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **FtpReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given folder/file path specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: wildcard - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	No
OPTION 2: wildcard - wildcardFileName	The file name with wildcard characters under the given folderPath/wildcardFolderPath to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has wildcard or this escape char inside. See more examples in Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When using this option, do not specify file name in dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No

PROPERTY	DESCRIPTION	REQUIRED
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
useBinaryTransfer	Specify whether to use the binary transfer mode. The values are true for binary mode (default), and false for ASCII.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

PROPERTY	DESCRIPTION	REQUIRED
disableChunking	When copying data from FTP, the service tries to get the file length first, then divide the file into multiple parts and read them in parallel. Specify whether your FTP server supports getting file length or seeking to read from a certain offset. Allowed values are **false** (default), **true**.	No

Example:

```
"activities":[
    {
        "name": "CopyFromFTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "FtpReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv",
                    "disableChunking": false
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	(empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using file list path in copy activity source.

Assuming you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Folder path: `root/FolderA` **In copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line with the relative path to the path configured in the dataset.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Delete activity properties

To learn details about the properties, check Delete activity

Legacy models

> **NOTE**
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **FileShare**	Yes
folderPath	Path to the folder. Wildcard filter is supported, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual folder name has wildcard or this escape char inside. Examples: rootfolder/subfolder/, see more examples in Folder and file filter examples.	Yes

PROPERTY	DESCRIPTION	REQUIRED
fileName	**Name or wildcard filter** for the file(s) under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual file name has wildcard or this escape char inside.	No
format	If you want to **copy files as-is** between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse files with a specific format, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, **ParquetFormat**. Set the **type** property under format to one of these values. For more information, see Text Format, Json Format, Avro Format, Orc Format, and Parquet Format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are: **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels are: **Optimal** and **Fastest**.	No
useBinaryTransfer	Specify whether to use the binary transfer mode. The values are true for binary mode (default), and false for ASCII.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a given name, specify **folderPath** with folder part and **fileName** with file name.
To copy a subset of files under a folder, specify **folderPath** with folder part and **fileName** with wildcard filter.

NOTE

If you were using "fileFilter" property for file filter, it is still supported as-is, while you are suggested to use the new filter capability added to "fileName" going forward.

Example:

```
{
    "name": "FTPDataset",
    "properties": {
        "type": "FileShare",
        "linkedServiceName":{
            "referenceName": "<FTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "folder/subfolder/",
            "fileName": "myfile.csv.gz",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **FileSystemSource**	Yes
recursive	Indicates whether the data is read recursively from the sub folders or only from the specified folder. Note when recursive is set to true and sink is file-based store, empty folder/sub-folder will not be copied/created at sink. Allowed values are: **true** (default), **false**	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromFTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<FTP input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "FileSystemSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Use GitHub to read Common Data Model entity references

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

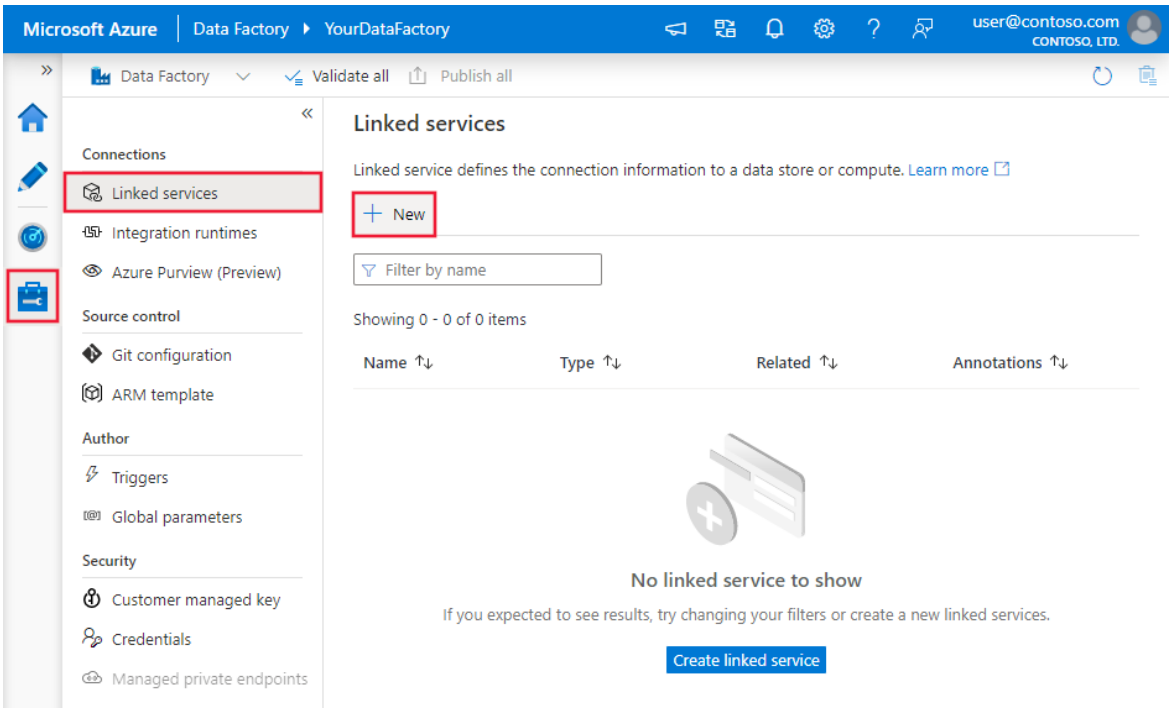
The GitHub connector in Azure Data Factory and Synapse Analytics pipelines is only used to receive the entity reference schema for the Common Data Model format in mapping data flow.

Create a linked service to GitHub using UI

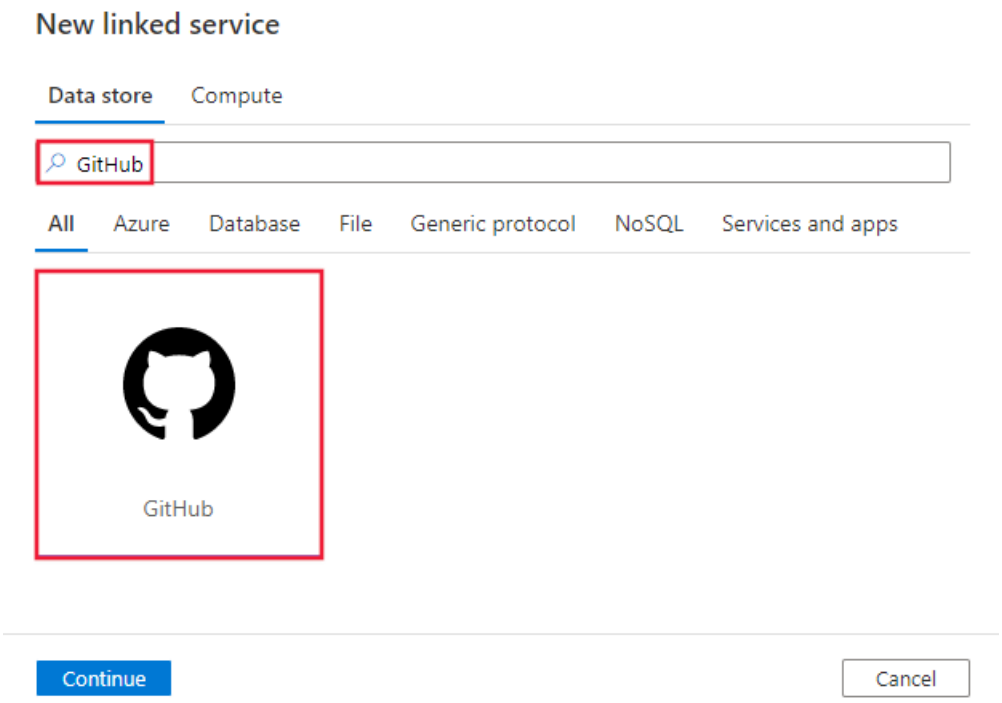
Use the following steps to create a linked service to GitHub in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

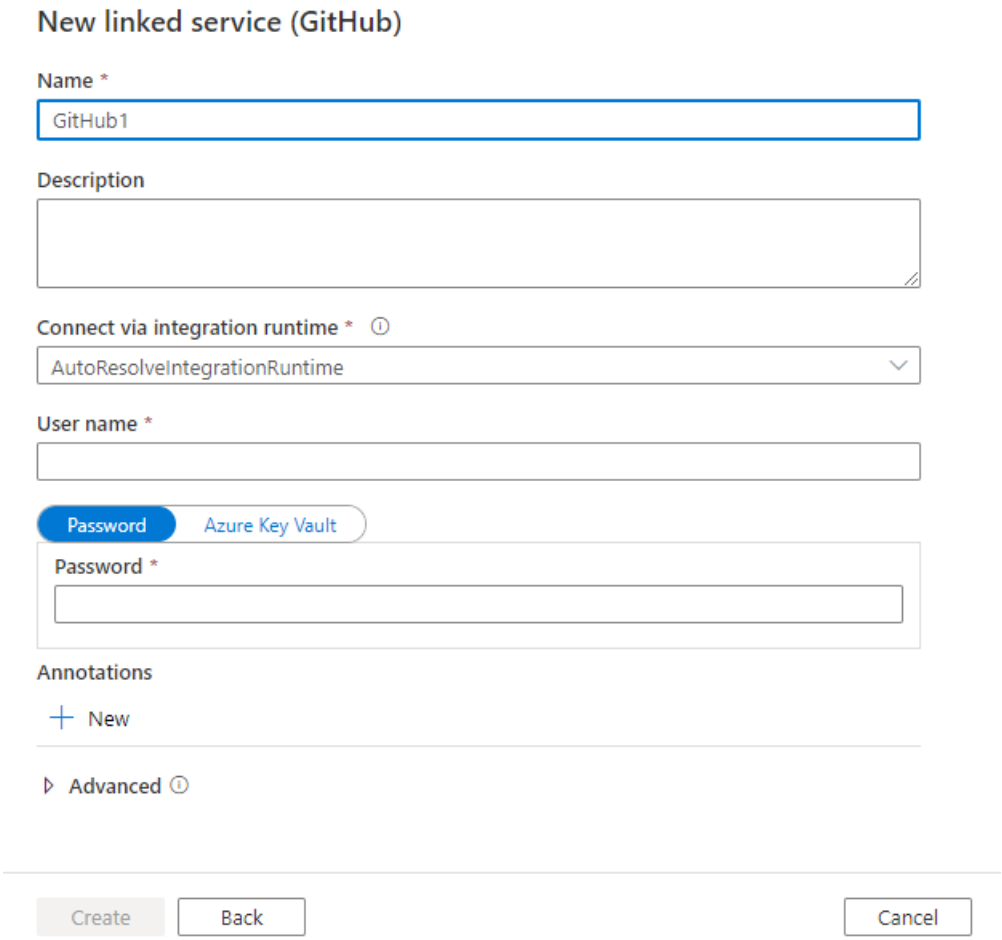
   - Azure Data Factory
   - Azure Synapse



2. Search for GitHub and select the GitHub connector.



3. Configure the service details, test the connection, and create the new linked service.



Linked service properties

The following properties are supported for the GitHub linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **GitHub**.	yes
userName	GitHub username	yes
password	GitHub password	yes

Next steps

Create a source dataset in mapping data flow.

Copy data from Google AdWords using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Google AdWords. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Google AdWords connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

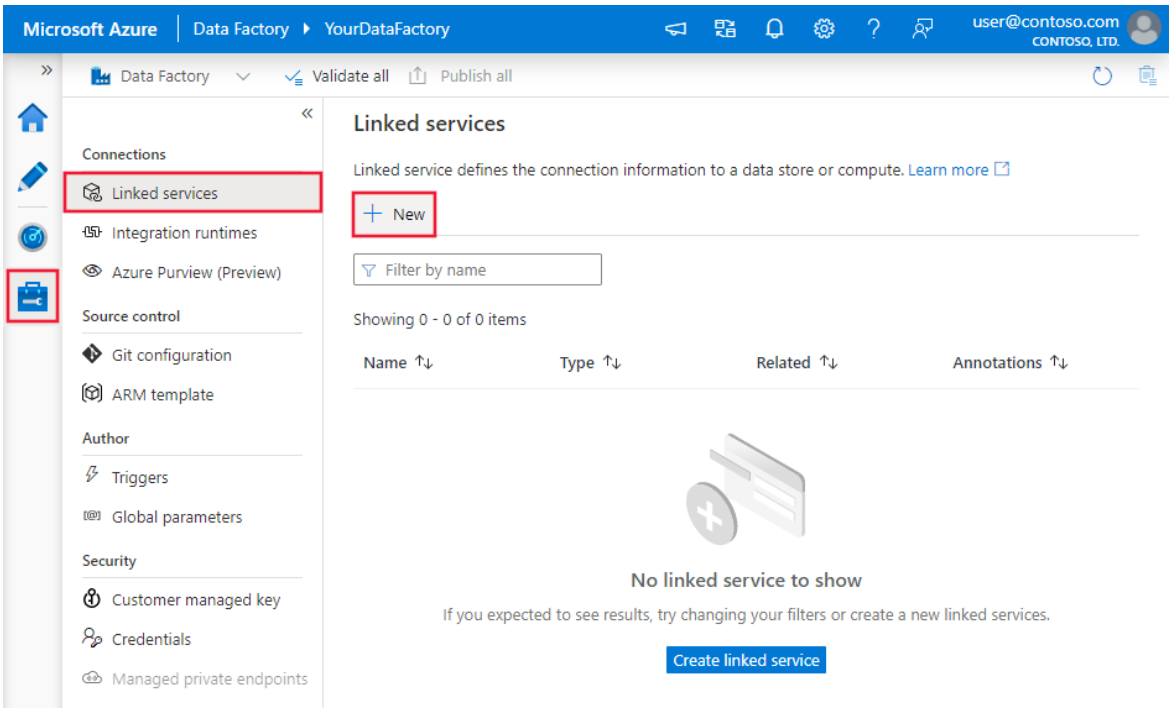
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Google AdWords using UI

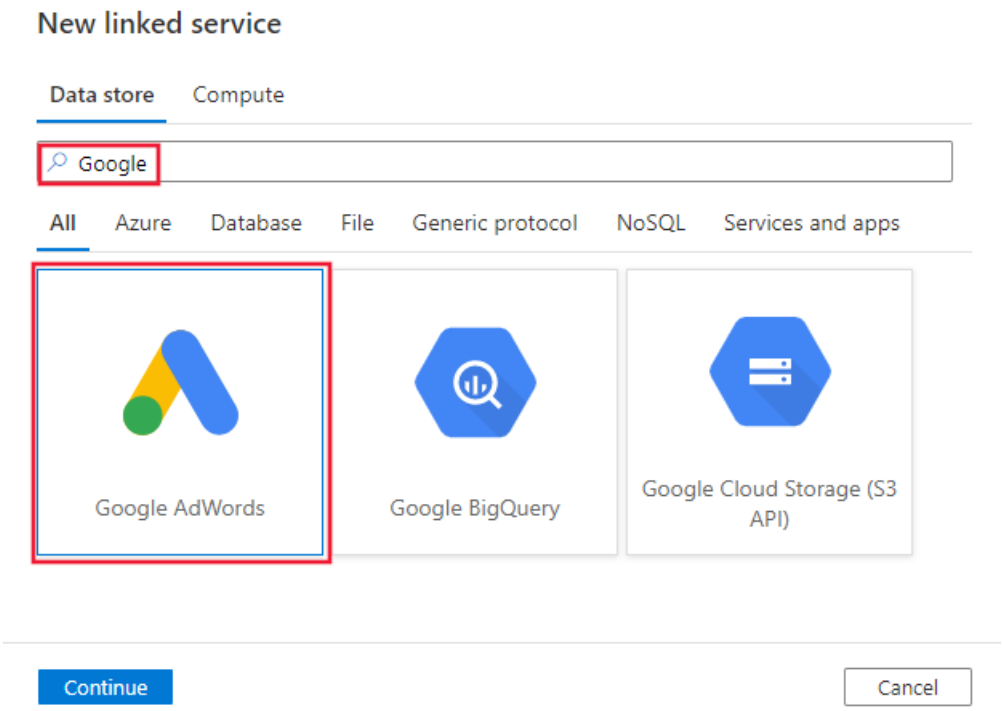
Use the following steps to create a linked service to Google AdWords in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

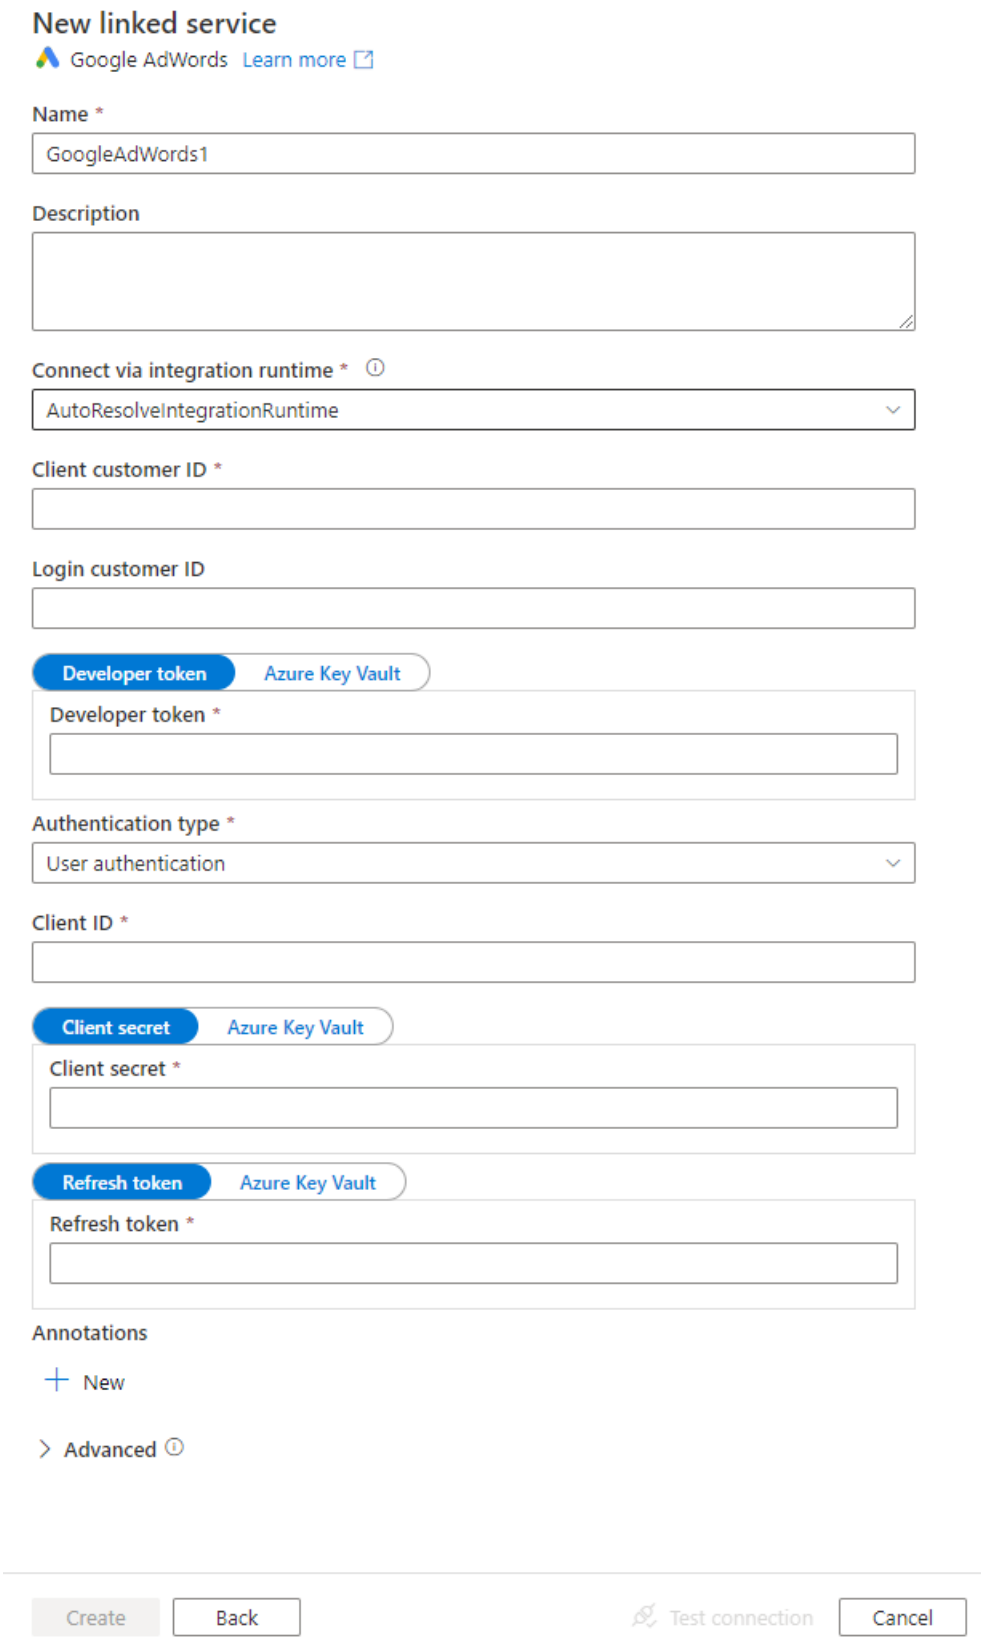
   - Azure Data Factory
   - Azure Synapse



2. Search for Google and select the Google AdWords connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Google AdWords connector.

Linked service properties

IMPORTANT

Due to the sunset of Google AdWords API by **April 27, 2022**, the service has upgraded to the new Google Ads API. Please refer this document for detailed migration steps and recommendations. Please make sure the migration to be done before **April 27, 2022**.

The following properties are supported for Google AdWords linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **GoogleAdWords**	Yes
connectionProperties	A group of properties that defines how to connect to Google AdWords.	Yes
Under `connectionProperties`***:***		
clientCustomerID	The Client customer ID of the AdWords account that you want to fetch report data for.	Yes
loginCustomerID	The customer ID of the Google AdWords manager account through which you want to fetch report data of specific customer.	No
developerToken	The developer token associated with the manager account that you use to grant access to the AdWords API. You can choose to mark this field as a SecureString to store it securely, or store password in Azure Key Vault and let the copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	Yes
authenticationType	The OAuth 2.0 authentication mechanism used for authentication. ServiceAuthentication can only be used on self-hosted IR. Allowed values are: **ServiceAuthentication**, **UserAuthentication**	Yes
refreshToken	The refresh token obtained from Google for authorizing access to AdWords for UserAuthentication. You can choose to mark this field as a SecureString to store it securely, or store password in Azure Key Vault and let the copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	No

PROPERTY	DESCRIPTION	REQUIRED
clientId	The client ID of the Google application used to acquire the refresh token. You can choose to mark this field as a SecureString to store it securely, or store password in Azure Key Vault and let the copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	No
clientSecret	The client secret of the google application used to acquire the refresh token. You can choose to mark this field as a SecureString to store it securely, or store password in Azure Key Vault and let the copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	No
email	The service account email ID that is used for ServiceAuthentication and can only be used on self-hosted IR.	No
keyFilePath	The full path to the `.p12` or `.json` key file that is used to authenticate the service account email address and can only be used on self-hosted IR.	No
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is false.	No

Example:

```
{
    "name": "GoogleAdWordsLinkedService",
    "properties": {
        "type": "GoogleAdWords",
        "typeProperties": {
            "connectionProperties": {
                "clientCustomerID": "<clientCustomerID>",
                "loginCustomerID": "<loginCustomerID>",
                "developerToken": {
                    "type": "SecureString",
                    "value": "<developerToken>"
                },
                "authenticationType": "ServiceAuthentication",
                "refreshToken": {
                    "type": "SecureString",
                    "value": "<refreshToken>"
                },
                "clientId": {
                    "type": "SecureString",
                    "value": "<clientId>"
                },
                "clientSecret": {
                    "type": "SecureString",
                    "value": "<clientSecret>"
                },
                "email": "<email>",
                "keyFilePath": "<keyFilePath>",
                "trustedCertPath": "<trustedCertPath>",
                "useSystemTrustStore": true,
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Google AdWords dataset.

To copy data from Google AdWords, set the type property of the dataset to **GoogleAdWordsObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **GoogleAdWordsObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "GoogleAdWordsDataset",
    "properties": {
        "type": "GoogleAdWordsObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<GoogleAdWords linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Google AdWords source.

Google AdWords as source

To copy data from Google AdWords, set the source type in the copy activity to **GoogleAdWordsSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **GoogleAdWordsSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromGoogleAdWords",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<GoogleAdWords input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "GoogleAdWordsSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Google BigQuery using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from Google BigQuery. It builds on the Copy Activity overview article that presents a general overview of the copy activity.

Supported capabilities

This Google BigQuery connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity. Therefore, you don't need to manually install a driver to use this connector.

> **NOTE**
> This Google BigQuery connector is built on top of the BigQuery APIs. Be aware that BigQuery limits the maximum rate of incoming requests and enforces appropriate quotas on a per-project basis, refer to Quotas & Limits - API requests. Make sure you do not trigger too many concurrent requests to the account.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

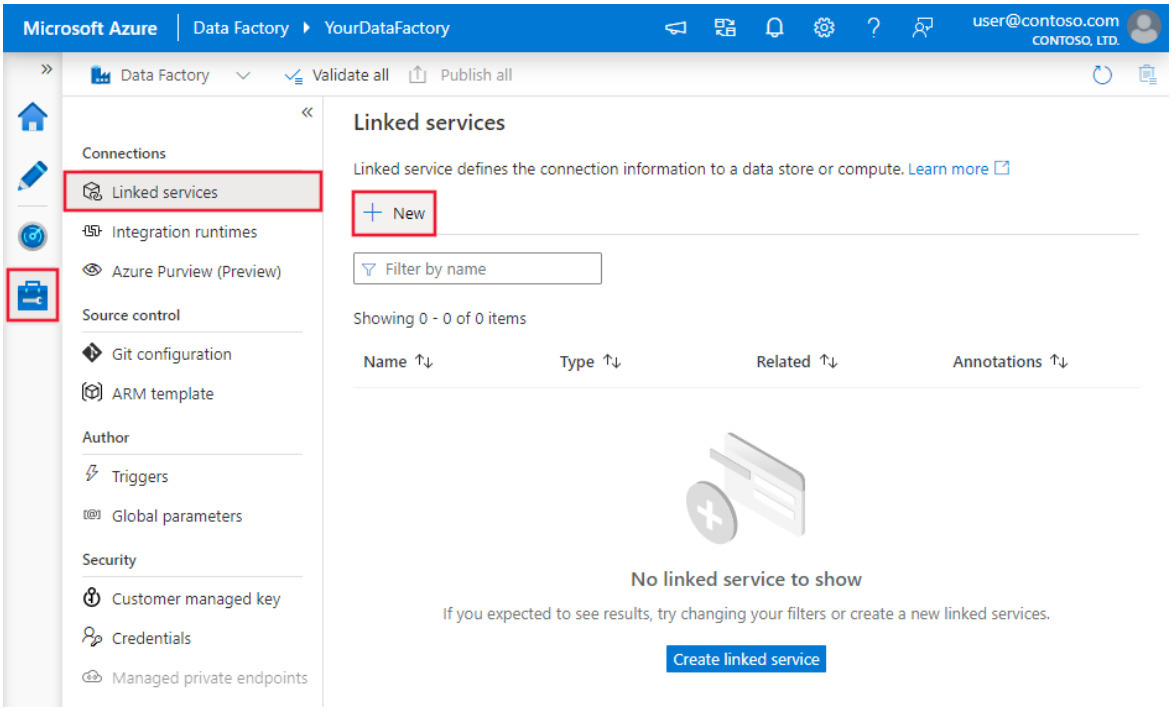
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Google BigQuery using UI

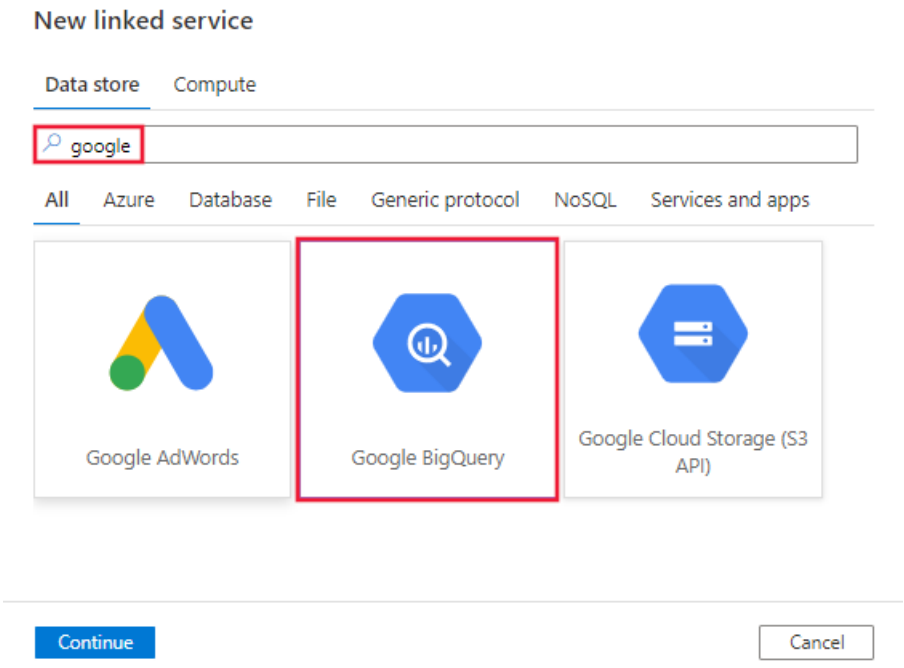
Use the following steps to create a linked service to Google BigQuery in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

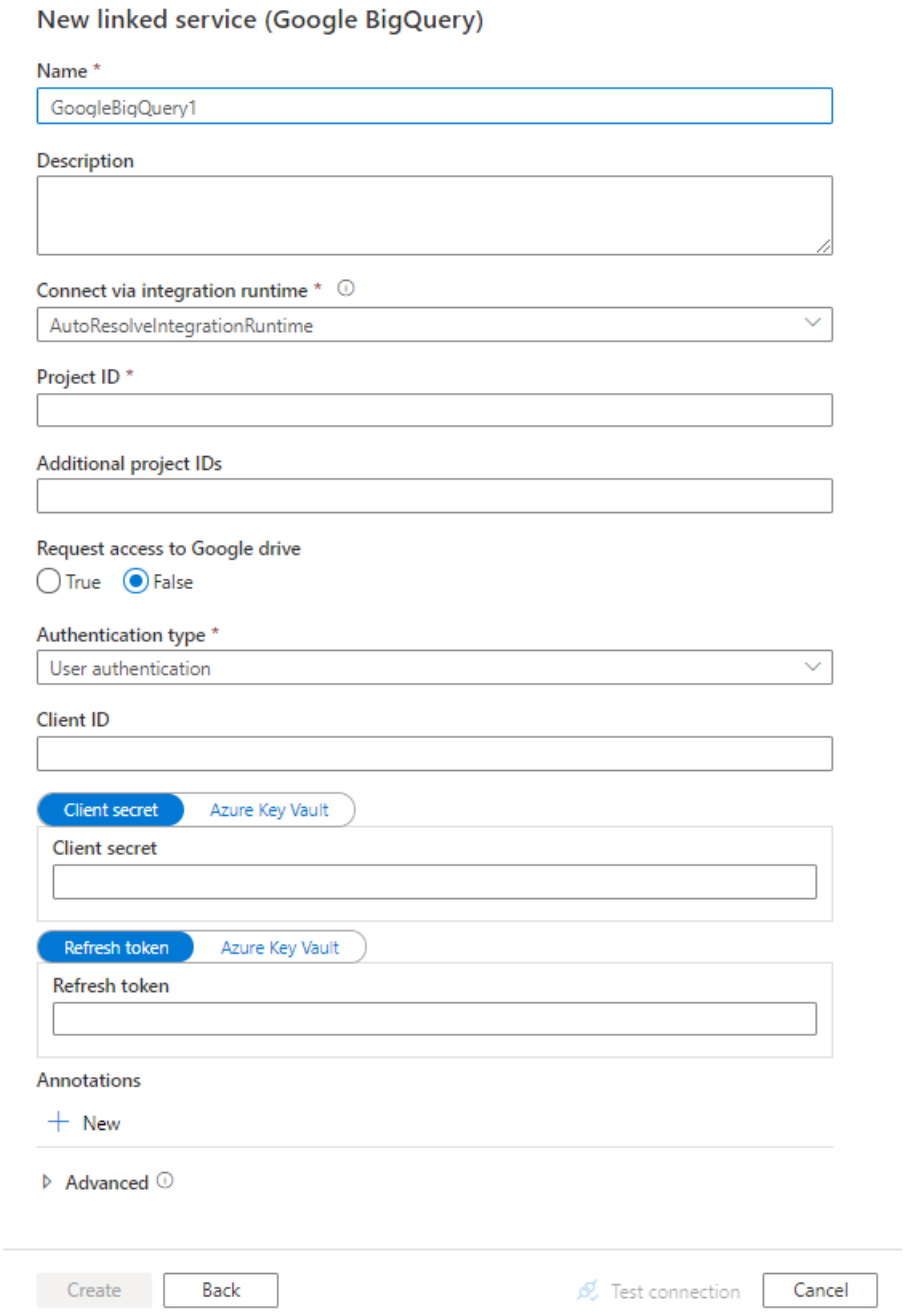
   - Azure Data Factory
   - Azure Synapse



2. Search for Google and select the Google BigQuery connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to the Google BigQuery connector.

Linked service properties

The following properties are supported for the Google BigQuery linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **GoogleBigQuery**.	Yes
project	The project ID of the default BigQuery project to query against.	Yes

PROPERTY	DESCRIPTION	REQUIRED
additionalProjects	A comma-separated list of project IDs of public BigQuery projects to access.	No
requestGoogleDriveScope	Whether to request access to Google Drive. Allowing Google Drive access enables support for federated tables that combine BigQuery data with data from Google Drive. The default value is **false**.	No
authenticationType	The OAuth 2.0 authentication mechanism used for authentication. ServiceAuthentication can be used only on Self-hosted Integration Runtime. Allowed values are **UserAuthentication** and **ServiceAuthentication**. Refer to sections below this table on more properties and JSON samples for those authentication types respectively.	Yes

Using user authentication

Set "authenticationType" property to **UserAuthentication**, and specify the following properties along with generic properties described in the previous section:

PROPERTY	DESCRIPTION	REQUIRED
clientId	ID of the application used to generate the refresh token.	No
clientSecret	Secret of the application used to generate the refresh token. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
refreshToken	The refresh token obtained from Google used to authorize access to BigQuery. Learn how to get one from Obtaining OAuth 2.0 access tokens and this community blog. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No

The minimum scope required to obtain an OAuth 2.0 refresh token is `https://www.googleapis.com/auth/bigquery.readonly`. If you plan to run a query that might return large results, other scope might be required. For more information, refer to this article.

Example:

```
{
    "name": "GoogleBigQueryLinkedService",
    "properties": {
        "type": "GoogleBigQuery",
        "typeProperties": {
            "project" : "<project ID>",
            "additionalProjects" : "<additional project IDs>",
            "requestGoogleDriveScope" : true,
            "authenticationType" : "UserAuthentication",
            "clientId": "<id of the application used to generate the refresh token>",
            "clientSecret": {
                "type": "SecureString",
                "value":"<secret of the application used to generate the refresh token>"
            },
            "refreshToken": {
                "type": "SecureString",
                "value": "<refresh token>"
            }
        }
    }
}
```

Using service authentication

Set "authenticationType" property to **ServiceAuthentication**, and specify the following properties along with generic properties described in the previous section. This authentication type can be used only on Self-hosted Integration Runtime.

PROPERTY	DESCRIPTION	REQUIRED
email	The service account email ID that is used for ServiceAuthentication. It can be used only on Self-hosted Integration Runtime.	No
keyFilePath	The full path to the `.p12` or `.json` key file that is used to authenticate the service account email address.	No
trustedCertPath	The full path of the .pem file that contains trusted CA certificates used to verify the server when you connect over TLS. This property can be set only when you use TLS on Self-hosted Integration Runtime. The default value is the cacerts.pem file installed with the integration runtime.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified .pem file. The default value is **false**.	No

Example:

```
{
    "name": "GoogleBigQueryLinkedService",
    "properties": {
        "type": "GoogleBigQuery",
        "typeProperties": {
            "project" : "<project id>",
            "requestGoogleDriveScope" : true,
            "authenticationType" : "ServiceAuthentication",
            "email": "<email>",
            "keyFilePath": "<.p12 or .json key path on the IR machine>"
        },
        "connectVia": {
            "referenceName": "<name of Self-hosted Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Google BigQuery dataset.

To copy data from Google BigQuery, set the type property of the dataset to **GoogleBigQueryObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **GoogleBigQueryObject**	Yes
dataset	Name of the Google BigQuery dataset.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table. This property is supported for backward compatibility. For new workload, use `dataset` and `table`.	No (if "query" in activity source is specified)

Example

```
{
    "name": "GoogleBigQueryDataset",
    "properties": {
        "type": "GoogleBigQueryObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<GoogleBigQuery linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Google BigQuery source type.

GoogleBigQuerySource as a source type

To copy data from Google BigQuery, set the source type in the copy activity to **GoogleBigQuerySource**. The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **GoogleBigQuerySource**.	Yes
query	Use the custom SQL query to read data. An example is `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromGoogleBigQuery",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<GoogleBigQuery input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "GoogleBigQuerySource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Google Cloud Storage using Azure Data Factory or Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data from Google Cloud Storage (GCS). To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This Google Cloud Storage connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

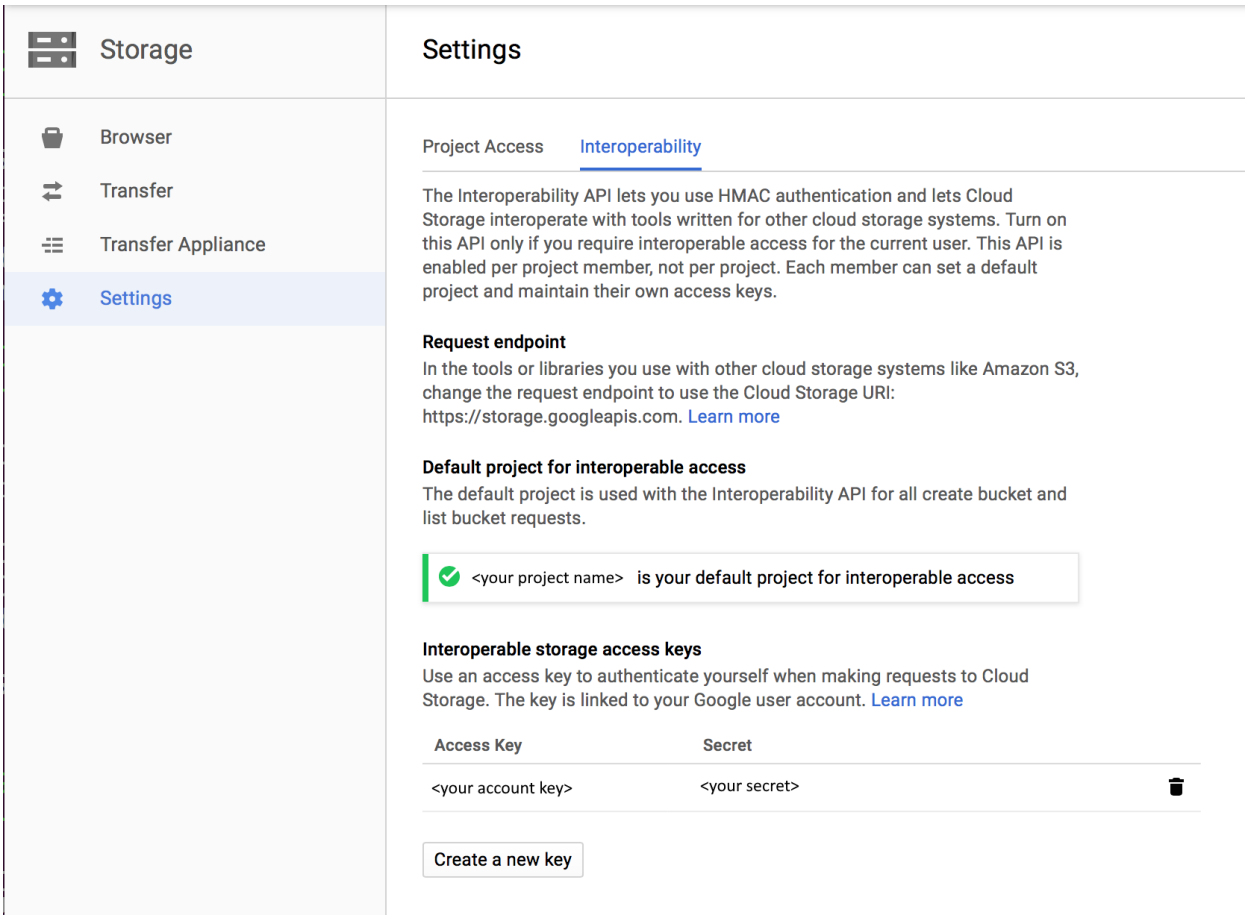
① Azure integration runtime ② Self-hosted integration runtime

Specifically, this Google Cloud Storage connector supports copying files as is or parsing files with the supported file formats and compression codecs. It takes advantage of GCS's S3-compatible interoperability.

Prerequisites

The following setup is required on your Google Cloud Storage account:

1. Enable interoperability for your Google Cloud Storage account
2. Set the default project that contains the data you want to copy from the target GCS bucket.
3. Create a service account and define the right levels of permissions by using Cloud IAM on GCP.
4. Generate the access keys for this service account.



Required permissions

To copy data from Google Cloud Storage, make sure you've been granted the following permissions for object operations: `storage.objects.get` and `storage.objects.list`.

If you use UI to author, additional `storage.buckets.list` permission is required for operations like testing connection to linked service and browsing from root. If you don't want to grant this permission, you can choose "Test connection to file path" or "Browse from specified path" options from the UI.

For the full list of Google Cloud Storage roles and associated permissions, see IAM roles for Cloud Storage on the Google Cloud site.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

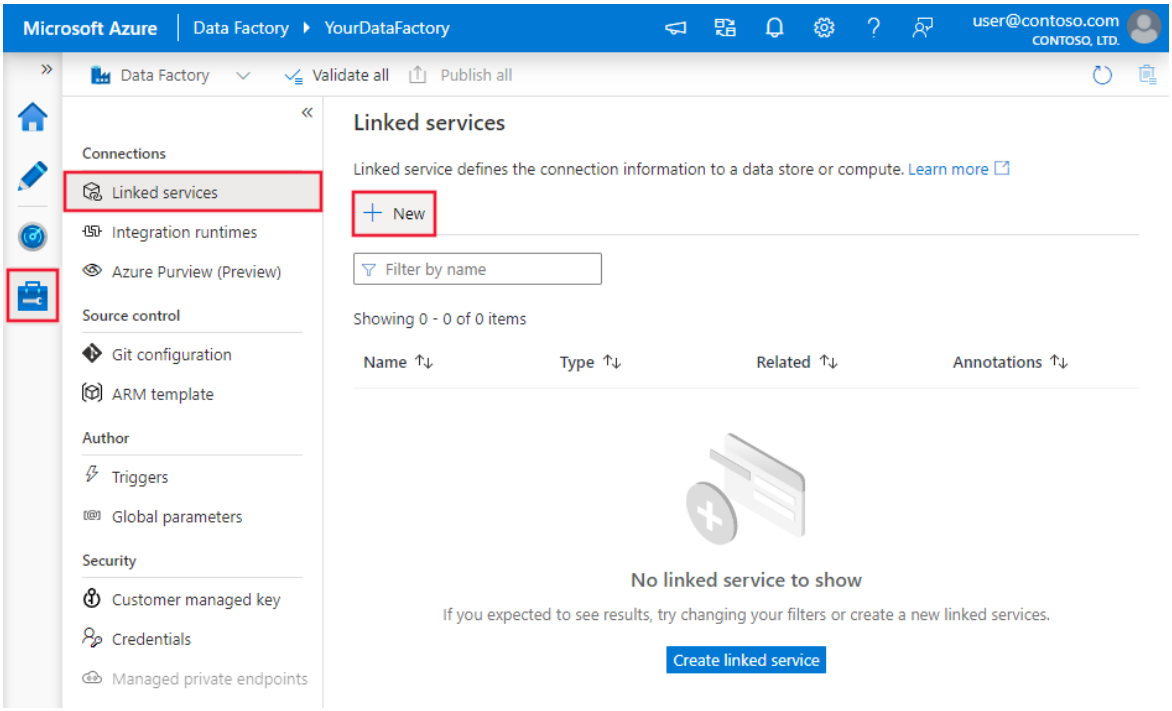
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Google Cloud Storage using UI

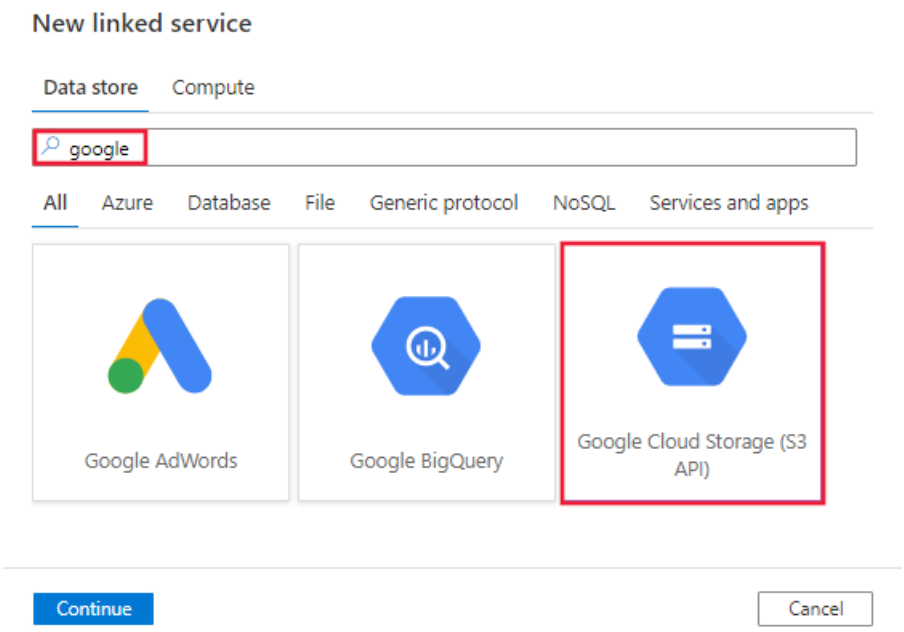
Use the following steps to create a linked service to Google Cloud Storage in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

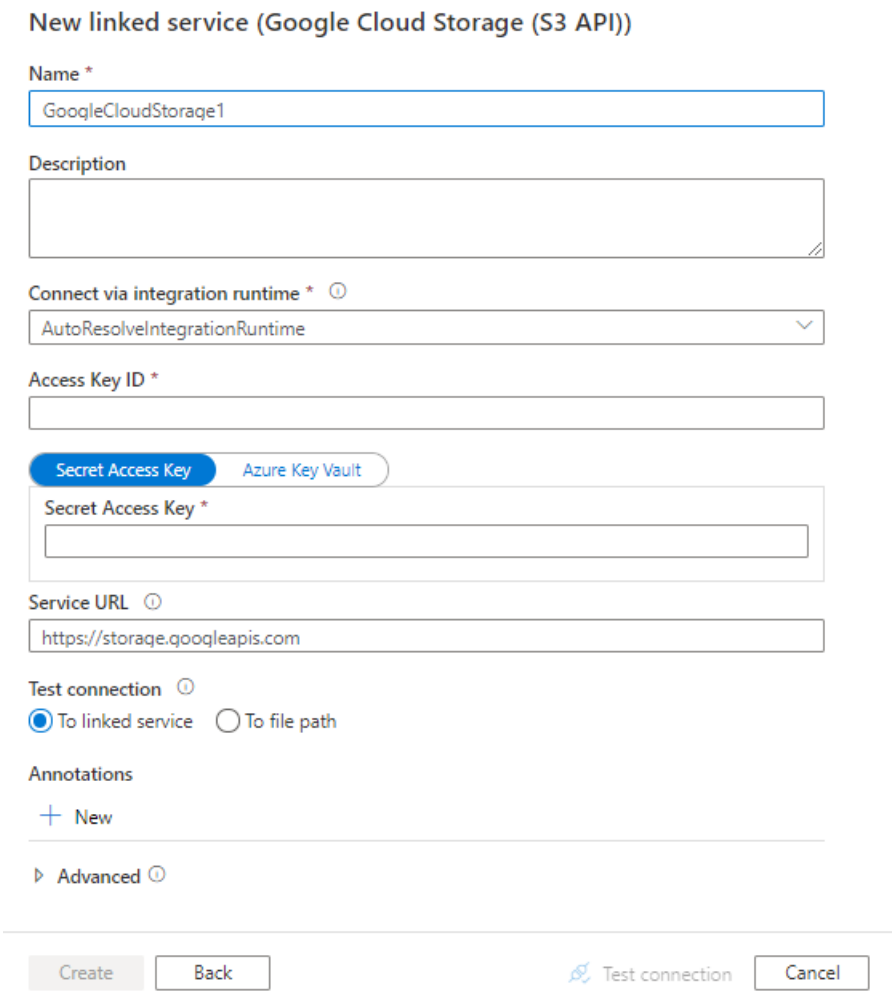
- Azure Data Factory
- Azure Synapse



2. Search for Google and select the Google Cloud Storage (S3 API) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Google Cloud Storage.

Linked service properties

The following properties are supported for Google Cloud Storage linked services:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **GoogleCloudStorage**.	Yes
accessKeyId	ID of the secret access key. To find the access key and secret, see Prerequisites.	Yes
secretAccessKey	The secret access key itself. Mark this field as **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes
serviceUrl	Specify the custom GCS endpoint as `https://storage.googleapis.com`.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Here's an example:

```
{
    "name": "GoogleCloudStorageLinkedService",
    "properties": {
        "type": "GoogleCloudStorage",
        "typeProperties": {
            "accessKeyId": "<access key id>",
            "secretAccessKey": {
                "type": "SecureString",
                "value": "<secret access key>"
            },
            "serviceUrl": "https://storage.googleapis.com"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Google Cloud Storage under `location` settings in a format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `location` in the dataset must be set to **GoogleCloudStorageLocation**.	Yes
bucketName	The GCS bucket name.	Yes

PROPERTY	DESCRIPTION	REQUIRED
folderPath	The path to folder under the given bucket. If you want to use a wildcard to filter the folder, skip this setting and specify that in activity source settings.	No
fileName	The file name under the given bucket and folder path. If you want to use a wildcard to filter the files, skip this setting and specify that in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Google Cloud Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "GoogleCloudStorageLocation",
                "bucketName": "bucketname",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties that the Google Cloud Storage source supports.

Google Cloud Storage as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Google Cloud Storage under `storeSettings` settings in a format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `storeSettings` must be set to **GoogleCloudStorageReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given bucket or folder/file path specified in the dataset. If you want to copy all files from a bucket or folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: GCS prefix - prefix	Prefix for the GCS key name under the given bucket configured in the dataset to filter source GCS files. GCS keys whose names start with `bucket_in_dataset/this_prefix` are selected. It utilizes GCS's service-side filter, which provides better performance than a wildcard filter.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given bucket configured in a dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	No
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given bucket and folder path (or wildcard folder path) to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your file name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When you're using this option, do not specify the file name in the dataset. See more examples in File list examples.	No
Additional settings:		

PROPERTY	DESCRIPTION	REQUIRED
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromGoogleCloudStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "GoogleCloudStorageReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	false	bucket FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	true	bucket FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	false	bucket FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	true	bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using a file list path in the Copy activity source.

Assume that you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Bucket: `bucket` - Folder path: `FolderA` **In copy activity source:** - File list path: `bucket/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line, with the relative path to the path configured in the dataset.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity.

Delete activity properties

To learn details about the properties, check Delete activity.

Legacy models

If you were using an Amazon S3 connector to copy data from Google Cloud Storage, it's still supported as is for backward compatibility. We suggest that you use the new model mentioned earlier. The authoring UI has switched to generating the new model.

Next steps

For a list of data stores that the Copy activity supports as sources and sinks, see Supported data stores.

Copy data from Greenplum using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Greenplum. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Greenplum connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK

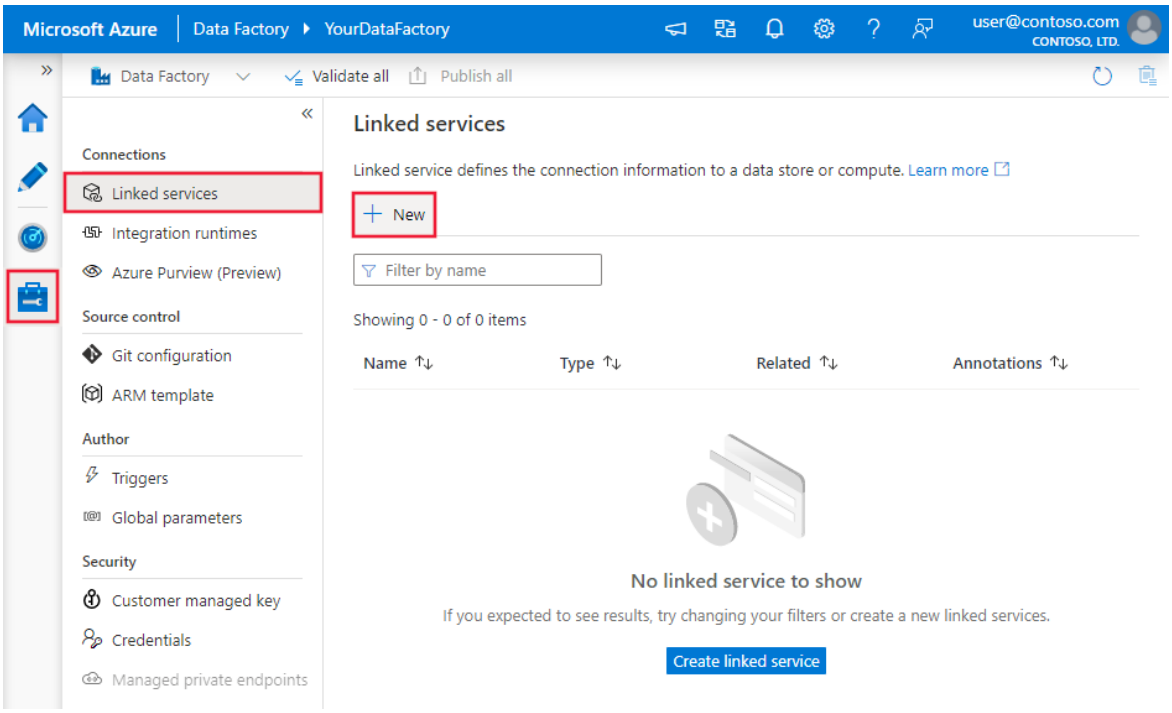
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Greenplum using UI

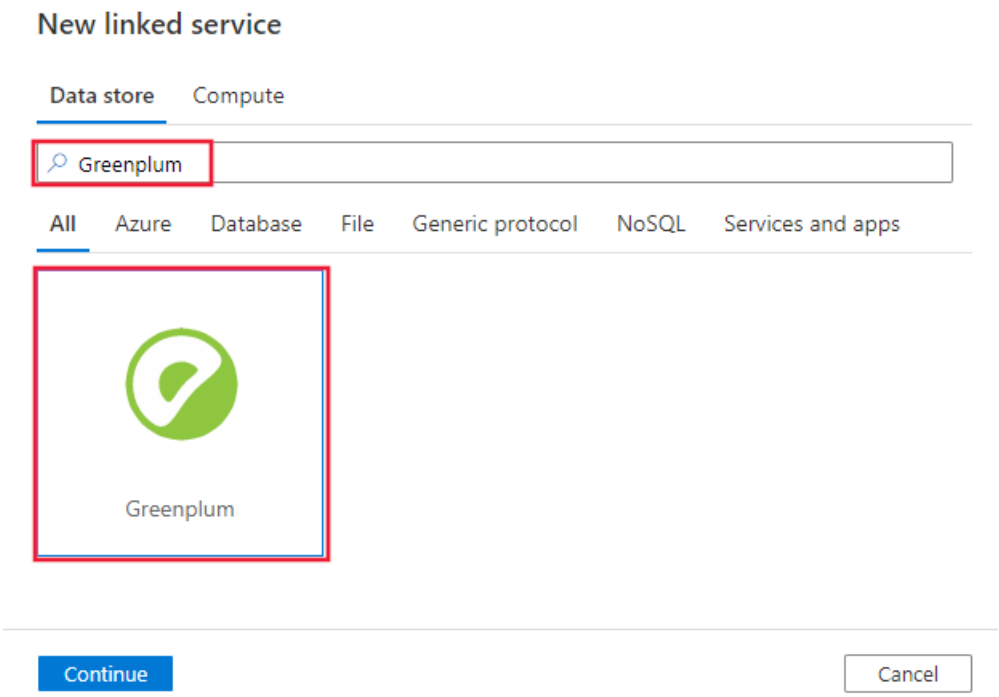
Use the following steps to create a linked service to Greenplum in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

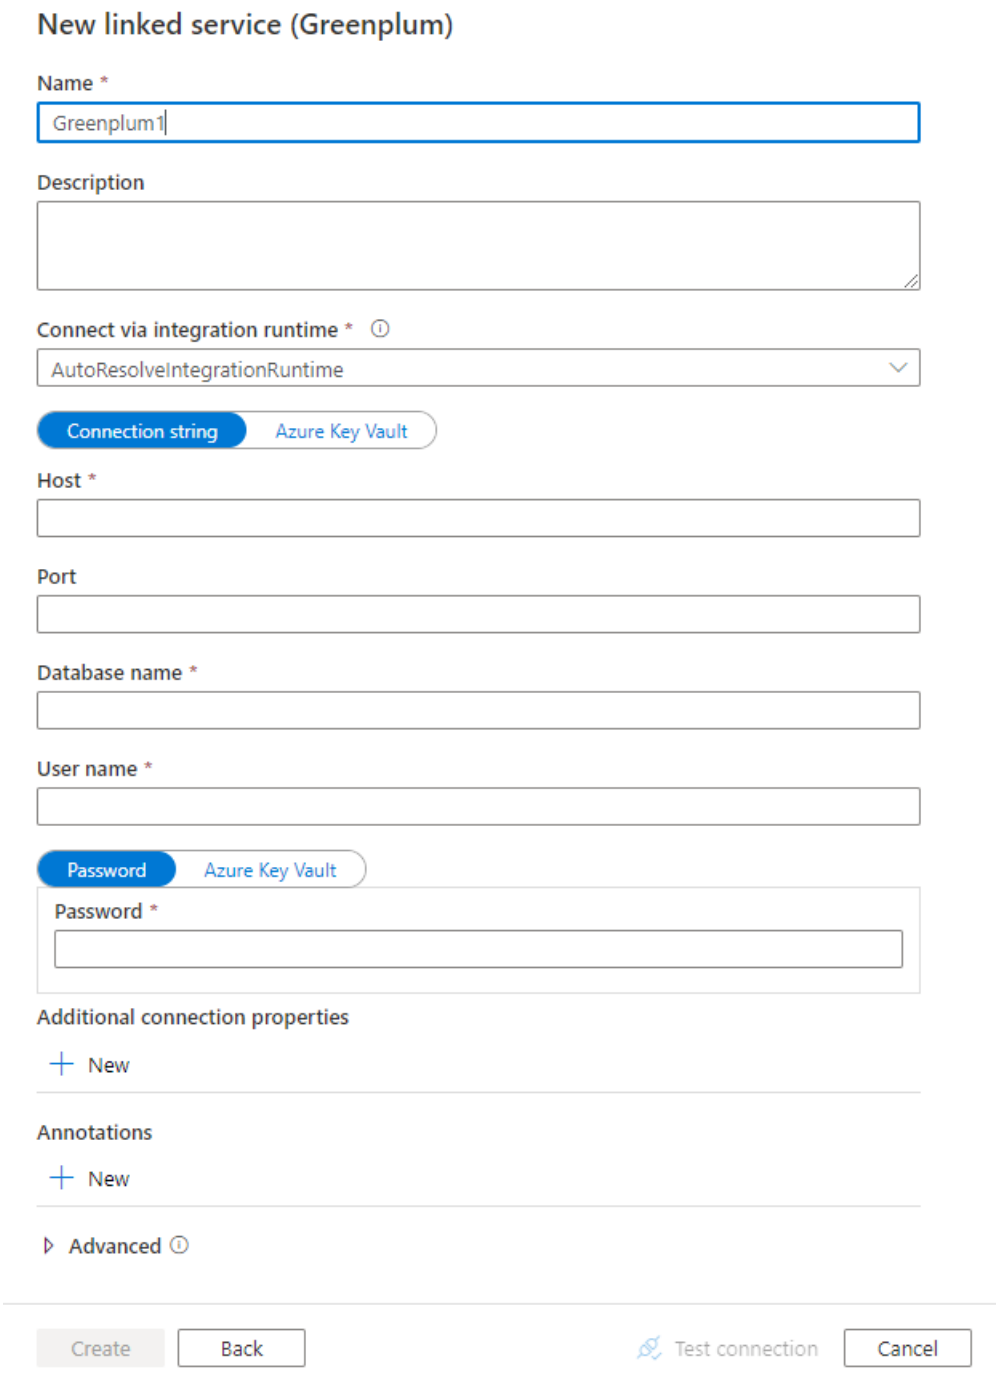
   - Azure Data Factory
   - Azure Synapse



2. Search for Greenplum and select the Greenplum connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Greenplum connector.

Linked service properties

The following properties are supported for Greenplum linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Greenplum**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to Greenplum. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "GreenplumLinkedService",
    "properties": {
        "type": "Greenplum",
        "typeProperties": {
            "connectionString": "HOST=<server>;PORT=<port>;DB=<database>;UID=<user name>;PWD=<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "GreenplumLinkedService",
    "properties": {
        "type": "Greenplum",
        "typeProperties": {
            "connectionString": "HOST=<server>;PORT=<port>;DB=<database>;UID=<user name>;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section

provides a list of properties supported by Greenplum dataset.

To copy data from Greenplum, set the type property of the dataset to **GreenplumTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **GreenplumTable**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "GreenplumDataset",
    "properties": {
        "type": "GreenplumTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Greenplum linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Greenplum source.

GreenplumSource as source

To copy data from Greenplum, set the source type in the copy activity to **GreenplumSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **GreenplumSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromGreenplum",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Greenplum input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "GreenplumSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from HBase using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from HBase. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This HBase connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell

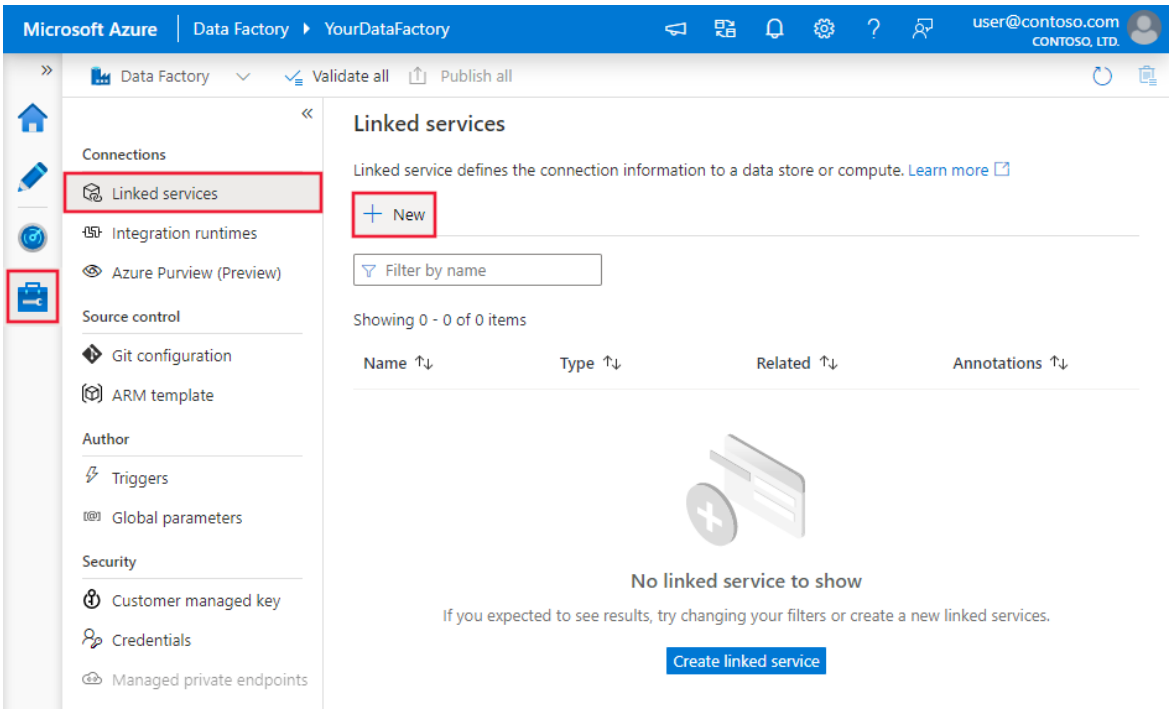
- The REST API
- The Azure Resource Manager template

Create a linked service to Hbase using UI

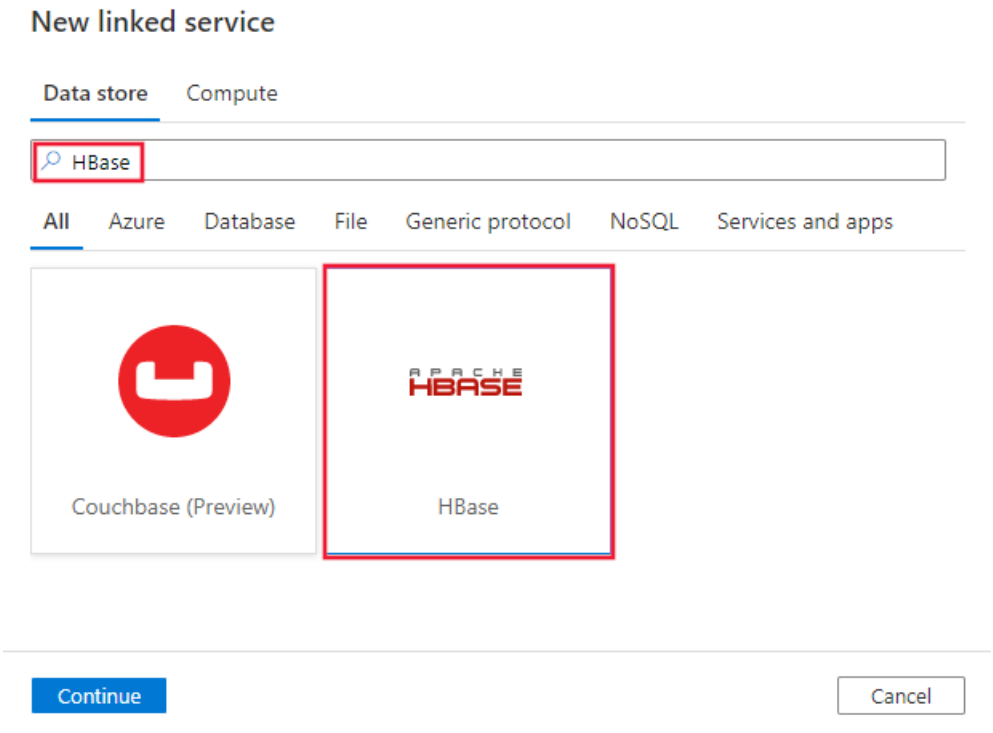
Use the following steps to create a linked service to Hbase in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

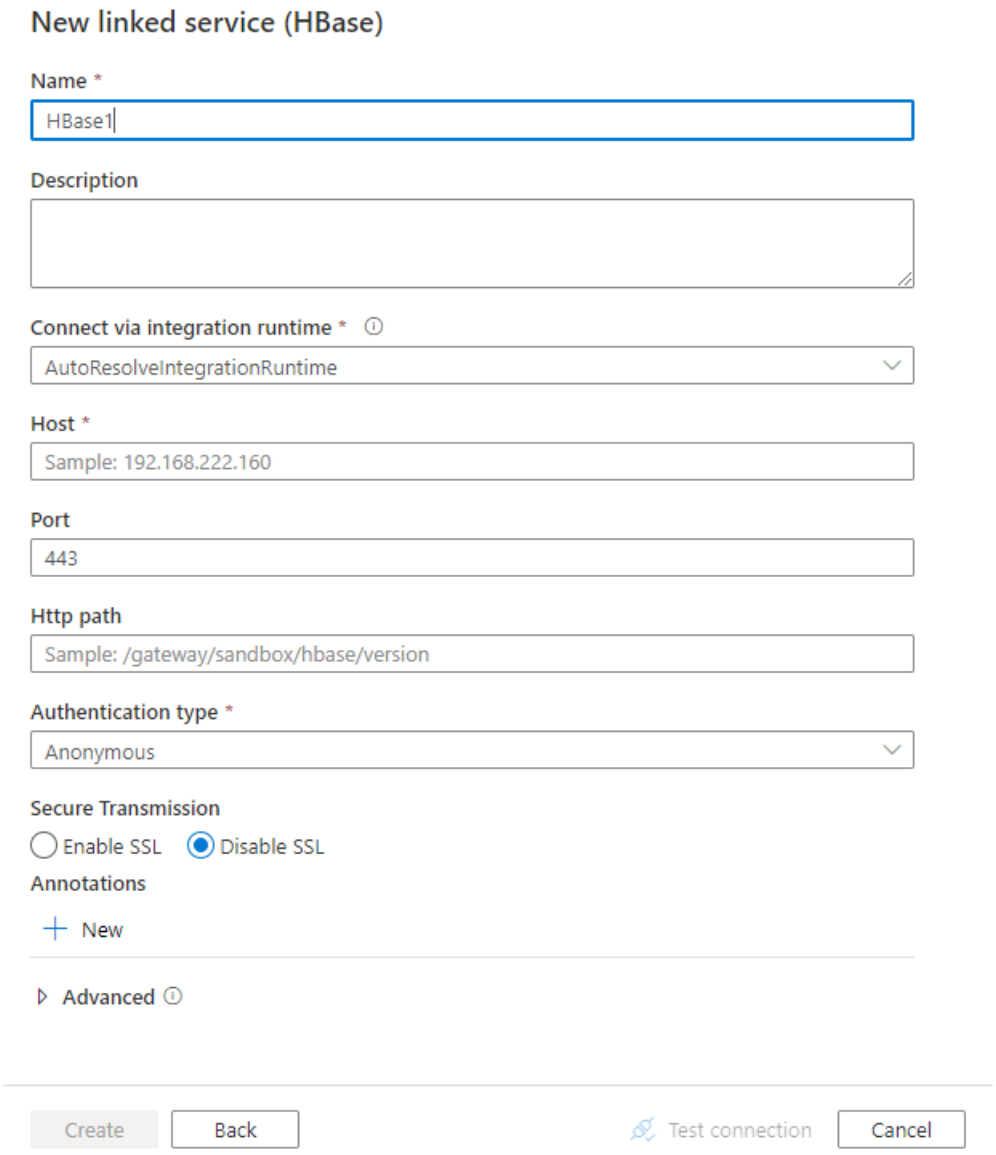
   - Azure Data Factory
   - Azure Synapse



2. Search for Hbase and select the Hbase connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to HBase connector.

Linked service properties

The following properties are supported for HBase linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **HBase**	Yes
host	The IP address or host name of the HBase server. (i.e. `[clustername].azurehdinsight.net`, `192.168.222.160`)	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	The TCP port that the HBase instance uses to listen for client connections. The default value is 9090. If you connect to Azure HDInsights, specify port as 443.	No
httpPath	The partial URL corresponding to the HBase server, e.g. `/hbaserest0` when using HDInsights cluster.	No
authenticationType	The authentication mechanism to use to connect to the HBase server. Allowed values are: **Anonymous**, **Basic**	Yes
username	The user name used to connect to the HBase instance.	No
password	The password corresponding to the user name. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when connecting over TLS. The default value is false.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

NOTE

If your cluster doesn't support sticky session e.g. HDInsight, explicitly add node index at the end of the http path setting, e.g. specify `/hbaserest0` instead of `/hbaserest`.

Example for HDInsights HBase:

```
{
    "name": "HBaseLinkedService",
    "properties": {
        "type": "HBase",
        "typeProperties": {
            "host" : "<cluster name>.azurehdinsight.net",
            "port" : "443",
            "httpPath" : "/hbaserest0",
            "authenticationType" : "Basic",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            },
            "enableSsl" : true
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example for generic HBase:

```
{
    "name": "HBaseLinkedService",
    "properties": {
        "type": "HBase",
        "typeProperties": {
            "host" : "<host e.g. 192.168.222.160>",
            "port" : "<port>",
            "httpPath" : "<e.g. /gateway/sandbox/hbase/version>",
            "authenticationType" : "Basic",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            },
            "enableSsl" : true,
            "trustedCertPath" : "<trustedCertPath>",
            "allowHostNameCNMismatch" : true,
            "allowSelfSignedServerCert" : true
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section

provides a list of properties supported by HBase dataset.

To copy data from HBase, set the type property of the dataset to **HBaseObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **HBaseObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "HBaseDataset",
    "properties": {
        "type": "HBaseObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<HBase linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by HBase source.

HBaseSource as source

To copy data from HBase, set the source type in the copy activity to **HBaseSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **HBaseSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromHBase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<HBase input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "HBaseSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Copy data from the HDFS server using Azure Data Factory or Synapse Analytics

8/19/2022 • 20 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data from the Hadoop Distributed File System (HDFS) server. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This HDFS connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, the HDFS connector supports:

- Copying files by using *Windows* (Kerberos) or *Anonymous* authentication.
- Copying files by using the *webhdfs* protocol or *built-in DistCp* support.
- Copying files as is or by parsing or generating files with the supported file formats and compression codecs.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

> **NOTE**
> Make sure that the integration runtime can access *all* the [name node server]:[name node port] and [data node servers]:[data node port] of the Hadoop cluster. The default [name node port] is 50070, and the default [data node port] is 50075.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

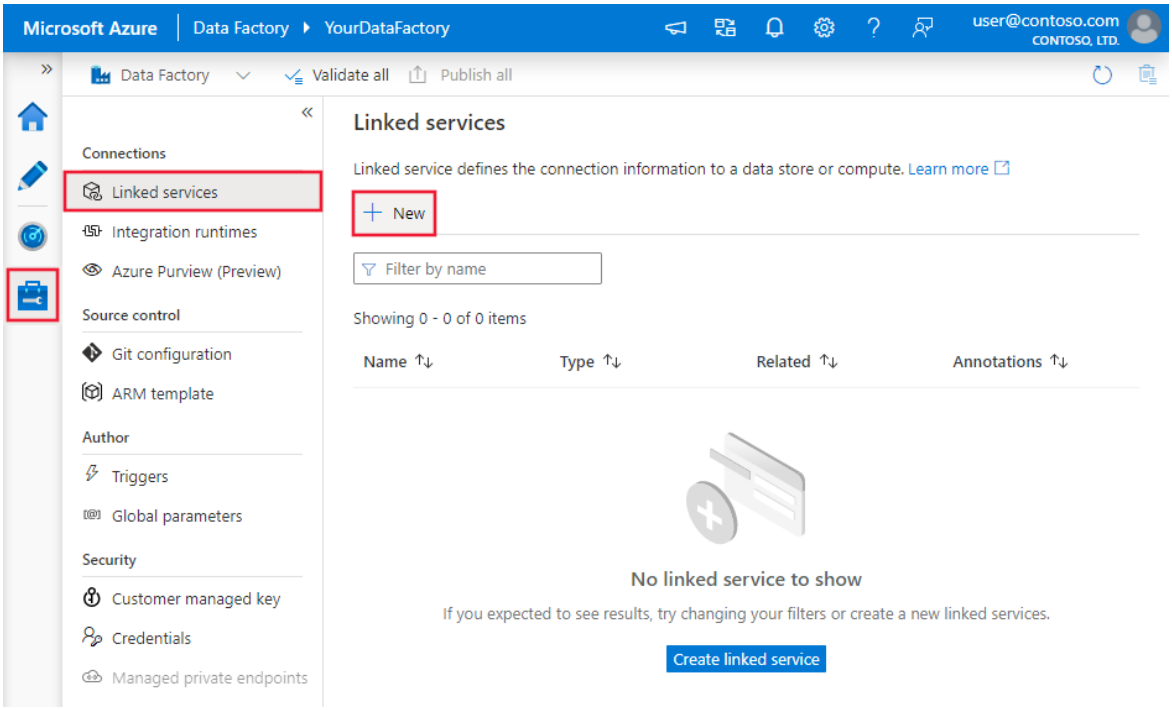
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to HDFS using UI

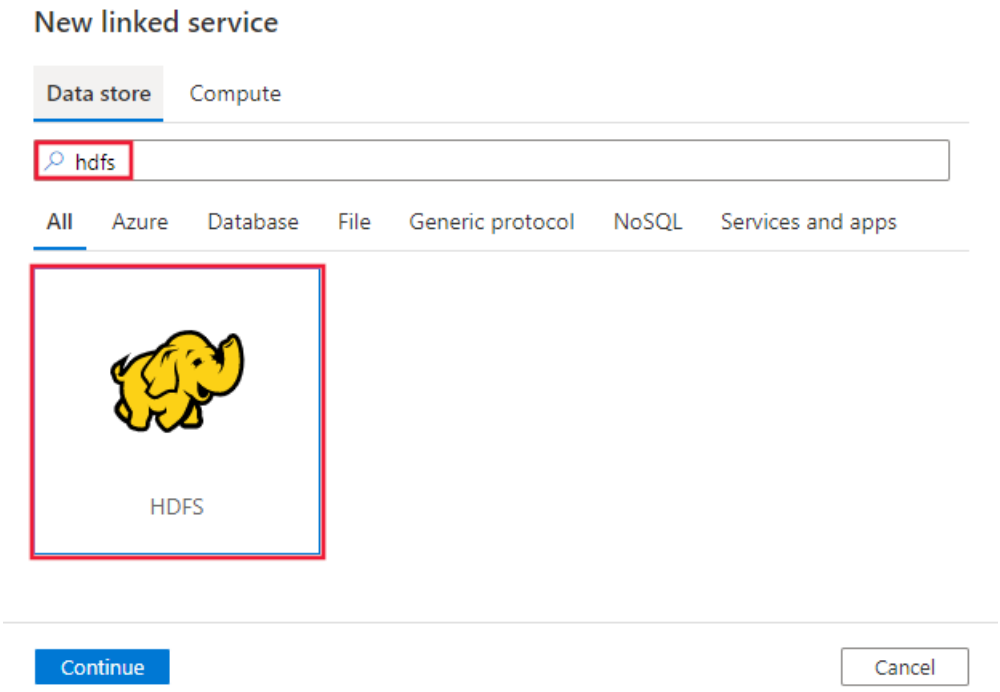
Use the following steps to create a linked service to HDFS in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

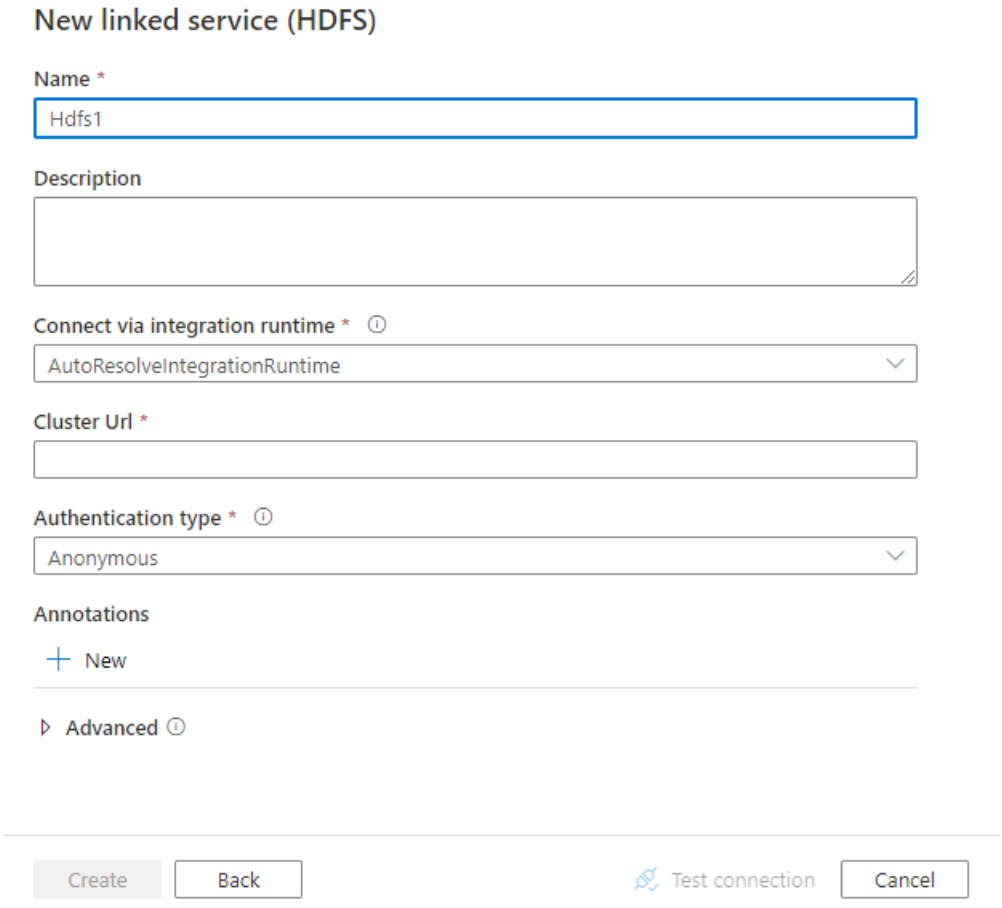
   - Azure Data Factory
   - Azure Synapse



2. Search for HDFS and select the HDFS connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to HDFS.

Linked service properties

The following properties are supported for the HDFS linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property must be set to *Hdfs*.	Yes
url	The URL to the HDFS	Yes
authenticationType	The allowed values are *Anonymous* or *Windows*. To set up your on-premises environment, see the Use Kerberos authentication for the HDFS connector section.	Yes
userName	The username for Windows authentication. For Kerberos authentication, specify **<username>@<domain>.com**.	Yes (for Windows authentication)
password	The password for Windows authentication. Mark this field as a SecureString to store it securely, or reference a secret stored in an Azure key vault.	Yes (for Windows Authentication)
connectVia	The integration runtime to be used to connect to the data store. To learn more, see the Prerequisites section. If the integration runtime isn't specified, the service uses the default Azure Integration Runtime.	No

Example: using Anonymous authentication

```
{
    "name": "HDFSLinkedService",
    "properties": {
        "type": "Hdfs",
        "typeProperties": {
            "url" : "http://<machine>:50070/webhdfs/v1/",
            "authenticationType": "Anonymous",
            "userName": "hadoop"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: using Windows authentication

```
{
    "name": "HDFSLinkedService",
    "properties": {
        "type": "Hdfs",
        "typeProperties": {
            "url" : "http://<machine>:50070/webhdfs/v1/",
            "authenticationType": "Windows",
            "userName": "<username>@<domain>.com (for Kerberos auth)",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for HDFS under `location` settings in the format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property under `location` in the dataset must be set to *HdfsLocation*.	Yes
folderPath	The path to the folder. If you want to use a wildcard to filter the folder, skip this setting and specify the path in activity source settings.	No
fileName	The file name under the specified folderPath. If you want to use a wildcard to filter files, skip this setting and specify the file name in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<HDFS linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "HdfsLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties that are available for defining activities, see Pipelines and activities. This section provides a list of properties that are supported by the HDFS source.

HDFS as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for HDFS under `storeSettings` settings in the format-based Copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property under `storeSettings` must be set to **HdfsReadSettings**.	Yes
Locate the files to copy		
OPTION 1: static path	Copy from the folder or file path that's specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	

PROPERTY	DESCRIPTION	REQUIRED
OPTION 2: wildcard - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your actual folder name has a wildcard or this escape character inside. For more examples, see Folder and file filter examples.	No
OPTION 2: wildcard - wildcardFileName	The file name with wildcard characters under the specified folderPath/wildcardFolderPath to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character); use `^` to escape if your actual file name has a wildcard or this escape character inside. For more examples, see Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a specified file set. Point to a text file that includes a list of files you want to copy (one file per line, with the relative path to the path configured in the dataset). When you use this option, do not specify file name in the dataset. For more examples, see File list examples.	No
Additional settings		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When `recursive` is set to *true* and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are *true* (default) and *false*. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of *2018-12-01T05:00:00Z*. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No
DistCp settings		
distcpSettings	The property group to use when you use HDFS DistCp.	No
resourceManagerEndpoint	The YARN (Yet Another Resource Negotiator) endpoint	Yes, if using DistCp
tempScriptPath	A folder path that's used to store the temp DistCp command script. The script file is generated and will be removed after the Copy job is finished.	Yes, if using DistCp
distcpOptions	Additional options provided to DistCp command.	No

Example:

```
"activities":[
    {
        "name": "CopyFromHDFS",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "HdfsReadSettings",
                    "recursive": true,
                    "distcpSettings": {
                        "resourceManagerEndpoint": "resourcemanagerendpoint:8088",
                        "tempScriptPath": "/usr/hadoop/tempscript",
                        "distcpOptions": "-m 100"
                    }
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior if you use a wildcard filter with the folder path and file name.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the behavior that results from using a file list path in the Copy activity source. It assumes that you have the following source folder structure and want to copy the files that are in bold type:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In the dataset:** - Folder path: `root/FolderA` **In the Copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy (one file per line, with the relative path to the path configured in the dataset).

Use DistCp to copy data from HDFS

DistCp is a Hadoop native command-line tool for doing a distributed copy in a Hadoop cluster. When you run a command in DistCp, it first lists all the files to be copied and then creates several Map jobs in the Hadoop cluster. Each Map job does a binary copy from the source to the sink.

The Copy activity supports using DistCp to copy files as is into Azure Blob storage (including staged copy) or an Azure data lake store. In this case, DistCp can take advantage of your cluster's power instead of running on the self-hosted integration runtime. Using DistCp provides better copy throughput, especially if your cluster is very powerful. Based on the configuration, the Copy activity automatically constructs a DistCp command, submits it to your Hadoop cluster, and monitors the copy status.

Prerequisites

To use DistCp to copy files as is from HDFS to Azure Blob storage (including staged copy) or the Azure data lake store, make sure that your Hadoop cluster meets the following requirements:

- The MapReduce and YARN services are enabled.
- YARN version is 2.5 or later.
- The HDFS server is integrated with your target data store: **Azure Blob storage** or **Azure Data Lake Store (ADLS Gen1)**:
  - Azure Blob FileSystem is natively supported since Hadoop 2.7. You need only to specify the JAR path in the Hadoop environment configuration.
  - Azure Data Lake Store FileSystem is packaged starting from Hadoop 3.0.0-alpha1. If your Hadoop cluster version is earlier than that version, you need to manually import Azure Data Lake Store-related JAR packages (azure-datalake-store.jar) into the cluster from here, and specify the JAR file path in the Hadoop environment configuration.
- Prepare a temp folder in HDFS. This temp folder is used to store a DistCp shell script, so it will occupy KB-level space.
- Make sure that the user account that's provided in the HDFS linked service has permission to:
  - Submit an application in YARN.
  - Create a subfolder and read/write files under the temp folder.

Configurations

For DistCp-related configurations and examples, go to the HDFS as source section.

Use Kerberos authentication for the HDFS connector

There are two options for setting up the on-premises environment to use Kerberos authentication for the HDFS connector. You can choose the one that better fits your situation.

- Option 1: Join a self-hosted integration runtime machine in the Kerberos realm
- Option 2: Enable mutual trust between the Windows domain and the Kerberos realm

For either option, make sure you turn on webhdfs for Hadoop cluster:

1. Create the HTTP principal and keytab for webhdfs.

   > **IMPORTANT**
   > The HTTP Kerberos principal must start with "**HTTP/**" according to Kerberos HTTP SPNEGO specification. Learn more from here.

   ```
   Kadmin> addprinc -randkey HTTP/<namenode hostname>@<REALM.COM>
   Kadmin> ktadd -k /etc/security/keytab/spnego.service.keytab HTTP/<namenode hostname>@<REALM.COM>
   ```

2. HDFS configuration options: add the following three properties in `hdfs-site.xml`.

```
<property>
    <name>dfs.webhdfs.enabled</name>
    <value>true</value>
</property>
<property>
    <name>dfs.web.authentication.kerberos.principal</name>
    <value>HTTP/_HOST@<REALM.COM></value>
</property>
<property>
    <name>dfs.web.authentication.kerberos.keytab</name>
    <value>/etc/security/keytab/spnego.service.keytab</value>
</property>
```

Option 1: Join a self-hosted integration runtime machine in the Kerberos realm

Requirements

- The self-hosted integration runtime machine needs to join the Kerberos realm and can't join any Windows domain.

How to configure

On the KDC server:

Create a principal, and specify the password.

> **IMPORTANT**
> The username should not contain the hostname.

```
Kadmin> addprinc <username>@<REALM.COM>
```

On the self-hosted integration runtime machine:

1. Run the Ksetup utility to configure the Kerberos Key Distribution Center (KDC) server and realm.

   The machine must be configured as a member of a workgroup, because a Kerberos realm is different from a Windows domain. You can achieve this configuration by setting the Kerberos realm and adding a KDC server by running the following commands. Replace *REALM.COM* with your own realm name.

   ```
   C:> Ksetup /setdomain REALM.COM
   C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
   ```

   After you run these commands, restart the machine.

2. Verify the configuration with the `Ksetup` command. The output should be like:

   ```
   C:> Ksetup
   default realm = REALM.COM (external)
   REALM.com:
       kdc = <your_kdc_server_address>
   ```

In your data factory or Synapse workspace:

- Configure the HDFS connector by using Windows authentication together with your Kerberos principal name and password to connect to the HDFS data source. For configuration details, check the HDFS linked service properties section.

Option 2: Enable mutual trust between the Windows domain and the Kerberos realm

Requirements

- The self-hosted integration runtime machine must join a Windows domain.
- You need permission to update the domain controller's settings.

How to configure

> **NOTE**
> Replace REALM.COM and AD.COM in the following tutorial with your own realm name and domain controller.

On the KDC server:

1. Edit the KDC configuration in the *krb5.conf* file to let KDC trust the Windows domain by referring to the following configuration template. By default, the configuration is located at */etc/krb5.conf*.

```
[logging]
 default = FILE:/var/log/krb5libs.log
 kdc = FILE:/var/log/krb5kdc.log
 admin_server = FILE:/var/log/kadmind.log

[libdefaults]
 default_realm = REALM.COM
 dns_lookup_realm = false
 dns_lookup_kdc = false
 ticket_lifetime = 24h
 renew_lifetime = 7d
 forwardable = true

[realms]
 REALM.COM = {
  kdc = node.REALM.COM
  admin_server = node.REALM.COM
 }
AD.COM = {
 kdc = windc.ad.com
 admin_server = windc.ad.com
}

[domain_realm]
 .REALM.COM = REALM.COM
 REALM.COM = REALM.COM
 .ad.com = AD.COM
 ad.com = AD.COM

[capaths]
 AD.COM = {
  REALM.COM = .
 }
```

   After you configure the file, restart the KDC service.

2. Prepare a principal named *krbtgt/REALM.COM@AD.COM* in the KDC server with the following command:

```
Kadmin> addprinc krbtgt/REALM.COM@AD.COM
```

3. In the *hadoop.security.auth_to_local* HDFS service configuration file, add `RULE:[1:$1@$0](.*\@AD.COM)s/\@.*//`.

On the domain controller:

1. Run the following `Ksetup` commands to add a realm entry:

```
C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
C:> ksetup /addhosttorealmmap HDFS-service-FQDN REALM.COM
```

2. Establish trust from the Windows domain to the Kerberos realm. [password] is the password for the principal *krbtgt/REALM.COM@AD.COM*.

```
C:> netdom trust REALM.COM /Domain: AD.COM /add /realm /password:[password]
```

3. Select the encryption algorithm that's used in Kerberos.

   a. Select **Server Manager** > **Group Policy Management** > **Domain** > **Group Policy Objects** > **Default or Active Domain Policy**, and then select **Edit**.

   b. On the **Group Policy Management Editor** pane, select **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Local Policies** > **Security Options**, and then configure **Network security: Configure Encryption types allowed for Kerberos**.

   c. Select the encryption algorithm you want to use when you connect to the KDC server. You can select all the options.

   d. Use the `Ksetup` command to specify the encryption algorithm to be used on the specified realm.

```
C:> ksetup /SetEncTypeAttr REALM.COM DES-CBC-CRC DES-CBC-MD5 RC4-HMAC-MD5 AES128-CTS-HMAC-SHA1-96
AES256-CTS-HMAC-SHA1-96
```

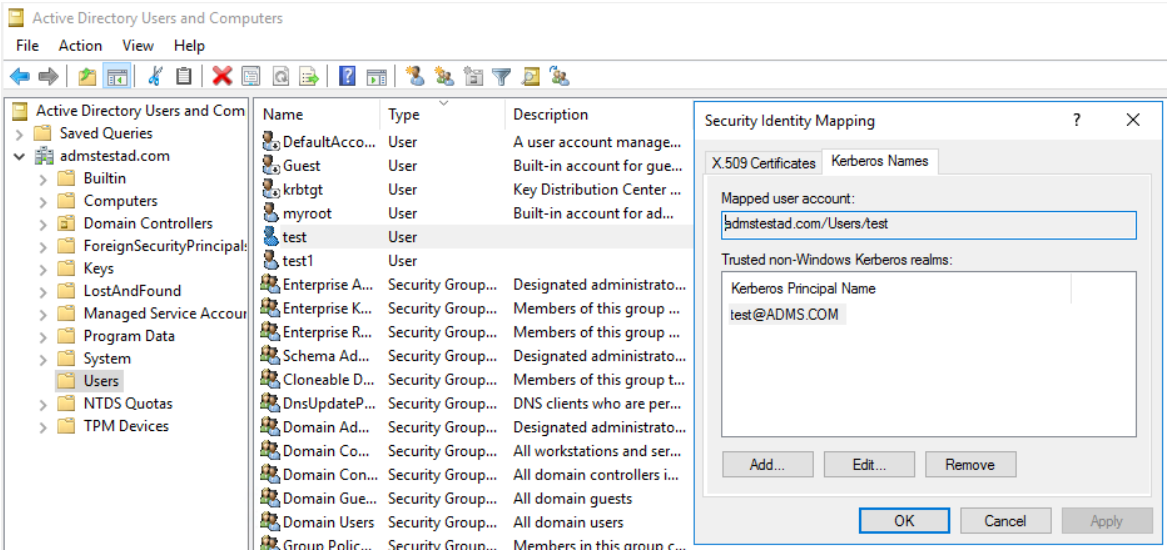
4. Create the mapping between the domain account and the Kerberos principal, so that you can use the Kerberos principal in the Windows domain.

   a. Select **Administrative tools** > **Active Directory Users and Computers**.

   b. Configure advanced features by selecting **View** > **Advanced Features**.

   c. On the **Advanced Features** pane, right-click the account to which you want to create mappings and, on the **Name Mappings** pane, select the **Kerberos Names** tab.

   d. Add a principal from the realm.



On the self-hosted integration runtime machine:

- Run the following `Ksetup` commands to add a realm entry.

```
C:> Ksetup /addkdc REALM.COM <your_kdc_server_address>
C:> ksetup /addhosttorealmmap HDFS-service-FQDN REALM.COM
```

In your data factory or Synapse workspace:

- Configure the HDFS connector by using Windows authentication together with either your domain account or Kerberos principal to connect to the HDFS data source. For configuration details, see the HDFS linked service properties section.

Lookup activity properties

For information about Lookup activity properties, see Lookup activity.

Delete activity properties

For information about Delete activity properties, see Delete activity.

Legacy models

> **NOTE**
> The following models are still supported as is for backward compatibility. We recommend that you use the previously discussed new model, because the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property of the dataset must be set to *FileShare*	Yes

PROPERTY	DESCRIPTION	REQUIRED
folderPath	The path to the folder. A wildcard filter is supported. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character); use `^` to escape if your actual file name has a wildcard or this escape character inside. Examples: rootfolder/subfolder/, see more examples in Folder and file filter examples.	Yes
fileName	The name or wildcard filter for the files under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual folder name has a wildcard or this escape character inside.	No
modifiedDatetimeStart	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format *2018-12-01T05:00:00Z*. Be aware that the overall performance of data movement will be affected by enabling this setting when you want to apply a file filter to large numbers of files. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeEnd	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format *2018-12-01T05:00:00Z*. Be aware that the overall performance of data movement will be affected by enabling this setting when you want to apply a file filter to large numbers of files. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected.	No
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both the input and output dataset definitions. If you want to parse files with a specific format, the following file format types are supported: *TextFormat*, *JsonFormat*, *AvroFormat*, *OrcFormat*, *ParquetFormat*. Set the *type* property under format to one of these values. For more information, see the Text format, JSON format, Avro format, ORC format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are: *Gzip*, *Deflate*, *Bzip2*, and *ZipDeflate*. Supported levels are: *Optimal* and *Fastest*.	No

TIP

To copy all files under a folder, specify **folderPath** only.
To copy a single file with a specified name, specify **folderPath** with folder part and **fileName** with file name.
To copy a subset of files under a folder, specify **folderPath** with folder part and **fileName** with wildcard filter.

Example:

```
{
    "name": "HDFSDataset",
    "properties": {
        "type": "FileShare",
        "linkedServiceName":{
            "referenceName": "<HDFS linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "folder/subfolder/",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy Copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property of the Copy activity source must be set to *HdfsSource*.	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When recursive is set to *true* and the sink is a file-based store, an empty folder or subfolder will not be copied or created at the sink. Allowed values are *true* (default) and *false*.	No
distcpSettings	The property group when you're using HDFS DistCp.	No
resourceManagerEndpoint	The YARN Resource Manager endpoint	Yes, if using DistCp

PROPERTY	DESCRIPTION	REQUIRED
tempScriptPath	A folder path that's used to store the temp DistCp command script. The script file is generated and will be removed after the Copy job is finished.	Yes, if using DistCp
distcpOptions	Additional options are provided to DistCp command.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example: HDFS source in Copy activity using DistCp

```
"source": {
    "type": "HdfsSource",
    "distcpSettings": {
        "resourceManagerEndpoint": "resourcemanagerendpoint:8088",
        "tempScriptPath": "/usr/hadoop/tempscript",
        "distcpOptions": "-m 100"
    }
}
```

Next steps

For a list of data stores that are supported as sources and sinks by the Copy activity, see supported data stores.

Copy and transform data from Hive using Azure Data Factory

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Hive. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Hive connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Mapping data flow (source/-)	①
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

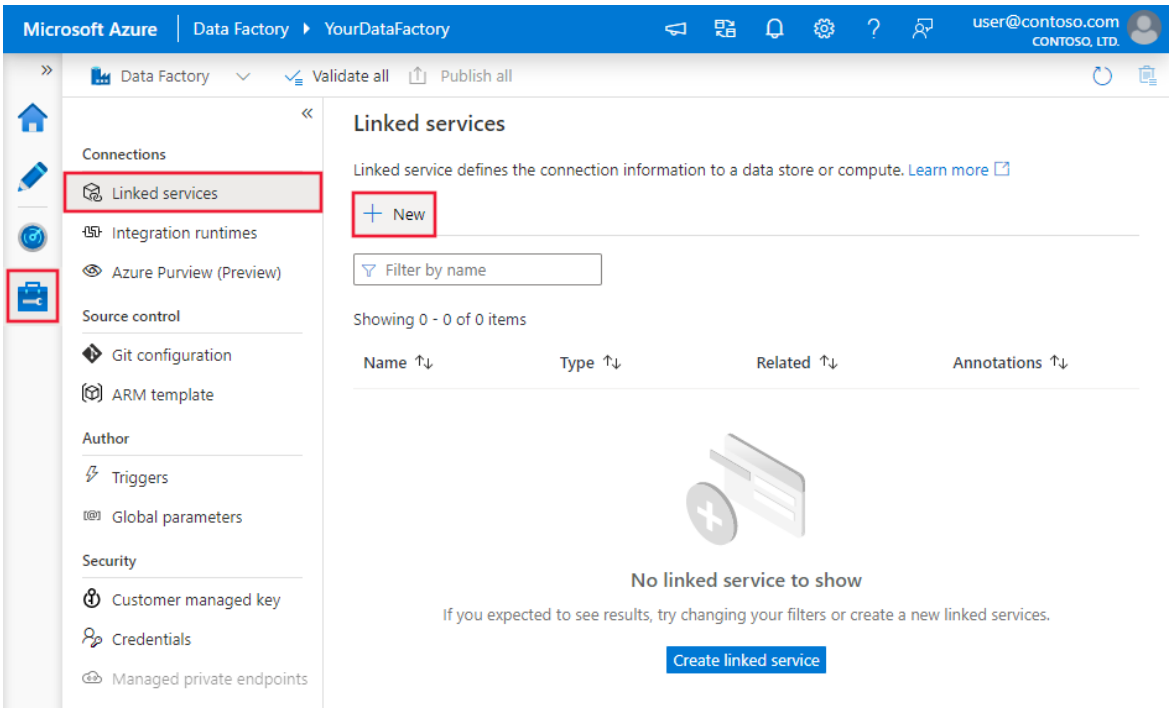
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Hive using UI

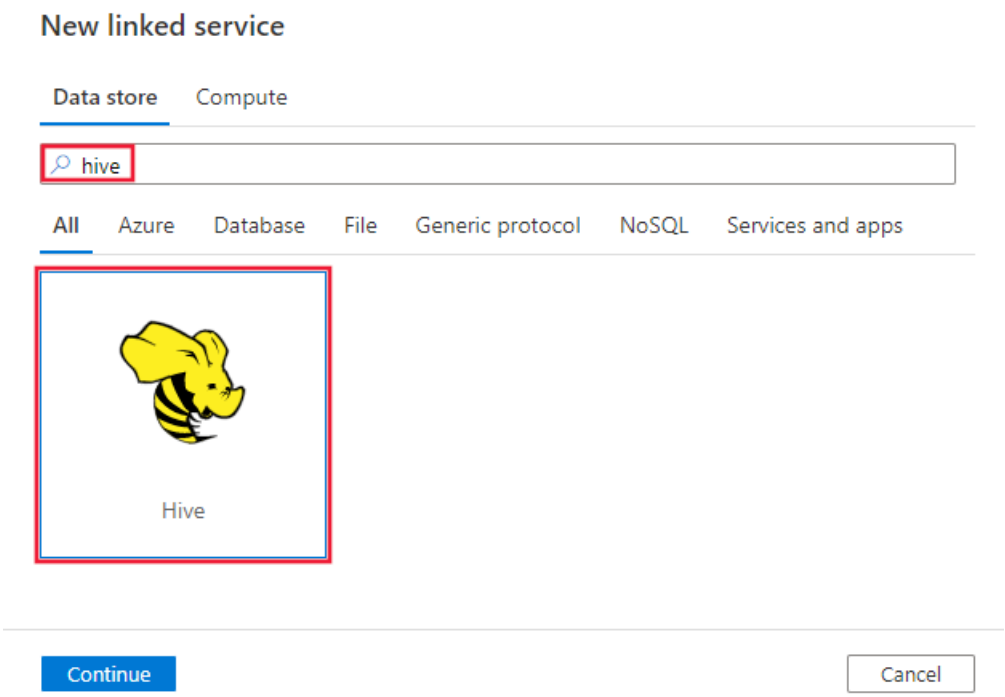
Use the following steps to create a linked service to Hive in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

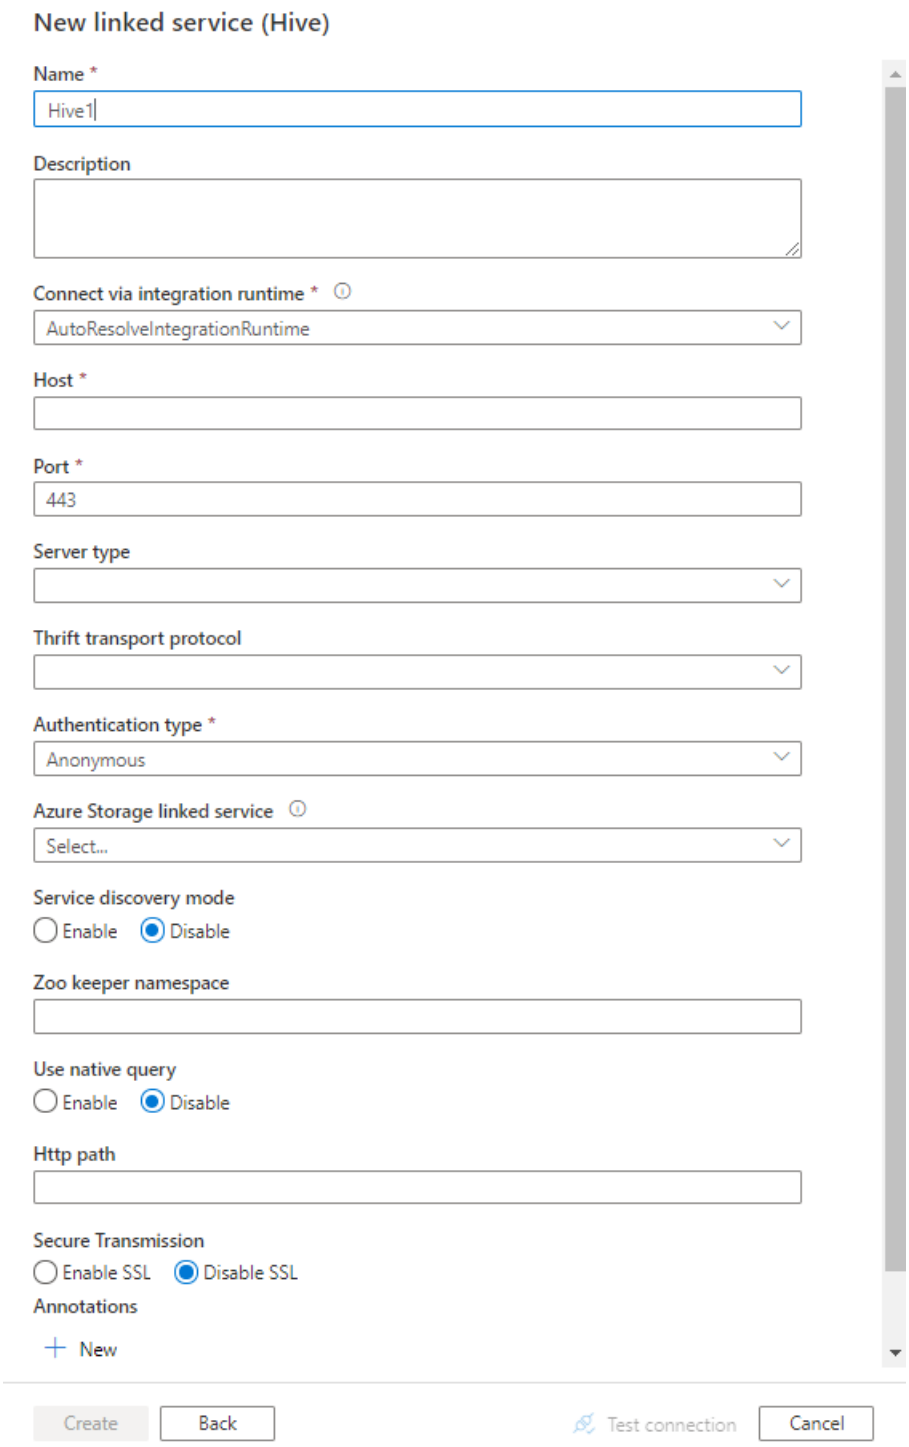
   - Azure Data Factory
   - Azure Synapse



2. Search for Hive and select the Hive connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Hive connector.

Linked service properties

The following properties are supported for Hive linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Hive**	Yes

PROPERTY	DESCRIPTION	REQUIRED
host	IP address or host name of the Hive server, separated by ';' for multiple hosts (only when serviceDiscoveryMode is enabled).	Yes
port	The TCP port that the Hive server uses to listen for client connections. If you connect to Azure HDInsight, specify port as 443.	Yes
serverType	The type of Hive server. Allowed values are: **HiveServer1**, **HiveServer2**, **HiveThriftServer**	No
thriftTransportProtocol	The transport protocol to use in the Thrift layer. Allowed values are: **Binary**, **SASL**, **HTTP**	No
authenticationType	The authentication method used to access the Hive server. Allowed values are: **Anonymous**, **Username**, **UsernameAndPassword**, **WindowsAzureHDInsightService**. Kerberos authentication is not supported now.	Yes
serviceDiscoveryMode	true to indicate using the ZooKeeper service, false not.	No
zooKeeperNameSpace	The namespace on ZooKeeper under which Hive Server 2 nodes are added.	No
useNativeQuery	Specifies whether the driver uses native HiveQL queries, or converts them into an equivalent form in HiveQL.	No
username	The user name that you use to access Hive Server.	No
password	The password corresponding to the user. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
httpPath	The partial URL corresponding to the Hive server.	No
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No

PROPERTY	DESCRIPTION	REQUIRED
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is false.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when connecting over TLS. The default value is false.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No
storageReference	A reference to the linked service of the storage account used for staging data in mapping data flow. This is required only when using the Hive linked service in mapping data flow	No

Example:

```
{
    "name": "HiveLinkedService",
    "properties": {
        "type": "Hive",
        "typeProperties": {
            "host" : "<cluster>.azurehdinsight.net",
            "port" : "<port>",
            "authenticationType" : "WindowsAzureHDInsightService",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section

provides a list of properties supported by Hive dataset.

To copy data from Hive, set the type property of the dataset to **HiveObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **HiveObject**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table including schema part. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No (if "query" in activity source is specified)

Example

```
{
    "name": "HiveDataset",
    "properties": {
        "type": "HiveObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Hive linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Hive source.

HiveSource as source

To copy data from Hive, set the source type in the copy activity to **HiveSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **HiveSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromHive",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Hive input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "HiveSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Mapping data flow properties

The hive connector is supported as an inline dataset source in mapping data flows. Read using a query or directly from a Hive table in HDInsight. Hive data gets staged in a storage account as parquet files before getting transformed as part of a data flow.

Source properties

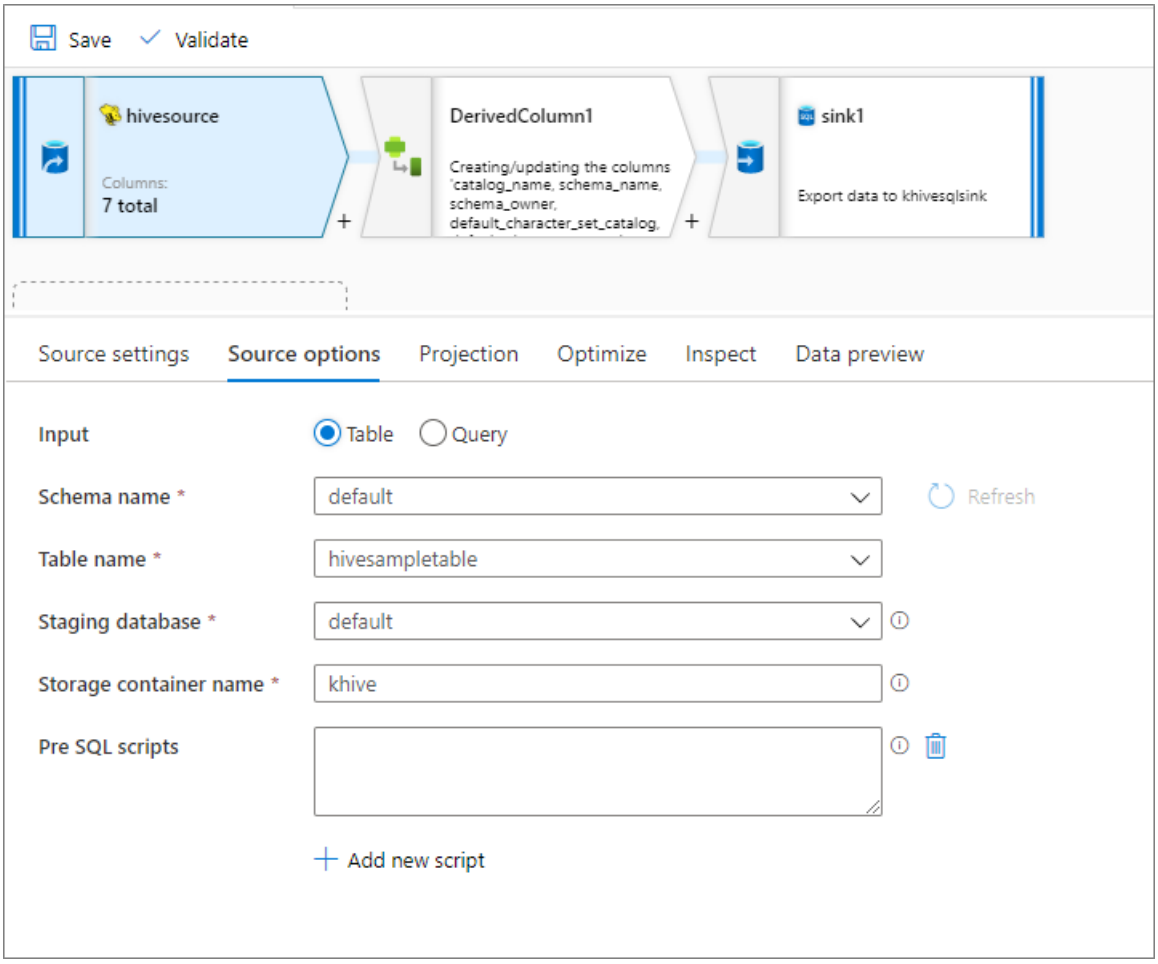
The below table lists the properties supported by a hive source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Store	Store must be `hive`	yes	`hive`	store
Format	Whether you are reading from a table or query	yes	`table` or `query`	format
Schema name	If reading from a table, the schema of the source table	yes, if format is `table`	String	schemaName
Table name	If reading from a table, the table name	yes, if format is `table`	String	tableName
Query	If format is `query`, the source query on the Hive linked service	yes, if format is `query`	String	query

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Staged	Hive table will always be staged.	yes	`true`	staged
Storage Container	Storage container used to stage data before reading from Hive or writing to Hive. The hive cluster must have access to this container.	yes	String	storageContainer
Staging database	The schema/database where the user account specified in the linked service has access to. It is used to create external tables during staging and dropped afterwards	no	`true` or `false`	stagingDatabaseName
Pre SQL Scripts	SQL code to run on the Hive table before reading the data	no	String	preSQLs

Source example

Below is an example of a Hive source configuration:



These settings translate into the following data flow script:

```
source(
    allowSchemaDrift: true,
    validateSchema: false,
    ignoreNoFilesFound: false,
    format: 'table',
    store: 'hive',
    schemaName: 'default',
    tableName: 'hivesampletable',
    staged: true,
    storageContainer: 'khive',
    storageFolderPath: '',
    stagingDatabaseName: 'default') ~> hivesource
```

Known limitations

- Complex types such as arrays, maps, structs, and unions are not supported for read.
- Hive connector only supports Hive tables in Azure HDInsight of version 4.0 or greater (Apache Hive 3.1.0)

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from an HTTP endpoint by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Azure Synapse to copy data from an HTTP endpoint. The article builds on Copy Activity, which presents a general overview of Copy Activity.

The difference among this HTTP connector, the REST connector and the Web table connector are:

- **REST connector** specifically support copying data from RESTful APIs;
- **HTTP connector** is generic to retrieve data from any HTTP endpoint, e.g. to download file. Before REST connector becomes available, you may happen to use the HTTP connector to copy data from RESTful APIs, which is supported but less functional comparing to REST connector.
- **Web table connector** extracts table content from an HTML webpage.

Supported capabilities

This HTTP connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see Supported data stores.

You can use this HTTP connector to:

- Retrieve data from an HTTP/S endpoint by using the HTTP **GET** or **POST** methods.
- Retrieve data by using one of the following authentications: **Anonymous**, **Basic**, **Digest**, **Windows**, or **ClientCertificate**.
- Copy the HTTP response as-is or parse it by using supported file formats and compression codecs.

> **TIP**
> To test an HTTP request for data retrieval before you configure the HTTP connector, learn about the API specification for header and body requirements. You can use tools like Postman or a web browser to validate.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow

list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

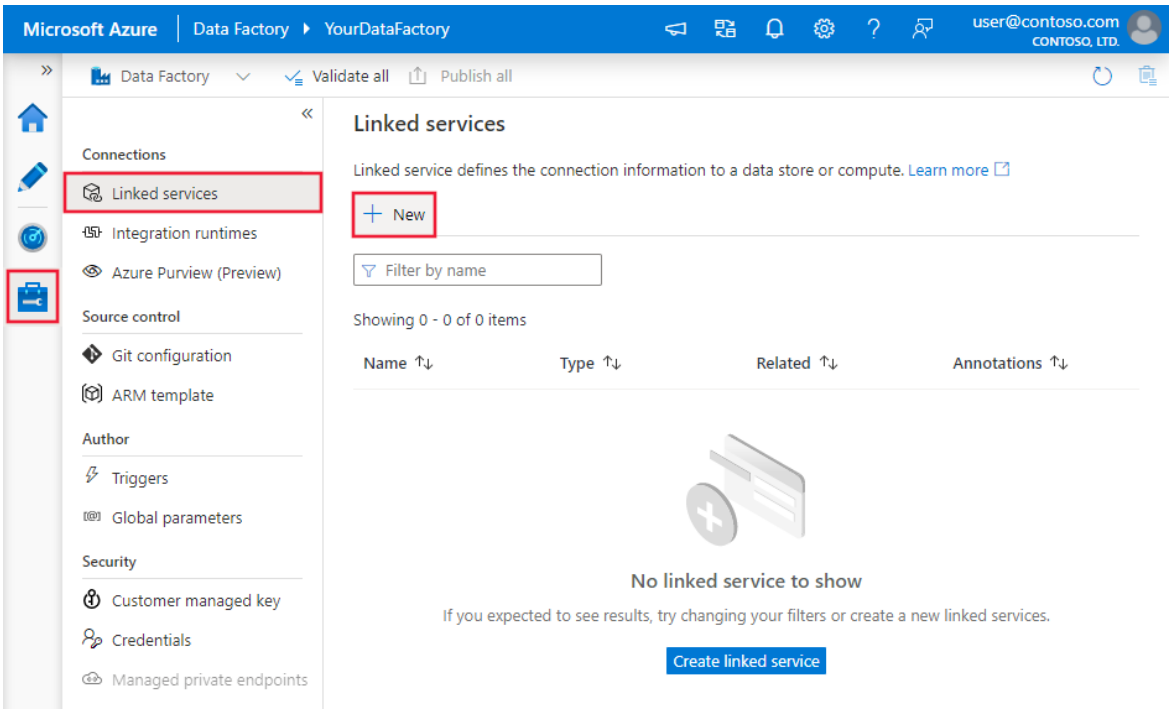
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an HTTP source using UI

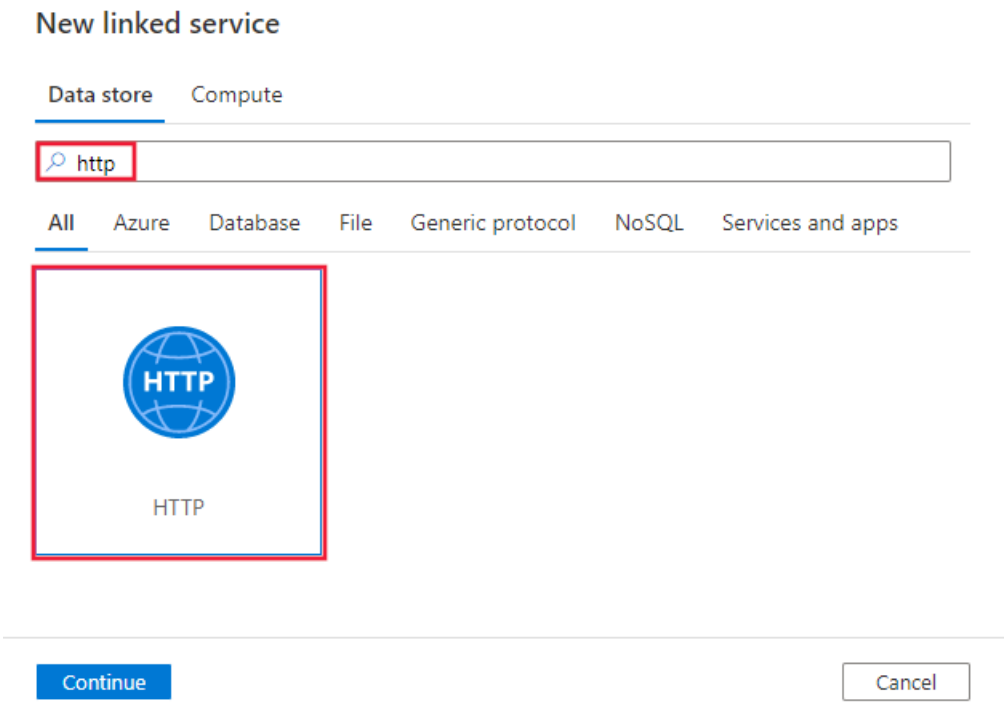
Use the following steps to create a linked service to an HTTP source in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

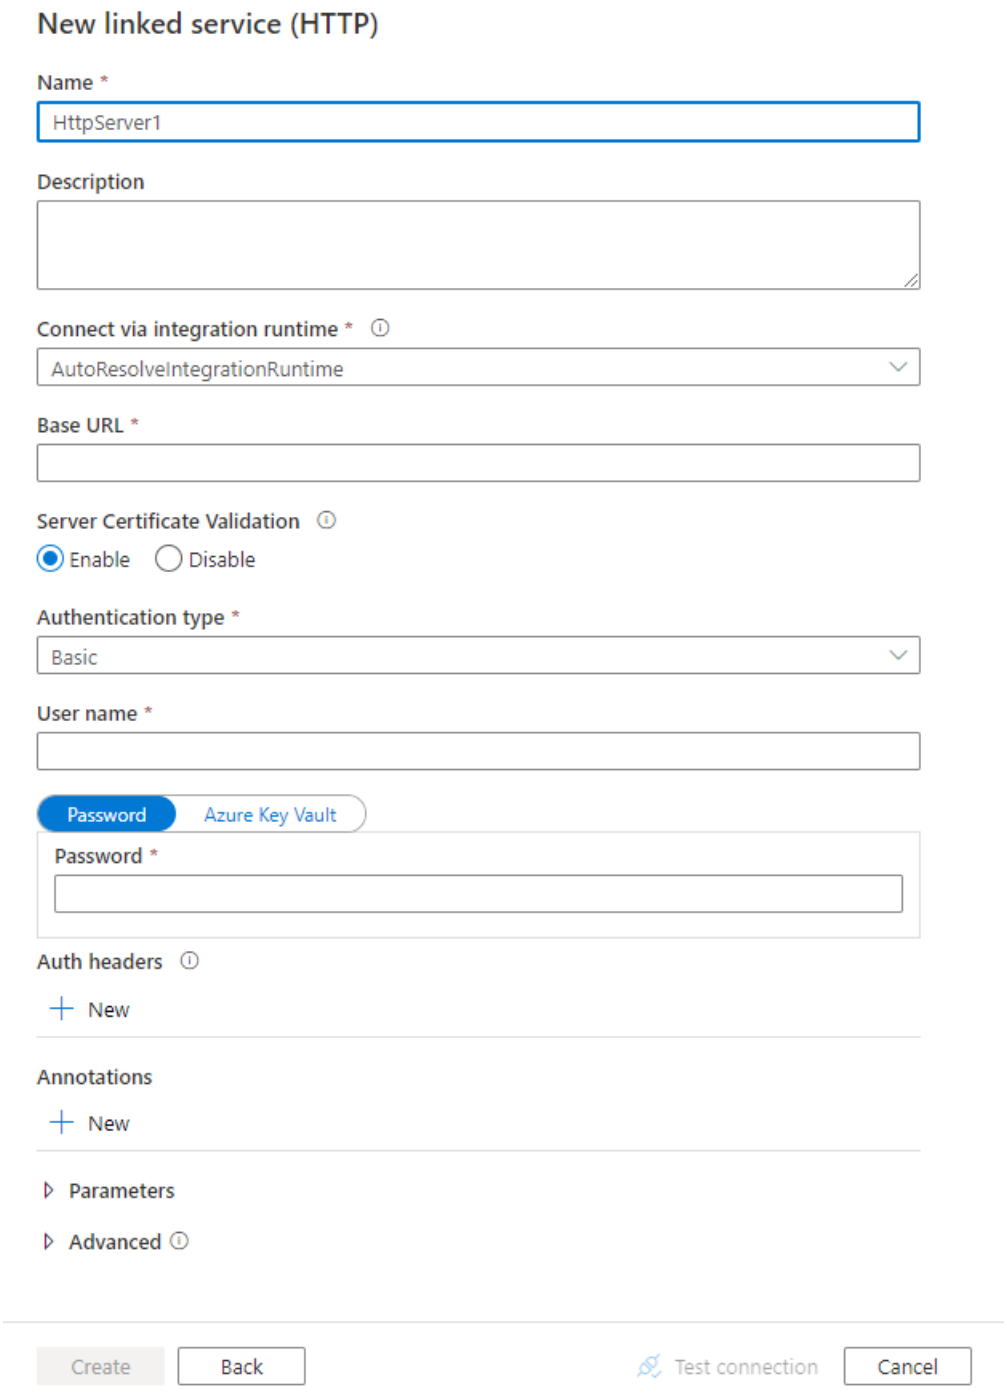
   - Azure Data Factory
   - Azure Synapse



2. Search for HTTP and select the HTTP connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define entities that are specific to the HTTP connector.

Linked service properties

The following properties are supported for the HTTP linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **HttpServer**.	Yes
url	The base URL to the web server.	Yes

PROPERTY	DESCRIPTION	REQUIRED
enableServerCertificateValidation	Specify whether to enable server TLS/SSL certificate validation when you connect to an HTTP endpoint. If your HTTPS server uses a self-signed certificate, set this property to **false**.	No (the default is **true**)
authenticationType	Specifies the authentication type. Allowed values are **Anonymous**, **Basic**, **Digest**, **Windows**, and **ClientCertificate**. You can additionally configure authentication headers in `authHeader` property. See the sections that follow this table for more properties and JSON samples for these authentication types.	Yes
authHeaders	Additional HTTP request headers for authentication. For example, to use API key authentication, you can select authentication type as "Anonymous" and specify API key in the header.	No
connectVia	The Integration Runtime to use to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure Integration Runtime is used.	No

Using Basic, Digest, or Windows authentication

Set the **authenticationType** property to **Basic**, **Digest**, or **Windows**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user name to use to access the HTTP endpoint.	Yes
password	The password for the user (the **userName** value). Mark this field as a **SecureString** type to store it securely. You can also reference a secret stored in Azure Key Vault.	Yes

Example

```
{
    "name": "HttpLinkedService",
    "properties": {
        "type": "HttpServer",
        "typeProperties": {
            "authenticationType": "Basic",
            "url" : "<HTTP endpoint>",
            "userName": "<user name>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Using ClientCertificate authentication

To use ClientCertificate authentication, set the **authenticationType** property to **ClientCertificate**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
embeddedCertData	Base64-encoded certificate data.	Specify either **embeddedCertData** or **certThumbprint**.
certThumbprint	The thumbprint of the certificate that's installed on your self-hosted Integration Runtime machine's cert store. Applies only when the self-hosted type of Integration Runtime is specified in the **connectVia** property.	Specify either **embeddedCertData** or **certThumbprint**.
password	The password that's associated with the certificate. Mark this field as a **SecureString** type to store it securely. You can also reference a secret stored in Azure Key Vault.	No

If you use **certThumbprint** for authentication and the certificate is installed in the personal store of the local computer, grant read permissions to the self-hosted Integration Runtime:

1. Open the Microsoft Management Console (MMC). Add the **Certificates** snap-in that targets **Local Computer**.
2. Expand **Certificates** > **Personal**, and then select **Certificates**.
3. Right-click the certificate from the personal store, and then select **All Tasks** > **Manage Private Keys**.
4. On the **Security** tab, add the user account under which the Integration Runtime Host Service (DIAHostService) is running, with read access to the certificate.
5. The HTTP connector loads only trusted certificates. If you're using a self-signed or nonintegrated CA-issued certificate, to enable trust, the certificate must also be installed in one of the following stores:
   - Trusted People
   - Third-Party Root Certification Authorities
   - Trusted Root Certification Authorities

Example 1: Using certThumbprint

```
{
    "name": "HttpLinkedService",
    "properties": {
        "type": "HttpServer",
        "typeProperties": {
            "authenticationType": "ClientCertificate",
            "url": "<HTTP endpoint>",
            "certThumbprint": "<thumbprint of certificate>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: Using embeddedCertData

```
{
    "name": "HttpLinkedService",
    "properties": {
        "type": "HttpServer",
        "typeProperties": {
            "authenticationType": "ClientCertificate",
            "url": "<HTTP endpoint>",
            "embeddedCertData": "<Base64-encoded cert data>",
            "password": {
                "type": "SecureString",
                "value": "password of cert"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Using authentication headers

In addition, you can configure request headers for authentication along with the built-in authentication types.

Example: Using API key authentication

```
{
    "name": "HttpLinkedService",
    "properties": {
        "type": "HttpServer",
        "typeProperties": {
            "url": "<HTTP endpoint>",
            "authenticationType": "Anonymous",
            "authHeader": {
                "x-api-key": {
                    "type": "SecureString",
                    "value": "<API key>"
                }
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for HTTP under `location` settings in format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `location` in dataset must be set to **HttpServerLocation**.	Yes
relativeUrl	A relative URL to the resource that contains the data. The HTTP connector copies data from the combined URL: `[URL specified in linked service][relative URL specified in dataset]` .	No

NOTE

The supported HTTP request payload size is around 500 KB. If the payload size you want to pass to your web endpoint is larger than 500 KB, consider batching the payload in smaller chunks.

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<HTTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "HttpServerLocation",
                "relativeUrl": "<relative url>"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties that the HTTP source supports.

For a full list of sections and properties that are available for defining activities, see Pipelines.

HTTP as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for HTTP under `storeSettings` settings in format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property under `storeSettings` must be set to **HttpReadSettings**.	Yes
requestMethod	The HTTP method. Allowed values are **Get** (default) and **Post**.	No
additionalHeaders	Additional HTTP request headers.	No
requestBody	The body for the HTTP request.	No

PROPERTY	DESCRIPTION	REQUIRED
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. The default value is **00:01:40**.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromHTTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "HttpReadSettings",
                    "requestMethod": "Post",
                    "additionalHeaders": "<header key: header value>\n<header key: header value>\n",
                    "requestBody": "<body for POST HTTP request>"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Legacy models

> **NOTE**
>
> The following models are still supported as-is for backward compatibility. You are suggested to use the new model mentioned in above sections going forward, and the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **HttpFile**.	Yes
relativeUrl	A relative URL to the resource that contains the data. When this property isn't specified, only the URL that's specified in the linked service definition is used.	No
requestMethod	The HTTP method. Allowed values are **Get** (default) and **Post**.	No
additionalHeaders	Additional HTTP request headers.	No
requestBody	The body for the HTTP request.	No
format	If you want to retrieve data from the HTTP endpoint as-is without parsing it, and then copy the data to a file-based store, skip the **format** section in both the input and output dataset definitions. If you want to parse the HTTP response content during copy, the following file format types are supported: **TextFormat**, **JsonFormat**, **AvroFormat**, **OrcFormat**, and **ParquetFormat**. Under **format**, set the **type** property to one of these values. For more information, see JSON format, Text format, Avro format, Orc format, and Parquet format.	No
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types: **GZip**, **Deflate**, **BZip2**, and **ZipDeflate**. Supported levels: **Optimal** and **Fastest**.	No

> **NOTE**
>
> The supported HTTP request payload size is around 500 KB. If the payload size you want to pass to your web endpoint is larger than 500 KB, consider batching the payload in smaller chunks.

Example 1: Using the Get method (default)

```
{
    "name": "HttpSourceDataInput",
    "properties": {
        "type": "HttpFile",
        "linkedServiceName": {
            "referenceName": "<HTTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "relativeUrl": "<relative url>",
            "additionalHeaders": "Connection: keep-alive\nUser-Agent: Mozilla/5.0\n"
        }
    }
}
```

Example 2: Using the Post method

```
{
    "name": "HttpSourceDataInput",
    "properties": {
        "type": "HttpFile",
        "linkedServiceName": {
            "referenceName": "<HTTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "relativeUrl": "<relative url>",
            "requestMethod": "Post",
            "requestBody": "<body for POST HTTP request>"
        }
    }
}
```

Legacy copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **HttpSource**.	Yes
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. The default value is **00:01:40**.	No

Example

```
"activities":[
    {
        "name": "CopyFromHTTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<HTTP input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "HttpSource",
                "httpRequestTimeout": "00:01:00"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Copy data from HubSpot using Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from HubSpot. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This HubSpot connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks , see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

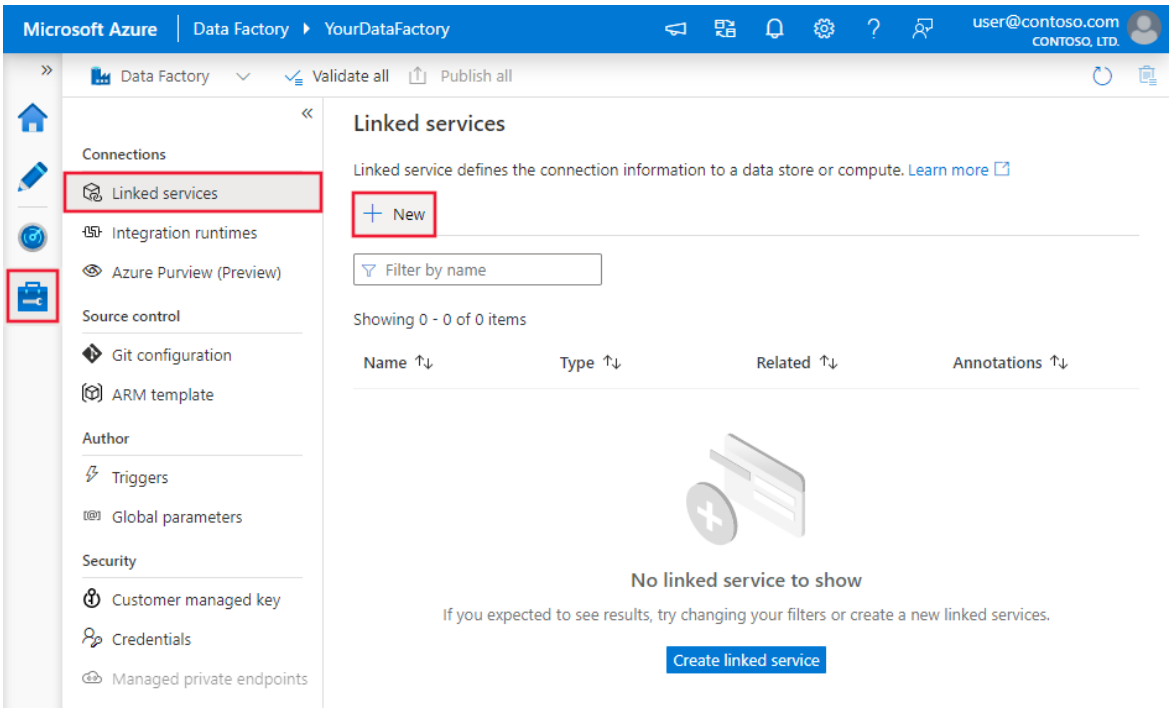
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to HubSpot using UI

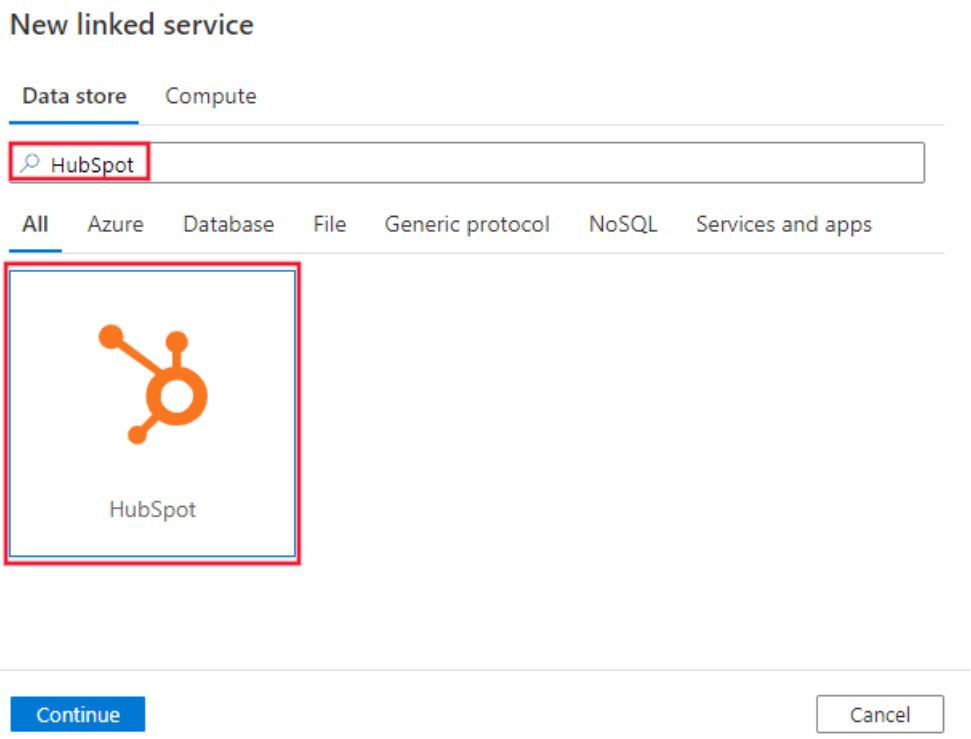
Use the following steps to create a linked service to HubSpot in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

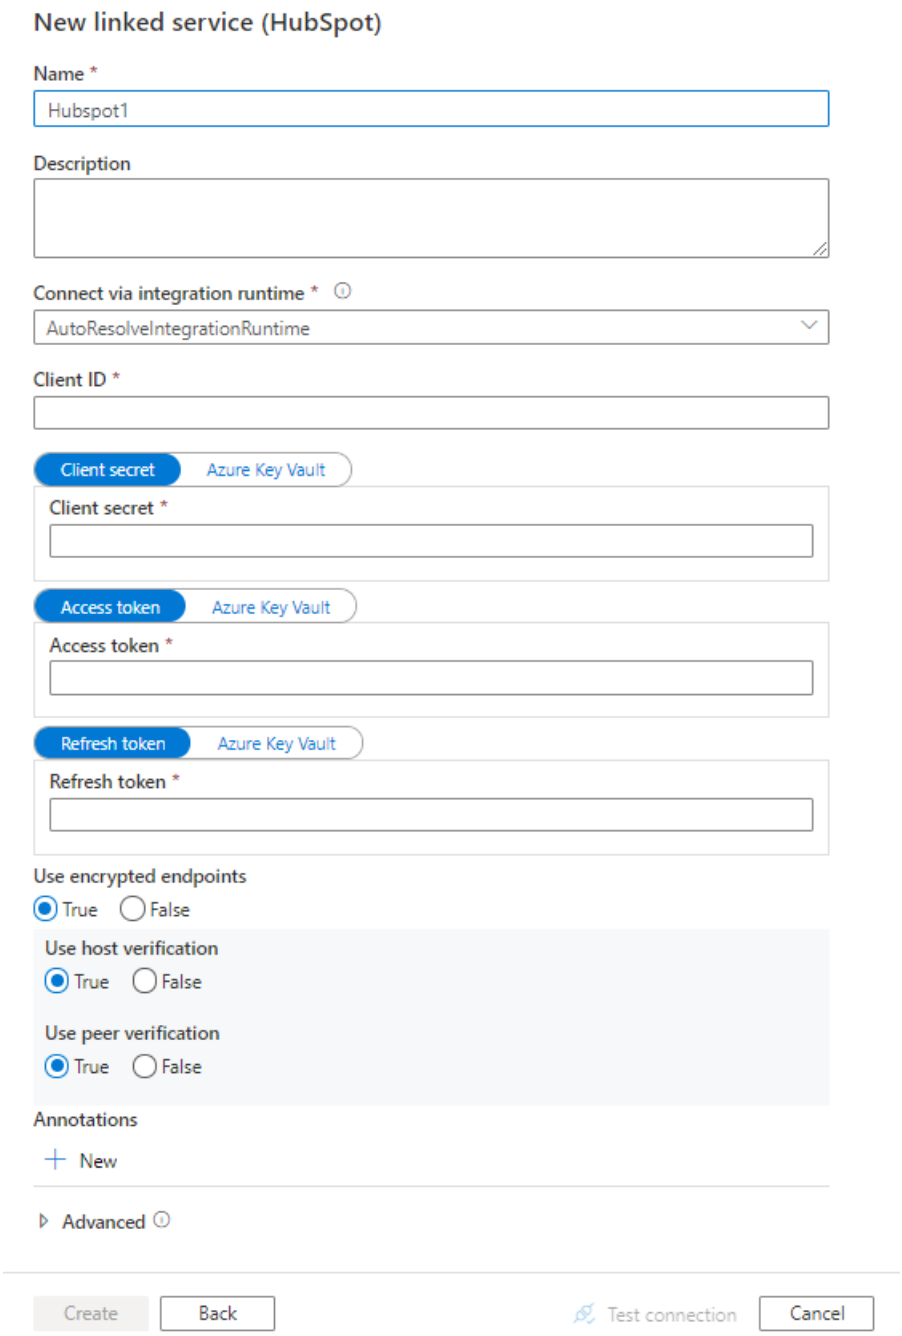
   - Azure Data Factory
   - Azure Synapse



2. Search for HubSpot and select the HubSpot connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to HubSpot connector.

Linked service properties

The following properties are supported for HubSpot linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Hubspot**	Yes
clientId	The client ID associated with your HubSpot application. Learn how to create an app in HubSpot from here.	Yes

PROPERTY	DESCRIPTION	REQUIRED
clientSecret	The client secret associated with your HubSpot application. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
accessToken	The access token obtained when initially authenticating your OAuth integration. Learn how to get access token with your client ID and secret from here. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
refreshToken	The refresh token obtained when initially authenticating your OAuth integration. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "HubSpotLinkedService",
    "properties": {
        "type": "Hubspot",
        "typeProperties": {
            "clientId" : "<clientId>",
            "clientSecret": {
                "type": "SecureString",
                "value": "<clientSecret>"
            },
            "accessToken": {
                "type": "SecureString",
                "value": "<accessToken>"
            },
            "refreshToken": {
                "type": "SecureString",
                "value": "<refreshToken>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by HubSpot dataset.

To copy data from HubSpot, set the type property of the dataset to **HubspotObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **HubspotObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "HubSpotDataset",
    "properties": {
        "type": "HubspotObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<HubSpot linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by HubSpot source.

HubspotSource as source

To copy data from HubSpot, set the source type in the copy activity to **HubspotSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **HubspotSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Companies where Company_Id = xxx"` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromHubspot",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<HubSpot input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "HubspotSource",
                "query": "SELECT * FROM Companies where Company_Id = xxx"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Impala using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Impala. It builds on the Copy Activity overview article that presents a general overview of the copy activity.

Supported capabilities

This Impala connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity. Therefore, you don't need to manually install a driver to use this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK

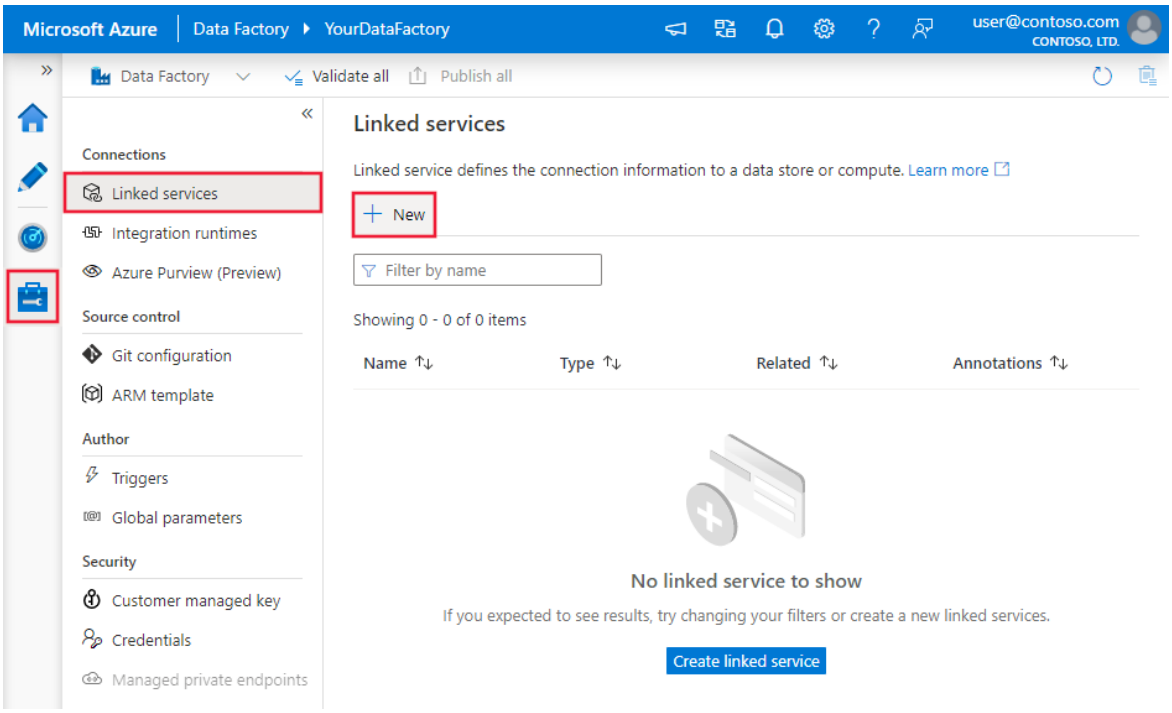
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Impala using UI

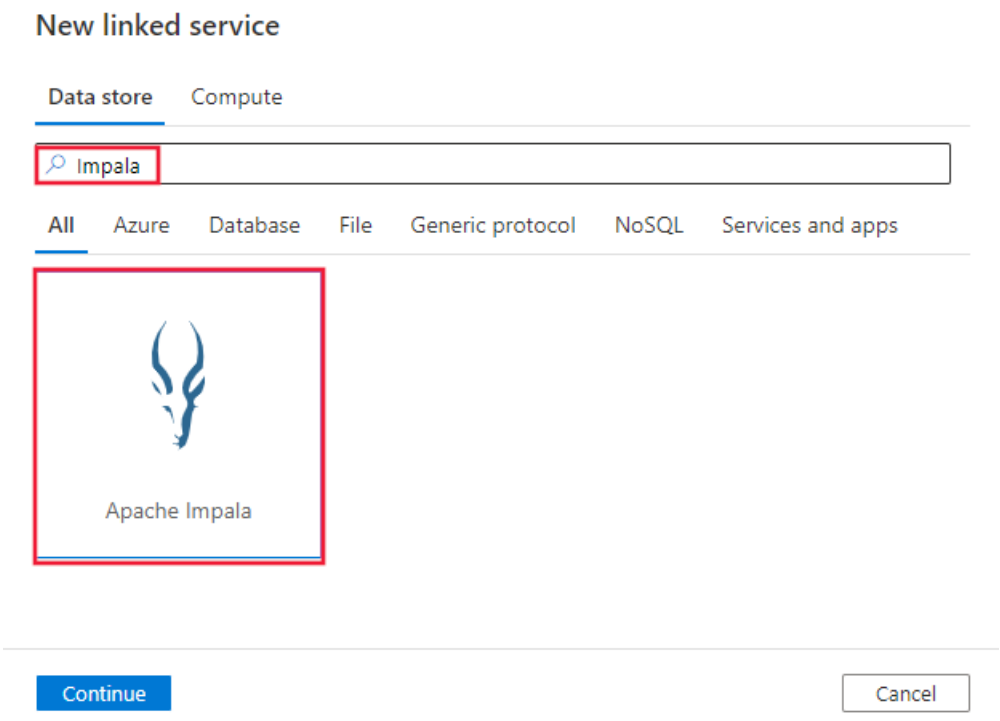
Use the following steps to create a linked service to Impala in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

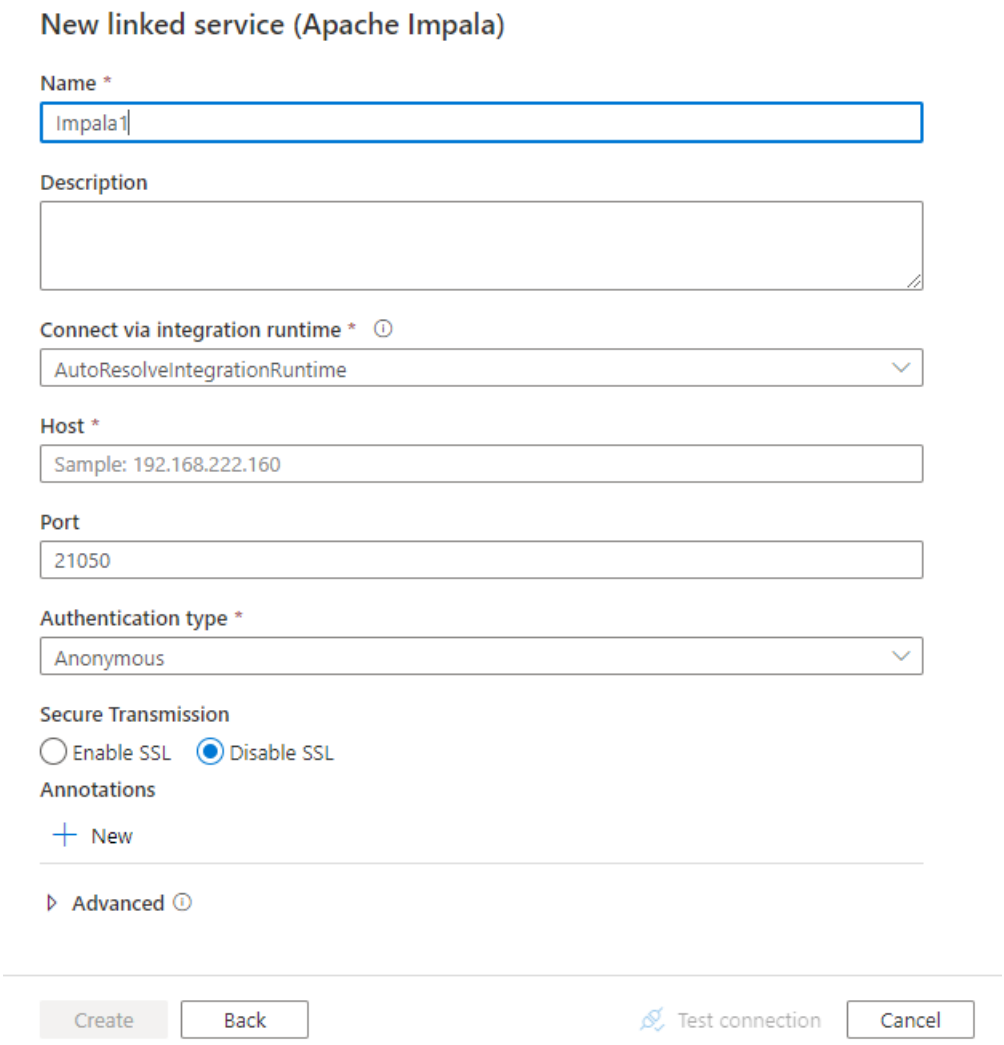
   - Azure Data Factory
   - Azure Synapse



2. Search for Impala and select the Impala connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to the Impala connector.

Linked service properties

The following properties are supported for Impala linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Impala**.	Yes
host	The IP address or host name of the Impala server (that is, 192.168.222.160).	Yes
port	The TCP port that the Impala server uses to listen for client connections. The default value is 21050.	No

PROPERTY	DESCRIPTION	REQUIRED
authenticationType	The authentication type to use. Allowed values are **Anonymous**, **SASLUsername**, and **UsernameAndPassword**.	Yes
username	The user name used to access the Impala server. The default value is anonymous when you use SASLUsername.	No
password	The password that corresponds to the user name when you use UsernameAndPassword. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
enableSsl	Specifies whether the connections to the server are encrypted by using TLS. The default value is **false**.	No
trustedCertPath	The full path of the .pem file that contains trusted CA certificates used to verify the server when you connect over TLS. This property can be set only when you use TLS on Self-hosted Integration Runtime. The default value is the cacerts.pem file installed with the integration runtime.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is **false**.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when you connect over TLS. The default value is **false**.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is **false**.	No
connectVia	The integration runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "ImpalaLinkedService",
    "properties": {
        "type": "Impala",
        "typeProperties": {
            "host" : "<host>",
            "port" : "<port>",
            "authenticationType" : "UsernameAndPassword",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Impala dataset.

To copy data from Impala, set the type property of the dataset to **ImpalaObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ImpalaObject**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "ImpalaDataset",
    "properties": {
        "type": "ImpalaObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Impala linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Impala source type.

Impala as a source type

To copy data from Impala, set the source type in the copy activity to **ImpalaSource**. The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **ImpalaSource**.	Yes
query	Use the custom SQL query to read data. An example is `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromImpala",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Impala input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ImpalaSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from and to IBM Informix using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from an IBM Informix data store. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Informix connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Prerequisites

To use this Informix connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Download the 64-bit Client SDK for Informix to create an ODBC connection for the data store on the Integration Runtime machine. For SDK download and setup, refer this article for details, or contact IBM support team for driver installation guidance.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

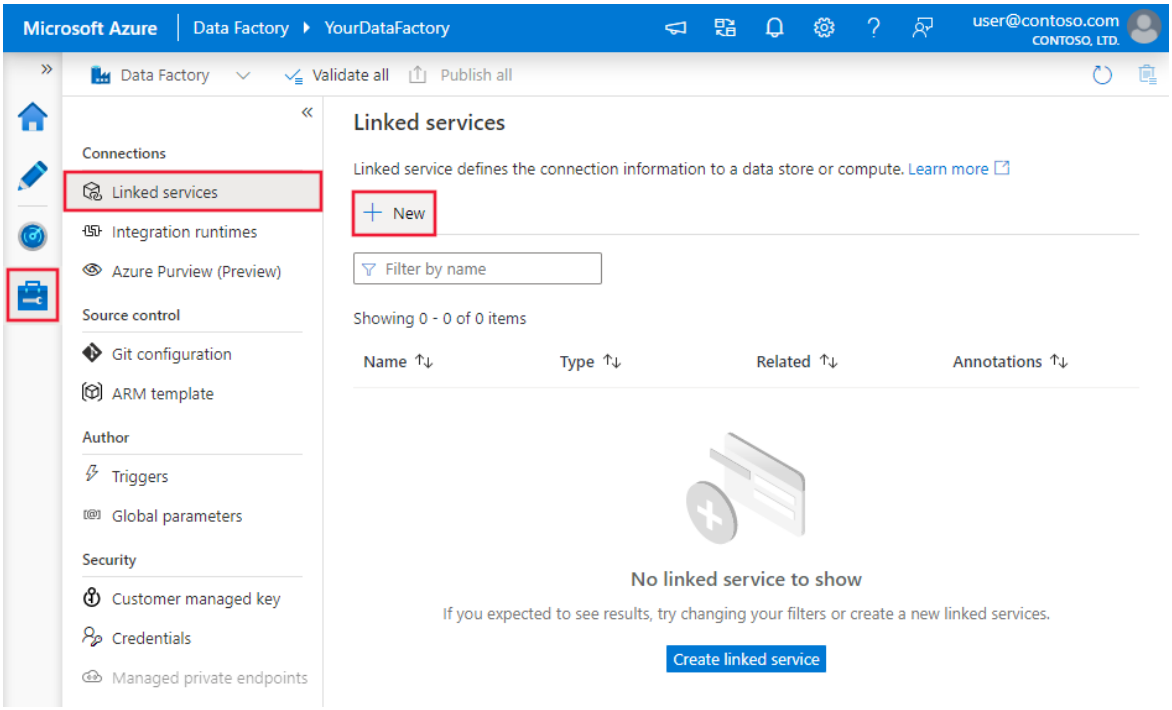
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Informix using UI

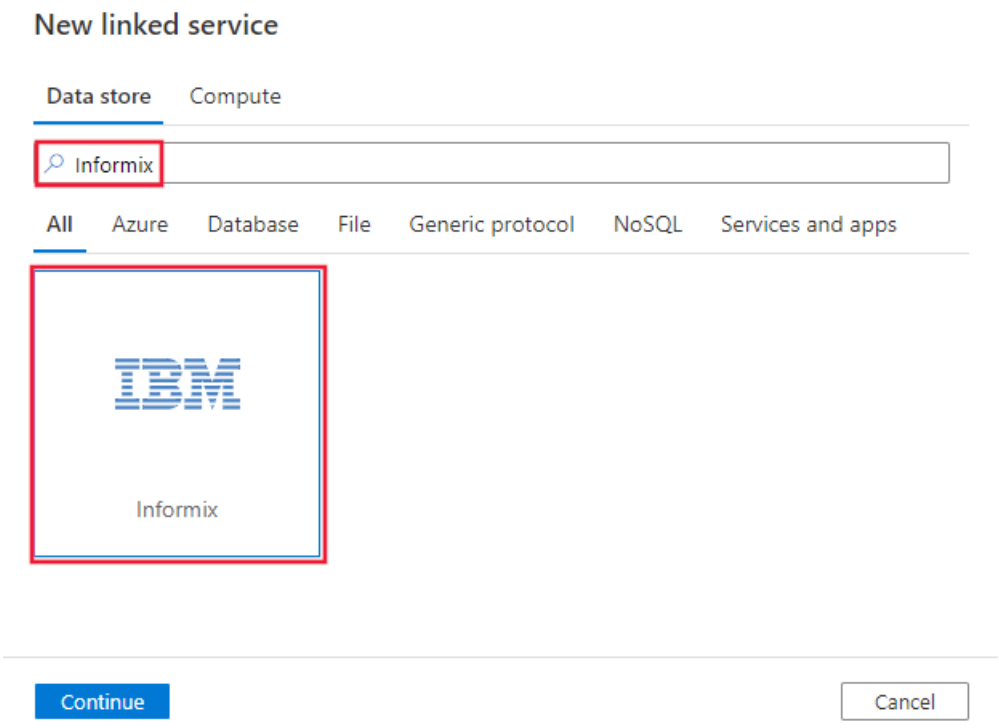
Use the following steps to create a linked service to Informix in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

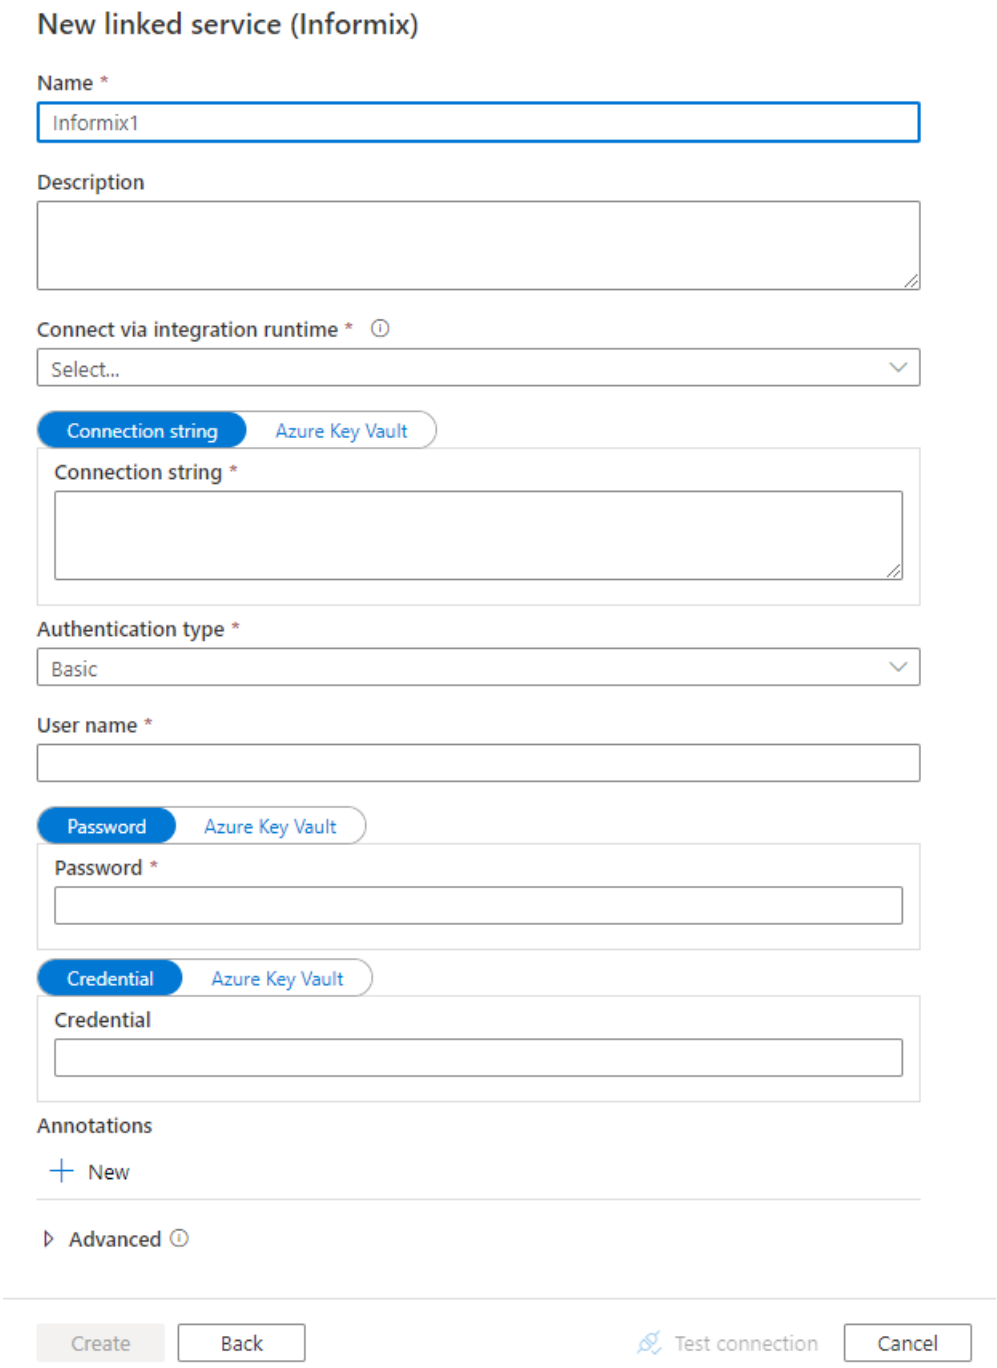
   - Azure Data Factory
   - Azure Synapse



2. Search for Informix and select the Informix connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Informix connector.

Linked service properties

The following properties are supported for Informix linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Informix**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	The ODBC connection string excluding the credential portion. You can specify the connection string or use the system DSN (Data Source Name) you set up on the Integration Runtime machine (you need still specify the credential portion in linked service accordingly). You can also put a password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to Store credentials in Azure Key Vault with more details.	Yes
authenticationType	Type of authentication used to connect to the Informix data store. Allowed values are: **Basic** and **Anonymous**.	Yes
userName	Specify user name if you are using Basic authentication.	No
password	Specify password for the user account you specified for the userName. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
credential	The access credential portion of the connection string specified in driver-specific property-value format. Mark this field as a SecureString.	No
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "InformixLinkedService",
    "properties": {
        "type": "Informix",
        "typeProperties": {
            "connectionString": "<Informix connection string or DSN>",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Informix dataset.

To copy data from Informix, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **InformixTable**	Yes
tableName	Name of the table in the Informix.	No for source (if "query" in activity source is specified); Yes for sink

Example

```
{
    "name": "InformixDataset",
    "properties": {
        "type": "InformixTable",
        "linkedServiceName": {
            "referenceName": "<Informix linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "<table name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Informix source.

Informix as source

To copy data from Informix, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **InformixSource**	Yes
query	Use the custom query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromInformix",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Informix input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "InformixSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Informix as sink

To copy data to Informix, the following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **InformixSink**	Yes
writeBatchTimeout	Wait time for the batch insert operation to complete before it times out. Allowed values are: timespan. Example: "00:30:00" (30 minutes).	No
writeBatchSize	Inserts data into the SQL table when the buffer size reaches writeBatchSize. Allowed values are: integer (number of rows).	No (default is 0 - auto detected)

PROPERTY	DESCRIPTION	REQUIRED
preCopyScript	Specify a SQL query for Copy Activity to execute before writing data into data store in each run. You can use this property to clean up the pre-loaded data.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToInformix",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Informix output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "InformixSink"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Jira using Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Jira. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Jira connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

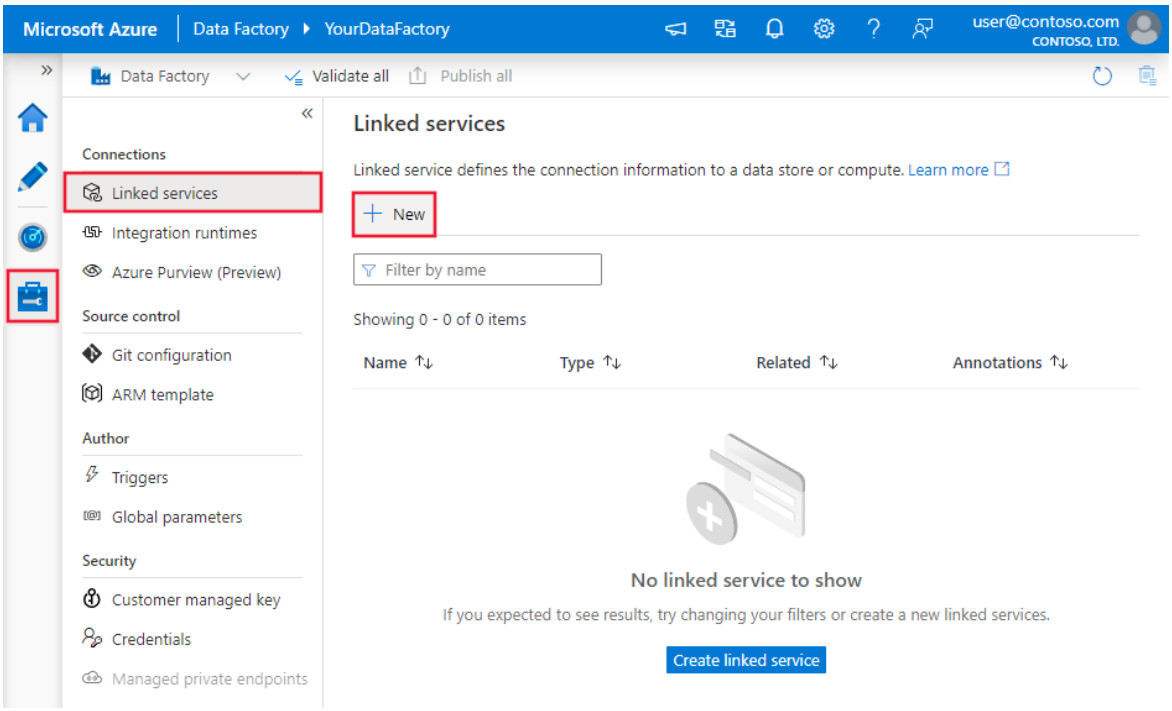
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Jira using UI

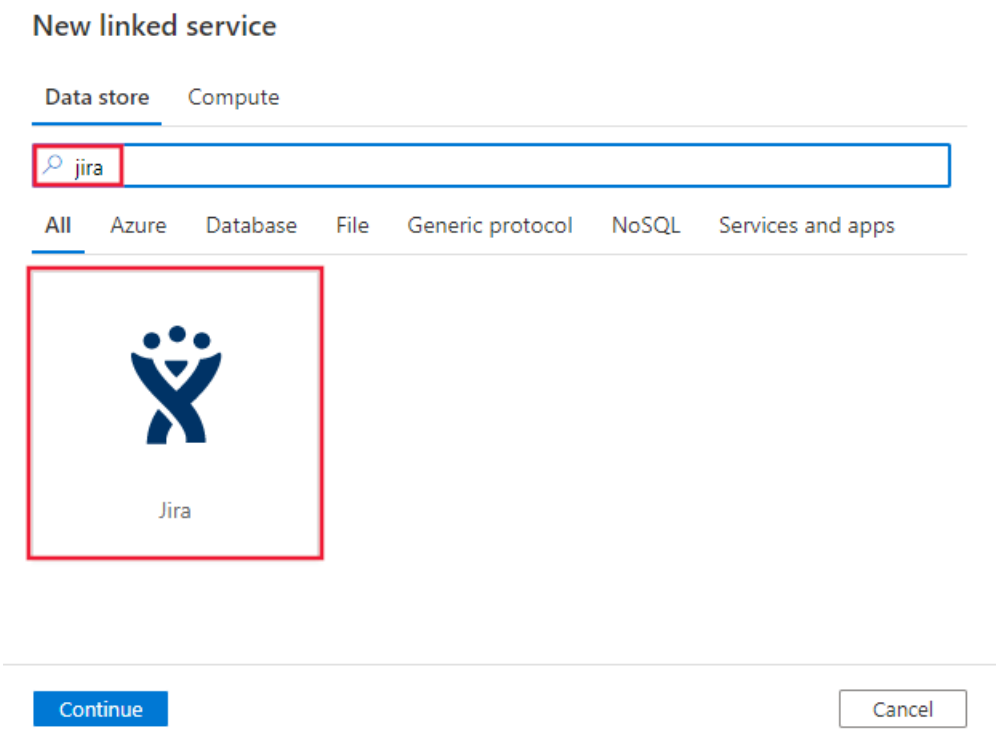
Use the following steps to create a linked service to Jira in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

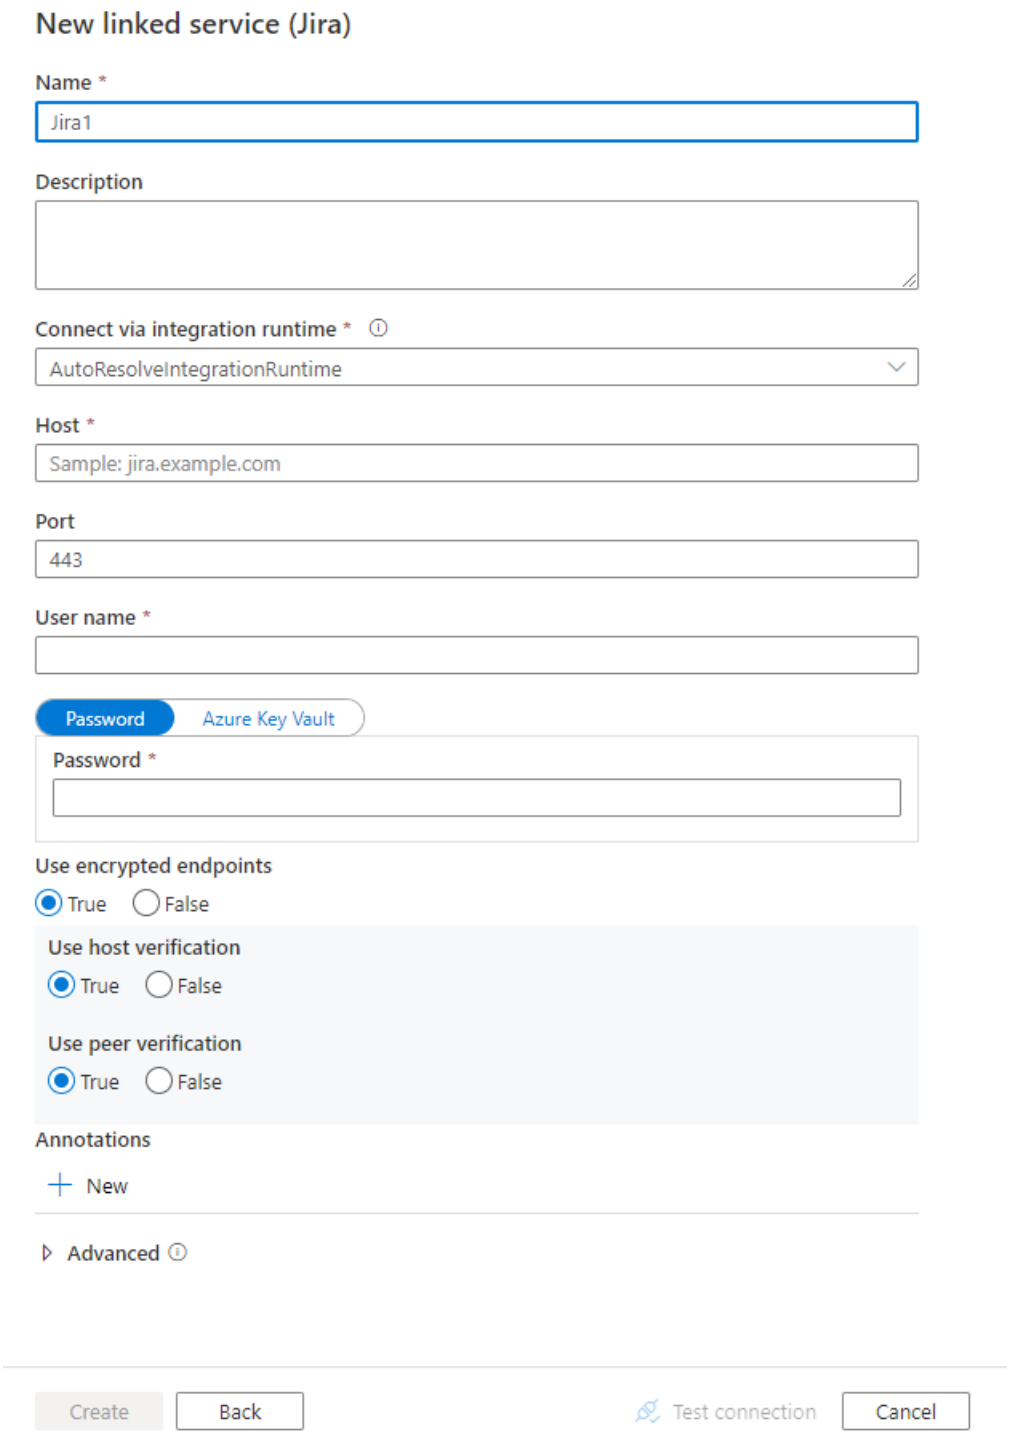
   - Azure Data Factory
   - Azure Synapse



2. Search for Jira and select the Jira connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Jira connector.

Linked service properties

The following properties are supported for Jira linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Jira**	Yes
host	The IP address or host name of the Jira service. (for example, jira.example.com)	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	The TCP port that the Jira server uses to listen for client connections. The default value is 443 if connecting through HTTPS, or 8080 if connecting through HTTP.	No
username	The user name that you use to access Jira Service.	Yes
password	The Atlassian API token (if two-step verification is enabled on the Atlassian account) or password corresponding to the user name that you provided in the username field. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "JiraLinkedService",
    "properties": {
        "type": "Jira",
        "typeProperties": {
            "host" : "<host>",
            "port" : "<port>",
            "username" : "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Jira dataset.

To copy data from Jira, set the type property of the dataset to **JiraObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **JiraObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "JiraDataset",
    "properties": {
        "type": "JiraObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Jira linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Jira source.

JiraSource as source

To copy data from Jira, set the source type in the copy activity to **JiraSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **JiraSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromJira",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Jira input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "JiraSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

JSON format in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the JSON files or write the data into JSON format**.

JSON format is supported for the following connectors:

- Amazon S3
- Amazon S3 Compatible Storage,
- Azure Blob
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Files
- File System
- FTP
- Google Cloud Storage
- HDFS
- HTTP
- Oracle Cloud Storage
- SFTP

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the JSON dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Json**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section.**	Yes

PROPERTY	DESCRIPTION	REQUIRED
encodingName	The encoding type used to read/write test files. Allowed values are as follows: "UTF-8","UTF-8 without BOM", "UTF-16", "UTF-16BE", "UTF-32", "UTF-32BE", "US-ASCII", "UTF-7", "BIG5", "EUC-JP", "EUC-KR", "GB2312", "GB18030", "JOHAB", "SHIFT-JIS", "CP875", "CP866", "IBM00858", "IBM037", "IBM273", "IBM437", "IBM500", "IBM737", "IBM775", "IBM850", "IBM852", "IBM855", "IBM857", "IBM860", "IBM861", "IBM863", "IBM864", "IBM865", "IBM869", "IBM870", "IBM01140", "IBM01141", "IBM01142", "IBM01143", "IBM01144", "IBM01145", "IBM01146", "IBM01147", "IBM01148", "IBM01149", "ISO-2022-JP", "ISO-2022-KR", "ISO-8859-1", "ISO-8859-2", "ISO-8859-3", "ISO-8859-4", "ISO-8859-5", "ISO-8859-6", "ISO-8859-7", "ISO-8859-8", "ISO-8859-9", "ISO-8859-13", "ISO-8859-15", "WINDOWS-874", "WINDOWS-1250", "WINDOWS-1251", "WINDOWS-1252", "WINDOWS-1253", "WINDOWS-1254", "WINDOWS-1255", "WINDOWS-1256", "WINDOWS-1257", "WINDOWS-1258".	No
compression	Group of properties to configure file compression. Configure this section when you want to do compression/decompression during activity execution.	No
type (*under* `compression`)	The compression codec used to read/write JSON files. Allowed values are **bzip2**, **gzip**, **deflate**, **ZipDeflate**, **TarGzip**, **Tar**, **snappy**, or **lz4**. Default is not compressed. **Note** currently Copy activity doesn't support "snappy" & "lz4", and mapping data flow doesn't support "ZipDeflate"", "TarGzip" and "Tar". **Note** when using copy activity to decompress **ZipDeflate/TarGzip/Tar** file(s) and write to file-based sink data store, by default files are extracted to the folder: `<path specified in dataset>/<folder named as source compressed file>/` , use `preserveZipFileNameAsFolder` / `preserveCompressionFileNameAsFolder` on copy activity source to control whether to preserve the name of the compressed file(s) as folder structure.	No.

PROPERTY	DESCRIPTION	REQUIRED
level (*under* `compression`)	The compression ratio. Allowed values are **Optimal** or **Fastest**. - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed. - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete. For more information, see Compression Level topic.	No

Below is an example of JSON dataset on Azure Blob Storage:

```
{
    "name": "JSONDataset",
    "properties": {
        "type": "Json",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "compression": {
                "type": "gzip"
            }
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the JSON source and sink.

Learn about how to extract data from JSON files and map to sink data store/format or vice versa from schema mapping.

JSON as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **JSONSource**.	Yes
formatSettings	A group of properties. Refer to **JSON read settings** table below.	No

PROPERTY	DESCRIPTION	REQUIRED
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **JSON read settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **JsonReadSettings**.	Yes
compressionProperties	A group of properties on how to decompress data for a given compression codec.	No
preserveZipFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `ZipDeflateReadSettings`)	Applies when input dataset is configured with **ZipDeflate** compression. Indicates whether to preserve the source zip file name as folder structure during copy. - When set to **true (default)**, the service writes unzipped files to `<path specified in dataset>/<folder named as source zip file>/`. - When set to **false**, the service writes unzipped files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source zip files to avoid racing or unexpected behavior.	No
preserveCompressionFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `TarGZipReadSettings` *or* `TarReadSettings`)	Applies when input dataset is configured with **TarGzip/Tar** compression. Indicates whether to preserve the source compressed file name as folder structure during copy. - When set to **true (default)**, the service writes decompressed files to `<path specified in dataset>/<folder named as source compressed file>/`. - When set to **false**, the service writes decompressed files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source files to avoid racing or unexpected behavior.	No

JSON as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **JSONSink**.	Yes
formatSettings	A group of properties. Refer to **JSON write settings** table below.	No
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **JSON write settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **JsonWriteSettings**.	Yes
filePattern	Indicate the pattern of data stored in each JSON file. Allowed values are: **setOfObjects** (JSON Lines) and **arrayOfObjects**. The **default** value is **setOfObjects**. See JSON file patterns section for details about these patterns.	No

JSON file patterns

When copying data from JSON files, copy activity can automatically detect and parse the following patterns of JSON files. When writing data to JSON files, you can configure the file pattern on copy activity sink.

- **Type I: setOfObjects**

  Each file contains single object, JSON lines, or concatenated objects.

  - **single object JSON example**

    ```
    {
        "time": "2015-04-29T07:12:20.9100000Z",
        "callingimsi": "466920403025604",
        "callingnum1": "678948008",
        "callingnum2": "567834760",
        "switch1": "China",
        "switch2": "Germany"
    }
    ```

  - **JSON Lines (default for sink)**

```
{"time":"2015-04-
29T07:12:20.9100000Z","callingimsi":"466920403025604","callingnum1":"678948008","callingnum2":
"567834760","switch1":"China","switch2":"Germany"}
{"time":"2015-04-
29T07:13:21.0220000Z","callingimsi":"466922202613463","callingnum1":"123436380","callingnum2":
"789037573","switch1":"US","switch2":"UK"}
{"time":"2015-04-
29T07:13:21.4370000Z","callingimsi":"466923101048691","callingnum1":"678901578","callingnum2":
"345626404","switch1":"Germany","switch2":"UK"}
```

- concatenated JSON example

```
{
    "time": "2015-04-29T07:12:20.9100000Z",
    "callingimsi": "466920403025604",
    "callingnum1": "678948008",
    "callingnum2": "567834760",
    "switch1": "China",
    "switch2": "Germany"
}
{
    "time": "2015-04-29T07:13:21.0220000Z",
    "callingimsi": "466922202613463",
    "callingnum1": "123436380",
    "callingnum2": "789037573",
    "switch1": "US",
    "switch2": "UK"
}
{
    "time": "2015-04-29T07:13:21.4370000Z",
    "callingimsi": "466923101048691",
    "callingnum1": "678901578",
    "callingnum2": "345626404",
    "switch1": "Germany",
    "switch2": "UK"
}
```

- Type II: arrayOfObjects

  Each file contains an array of objects.

```
[
    {
        "time": "2015-04-29T07:12:20.9100000Z",
        "callingimsi": "466920403025604",
        "callingnum1": "678948008",
        "callingnum2": "567834760",
        "switch1": "China",
        "switch2": "Germany"
    },
    {
        "time": "2015-04-29T07:13:21.0220000Z",
        "callingimsi": "466922202613463",
        "callingnum1": "123436380",
        "callingnum2": "789037573",
        "switch1": "US",
        "switch2": "UK"
    },
    {
        "time": "2015-04-29T07:13:21.4370000Z",
        "callingimsi": "466923101048691",
        "callingnum1": "678901578",
        "callingnum2": "345626404",
        "switch1": "Germany",
        "switch2": "UK"
    }
]
```

Mapping data flow properties

In mapping data flows, you can read and write to JSON format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and SFTP, and you can read JSON format in Amazon S3.

Source properties

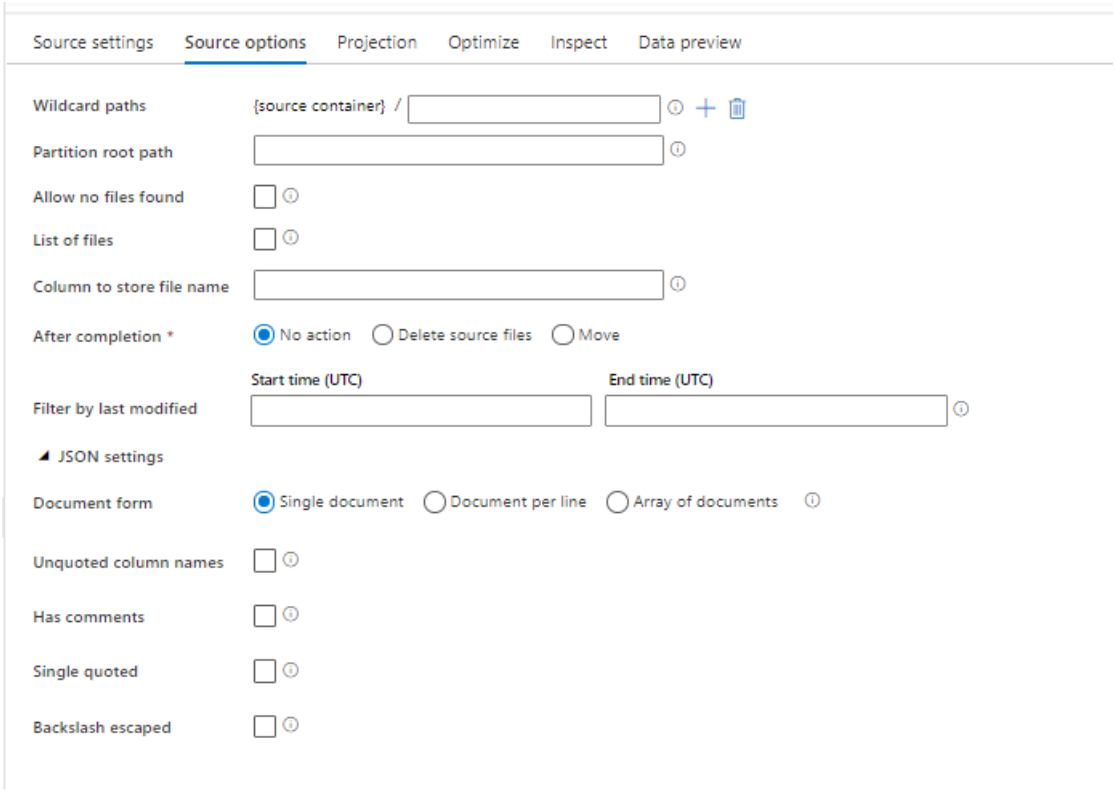
The below table lists the properties supported by a json source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Single document	Mapping data flows read one JSON document from each file	no	`true` or `false`	singleDocument
Unquoted column names	If **Unquoted column names** is selected, mapping data flows reads JSON columns that aren't surrounded by quotes.	no	`true` or `false`	unquotedColumnNames
Has comments	Select **Has comments** if the JSON data has C or C++ style commenting	no	`true` or `false`	asComments
Single quoted	Reads JSON columns that aren't surrounded by quotes	no	`true` or `false`	singleQuoted
Backslash escaped	Select **Backslash escaped** if backslashes are used to escape characters in the JSON data	no	`true` or `false`	backslashEscape
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

Source format options

Using a JSON dataset as a source in your data flow allows you to set five additional settings. These settings can be found under the **JSON settings** accordion in the **Source Options** tab. For **Document Form** setting, you can select one of **Single document**, **Document per line** and **Array of documents** types.



Default

By default, JSON data is read in the following format.

```
{ "json": "record 1" }
{ "json": "record 2" }
{ "json": "record 3" }
```

Single document

If **Single document** is selected, mapping data flows read one JSON document from each file.

```
File1.json
{
    "json": "record 1"
}
File2.json
{
    "json": "record 2"
}
File3.json
{
    "json": "record 3"
}
```

If **Document per line** is selected, mapping data flows read one JSON document from each line in a file.

```
File1.json
{"json": "record 1"}

File2.json
 {"time":"2015-04-
29T07:12:20.9100000Z","callingimsi":"466920403025604","callingnum1":"678948008","callingnum2":"567834760","s
witch1":"China","switch2":"Germany"}
 {"time":"2015-04-
29T07:13:21.0220000Z","callingimsi":"466922202613463","callingnum1":"123436380","callingnum2":"789037573","s
witch1":"US","switch2":"UK"}

File3.json
 {"time":"2015-04-
29T07:12:20.9100000Z","callingimsi":"466920403025604","callingnum1":"678948008","callingnum2":"567834760","s
witch1":"China","switch2":"Germany"}
 {"time":"2015-04-
29T07:13:21.0220000Z","callingimsi":"466922202613463","callingnum1":"123436380","callingnum2":"789037573","s
witch1":"US","switch2":"UK"}
 {"time":"2015-04-
29T07:13:21.4370000Z","callingimsi":"466923101048691","callingnum1":"678901578","callingnum2":"345626404","s
witch1":"Germany","switch2":"UK"}
```

If **Array of documents** is selected, mapping data flows read one array of document from a file.

```
File.json
[
        {
            "time": "2015-04-29T07:12:20.9100000Z",
            "callingimsi": "466920403025604",
            "callingnum1": "678948008",
            "callingnum2": "567834760",
            "switch1": "China",
            "switch2": "Germany"
        },
        {
            "time": "2015-04-29T07:13:21.0220000Z",
            "callingimsi": "466922202613463",
            "callingnum1": "123436380",
            "callingnum2": "789037573",
            "switch1": "US",
            "switch2": "UK"
        },
        {
            "time": "2015-04-29T07:13:21.4370000Z",
            "callingimsi": "466923101048691",
            "callingnum1": "678901578",
            "callingnum2": "345626404",
            "switch1": "Germany",
            "switch2": "UK"
        }
    ]
```

> **NOTE**
> If data flows throw an error stating "corrupt_record" when previewing your JSON data, it is likely that your data contains contains a single document in your JSON file. Setting "single document" should clear that error.

Unquoted column names

If **Unquoted column names** is selected, mapping data flows reads JSON columns that aren't surrounded by quotes.

```
{ json: "record 1" }
{ json: "record 2" }
{ json: "record 3" }
```

Has comments

Select **Has comments** if the JSON data has C or C++ style commenting.

```
{ "json": /** comment **/ "record 1" }
{ "json": "record 2" }
{ /** comment **/ "json": "record 3" }
```

Single quoted

Select **Single quoted** if the JSON fields and values use single quotes instead of double quotes.

```
{ 'json': 'record 1' }
{ 'json': 'record 2' }
{ 'json': 'record 3' }
```

Backslash escaped

Select **Backslash escaped** if backslashes are used to escape characters in the JSON data.

```
{ "json": "record 1" }
{ "json": "\} \" \' \\ \n \\n record 2" }
{ "json": "record 3" }
```

Sink Properties

The below table lists the properties supported by a json sink. You can edit these properties in the **Settings** tab.

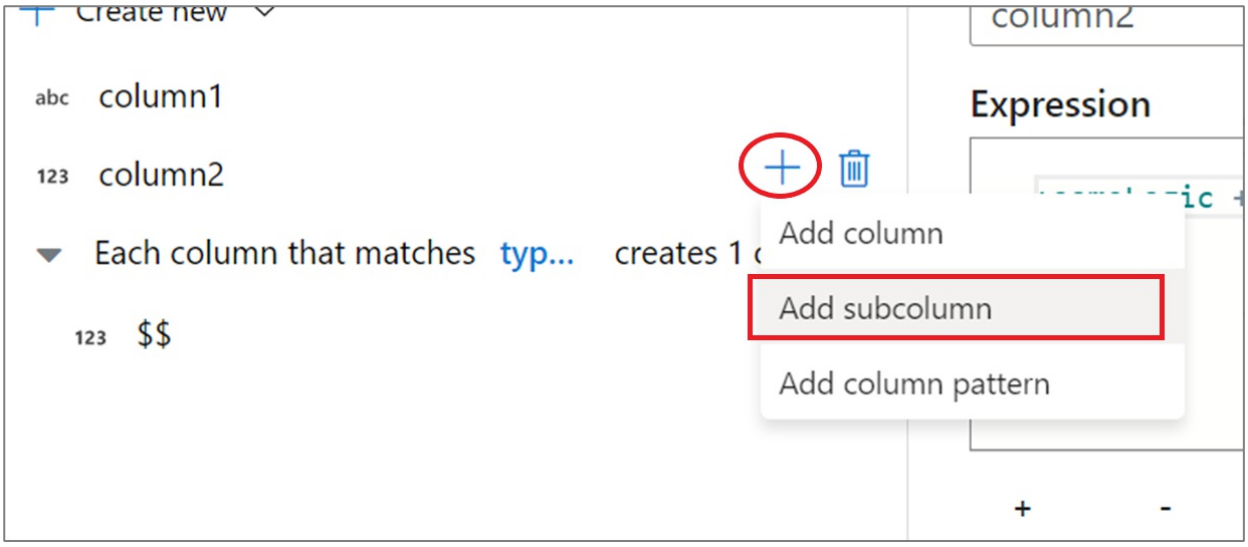
NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>`	no	Pattern: String Per partition: String[] As data in column: String Output to single file: `['<fileName>']`	filePattern partitionFileNames rowUrlColumn partitionFileNames

Creating JSON structures in a derived column

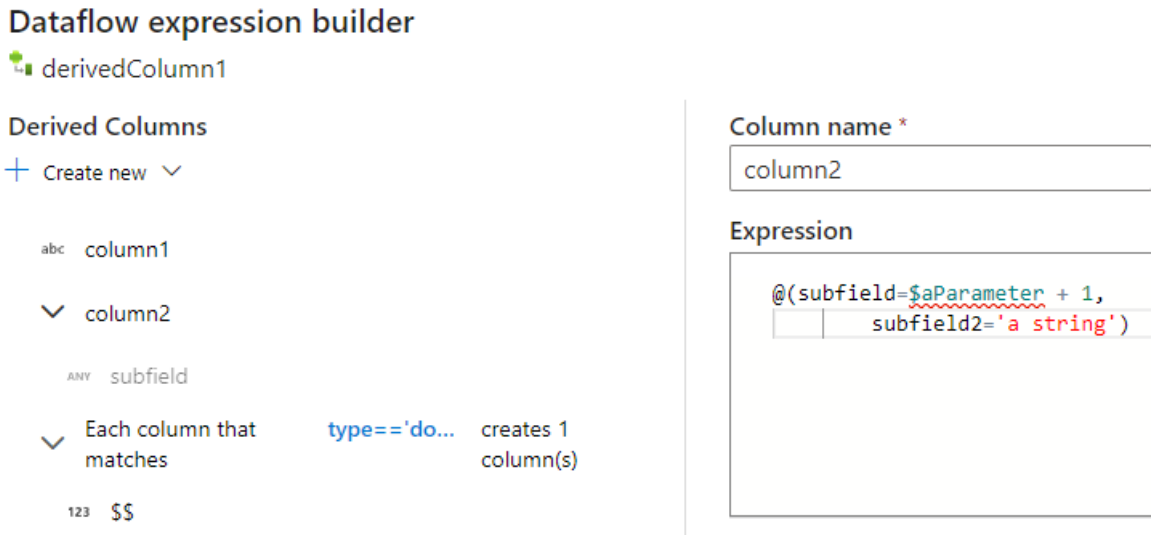
You can add a complex column to your data flow via the derived column expression builder. In the derived column transformation, add a new column and open the expression builder by clicking on the blue box. To make a column complex, you can enter the JSON structure manually or use the UX to add subcolumns interactively.

Using the expression builder UX

In the output schema side pane, hover over a column and click the plus icon. Select **Add subcolumn** to make the column a complex type.



You can add additional columns and subcolumns in the same way. For each non-complex field, an expression can be added in the expression editor to the right.



Entering the JSON structure manually

To manually add a JSON structure, add a new column and enter the expression in the editor. The expression follows the following general format:

```
@(
    field1=0,
    field2=@(
        field1=0
    )
)
```

If this expression were entered for a column named "complexColumn", then it would be written to the sink as the following JSON:

```
{
    "complexColumn": {
        "field1": 0,
        "field2": {
            "field1": 0
        }
    }
}
```

Sample manual script for complete hierarchical definition

```
@(
    title=Title,
    firstName=FirstName,
    middleName=MiddleName,
    lastName=LastName,
    suffix=Suffix,
    contactDetails=@(
        email=EmailAddress,
        phone=Phone
    ),
    address=@(
        line1=AddressLine1,
        line2=AddressLine2,
        city=City,
        state=StateProvince,
        country=CountryRegion,
        postCode=PostalCode
    ),
    ids=[
        toString(CustomerID), toString(AddressID), rowguid
    ]
)
```

Related connectors and formats

Here are some common connectors and formats related to the JSON format:

- Azure Blob Storage (connector-azure-blob-storage.md)
- Delimited text format(format-delimited-text.md)
- OData connector(connector-odata.md)
- Parquet format(format-parquet.md)

Copy data from Magento using Azure Data Factory or Synapse Analytics(Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Magento. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Magento connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

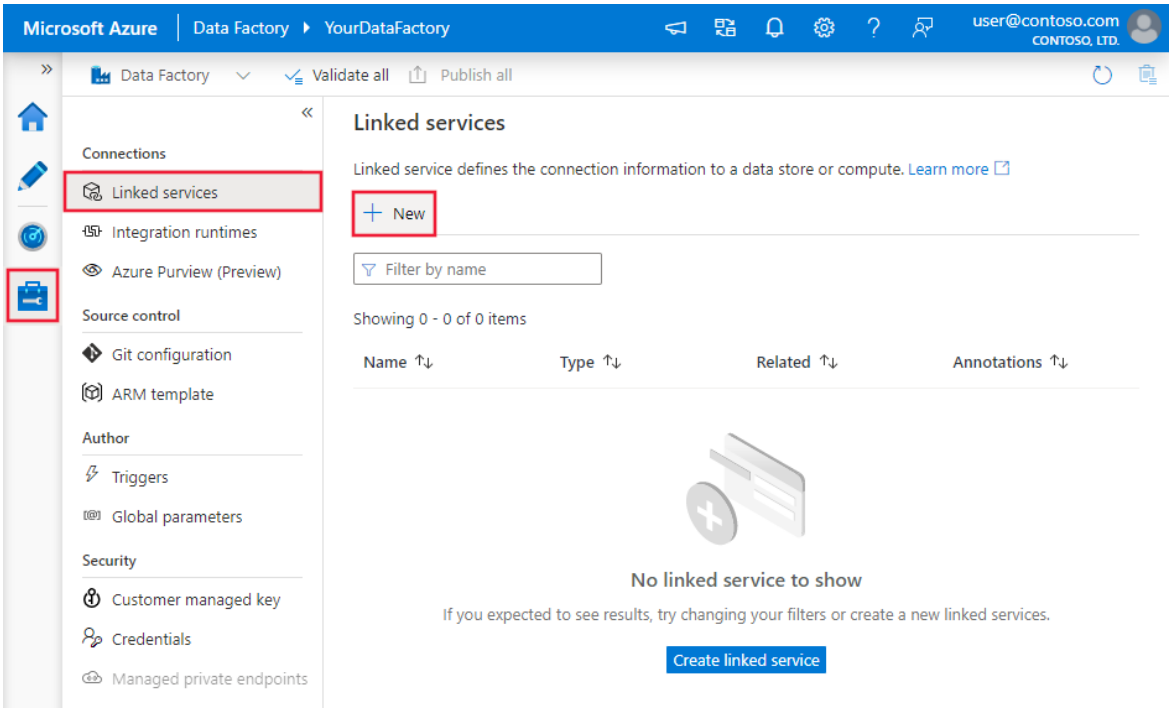
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Magento using UI

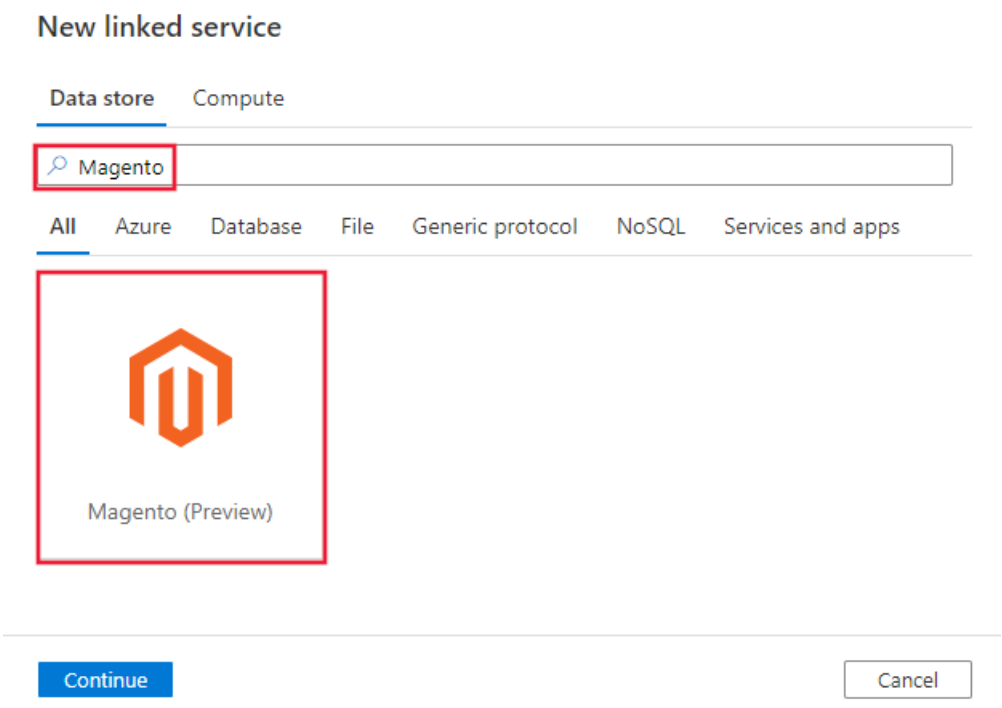
Use the following steps to create a linked service to Magento in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

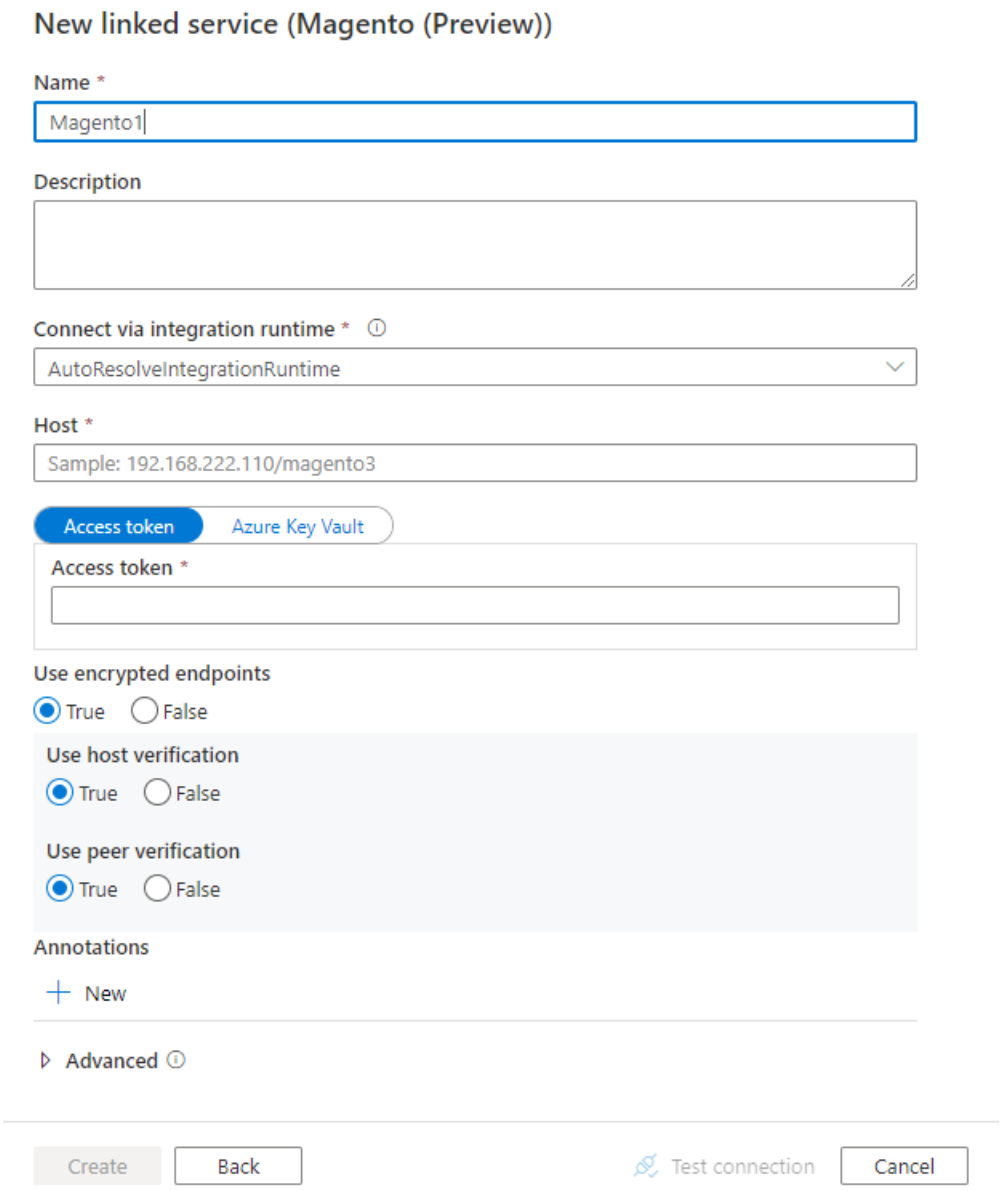
- Azure Data Factory
- Azure Synapse



2. Search for Magento and select the Magento connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Magento connector.

Linked service properties

The following properties are supported for Magento linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Magento**	Yes
host	The URL of the Magento instance. (that is, 192.168.222.110/magento3)	Yes
accessToken	The access token from Magento. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes

PROPERTY	DESCRIPTION	REQUIRED
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "MagentoLinkedService",
    "properties": {
        "type": "Magento",
        "typeProperties": {
            "host" : "192.168.222.110/magento3",
            "accessToken": {
                "type": "SecureString",
                "value": "<accessToken>"
            },
            "useEncryptedEndpoints" : true,
            "useHostVerification" : true,
            "usePeerVerification" : true
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Magento dataset.

To copy data from Magento, set the type property of the dataset to **MagentoObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MagentoObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "MagentoDataset",
    "properties": {
        "type": "MagentoObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Magento linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Magento source.

Magento as source

To copy data from Magento, set the source type in the copy activity to **MagentoSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MagentoSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Customers"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMagento",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Magento input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MagentoSource",
                "query": "SELECT * FROM Customers where Id > XXX"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

Copy data from MariaDB using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from MariaDB. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This MariaDB connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

This connector currently supports MariaDB of version 10.0 to 10.5.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

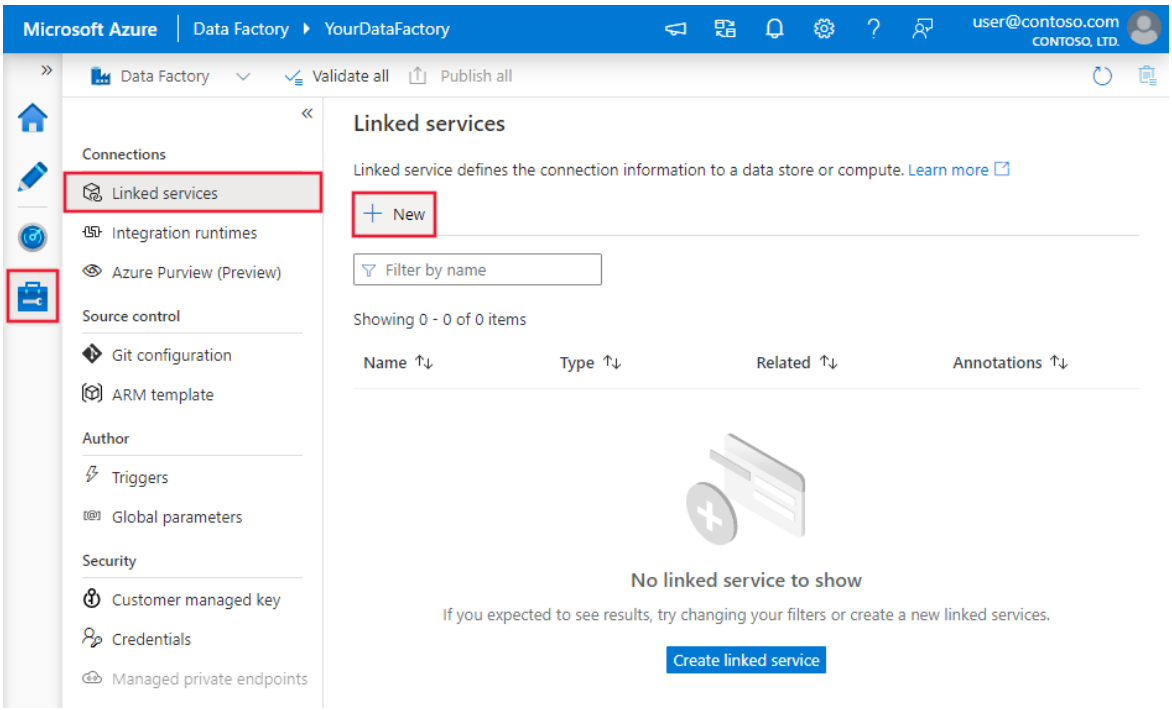
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to MariaDB using UI

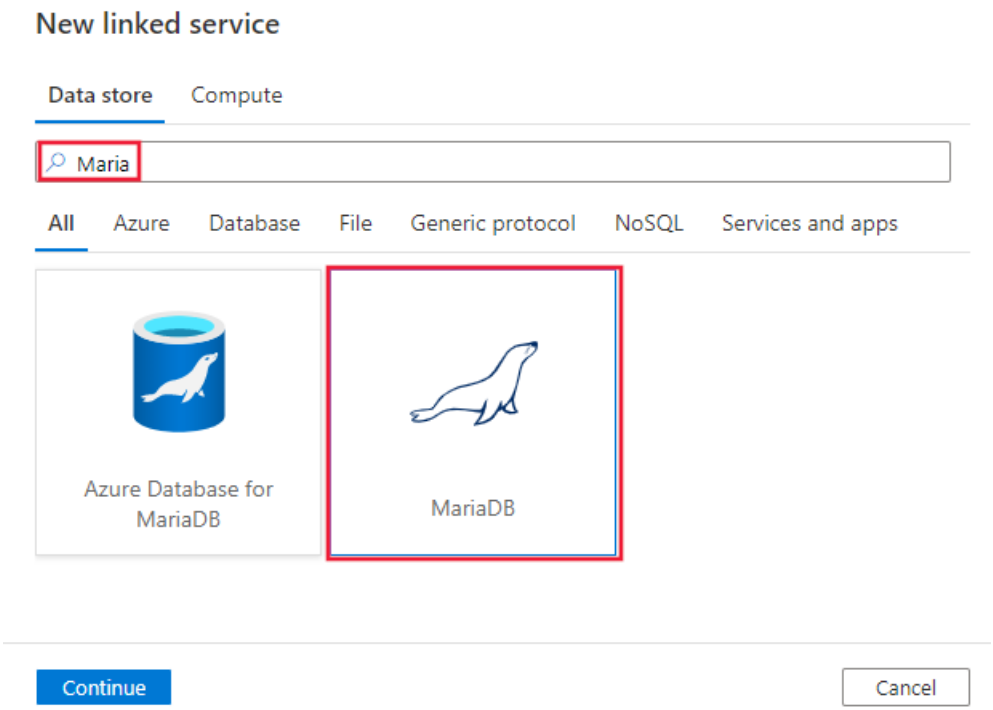
Use the following steps to create a linked service to MariaDB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

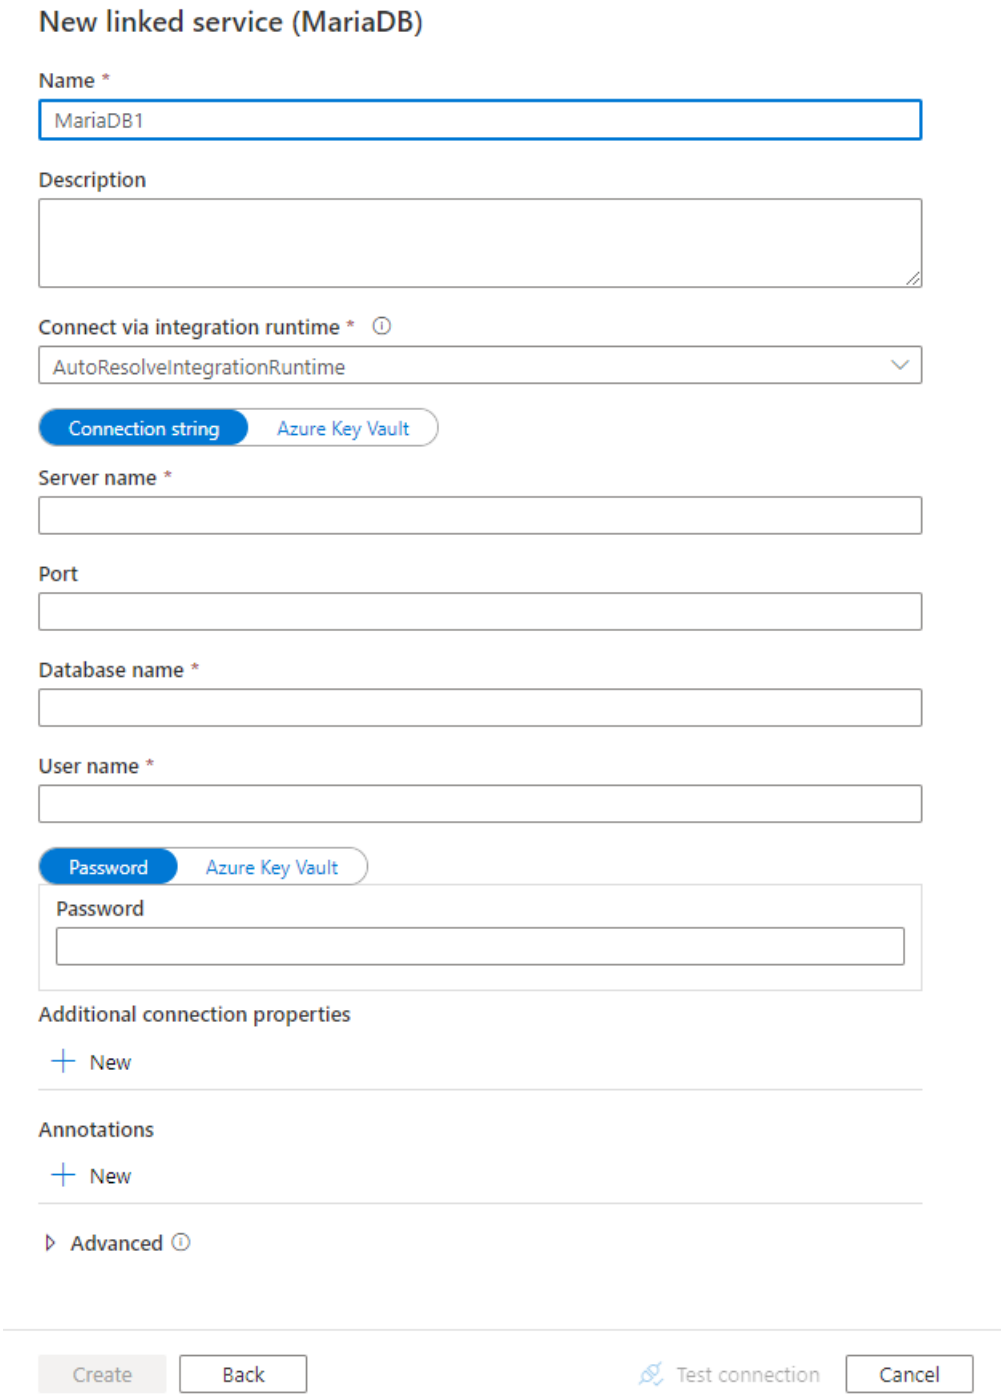
   - Azure Data Factory
   - Azure Synapse



2. Search for Maria and select the MariaDB connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to MariaDB connector.

Linked service properties

The following properties are supported for MariaDB linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MariaDB**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to MariaDB. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "MariaDBLinkedService",
    "properties": {
        "type": "MariaDB",
        "typeProperties": {
            "connectionString": "Server=<host>;Port=<port>;Database=<database>;UID=<user name>;PWD=
<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "MariaDBLinkedService",
    "properties": {
        "type": "MariaDB",
        "typeProperties": {
            "connectionString": "Server=<host>;Port=<port>;Database=<database>;UID=<user name>;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section

provides a list of properties supported by MariaDB dataset.

To copy data from MariaDB, set the type property of the dataset to **MariaDBTable**. There is no additional type-specific property in this type of dataset.

Example

```
{
    "name": "MariaDBDataset",
    "properties": {
        "type": "MariaDBTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<MariaDB linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by MariaDB source.

MariaDB as source

To copy data from MariaDB, set the source type in the copy activity to **MariaDBSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MariaDBSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMariaDB",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<MariaDB input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MariaDBSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Marketo using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Marketo. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Marketo connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Currently, Marketo instance which is integrated with external CRM is not supported.

> **NOTE**
> This Marketo connector is built on top of the Marketo REST API. Be aware that the Marketo has concurrent request limit on service side. If you hit errors saying "Error while attempting to use REST API: Max rate limit '100' exceeded with in '20' secs (606)" or "Error while attempting to use REST API: Concurrent access limit '10' reached (615)", consider to reduce the concurrent copy activity runs to reduce the number of requests to the service.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

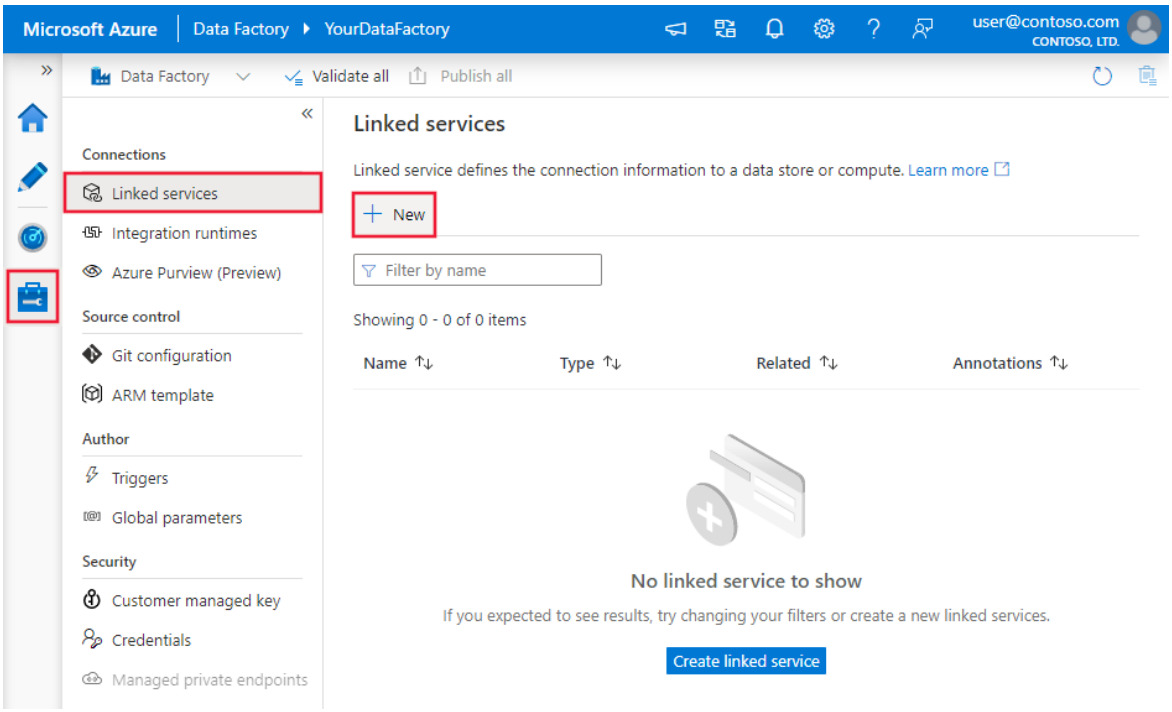
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Marketo using UI

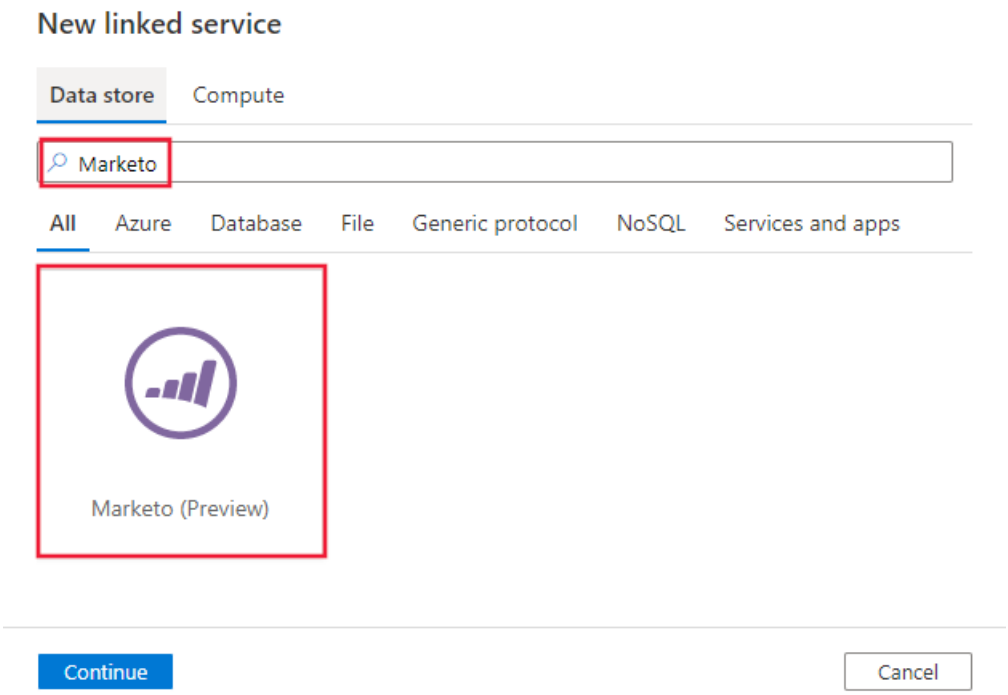
Use the following steps to create a linked service to Marketo in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

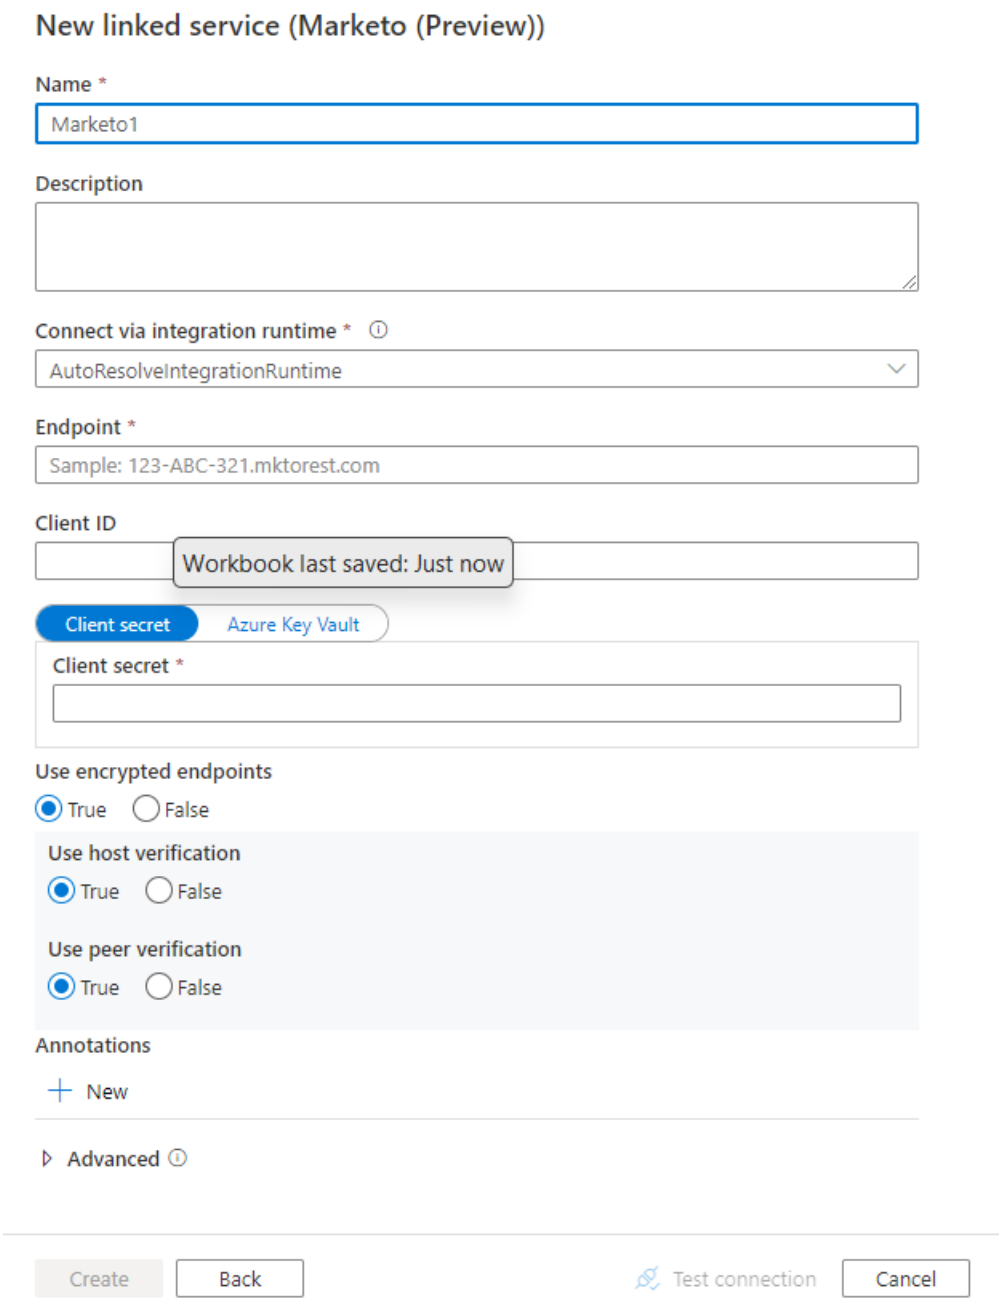
   - Azure Data Factory
   - Azure Synapse



2. Search for Marketo and select the Marketo connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Marketo connector.

Linked service properties

The following properties are supported for Marketo linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Marketo**	Yes
endpoint	The endpoint of the Marketo server. (i.e. 123-ABC-321.mktorest.com)	Yes
clientId	The client Id of your Marketo service.	Yes

PROPERTY	DESCRIPTION	REQUIRED
clientSecret	The client secret of your Marketo service. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "MarketoLinkedService",
    "properties": {
        "type": "Marketo",
        "typeProperties": {
            "endpoint" : "123-ABC-321.mktorest.com",
            "clientId" : "<clientId>",
            "clientSecret": {
                "type": "SecureString",
                "value": "<clientSecret>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Marketo dataset.

To copy data from Marketo, set the type property of the dataset to **MarketoObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MarketoObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "MarketoDataset",
    "properties": {
        "type": "MarketoObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Marketo linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Marketo source.

Marketo as source

To copy data from Marketo, set the source type in the copy activity to **MarketoSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MarketoSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Activitiy_Types"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMarketo",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Marketo input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MarketoSource",
                "query": "SELECT top 1000 * FROM Activitiy_Types"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from and to Microsoft Access using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from a Microsoft Access data store. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Microsoft Access connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Prerequisites

To use this Microsoft Access connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Install the Microsoft Access ODBC driver for the data store on the Integration Runtime machine.

> **NOTE**
> Microsoft Access 2016 version of ODBC driver doesn't work with this connector. Use Microsoft Access 2013 or 2010 version of ODBC driver instead.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

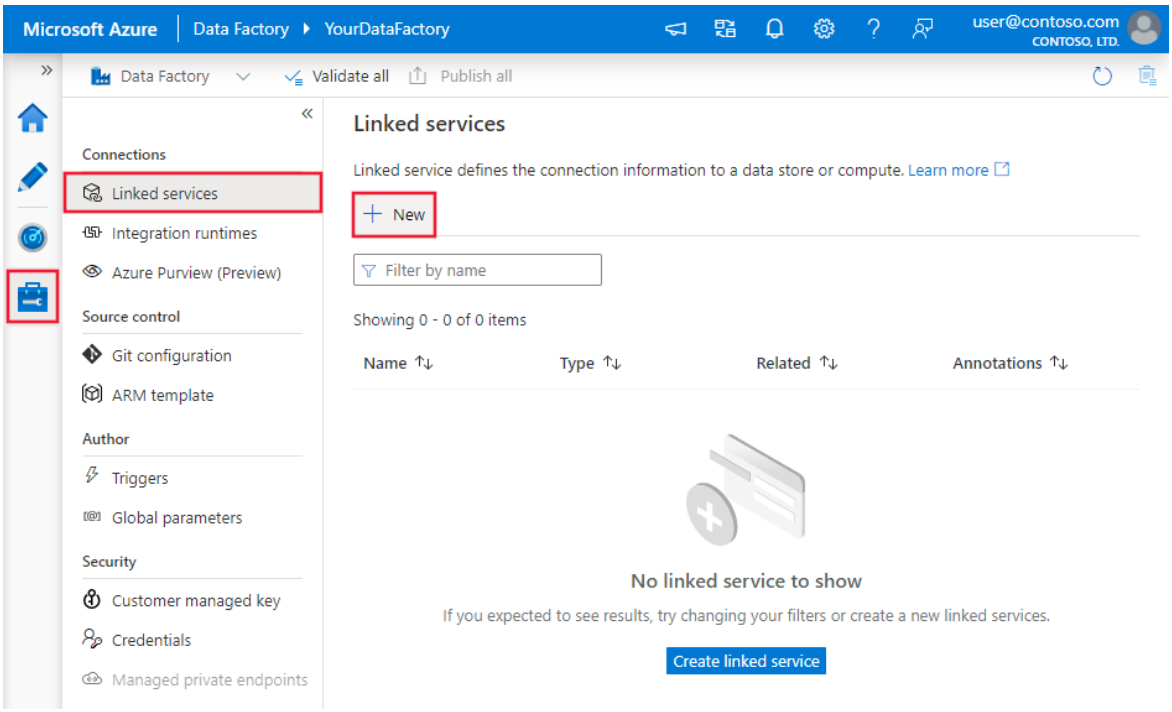
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Microsoft Access using UI

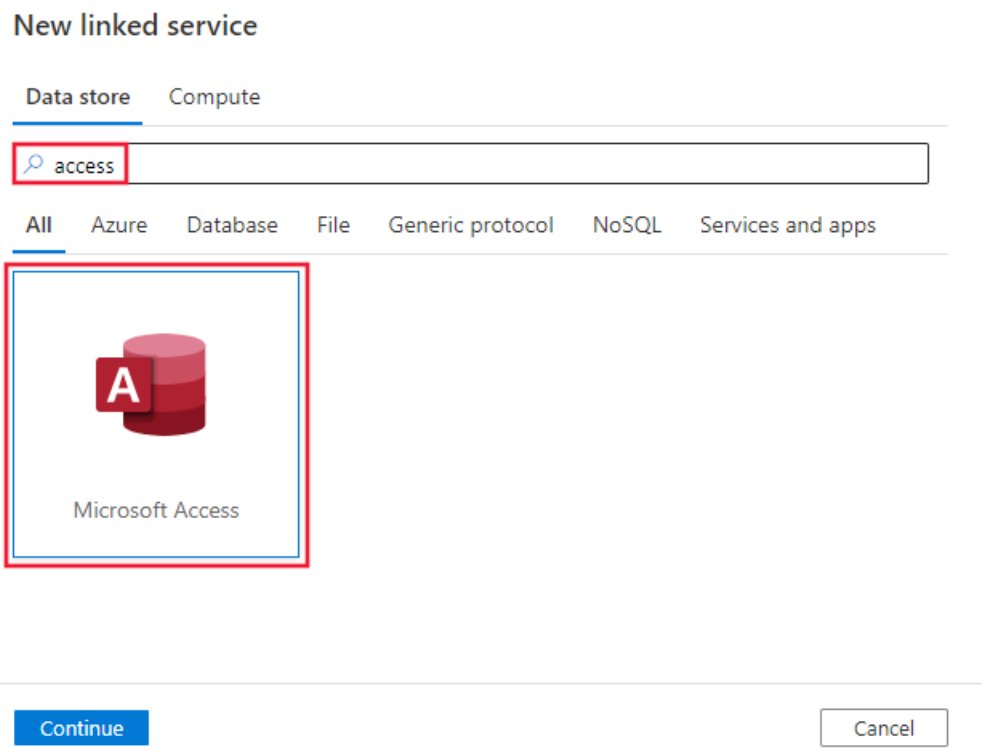
Use the following steps to create a linked service to Microsoft Access in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

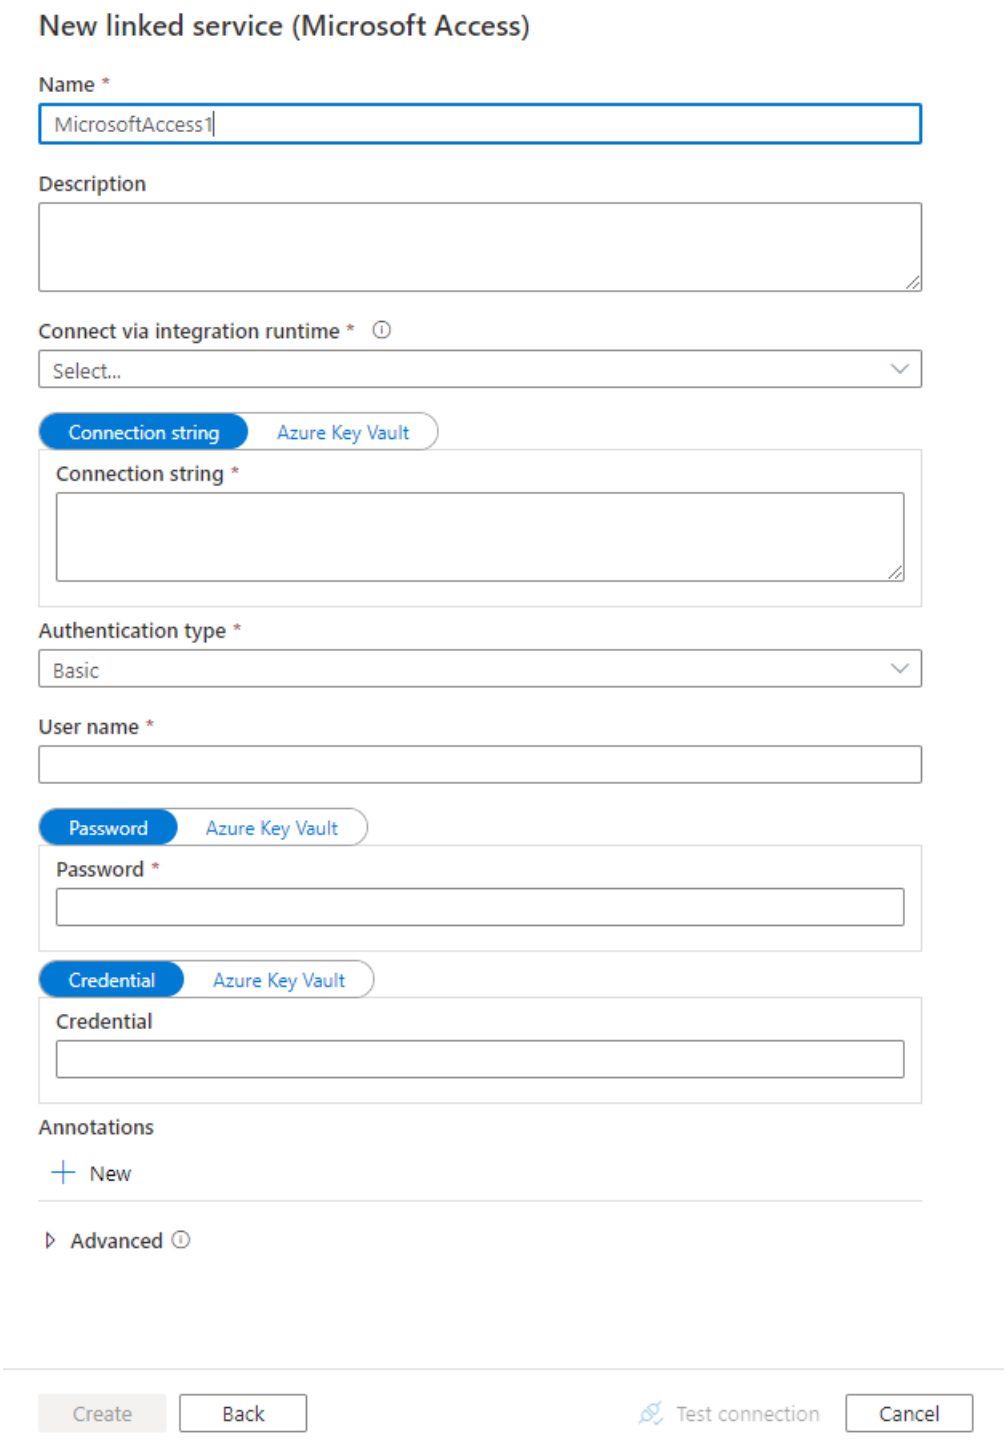
   - Azure Data Factory
   - Azure Synapse



2. Search for Access and select the Microsoft Access connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Microsoft Access connector.

Linked service properties

The following properties are supported for Microsoft Access linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MicrosoftAccess**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	The ODBC connection string excluding the credential portion. You can specify the connection string or use the system DSN (Data Source Name) you set up on the Integration Runtime machine (you need still specify the credential portion in linked service accordingly). You can also put a password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to Store credentials in Azure Key Vault with more details.	Yes
authenticationType	Type of authentication used to connect to the Microsoft Access data store. Allowed values are: **Basic** and **Anonymous**.	Yes
userName	Specify user name if you are using Basic authentication.	No
password	Specify password for the user account you specified for the userName. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
credential	The access credential portion of the connection string specified in driver-specific property-value format. Mark this field as a SecureString.	No
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "MicrosoftAccessLinkedService",
    "properties": {
        "type": "MicrosoftAccess",
        "typeProperties": {
            "connectionString": "Driver={Microsoft Access Driver (*.mdb, *.accdb)};Dbq=<path to your DB file
e.g. C:\\mydatabase.accdb>;",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Microsoft Access dataset.

To copy data from Microsoft Access, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MicrosoftAccessTable**	Yes
tableName	Name of the table in the Microsoft Access.	No for source (if "query" in activity source is specified); Yes for sink

Example

```
{
    "name": "MicrosoftAccessDataset",
    "properties": {
        "type": "MicrosoftAccessTable",
        "linkedServiceName": {
            "referenceName": "<Microsoft Access linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "<table name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Microsoft Access source.

Microsoft Access as source

To copy data from Microsoft Access, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MicrosoftAccessSource**	Yes
query	Use the custom query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMicrosoftAccess",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Microsoft Access input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MicrosoftAccessSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Microsoft Access as sink

To copy data to Microsoft Access, the following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **MicrosoftAccessSink**	Yes
writeBatchTimeout	Wait time for the batch insert operation to complete before it times out. Allowed values are: timespan. Example: “00:30:00” (30 minutes).	No

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	Inserts data into the SQL table when the buffer size reaches writeBatchSize. Allowed values are: integer (number of rows).	No (default is 0 - auto detected)
preCopyScript	Specify a SQL query for Copy Activity to execute before writing data into data store in each run. You can use this property to clean up the pre-loaded data.	No
maxConcurrentConnections	The upper limit of concurrent connecti ons established to the data store durin g the activity run.Specify a value only when you want to limit concurrent con nections.	No

Example:

```
"activities":[
    {
        "name": "CopyToMicrosoftAccess",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Microsoft Access output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "MicrosoftAccessSink"
            }
        }
    }
]
```

Lookup activity properties

Copy data from or to MongoDB using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory Synapse Analytics pipelines to copy data from and to a MongoDB database. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> The new MongoDB connector provides improved native MongoDB support. If you are using the legacy MongoDB connector in your solution, supported as-is for backward compatibility only, refer to MongoDB connector (legacy) article.

Supported capabilities

This MongoDB connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this MongoDB connector supports **versions up to 4.2**.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

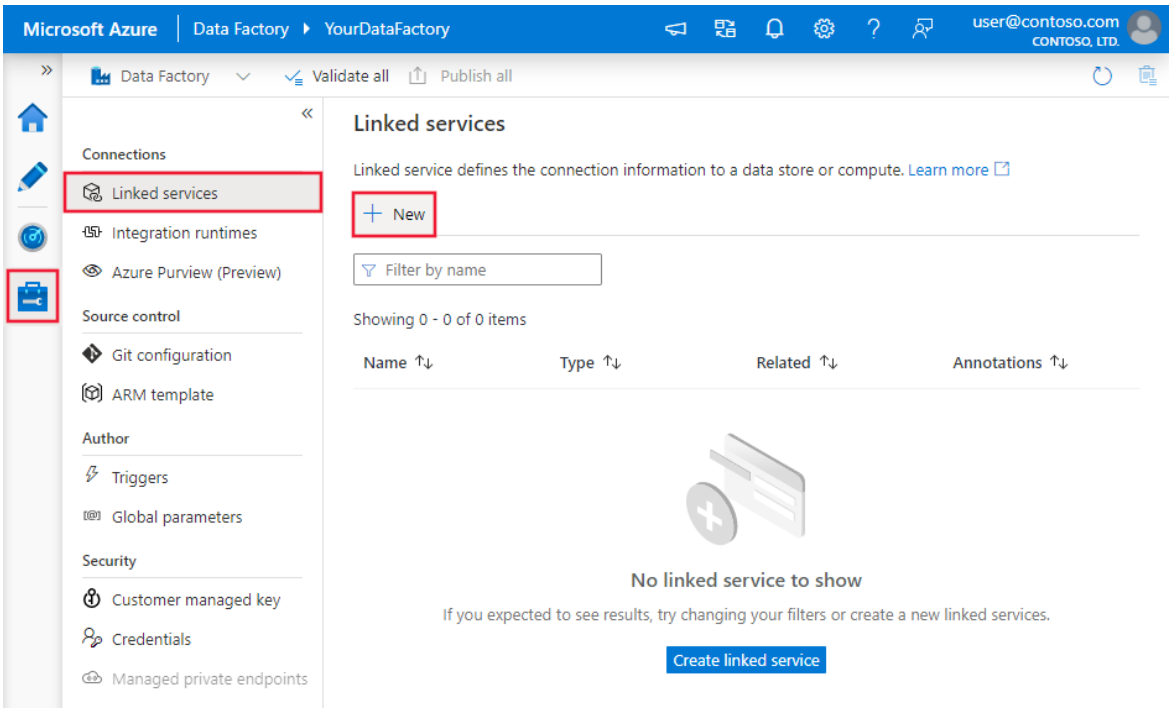
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to MongoDB using UI

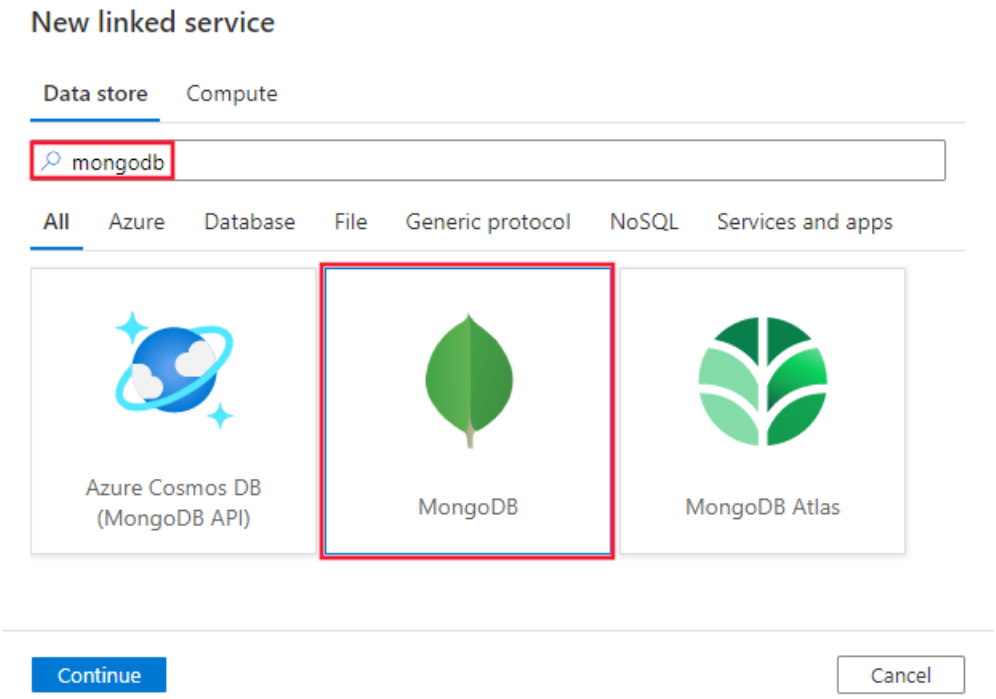
Use the following steps to create a linked service to MongoDB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

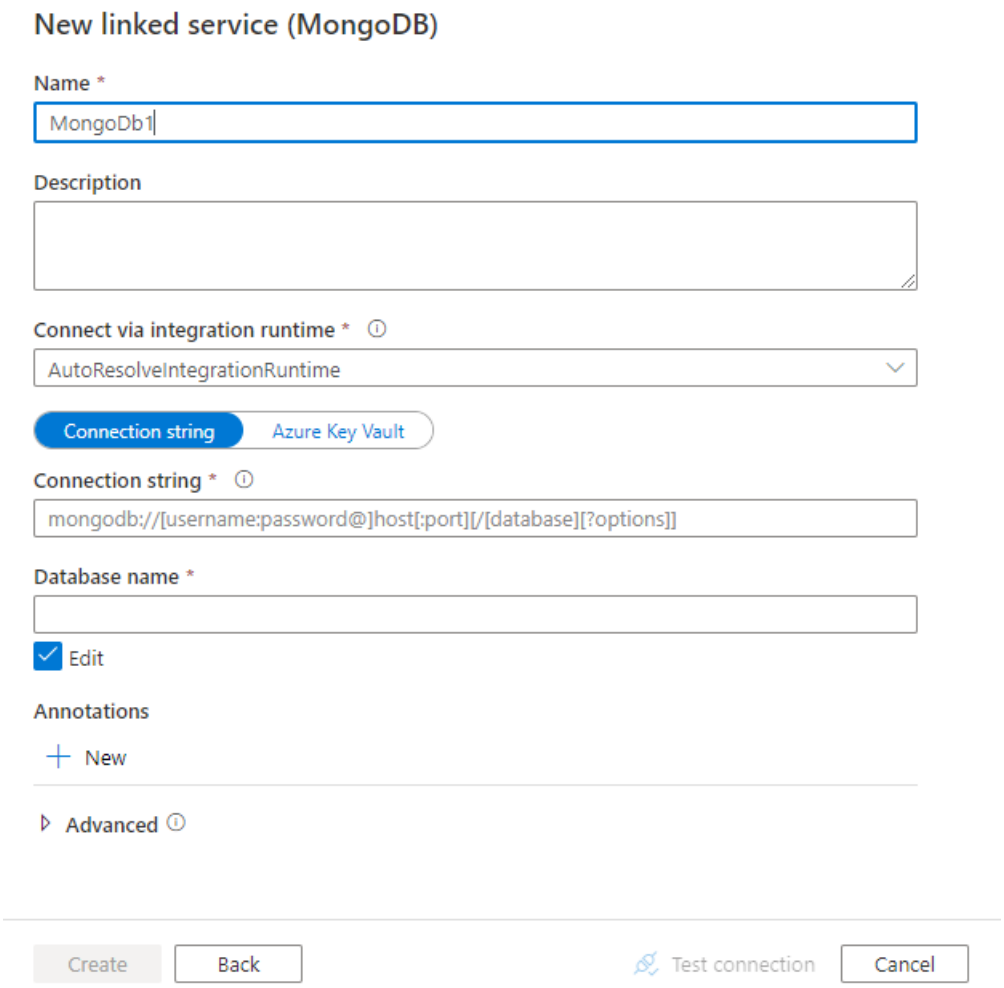
   - Azure Data Factory
   - Azure Synapse



2. Search for MongoDB and select the MongoDB connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to MongoDB connector.

Linked service properties

The following properties are supported for MongoDB linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MongoDbV2**	Yes
connectionString	Specify the MongoDB connection string e.g. `mongodb://[username:password@]host[:port][/[database][?options]]`. Refer to MongoDB manual on connection string for more details. You can also put a connection string in Azure Key Vault. Refer to Store credentials in Azure Key Vault with more details.	Yes

PROPERTY	DESCRIPTION	REQUIRED
database	Name of the database that you want to access.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "MongoDBLinkedService",
    "properties": {
        "type": "MongoDbV2",
        "typeProperties": {
            "connectionString": "mongodb://[username:password@]host[:port][/[database][?options]]",
            "database": "myDatabase"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services. The following properties are supported for MongoDB dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MongoDbV2Collection**	Yes
collectionName	Name of the collection in MongoDB database.	Yes

Example:

```
{
    "name": "MongoDbDataset",
    "properties": {
        "type": "MongoDbV2Collection",
        "typeProperties": {
            "collectionName": "<Collection name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<MongoDB linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by MongoDB source and sink.

MongoDB as source

The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MongoDbV2Source**	Yes
filter	Specifies selection filter using query operators. To return all documents in a collection, omit this parameter or pass an empty document ({}).	No
cursorMethods.project	Specifies the fields to return in the documents for projection. To return all fields in the matching documents, omit this parameter.	No
cursorMethods.sort	Specifies the order in which the query returns matching documents. Refer to cursor.sort().	No
cursorMethods.limit	Specifies the maximum number of documents the server returns. Refer to cursor.limit().	No
cursorMethods.skip	Specifies the number of documents to skip and from where MongoDB begins to return results. Refer to cursor.skip().	No
batchSize	Specifies the number of documents to return in each batch of the response from MongoDB instance. In most cases, modifying the batch size will not affect the user or the application. Cosmos DB limits each batch cannot exceed 40 MB in size, which is the sum of the batchSize number of documents' size, so decrease this value if your document size being large.	No (the default is **100**)

TIP

The service supports consuming BSON document in **Strict mode**. Make sure your filter query is in Strict mode instead of Shell mode. More description can be found at MongoDB manual.

Example:

```
"activities":[
    {
        "name": "CopyFromMongoDB",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<MongoDB input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MongoDbV2Source",
                "filter": "{datetimeData: {$gte: ISODate(\"2018-12-11T00:00:00.000Z\"),$lt: ISODate(\"2018-
12-12T00:00:00.000Z\")}, _id: ObjectId(\"5acd7c3d0000000000000000\") }",
                "cursorMethods": {
                    "project": "{ _id : 1, name : 1, age: 1, datetimeData: 1 }",
                    "sort": "{ age : 1 }",
                    "skip": 3,
                    "limit": 3
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

MongoDB as sink

The following properties are supported in the Copy Activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity sink must be set to **MongoDbV2Sink**.	Yes
writeBehavior	Describes how to write data to MongoDB. Allowed values: **insert** and **upsert**. The behavior of **upsert** is to replace the document if a document with the same `_id` already exists; otherwise, insert the document. **Note**: The service automatically generates an `_id` for a document if an `_id` isn't specified either in the original document or by column mapping. This means that you must ensure that, for **upsert** to work as expected, your document has an ID.	No (the default is **insert**)

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	The **writeBatchSize** property controls the size of documents to write in each batch. You can try increasing the value for **writeBatchSize** to improve performance and decreasing the value if your document size being large.	No (the default is **10,000**)
writeBatchTimeout	The wait time for the batch insert operation to finish before it times out. The allowed value is timespan.	No (the default is **00:30:00** - 30 minutes)

TIP

To import JSON documents as-is, refer to Import or export JSON documents section; to copy from tabular-shaped data, refer to Schema mapping.

Example

```
"activities":[
    {
        "name": "CopyToMongoDB",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Document DB output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "MongoDbV2Sink",
                "writeBehavior": "upsert"
            }
        }
    }
]
```

Import and export JSON documents

You can use this MongoDB connector to easily:

- Copy documents between two MongoDB collections as-is.
- Import JSON documents from various sources to MongoDB, including from Azure Cosmos DB, Azure Blob storage, Azure Data Lake Store, and other supported file-based stores.
- Export JSON documents from a MongoDB collection to various file-based stores.

To achieve such schema-agnostic copy, skip the "structure" (also called *schema*) section in dataset and schema mapping in copy activity.

Schema mapping

To copy data from MongoDB to tabular sink or reversed, refer to schema mapping.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from MongoDB using Azure Data Factory or Synapse Analytics (legacy)

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from a MongoDB database. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> The service has released a new MongoDB connector which provides better native MongoDB support comparing to this ODBC-based implementation, refer to MongoDB connector article on details. This legacy MongoDB connector is kept supported as-is for backward compatibility, while for any new workload, please use the new connector.

Supported capabilities

You can copy data from MongoDB database to any supported sink data store. For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this MongoDB connector supports:

- MongoDB **versions 2.4, 2.6, 3.0, 3.2, 3.4 and 3.6**.
- Copying data using **Basic** or **Anonymous** authentication.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The Integration Runtime provides a built-in MongoDB driver, therefore you don't need to manually install any driver when copying data from MongoDB.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

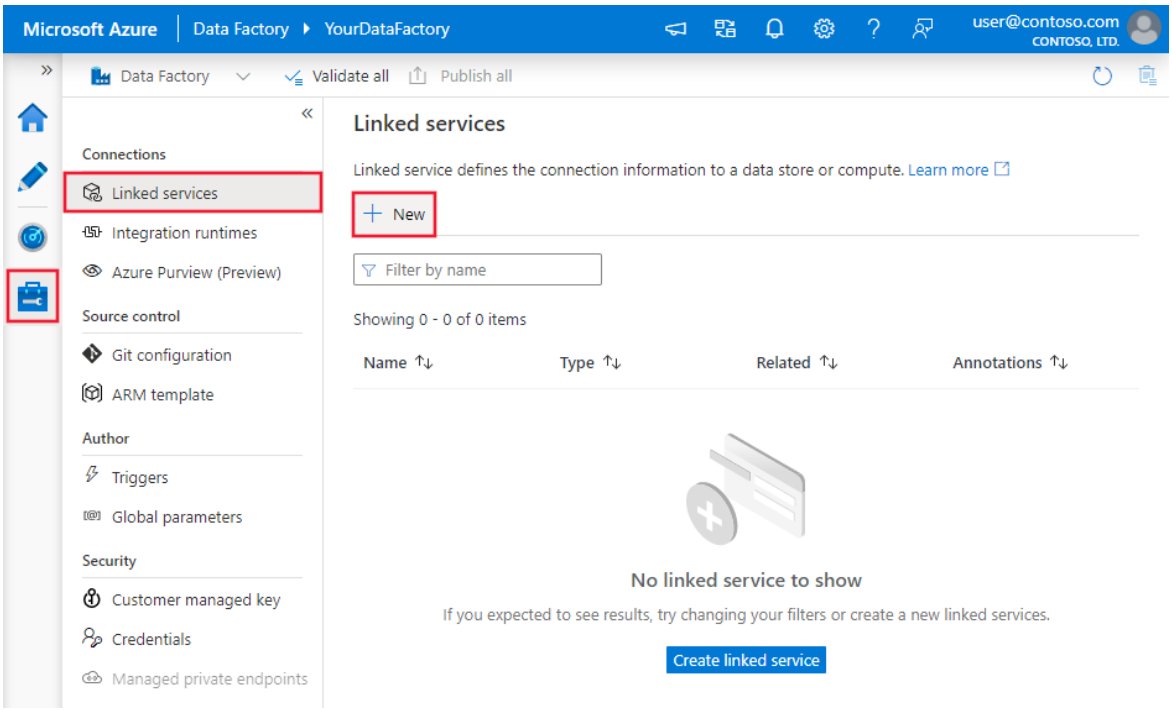
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to MongoDB using UI

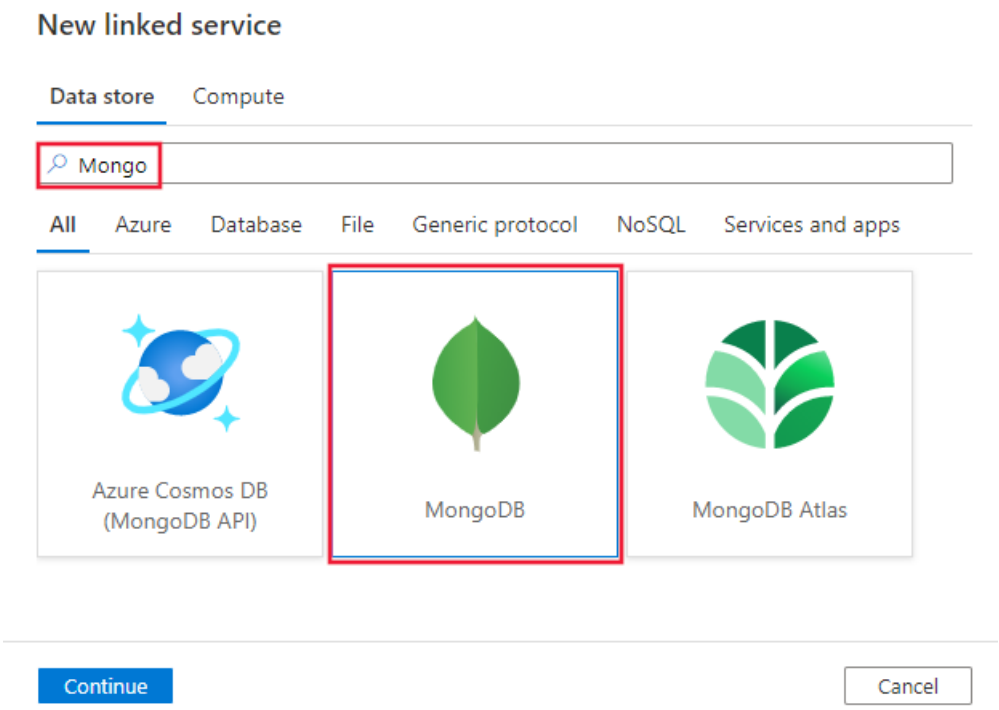
Use the following steps to create a linked service to MongoDB in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

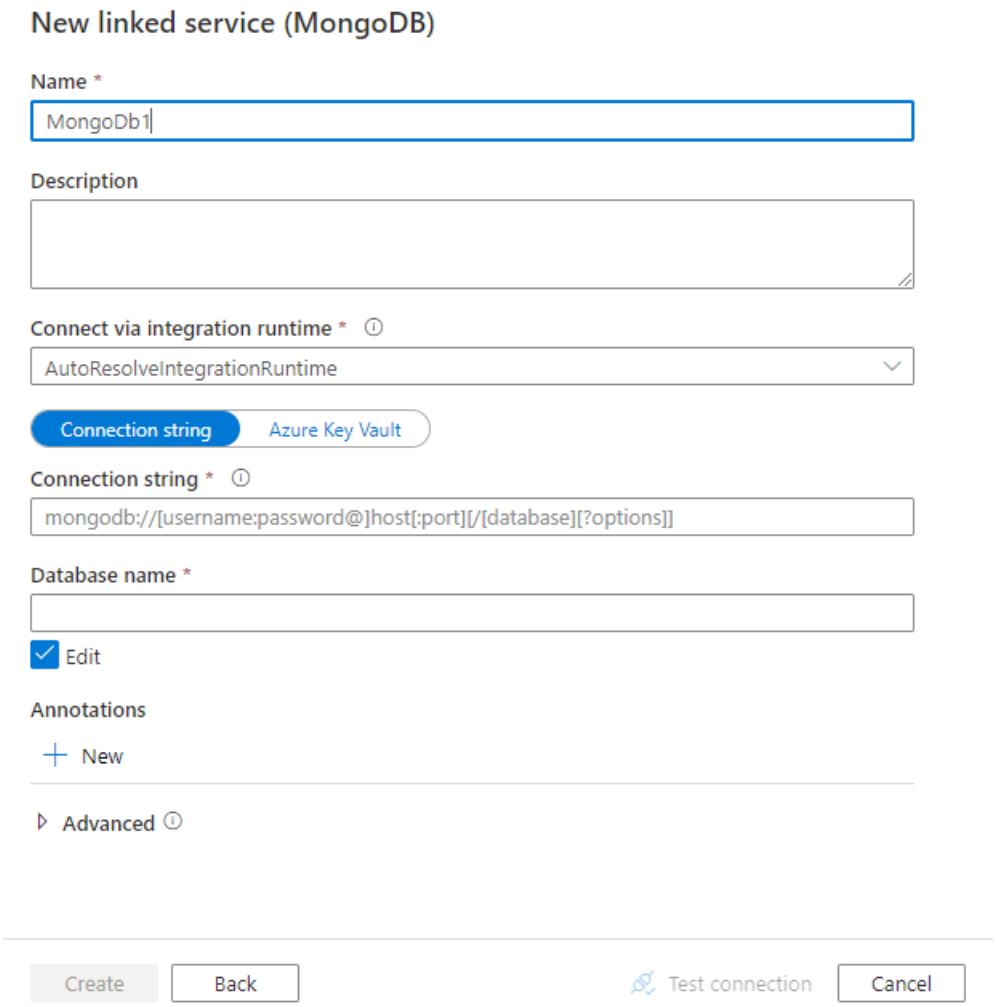
   - Azure Data Factory
   - Azure Synapse



2. Search for Mongo and select the MongoDB connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to MongoDB connector.

Linked service properties

The following properties are supported for MongoDB linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MongoDb**	Yes
server	IP address or host name of the MongoDB server.	Yes
port	TCP port that the MongoDB server uses to listen for client connections.	No (default is 27017)
databaseName	Name of the MongoDB database that you want to access.	Yes
authenticationType	Type of authentication used to connect to the MongoDB database. Allowed values are: **Basic**, and **Anonymous**.	Yes
username	User account to access MongoDB.	Yes (if basic authentication is used).
password	Password for the user. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes (if basic authentication is used).
authSource	Name of the MongoDB database that you want to use to check your credentials for authentication.	No. For basic authentication, default is to use the admin account and the database specified using databaseName property.
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "MongoDBLinkedService",
    "properties": {
        "type": "MongoDb",
        "typeProperties": {
            "server": "<server name>",
            "databaseName": "<database name>",
            "authenticationType": "Basic",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services. The following properties are supported for MongoDB dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MongoDbCollection**	Yes
collectionName	Name of the collection in MongoDB database.	Yes

Example:

```
{
    "name": "MongoDbDataset",
    "properties": {
        "type": "MongoDbCollection",
        "linkedServiceName": {
            "referenceName": "<MongoDB linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "collectionName": "<Collection name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by MongoDB source.

MongoDB as source

The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MongoDbSource**	Yes
query	Use the custom SQL-92 query to read data. For example: select * from MyTable.	No (if "collectionName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMongoDB",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<MongoDB input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MongoDbSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

TIP

When specify the SQL query, pay attention to the DateTime format. For example: `SELECT * FROM Account WHERE LastModifiedDate >= '2018-06-01' AND LastModifiedDate < '2018-06-02'` or to use parameter

```
SELECT * FROM Account WHERE LastModifiedDate >= '@{formatDateTime(pipeline().parameters.StartTime,'yyyy-MM-dd HH:mm:ss')}' AND LastModifiedDate < '@{formatDateTime(pipeline().parameters.EndTime,'yyyy-MM-dd HH:mm:ss')}'
```

Schema by Data Factory

Azure Data Factory service infers schema from a MongoDB collection by using the **latest 100 documents** in the collection. If these 100 documents do not contain full schema, some columns may be ignored during the copy operation.

Data type mapping for MongoDB

When copying data from MongoDB, the following mappings are used from MongoDB data types to interim data types used within the service internally. See Schema and data type mappings to learn about how copy activity

maps the source schema and data type to the sink.

MONGODB DATA TYPE	INTERIM SERVICE DATA TYPE
Binary	Byte[]
Boolean	Boolean
Date	DateTime
NumberDouble	Double
NumberInt	Int32
NumberLong	Int64
ObjectID	String
String	String
UUID	Guid
Object	Renormalized into flatten columns with "_" as nested separator

> **NOTE**
>
> To learn about support for arrays using virtual tables, refer to Support for complex types using virtual tables section.
>
> Currently, the following MongoDB data types are not supported: DBPointer, JavaScript, Max/Min key, Regular Expression, Symbol, Timestamp, Undefined.

Support for complex types using virtual tables

The service uses a built-in ODBC driver to connect to and copy data from your MongoDB database. For complex types such as arrays or objects with different types across the documents, the driver re-normalizes data into corresponding virtual tables. Specifically, if a table contains such columns, the driver generates the following virtual tables:

- A **base table**, which contains the same data as the real table except for the complex type columns. The base table uses the same name as the real table that it represents.
- A **virtual table** for each complex type column, which expands the nested data. The virtual tables are named using the name of the real table, a separator "_" and the name of the array or object.

Virtual tables refer to the data in the real table, enabling the driver to access the de-normalized data. You can access the content of MongoDB arrays by querying and joining the virtual tables.

Example

For example, ExampleTable here is a MongoDB table that has one column with an array of Objects in each cell – Invoices, and one column with an array of Scalar types – Ratings.

_ID	CUSTOMER NAME	INVOICES	SERVICE LEVEL	RATINGS
1111	ABC	[{invoice_id:"123", item:"toaster", price:"456", discount:"0.2"}, {invoice_id:"124", item:"oven", price: "1235", discount: "0.2"}]	Silver	[5,6]
2222	XYZ	[{invoice_id:"135", item:"fridge", price: "12543", discount: "0.0"}]	Gold	[1,2]

The driver would generate multiple virtual tables to represent this single table. The first virtual table is the base table named "ExampleTable", shown in the example. The base table contains all the data of the original table, but the data from the arrays has been omitted and is expanded in the virtual tables.

_ID	CUSTOMER NAME	SERVICE LEVEL
1111	ABC	Silver
2222	XYZ	Gold

The following tables show the virtual tables that represent the original arrays in the example. These tables contain the following:

- A reference back to the original primary key column corresponding to the row of the original array (via the _id column)
- An indication of the position of the data within the original array
- The expanded data for each element within the array

Table "ExampleTable_Invoices":

_ID	EXAMPLETABLE_INVOICES_DIM1_IDX	INVOICE_ID	ITEM	PRICE	DISCOUNT
1111	0	123	toaster	456	0.2
1111	1	124	oven	1235	0.2
2222	0	135	fridge	12543	0.0

Table "ExampleTable_Ratings":

_ID	EXAMPLETABLE_RATINGS_DIM1_IDX	EXAMPLETABLE_RATINGS
1111	0	5
1111	1	6
2222	0	1

_ID	EXAMPLETABLE_RATINGS_DIM1_IDX	EXAMPLETABLE_RATINGS
2222	1	2

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from or to MongoDB Atlas using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from and to a MongoDB Atlas database. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This MongoDB Atlas connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this MongoDB Atlas connector supports **versions up to 4.2**.

Prerequisites

If you use Azure Integration Runtime for copy, make sure you add the effective region's Azure Integration Runtime IPs to the MongoDB Atlas IP Access List.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

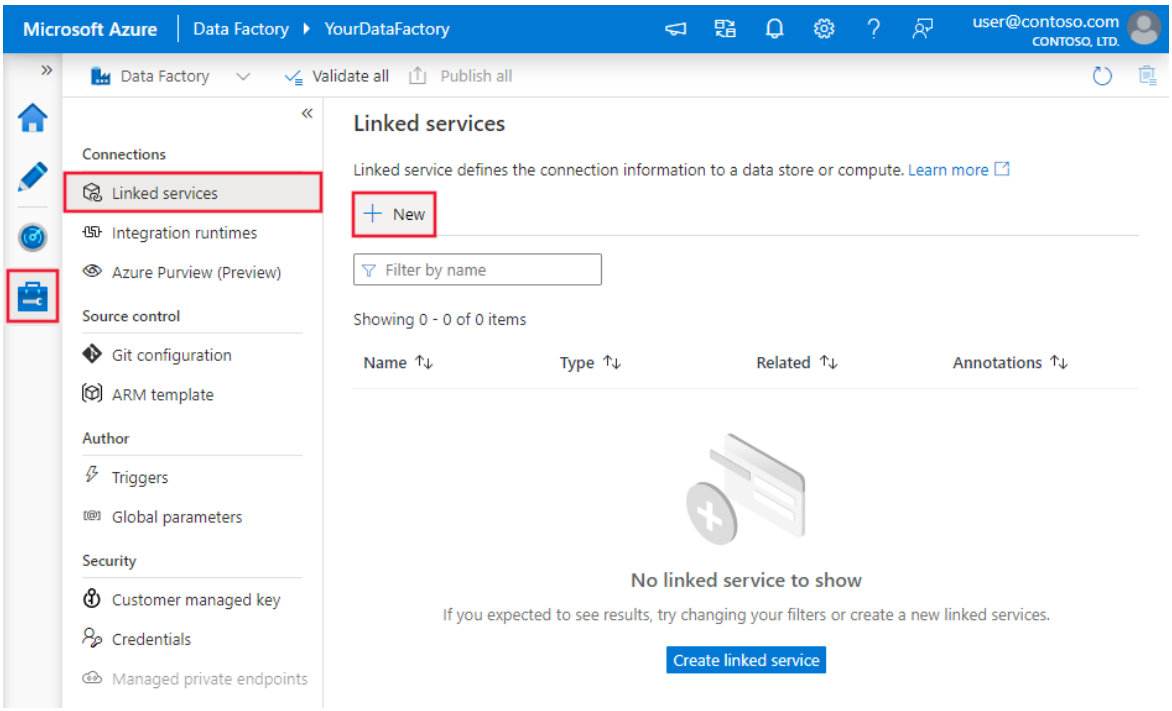
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to MongoDB Atlas using UI

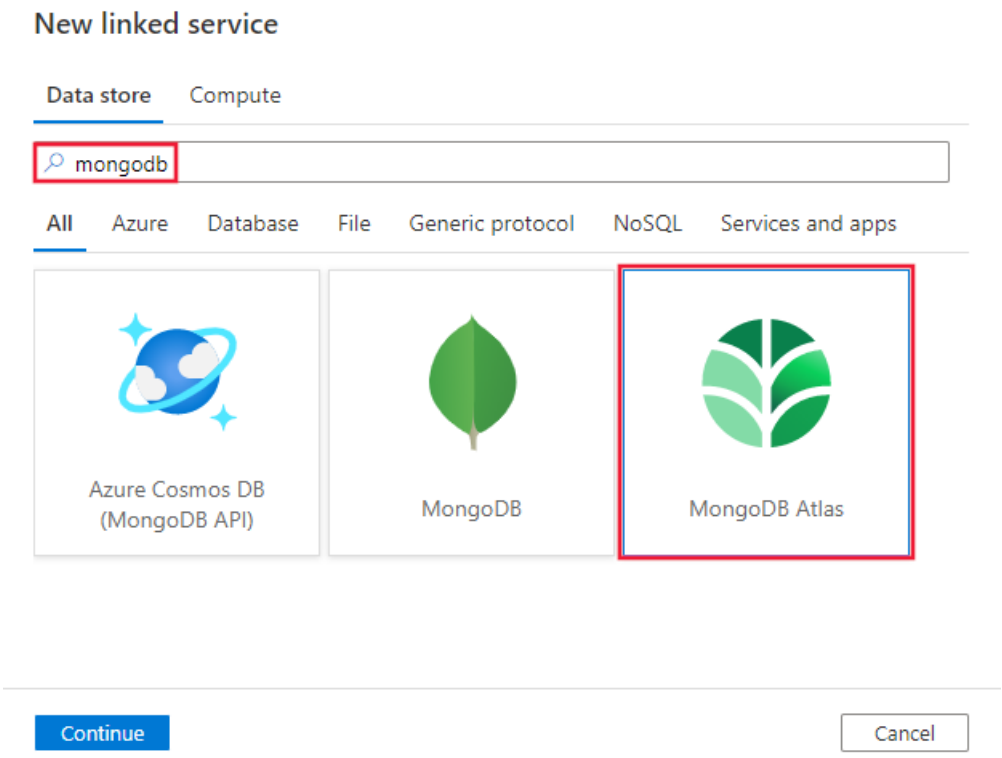
Use the following steps to create a linked service to MongoDB Atlas in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

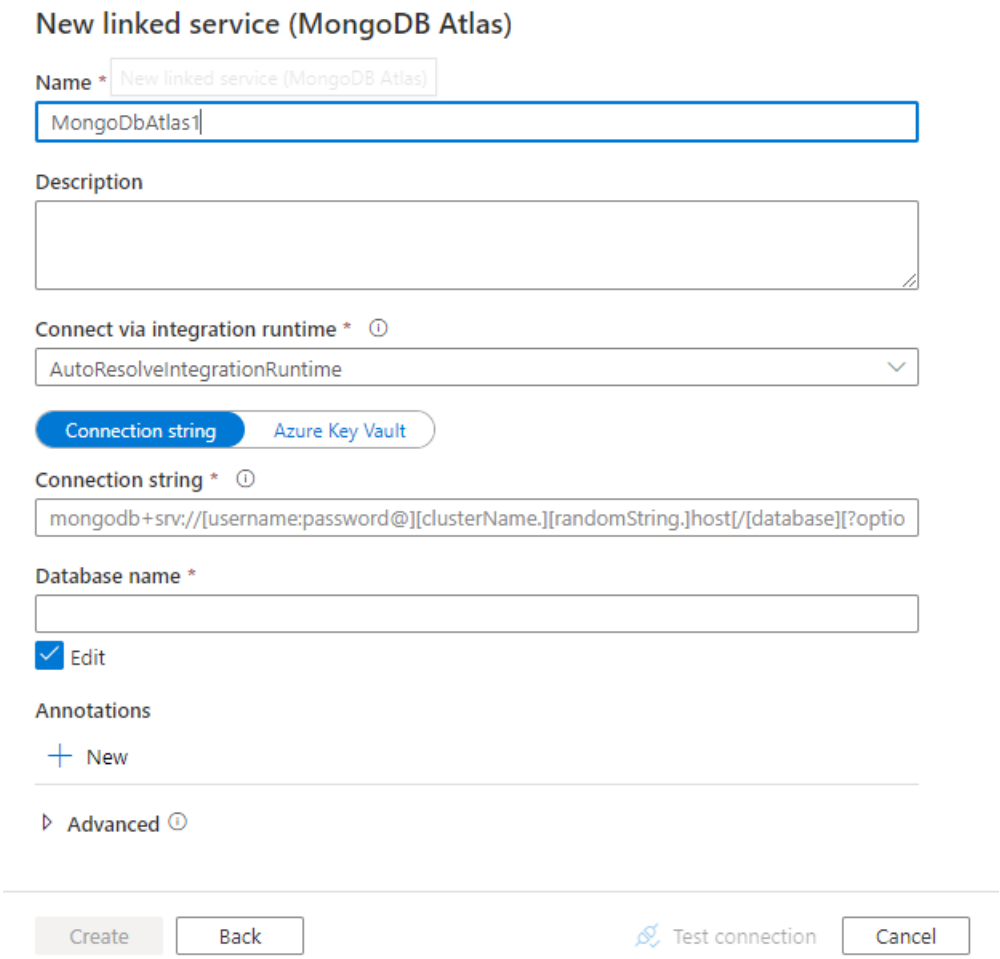
   - Azure Data Factory
   - Azure Synapse



2. Search for MongoDB and select the MongoDB Atlas connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to MongoDB Atlas connector.

Linked service properties

The following properties are supported for MongoDB Atlas linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MongoDbAtlas**	Yes
connectionString	Specify the MongoDB Atlas connection string e.g. `mongodb+srv://<username>:<password>@<clustername>.<randomString>.<hostName>/<dbname>?<otherProperties>`. You can also put a connection string in Azure Key Vault. Refer to Store credentials in Azure Key Vault with more details.	Yes
database	Name of the database that you want to access.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "MongoDbAtlasLinkedService",
    "properties": {
        "type": "MongoDbAtlas",
        "typeProperties": {
            "connectionString": "mongodb+srv://<username>:<password>@<clustername>.<randomString>.
<hostName>/<dbname>?<otherProperties>",
            "database": "myDatabase"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services. The following properties are supported for MongoDB Atlas dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MongoDbAtlasCollection**	Yes
collectionName	Name of the collection in MongoDB Atlas database.	Yes

Example:

```
{
    "name": "MongoDbAtlasDataset",
    "properties": {
        "type": "MongoDbAtlasCollection",
        "typeProperties": {
            "collectionName": "<Collection name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<MongoDB Atlas linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by MongoDB Atlas source and sink.

MongoDB Atlas as source

The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MongoDbAtlasSource**	Yes
filter	Specifies selection filter using query operators. To return all documents in a collection, omit this parameter or pass an empty document ({}).	No
cursorMethods.project	Specifies the fields to return in the documents for projection. To return all fields in the matching documents, omit this parameter.	No
cursorMethods.sort	Specifies the order in which the query returns matching documents. Refer to cursor.sort().	No
cursorMethods.limit	Specifies the maximum number of documents the server returns. Refer to cursor.limit().	No
cursorMethods.skip	Specifies the number of documents to skip and from where MongoDB Atlas begins to return results. Refer to cursor.skip().	No
batchSize	Specifies the number of documents to return in each batch of the response from MongoDB Atlas instance. In most cases, modifying the batch size will not affect the user or the application. Cosmos DB limits each batch cannot exceed 40MB in size, which is the sum of the batchSize number of documents' size, so decrease this value if your document size being large.	No (the default is **100**)

TIP

The service supports consuming BSON document in **Strict mode**. Make sure your filter query is in Strict mode instead of Shell mode. More description can be found at MongoDB manual.

Example:

```
"activities":[
    {
        "name": "CopyFromMongoDbAtlas",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<MongoDB Atlas input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MongoDbAtlasSource",
                "filter": "{datetimeData: {$gte: ISODate(\"2018-12-11T00:00:00.000Z\"),$lt: ISODate(\"2018-
12-12T00:00:00.000Z\")}, _id: ObjectId(\"5acd7c3d0000000000000000\") }",
                "cursorMethods": {
                    "project": "{ _id : 1, name : 1, age: 1, datetimeData: 1 }",
                    "sort": "{ age : 1 }",
                    "skip": 3,
                    "limit": 3
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

MongoDB Atlas as sink

The following properties are supported in the Copy Activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity sink must be set to **MongoDbAtlasSink**.	Yes
writeBehavior	Describes how to write data to MongoDB Atlas. Allowed values: **insert** and **upsert**. The behavior of **upsert** is to replace the document if a document with the same `_id` already exists; otherwise, insert the document. **Note**: The service automatically generates an `_id` for a document if an `_id` isn't specified either in the original document or by column mapping. This means that you must ensure that, for **upsert** to work as expected, your document has an ID.	No (the default is **insert**)

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	The **writeBatchSize** property controls the size of documents to write in each batch. You can try increasing the value for **writeBatchSize** to improve performance and decreasing the value if your document size being large.	No (the default is **10,000**)
writeBatchTimeout	The wait time for the batch insert operation to finish before it times out. The allowed value is timespan.	No (the default is **00:30:00** - 30 minutes)

TIP

To import JSON documents as-is, refer to Import or export JSON documents section; to copy from tabular-shaped data, refer to Schema mapping.

Example

```
"activities":[
    {
        "name": "CopyToMongoDBAtlas",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Document DB output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "MongoDbAtlasSink",
                "writeBehavior": "upsert"
            }
        }
    }
]
```

Import and Export JSON documents

You can use this MongoDB Atlas connector to easily:

- Copy documents between two MongoDB Atlas collections as-is.
- Import JSON documents from various sources to MongoDB Atlas, including from Azure Cosmos DB, Azure Blob storage, Azure Data Lake Store, and other supported file-based stores.
- Export JSON documents from a MongoDB Atlas collection to various file-based stores.

To achieve such schema-agnostic copy, skip the "structure" (also called *schema*) section in dataset and schema mapping in copy activity.

Schema mapping

To copy data from MongoDB Atlas to tabular sink or reversed, refer to schema mapping.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from MySQL using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from a MySQL database. It builds on the copy activity overview article that presents a general overview of copy activity.

> **NOTE**
> To copy data from or to Azure Database for MySQL service, use the specialized Azure Database for MySQL connector.

Supported capabilities

This MySQL connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this MySQL connector supports MySQL **version 5.6, 5.7 and 8.0**.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The Integration Runtime provides a built-in MySQL driver starting from version 3.7, therefore you don't need to manually install any driver.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

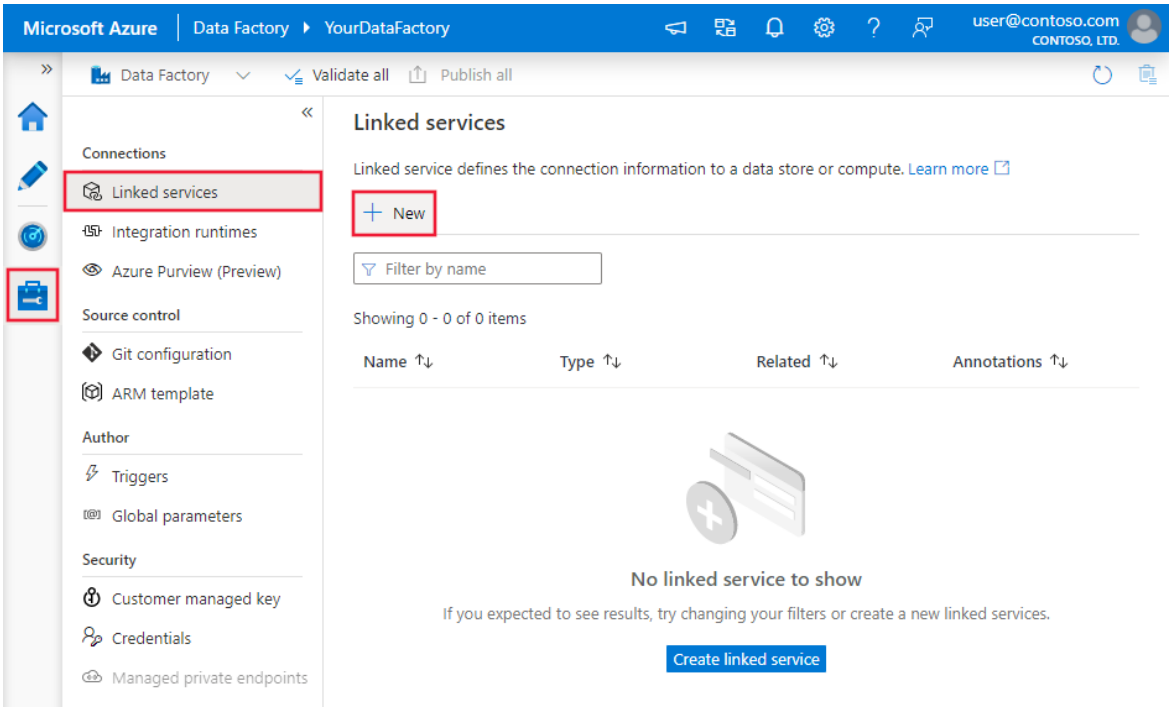
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to MySQL using UI

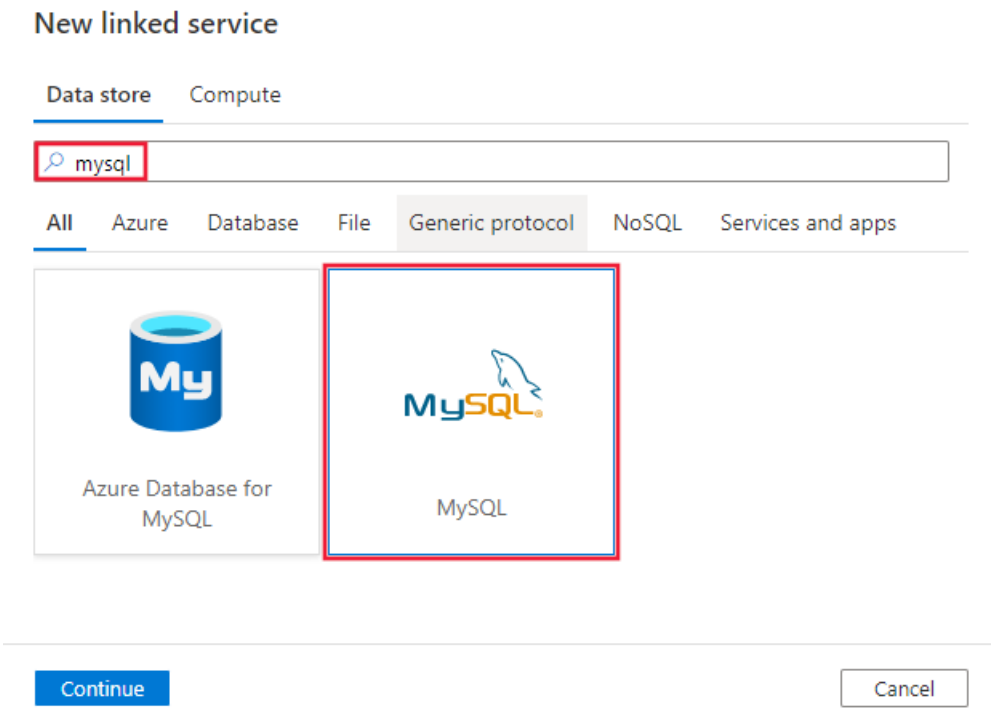
Use the following steps to create a linked service to MySQL in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

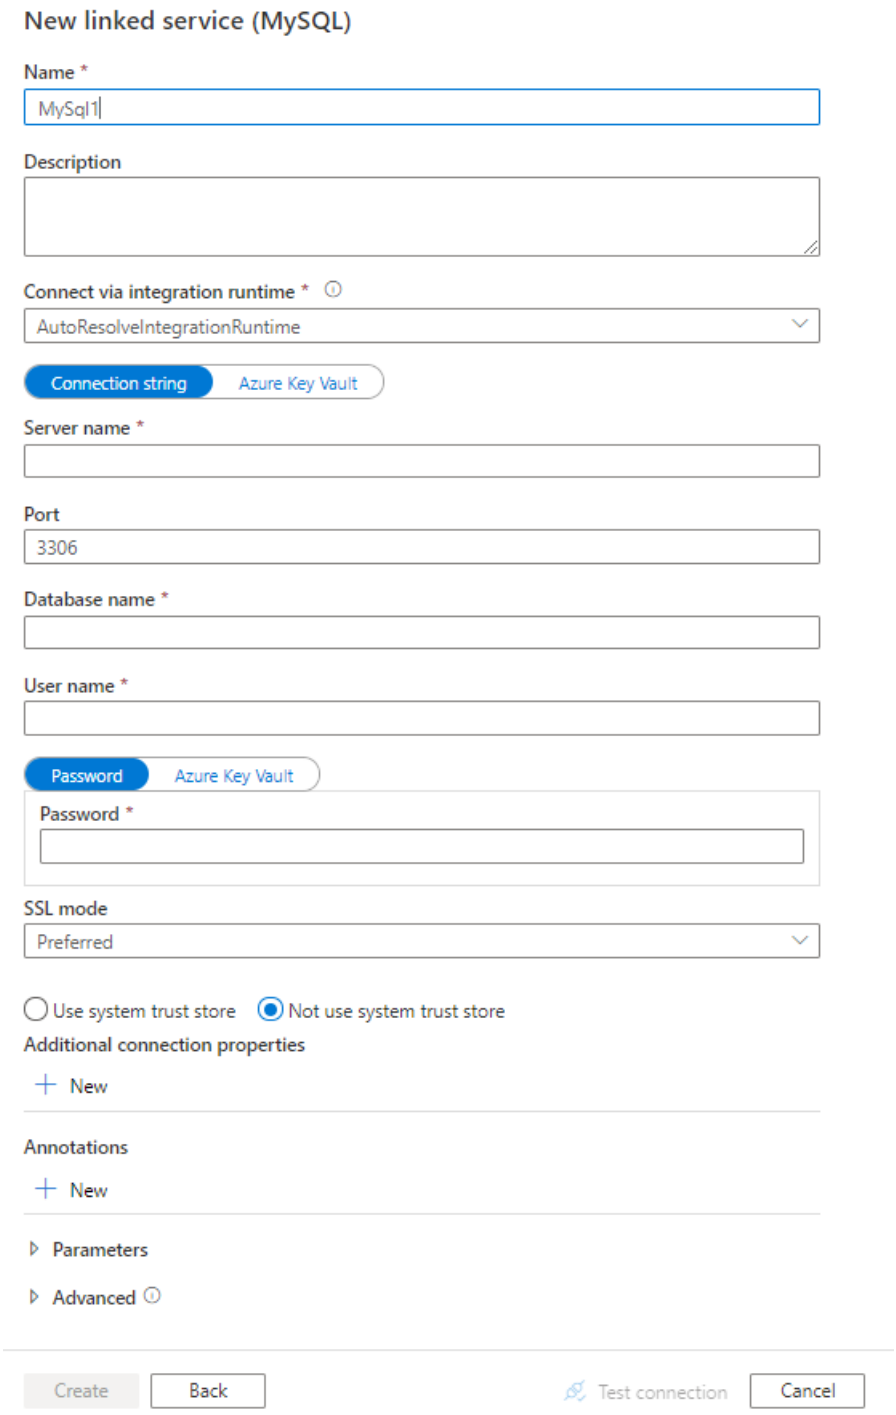
   - Azure Data Factory
   - Azure Synapse



2. Search for MySQL and select the MySQL connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to MySQL connector.

Linked service properties

The following properties are supported for MySQL linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **MySql**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify information needed to connect to the Azure Database for MySQL instance. You can also put password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

A typical connection string is `Server=<server>;Port=<port>;Database=<database>;UID=<username>;PWD=<password>`.
More properties you can set per your case:

PROPERTY	DESCRIPTION	OPTIONS	REQUIRED
SSLMode	This option specifies whether the driver uses TLS encryption and verification when connecting to MySQL. E.g., `SSLMode=<0/1/2/3/4>`.	DISABLED (0) / PREFERRED (1) **(Default)** / REQUIRED (2) / VERIFY_CA (3) / VERIFY_IDENTITY (4)	No
SSLCert	The full path and name of a .pem file containing the SSL certificate used for proving the identity of the client. To specify a private key for encrypting this certificate before sending it to the server, use the `SSLKey` property.		Yes, if using two-way SSL verification.
SSLKey	The full path and name of a file containing the private key used for encrypting the client-side certificate during two-way SSL verification.		Yes, if using two-way SSL verification.
UseSystemTrustStore	This option specifies whether to use a CA certificate from the system trust store, or from a specified PEM file. E.g. `UseSystemTrustStore=<0/1>;`	Enabled (1) / Disabled (0) **(Default)**	No

Example:

```
{
    "name": "MySQLLinkedService",
    "properties": {
        "type": "MySql",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<username>;PWD=
<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "MySQLLinkedService",
    "properties": {
        "type": "MySql",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

If you were using MySQL linked service with the following payload, it is still supported as-is, while you are suggested to use the new one going forward.

Previous payload:

```
{
    "name": "MySQLLinkedService",
    "properties": {
        "type": "MySql",
        "typeProperties": {
            "server": "<server>",
            "database": "<database>",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by MySQL dataset.

To copy data from MySQL, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **MySqlTable**	Yes
tableName	Name of the table in the MySQL database.	No (if "query" in activity source is specified)

Example

```
{
    "name": "MySQLDataset",
    "properties":
    {
        "type": "MySqlTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<MySQL linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by MySQL source.

MySQL as source

To copy data from MySQL, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **MySqlSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromMySQL",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<MySQL input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "MySqlSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Data type mapping for MySQL

When copying data from MySQL, the following mappings are used from MySQL data types to interim data types used by the service internally. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`bigint`	`Int64`
`bigint unsigned`	`Decimal`
`bit(1)`	`Boolean`

MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`bit(M), M>1`	`Byte[]`
`blob`	`Byte[]`
`bool`	`Int16`
`char`	`String`
`date`	`Datetime`
`datetime`	`Datetime`
`decimal`	`Decimal, String`
`double`	`Double`
`double precision`	`Double`
`enum`	`String`
`float`	`Single`
`int`	`Int32`
`int unsigned`	`Int64`
`integer`	`Int32`
`integer unsigned`	`Int64`
`long varbinary`	`Byte[]`
`long varchar`	`String`
`longblob`	`Byte[]`
`longtext`	`String`
`mediumblob`	`Byte[]`
`mediumint`	`Int32`
`mediumint unsigned`	`Int64`
`mediumtext`	`String`
`numeric`	`Decimal`

MYSQL DATA TYPE	INTERIM SERVICE DATA TYPE
`real`	`Double`
`set`	`String`
`smallint`	`Int16`
`smallint unsigned`	`Int32`
`text`	`String`
`time`	`TimeSpan`
`timestamp`	`Datetime`
`tinyblob`	`Byte[]`
`tinyint`	`Int16`
`tinyint unsigned`	`Int16`
`tinytext`	`String`
`varchar`	`String`
`year`	`Int`

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Netezza by using Azure Data Factory or Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory or Synapse Analytics pipelines to copy data from Netezza. The article builds on Copy Activity, which presents a general overview of Copy Activity.

> **TIP**
> For data migration scenario from Netezza to Azure, learn more from Migrate data from on-premises Netezza server to Azure.

Supported capabilities

This Netezza connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Netezza connector supports parallel copying from source. See the Parallel copy from Netezza section for details.

The service provides a built-in driver to enable connectivity. You don't need to manually install any driver to use this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

You can create a pipeline that uses a copy activity by using the .NET SDK, the Python SDK, Azure PowerShell, the

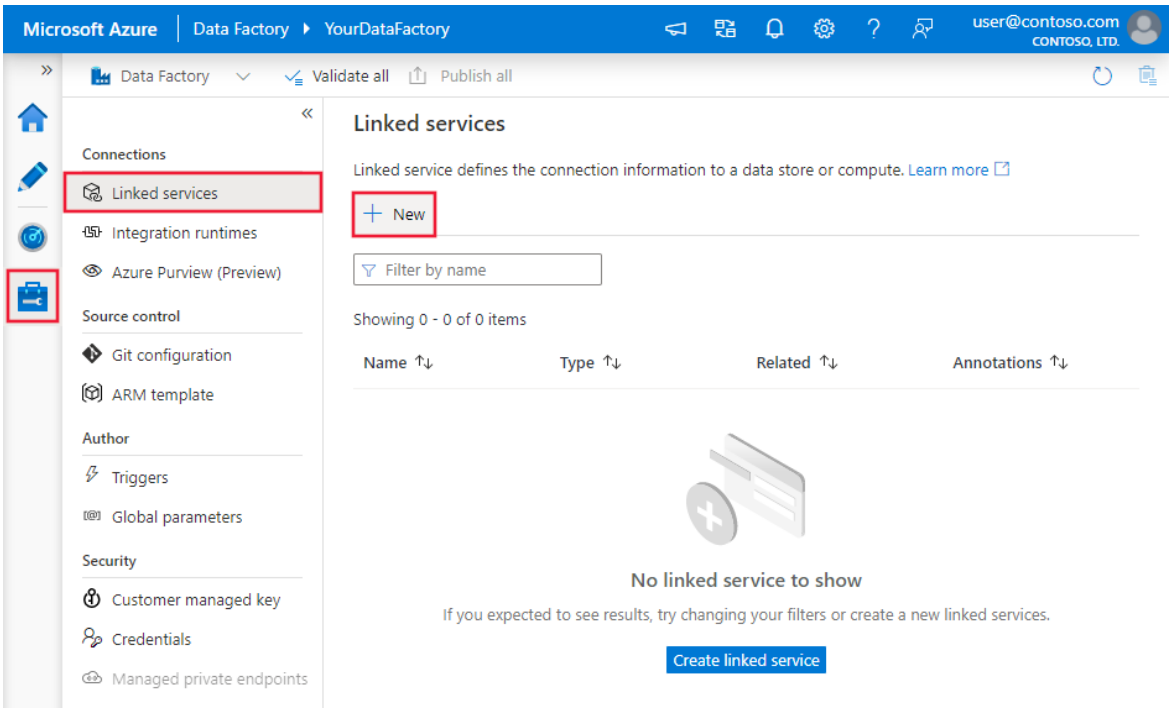
REST API, or an Azure Resource Manager template. See the Copy Activity tutorialfor step-by-step instructions to create a pipeline with a copy activity.

Create a linked service to Netezza using UI

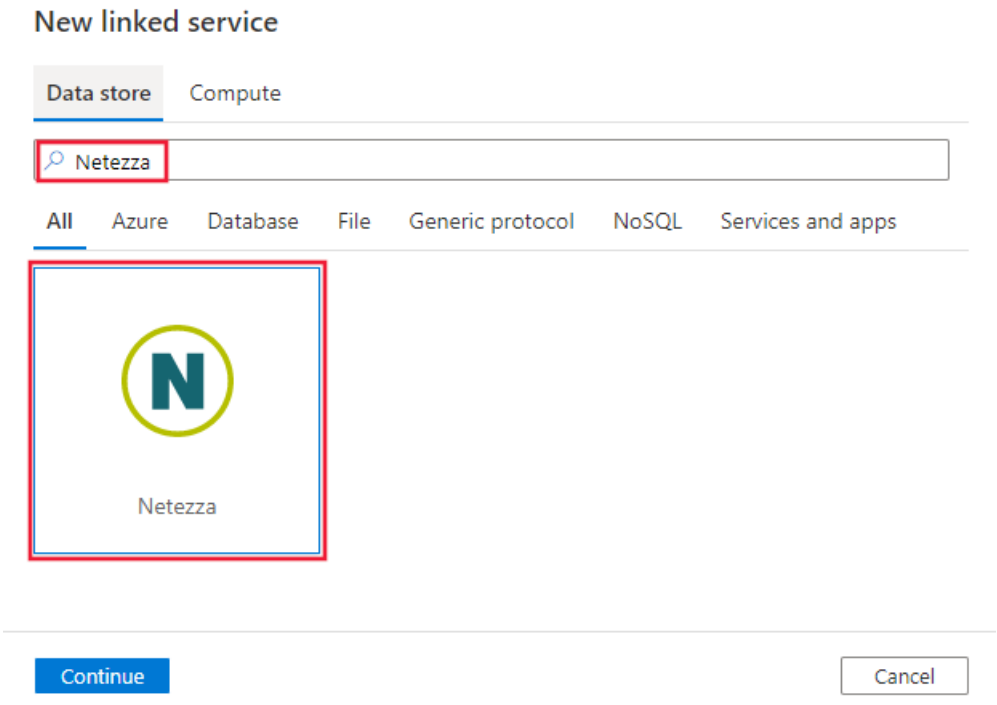
Use the following steps to create a linked service to Netezza in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

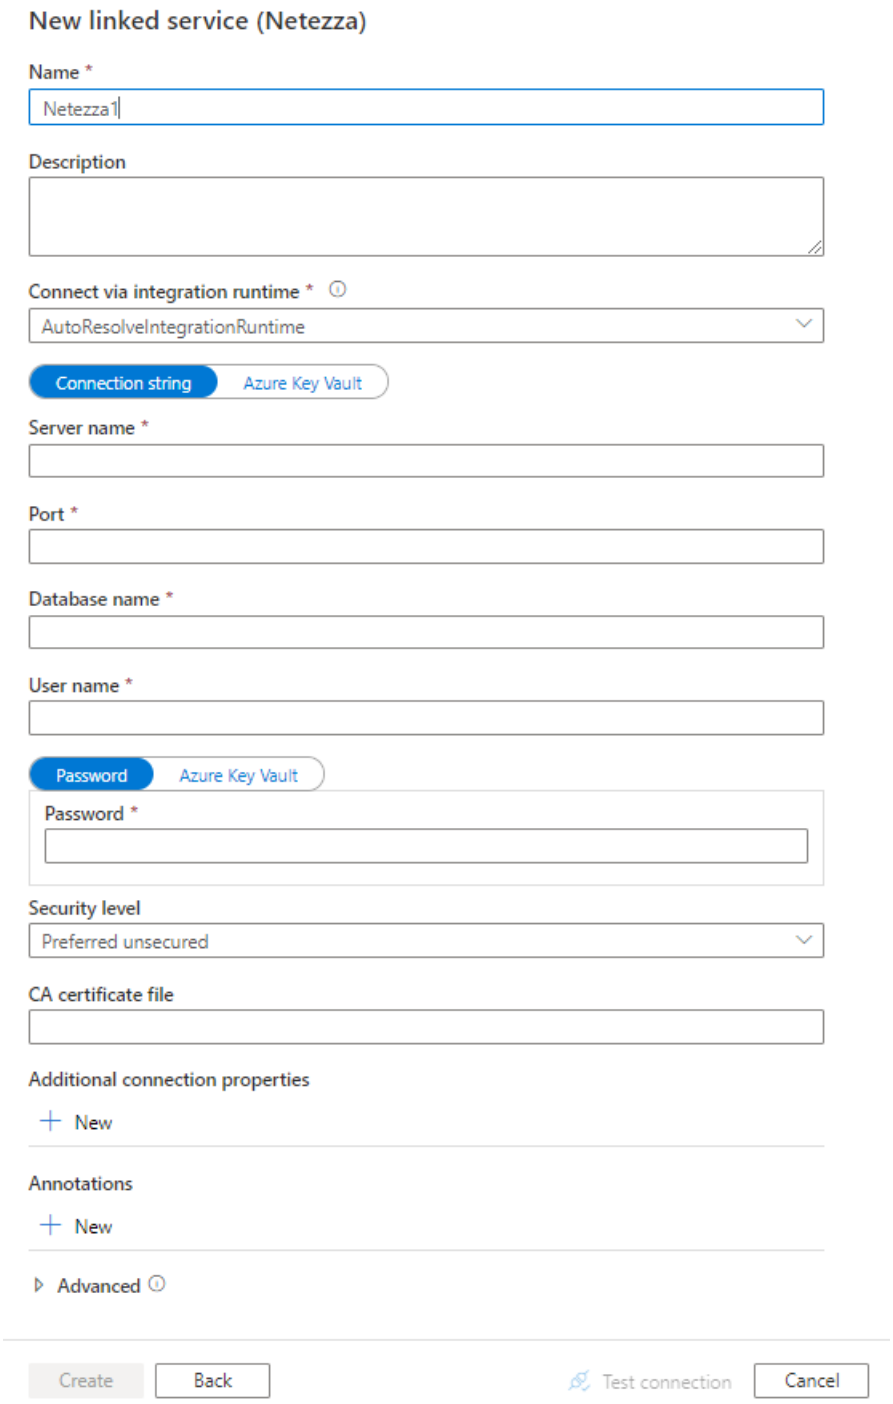
   - Azure Data Factory
   - Azure Synapse



2. Search for Netezza and select the Netezza connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define entities that are specific to the Netezza connector.

Linked service properties

The following properties are supported for the Netezza linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **Netezza**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to Netezza. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to use to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure Integration Runtime is used.	No

A typical connection string is `Server=<server>;Port=<port>;Database=<database>;UID=<user name>;PWD=<password>`.
The following table describes more properties that you can set:

PROPERTY	DESCRIPTION	REQUIRED
