- Azure Synapse Analytics
- Switch to dedicated SQL pool (formerly SQL DW) >
- Overview
  - What is Azure Synapse?
  - What's new?
  - Terminology
  - FAQ
- Quickstarts
  - Get started
  - 1 Create a Synapse workspace
  - 2 Analyze using serverless SQL pool
  - 3 Analyze using a Data Explorer pool
  - 4 Analyze using a serverless Spark pool
  - 5 Analyze using a dedicated SQL pool
  - 6 Analyze data in a storage account
  - 7 Integrate with pipelines
  - 8 Visualize with Power BI
  - 9 Monitor
  - 10 Explore the Knowledge center
  - 11 Add an administrator
- Workspace
  - Quickstarts
    - Create a workspace
      - Azure portal
      - Azure CLI
      - Azure PowerShell
      - ARM template
    - Link a Power BI workspace
    - Read ADLS Gen2 into Pandas dataframe

- Connect to Azure Data Explorer
- Partner solutions
- Concepts
  - Shared metadata management
    - Overview
    - Metadata objects
      - Shared databases
      - Shared tables
    - Code artifacts
      - Apache Spark Notebooks
      - SQL script
      - Data Flow
  - Maintenance schedule
  - Source control
  - Continuous integration and delivery
  - Security
    - Security baseline
    - Security Controls by Azure Policy
    - Encryption
    - Network Security
      - Synapse workspace IP firewall rules
      - Connectivity settings
      - Synapse workspace Managed virtual network
      - Synapse workspace Managed private endpoints
      - Synapse workspace data exfiltration protection
      - Synapse workspace with private link hubs
      - Connect to a secured storage account
    - Authentication and pass-through
      - Azure Active Directory
      - Multi-factor authentication
      - SQL authorization
      - Conditional Access

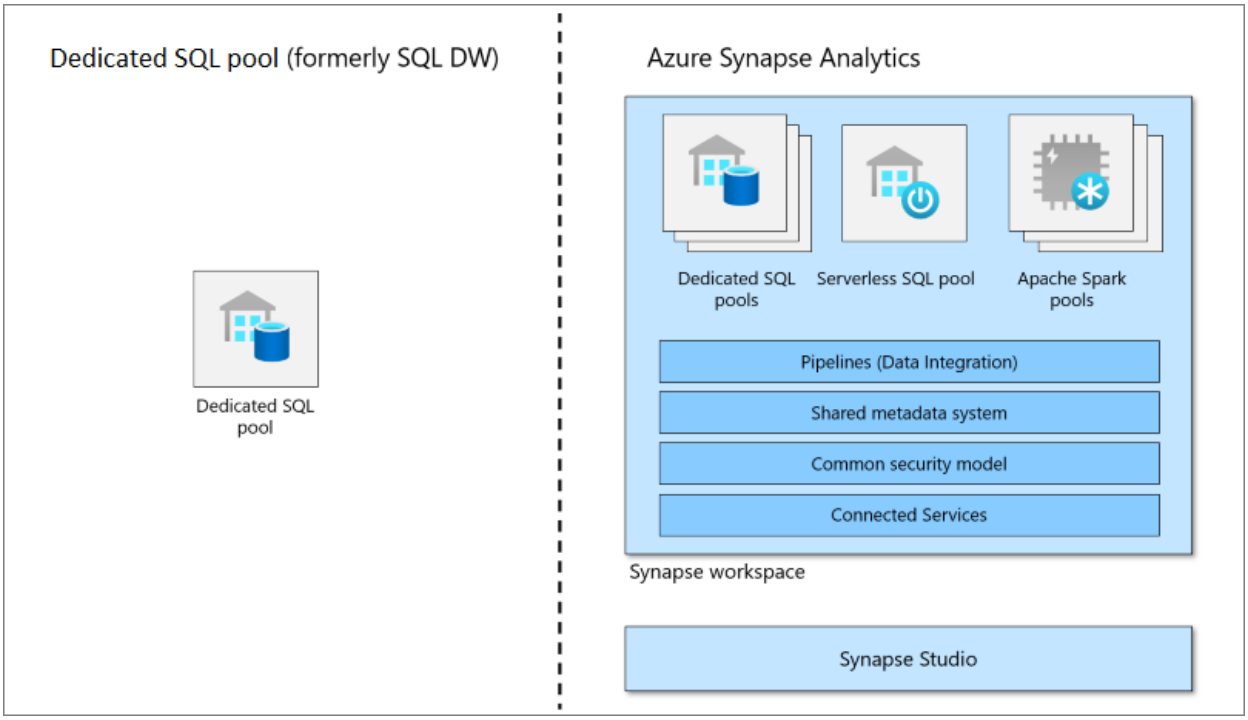
What is dedicated SQL pool (formerly SQL DW) in Azure Synapse Analytics?

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics is an analytics service that brings together enterprise data warehousing and Big Data analytics. Dedicated SQL pool (formerly SQL DW) refers to the enterprise data warehousing features that are available in Azure Synapse Analytics.



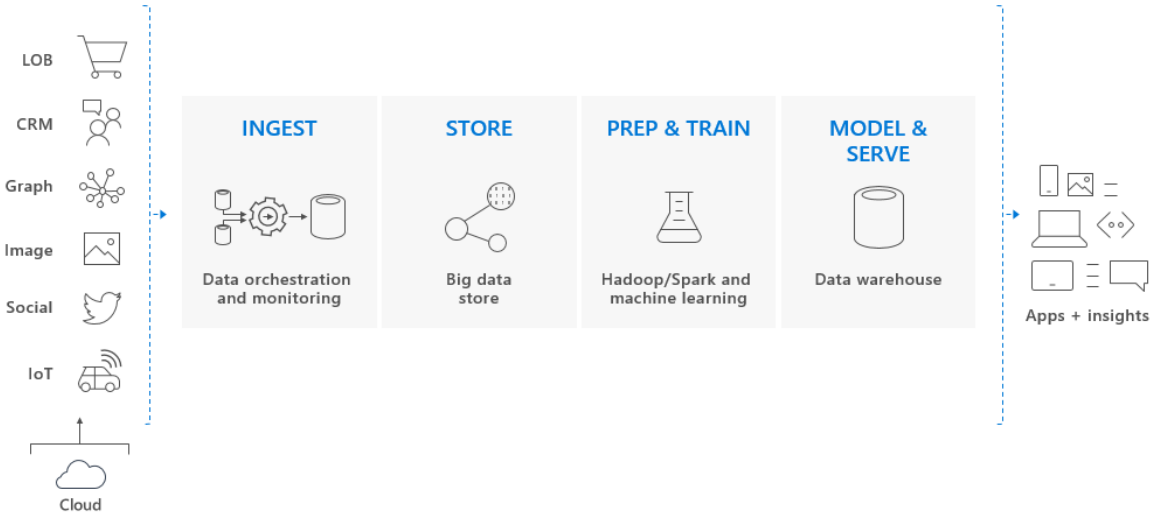
Dedicated SQL pool (formerly SQL DW) represents a collection of analytic resources that are provisioned when using Synapse SQL. The size of a dedicated SQL pool (formerly SQL DW) is determined by Data Warehousing Units (DWU).

Once your dedicated SQL pool is created, you can import big data with simple PolyBase T-SQL queries, and then use the power of the distributed query engine to run high-performance analytics. As you integrate and analyze the data, dedicated SQL pool (formerly SQL DW) will become the single version of truth your business can count on for faster and more robust insights.

> **NOTE**
> Not all features of the dedicated SQL pool in Azure Synapse workspaces apply to dedicated SQL pool (formerly SQL DW), and vice versa. To enable workspace features for an existing dedicated SQL pool (formerly SQL DW) refer to How to enable a workspace for your dedicated SQL pool (formerly SQL DW). Explore the Azure Synapse Analytics documentation and Get Started with Azure Synapse.

Key component of a big data solution

Data warehousing is a key component of a cloud-based, end-to-end big data solution.



In a cloud data solution, data is ingested into big data stores from a variety of sources. Once in a big data store, Hadoop, Spark, and machine learning algorithms prepare and train the data. When the data is ready for complex analysis, dedicated SQL pool uses PolyBase to query the big data stores. PolyBase uses standard T-SQL queries to bring the data into dedicated SQL pool (formerly SQL DW) tables.

Dedicated SQL pool (formerly SQL DW) stores data in relational tables with columnar storage. This format significantly reduces the data storage costs, and improves query performance. Once data is stored, you can run analytics at massive scale. Compared to traditional database systems, analysis queries finish in seconds instead of minutes, or hours instead of days.

The analysis results can go to worldwide reporting databases or applications. Business analysts can then gain insights to make well-informed business decisions.

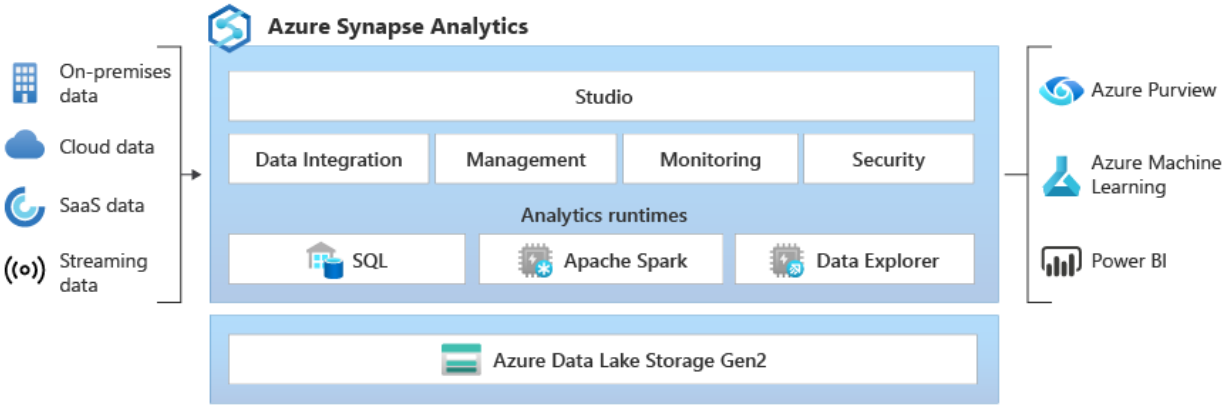
What is Azure Synapse Analytics?

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse is an enterprise analytics service that accelerates time to insight across data warehouses and big data systems. Azure Synapse brings together the best of **SQL** technologies used in enterprise data warehousing, **Spark** technologies used for big data, **Data Explorer** for log and time series analytics, **Pipelines** for data integration and ETL/ELT, and deep integration with other Azure services such as **Power BI**, **CosmosDB**, and **AzureML**.



Industry-leading SQL

Synapse SQL is a distributed query system for T-SQL that enables data warehousing and data virtualization scenarios and extends T-SQL to address streaming and machine learning scenarios.

- Synapse SQL offers both **serverless** and **dedicated** resource models. For predictable performance and cost, create dedicated SQL pools to reserve processing power for data stored in SQL tables. For unplanned or bursty workloads, use the always-available, serverless SQL endpoint.
- Use built-in **streaming** capabilities to land data from cloud data sources into SQL tables
- Integrate AI with SQL by using **machine learning** models to score data using the T-SQL PREDICT function

Industry-standard Apache Spark

Apache Spark for Azure Synapse deeply and seamlessly integrates Apache Spark--the most popular open source big data engine used for data preparation, data engineering, ETL, and machine learning.

- ML models with SparkML algorithms and AzureML integration for Apache Spark 3.1 with built-in support for Linux Foundation Delta Lake.
- Simplified resource model that frees you from having to worry about managing clusters.
- Fast Spark start-up and aggressive autoscaling.
- Built-in support for .NET for Spark allowing you to reuse your C# expertise and existing .NET code within a Spark application.

Working with your Data Lake

Azure Synapse removes the traditional technology barriers between using SQL and Spark together. You can seamlessly mix and match based on your needs and expertise.

- Tables defined on files in the data lake are seamlessly consumed by either Spark or Hive.

- SQL and Spark can directly explore and analyze Parquet, CSV, TSV, and JSON files stored in the data lake.
- Fast, scalable data loading between SQL and Spark databases

Built-in data integration

Azure Synapse contains the same Data Integration engine and experiences as Azure Data Factory, allowing you to create rich at-scale ETL pipelines without leaving Azure Synapse Analytics.

- Ingest data from 90+ data sources
- Code-Free ETL with Data flow activities
- Orchestrate notebooks, Spark jobs, stored procedures, SQL scripts, and more

Data Explorer (Preview)

Azure Synapse Data Explorer provides customers with an interactive query experience to unlock insights from log and telemetry data. To complement existing SQL and Apache Spark analytics runtime engines, Data Explorer analytics runtime is optimized for efficient log analytics using powerful indexing technology to automatically index free-text and semi-structured data commonly found in the telemetry data.

Use Data Explorer as a data platform for building near real-time log analytics and IoT analytics solutions to:

- Consolidate and correlate your logs and events data across on-premises, cloud, third-party data sources.
- Accelerate your AI Ops journey (pattern recognition, anomaly detection, forecasting, and more)
- Replace infrastructure-based log search solutions to save cost and increase productivity.
- Build IoT Analytics solution for your IoT data.
- Build Analytical SaaS solutions to offer services to your internal and external customers.

Unified experience

Synapse Studio provides a single way for enterprises to build solutions, maintain, and secure all in a single user experience

- Perform key tasks: ingest, explore, prepare, orchestrate, visualize
- Monitor resources, usage, and users across SQL, Spark, and Data Explorer
- Use Role-based access control to simplify access to analytics resources
- Write SQL, Spark or KQL code and integrate with enterprise CI/CD processes

Engage with the Synapse community

- Microsoft Q&A: Ask technical questions.
- Stack Overflow: Ask development questions.

Next steps

- Get started with Azure Synapse Analytics
- Create a workspace
- Use serverless SQL pool
- Create a Data Explorer pool using Synapse Studio (Preview)

What's new in Azure Synapse Analytics?

8/19/2022 • 5 minutes to read • Edit Online

This article lists updates to Azure Synapse Analytics that are published in April 2022. Each update links to the Azure Synapse Analytics blog and an article that provides more information. For previous months releases, check out Azure Synapse Analytics - updates archive.

General

- **Azure Orbital analytics with Synapse Analytics** - We now offer an Azure Orbital analytics sample solution showing an end-to-end implementation of extracting, loading, transforming, and analyzing spaceborne data by using geospatial libraries and AI models withAzure Synapse Analytics. The sample solution also demonstrates how to integrate geospatial-specificAzure Cognitive Servicesmodels, AI models from partners, and bring-your-own-data models.

- **Azure Synapse success by design** - Project success is no accident and requires careful planning and execution. The Synapse Analytics' Success by Design playbooks are now available. The Azure Synapse proof of concept playbook provides a guide to scope, design, execute, and evaluate a proof of concept for SQL or Spark workloads. These guides contain best practices from the most challenging and complex solution implementations incorporating Azure Synapse. To learn more about the Azure Synapse proof of concept playbook, read Success by Design.

SQL

Result set size limit increase - We know that you turn to Azure Synapse Analytics to work with large amounts of data. With that in mind, the maximum size of query result sets in Serverless SQL pools has been increased from 200GB to 400GB. This limit is shared between concurrent queries. To learn more about this size limit increase and other constraints, read Self-help for serverless SQL pool.

Synapse data explorer

- **Web Explorer new homepage** - The new Synapse Web Explorer homepage makes it even easier to get started with Synapse Web Explorer. The Web Explorer homepage now includes the following sections:
    - Get started – Sample gallery offering example queries and dashboards for popular Synapse Data Explorer use cases.
    - Recommended – Popular learning modules designed to help you master Synapse Web Explorer and KQL.
    - Documentation – Synapse Web Explorer basic and advanced documentation.
- **Web Explorer sample gallery** - A great way to learn about a product is to see how it is being used by others. The Web Explorer sample gallery provides end-to-end samples of how customers leverage Synapse Data Explorer popular use cases such as Logs Data, Metrics Data, IoT data and Basic big data examples. Each sample includes the dataset, well-documented queries, and a sample dashboard. To learn more about the sample gallery, read Azure Data Explorer in 60 minutes with the new samples gallery.

- **Web Explorer dashboards drill through capabilities** - You can now add drill through capabilities to your Synapse Web Explorer dashboards. The new drill through capabilities allow you to easily jump back and forth between dashboard pages. This is made possible by using a contextual filter to connect your dashboards. Defining these contextual drill throughs is done by editing the visual interactions of the selected tile in your dashboard. To learn more about drill through capabilities, read Use drillthroughs as

dashboard parameters.

- **Time Zone settings for Web Explorer** - Being able to display data in different time zones is very powerful. You can now decide to view the data in UTC time, your local time zone, or the time zone of the monitored device/machine. The Time Zone settings of the Web Explorer now apply to both the Query results and to the Dashboard. By changing the time zone, the dashboards will be automatically refreshed to present the data with the selected time zone. For more information on time zone settings, read Change datetime to specific time zone.

Data integration

- **Fuzzy Join option in Join Transformation** - Fuzzy matching with a sliding similarity score option has been added to the Join transformation in Mapping Data Flows. You can create inner and outer joins on data values that are similar rather than exact matches! Previously, you would have had to use an exact match. The sliding scale value goes from 60% to 100%, making it easy to adjust the similarity threshold of the match. For learn more about fuzzy joins, read Join transformation in mapping data flow.

- **Map Data [Generally Available]** - We're excited to announce that the Map Data tool is now Generally Available. The Map Data tool is a guided process to help you create ETL mappings and mapping data flows from your source data to Synapse without writing code. To learn more about Map Data, read Map Data in Azure Synapse Analytics.

- **Rerun pipeline with new parameters** - You can now change pipeline parameters when re-running a pipeline from the Monitoring page without having to return to the pipeline editor. After running a pipeline with new parameters, you can easily monitor the new run against the old ones without having to toggle between pages. To learn more about rerunning pipelines with new parameters, read Rerun pipelines and activities.

- **User Defined Functions [Generally Available]** - We're excited to announce that user defined functions (UDFs) are now Generally Available. With user-defined functions, you can create customized expressions that can be reused across multiple mapping data flows. You no longer have to use the same string manipulation, math calculations, or other complex logic several times. User-defined functions will be grouped in libraries to help developers group common sets of functions. To learn more about user defined functions, read User defined functions in mapping data flows.

Machine learning

Distributed Deep Neural Network Training with Horovod and Petastorm [Public Preview] - To simplify the process for creating and managing GPU-accelerated pools, Azure Synapse takes care of pre-installing low-level libraries and setting up all the complex networking requirements between compute nodes. This integration allows users to get started with GPU- accelerated pools within just a few minutes.

Now, Azure Synapse Analytics provides built-in support for deep learning infrastructure. The Azure Synapse Analytics runtime for Apache Spark 3.1 and 3.2 now includes support for the most common deep learning libraries like TensorFlow and PyTorch. The Azure Synapse runtime also includes supporting libraries like Petastorm and Horovod, which are commonly used for distributed training. This feature is currently available in Public Preview.

To learn more about how to leverage these libraries within your Azure Synapse Analytics GPU-accelerated pools, read the Deep learning tutorials.

Get started with Azure Synapse Analytics

Azure Synapse Analytics terminology

8/19/2022 • 3 minutes to read • Edit Online

This document guides you through the basic concepts of Azure Synapse Analytics.

Basics

A **Synapse workspace** is a securable collaboration boundary for doing cloud-based enterprise analytics in Azure. A workspace is deployed in a specific region and has an associated ADLS Gen2 account and file system (for storing temporary data). A workspace is under a resource group.

A workspace allows you to perform analytics with SQL and Apache spark. Resources available for SQL and Spark analytics are organized into SQL and Spark **pools**.

Linked services

A workspace can contain any number of **Linked service**, essentially connection strings that define the connection information needed for the workspace to connect to external resources.

Synapse SQL

Synapse SQL is the ability to do T-SQL based analytics in Synapse workspace. Synapse SQL has two consumption models: dedicated and serverless. For the dedicated model, use **dedicated SQL pools**. A workspace can have any number of these pools. To use the serverless model, use the **serverless SQL pools**. Every workspace has one of these pools.

Inside Synapse Studio, you can work with SQL pools by running **SQL scripts**.

> **NOTE**
> Dedicated SQL pools in Azure Synapse is different from the dedicated SQL pool (formerly SQL DW). Not all features of the dedicated SQL pool in Azure Synapse workspaces apply to dedicated SQL pool (formerly SQL DW), and vice versa. To enable workspace features for an existing dedicated SQL pool (formerly SQL DW), see How to enable a workspace for your dedicated SQL pool (formerly SQL DW).

Apache Spark for Synapse

To use Spark analytics, create and use **serverless Apache Spark pools** in your Synapse workspace. When you start using a Spark pool, the workspaces creates a **spark session** to handle the resources associated with that session.

There are two ways within Synapse to use Spark:

- **Spark Notebooks** for doing data Data Science and Engineering use Scala, PySpark, C#, and SparkSQL
- **Spark job definitions** for running batch Spark jobs using jar files.

Pipelines

Pipelines are how Azure Synapse provides Data Integration - allowing you to move data between services and orchestrate activities.

- **Pipeline** are logical grouping of activities that perform a task together.
- **Activities** defines actions within a Pipeline to perform on data such as copying data, running a Notebook or a SQL script.
- **Data flows** are a specific kind of activity that provide a no-code experience for doing data transformation that uses Synapse Spark under-the-covers.
- **Trigger** - Executes a pipeline. It can be run manually or automatically (schedule, tumbling window or event-based)
- **Integration dataset** - Named view of data that simply points or references the data to be used in an activity as input and output. It belongs to a Linked Service.

Data Explorer (Preview)

Azure Synapse Data Explorer provides customers with an interactive query experience to unlock insights from log and telemetry data.

- **Data Explorer pools** are dedicated clusters that includes two or more compute nodes with local SSD storage (hot cache) for optimized query performance and multiple blob storage (cold cache) for persistence.
- **Data Explorer databases** are hosted on Data Explorer pools and are logical entities made up of collections of tables and other database objects. You can have more than one database per pool.
- **Tables** are database objects that contain data that is organized using a traditional relational data model. Data is stored in records that adhere to Data Explorer's well-defined table schema that defines an ordered list of columns, each column having a name and scalar data type. Scalar data types can be structured (*int*, *real*, *datetime*, or *timespan*), semi-structured (*dynamic*), or free text (*string*). The dynamic type is similar to JSON in that it can hold a single scalar value, an array, or a dictionary of such values.
- **External Tables** are tables that reference a storage or SQL data source outside the Data Explorer database. Similar to tables, an external table has a well-defined schema (an ordered list of column name and data type pairs). Unlike Data Explorer tables where data is ingested into Data Explorer pools, external tables operate on data stored and managed outside pools. External tables don't persist any data and are used to query or export data to an external data store.

- Create a Data Explorer pool using Synapse Studio

Get Started with Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

This tutorial is a step-by-step guide through the major feature areas of Azure Synapse Analytics. The tutorial is the ideal starting point for someone who wants a guided tour through the key scenarios of Azure Synapse Analytics. After following the steps in the tutorial, you will have a Synapse workspace. This tutorial also includes steps to enable a workspace for your dedicated SQL pool (formerly SQL DW). Once your workspace is created, you can start analyzing data using dedicated SQL pool, serverless SQL pool, or serverless Apache Spark pool.

Follow the steps *in order* as shown below and you'll take a tour through many of the capabilities and learn how to exercise its core features.

- STEP 1 - Create and setup a Synapse workspace
- STEP 2 - Analyze using a serverless SQL pool
- STEP 3 - Analyze using a Data Explorer pool
- STEP 4 - Analyze using Apache Spark
- STEP 5 - Analyze using a dedicated SQL pool
- STEP 6 - Analyze data in a storage account
- STEP 7 - Orchestrate with pipelines
- STEP 8 - Visualize data with Power BI
- STEP 9 - Monitor activities
- STEP 10 - Explore the Knowledge center
- STEP 11 - Add an administrator

Creating a Synapse workspace

8/19/2022 • 3 minutes to read • Edit Online

In this tutorial, you'll learn how to create a Synapse workspace, a dedicated SQL pool, and a serverless Apache Spark pool.

Prerequisites

To complete this tutorial's steps, you need to have access to a resource group for which you are assigned the **Owner** role. Create the Synapse workspace in this resource group.

Create a Synapse workspace in the Azure portal

Start the process

1. Open the Azure portal, in the search bar enter **Synapse** without hitting enter.
2. In the search results, under **Services**, select **Azure Synapse Analytics**.
3. Select **Create** to create a workspace.

Basics tab > Project Details

Fill in the following fields:

1. **Subscription** - Pick any subscription.
2. **Resource group** - Use any resource group.
3. **Managed Resource group** - Leave this blank.

Basics tab > Workspace details

Fill in the following fields:

1. **Workspace name** - Pick any globally unique name. In this tutorial, we'll use **myworkspace**.
2. **Region** - Pick the region where you have placed your client applications/services (for example, Azure VM, Power BI, Azure Analysis Service) and storages that contain data (for example Azure Data Lake storage, Azure Cosmos DB analytical storage).

> **NOTE**
> A workspace that is not co-located with the client applications or storage can be the root cause of many performance issues. If your data or the clients are placed in multiple regions, you can create separate workspaces in different regions co-located with your data and clients.

Under **Select Data Lake Storage Gen 2**:

1. By **Account name**, select **Create New** and name the new storage account **contosolake** or similar as the name must be unique.
2. By **File system name**, select **Create New** and name it **users**. This will create a storage container called **users**. The workspace will use this storage account as the "primary" storage account to Spark tables and Spark application logs.
3. Check the "Assign myself the Storage Blob Data Contributor role on the Data Lake Storage Gen2 account"

box.

Completing the process

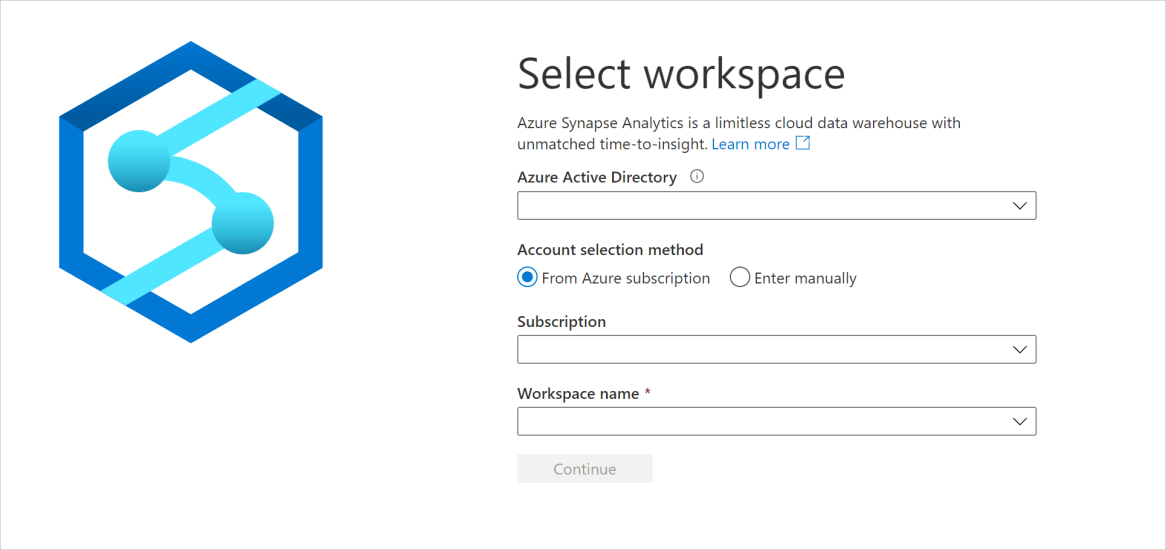
Select **Review + create** > **Create**. Your workspace is ready in a few minutes.

> **NOTE**
> To enable workspace features from an existing dedicated SQL pool (formerly SQL DW) refer to How to enable a workspace for your dedicated SQL pool (formerly SQL DW).

Open Synapse Studio

After your Azure Synapse workspace is created, you have two ways to open Synapse Studio:

1. Open your Synapse workspace in the Azure portal, in the **Overview** section of the Synapse workspace, select **Open** in the Open Synapse Studio box.
2. Go to the `https://web.azuresynapse.net` and sign in to your workspace.



> **NOTE**
> To sign into your workspace, there are two **Account selection methods**. One is from **Azure subscription**, the other is from **Enter manually**. If you have the Synapse Azure role or higher level Azure roles, you can use both methods to log into the workspace. If you don't have the related Azure roles, and you were granted as the Synapse RBAC role, **Enter manually** is the only way to log into the workspace. To learn more about the Synapse RBAC, refer to What is Synapse role-based access control (RBAC).

Place sample data into the primary storage account

We are going to use a small 100K row sample dataset of NYX Taxi Cab data for many examples in this getting started guide. We begin by placing it in the primary storage account you created for the workspace.

- Download this file to your computer: https://azuresynapsestorage.blob.core.windows.net/sampledata/NYCTaxiSmall/NYCTripSmall.parquet
- In Synapse Studio, navigate to the Data Hub.
- Select **Linked**.
- Under the category **Azure Data Lake Storage Gen2** you'll see an item with a name like **myworkspace (**

Primary - contosolake).

- Select the container named **users (Primary)**.
- Select **Upload** and select the `NYCTripSmall.parquet` file you downloaded.

Once the parquet file is uploaded it is available through two equivalent URIs:

- `https://contosolake.dfs.core.windows.net/users/NYCTripSmall.parquet`
- `abfss://users@contosolake.dfs.core.windows.net/NYCTripSmall.parquet`

In the examples that follow in this tutorial, make sure to replace **contosolake** in the UI with the name of the primary storage account that you selected for your workspace.

Next steps

Analyze using a serverless SQL pool

Analyze data with a serverless SQL pool

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to analyze data with serverless SQL pool.

The Built-in serverless SQL pool

Serverless SQL pools let you use SQL without having to reserve capacity. Billing for a serverless SQL pool is based on the amount of data processed to run the query and not the number of nodes used to run the query.

Every workspace comes with a pre-configured serverless SQL pool called **Built-in**.

Analyze NYC Taxi data with a serverless SQL pool

> **NOTE**
> Make sure you have placed the sample data into the primary storage account

1. In Synapse Studio, go to the **Develop** hub
2. Create a new SQL script.
3. Paste the following code into the script.

```
SELECT
    TOP 100 *
FROM
    OPENROWSET(
        BULK 'https://contosolake.dfs.core.windows.net/users/NYCTripSmall.parquet',
        FORMAT='PARQUET'
    ) AS [result]
```

4. Click **Run**.

Data exploration is just a simplified scenario where you can understand the basic characteristics of your data. Learn more about data exploration and analysis in this tutorial.

Create data exploration database

You can browse the content of the files directly via `master` database. For some simple data exploration scenarios, you don't need to create a separate database. However, as you continue data exploration, you might want to create some utility objects, such as:

- External data sources that represent the named references for storage accounts.
- Database scoped credentials that enable you to specify how to authenticate to external data source.
- Database users with the permissions to access some data sources or database objects.
- Utility views, procedures, and functions that you can use in the queries.

1. Use the `master` database to create a separate database for custom database objects. Custom database objects, cannot be created in the `master` database.

```
CREATE DATABASE DataExplorationDB
               COLLATE Latin1_General_100_BIN2_UTF8
```

> **IMPORTANT**
> Use a collation with `_UTF8` suffix to ensure that UTF-8 text is properly converted to `VARCHAR` columns. `Latin1_General_100_BIN2_UTF8` provides the best performance in the queries that read data from Parquet files and cosmos Db containers.

2. Switch from master to `DataExplorationDB` using the following command. You can also use the UI control **use database** to switch your current database:

```
USE DataExplorationDB
```

3. From the 'DataExplorationDB', create utility objects such as credentials and data sources.

```
CREATE EXTERNAL DATA SOURCE ContosoLake
WITH ( LOCATION = 'https://contosolake.dfs.core.windows.net')
```

> **NOTE**
> An external data source can be created without a credential. If a credential does not exist, the caller's identity will be used to access the external data source.

4. Optionally, use the newly created 'DataExplorationDB' database to create a login for a user in DataExplorationDB that will access external data:

```
CREATE LOGIN data_explorer WITH PASSWORD = 'My Very Strong Password 1234!';
```

   Next create a database user in 'DataExplorationDB' for the above login and grant the `ADMINISTER DATABASE BULK OPERATIONS` permission.

```
CREATE USER data_explorer FOR LOGIN data_explorer;
GO
GRANT ADMINISTER DATABASE BULK OPERATIONS TO data_explorer;
GO
```

5. Explore the content of the file using the relative path and the data source:

```
SELECT
    TOP 100 *
FROM
    OPENROWSET(
            BULK '/users/NYCTripSmall.parquet',
            DATA_SOURCE = 'ContosoLake',
            FORMAT='PARQUET'
    ) AS [result]
```

6. **Publish** your changes to the workspace.

Data exploration database is just a simple placeholder where you can store your utility objects. Synapse SQL

pool enables you to do much more and create a Logical Data Warehouse - a relational layer built on top of Azure data sources. Learn more about building Logical Data Warehouse in this tutorial.

Next steps

Analyze data with a serverless Spark pool

Quickstart: Analyze with Data Explorer (Preview)

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll learn the basic steps to load and analyze data with Data Explorer for Azure Synapse.

Create a Data Explorer pool

1. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.
2. Select **New**, and then enter the following details on the **Basics** tab:

SETTING	SUGGESTED VALUE	DESCRIPTION
Data Explorer pool name	contosodataexplorer	This is the name that the Data Explorer pool will have.
Workload	Compute optimized	This workload provides a higher CPU to SSD storage ratio.
Node size	Small (4 cores)	Set this to the smallest size to reduce costs for this quickstart

> **IMPORTANT**
> Note that there are specific limitations for the names that Data Explorer pools can use. Names must contain lowercase letters and numbers only, must be between 4 and 15 characters, and must start with a letter.

3. Select **Review + create** > **Create**. Your Data Explorer pool will start the provisioning process.

Create a Data Explorer database

1. In Synapse Studio, on the left-side pane, select **Data**.
2. Select **+** (Add new resource) > **Data Explorer database**, and paste the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.

SETTING	SUGGESTED VALUE	DESCRIPTION
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

3. Select **Create** to create the database. Creation typically takes less than a minute.

Ingest sample data and analyze with a simple query

1. In Synapse Studio, on the left-side pane, select **Develop**.
2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
3. In the **Connect to** menu, select *contosodataexplorer*.
4. In the **Use database** menu, select *TestDatabase*.
5. Paste in the following command, and select **Run** to create a StormEvents table.

```
.create table StormEvents (StartTime: datetime, EndTime: datetime, EpisodeId: int, EventId: int,
State: string, EventType: string, InjuriesDirect: int, InjuriesIndirect: int, DeathsDirect: int,
DeathsIndirect: int, DamageProperty: int, DamageCrops: int, Source: string, BeginLocation: string,
EndLocation: string, BeginLat: real, BeginLon: real, EndLat: real, EndLon: real, EpisodeNarrative:
string, EventNarrative: string, StormSummary: dynamic)
```

> **TIP**
> Verify that the table was successfully created. On the left-side pane, select **Data**, select the *contosodataexplorer* more menu, and then select **Refresh**. Under *contosodataexplorer*, expand **Tables** and make sure that the *StormEvents* table appears in the list.

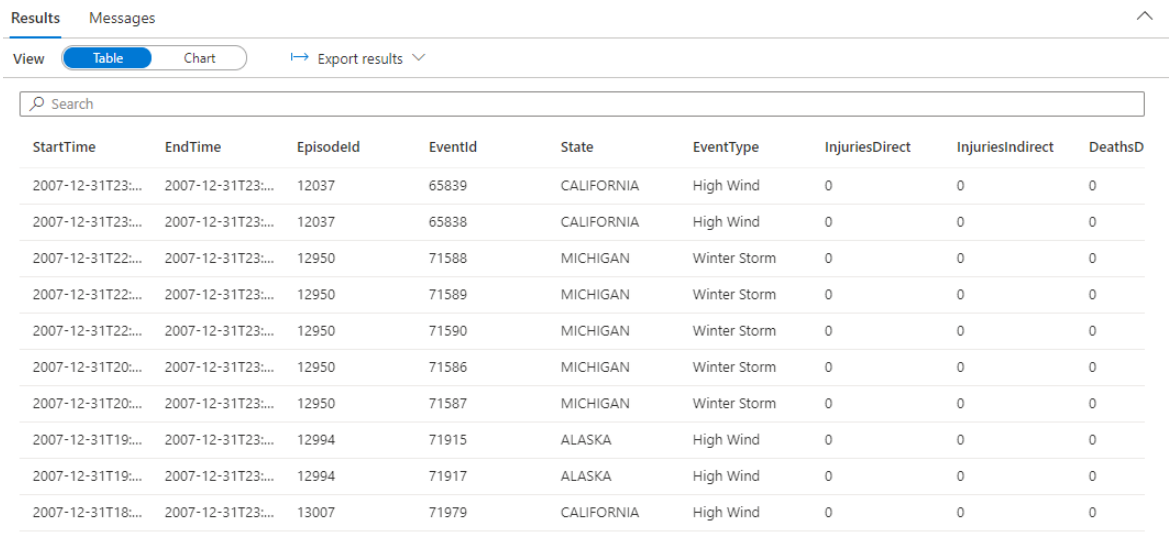
6. Paste in the following command, and select **Run** to ingest data into StormEvents table.

```
.ingest into table StormEvents
'https://kustosamplefiles.blob.core.windows.net/samplefiles/StormEvents.csv?sv=2019-12-
12&ss=b&srt=o&sp=r&se=2022-09-05T02:23:52Z&st=2020-09-
04T18:23:52Z&spr=https&sig=VrOfQMT1gUrHltJ8uhjYcCequEcfhjyyMX%2FSc3xsCy4%3D' with
(ignoreFirstRecord=true)
```

7. After ingestion completes, paste in the following query, select the query in the window, and select **Run**.

```
StormEvents
| sort by StartTime desc
| take 10
```

The query returns the following results from the ingested sample data.



StartTime	EndTime	EpisodeId	EventId	State	EventType	InjuriesDirect	InjuriesIndirect	DeathsD
2007-12-31T23:...	2007-12-31T23:...	12037	65839	CALIFORNIA	High Wind	0	0	0
2007-12-31T23:...	2007-12-31T23:...	12037	65838	CALIFORNIA	High Wind	0	0	0
2007-12-31T22:...	2007-12-31T23:...	12950	71588	MICHIGAN	Winter Storm	0	0	0
2007-12-31T22:...	2007-12-31T23:...	12950	71589	MICHIGAN	Winter Storm	0	0	0
2007-12-31T22:...	2007-12-31T23:...	12950	71590	MICHIGAN	Winter Storm	0	0	0
2007-12-31T20:...	2007-12-31T23:...	12950	71586	MICHIGAN	Winter Storm	0	0	0
2007-12-31T20:...	2007-12-31T23:...	12950	71587	MICHIGAN	Winter Storm	0	0	0
2007-12-31T19:...	2007-12-31T23:...	12994	71915	ALASKA	High Wind	0	0	0
2007-12-31T19:...	2007-12-31T23:...	12994	71917	ALASKA	High Wind	0	0	0
2007-12-31T18:...	2007-12-31T23:...	13007	71979	CALIFORNIA	High Wind	0	0	0

- Tutorial: Use KQL queries
- Monitor Data Explorer pools

Analyze with Apache Spark

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn the basic steps to load and analyze data with Apache Spark for Azure Synapse.

Create a serverless Apache Spark pool

1. In Synapse Studio, on the left-side pane, select **Manage** > **Apache Spark pools**.
2. Select **New**
3. For **Apache Spark pool name** enter **Spark1**.
4. For **Node size** enter **Small**.
5. For **Number of nodes** Set the minimum to 3 and the maximum to 3
6. Select **Review + create** > **Create**. Your Apache Spark pool will be ready in a few seconds.

Understanding serverless Apache Spark pools

A serverless Spark pool is a way of indicating how a user wants to work with Spark. When you start using a pool, a Spark session is created if needed. The pool controls how many Spark resources will be used by that session and how long the session will last before it automatically pauses. You pay for spark resources used during that session not for the pool itself. In this way a Spark pool lets you work with Spark, without having to worry managing clusters. This is similar to how a serverless SQL pool works.

Analyze NYC Taxi data with a Spark pool

> **NOTE**
>
> Make sure you have placed the sample data in the primary storage account.

1. In Synapse Studio, go to the **Develop** hub.
2. Create a new notebook.
3. Create a new code cell and paste the following code in that cell:

```
%%pyspark
df = spark.read.load('abfss://users@contosolake.dfs.core.windows.net/NYCTripSmall.parquet',
format='parquet')
display(df.limit(10))
```

4. Modify the load URI, so it references the sample file in your storage account according to the abfss URI scheme.
5. In the notebook, in the **Attach to** menu, choose the **Spark1** serverless Spark pool that we created earlier.
6. Select **Run** on the cell. Synapse will start a new Spark session to run this cell if needed. If a new Spark session is needed, initially it will take about two seconds to be created.
7. If you just want to see the schema of the dataframe run a cell with the following code:

```
%%pyspark
df.printSchema()
```

Load the NYC Taxi data into the Spark nyctaxi database

Data is available via the dataframe named **df**. Load it into a Spark database named **nyctaxi**.

1. Add a new code cell to the notebook, and then enter the following code:

```
%%pyspark
spark.sql("CREATE DATABASE IF NOT EXISTS nyctaxi")
df.write.mode("overwrite").saveAsTable("nyctaxi.trip")
```

Analyze the NYC Taxi data using Spark and notebooks

1. Create a new code cell and enter the following code.

```
%%pyspark
df = spark.sql("SELECT * FROM nyctaxi.trip")
display(df)
```

2. Run the cell to show the NYC Taxi data we loaded into the **nyctaxi** Spark database.

3. Create a new code cell and enter the following code. We will analyze this data and save the results into a table called **nyctaxi.passengercountstats**.

```
%%pyspark
df = spark.sql("""
   SELECT PassengerCount,
       SUM(TripDistanceMiles) as SumTripDistance,
       AVG(TripDistanceMiles) as AvgTripDistance
   FROM nyctaxi.trip
   WHERE TripDistanceMiles > 0 AND PassengerCount > 0
   GROUP BY PassengerCount
   ORDER BY PassengerCount
""")
display(df)
df.write.saveAsTable("nyctaxi.passengercountstats")
```

4. In the cell results, select **Chart** to see the data visualized.

Next steps

Analyze data with dedicated SQL pool

Analyze data with dedicated SQL pools

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll use the NYC Taxi data to explore a dedicated SQL pool's capabilities.

Create a dedicated SQL pool

1. In Synapse Studio, on the left-side pane, select **Manage** > **SQL pools** under **Analytics pools**.
2. Select **New**
3. For **Dedicated SQL pool name** select **SQLPOOL1**
4. For **Performance level** choose **DW100C**
5. Select **Review + create** > **Create**. Your dedicated SQL pool will be ready in a few minutes.

Your dedicated SQL pool is associated with a SQL database that's also called **SQLPOOL1**.

1. Navigate to **Data** > **Workspace**.
2. You should see a database named **SQLPOOL1**. If you do not see it, click **Refresh**.

A dedicated SQL pool consumes billable resources as long as it's active. You can pause the pool later to reduce costs.

> **NOTE**
> When creating a new dedicated SQL pool (formerly SQL DW) in your workspace, the dedicated SQL pool provisioning page will open. Provisioning will take place on the logical SQL server.

Load the NYC Taxi Data into SQLPOOL1

1. In Synapse Studio, navigate to the **Develop** hub, click the **+** button to add new resource, then create new SQL script.
2. Select the pool 'SQLPOOL1' (pool created in STEP 1 of this tutorial) in **Connect to** drop down list above the script.
3. Enter the following code:

```
IF NOT EXISTS (SELECT * FROM sys.objects O JOIN sys.schemas S ON O.schema_id = S.schema_id WHERE
O.NAME = 'NYCTaxiTripSmall' AND O.TYPE = 'U' AND S.NAME = 'dbo')
CREATE TABLE dbo.NYCTaxiTripSmall
    (
     [DateID] int,
     [MedallionID] int,
     [HackneyLicenseID] int,
     [PickupTimeID] int,
     [DropoffTimeID] int,
     [PickupGeographyID] int,
     [DropoffGeographyID] int,
     [PickupLatitude] float,
     [PickupLongitude] float,
     [PickupLatLong] nvarchar(4000),
     [DropoffLatitude] float,
     [DropoffLongitude] float,
     [DropoffLatLong] nvarchar(4000),
     [PassengerCount] int,
     [TripDurationSeconds] int,
     [TripDistanceMiles] float,
     [PaymentType] nvarchar(4000),
     [FareAmount] numeric(19,4),
     [SurchargeAmount] numeric(19,4),
     [TaxAmount] numeric(19,4),
     [TipAmount] numeric(19,4),
     [TollsAmount] numeric(19,4),
     [TotalAmount] numeric(19,4)
    )
WITH
    (
    DISTRIBUTION = ROUND_ROBIN,
     CLUSTERED COLUMNSTORE INDEX
     -- HEAP
    )
GO

COPY INTO dbo.NYCTaxiTripSmall
(DateID 1, MedallionID 2, HackneyLicenseID 3, PickupTimeID 4, DropoffTimeID 5,
PickupGeographyID 6, DropoffGeographyID 7, PickupLatitude 8, PickupLongitude 9,
PickupLatLong 10, DropoffLatitude 11, DropoffLongitude 12, DropoffLatLong 13,
PassengerCount 14, TripDurationSeconds 15, TripDistanceMiles 16, PaymentType 17,
FareAmount 18, SurchargeAmount 19, TaxAmount 20, TipAmount 21, TollsAmount 22,
TotalAmount 23)
FROM 'https://contosolake.dfs.core.windows.net/users/NYCTripSmall.parquet'
WITH
(
    FILE_TYPE = 'PARQUET'
    ,MAXERRORS = 0
    ,IDENTITY_INSERT = 'OFF'
)
```

4. Click the **Run** button to execute the script.
5. This script will finish in less than 60 seconds. It loads 2 million rows of NYC Taxi data into a table called `dbo.NYCTaxiTripSmall`.

Explore the NYC Taxi data in the dedicated SQL pool

1. In Synapse Studio, go to the **Data** hub.
2. Go to **SQLPOOL1** > **Tables**.
3. Right-click the **dbo.NYCTaxiTripSmall** table and select **New SQL Script** > **Select TOP 100 Rows**.
4. Wait while a new SQL script is created and runs.

5. Notice that at the top of the SQL script **Connect to** is automatically set to the SQL pool called **SQLPOOL1**.

6. Replace the text of the SQL script with this code and run it.

```
SELECT PassengerCount,
      SUM(TripDistanceMiles) as SumTripDistance,
      AVG(TripDistanceMiles) as AvgTripDistance
FROM  dbo.NYCTaxiTripSmall
WHERE TripDistanceMiles > 0 AND PassengerCount > 0
GROUP BY PassengerCount
ORDER BY PassengerCount;
```

   This query shows how the total trip distances and average trip distance relate to the number of passengers.

7. In the SQL script result window, change the **View** to **Chart** to see a visualization of the results as a line chart.

Next steps

Analyze data in an Azure Storage account

Analyze data in a storage account

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to analyze data located in a storage account.

Overview

So far, we've covered scenarios where data resides in databases in the workspace. Now we'll show you how to work with files in storage accounts. In this scenario, we'll use the primary storage account of the workspace and container that we specified when creating the workspace.

- The name of the storage account: **contosolake**
- The name of the container in the storage account: **users**

Create CSV and Parquet files in your storage account

Run the following code in a notebook in a new code cell. It creates a CSV file and a parquet file in the storage account.

```
%%pyspark
df = spark.sql("SELECT * FROM nyctaxi.passengercountstats")
df = df.repartition(1) # This ensures we'll get a single file during write()
df.write.mode("overwrite").csv("/NYCTaxi/PassengerCountStats_csvformat")
df.write.mode("overwrite").parquet("/NYCTaxi/PassengerCountStats_parquetformat")
```

Analyze data in a storage account

You can analyze the data in your workspace default ADLS Gen2 account or you can link an ADLS Gen2 or Blob storage account to your workspace through "**Manage**" > "**Linked Services**" > "**New**" (The steps below will refer to the primary ADLS Gen2 account).

1. In Synapse Studio, go to the **Data** hub, and then select **Linked**.
2. Go to **Azure Data Lake Storage Gen2** > **myworkspace (Primary - contosolake)**.
3. Select **users (Primary)**. You should see the **NYCTaxi** folder. Inside you should see two folders called **PassengerCountStats_csvformat** and **PassengerCountStats_parquetformat**.
4. Open the **PassengerCountStats_parquetformat** folder. Inside, you'll see a parquet file with a name like `part-00000-2638e00c-0790-496b-a523-578da9a15019-c000.snappy.parquet`.
5. Right-click **.parquet**, then select **New notebook**, then select **Load to DataFrame**. A new notebook is created with a cell like this:

   ```
   %%pyspark
   abspath =
   'abfss://users@contosolake.dfs.core.windows.net/NYCTaxi/PassengerCountStats_parquetformat/part-00000-
   1f251a58-d8ac-4972-9215-8d528d490690-c000.snappy.parquet'
   df = spark.read.load(abspath, format='parquet')
   display(df.limit(10))
   ```

6. Attach to the Spark pool named **Spark1**. Run the cell.
7. Select back to the **users** folder. Right-click the **.parquet** file again, and then select **New SQL script** > **SELECT TOP 100 rows**. It creates a SQL script like this:

```
SELECT
    TOP 100 *
FROM OPENROWSET(
    BULK
'https://contosolake.dfs.core.windows.net/users/NYCTaxi/PassengerCountStats_parquetformat/part-00000-
1f251a58-d8ac-4972-9215-8d528d490690-c000.snappy.parquet',
    FORMAT='PARQUET'
) AS [result]
```

In the script window, make sure the **Connect to** field is set to the **Built-in** serverless SQL pool.

8. Run the script.

Next steps

Orchestrate activities with pipelines

Integrate with pipelines

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to integrate pipelines and activities using Synapse Studio.

Create a pipeline and add a notebook activity

1. In Synapse Studio, go to the **Integrate** hub.
2. Select **+** > **Pipeline** to create a new pipeline. Click on the new pipeline object to open the Pipeline designer.
3. Under **Activities**, expand the **Synapse** folder, and drag a **Notebook** object into the designer.
4. Select the **Settings** tab of the Notebook activity properties. Use the drop-down list to select a notebook from your current Synapse workspace.

Schedule the pipeline to run every hour

1. In the pipeline, select **Add trigger** > **New/edit**.
2. In **Choose trigger**, select **New**, and set the **Recurrence** to "every 1 hour".
3. Select **OK**.
4. Select **Publish All**.

Forcing a pipeline to run immediately

Once the pipeline is published, you may want to run it immediately without waiting for an hour to pass.

1. Open the pipeline.
2. Click **Add trigger** > **Trigger now**.
3. Select **OK**.

Monitor pipeline execution

1. Go to the **Monitor** hub.
2. Select **Pipeline runs** to monitor pipeline execution progress.
3. In this view you can switch between tabular **List** display a graphical **Gantt** chart.
4. Click on a pipeline name to see the status of activities in that pipeline.

Next steps

Visualize data with Power BI

Visualize data with Power BI

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to create a Power BI workspace, link your Azure Synapse workspace, and create a Power BI data set that utilizes data in your Azure Synapse workspace.

Prerequisites

To complete this tutorial, install Power BI Desktop.

Overview

From the NYC Taxi data, we created aggregated datasets in two tables:

- **nyctaxi.passengercountstats**
- **SQLDB1.dbo.PassengerCountStats**

You can link a Power BI workspace to your Azure Synapse workspace. This capability allows you to easily get data into your Power BI workspace. You can edit your Power BI reports directly in your Azure Synapse workspace.

Create a Power BI workspace

1. Sign in to powerbi.microsoft.com.
2. Click on **Workspaces**, then select **Create a workspace**. Create a new Power BI workspace named **NYCTaxiWorkspace1** or similar, since this name must be unique.

Link your Azure Synapse workspace to your new Power BI workspace

1. In Synapse Studio, go to **Manage** > **Linked Services**.
2. Select **New** > **Connect to Power BI**.
3. Set **Name** to **NYCTaxiWorkspace1**.
4. Set **Workspace name** to the Power BI workspace you created above, similar to **NYCTaxiWorkspace1**.
5. Select **Create**.

Create a Power BI dataset that uses data in your Azure Synapse workspace

1. In Synapse Studio, go to **Develop** > **Power BI**.
2. Go to **NYCTaxiWorkspace1** > **Power BI datasets** and select **New Power BI dataset**. Click **Start**.
3. Select the **SQLPOOL1** data source, click **Continue**.
4. Click **Download** to download the .pbids file for your **NYCTaxiWorkspace1SQLPOOL1.pbids** file. Click **Continue**.
5. Open the downloaded **.pbids** file. Power BI Desktop opens and automatically connects to **SQLDB1** in your Azure Synapse workspace.
6. If you see a dialog box appear called **SQL Server database**:
   a. Select **Microsoft account**.
   b. Select **Sign in** and sign in to your account.
   c. Select **Connect**.
7. After the **Navigator** dialog box opens, check the **PassengerCountStats** table and select **Load**.
8. After the **Connection settings** dialog box appears, select **DirectQuery** > **OK**.
9. Select the **Report** button on the left side.

10. Under **Visualizations**, click to the line chart icon to add a **Line chart** to your report.
    a. Under **Fields**, drag the **PassengerCount** column to **Visualizations** > **Axis**.
    b. Drag the **SumTripDistance** and **AvgTripDistance** columns to **Visualizations** > **Values**.
11. On the **Home** tab, select **Publish**.
12. Select **Save** to save your changes.
13. Choose the file name **PassengerAnalysis.pbix**, and then select **Save**.
14. In the **Publish to Power BI** window, under **Select a destination**, choose your **NYCTaxiWorkspace1**, and then click **Select**.
15. Wait for publishing to finish.

Configure authentication for your dataset

1. Open powerbi.microsoft.com and **Sign in**.
2. On the left side, under **Workspaces**, select the **NYCTaxiWorkspace1** workspace.
3. Inside that workspace, locate a dataset called **Passenger Analysis** and a report called **Passenger Analysis**.
4. Hover over the **PassengerAnalysis** dataset, select the ellipsis (...) button, and then select **Settings**.
5. In **Data source credentials**, click **Edit**, set the **Authentication method** to **OAuth2**, and then select **Sign in**.

Edit a report in Synapse Studio

1. Go back to Synapse Studio and select **Close and refresh**.
2. Go to the **Develop** hub.
3. To the right of the **Power BI** layer, ellipsis (...) button, and click **refresh** to refresh the **Power BI reports** node.
4. Under **Power BI** you should see:
    - In **NYCTaxiWorkspace1** > **Power BI datasets**, a new dataset called **PassengerAnalysis**.
    - Under **NYCTaxiWorkspace1** > **Power BI reports**, a new report called **PassengerAnalysis**.
5. Select the **PassengerAnalysis** report. The report opens and you can edit it directly within Synapse Studio.

Next steps

Monitor

Monitor your Synapse Workspace

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to monitor activities in your Synapse workspace. You can monitor current and historical activities for SQL, Apache Spark, and Pipelines.

Introduction to the Monitor Hub

Open Synapse Studio and navigate to the **Monitor** hub. Here, you can see a history of all the activities taking place in the workspace and which ones are active now.

- Under **Integration**, you can monitor pipelines, triggers, and integration runtimes.
- Under **Activities**, you can monitor Spark and SQL activities.

Integration

1. Navigate to **Integration** > **Pipeline runs**. In this view, you can see every time a pipeline has run in your workspace.
2. Find the pipeline that you ran in the previous step and click on its **Pipeline name** to view the details.
3. Click **Breadcrumb bar** near the top of Synapse Studio, click **All pipeline runs** to return to the previous view.

Data Explorer activities

1. Navigate to **Activities** > **KQL requests**.
2. In this view you can see KQL requests.
3. Select a **Pool** to monitor from the **Pool** filter. Now you can see all KQL requests that are running or have run in your workspace in that pool.
4. Find a specific KQL request and click on the **More** link to see the full text of the KQL request.

Apache Spark activities

1. Navigate to **Activities** > **Apache Spark applications**. Now you can see all the Spark applications that are running or have run in your workspace.
2. Find an application that is no longer running and click on its **Application name**. Now you can see the details of the spark application.
3. If you are familiar with Apache Spark, you can find the standard Apache Spark history server UI by clicking on **Spark history server**.

SQL activities

1. Navigate to **Activities** > **SQL requests**.
2. In this view you can see SQL requests.
3. Select a **Pool** to monitor from the **Pool** filter. Now you can see all SQL requests that are running or have run in your workspace in that pool.
4. Find a specific SQL request and click on the **More** link to see the full text of the SQL request.

> **NOTE**
>
> SQL requests submitted via the Synapse Studio in a workspace enabled dedicated SQL pool (formerly SQL DW) can be viewed in the Monitor hub. For all other monitoring activities, you can go to Azure portal dedicated SQL pool (formerly SQL DW) monitoring.

Next steps

Explore the Knowledge center

Explore the Synapse Knowledge center

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to use the Synapse Studio **Knowledge center**.

Finding the Knowledge center

There are two ways of finding the **Knowledge center** in Synapse Studio:

1. In the Home hub, near the top-right of the page click on **Learn**.
2. In the menu bar at the top, click **?** and then **Knowledge center**.

Pick either method and open the **Knowledge center**.

Exploring the Knowledge center

Once it is visible, you will see that the **Knowledge center** allows you to do three things:

- **Use samples immediately**. If you want a quick example of how Synapse works, choose this option.
- **Browse gallery**. This option lets you link sample data sets and add sample code in the form of SQL scripts, notebooks, and pipelines.
- **Tour Synapse Studio**. This option takes you on a brief tour of the basic parts of Synapse Studio. This is useful if you have never used Synapse Studio before.

Use samples immediately: Three samples to help you get started fast

There are three items in this section:

- Explore sample data with Spark
- Query data with SQL
- Create external table with SQL

1. In the **Knowledge center**, click **Use samples immediately**.
2. Select **Query data with SQL**.
3. Click **Use sample**.
4. A new sample SQL script will open.
5. Scroll to the first query (lines 28 to 32) and select the query text.
6. Click Run. It will run only code you have selected.

Gallery: A collection of sample datasets and sample code

1. Go to the **Knowledge center**, click **Browse gallery**.
2. Select the **SQL scripts** tab at the top.
3. Select **Load the New York Taxicab dataset** Data ingestion sample, click **Continue**.
4. Under **SQL pool**, choose **Select an existing pool** and select **SQLPOOL1**, and select the **SQLPOOL1** database you created earlier.
5. Click **Open Script**.

6. A new sample SQL script will open.
7. Click **Run**
8. This will create several tables for all of the NYC Taxi data and load them using the T-SQL COPY command. If you had created these tables in the previous quick start steps, select and execute only code to CREATE and COPY for tables that do not exist.

> **NOTE**
> When using the sample gallery for SQL script with a dedicated SQL pool (formerly SQL DW), you will only be able to use an existing dedicated SQL pool (formerly SQL DW).

Next steps

Add an administrator

Add an administrator to your Synapse workspace

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to add an administrator to your Synapse workspace. This user will have full control over the workspace.

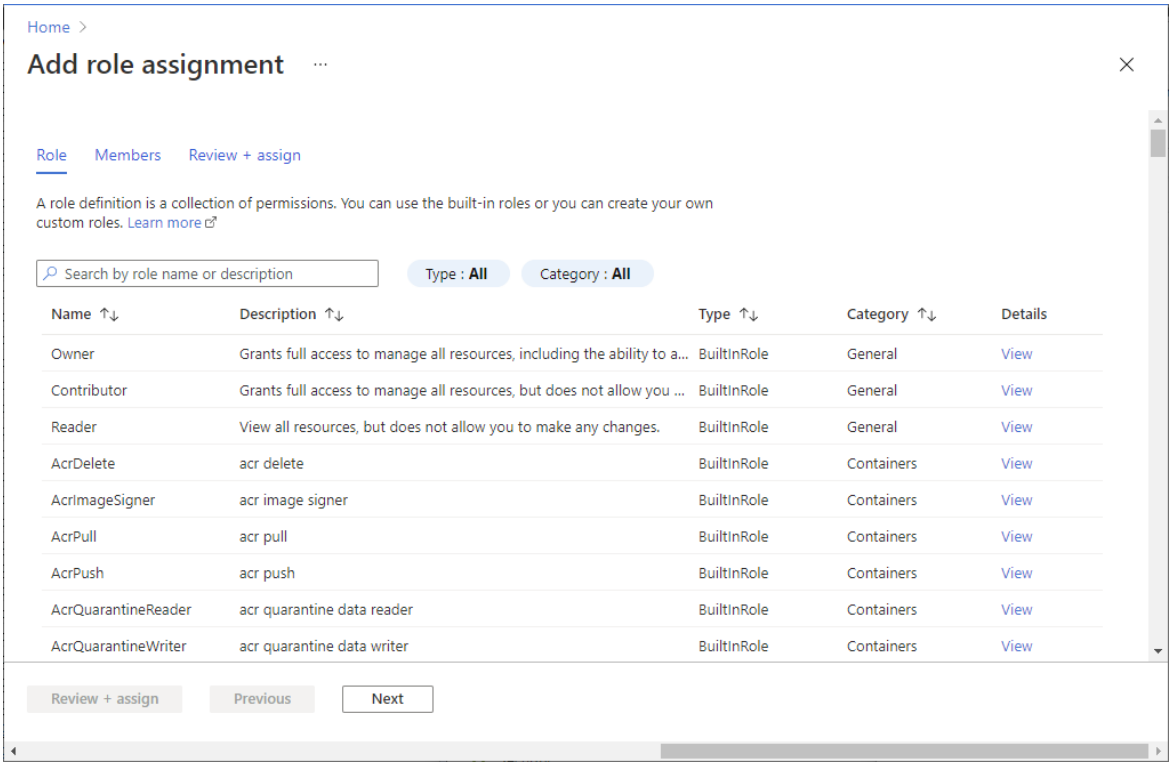
Overview

So far in the get started guide, we've focused on activities *you* do in the workspace. Because you created the workspace in STEP 1, you are an administrator of the Synapse workspace. Now, we will make another user Ryan (`ryan@contoso.com`) an administrator. When we are done, Ryan will be able to do everything you can do in the workspace.

Azure RBAC: Owner role for the workspace

1. Open the Azure portal and open your Synapse workspace.
2. On the left side, select **Access control (IAM)**.
3. Select **Add** > **Add role assignment** to open the Add role assignment page.
4. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Owner
Assign access to	USER
Member	ryan@contoso.com



5. Select **Save**.

Synapse RBAC: Synapse Administrator role for the workspace

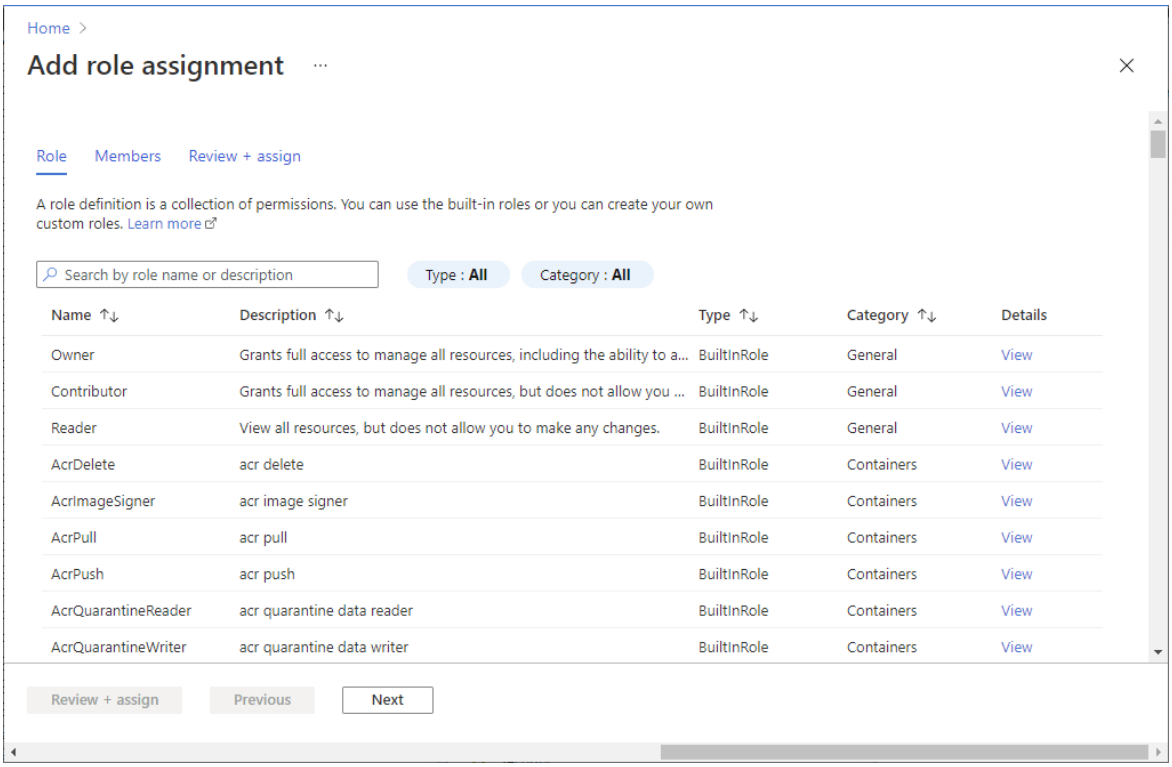
Assign to `ryan@contoso.com` to Synapse RBAC **Synapse Administrator** role on the workspace.

1. Open your workspace in Synapse Studio.
2. On the left side, select **Manage** to open the Manage hub.
3. Under **Security**, select **Access control**.
4. Select **Add**.
5. Leave **Scope** set to **Workspace**.
6. Add `ryan@contoso.com` to the **Synapse Administrator** role.
7. Then select **Apply**.

Azure RBAC: Role assignments on the workspace's primary storage account

1. Open the workspace's primary storage account in the Azure portal.
2. On the left side, select **Access control (IAM)**.
3. Select **Add** > **Add role assignment** to open the Add role assignment page.
4. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role 1	Owner
Role 2	Azure Storage Blob Data Contributor
Assign access to	USER
Member	ryan@contoso.com



Dedicated SQL pools: db_owner role

Assign `ryan@contoso.com` to the **db_owner** on each dedicated SQL pool in the workspace.

```
CREATE USER [ryan@contoso.com] FROM EXTERNAL PROVIDER;
EXEC sp_addrolemember 'db_owner', 'ryan@contoso.com'
```

Next steps

- Get started with Azure Synapse Analytics
- Create a workspace
- Use serverless SQL pool

Quickstart: Create a Synapse workspace

8/19/2022 • 2 minutes to read • Edit Online

This quickstart describes the steps to create an Azure Synapse workspace by using the Azure portal.

Create a Synapse workspace

1. Open the Azure portal, and at the top search for **Synapse**.
2. In the search results, under **Services**, select **Azure Synapse Analytics**.
3. Select **Add** to create a workspace.
4. In the **Basics** tab, give the workspace a unique name. We'll use **mysworkspace** in this document
5. You need an ADLSGEN2 account to create a workspace. The simplest choice is to create a new one. If you want to re-use an existing one you'll need to perform some additional configuration.
6. OPTION 1 Creating a new ADLSGEN2 account
   a. Under **Select Data Lake Storage Gen 2**, click **Create New** and name it **contosolake**.
   b. Under **Select Data Lake Storage Gen 2**, click **File System** and name it **users**.
7. OPTION 2 See the **Prepare a Storage Account** instructions at the bottom of this document.
8. Your Azure Synapse workspace will use this storage account as the "primary" storage account and the container to store workspace data. The workspace stores data in Apache Spark tables. It stores Spark application logs under a folder called **/synapse/workspacename**.
9. Select **Review + create** > **Create**. Your workspace is ready in a few minutes.

> **NOTE**
> After creating your Azure Synapse workspace, you will not be able to move the workspace to another Azure Active Directory tenant. If you do so through subscription migration or other actions, you may lose access to the artifacts within the workspace.

Open Synapse Studio

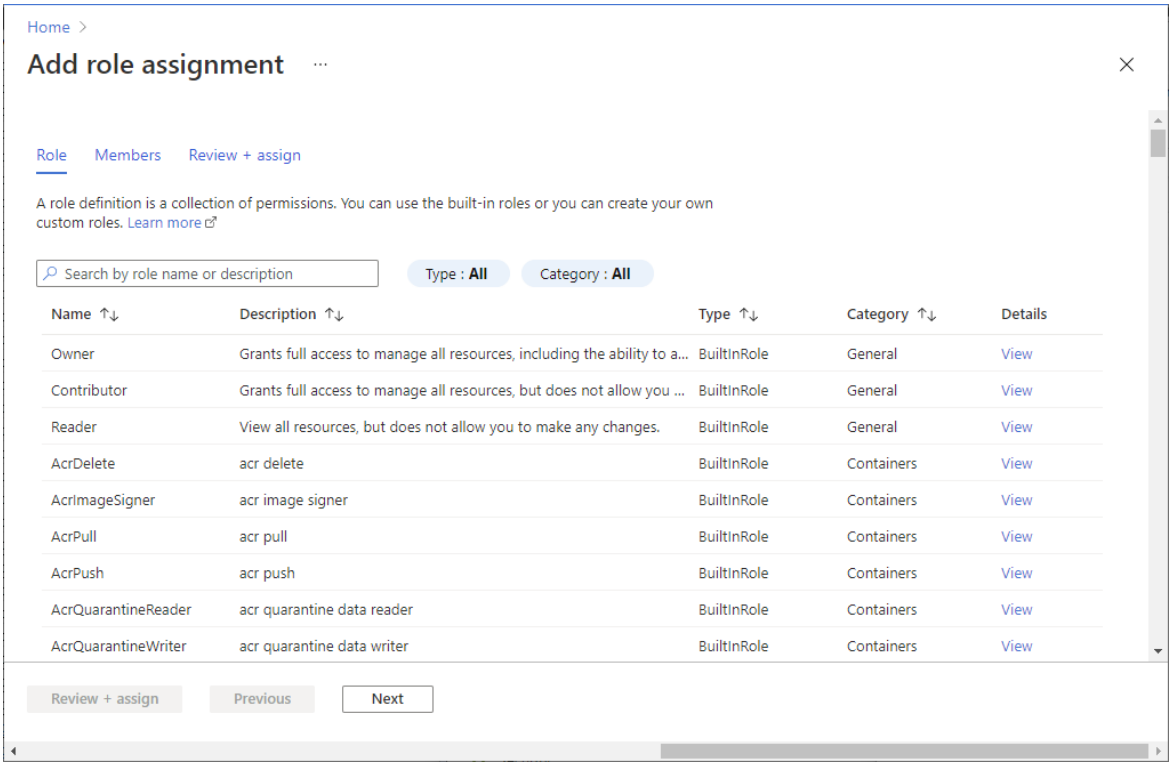
After your Azure Synapse workspace is created, you have two ways to open Synapse Studio:

- Open your Synapse workspace in the Azure portal. On the top of the **Overview** section, select **Launch Synapse Studio**.
- Go to the `https://web.azuresynapse.net` and sign in to your workspace.

Prepare an existing storage account for use with Azure Synapse Analytics

1. Open the Azure portal.
2. Navigate to an existing ADLSGEN2 storage account
3. Select **Access control (IAM)**.
4. Select **Add** > **Add role assignment** to open the Add role assignment page.
5. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Owner and Storage Blob Data Owner
Assign access to	USER
Members	your user name



6. On the left pane, select **Containers** and create a container.
7. You can give the container any name. In this document, we'll name the container **users**.
8. Accept the default setting **Public access level**, and then select **Create**.

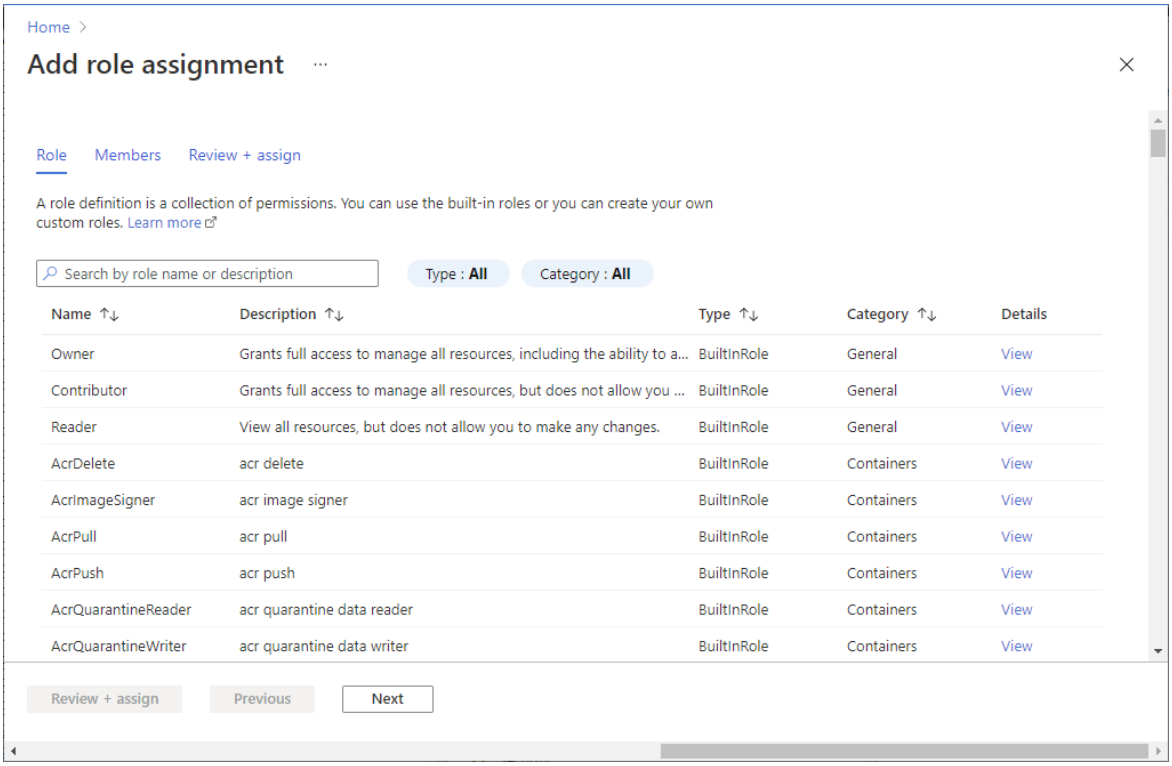
Configure access to the storage account from your workspace

Managed identities for your Azure Synapse workspace might already have access to the storage account. Follow these steps to make sure:

1. Open the Azure portal and the primary storage account chosen for your workspace.
2. Select **Access control (IAM)**.
3. Select **Add** > **Add role assignment** to open the Add role assignment page.
4. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Contributor
Assign access to	MANAGEDIDENTITY
Members	myworkspace

> **NOTE**
>
> The managed identity name is also the workspace name.



5. Select **Save**.

Next steps

- Create a dedicated SQL pool
- Create a serverless Apache Spark pool
- Use serverless SQL pool

Quickstart: Create an Azure synapse workspace with Azure CLI

8/19/2022 • 3 minutes to read • Edit Online

The Azure CLI is Azure's command-line experience for managing Azure resources. You can use it in your browser with Azure Cloud Shell. You can also install it on macOS, Linux, or Windows and run it from the command line.

In this quickstart, you learn to create a Synapse workspace by using the Azure CLI.

If you don't have an Azure subscription, create an Azure free account before you begin.

Prerequisites

- Download and install jq, a lightweight and flexible command-line JSON processor
- Azure Data Lake Storage Gen2 storage account

  > **IMPORTANT**
  > The Azure Synapse workspace needs to be able to read and write to the selected ADLS Gen2 account. In addition, for any storage account that you link as the primary storage account, you must have enabled **hierarchical namespace** at the creation of the storage account, as described on the Create a Storage Account page.

- Use the Bash environment in Azure Cloud Shell. For more information, see Azure Cloud Shell Quickstart - Bash.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.
  - If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
  - When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
  - Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Create an Azure Synapse workspace using the Azure CLI

1. Define necessary environment variables to create resources for Azure Synapse workspace.

ENVIRONMENT VARIABLE NAME	DESCRIPTION
StorageAccountName	Name for your existing ADLS Gen2 storage account.

ENVIRONMENT VARIABLE NAME	DESCRIPTION
StorageAccountResourceGroup	Name of your existing ADLS Gen2 storage account resource group.
FileShareName	Name of your existing storage file system.
SynapseResourceGroup	Choose a new name for your Azure Synapse resource group.
Region	Choose one of the Azure regions.
SynapseWorkspaceName	Choose a unique name for your new Azure Synapse Workspace.
SqlUser	Choose a value for a new username.
SqlPassword	Choose a secure password.

2. Create a resource group as a container for your Azure Synapse workspace:

```
az group create --name $SynapseResourceGroup --location $Region
```

3. Create an Azure Synapse Workspace:

```
az synapse workspace create \
  --name $SynapseWorkspaceName \
  --resource-group $SynapseResourceGroup \
  --storage-account $StorageAccountName \
  --file-system $FileShareName \
  --sql-admin-login-user $SqlUser \
  --sql-admin-login-password $SqlPassword \
  --location $Region
```

4. Get Web and Dev URL for Azure Synapse Workspace:

```
WorkspaceWeb=$(az synapse workspace show --name $SynapseWorkspaceName --resource-group
$SynapseResourceGroup | jq -r '.connectivityEndpoints | .web')

WorkspaceDev=$(az synapse workspace show --name $SynapseWorkspaceName --resource-group
$SynapseResourceGroup | jq -r '.connectivityEndpoints | .dev')
```

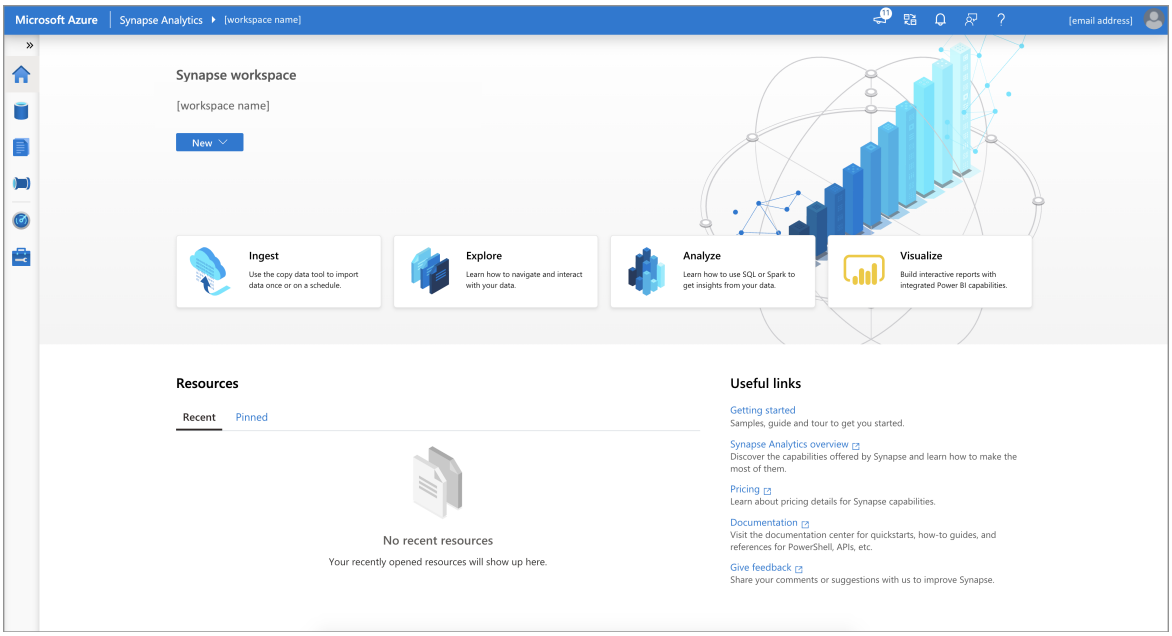
5. Create a Firewall Rule to allow your access to Azure Synapse Workspace from your machine:

```
ClientIP=$(curl -sb -H "Accept: application/json" "$WorkspaceDev" | jq -r '.message')
ClientIP=${ClientIP##'Client Ip address : '}
echo "Creating a firewall rule to enable access for IP address: $ClientIP"

az synapse workspace firewall-rule create --end-ip-address $ClientIP --start-ip-address $ClientIP --
name "Allow Client IP" --resource-group $SynapseResourceGroup --workspace-name $SynapseWorkspaceName
```

6. Open the Azure Synapse Workspace Web URL address stored in environment variable `WorkspaceWeb` to access your workspace:

```
echo "Open your Azure Synapse Workspace Web URL in the browser: $WorkspaceWeb"
```



7. Once deployed, additional permissions are required.

- In the Azure portal, assign other users of the workspace to the **Contributor** role in the workspace. For detailed steps, see Assign Azure roles using the Azure portal.
- Assign other users the appropriate **Synapse RBAC roles** using Synapse Studio.
- A member of the **Owner** role of the Azure Storage account must assign the **Storage Blob Data Contributor** role to the Azure Synapse workspace MSI and other users.

Clean up resources

Follow the steps below to delete the Azure Synapse workspace.

> **WARNING**
>
> Deleting an Azure Synapse workspace will remove the analytics engines and the data stored in the database of the contained SQL pools and workspace metadata. It will no longer be possible to connect to the SQL or Apache Spark endpoints. All code artifacts will be deleted (queries, notebooks, job definitions and pipelines).
>
> Deleting the workspace will **not** affect the data in the Data Lake Store Gen2 linked to the workspace.

If you want to delete the Azure Synapse workspace, complete the following command:

```
az synapse workspace delete --name $SynapseWorkspaceName --resource-group $SynapseResourceGroup
```

Next steps

Next, you can create SQL pools or create Apache Spark pools to start analyzing and exploring your data.

Quickstart: Create an Azure synapse workspace with Azure PowerShell

8/19/2022 • 3 minutes to read • Edit Online

Azure PowerShell is a set of cmdlets for managing Azure resources directly from PowerShell. You can use it in your browser with Azure Cloud Shell. You can also install it on macOS, Linux, or Windows.

In this quickstart, you learn to create a Synapse workspace using Azure PowerShell.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Data Lake Storage Gen2 storage account

> **IMPORTANT**
> The Azure Synapse workspace needs to be able to read and write to the selected ADLS Gen2 account. For any storage account that you link as the primary storage account, you must enable **hierarchical namespace** at the creation of the storage account as described in Create a storage account.

If you choose to use Cloud Shell, see Overview of Azure Cloud Shell for more information.

Install the Azure PowerShell module locally

If you choose to use PowerShell locally, this article requires that you install the Az PowerShell module and connect to your Azure account using the Connect-AzAccount cmdlet. For more information about installing the Az PowerShell module, see Install Azure PowerShell.

For more information about authentication with Azure PowerShell, see Sign in with Azure PowerShell.

Install the Azure Synapse PowerShell module

> **IMPORTANT**
> While the **Az.Synapse** PowerShell module is in preview, you must install it separately using the `Install-Module` cmdlet. After this PowerShell module becomes generally available, it will be part of future Az PowerShell module releases and available by default from within Azure Cloud Shell.

```
Install-Module -Name Az.Synapse
```

Create an Azure Synapse workspace using Azure PowerShell

1. Define necessary environment variables to create resources for Azure Synapse workspace.

VARIABLE NAME	DESCRIPTION
StorageAccountName	Name for your existing ADLS Gen2 storage account.

VARIABLE NAME	DESCRIPTION
StorageAccountResourceGroup	Name of your existing ADLS Gen2 storage account resource group.
FileShareName	Name of your existing storage file system.
SynapseResourceGroup	Choose a new name for your Azure Synapse resource group.
Region	Choose one of the Azure regions.
SynapseWorkspaceName	Choose a unique name for your new Azure Synapse Workspace.
SqlUser	Choose a value for a new username.
SqlPassword	Choose a secure password.
ClientIP	Public IP Address of the system you're running PowerShell from.

2. Create a resource group as a container for your Azure Synapse workspace:

```
New-AzResourceGroup -Name $SynapseResourceGroup -Location $Region
```

3. Create an Azure Synapse Workspace:

```
$Cred = New-Object -TypeName System.Management.Automation.PSCredential ($SqlUser, (ConvertTo-
SecureString $SqlPassword -AsPlainText -Force))

$WorkspaceParams = @{
  Name = $SynapseWorkspaceName
  ResourceGroupName = $SynapseResourceGroup
  DefaultDataLakeStorageAccountName = $StorageAccountName
  DefaultDataLakeStorageFilesystem = $FileShareName
  SqlAdministratorLoginCredential = $Cred
  Location = $Region
}
New-AzSynapseWorkspace @WorkspaceParams
```

4. Get Web and Dev URL for Azure Synapse Workspace:

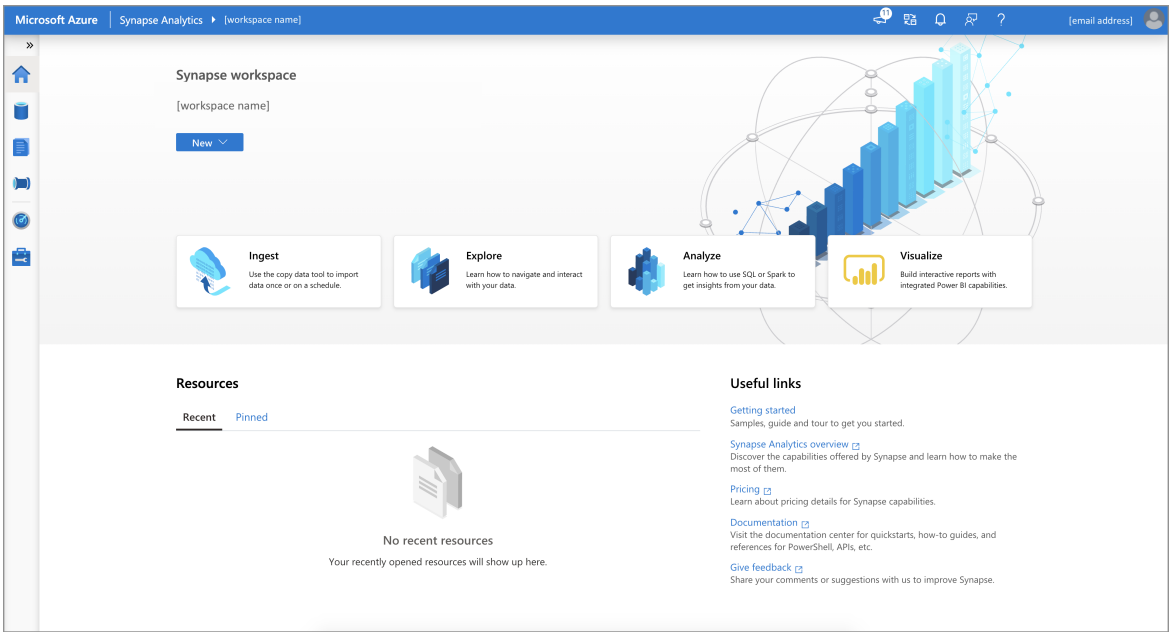
```
$WorkspaceWeb = (Get-AzSynapseWorkspace -Name $SynapseWorkspaceName -ResourceGroupName
$StorageAccountResourceGroup).ConnectivityEndpoints.web
$WorkspaceDev = (Get-AzSynapseWorkspace -Name $SynapseWorkspaceName -ResourceGroupName
$StorageAccountResourceGroup).ConnectivityEndpoints.dev
```

5. Create a Firewall Rule to allow your access to Azure Synapse Workspace from your machine:

```
$FirewallParams = @{
  WorkspaceName = $SynapseWorkspaceName
  Name = 'Allow Client IP'
  ResourceGroupName = $StorageAccountResourceGroup
  StartIpAddress = $ClientIP
  EndIpAddress = $ClientIP
}
New-AzSynapseFirewallRule @FirewallParams
```

6. Open the Azure Synapse Workspace Web URL address stored in environment variable `WorkspaceWeb` to access your workspace:

```
Start-Process $WorkspaceWeb
```



7. Once deployed, additional permissions are required.

- In the Azure portal, assign other users of the workspace to the **Contributor** role in the workspace. For detailed steps, see Assign Azure roles using the Azure portal.
- Assign other users the appropriate **Synapse RBAC roles** using Synapse Studio.
- A member of the **Owner** role of the Azure Storage account must assign the **Storage Blob Data Contributor** role to the Azure Synapse workspace MSI and other users.

Clean up resources

Follow the steps below to delete the Azure Synapse workspace.

> **WARNING**
> Deleting an Azure Synapse workspace will remove the analytics engines and the data stored in the database of the contained SQL pools and workspace metadata. It will no longer be possible to connect to the SQL or Apache Spark endpoints. All code artifacts will be deleted (queries, notebooks, job definitions and pipelines). Deleting the workspace will **not** affect the data in the Data Lake Store Gen2 linked to the workspace.

If the Azure Synapse workspace created in this article isn't needed, you can delete it by running the following example.

```
Remove-AzSynapseWorkspace -Name $SynapseWorkspaceNam -ResourceGroupName $SynapseResourceGroup
```

Next steps

Next, you can create SQL pools or create Apache Spark pools to start analyzing and exploring your data.

Quickstart: Create an Azure Synapse workspace using an ARM template

8/19/2022 • 2 minutes to read • Edit Online

This Azure Resource Manager (ARM) template will create an Azure Synapse workspace with underlying Data Lake Storage. The Azure Synapse workspace is a securable collaboration boundary for analytics processes in Azure Synapse Analytics.

An ARM template is a JavaScript Object Notation (JSON) file that defines the infrastructure and configuration for your project. The template uses declarative syntax. In declarative syntax, you describe your intended deployment without writing the sequence of programming commands to create the deployment.

If your environment meets the prerequisites and you're familiar with using ARM templates, select the **Deploy to Azure** button. The template will open in the Azure portal.

Prerequisites

If you don't have an Azure subscription, create a free account before you begin.

To create an Azure Synapse workspace, a user must have **Azure Contributor** role and **User Access Administrator** permissions, or the **Owner** role in the subscription. For detailed steps, see Assign Azure roles using the Azure portal.

Review the template

You can review the template by selecting the **Visualize** link. Then select **Edit template**.

The template defines two resources:

- Storage account
- Workspace

Deploy the template

1. Select the following image to sign in to Azure and open the template. This template creates a Synapse workspace.

2. Enter or update the following values:

   - **Subscription**: Select an Azure subscription.
   - **Resource group**: Select **Create new** and enter a unique name for the resource group and select **OK**. A new resource group will facilitate resource clean up.
   - **Region**: Select a region. For example, **Central US**.
   - **Name**: Enter a name for your workspace.

- **SQL Administrator login**: Enter the administrator username for the SQL Server.
- **SQL Administrator password**: Enter the administrator password for the SQL Server.
- **Tag Values**: Accept the default.
- **Review and Create**: Select.
- **Create**: Select.

3. Once deployed, additional permissions are required.

- In the Azure portal, assign other users of the workspace to the **Contributor** role in the workspace. For detailed steps, see Assign Azure roles using the Azure portal.
- Assign other users the appropriate **Synapse RBAC roles** using Synapse Studio.
- A member of the **Owner** role of the Azure Storage account must assign the **Storage Blob Data Contributor** role to the Azure Synapse workspace MSI and other users.

Next steps

To learn more about Azure Synapse Analytics and Azure Resource Manager,

- Read an Overview of Azure Synapse Analytics
- Learn more about Azure Resource Manager
- Create and deploy your first ARM template

Next, you can create SQL pools or create Apache Spark pools to start analyzing and exploring your data.

Quickstart: Linking a Power BI workspace to a Synapse workspace

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you will learn how to connect a Power BI workspace to an Azure Synapse Analytics workspace to create new Power BI reports and datasets from Synapse Studio.

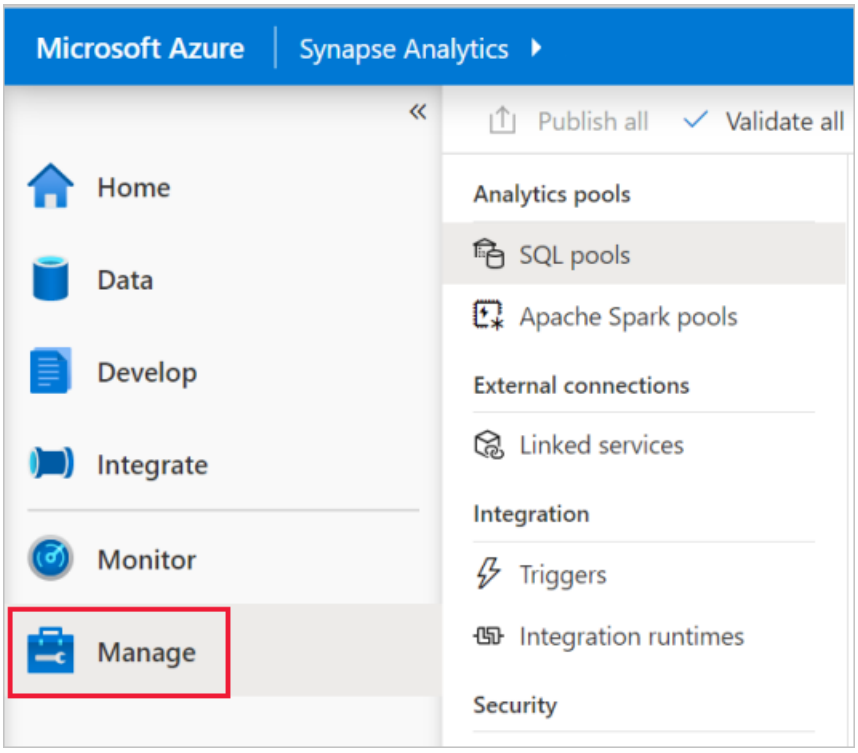
If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

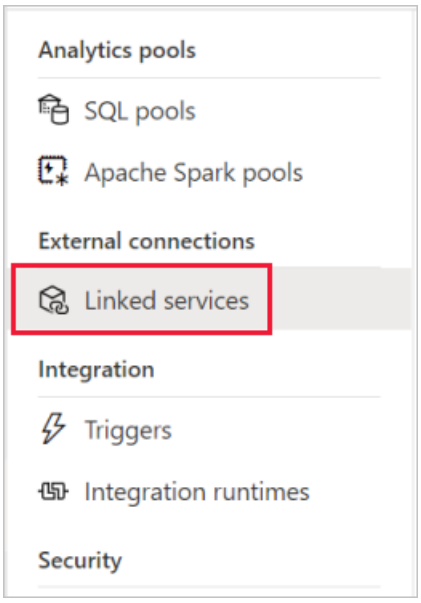
- Create an Azure Synapse workspace and associated storage account
- A Power BI Professional or Premium workspace

Link Power BI workspace to your Synapse workspace

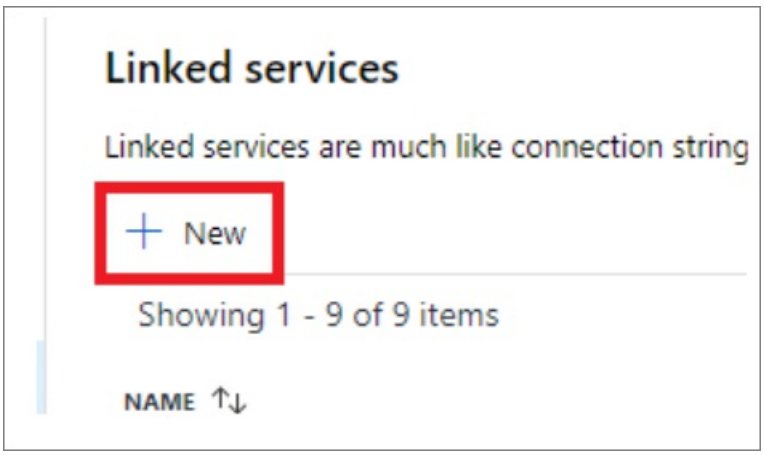
1. Starting from Synapse Studio, click **Manage**.



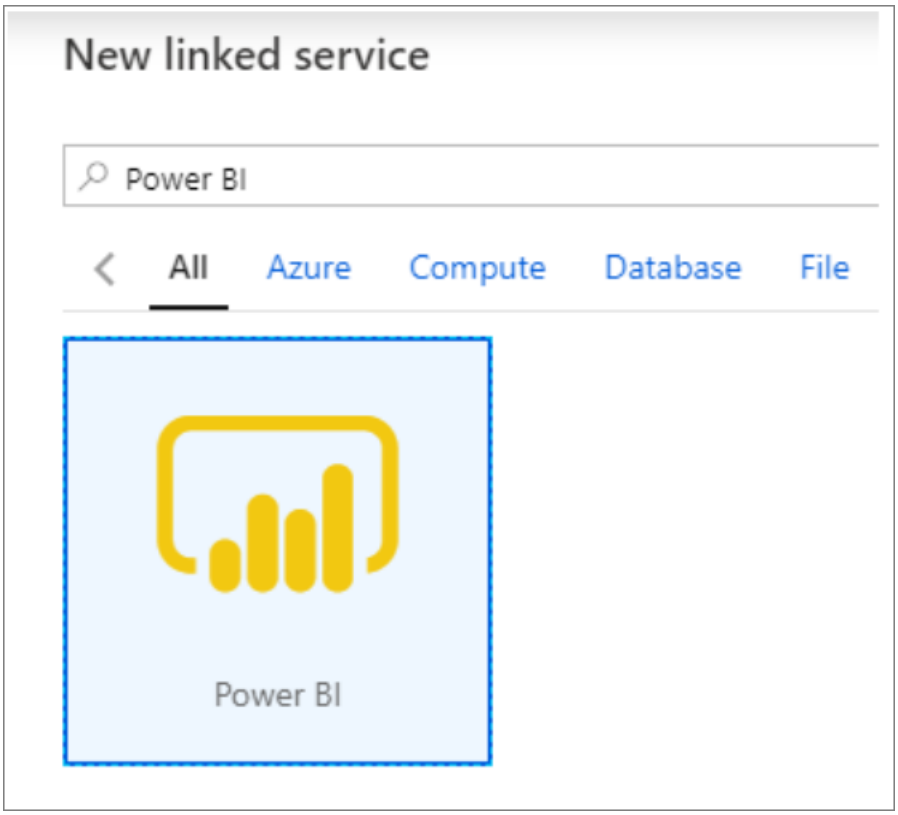
2. Under **External Connections**, click **Linked services**.



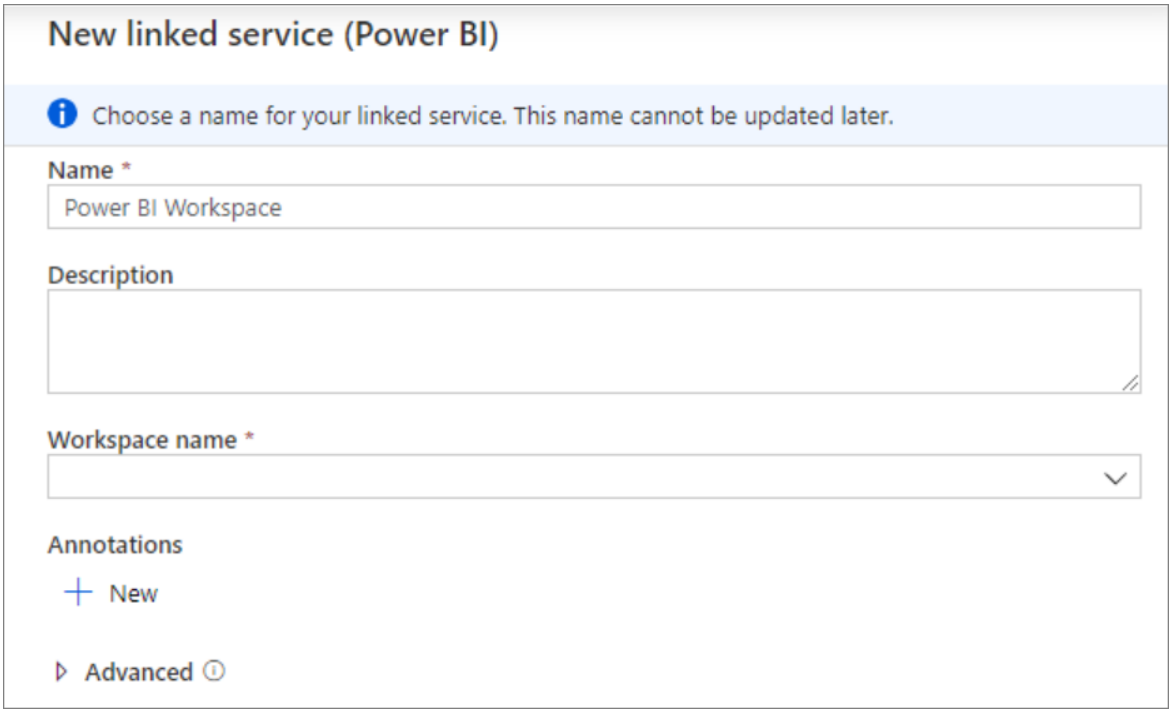
3. Click + **New**.



4. Click **Power BI** and click **Continue**.



5. Enter a name for the linked service and select a workspace from the dropdown list.

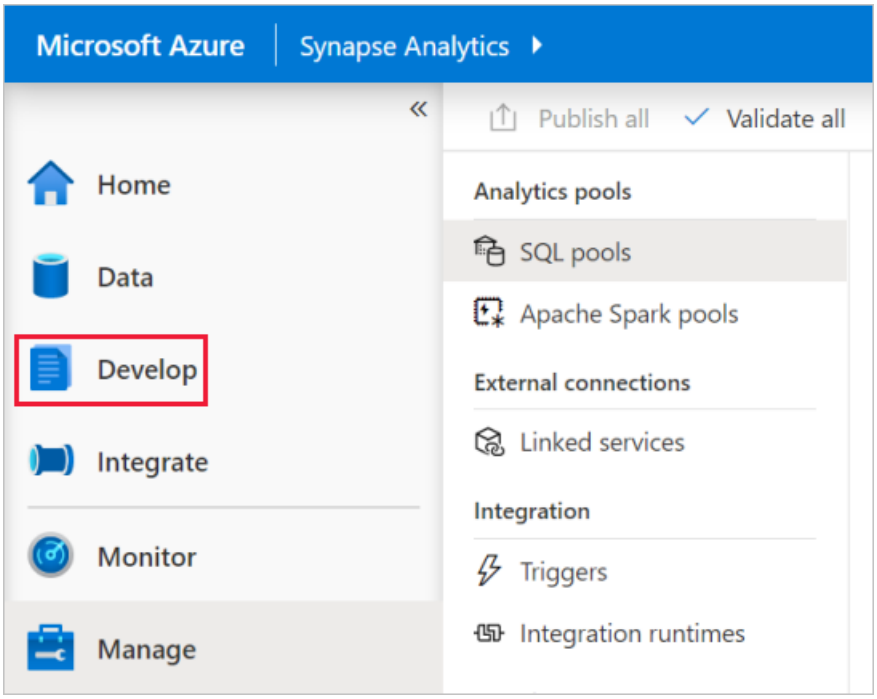


6. Click **Create**.

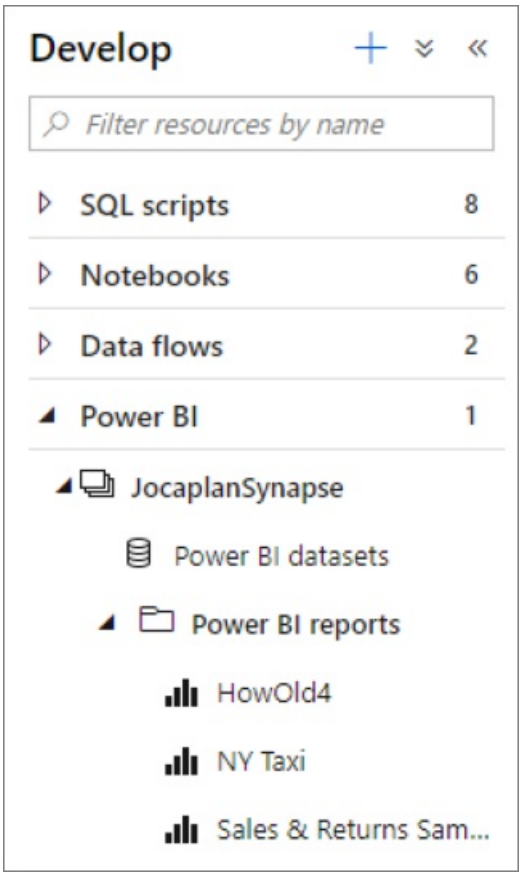
View Power BI workspace in Synapse Studio

Once your workspaces are linked, you can browse your Power BI datasets, edit/create new Power BI Reports from Synapse Studio.

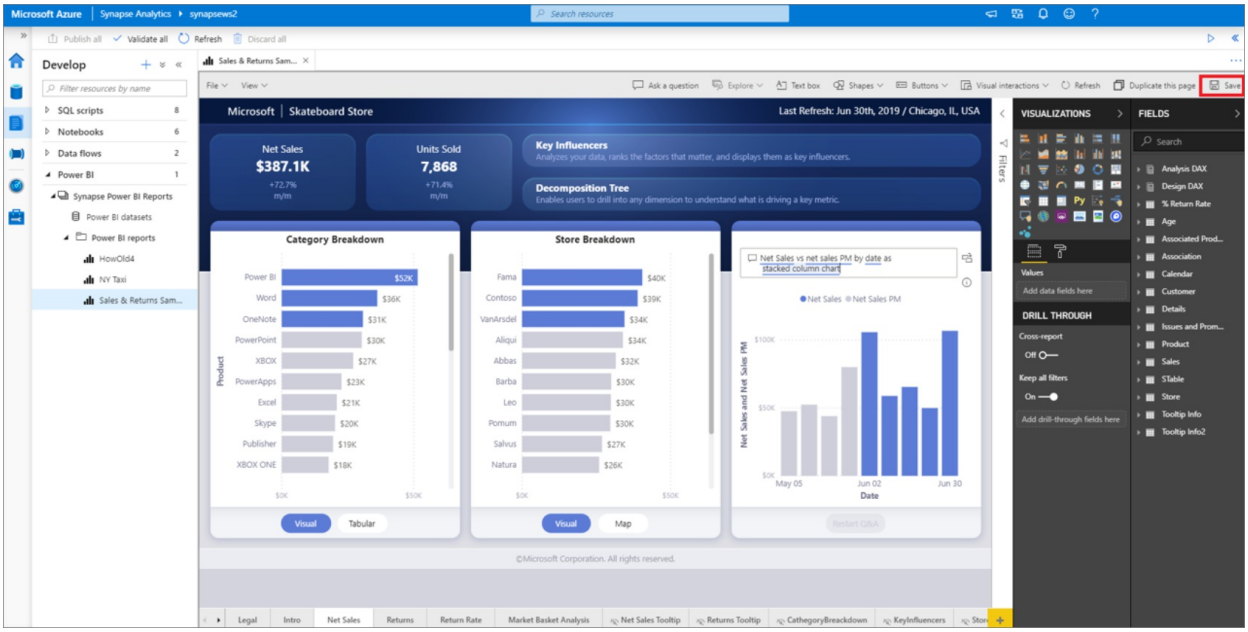
1. Click **Develop**.



2. Expand Power BI and the workspace you wish to use.



New reports can be created clicking **+** at the top of the **Develop** tab. Existing reports can be edited by clicking on the report name. Any saved changes will be written back to the Power BI workspace.



Next steps

Learn more about creating Power BI report on files stored on Azure Storage.

Quickstart: Read data from ADLS Gen2 to Pandas dataframe in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you'll learn how to easily use Python to read data from an Azure Data Lake Storage (ADLS) Gen2 into a Pandas dataframe in Azure Synapse Analytics.

From a Synapse Studio notebook, you'll:

- Connect to a container in Azure Data Lake Storage (ADLS) Gen2 that is linked to your Azure Synapse Analytics workspace.
- Read the data from a PySpark Notebook using `spark.read.load`.
- Convert the data to a Pandas dataframe using `.toPandas()`.

Prerequisites

- Azure subscription - Create one for free.
- Synapse Analytics workspace with ADLS Gen2 configured as the default storage - You need to be the **Storage Blob Data Contributor** of the ADLS Gen2 filesystem that you work with. For details on how to create a workspace, see Creating a Synapse workspace.
- Apache Spark pool in your workspace - See Create a serverless Apache Spark pool.

Sign in to the Azure portal

Sign in to the Azure portal.

Upload sample data to ADLS Gen2

1. In the Azure portal, create a container in the same ADLS Gen2 used by Synapse Studio. You can skip this step if you want to use the default linked storage account in your Azure Synapse Analytics workspace.
2. In Synapse Studio, select **Data**, select the **Linked** tab, and select the container under **Azure Data Lake Storage Gen2**.
3. Download the sample file RetailSales.csv and upload it to the container.
4. Select the uploaded file, select **Properties**, and copy the **ABFSS Path** value.

Read data from ADLS Gen2 into a Pandas dataframe

1. In the left pane, select **Develop**.
2. Select **+** and select "Notebook" to create a new notebook.
3. In **Attach to**, select your Apache Spark Pool. If you don't have one, select **Create Apache Spark pool**.
4. In the notebook code cell, paste the following Python code, inserting the ABFSS path you copied earlier:

```
%%pyspark
data_path = spark.read.load('<ABFSS Path to RetailSales.csv>', format='csv', header=True)
data_path.show(10)

print('Converting to Pandas.')

pdf = data_path.toPandas()
print(pdf)
```

5. Run the cell.

After a few minutes, the text displayed should look similar to the following.

```
Command executed in 25s 324ms by gary on 03-23-2021 17:40:23.481 -07:00

Job execution Succeeded Spark 2 executors 8 cores

Connect to Azure Data Explorer using Apache Spark for Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

This article describes how to access an Azure Data Explorer database from Synapse Studio with Apache Spark for Azure Synapse Analytics.

Prerequisites

- Create an Azure Data Explorer cluster and database.
- Have an existing Azure Synapse Analytics workspace, or create a new workspace by following the steps in Quickstart: Create an Azure Synapse workspace.
- Have an existing Apache Spark pool, or create a new pool by following the steps in Quickstart: Create an Apache Spark pool using the Azure portal.
- Create an Azure Active Directory (Azure AD) app by provisioning an Azure AD application.
- Grant your Azure AD app access to your database by following the steps in Manage Azure Data Explorer database permissions.

Go to Synapse Studio

From an Azure Synapse workspace, select **Launch Synapse Studio**. On the Synapse Studio home page, select **Data** to go to **Data Object Explorer**.

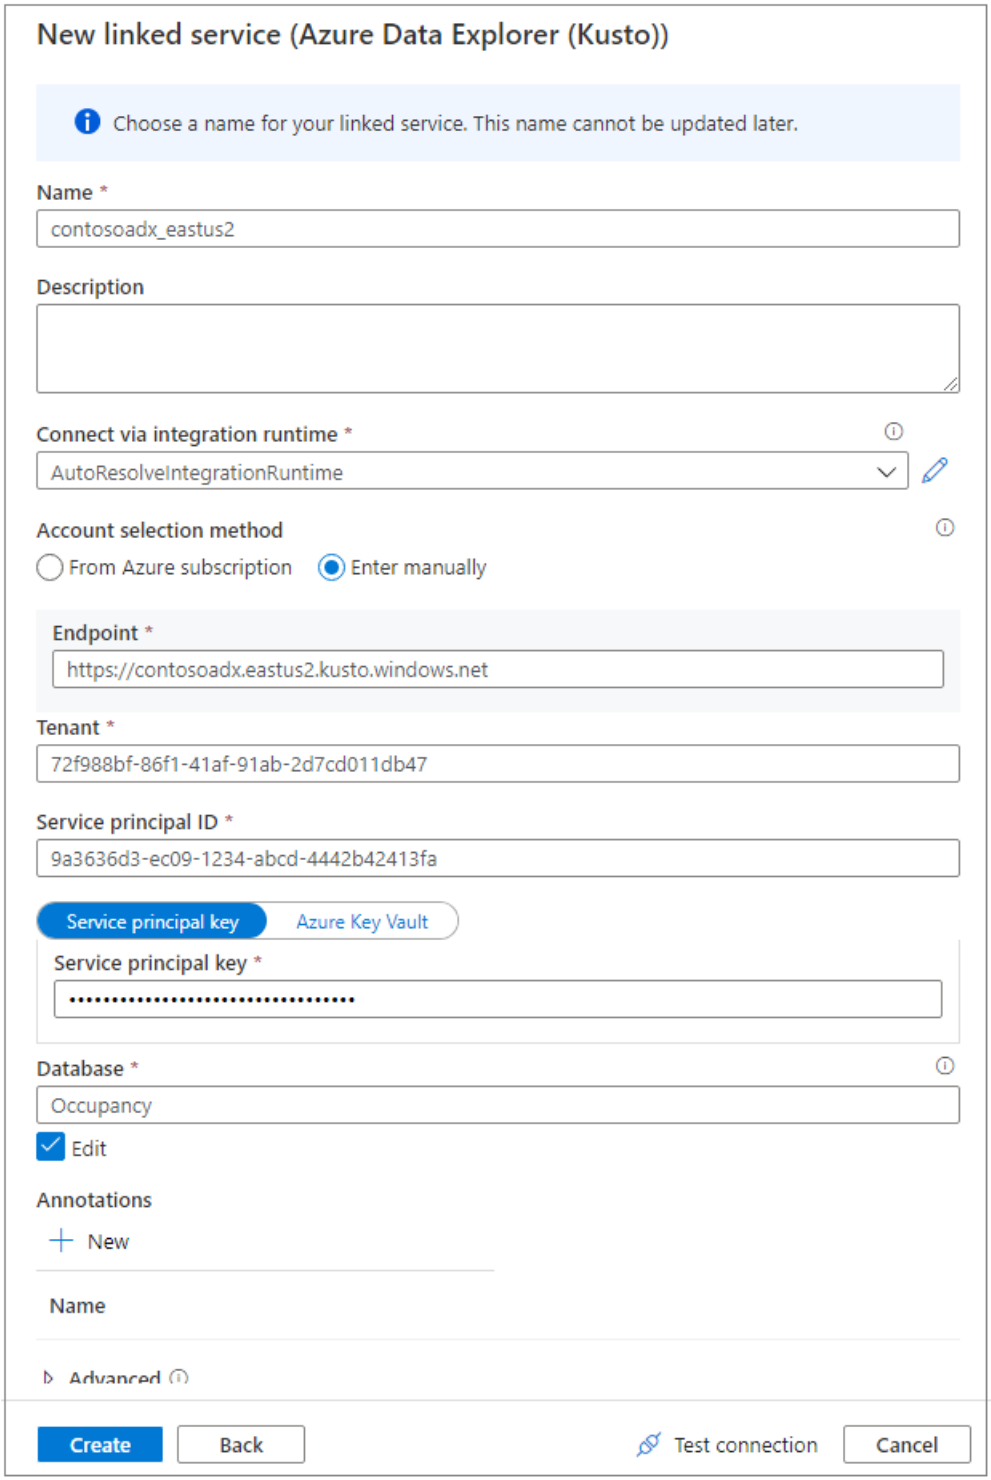
Connect an Azure Data Explorer database to an Azure Synapse workspace

Connecting an Azure Data Explorer database to a workspace is done through a linked service. With an Azure Data Explorer linked service, you can browse and explore data, read, and write from Apache Spark for Azure Synapse. You can also run integration jobs in a pipeline.

From the Data Object Explorer, follow these steps to directly connect an Azure Data Explorer cluster:

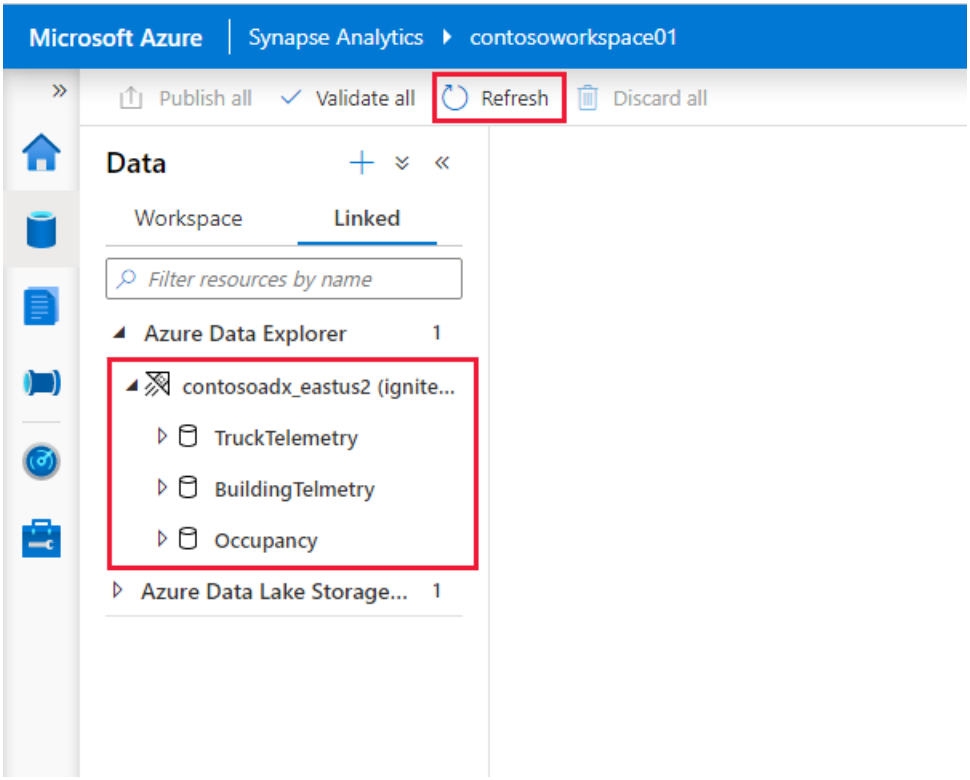
1. Select the **+** icon near **Data**.
2. Select **Connect** to connect to external data.
3. Select **Azure Data Explorer (Kusto)**.
4. Select **Continue**.
5. Use a friendly name to name the linked service. The name will appear in the Data Object Explorer and is used by Azure Synapse runtimes to connect to the database.
6. Select the Azure Data Explorer cluster from your subscription, or enter the URI.
7. Enter the **Service principal ID** and **Service principal key**. Ensure this service principal has view access on the database for read operation and ingestor access for ingesting data.
8. Enter the Azure Data Explorer database name.
9. Select **Test connection** to ensure you have the right permissions.

10. Select **Create**.



> **NOTE**
>
> (Optional) **Test connection** doesn't validate write access. Ensure your service principal ID has write access to the Azure Data Explorer database.

11. Azure Data Explorer clusters and databases appear on the **Linked** tab under the **Azure Data Explorer** section.

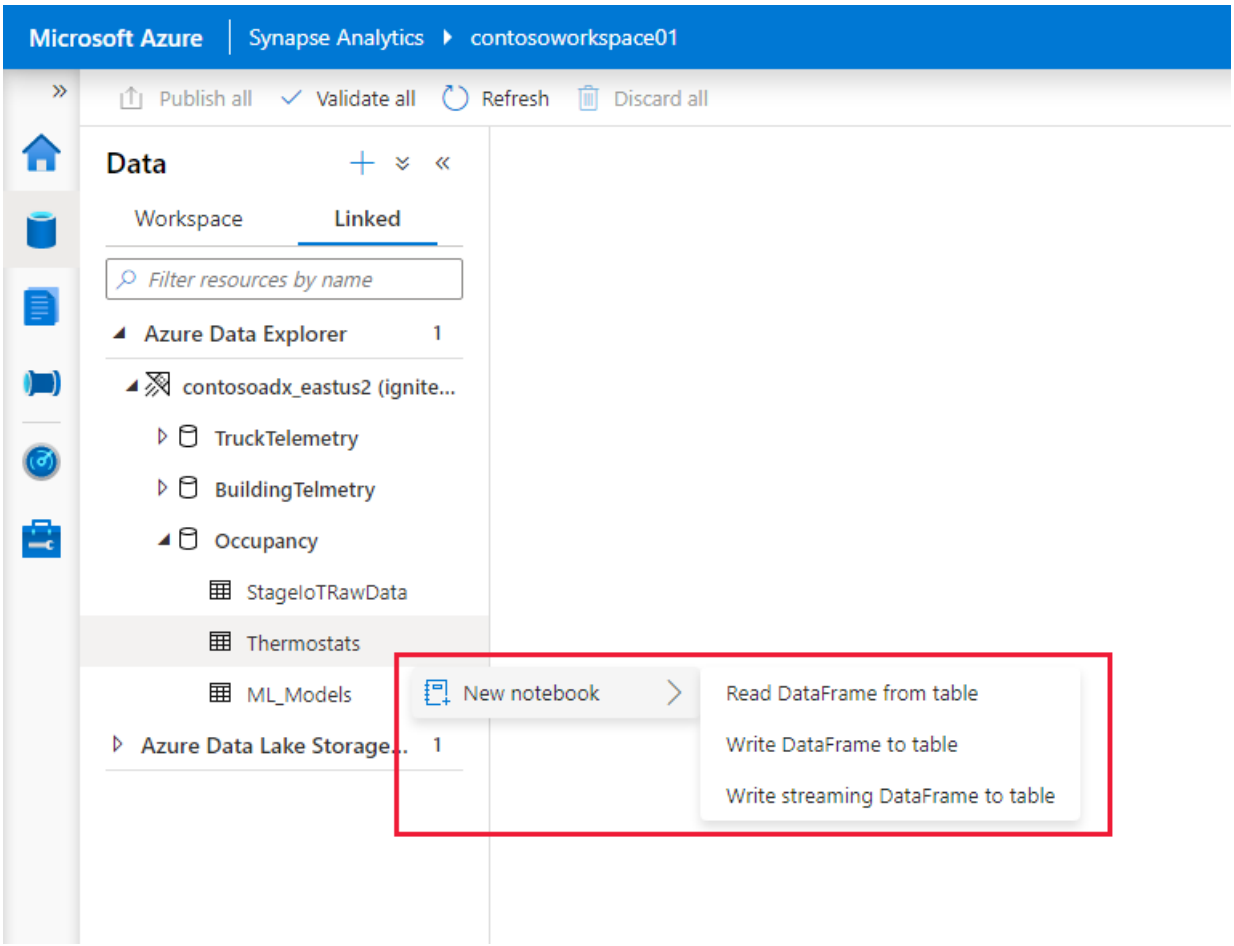


12. Before you can interact with the linked service from a notebook, it must be published to the Workspace. Click **Publish** in the toolbar, review the pending changes and click **OK**.

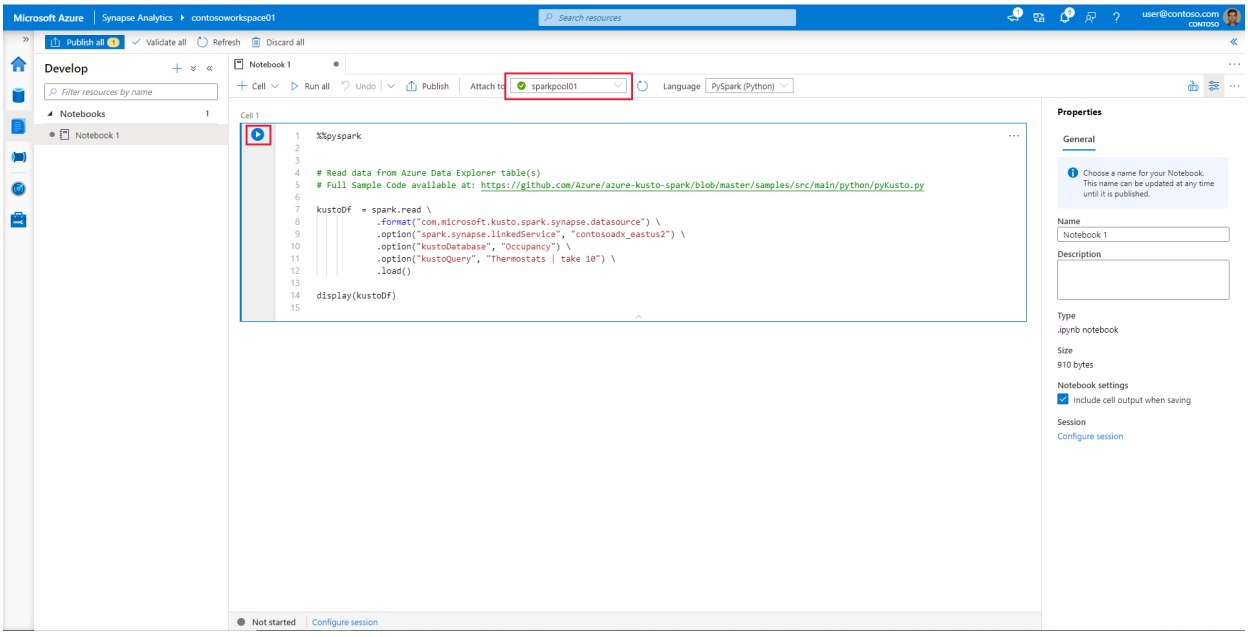
> **NOTE**
>
> In the current release, the database objects are populated based on your Azure AD account permissions on the Azure Data Explorer databases. When you run the Apache Spark notebooks or integration jobs, the credential in the link service will be used (for example, service principal).

Quickly interact with code-generated actions

When you right-click a database or table, a list of sample Spark notebooks appears. Select an option to read, write, or stream data to Azure Data Explorer.



Here's an example of reading data. Attach the notebook to your Spark pool, and run the cell.



> **NOTE**
>
> First-time execution might take more than three minutes to initiate the Spark session. Subsequent executions will be significantly faster.

Limitations

The Azure Data Explorer connector is currently not supported with Azure Synapse managed virtual networks.

- Azure Data Explorer (Kusto) Spark connector

Discover partner solutions through Synapse Studio

8/19/2022 • 2 minutes to read • Edit Online

Synapse Studio allows the discovery of solution partners that extend the capabilities of Azure Synapse. From data connectors, through data wrangling tools, orchestration engines, and other workloads, the **browse partners** page serves as a hub for discovering third-party ISV applications and solutions verified to work with Azure Synapse Analytics. Synapse Studio simplifies getting started with these partners, in many cases with automated setup of the initial connection to the partner platform.

Participating partners

The following table lists partner solutions that are currently supported. Make sure you check back often as we add new partners to this list.

PARTNER	SOLUTION NAME
	Incorta Intelligent Ingest for Azure Synapse
	InformaticaIntelligent DataManagement Cloud
	Qlik Data Integration (formerly Attunity)

Requirements

When you chose a partner application, Azure Synapse Studio provisions a sandbox environment you can use for this trial, ensuring you can experiment with partner solutions quickly before you decide to use it with your production data. The following objects are created:

OBJECT	DETAILS
A dedicated SQL pool named **Partner_[PartnerName]_pool**	DW100c performance level.
A SQL login named **Partner_[PartnerName]_login**	Created on your `master` database. The password for this SQL login is specified by you at the creation of your trial.
A database user	A new database user, mapped to the new SQL login. This user is added to the db_owner role for the newly created database.

In all cases, **[PartnerName]** is the name of the third-party ISV who offers the trial.

Security

After the required objects are created, Synapse Studio sends information about your new sandbox environment to the partner application, allowing a customized trial experience. The following information is sent to our

partners:

- First name
- Last name
- E-mail address
- Details about the Synapse environment required to establish a connection:
  - DNS name of your Synapse Workspace (server name)
  - Name of the SQL pool (database)
  - SQL login (username only)

We never share any passwords with the partner application, including the password of the newly created SQL login. You'll be required to type your password in the partner application.

Costs

The dedicated SQL pool that is created for your partner trial incurs ongoing costs, which are based on the number of DWU blocks and hours running. Make sure you pause the SQL pool created for this partner trial when it isn't in use, to avoid unnecessary charges.

Starting a new partner trial

1. On the Synapse Studio home page, under **Discover more**, select **browse partners**.
2. The Browse partners page shows all partners currently offering trials that allow direct connectivity with Azure Synapse. Choose a partner solution.
3. The partner details page shows you relevant information about this application and links to learn more about their solution. When you're ready to start a trial, select **Connect to partner**.
4. In the **Connect to [PartnerName] Solution** page, note requirements of this partner connection. Change the SQL pool name and SQL login parameters if wanted (or accept the defaults), type the password of your new SQL login, and select **Connect**.

The required objects will be created for your partner trial. You'll then be forwarded to a partner page to provide additional information (if needed) and to start your trial.

> **NOTE**
> Microsoft doesn't control the partner trial experience. Partners offer product trials on their own terms and the experience, trial availability, and features may vary depending on the partner. Microsoft does not offer support to third-party applications offered in Synapse Studio.

Azure Synapse Analytics shared metadata

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics allows the different workspace computational engines to share databases and tables between Apache Spark pools and serverless SQL pool.

The sharing supports the so-called modern data warehouse pattern and gives the workspace SQL engines access to databases and tables created with Spark. It also allows the SQL engines to create their own objects that aren't being shared with the other engines.

Support the modern data warehouse

The shared metadata model supports the modern data warehouse pattern in the following way:

1. Data from the data lake is prepared and structured efficiently with Spark by storing the prepared data in (possibly partitioned) Parquet-backed tables contained in possibly several databases.
2. The Spark created databases and all their tables become visible in any of the Azure Synapse workspace Spark pool instances and can be used from any of the Spark jobs. This capability is subject to the permissions since all Spark pools in a workspace share the same underlying catalog meta store.
3. The Spark created databases and their Parquet-backed or CSV-backed tables become visible in the workspace serverless SQL pool. Databases are created automatically in the serverless SQL pool metadata, and both the external and managed tables created by a Spark job are made accessible as external tables in the serverless SQL pool metadata in the `dbo` schema of the corresponding database.

Object synchronization occurs asynchronously. Objects will have a slight delay of a few seconds until they appear in the SQL context. Once they appear, they can be queried, but not updated nor changed by the SQL engines that have access to them.

Shared metadata objects

Spark allows you to create databases, external tables, managed tables, and views. Since Spark views require a Spark engine to process the defining Spark SQL statement, and cannot be processed by a SQL engine, only databases and their contained external and managed tables that use the Parquet or CSV storage format are shared with the workspace SQL engine. Spark views are only shared among the Spark pool instances.

Security model at a glance

The Spark databases and tables, along with their synchronized representations in the SQL engine, are secured at the underlying storage level. When the table is queried by any of the engines that the query submitter has the right to use, the query submitter's security principal is being passed through to the underlying files. Permissions are checked at the file system level.

For more information, see Azure Synapse Analytics shared database.

Change maintenance

If a metadata object is deleted or changed with Spark, the changes are picked up and propagated to the serverless SQL pool. Synchronization is asynchronous and changes are reflected in the SQL engine after a short delay.

Access lake databases using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

The Azure Synapse Analytics workspace enables you to create two types of databases on top of a Spark data lake:

- **Lake databases** where you can define tables on top of lake data using Apache Spark notebooks, database templates, or Microsoft Dataverse (previously Common Data Service). These tables will be available for querying using T-SQL (Transact-SQL) language using the serverless SQL pool.
- **SQL databases** where you can define your own databases and tables directly using the serverless SQL pools. You can use T-SQL CREATE DATABASE, CREATE EXTERNAL TABLE to define the objects and add additional SQL views, procedures, and inline-table-value functions on top of the tables.

This article focuses on lake databases in a serverless SQL pool in Azure Synapse Analytics.

Azure Synapse Analytics allows you to create lake databases and tables using Spark or database designer, and then analyze data in the lake databases using the serverless SQL pool. The lake databases and the tables (parquet or CSV-backed) that are created on the Apache Spark pools, database templates, or Dataverse are automatically available for querying with the serverless SQL pool engine. The lake databases and tables that are modified will be available in serverless SQL pool after some time. There will be a delay until the changes made in Spark or Database designed appear in serverless.

Manage lake database

To manage Spark created lake databases, you can use Apache Spark pools or Database designer. For example, create or delete a lake database through a Spark pool job. You can't create a lake database or the objects in the lake databases using the serverless SQL pool.

The Spark default database is available in the serverless SQL pool context as a lake database called `default`.

> **NOTE**
> You cannot create a lake and a SQL database in the serverless SQL pool with the same name.

Tables in the lake databases cannot be modified from a serverless SQL pool. Use the Database designer or Apache Spark pools to modify a lake database. The serverless SQL pool enables you to make the following changes in a lake database using Transact-SQL commands:

- Adding, altering, and dropping views, procedures, inline table-value functions in a lake database.
- Adding and removing database-scoped Azure AD users.
- Add or remove Azure AD database users to the **db_datareader** role. Azure AD database users in the **db_datareader** role have permission to read all tables in the lake database, but cannot read data from other databases.

Security model

The lake databases and tables are secured at two levels:

- The underlying storage layer by assigning to Azure AD users one of the following:

    - Azure role-based access control (Azure RBAC)
    - Azure attribute-based access control (Azure ABAC) role
    - ACL permissions
- The SQL layer where you can define an Azure AD user and grant SQL permissions to SELECT data from tables referencing the lake data.

Lake security model

Access to lake database files is controlled using the lake permissions on storage layer. Only Azure AD users can use tables in the lake databases, and they can access the data in the lake using their own identities.

You can grant access to the underlying data used for external tables to a security principal, such as: a user, an Azure AD application with assigned service principal, or a security group. For data access, grant both of the following permissions:

- Grant `read (R)` permission on files (such as the table's underlying data files).
- Grant `execute (X)` permission on the folder where the files are stored and on every parent folder up to the root. You can read more about these permissions on Access control lists(ACLs) page.

For example, in

```
https://<storage-
name>.dfs.core.windows.net/<fs>/synapse/workspaces/<synapse_ws>/warehouse/mytestdb.db/myparquettable/
```

, security principals need:

- `execute (X)` permissions on all the folders starting at the `<fs>` to the `myparquettable`.
- `read (R)` permissions on `myparquettable` and files inside that folder, to be able to read a table in a database (synchronized or original one).

If a security principal requires the ability to create objects or drop objects in a database, additional `write (W)` permissions are required on the folders and files in the `warehouse` folder. Modifying objects in a database is not possible from serverless SQL pool, only from Spark pools or the database designer.

SQL security model

The Azure Synapse workspace provides a T-SQL endpoint that enables you to query the lake database using the serverless SQL pool. In addition to the data access, SQL interface enables you to control who can access the tables. You need to enable a user to access the shared lake databases using the serverless SQL pool. There are two types of users who can access the lake databases:

- Administrators: Assign the **Synapse SQL Administrator** workspace role or **sysadmin** server-level role inside the serverless SQL pool. This role has full control over all databases. The **Synapse Administrator** and **Synapse SQL Administrator** roles also have all permissions on all objects in a serverless SQL pool, by default.
- Workspace readers: Grant the server-level permissions **GRANT CONNECT ANY DATABASE** and **GRANT SELECT ALL USER SECURABLES** on serverless SQL pool to a login that will enable the login to access and read any database. This might be a good choice for assigning reader/non-admin access to a user.
- Database readers: Create database users from Azure AD in your lake database and add them to **db_datareader** role, which will enable them to read data in the lake database.

Learn more about setting access control on shared databases here.

Custom SQL objects in lake databases

Lake databases allow creation of custom T-SQL objects, such as schemas, procedures, views, and the inline table-value functions (iTVFs). In order to create custom SQL objects, you **MUST** create a schema where you will place the objects. Custom SQL objects cannot be placed in `dbo` schema because it is reserved for the lake tables

that are defined in Spark, database designer, or Dataverse.

> **IMPORTANT**
> You must create custom SQL schema where you will place your SQL objects. The custom SQL objects cannot be placed in the `dbo` schema. The `dbo` schema is reserved for the lake tables that are originally created in Spark or database designer.

Examples

Create SQL database reader in lake database

In this example, we are adding an Azure AD user in the lake database who can read data via shared tables. The users are added in the lake database via the serverless SQL pool. Then, assign the user to the **db_datareader** role so they can read data.

```
CREATE USER [customuser@contoso.com] FROM EXTERNAL PROVIDER;
GO
ALTER ROLE db_datareader
ADD MEMBER [customuser@contoso.com];
```

Create workspace-level data reader

A login with `GRANT CONNECT ANY DATABASE` and `GRANT SELECT ALL USER SECURABLES` permissions is able to read all tables using the serverless SQL pool, but not able to create SQL databases or modify the objects in them.

```
CREATE LOGIN [wsdatareader@contoso.com] FROM EXTERNAL PROVIDER
GRANT CONNECT ANY DATABASE TO [wsdatareader@contoso.com]
GRANT SELECT ALL USER SECURABLES TO [wsdatareader@contoso.com]
```

This script enables you to create users without admin privileges who can read any table in Lake databases.

Create and connect to Spark database with serverless SQL pool

First, create a new Spark database named `mytestdb` using a Spark cluster you have already created in your workspace. You can achieve that, for example, using a Spark C# Notebook with the following .NET for Spark statement:

```
spark.Sql("CREATE DATABASE mytestlakedb")
```

After a short delay, you can see the lake database from serverless SQL pool. For example, run the following statement from serverless SQL pool.

```
SELECT * FROM sys.databases;
```

Verify that `mytestlakedb` is included in the results.

Create custom SQL objects in lake database

The following example shows how to create a custom view, procedure, and inline table-value function (iTVF) in the `reports` schema:

```
CREATE SCHEMA reports
GO

CREATE OR ALTER VIEW reports.GreenReport
AS SELECT puYear, puMonth,
            fareAmount = SUM(fareAmount),
            tipAmount = SUM(tipAmount),
            mtaTax = SUM(mtaTax)
FROM dbo.green
GROUP BY puYear, puMonth
GO

CREATE OR ALTER PROCEDURE reports.GreenReportSummary
AS BEGIN
SELECT puYear, puMonth,
            fareAmount = SUM(fareAmount),
            tipAmount = SUM(tipAmount),
            mtaTax = SUM(mtaTax)
FROM dbo.green
GROUP BY puYear, puMonth
END
GO

CREATE OR ALTER FUNCTION reports.GreenDataReportMonthly(@year int)
RETURNS TABLE
RETURN ( SELECT puYear = @year, puMonth,
                fareAmount = SUM(fareAmount),
                tipAmount = SUM(tipAmount),
                mtaTax = SUM(mtaTax)
        FROM dbo.green
        WHERE puYear = @year
        GROUP BY puMonth )
GO
```

Azure Synapse Analytics shared metadata tables

8/19/2022 • 7 minutes to read • Edit Online

Azure Synapse Analytics allows the different workspace computational engines to share databases and tables between its Apache Spark pools and serverless SQL pool.

Once a database has been created by a Spark job, you can create tables in it with Spark that use Parquet, Delta, or CSV as the storage format. Table names will be converted to lower case and need to be queried using the lower case name. These tables will immediately become available for querying by any of the Azure Synapse workspace Spark pools. They can also be used from any of the Spark jobs subject to permissions.

The Spark created, managed, and external tables are also made available as external tables with the same name in the corresponding synchronized database in serverless SQL pool. Exposing a Spark table in SQL provides more detail on the table synchronization.

Since the tables are synchronized to serverless SQL pool asynchronously, there will be a small delay until they appear.

Manage a Spark created table

Use Spark to manage Spark created databases. For example, delete it through a serverless Apache Spark pool job, and create tables in it from Spark.

Objects in synchronized databases cannot be modified from serverless SQL pool.

Expose a Spark table in SQL

Shared Spark tables

Spark provides two types of tables that Azure Synapse exposes in SQL automatically:

- Managed tables

  Spark provides many options for how to store data in managed tables, such as TEXT, CSV, JSON, JDBC, PARQUET, ORC, HIVE, DELTA, and LIBSVM. These files are normally stored in the `warehouse` directory where managed table data is stored.

- External tables

  Spark also provides ways to create external tables over existing data, either by providing the `LOCATION` option or using the Hive format. Such external tables can be over a variety of data formats, including Parquet.

Azure Synapse currently only shares managed and external Spark tables that store their data in Parquet, DELTA, or CSV format with the SQL engines. Tables backed by other formats are not automatically synced. You may be able to sync such tables explicitly yourself as an external table in your own SQL database if the SQL engine supports the table's underlying format.

> **NOTE**
>
> Currently, only Parquet and CSV formats are fully supported in serverless SQL pool. Spark Delta tables are also available in the serverless SQL pool, but this feature is in **public preview**. External tables created in Spark are not available in dedicated SQL pool databases.

Share Spark tables

The shareable managed and external Spark tables exposed in the SQL engine as external tables with the following properties:

- The SQL external table's data source is the data source representing the Spark table's location folder.
- The SQL external table's file format is Parquet, Delta, or CSV.
- The SQL external table's access credential is pass-through.

Since all Spark table names are valid SQL table names and all Spark column names are valid SQL column names, the Spark table and column names will be used for the SQL external table.

Spark tables provide different data types than the Synapse SQL engines. The following table maps Spark table data types map to the SQL types:

SPARK DATA TYPE	SQL DATA TYPE	COMMENTS
`LongType`, `long`, `bigint`	`bigint`	**Spark**: *LongType* represents 8-byte signed integer numbers. **SQL**: See int, bigint, smallint, and tinyint.
`BooleanType`, `boolean`	`bit` (Parquet), `varchar(6)` (CSV)	**Spark**: Boolean. **SQL**: See [/sql/t-sql/data-types/bit-transact-sql).
`DecimalType`, `decimal`, `dec`, `numeric`	`decimal`	**Spark**: *DecimalType* represents arbitrary-precision signed decimal numbers. Backed internally by java.math.BigDecimal. A BigDecimal consists of an arbitrary precision integer unscaled value and a 32-bit integer scale. **SQL**: Fixed precision and scale numbers. When maximum precision is used, valid values are from - 10^38 +1 through 10^38 - 1. The ISO synonyms for decimal are dec and dec(p, s). numeric is functionally identical to decimal. See decimal and numeric.
`IntegerType`, `Integer`, `int`	`int`	**Spark** *IntegerType* represents 4-byte signed integer numbers. **SQL**: See int, bigint, smallint, and tinyint.
`ByteType`, `Byte`, `tinyint`	`smallint`	**Spark**: *ByteType* represents 1-byte signed integer numbers [-128 to 127] and ShortType represents 2-byte signed integer numbers [-32768 to 32767]. **SQL**: Tinyint represents 1-byte signed integer numbers [0, 255] and smallint represents 2-byte signed integer numbers [-32768, 32767]. See int, bigint, smallint, and tinyint.
`ShortType`, `Short`, `smallint`	`smallint`	Same as above.

SPARK DATA TYPE	SQL DATA TYPE	COMMENTS
`DoubleType`, `Double`	`float`	**Spark**: *DoubleType* represents 8-byte double-precision floating point numbers. **SQL**: See float and real.
`FloatType`, `float`, `real`	`real`	**Spark**: *FloatType* represents 4-byte double-precision floating point numbers. **SQL**: See float and real.
`DateType`, `date`	`date`	**Spark**: *DateType* represents values comprising values of fields year, month and day, without a time-zone. **SQL**: See date.
`TimestampType`, `timestamp`	`datetime2`	**Spark**: *TimestampType* represents values comprising values of fields year, month, day, hour, minute, and second, with the session local time-zone. The timestamp value represents an absolute point in time. **SQL**: See datetime2.
`char`	`char`	
`StringType`, `String`, `varchar`	`Varchar(n)`	**Spark**: *StringType* represents character string values. *VarcharType(n)* is a variant of StringType which has a length limitation. Data writing will fail if the input string exceeds the length limitation. This type can only be used in table schema, not functions/operators. *CharType(n)* is a variant of *VarcharType(n)* which is fixed length. Reading column of type *CharType(n)* always returns string values of length n. *CharType(n)* column comparison will pad the short one to the longer length. **SQL**: If there's a length provided from Spark, n in *varchar(n)* will be set to that length. If it is partitioned column, n can be max 2048. Otherwise, it will be *varchar(max)*. See char and varchar. Use it with collation `Latin1_General_100_BIN2_UTF8`.
`BinaryType`, `binary`	`varbinary(n)`	**SQL**: If there's a length provided from Spark, `n` in *Varbinary(n)* will be set to that length. If it is partitioned column, n can be max 2048. Otherwise, it will be *Varbinary(max)*. See binary and varbinary.
`array`, `map`, `struct`	`varchar(max)`	**SQL**: Serializes into JSON with collation `Latin1_General_100_BIN2_UTF8`. See JSON Data.

> **NOTE**
> Database level collation is `Latin1_General_100_CI_AS_SC_UTF8`.

Security model

The Spark databases and tables, as well as their synchronized representations in the SQL engine will be secured at the underlying storage level. Since they do not currently have permissions on the objects themselves, the objects can be seen in the object explorer.

The security principal who creates a managed table is considered the owner of that table and has all the rights to the table as well as the underlying folders and files. In addition, the owner of the database will automatically become co-owner of the table.

If you create a Spark or SQL external table with authentication pass-through, the data is only secured at the folder and file levels. If someone queries this type of external table, the security identity of the query submitter is passed down to the file system, which will check for access rights.

For more information on how to set permissions on the folders and files, see Azure Synapse Analytics shared database.

Examples

Create a managed table in Spark and query from serverless SQL pool

In this scenario, you have a Spark database named `mytestdb`. See Create and connect to a Spark database with serverless SQL pool.

Create a managed Spark table with SparkSQL by running the following command:

```
CREATE TABLE mytestdb.myparquettable(id int, name string, birthdate date) USING Parquet
```

This command creates the table `myparquettable` in the database `mytestdb`. Table names will be converted to lowercase. After a short delay, you can see the table in your serverless SQL pool. For example, run the following statement from your serverless SQL pool.

```
USE mytestdb;
SELECT * FROM sys.tables;
```

Verify that `myparquettable` is included in the results.

> **NOTE**
> A table that is not using Delta, Parquet or CSV as its storage format will not be synchronized.

Next, insert some values into the table from Spark, for example with the following C# Spark statements in a C# notebook:

```
using Microsoft.Spark.Sql.Types;

var data = new List<GenericRow>();

data.Add(new GenericRow(new object[] { 1, "Alice", new Date(2010, 1, 1)}));
data.Add(new GenericRow(new object[] { 2, "Bob", new Date(1990, 1, 1)}));

var schema = new StructType
    (new List<StructField>()
        {
            new StructField("id", new IntegerType()),
            new StructField("name", new StringType()),
            new StructField("birthdate", new DateType())
        }
    );

var df = spark.CreateDataFrame(data, schema);
df.Write().Mode(SaveMode.Append).InsertInto("mytestdb.myparquettable");
```

Now you can read the data from your serverless SQL pool as follows:

```
SELECT * FROM mytestdb.dbo.myparquettable WHERE name = 'Alice';
```

You should get the following row as result:

```
id | name | birthdate
---+-------+-----------
1 | Alice | 2010-01-01
```

Create an external table in Spark and query from serverless SQL pool

In this example, we will create an external Spark table over the Parquet data files that got created in the previous example for the managed table.

For example, with SparkSQL run:

```
CREATE TABLE mytestdb.myexternalparquettable
    USING Parquet
    LOCATION "abfss://<storage-
name>.dfs.core.windows.net/<fs>/synapse/workspaces/<synapse_ws>/warehouse/mytestdb.db/myparquettable/"
```

Replace the placeholder `<storage-name>` with the ADLS Gen2 storage account name that you are using, `<fs>` with the file system name you're using and the placeholder `<synapse_ws>` with the name of the Azure Synapse workspace you're using to run this example.

The previous example creates the table `myextneralparquettable` in the database `mytestdb`. After a short delay, you can see the table in your serverless SQL pool. For example, run the following statement from your serverless SQL pool.

```
USE mytestdb;
SELECT * FROM sys.tables;
```

Verify that `myexternalparquettable` is included in the results.

Now you can read the data from your serverless SQL pool as follows:

```
SELECT * FROM mytestdb.dbo.myexternalparquettable WHERE name = 'Alice';
```

You should get the following row as result:

```
id | name | birthdate
---+-------+-----------
1 | Alice | 2010-01-01
```

Create, develop, and maintain Synapse notebooks in Azure Synapse Analytics

8/19/2022 • 19 minutes to read • Edit Online

A Synapse notebook is a web interface for you to create files that contain live code, visualizations, and narrative text. Notebooks are a good place to validate ideas and use quick experiments to get insights from your data. Notebooks are also widely used in data preparation, data visualization, machine learning, and other Big Data scenarios.

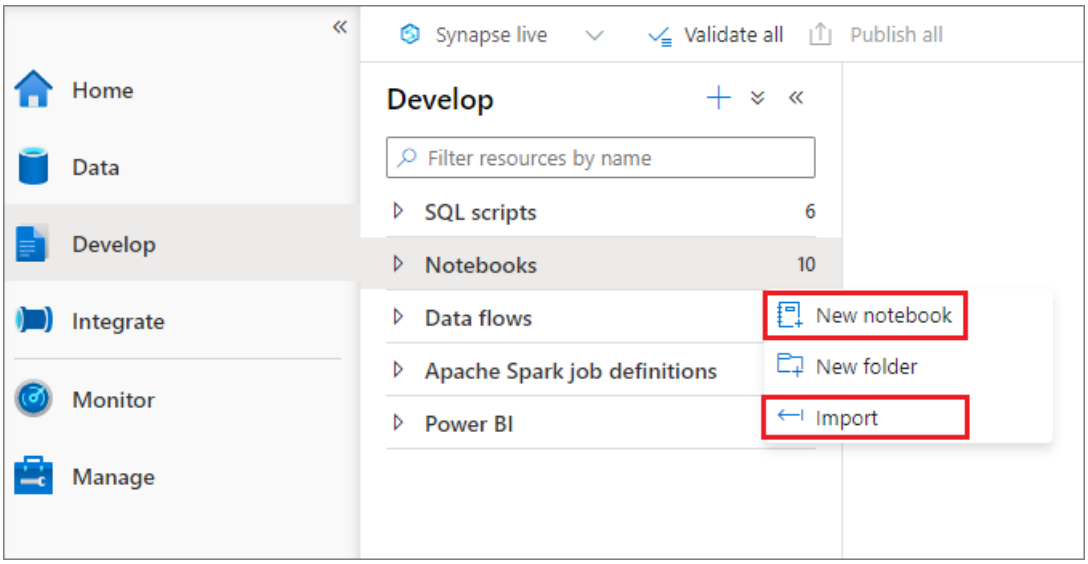
With a Synapse notebook, you can:

- Get started with zero setup effort.
- Keep data secure with built-in enterprise security features.
- Analyze data across raw formats (CSV, txt, JSON, etc.), processed file formats (parquet, Delta Lake, ORC, etc.), and SQL tabular data files against Spark and SQL.
- Be productive with enhanced authoring capabilities and built-in data visualization.

This article describes how to use notebooks in Synapse Studio.

Create a notebook

There are two ways to create a notebook. You can create a new notebook or import an existing notebook to a Synapse workspace from the **Object Explorer**. Synapse notebooks recognize standard Jupyter Notebook IPYNB files.



Develop notebooks

Notebooks consist of cells, which are individual blocks of code or text that can be run independently or as a group.

We provide rich operations to develop notebooks:

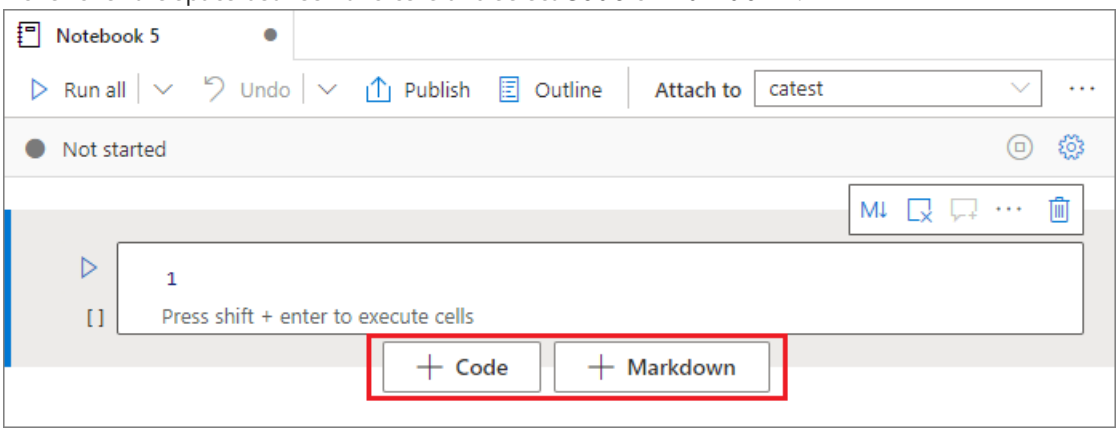
- Add a cell
- Set a primary language
- Use multiple languages

- Use temp tables to reference data across languages
- IDE-style IntelliSense
- Code Snippets
- Format text cell with toolbar buttons
- Undo/Redo cell operation
- Code cell commenting
- Move a cell
- Delete a cell
- Collapse a cell input
- Collapse a cell output
- Notebook outline

Add a cell

There are multiple ways to add a new cell to your notebook.

1. Hover over the space between two cells and select **Code** or **Markdown**.



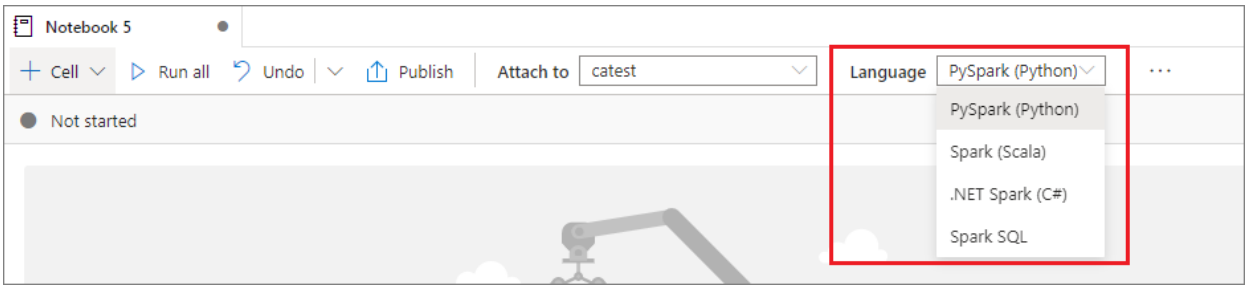
2. Use aznb Shortcut keys under command mode. Press **A** to insert a cell above the current cell. Press **B** to insert a cell below the current cell.

Set a primary language

Synapse notebooks support four Apache Spark languages:

- PySpark (Python)
- Spark (Scala)
- Spark SQL
- .NET Spark (C#)

You can set the primary language for new added cells from the dropdown list in the top command bar.

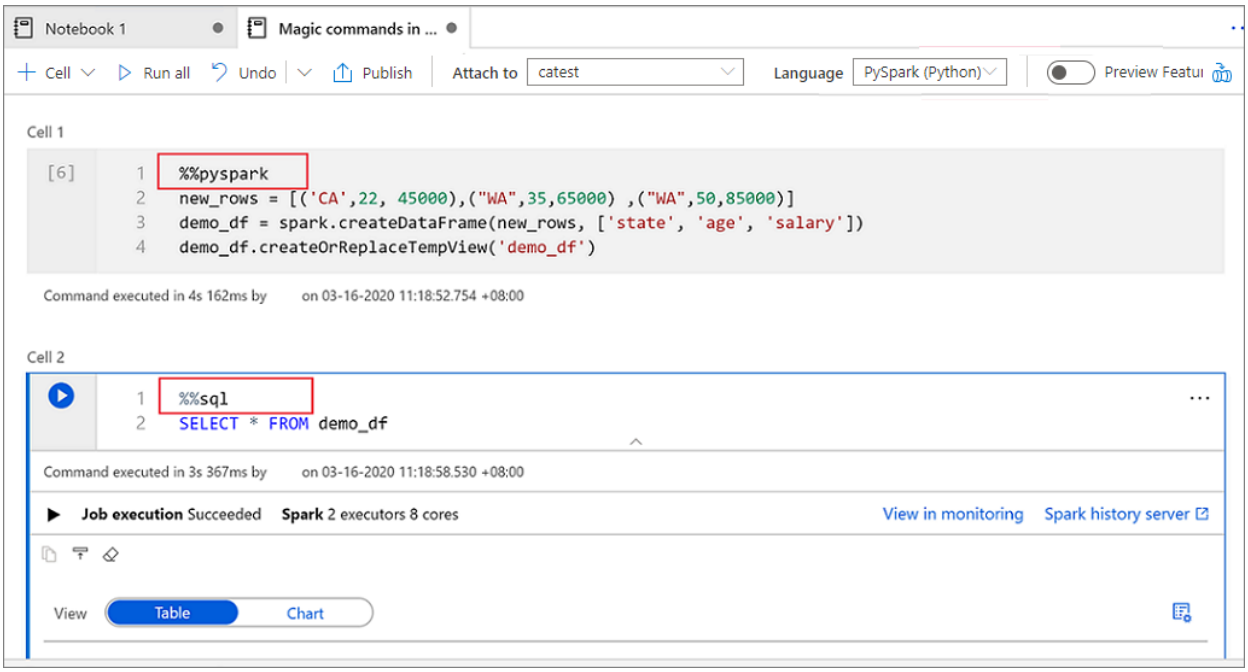


Use multiple languages

You can use multiple languages in one notebook by specifying the correct language magic command at the beginning of a cell. The following table lists the magic commands to switch cell languages.

MAGIC COMMAND	LANGUAGE	DESCRIPTION
%%pyspark	Python	Execute a **Python** query against Spark Context.
%%spark	Scala	Execute a **Scala** query against Spark Context.
%%sql	SparkSQL	Execute a **SparkSQL** query against Spark Context.
%%csharp	.NET for Spark C#	Execute a **.NET for Spark C#** query against Spark Context.

The following image is an example of how you can write a PySpark query using the **%%pyspark** magic command or a SparkSQL query with the **%%sql** magic command in a **Spark(Scala)** notebook. Notice that the primary language for the notebook is set to pySpark.



Use temp tables to reference data across languages

You cannot reference data or variables directly across different languages in a Synapse notebook. In Spark, a temporary table can be referenced across languages. Here is an example of how to read a `Scala` DataFrame in `PySpark` and `SparkSQL` using a Spark temp table as a workaround.

1. In Cell 1, read a DataFrame from a SQL pool connector using Scala and create a temporary table.

```
%%spark
val scalaDataFrame = spark.read.sqlanalytics("mySQLPoolDatabase.dbo.mySQLPoolTable")
scalaDataFrame.createOrReplaceTempView( "mydataframetable" )
```

2. In Cell 2, query the data using Spark SQL.

```
%%sql
SELECT * FROM mydataframetable
```

3. In Cell 3, use the data in PySpark.

```
%%pyspark
myNewPythonDataFrame = spark.sql("SELECT * FROM mydataframetable")
```

IDE-style IntelliSense

Synapse notebooks are integrated with the Monaco editor to bring IDE-style IntelliSense to the cell editor. Syntax highlight, error marker, and automatic code completions help you to write code and identify issues quicker.

The IntelliSense features are at different levels of maturity for different languages. Use the following table to see what's supported.

LANGUAGES	SYNTAX HIGHLIGHT	SYNTAX ERROR MARKER	SYNTAX CODE COMPLETION	VARIABLE CODE COMPLETION	SYSTEM FUNCTION CODE COMPLETION	USER FUNCTION CODE COMPLETION	SMART INDENT	CODE FOLDING
PySpark (Python)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Spark (Scala)	Yes	Yes	Yes	Yes	Yes	Yes	-	Yes
SparkSQL	Yes	Yes	Yes	Yes	Yes	-	-	-
.NET for Spark (C#)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes

> **NOTE**
> An active Spark session is required to benefit the Variable Code Completion, System Function Code Completion, User Function Code Completion for .NET for Spark (C#).

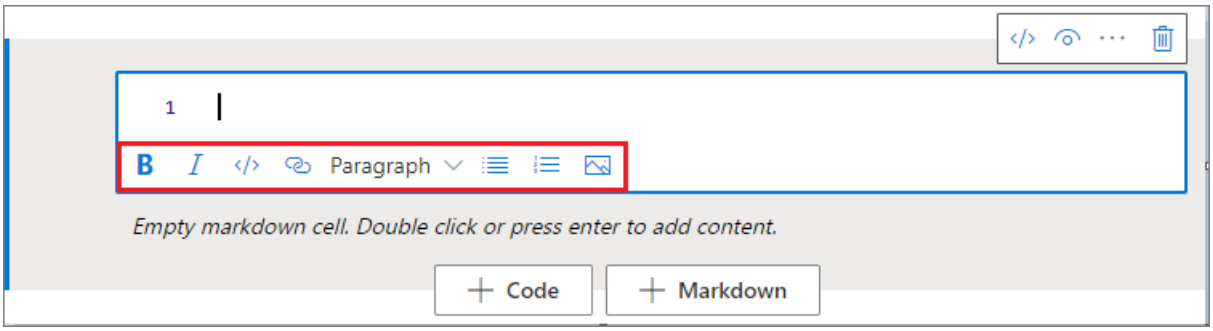
Code Snippets

Synapse notebooks provide code snippets that make it easier to enter common used code patterns, such as configuring your Spark session, reading data as a Spark DataFrame, or drawing charts with matplotlib etc.

Snippets appear in Shortcut keys of IDE style IntelliSense mixed with other suggestions. The code snippets contents align with the code cell language. You can see available snippets by typing **Snippet** or any keywords appear in the snippet title in the code cell editor. For example, by typing **read** you can see the list of snippets to read data from various data sources.

Format text cell with toolbar buttons

You can use the format buttons in the text cells toolbar to do common markdown actions. It includes bolding text, italicizing text, paragraph/headers through a dropdown, inserting code, inserting unordered list, inserting ordered list, inserting hyperlink and inserting image from URL.



Undo/Redo cell operation

Select the **Undo** / **Redo** button or press **Z** / **Shift+Z** to revoke the most recent cell operations. Now you can undo/redo up to the latest 10 historical cell operations.

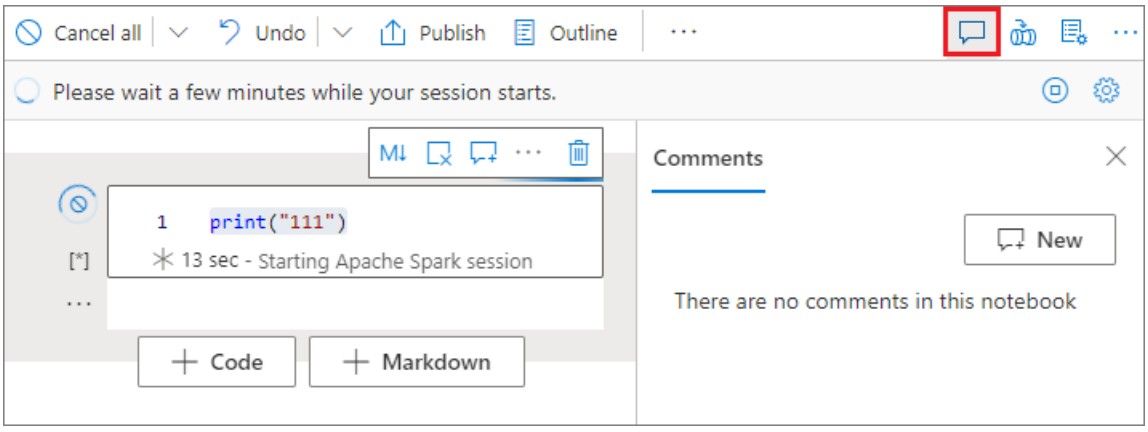
Supported undo cell operations:

- Insert/Delete cell: You could revoke the delete operations by selecting **Undo**, the text content will be kept along with the cell.
- Reorder cell.
- Toggle parameter.
- Convert between Code cell and Markdown cell.

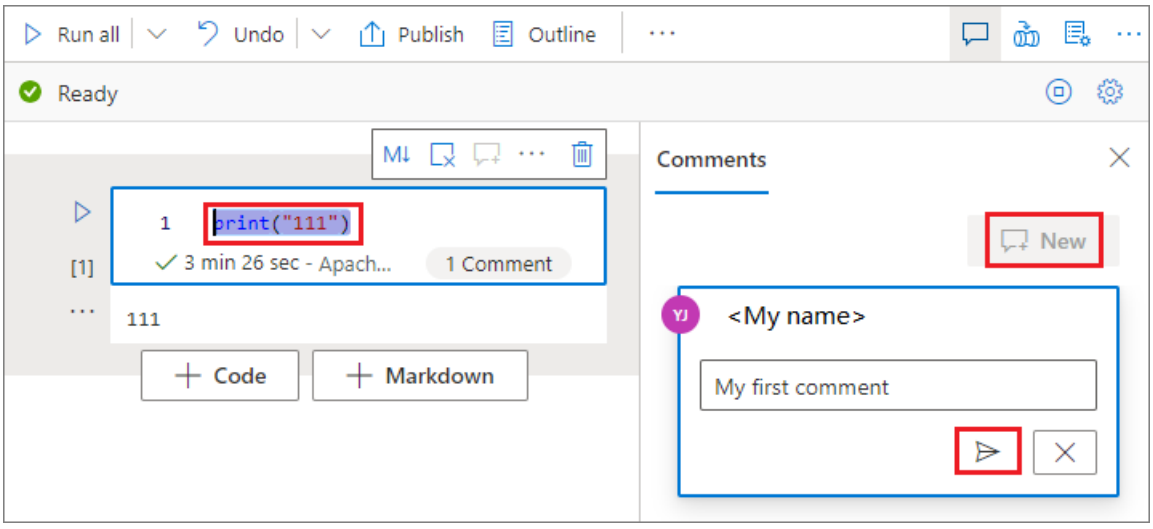
> **NOTE**
> In-cell text operations and code cell commenting operations are not undoable. Now you can undo/redo up to the latest 10 historical cell operations.

Code cell commenting

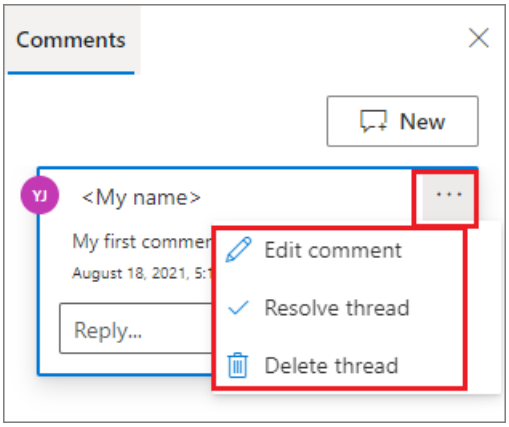
1. Select **Comments** button on the notebook toolbar to open **Comments** pane.



2. Select code in the code cell, click **New** in the **Comments** pane, add comments then click **Post comment** button to save.

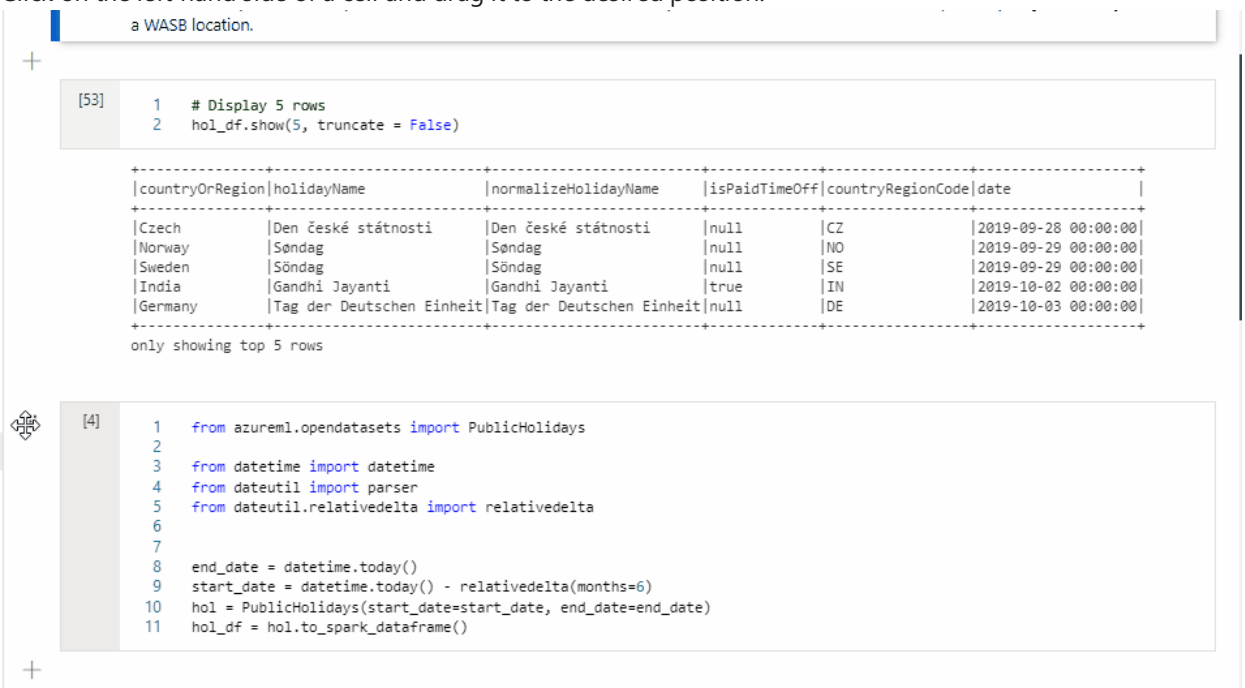


3. You could perform **Edit comment**, **Resolve thread**, or **Delete thread** by clicking the **More** button besides your comment.



Move a cell

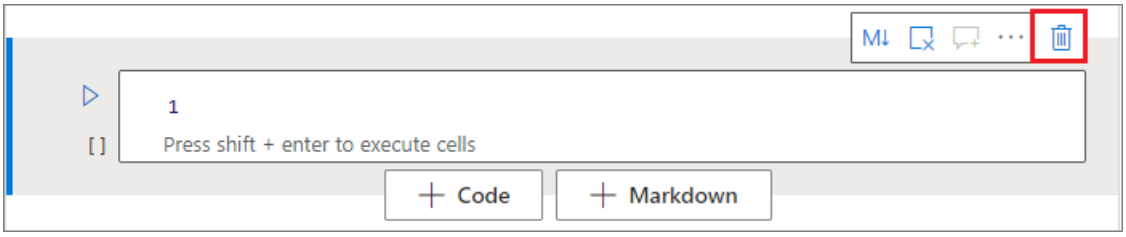
Click on the left-hand side of a cell and drag it to the desired position.



Delete a cell

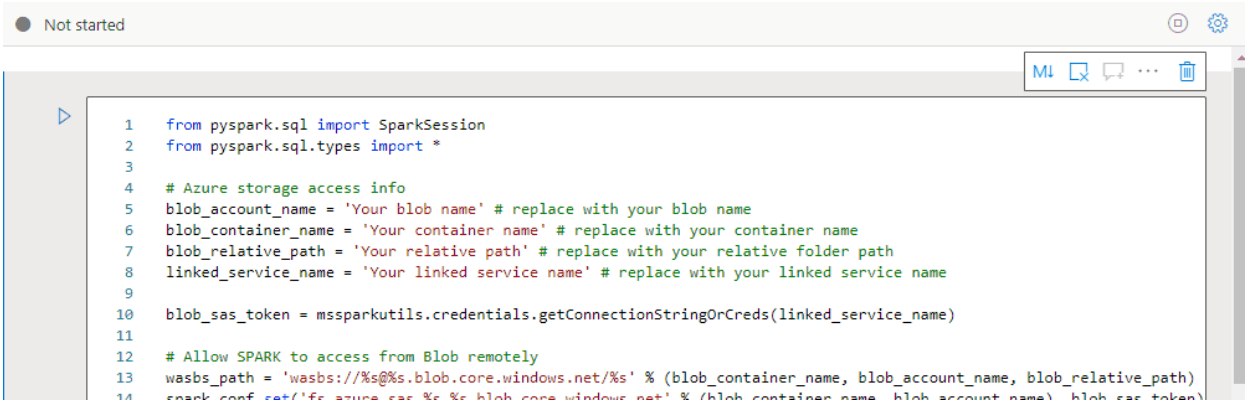
To delete a cell, select the delete button at the right hand of the cell.

You can also use shortcut keys under command mode. Press **Shift+D** to delete the current cell.



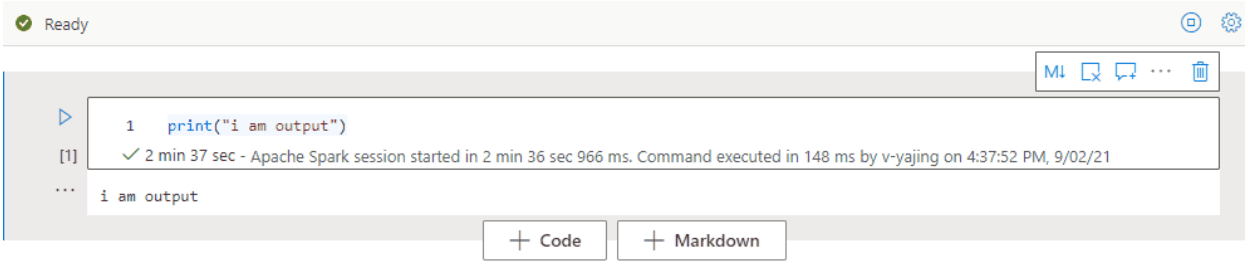
Collapse a cell input

Select the **More commands** ellipses (...) on the cell toolbar and **Hide input** to collapse current cell's input. To expand it, Select the **Show input** while the cell is collapsed.



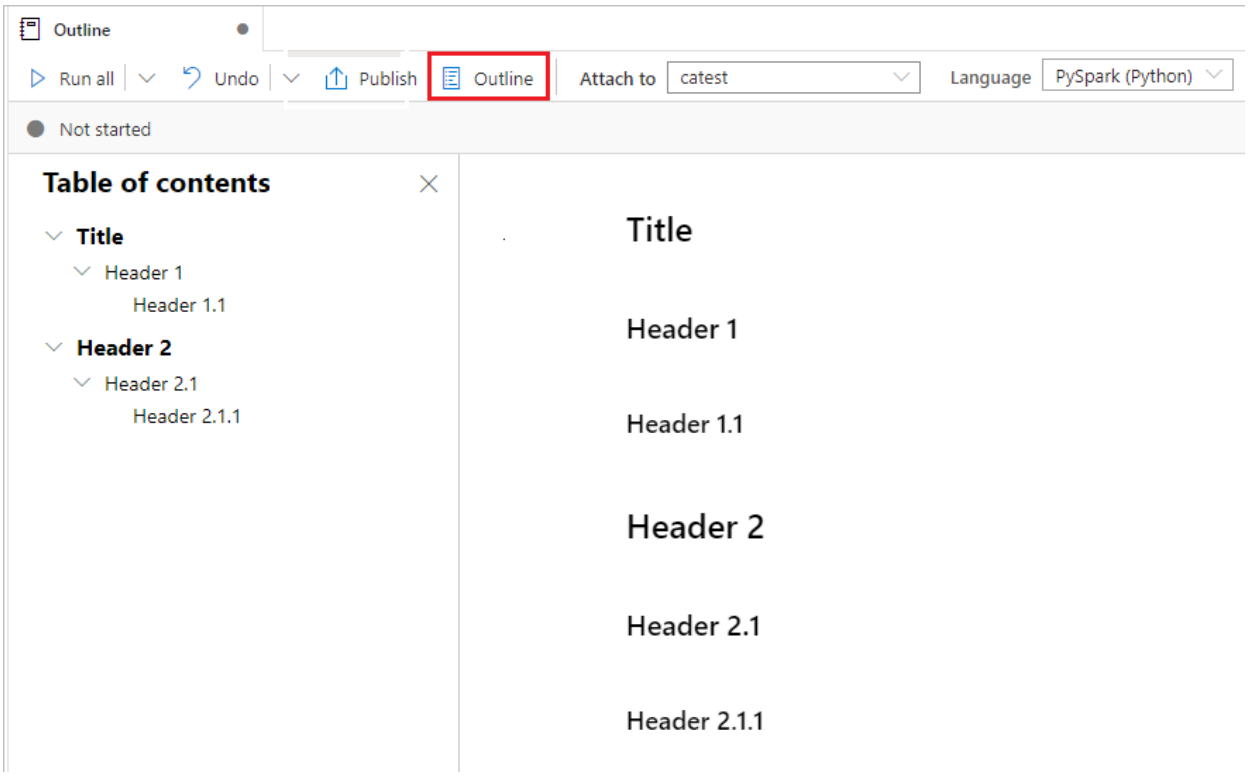
Collapse a cell output

Select the **More commands** ellipses (...) on the cell toolbar and **Hide output** to collapse current cell's output. To expand it, select the **Show output** while the cell's output is hidden.



Notebook outline

The Outlines (Table of Contents) presents the first markdown header of any markdown cell in a sidebar window for quick navigation. The Outlines sidebar is resizable and collapsible to fit the screen in the best ways possible. You can select the **Outline** button on the notebook command bar to open or hide sidebar



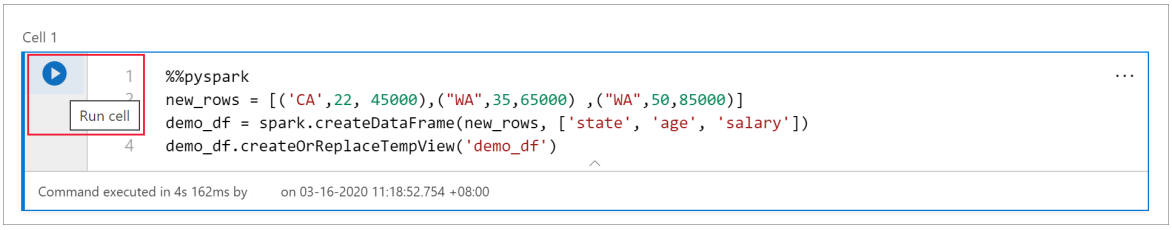
Run notebooks

You can run the code cells in your notebook individually or all at once. The status and progress of each cell is represented in the notebook.

Run a cell

There are several ways to run the code in a cell.

1. Hover on the cell you want to run and select the **Run Cell** button or press **Ctrl+Enter**.



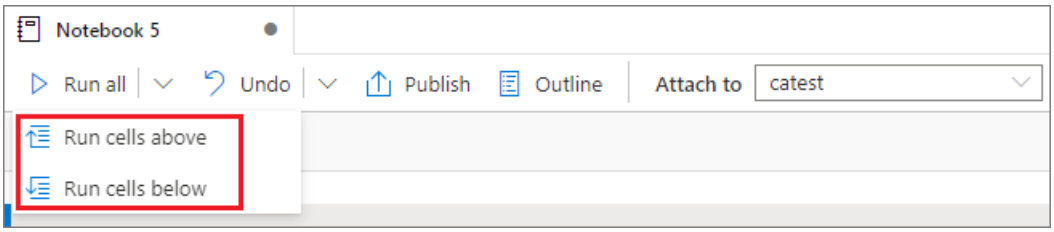
2. Use Shortcut keys under command mode. Press **Shift+Enter** to run the current cell and select the cell below. Press **Alt+Enter** to run the current cell and insert a new cell below.

Run all cells

Select the **Run All** button to run all the cells in current notebook in sequence.

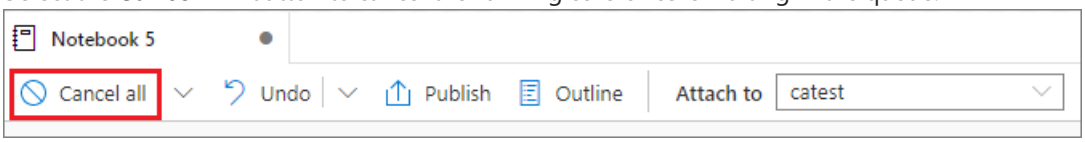
Run all cells above or below

Expand the dropdown list from **Run all** button, then select **Run cells above** to run all the cells above the current in sequence. Select **Run cells below** to run all the cells below the current in sequence.



Cancel all running cells

Select the **Cancel All** button to cancel the running cells or cells waiting in the queue.



Notebook reference

You can use `%run <notebook path>` magic command to reference another notebook within current notebook's context. All the variables defined in the reference notebook are available in the current notebook. `%run` magic command supports nested calls but not support recursive calls. You will receive an exception if the statement depth is larger than **five**.

Example:

```
%run /<path>/Notebook1 { "parameterInt": 1, "parameterFloat": 2.5, "parameterBool": true, "parameterString": "abc" }
```

.

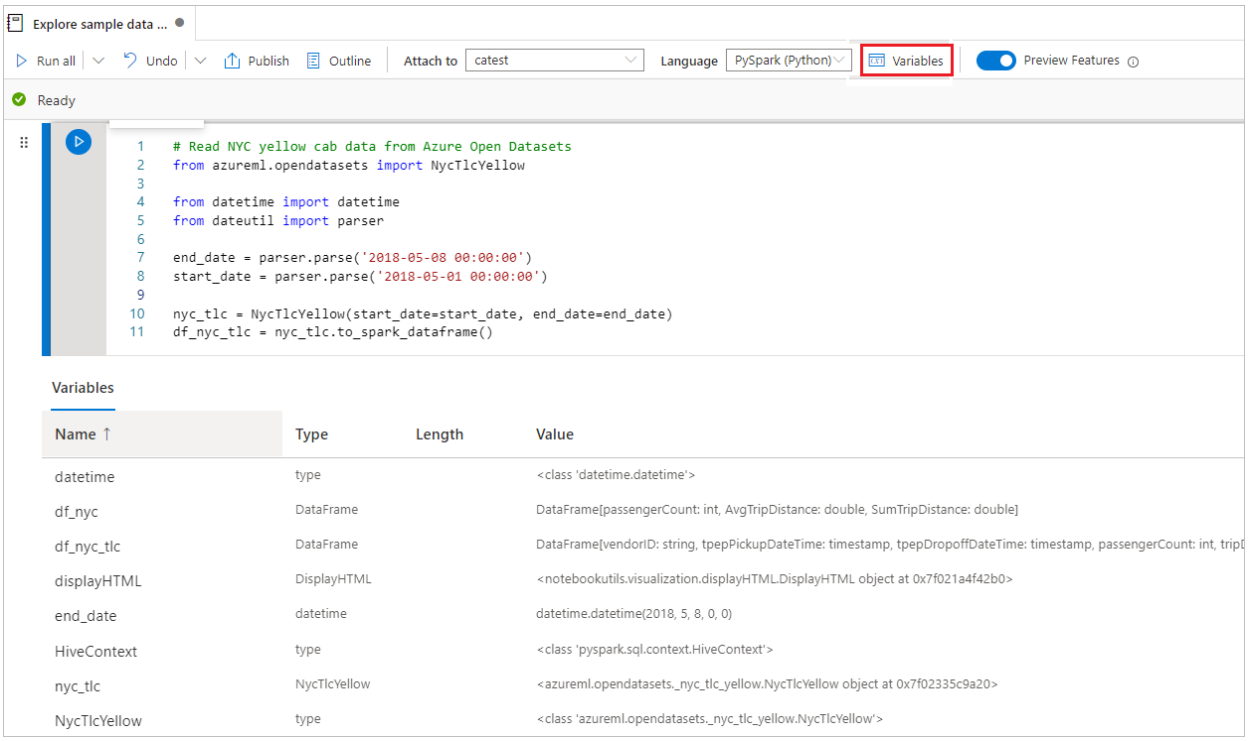
Notebook reference works in both interactive mode and Synapse pipeline.

> **NOTE**
>
> - `%run` command currently only supports to pass a absolute path or notebook name only as parameter, relative path is not supported.
> - `%run` command currently only supports to 4 parameter value types: `int`, `float`, `bool`, `string`, variable replacement operation is not supported.
> - The referenced notebooks are required to be published. You need to publish the notebooks to reference them unless Reference unpublished notebook is enabled. Synapse Studio does not recognize the unpublished notebooks from the Git repo.
> - Referenced notebooks do not support statement that depth is larger than **five**.

Variable explorer

Synapse notebook provides a built-in variables explorer for you to see the list of the variables name, type, length, and value in the current Spark session for PySpark (Python) cells. More variables will show up automatically as they are defined in the code cells. Clicking on each column header will sort the variables in the table.

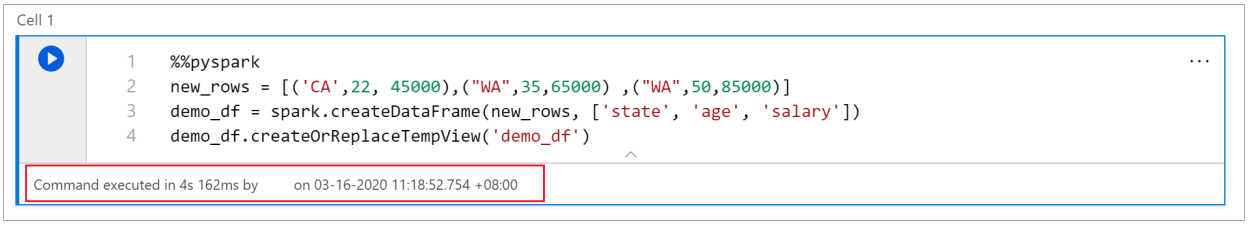
You can select the **Variables** button on the notebook command bar to open or hide the variable explorer.



> **NOTE**
>
> Variable explorer only supports python.

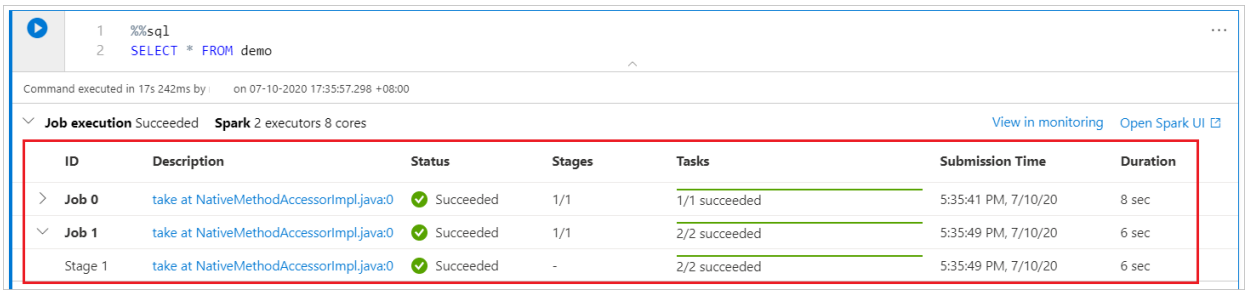
Cell status indicator

A step-by-step cell execution status is displayed beneath the cell to help you see its current progress. Once the cell run is complete, an execution summary with the total duration and end time are shown and kept there for future reference.



Spark progress indicator

Synapse notebook is purely Spark based. Code cells are executed on the serverless Apache Spark pool remotely. A Spark job progress indicator is provided with a real-time progress bar appears to help you understand the job execution status. The number of tasks per each job or stage help you to identify the parallel level of your spark job. You can also drill deeper to the Spark UI of a specific job (or stage) via selecting the link on the job (or stage) name.

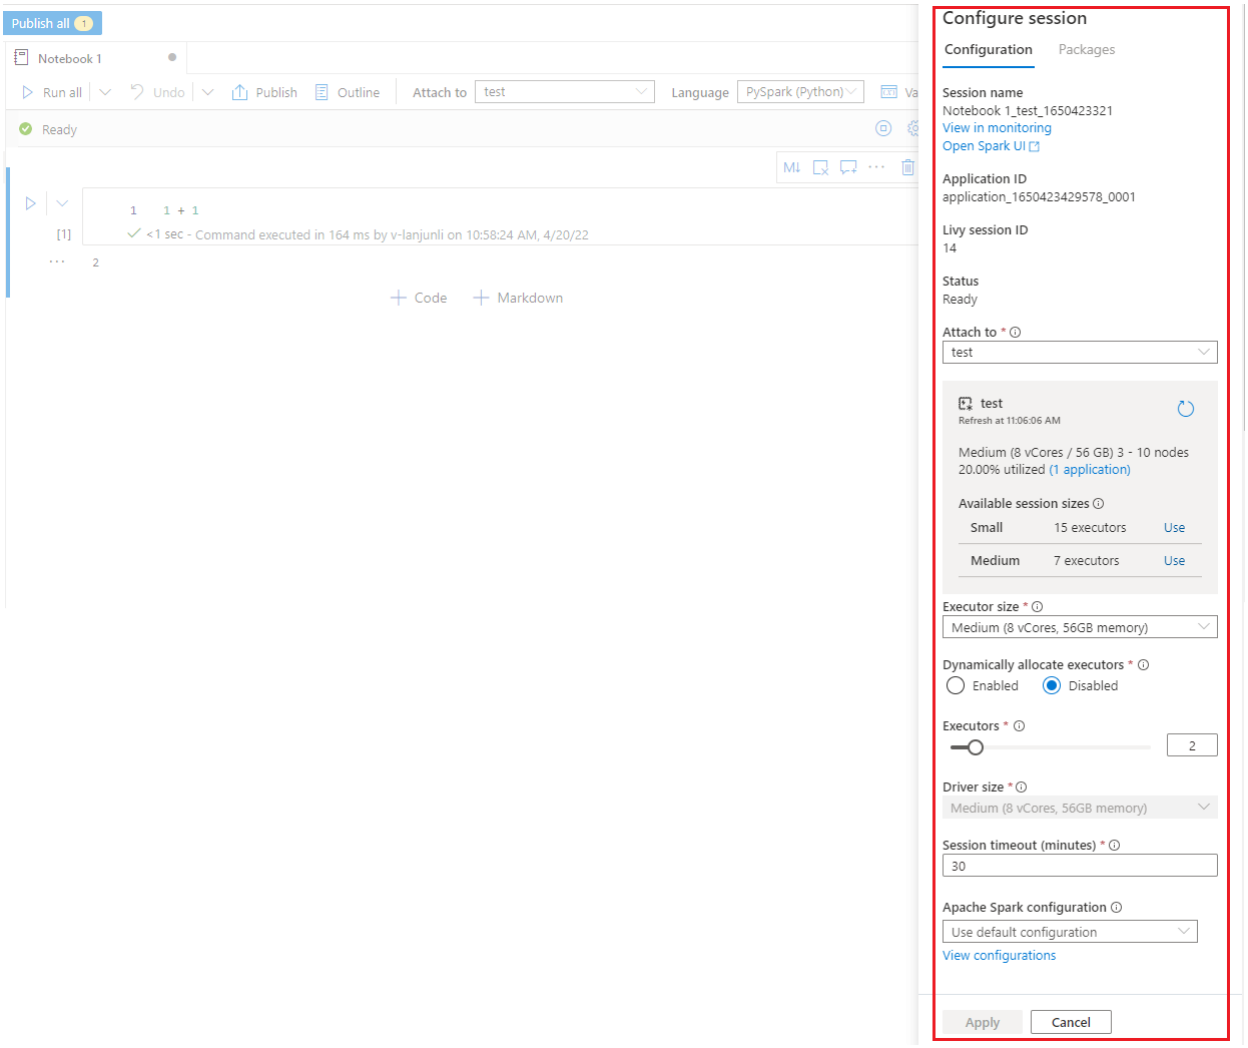


Spark session configuration

You can specify the timeout duration, the number, and the size of executors to give to the current Spark session

in **Configure session**. Restart the Spark session is for configuration changes to take effect. All cached notebook variables are cleared.

You can also create a configuration from the Apache Spark configuration or select an existing configuration. For details, please refer to Apache Spark Configuration Management.



Spark session configuration magic command

You can also specify spark session settings via a magic command **%%configure**. The spark session needs to restart to make the settings effect. We recommend you to run the **%%configure** at the beginning of your notebook. Here is a sample, refer to https://github.com/cloudera/livy#request-body for full list of valid parameters.

```
%%configure
{
    //You can get a list of valid parameters to config the session from
https://github.com/cloudera/livy#request-body.
    "driverMemory":"28g", // Recommended values: ["28g", "56g", "112g", "224g", "400g", "472g"]
    "driverCores":4, // Recommended values: [4, 8, 16, 32, 64, 80]
    "executorMemory":"28g",
    "executorCores":4,
    "jars":
["abfs[s]://<file_system>@<account_name>.dfs.core.windows.net/<path>/myjar.jar","wasb[s]://<containername>@<
accountname>.blob.core.windows.net/<path>/myjar1.jar"],
    "conf":{
    //Example of standard spark property, to find more available properties please
visit:https://spark.apache.org/docs/latest/configuration.html#application-properties.
        "spark.driver.maxResultSize":"10g",
    //Example of customized property, you can specify count of lines that Spark SQL returns by configuring
"livy.rsc.sql.num-rows".
        "livy.rsc.sql.num-rows":"3000"
    }
}
```

NOTE

- "DriverMemory" and "ExecutorMemory" are recommended to set as same value in %%configure, so do "driverCores" and "executorCores".
- You can use %%configure in Synapse pipelines, but if it's not set in the first code cell, the pipeline run will fail due to cannot restart session.
- The %%configure used in mssparkutils.notebook.run is going to be ignored but used in %run notebook will continue executing.
- The standard Spark configuration properties must be used in the "conf" body. We do not support first level reference for the Spark configuration properties.
- Some special spark properties including "spark.driver.cores", "spark.executor.cores", "spark.driver.memory", "spark.executor.memory", "spark.executor.instances" won't take effect in "conf" body.

Parameterized session configuration from pipeline

Parameterized session configuration allows you to replace the value in %%configure magic with Pipeline run (Notebook activity) parameters. When preparing %%configure code cell, you can override default values (also configurable, 4 and "2000" in the below example) with an object like this:

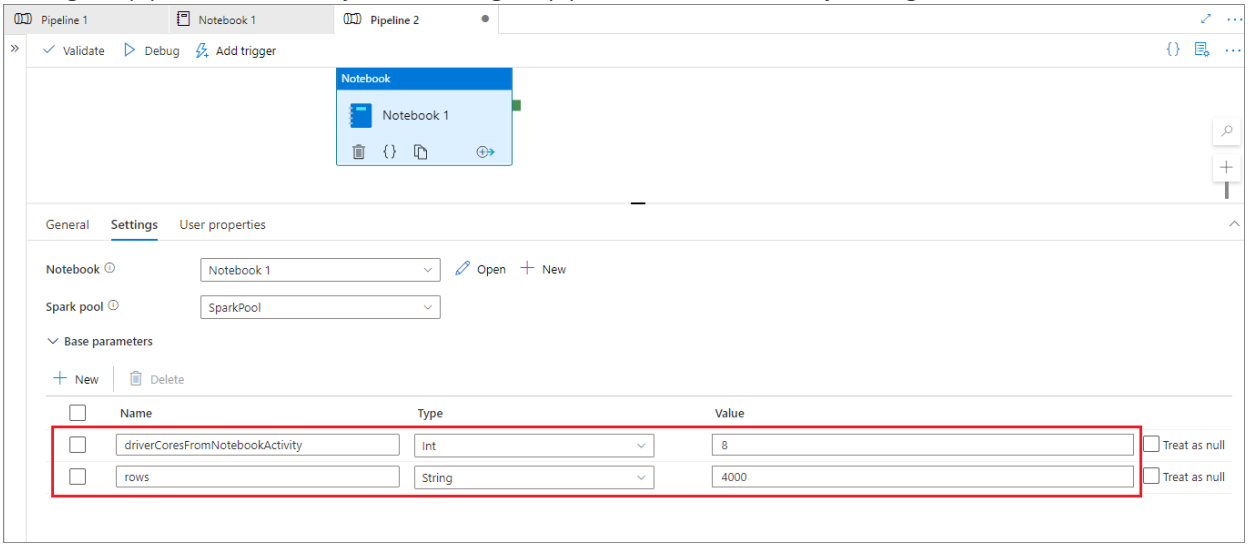
```
{
      "activityParameterName": "paramterNameInPipelineNotebookActivity",
      "defaultValue": "defaultValueIfNoParamterFromPipelineNotebookActivity"
}
```

```
%%configure

{
    "driverCores":
    {
        "activityParameterName": "driverCoresFromNotebookActivity",
        "defaultValue": 4
    },
    "conf":
    {
        "livy.rsc.sql.num-rows":
        {
            "activityParameterName": "rows",
            "defaultValue": "2000"
        }
    }
}
```

Notebook will use default value if run a notebook in interactive mode directly or no parameter that match "activityParameterName" is given from Pipeline Notebook activity.

During the pipeline run mode, you can configure pipeline Notebook activity settings as below:



If you want to change the session configuration, pipeline Notebook activity parameters name should be same as activityParameterName in the notebook. When running this pipeline, in this example driverCores in %%configure will be replaced by 8 and livy.rsc.sql.num-rows will be replaced by 4000.

> **NOTE**
> If run pipeline failed because of using this new %%configure magic, you can check more error information by running %%configure magic cell in the interactive mode of the notebook.

Bring data to a notebook

You can load data from Azure Blob Storage, Azure Data Lake Store Gen 2, and SQL pool as shown in the code samples below.

Read a CSV from Azure Data Lake Store Gen2 as a Spark DataFrame

```
from pyspark.sql import SparkSession
from pyspark.sql.types import *
account_name = "Your account name"
container_name = "Your container name"
relative_path = "Your path"
adls_path = 'abfss://%s@%s.dfs.core.windows.net/%s' % (container_name, account_name, relative_path)

df1 = spark.read.option('header', 'true') \
                .option('delimiter', ',') \
                .csv(adls_path + '/Testfile.csv')
```

Read a CSV from Azure Blob Storage as a Spark DataFrame

```
from pyspark.sql import SparkSession

# Azure storage access info
blob_account_name = 'Your account name' # replace with your blob name
blob_container_name = 'Your container name' # replace with your container name
blob_relative_path = 'Your path' # replace with your relative folder path
linked_service_name = 'Your linked service name' # replace with your linked service name

blob_sas_token = mssparkutils.credentials.getConnectionStringOrCreds(linked_service_name)

# Allow SPARK to access from Blob remotely

wasb_path = 'wasbs://%s@%s.blob.core.windows.net/%s' % (blob_container_name, blob_account_name,
blob_relative_path)

spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name, blob_account_name),
blob_sas_token)
print('Remote blob path: ' + wasb_path)

df = spark.read.option("header", "true") \
            .option("delimiter","|") \
            .schema(schema) \
            .csv(wasbs_path)
```

Read data from the primary storage account

You can access data in the primary storage account directly. There's no need to provide the secret keys. In Data Explorer, right-click on a file and select **New notebook** to see a new notebook with data extractor autogenerated.

IPython Widgets

Widgets are eventful python objects that have a representation in the browser, often as a control like a slider, textbox etc. IPython Widgets only works in Python environment, it's not supported in other languages (e.g. Scala, SQL, C#) yet.

To use IPython Widget

1. You need to import `ipywidgets` module first to use the Jupyter Widget framework.

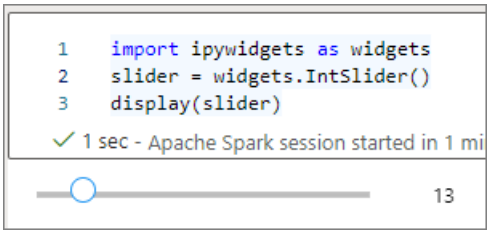
```
import ipywidgets as widgets
```

2. You can use top-level `display` function to render a widget, or leave an expression of **widget** type at the last line of code cell.

```
slider = widgets.IntSlider()
display(slider)
```

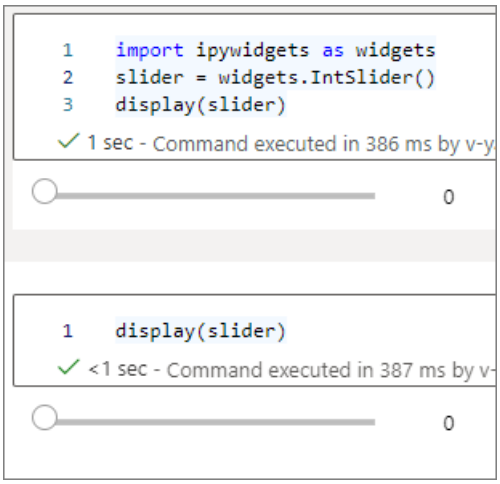
```
slider = widgets.IntSlider()
slider
```

3. Run the cell, the widget will display at the output area.



4. You can use multiple `display()` calls to render the same widget instance multiple times, but they will remain in sync with each other.

```
slider = widgets.IntSlider()
display(slider)
display(slider)
```



5. To render two widgets independent of each other, create two widget instances:

```
slider1 = widgets.IntSlider()
slider2 = widgets.IntSlider()
display(slider1)
display(slider2)
```

Supported widgets

WIDGETS TYPE	WIDGETS
Numeric widgets	IntSlider, FloatSlider, FloatLogSlider, IntRangeSlider, FloatRangeSlider, IntProgress, FloatProgress, BoundedIntText, BoundedFloatText, IntText, FloatText
Boolean widgets	ToggleButton, Checkbox, Valid
Selection widgets	Dropdown, RadioButtons, Select, SelectionSlider, SelectionRangeSlider, ToggleButtons, SelectMultiple
String Widgets	Text, Text area, Combobox, Password, Label, HTML, HTML Math, Image, Button
Play (Animation) widgets	Date picker, Color picker, Controller
Container/Layout widgets	Box, HBox, VBox, GridBox, Accordion, Tabs, Stacked

Known limitations

1. The following widgets are not supported yet, you could follow the corresponding workaround as below:

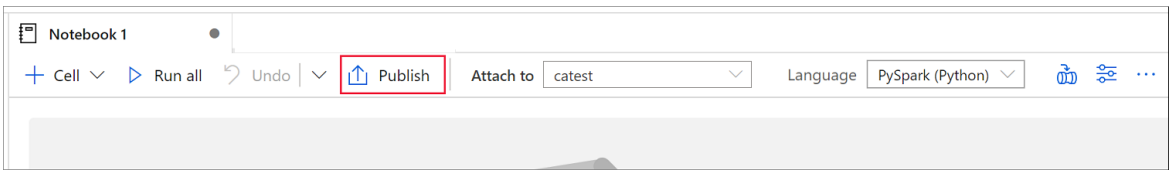
FUNCTIONALITY	WORKAROUND
`Output` widget	You can use `print()` function instead to write text into stdout.
`widgets.jslink()`	You can use `widgets.link()` function to link two similar widgets.
`FileUpload` widget	Not support yet.

2. Global `display` function provided by Synapse does not support displaying multiple widgets in 1 call (i.e. `display(a, b)`), which is different from IPython `display` function.
3. If you close a notebook that contains IPython Widget, you will not be able to see or interact with it until you execute the corresponding cell again.

Save notebooks

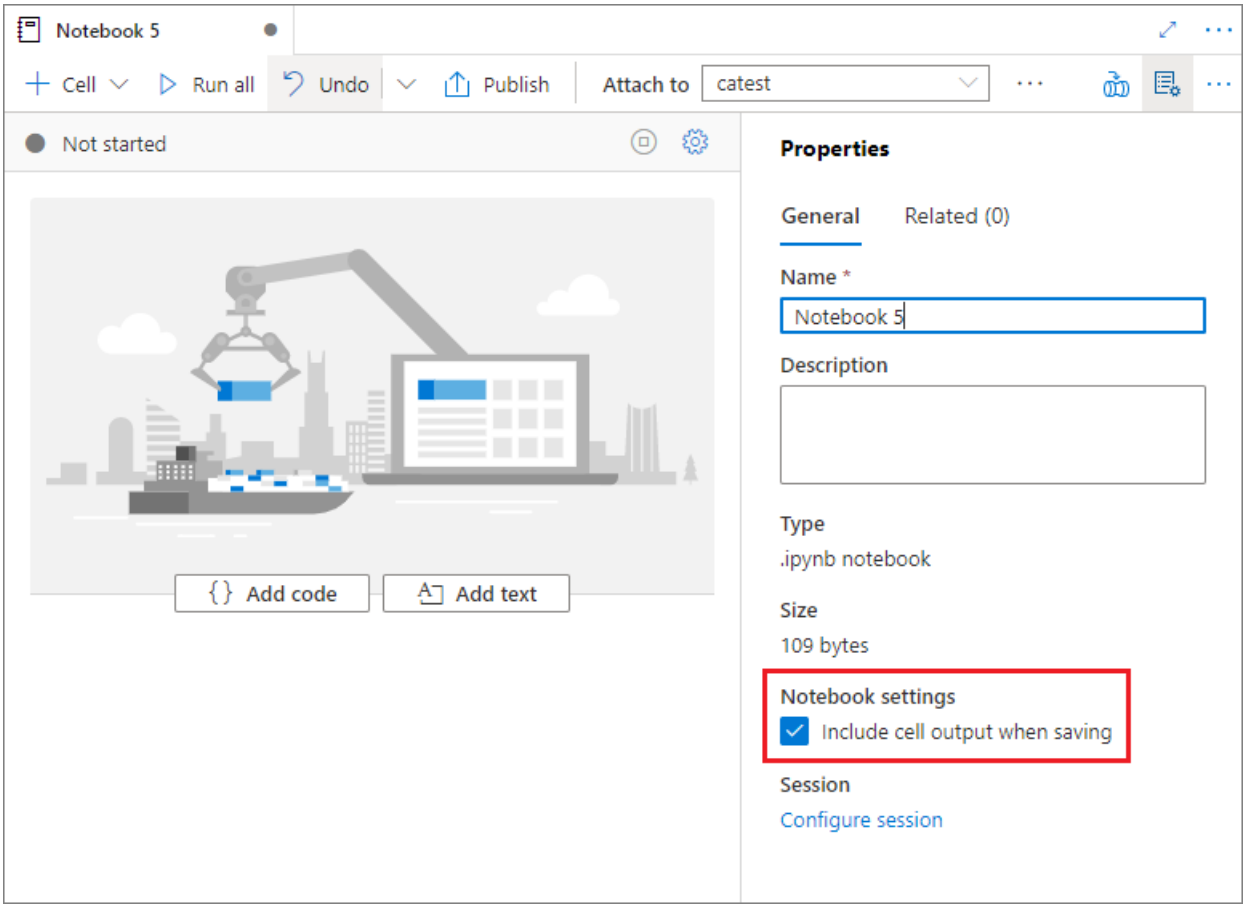
You can save a single notebook or all notebooks in your workspace.

1. To save changes you made to a single notebook, select the **Publish** button on the notebook command bar.



2. To save all notebooks in your workspace, select the **Publish all** button on the workspace command bar.

In the notebook properties, you can configure whether to include the cell output when saving.



Magic commands

You can use familiar Jupyter magic commands in Synapse notebooks. Review the following list as the current available magic commands. Tell us your use cases on GitHub so that we can continue to build out more magic commands to meet your needs.

> **NOTE**
> Only following magic commands are supported in Synapse pipeline : %%pyspark, %%spark, %%csharp, %%sql.

Available line magics: %lsmagic, %time, %timeit, %history, %run, %load

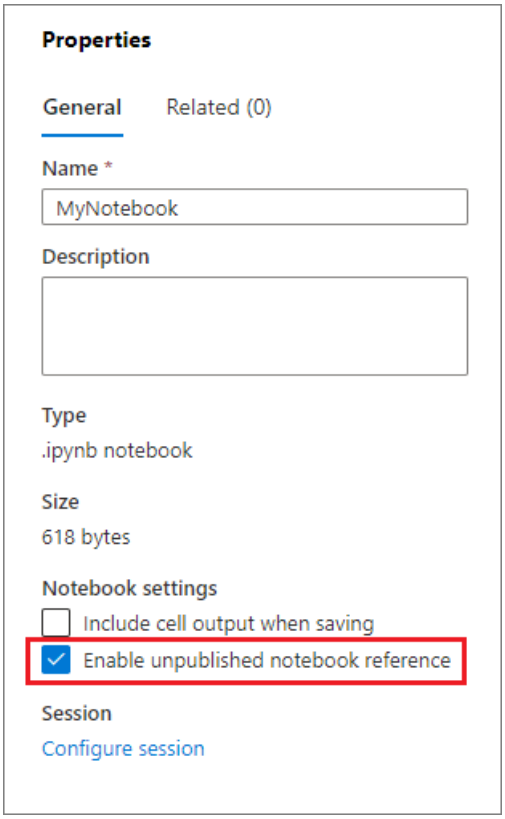
Available cell magics: %%time, %%timeit, %%capture, %%writefile, %%sql, %%pyspark, %%spark, %%csharp, %%html, %%configure

Reference unpublished notebook

Reference unpublished notebook is helpful when you want to debug "locally", when enabling this feature, notebook run will fetch the current content in web cache, if you run a cell including a reference notebooks statement, you will reference the presenting notebooks in the current notebook browser instead of a saved versions in cluster, that means the changes in your notebook editor can be referenced immediately by other

notebooks without having to be published(Live mode) or committed(Git mode), by leveraging this approach you can easily avoid common libraries getting polluted during developing or debugging process.

You can enable Reference unpublished notebook from Properties panel:



For different cases comparison please check the table below:

Notice that %run and mssparkutils.notebook.run has same behavior here. We use `%run` here as an example.

CASE	DISABLE	ENABLE
Live Mode		
- Nb1 (Published) `%run Nb1`	Run published version of Nb1	Run published version of Nb1
- Nb1 (New) `%run Nb1`	Error	Run new Nb1
- Nb1 (Previously published, edited) `%run Nb1`	Run **published** version of Nb1	Run **edited** version of Nb1
Git Mode		
- Nb1 (Published) `%run Nb1`	Run published version of Nb1	Run published version of Nb1
- Nb1 (New) `%run Nb1`	Error	Run new Nb1
- Nb1 (Not published, committed) `%run Nb1`	Error	Run committed Nb1

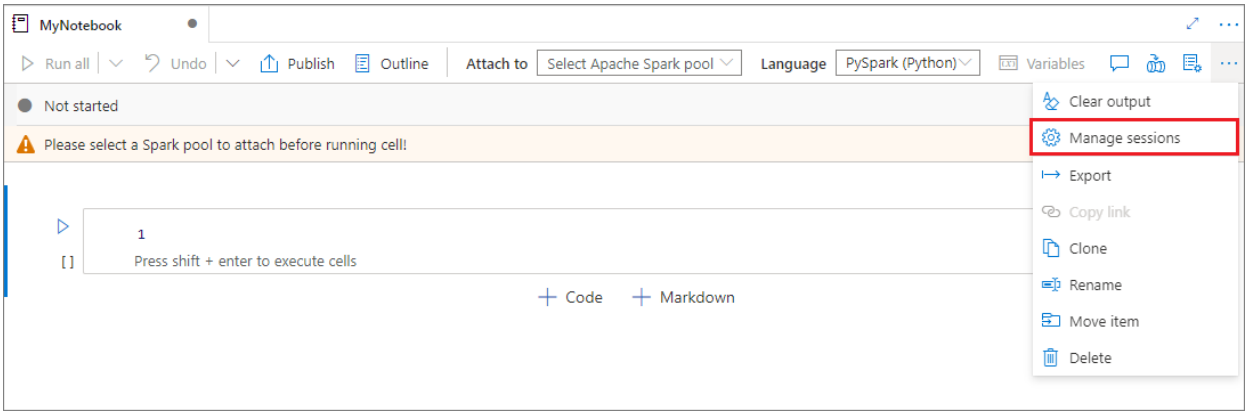
CASE	DISABLE	ENABLE
- Nb1 (Previously published, committed) `%run Nb1`	Run **published** version of Nb1	Run **committed** version of Nb1
- Nb1 (Previously published, new in current branch) `%run Nb1`	Run **published** version of Nb1	Run **new** Nb1
- Nb1 (Not published, previously committed, edited) `%run Nb1`	Error	Run **edited** version of Nb1
- Nb1 (Previously published and committed, edited) `%run Nb1`	Run **published** version of Nb1	Run **edited** version of Nb1

Conclusion

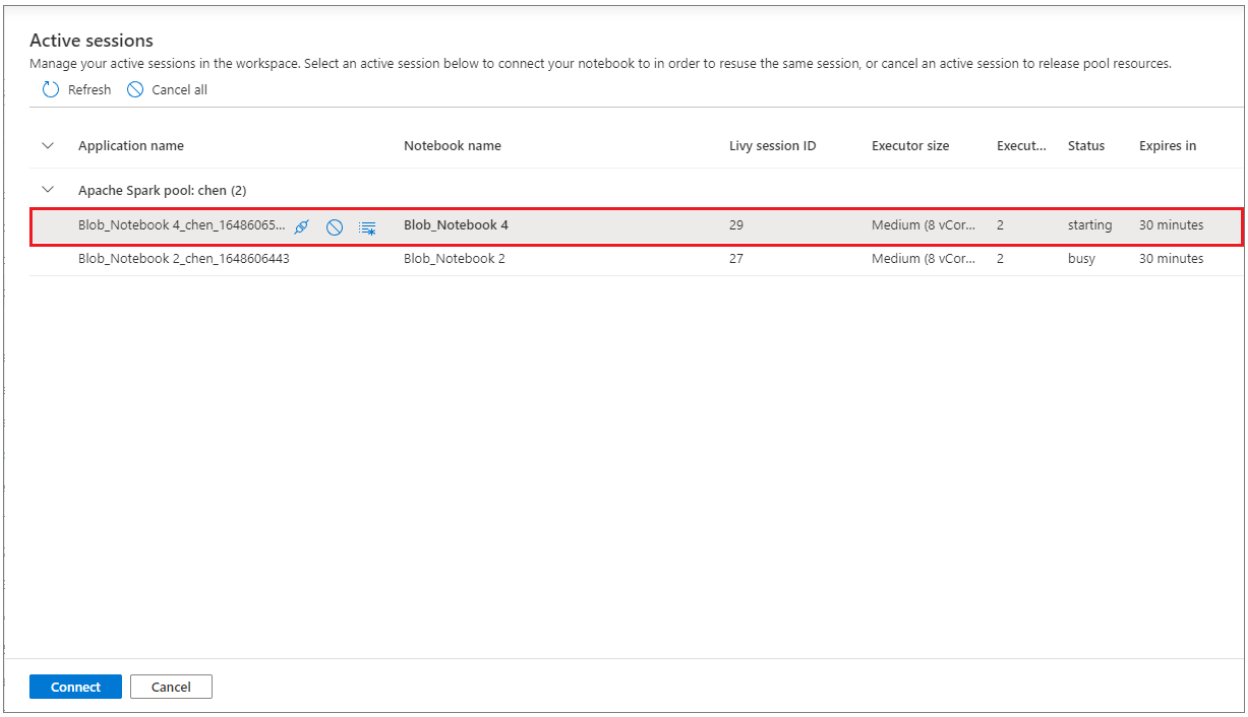
- If disabled, always run **published** version.
- If enabled, priority is: edited / new > committed > published.

Active session management

You can reuse your notebook sessions conveniently now without having to start new ones. Synapse notebook now supports managing your active sessions in the **Manage sessions** list, you can see all the sessions in the current workspace started by you from notebook.



In the **Active sessions** list you can see the session information and the corresponding notebook that is currently attached to the session. You can operate Detach with notebook, Stop the session, and View in monitoring from here. Moreover, you can easily connect your selected notebook to an active session in the list started from another notebook, the session will be detached from the previous notebook (if it's not idle) then attach to the current one.



Python logging in Notebook

You can find Python logs and set different log levels and format following the sample code below:

```
import logging

# Customize the logging format for all loggers
FORMAT = "%(asctime)s - %(name)s - %(levelname)s - %(message)s"
formatter = logging.Formatter(fmt=FORMAT)
for handler in logging.getLogger().handlers:
    handler.setFormatter(formatter)

# Customize log level for all loggers
logging.getLogger().setLevel(logging.INFO)

# Customize the log level for a specific logger
customizedLogger = logging.getLogger('customized')
customizedLogger.setLevel(logging.WARNING)

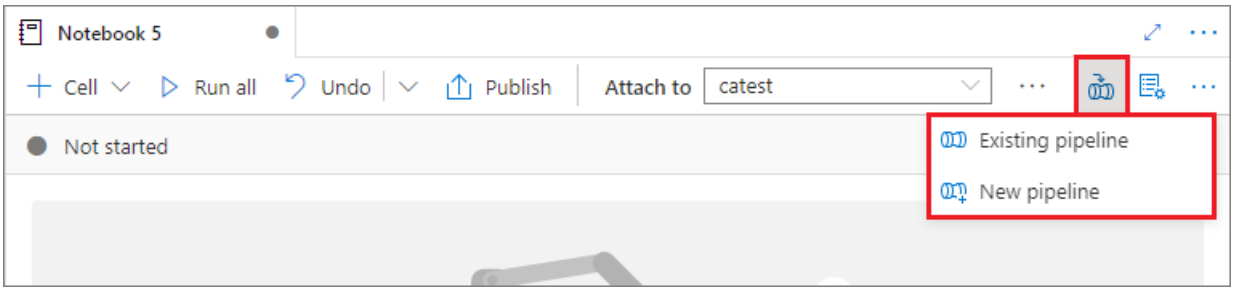
# logger that use the default global log level
defaultLogger = logging.getLogger('default')
defaultLogger.debug("default debug message")
defaultLogger.info("default info message")
defaultLogger.warning("default warning message")
defaultLogger.error("default error message")
defaultLogger.critical("default critical message")

# logger that use the customized log level
customizedLogger.debug("customized debug message")
customizedLogger.info("customized info message")
customizedLogger.warning("customized warning message")
customizedLogger.error("customized error message")
customizedLogger.critical("customized critical message")
```

Integrate a notebook

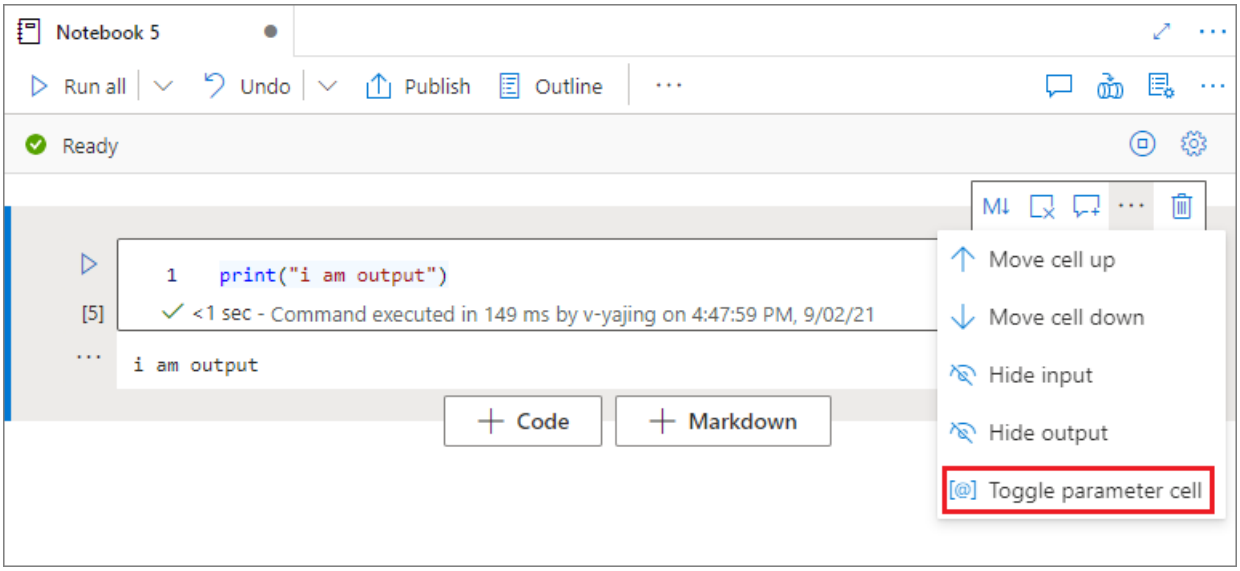
Add a notebook to a pipeline

Select the **Add to pipeline** button on the upper right corner to add a notebook to an existing pipeline or create a new pipeline.



Designate a parameters cell

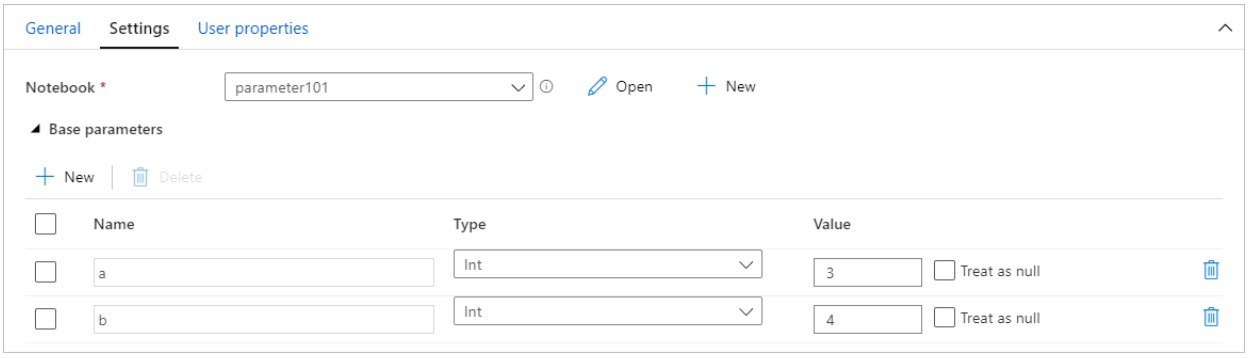
To parameterize your notebook, select the ellipses (...) to access the **more commands** at the cell toolbar. Then select **Toggle parameter cell** to designate the cell as the parameters cell.



Azure Data Factory looks for the parameters cell and treats this cell as defaults for the parameters passed in at execution time. The execution engine will add a new cell beneath the parameters cell with input parameters in order to overwrite the default values.

Assign parameters values from a pipeline

Once you've created a notebook with parameters, you can execute it from a pipeline with the Synapse Notebook activity. After you add the activity to your pipeline canvas, you will be able to set the parameters values under **Base parameters** section on the **Settings** tab.

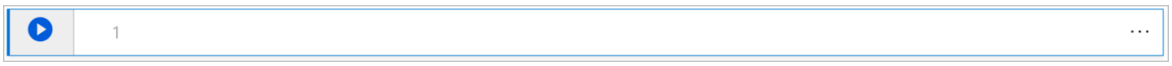


When assigning parameter values, you can use the pipeline expression language or system variables.

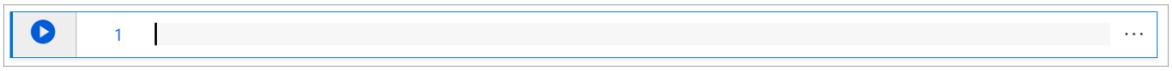
Shortcut keys

Similar to Jupyter Notebooks, Synapse notebooks have a modal user interface. The keyboard does different things depending on which mode the notebook cell is in. Synapse notebooks support the following two modes for a given code cell: command mode and edit mode.

1. A cell is in command mode when there is no text cursor prompting you to type. When a cell is in Command mode, you can edit the notebook as a whole but not type into individual cells. Enter command mode by pressing `ESC` or using the mouse to select outside of a cell's editor area.



2. Edit mode is indicated by a text cursor prompting you to type in the editor area. When a cell is in edit mode, you can type into the cell. Enter edit mode by pressing `Enter` or using the mouse to select on a cell's editor area.



Shortcut keys under command mode

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Run the current cell and select below	Shift+Enter
Run the current cell and insert below	Alt+Enter
Run current cell	Ctrl+Enter
Select cell above	Up
Select cell below	Down
Select previous cell	K
Select next cell	J
Insert cell above	A
Insert cell below	B
Delete selected cells	Shift+D
Switch to edit mode	Enter

Shortcut keys under edit mode

Using the following keystroke shortcuts, you can more easily navigate and run code in Synapse notebooks when in Edit mode.

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Move cursor up	Up
Move cursor down	Down
Undo	Ctrl + Z
Redo	Ctrl + Y

ACTION	SYNAPSE NOTEBOOK SHORTCUTS
Comment/Uncomment	Ctrl + /
Delete word before	Ctrl + Backspace
Delete word after	Ctrl + Delete
Go to cell start	Ctrl + Home
Go to cell end	Ctrl + End
Go one word left	Ctrl + Left
Go one word right	Ctrl + Right
Select all	Ctrl + A
Indent	Ctrl +]
Dedent	Ctrl + [
Switch to command mode	Esc

Synapse Studio SQL scripts in Azure Synapse Analytics

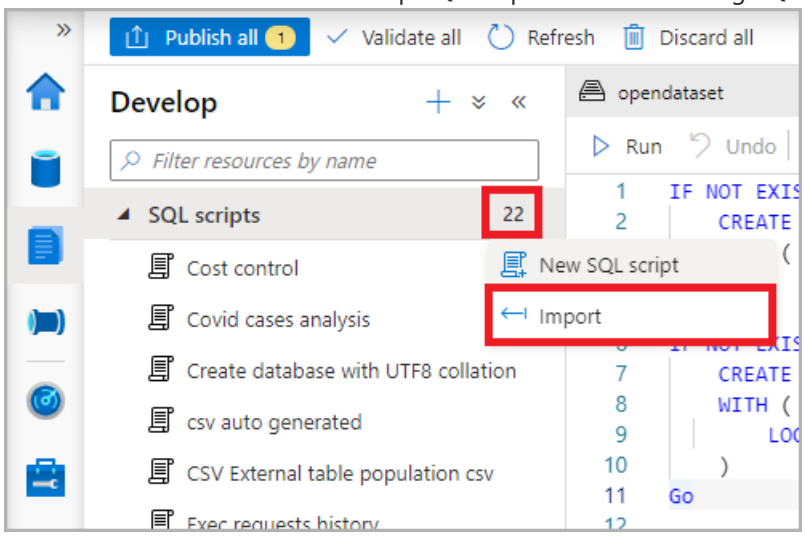
8/19/2022 • 2 minutes to read • Edit Online

Synapse Studio provides a SQL script web interface for you to author SQL queries.

Begin authoring in SQL script

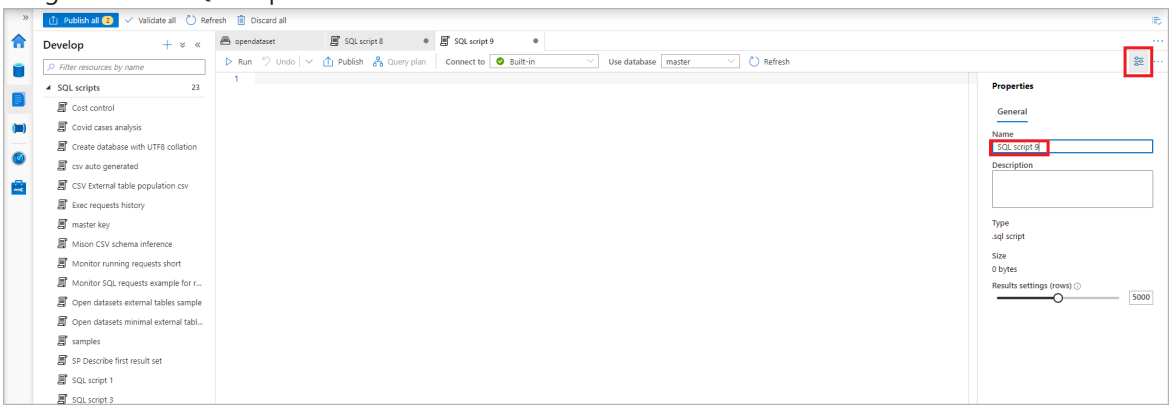
There are several ways to start the authoring experience in SQL script. You can create a new SQL script through one of the following methods.

1. From the Develop menu, select the **"+"** icon and choose **SQL script**.
2. From the **Actions** menu, choose **New SQL script**.
3. Choose **Import** from the **Actions** menu under Develop SQL scripts. Select an existing SQL script from your local storage.

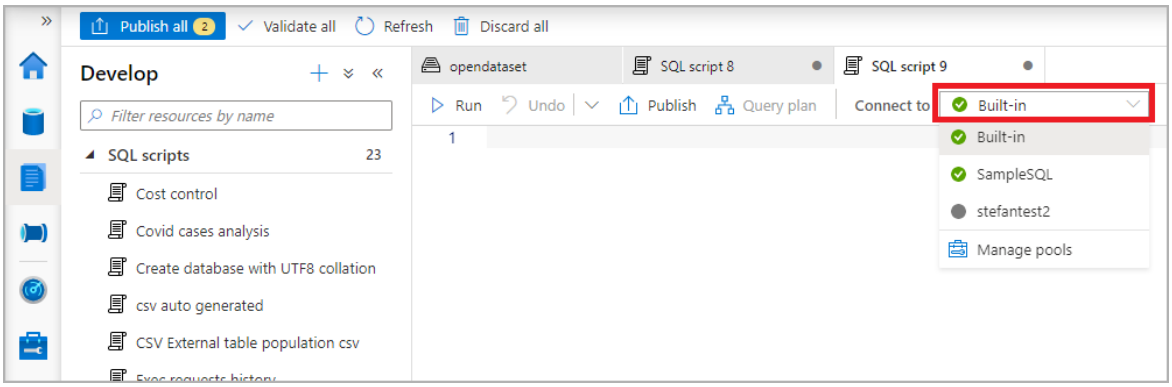


Create your SQL script

1. Choose a name for your SQL script by selecting the **Property** button and replacing the default name assigned to the SQL script.



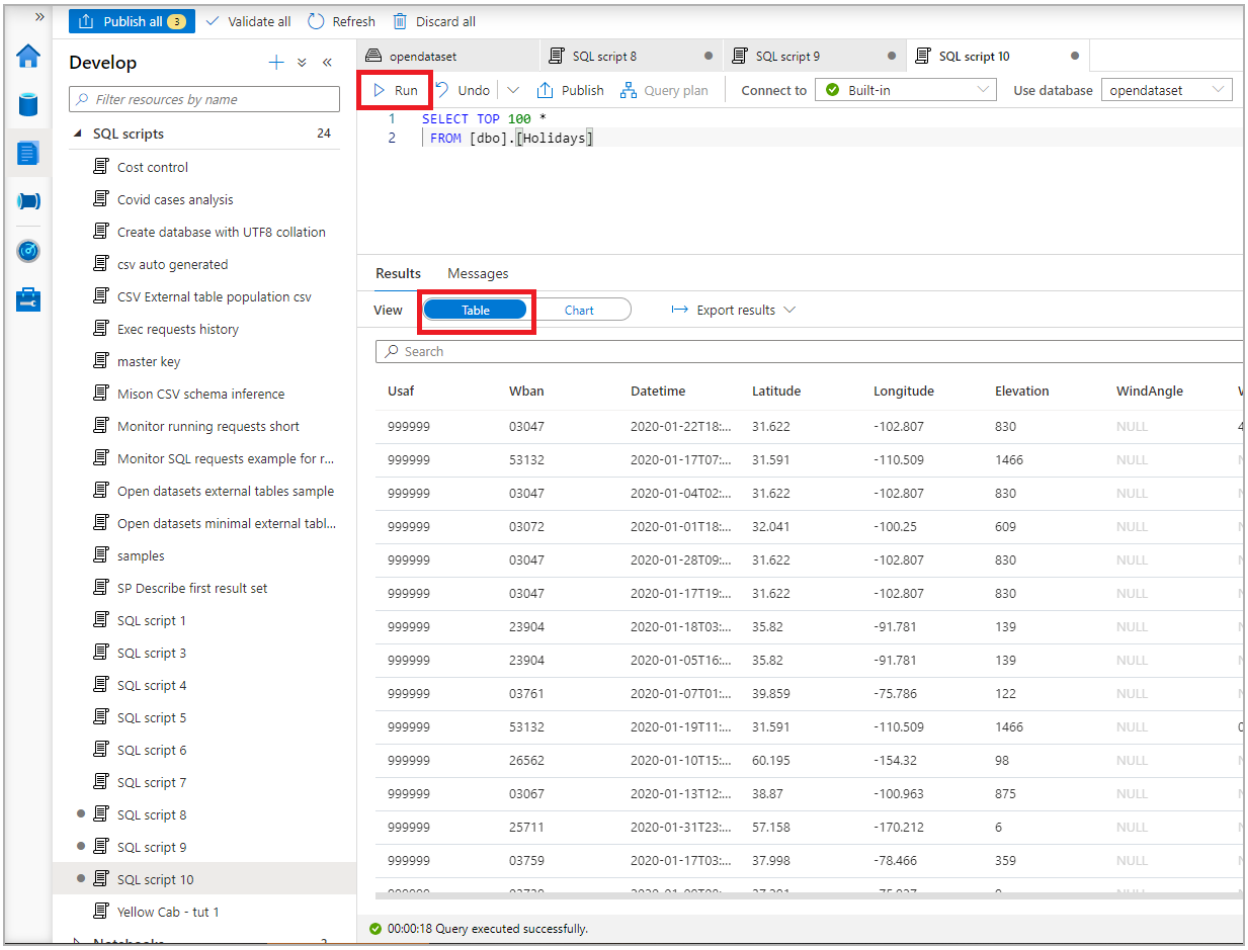
2. Choose the specific dedicated SQL pool or serverless SQL pool from the **Connect to** drop-down menu. Or if necessary, choose the database from **Use database**.



3. Start authoring your SQL script using the intellisense feature.

Run your SQL script

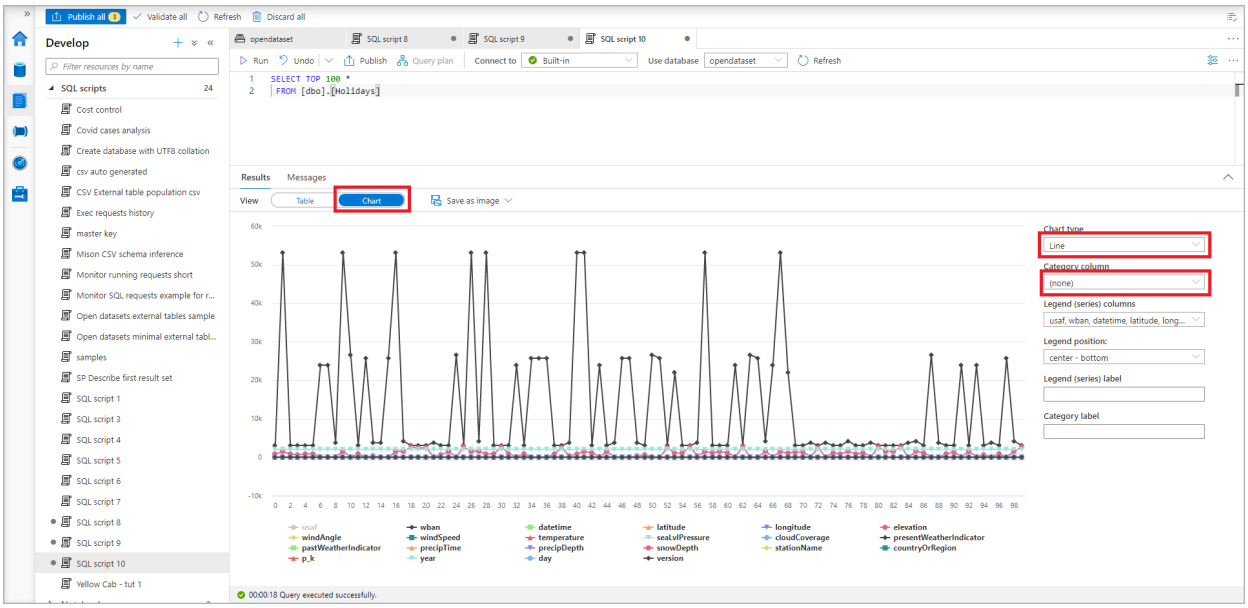
Select the **Run** button to execute your SQL script. The results are displayed by default in a table.



Export your results

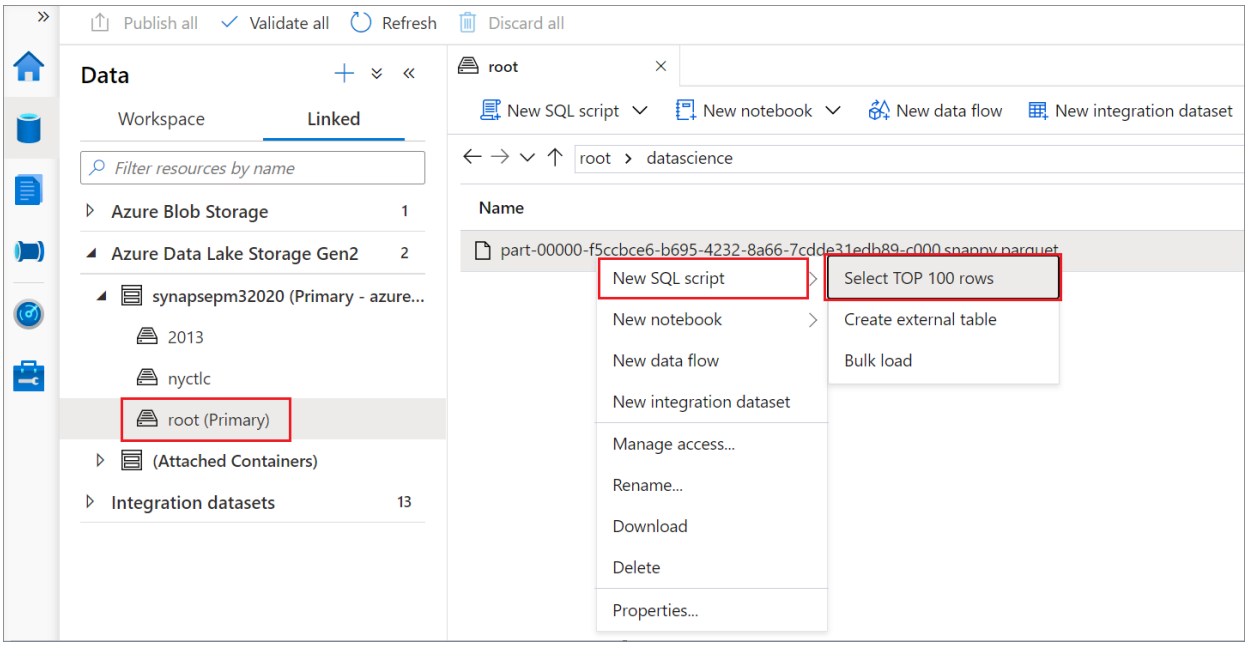
You can export the results to your local storage in different formats (including CSV, Excel, JSON, XML) by selecting "Export results" and choosing the extension.

You can also visualize the SQL script results in a chart by selecting the **Chart** button. Select the "Chart type" and **Category column**. You can export the chart into a picture by selecting **Save as image**.



Explore data from a Parquet file

You can explore Parquet files in a storage account using SQL script to preview the file contents.

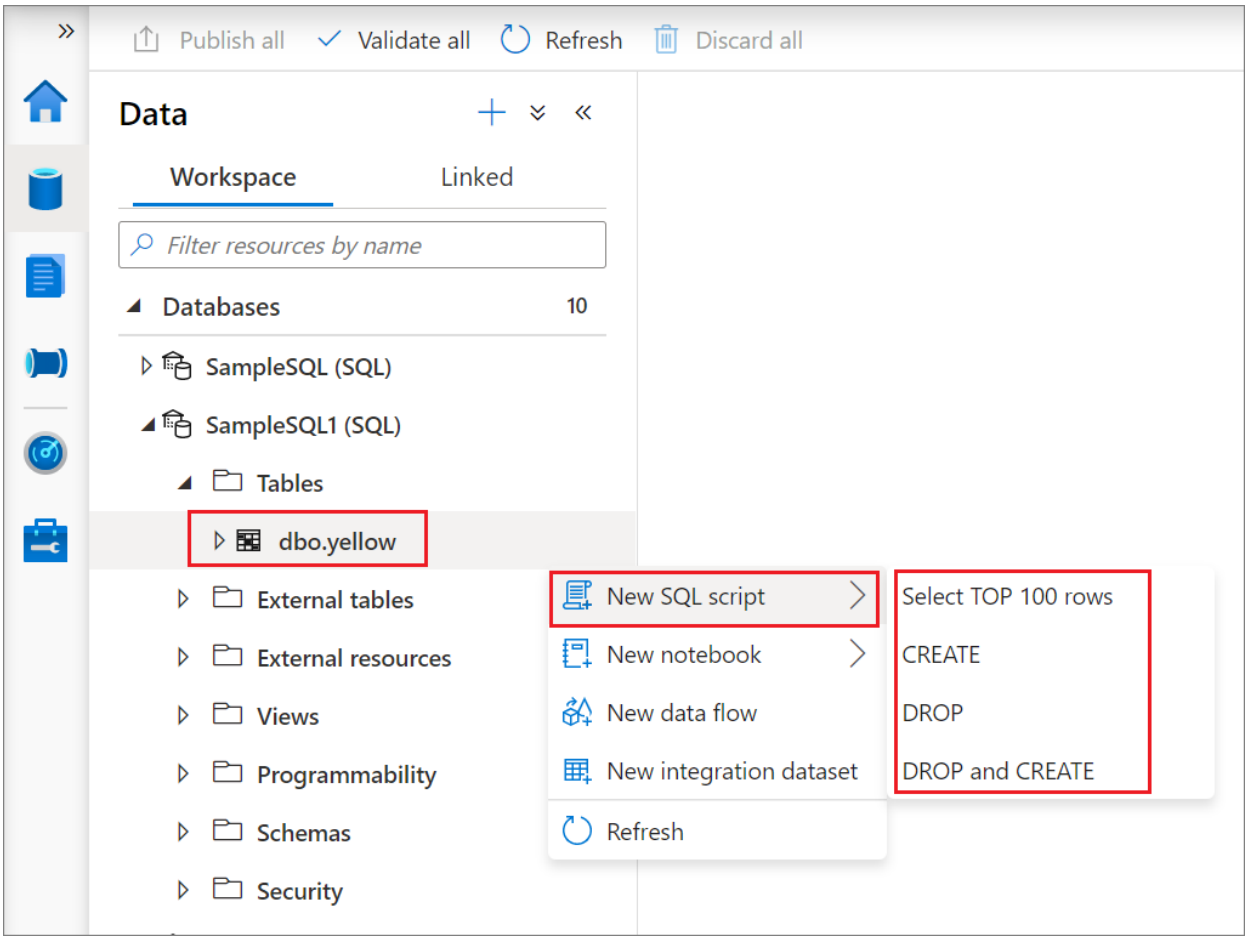


SQL Tables, external tables, views

By selecting the **Actions** menu under data, you can select several actions such as:

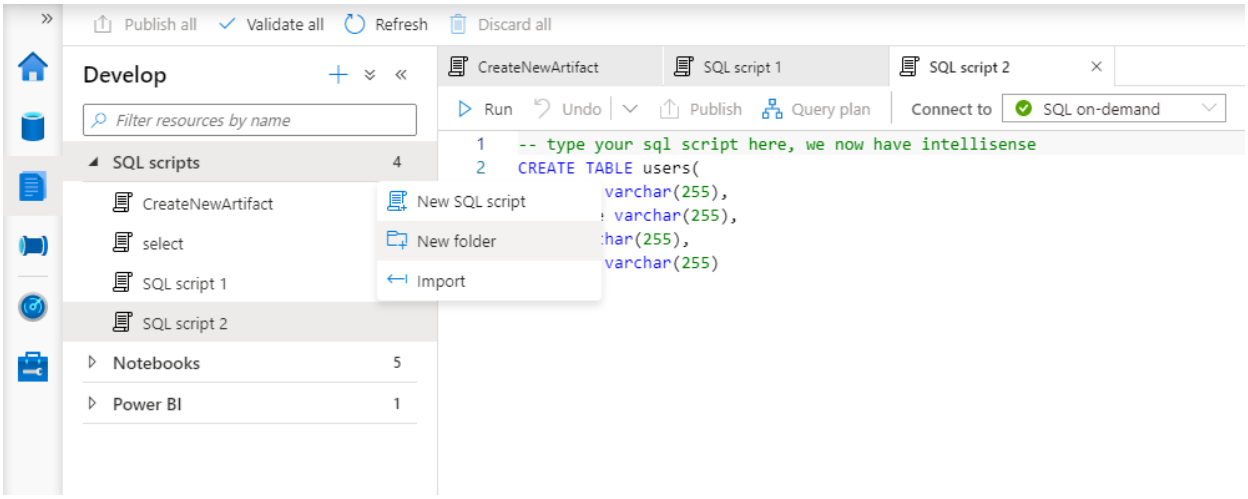
- New SQL script
- Select TOP 1000 rows
- CREATE
- DROP and CREATE

Explore the available gesture by right-clicking the nodes of SQL databases.

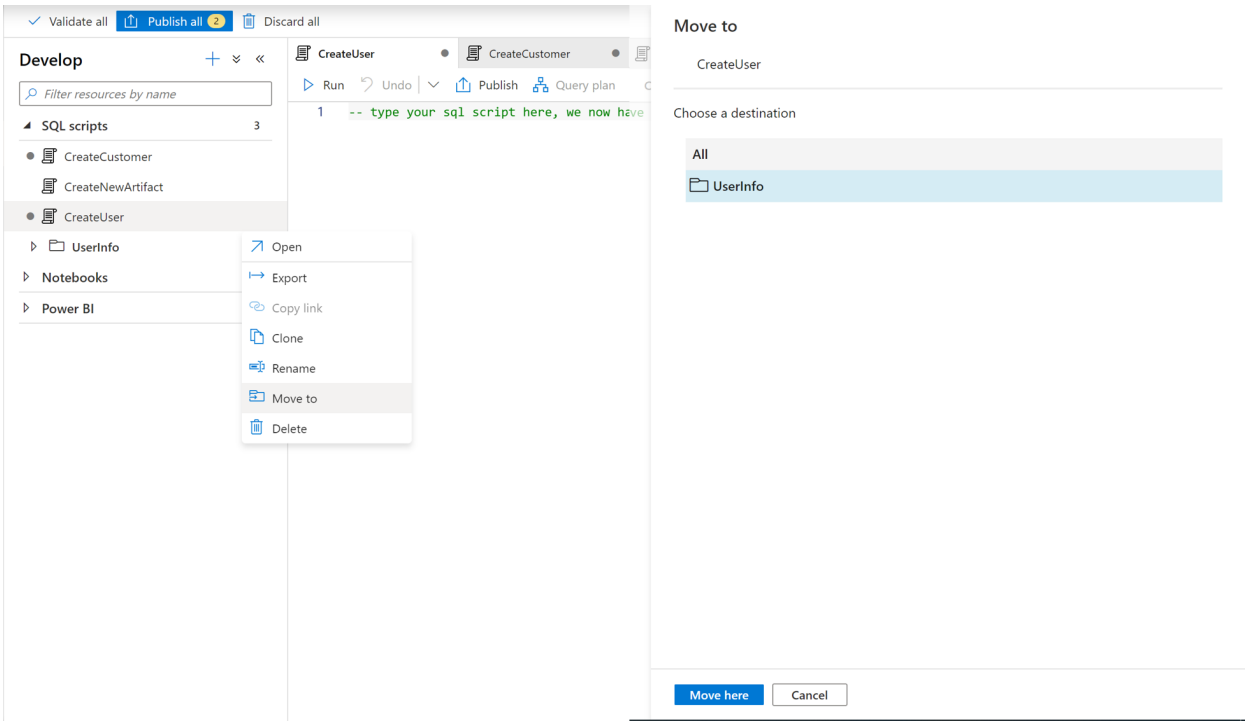


Create folders and move SQL scripts into a folder

From the Actions menu under Develop SQL scripts Choose "New folder" from the "Actions" menu under Develop SQL scripts. And type in the name of the new folder in the pop-up window.



To move a SQL script into a folder, you can select the sql script and choose "Move To" from the Actions menu. Then find the destination folder in the new window and move the sql script into selected folder.You can also quickly drag the sql script and drop it into a folder.



Next steps

For more information about authoring a SQL script, see Azure Synapse Analytics.

Data flows in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

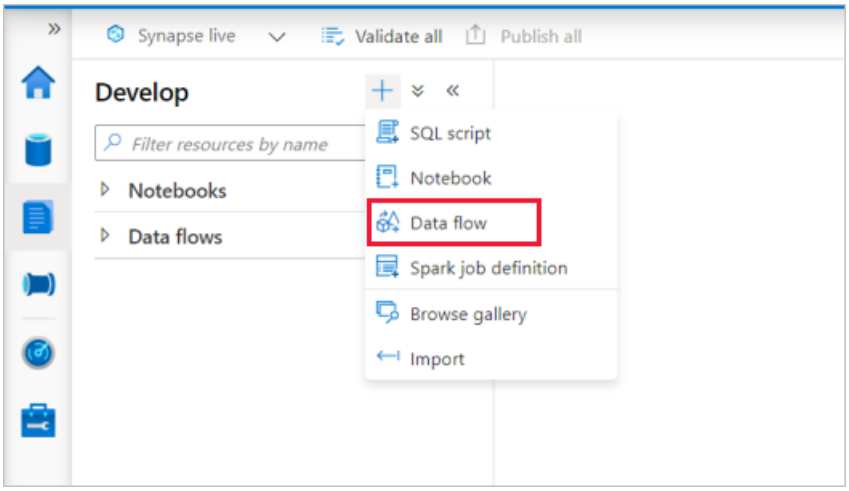
What are data flows?

Data flows are visually designed data transformations in Azure Synapse Analytics. Data flows allow data engineers to develop data transformation logic without writing code. The resulting data flows are executed as activities within Azure Synapse Analytics pipelines that use scaled-out Apache Spark clusters. Data flow activities can be operationalized using existing Azure Synapse Analytics scheduling, control, flow, and monitoring capabilities.

Data flows provide an entirely visual experience with no coding required. Your data flows run on Synapse-managed execution clusters for scaled-out data processing. Azure Synapse Analytics handles all the code translation, path optimization, and execution of your data flow jobs.

Getting started

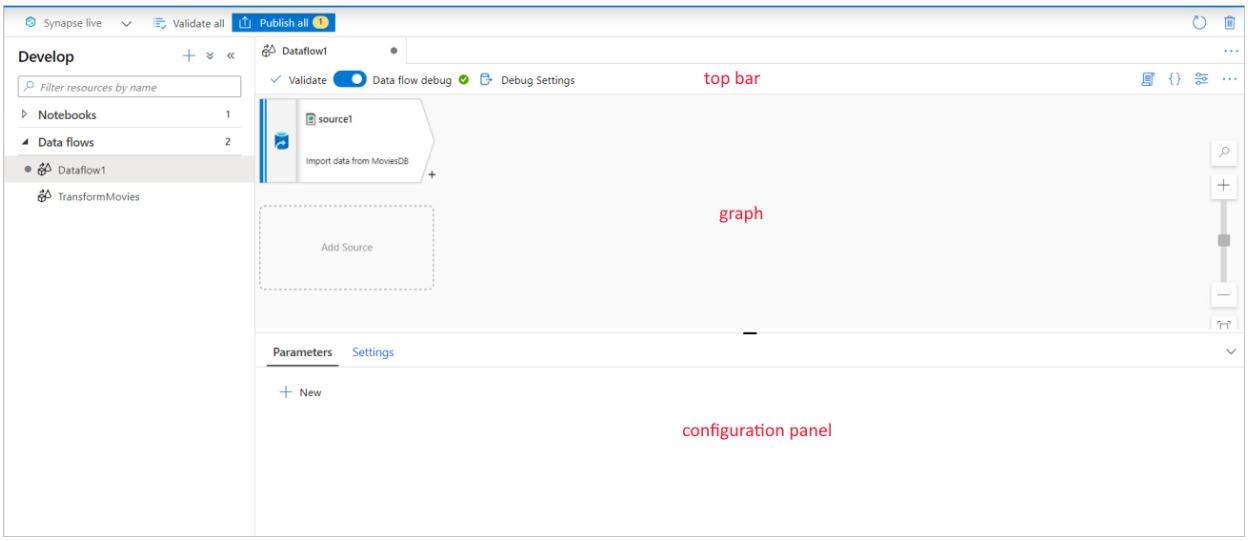
Data flows are created from the Develop pane in Synapse studio. To create a data flow, select the plus sign next to **Develop**, and then select **Data Flow**.



This action takes you to the data flow canvas, where you can create your transformation logic. Select **Add source** to start configuring your source transformation. For more information, see Source transformation.

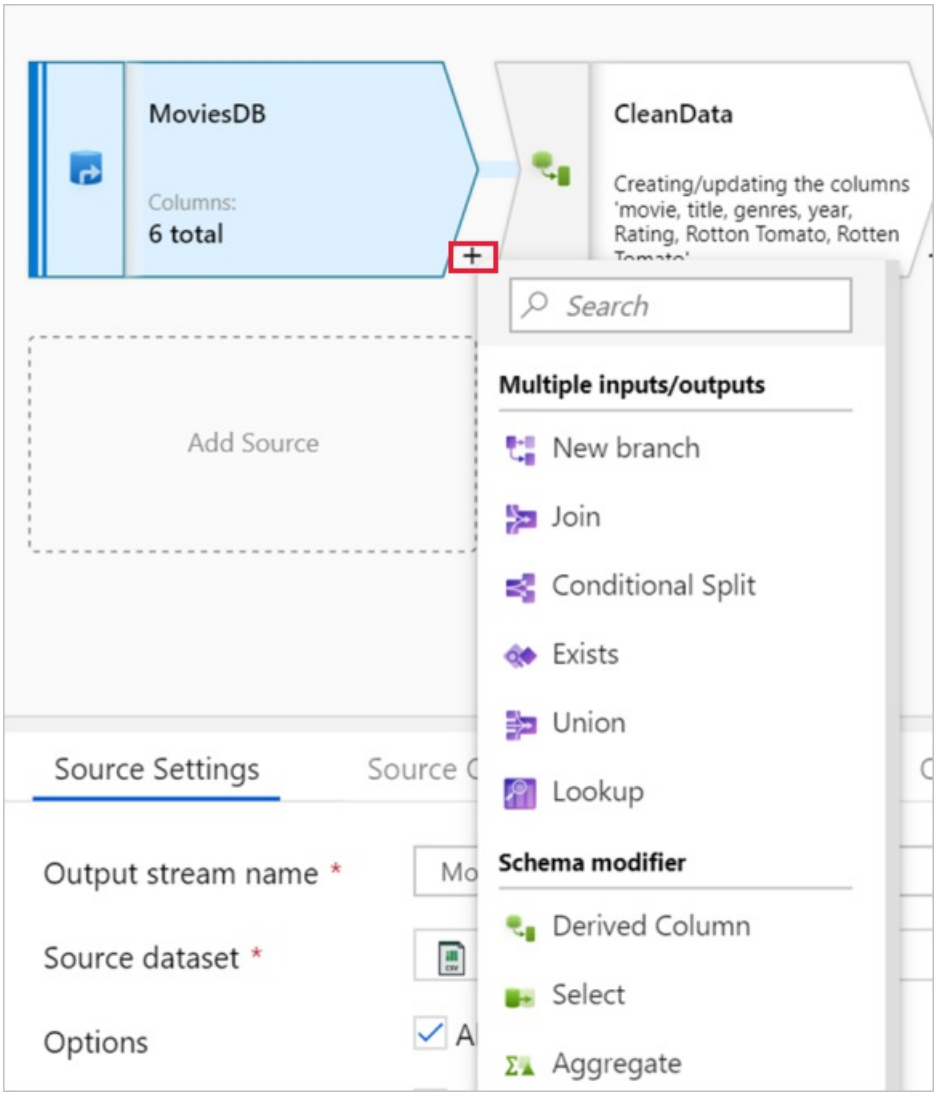
Authoring data flows

Data flow has a unique authoring canvas designed to make building transformation logic easy. The data flow canvas is separated into three parts: the top bar, the graph, and the configuration panel.



Graph

The graph displays the transformation stream. It shows the lineage of source data as it flows into one or more sinks. To add a new source, select **Add source**. To add a new transformation, select the plus sign on the lower right of an existing transformation. Learn more on how to manage the data flow graph.



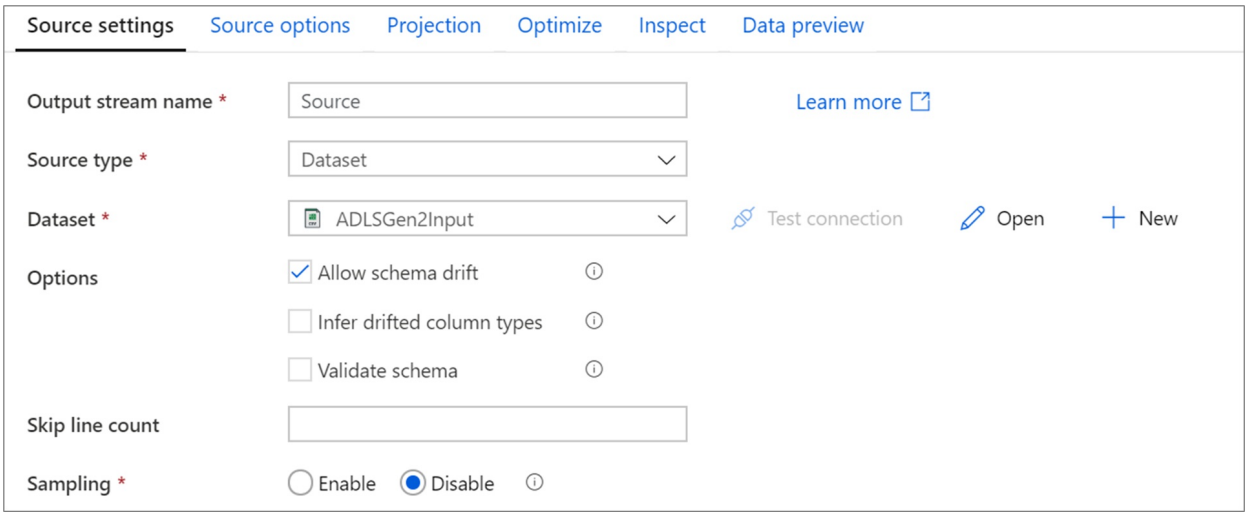
Configuration panel

The configuration panel shows the settings specific to the currently selected transformation. If no transformation is selected, it shows the data flow. In the overall data flow configuration, you can add parameters via the **Parameters** tab. For more information, see Data flow parameters.

Each transformation contains at least four configuration tabs.

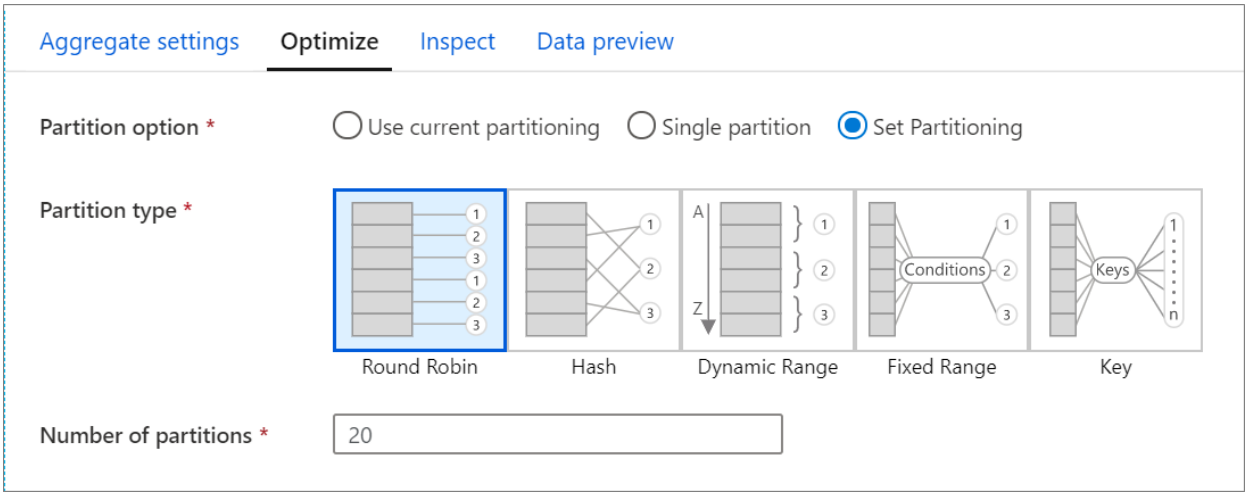
Transformation settings

The first tab in each transformation's configuration pane contains the settings specific to that transformation. For more information, see that transformation's documentation page.



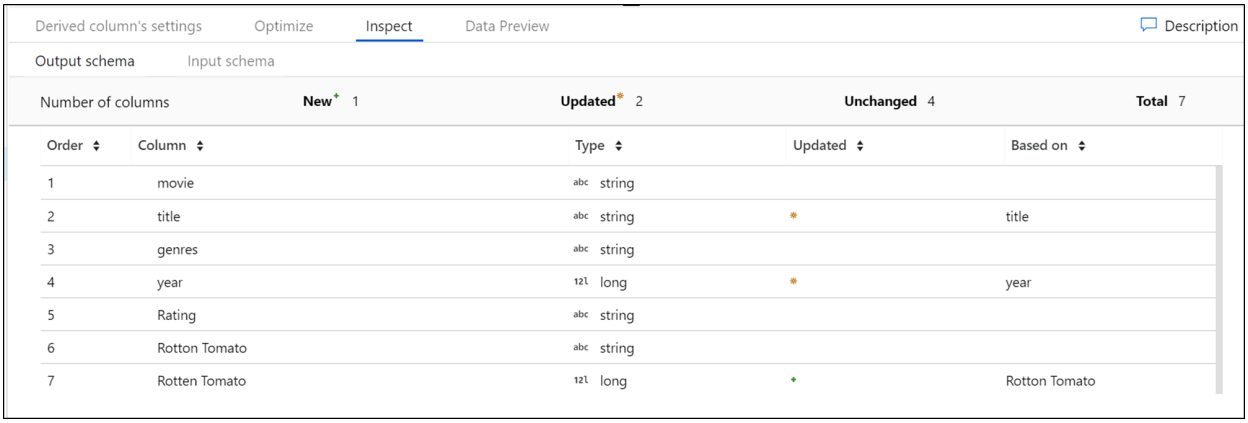
Optimize

The **Optimize** tab contains settings to configure partitioning schemes. To learn more about how to optimize your data flows, see the mapping data flow performance guide.



Inspect

The **Inspect** tab provides a view into the metadata of the data stream that you're transforming. You can see column counts, the columns changed, the columns added, data types, the column order, and column references. **Inspect** is a read-only view of your metadata. You don't need to have debug mode enabled to see metadata in the **Inspect** pane.



As you change the shape of your data through transformations, you'll see the metadata changes flow in the **Inspect** pane. If there isn't a defined schema in your source transformation, then metadata won't be visible in the **Inspect** pane. Lack of metadata is common in schema drift scenarios.

Data preview

If debug mode is on, the **Data Preview** tab gives you an interactive snapshot of the data at each transform. For more information, see Data preview in debug mode.

Top bar

The top bar contains actions that affect the whole data flow, like validation and debug settings. You can view the underlying JSON code and data flow script of your transformation logic as well.

Available transformations

View the mapping data flow transformation overview to get a list of available transformations.

Data flow activity

Data flows are operationalized within Azure Synapse Analytics pipelines using the data flow activity. All a user has to do is specify which integration runtime to use and pass in parameter values. For more information, learn about the Azure integration runtime.

Debug mode

Debug mode allows you to interactively see the results of each transformation step while you build and debug your data flows. The debug session can be used both in when building your data flow logic and running pipeline debug runs with data flow activities. To learn more, see the debug mode documentation.

Monitoring data flows

Data flow integrates with existing Azure Synapse Analytics monitoring capabilities. To learn how to understand data flow monitoring output, see monitoring mapping data flows.

The Azure Synapse Analytics team has created a performance tuning guide to help you optimize the execution time of your data flows after building your business logic.

Next steps

- Learn how to create a source transformation.
- Learn how to build your data flows in debug mode.

Use maintenance schedules to manage service updates and maintenance

8/19/2022 • 5 minutes to read • Edit Online

The maintenance schedule feature integrates the Service Health Planned Maintenance Notifications, Resource Health Check Monitor, and maintenance scheduling service for Synapse SQL pool (data warehouse) within Azure Synapse Analytics.

You should use maintenance scheduling to choose a time window when it's convenient to receive new features, upgrades, and patches. You will need to choose a primary and a secondary maintenance window within a seven-day period, each window must be within separate day ranges.

For example, you can schedule a primary window of Saturday 22:00 to Sunday 01:00, and then schedule a secondary window of Wednesday 19:00 to 22:00. If maintenance can't be performed during your primary maintenance window, it will try the maintenance again during your secondary maintenance window. Service maintenance could on occasion occur during both the primary and secondary windows. To ensure rapid completion of all maintenance operations, DW400c and lower data warehouse tiers could complete maintenance outside of a designated maintenance window.

All newly created data warehouse instances will have a system-defined maintenance schedule applied during deployment. The schedule can be edited as soon as deployment is complete.

Although a maintenance window can be between three and eight hours this does not mean the data warehouse will be offline for the duration. Maintenance can occur at any time within that window and you should expect a single disconnect during that period lasting ~5 -6 mins as the service deploys new code to your data warehouse. DW400c and lower may experience multiple brief losses in connectivity at various times during the maintenance window. When maintenance starts, all active sessions will be canceled, and non-committed transactions will be rolled back. To minimize instance downtime, make sure that your data warehouse has no long-running transactions before your chosen maintenance period.

All maintenance operations should finish within the specified maintenance windows unless we are required to deploy a time sensitive update. If your data warehouse is paused during a scheduled maintenance, it will be updated during the resume operation. You'll be notified immediately after your data warehouse maintenance is completed.

Alerts and monitoring

Integration with Service Health notifications and the Resource Health Check Monitor allows customers to stay informed of impending maintenance activity. This automation takes advantage of Azure Monitor. You can decide how you want to be notified of impending maintenance events. Also, you can choose which automated flows will help you manage downtime and minimize operational impact.

A 24-hour advance notification precedes all maintenance events that aren't for the DWC400c and lower tiers.

> **NOTE**
> In the event we are required to deploy a time critical update, advanced notification times may be significantly reduced. This could occur outside an identified maintenance window due to the critical nature of the update.

If you received advance notification that maintenance will take place, but maintenance can't be performed

during the time period in the notification, you'll receive a cancellation notification. Maintenance will then resume during the next scheduled maintenance period.

All active maintenance events appear in the **Service Health - Planned Maintenance** section. The Service Health history includes a full record of past events. You can monitor maintenance via the Azure Service Health check portal dashboard during an active event.

Maintenance schedule availability

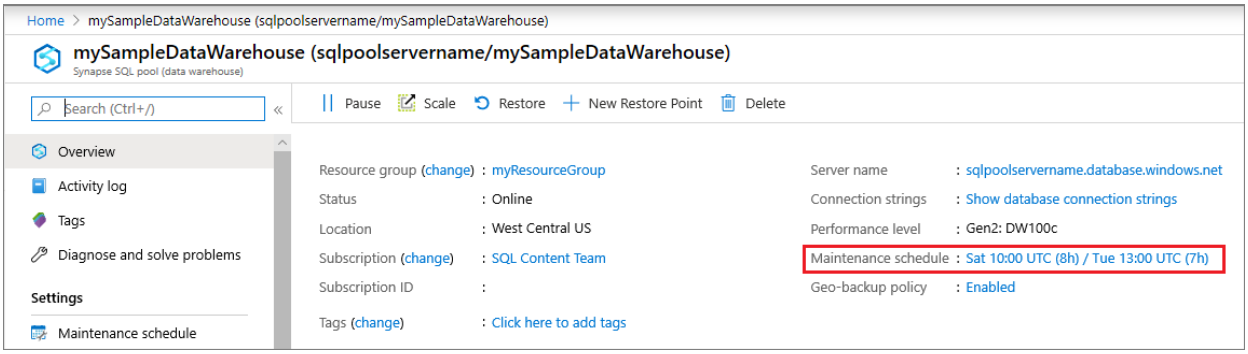
Even if maintenance scheduling isn't available in your selected region, you can view and edit your maintenance schedule at any time. When maintenance scheduling becomes available in your region, the identified schedule will immediately become active on your Synapse SQL pool.

View a maintenance schedule

By default, all newly created data warehouse instances have an eight-hour primary and secondary maintenance window applied during deployment. As indicated above, you can change the windows as soon deployment is complete. No maintenance will take place outside the specified maintenance windows without prior notification.

To view the maintenance schedule that has been applied to your Synapse SQL pool, complete the following steps:

1. Sign in to the Azure portal.
2. Select the Synapse SQL pool that you want to view.
3. The selected Synapse SQL pool opens on the overview blade. The maintenance schedule that's applied to the data warehouse appears below **Maintenance schedule**.



Change a maintenance schedule

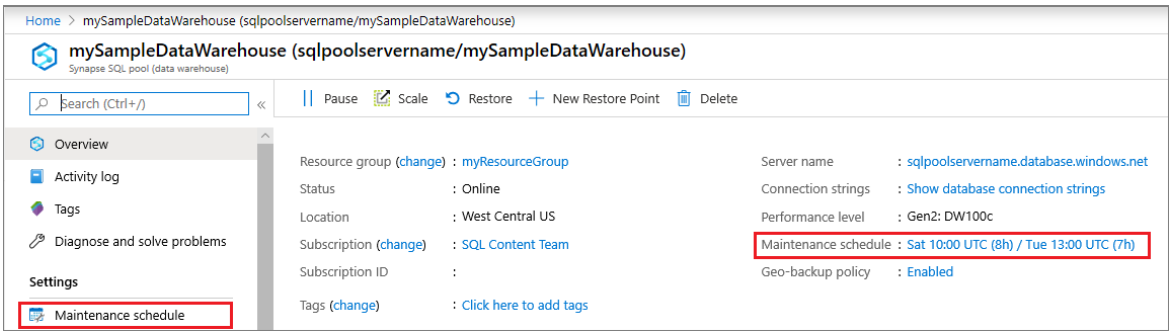
A maintenance schedule can be updated or changed at any time. If the selected instance is going through an active maintenance cycle, the settings will be saved. They'll become active during the next identified maintenance period. Learn more about monitoring your data warehouse during an active maintenance event.

Identifying the primary and secondary windows

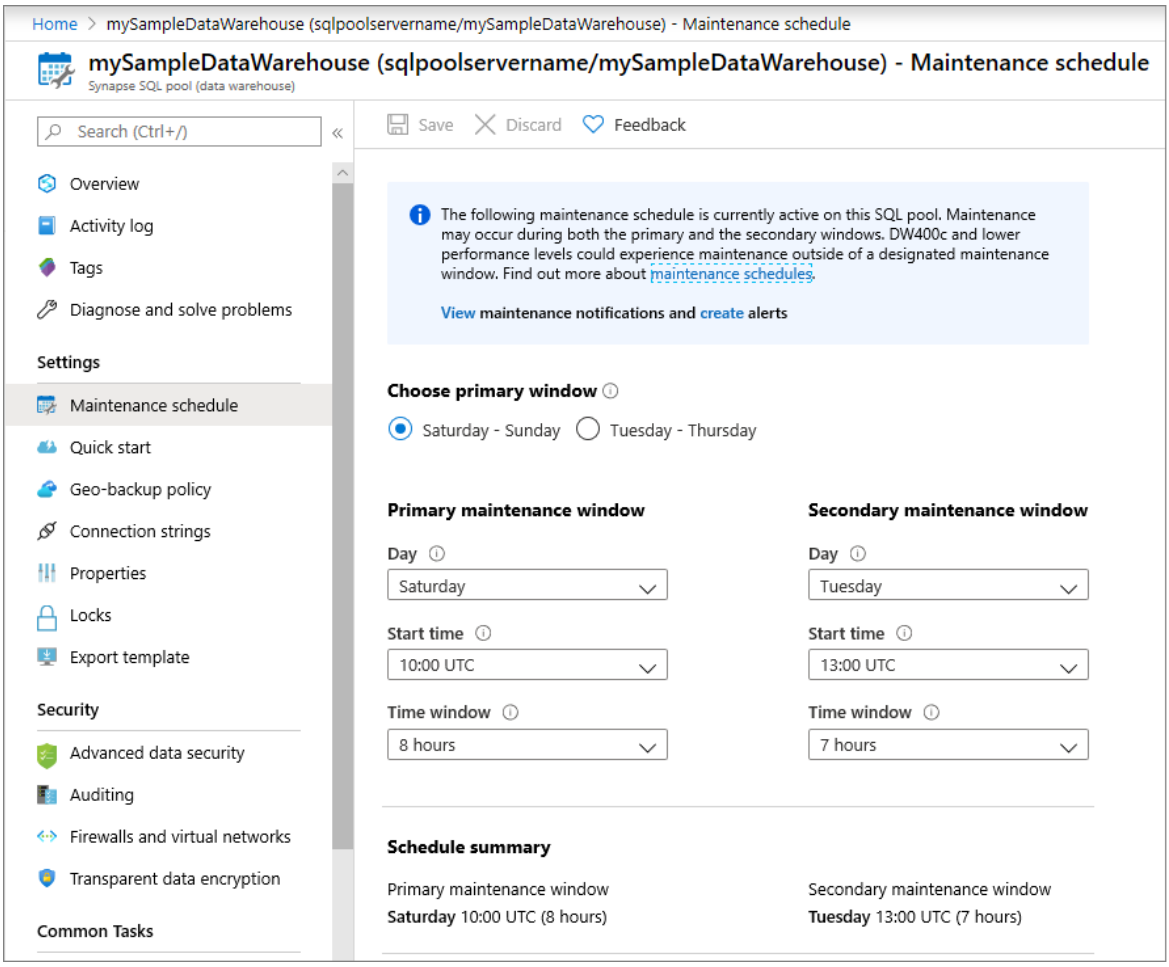
The primary and secondary windows must have separate day ranges. An example is a primary window of Tuesday–Thursday and a secondary of window of Saturday–Sunday.

To change the maintenance schedule for your Synapse SQL pool, complete the following steps:

1. Sign in to the Azure portal.
2. Select the Synapse SQL pool that you want to update. The page opens on the overview blade. Open the page for maintenance schedule settings by selecting the **Maintenance Schedule summary** link on the overview blade. Or, select the **Maintenance Schedule** option on the left-side resource menu.



3. Identify the preferred day range for your primary maintenance window by using the options at the top of the page. This selection determines if your primary window will occur on a weekday or over the weekend. Your selection will update the drop-down values. During preview, some regions might not yet support the full set of available **Day** options.



4. Choose your preferred primary and secondary maintenance windows by using the drop-down list boxes:

   - **Day**: Preferred day to perform maintenance during the selected window.
   - **Start time**: Preferred start time for the maintenance window.
   - **Time window**: Preferred duration of your time window.

   The **Schedule summary** area at the bottom of the blade is updated based on the values that you selected.

5. Select **Save**. A message appears, confirming that your new schedule is now active.

   If you're saving a schedule in a region that doesn't support maintenance scheduling, the following message appears. Your settings are saved and become active when the feature becomes available in your selected region.

Source control in Synapse Studio

8/19/2022 • 11 minutes to read • Edit Online

By default, Synapse Studio authors directly against the Synapse service. If you have a need for collaboration using Git for source control, Synapse Studio allows you to associate your workspace with a Git repository, Azure DevOps, or GitHub.

This article will outline how to configure and work in a Synapse workspace with git repository enabled. And we also highlight some best practices and a troubleshooting guide.

> **NOTE**
> To use GitHub in Azure Gov and Azure China, you can bring your own GitHub OAuth application in Synapse Studio for git integration. The configure experience is same with ADF. You can refer to the announcement blog.

Prerequisites

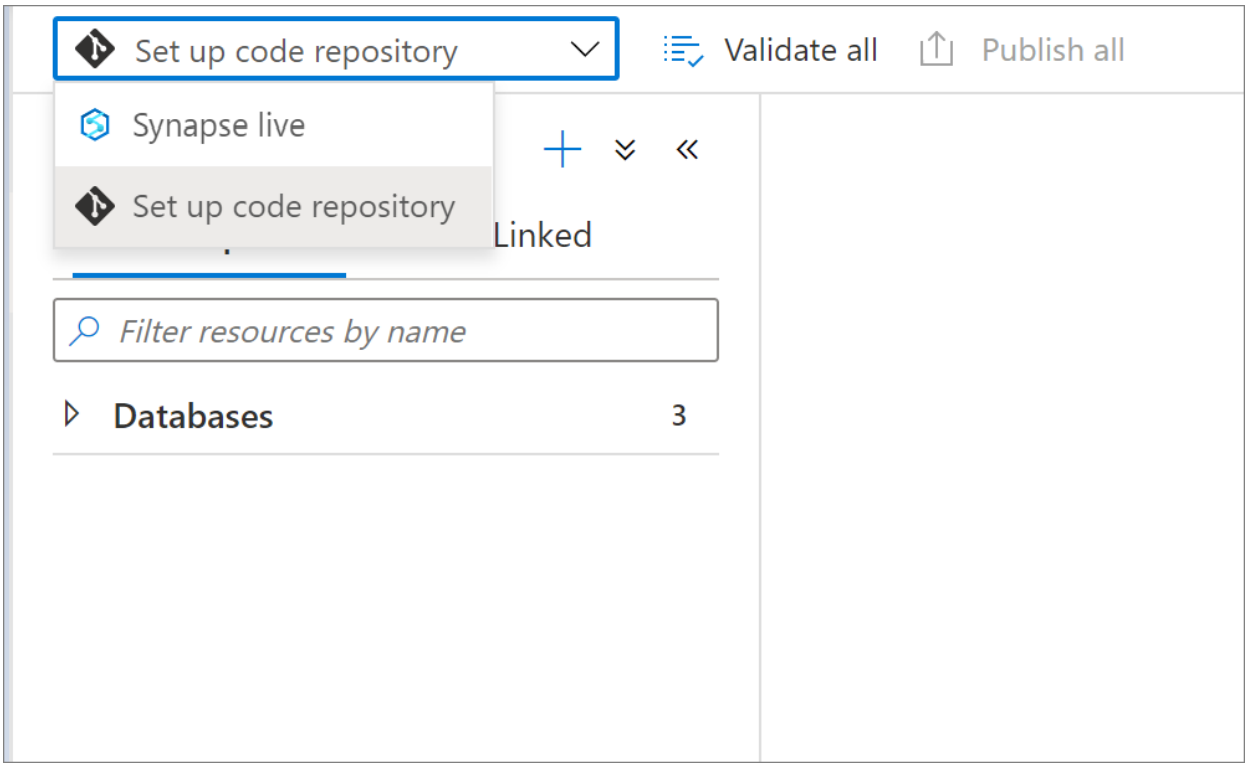
Users must have the Azure Contributor (Azure RBAC) or higher role on the Synapse workspace to configure, edit settings and disconnect a Git repository with Synapse.

Configure Git repository in Synapse Studio

After launching your Synapse Studio, you can configure a git repository in your workspace. A Synapse Studio workspace can be associated with only one git repository at a time.

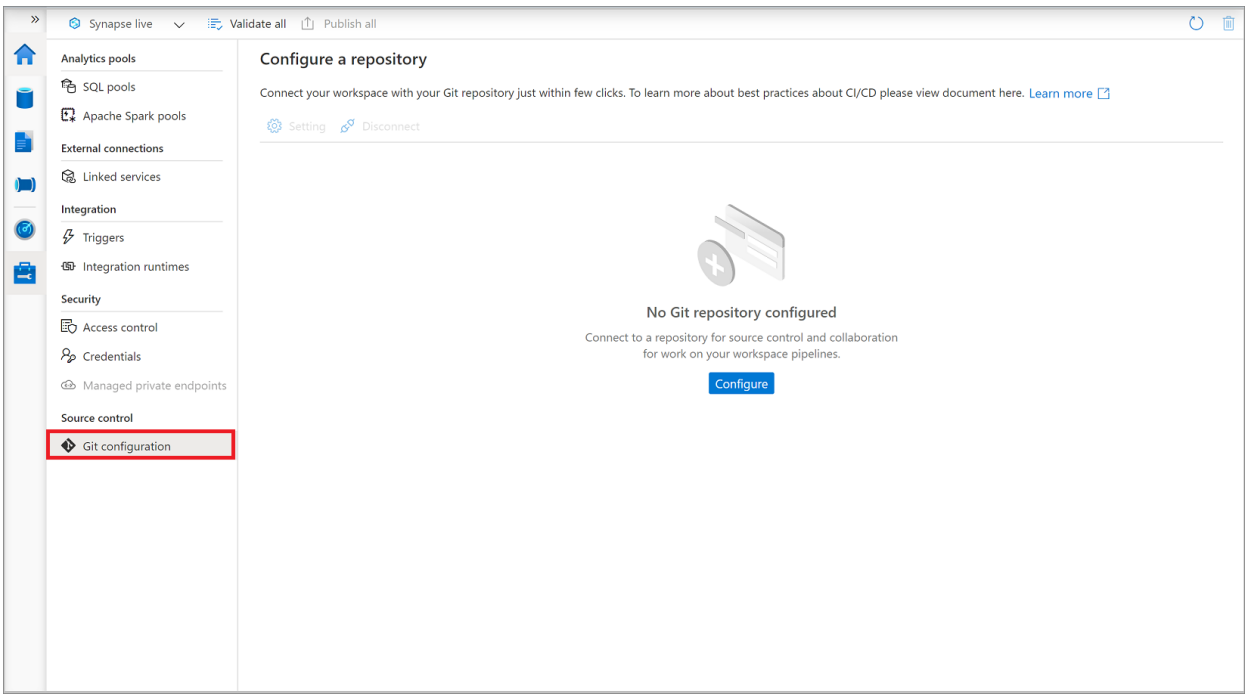
Configuration method 1: global bar

In the Synapse Studio global bar, select the **Synapse Live** drop-down menu, and then select **Set up code repository**.



Configuration method 2: Manage hub

Go to the Manage hub of Synapse Studio. Select **Git configuration** in the **Source control** section. If you have no repository connected, click **Configure**.



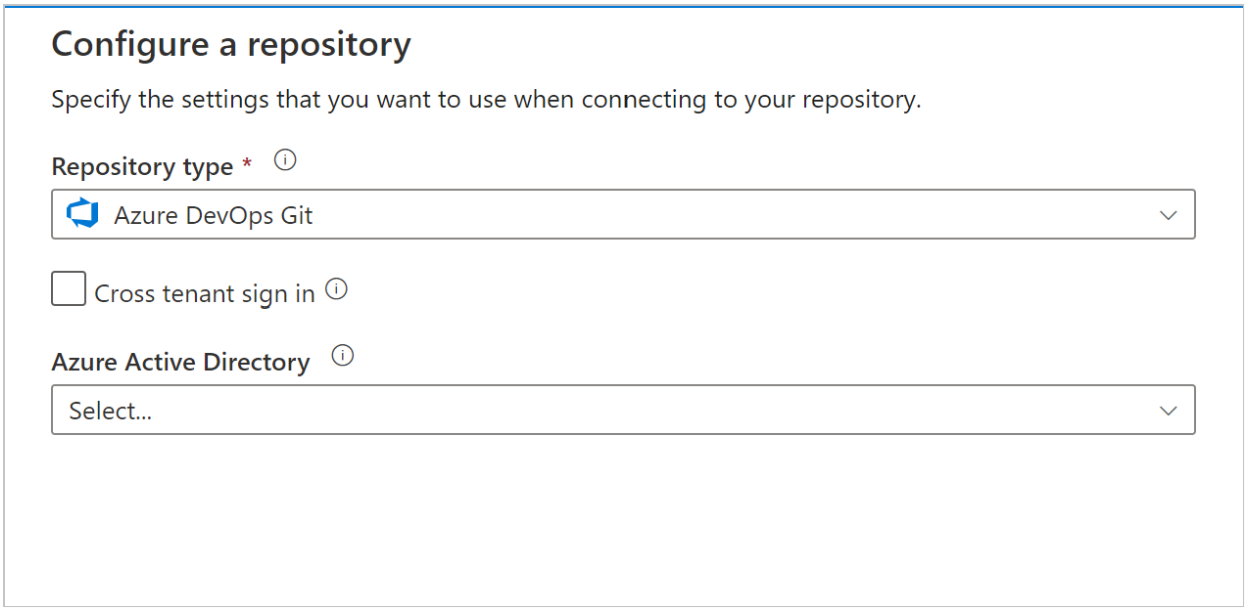
You can connect either Azure DevOps or GitHub git repository in your workspace.

Connect with Azure DevOps Git

You can associate a Synapse workspace with an Azure DevOps Repository for source control, collaboration, versioning, and so on. If you don't have an Azure DevOps repository, follow these instructions to create your repository resources.

Azure DevOps Git repository settings

When connecting to your git repository, first select your repository type as Azure DevOps git, and then select one Azure AD tenant from the dropdown list, and click **Continue**.



The configuration pane shows the following Azure DevOps git settings:

SETTING	DESCRIPTION	VALUE
Repository Type	The type of the Azure Repos code repository.	Azure DevOps Git or GitHub
Cross tenant sign in	Checkbox to sign in with cross tenant account.	unselected (default)
Azure Active Directory	Your Azure AD tenant name.	`<your tenant name>`
Azure DevOps account	Your Azure Repos organization name. You can locate your Azure Repos organization name at `https://{organization name}.visualstudio.com`. You can sign in to your Azure Repos organization to access your Visual Studio profile and see your repositories and projects.	`<your organization name>`
ProjectName	Your Azure Repos project name. You can locate your Azure Repos project name at `https://{organization name}.visualstudio.com/{project name}`.	`<your Azure Repos project name>`
RepositoryName	Your Azure Repos code repository name. Azure Repos projects contain Git repositories to manage your source code as your project grows. You can create a new repository or use an existing repository that's already in your project.	`<your Azure Repos code repository name>`
Collaboration branch	Your Azure Repos collaboration branch that is used for publishing. By default, its `master`. Change this setting in case you want to publish resources from another branch. You can select existing branches or create new	`<your collaboration branch name>`
Root folder	Your root folder in your Azure Repos collaboration branch.	`<your root folder name>`
Import existing resources to repository	Specifies whether to import existing resources from the Synapse Studio into an Azure Repos Git repository. Check the box to import your workspace resources (except pools) into the associated Git repository in JSON format. This action exports each resource individually. When this box isn't checked, the existing resources aren't imported.	Checked (default)
Import resource into this branch	Select which branch the resources (sql script, notebook, spark job definition, dataset, dataflow etc.) are imported to.	

Your can also use repository link to quickly point to the git repository you want to connect with.

Use a different Azure Active Directory tenant

The Azure Repos Git repo can be in a different Azure Active Directory tenant. To specify a different Azure AD tenant, you have to have administrator permissions for the Azure subscription that you're using. For more info, see change subscription administrator

> **IMPORTANT**
> To connect to another Azure Active Directory, the user logged in must be a part of that active directory.

Use your personal Microsoft account

To use a personal Microsoft account for Git integration, you can link your personal Azure Repo to your organization's Active Directory.

1. Add your personal Microsoft account to your organization's Active Directory as a guest. For more info, see Add Azure Active Directory B2B collaboration users in the Azure portal.
2. Log in to the Azure portal with your personal Microsoft account. Then switch to your organization's Active Directory.
3. Go to the Azure DevOps section, where you now see your personal repo. Select the repo and connect with Active Directory.

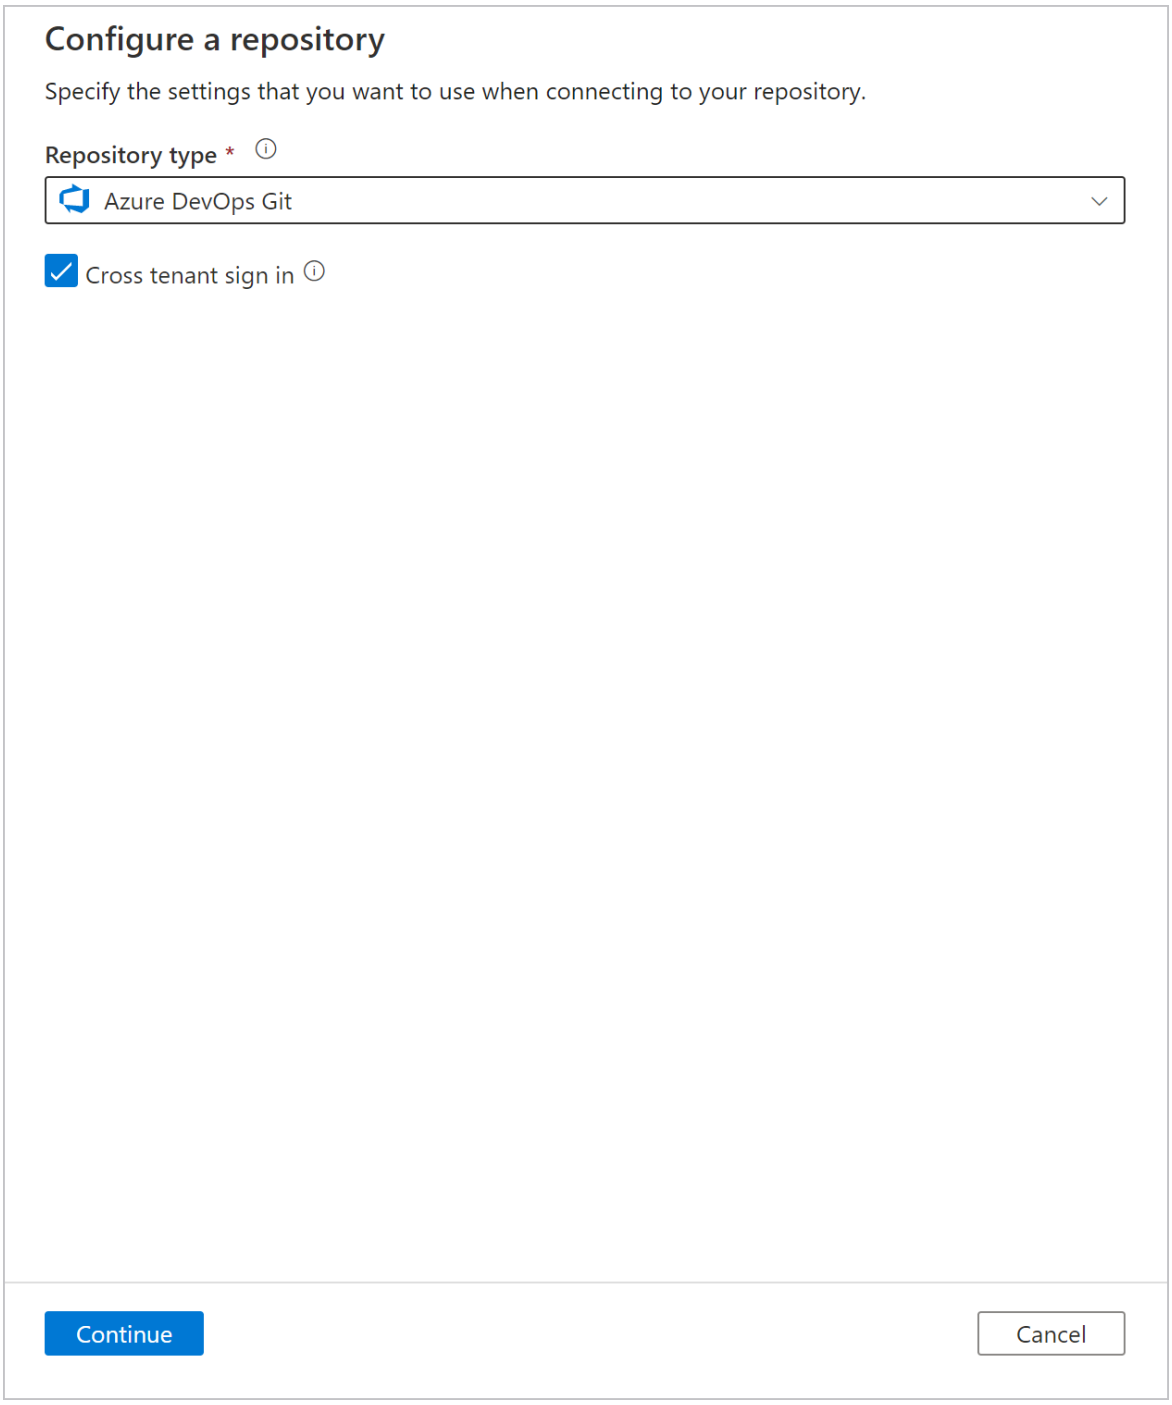
After these configuration steps, your personal repo is available when you set up Git integration in the Synapse Studio.

For more info about connecting Azure Repos to your organization's Active Directory, see Connect your organization to Azure Active Directory.

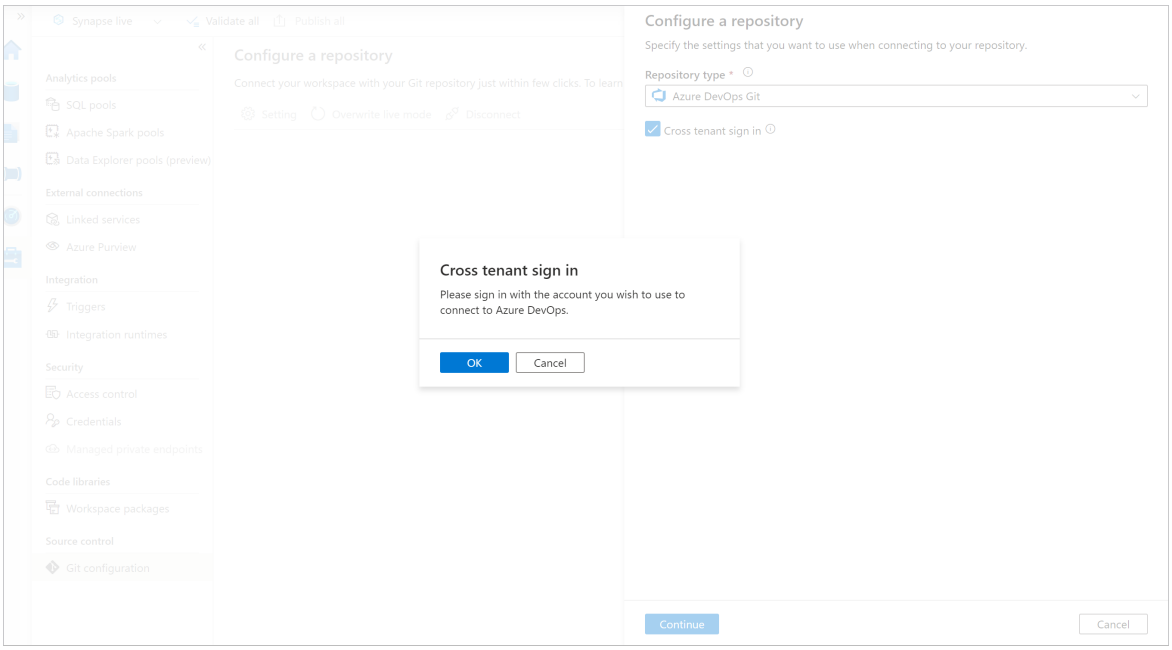
Use a cross tenant Azure DevOps account

When your Azure DevOps is not in the same tenant as the Synapse workspace, you can configure the workspace with your cross tenant Azure DevOps account with the guide below.

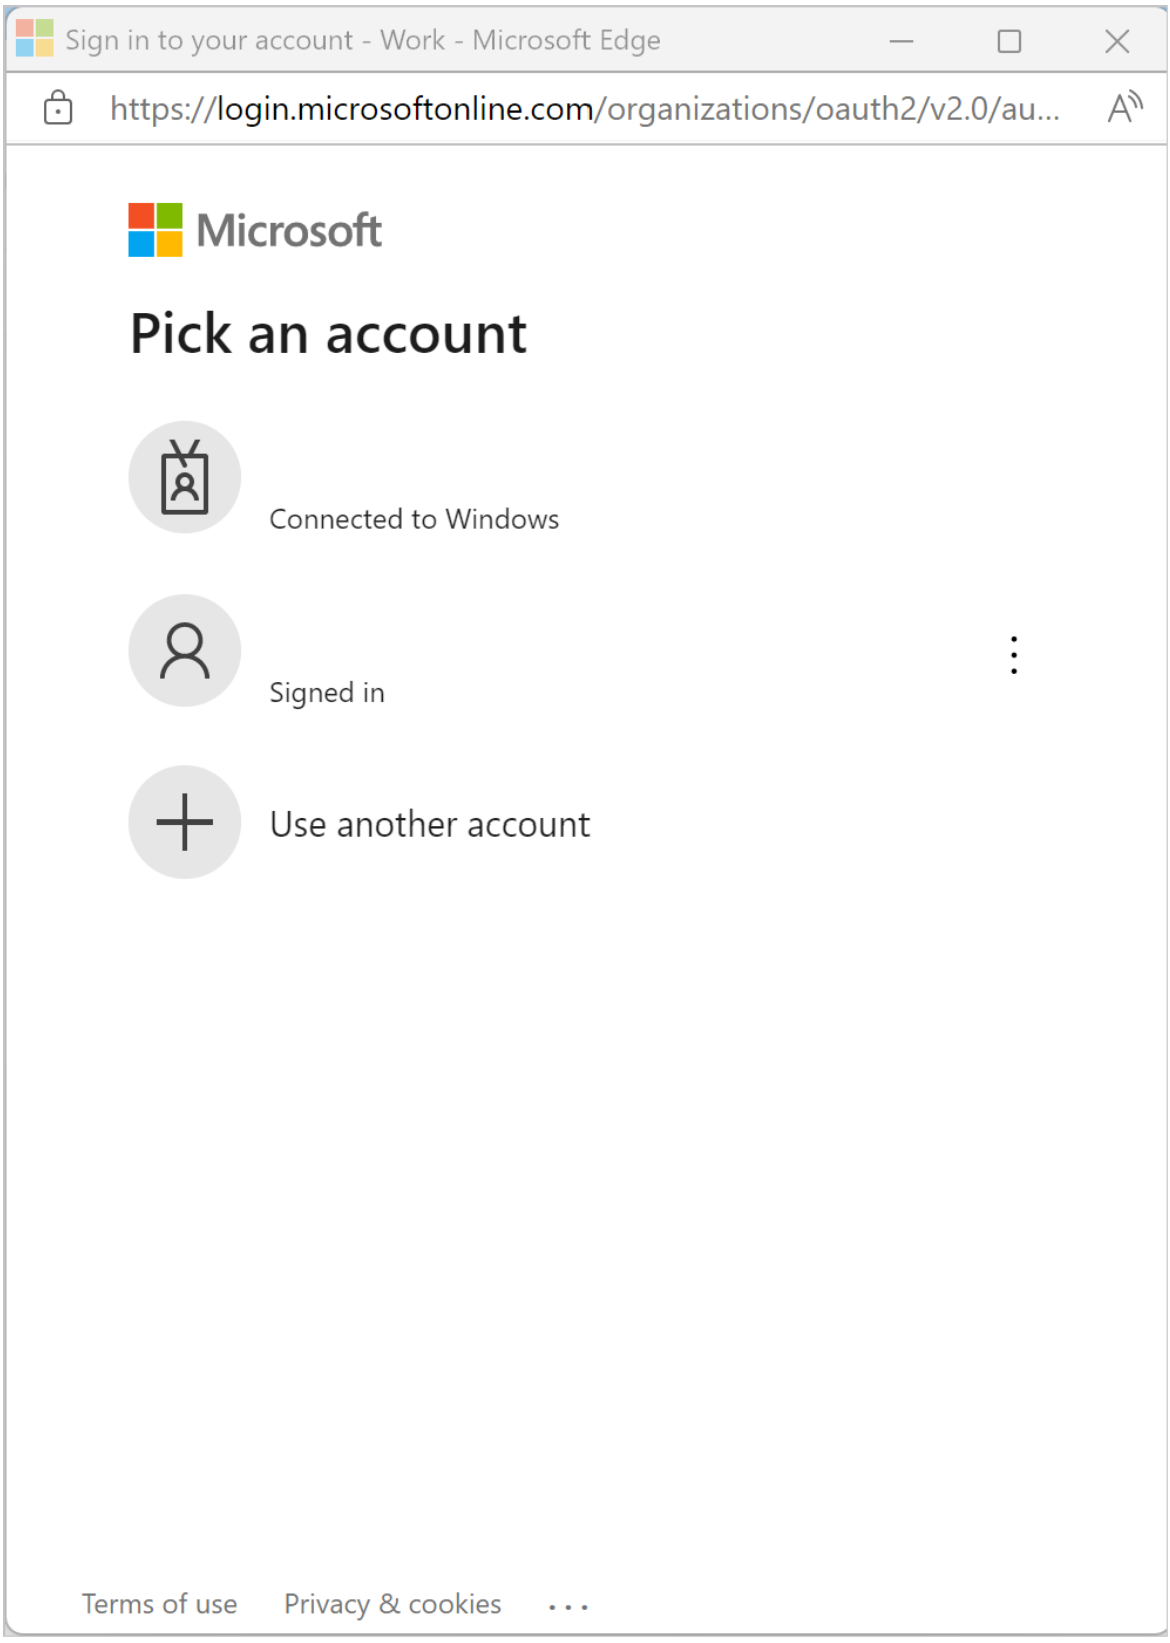
1. Select the **Cross tenant sign in** option and click **Continue**



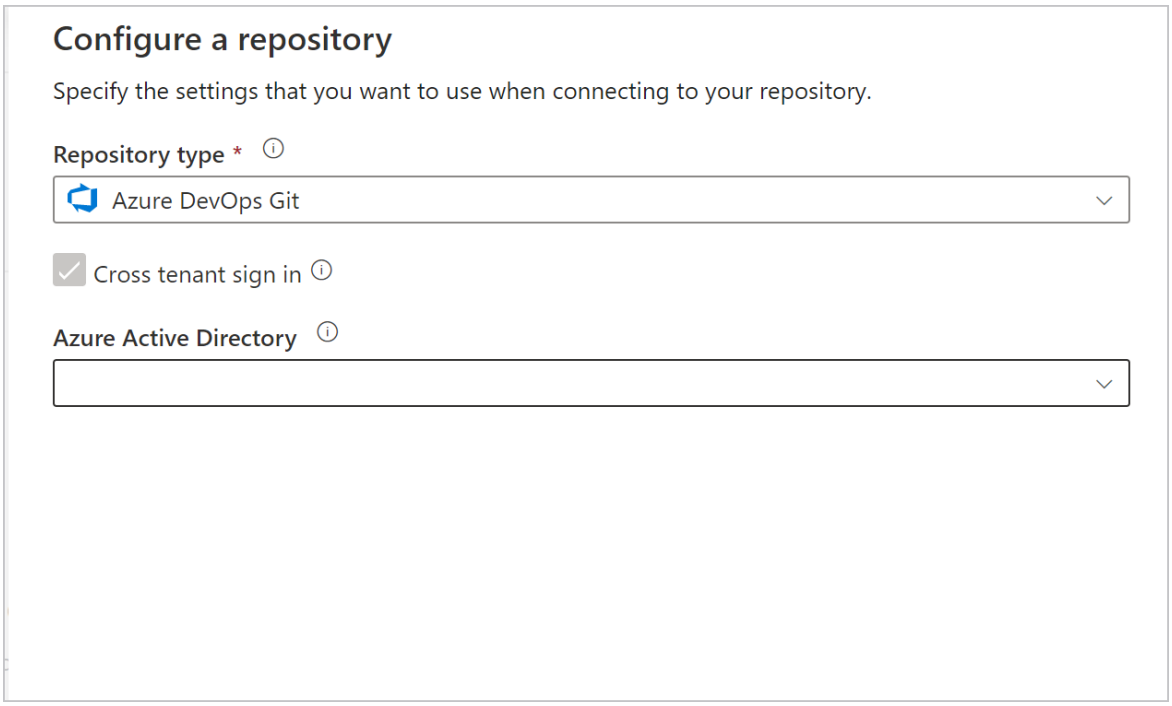
2. Select **OK** in the dialog box.



3. click **Use another account** and login with your Azure DevOps account.



4. After signing in, choose the directory and repository and configure it accordingly.



NOTE

To login the workspace, you need to use the first sign-in to log into to your Synapse workspace user account. Your cross tenant Azure DevOps account is only used for signing into and getting access to the Azure DevOps repo associated with this Synapse workspace.

Connect with GitHub

You can associate a workspace with a GitHub repository for source control, collaboration, versioning. If you don't have a GitHub account or repository, follow these instructions to create your resources.

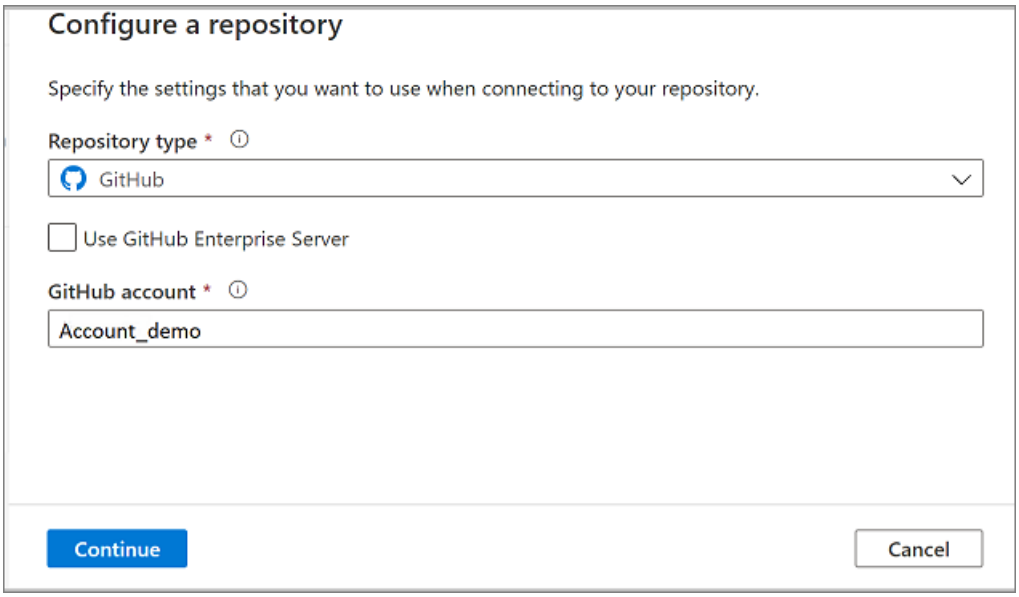
The GitHub integration with Synapse Studio supports both public GitHub (that is, https://github.com) and GitHub Enterprise. You can use both public and private GitHub repositories as long you have read and write permission to the repository in GitHub.

GitHub settings

When connecting to your git repository, first select your repository type as GitHub, and then provide your GitHub account, your GitHub Enterprise Server URL if you use GitHub Enterprise Server, or your GitHub Enterprise organization name if you use GitHub Enterprise Cloud. Select **Continue**.

NOTE

If you're using GitHub Enterprise Cloud, leave the **Use GitHub Enterprise Server** checkbox cleared.



The configuration pane shows the following GitHub repository settings:

SETTING	DESCRIPTION	VALUE
Repository Type	The type of the Azure Repos code repository.	GitHub
Use GitHub Enterprise	Checkbox to select GitHub Enterprise	unselected (default)
GitHub Enterprise URL	The GitHub Enterprise root URL (must be HTTPS for local GitHub Enterprise server). For example: `https://github.mydomain.com`. Required only if **Use GitHub Enterprise** is selected	`<your GitHub enterprise url>`
GitHub account	Your GitHub account name. This name can be found from https://github.com/{account name}/{repository name}. Navigating to this page prompts you to enter GitHub OAuth credentials to your GitHub account.	`<your GitHub account name>`
Repository Name	Your GitHub code repository name. GitHub accounts contain Git repositories to manage your source code. You can create a new repository or use an existing repository that's already in your account.	`<your repository name>`
Collaboration branch	Your GitHub collaboration branch that is used for publishing. By default, its master. Change this setting in case you want to publish resources from another branch.	`<your collaboration branch>`
Root folder	Your root folder in your GitHub collaboration branch.	`<your root folder name>`

SETTING	DESCRIPTION	VALUE
Import existing resources to repository	Specifies whether to import existing resources from the Synapse Studio into a Git repository. Check the box to import your workspace resources (except pools) into the associated Git repository in JSON format. This action exports each resource individually. When this box isn't checked, the existing resources aren't imported.	Selected (default)
Import resource into this branch	Select which branch the resources (sql script, notebook, spark job definition, dataset, dataflow etc.) is imported.	

GitHub organizations

Connecting to a GitHub organization requires the organization to grant permission to Synapse Studio. A user with ADMIN permissions on the organization must perform the below steps.

Connecting to GitHub for the first time

If you're connecting to GitHub from Synapse Studio for the first time, follow these steps to connect to a GitHub organization.

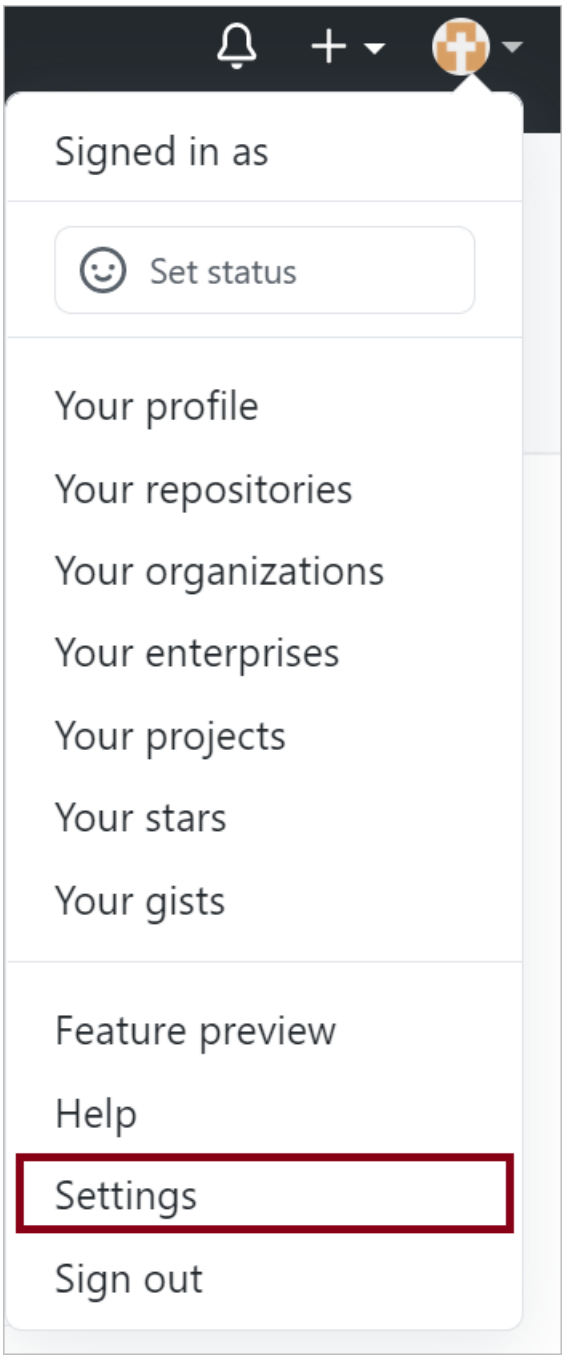
1. In the Git configuration pane, enter the organization name in the *GitHub Account* field. A prompt to login into GitHub will appear.
2. Login using your user credentials.
3. You'll be asked to authorize Synapse as an application called *Azure Synapse*. On this screen, you will see an option to grant permission for Synapse to access the organization. If you don't see the option to grant permission, ask an admin to manually grant the permission through GitHub.

Once you follow these steps, your workspace will be able to connect to both public and private repositories within your organization. If you are unable to connect, try clearing the browser cache and retrying.

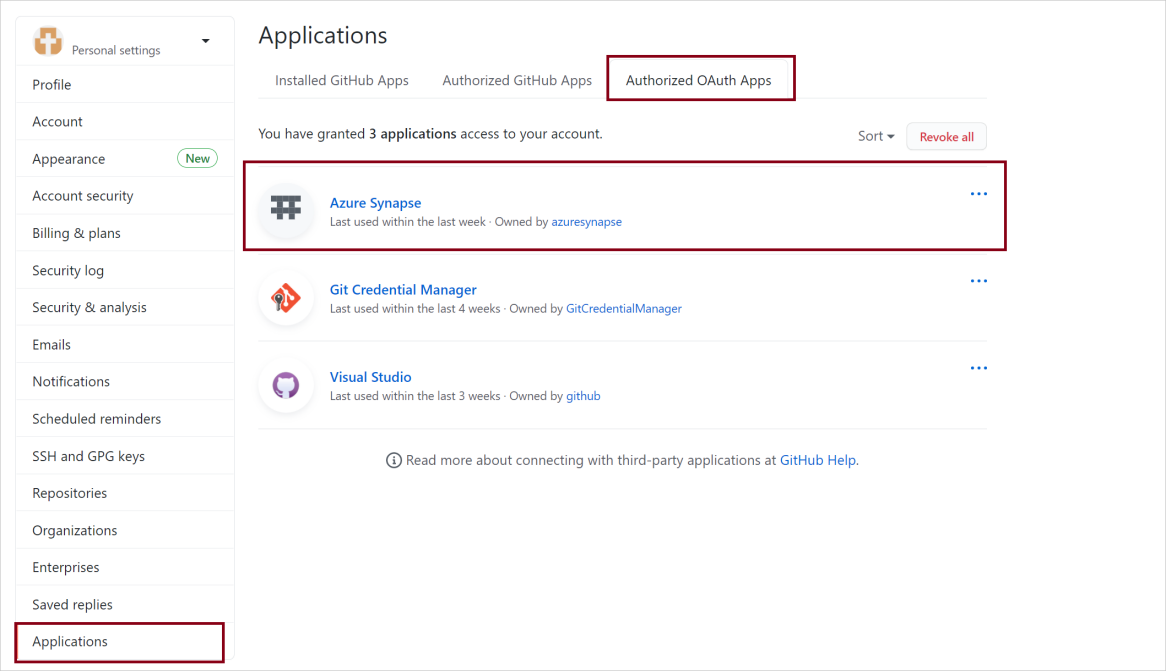
Already connected to GitHub using a personal account

If you have already connected to GitHub and only granted permission to access a personal account, follow the below steps to grant permissions to an organization.

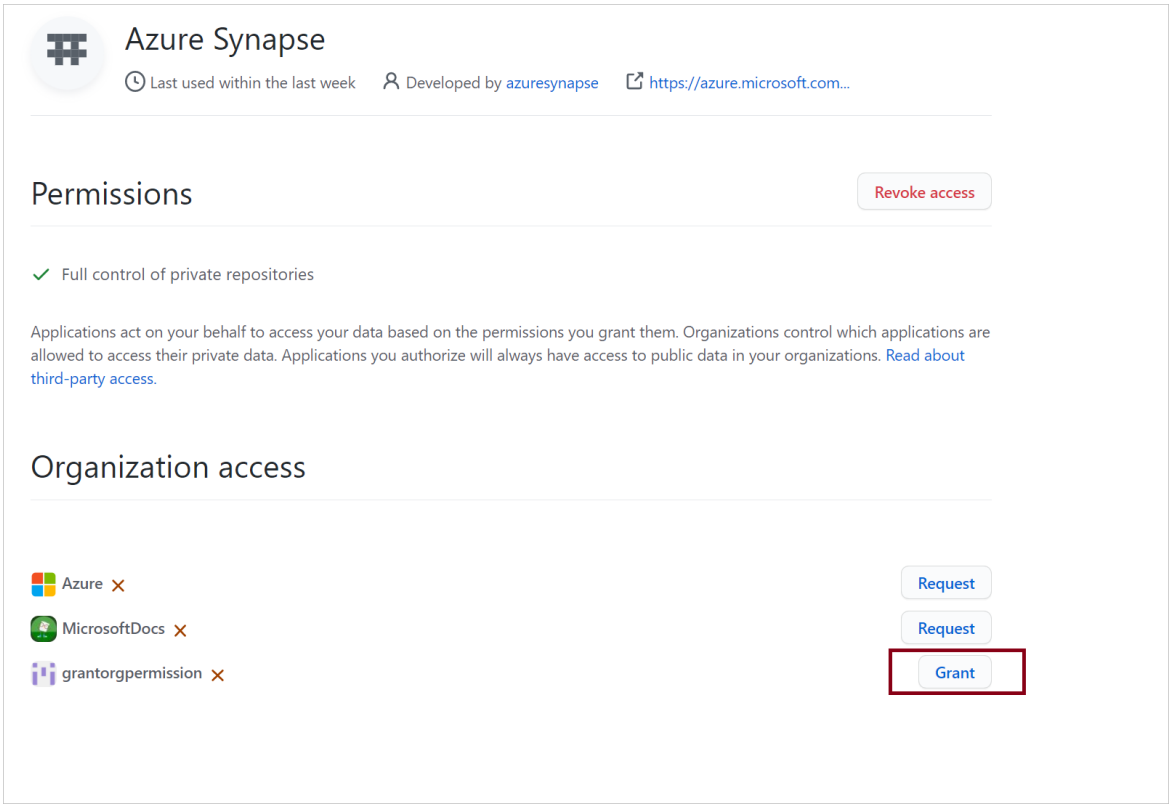
1. Go to GitHub and open **Settings**.



2. Select **Applications**. In the **Authorized OAuth apps** tab, you should see *Azure Synapse*.



3. Select the *Azure Synapse* and grant the access to your organization.



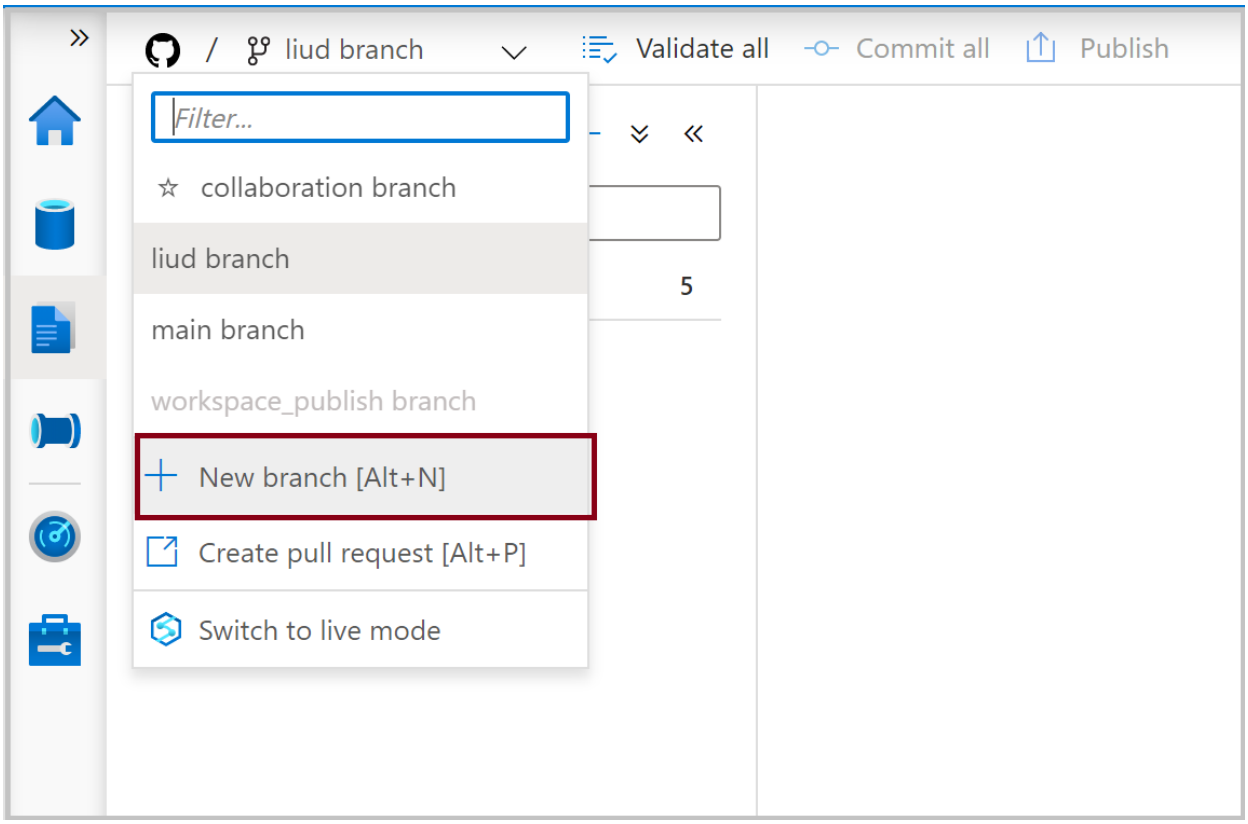
Once you complete these steps, your workspace will be able to connect to both public and private repositories within your organization.

Version control

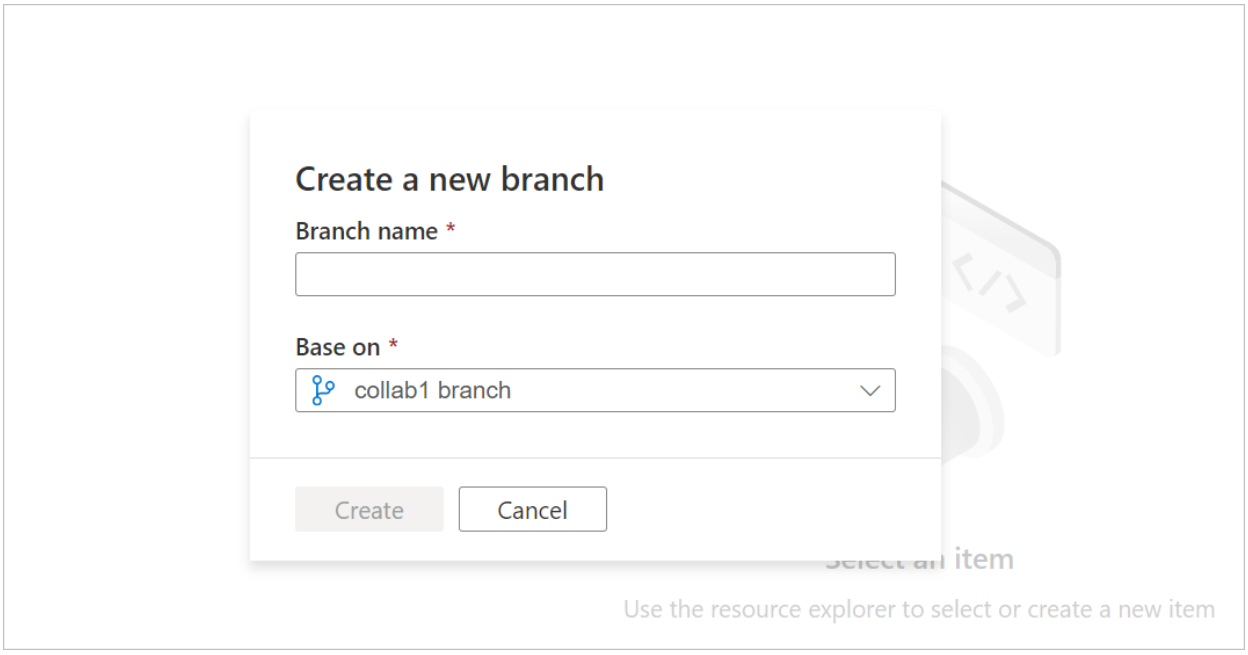
Version control systems (also known as *source control*) allows developers to collaborate on code and track changes.Source control is an essential tool for multi-developer projects.

Creating feature branches

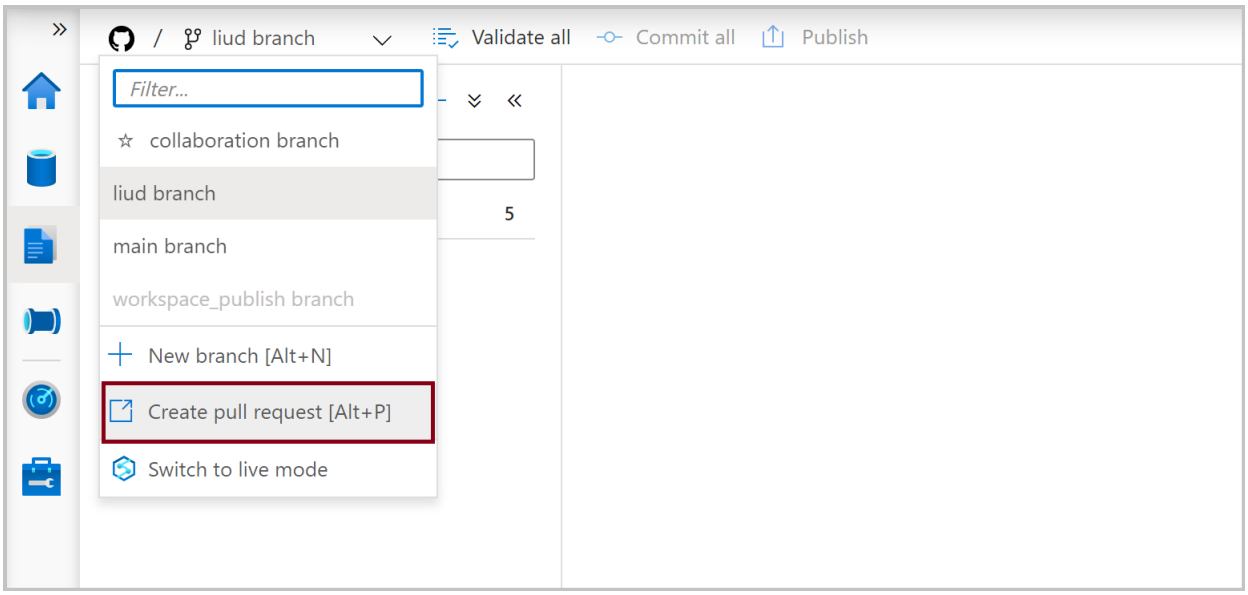
Each Git repository that's associated with a Synapse Studio has a collaboration branch. (`main` or `master` is the default collaboration branch). Users can also create feature branches by clicking **+ New Branch** in the branch dropdown.



Once the new branch pane appears, enter the name of your feature branch and select a branch to base the work off of.



When you are ready to merge the changes from your feature branch to your collaboration branch, click on the branch dropdown and select **Create pull request**. This action takes you to Git provider where you can raise pull requests, do code reviews, and merge changes to your collaboration branch. You are only allowed to publish to the Synapse service from your collaboration branch.



Configure publishing settings

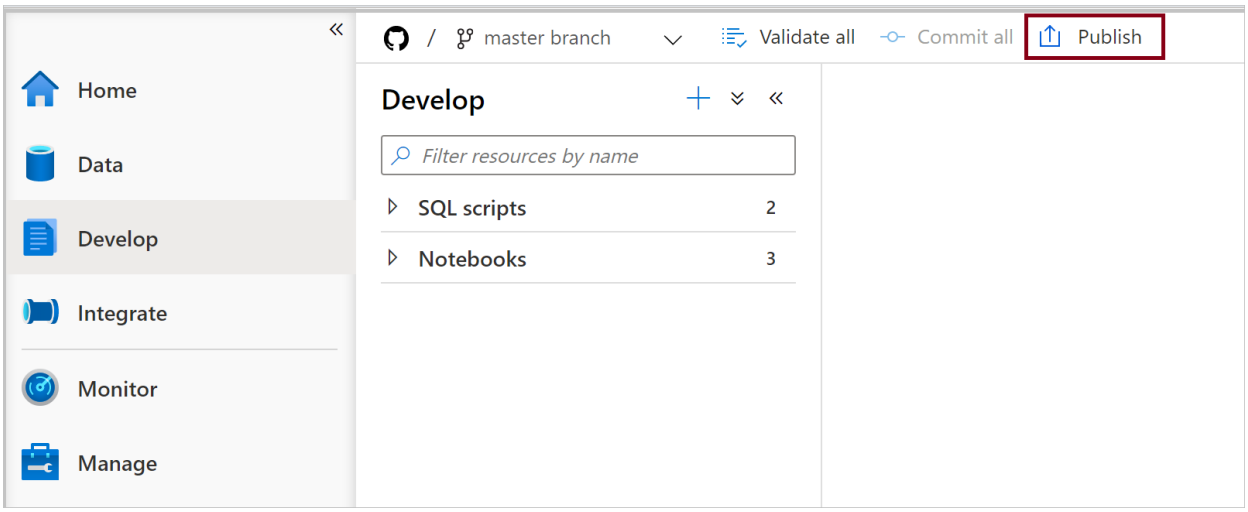
By default, Synapse Studio generates the workspace templates and saves them into a branch called `workspace_publish`. To configure a custom publish branch, add a `publish_config.json` file to the root folder in the collaboration branch. When publishing, Synapse Studio reads this file, looks for the field `publishBranch`, and saves workspace template files to the specified location. If the branch doesn't exist, Synapse Studio will automatically create it. And example of what this file looks like is below:

```
{
    "publishBranch": "workspace_publish"
}
```

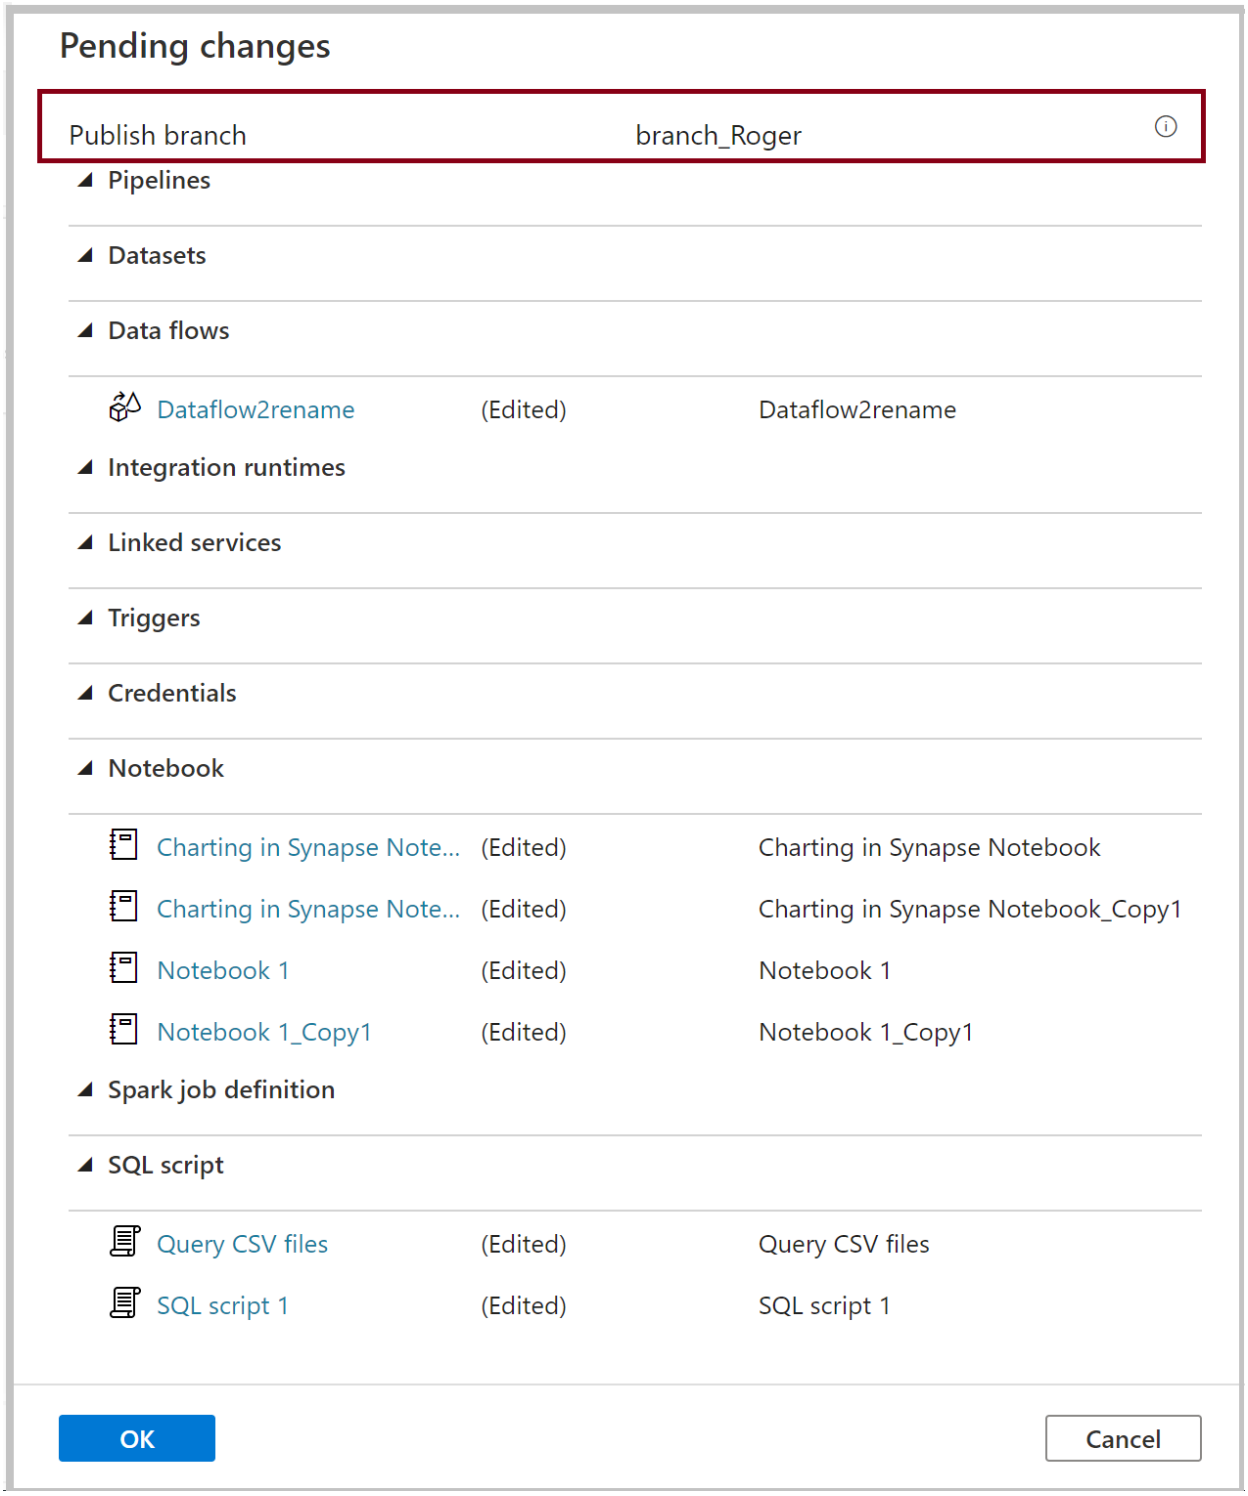
Synapse Studio can only have one publish branch at a time. When you specify a new publish branch, the previous publish branch would not been deleted. If you want to remove the previous publish branch, delete it manually.

Publish code changes

After merging changes to the collaboration branch , click **Publish** to manually publish your code changes in the collaboration branch to the Synapse service.



A side pane will open where you confirm that the publish branch and pending changes are correct. Once you verify your changes, click **OK** to confirm the publish.

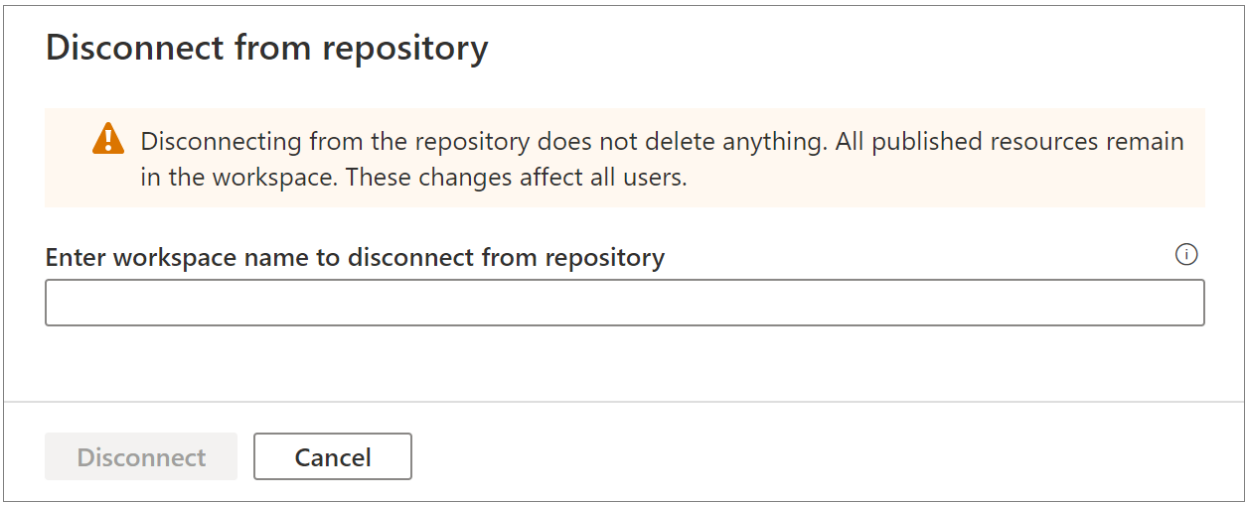


IMPORTANT

The collaboration branch is not representative of what's deployed in the service. The changes in collaboration branch *must* be published manually.

Switch to a different Git repository

To switch to a different Git repository, go to Git configuration page in the management hub under **Source control**. Select **Disconnect**.



Enter your workspace name and click **Disconnect** to remove the Git repository associated with your workspace.

After you remove the association with the current repo, you can configure your Git settings to use a different repo and then import existing resources to the new repo.

> **IMPORTANT**
> Removing Git configuration from a workspace doesn't delete anything from the repository. Synapse workspace will contain all published resources. You can continue to edit the workspace directly against the service.

Best practices for Git integration

- **Permissions**. After you have a git repository connected to your workspace, anyone who can access to your git repo with any role in your workspace will be able to update artifacts, like sql script, notebook,spark job definition, dataset, dataflow and pipeline in git mode. Typically you don't want every team member to have permissions to update workspace. Only grant git repository permission to Synapse workspace artifact authors.
- **Collaboration**. It's recommended to not allow direct check-ins to the collaboration branch. This restriction can help prevent bugs as every check-in will go through a pull request review process described in Creating feature branches.
- **Synapse live mode**. After publishing in git mode, all changes will be reflected in Synapse live mode. In Synapse live mode, publishing is disabled. And you can view, run artifacts in live mode if you have been granted the right permission.
- **Edit artifacts in Studio**. Synapse studio is the only place you can enable workspace source control and sync changes to git automatically. Any change via SDK, PowerShell, will not be synced to git. We recommend you always edit artifact in Studio when git is enabled.

Troubleshooting git integration

Access to git mode

If you have been granted the permission to the GitHub git repository linked with your workspace, but you can not access to Git mode:

1. Clear your cache and refresh the page.
2. Login your GitHub account.

Stale publish branch

If the publish branch is out of sync with the collaboration branch and contains out-of-date resources despite a recent publish, try following these steps:

1. Remove your current Git repository
2. Reconfigure Git with the same settings, but make sure **Import existing resources to repository** is checked and choose the same branch.
3. Create a pull request to merge the changes to the collaboration branch

Unsupported features

- Synapse Studio doesn't allow cherry-picking of commits or selective publishing of resources.
- Synapse Studio doesn't support customize commit message.
- By design, delete action in Studio will be committed to git directly

Next steps

- To implement continuous integration and deployment, see Continuous integration and delivery (CI/CD).

Continuous integration and delivery for an Azure Synapse Analytics workspace

8/19/2022 • 16 minutes to read • Edit Online

Continuous integration (CI) is the process of automating the build and testing of code every time a team member commits a change to version control. Continuous delivery (CD) is the process of building, testing, configuring, and deploying from multiple testing or staging environments to a production environment.

In an Azure Synapse Analytics workspace, CI/CD moves all entities from one environment (development, test, production) to another environment. Promoting your workspace to another workspace is a two-part process. First, use an Azure Resource Manager template (ARM template) to create or update workspace resources (pools and workspace). Then, migrate artifacts like SQL scripts and notebooks, Spark job definitions, pipelines, datasets, and other artifacts by using **Synapse Workspace Deployment** tools in Azure DevOps or on GitHub.

This article outlines how to use an Azure DevOps release pipeline and GitHub Actions to automate the deployment of an Azure Synapse workspace to multiple environments.

Prerequisites

To automate the deployment of an Azure Synapse workspace to multiple environments, the following prerequisites and configurations must be in place.

Azure DevOps

- Prepare an Azure DevOps project for running the release pipeline.
- Grant any users who will check in code Basic access at the organization level, so they can see the repository.
- Grant Owner permission to the Azure Synapse repository.
- Make sure that you've created a self-hosted Azure DevOps VM agent or use an Azure DevOps hosted agent.
- Grant permissions to create an Azure Resource Manager service connection for the resource group.
- An Azure Active Directory (Azure AD) administrator must install the Azure DevOps Synapse Workspace Deployment Agent extension in the Azure DevOps organization.
- Create or nominate an existing service account for the pipeline to run as. You can use a personal access token instead of a service account, but your pipelines won't work after the user account is deleted.

GitHub

- Create a GitHub repository that contains the Azure Synapse workspace artifacts and the workspace template.
- Make sure that you've created a self-hosted runner or use a GitHub-hosted runner.

Azure Active Directory

- If you're using a service principal, in Azure AD, create a service principal to use for deployment.
- If you're using a managed identity, enable the system-assigned managed identity on your VM in Azure as the agent or runner, and then add it to Azure Synapse Studio as Synapse admin.
- Use the Azure AD admin role to complete these actions.

Azure Synapse Analytics

> **NOTE**
>
> You can automate and deploy these prerequisites by using the same pipeline, an ARM template, or the Azure CLI, but these processes aren't described in this article.

- The "source" workspace that's used for development must be configured with a Git repository in Azure Synapse Studio. For more information, see Source control in Azure Synapse Studio.
- Set up a blank workspace to deploy to:
    1. Create a new Azure Synapse workspace.
    2. Grant the VM agent and the service principal Contributor permission to the resource group in which the new workspace is hosted.
    3. In the workspace, don't configure the Git repository connection.
    4. In the Azure portal, find the new Azure Synapse workspace, and then grant Owner permission to yourself and to the user that will run the Azure DevOps pipeline Azure Synapse workspace.
    5. Add the Azure DevOps VM agent and the service principal to the Contributor role for the workspace. (The role should have been inherited, but verify that it is.)
    6. In the Azure Synapse workspace, go to **Studio** > **Manage** > **Access Control**. Add the Azure DevOps VM agent and the service principal to the workspace admin group.
    7. Open the storage account that's used for the workspace. On the **Identity and access management** pane, add the VM agent and the service principal to the Storage Blob Data Contributor role.
    8. Create a key vault in the support subscription, and ensure that both the existing workspace and the new workspace have at least GET and LIST permissions to the vault.
    9. For the automated deployment to work, ensure that any connection strings that are specified in your linked services are in the key vault.

Other prerequisites

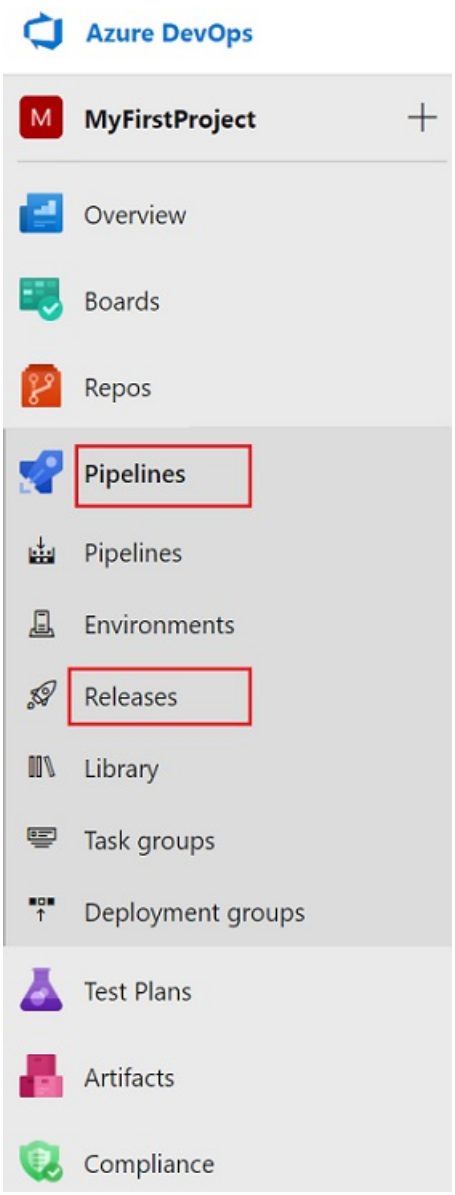
- Spark pools and self-hosted integration runtimes aren't created in a workspace deployment task. If you have a linked service that uses a self-hosted integration runtime, manually create the runtime in the new workspace.
- If the items in the development workspace are attached with the specific pools, make sure that you create or parameterize the same names for the pools in the target workspace in the parameter file.
- If your provisioned SQL pools are paused when you attempt to deploy, the deployment might fail.

For more information, see CI/CD in Azure Synapse Analytics Part 4 - The release pipeline.

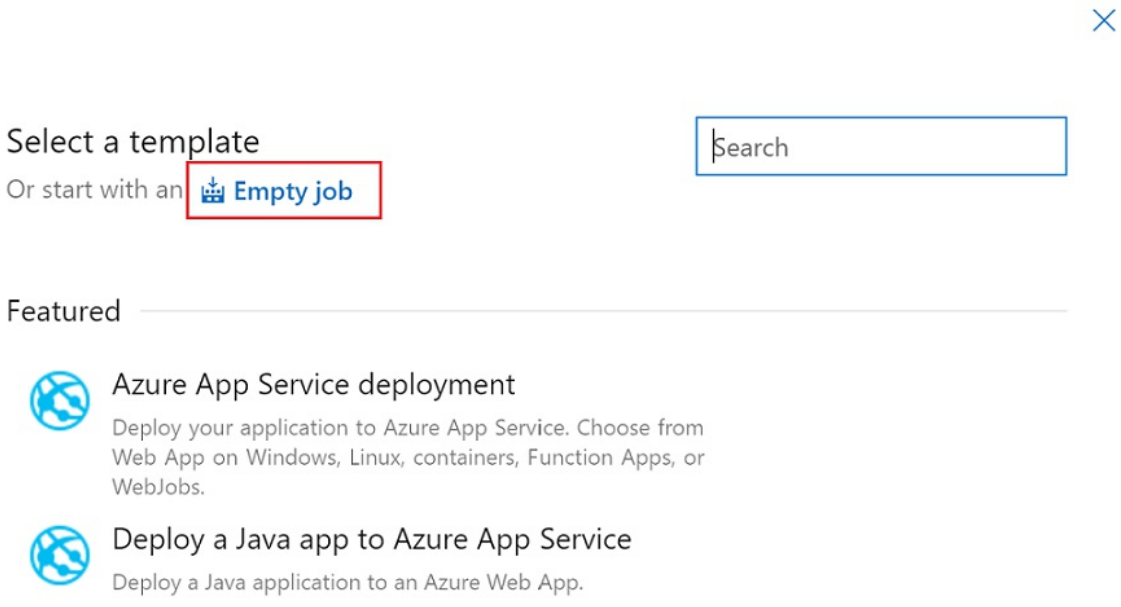
Set up a release pipeline in Azure DevOps

In this section, you'll learn how to deploy an Azure Synapse workspace in Azure DevOps.

1. In Azure DevOps, open the project you created for the release.
2. On the left menu, select **Pipelines** > **Releases**.

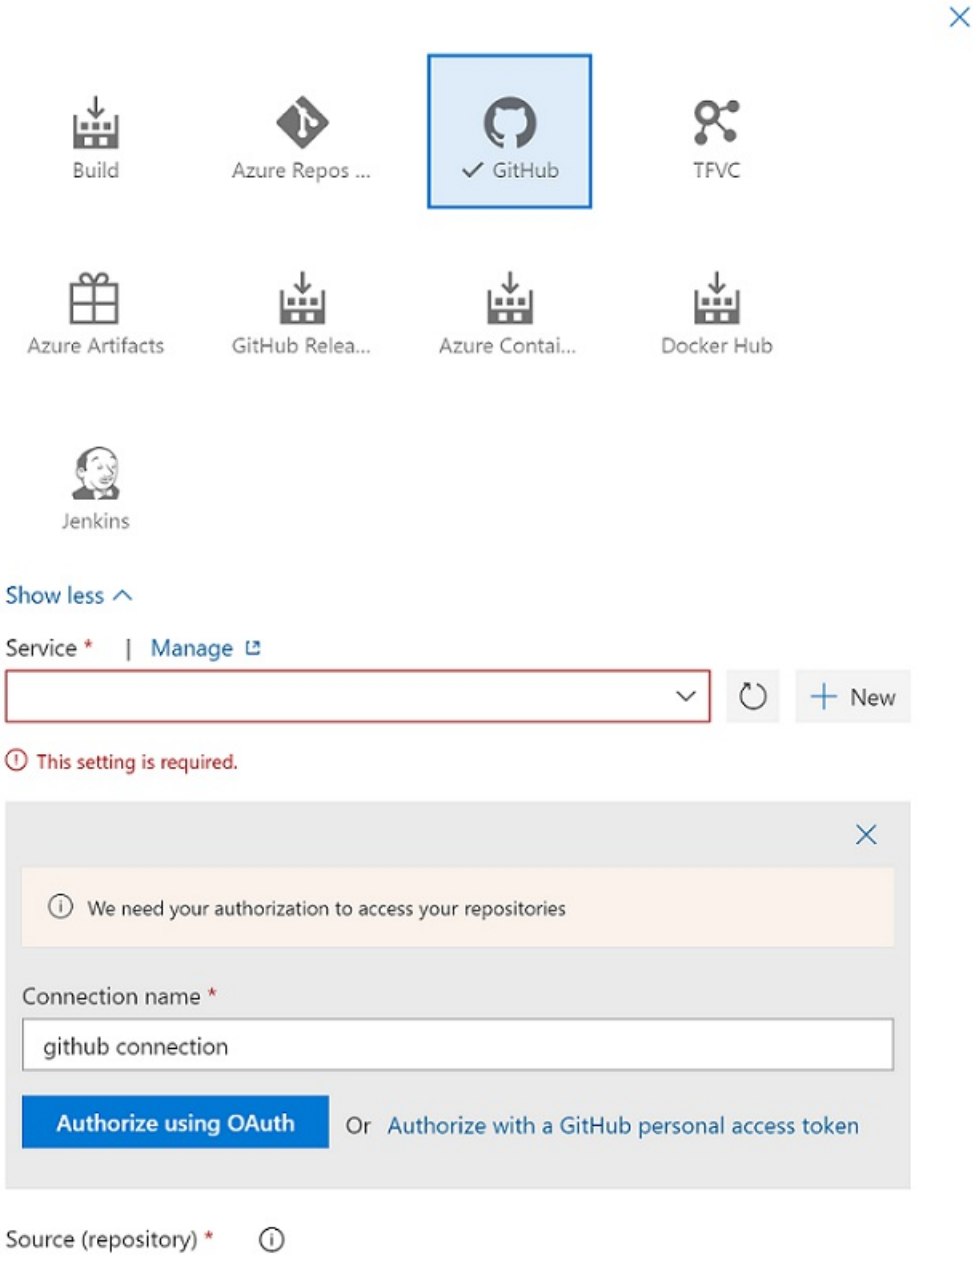


3. Select **New pipeline**. If you have existing pipelines, select **New** > **New release pipeline**.
4. Select the **Empty job** template.

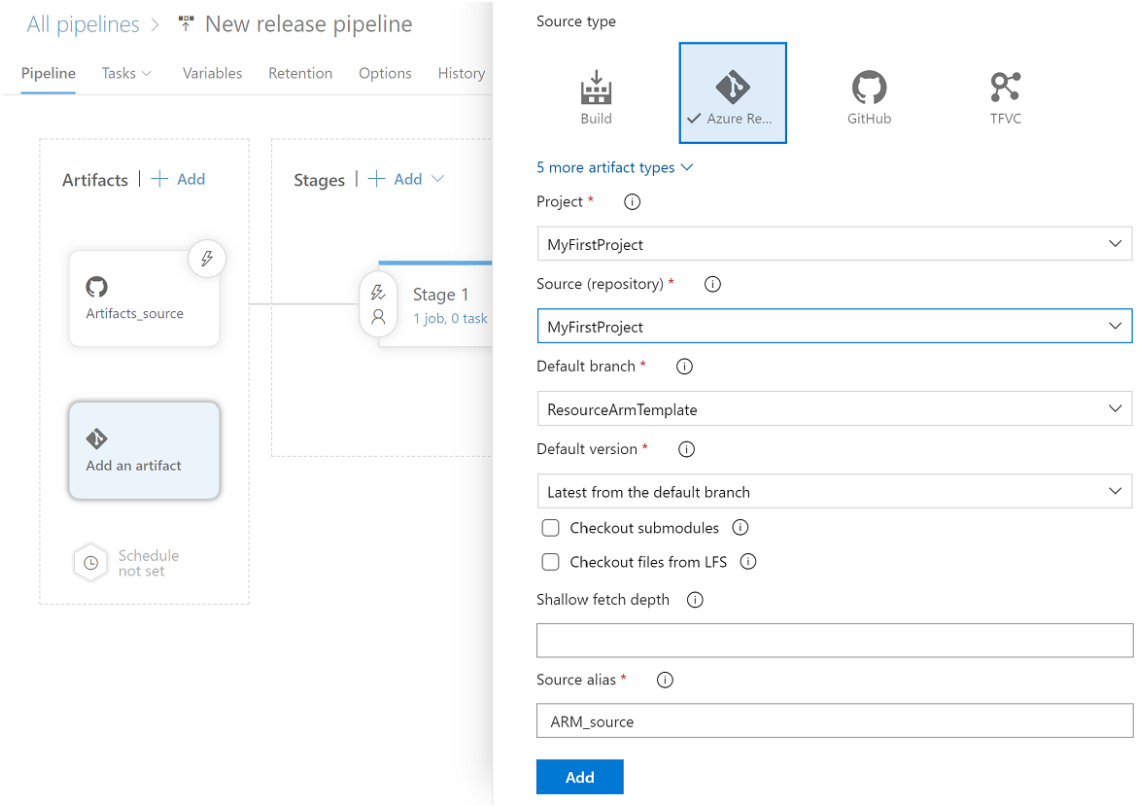


5. In **Stage name**, enter the name of your environment.

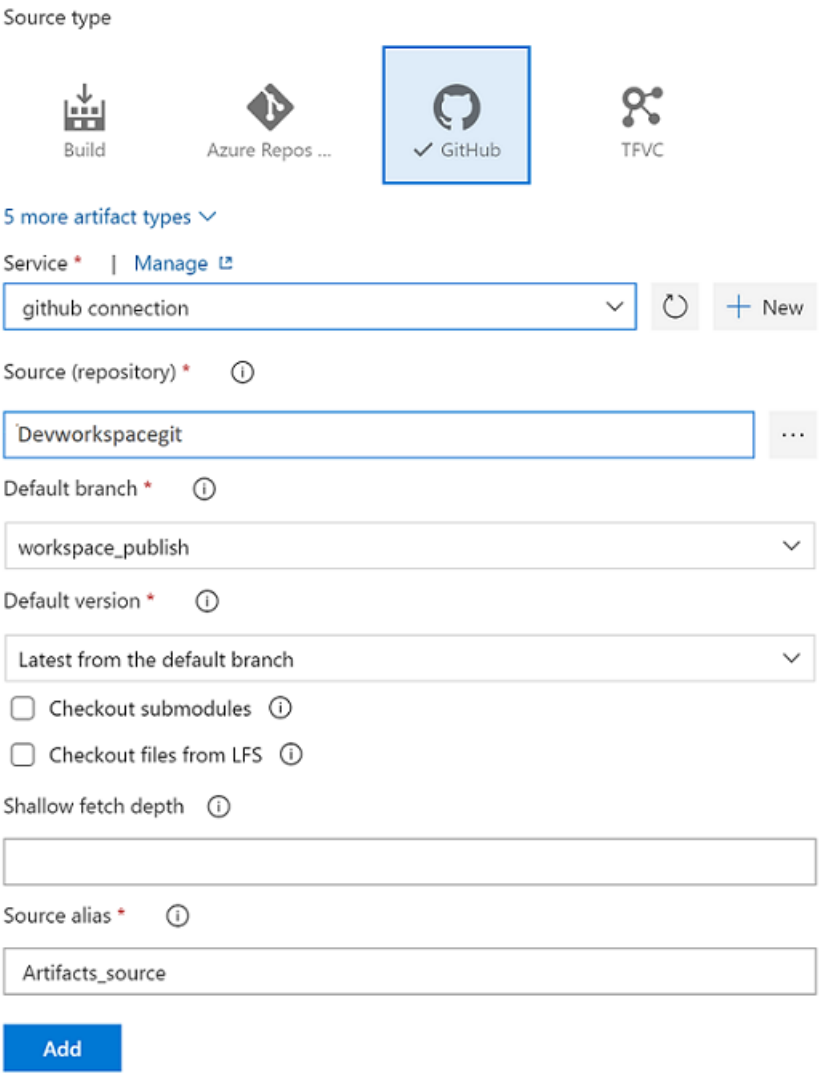
6. Select **Add artifact**, and then select the Git repository that's configured with Azure Synapse Studio in your development environment. Select the Git repository in which you manage your pools and workspace ARM template. If you use GitHub as the source, create a service connection for your GitHub account and pull repositories. For more information, see service connections.



7. Select the resource ARM template branch. For the **Default version**, select **Latest from default branch**.



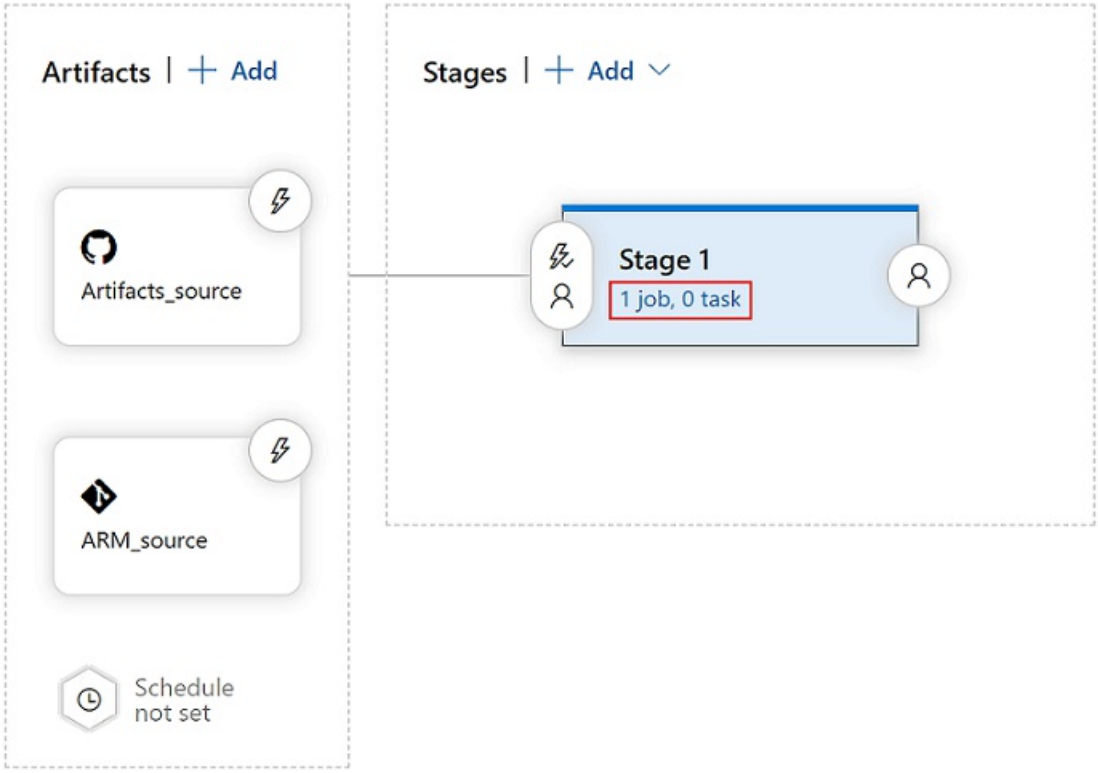
8. For the artifacts **Default branch**, select the repository publish branch or other non-publish branches which include Synapse artifacts. By default, the publish branch is `workspace_publish`. For the **Default version**, select **Latest from default branch**.



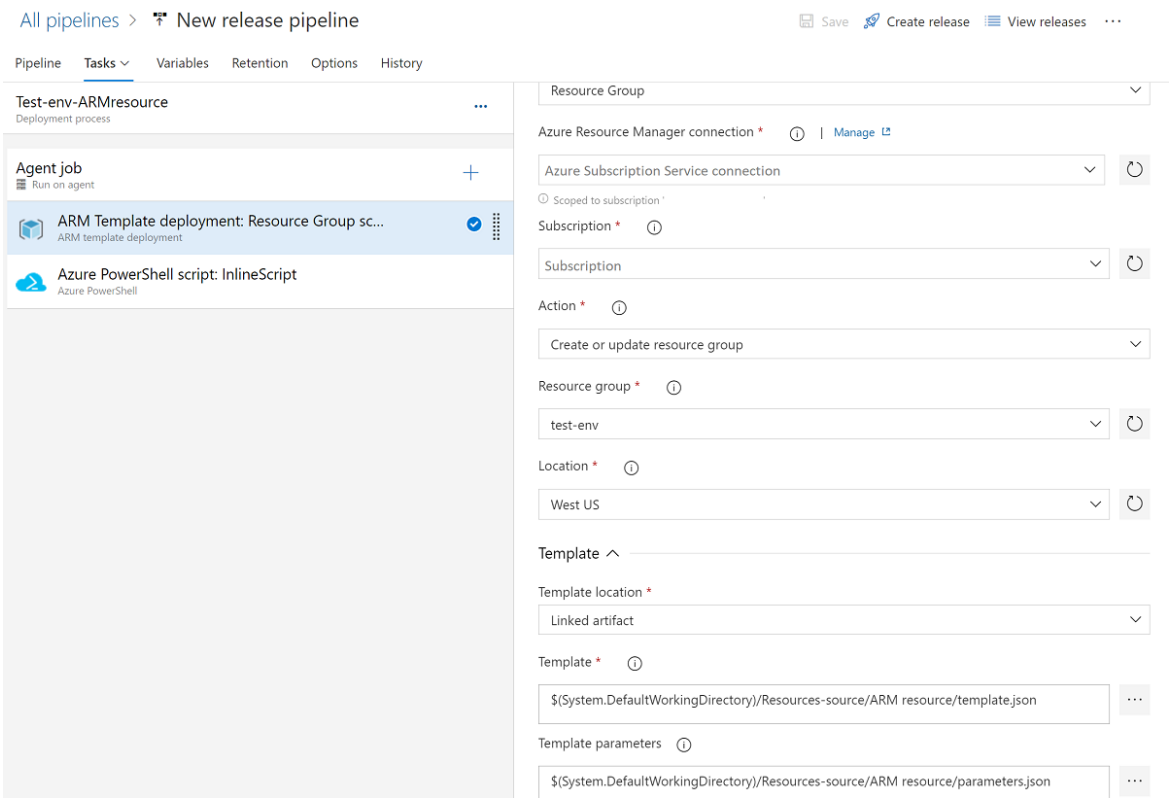
Set up a stage task for an ARM template to create and update a resource

If you have an ARM template that deploys a resource, such as an Azure Synapse workspace, a Spark and SQL pool, or a key vault, add an Azure Resource Manager deployment task to create or update those resources:

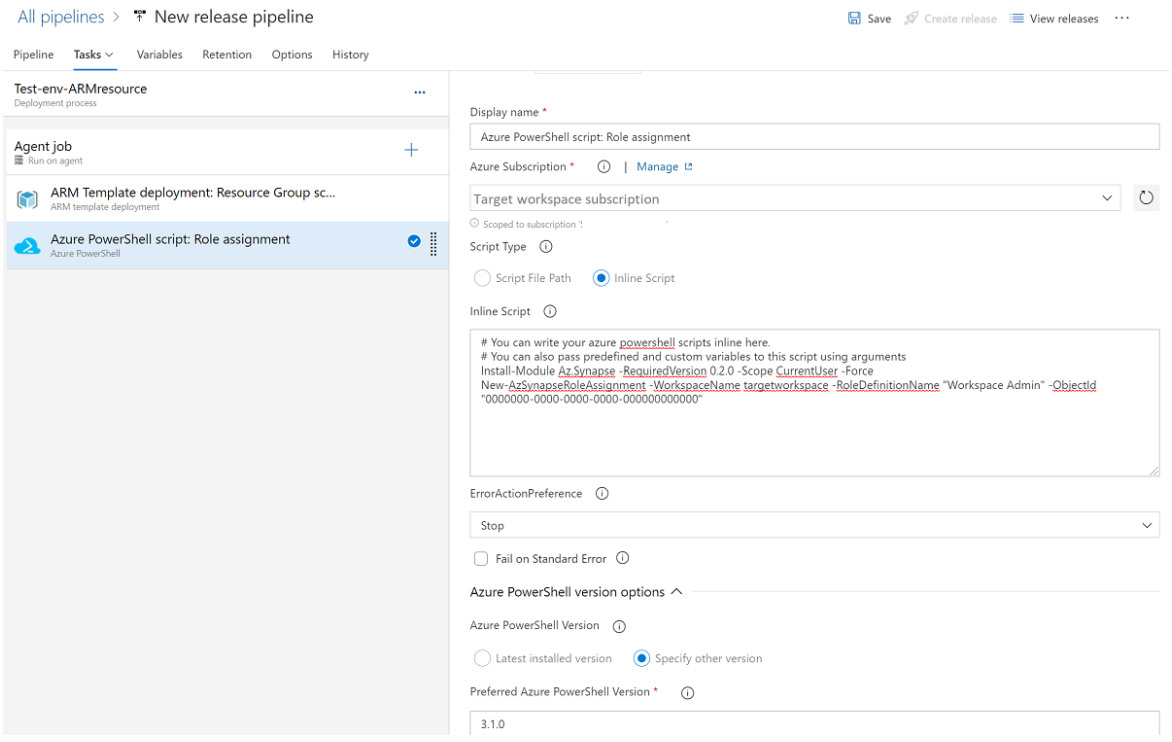
1. In the stage view, select **View stage tasks**.



2. Create a new task. Search for **ARM Template Deployment**, and then select **Add**.
3. On the deployment **Tasks** tab, select the subscription, resource group, and location for the workspace. Provide credentials if necessary.
4. For **Action**, select **Create or update resource group**.
5. For **Template**, select the ellipsis button (...). Go to the ARM template of the workspace.
6. For **Template parameters**, select ... to choose the parameters file.



7. For **Override template parameters**, select ..., and then enter the parameter values you want to use for the workspace.
8. For **Deployment mode**, select **Incremental**.
9. (Optional) Add **Azure PowerShell** for the grant and update the workspace role assignment. If you use a release pipeline to create an Azure Synapse workspace, the pipeline's service principal is added as the default workspace admin. You can run PowerShell to grant other accounts access to the workspace.



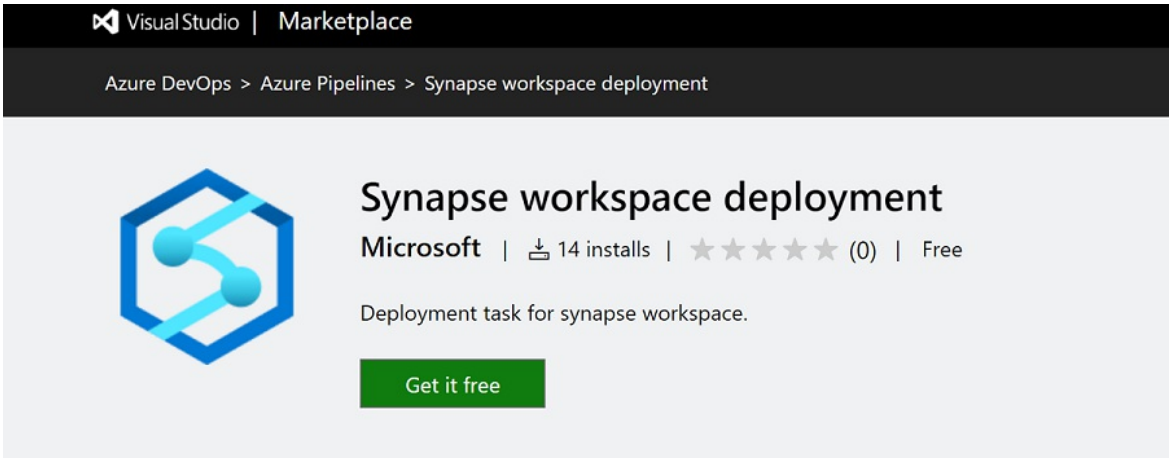
> **WARNING**
> In complete deployment mode, resources in the resource group that aren't specified in the new ARM template are *deleted*. For more information, see Azure Resource Manager deployment modes.

Set up a stage task for Azure Synapse artifacts deployment

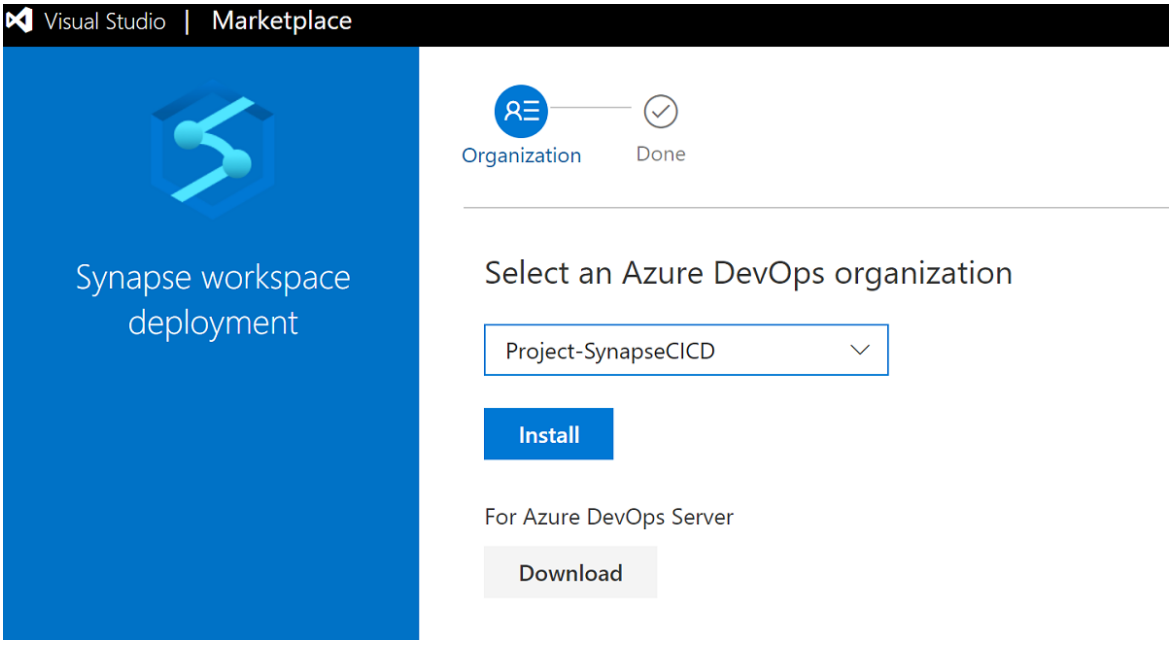
Use the Synapse workspace deployment extension to deploy other items in your Azure Synapse workspace. Items that you can deploy include datasets, SQL scripts and notebooks, spark job definitions, integration runtime, data flow, credentials, and other artifacts in workspace.

Install and add deployment extension

1. Search for and get the extension from Visual Studio Marketplace.

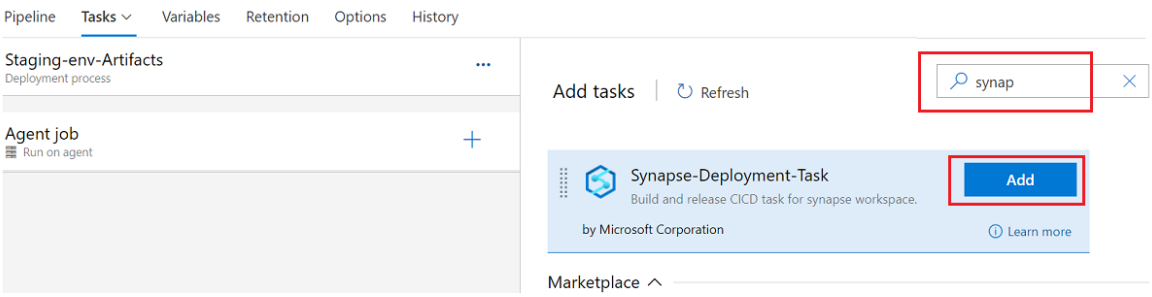


2. Select the Azure DevOps organization in which you want to install the extension.



3. Make sure that the Azure DevOps pipeline's service principal has been granted the Subscription permission and is assigned as the Synapse workspace admin for the workspace.

4. To create a new task, search for **Synapse workspace deployment**, and then select **Add**.



Configure the deployment task

The deployment task supports 3 types of operations, validate only, deploy and validate and deploy.

Validate is to validate the Synapse artifacts in non-publish branch with the task and generate the workspace template and parameter template file. The validation operation only works in the YAML pipeline. The sample YAML file is as below:

```
pool:
  vmImage: ubuntu-latest

resources:
  repositories:
  - repository: <repository name>
    type: git
    name: <name>
    ref: <user/collaboration branch>

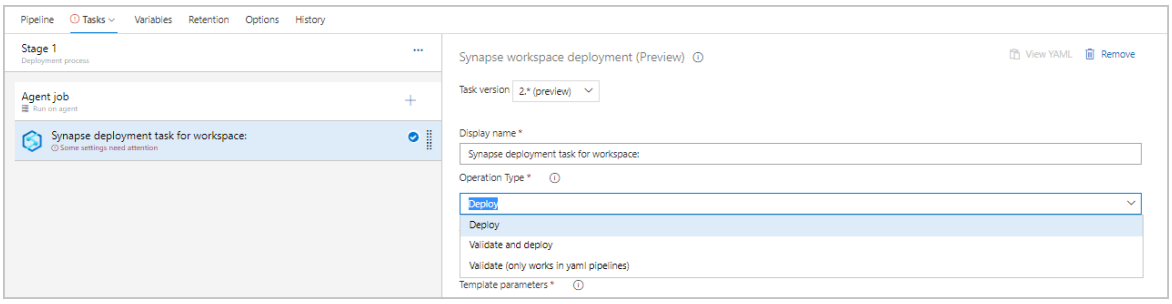
steps:
  - checkout: <name>
  - task: Synapse workspace deployment@2
    continueOnError: true
    inputs:
      operation: 'validate'
      ArtifactsFolder: '$(System.DefaultWorkingDirectory)/ArtifactFolder'
      TargetWorkspaceName: '<target workspace name>'
```

Deploy The inputs of the operation deploy include Synapse workspace template and parameter template, which can be created after publishing in the workspace publish branch or after the validation. It is same as the version 1.x.

Validate and deploy can be used to directly deploy the workspace from non-publish branch with the artifact root folder.

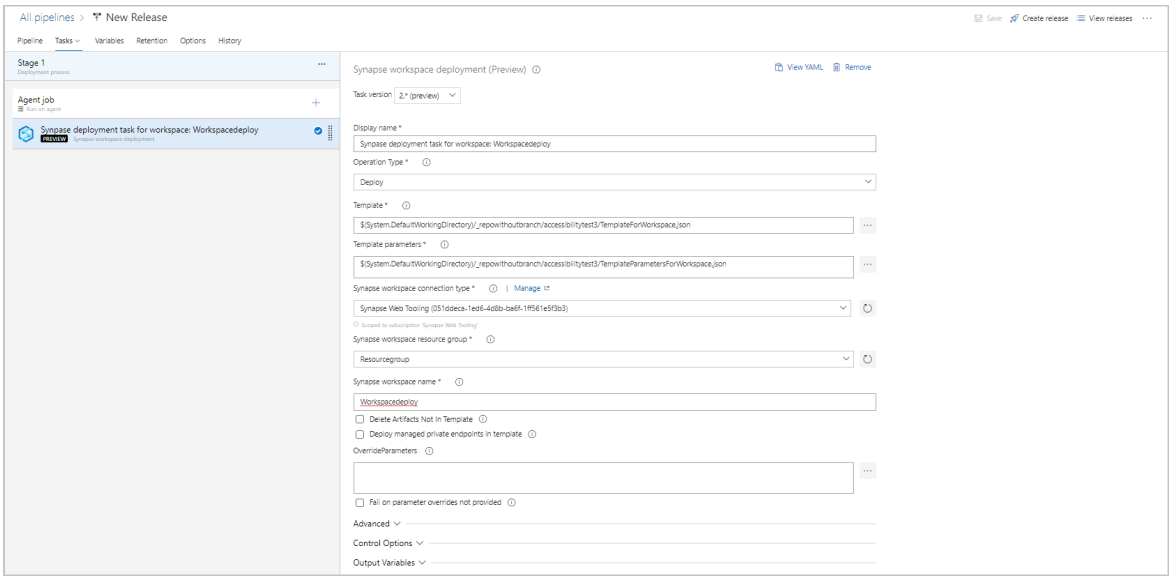
You can choose the operation types based on the use case. Following part is an example of the deploy.

1. In the task, select the operation type as **Deploy**.

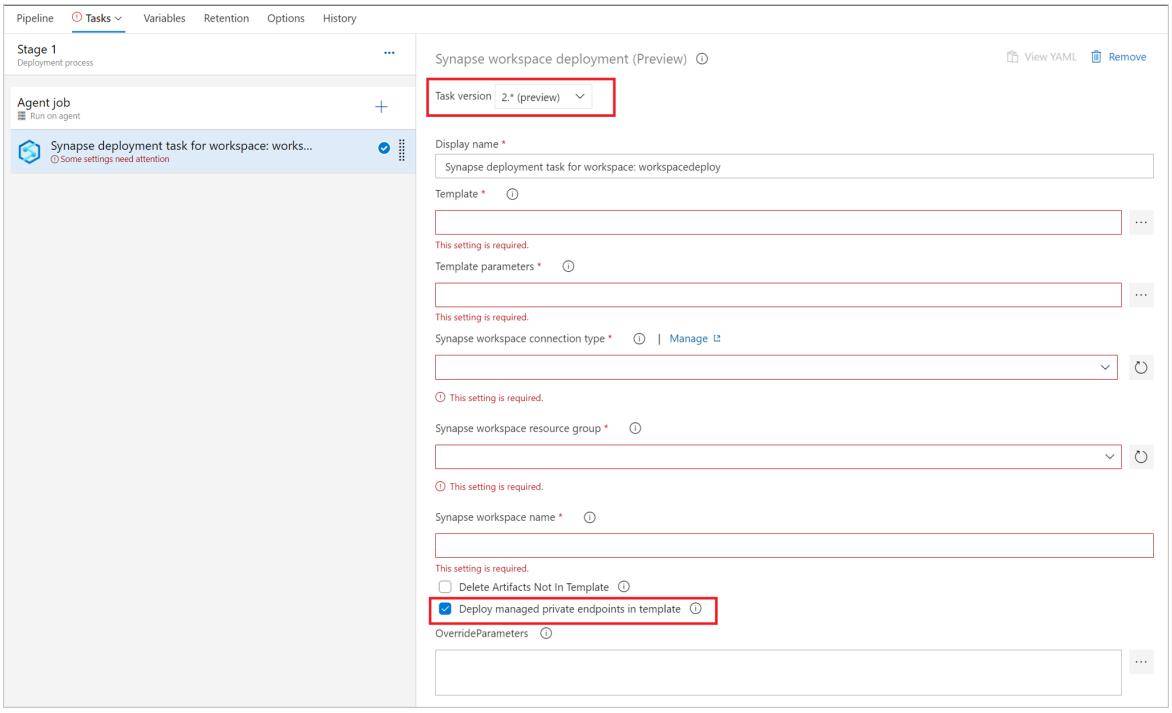


2. In the task, next to **Template**, select ... to choose the template file.
3. Next to **Template parameters**, select ... to choose the parameters file.
4. Select a connection, resource group, and name for the workspace.

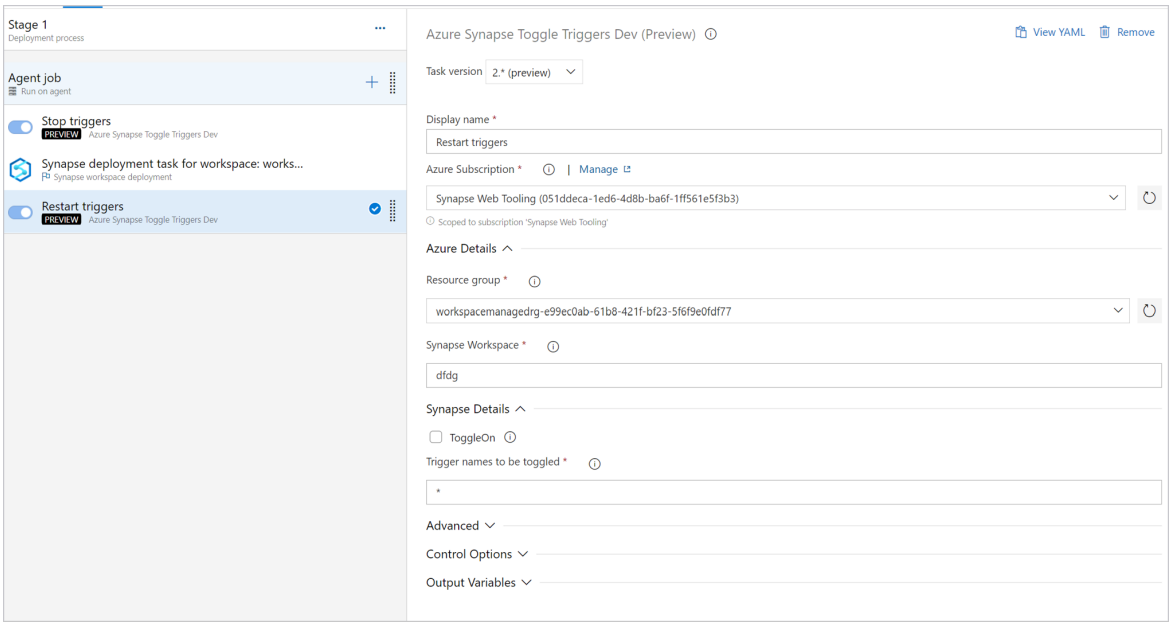
5. Next to **Override template parameters**, select ... . Enter the parameter values you want to use for the workspace, including connection strings and account keys that are used in your linked services. For more information, see CI/CD in Azure Synapse Analytics.



6. The deployment of managed private endpoint is only supported in version 2.x. please make sure you select the right version and check the **Deploy managed private endpoints in template**.



7. To manage triggers, you can use trigger toggle to stop the triggers before deployment. And you can also add a task to restart the triggers after the deployment task.

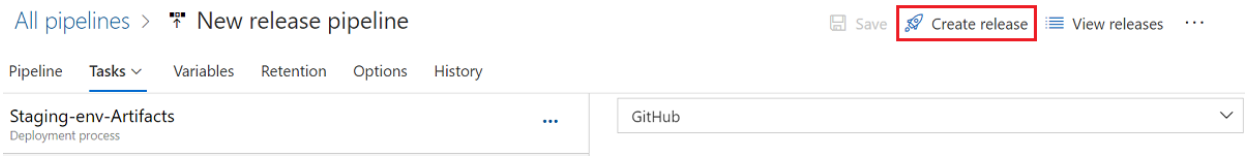


IMPORTANT

In CI/CD scenarios, the integration runtime type in different environments must be the same. For example, if you have a self-hosted integration runtime in the development environment, the same integration runtime must be self-hosted in other environments, such as in test and production. Similarly, if you're sharing integration runtimes across multiple stages, the integration runtimes must be linked and self-hosted in all environments, such as in development, test, and production.

Create a release for deployment

After you save all changes, you can select **Create release** to manually create a release. To learn how to automate release creation, see Azure DevOps release triggers.



Set up a release in GitHub Actions

In this section, you'll learn how to create GitHub workflows by using GitHub Actions for Azure Synapse workspace deployment.

You can use the GitHub Actions for Azure Resource Manager template to automate deploying an ARM template to Azure for the workspace and compute pools.

Workflow file

Define a GitHub Actions workflow in a YAML (.yml) file in the */.github/workflows/* path in your repository. The definition contains the various steps and parameters that make up the workflow.

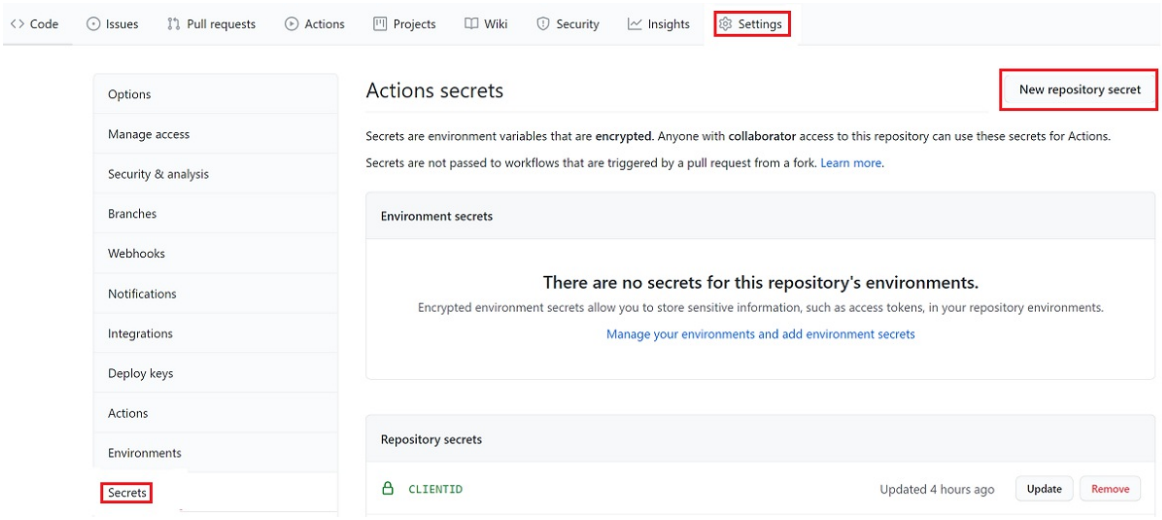
The .yml file has two sections:

SECTION	TASKS
Authentication	1. Define a service principal. 2. Create a GitHub secret.
Deploy	Deploy the workspace artifacts.

Configure GitHub Actions secrets

GitHub Actions secrets are environment variables that are encrypted. Anyone who has Collaborator permission to this repository can use these secrets to interact with Actions in the repository.

1. In the GitHub repository, select the **Settings** tab, and then select **Secrets** > **New repository secret**.



2. Add a new secret for the client ID, and add a new client secret if you use the service principal for deployment. You can also choose to save the subscription ID and tenant ID as secrets.

Add your workflow

In your GitHub repository, go to **Actions**.

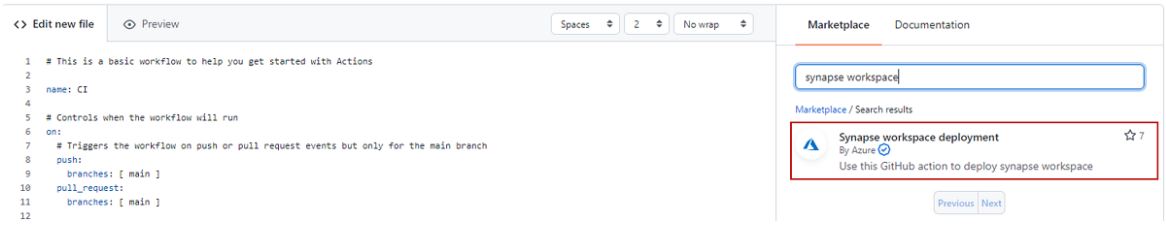
1. Select **Set up your workflow yourself**.

2. In the workflow file, delete everything after the `on:` section. For example, your remaining workflow might look like this example:

```
name: CI

on:
push:
    branches: [ master ]
pull_request:
    branches: [ master ]
```

3. Rename your workflow. On the **Marketplace** tab, search for the Synapse workspace deployment action, and then add the action.



4. Set the required values and the workspace template:

```
name: workspace deployment

on:
    push:
        branches: [ publish_branch ]
jobs:
    release:
        # You also can use the self-hosted runners.
        runs-on: windows-latest
        steps:
        # Checks out your repository under $GITHUB_WORKSPACE, so your job can access it.
        - uses: actions/checkout@v2
        - uses: azure/synapse-workspace-deployment@release-1.0
        with:
          TargetWorkspaceName: 'target workspace name'
          TemplateFile: './path of the TemplateForWorkspace.json'
          ParametersFile: './path of the TemplateParametersForWorkspace.json'
          OverrideArmParameters: './path of the parameters.yaml'
          environment: 'Azure Public'
          resourceGroup: 'target workspace resource group'
          clientId: ${{secrets.CLIENTID}}
          clientSecret:  ${{secrets.CLIENTSECRET}}
          subscriptionId: 'subscriptionId of the target workspace'
          tenantId: 'tenantId'
          DeleteArtifactsNotInTemplate: 'true'
          managedIdentity: 'False'
```

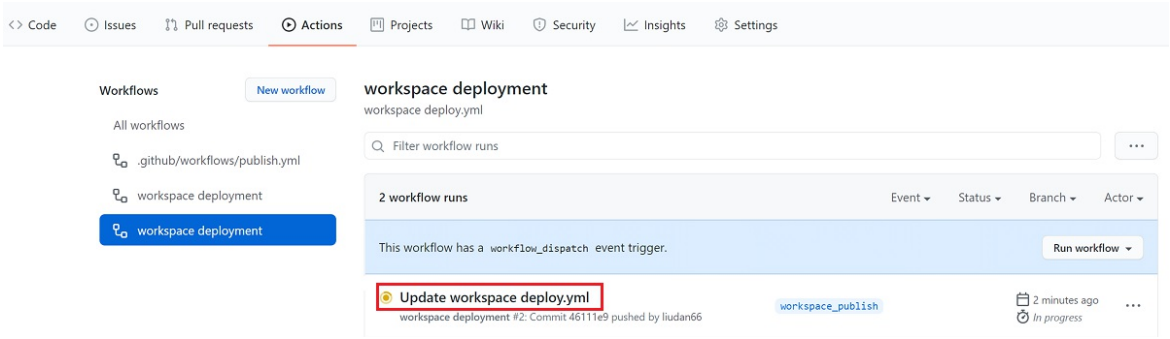
5. You're ready to commit your changes. Select **Start commit**, enter the title, and then add a description (optional). Then, select **Commit new file**.

The file appears in the *.github/workflows* folder in your repository.

> **NOTE**
> Managed identity is supported only with self-hosted VMs in Azure. Be sure to set the runner to self-hosted. Enable the system-assigned managed identity for your VM and add it to Azure Synapse Studio as Synapse admin.

Review your deployment

1. In your GitHub repository, go to **Actions**.
2. To see detailed logs of your workflow's run, open the first result:



Create custom parameters in the workspace template

If you use automated CI/CD and want to change some properties during deployment, but the properties aren't parameterized by default, you can override the default parameter template.

To override the default parameter template, create a custom parameter template named *template-parameters-definition.json* in the root folder of your Git branch. You must use this exact file name. When Azure Synapse workspace publishes from the collaboration branch or the deployment task validates the artifacts in other branches, it reads this file and uses its configuration to generate the parameters. If Azure Synapse workspace doesn't find that file, is uses the default parameter template.

Custom parameter syntax

You can use the following guidelines to create a custom parameters file:

- Enter the property path under the relevant entity type.
- Setting a property name to `*` indicates that you want to parameterize all properties under the property (only down to the first level, not recursively). You can set exceptions to this configuration.
- Setting the value of a property as a string indicates that you want to parameterize the property. Use the format `<action>:<name>:<stype>`.
  - `<action>` can be one of these characters:
    - `=` means keep the current value as the default value for the parameter.
    - `-` means don't keep the default value for the parameter.
    - `|` is a special case for secrets from Azure Key Vault for connection strings or keys.
  - `<name>` is the name of the parameter. If it's blank, it takes the name of the property. If the value starts with a `-` character, the name is shortened. For example, `AzureStorage1_properties_typeProperties_connectionString` would be shortened to `AzureStorage1_connectionString`.
  - `<stype>` is the type of parameter. If `<stype>` is blank, the default type is `string`. Supported values: `string`, `securestring`, `int`, `bool`, `object`, `secureobject` and `array`.
- Specifying an array in the file indicates that the matching property in the template is an array. Azure Synapse iterates through all the objects in the array by using the definition that's specified. The second object, a string, becomes the name of the property, which is used as the name for the parameter for each iteration.
- A definition can't be specific to a resource instance. Any definition applies to all resources of that type.
- By default, all secure strings (such as Key Vault secrets) and secure strings (such as connection strings, keys, and tokens) are parameterized.

Parameter template definition example

Here's an example of what a parameter template definition looks like:

```
{
    "Microsoft.Synapse/workspaces/notebooks": {
        "properties": {
            "bigDataPool": {
```

```
                "referenceName": "="
            }
        }
    },
    "Microsoft.Synapse/workspaces/sqlscripts": {
        "properties": {
            "content": {
                "currentConnection": {
                    "*": "-"
                }
            }
        }
    },
    "Microsoft.Synapse/workspaces/pipelines": {
        "properties": {
            "activities": [{
                "typeProperties": {
                    "waitTimeInSeconds": "-::int",
                    "headers": "=::object",
                    "activities": [
                        {
                            "typeProperties": {
                                "url": "-:-webUrl:string"
                            }
                        }
                    ]
                }
            }]
        }
    },
    "Microsoft.Synapse/workspaces/integrationRuntimes": {
        "properties": {
            "typeProperties": {
                "*": "="
            }
        }
    },
    "Microsoft.Synapse/workspaces/triggers": {
        "properties": {
            "typeProperties": {
                "recurrence": {
                    "*": "=",
                    "interval": "=:triggerSuffix:int",
                    "frequency": "=:-freq"
                },
                "maxConcurrency": "="
            }
        }
    },
    "Microsoft.Synapse/workspaces/linkedServices": {
        "*": {
            "properties": {
                "typeProperties": {
                    "accountName": "=",
                    "username": "=",
                    "connectionString": "|:-connectionString:secureString",
                    "secretAccessKey": "|"
                }
            }
        },
        "AzureDataLakeStore": {
            "properties": {
                "typeProperties": {
                    "dataLakeStoreUri": "="
                }
            }
        },
        "AzureKeyVault": {
            "properties": {
```

```
                "typeProperties": {
                    "baseUrl": "|:baseUrl:secureString"
                },
                "parameters": {
                    "KeyVaultURL": {
                        "type": "=",
                        "defaultValue": "|:defaultValue:secureString"
                    }
                }
            }
        }
    },
    "Microsoft.Synapse/workspaces/datasets": {
        "properties": {
            "typeProperties": {
                "*": "="
            }
        }
    },
    "Microsoft.Synapse/workspaces/credentials" : {
        "properties": {
            "typeProperties": {
                "resourceId": "="
            }
        }
    }
}
```

Here's an explanation of how the preceding template is constructed, by resource type.

`notebooks`

- Any property in the `properties/bigDataPool/referenceName` path is parameterized with its default value. You can parameterize an attached Spark pool for each notebook file.

`sqlscripts`

- In the `properties/content/currentConnection` path, both the `poolName` and the `databaseName` properties are parameterized as strings without the default values in the template.

`pipelines`

- Any property in the `activities/typeProperties/waitTimeInSeconds` path is parameterized. Any activity in a pipeline that has a code-level property named `waitTimeInSeconds` (for example, the `Wait` activity) is parameterized as a number, with a default name. The property won't have a default value in the Resource Manager template. Instead, the property will be required input during Resource Manager deployment.
- The `headers` property (for example, in a `Web` activity) is parameterized with the `object` type (Object). The `headers` property has a default value that is the same value as the source factory.

`integrationRuntimes`

- All properties in the `typeProperties` path are parameterized with their respective default values. For example, two properties are under `IntegrationRuntimes` type properties: `computeProperties` and `ssisProperties`. Both property types are created with their respective default values and types (Object).

`triggers`

- Under `typeProperties`, two properties are parameterized:
  - The `maxConcurrency` property has a default value and is the `string` type. The default parameter name of the `maxConcurrency` property is `<entityName>_properties_typeProperties_maxConcurrency`.
  - The `recurrence` property also is parameterized. All properties under the `recurrence` property are set

to be parameterized as strings, with default values and parameter names. An exception is the `interval` property, which is parameterized as the `int` type. The parameter name is suffixed with `<entityName>_properties_typeProperties_recurrence_triggerSuffix`. Similarly, the `freq` property is a string and is parameterized as a string. However, the `freq` property is parameterized without a default value. The name is shortened and suffixed, such as `<entityName>_freq`.

`linkedServices`

- Linked services are unique. Because linked services and datasets have a wide range of types, you can provide type-specific customization. In the preceding example, for all linked services of the `AzureDataLakeStore` type, a specific template is applied. For all others (identified through the use of the `*` character), a different template is applied.
- The `connectionString` property is parameterized as a `securestring` value. It doesn't have a default value. The parameter name is shortened and suffixed with `connectionString`.
- The `secretAccessKey` property is parameterized as an `AzureKeyVaultSecret` value (for example, in an Amazon S3 linked service). The property is automatically parameterized as an Azure Key Vault secret and fetched from the configured key vault. You also can parameterize the key vault itself.

`datasets`

- Although you can customize types in datasets, an explicit *-level configuration isn't required. In the preceding example, all dataset properties under `typeProperties` are parameterized.

Best practices for CI/CD

If you're using Git integration with your Azure Synapse workspace and you have a CI/CD pipeline that moves your changes from development to test, and then to production, we recommend these best practices:

- **Integrate only the development workspace with Git**. If you use Git integration, integrate only your *development* Azure Synapse workspace with Git. Changes to test and production workspaces are deployed via CI/CD and don't need Git integration.
- **Prepare pools before you migrate artifacts**. If you have a SQL script or notebook attached to pools in the development workspace, use the same name for pools in different environments.
- **Sync versioning in infrastructure as code scenarios**. To manage infrastructure (networks, virtual machines, load balancers, and connection topology) in a descriptive model, use the same versioning that the DevOps team uses for source code.
- **Review Azure Data Factory best practices**. If you use Data Factory, see the best practices for Data Factory artifacts.

Troubleshoot artifacts deployment

Use the Synapse workspace deployment task

In Azure Synapse, unlike in Data Factory, some artifacts aren't Resource Manager resources. You can't use the ARM template deployment task to deploy Azure Synapse artifacts. Instead, use the Synapse workspace deployment task.

Unexpected token error in release

If your parameter file has parameter values that aren't escaped, the release pipeline fails to parse the file and generates an `unexpected token` error. We suggest that you override parameters or use Key Vault to retrieve parameter values. You also can use double escape characters to resolve the issue.

Azure Policy Regulatory Compliance controls for Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Regulatory Compliance in Azure Policy provides Microsoft created and managed initiative definitions, known as *built-ins*, for the **compliance domains** and **security controls** related to different compliance standards. This page lists the **compliance domains** and **security controls** for Azure App Configuration. You can assign the built-ins for a **security control** individually to help make your Azure resources compliant with the specific standard.

The title of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Policy Version** column to view the source on the Azure Policy GitHub repo.

> **IMPORTANT**
>
> Each control is associated with one or more Azure Policy definitions. These policies might help you assess compliance with the control. However, there often isn't a one-to-one or complete match between a control and one or more policies. As such, **Compliant** in Azure Policy refers only to the policies themselves. This doesn't ensure that you're fully compliant with all requirements of a control. In addition, the compliance standard includes controls that aren't addressed by any Azure Policy definitions at this time. Therefore, compliance in Azure Policy is only a partial view of your overall compliance status. The associations between controls and Azure Policy Regulatory Compliance definitions for these compliance standards can change over time.

CMMC Level 3

To review how the available Azure Policy built-ins for all Azure services map to this compliance standard, see Azure Policy Regulatory Compliance - CMMC Level 3. For more information about this compliance standard, see Cybersecurity Maturity Model Certification (CMMC).

DOMAIN	CONTROL ID	CONTROL TITLE	POLICY (AZURE PORTAL)	POLICY VERSION (GITHUB)

Encryption for Azure Synapse Analytics workspaces

8/19/2022 • 5 minutes to read • Edit Online

This article will describe:

- Encryption of data at rest in Synapse Analytics workspaces.
- Configuration of Synapse workspaces to enable encryption with a customer managed key.
- Managing keys used to encrypt data in workspaces.

Encryption of data at rest

A complete Encryption-at-Rest solution ensures the data is never persisted in unencrypted form. Double encryption of data at rest mitigates threats with two, separate layers of encryption to protect against compromises of any single layer. Azure Synapse Analytics offers a second layer of encryption for the data in your workspace with a customer-managed key. This key is safeguarded in your Azure Key Vault, which allows you to take ownership of key management and rotation.

The first layer of encryption for Azure services is enabled with platform-managed keys. By default, Azure Disks, and data in Azure Storage accounts are automatically encrypted at rest. Learn more about how encryption is used in Microsoft Azure in the Azure Encryption Overview.

> **NOTE**
> Some items considered customer content, such as table names, object names, and index names, may be transmitted in log files for support and troubleshooting by Microsoft.

Azure Synapse encryption

This section will help you better understand how customer-managed key encryption is enabled and enforced in Synapse workspaces. This encryption uses existing keys or new keys generated in Azure Key Vault. A single key is used to encrypt all the data in a workspace. Synapse workspaces support RSA 2048 and 3072 byte-sized keys, and RSA-HSM keys.

> **NOTE**
> Synapse workspaces do not support the use of EC, EC-HSM, and oct-HSM keys for encryption.

The data in the following Synapse components is encrypted with the customer-managed key configured at the workspace level:

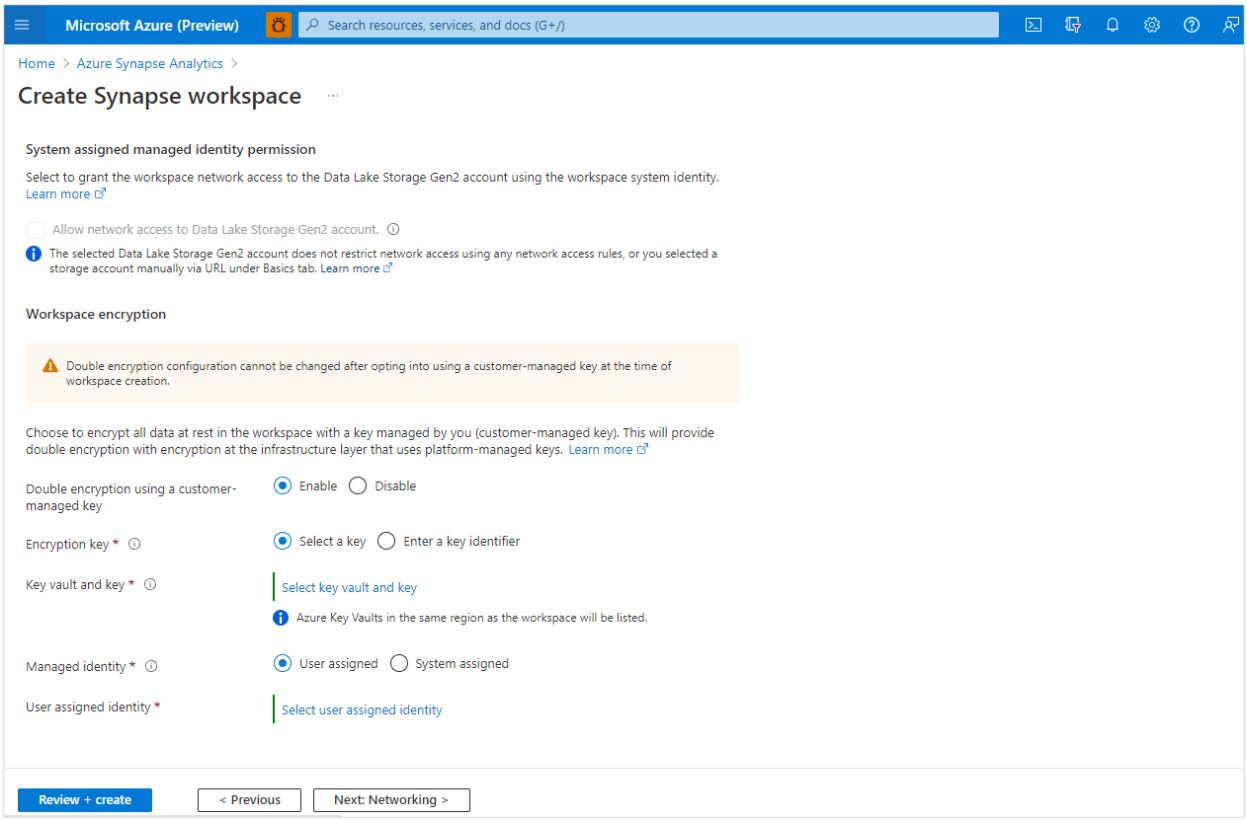
- SQL pools
- Dedicated SQL pools
- Serverless SQL pools
- Apache Spark pools
- Azure Data Factory integration runtimes, pipelines, datasets.

Workspace encryption configuration

Workspaces can be configured to enable double encryption with a customer-managed key at the time of

workspace creation. Enable double encryption using a customer-managed key on the "Security" tab when creating your new workspace. You can choose to enter a key identifier URI or select from a list of key vaults in the **same region** as the workspace. The Key Vault itself needs to have **purge protection enabled**.

> **IMPORTANT**
>
> The configuration setting for double encryption cannot be changed after the workspace is created.



Key access and workspace activation

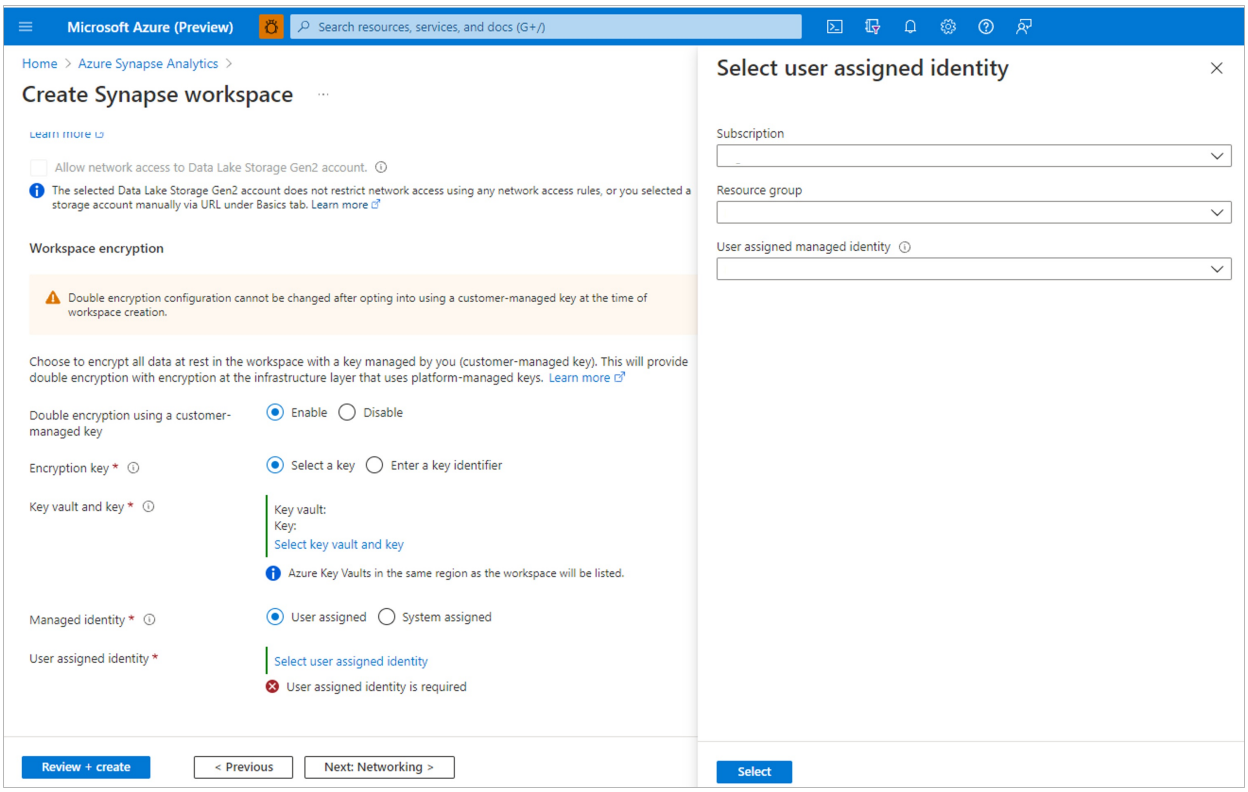
The Azure Synapse encryption model with customer-managed keys involves the workspace accessing the keys in Azure Key Vault to encrypt and decrypt as needed. The keys are made accessible to the workspace either through an access policy or Azure Key Vault RBAC. When granting permissions via an Azure Key Vault access policy, choose the "Application-only" option during policy creation (select the workspaces managed identity and do not add it as an authorized application).

The workspace managed identity must be granted the permissions it needs on the key vault before the workspace can be activated. This phased approach to workspace activation ensures that data in the workspace is encrypted with the customer-managed key. Encryption can be enabled or disabled for individual dedicated SQL Pools. Each dedicated pool is not enabled for encryption by default.

Using a User-assigned Managed identity

Workspaces can be configured to use a User-assigned Managed identity to access your customer-managed key stored in Azure Key Vault. Configure a User-assigned Managed identity to avoid phased activation of your Azure Synapse workspace when using double encryption with customer-managed keys. The Managed Identity Contributor built-in role is required to assign a user-assigned managed identity to an Azure Synapse workspace.

> **NOTE**
>
> A User-assigned Managed Identity cannot be configured to access customer-managed key when Azure Key Vault is behind a firewall.



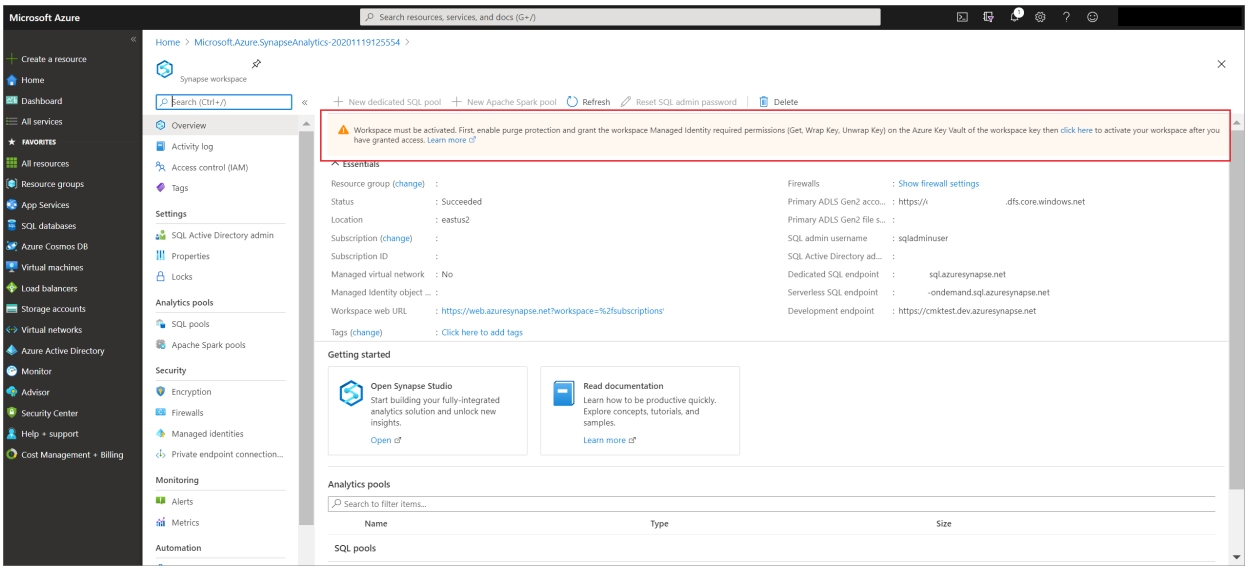
Permissions

To encrypt or decrypt data at rest, the managed identity must have the following permissions. Similarly, if you are using a Resource Manager template to create a new key, the 'keyOps' parameter of the template must have the following permissions:

- WrapKey (to insert a key into Key Vault when creating a new key).
- UnwrapKey (to get the key for decryption).
- Get (to read the public part of a key)

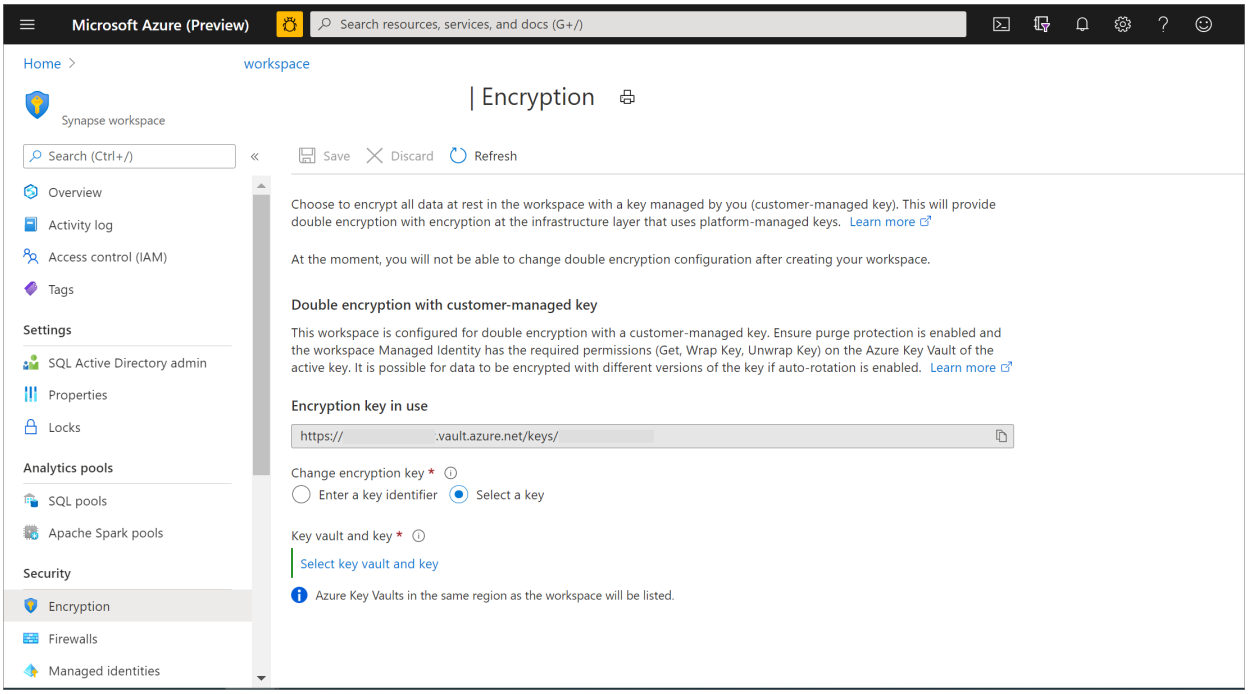
Workspace activation

If you do not configure a user-assigned managed identity to access customer managed keys during workspace creation, your workspace will remain in a "Pending" state until activation succeeds. The workspace must be activated before you can fully use all functionality. For example, you can only create a new dedicated SQL pool once activation succeeds. Grant the workspace managed identity access to the key vault and select the activation link in the workspace Azure portal banner. Once the activation completes successfully, your workspace is ready to use with the assurance that all data in it's protected with your customer-managed key. As previously noted, the key vault must have purge protection enabled for activation to succeed.



Manage the workspace customer-managed key

You can change the customer-managed key used to encrypt data from the **Encryption** page in the Azure portal. Here too, you can choose a new key using a key identifier or select from Key Vaults that you have access to in the same region as the workspace. If you choose a key in a different key vault from the ones previously used, grant the workspace-managed identity "Get", "Wrap", and "Unwrap" permissions on the new key vault. The workspace will validate its access to the new key vault and all data in the workspace will be re-encrypted with the new key.



> **IMPORTANT**
>
> When changing the encryption key of a workspace, retain the key until you replace it in the workspace with a new key. This is to allow decryption of data with the old key before it gets re-encrypted with the new key.

Azure Key Vaults policies for automatic, periodic rotation of keys, or actions on the keys can result in the creation of new key versions. You can choose to re-encrypt all the data in the workspace with the latest version of the active key. To-re-encrypt, change the key in the Azure portal to a temporary key and then switch back to the key you wish to use for encryption. As an example, to update data encryption using the latest version of active key Key1, change the workspace customer-managed key to temporary key, Key2. Wait for encryption with Key2 to finish. Then switch the workspace customer-managed key back to Key1-data in the workspace will be re-encrypted with the latest version of Key1.

> **NOTE**
>
> Azure Synapse Analytics does not automatically re-encrypt data when new key versions are created. To ensure consistency in your workspace, force the re-encryption of data using the process detailed above.

SQL Transparent Data Encryption with service-managed keys

SQL Transparent Data Encryption (TDE) is available for dedicated SQL Pools in workspaces *not* enabled for double encryption. In this type of workspace, a service-managed key is used to provide double encryption for the data in the dedicated SQL pools. TDE with the service-managed key can be enabled or disabled for individual dedicated SQL pools.

Next steps

- Use built-in Azure Policies to implement encryption protection for Synapse workspaces
- Create an Azure key vault and a key by using Resource Manager template

Azure Synapse Analytics IP firewall rules

8/19/2022 • 2 minutes to read • Edit Online

This article will explain IP firewall rules and teach you how to configure them in Azure Synapse Analytics.

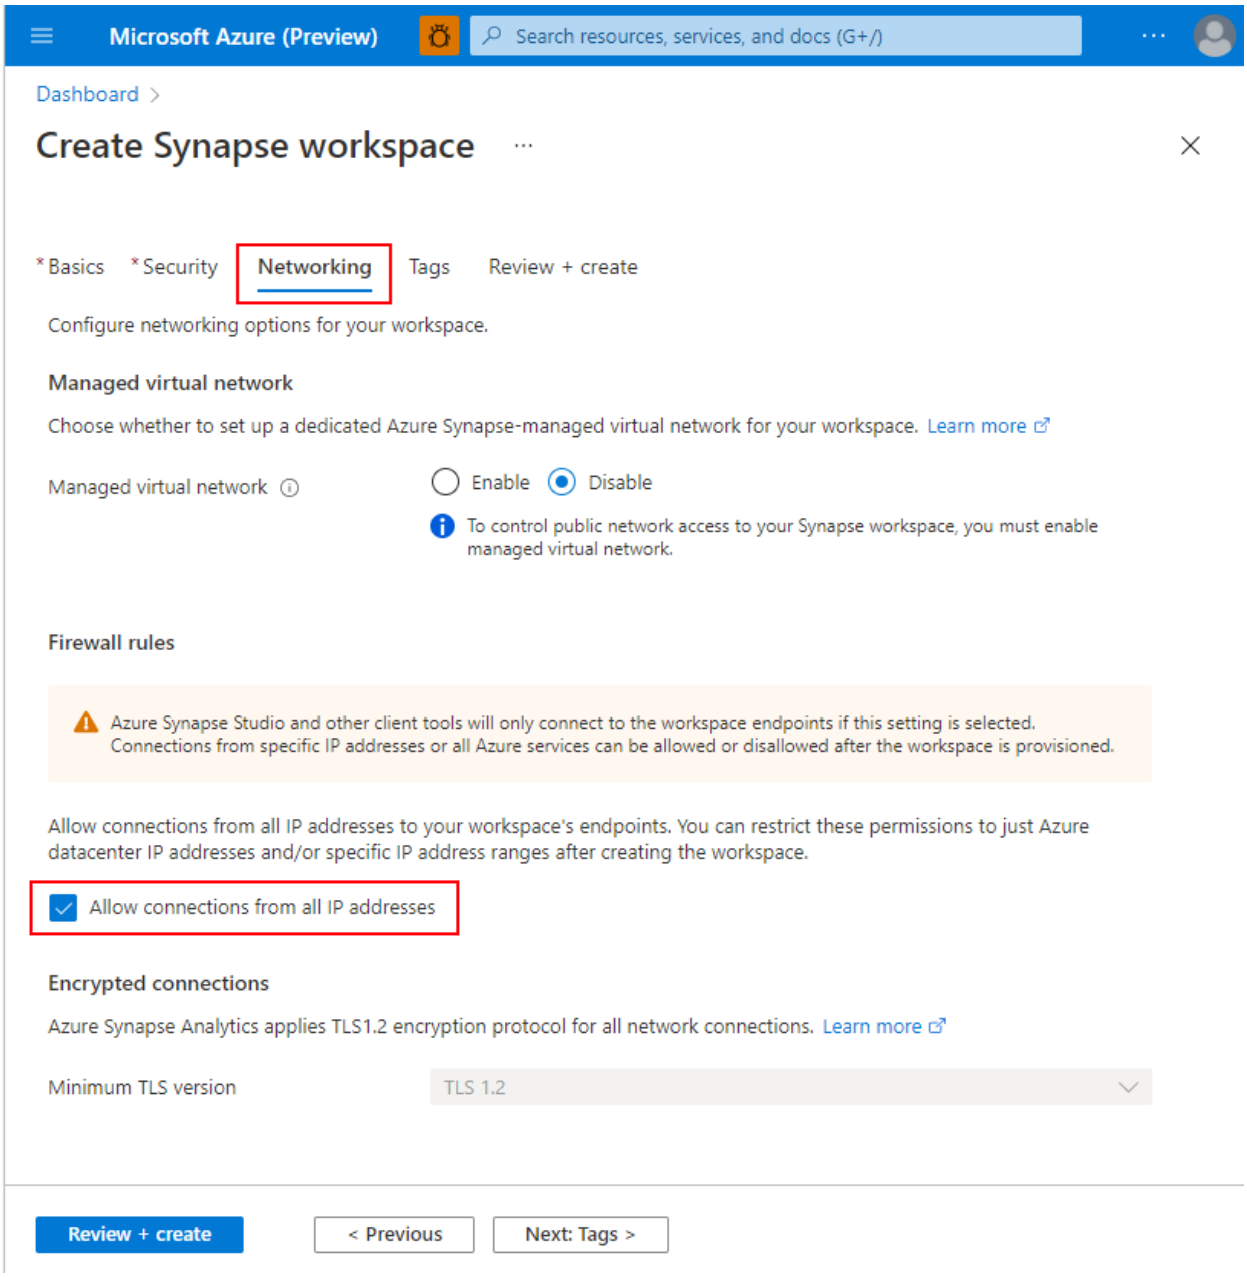
IP firewall rules

IP firewall rules grant or deny access to your Azure Synapse workspace based on the originating IP address of each request. You can configure IP firewall rules for your workspace. IP firewall rules configured at the workspace level apply to all public endpoints of the workspace (dedicated SQL pools, serverless SQL pool, and development).

Create and manage IP firewall rules

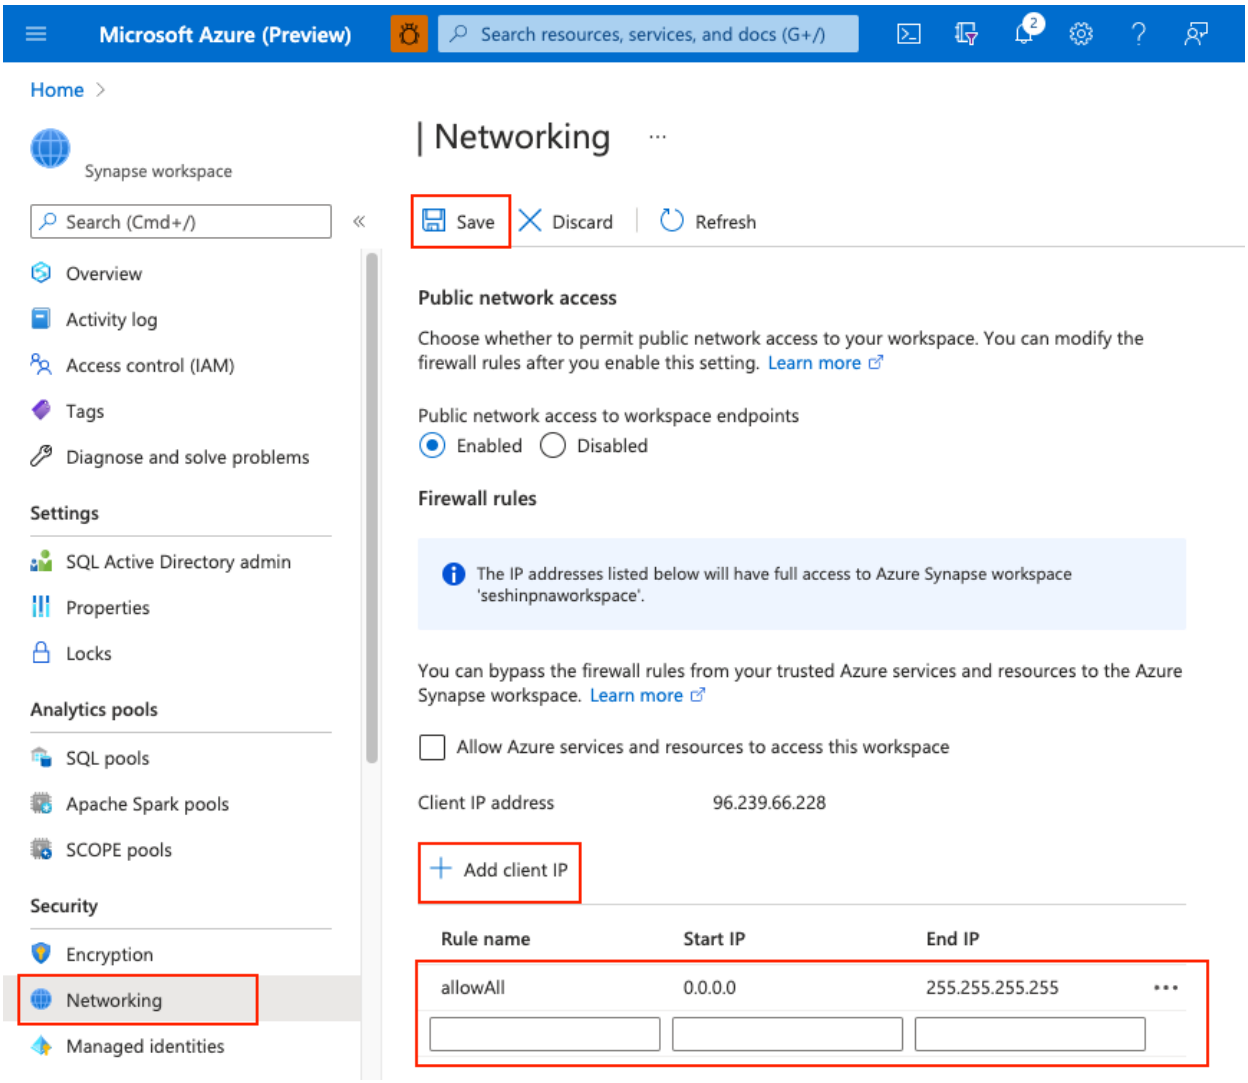
There are two ways IP firewall rules are added to an Azure Synapse workspace. To add an IP firewall to your workspace, select **Networking** and check **Allow connections from all IP addresses** during workspace creation.

> **IMPORTANT**
> This feature is only available to Azure Synapse workspaces not associated with a Managed VNet.



You can also add IP firewall rules to a Synapse workspace after the workspace is created. Select **Firewalls** under **Security** from Azure portal. To add a new IP firewall rule, give it a name, Start IP, and End IP. Select **Save** when done.

> **NOTE**
>
> The Public network access feature is only available to Azure Synapse workspaces associated with Azure Synapse Analytics Managed Virtual Network. However, you can still open your Azure Synapse workspaces to the public network regardless of its association with managed VNet. For more information, see Public network access.



Connect to Azure Synapse from your own network

You can connect to your Synapse workspace using Synapse Studio. You can also use SQL Server Management Studio (SSMS) to connect to the SQL resources (dedicated SQL pools and serverless SQL pool) in your workspace.

Make sure that the firewall on your network and local computer allows outgoing communication on TCP ports 80, 443 and 1443 for Synapse Studio.

Also, you need to allow outgoing communication on UDP port 53 for Synapse Studio. To connect using tools such as SSMS and Power BI, you must allow outgoing communication on TCP port 1433.

Manage the Azure Synapse workspace firewall

For more information on managing the firewall, see the Azure SQL documentation to manage server-level firewalls. Azure Synapse only supports server-level IP firewall rules. It doesn't support database-level IP firewall rules.

For more information on the methods to manage the firewall programmatically, see:

- API
- PowerShell
- Azure CLI

Azure Synapse Analytics connectivity settings

8/19/2022 • 2 minutes to read • Edit Online

This article will explain connectivity settings in Azure Synapse Analytics and how to configure them where applicable.

Public network access

You can use the public network access feature to allow incoming public network connectivity to you Azure Synapse workspace.

- When public network access is **disabled**, you can connect to your workspace only using private endpoints.
- When public network access is **enabled**, you can connect to your workspace also from public networks. You can manage this feature both during and after your workspace creation.

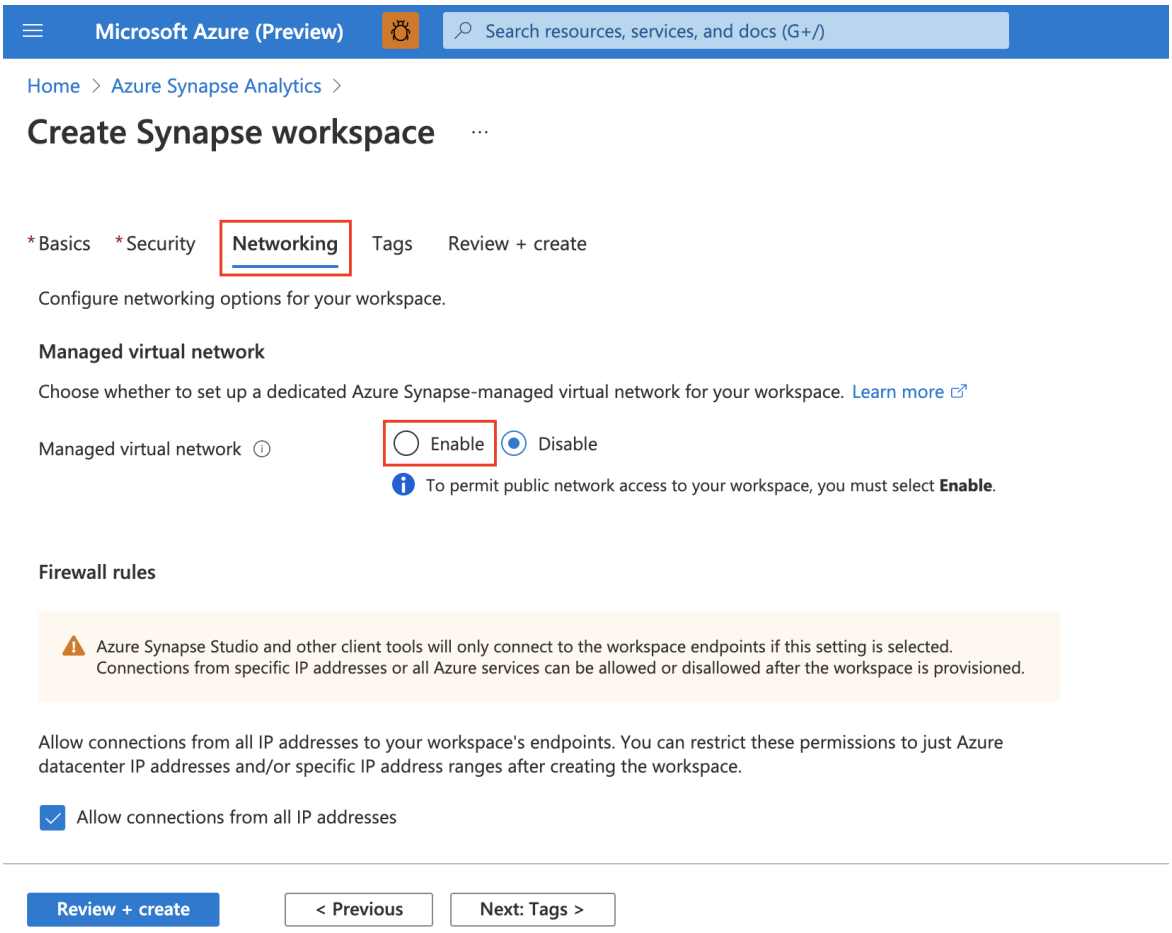
> **IMPORTANT**
> This feature is only available to Azure Synapse workspaces associated with Azure Synapse Analytics Managed Virtual Network. However, you can still open your Synapse workspaces to the public network regardless of its association with managed VNet.

Selecting the **Disable** option will not apply any firewall rules that you may configure. Additionally, your firewall rules will appear greyed out in the Network setting in Synapse portal. Your firewall configurations will be reapplied when you enable public network access again.

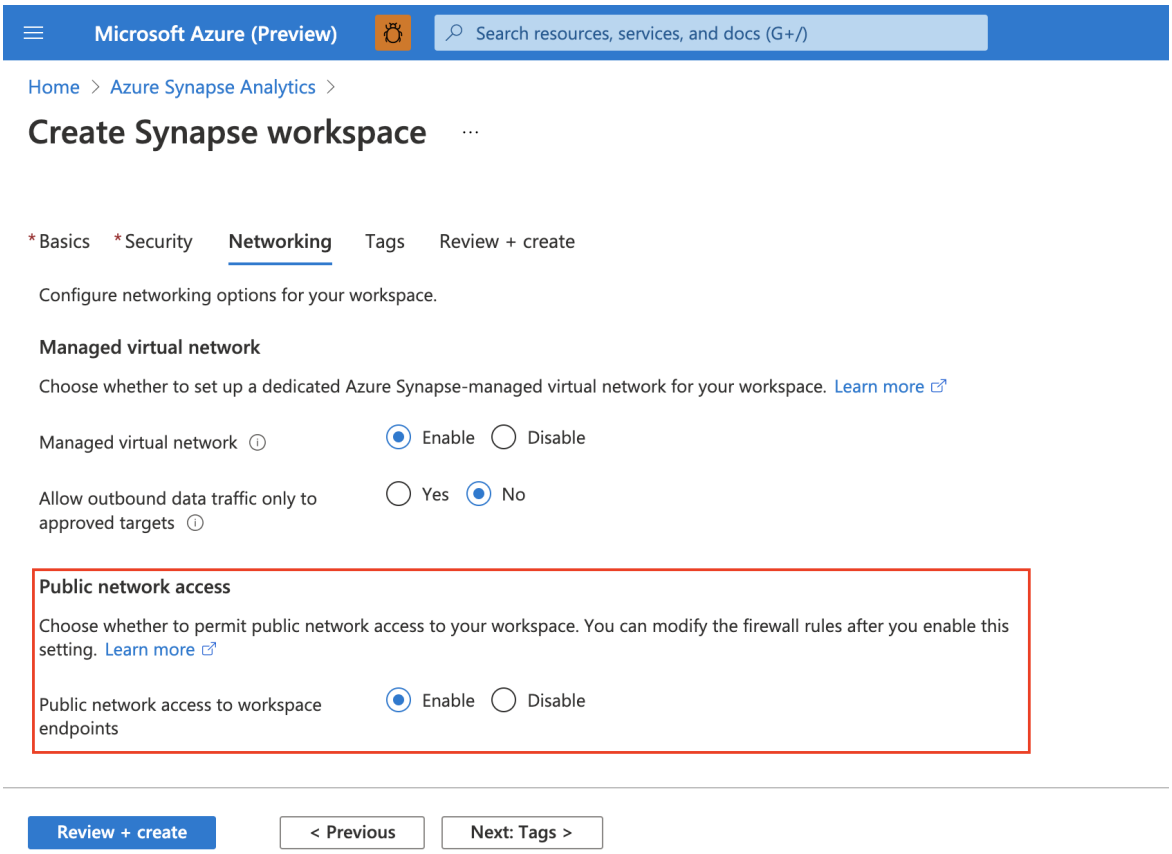
> **TIP**
> When you revert to enable, allow some time before editing the firewall rules.

Configure public network access when you create your workspace

1. Select the **Networking** tab when you create your workspace in Azure portal.
2. Under Managed virtual network, select **Enable** to associate your workspace with managed virtual network and permit public network access.



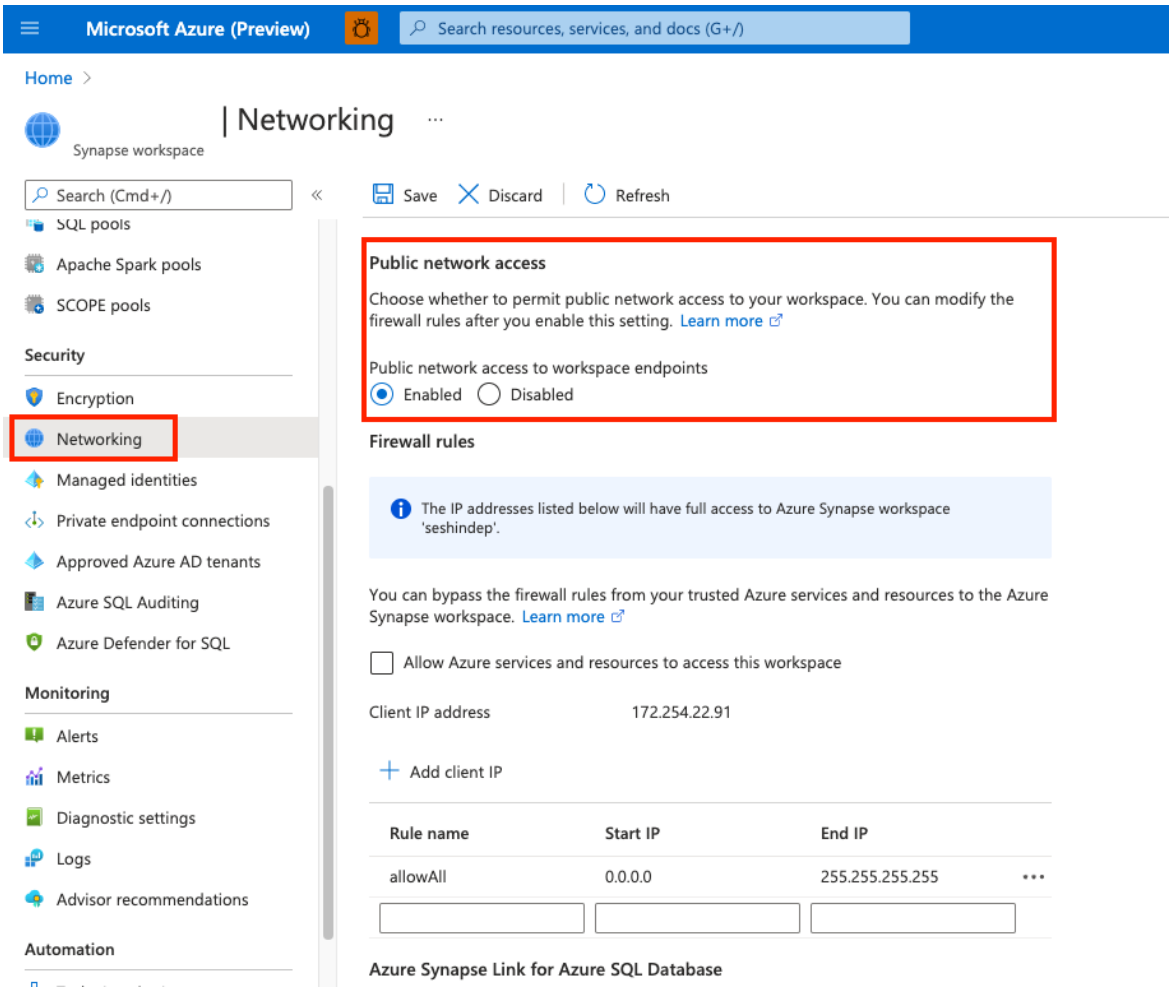
3. Under **Public network access**, select **Disable** to deny public access to your workspace. Select **Enable** if you want to allow public access to your workspace.



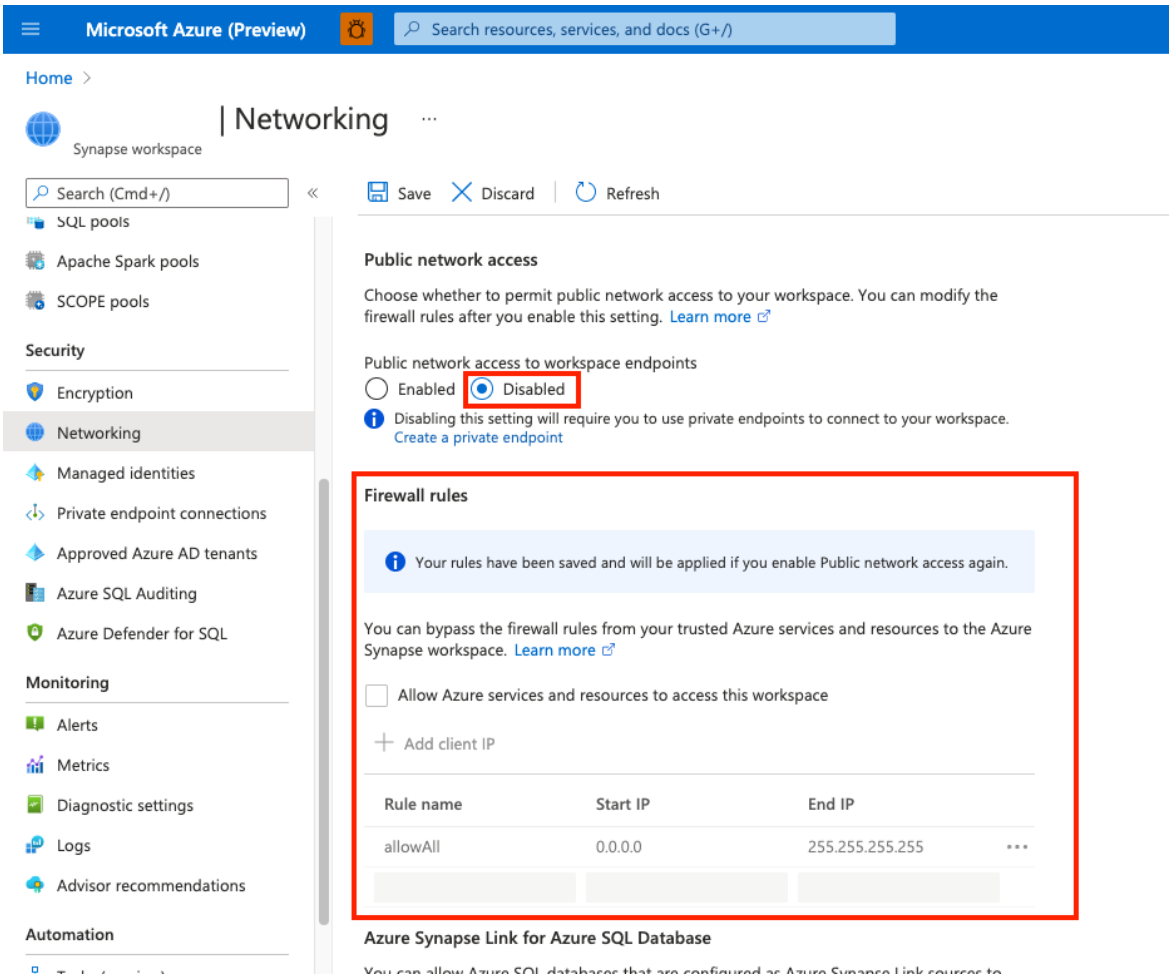
4. Complete the rest of the workspace creation flow.

Configure public network access after you create your workspace

1. Select your Synapse workspace in Azure portal.
2. Select **Networking** from the left navigation.
3. Select **Disabled** to deny public access to your workspace. Select **Enabled** if you want to allow public access to your workspace.



4. When disabled, the **Firewall rules** gray out to indicate that firewall rules are not in effect. Firewall rule configurations will be retained.



5. Select **Save** to save the change. A notification will confirm that the network setting was successfully saved.

Connection policy

The connection policy for Synapse SQL in Azure Synapse Analytics is set to *Default*. You cannot change this in Azure Synapse Analytics. You can learn more about how that affects connections to Synapse SQL in Azure Synapse Analytics here.

Minimal TLS version

The serverless SQL endpoint and development endpoint only accept TLS 1.2 and above.

Starting in December 2021, a requirement for TLS 1.2 has been implemented for workspace-managed dedicated SQL pools in new Synapse workspaces. Login attempts from connections using a TLS version lower than 1.2 will fail. Customers can raise or lower the minimal TLS version using the API, for both new Synapse workspaces or existing workspaces, so users who need to use a lower client version in the workspaces can connect. Customers can also raise the minimum TLS version to meet their security needs. Learn more by reading minimal TLS REST API.

Next steps

- Create an Azure Synapse Workspace.

Azure Synapse Analytics Managed Virtual Network

8/19/2022 • 3 minutes to read • Edit Online

This article will explain Managed Virtual Network in Azure Synapse Analytics.

Managed workspace Virtual Network

When you create your Azure Synapse workspace, you can choose to associate it to a Microsoft Azure Virtual Network. The Virtual Network associated with your workspace is managed by Azure Synapse. This Virtual Network is called a *Managed workspace Virtual Network*.

Managed workspace Virtual Network provides you value in four ways:

- With a Managed workspace Virtual Network you can offload the burden of managing the Virtual Network to Azure Synapse.
- You don't have to configure inbound NSG rules on your own Virtual Networks to allow Azure Synapse management traffic to enter your Virtual Network. Misconfiguration of these NSG rules causes service disruption for customers.
- You don't need to create a subnet for your Spark clusters based on peak load.
- Managed workspace Virtual Network along with Managed private endpoints protects against data exfiltration. You can only create Managed private endpoints in a workspace that has a Managed workspace Virtual Network associated with it.

Creating a workspace with a Managed workspace Virtual Network associated with it ensures that your workspace is network isolated from other workspaces. Azure Synapse provides various analytic capabilities in a workspace: Data integration,serverless Apache Spark pool, dedicated SQL pool, and serverless SQL pool.

If your workspace has a Managed workspace Virtual Network, Data integration and Spark resources are deployed in it. A Managed workspace Virtual Network also provides user-level isolation for Spark activities because each Spark cluster is in its own subnet.

Dedicated SQL pool and serverless SQL pool are multi-tenant capabilities and therefore reside outside of the Managed workspace Virtual Network. Intra-workspace communication to dedicated SQL pool and serverless SQL pool use Azure private links. These private links are automatically created for you when you create a workspace with a Managed workspace Virtual Network associated to it.

> **IMPORTANT**
> You cannot change this workspace configuration after the workspace is created. For example, you cannot reconfigure a workspace that does not have a Managed workspace Virtual Network associated with it and associate a Virtual Network to it. Similarly, you cannot reconfigure a workspace with a Managed workspace Virtual Network associated to it and disassociate the Virtual Network from it.

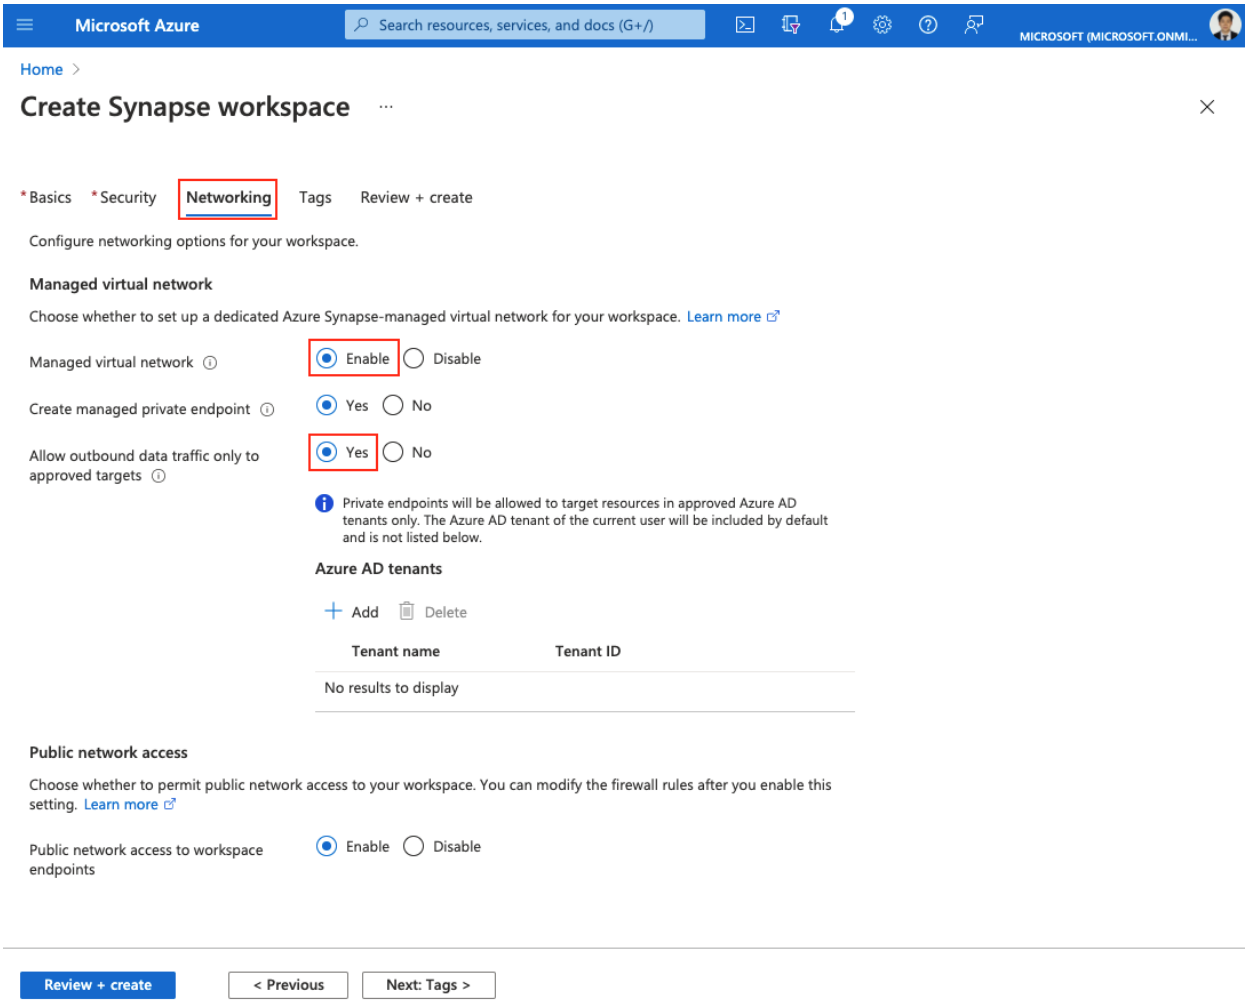
Create an Azure Synapse workspace with a Managed workspace Virtual Network

If you have not already done so, register the Network resource provider. Registering a resource provider configures your subscription to work with the resource provider. Choose *Microsoft.Network* from the list of resource providers when you register.

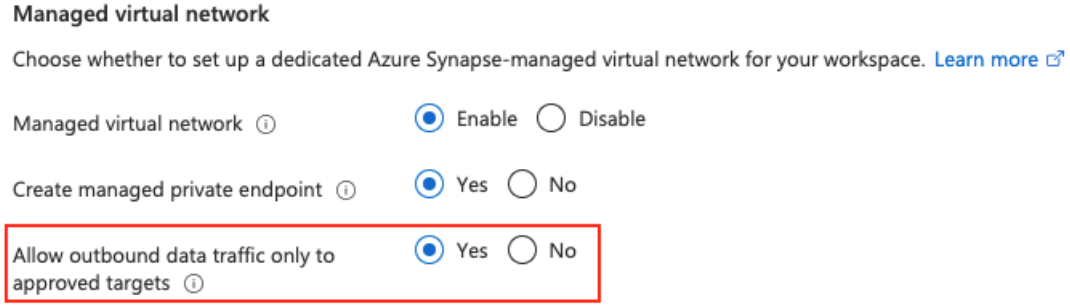
To create an Azure Synapse workspace that has a Managed workspace Virtual Network associated with it, select the **Networking** tab in Azure portal and check the **Enable managed virtual network** checkbox.

If you leave the checkbox unchecked, then your workspace won't have a Virtual Network associated with it.

> **IMPORTANT**
> You can only use private links in a workspace that has a Managed workspace Virtual Network.



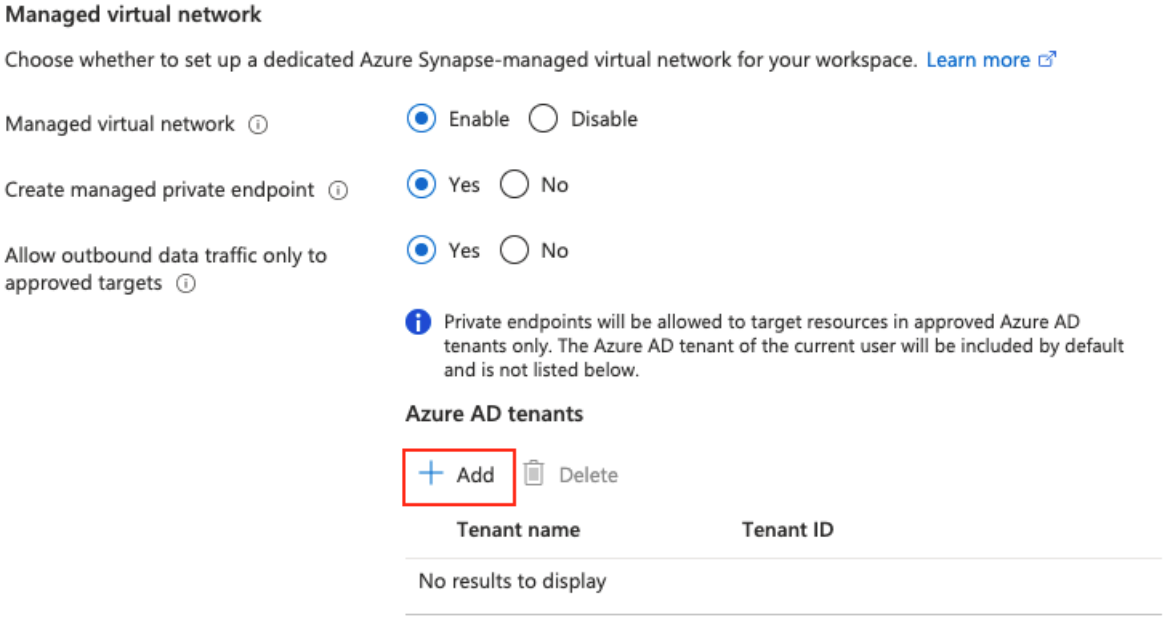
After you choose to associate a Managed workspace Virtual Network with your workspace, you can protect against data exfiltration by allowing outbound connectivity from the Managed workspace Virtual Network only to approved targets using Managed private endpoints. Select **Yes** to limit outbound traffic from the Managed workspace Virtual Network to targets through Managed private endpoints.



Select **No** to allow outbound traffic from the workspace to any target.

You can also control the targets to which Managed private endpoints are created from your Azure Synapse workspace. By default, Managed private endpoints to resources in the same AAD tenant that your subscription

belongs to are allowed. If you want to create a Managed private endpoint to a resource in an AAD tenant that is different from the one that your subscription belongs to, then you can add that AAD tenant by selecting **+ Add**. You can either select the AAD tenant from the dropdown or manually enter the AAD tenant ID.



After the workspace is created, you can check whether your Azure Synapse workspace is associated to a Managed workspace Virtual Network by selecting **Overview** from Azure portal.

Create Managed private endpoints to your data sources

Synapse Managed private endpoints

8/19/2022 • 2 minutes to read • Edit Online

This article will explain Managed private endpoints in Azure Synapse Analytics.

Managed private endpoints

Managed private endpoints are private endpoints created in a Managed Virtual Network associated with your Azure Synapse workspace. Managed private endpoints establish a private link to Azure resources. Azure Synapse manages these private endpoints on your behalf. You can create Managed private endpoints from your Azure Synapse workspace to access Azure services (such as Azure Storage or Azure Cosmos DB) and Azure hosted customer/partner services.

When you use Managed private endpoints, traffic between your Azure Synapse workspace and other Azure resources traverse entirely over the Microsoft backbone network. Managed private endpoints protect against data exfiltration. A Managed private endpoint uses private IP address from your Managed Virtual Network to effectively bring the Azure service that your Azure Synapse workspace is communicating into your Virtual Network. Managed private endpoints are mapped to a specific resource in Azure and not the entire service. Customers can limit connectivity to a specific resource approved by their organization.

Learn more about private links and private endpoints.

> **IMPORTANT**
>
> Managed private endpoints are only supported in Azure Synapse workspaces with a Managed workspace Virtual Network.

> **NOTE**
>
> When creating an Azure Synapse workspace, you can choose to associate a Managed Virtual Network to it. If you choose to have a Managed Virtual Network associated to your workspace, you can also choose to limit outbound traffic from your workspace to only approved targets. You must create Managed private endpoints to these targets.

A private endpoint connection is created in a "Pending" state when you create a Managed private endpoint in Azure Synapse. An approval workflow is started. The private link resource owner is responsible to approve or reject the connection. If the owner approves the connection, the private link is established. But, if the owner doesn't approve the connection, then the private link won't be established. In either case, the Managed private endpoint will be updated with the status of the connection. Only a Managed private endpoint in an approved state can be used to send traffic to the private link resource that is linked to the Managed private endpoint.

Managed private endpoints for dedicated SQL pool and serverless SQL pool

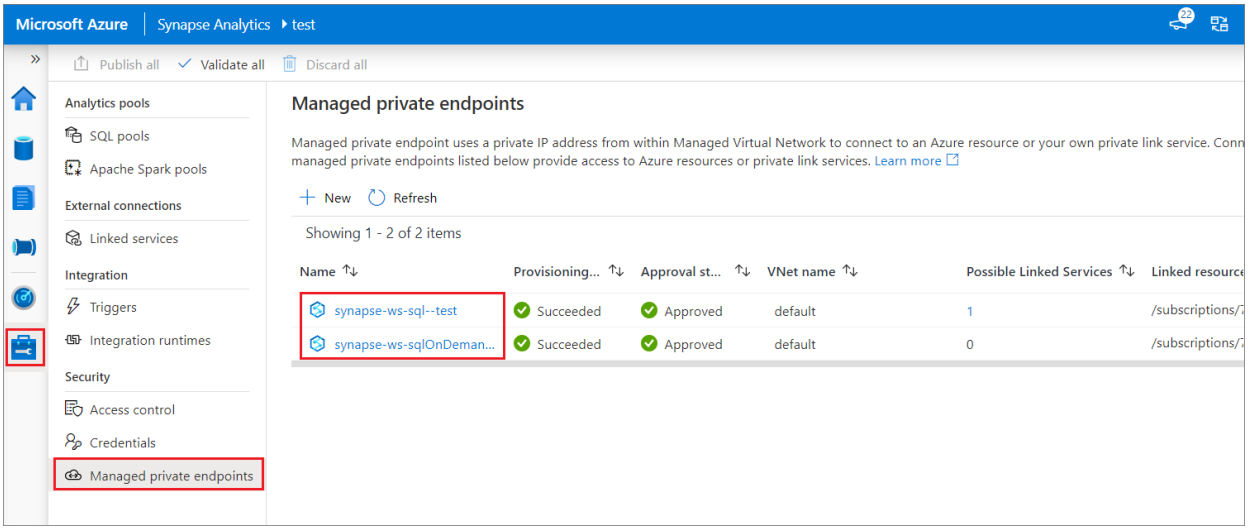
Dedicated SQL pool and serverless SQL pool are analytic capabilities in your Azure Synapse workspace. These capabilities use multi-tenant infrastructure that isn't deployed into the Managed workspace Virtual Network.

When a workspace is created, Azure Synapse creates two Managed private endpoints in the workspace, one for dedicated SQL pool and one for serverless SQL pool.

These two Managed private endpoints are listed in Synapse Studio. Select **Manage** in the left navigation, then

select **Managed private endpoints** to see them in the Studio.

The Managed private endpoint that targets SQL pool is called *synapse-ws-sql--<workspacename>* and the one that targets serverless SQL pool is called *synapse-ws-sqlOnDemand--<workspacename>*.



These two Managed private endpoints are automatically created for you when you create your Azure Synapse workspace. You aren't charged for these two Managed private endpoints.

Next steps

To learn more, advance to the Create Managed private endpoints to your data sources article.

Data exfiltration protection for Azure Synapse Analytics workspaces

8/19/2022 • 2 minutes to read • Edit Online

This article will explain data exfiltration protection in Azure Synapse Analytics

Securing data egress from Synapse workspaces

Azure Synapse Analytics workspaces support enabling data exfiltration protection for workspaces. With exfiltration protection, you can guard against malicious insiders accessing your Azure resources and exfiltrating sensitive data to locations outside of your organization's scope. At the time of workspace creation, you can choose to configure the workspace with a managed virtual network and additional protection against data exfiltration. When a workspace is created with a managed virtual network, Data integration and Spark resources are deployed in the managed virtual network. The workspace's dedicated SQL pools and serverless SQL pools have multi-tenant capabilities and as such, need to exist outside the managed virtual network. For workspaces with data exfiltration protection, resources within the managed virtual network always communicate over managed private endpoints and the Synapse SQL resources can only connect to authorized Azure resources (targets of approved managed private endpoint connections from the workspace).

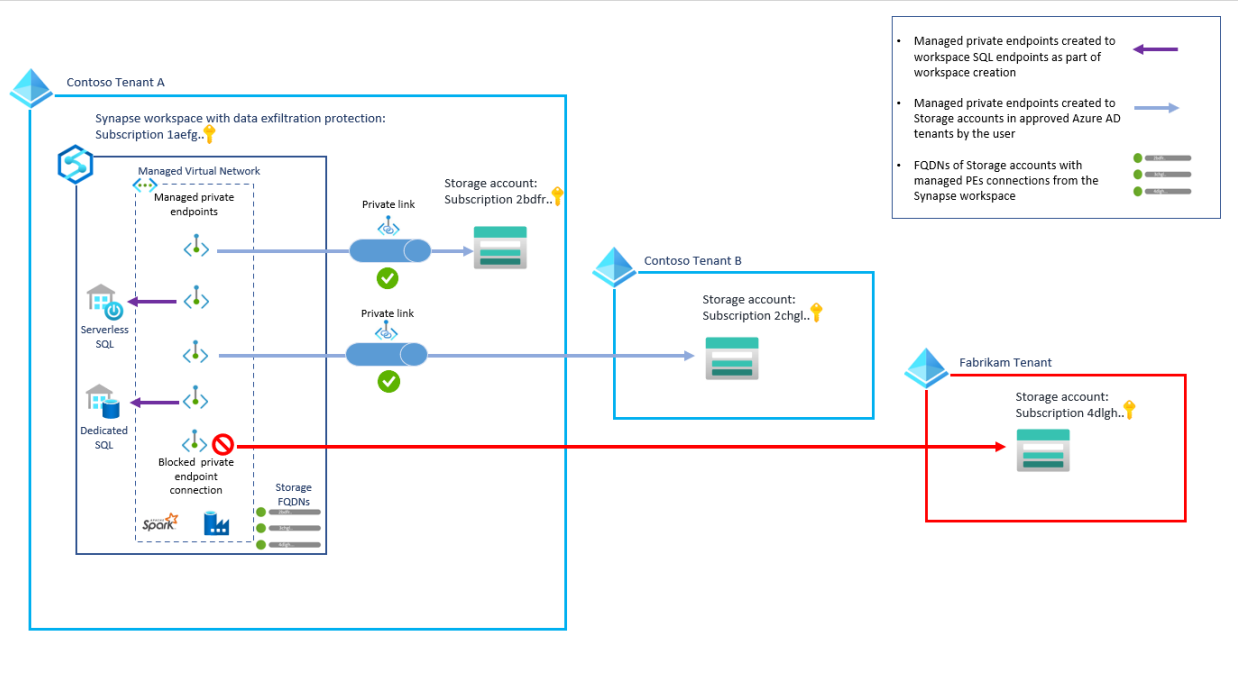
> **NOTE**
> You cannot change the workspace configuration for managed virtual network and data exfiltration protection after the workspace is created.

Managing Synapse workspace data egress to approved targets

After the workspace is created with data exfiltration protection enabled, the owners of the workspace resource can manage the list of approved Azure AD tenants for the workspace. Users with the right permissions on the workspace can use the Synapse Studio to create managed private endpoint connection requests to resources in the workspace's approved Azure AD tenants. Managed private endpoint creation will be blocked if the user attempts to create a private endpoint connection to a resource in an unapproved tenant.

Sample workspace with data exfiltration protection enabled

Let us use an example to illustrate data exfiltration protection for Synapse workspaces. Contoso has Azure resources in Tenant A and Tenant B and there is a need for these resources to connect securely. A Synapse workspace has been created in Tenant A with Tenant B added as an approved Azure AD tenant. The diagram shows private endpoint connections to Azure Storage accounts in Tenant A and Tenant B that have been approved by the Storage account owners. The diagram also shows blocked private endpoint creation. The creation of this private endpoint was blocked as it targeted an Azure Storage account in the Fabrikam Azure AD tenant, which is not an approved Azure AD tenant for Contoso's workspace.



IMPORTANT

Resources in tenants other than the workspace's tenant must not have blocking firewall rules in place for the SQL pools to connect to them. Resources within the workspace's managed virtual network, such as Spark clusters, can connect over managed private links to firewall-protected resources.

Create Managed private endpoints to your data sources

Connect to Azure Synapse Studio using Azure Private Link Hubs

8/19/2022 • 2 minutes to read • Edit Online

This article explains how Azure Synapse Analytics Private Link Hubs private links are used to securely connect to Synapse Studio.

Azure Private Link Hubs

You can securely connect to Azure Synapse Studio from your Azure virtual network using private links. Azure Synapse Analytics private link hubs are Azure resources which act as connectors between your secured network and the Synapse Studio web experience.

There are two steps to connect to Synapse Studio using private links. First, you must create a private link hubs resource. Second, you must create a private endpoint from your Azure virtual network to this private link hub. You can then use private endpoints to securely communicate with Synapse Studio. You must integrate the private endpoints with your DNS solution, either your on-premises solution or Azure Private DNS.

Azure Private Links Hubs and Azure Synapse Studio

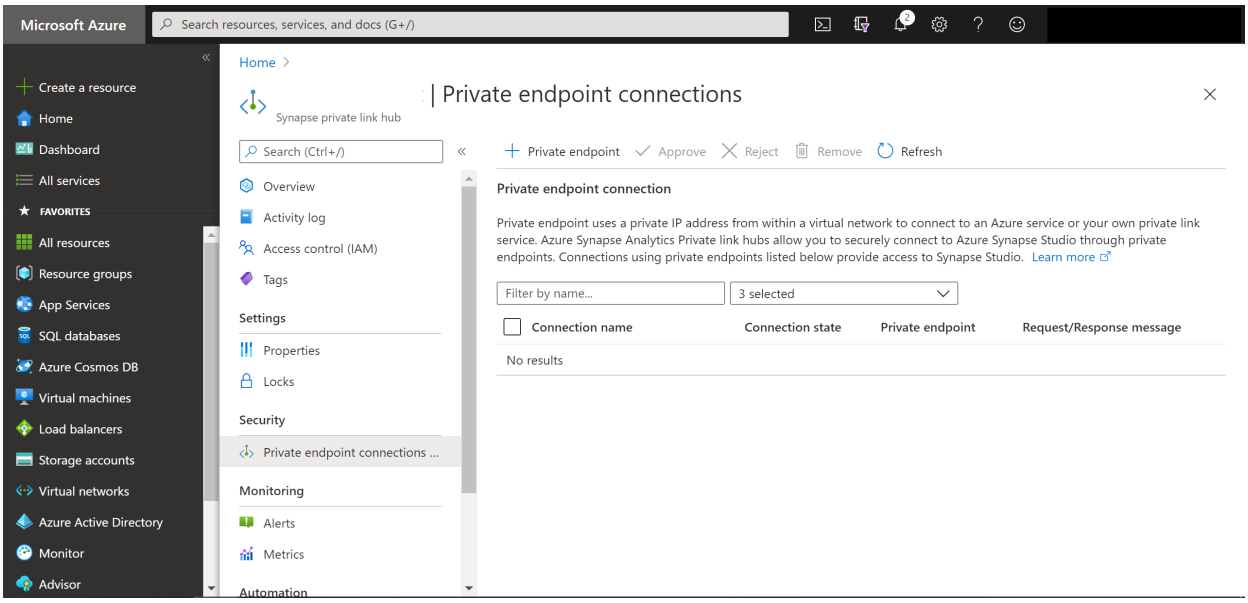
You can use a single Azure Synapse private link hub resource to privately connect to all your Azure Synapse Analytics workspaces using Azure Synapse Studio. The workspaces do not have to be in the same region as the Azure Synapse Private link hub. The Azure Synapse Private link hub resource can also be used for connections to Synapse workspaces in different subscriptions or Azure AD tenants.

You can create your private link hub by searching for *Synapse private link hubs* in the Azure portal and selecting **Azure Synapse Analytics (private link hubs)** from Services. Follow the steps in the guide for how to connect to workspace resources from a restricted network for details.

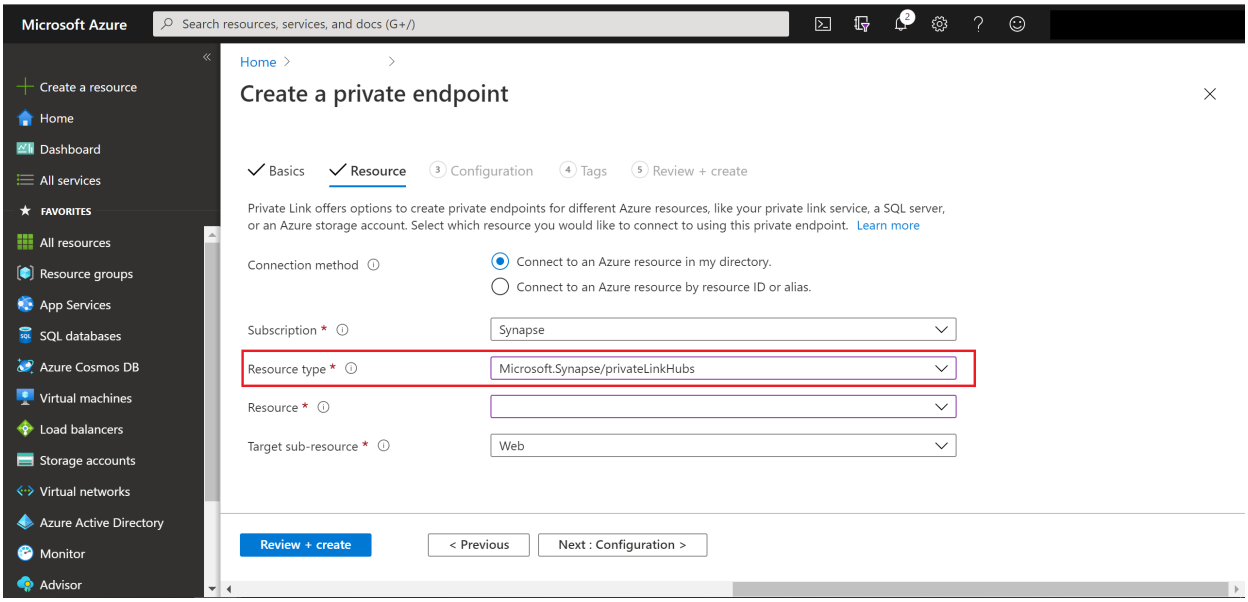
> **NOTE**
> Private link hubs are intended for securely loading the static content Synapse Studio over private links. You must create **separate, private endpoints** to the resources you wish to connect to within the workspace, such as provisioned/dedicated SQL pools, or Spark pools.

Azure Private Links Hubs and Azure Virtual Network

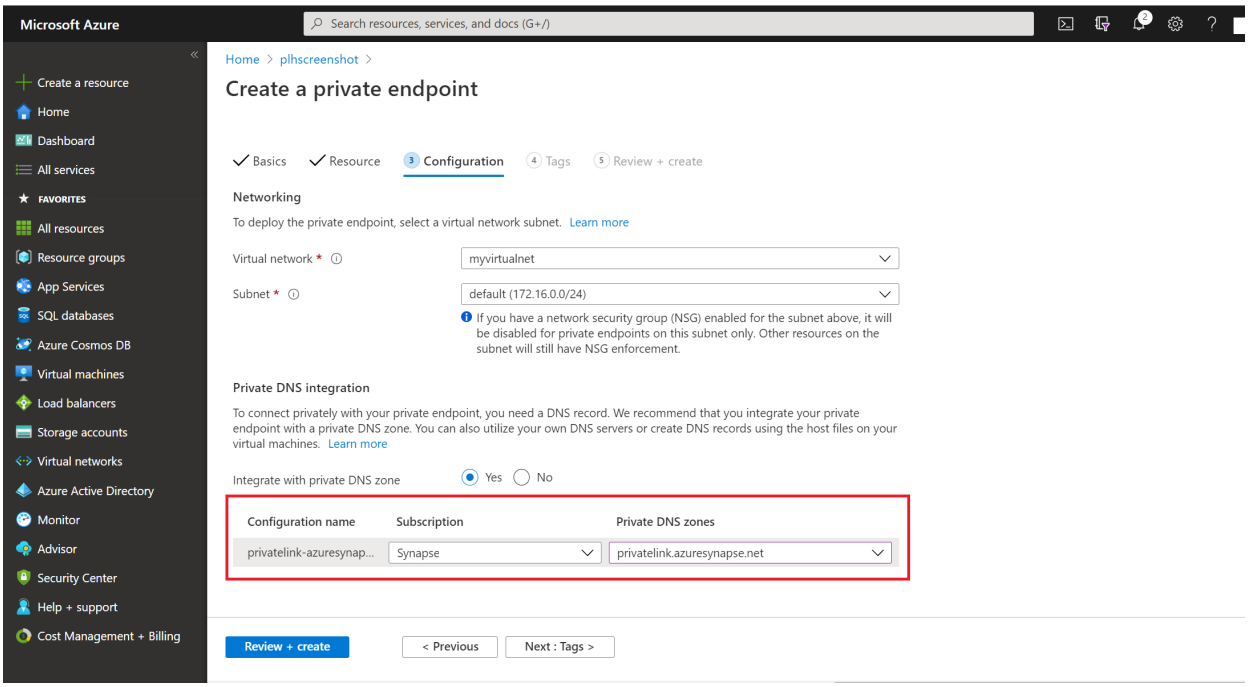
You must connect your Azure virtual network to the Synapse private link hub resource to secure the end-to-end connection to Synapse Studio. For this, you must create a private endpoint from your virtual network to the private link hub you created. You can use the Azure portal for your private link hub and go to the Private endpoint section. Select "+ Private endpoint" to create a new private endpoint that connects to your private link hub.



Make sure to choose the "Microsoft.Synapse/privateLinkHubs" Resource type on the "Resource" tab.



On "Configuration" tab, select "privatelink.azuresynapse.net" for Private DNS Zones when integrating with your virtual network and private DNS zone.



Next steps

Connect to workspace resources from a restricted network

Learn more about Managed workspace Virtual Network

Learn more about Managed private endpoints

Create Managed private endpoints to your data sources

Connect to Synapse workspace using private endpoints

Connect to a secure Azure storage account from your Synapse workspace

8/19/2022 • 3 minutes to read • Edit Online

This article will teach you how to connect to a secure Azure storage account from your Azure Synapse workspace. You can link an Azure storage account to your Synapse workspace when you create your workspace. You can link more storage accounts after you create your workspace.

Secured Azure storage accounts

Azure storage provides a layered security model that enables you to secure and control access to your storage accounts. You can configure IP firewall rules to grant traffic from selected public IP address ranges access to your storage account. You can also configure network rules to grant traffic from selected virtual networks access to your storage account. You can combine IP firewall rules that allow access from selected IP address ranges and network rules that grant access from selected virtual networks on the same storage account. These rules apply to the public endpoint of a storage account. You do not need any access rules to allow traffic from Managed private endpoints created in your workspace to a storage account. Storage firewall rules can be applied to existing storage accounts, or to new storage accounts when you create them. You can learn more about securing your storage account here.

Synapse workspaces and virtual networks

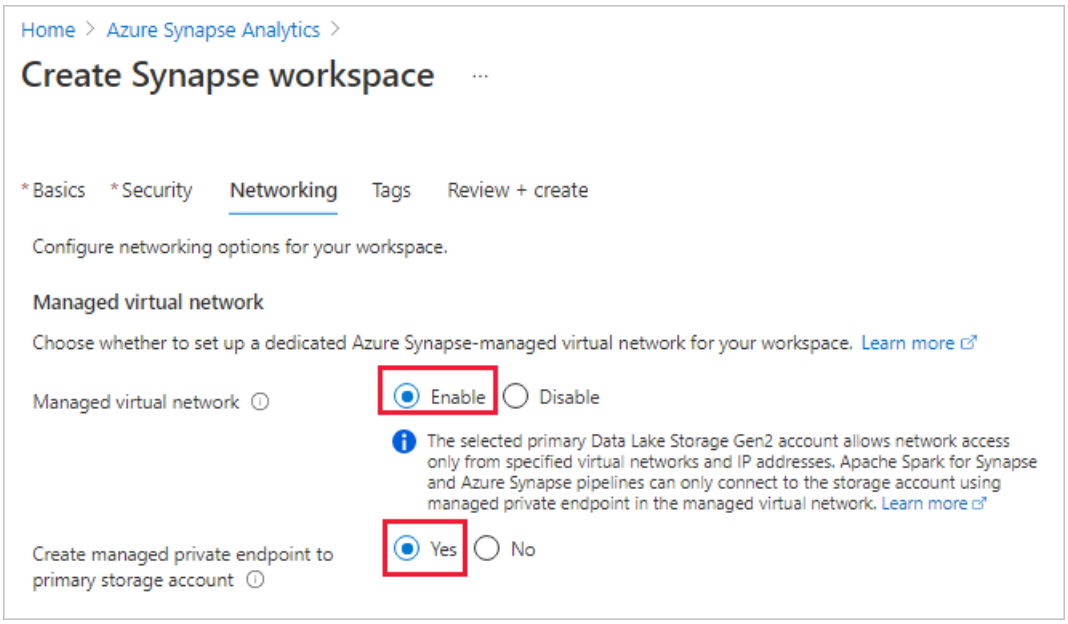
When you create a Synapse workspace, you can choose to enable a Managed virtual network to be associated with it. If you do not enable Managed virtual network for your workspace when you create it, your workspace is in a shared virtual network along with other Synapse workspaces that do not have a Managed virtual network associated with it. If you enabled Managed virtual network when you created the workspace, then your workspace is associated with a dedicated virtual network managed by Azure Synapse. These virtual networks are not created in your customer subscription. Therefore, you will not be able to grant traffic from these virtual networks access to your secured storage account using network rules described above.

Access a secured storage account

Synapse operates from networks that cannot be included in your network rules. The following needs to be done to enable access from your workspace to your secure storage account.

- Create an Azure Synapse workspace with a managed virtual network associated with it and create managed private endpoints from it to the secure storage account.

  If you use Azure Portal to create your workspace, you can enable managed virtual network under the **Networking** tab as shown below. If you enable managed virtual network or Synapse determines that the primary storage account is a secure storage account, then you have the option to create a managed private endpoint connection request to the secure storage account as shown below. The storage account owner will need to approve the connection request to establish the private link. Alternatively, Synapse will approve this connection request if the user creating an Apache Spark pool in the workspace has sufficient privileges to approve the connection request.



- Grant your Azure Synapse workspace access to your secure storage account as a trusted Azure service. As a trusted service, Azure Synapse will then use strong authentication to securely connect to your storage account.

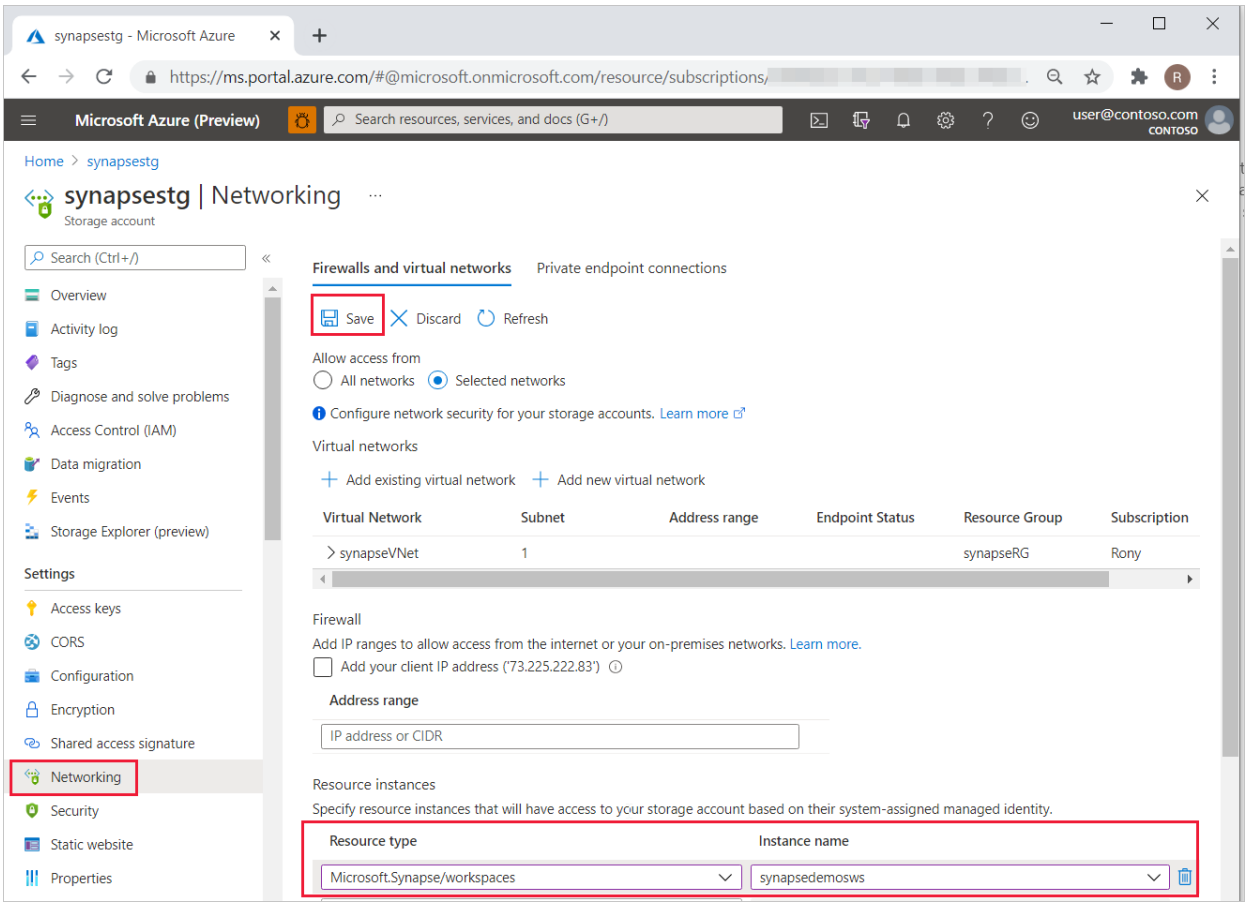
Create a Synapse workspace with a managed virtual network and create managed private endpoints to your storage account

You can follow these steps to create a Synapse workspace that has a managed virtual network associated with it. Once the workspace with an associated managed virtual network is created, you can create a managed private endpoint to your secure storage account by following the steps listed here.

Grant your Azure Synapse workspace access to your secure storage account as a trusted Azure service

Analytic capabilities such as Dedicated SQL pool and Serverless SQL pool use multi-tenant infrastructure that is not deployed into the managed virtual network. In order for traffic from these capabilities to access the secured storage account, you must configure access to your storage account based on the workspace's system-assigned managed identity by following the steps below.

In Azure portal, navigate to your secured storage account. Select **Networking** from the left navigation pane. In the **Resource instances** section, select *Microsoft.Synapse/workspaces* as the **Resource type** and enter your workspace name for **Instance name**. Select **Save**.



You should now be able to access your secured storage account from the workspace.

Next steps

Learn more about Managed workspace virtual network.

Learn more about Managed private endpoints.

Use Azure Active Directory Authentication for authentication with Synapse SQL

8/19/2022 • 7 minutes to read • Edit Online

Azure Active Directory authentication is a mechanism that connects to Azure Synapse Analytics by using identities in Azure Active Directory (Azure AD).

With Azure AD authentication, you can centrally manage user identities that have access to Azure Synapse to simplify permission management. Benefits include the following:

- It provides an alternative to regular username and password authentication.
- Helps stop the proliferation of user identities across servers.
- Allows password rotation in a single place.
- Customers can manage permissions using external (Azure AD) groups.
- It can eliminate storing passwords by enabling integrated Windows authentication and other forms of authentication supported by Azure Active Directory.
- Azure AD supports token-based authentication for applications connecting to Azure Synapse.
- Azure AD authentication supports ADFS (domain federation) or native user/password authentication for a local Azure Active Directory without domain synchronization.
- Azure AD supports connections from SQL Server Management Studio that use Active Directory Universal Authentication, which includes multi-factor authentication (MFA). MFA includes strong authentication with a range of easy verification options, including phone call, text message, smart cards with pin, or mobile app notification. For more information, see SSMS support for Azure AD MFA with Synapse SQL.
- Azure AD supports similar connections from SQL Server Data Tools (SSDT) that use Active Directory Interactive Authentication. For more information, see Azure Active Directory support in SQL Server Data Tools (SSDT).

The configuration steps include the following procedures to configure and use Azure Active Directory authentication.

1. Create and populate Azure AD.
2. Create an Azure Active Directory identity
3. Assign role to created Azure Active Directory identity in Synapse workspace
4. Connect to Synapse Studio by using Azure AD identities.

Azure AD pass-through in Azure Synapse Analytics

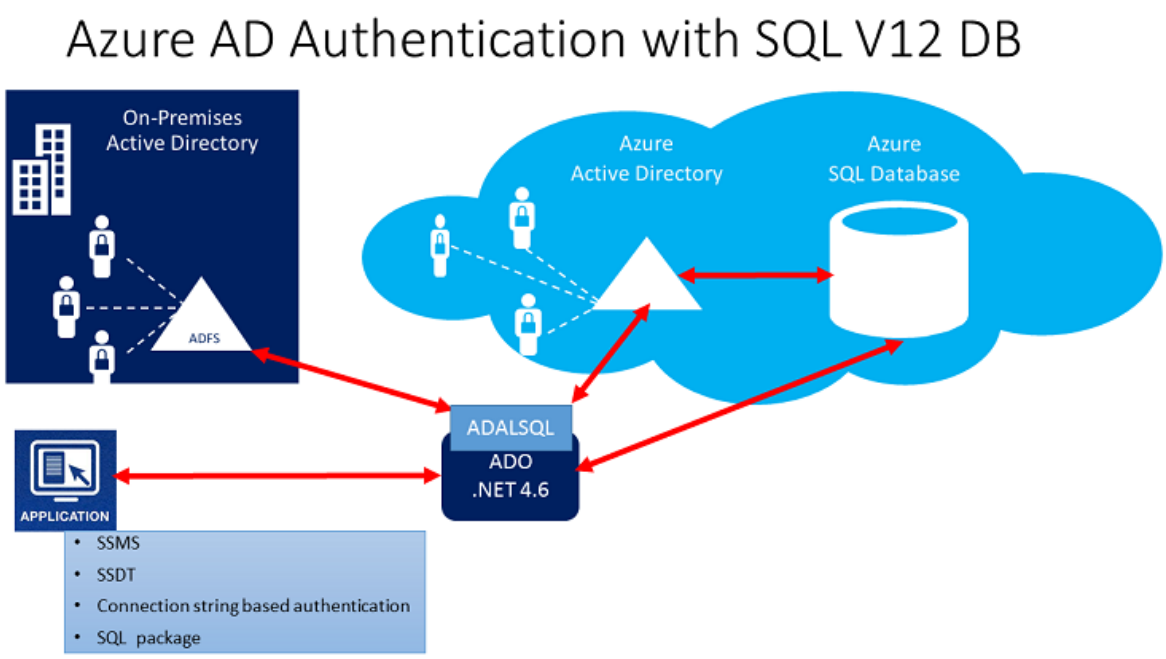
Azure Synapse Analytics enables you to access the data in the data lake using your Azure Active Directory identity.

Defining access rights on the files and data that is respected in different data engines enables you to simplify your data lake solutions by having a single place where the permissions are defined instead of having to define them in multiple places.

Trust architecture

The following high-level diagram summarizes the solution architecture of using Azure AD authentication with Synapse SQL. To support Azure AD native user password, only the Cloud portion and Azure AD/Synapse Synapse SQL is considered. To support Federated authentication (or user/password for Windows credentials),

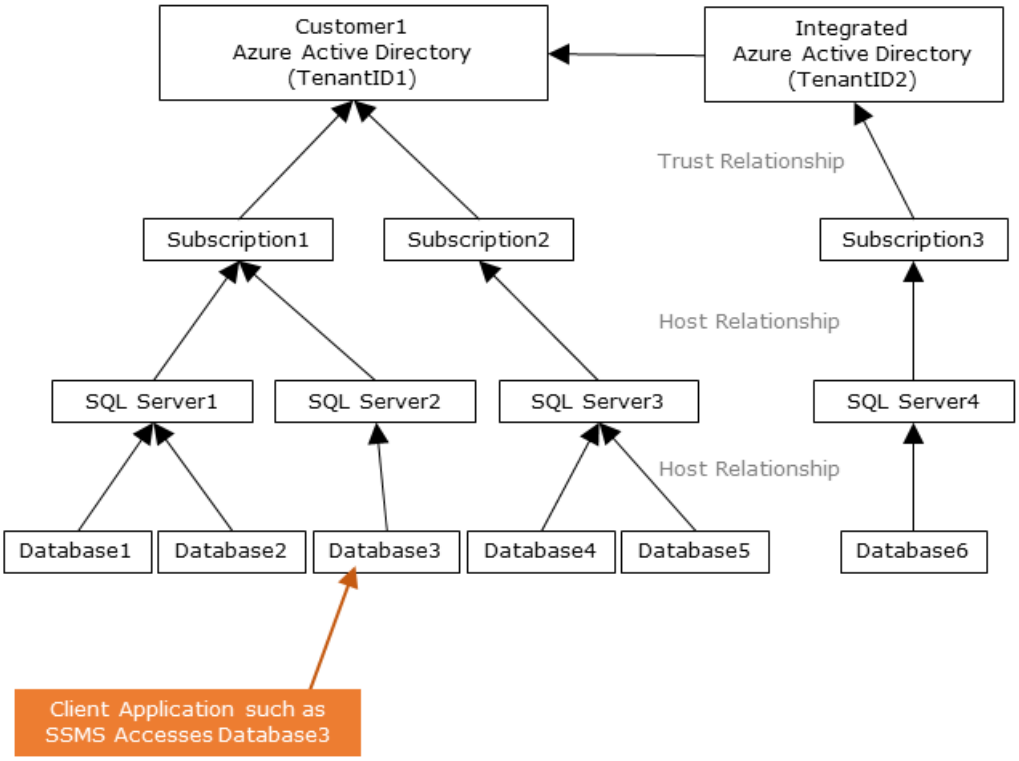
the communication with ADFS block is required. The arrows indicate communication pathways.



The following diagram indicates the federation, trust, and hosting relationships that allow a client to connect to a database by submitting a token. The token is authenticated by an Azure AD, and is trusted by the database.

Customer 1 can represent an Azure Active Directory with native users or an Azure AD with federated users. Customer 2 represents a possible solution including imported users; in this example coming from a federated Azure Active Directory with ADFS being synchronized with Azure Active Directory.

It's important to understand that access to a database using Azure AD authentication requires that the hosting subscription is associated to the Azure AD. The same subscription must be used to create the SQL Server hosting the Azure SQL Database or dedicated SQL pool.

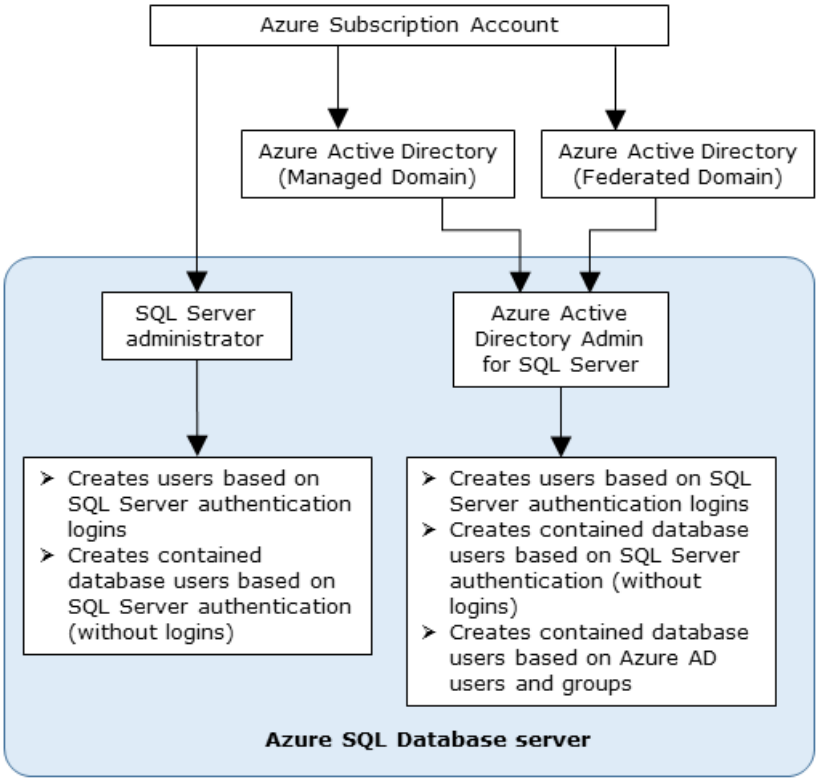


Administrator structure

When using Azure AD authentication, there are two Administrator accounts for the Synapse SQL; the original SQL administrator (using SQL authentication) and the Azure AD administrator. Only the administrator based on an Azure AD account can create the first Azure AD contained database user in a user database.

The Azure AD administrator login can be an Azure AD user or an Azure AD group. When the administrator is a group account, it can be used by any group member, enabling multiple Azure AD administrators for the Synapse SQL instance.

Using group account as an administrator enhances manageability by allowing you to centrally add and remove group members in Azure AD without changing the users or permissions in Azure Synapse Analytics workspace. Only one Azure AD administrator (a user or group) can be configured at any time.



Permissions

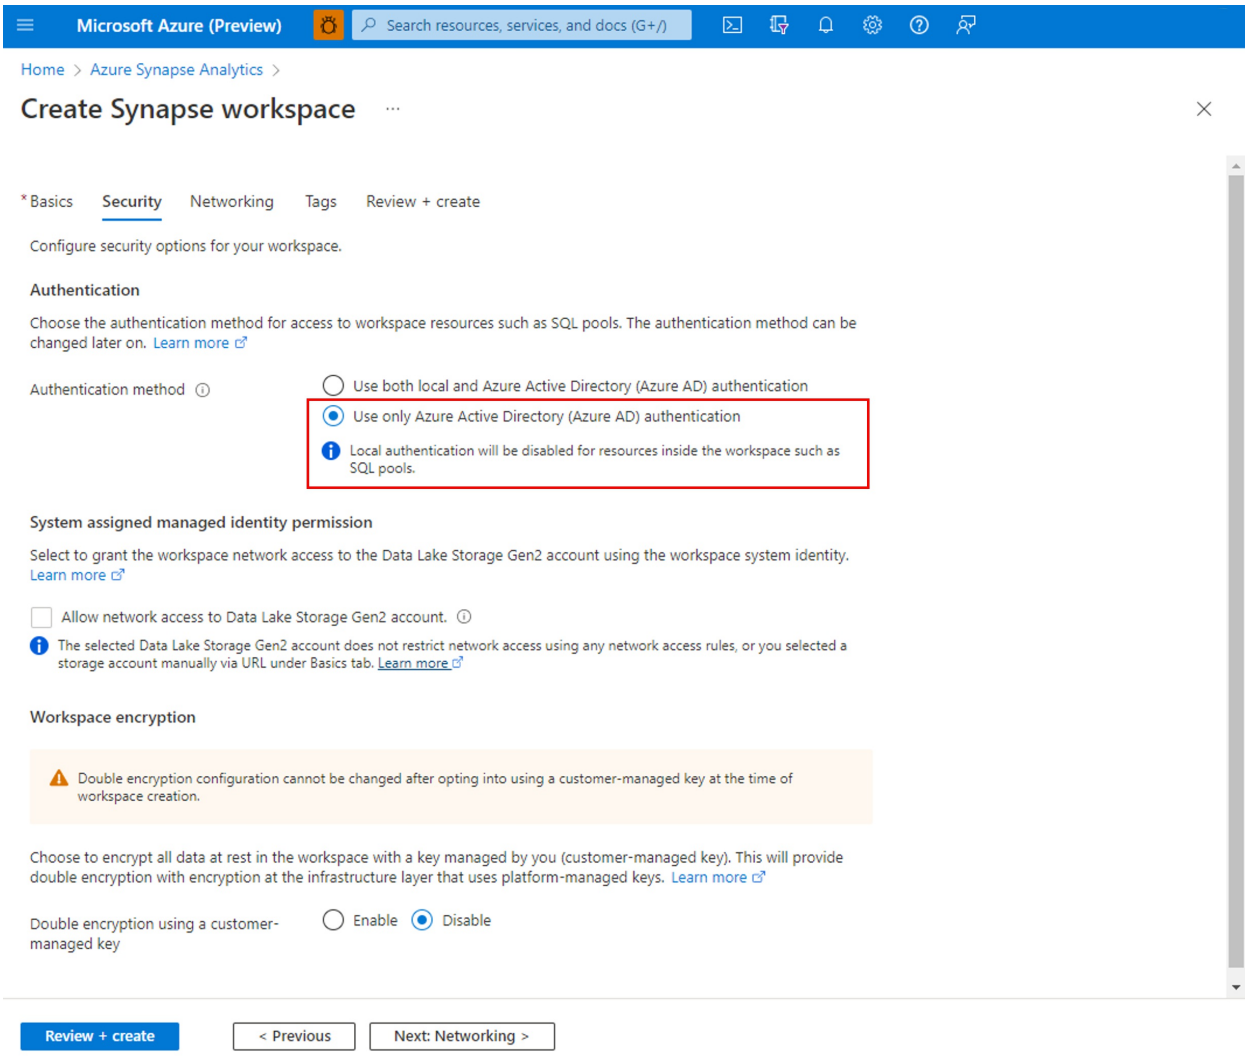
To create new users, you must have the `ALTER ANY USER` permission in the database. The `ALTER ANY USER` permission can be granted to any database user. The `ALTER ANY USER` permission is also held by the SQL administrator and Azure AD administrator accounts, and database users with the `CONTROL ON DATABASE` or `ALTER ON DATABASE` permission for that database, and by members of the `db_owner` database role.

To create a contained database user in Synapse SQL, you must connect to the database or instance using an Azure AD identity. To create the first contained database user, you must connect to the database by using an Azure AD administrator (who is the owner of the database).

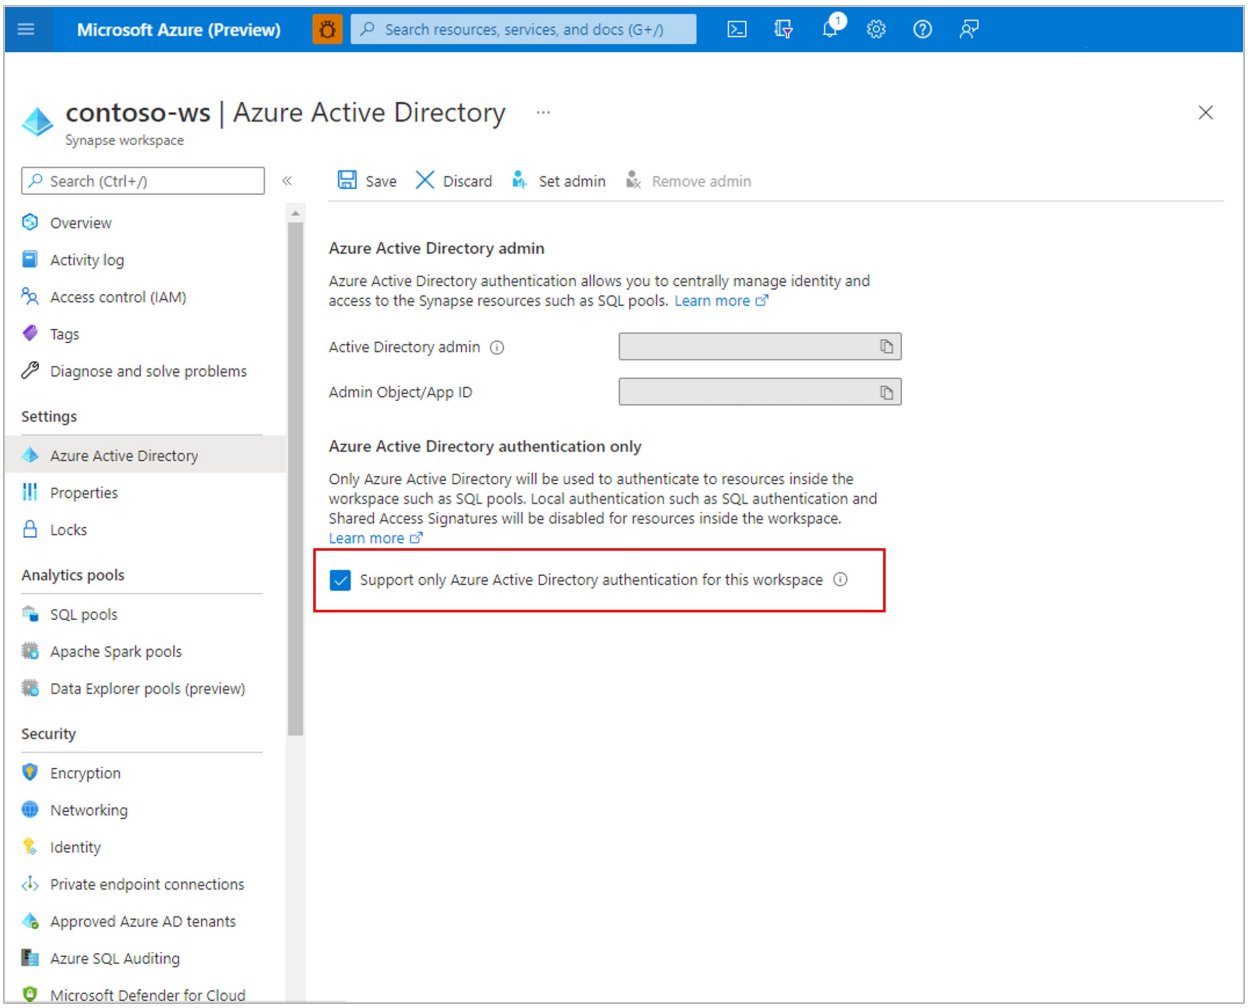
Any Azure AD authentication is only possible if the Azure AD admin was created for Synapse SQL. If the Azure Active Directory admin was removed from the server, existing Azure Active Directory users created previously inside Synapse SQL can no longer connect to the database using their Azure Active Directory credentials.

Disable local authentication

By allowing only Azure Active Directory authentication, centrally manage access to Azure Synapse resources, such as SQL pools. To disable local authentication in Synapse during workspace creation, select **Use only Azure Active Directory (Azure AD) authentication** as the authentication method. A SQL Administrator login will still be created but it will be disabled. Local authentication can be enabled later by an Azure Owner or Contributor of the Synapse workspace.



You can also disable local authentication after a workspace is created through the Azure portal. Local authentication cannot be disabled until an Azure Active Directory admin is created for the Azure Synapse workspace.



Azure AD features and limitations

- The following members of Azure AD can be provisioned in Synapse SQL:
  - Native members: A member created in Azure AD in the managed domain or in a customer domain. For more information, see Add your own domain name to Azure AD.
  - Federated domain members: A member created in Azure AD with a federated domain. For more information, see Microsoft Azure now supports federation with Windows Server Active Directory.
  - Imported members from other Azure ADs who are native or federated domain members.
  - Active Directory groups created as security groups.
- Azure AD users that are part of a group that has `db_owner` server role can't use the **CREATE DATABASE SCOPED CREDENTIAL** syntax in Synapse SQL. You will see the following error:

  ```
  SQL Error [2760] [S0001]: The specified schema name 'user@mydomain.com' either does not exist or you
  do not have permission to use it.
  ```

  Grant the `db_owner` role directly to the individual Azure AD user to mitigate the **CREATE DATABASE SCOPED CREDENTIAL** issue.

- These system functions return NULL values when executed under Azure AD principals:
  - `SUSER_ID()`
  - `SUSER_NAME(<admin ID>)`
  - `SUSER_SNAME(<admin SID>)`
  - `SUSER_ID(<admin name>)`
  - `SUSER_SID(<admin name>)`

Connect using Azure AD identities

Azure Active Directory authentication supports the following methods of connecting to a database using Azure AD identities:

- Azure Active Directory Password
- Azure Active Directory Integrated
- Azure Active Directory Universal with MFA
- Using Application token authentication

The following authentication methods are supported for Azure AD server principals (logins):

- Azure Active Directory Password
- Azure Active Directory Integrated
- Azure Active Directory Universal with MFA

Additional considerations

- To enhance manageability, we recommend you provision a dedicated Azure AD group as an administrator.
- Only one Azure AD administrator (a user or group) can be configured for Synapse SQL pool at any time.
  - The addition of Azure AD server principals (logins) for Synapse SQL allows the possibility of creating multiple Azure AD server principals (logins) that can be added to the `sysadmin` role.
- Only an Azure AD administrator for Synapse SQL can initially connect to Synapse SQL using an Azure Active Directory account. The Active Directory administrator can configure subsequent Azure AD database users.
- We recommend setting the connection timeout to 30 seconds.
- SQL Server 2016 Management Studio and SQL Server Data Tools for Visual Studio 2015 (version 14.0.60311.1April 2016 or later) support Azure Active Directory authentication. (Azure AD authentication is supported by the **.NET Framework Data Provider for SqlServer**; at least version .NET Framework 4.6). So, the newest versions of these tools and data-tier applications (DAC and .BACPAC) can use Azure AD authentication.
- Beginning with version 15.0.1, sqlcmd utility and bcp utility support Active Directory Interactive authentication with MFA.
- SQL Server Data Tools for Visual Studio 2015 requires at least the April 2016 version of the Data Tools (version 14.0.60311.1). Currently, Azure AD users aren't shown in SSDT Object Explorer. As a workaround, view the users in sys.database_principals.
- Microsoft JDBC Driver 6.0 for SQL Server supports Azure AD authentication. Also, see Setting the Connection Properties.
- The Azure Active Directory admin account controls access to dedicated SQL pools, while Synapse RBAC roles are used to control access to serverless pools, for example, the **Synapse Administrator** role. Configure Synapse RBAC roles via Synapse Studio, for more information, see How to manage Synapse RBAC role assignments in Synapse Studio.

Next steps

- For an overview of access and control in Synapse SQL, see Synapse SQL access control.
- For more information about database principals, see Principals.
- For more information about database roles, see Database roles.

Use Multi-factor AAD authentication with Synapse SQL (SSMS support for MFA)

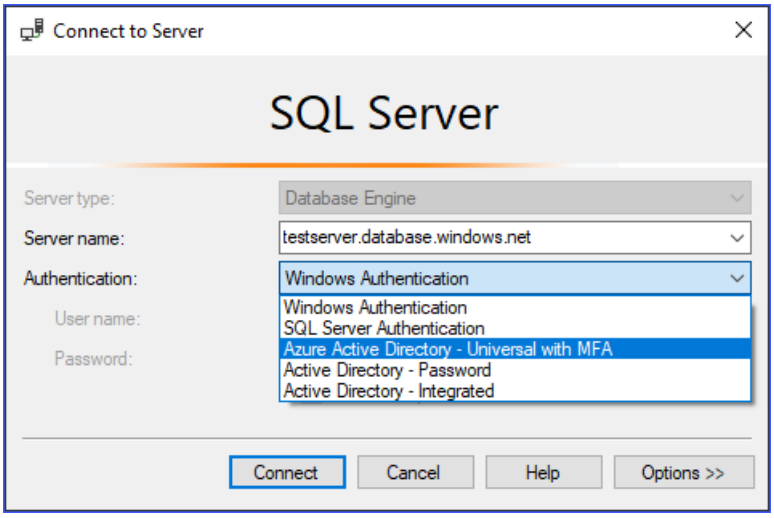
8/19/2022 • 4 minutes to read • Edit Online

Synapse SQL support connections from SQL Server Management Studio (SSMS) using *Active Directory Universal Authentication*.

This article discusses the differences between the various authentication options, and also the limitations associated with using Universal Authentication.

Download the latest SSMS - On the client computer, download the latest version of SSMS, from Download SQL Server Management Studio (SSMS).

For all the features discussed in this article, use at least July 2017, version 17.2. The most recent connection dialog box, should look similar to the following image:



The five authentication options

Active Directory Universal Authentication supports the two non-interactive authentication methods: - `Active Directory - Password` authentication - `Active Directory - Integrated` authentication

There are two non-interactive authentication models as well, which can be used in many different applications (ADO.NET, JDCB, ODC, etc.). These two methods never result in pop-up dialog boxes:

- `Active Directory - Password`
- `Active Directory - Integrated`

The interactive method is that also supports Azure AD Multi-Factor Authentication (MFA) is:

- `Active Directory - Universal with MFA`

Azure AD MFA helps safeguard access to data and applications while meeting user demand for a simple sign-in process. It delivers strong authentication with a range of easy verification options (phone call, text message, smart cards with pin, or mobile app notification), allowing users to choose the method they prefer. Interactive MFA with Azure AD can result in a pop-up dialog box for validation.

For a description of Multi-Factor Authentication, see Multi-Factor Authentication.

Azure AD domain name or tenant ID parameter

Beginning with SSMS version 17, users that are imported into the current Active Directory from other Azure Active Directories as guest users, can provide the Azure AD domain name, or tenant ID when they connect.

Guest users include users invited from other Azure ADs, Microsoft accounts such as outlook.com, hotmail.com, live.com, or other accounts like gmail.com. This information, allows **Active Directory Universal with MFA Authentication** to identify the correct authenticating authority. This option is also required to support Microsoft accounts (MSA) such as outlook.com, hotmail.com, live.com, or non-MSA accounts.

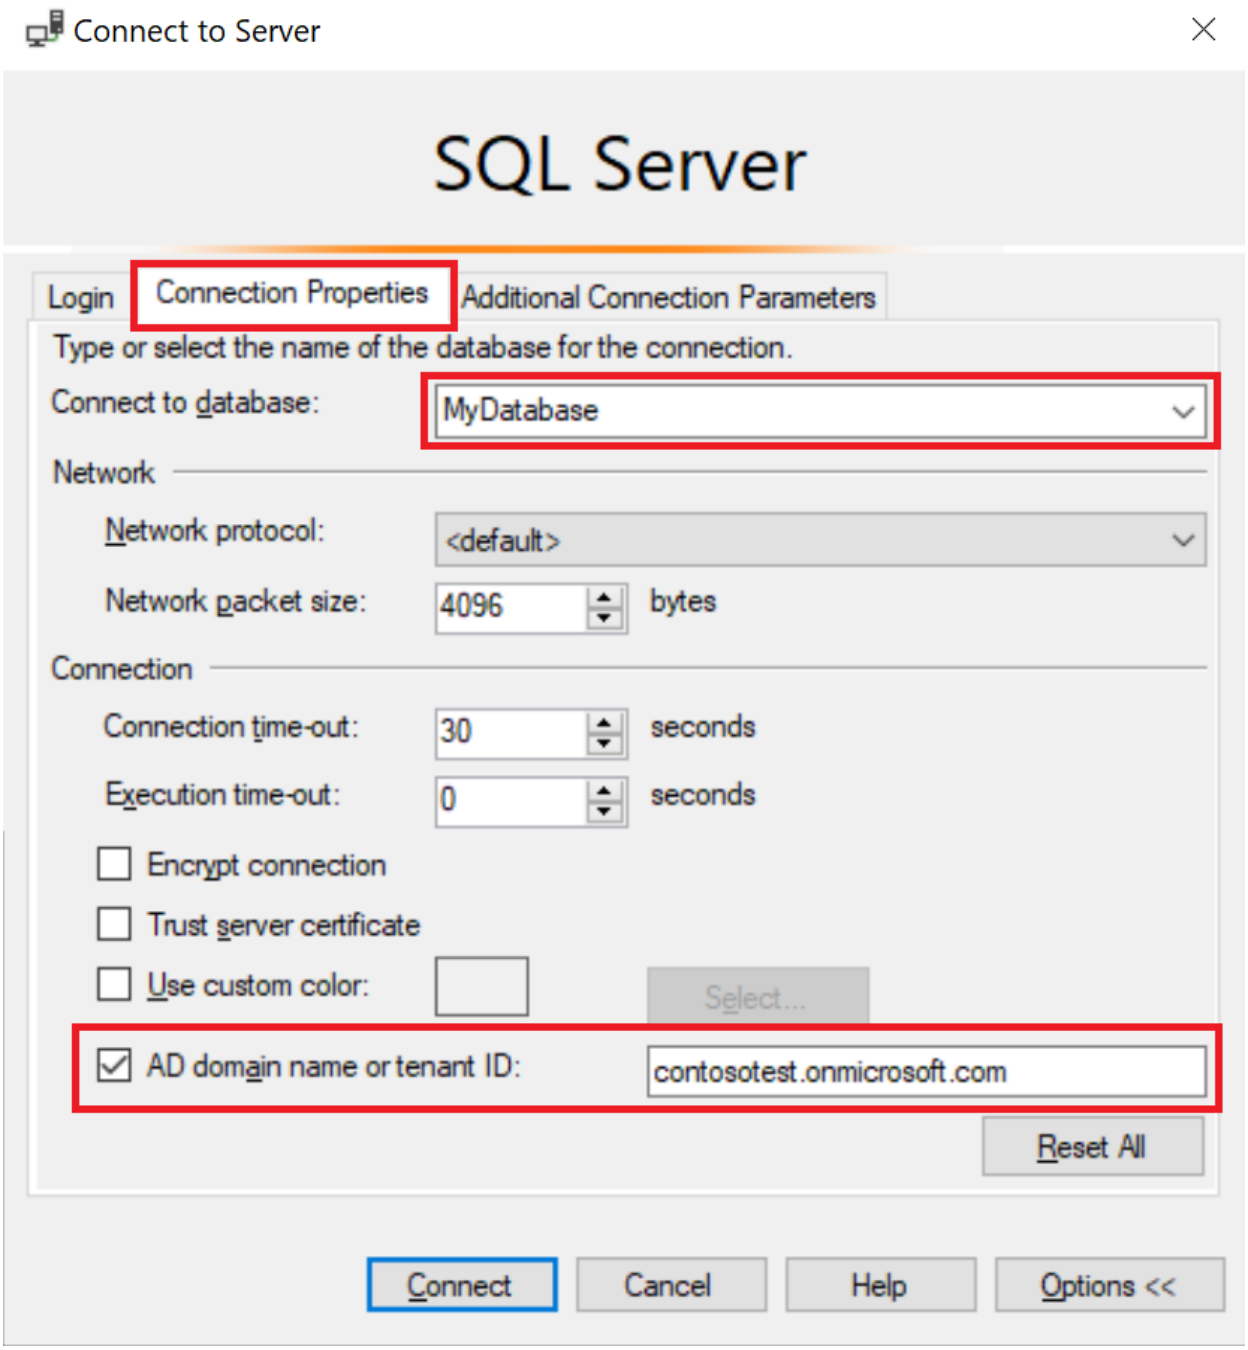
All these users who want to be authenticated using Universal Authentication must enter their Azure AD domain name or tenant ID. This parameter represents the current Azure AD domain name/tenant ID the Azure Server is linked with.

For example, if Azure Server is associated with Azure AD domain `contosotest.onmicrosoft.com` where user `joe@contosodev.onmicrosoft.com` is hosted as an imported user from Azure AD domain `contosodev.onmicrosoft.com`, the domain name required to authenticate this user is `contosotest.onmicrosoft.com`.

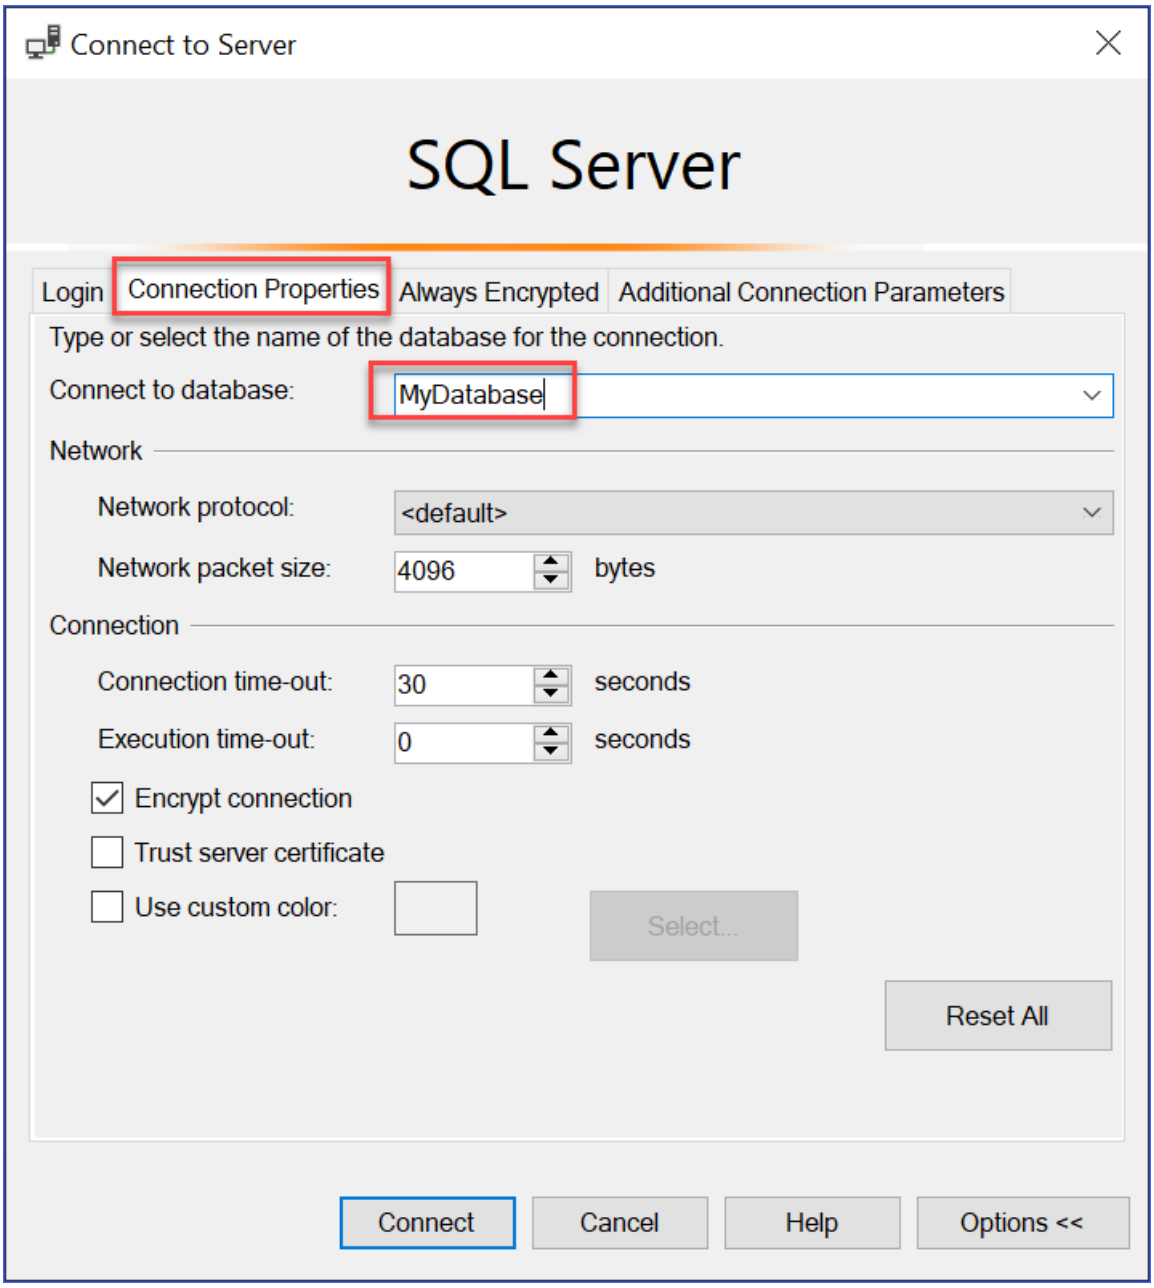
When the user is a native user of the Azure AD linked to Azure Server, and is not an MSA account, no domain name or tenant ID is required.

To enter the parameter (beginning with SSMS version 17.2), in the **Connect to Database** dialog box, complete the dialog box, selecting **Active Directory - Universal with MFA** authentication, select **Options**, complete the **User name** box, and then select the **Connection Properties** tab.

Check the **AD domain name or tenant ID** box, and provide authenticating authority, such as the domain name (**contosotest.onmicrosoft.com**) or the GUID of the tenant ID.



If you are running SSMS 18.x or later, then the AD domain name or tenant ID is no longer needed for guest users because 18.x or later automatically recognizes it.



Azure AD business to business support

Azure AD users supported for Azure AD B2B scenarios as guest users (see What is Azure B2B collaboration can connect to Synapse SQL only as part of members of a group created in current Azure AD and mapped manually using the Transact-SQL `CREATE USER` statement in a given database.

For example, if `steve@gmail.com` is invited to Azure AD `contosotest` (with the Azure Ad domain `contosotest.onmicrosoft.com`), an Azure AD group, such as `usergroup` must be created in the Azure AD that contains the `steve@gmail.com` member. Then, this group must be created for a specific database (that is, MyDatabase) by Azure AD SQL admin or Azure AD DBO by executing a Transact-SQL `CREATE USER [usergroup] FROM EXTERNAL PROVIDER` statement.

After the database user is created, then the user `steve@gmail.com` can log in to `MyDatabase` using the SSMS authentication option `Active Directory - Universal with MFA support`.

The usergroup, by default, has only the connect permission and any further data access that will need to be granted in the normal way.

As a guest user, `steve@gmail.com` must check the box and add the AD domain name `contosotest.onmicrosoft.com` in the SSMS **Connection Property** dialog box. The **AD domain name or tenant ID** option is only supported for the Universal with MFA connection options, otherwise it is greyed out.

Universal Authentication limitations for Synapse SQL

- SSMS and SqlPackage.exe are the only tools currently enabled for MFA through Active Directory Universal Authentication.
- SSMS version 17.2, supports multi-user concurrent access using Universal Authentication with MFA. Version 17.0 and 17.1, restricted a login for an instance of SSMS using Universal Authentication to a single Azure Active Directory account. To log in as another Azure AD account, you must use another instance of SSMS. (This restriction is limited to Active Directory Universal Authentication; you can log in to different servers using Active Directory Password Authentication, Active Directory Integrated Authentication, or SQL Server Authentication).
- SSMS supports Active Directory Universal Authentication for Object Explorer, Query Editor, and Query Store visualization.
- SSMS version 17.2 provides DacFx Wizard support for Export/Extract/Deploy Data database. Once a specific user is authenticated through the initial authentication dialog using Universal Authentication, the DacFx Wizard functions the same way it does for all other authentication methods.
- The SSMS Table Designer doesn't support Universal Authentication.
- There are no additional software requirements for Active Directory Universal Authentication except that you must use a supported version of SSMS.
- The Active Directory Authentication Library (ADAL) version for Universal authentication was updated to its latest ADAL.dll 3.13.9 available released version. See Active Directory Authentication Library 3.14.1.

SQL Authentication in Azure Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

Azure Synapse Analytics has two SQL form-factors that enable you to control your resource consumption. This article explains how the two form-factors control the user authentication.

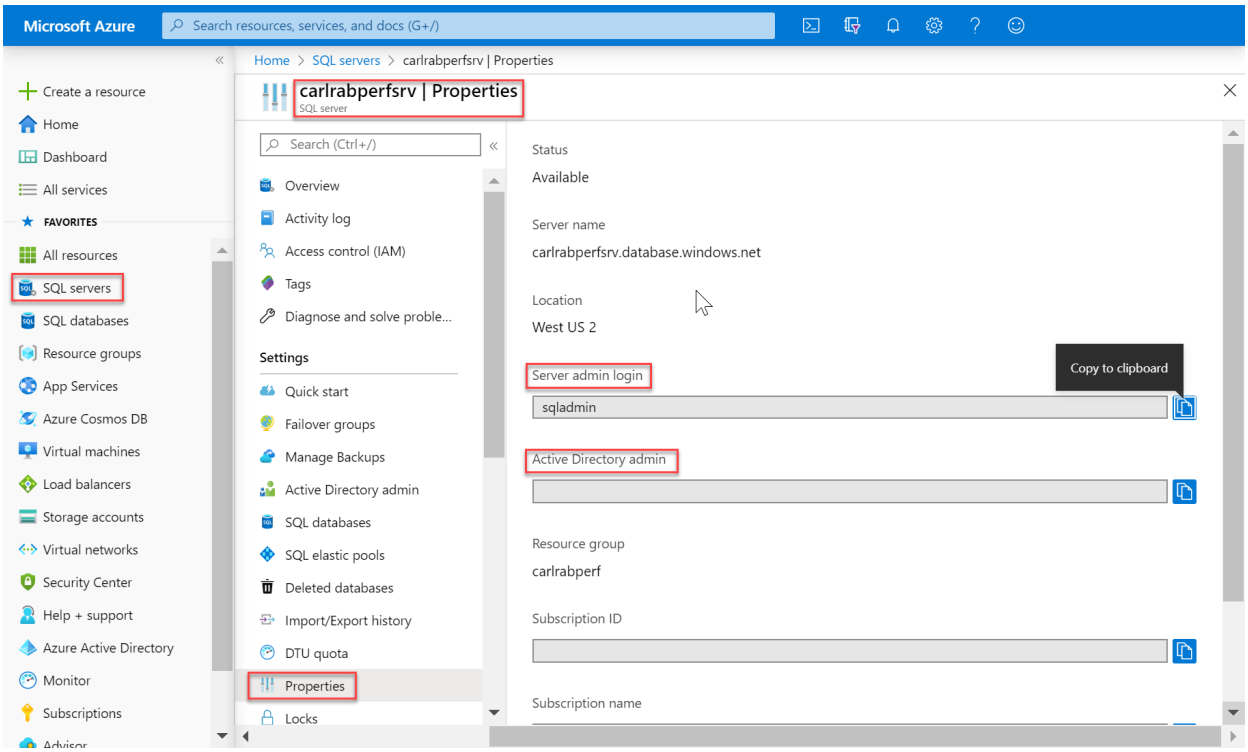
To authorize to Synapse SQL, you can use two authorization types:

- Azure Active Directory authorization
- SQL authorization

SQL authorization enables legacy applications to connect to Azure Synapse SQL in a familiar way. However, Azure Active Directory authentication allows you to centrally manage access to Azure Synapse resources, such as SQL pools. Azure Synapse Analytics supports disabling local authentication, such as SQL authentication, both during and after workspace creation. Once disabled, local authentication can be enabled at any time by authorized users. For more information on Azure AD-only authentication, see Disabling local authentication in Azure Synapse Analytics.

Administrative accounts

There are two administrative accounts (**SQL admin username** and **SQL Active Directory admin**) that act as administrators. To identify these administrator accounts for your SQL pools open the Azure portal, and navigate to the Properties tab of your Synapse workspace.



- **SQL admin username**

  When you create an Azure Synapse Analytics, you must name a **Server admin login**. SQL server creates that account as a login in the `master` database. This account connects using SQL Server authentication (user name and password). Only one of these accounts can exist.

- **SQL Active Directory admin**

One Azure Active Directory account, either an individual or security group account, can also be configured as an administrator. It's optional to configure an Azure AD administrator, but an Azure AD administrator **must** be configured if you want to use Azure AD accounts to connect to Synapse SQL.

- The Azure Active Directory admin account controls access to dedicated SQL pools, while Synapse RBAC roles are used to control access to serverless pools, for example, the **Synapse Administrator** role. Changing the Azure Active Directory administrator account will only affect the account's access to dedicated SQL pools.

The **SQL admin username** and **SQL Active Directory admin** accounts have the following characteristics:

- Are the only accounts that can automatically connect to any SQL Database on the server. (To connect to a user database, other accounts must either be the owner of the database, or have a user account in the user database.)
- These accounts enter user databases as the `dbo` user and they have all the permissions in the user databases. (The owner of a user database also enters the database as the `dbo` user.)
- Don't enter the `master` database as the `dbo` user, and have limited permissions in the `master` database.
- Are **not** members of the standard SQL Server `sysadmin` fixed server role, which is not available in SQL Database.
- Can create, alter, and drop databases, logins, users in the `master` database, and server-level IP firewall rules.
- Can add and remove members to the `dbmanager` and `loginmanager` roles.
- Can view the `sys.sql_logins` system table.

- Serverless SQL pool
- Dedicated SQL pool

To manage the users having access to serverless SQL pool, you can use the instructions below.

To create a login to serverless SQL pool, use the following syntax:

```
CREATE LOGIN Mary WITH PASSWORD = '<strong_password>';
-- or
CREATE LOGIN [Mary@domainname.net] FROM EXTERNAL PROVIDER;
```

When the login exists, you can create users in the individual databases within the serverless SQL pool endpoint and grant required permissions to these users. To create a user, you can use the following syntax:

```
CREATE USER Mary FROM LOGIN Mary;
-- or
CREATE USER Mary FROM LOGIN Mary@domainname.net;
-- or
CREATE USER [mike@contoso.com] FROM EXTERNAL PROVIDER;
```

Once login and user are created, you can use the regular SQL Server syntax to grant rights.

Non-administrator users

Generally, non-administrator accounts don't need access to the `master` database. Create contained database users at the database level using the CREATE USER (Transact-SQL) statement.

The user can be an Azure Active Directory authentication contained database user (if you have configured your environment for Azure AD authentication), or a SQL Server authentication contained database user, or a SQL Server authentication user based on a SQL Server authentication login (created in the previous step.)

To create users, connect to the database, and execute statements similar to the following examples:

```
CREATE USER Mary FROM LOGIN Mary;
CREATE USER [mike@contoso.com] FROM EXTERNAL PROVIDER;
```

Initially, only one of the administrators or the owner of the database can create users. To authorize additional users to create new users, grant that selected user the `ALTER ANY USER` permission, by using a statement such as:

```
GRANT ALTER ANY USER TO Mary;
```

To give additional users full control of the database, make them a member of the **db_owner** fixed database role.

In Azure SQL Database or synapse serverless, use the `ALTER ROLE` statement.

```
ALTER ROLE db_owner ADD MEMBER Mary;
```

In dedicated SQL pool use EXEC sp_addrolemember.

```
EXEC sp_addrolemember 'db_owner', 'Mary';
```

> **NOTE**
> One common reason to create a database user based on a server login is for users that need access to multiple databases. Since contained database users are individual entities, each database maintains its own user and its own password. This can cause overhead as the user must then remember each password for each database, and it can become untenable when having to change multiple passwords for many databases.

Groups and roles

Efficient access management uses permissions assigned to groups and roles instead of individual users.

- When using Azure Active Directory authentication, put Azure Active Directory users into an Azure Active Directory group. Create a contained database user for the group. Place one or more database users into a database role and then assign permissions to the database role.
- When using SQL Server authentication, create contained database users in the database. Place one or more database users into a database role and then assign permissions to the database role.

The database roles can be the built-in roles such as **db_owner**, **db_ddladmin**, **db_datawriter**, **db_datareader**, **db_denydatawriter**, and **db_denydatareader**. **db_owner** is commonly used to grant full permission to only a few users. The other fixed database roles are useful for getting a simple database in development quickly, but are not recommended for most production databases.

For example, the **db_datareader** fixed database role grants read access to every table in the database, which is usually more than is strictly necessary.

It's far better to use the CREATE ROLE statement to create your own user-defined database roles and carefully grant each role the least permissions necessary for the business need. When a user is a member of multiple roles, they aggregate the permissions of them all.

Permissions

There are over 100 permissions that can be individually granted or denied in SQL Database. Many of these permissions are nested. For example, the `UPDATE` permission on a schema includes the `UPDATE` permission on

each table within that schema. As in most permission systems, the denial of a permission overrides a grant.

Because of the nested nature and the number of permissions, it can take careful study to design an appropriate permission system to properly protect your database.

Start with the list of permissions at Permissions (Database Engine) and review the poster size graphic of database engine permissions.

Considerations and restrictions

When managing logins and users in SQL Database, consider the following points:

- You must be connected to the `master` database when executing the `CREATE/ALTER/DROP DATABASE` statements.
- The database user corresponding to the **Server admin** login can't be altered or dropped.
- **Server admin** will be disabled if Azure AD-only authentication is enabled.
- US-English is the default language of the **Server admin** login.
- Only the administrators (**Server admin** login or Azure AD administrator) and the members of the **dbmanager** database role in the `master` database have permission to execute the `CREATE DATABASE` and `DROP DATABASE` statements.
- You must be connected to the `master` database when executing the `CREATE/ALTER/DROP LOGIN` statements. However, using logins is discouraged. Use contained database users instead. For more information, see Contained Database Users - Making Your Database Portable.
- To connect to a user database, you must provide the name of the database in the connection string.
- Only the server-level principal login and the members of the **loginmanager** database role in the `master` database have permission to execute the `CREATE LOGIN`, `ALTER LOGIN`, and `DROP LOGIN` statements.
- When executing the `CREATE/ALTER/DROP LOGIN` and `CREATE/ALTER/DROP DATABASE` statements in an ADO.NET application, using parameterized commands isn't allowed. For more information, see Commands and Parameters.
- When executing the `CREATE USER` statement with the `FOR/FROM LOGIN` option, it must be the only statement in a Transact-SQL batch.
- When executing the `ALTER USER` statement with the `WITH LOGIN` option, it must be the only statement in a Transact-SQL batch.
- `CREATE/ALTER/DROP LOGIN` and `CREATE/ALTER/DROP USER` statements are not supported when Azure AD-only authentication is enabled for the Azure Synapse workspace.
- To `CREATE/ALTER/DROP` a user requires the `ALTER ANY USER` permission on the database.
- When the owner of a database role tries to add or remove another database user to or from that database role, the following error may occur: **User or role 'Name' does not exist in this database.** This error occurs because the user isn't visible to the owner. To resolve this issue, grant the role owner the `VIEW DEFINITION` permission on the user.

For more information, see Contained Database Users - Making Your Database Portable.

Conditional Access in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

You can now configure conditional access policies for Azure Synapse workspaces. Conditional access is a tool provided by Azure Active Directory to bring several signals such as device type and device IP location together to make decisions to grant access, block access, or enforce multi-factor authentication for a resource. Conditional access policies are configured in Azure Active Directory. Learn more about conditional access.

Configure conditional access

The following steps show how to configure a conditional access policy for Azure Synapse workspaces.

1. Sign in to the Azure portal using an account with *global administrator permissions*, select **Azure Active Directory**, choose **Security** from the menu.
2. Select **Conditional Access**, then choose **+ New Policy**, and provide a name for the policy.
3. Under **Assignments**, select **Users and groups**, check the **Select users and groups** option, and then select an Azure AD user or group for Conditional access. Click Select, and then click Done.
4. Select **Cloud apps**, click **Select apps**. Select **Microsoft Azure Synapse Gateway**. Then click Select and Done.
5. Under **Access Controls**, select **Grant** and then check the policy you want to apply, and select Done.
6. Set the **Enable policy** toggle to **On**, then select Create.

Next steps

Azure Synapse access control

8/19/2022 • 6 minutes to read • Edit Online

This article provides an overview of the mechanisms available to control access to Azure Synapse compute resources and data.

Overview

Azure Synapse provides a comprehensive and fine-grained access control system, that integrates:

- **Azure roles** for resource management and access to data in storage,
- **Synapse roles** for managing live access to code and execution,
- **SQL roles** for data plane access to data in SQL pools, and
- **Git permissions** for source code control, including continuous integration and deployment support.

Azure Synapse roles provide sets of permissions that can be applied at different scopes. This granularity makes it easy to grant appropriate access to administrators, developers, security personnel, and operators to compute resources and data.

Access control can be simplified by using security groups that are aligned with people's job roles. You only need to add and remove users from appropriate security groups to manage access.

Access control elements

Create and manage Azure Synapse compute resources

Azure roles are used to control management of:

- Dedicated SQL pools
- Data Explorer pools
- Apache Spark pools
- Integration runtimes

To *create* these resources, you need to be an Azure Owner or Contributor on the resource group. To *manage* them once created, you need to be an Azure Owner or Contributor on either the resource group or the individual resources.

An Azure Owner or Contributor can enable or disable Azure AD-only authentication for Azure Synapse workspaces. For more information on Azure AD-only authentication, see Disabling local authentication in Azure Synapse Analytics.

Develop and execute code in Azure Synapse

Synapse supports two development models.

- **Synapse live development**. You develop and debug code in Synapse Studio and then **publish** it to save and execute. The Synapse service is the source of truth for code editing and execution. Any unpublished work is lost when you close Synapse Studio.
- **Git-enabled development**. You develop and debug code in Synapse Studio and **commit** changes to a working branch of a Git repo. Work from one or more branches is integrated into a collaboration branch, from where you **publish** it to the service. The Git repo is the source of truth for code editing, while the service is the source of truth for execution. Changes must be committed to the Git repo or published to the service before closing Synapse Studio. Learn more about using Synapse Analytics with Git.

In both development models, any user with access to Synapse Studio can create code artifacts. However, you need additional permissions to publish artifacts to the service, read published artifacts, to commit changes to Git, to execute code, and to access linked data protected by credentials.

Azure Synapse roles

Azure Synapse roles are used to control access to the Synapse service. Different roles can permit you to:

- List published code artifacts,
- Publish code artifacts, linked services, and credential definitions,
- Execute code or pipelines that use Synapse compute resources,
- Execute code or pipelines that access linked data protected by credentials,
- View outputs associated with published code artifacts,
- Monitor compute resource status, and view runtime logs.

Azure Synapse roles can be assigned at the workspace scope or at finer-grained scopes to limit the permissions granted to specific Azure Synapse resources.

Git permissions

When using Git-enabled development in Git mode, you need Git permissions in addition to the Synapse User or Synapse RBAC (role-based access control) roles to read code artifacts, including linked service and credential definitions. To commit changes to code artifacts in Git mode, you need Git permissions, and the Synapse Artifact Publisher (Synapse RBAC) role.

Access data in SQL

When working with dedicated and serverless SQL pools, data plane access is controlled using SQL permissions.

The creator of a workspace is assigned as the Active Directory Admin on the workspace. After creation, this role can be assigned to a different user or to a security group in the Azure portal.

Serverless SQL pools: Synapse Administrators are granted `db_owner` (`DBO`) permissions on the serverless SQL pool, 'Built-in'. To grant other users access to serverless SQL pools, Synapse administrators need to run SQL scripts on each serverless pool.

Dedicated SQL pools: Synapse Administrators have full access to data in dedicated SQL pools, and the ability to grant access to other users. Synapse Administrators can also perform configuration and maintenance activities on dedicated pools, except for dropping databases. Active Directory Admin permission is granted to the creator of the workspace and the workspace MSI. Permission to access dedicated SQL pools isn't otherwise granted automatically. To grant other users or groups access to dedicated SQL pools, the Active Directory Admin or Synapse Administrator must run SQL scripts against each dedicated SQL pool.

See How to set up Synapse Access Control for examples of SQL scripts for granting SQL permissions in SQL pools.

Accessing data in Data Explorer pools

When working with Data Explorer pools, data plane access is controlled through Data Explorer permissions. Synapse Administrators are granted `All Database admin` permissions on Data Explorer pools. To grant other users or groups access to Data Explorer pools, Synapse administrators should refer to Security roles management. For more information on data plane access, see Data Explorer access control overview.

Accessing system-managed data in storage

Serverless SQL pools and Apache Spark tables store their data in an ADLS Gen2 container associated with the workspace. User-installed Apache Spark libraries are also managed in the same storage account. To enable these use cases, users and the workspace MSI must be granted **Storage Blob Data Contributor** access to this workspace ADLS Gen2 storage container.

Using security groups as a best practice

To simplify managing access control, you can use security groups to assign roles to individuals and groups. Security groups can be created to mirror personas or job functions in your organization that need access to Synapse resources or artifacts. These persona-based security groups can then be assigned one or more Azure roles, Synapse roles, SQL permissions, or Git permissions. With well-chosen security groups, it's easy to assign a user the required permissions by adding them to the appropriate security group.

> **NOTE**
> If using security groups to manage access, there is additional latency introduced by Azure Active Directory before changes take effect.

Access control enforcement in Synapse Studio

Synapse Studio will behave differently based on your permissions and the current mode:

- **Synapse live mode:** Synapse Studio will prevent you from seeing published content, publishing content, or taking other actions if you don't have the required permission. In some cases, you'll be prevented from creating code artifacts that you can't use or save.
- **Git-mode:** If you have Git permissions that let you commit changes to the current branch, then the commit action will be permitted if you have permission to publish changes to the live service (Synapse Artifact Publisher role).

In some cases, you're allowed to create code artifacts even without permission to publish or commit. This allows you to execute code (with the required execution permissions). For more information on the roles required for common tasks, see Understand the roles required to perform common tasks in Azure Synapse.

If a feature is disabled in Synapse Studio, a tooltip will indicate the required permission. Use the Synapse RBAC roles guide to look up which role is required to provide the missing permission.

What is Synapse role-based access control (RBAC)?

8/19/2022 • 3 minutes to read • Edit Online

Synapse RBAC extends the capabilities of Azure RBAC for Synapse workspaces and their content.

Azure RBAC is used to manage who can create, update, or delete the Synapse workspace and its SQL pools, Apache Spark pools, and Integration runtimes.

Synapse RBAC is used to manage who can:

- Publish code artifacts and list or access published code artifacts,
- Execute code on Apaches Spark pools and Integration runtimes,
- Access linked (data) services protected by credentials
- Monitor or cancel job execution, review job output, and execution logs.

> **NOTE**
> While Synapse RBAC is used to manage access to published SQL scripts, it provides only limited access control to serverless and dedicated SQL pools. Access to SQL pools is primarily controlled using SQL security.

What can I do with Synapse RBAC?

Here are some examples of what you can do with Synapse RBAC:

- Allow a user to publish changes made to Apache Spark notebooks and jobs to the live service.
- Allow a user to run and cancel notebooks and spark jobs on a specific Apache Spark pool.
- Allow a user to use specific credentials so they can run pipelines secured by the workspace system identity and access data in linked services secured with credentials.
- Allow an administrator to manage, monitor, and cancel job execution on specific Spark Pools.

How Synapse RBAC works

Like Azure RBAC, Synapse RBAC works by creating role assignments. A role assignment consists of three elements: a security principal, a role definition, and a scope.

Security Principals

A *security principal* is a user, group, service principal, or managed identity.

Roles

A *role* is a collection of permissions or actions that can be performed on specific resource types or artifact types.

Synapse provides built-in roles that define collections of actions that match the needs of different personas:

- Administrators can get full access to create and configure a workspace
- Developers can create, update and debug SQL scripts, notebooks, pipelines, and dataflows, but not be able to publish or execute this code on production compute resources/data
- Operators can monitor and manage system status, application execution and review logs, without access to code or the outputs from execution.
- Security staff can manage and configure endpoints without having access to code, compute resources or data.

Learn more about the built-in Synapse roles.

Scopes

A *scope* defines the resources or artifacts that the access applies to. Azure Synapse supports hierarchical scopes. Permissions granted at a higher-level scope are inherited by objects at a lower level. In Synapse RBAC, the top-level scope is a workspace. Assigning a role with workspace scope grants permissions to all applicable objects in the workspace.

Current supported scopes within a workspace are:

- Apache Spark pool
- Integration runtime
- linked service
- credential

Access to code artifacts is granted with workspace scope. Granting access to collections of artifacts within a workspace will be supported in a later release.

Resolving role assignments to determine permissions

A role assignment grants a principal the permissions defined by the role at the specified scope.

Synapse RBAC is an additive model like Azure RBAC. Multiple roles may be assigned to a single principal and at different scopes. When computing the permissions of a security principal, the system considers all roles assigned to the principal and to groups that directly or indirectly include the principal. It also considers the scope of each assignment in determining the permissions that apply.

Enforcing assigned permissions

In Synapse Studio, specific buttons or options may be grayed out or a permissions error may be returned when attempting an action if you don't have the required permissions.

If a button or option is disabled, hovering over the button or option shows a tooltip with the required permission. Contact a Synapse Administrator to assign a role that grants the required permission. You can see the roles that provide specific actions, see Synapse RBAC Roles.

Who can assign Synapse RBAC roles?

Synapse Administrators can assign Synapse RBAC roles. A Synapse Administrator at the workspace level can grant access at any scope. A Synapse Administrator at a lower-level scope can only grant access at that scope.

When a new workspace is created, the creator is automatically given the Synapse Administrator role at workspace scope.

To help you regain access to a workspace in the event that no Synapse Administrators are assigned or available to you, users with permissions to manage Azure RBAC role assignments on the workspace can also manage Synapse RBAC role assignments, allowing the addition of Synapse Administrator or other Synapse role assignments.

Where do I manage Synapse RBAC?

Synapse RBAC is managed from within Synapse Studio using the access control tools in the **Manage** hub.

Learn how to assign Synapse RBAC roles

Synapse RBAC Roles

8/19/2022 • 8 minutes to read • Edit Online

The article describes the built-in Synapse RBAC (role-based access control) roles, the permissions they grant, and the scopes at which they can be used.

For more information on reviewing and assigning Synapse role memberships, see how to review Synapse RBAC role assignments and how to assign Synapse RBAC roles.

What's changed since the preview?

For users familiar with the Synapse RBAC roles provided during the preview, the following changes apply:

- Workspace Admin is renamed **Synapse Administrator**
- Apache Spark Admin is renamed **Synapse Apache Spark Administrator** and has permission to see all published code artifacts, including SQL scripts. This role no longer gives permission to use the workspace MSI, which requires the Synapse Credential User role. This permission is required to run pipelines.
- SQL Admin is renamed **Synapse SQL Administrator** and has permission to see all published code artifacts, including Spark notebooks and jobs. This role no longer gives permission to use the workspace MSI, which requires the Synapse Credential User role. This permission is required to run pipelines.
- **New finer-grained Synapse RBAC roles** are introduced that focus on supporting development and operations personas rather than specific analytics runtimes.
- **New lower-level scopes** are introduced for several roles. These scopes allow roles to be restricted to specific resources or objects.

Built-in Synapse RBAC roles and scopes

The following table describes the built-in roles and the scopes at which they can be used.

> **NOTE**
> Users with any Synapse RBAC role at any scope automatically have the Synapse User role at workspace scope.

> **IMPORTANT**
> Synapse RBAC roles do not grant permissions to create or manage SQL pools, Apache Spark pools, and Integration runtimes in Azure Synapse workspaces. Azure Owner or Azure Contributor roles on the resource group are required for these actions.

ROLE	PERMISSIONS	SCOPES

ROLE	PERMISSIONS	SCOPES
Synapse Administrator	Full Synapse access to SQL pools, Data Explorer pools, Apache Spark pools, and Integration runtimes. Includes create, read, update, and delete access to all published code artifacts. Includes Compute Operator, Linked Data Manager, and Credential User permissions on the workspace system identity credential. Includes assigning Synapse RBAC roles. In addition to Synapse Administrator, Azure Owners can also assign Synapse RBAC roles. Azure permissions are required to create, delete, and manage compute resources. *Can read and write artifacts* *Can do all actions on Spark activities.* *Can view Spark pool logs* *Can view saved notebook and pipeline output* *Can use the secrets stored by linked services or credentials* *Can assign and revoke Synapse RBAC roles at current scope*	Workspace Spark pool Integration runtime Linked service Credential
Synapse Apache Spark Administrator	Full Synapse access to Apache Spark Pools. Create, read, update, and delete access to published Spark job definitions, notebooks and their outputs, and to libraries, linked services, and credentials. Includes read access to all other published code artifacts. Doesn't include permission to use credentials and run pipelines. Doesn't include granting access. *Can do all actions on Spark artifacts* *Can do all actions on Spark activities*	Workspace Spark pool
Synapse SQL Administrator	Full Synapse access to serverless SQL pools. Create, read, update, and delete access to published SQL scripts, credentials, and linked services. Includes read access to all other published code artifacts. Doesn't include permission to use credentials and run pipelines. Doesn't include granting access. *Can do all actions on SQL scripts* *Can connect to SQL serverless endpoints with SQL* `db_datareader`, `db_datawriter`, `connect`, *and* `grant` *permissions*	Workspace

ROLE	PERMISSIONS	SCOPES
Synapse Contributor	Full Synapse access to Apache Spark pools and Integration runtimes. Includes create, read, update, and delete access to all published code artifacts and their outputs, including credentials and linked services. Includes compute operator permissions. Doesn't include permission to use credentials and run pipelines. Doesn't include granting access. *Can read and write artifacts* *Can view saved notebook and pipeline output* *Can do all actions on Spark activities* *Can view Spark pool logs*	Workspace Spark pool Integration runtime
Synapse Artifact Publisher	Create, read, update, and delete access to published code artifacts and their outputs. Doesn't include permission to run code or pipelines, or to grant access. *Can read published artifacts and publish artifacts* *Can view saved notebook, Spark job, and pipeline output*	Workspace
Synapse Artifact User	Read access to published code artifacts and their outputs. Can create new artifacts but can't publish changes or run code without additional permissions.	Workspace
Synapse Compute Operator	Submit Spark jobs and notebooks and view logs. Includes canceling Spark jobs submitted by any user. Requires additional use credential permissions on the workspace system identity to run pipelines, view pipeline runs and outputs. *Can submit and cancel jobs, including jobs submitted by others* *Can view Spark pool logs*	Workspace Spark pool Integration runtime
Synapse Monitoring Operator	Read published code artifacts, including logs and outputs for notebooks and pipeline runs. Includes ability to list and view details of serverless SQL pools, Apache Spark pools, Data Explorer pools, and Integration runtimes. Requires additional permissions to run/cancel pipelines, Spark notebooks, and Spark jobs.	Workspace

ROLE	PERMISSIONS	SCOPES
Synapse Credential User	Runtime and configuration-time use of secrets within credentials and linked services in activities like pipeline runs. To run pipelines, this role is required, scoped to the workspace system identity. *Scoped to a credential, permits access to data via a linked service that is protected by the credential (may also require compute use permission)* *Allows execution of pipelines protected by the workspace system identity credential*	Workspace Linked Service Credential
Synapse Linked Data Manager	Creation and management of managed private endpoints, linked services, and credentials. Can create managed private endpoints that use linked services protected by credentials	Workspace
Synapse User	List and view details of SQL pools, Apache Spark pools, Integration runtimes, and published linked services and credentials. Doesn't include other published code artifacts. Can create new artifacts but can't run or publish without additional permissions. *Can list and read Spark pools, Integration runtimes.*	Workspace, Spark pool Linked service Credential

Synapse RBAC roles and the actions they permit

NOTE

- All actions listed in the tables below are prefixed, "Microsoft.Synapse/..."
- All artifact read, write, and delete actions are with respect to published artifacts in the live service. These permissions do not affect access to artifacts in a connected Git repo.

The following table lists the built-in roles and the actions/permissions that each support.

ROLE	ACTIONS

ROLE	ACTIONS

Synapse RBAC actions and the roles that permit them

The following table lists Synapse actions and the built-in roles that permit these actions:

ACTION	ROLE
workspaces/read	Synapse Administrator Synapse Apache Spark Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher Synapse Artifact User Synapse Compute Operator Synapse Monitoring Operator Synapse Credential User Synapse Linked Data Manager Synapse User
workspaces/roleAssignments/write, delete	Synapse Administrator
workspaces/managedPrivateEndpoint/write, delete	Synapse Administrator Synapse Linked Data Manager
workspaces/bigDataPools/useCompute/action	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Compute Operator Synapse Monitoring Operator
workspaces/bigDataPools/viewLogs/action	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Compute Operator
workspaces/integrationRuntimes/useCompute/action	Synapse Administrator Synapse Contributor Synapse Compute Operator Synapse Monitoring Operator
workspaces/integrationRuntimes/viewLogs/action	Synapse Administrator Synapse Contributor Synapse Compute Operator Synapse Monitoring Operator

ACTION	ROLE
workspaces/linkConnections/read	Synapse Administrator Synapse Contributor Synapse Compute Operator
workspaces/linkConnections/useCompute/action	Synapse Administrator Synapse Contributor Synapse Compute Operator
workspaces/artifacts/read	Synapse Administrator Synapse Apache Spark Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher Synapse Artifact User
workspaces/notebooks/write, delete	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/sparkJobDefinitions/write, delete	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/sqlScripts/write, delete	Synapse Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/kqlScripts/write, delete	Synapse Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/dataFlows/write, delete	Synapse Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/pipelines/write, delete	Synapse Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/linkConnections/write, delete	Synapse Administrator Synapse Contributor
workspaces/triggers/write, delete	Synapse Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/datasets/write, delete	Synapse Administrator Synapse Contributor Synapse Artifact Publisher

ACTION	ROLE
workspaces/libraries/write, delete	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Artifact Publisher
workspaces/linkedServices/write, delete	Synapse Administrator Synapse Apache Spark Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher Synapse Linked Data Manager
workspaces/credentials/write, delete	Synapse Administrator Synapse Apache Spark Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher Synapse Linked Data Manager
workspaces/notebooks/viewOutputs/action	Synapse Administrator Synapse Apache Spark Administrator Synapse Contributor Synapse Artifact Publisher Synapse Artifact User
workspaces/pipelines/viewOutputs/action	Synapse Administrator Synapse Contributor Synapse Artifact Publisher Synapse Artifact User
workspaces/linkedServices/useSecret/action	Synapse Administrator Synapse Credential User
workspaces/credentials/useSecret/action	Synapse Administrator Synapse Credential User

Synapse RBAC scopes and their supported roles

The table below lists Synapse RBAC scopes and the roles that can be assigned at each scope.

> **NOTE**
> To create or delete an object you must have permissions at a higher-level scope.

SCOPE	ROLES

SCOPE	ROLES
Workspace	Synapse Administrator Synapse Apache Spark Administrator Synapse SQL Administrator Synapse Contributor Synapse Artifact Publisher Synapse Artifact User Synapse Compute Operator Synapse Monitoring Operator Synapse Credential User Synapse Linked Data Manager Synapse User
Apache Spark pool	Synapse Administrator Synapse Contributor Synapse Compute Operator
Integration runtime	Synapse Administrator Synapse Contributor Synapse Compute Operator
Linked service	Synapse Administrator Synapse Credential User
Credential	Synapse Administrator Synapse Credential User

NOTE

All artifact roles and actions are scoped at the workspace level.

Understand the roles required to perform common tasks in Azure Synapse

8/19/2022 • 7 minutes to read • Edit Online

This article will help you understand which Synapse RBAC (role-based access control) roles or Azure RBAC roles you need to get work done in Synapse Studio. To manage role membership, see Manage Synapse RBAC role assignments.

Synapse Studio access control and workflow summary

Access Synapse Studio

You can open Synapse Studio and view details of the workspace and list any of its Azure resources such as SQL pools, Spark pools, or Integration runtimes. You will see if you've been assigned any Synapse RBAC role or have the Azure Owner, Contributor, or Reader role on the workspace.

Resource management

You can create SQL pools, Data Explorer pools, Apache Spark pools, and Integration runtimes if you're an Azure Owner or Contributor on the workspace. When using ARM templates for automated deployment, you need to be an Azure Contributor on the resource group.

You can pause or scale a dedicated SQL pool, configure a Spark pool, or an integration runtime if you're an Azure Owner or Contributor on the workspace or that resource.

View and edit code artifacts

With access to Synapse Studio, you can create new code artifacts, such as SQL scripts, KQL scripts, notebooks, spark jobs, linked services, pipelines, dataflows, triggers, and credentials. These artifacts can be published or saved with additional permissions.

If you're a Synapse Artifact User, Synapse Artifact Publisher, Synapse Contributor, or Synapse Administrator you can list, open, and edit already published code artifacts.

Execute your code

You can execute SQL scripts on SQL pools if you have the necessary SQL permissions defined in the SQL pools. You can execute KQL scripts on Data Explorer pools if you have the necessary permissions.

You can run notebooks and Spark jobs if you have Synapse Compute Operator permissions on the workspace or specific Apache Spark pools.

With Compute Operator permissions on the workspace or specific integration runtimes, and appropriate credential permissions you can execute pipelines.

Monitor and manage execution

You can review the status of running notebooks and jobs in Apache Spark pools if you're a Synapse User.

You can review logs and cancel running jobs and pipelines if you're a Synapse Compute Operator at the workspace or for a specific Spark pool or pipeline.

Publish and save your code

You can publish new or updated code artifacts to the service if you're a Synapse Artifact Publisher, Synapse Contributor, or Synapse Administrator.

You can commit code artifacts to a working branch of a Git repository if the workspace is Git-enabled and you have Git permissions. With Git enabled, publishing is only allowed from the collaboration branch.

If you close Synapse Studio without publishing or committing changes to code artifacts, then those changes will be lost.

Tasks and required roles

The table below lists common tasks and for each task, the Synapse RBAC, or Azure RBAC roles required.

> **NOTE**
> Synapse Administrator is not listed for each task unless it is the only role that provides the necessary permission. A Synapse Administrator can perform all tasks enabled by other Synapse RBAC roles.

> **NOTE**
> Guest users from another tenant are also able to review, add, or change role assignments once they have been assigned as Synapse Administrator.

The minimum Synapse RBAC role required is shown.

All Synapse RBAC roles at any scope provide you Synapse User permissions at the workspace.

All Synapse RBAC permissions/actions shown in the table are prefixed `Microsoft/Synapse/workspaces/...`.

TASK (I WANT TO...)	ROLE (I NEED TO BE...)	SYNAPSE RBAC PERMISSION/ACTION
Open Synapse Studio on a workspace	Synapse User or	read
	Azure Owner or Contributor, or Reader on the workspace	none
List SQL pools or Data Explorer pools or Apache Spark pools, or Integration runtimes and access their configuration details	Synapse User or	read
	Azure Owner or Contributor, or Reader on the workspace	none
List linked services or credentials or managed private endpoints	Synapse User	read
SQL POOLS		
Create a dedicated SQL pool or a serverless SQL pool	Azure Owner or Contributor on the workspace	none
Manage (pause or scale, or delete) a dedicated SQL pool	Azure Owner or Contributor on the SQL pool or workspace	none

TASK (I WANT TO...)	ROLE (I NEED TO BE...)	SYNAPSE RBAC PERMISSION/ACTION
Create a SQL script	Synapse User or Azure Owner or Contributor on the workspace. *Additional SQL permissions are required to run a SQL script, publish, or commit changes*.	
List and open any published SQL script	Synapse Artifact User or Artifact Publisher, or Synapse Contributor	artifacts/read
Run a SQL script on a serverless SQL pool	SQL permissions on the pool (granted automatically to a Synapse Administrator)	none
Run a SQL script on a dedicated SQL pool	SQL permissions on the pool (granted automatically to a Synapse Administrator)	none
Publish a new or updated, or deleted SQL script	Synapse Artifact Publisher or Synapse Contributor	sqlScripts/write, delete
Commit changes to a SQL script to the Git repo	Requires Git permissions on the repo	
Assign Active Directory Admin on the workspace (via workspace properties in the Azure Portal)	Azure Owner or Contributor on the workspace	
DATA EXPLORER POOLS		
Create a Data Explorer pool	Azure Owner or Contributor on the workspace	none
Manage (pause or scale, or delete) a Data Explorer pool	Azure Owner or Contributor on the Data Explorer pool or workspace	none
Create a KQL script	Synapse User. *Additional Data Explorer permissions are required to run a script, publish, or commit changes*.	
List and open any published KQL script	Synapse Artifact User or Artifact Publisher, or Synapse Contributor	artifacts/read
Run a KQL script on a Data Explorer pool	Data Explorer permissions on the pool (granted automatically to a Synapse Administrator)	none
Publish new, update, or delete KQL script	Synapse Artifact Publisher or Synapse Contributor	kqlScripts/write, delete
Commit changes to a KQL script to the Git repo	Requires Git permissions on the repo	

TASK (I WANT TO...)	ROLE (I NEED TO BE...)	SYNAPSE RBAC PERMISSION/ACTION
APACHE SPARK POOLS		
Create an Apache Spark pool	Azure Owner or Contributor on the workspace	
Monitor Apache Spark applications	Synapse User	read
View the logs for notebook and job execution	Synapse Monitoring Operator	
Cancel any notebook or Spark job running on an Apache Spark pool	Synapse Compute Operator on the Apache Spark pool.	bigDataPools/useCompute
Create a notebook or job definition	Synapse User or Azure Owner or Contributor, or Reader on the workspace *Additional permissions are required to run, publish, or commit changes*	read
List and open a published notebook or job definition, including reviewing saved outputs	Synapse Artifact User or Synapse Monitoring Operator on the workspace	artifacts/read
Run a notebook and review its output, or submit a Spark job	Synapse Apache Spark Administrator or Synapse Compute Operator on the selected Apache Spark pool	bigDataPools/useCompute
Publish or delete a notebook or job definition (including output) to the service	Artifact Publisher on the workspace or Synapse Apache Spark Administrator	notebooks/write, delete
Commit changes to a notebook or job definition to the Git repo	Git permissions	none
PIPELINES, INTEGRATION RUNTIMES, DATAFLOWS, DATASETS & TRIGGERS		
Create, update, or delete an Integration runtime	Azure Owner or Contributor on the workspace	
Monitor Integration runtime status	Synapse Monitoring Operator	read, integrationRuntimes/viewLogs
Review pipeline runs	Synapse Monitoring Operator	read, pipelines/viewOutputs
Create a pipeline	Synapse User *Additional Synapse permissions are required to debug, add triggers, publish, or commit changes*	read

TASK (I WANT TO...)	ROLE (I NEED TO BE...)	SYNAPSE RBAC PERMISSION/ACTION
Create a dataflow or dataset	Synapse User *Additional Synapse permissions are required to publish, or commit changes*	read
List and open a published pipeline	Synapse Artifact User or Synapse Monitoring Operator	artifacts/read
Preview dataset data	Synapse User and Synapse Credential User on the WorkspaceSystemIdentity	
Debug a pipeline using the default Integration runtime	Synapse User and Synapse Credential User on the WorkspaceSystemIdentity credential	read, credentials/useSecret
Create a trigger, including trigger now (requires permission to execute the pipeline)	Synapse User and Synapse Credential User on the WorkspaceSystemIdentity	read, credentials/useSecret/action
Execute/run a pipeline	Synapse User and Synapse Credential User on the WorkspaceSystemIdentity	read, credentials/useSecret/action
Copy data using the Copy Data tool	Synapse User and Synapse Credential User on the Workspace System Identity	read, credentials/useSecret/action
Ingest data (using a schedule)	Synapse Author and Synapse Credential User on the Workspace System Identity	read, credentials/useSecret/action
Publish a new, updated, or deleted pipeline, dataflow, or trigger to the service	Synapse Artifact Publisher on the workspace	pipelines/write, delete dataflows/write, delete triggers/write, delete
Commit changes to pipelines, dataflows, datasets, or triggers to the Git repo	Git permissions	none
LINKED SERVICES		
Create a linked service (includes assigning a credential)	Synapse User *Additional permissions are required to use a linked service with credentials, or to publish, or commit changes*	read
List and open a published linked service	Synapse Artifact User	linkedServices/write, delete
Test connection on a linked service secured by a credential	Synapse User and Synapse Credential User	credentials/useSecret/action
Publish a linked service	Synapse Artifact Publisher or Synapse Linked Data Manager	linkedServices/write, delete

TASK (I WANT TO...)	ROLE (I NEED TO BE...)	SYNAPSE RBAC PERMISSION/ACTION
Commit linked service definitions to the Git repo	Git permissions	none
ACCESS MANAGEMENT		
Review Synapse RBAC role assignments at any scope	Synapse User	read
Assign and remove Synapse RBAC role assignments for users, groups, and service principals	Synapse Administrator at the workspace or at a specific workspace item scope	roleAssignments/write, delete

Managed identity for Azure Synapse

8/19/2022 • 7 minutes to read • Edit Online

This article helps you understand managed identity (formerly known as Managed Service Identity/MSI) and how it works in Azure Synapse.

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Overview

Managed identities eliminate the need to manage credentials. Managed identities provide an identity for the service instance when connecting to resources that support Azure Active Directory (Azure AD) authentication. For example, the service can use a managed identity to access resources like Azure Key Vault, where data admins can securely store credentials or access storage accounts. The service uses the managed identity to obtain Azure AD tokens.

There are two types of supported managed identities:

- **System-assigned:** You can enable a managed identity directly on a service instance. When you allow a system-assigned managed identity during the creation of the service, an identity is created in Azure AD tied to that service instance's lifecycle. By design, only that Azure resource can use this identity to request tokens from Azure AD. So when the resource is deleted, Azure automatically deletes the identity for you. Azure Synapse Analytics requires that a system-assigned managed identity must be created along with the Synapse workspace.
- **User-assigned:** You may also create a managed identity as a standalone Azure resource. You can create a user-assigned managed identity and assign it to one or more instances of a Synapse workspace. In user-assigned managed identities, the identity is managed separately from the resources that use it.

Managed identity provides the below benefits:

- Store credential in Azure Key Vault, in which case-managed identity is used for Azure Key Vault authentication.
- Access data stores or computes using managed identity authentication, including Azure Blob storage, Azure Data Explorer, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, REST, Databricks activity, Web activity, and more. Check the connector and activity articles for details.
- Managed identity is also used to encrypt/decrypt data and metadata using the customer-managed key stored in Azure Key Vault, providing double encryption.

System-assigned managed identity

> **NOTE**
>
> System-assigned managed identity is also referred to as 'Managed identity' elsewhere in the documentation and in the Synapse Studio UI for backward compatibility purpose. We will explicitly mention 'User-assigned managed identity' when referring to it.

Generate system-assigned managed identity

System-assigned managed identity is generated as follows:

- When creating a Synapse workspace through **Azure portal or PowerShell**, managed identity will always be created automatically.
- When creating a workspace through **SDK**, managed identity will be created only if you specify Identity = new ManagedIdentity" in the Synapse workspace object for creation." See example in .NET Quickstart - Create data factory.
- When creating Synapse workspace through **REST API**, managed identity will be created only if you specify "identity" section in request body. See example in REST quickstart - create data factory.

If you find your service instance doesn't have a managed identity associated following retrieve managed identity instruction, you can explicitly generate one by updating it with identity initiator programmatically:

- Generate managed identity using PowerShell
- Generate managed identity using REST API
- Generate managed identity using an Azure Resource Manager template
- Generate managed identity using SDK

> **NOTE**
>
> - Managed identity cannot be modified. Updating a service instance which already has a managed identity won't have any impact, and the managed identity is kept unchanged.
> - If you update a service instance which already has a managed identity without specifying the "identity" parameter in the factory or workspace objects or without specifying "identity" section in REST request body, you will get an error.
> - When you delete a service instance, the associated managed identity will be deleted along.

Generate system-assigned managed identity using PowerShell

Call **New-AzSynapseWorkspace** command, then you see "Identity" fields being newly generated:

```
PS C:\> $creds = New-Object System.Management.Automation.PSCredential ("ContosoUser", $password)
PS C:\> New-AzSynapseWorkspace -ResourceGroupName <resourceGroupName> -Name <workspaceName> -Location
<region> -DefaultDataLakeStorageAccountName <storageAccountName> -DefaultDataLakeStorageFileSystem
<fileSystemName> -SqlAdministratorLoginCredential $creds

DefaultDataLakeStorage           : Microsoft.Azure.Commands.Synapse.Models.PSDataLakeStorageAccountDetails
ProvisioningState                : Succeeded
SqlAdministratorLogin            : ContosoUser
VirtualNetworkProfile            :
Identity                         : Microsoft.Azure.Commands.Synapse.Models.PSManagedIdentity
ManagedVirtualNetwork            :
PrivateEndpointConnections       : {}
WorkspaceUID                     : <workspaceUid>
ExtraProperties                  : {[WorkspaceType, Normal], [IsScopeEnabled, False]}
ManagedVirtualNetworkSettings    :
Encryption                       : Microsoft.Azure.Commands.Synapse.Models.PSEncryptionDetails
WorkspaceRepositoryConfiguration :
Tags                             :
TagsTable                        :
Location                         : <region>
Id                               : /subscriptions/<subsID>/resourceGroups/<resourceGroupName>/providers/
                                   Microsoft.Synapse/workspaces/<workspaceName>
Name                             : <workspaceName>
Type                             : Microsoft.Synapse/workspaces
```

Generate system-assigned managed identity using REST API

> **NOTE**
>
> If you attempt to update a service instance that already has a managed identity without either specifying the **identity** parameter in the workspace object or providing an **identity** section in the REST request body, you will get an error.

Call the API below with the "identity" section in the request body:

```
PATCH
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Mic
rosoft.Synapse/workspaces/{workspaceName}?api-version=2018-06-01
```

Request body: add "identity": { "type": "SystemAssigned" }.

```
{
    "name": "<workspaceName>",
    "location": "<region>",
    "properties": {},
    "identity": {
        "type": "SystemAssigned"
    }
}
```

Response: managed identity is created automatically, and "identity" section is populated accordingly.

```
{
    "name": "<workspaceName>",
    "tags": {},
    "properties": {
        "provisioningState": "Succeeded",
        "loggingStorageAccountKey": "**********",
        "createTime": "2021-09-26T04:10:01.1135678Z",
        "version": "2018-06-01"
    },
    "identity": {
        "type": "SystemAssigned",
        "principalId": "765ad4ab-XXXX-XXXX-XXXX-51ed985819dc",
        "tenantId": "72f988bf-XXXX-XXXX-XXXX-2d7cd011db47"
    },
    "id":
"/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.Synapse/workspaces/<
workspaceName>",
    "type": "Microsoft.Synapse/workspaces",
    "location": "<region>"
}
```

Generate system-assigned managed identity using an Azure Resource Manager template

Template: add "identity": { "type": "SystemAssigned" }.

```
{
    "contentVersion": "1.0.0.0",
    "$schema": "https://schema.management.azure.com/schemas/2019-04-01/deploymentTemplate.json#",
    "resources": [{
        "name": "<workspaceName>",
        "apiVersion": "2018-06-01",
        "type": "Microsoft.Synapse/workspaces",
        "location": "<region>",
        "identity": {
            "type": "SystemAssigned"
        }
    }]
}
```

Generate system-assigned managed identity using SDK

```
Workspace workspace = new Workspace
{
    Identity = new ManagedIdentity
    {
        Type = ResourceIdentityType.SystemAssigned
    },
    DefaultDataLakeStorage = new DataLakeStorageAccountDetails
    {
        AccountUrl = <defaultDataLakeStorageAccountUrl>,
        Filesystem = <DefaultDataLakeStorageFilesystem>
    },
    SqlAdministratorLogin = <SqlAdministratorLoginCredentialUserName>
    SqlAdministratorLoginPassword = <SqlAdministratorLoginCredentialPassword>,
    Location = <region>
};
client.Workspaces.CreateOrUpdate(resourceGroupName, workspaceName, workspace);
```

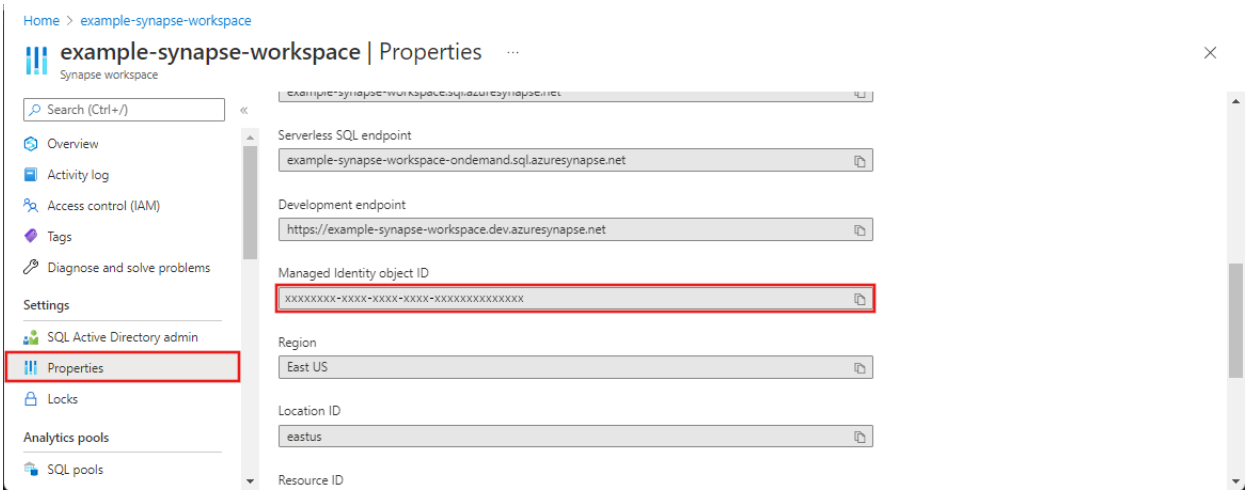
Retrieve system-assigned managed identity

You can retrieve the managed identity from Azure portal or programmatically. The following sections show some samples.

> **TIP**
>
> If you don't see the managed identity, generate managed identity by updating your service instance.

Retrieve system-assigned managed identity using Azure portal

You can find the managed identity information from Azure portal -> your Synapse workspace -> Properties.

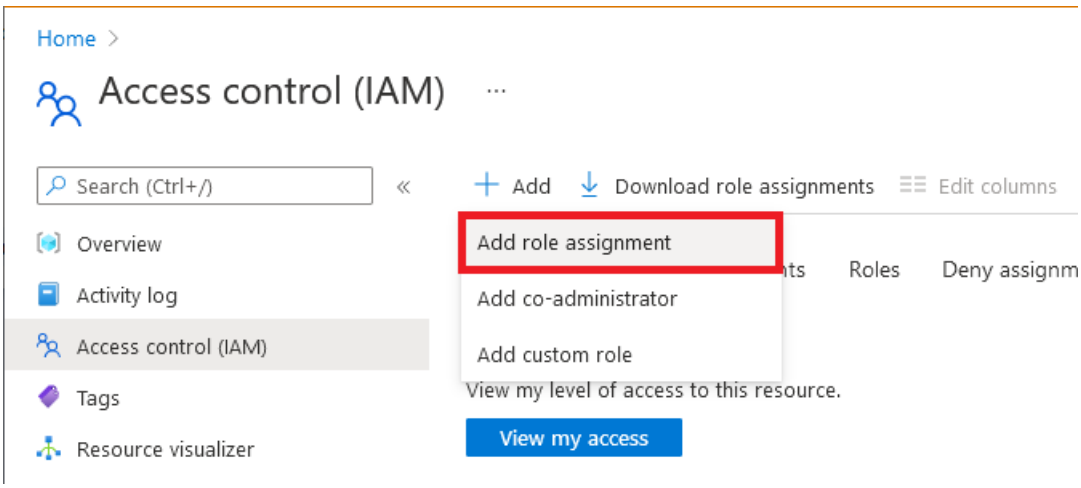


- Managed Identity Object ID

The managed identity information will also show up when you create linked service, which supports managed identity authentication, like Azure Blob, Azure Data Lake Storage, Azure Key Vault, etc.

To grant permissions, follow these steps. For detailed steps, see Assign Azure roles using the Azure portal.

1. Select **Access control (IAM)**.
2. Select **Add** > **Add role assignment**.



3. On the **Members** tab, select **Managed identity**, and then select **Select members**.
4. Select your Azure subscription.
5. Under **System-assigned managed identity**, select **Synapse workspace**, and then select a workspace. You can also use the object ID or workspace name (as the managed-identity name) to find this identity. To get the managed identity's application ID, use PowerShell.
6. On the **Review + assign** tab, select **Review + assign** to assign the role.

Retrieve system-assigned managed identity using PowerShell

The managed identity principal ID and tenant ID will be returned when you get a specific service instance as

follows. Use the **PrincipalId** to grant access:

```
PS C:\> (Get-AzSynapseWorkspace -ResourceGroupName <resourceGroupName> -Name <workspaceName>).Identity

IdentityType   PrincipalId                          TenantId
------------   -----------                          --------
SystemAssigned cadadb30-XXXX-XXXX-XXXX-ef3500e2ff05 72f988bf-XXXX-XXXX-XXXX-2d7cd011db47
```

You can get the application ID by copying above principal ID, then running below Azure Active Directory command with principal ID as parameter.

```
PS C:\> Get-AzADServicePrincipal -ObjectId cadadb30-XXXX-XXXX-XXXX-ef3500e2ff05

ServicePrincipalNames : {76f668b3-XXXX-XXXX-XXXX-1b3348c75e02,
https://identity.azure.net/P86P8g6nt1QxfPJx22om8MOooMf/Ag0Qf/nnREppHkU=}
ApplicationId         : 76f668b3-XXXX-XXXX-XXXX-1b3348c75e02
DisplayName           : <workspaceName>
Id                    : cadadb30-XXXX-XXXX-XXXX-ef3500e2ff05
Type                  : ServicePrincipal
```

Retrieve managed identity using REST API

The managed identity principal ID and tenant ID will be returned when you get a specific service instance as follows.

Call below API in the request:

```
GET
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Mic
rosoft.Synapse/workspaces/{workspaceName}?api-version=2018-06-01
```

Response: You will get response like shown in below example. The "identity" section is populated accordingly.

```
{
  "properties": {
    "defaultDataLakeStorage": {
      "accountUrl": "https://exampledatalakeaccount.dfs.core.windows.net",
      "filesystem": "examplefilesystem"
    },
    "encryption": {
      "doubleEncryptionEnabled": false
    },
    "provisioningState": "Succeeded",
    "connectivityEndpoints": {
      "web": "https://web.azuresynapse.net?
workspace=%2fsubscriptions%2{subscriptionId}%2fresourceGroups%2f{resourceGroupName}%2fproviders%2fMicrosoft.
Synapse%2fworkspaces%2f{workspaceName}",
      "dev": "https://{workspaceName}.dev.azuresynapse.net",
      "sqlOnDemand": "{workspaceName}-ondemand.sql.azuresynapse.net",
      "sql": "{workspaceName}.sql.azuresynapse.net"
    },
    "managedResourceGroupName": "synapseworkspace-managedrg-f77f7cf2-XXXX-XXXX-XXXX-c4cb7ac3cf4f",
    "sqlAdministratorLogin": "sqladminuser",
    "privateEndpointConnections": [],
    "workspaceUID": "e56f5773-XXXX-XXXX-XXXX-a0dc107af9ea",
    "extraProperties": {
      "WorkspaceType": "Normal",
      "IsScopeEnabled": false
    },
    "publicNetworkAccess": "Enabled",
    "cspWorkspaceAdminProperties": {
      "initialWorkspaceAdminObjectId": "3746a407-XXXX-XXXX-XXXX-842b6cf1fbcc"
    },
    "trustedServiceBypassEnabled": false
  },
  "type": "Microsoft.Synapse/workspaces",
  "id":
"/subscriptions/{subscriptionId}/resourceGroups/{resourceGroupName}/providers/Microsoft.Synapse/workspaces/{
workspaceName}",
  "location": "eastus",
  "name": "{workspaceName}",
  "identity": {
    "type": "SystemAssigned",
    "tenantId": "72f988bf-XXXX-XXXX-XXXX-2d7cd011db47",

  },
  "tags": {}
}
```

TIP

To retrieve the managed identity from an ARM template, add an **outputs** section in the ARM JSON:

```
{
    "outputs":{
        "managedIdentityObjectId":{
            "type":"string",
            "value":"[reference(resourceId('Microsoft.Synapse/workspaces', parameters('<workspaceName>')),
'2018-06-01', 'Full').identity.principalId]"
        }
    }
}
```

Execute Azure Synapse Spark Notebooks with system assigned managed identity

You can easily execute Synapse Spark Notebooks with the system assigned managed identity (or workspace

managed identity) by enabling *Run as managed identity* from the *Configure session* menu. To execute Spark Notebooks with workspace managed identity, users need to have following RBAC roles:

- Synapse Compute Operator on the workspace or selected Spark pool
- Synapse Credential User on the workspace managed identity

User-assigned managed identity

You can create, delete, manage user-assigned managed identities in Azure Active Directory. For more details refer to Create, list, delete, or assign a role to a user-assigned managed identity using the Azure portal.

In order to use a user-assigned managed identity, you must first create credentials in your service instance for the UAMI.

Next steps

- Create credentials.

See the following topics that introduce when and how to use managed identity:

- Store credential in Azure Key Vault.
- Copy data from/to Azure Data Lake Store using managed identities for Azure resources authentication.

See Managed Identities for Azure Resources Overview for more background on managed identities for Azure resources, on which managed identity in Azure Synapse is based.

Credentials in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Prerequisites

Users must have the Managed Identity Operator (Azure RBAC) role or a custom role with **Microsoft.ManagedIdentity/userAssignedIdentities/*/assign/action** RBAC action to configure a user assigned managed identity as a credential. Additional RBAC is required to create and use credentials in Synapse. Learn more.

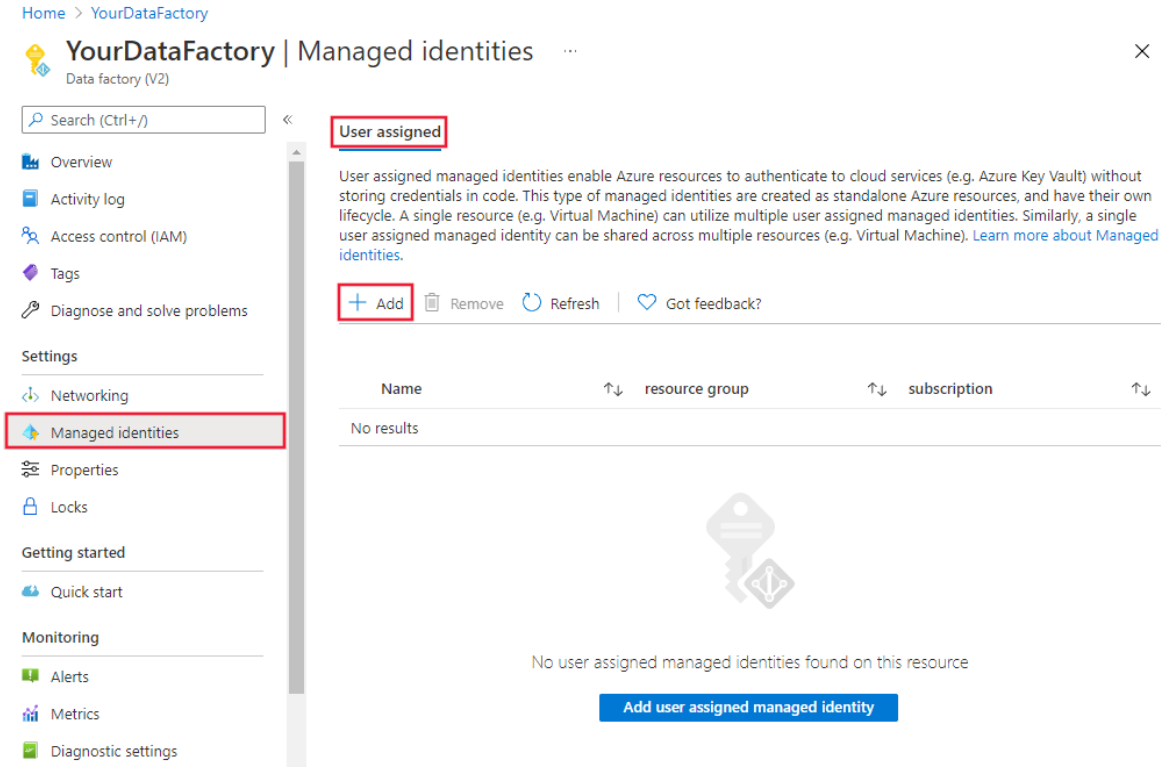
Using credentials

We are introducing Credentials which can contain user-assigned managed identities, service principals, and also lists the system-assigned managed identity that you can use in the linked services that support Azure Active Directory (AAD) authentication. It helps you consolidate and manage all your AAD-based credentials.

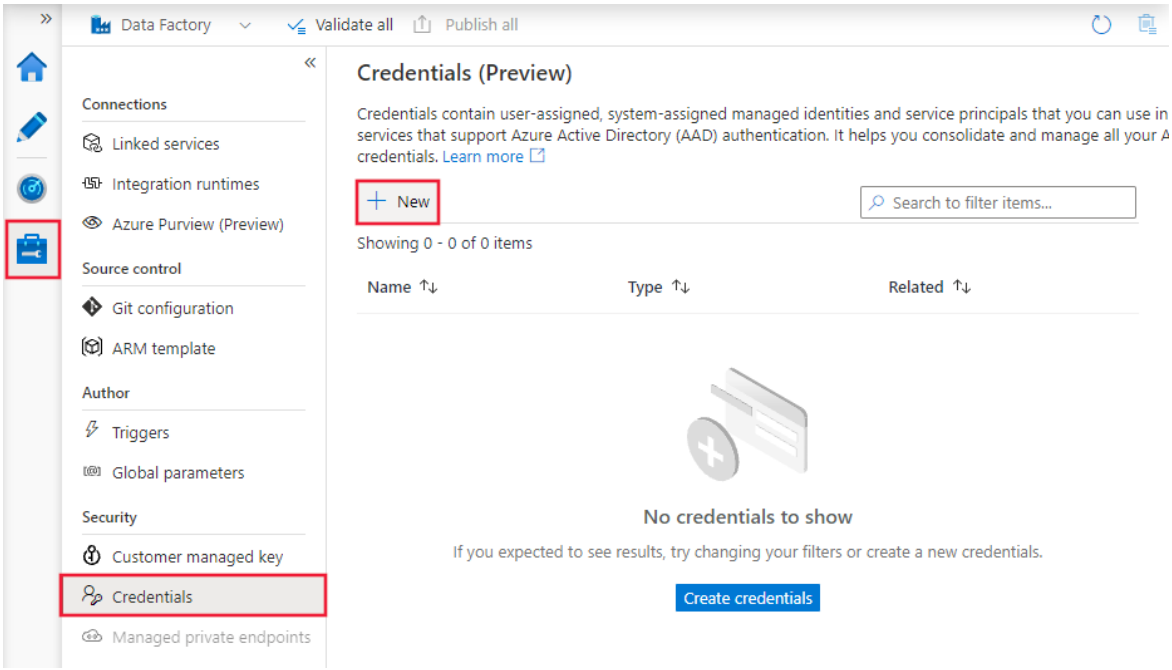
Below are the generic steps for using a **user-assigned managed identity** in the linked services for authentication.

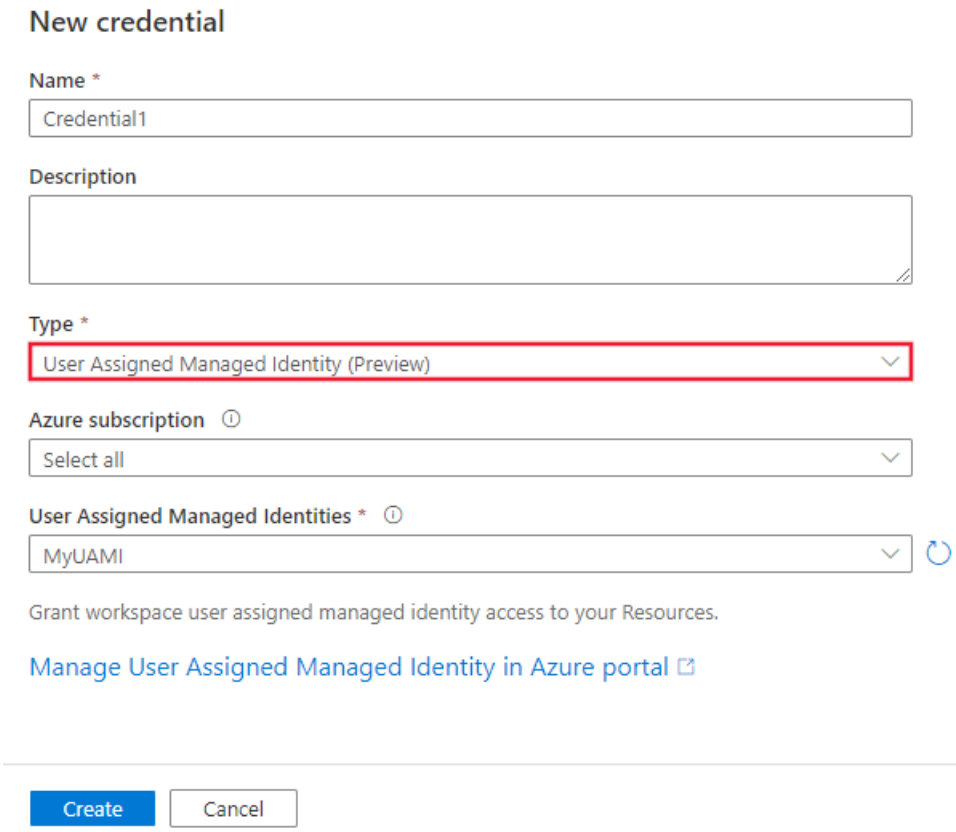
- Azure Data Factory
- Azure Synapse

1. If you do not have a user-assigned managed identity created in Azure, first create one in the Azure portal Managed Identities page.
2. Associate the user-assigned managed identity to the data factory instance using Azure portal, SDK, PowerShell, REST API. The screenshot below used Azure portal (data factory blade) to associate the user-assigned managed identity.

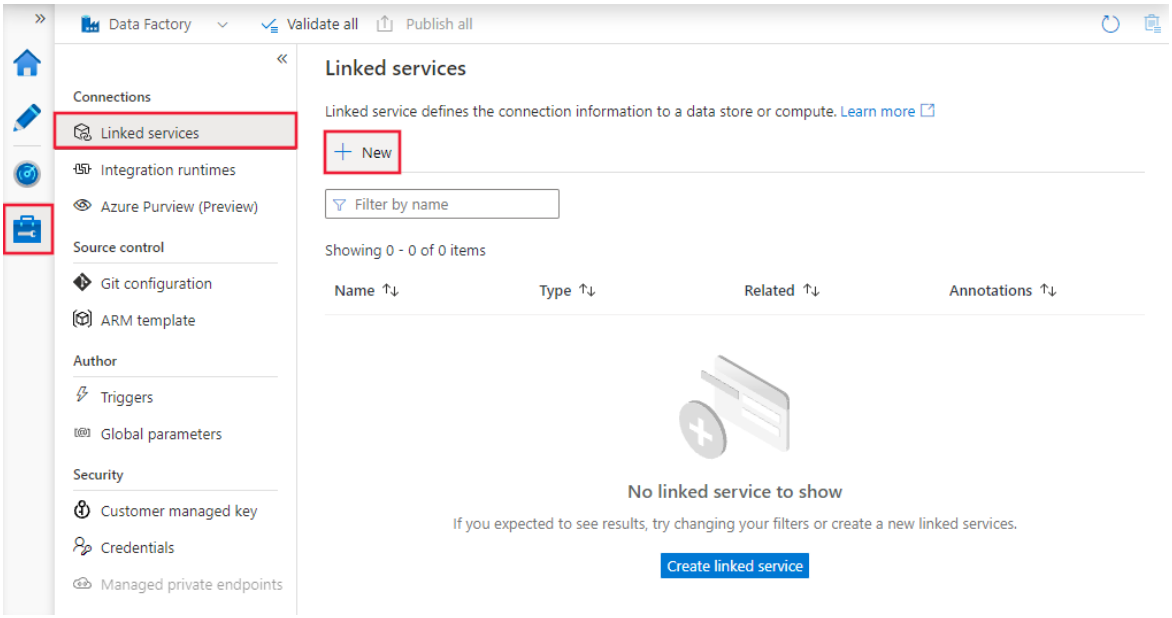


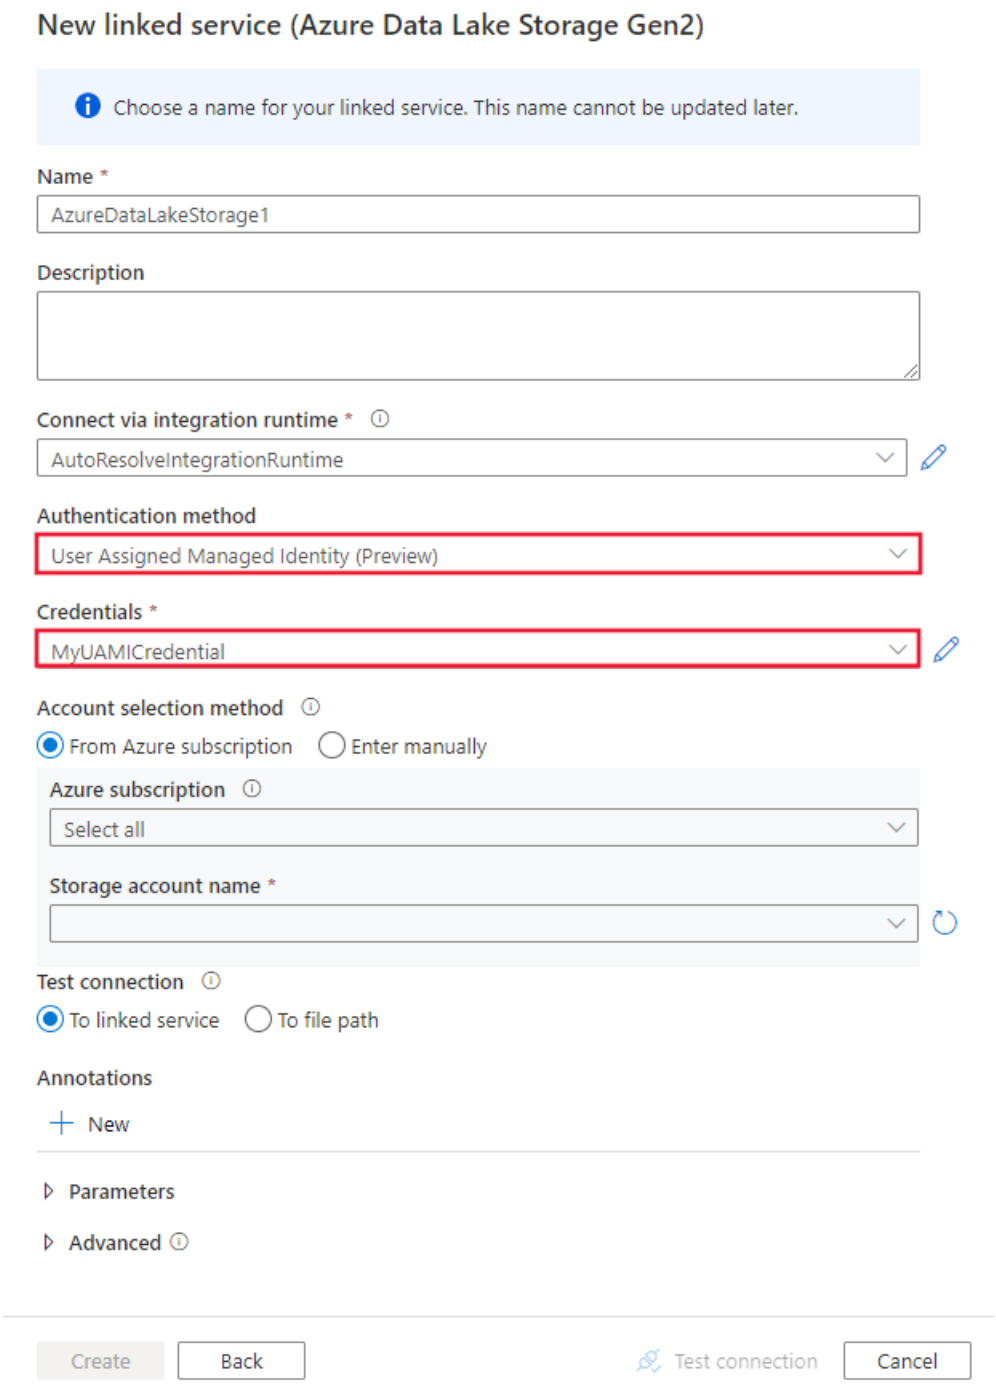
3. Create a **Credential** in data factory user interface interactively. You can select the user-assigned managed identity associated with the data factory in Step 1.





4. Create a new linked service and select **User-assigned managed identity** under authentication





NOTE

You can use SDK/ PowerShell/ REST APIs for the above actions. Linked services with user-assigned managed identity are currently not supported in Synapse Spark.

Next steps

- Managed identity

See the following topics that introduce when and how to use managed identity:

- Store credential in Azure Key Vault
- Copy data from/to Azure Data Lake Store using managed identities for Azure resources authentication

See Managed Identities for Azure Resources Overview for more background on managed identities for Azure resources, which data factory managed identity is based upon.

Use Azure Monitor with your Azure Synapse Analytics workspace

8/19/2022 • 9 minutes to read • Edit Online

Cloud applications are complex and have many moving parts. Monitors provide data to help ensure that your applications stay up and running in a healthy state. Monitors also help you avoid potential problems and troubleshoot past ones. You can use monitoring data to gain deep insights about your applications. This knowledge helps you improve application performance and maintainability. It also helps you automate actions that otherwise require manual intervention.

Azure Monitor provides base-level infrastructure metrics, alerts, and logs for most Azure services. Azure diagnostic logs are emitted by a resource and provide rich, frequent data about the operation of that resource. Azure Synapse Analytics can write diagnostic logs in Azure Monitor.

For more information, see Azure Monitor overview.

Metrics

With Monitor, you can gain visibility into the performance and health of your Azure workloads. The most important type of Monitor data is the metric, which is also called the performance counter. Metrics are emitted by most Azure resources. Monitor provides several ways to configure and consume these metrics for monitoring and troubleshooting.

To access these metrics, complete the instructions in Azure Monitor data platform.

Workspace-level metrics

Here are some of the metrics emitted by workspaces:

METRIC	METRIC CATEGORY, DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
IntegrationActivityRunsEnded	Integration, Activity runs metric	Count	Sum (default), Count	The total number of activity runs that occurred/ended within a 1-minute window. Use the Result dimension of this metric to filter by Succeeded, Failed, or Cancelled final state.

METRIC	METRIC CATEGORY, DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
IntegrationPipelineRunsEnded	Integration, Pipeline runs metric	Count	Sum (default), Count	The total number of pipeline runs that occurred/ended within a 1-minute window. Use the Result dimension of this metric to filter by Succeeded, Failed, or Cancelled final state.
IntegrationTriggerRunsEnded	Integration, Trigger runs metric	Count	Sum (default), Count	The total number of trigger runs that occurred/ended within a 1-minute window. Use the Result dimension of this metric to filter by Succeeded, Failed, or Cancelled final state.
BuiltinSqlPoolDataProcessedBytes	Built-in SQL pool, Data processed (bytes)	Byte	Sum (default)	Amount of data processed by the built-in serverless SQL pool.
BuiltinSqlPoolLoginAttempts	Built-in SQL pool, Login attempts	Count	Sum (default)	Number of login attempts for the built-in serverless SQL pool.
BuiltinSqlPoolDataRequestsEnded	Built-in SQL pool, Requests ended (bytes)	Count	Sum (default)	Number of ended SQL requests for the built-in serverless SQL pool. Use the Result dimension of this metric to filter by final state.

Dedicated SQL pool metrics

Here are some of the metrics emitted by dedicated SQL pools:

METRIC	DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
DWULimit	DWU limit	Count	Max (default), Min, Avg	Configured size of the SQL pool

METRIC	DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
DWUUsed	DWU used	Count	Max (default), Min, Avg	Represents a high-level representation of usage across the SQL pool. Measured by DWU limit * DWU percentage
DWUUsedPercent	DWU used percentage	Percent	Max (default), Min, Avg	Represents a high-level representation of usage across the SQL pool. Measured by taking the maximum between CPU percentage and Data IO percentage
ConnectionsBlockedByFirewall	Connections blocked by firewall	Count	Sum (default)	Count of connections blocked by firewall rules. Revisit access control policies for your SQL pool and monitor these connections if the count is high
AdaptiveCacheHitPercent	Adaptive cache hit percentage	Percent	Max (default), Min, Avg	Measures how well workloads are utilizing the adaptive cache. Use this metric with the cache hit percentage metric to determine whether to scale for additional capacity or rerun workloads to hydrate the cache
AdaptiveCacheUsedPercent	Adaptive cache used percentage	Percent	Max (default), Min, Avg	Measures how well workloads are utilizing the adaptive cache. Use this metric with the cache used percentage metric to determine whether to scale for additional capacity or rerun workloads to hydrate the cache
LocalTempDBUsedPercent	Local tempdb used percentage	Percent	Max (default), Min, Avg	Local tempdb utilization across all compute nodes - values are emitted every five minute
MemoryUsedPercent	Memory used percentage	Percent	Max (default), Min, Avg	Memory utilization across all nodes in the SQL pool

METRIC	DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
CPUPercent	CPU used percentage	Percent	Max (default), Min, Avg	CPU utilization across all nodes in the SQL pool
Connections	Connections	Count	Sum (default)	Count of total logins to the SQL pool
ActiveQueries	Active queries	Count	Sum (default)	The active queries. Using this metric unfiltered and unsplit displays all active queries running on the system
QueuedQueries	Queued queries	Count	Sum (default)	Cumulative count of requests queued after the max concurrency limit was reached
WLGActiveQueries	Workload group active queries	Count	Sum (default)	The active queries within the workload group. Using this metric unfiltered and unsplit displays all active queries running on the system
WLGActiveQueriesTimeouts	Workload group query timeouts	Count	Sum (default)	Queries for the workload group that have timed out. Query timeouts reported by this metric are only once the query has started executing (it does not include wait time due to locking or resource waits)
WLGQueuedQueries	Workload group queued queries	Count	Sum (default)	Cumulative count of requests queued after the max concurrency limit was reached
WLGAllocationBySystemPercent	Workload group allocation by system percent	Percent	Max (default), Min, Avg, Sum	The percentage allocation of resources relative to the entire system

METRIC	DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
WLGAllocationByEffectiveCapResourcePercent	Workload group allocation by max resource percent	Percent	Max (default), Min, Avg	Displays the percentage allocation of resources relative to the effective cap resource percent per workload group. This metric provides the effective utilization of the workload group
WLGEffectiveCapResourcePercent	Effective cap resource percent	Percent	Max (default), Min, Avg	The effective cap resource percent for the workload group. If there are other workload groups with min_percentage_resource > 0, the effective_cap_percentage_resource is lowered proportionally
WLGEffectiveMinResourcePercent	Effective min resource percent	Percent	Max (default), Min, Avg, Sum	The effective min resource percentage setting allowed considering the service level and the workload group settings. The effective min_percentage_resource can be adjusted higher on lower service levels

Apache Spark pool metrics

Here are some of the metrics emitted by Apache Spark pools:

METRIC	METRIC CATEGORY, DISPLAY NAME	UNIT	AGGREGATION TYPES	DESCRIPTION
BigDataPoolApplicationsEnded	Ended Apache Spark applications	Count	Sum (default)	Number of Apache Spark pool applications ended
BigDataPoolAllocatedCores	Number of vCores allocated to the Apache Spark pool	Count	Max (default), Min, Avg	Allocated vCores for an Apache Spark Pool
BigDataPoolAllocatedMemory	Amount of memory (GB) allocated to the Apache Spark pool	Count	Max (default), Min, Avg	Allocated Memory for Apache Spark Pool (GB)
BigDataPoolApplicationsActive	Active Apache Spark applications	Count	Max (default), Min, Avg	Number of active Apache Spark pool applications

Alerts

Sign in to the Azure portal and select **Monitor** > **Alerts** to create alerts.

Create Alerts

1. Select **+ New Alert rule** to create a new alert.
2. Define the **alert condition** to specify when the alert should fire.

> **NOTE**
> Make sure to select **All** in the **Filter by resource type** drop-down list.

3. Define the **alert details** to further specify how the alert should be configured.
4. Define the **action group** to determine who should receive the alerts (and how).

Logs

Workspace-level logs

Here are the logs emitted by Azure Synapse Analytics workspaces:

LOG ANALYTICS TABLE NAME	LOG CATEGORY NAME	DESCRIPTION
SynapseGatewayApiRequests	GatewayApiRequests	Azure Synapse gateway API requests.
SynapseRbacOperations	SynapseRbacOperations	Azure Synapse role-based access control (SRBAC) operations.
SynapseBuiltinSqlReqsEnded	BuiltinSqlReqsEnded	Azure Synapse built-in serverless SQL pool ended requests.
SynapseIntegrationPipelineRuns	IntegrationPipelineRuns	Azure Synapse integration pipeline runs.
SynapseIntegrationActivityRuns	IntegrationActivityRuns	Azure Synapse integration activity runs.
SynapseIntegrationTriggerRuns	IntegrationTriggerRuns	Azure Synapse integration trigger runs.

Dedicated SQL pool logs

Here are the logs emitted by dedicated SQL pools:

LOG ANALYTICS TABLE NAME	LOG CATEGORY NAME	DESCRIPTION
SynapseSqlPoolExecRequests	ExecRequests	Information about SQL requests/queries in an Azure Synapse dedicated SQL pool.
SynapseSqlPoolDmsWorkers	DmsWorkers	Information about workers completing DMS steps in an Azure Synapse dedicated SQL pool.

LOG ANALYTICS TABLE NAME	LOG CATEGORY NAME	DESCRIPTION
SynapseSqlPoolRequestSteps	RequestSteps	Information about request steps that compose a given SQL request/query in an Azure Synapse dedicated SQL pool.
SynapseSqlPoolSqlRequests	SqlRequests	Information about query distributions of the steps of SQL requests/queries in an Azure Synapse dedicated SQL pool.
SynapseSqlPoolWaits	Waits	Information about the wait states encountered during execution of a SQL request/query in an Azure Synapse dedicated SQL pool, including locks and waits on transmission queues.

For more information on these logs, see the following information:

- sys.dm_pdw_exec_requests
- sys.dm_pdw_request_steps
- sys.dm_pdw_dms_workers
- sys.dm_pdw_waits
- sys.dm_pdw_sql_requests

Apache Spark pool log

Here is the log emitted by Apache Spark pools:

LOG ANALYTICS TABLE NAME	LOG CATEGORY NAME	DESCRIPTION
SynapseBigDataPoolApplicationsEnded	BigDataPoolAppsEnded	Information about ended Apache Spark applications

Diagnostic settings

Use diagnostic settings to configure diagnostic logs for non-compute resources. The settings for a resource control have the following features:

- They specify where diagnostic logs are sent. Examples include an Azure storage account, an Azure event hub, or Monitor logs.
- They specify which log categories are sent.
- They specify how long each log category should be kept in a storage account.
- A retention of zero days means logs are kept forever. Otherwise, the value can be any number of days from 1 through 2,147,483,647.
- If retention policies are set but storing logs in a storage account is disabled, the retention policies have no effect. For example, this condition can happen when only Event Hubs or Monitor logs options are selected.
- Retention policies are applied per day. The boundary between days occurs at midnight Coordinated Universal Time (UTC). At the end of a day, logs from days that are beyond the retention policy are deleted. For example, if you have a retention policy of one day, at the beginning of today the logs from before yesterday are deleted.

With Azure Monitor diagnostic settings, you can route diagnostic logs for analysis to multiple different targets.

- **Storage account**: Save your diagnostic logs to a storage account for auditing or manual inspection. You can use the diagnostic settings to specify the retention time in days.
- **Event Hub**: Stream the logs to Azure Event Hubs. The logs become input to a partner service/custom

analytics solution like Power BI.

- **Log Analytics workspace**: Analyze the logs with Log Analytics. The Azure Synapse integration with Log Analytics is useful in the following scenarios:
  - You want to write complex queries on a rich set of metrics that are published by Azure Synapse to Log Analytics. You can create custom alerts on these queries via Azure Monitor.
  - You want to monitor across workspaces. You can route data from multiple workspaces to a single Log Analytics workspace.

You can also use a storage account or Event Hub namespace that isn't in the subscription of the resource that emits logs. The user who configures the setting must have appropriate Azure role-based access control (Azure RBAC) access to both subscriptions.

Configure diagnostic settings

Create or add diagnostic settings for your workspace, dedicated SQL pool, or Apache Spark pool.

1. In the portal, go to Monitor. Select **Settings** > **Diagnostic settings**.
2. Select the Synapse workspace, dedicated SQL pool, or Apache Spark pool for which you want to create a diagnostic setting.
3. If no diagnostic settings exist on the selected workspace, you're prompted to create a setting. Select **Turn on diagnostics**.

   If there are existing diagnostic settings on the workspace, you will see a list of settings already configured on the resource. Select **Add diagnostic setting**.
4. Give your setting a name, select **Send to Log Analytics**, and then select a workspace from **Log Analytics workspace**.

   > **NOTE**
   > Because an Azure log table can't have more than 500 columns, we **highly recommended** you select *Resource-Specific mode*. For more information, see AzureDiagnostics Logs reference.
5. Select **Save**.

After a few moments, the new setting appears in your list of settings for your workspace, dedicated SQL pool, or Apache Spark pool. Diagnostic logs are streamed to that workspace as soon as new event data are generated. Up to 15 minutes might elapse between when an event is emitted and when it appears in Log Analytics.

Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs in Synapse Studio article.

For more information on monitoring Apache Spark applications, see the Monitor Apache Spark applications in Synapse Studio article.

For more information on monitoring SQL requests, see the Monitor SQL requests in Synapse Studio article.

How to set up access control for your Azure Synapse workspace

8/19/2022 • 10 minutes to read • Edit Online

This article teaches you how to control access to a Microsoft Azure Synapse workspace. We'll use a combination of Azure roles, Azure Synapse roles, SQL permissions, and Git permissions to achieve this.

In this guide, you'll set up a workspace and configure a basic access control system. You can use this information in many types of Synapse projects. You'll also find advanced options for finer-grained control should you need it.

Synapse access control can be simplified by aligning roles and personas in your organization with security groups. This enables you to manage access to security groups simply by adding and removing users.

Before you begin this walkthrough, read the Azure Synapse access control overview to familiarize yourself with access control mechanisms used by Synapse Analytics.

Access control mechanisms

> **NOTE**
> The approach in this guide is to create security groups. When you assign roles to these security groups, you only need to manage memberships within those groups to control access to workspaces.

To secure a Synapse workspace, you'll configure the following items:

- **Security Groups**, to group users with similar access requirements.
- **Azure roles**, to control who can create and manage SQL pools, Apache Spark pools and Integration runtimes, and access ADLS Gen2 storage.
- **Synapse roles**, to control access to published code artifacts, use of Apache Spark compute resources and integration runtimes.
- **SQL permissions**, to control administrative and data plane access to SQL pools.
- **Git permissions**, to control who can access code artifacts in source control if you configure Git-support for workspaces.

Steps to secure a Synapse workspace

This document uses standard names to simplify instructions. Replace them with names of your choice.

SETTING	STANDARD NAME	DESCRIPTION
Synapse workspace	`workspace1`	The name that the Azure Synapse workspace will have.
ADLSGEN2 account	`storage1`	The ADLS account to use with your workspace.
Container	`container1`	The container in STG1 that the workspace will use by default.

SETTING	STANDARD NAME	DESCRIPTION
Active directory tenant	`contoso`	the active directory tenant name.

STEP 1: Set up security groups

> **NOTE**
> During the preview, you were encouraged to create security groups and to map them to Azure Synapse **Synapse SQL Administrator** and **Synapse Apache Spark Administrator** roles. With the introduction of new finer-grained Synapse RBAC roles and scopes, you are now encouraged to use newer options to control access to your workspace. They give you greater configuration flexibility and they acknowledge that developers often use a mix of SQL and Spark to create analytics applications. So developers may need access to individual resources rather than an entire workspace. Learn more about Synapse RBAC.

Create the following security groups for your workspace:

- `workspace1_SynapseAdministrators`, for users who need complete control over a workspace. Add yourself to this security group, at least initially.
- `workspace1_SynapseContributors`, for developers who need to develop, debug, and publish code to a service.
- `workspace1_SynapseComputeOperators`, for users who need to manage and monitor Apache Spark pools and Integration runtimes.
- `workspace1_SynapseCredentialUsers`, for users who need to debug and run orchestration pipelines using workspace MSI (managed service identity) credentials and cancel pipeline runs.

You'll assign Synapse roles to these groups at the workspace scope shortly.

Also create this security group:

- `workspace1_SQLAdmins`, group for users who need SQL Active Directory Admin authority, within SQL pools in the workspace.

The `workspace1_SQLAdmins` group to configure SQL permissions when you create SQL pools.

These five groups are sufficient for a basic setup. Later, you can add security groups to handle users who need more specialized access or restrict access to individual resources only.

> **NOTE**
> - Learn how to create a security group in Create a basic group and add members using Azure Active Directory.
> - Learn how to add a security group from another security group in Add or remove a group from another group using Azure Active Directory.

> **TIP**
> Individual Synapse users can use Azure Active Directory in the Azure portal to view their group memberships. This allows them to determine which roles they've been granted.

STEP 2: Prepare your ADLS Gen2 storage account

Synapse workspaces use default storage containers for:

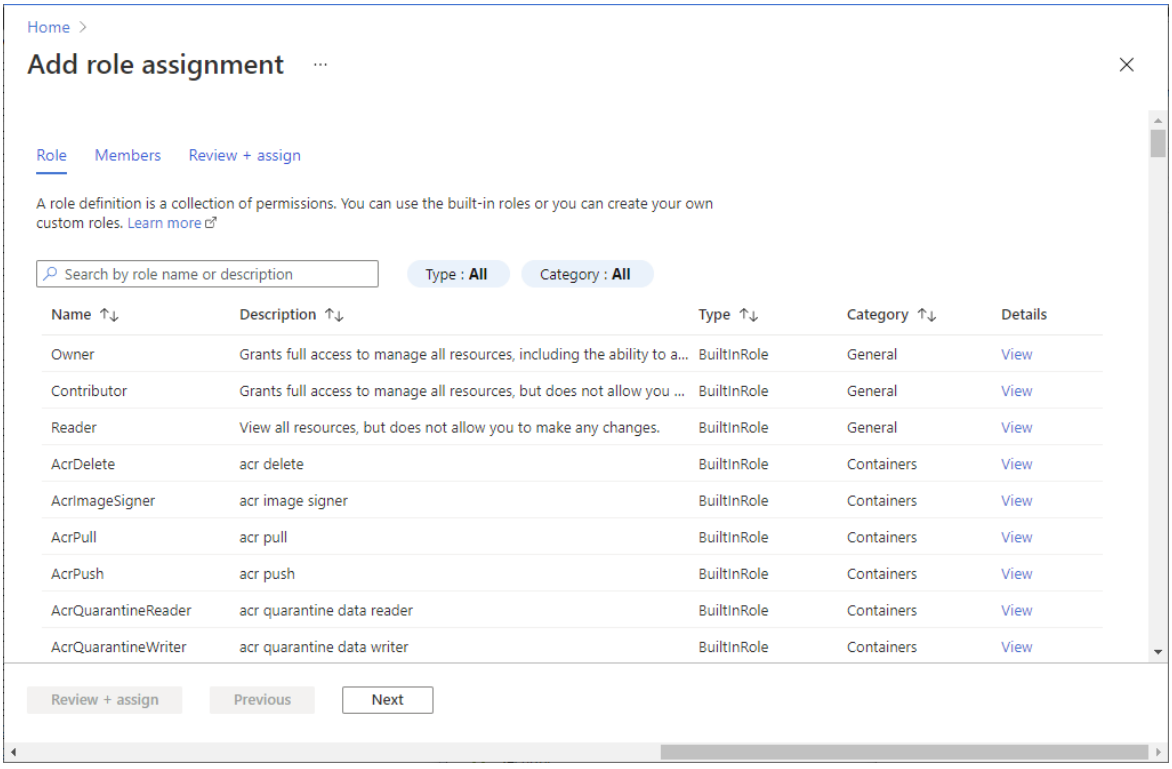
- Storage of backing data files for Spark tables

- Execution logs for Spark jobs
- Management of libraries that you choose to install

Identify the following information about your storage:

- The ADLS Gen2 account to use for your workspace. This document calls it `storage1`. `storage1` is considered the "primary" storage account for your workspace.
- The container inside `workspace1` that your Synapse workspace will use by default. This document calls it `container1`.
- Select **Access control (IAM)**.
- Select **Add** > **Add role assignment** to open the Add role assignment page.
- Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Contributor
Assign access to	SERVICEPRINCIPAL
Members	workspace1_SynapseAdministrators, workspace1_SynapseContributors, and workspace1_SynapseComputeOperators



STEP 3: Create and configure your Synapse workspace

In Azure portal, create a Synapse workspace:

- Select your subscription
- Select or create a resource group for which you have an Azure **Owner** role.
- Name the workspace `workspace1`

- Choose `storage1` for the Storage account
- Choose `container1` for the container that is being used as the "filesystem".
- Open WS1 in Synapse Studio
- In Synapse Studio, navigate to **Manage** > **Access Control**. In **workspace scope**, assign Synapse roles to security groups as follows:
  - Assign the **Synapse Administrator** role to `workspace1_SynapseAdministrators`
  - Assign the **Synapse Contributor** role to `workspace1_SynapseContributors`
  - Assign the **Synapse Compute Operator** role to `workspace1_SynapseComputeOperators`

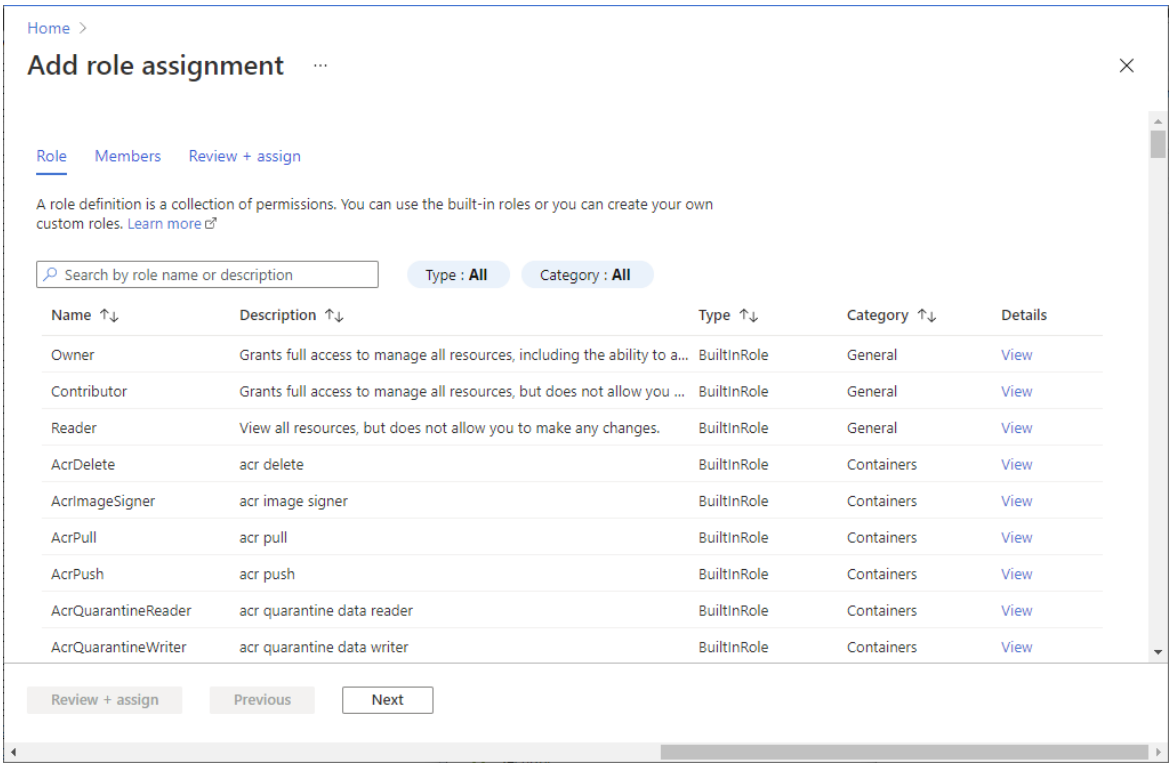
STEP 4: Grant the workspace MSI access to the default storage container

To run pipelines and perform system tasks, Azure Synapse requires managed service identity (MSI) to have access to `container1` in the default ADLS Gen2 account, for the workspace. For more information, see Azure Synapse workspace managed identity.

- Open Azure portal
- Locate the storage account, `storage1`, and then `container1`.
- Select **Access control (IAM)**.
- To open the **Add role assignment** page, select **Add** > **Add role assignment** .
- Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Contributor
Assign access to	MANAGEDIDENTITY
Members	managed identity name

> **NOTE**
> The managed identity name is also the workspace name.

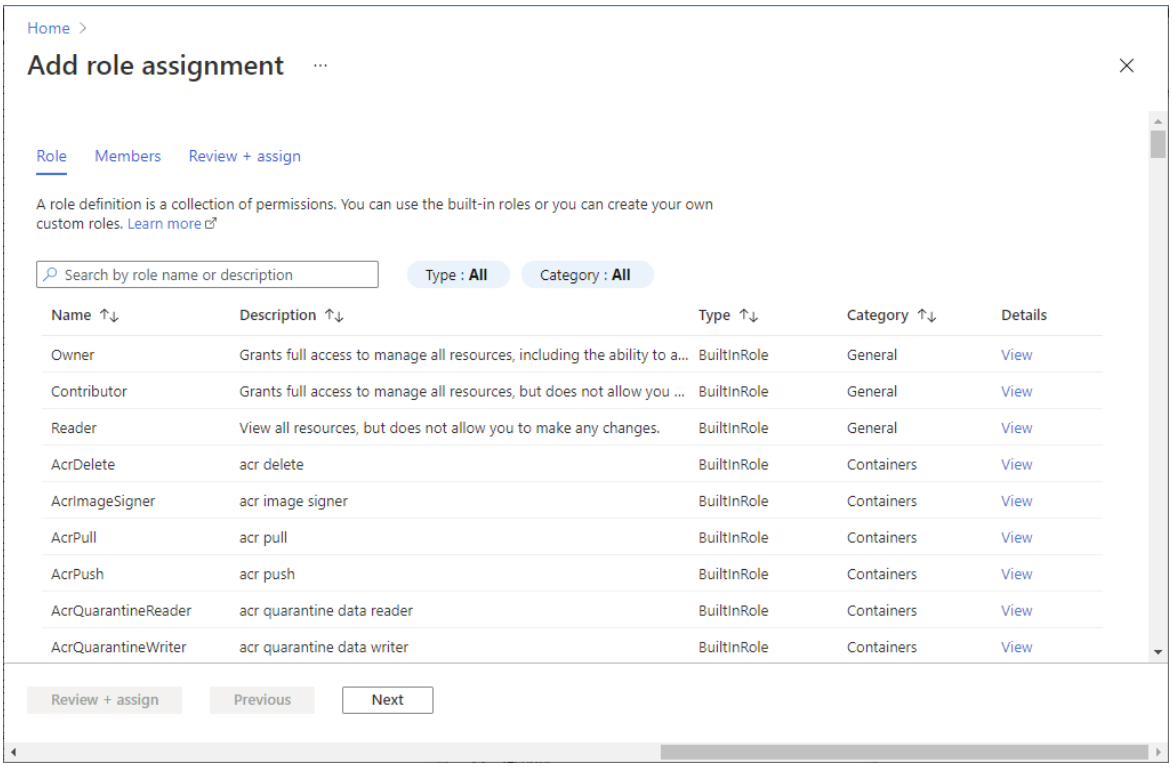


STEP 5: Grant Synapse administrators an Azure Contributor role for the workspace

To create SQL pools, Apache Spark pools and Integration runtimes, users need an Azure Contributor role for the workspace, at minimum. A Contributor role also allows users to manage resources, including pausing and scaling. To use Azure portal or Synapse Studio to create SQL pools, Apache Spark pools and Integration runtimes, you need a Contributor role at the resource group level.

- Open Azure portal
- Locate the workspace, `workspace1`
- Select **Access control (IAM)**.
- To open the **Add role assignment** page, select **Add** > **Add role assignment**.
- Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Contributor
Assign access to	SERVICEPRINCIPAL
Members	workspace1_SynapseAdministrators



STEP 6: Assign an SQL Active Directory Admin role

The *workspace creator* is automatically assigned as *SQL Active Directory Admin* for the workspace. Only a single user or a group can be granted this role. In this step, you assign the SQL Active Directory Admin for the workspace to the `workspace1_SQLAdmins` security group. This gives the group highly privileged admin access to all SQL pools and databases in the workspace.

- Open Azure portal
- Navigate to `workspace1`
- Under **Settings**, select **Azure Active Directory**
- Select **Set admin** and choose `workspace1_SQLAdmins`

> **NOTE**
> Step 6 is optional. You might choose to grant the `workspace1_SQLAdmins` group a less privileged role. To assign `db_owner` or other SQL roles, you must run scripts on each SQL database.

STEP 7: Grant access to SQL pools

The Synapse Administrator is by default given the SQL `db_owner` role for serverless SQL pools in the workspace as well.

Access to SQL pools for other users is controlled by SQL permissions. Assigning SQL permissions requires SQL scripts to be run on each SQL database post-creation. The following are examples that require you to run these scripts:

1. To grant users access to the serverless SQL pool, 'Built-in', and its databases.
2. To grant users access to dedicated SQL pool databases. Example SQL scripts are included later in this article.
3. To grant access to a dedicated SQL pool database, scripts can be run by the workspace creator or any member of the `workspace1_SynapseAdministrators` group.

4. To grant access to the serverless SQL pool, 'Built-in', scripts can be run by any member of the `workspace1_SQLAdmins` group or the `workspace1_SynapseAdministrators` group.

> **TIP**
> You can grant access to all SQL databases by taking the following steps for **each** SQL pool. Section Configure-Workspace-scoped permissions is an exception to the rule and it allows you to assign a user a sysadmin role at the workspace level.

STEP 7.1: Serverless SQL pool, Built-in

You can use the script examples in this section to give users permission to access an individual database or all databases in the serverless SQL pool, `Built-in`.

> **NOTE**
> In the script examples, replace *alias* with the alias of the user or group being granted access. Replace *domain* with the company domain you are using.

Configure Database-scoped permissions

You can grant users access to a **single** serverless SQL database with the steps outlined in this example:

1. Create a login. Change to the `master` database context.

```
--In the master database
CREATE LOGIN [alias@domain.com] FROM EXTERNAL PROVIDER;
```

2. Create user in your database. Change context to your database.

```
-- In your database
CREATE USER alias FROM LOGIN [alias@domain.com];
```

3. Add user as a member of the specified role in your database (in this case, the **db_owner** role).

```
ALTER ROLE db_owner ADD member alias; -- Type USER name from step 2
```

Configure Workspace-scoped permissions

You can grant full access to **all** serverless SQL pools in the workspace. Run the script in this example in the `master` database:

```
CREATE LOGIN [alias@domain.com] FROM EXTERNAL PROVIDER;
ALTER SERVER ROLE sysadmin ADD MEMBER [alias@domain.com];
```

STEP 7.2: configure Dedicated SQL pools

You can grant access to a **single**, dedicated, SQL pool database. Use these steps in the Azure Synapse SQL script editor:

1. Create a user in the database by running the following commands. Select the target database in the *Connect to* dropdown:

```
--Create user in the database
CREATE USER [<alias@domain.com>] FROM EXTERNAL PROVIDER;
```

2. Grant the user a role to access the database:

```
--Grant role to the user in the database
EXEC sp_addrolemember 'db_owner', '<alias@domain.com>';
```

> **IMPORTANT**
> **db_datareader** and **db_datawriter** database roles can provide read/write permission when you do not want to give **db_owner** permissions. However, **db_owner** permission is necessary for Spark users to read and write directly from Spark into or from an SQL pool.

You can run queries to confirm that serverless SQL pools can query storage accounts, after you have created your users.

STEP 8: Add users to security groups

The initial configuration for your access control system is now complete.

You can now add and remove users to the security groups you've set up, to manage access to them. You can manually assign users to Azure Synapse roles, but this sets permissions inconsistently. Instead, only add or remove users to your security groups.

STEP 9: Network security

As a final step to secure your workspace, you should secure network access, using the workspace firewall.

- With and without a managed virtual network, you can connect to your workspace from public networks. For more information, see Connectivity Settings.
- Access from public networks can be controlled by enabling the public network access feature or the workspace firewall.
- Alternatively, you can connect to your workspace using a managed private endpoint and private Link. Azure Synapse workspaces without the Azure Synapse Analytics Managed Virtual Network do not have the ability to connect via managed private endpoints.

STEP 10: Completion

Your workspace is now fully configured and secured.

Supporting more advanced scenarios

This guide has focused on setting up a basic access control system. You can support more advanced scenarios by creating additional security groups and assigning these groups more granular roles at more specific scopes. Consider the following cases:

Enable Git-support for the workspace for more advanced development scenarios including CI/CD. While in Git mode, Git permissions and Synapse RBAC will determine whether a user can commit changes to their working branch. Publishing to the service only takes place from the collaboration branch. Consider creating a security group for developers who need to develop and debug updates in a working branch but don't need to publish changes to the live service.

Restrict developer access to specific resources. Create additional finer-grained security groups for developers who need access only to specific resources. Assign these groups appropriate Azure Synapse roles that are scoped to specific Spark pools, Integration runtimes, or credentials.

Restrict operators from accessing code artifacts. Create security groups for operators who need to monitor operational status of Synapse compute resources and view logs but who don't need access to code or to publish updates to the service. Assign these groups the Compute Operator role scoped to specific Spark pools and Integration runtimes.

Disable local authentication. By allowing only Azure Active Directory authentication, you can centrally manage access to Azure Synapse resources, such as SQL pools. Local authentication for all resources within the workspace can be disabled during or after workspace creation. For more information on Azure AD-only authentication, see Disabling local authentication in Azure Synapse Analytics.

How to review Synapse RBAC role assignments

8/19/2022 • 2 minutes to read • Edit Online

Synapse RBAC roles are used to assign permissions to users, groups, and other security principals to enable access and use of Synapse resources. For more information, see What is Synapse role-based access control (RBAC)?

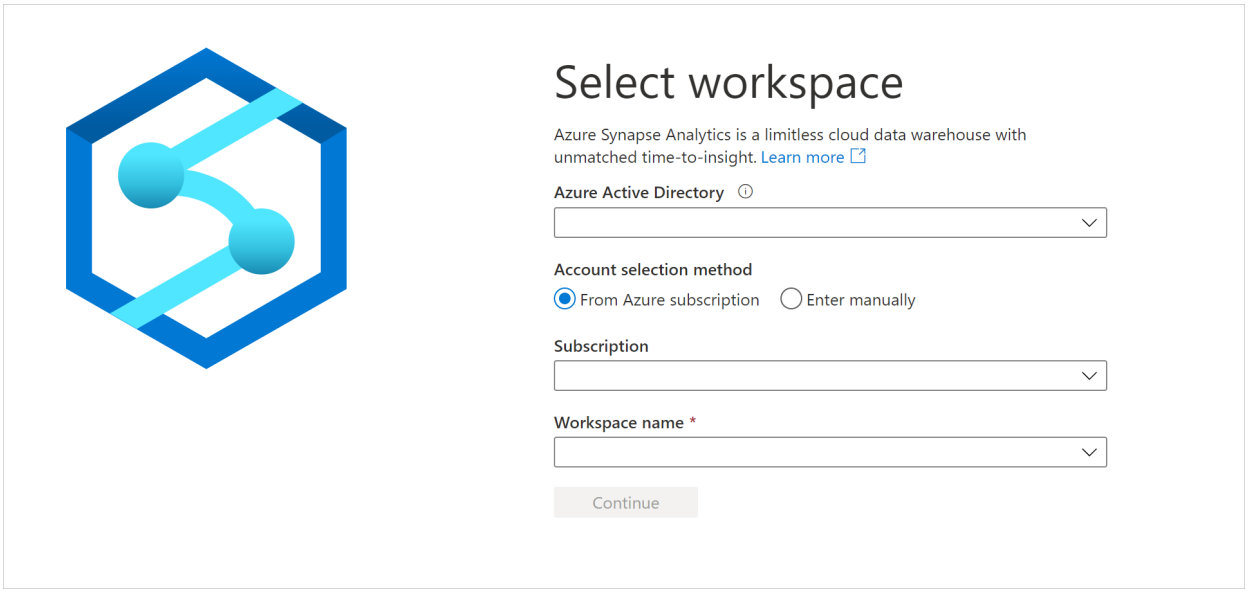
This article explains how to review the current role assignments for a workspace.

With any Synapse RBAC role, you can list Synapse RBAC role assignments for all scopes, including assignments for objects you don't have access to. Only a Synapse Administrator can grant Synapse RBAC access.

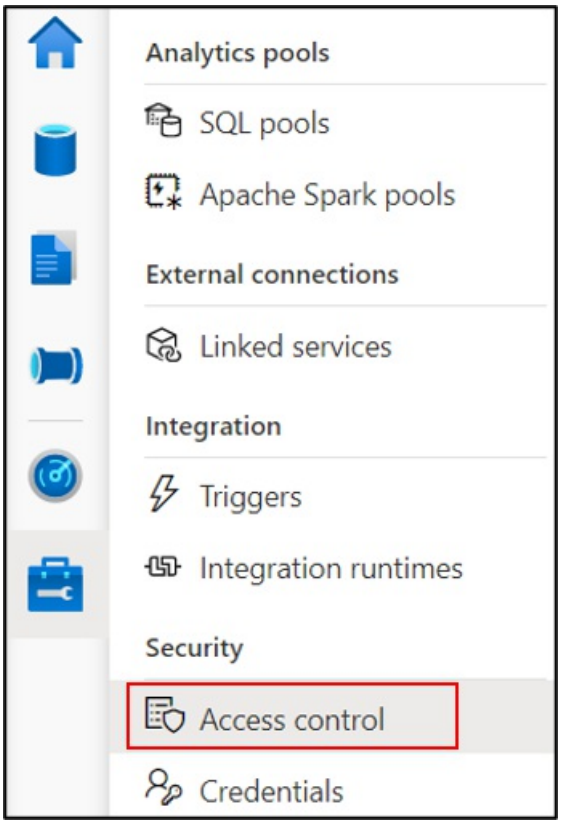
> **NOTE**
> A guest users (users from a different AD tenant) can also see and manage role assignment after being assigned the Synapse Administrator role.

Open Synapse Studio

To review role assignments, first open the Synapse Studio and select your workspace. To sign into your workspace, there are two **Account selection methods**. One is from **Azure subscription**, the other is from **Enter manually**. If you have the Synapse Azure role or higher level Azure roles, you can use both methods to log into the workspace. If you don't have the related Azure roles, and you were granted as the Synapse RBAC role, **Enter manually** is the only way to log into the workspace.

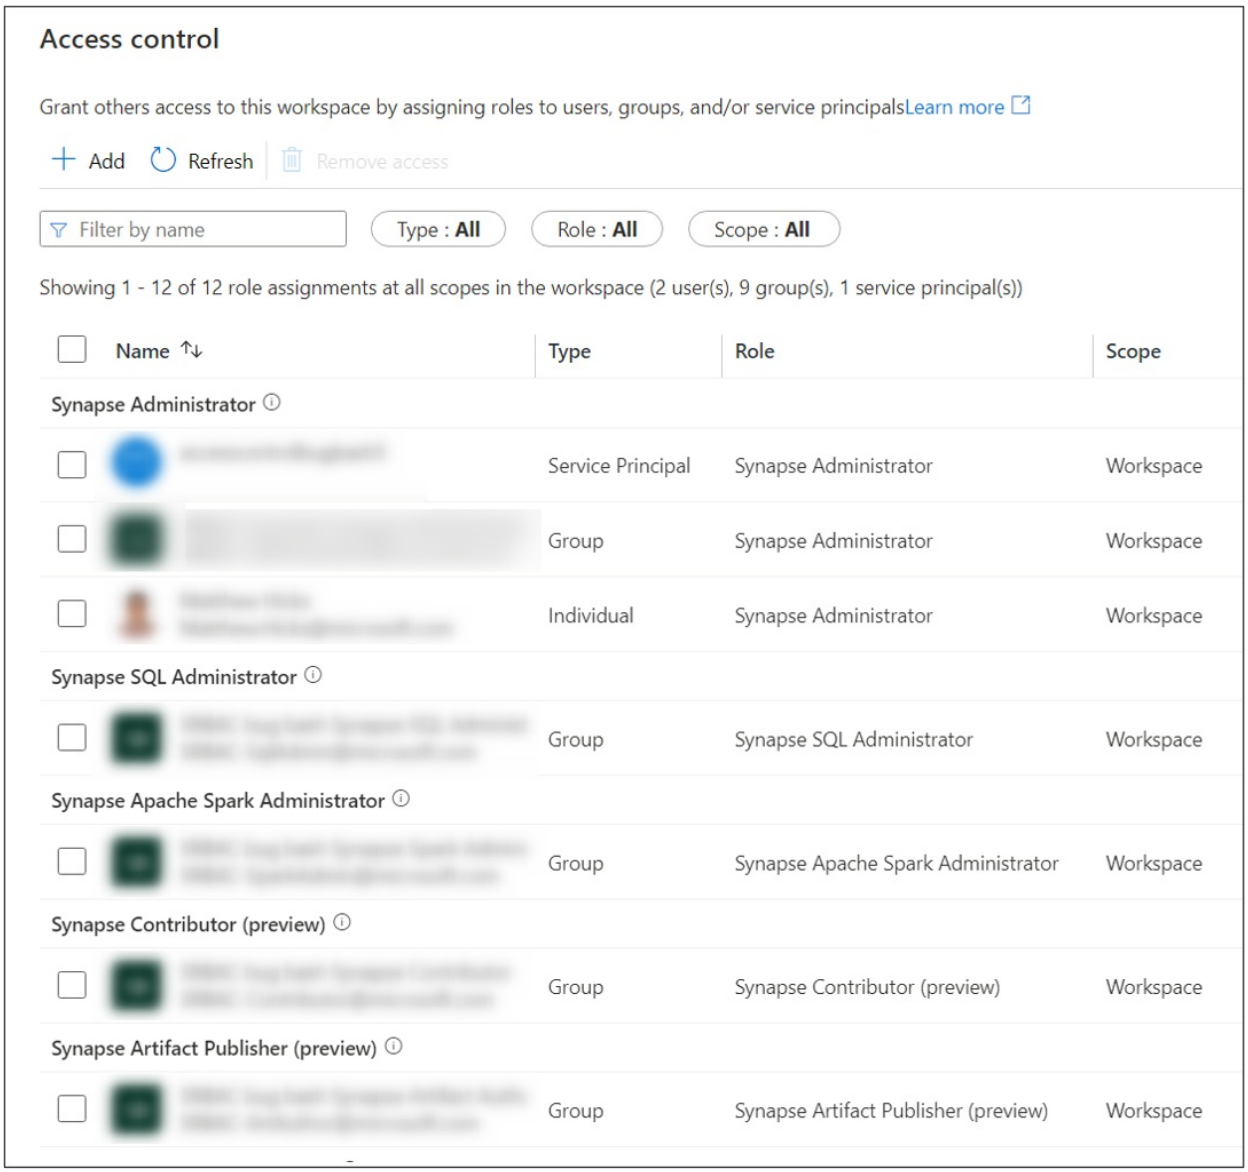


Once you've opened your workspace, select the **Manage** hub on the left, then expand the **Security** section and select **Access control**.



Review workspace role assignments

The Access control screen lists all current role assignments for the workspace, grouped by role. Each assignment includes the principal name, principal type, role, and its scope.



If a principal is assigned the same role at different scopes, you'll see multiple assignments for the principal, one for each scope.

If a role is assigned to a security group, you'll see the roles explicitly assigned to the group but not roles inherited from parent groups.

You can filter the list by principal name or email, and selectively filter the object types, roles, and scopes. enter your name or email alias in the Name filter to see roles assigned to you. Only a Synapse Administrator can change your roles.

> **IMPORTANT**
> If you are directly or indirectly a member of a group that is assigned roles, you may have permissions that are not shown.

> **TIP**
> You can find your group memberships using Azure Active Directory in the Azure portal.

If you create a new workspace, you and the workspace MSI service principal are automatically given the Synapse Administrator role at workspace scope.

Next steps

Learn how to manage Synapse RBAC role assignments.

Learn which role you need to do specific tasks

How to manage Synapse RBAC role assignments in Synapse Studio

8/19/2022 • 2 minutes to read • Edit Online

Synapse RBAC uses roles to assign permissions to users, groups, and other security principals to enable access and use of Synapse resources and code artifacts. For more information, see What is Synapse role-based access control (RBAC)?

This article shows how to add and delete Synapse RBAC role assignments.

NOTE

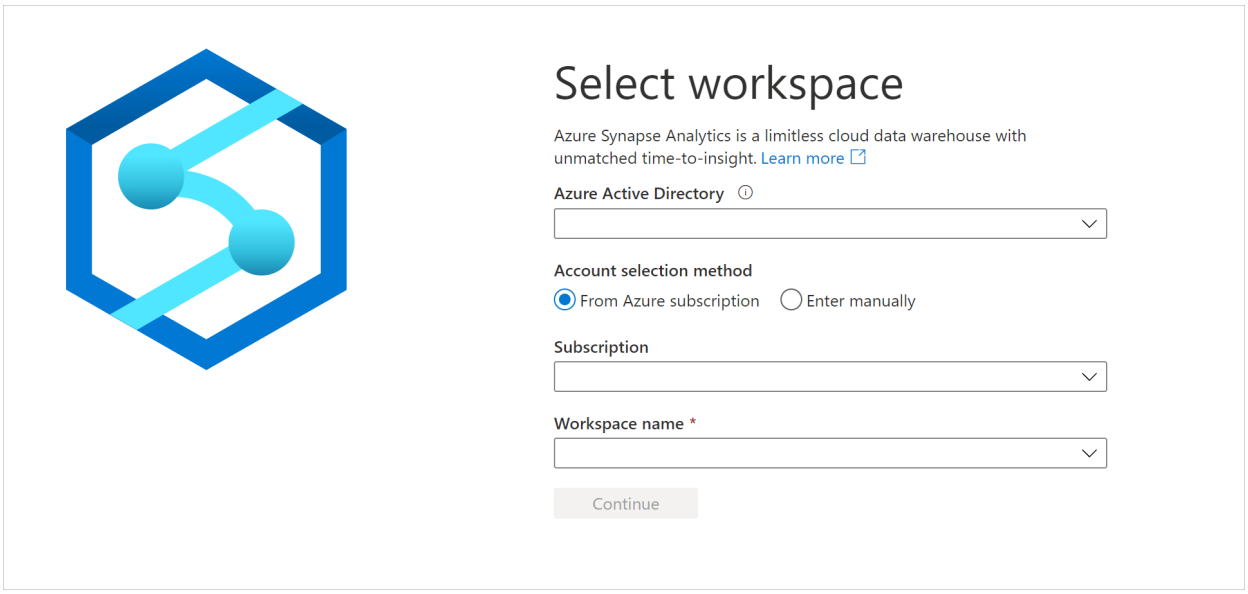
- To manage Synapse RBAC role assignments you need to have the Synapse Administrator role on the workspace or at a lower-level scope that includes the objects you want to manage. If you are a Synapse Administrator on the workspace you can grant access to all objects in the workspace.
- **Guest users** from a different AD tenant can also see and manage role assignments after being assigned the Synapse Administrator role.
- To help you regain access to a workspace in the event that no Synapse Administrators are assigned or available to you, users with permissions to manage **Azure RBAC** role assignments on the workspace can also manage **Synapse RBAC** role assignments, allowing the addition of Synapse Administrator or other Synapse role assignments.
- Access to SQL pools is managed using SQL permissions. With the exception of the Synapse Administrator and Synapse SQL Administrator roles, Synapse RBAC roles do not grant access to SQL pools.

IMPORTANT

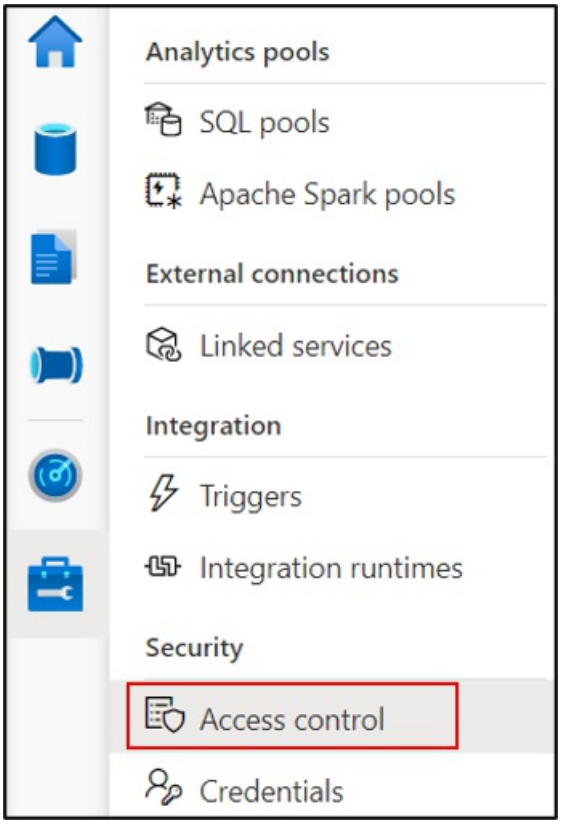
- Changes made to Synapse RBAC role assignments may take 2-5 minutes to take effect.
- If you are managing Synapse RBAC permissions by modifying membership of security groups, then changes to membership are managed using Azure Active Directory. Changes to group memberships may take 10-15 minutes or longer to take effect.

Open Synapse Studio

To assign a role to a user, group, service principal, or managed identity, first open the Synapse Studio and log into your workspace.



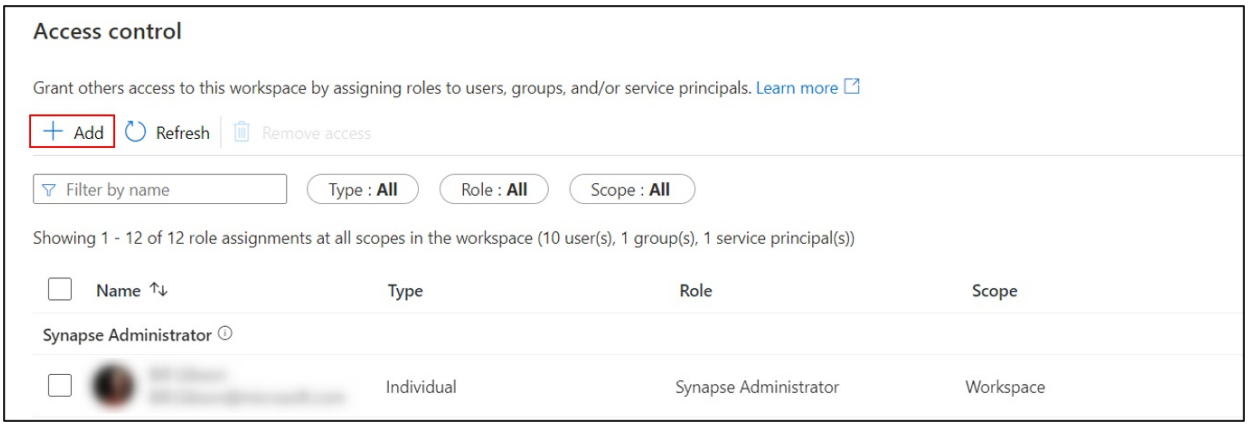
Once you've opened your workspace, expand the **Security** section on the left and select **Access control**.



The Access control screen lists current role assignments. You can filter the list by principal name or email, and selectively filter the object types, roles, or scopes included. From this screen, you can add or remove role assignments.

Add a Synapse role assignment

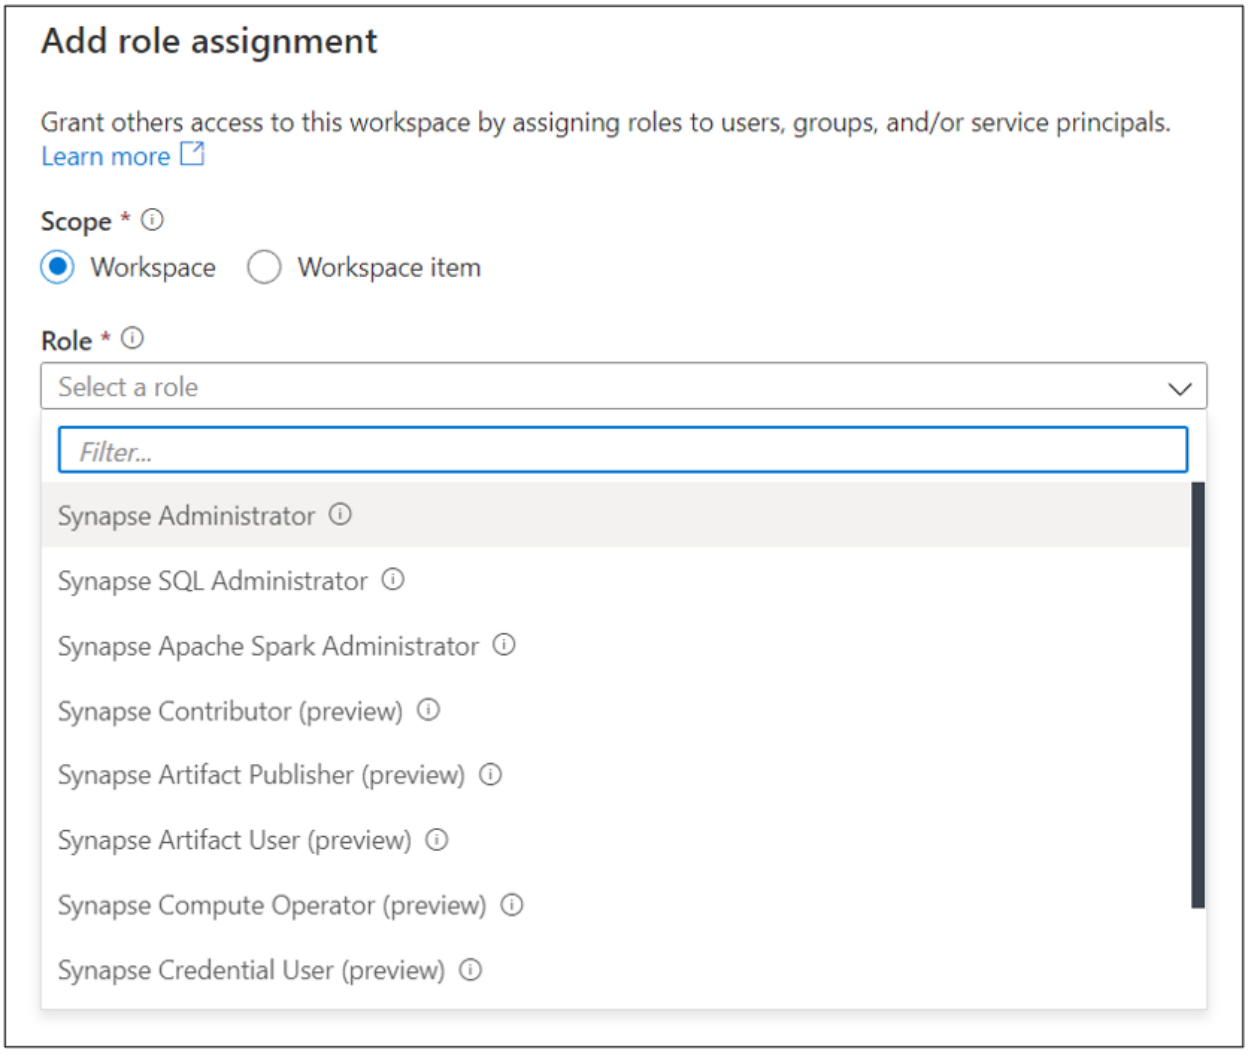
On the access control screen, select **+Add** to create a new role assignment



On the Add role assignment tab, you can create role assignments at workspace scope or workspace item scope.

Add workspace-scoped role assignment

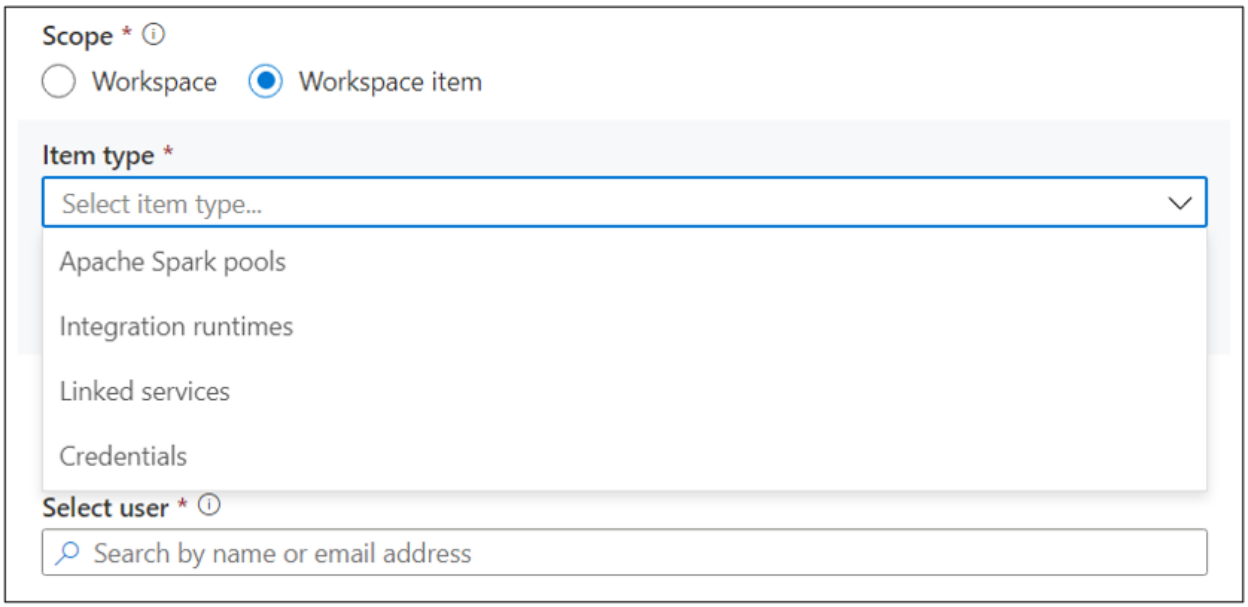
First, select **Workspace** as the scope, then select the **Synapse RBAC role**. Select the **principal(s)** to be assigned the role, then create the role assignment(s).



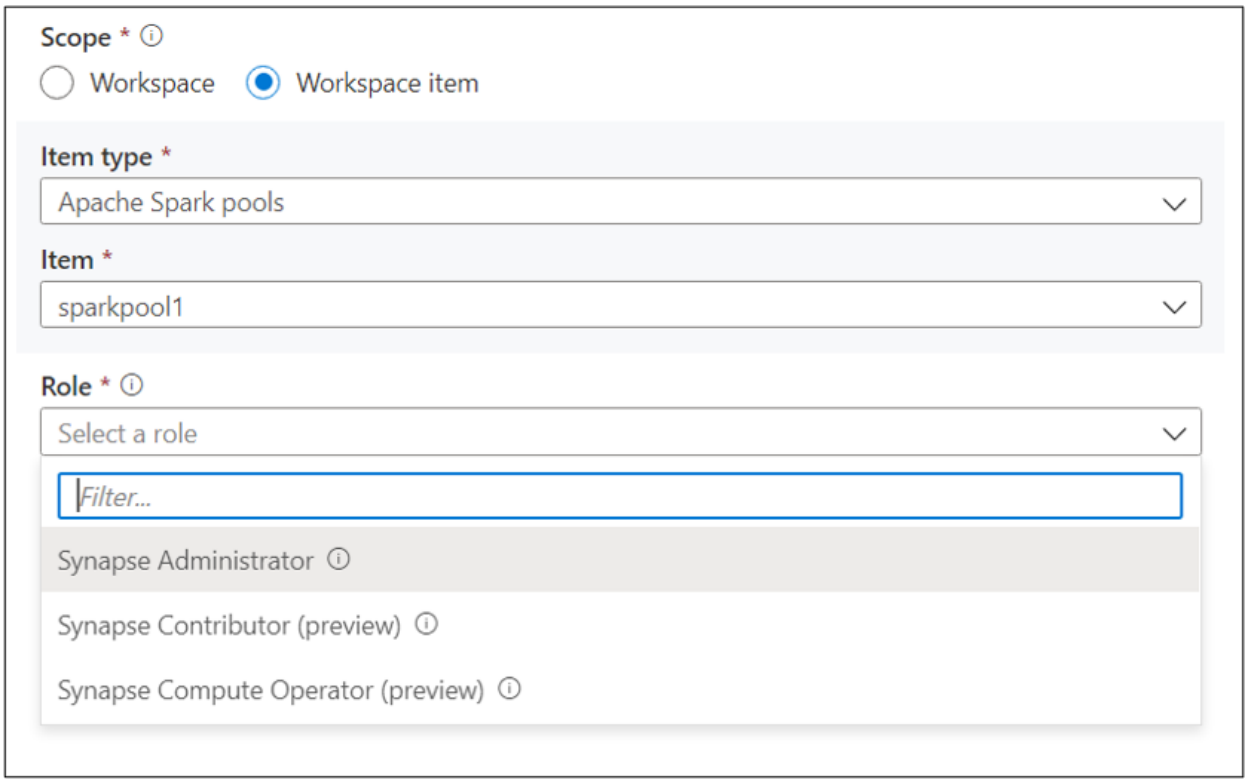
The assigned role will apply for all applicable objects in the workspace.

Add workspace item-scoped role assignment

To assign a role at a finer-grained scope, select **Workspace item** as the scope, then select the scoping **Item type**.



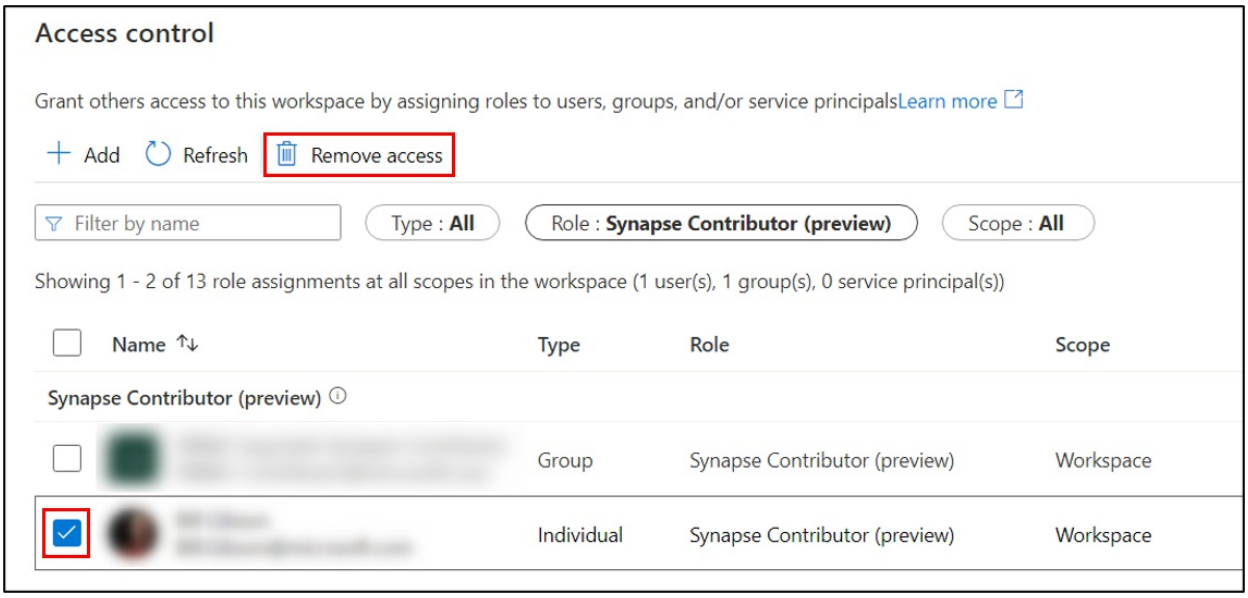
Select the specific **item** to be used as the scope, then select the **role** to be assigned from the drop-down. The drop-down lists only those roles that are valid for the selected item type. Learn more.



Then **select the principal(s)** to which the role is to be assigned. You can iteratively select multiple principals. Select **Apply** to create the role assignment(s).

Remove a Synapse RBAC role assignment

To revoke Synapse RBAC access, you remove the appropriate role assignments. On the Access control screen, use the filters to locate the role assignment(s) to be removed. Check the role assignments and then select **Remove access**.



Remember that changes to role assignments will take 2-5 minutes to take effect.

Next steps

Understand the Synapse RBAC roles required to perform common tasks

Grant permissions to workspace managed identity

8/19/2022 • 2 minutes to read • Edit Online

This article teaches you how to grant permissions to the managed identity in Azure synapse workspace. Permissions, in turn, allow access to dedicated SQL pools in the workspace and ADLS Gen2 storage account through the Azure portal.

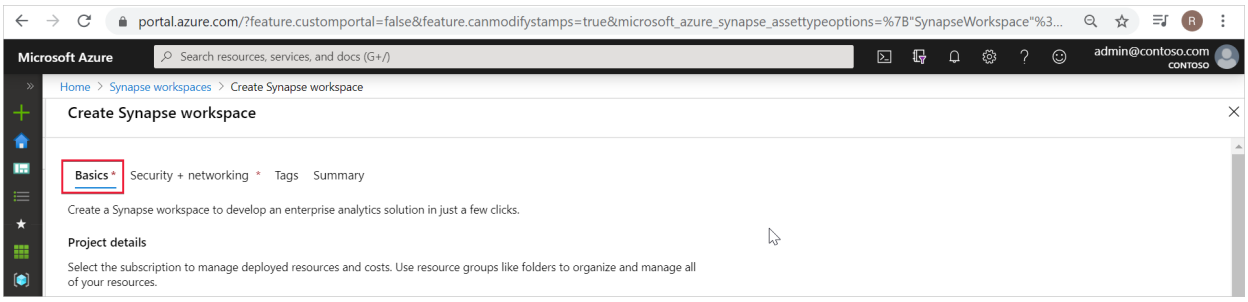
> **NOTE**
>
> This workspace managed identity will be referred to as managed identity through the rest of this document.

Grant the managed identity permissions to ADLS Gen2 storage account

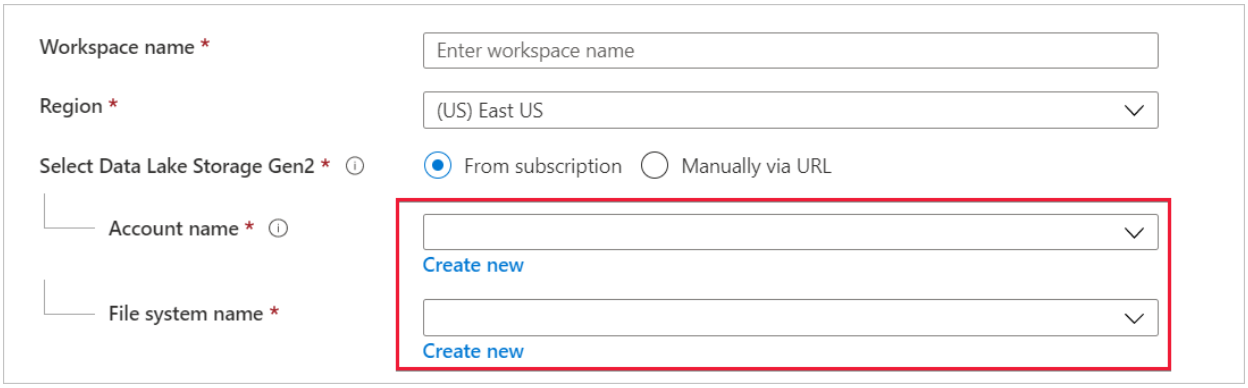
An ADLS Gen2 storage account is required to create an Azure Synapse workspace. To successfully launch Spark pools in Azure Synapse workspace, the Azure Synapse managed identity needs the *Storage Blob Data Contributor* role on this storage account . Pipeline orchestration in Azure Synapse also benefits from this role.

Grant permissions to managed identity during workspace creation

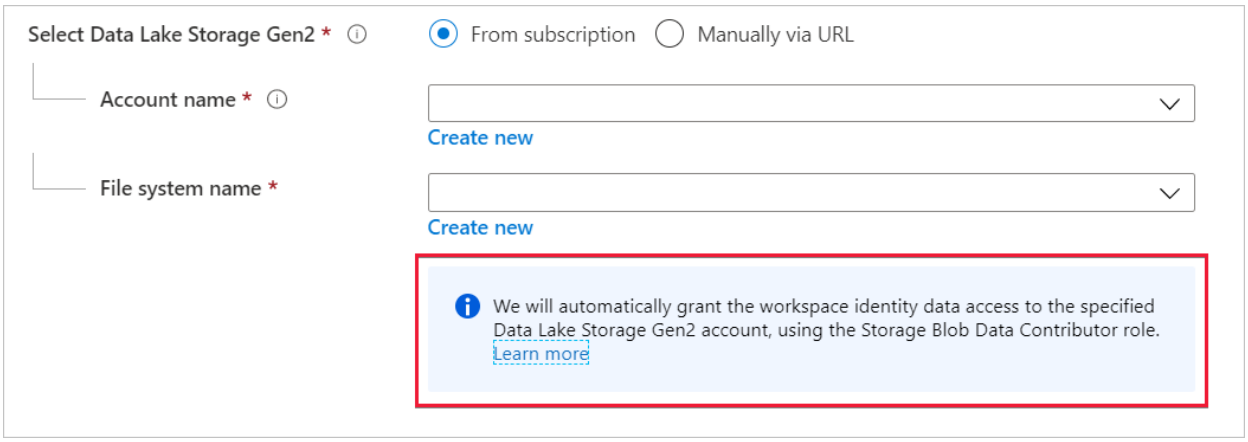
Azure Synapse will attempt to grant the Storage Blob Data Contributor role to the managed identity after you create the Azure Synapse workspace using Azure portal. You provide the ADLS Gen2 storage account details in the **Basics** tab.



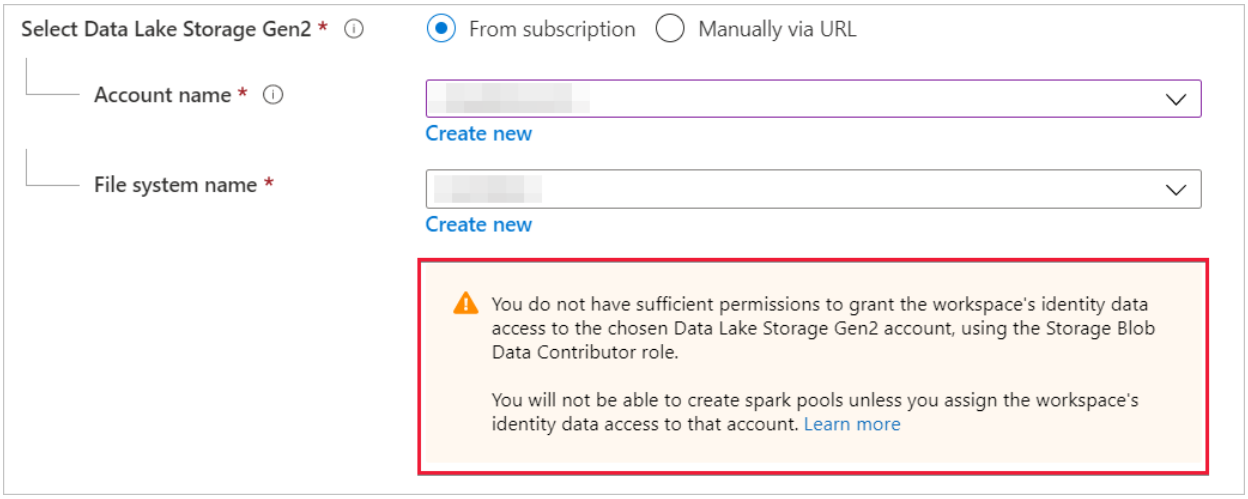
Choose the ADLS Gen2 storage account and filesystem in **Account name** and **File system name**.



If the workspace creator is also **Owner** of the ADLS Gen2 storage account, then Azure Synapse will assign the *Storage Blob Data Contributor* role to the managed identity. You'll see the following message below the storage account details that you entered.



If the workspace creator isn't the owner of the ADLS Gen2 storage account, then Azure Synapse doesn't assign the *Storage Blob Data Contributor* role to the managed identity. The message appearing below the storage account details notifies the workspace creator that they don't have sufficient permissions to grant the *Storage Blob Data Contributor* role to the managed identity.



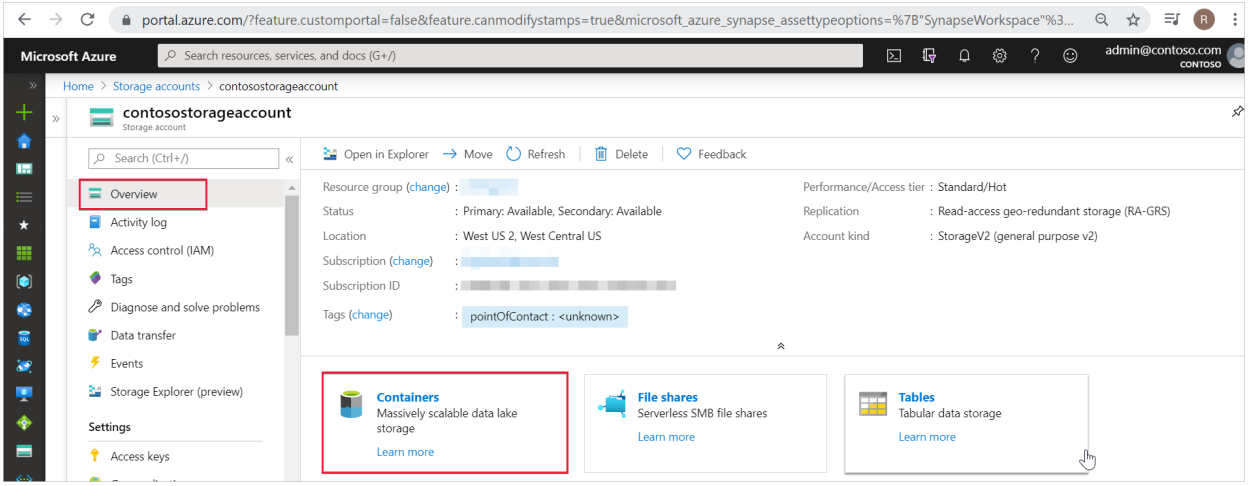
As the message states, you can't create Spark pools unless the *Storage Blob Data Contributor* is assigned to the managed identity.

Grant permissions to managed identity after workspace creation

During workspace creation, if you don't assign the *Storage Blob Data contributor* to the managed identity, then the **Owner** of the ADLS Gen2 storage account manually assigns that role to the identity. The following steps will help you to accomplish manual assignment.

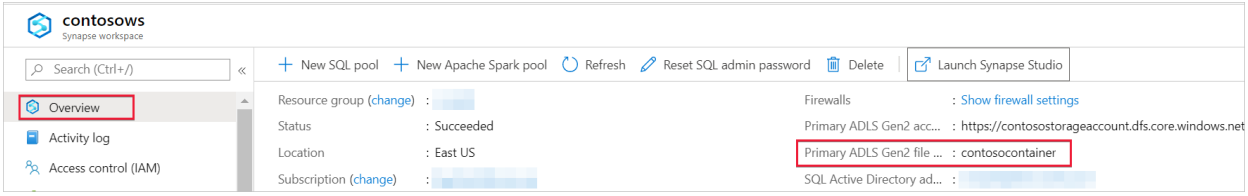
Step 1: Navigate to the ADLS Gen2 storage account in Azure portal

In Azure portal, open the ADLS Gen2 storage account and select **Overview** from the left navigation. You'll only need to assign The *Storage Blob Data Contributor* role at the container or filesystem level. Select **Containers**.

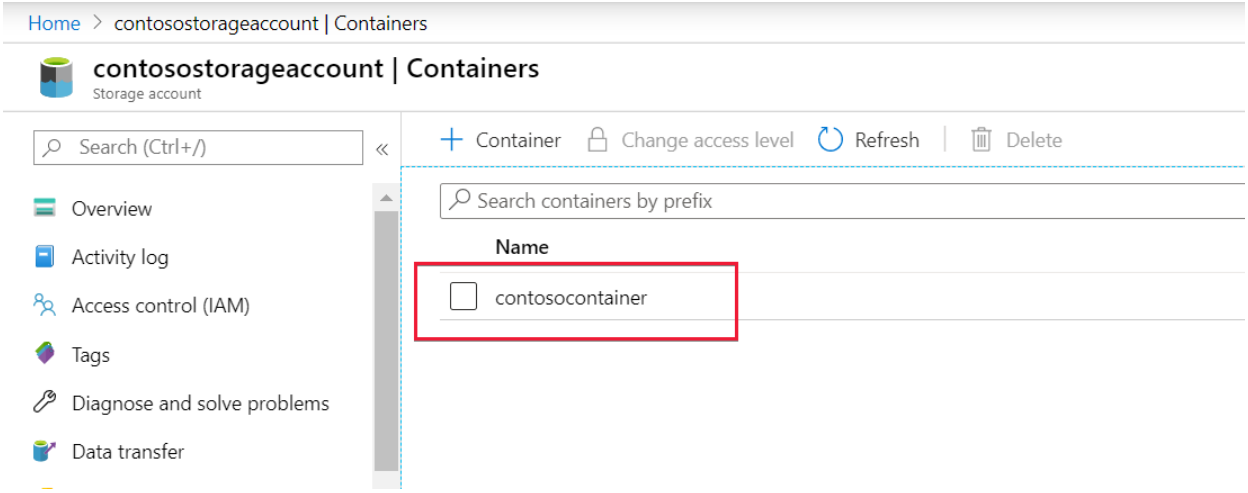


Step 2: Select the container

The managed identity should have data access to the container (file system) that was provided when the workspace was created. You can find this container or file system in Azure portal. Open the Azure Synapse workspace in Azure portal and select the **Overview** tab from the left navigation.



Select that same container or file system to grant the *Storage Blob Data Contributor* role to the managed identity.

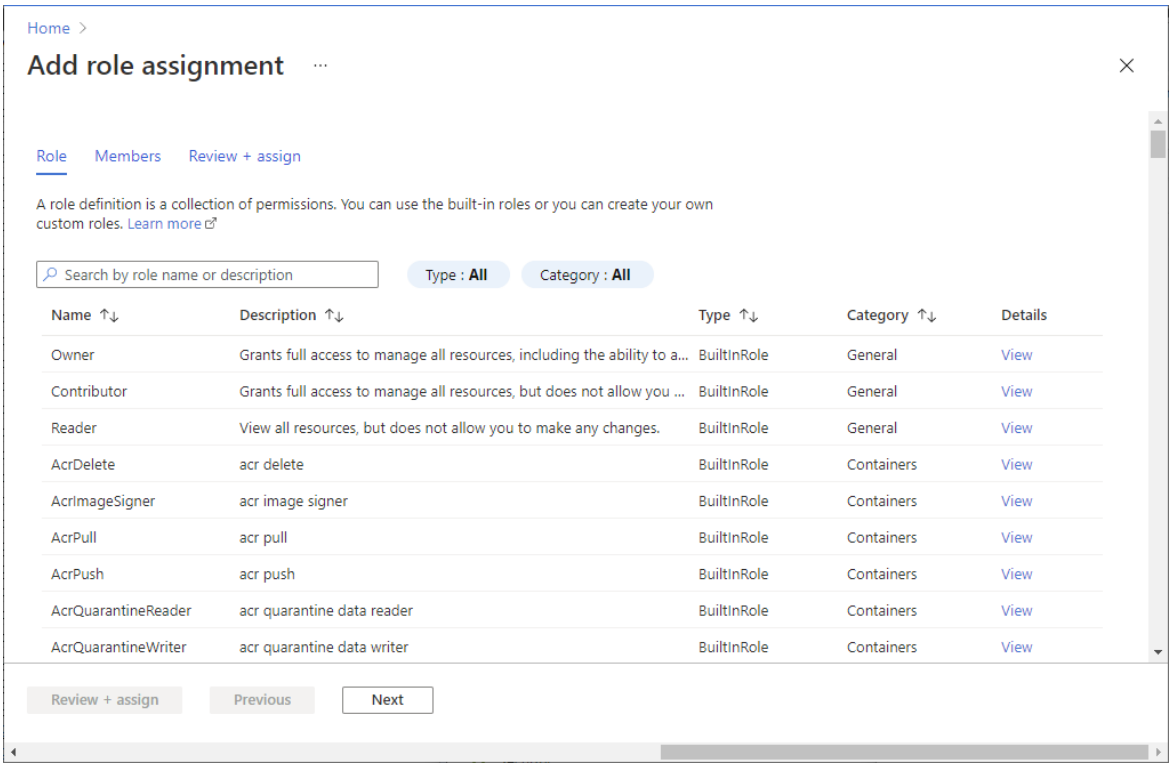


Step 3: Open Access control and add role assignment

1. Select **Access control (IAM)**.
2. Select **Add** > **Add role assignment** to open the Add role assignment page.
3. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Contributor
Assign access to	MANAGEDIDENTITY
Members	managed identity name

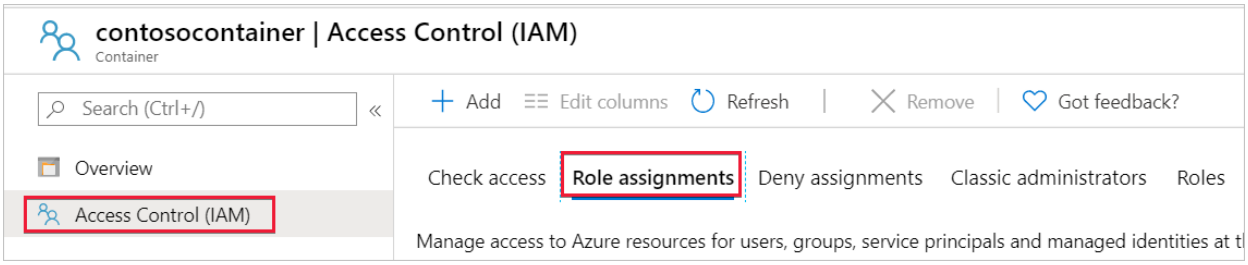
> **NOTE**
> The managed identity name is also the workspace name.



4. Select **Save** to add the role assignment.

Step 4: Verify that the Storage Blob Data Contributor role is assigned to the managed identity

Select **Access Control(IAM)** and then select **Role assignments**.



You should see your managed identity listed under the **Storage Blob Data Contributor** section with the *Storage Blob Data Contributor* role assigned to it.

Learn more about Workspace managed identity

Create a workspace with data exfiltration protection enabled

8/19/2022 • 2 minutes to read • Edit Online

This article describes how to create a workspace with data exfiltration protection enabled and how to manage the approved Azure AD tenants for this workspace.

> **NOTE**
> You cannot change the workspace configuration for managed virtual network and data exfiltration protection after the workspace is created.

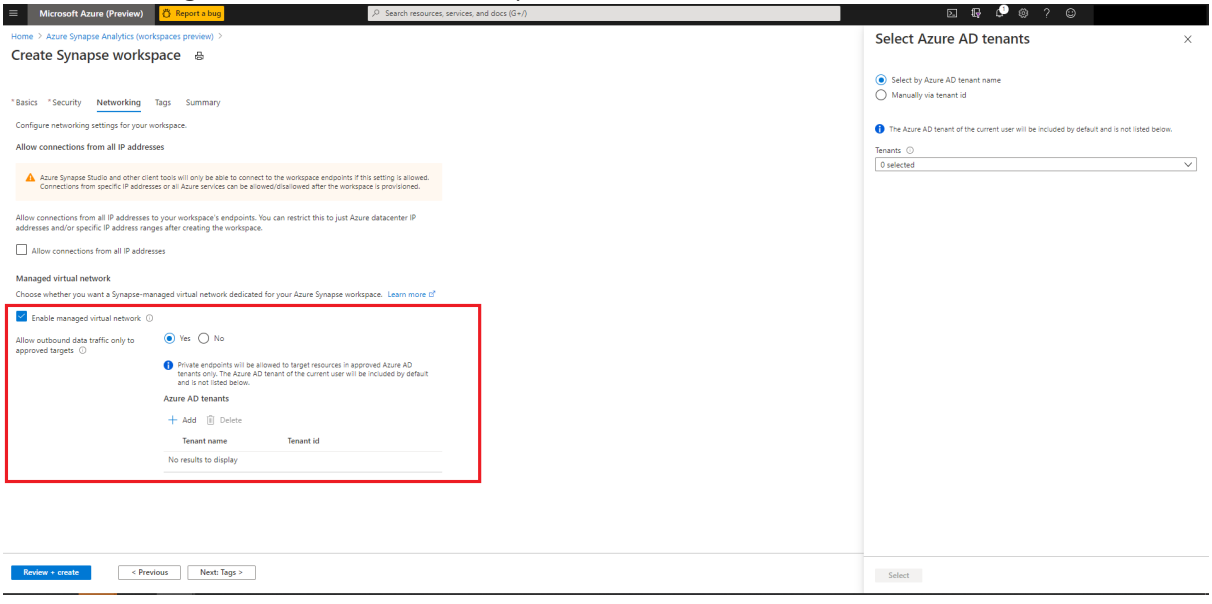
Prerequisites

- Permissions to create a workspace resource in Azure.
- Synapse workspace permissions to create managed private endpoints.
- Subscriptions registered for the Networking resource provider. Learn more.

Follow the steps listed in Quickstart: Create a Synapse workspace to get started with creating your workspace. Before creating your workspace, use the information below to add data exfiltration protection to your workspace.

Add data exfiltration protection when creating your workspace

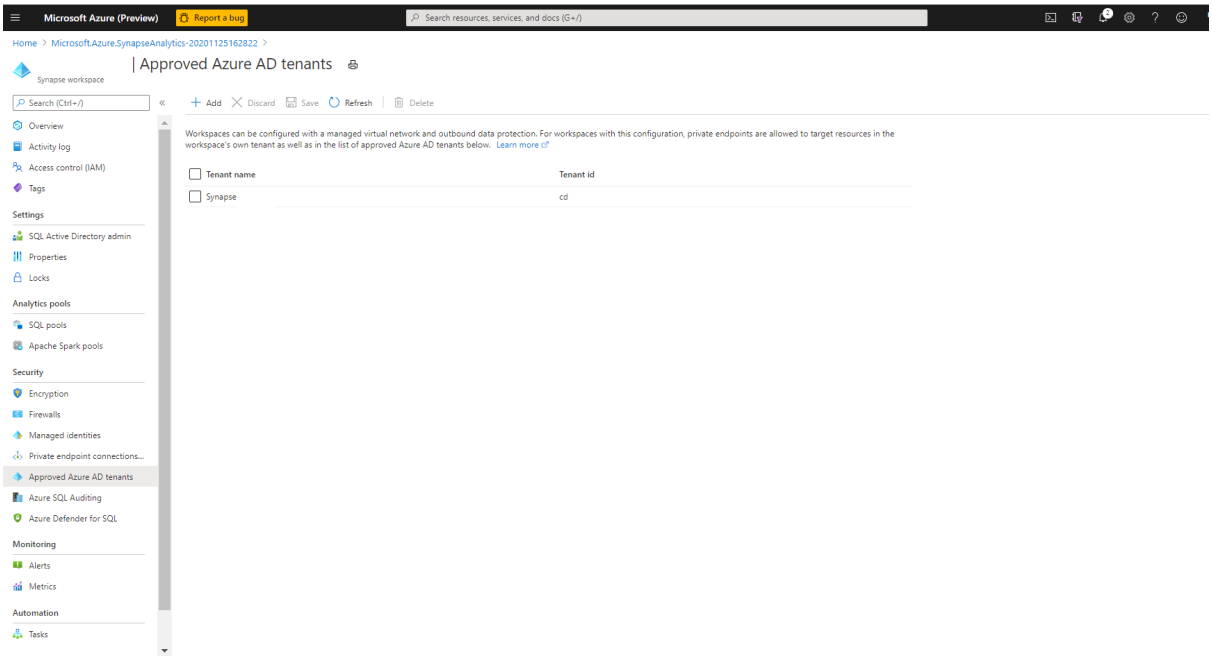
1. On the Networking tab, select the "Enable managed virtual network" checkbox.
2. Select "Yes" for the "Allow outbound data traffic only to approved targets" option.
3. Choose the approved Azure AD tenants for this workspace.
4. Review the configuration and create the workspace.



Manage approved Azure Active Directory tenants for the workspace

1. From the workspace's Azure portal, navigate to "Approved Azure AD tenants". The list of approved Azure AD tenants for the workspace will be listed here. The workspace's tenant is included by default and is not listed.

2. Use "+Add" to include new tenants to the approved list.
3. To remove an Azure AD tenant from the approved list, select the tenant and select on "Delete" and then "Save".



Connecting to Azure resources in approved Azure AD tenants

You can create managed private endpoints to connect to Azure resources that reside in Azure AD tenants, which are approved for a workspace. Follow the steps listed in the guide for creating managed private endpoints.

> **IMPORTANT**
> Resources in tenants other than the workspace's tenant must not have blocking firewall rules in place for the SQL pools to connect to them. Resources within the workspace's managed virtual network, such as Spark clusters, can connect over managed private links to firewall-protected resources.

Known limitations

Users can provide an environment configuration file to install Python packages from public repositories like PyPI. In data exfiltration protected workspaces, connections to outbound repositories are blocked. As a result, Python library installed from public repositories like PyPI are not supported.

As an alternative, users can upload workspace packages or create a private channel within their primary Azure Data Lake Storage account. For more information, visit Package management in Azure Synapse Analytics

Learn more about data exfiltration protection in Synapse workspaces

Learn more about Managed workspace Virtual Network

Learn more about Managed private endpoints

Create Managed private endpoints to your data sources

Create a Managed private endpoint to your data source

8/19/2022 • 2 minutes to read • Edit Online

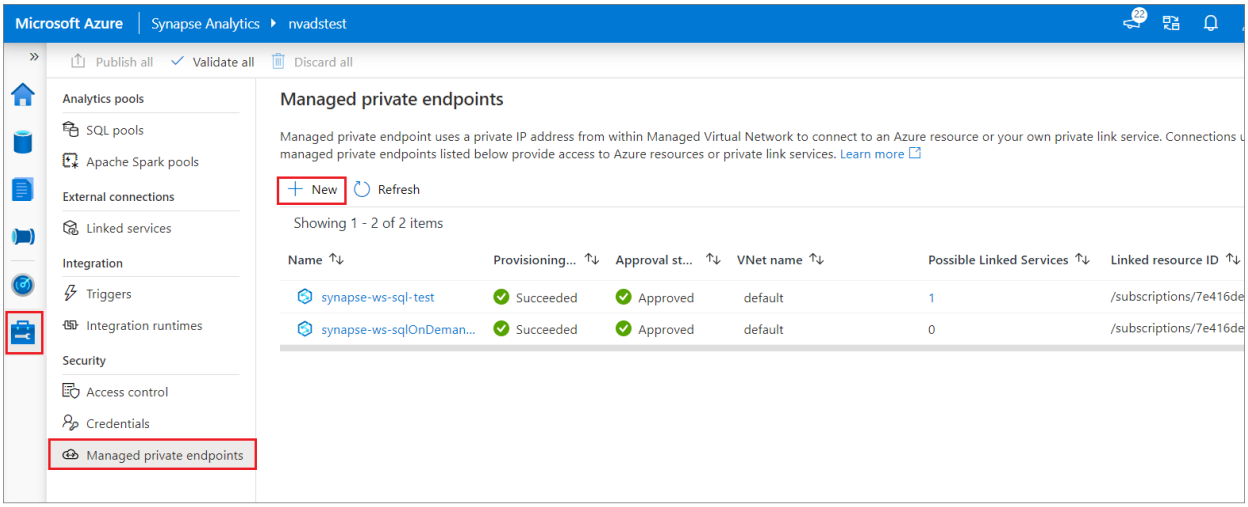
This article will teach you how to create a Managed private endpoint to your data source in Azure. See Managed private endpoints to learn more.

Step 1: Open your Azure Synapse workspace in Azure portal

You can create a Managed private endpoint to your data source from Azure Synapse Studio. Select the **Overview** tab in Azure portal and select **Open** on the Open Synapse Studio card in the Getting started section.

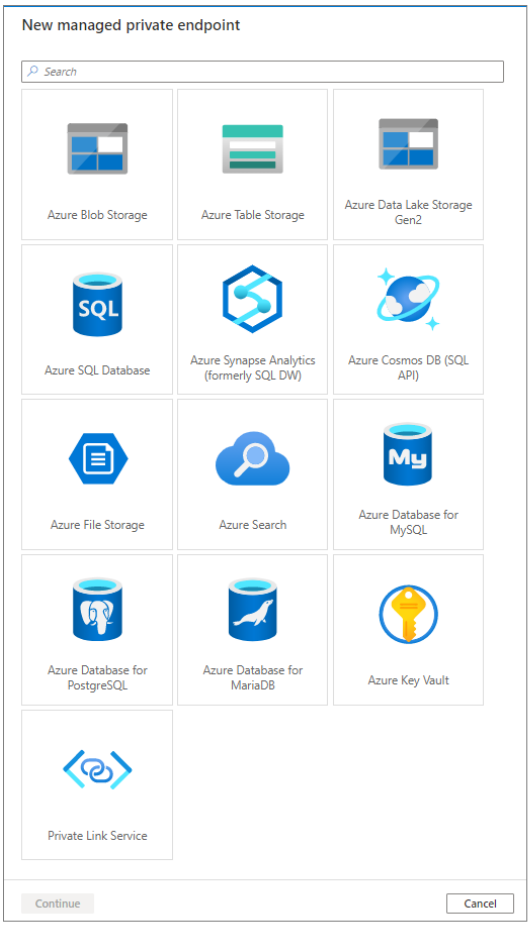
Step 2: Navigate to the Managed Virtual Networks tab in Synapse Studio

In Azure Synapse Studio, select the **Manage** tab from the left navigation. Select **Managed private endpoints** and then select **+ New**.



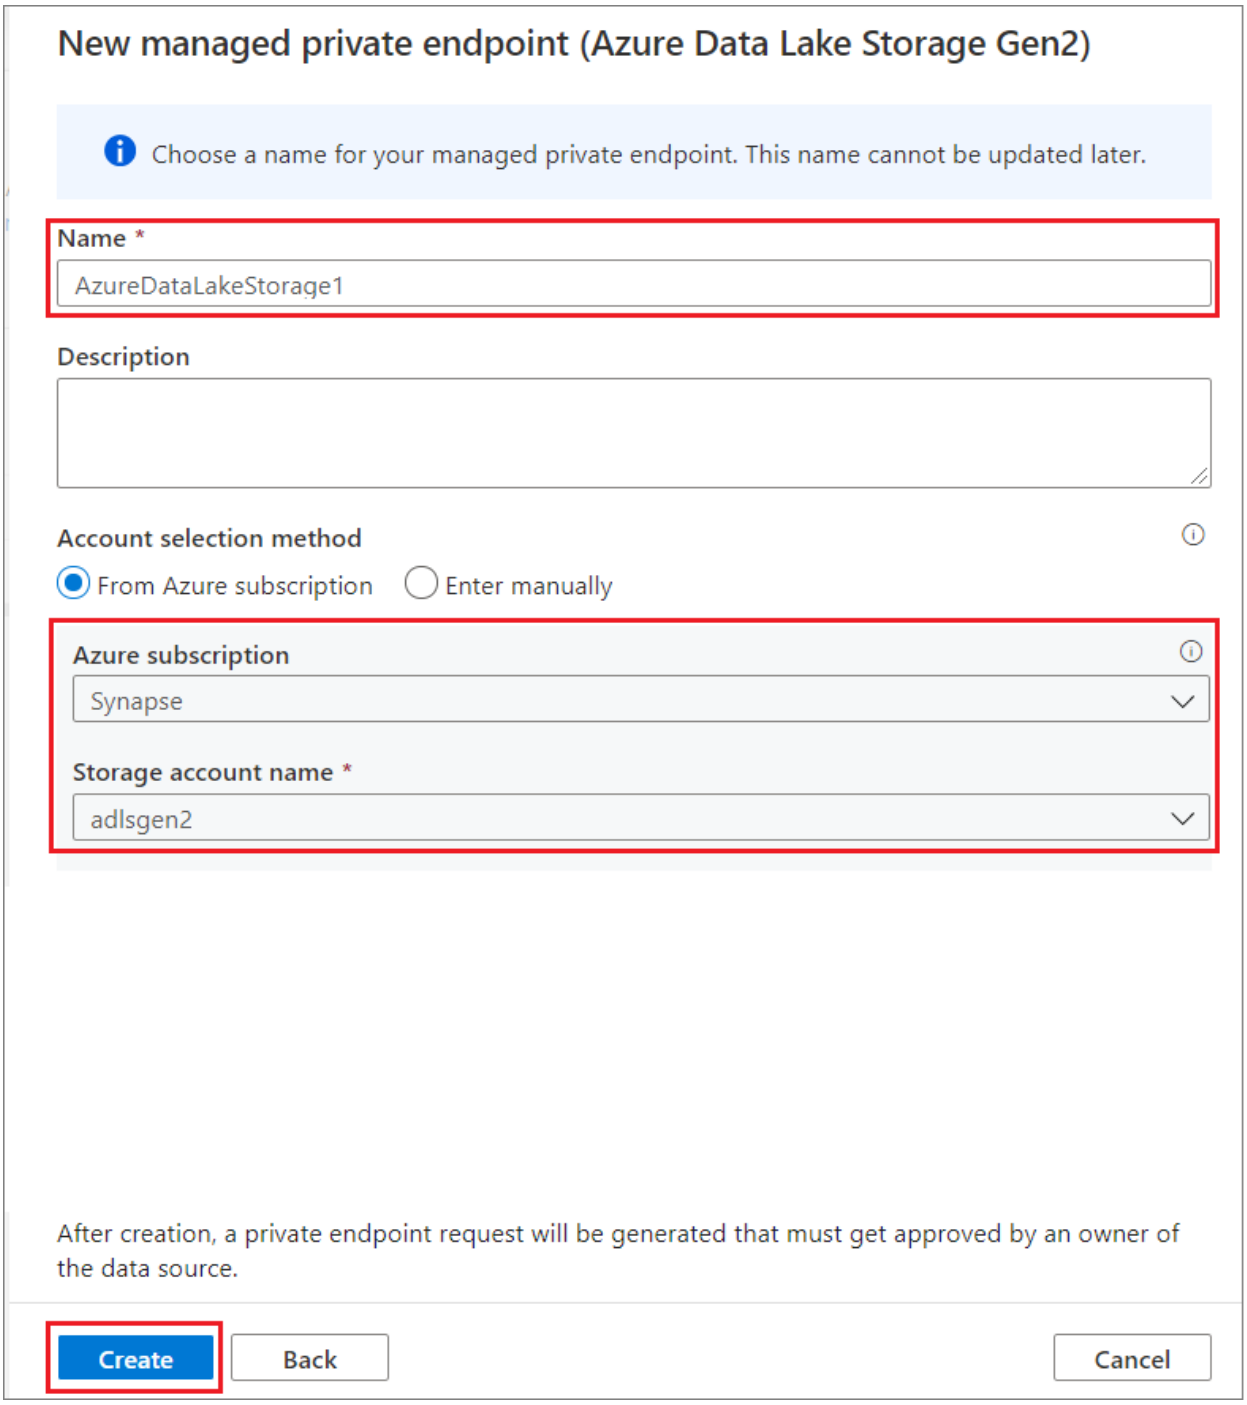
Step 3: Select the data source type

Select the data source type. In this case, the target data source is an ADLS Gen2 account. Select **Continue**.



Step 4: Enter information about the data source

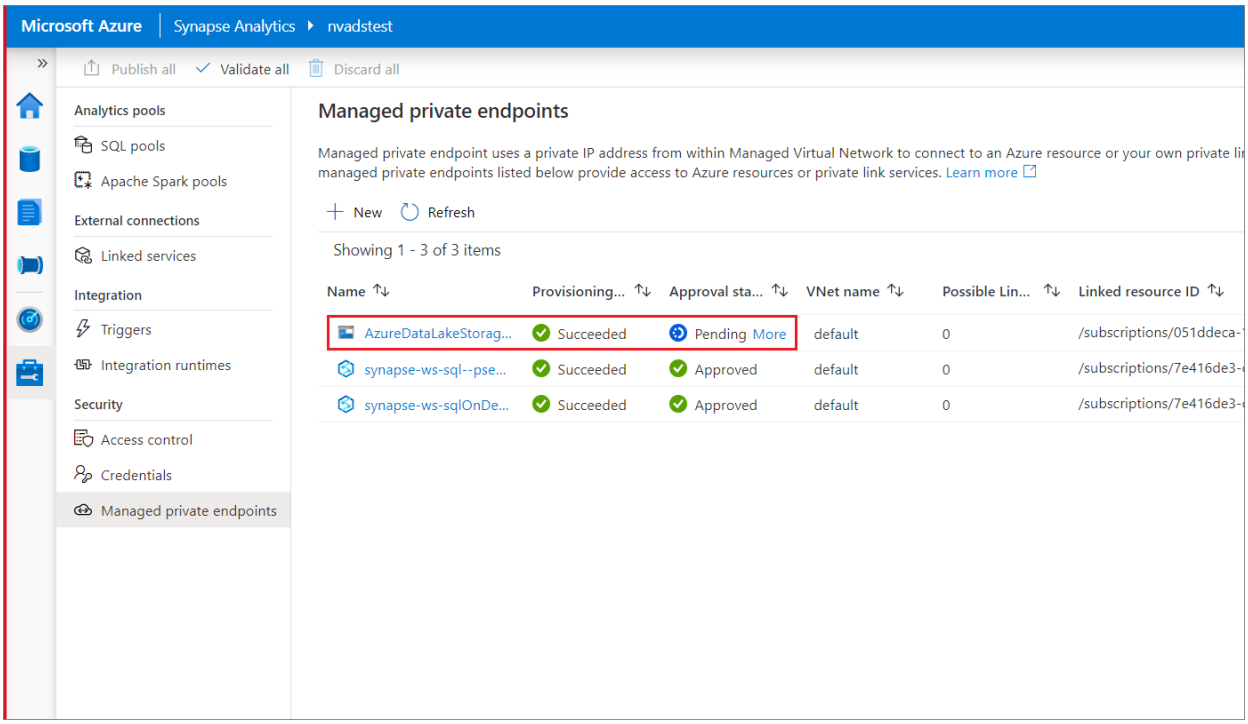
In the next window, enter information about the data source. In this example, we're creating a Managed private endpoint to an ADLS Gen2 account. Enter a **Name** for the Managed private endpoint. Provide an **Azure subscription** and a **Storage account name**. Select **Create**.



Step 5: Verify that your Managed private endpoint was successfully created

After submitting the request, you'll see its status. To verify the successful creation of your Managed private endpoint was created, check its *Provisioning State*. You may need to wait 1 minute and select **Refresh** to update the provisioning state. You can see that the Managed private endpoint to the ADLS Gen2 account was successfully created.

You can also see that the *Approval State* is *Pending*. The owner of the target resource can approve or deny the private endpoint connection request. If the owner approves the private endpoint connection request, then a private link is established. If denied, then a private link isn't established.



Next steps

Learn more about Managed private endpoints

Connect to your Azure Synapse workspace using private links

8/19/2022 • 2 minutes to read • Edit Online

This article will teach you how to create a private endpoint to your Azure Synapse workspace. See private links and private endpoints to learn more.

Step 1: Register Network resource provider

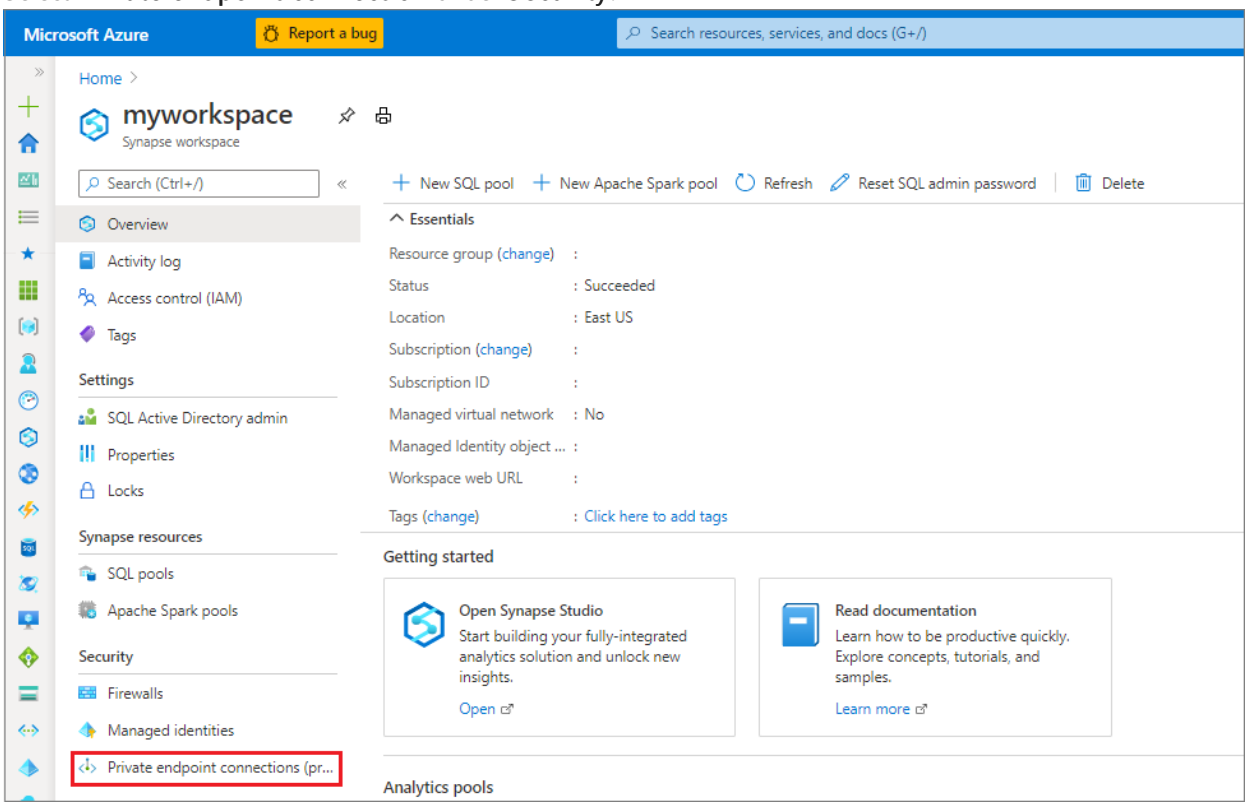
If you haven't already done so, register the Network resource provider in the subscription hosting the Azure Synapse Workspace. Registering a resource provider configures your subscription to work with the resource provider. Choose *Microsoft.Network* from the list of resource providers when you register.

If you are creating a private endpoint in a different subscription than the subscription hosting the Azure Synapse Workspace, register *Microsoft.Synapse* in the subscription hosting the private endpoint. This is required when trying to approve or delete the private endpoint connection.

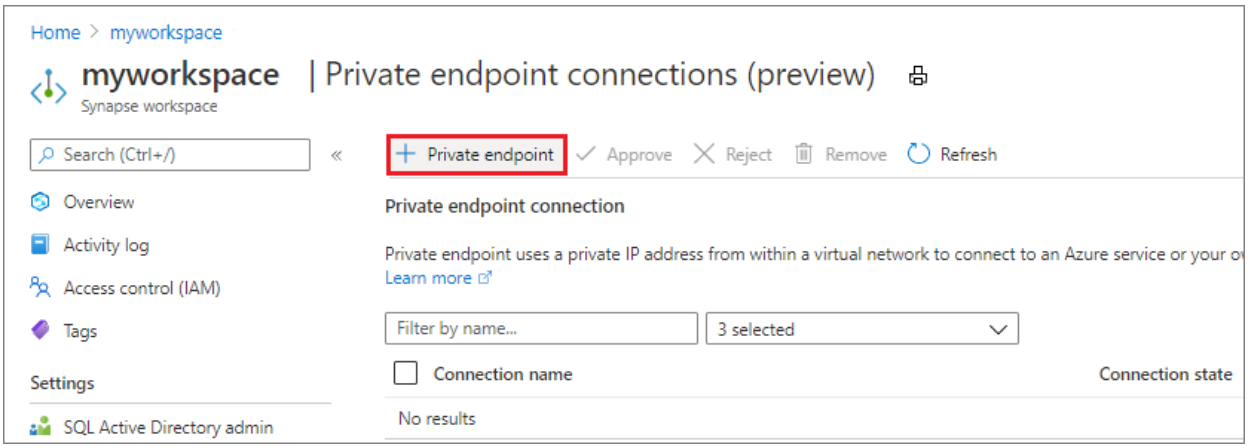
If the required resource provider is already registered, then proceed to Step 2.

Step 2: Open your Azure Synapse workspace in Azure portal

Select **Private endpoint connection** under **Security**.



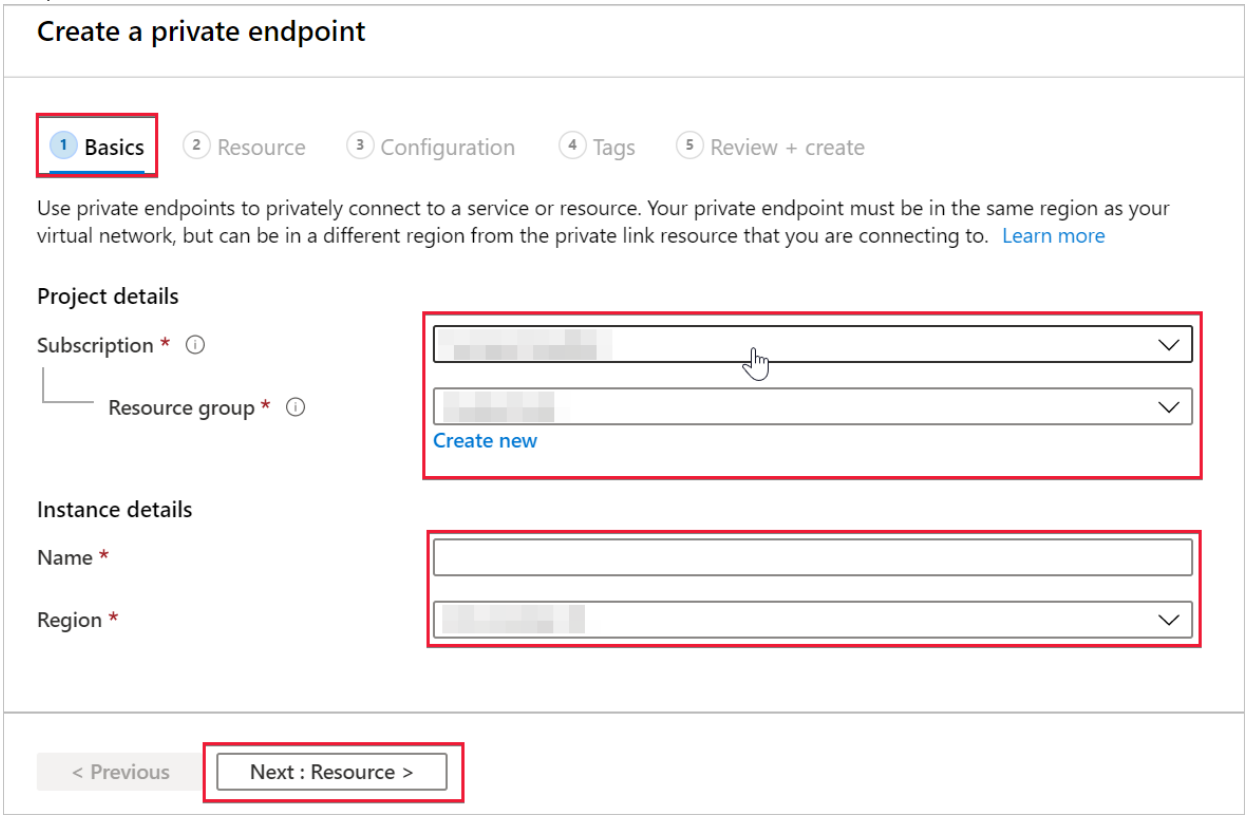
On the next screen select **+ Private endpoint**.



Step 3: Select your subscription and region details

Under the **Basics** tab in the **Create a private endpoint** window, choose your **Subscription** and **Resource Group**. Give a **Name** to the private endpoint that you want to create. Select the **Region** where you want the private endpoint created.

Private endpoints are created in a subnet. The subscription, resource group, and region selected filter the private endpoint subnets. Select **Next: Resource >** when done.



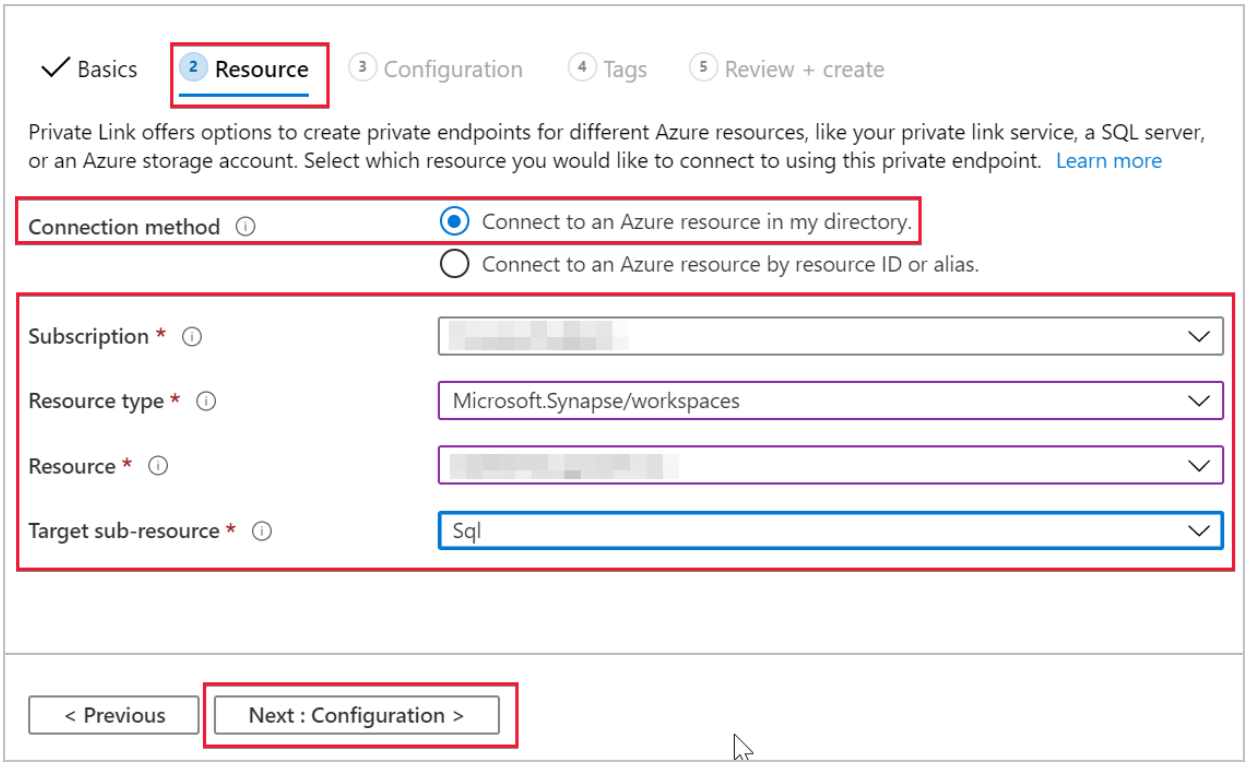
Step 4: Select your Azure Synapse workspace details

Select **Connect to an Azure resource in my directory** in the **Resource** tab. Select the **Subscription** that contains your Azure Synapse workspace. The **Resource type** for creating private endpoints to an Azure Synapse workspace is *Microsoft.Synapse/workspaces*.

Select your Azure Synapse workspace as the **Resource**. Every Azure Synapse workspace has three **Target sub-resource** that you can create a private endpoint to: Sql, SqlOnDemand, and Dev.

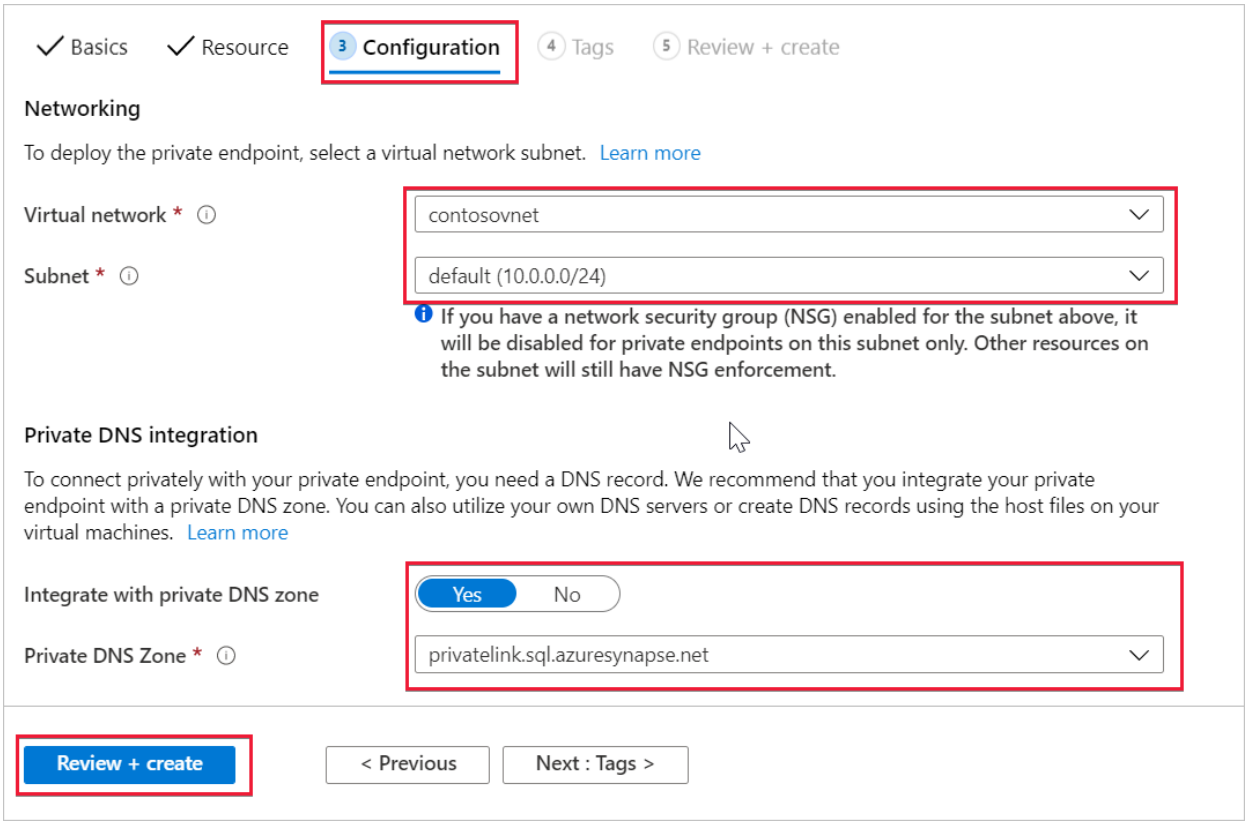
- Sql is for SQL query execution in SQL pool.
- SqlOnDemand is for SQL built-in query execution.
- Dev is for accessing everything else inside Azure Synapse Analytics Studio workspaces.

Select **Next: Configuration>** to advance to the next part of the setup.

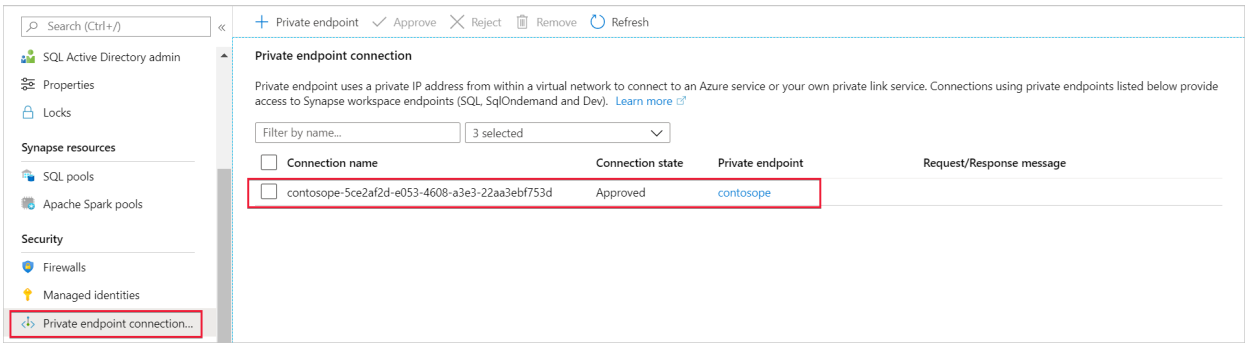


In the **Configuration** tab, select the **Virtual network** and the **Subnet** in which the private endpoint should be created. You also need to create a DNS record that maps to the private endpoint.

Select **Yes** for **Integrate with private DNS zone** to integrate your private endpoint with a private DNS zone. If you don't have a private DNS zone associated with your Microsoft Azure Virtual Network, then a new private DNS zone is created. Select **Review + create** when done.



When the deployment is complete, open your Azure Synapse workspace in Azure portal and select **Private endpoint connections**. The new private endpoint and private endpoint connection name associated to the private endpoint are shown.



Next steps

Learn more about Managed workspace Virtual Network

Learn more about Managed private endpoints

Create Managed private endpoints to your data sources

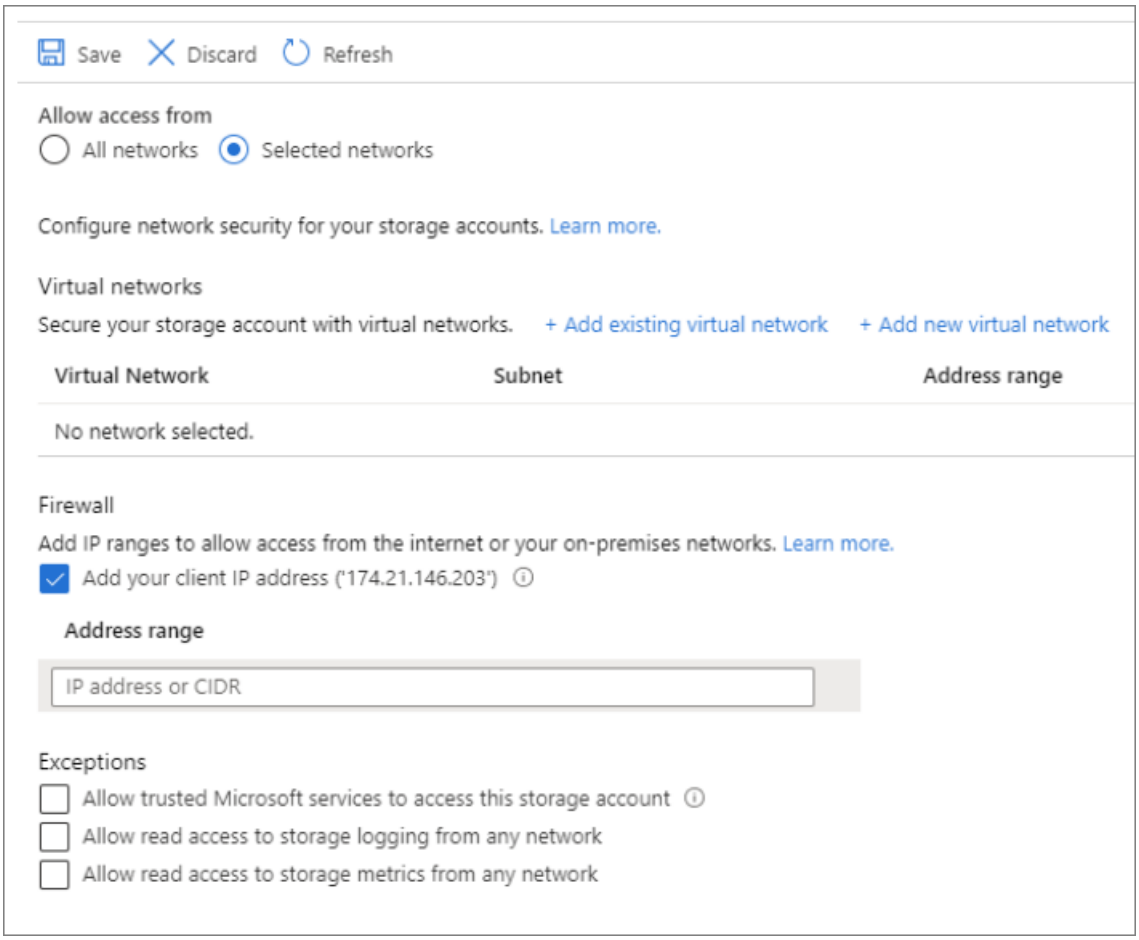
Secure a linked service with Private Links

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll learn how to secure a linked service in Synapse with a private endpoint.

Prerequisites

- **Azure subscription**: If you don't have an Azure subscription, create a free Azure account before you begin.
- **Azure Storage account**: You use Azure Data Lake Gen 2 as a *source* data store. If you don't have a storage account, see Create an Azure Storage account for steps to create one. Make sure that the Storage Account has the Synapse Studio IP filtering for accessing it and that you only allow **Selected networks** to access the Storage account. The setting under the blade **Firewalls and virtual networks** should look like the picture below.



Create a linked service with Private Links

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll add Azure Synapse Analytics and Azure Data Lake Gen 2 as linked services.

1. Open the Synapse Studio and go to the **Manage** tab.
2. Under **External connections**, select **Linked services**.
3. To add a linked service, select **New**.
4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
5. Make sure you enable **Interactive Authoring**. It might take around 1 minute to be enabled.

6. Enter your authentication credentials. Account key, service principal, and managed identity are currently supported authentication types. Select test connection to verify your credentials are correct.
7. Select **Test connection**, it should fail because the Storage Account doesn't enable access into it without the creation and approval of a Private Endpoint. In the error message, you should see a link to create a **private endpoint** that you can follow to go to the next part. If you follow that link, skip the next part.
8. Select **Create** when finished.

Create a managed private endpoint

If you didn't select into the hyperlink when testing the connection above, follow the following path. Create a managed private endpoint that you'll connect to the linked service created above.

1. Go to the **Manage** tab.
2. Go to the **Managed Virtual Networks** section.
3. Select **+ New** under Managed private endpoint.
4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
5. Enter the name of the Storage Account you created above.
6. Select **Create**
7. You should see after waiting some seconds that the private link created needs an approval.

Private link approval

1. Select the Private Endpoint that you created above. You can see a hyperlink that will let you approve the Private Endpoint at the Storage Account level. *An alternative is to go directly to the Azure portal Storage Account and go into the **Private endpoint connections** blade.*
2. Tick the Private endpoint you created in the Studio and select **Approve**.
3. Add a description and select **yes**
4. Go back to Synapse Studio in under the **Managed Virtual Networks** section of the **Manage** tab.
5. It should take around 1 minute to get the approval reflected for your private endpoint.

Check the connection works

1. Go to the **Manage** tab and select the linked service you created.
2. Make sure that **Interactive authoring** is active.
3. Select **Test connection**. You should see the connection be successful.

You've now established a secure and private connection between Synapse and your linked service.

Next steps

To develop further understanding of Managed private endpoint in Azure Synapse Analytics, see Managed private endpoints.

For more information on data integration for Azure Synapse Analytics, see the Ingesting data into a Data Lake article.

Connect to workspace resources from a restricted network

8/19/2022 • 5 minutes to read • Edit Online

Suppose you are an IT administrator who is managing your organization's restricted network. You want to enable the network connection between Azure Synapse Analytics Studio and a workstation within this restricted network. This article shows you how.

Prerequisites

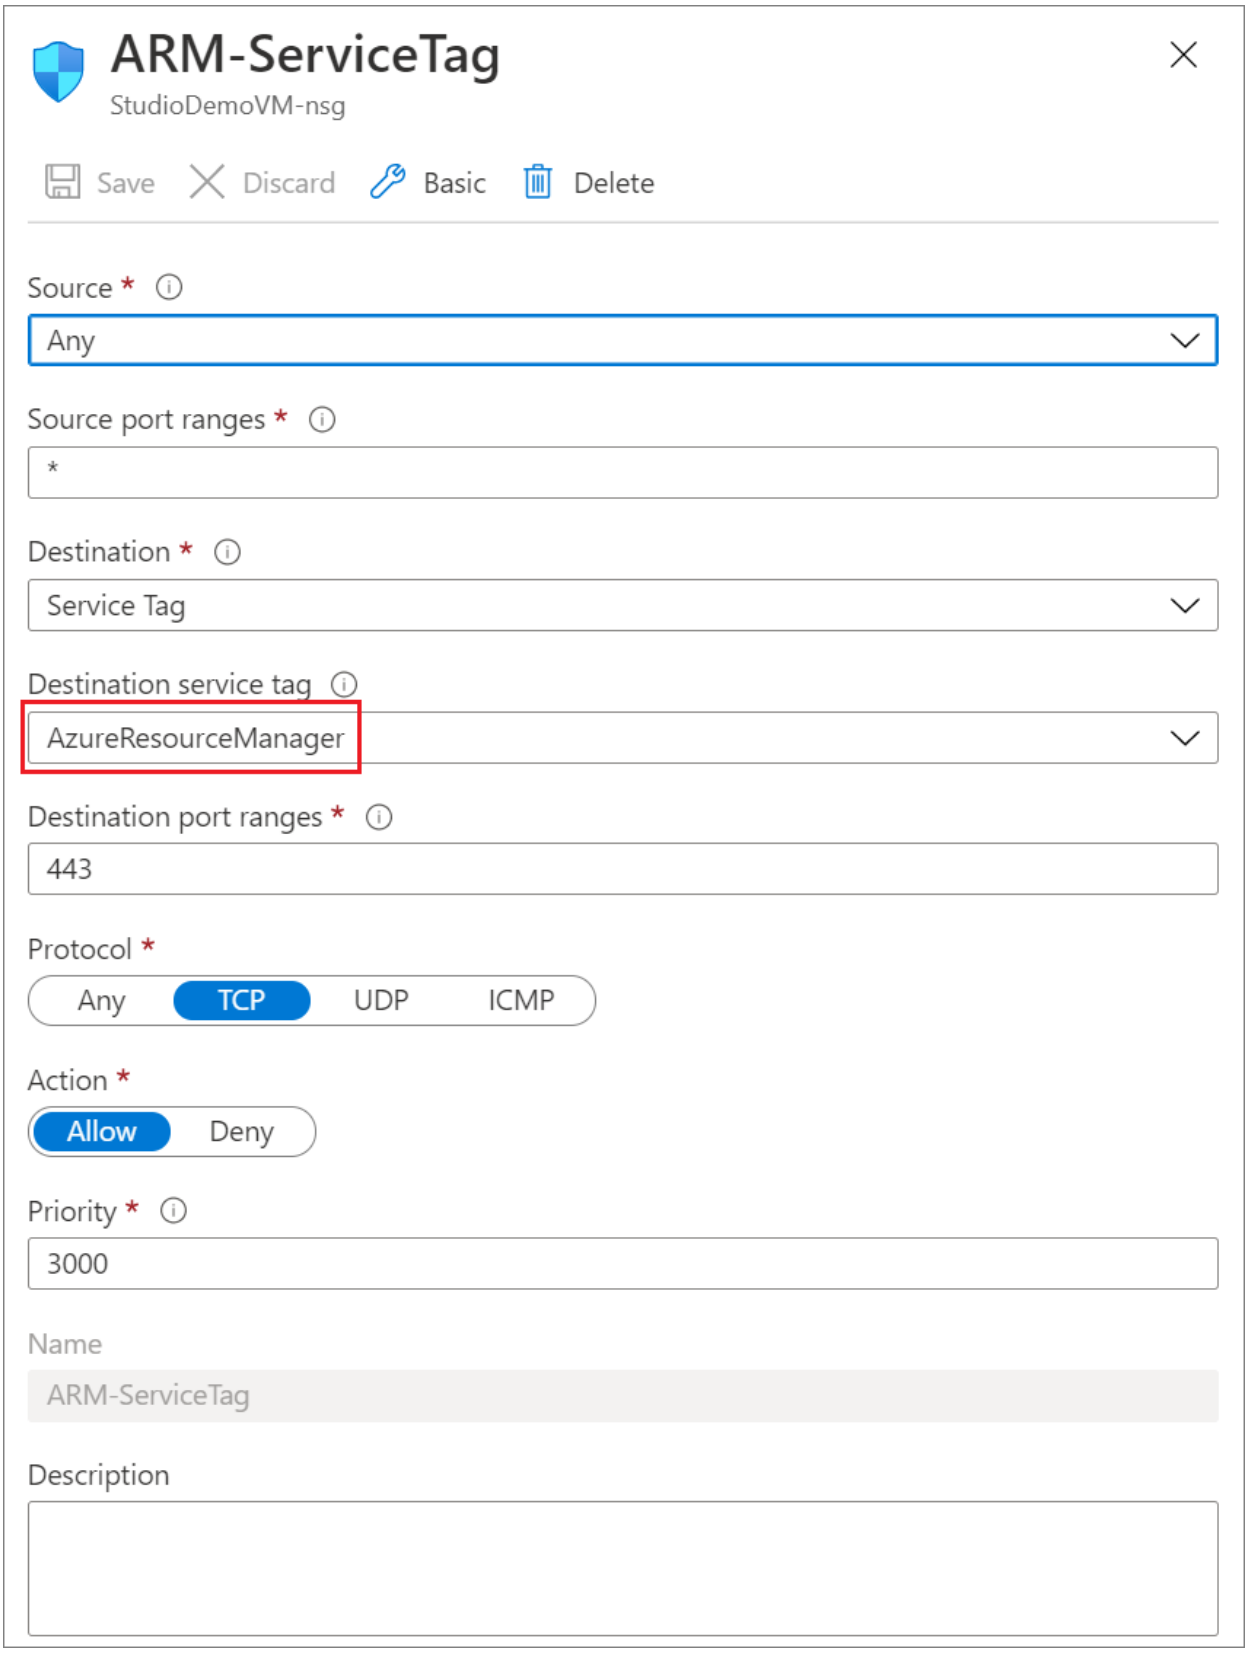
- **Azure subscription**: If you don't have an Azure subscription, create a free Azure account before you begin.
- **Azure Synapse Analytics workspace**: You can create one from Azure Synapse Analytics. You need the workspace name in step 4.
- **A restricted network**: The IT admin maintains the restricted network for the organization, and has permission to configure the network policy. You need the virtual network name and its subnet in step 3.

Step 1: Add network outbound security rules to the restricted network

You'll need to add four network outbound security rules with four service tags.

- AzureResourceManager
- AzureFrontDoor.Frontend
- AzureActiveDirectory
- AzureMonitor (This type of rule is optional. Add it only when you want to share the data with Microsoft.)

The following screenshot shows details for the Azure Resource Manager outbound rule.

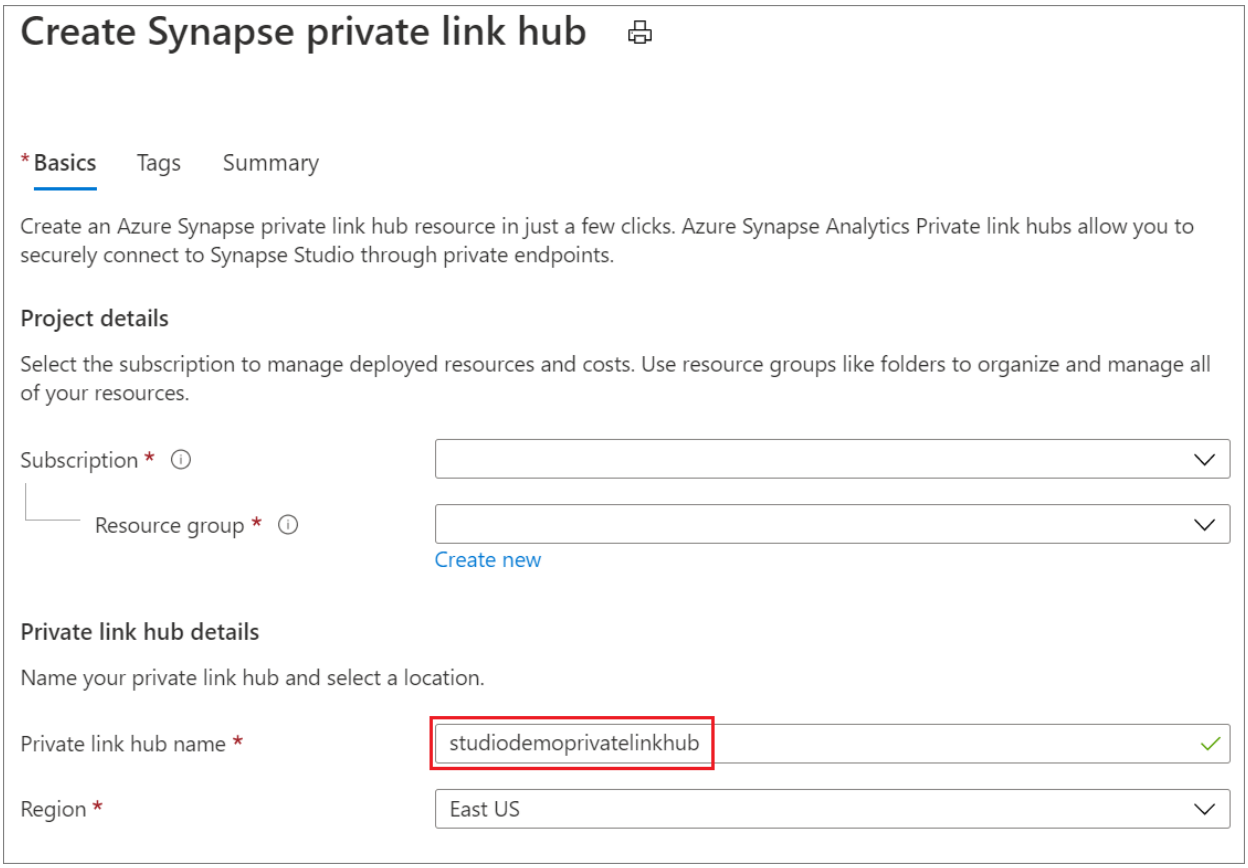


When you're creating the other three rules, replace the value of **Destination service tag** with **AzureFrontDoor.Frontend**, **AzureActiveDirectory**, or **AzureMonitor** from the list.

For more information, see Service tags overview.

Step 2: Create private link hubs

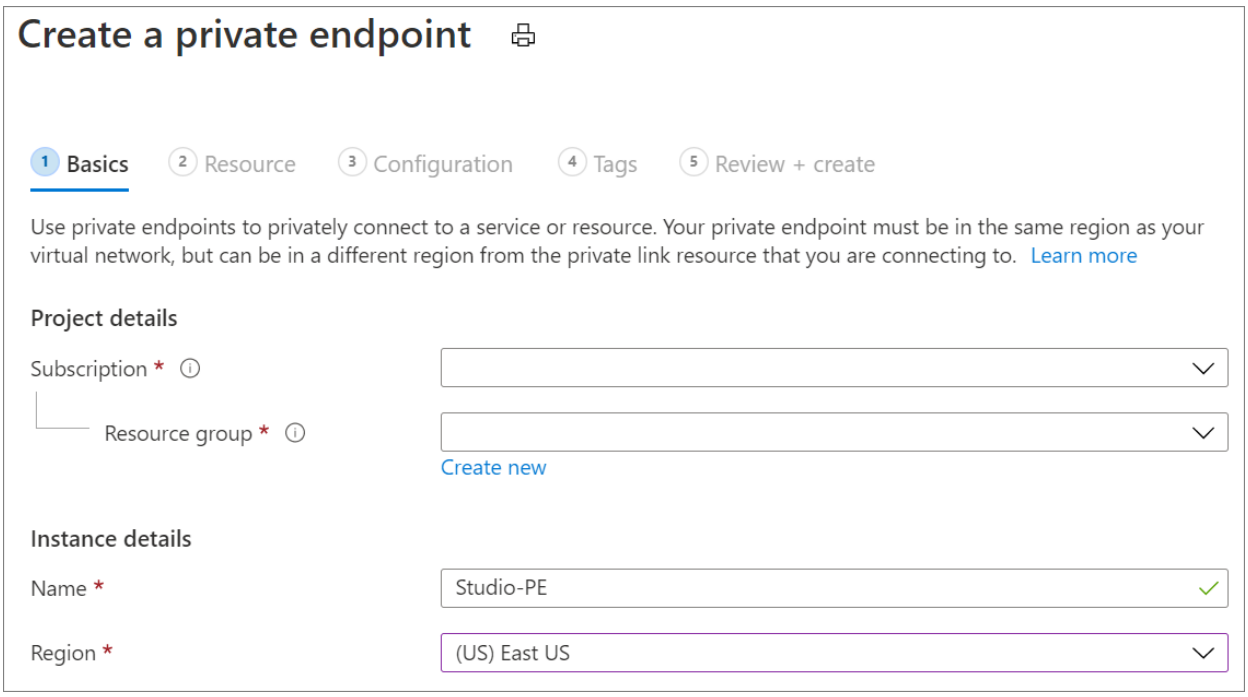
Next, create private link hubs from the Azure portal. To find this in the portal, search for *Azure Synapse Analytics (private link hubs)*, and then fill in the required information to create it.



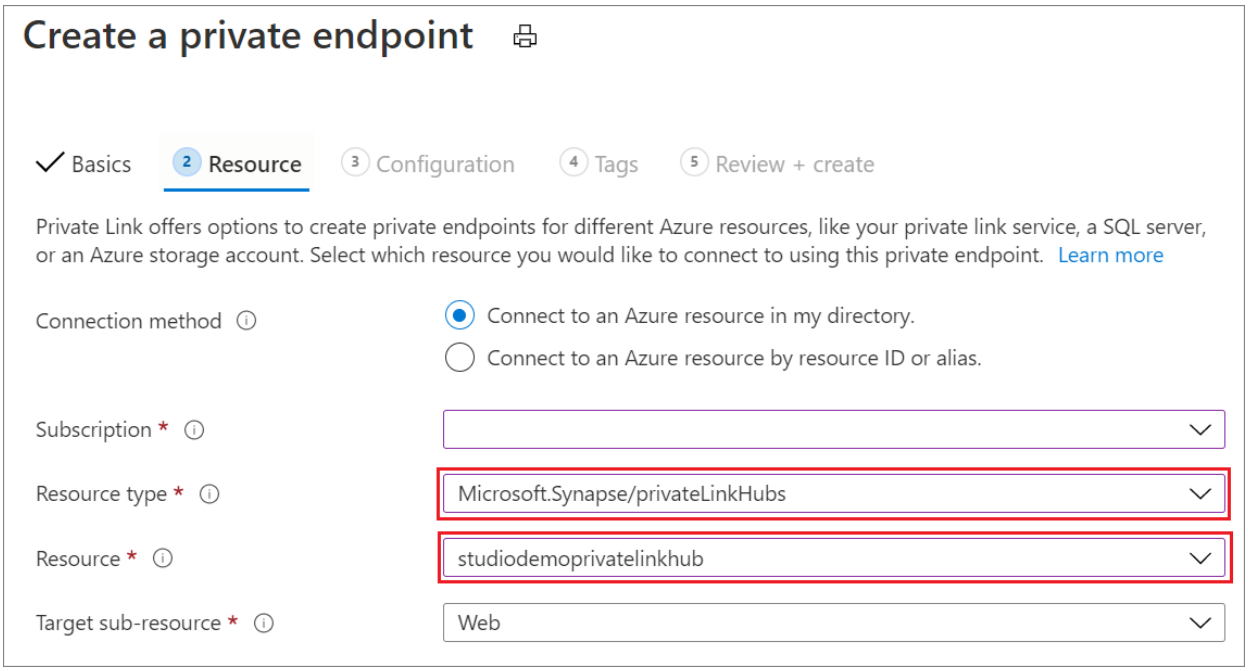
Step 3: Create a private endpoint for your Synapse Studio

To access the Azure Synapse Analytics Studio, you must create a private endpoint from the Azure portal. To find this in the portal, search for *Private Link*. In the **Private Link Center**, select **Create private endpoint**, and then fill in the required information to create it.

> **NOTE**
> Ensure that the **Region** value is the same as the one where your Azure Synapse Analytics workspace is.

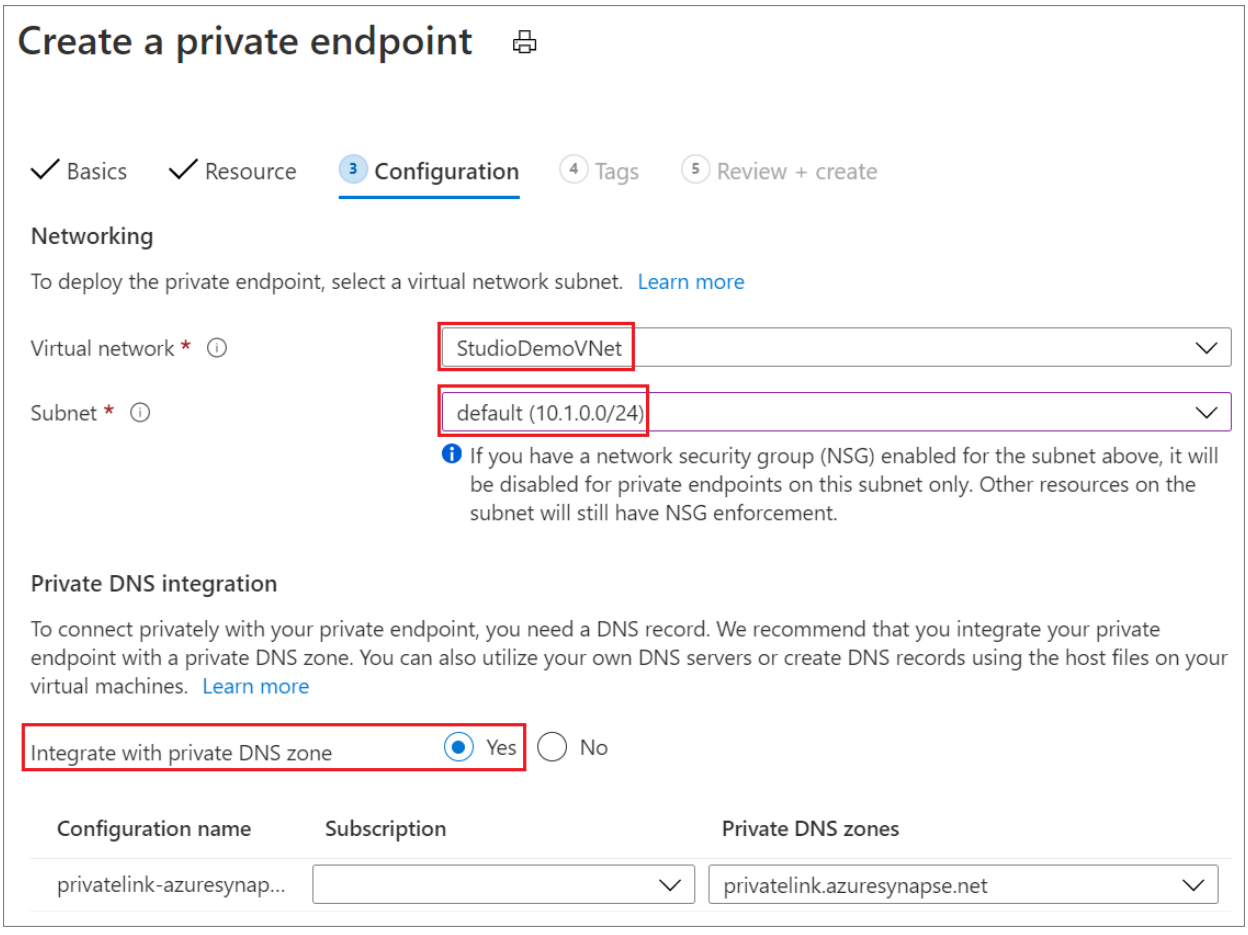


On the **Resource** tab, choose the private link hub, which you created in step 2.



On the **Configuration** tab:

- For **Virtual network**, select the restricted virtual network name.
- For **Subnet**, select the subnet of the restricted virtual network.
- For **Integrate with private DNS zone**, select **Yes**.



After the private link endpoint is created, you can access the sign-in page of the web tool for Azure Synapse Analytics Studio. However, you aren't able to access the resources inside your workspace yet. For that, you need to complete the next step.

Step 4: Create private endpoints for your workspace resource

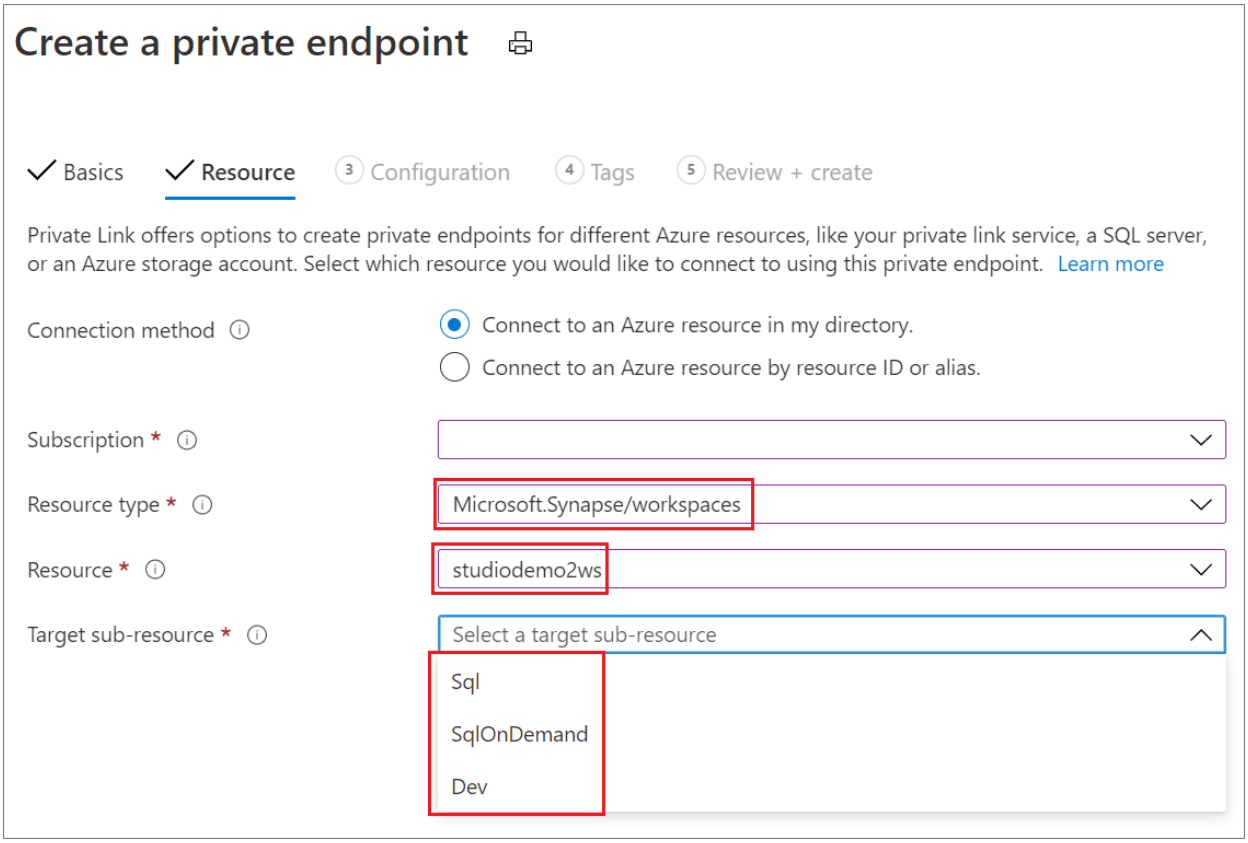
To access the resources inside your Azure Synapse Analytics Studio workspace resource, you need to create the following:

- At least one private link endpoint with a **Target sub-resource** type of **Dev**.
- Two other optional private link endpoints with types of **Sql** or **SqlOnDemand**, depending on what resources in the workspace you want to access.

Creating these is similar to how you create the endpoint in the previous step.

On the **Resource** tab:

- For **Resource type**, select **Microsoft.Synapse/workspaces**.
- For **Resource**, select the workspace name that you created previously.
- For **Target sub-resource**, select the endpoint type:
  - **Sql** is for SQL query execution in SQL pool.
  - **SqlOnDemand** is for SQL built-in query execution.
  - **Dev** is for accessing everything else inside Azure Synapse Analytics Studio workspaces. You need to create at least one private link endpoint of this type.

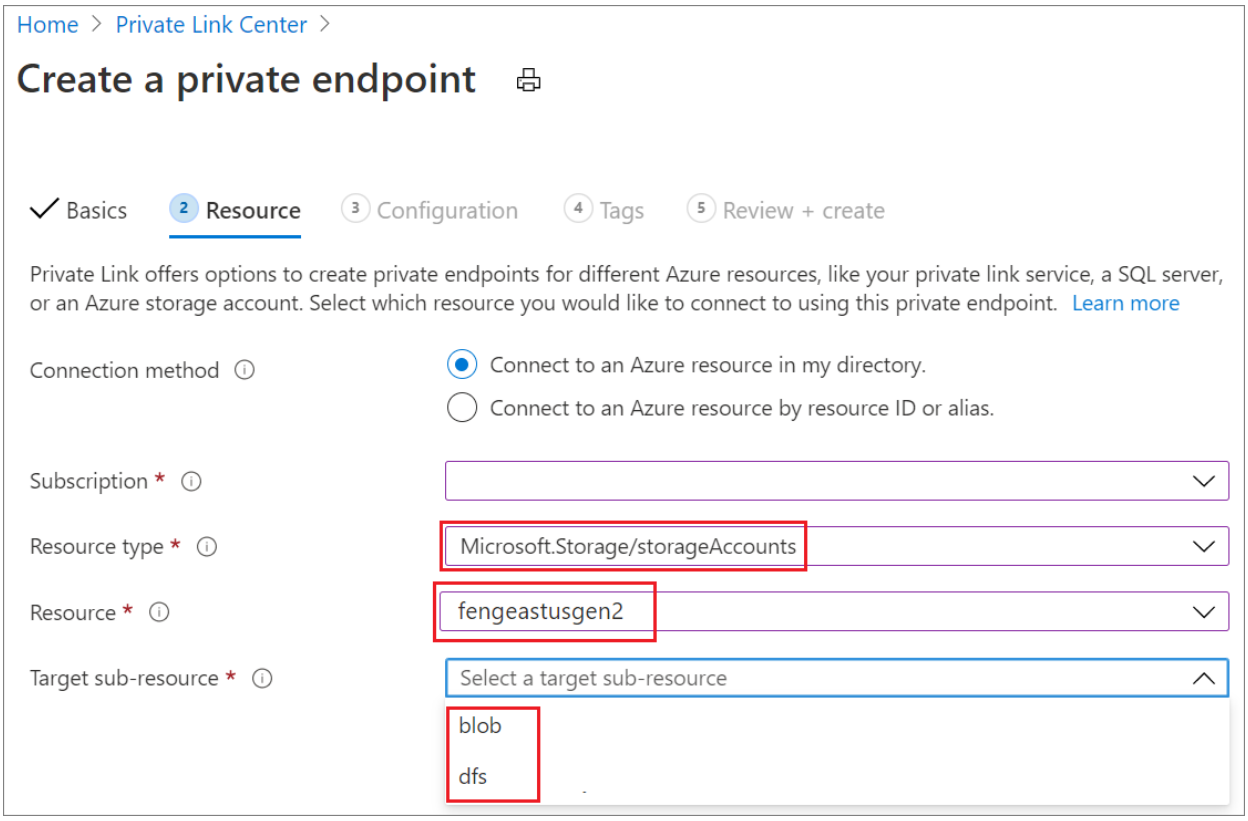


Step 5: Create private endpoints for workspace linked storage

To access the linked storage with the storage explorer in Azure Synapse Analytics Studio workspace, you must create one private endpoint. The steps for this are similar to those of step 3.

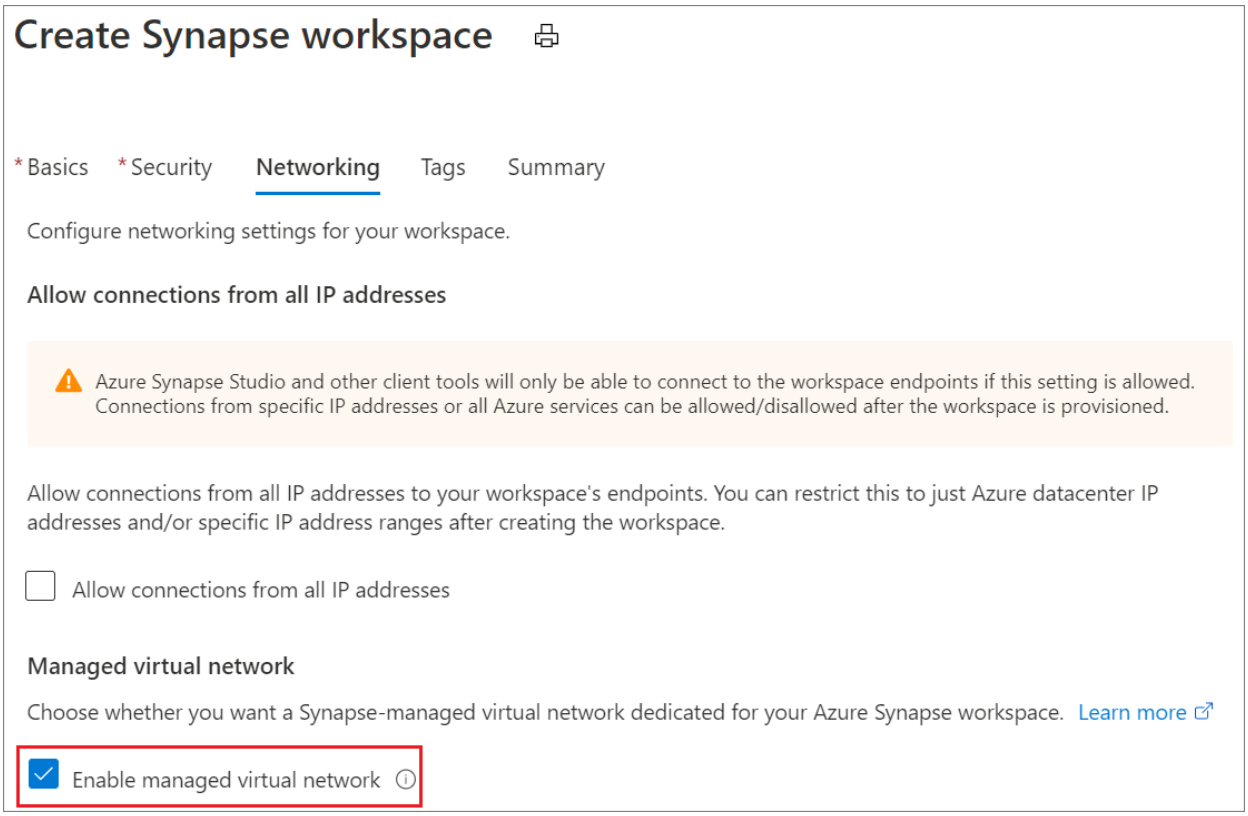
On the **Resource** tab:

- For **Resource type**, select **Microsoft.Storage/storageAccounts**.
- For **Resource**, select the storage account name that you created previously.
- For **Target sub-resource**, select the endpoint type:
  - **blob** is for Azure Blob Storage.
  - **dfs** is for Azure Data Lake Storage Gen2.



Now, you can access the linked storage resource. Within your virtual network, in your Azure Synapse Analytics Studio workspace, you can use the storage explorer to access the linked storage resource.

You can enable a managed virtual network for your workspace, as shown in this screenshot:



If you want your notebook to access the linked storage resources under a certain storage account, add managed private endpoints under your Azure Synapse Analytics Studio. The storage account name should be the one your notebook needs to access. For more information, see Create a managed private endpoint to your data source.

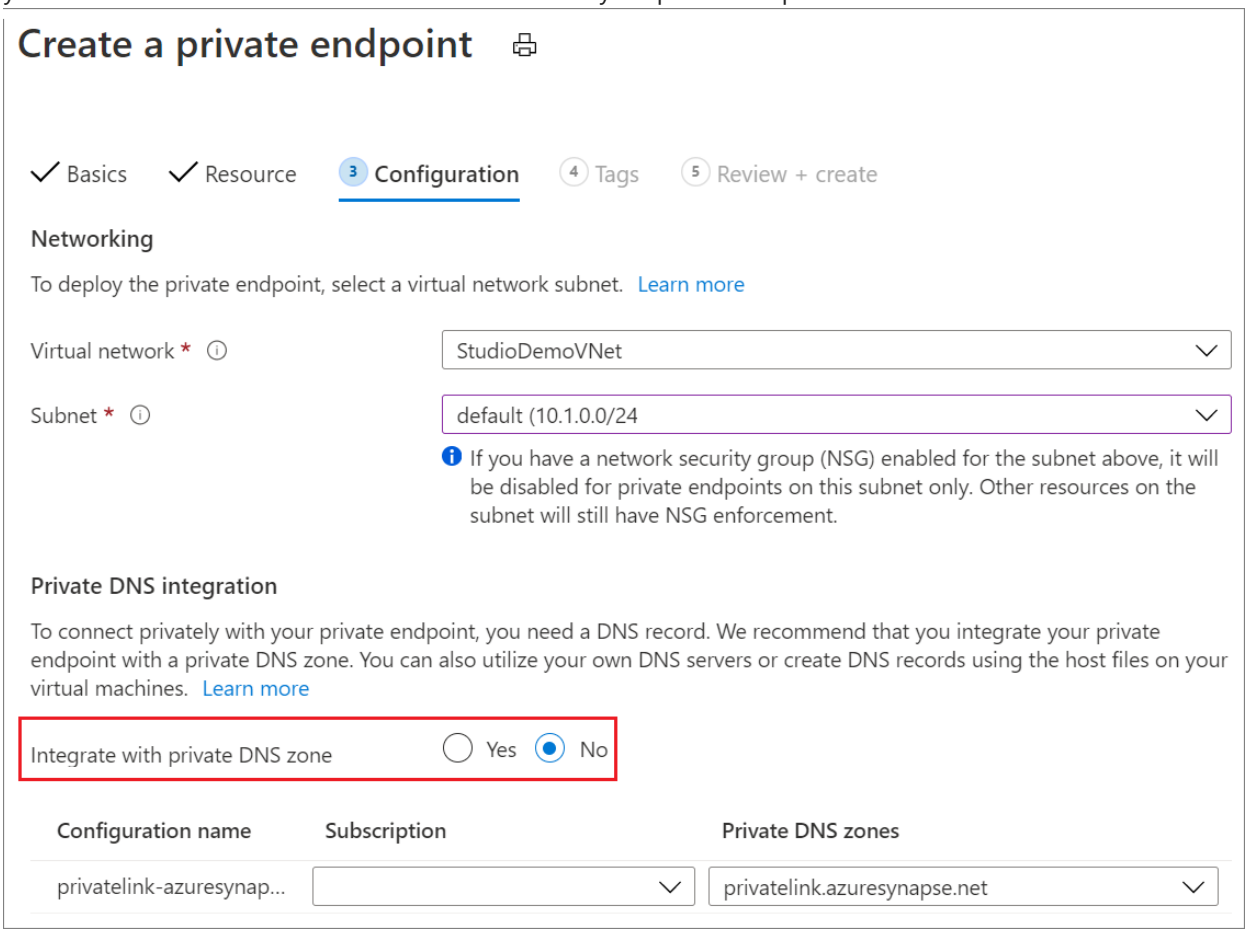
After you create this endpoint, the approval state shows a status of **Pending**. Request approval from the owner of this storage account, in the **Private endpoint connections** tab of this storage account in the Azure portal.

After it's approved, your notebook can access the linked storage resources under this storage account.

Now, all set. You can access your Azure Synapse Analytics Studio workspace resource.

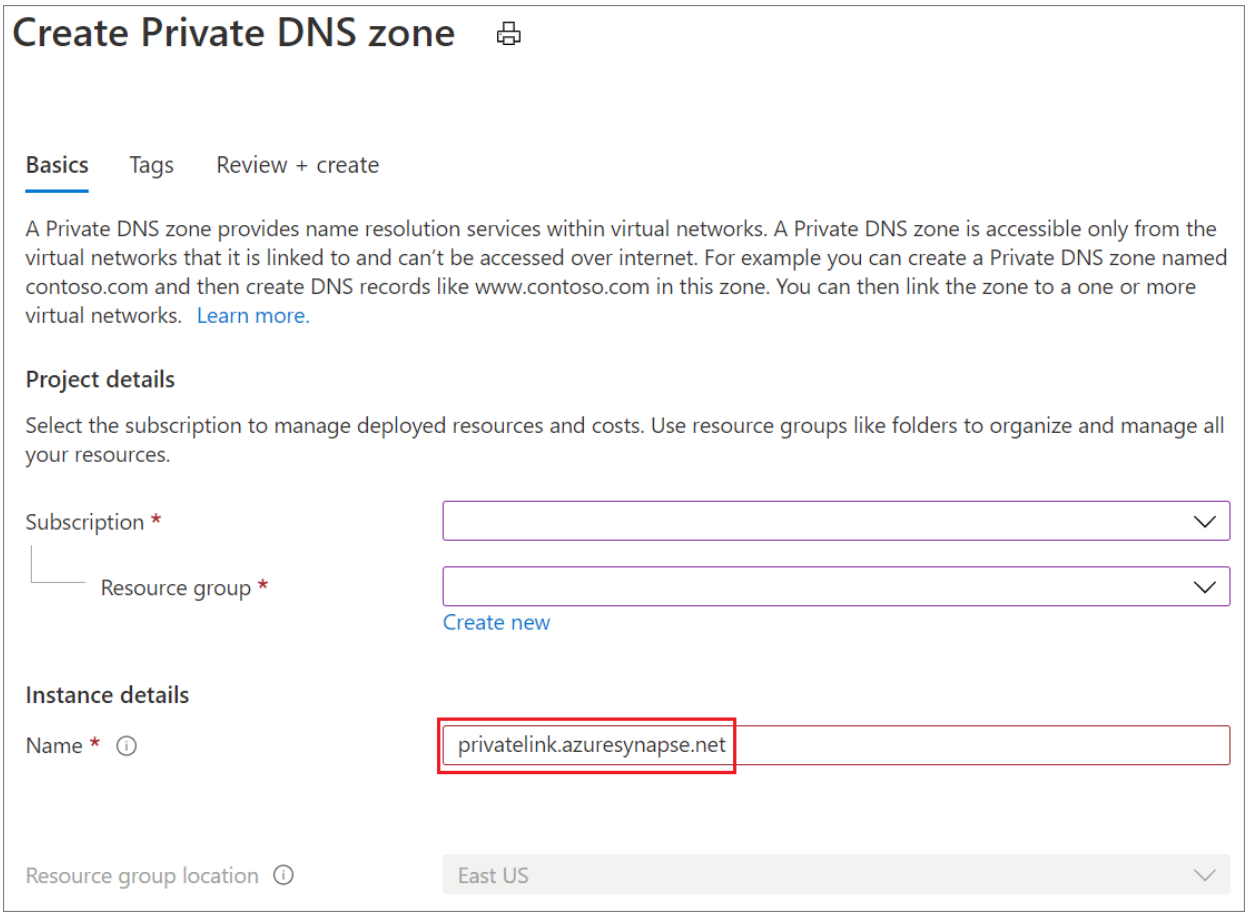
Appendix: DNS registration for private endpoint

If the "Integrate with private DNS zone" is not enabled during the private endpoint creation as screenshot below, you must create the "**Private DNS zone**" for each of your private endpoints.

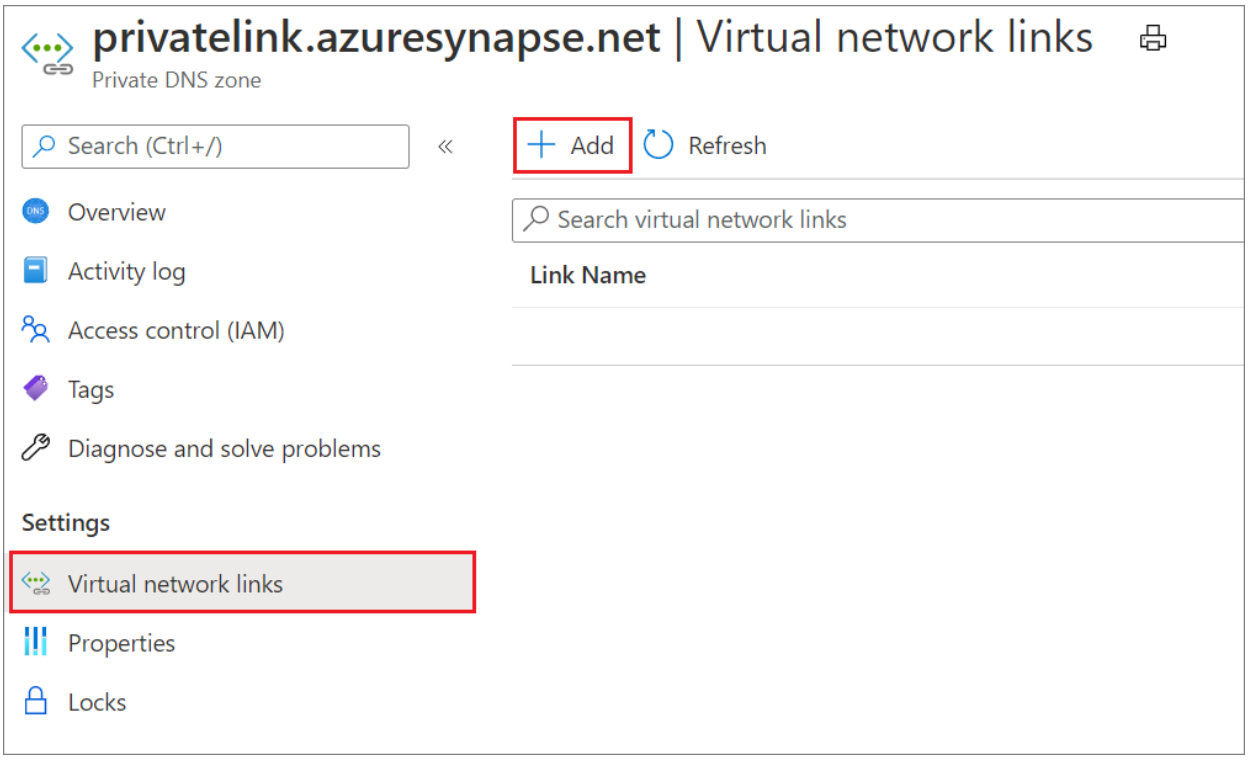


To find the **Private DNS zone** in the portal, search for *Private DNS zone*. In the **Private DNS zone**, fill in the required information below to create it.

- For **Name**, input the private DNS zone dedicated name for specific private endpoint as below:
  - `privatelink.azuresynapse.net` is for the private endpoint of accessing Azure Synapse Analytics Studio gateway. See this type of private endpoint creation in step 3.
  - `privatelink.sql.azuresynapse.net` is for this type of private endpoint of sql query execution in SQL pool and built-in pool. See the endpoint creation in step 4.
  - `privatelink.dev.azuresynapse.net` is for this type of private endpoint of accessing everything else inside Azure Synapse Analytics Studio workspaces. See this type of private endpoint creation in step 4.
  - `privatelink.dfs.core.windows.net` is for the private endpoint of accessing workspace linked Azure Data Lake Storage Gen2. See this type of private endpoint creation in step 5.
  - `privatelink.blob.core.windows.net` is for the private endpoint of accessing workspace linked Azure Blob Storage. See this type of private endpoint creation in step 5.

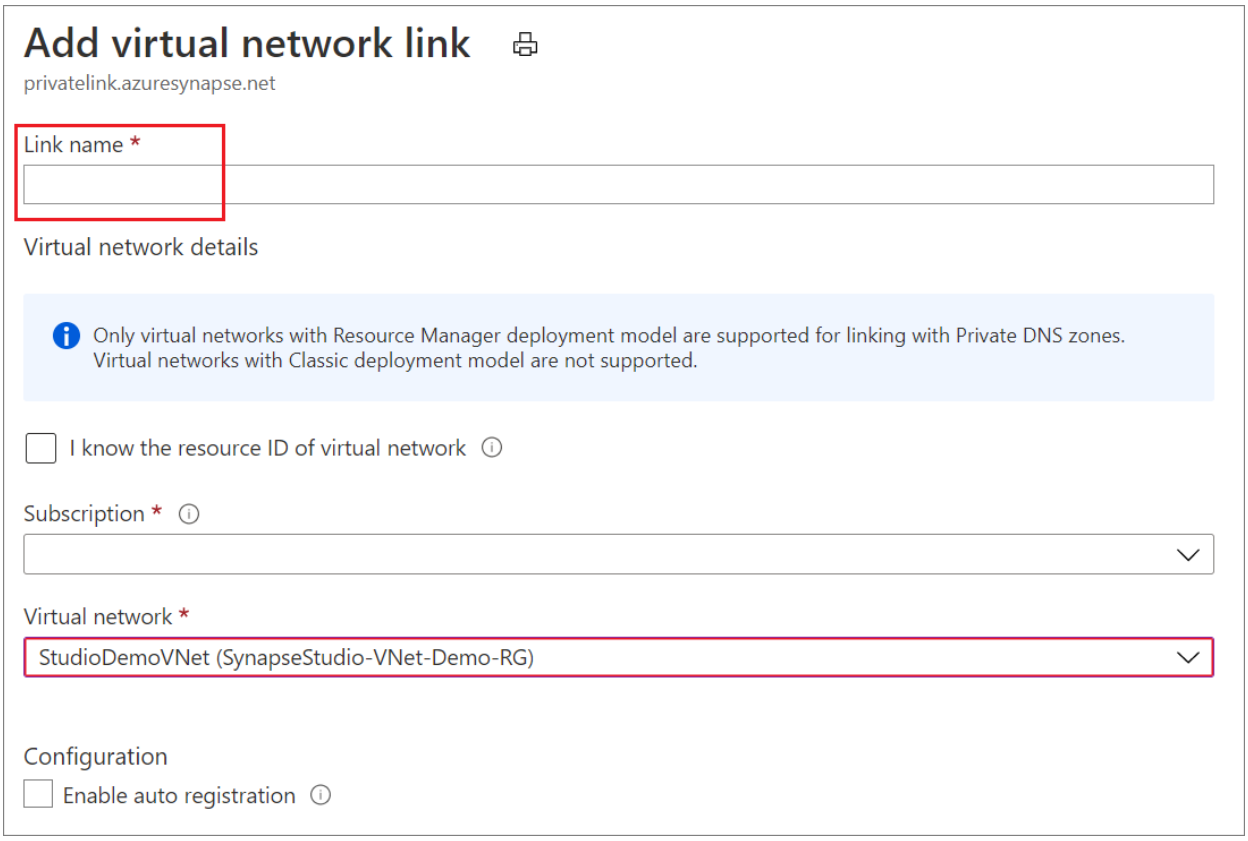


After the **Private DNS zone** created, enter the created private DNS zone and select the **Virtual network links** to add the link to your virtual network.



Fill in the mandatory fields as below:

- For **Link name**, input the link name.
- For **Virtual network**, select your virtual network.



After the virtual network link is added, you need to add the DNS record set in the **Private DNS zone** you created before.

- For **Name**, input the dedicated name strings for different private endpoint:
  - **web** is for the private endpoint of accessing Azure Synapse Analytics Studio.
  - "***YourWorkSpaceName***" is for the private endpoint of sql query execution in SQL pool and also for the private endpoint of accessing everything else inside Azure Synapse Analytics Studio workspaces.
  - "***YourWorkSpaceName*-ondemand**" is for the private endpoint of sql query execution in built-in pool.
- For **Type**, select DNS record type **A** only.
- For **IP address**, input the corresponding IP address of each private endpoint. You can get the IP address in **Network interface** from your private endpoint overview.

Synapse Studio troubleshooting

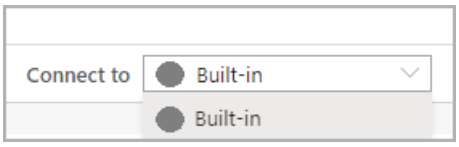
8/19/2022 • 5 minutes to read • Edit Online

This trouble-shooting guide provides instruction on what information to provide when opening a support ticket on network connectivity issues. With the proper information, we can possibly resolve the issue more quickly.

Serverless SQL pool service connectivity issue

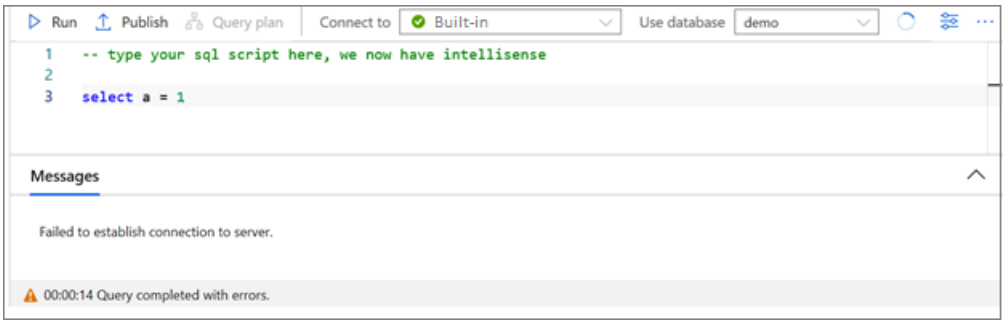
Symptom 1

"Serverless SQL pool" option is grayed out in the "Connect to" dropdown.



Symptom 2

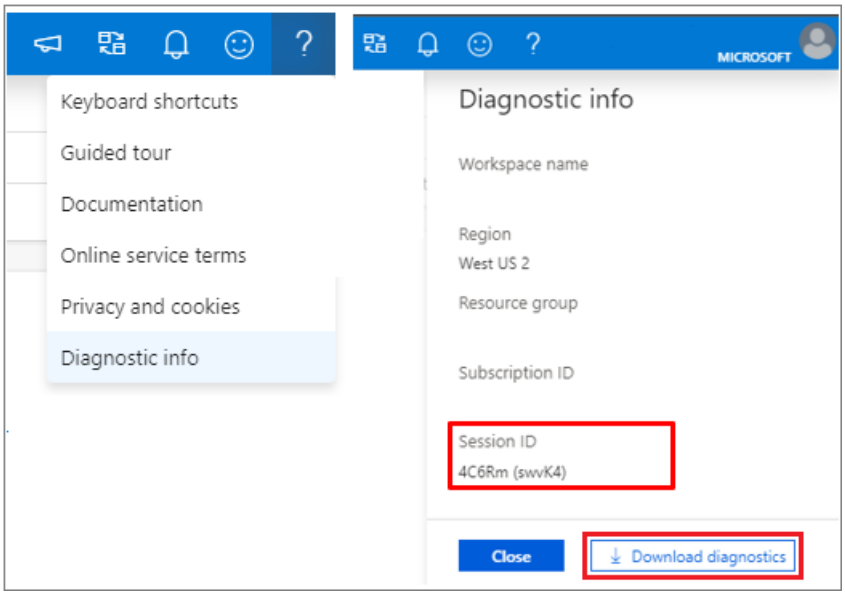
Running the query with "serverless SQL pool" gives you the "Failed to establish connection to server" error message.



Troubleshooting steps

> **NOTE**
> The following troubleshooting steps are for Chromium Edge and Chrome. You may use other browsers (such as FireFox) with the same troubleshooting steps, but the "Developer Tool" window may have different layout from the screenshots in this TSG. If possible, DO NOT use classical Edge for troubleshooting, as it may show inaccurate information in certain situation.

Open the "Diagnostic Info" panel, select the "Download Diagnostic" button. Keep the downloaded information for error reporting. You can instead, copy the "Session ID" and attach it when opening the support ticket.



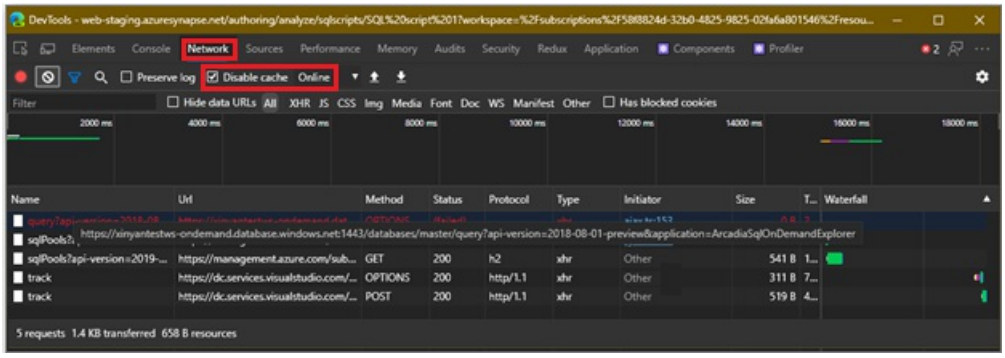
To begin troubleshooting, retry the operation you performed in Synapse Studio.

- For symptom 1, select the "Refresh" button to the right of the "Use database" dropdown in the "SQL script" tab and check whether you can see "serverless SQL pool".
- For symptom 2, try running the query again to see if it executes successfully.

If the problem still exists, press F12 in your browser to open "Developer Tools" (DevTools).

In the "Developer Tools" window, switch to the "Network" panel. Select the "Clear" button on the toolbar in "Network" panel if necessary. Make sure "Disable cache" in "Network" panel is checked.

Retry the operation you performed in Azure Synapse Studio. You may see new items shown in the "Network" list in "Developer Tools". Note your current system time to provide in the support ticket.



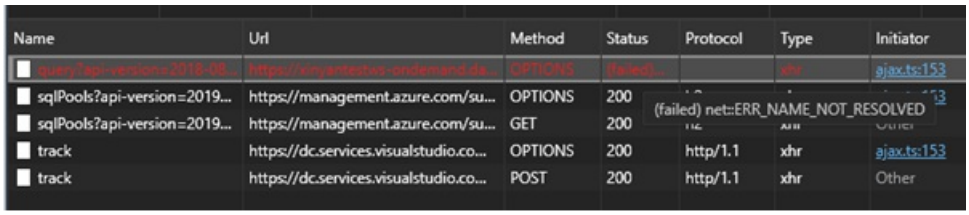
Find the item whose Url column matches the following pattern:

```
https://[*A*]-ondemand.database.windows.net:1443/databases/[*B*]/query?api-version=2018-08-01-preview&application=ArcadiaSqlOnDemandExplorer
```

Where [*A*] is your workspace name, and "-ondemand" could be "-sqlod" and where [*B*] should be a database name, such as "master". There should be at most two items with the same URL value but different method values; OPTIONS and POST. Check whether these two items have "200" or "20x" under the status column, where "x" could be any single digit.

If either one of them has something other than "20x" and:

- Status starts with "(failed)", either widen the "Status" column or hover your pointer over the status text to see the complete text. Include the text and/or screenshot when opening the support ticket.

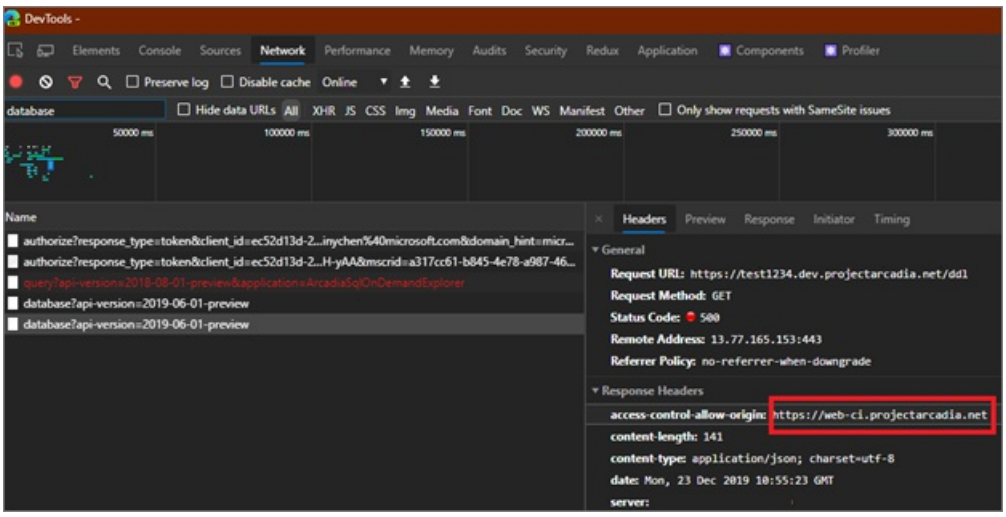


- If you see ERR_NAME_NOT_RESOLVED and you created your workspace within 10 minutes, wait for 10 minutes and retry to see whether the problem still exists.
- If you see ERR_INTERNET_DISCONNECTED or ERR_NETWORK_CHANGED, it may indicate your PC network connection is having issues. Check your network connection and retry the operation.
- If you see ERR_CONNECTION_RESET, ERR_SSL_PROTOCOL_ERROR or other error codes containing "SSL", it may indicate your local SSL configuration is having issues, or your network administrator has blocked access to the serverless SQL pool server. Open a support ticket and attach the error code in the description.
- If you see ERR_NETWORK_ACCESS_DENIED, you may need to check with the administrator on whether your local firewall policy has blocked access to either *.database.windows.net domain, or remote port 1443.
- Optionally, try the same operation immediately on a different machine and/or network environment to rule out a network configuration issue on your PC.

- Status is "40x", "50x", or other numbers, select on the item(s) to see the details. You should see the item details to the right. Find the "Response Header" section; then check whether an item named "access-control-allow-origin" exists. If so, check whether it has one of the following values:
  - `*` (single asterisk)
  - https://web.azuresynapse.net/ (or other value that the text in your browser address bar starts with)

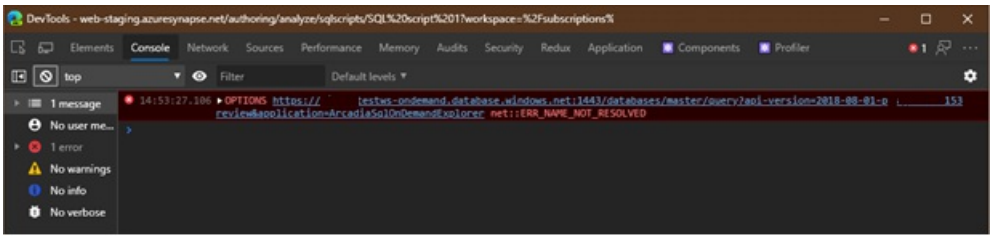
If the response header contains one of the above values, it means we should have already collected the failure information. You can open a support ticket if needed, and optionally attach the screenshot of the item details.

If you can't see the header, or the header does not have one of the values listed above, attach a screenshot of the item details when you open the ticket.



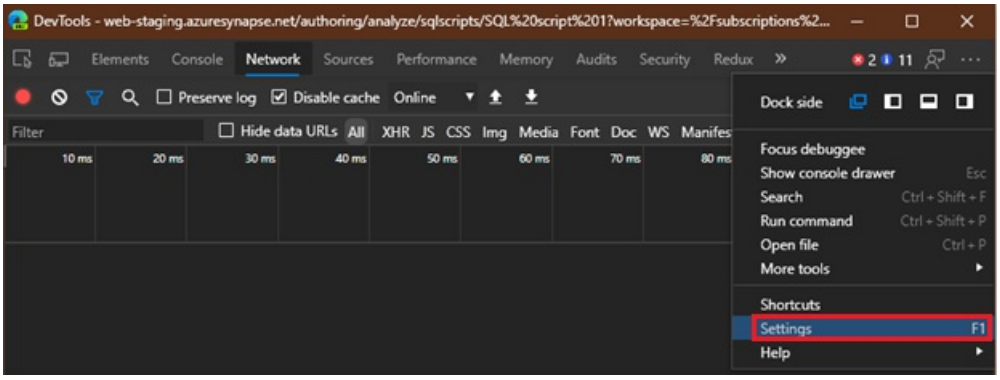
If the steps above do not solve your issue, you may need to open a support ticket. When submitting your support ticket, include the "Session ID" or "Diagnostic Info" downloaded at the beginning of this guide.

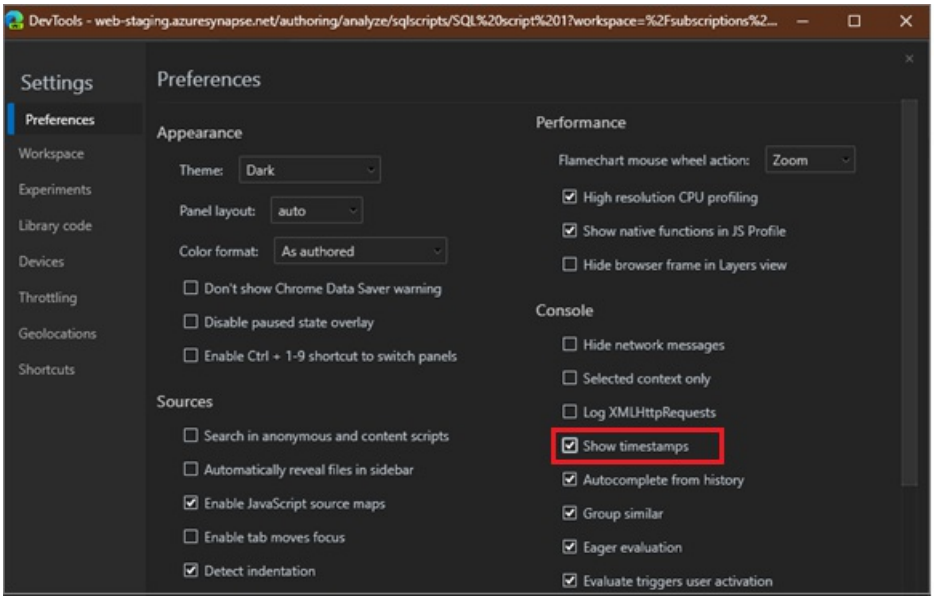
When reporting the issue, you may optionally take a screenshot of your "Console" tab in the "Developer Tools" and attach it to the support ticket. Scroll the content and take more than one screenshot if necessary to capture the entire message.



If you're attaching screenshots, provide the time (or an estimated time range) of when you took the screenshots. It will help us when looking into the problem.

Certain browsers support showing timestamps in the "Console" tab. For Chromium Edge/Chrome, open the "Settings" dialog in "Developer Tools", and check "Show timestamps" in "Preferences" tab.

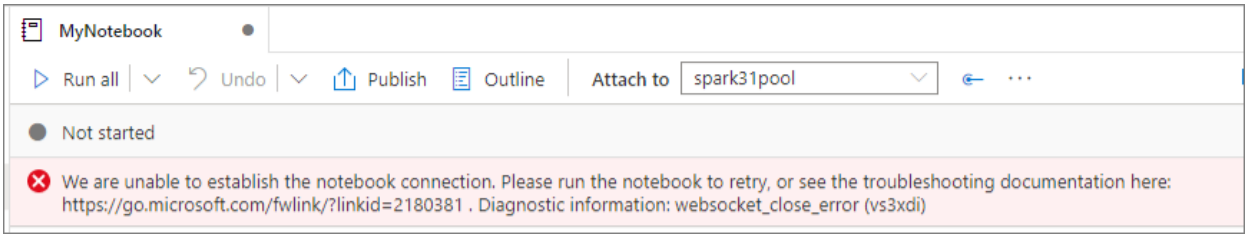




Notebook websocket connection issue

Symptom

Error message shows: your notebook connection has closed unexpectedly. To re-establish the connection, run the notebook again. Diagnostic information: websocket_close_error (correlation id)



Root cause:

Notebook execution depends on establishing a WebSocket connection to the following URL

```
wss://{workspace}.dev.azuresynapse.net/jupyterApi/versions/1/sparkPools/{spark-pool}/api/kernels/{kernel-id}/channels
```

- **{workspace}** is the name of Synapse workspace,
- **{spark-pool}** is the name of Spark pool you are currently working on,
- **{kernel-id}** is a GUID used for distinguishing notebook sessions.

When setting up WebSocket connection, Synapse Studio will include an access token (JWT bearer token) in the Sec-WebSocket-Protocol header of the WebSocket request.

Sometimes, WebSocket request might be blocked, or JWT token in the request header might be redacted in your network environment. This will cause Synapse Notebook unable to establish the connection to our server and run your notebook.

Action:

If possible, please try to switch your network environment, such as inside/outside corpnet, or access Synapse Notebook on another workstation.

- If you can run notebook on the same workstation but in a different network environment, please work with your network administrator to find out whether the WebSocket connection has been blocked.
- If you can run notebook on a different workstation but in the same network environment, please ensure you didn't install any browser plugin that may block the WebSocket request.

Otherwise, please contact your network administrator and ensure the outbound WebSocket requests with the following URL pattern is allowed and their request header is not redacted:

```
wss://{workspace}.dev.azuresynapse.net/{path}
```

- **{workspace}** is the Synapse workspace name;
- **{path}** indicates any sub-path (i.e., slash character is included) in URI.

This URL pattern is looser than the one shown in "Root Cause" section because it allows for us adding new WebSocket-dependent features to Synapse without any potential connectivity issue in the future.

Troubleshoot Synapse Studio connectivity with PowerShell

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Studio depends on a set of Web API endpoints to work properly. This guide will help you identify causes of connectivity issues when you're:

- configuring your local network (such as network behind a corporate firewall) for accessing Azure Synapse Studio.
- experiencing connectivity issues using Azure Synapse Studio.

Prerequisite

- PowerShell 5.0 or higher version on Windows, or
- PowerShell Core 6.0 or higher version on Windows or Linux.

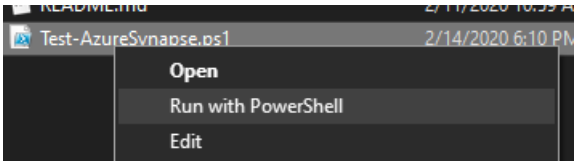
Troubleshooting steps

Right-click on the following link, and select "Save target as":

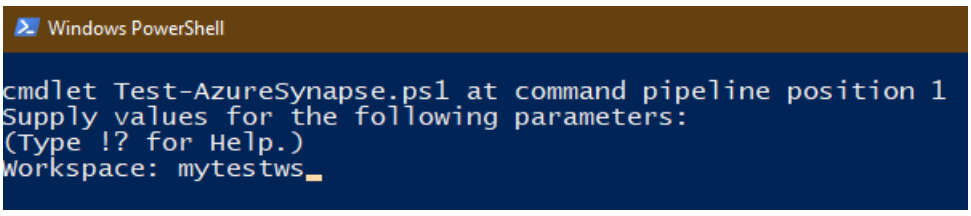
- Test-AzureSynapse.ps1

Alternatively, you may open the link directly, and save the opened script file. Don't save the address of the link above, as it may change in the future.

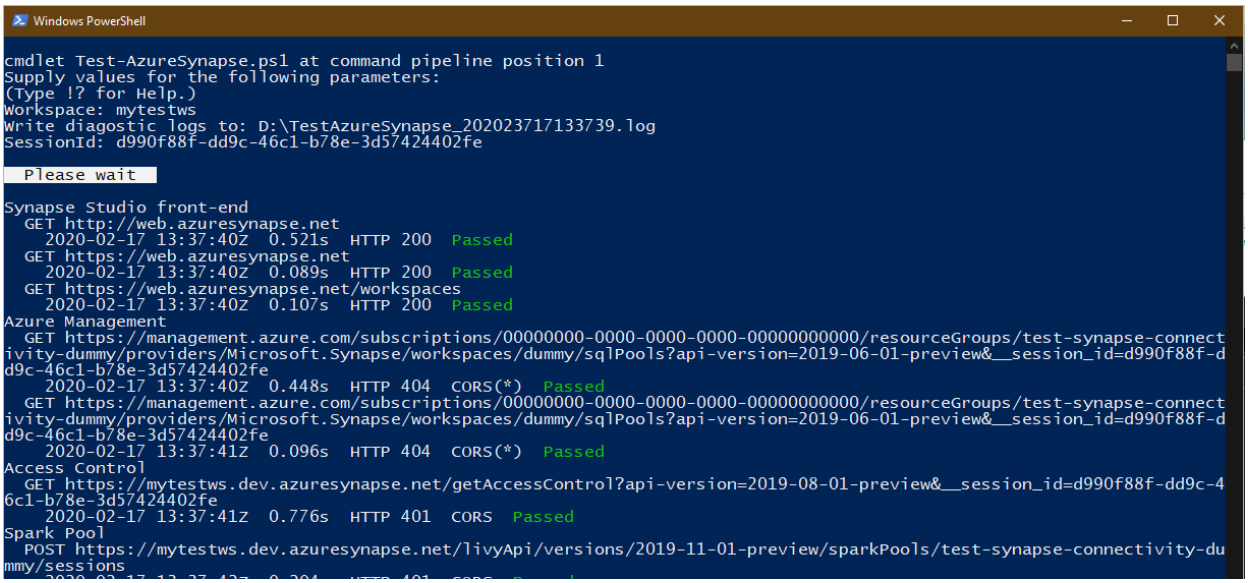
In file explorer, right-click on the downloaded script file, and select "Run with PowerShell".



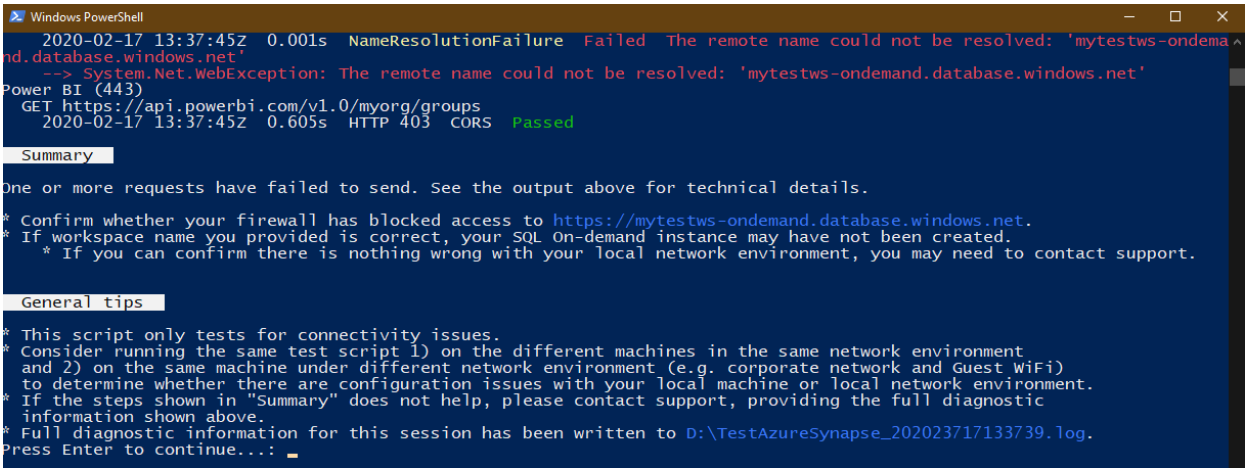
When prompted, enter the Azure Synapse workspace name that is currently experiencing a problem or that you want to test for connectivity, and press enter.



The diagnostic session will be started. Wait for it to complete.



In the end, a diagnosis summary will be shown. If your PC cannot connect to one or more of the endpoints, it will show some suggestions in the "Summary" section.



Additionally, a diagnostic log file for this session will be generated in the same folder as the troubleshooting script. Its location is shown in "General tips" section (`D:\TestAzureSynapse_2020....log`). You may send this file to technical support if necessary.

If you're a network administrator and tuning your firewall configuration for Azure Synapse Studio, the technical details shown above the "Summary" section may help.

- All the test items (requests) marked with "Passed" mean they have passed connectivity tests, regardless of the HTTP status code. For the failed requests, the reason is shown in yellow, such as `NamedResolutionFailure` or `ConnectFailure` . These reasons may help you figure out whether there are misconfigurations with your network environment.

Next steps

If the previous steps don't help to resolve your issue, create a support ticket.

Troubleshoot connectivity between Azure Synapse Analytics Synapse Studio and storage

8/19/2022 • 2 minutes to read • Edit Online

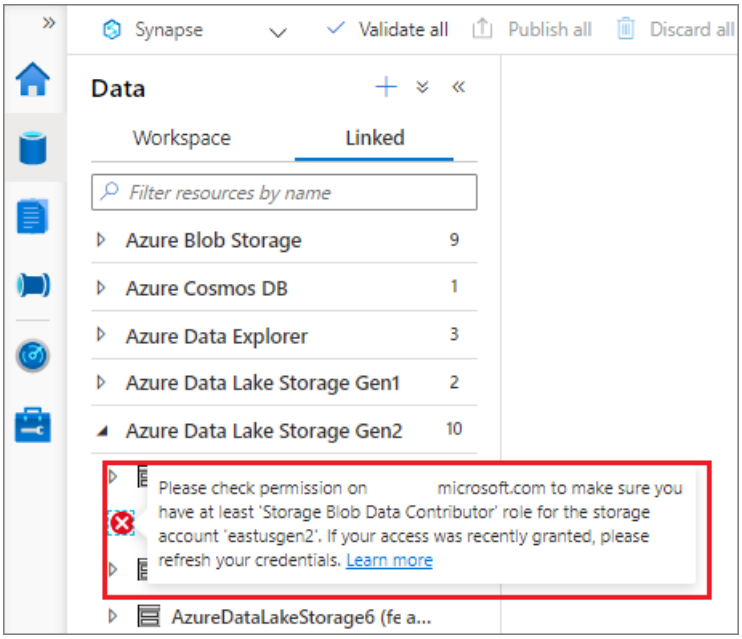
In Synapse Studio, you can explore data resources located in your linked storage. This guide will help you solve connectivity issues when you're trying to access your data resources.

Case #1: Storage account lacks proper permissions

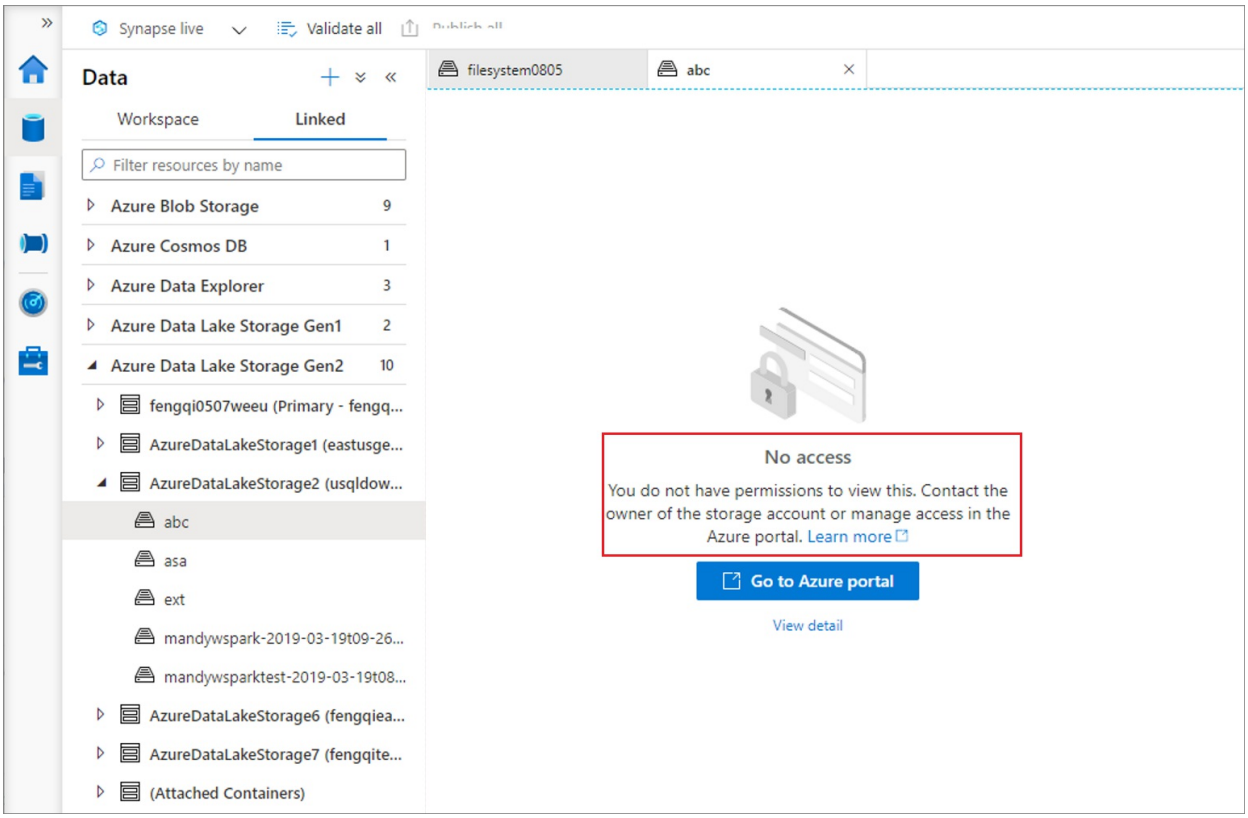
If your storage account lacks the proper permissions, you aren't able to expand the storage structure through "Data" --> "Linked" in Synapse Studio. See the issue symptom screenshot below.

The detailed error message may vary, but the general meaning of the error message is: "This request is not authorized to perform this operation.".

In the linked storage node:



In the storage container node:

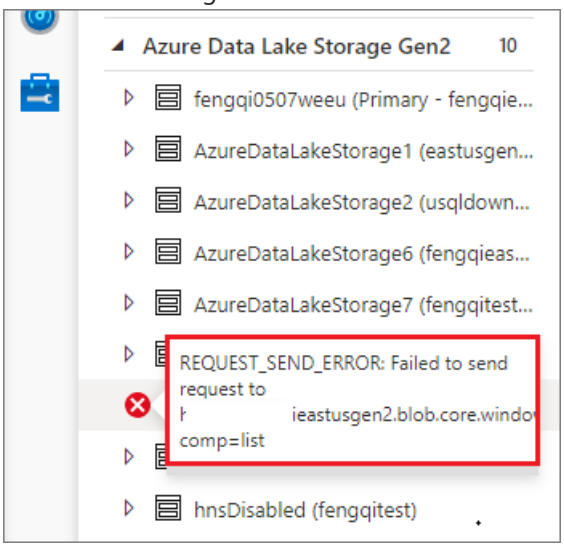


SOLUTION: To assign your account to the proper role, see Use the Azure portal to assign an Azure role for access to blob and queue data

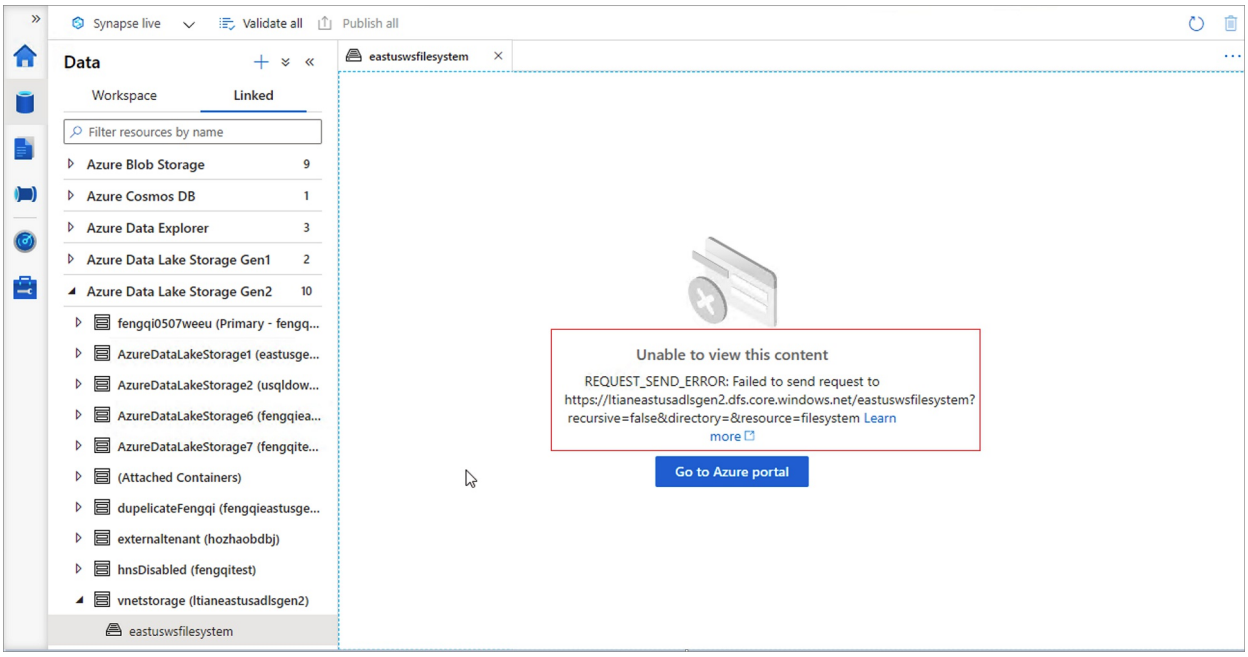
Case #2: Failed to send the request to storage server

When selecting the arrow to expand the storage structure in "Data" --> "Linked" in Synapse Studio, you may see the "REQUEST_SEND_ERROR" issue in the left panel. See the issue symptom screenshot below:

In the linked storage node:



In the storage container node:



There might be several possible reasons behind this issue:

The storage resource is behind a vNet and a storage private endpoint needs to configure

SOLUTION: In this case, you need to configure the storage private endpoint for your storage account. For how to configure the storage private endpoint for vNet, see Use the Azure portal to assign an Azure role for access to blob and queue data.

You can use the command "nslookup <storage-account-name>.dfs.core.windows.net" to check the connectivity after the storage private endpoint is configured. It should return a string similar to: "<storage-account-name>.privatelink.dfs.core.windows.net".

The storage resource is not behind a vNet but the Blob service (Azure AD) endpoint is not accessible due to firewall configured

SOLUTION: In this case, you need to open your storage account in the Azure portal. In the left navigation scroll down to **Support + troubleshooting** and select **Connectivity check** to check the **Blob service (Azure AD)** connectivity status. If it is not accessible, follow the promoted guide to check the **Firewalls and virtual networks** configuration under your storage account page. For more information about storage firewalls, see Configure Azure Storage firewalls and virtual networks.

Other issues to check

- The storage resource you are accessing is Azure Data Lake Storage Gen2 and is behind a firewall and vNet (with storage private endpoint configured) at the same time.
- The container resource you are accessing has been deleted or doesn't exist.
- Crossing-tenant: the workspace tenant that user used to login is not same with the tenant of the storage account.

Next steps

If the previous steps don't help to resolve your issue, create a support ticket.

Troubleshoot Azure Synapse Analytics workspaces created using SDK

8/19/2022 • 2 minutes to read • Edit Online

This article provides troubleshooting steps for launching Synapse Studio from a Synapse workspace that was created with a software development kit (SDK).

Prerequisites

- Synapse workspace created using SDK

Workaround

To launch Synapse Studio from your SDK created workspace, complete the following steps:

1. Create workspace by running `az synapse workspace create`.
2. Extract managed identity ID by running

   ```
   $identity=$(az synapse workspace show --name {workspace name} --resource-group {resource group name} --query "identity.principalId")
   ```

   .
3. Grant Storage Blob Data Contributor role to the managed identity storage account by running

   ```
   az role assignment create --role "Storage Blob Data Contributor" --assignee-object-id {identity } --scope {storage account resource id}.
   ```
4. Add firewall rule by running

   ```
   az synapse firewall-rule create --name allowAll --start-ip-address 0.0.0.0 --end-ip-address 255.255.255.255
   ```

   .

Troubleshoot reading UTF-8 text from CSV or Parquet files using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

This article provides troubleshooting steps for reading UTF-8 text from CSV or Parquet files using serverless SQL pool in Azure Synapse Analytics.

When UTF-8 text is read from a CSV or PARQUET file using serverless SQL pool, some special characters like ü and ö are incorrectly converted if the query returns VARCHAR columns with non-UTF8 collations. This is a known issue in SQL Server and Azure SQL. Non-UTF8 collation is the default in Synapse SQL so customer queries will be affected. Customers who use standard English characters and some subset of extended Latin characters may not notice the conversion errors. The incorrect conversion is explained in more detail in Always use UTF-8 collations to read UTF-8 text in serverless SQL pool

Workaround

The workaround to this issue is to always use UTF-8 collation when reading UTF-8 text from CSV or PARQUET files.

- In many cases, you just need to set UTF8 collation on the database (metadata operation).

```
alter database MyDB
       COLLATE Latin1_General_100_BIN2_UTF8;
```

- You can explicitly define collation on VARCHAR column in OPENROWSET or external table:

```
select geo_id, cases = sum(cases)
from openrowset(
         bulk 'latest/ecdc_cases.parquet', data_source = 'covid', format = 'parquet'
     ) with ( cases int,
              geo_id VARCHAR(6) COLLATE Latin1_General_100_BIN2_UTF8 ) as rows
group by geo_id
```

- If you did not specify UTF8 collation on external tables that read UTF8 data, you need to re-create impacted external tables and set UTF8 collation on VARCHAR columns (metadata operation).

Next steps

- Query Parquet files with Synapse SQL
- Query CSV files with Synapse SQL
- CETAS with Synapse SQL
- Quickstart: Use serverless SQL pool

Move an Azure Synapse Analytics workspace from one region to another

8/19/2022 • 15 minutes to read • Edit Online

This article is a step-by-step guide that shows you how to move an Azure Synapse Analytics workspace from one Azure region to another.

> **NOTE**
> The steps in this article don't actually move the workspace. The steps show you how to create a new workspace in a new region by using Azure Synapse Analytics-dedicated SQL pool backups and artifacts from the source region.

Prerequisites

- Integrate the source region Azure Synapse workspace with Azure DevOps or GitHub. For more information, see Source control in Synapse Studio.
- Have Azure PowerShell and Azure CLI modules installed on the server where scripts are executed.
- Make sure all dependent services, for example, Azure Machine Learning, Azure Storage, and Azure Private Link hubs, are re-created in the target region or moved to the target region if the service supports a region move.
- Move Azure Storage to a different region. For more information, see Move an Azure Storage account to another region.
- Ensure the dedicated SQL pool name and the Apache Spark pool name are the same in the source region and the target region workspace.

Scenarios for a region move

- **New compliance requirements**: Organizations require data and services to be placed in the same region as part of new compliance requirements.
- **Availability of a new Azure region**: Scenarios where a new Azure region is available and there are project or business requirements to move the workspace and other Azure resources to the newly available Azure region.
- **Wrong region selected**: The wrong region was selected when the Azure resources were created.

Steps to move an Azure Synapse workspace to another region

Moving an Azure Synapse workspace from one region to another region is a multistep process. Here are the high-level steps:

1. Create a new Azure Synapse workspace in the target region along with a Spark pool with the same configurations as used in the source region workspace.
2. Restore the dedicated SQL pool to the target region by using restore points or geo-backups.
3. Re-create all the required logins on the new logical SQL Server.
4. Create serverless SQL pool and Spark pool databases and objects.
5. Add an Azure DevOps Service Principal to the Azure Synapse role-based access control (RBAC) Synapse Artifact Publisher role if you're using an Azure DevOps release pipeline to deploy the artifacts.
6. Deploy code artifact (SQL Scripts, Notebooks), linked services, pipelines, datasets, Spark Job definitions triggers, and credentials from Azure DevOps release pipelines to the target region Azure Synapse workspace.
7. Add Azure Active Directory (Azure AD) users or groups to Azure Synapse RBAC roles. Granting Storage Blob Contributor access to system-assigned managed identity (SA-MI) on Azure Storage and Azure Key Vault if you're authenticating by using managed identity.
8. Grant Storage Blob Reader or Storage Blob Contributor roles to required Azure AD users on default attached storage or on the Storage account that has data to be queried by using a serverless SQL pool.
9. Re-create self-hosted integration runtime (SHIR).

10. Manually upload all required libraries and jars in the target Azure Synapse workspace.
11. Create all managed private endpoints if the workspace is deployed in a managed virtual network.
12. Test the new workspace on the target region and update any DNS entries, which are pointing to the source region workspace.
13. If there's a private endpoint connection created on the source workspace, create one on the target region workspace.
14. You can delete the workspace in the source region after you test it thoroughly and route all the connections to the target region workspace.

Prepare

Step 1: Create an Azure Synapse workspace in a target region

In this section, you'll create the Azure Synapse workspace by using Azure PowerShell, the Azure CLI, and the Azure portal. You'll create a resource group along with an Azure Data Lake Storage Gen2 account that will be used as the default storage for the workspace as part of the PowerShell script and the CLI script. If you want to automate the process of deployment, invoke these PowerShell or CLI scripts from the DevOps release pipeline.

Azure portal

To create a workspace from the Azure portal, follow the steps in Quickstart: Create a Synapse workspace.

Azure PowerShell

The following script creates the resource group and Azure Synapse workspace by using the New-AzResourceGroup and New-AzSynapseWorkspace cmdlets.

Create a resource group

```
$storageAccountName= "<YourDefaultStorageAccountName>"
$resourceGroupName="<YourResourceGroupName>"
$regionName="<YourTargetRegionName>"
$containerName="<YourFileSystemName>" # This is the file system name
$workspaceName="<YourTargetRegionWorkspaceName>"

$sourcRegionWSName="<Your source region workspace name>"
$sourceRegionRGName="<YourSourceRegionResourceGroupName>"
$sqlUserName="<SQLUserName>"
$sqlPassword="<SQLStrongPassword>"

$sqlPoolName ="<YourTargetSQLPoolName>" #Both Source and target workspace SQL pool name will be same
$sparkPoolName ="<YourTargetWorkspaceSparkPoolName>"
$sparkVersion="2.4"

New-AzResourceGroup -Name $resourceGroupName -Location $regionName
```

Create a Data Lake Storage Gen2 account

```
#If the Storage account is already created, then you can skip this step.
New-AzStorageAccount -ResourceGroupName $resourceGroupName `
  -Name $storageAccountName `
  -Location  $regionName `
  -SkuName Standard_LRS `
  -Kind StorageV2 `
  -EnableHierarchicalNamespace $true
```

Create an Azure Synapse workspace

```
$password = ConvertTo-SecureString $sqlPassword -AsPlainText -Force
$creds = New-Object System.Management.Automation.PSCredential ($sqlUserName, $password)

New-AzSynapseWorkspace -ResourceGroupName $resourceGroupName `
                       -Name $workspaceName -Location $regionName `
                       -DefaultDataLakeStorageAccountName $storageAccountName `
                       -DefaultDataLakeStorageFilesystem $containerName `
                       -SqlAdministratorLoginCredential $creds
```

If you want to create the workspace with a Managed Virtual Network, add the extra parameter "ManagedVirtualNetwork" to the script. To learn more about the options available, see Managed Virtual

Network Config.

```
#Creating a managed virtual network configuration
$config = New-AzSynapseManagedVirtualNetworkConfig -PreventDataExfiltration -AllowedAadTenantIdsForLinking
ContosoTenantId

#Creating an Azure Synapse workspace
New-AzSynapseWorkspace -ResourceGroupName $resourceGroupName `
                       -Name $workspaceName -Location $regionName `
                       -DefaultDataLakeStorageAccountName $storageAccountName `
                       -DefaultDataLakeStorageFilesystem $containerName `
                       -SqlAdministratorLoginCredential $creds `
                             -ManagedVirtualNetwork $config
```

Azure CLI

This Azure CLI script creates a resource group, a Data Lake Storage Gen2 account, and a file system. Then it creates the Azure Synapse workspace.

Create a resource group

```
az group create --name $resourceGroupName --location $regionName
```

Create a Data Lake Storage Gen2 account

The following script creates a storage account and container.

```
# Checking if name is not used only then creates it.
$StorageAccountNameAvailable=(az storage account check-name --name $storageAccountName --subscription
$subscriptionId | ConvertFrom-Json).nameAvailable

if($StorageAccountNameAvailable)
{
Write-Host "Storage account Name is available to be used...creating storage account"

#Creating a Data Lake Storage Gen2 account
$storgeAccountProvisionStatus=az storage account create `
  --name $storageAccountName `
  --resource-group $resourceGroupName `
  --location $regionName `
  --sku Standard_GRS `
  --kind StorageV2 `
  --enable-hierarchical-namespace $true

($storgeAccountProvisionStatus| ConvertFrom-Json).provisioningState
}
else
{
    Write-Host "Storage account Name is NOT available to be used...use another name --    exiting the
script..."
    EXIT
}

#Creating a container in a Data Lake Storage Gen2 account

$key=(az storage account keys list -g $resourceGroupName -n $storageAccountName|ConvertFrom-Json)[0].value

$fileShareStatus=(az storage share create --account-name $storageAccountName --name $containerName --
account-key $key)

if(($fileShareStatus|ConvertFrom-Json).created -eq "True")
{
      Write-Host f"Successfully created the fileshare - '$containerName'"
}
```

Create an Azure Synapse workspace

```
az synapse workspace create `
  --name $workspaceName `
  --resource-group $resourceGroupName `
  --storage-account $storageAccountName `
  --file-system $containerName `
  --sql-admin-login-user $sqlUserName `
  --sql-admin-login-password $sqlPassword `
  --location $regionName
```

To enable a managed virtual network, include the parameter `--enable-managed-virtual-network` in the preceding script. For more options, see workspace managed virtual network.

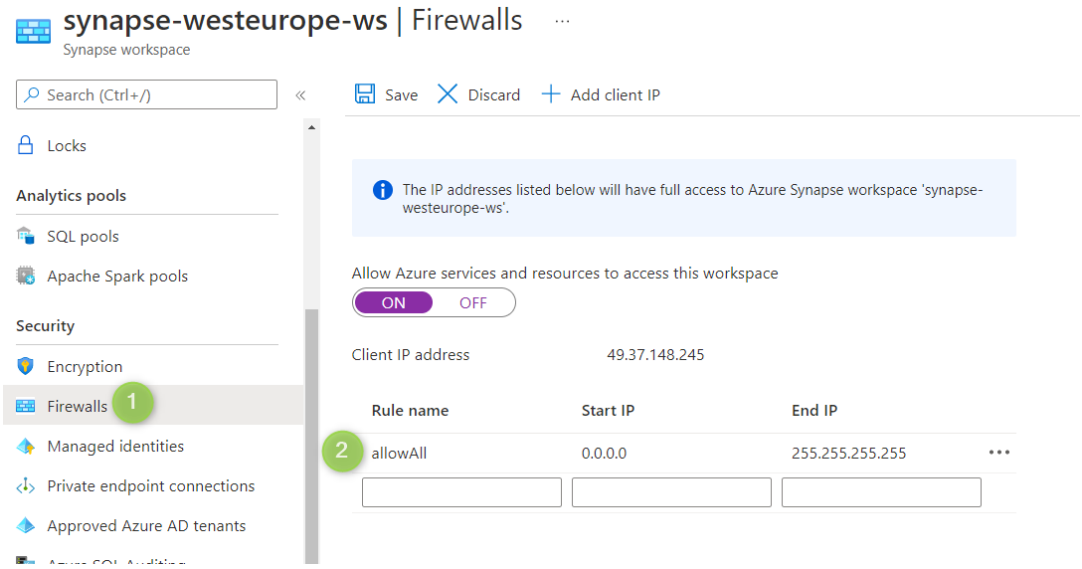
```
az synapse workspace create `
  --name $workspaceName `
  --resource-group $resourceGroupName `
  --storage-account $storageAccountName `
  --file-system $FileShareName `
  --sql-admin-login-user $sqlUserName `
  --sql-admin-login-password $sqlPassword `
  --location $regionName `
  --enable-managed-virtual-network true `
  --allowed-tenant-ids "Contoso"
```

Step 2: Create an Azure Synapse workspace firewall rule

After the workspace is created, add the firewall rules for the workspace. Restrict the IPs to a certain range. You can add a firewall from the Azure portal or by using PowerShell or the CLI.

Azure portal

Select the firewall options and add the range of IP addresses as shown in the following screenshot.



Azure PowerShell

Run the following PowerShell commands to add firewall rules by specifying the start and end IP addresses. Update the IP address range as per your requirements.

```
$WorkspaceWeb = (Get-AzSynapseWorkspace -Name $workspaceName -ResourceGroupName
$resourceGroup).ConnectivityEndpoints.Web
$WorkspaceDev = (Get-AzSynapseWorkspace -Name $workspaceName -ResourceGroupName
$resourceGroup).ConnectivityEndpoints.Dev

# Adding firewall rules
$FirewallParams = @{
  WorkspaceName = $workspaceName
  Name = 'Allow Client IP'
  ResourceGroupName = $resourceGroup
  StartIpAddress = "0.0.0.0"
  EndIpAddress = "255.255.255.255"
}
New-AzSynapseFirewallRule @FirewallParams
```

Run the following script to update the managed identity SQL control settings of the workspace:

```
Set-AzSynapseManagedIdentitySqlControlSetting -WorkspaceName $workspaceName -Enabled $true
```

Azure CLI

```
az synapse workspace firewall-rule create --name allowAll --workspace-name $workspaceName  `
--resource-group $resourceGroupName --start-ip-address 0.0.0.0 --end-ip-address 255.255.255.255
```

Run the following script to update the managed identity SQL control settings of the workspace:

```
az synapse workspace managed-identity grant-sql-access `
--workspace-name $workspaceName --resource-group $resourceGroupName
```

Step 3: Create an Apache Spark pool

Create the Spark pool with the same configuration that's used in the source region workspace.

Azure portal

To create a Spark pool from the Azure portal, see Quickstart: Create a new serverless Apache Spark pool using the Azure portal.

You can also create the Spark pool from Synapse Studio by following the steps in Quickstart: Create a serverless Apache Spark pool by using Synapse Studio.

Azure PowerShell

The following script creates a Spark pool with two workers and one driver node, and a small cluster size with 4 cores and 32-GB RAM. Update the values to match your source region workspace Spark pool.

```
#Creating a Spark pool with 3 nodes (2 worker + 1 driver) and a small cluster size with 4 cores and 32 GB
RAM.
New-AzSynapseSparkPool `
    -WorkspaceName  $workspaceName `
    -Name $sparkPoolName `
    -NodeCount 3 `
    -SparkVersion $sparkVersion `
    -NodeSize Small
```

Azure CLI

```
az synapse spark pool create --name $sparkPoolName --workspace-name $workspaceName --resource-group
$resourceGroupName `
--spark-version $sparkVersion --node-count 3 --node-size small
```

Move

Step 4: Restore a dedicated SQL pool

Restore from geo-redundant backups

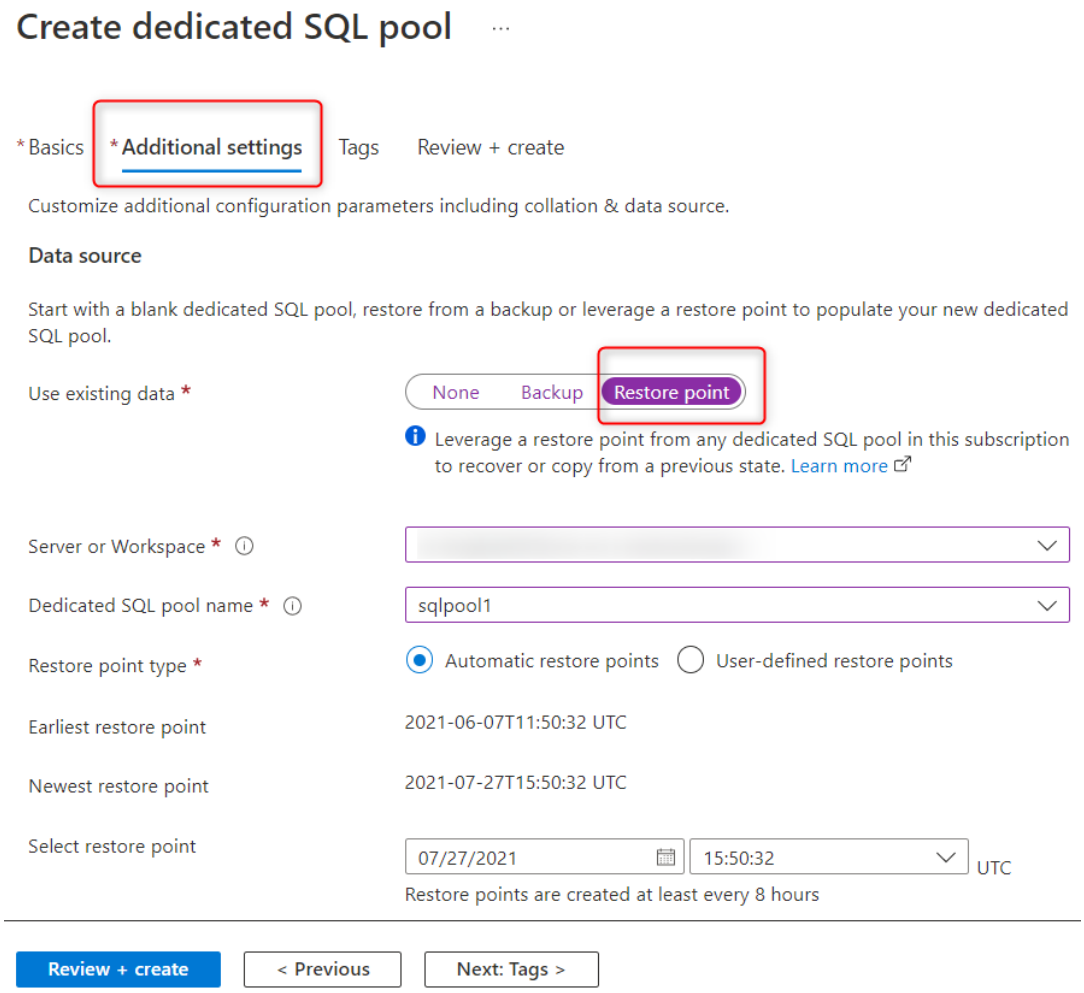
To restore the dedicated SQL pools from geo-backup by using the Azure portal and PowerShell, see Geo-restore a dedicated SQL pool in Azure Synapse Analytics.

Restore by using restore points from the source region workspace dedicated SQL pool

Restore the dedicated SQL pool to the target region workspace by using the restore point of the source region workspace dedicated SQL pool. You can use the Azure portal, Synapse Studio, or PowerShell to restore from restore points. If the source region isn't accessible, you can't restore by using this option.

Synapse Studio

From Synapse Studio, you can restore the dedicated SQL pool from any workspace in the subscription by using *restore points*. While you create the dedicated SQL pool, under **Additional settings**, select **Restore point** and select the workspace as shown in the following screenshot. If you created a user-defined restore point, use it to restore the SQL pool. Otherwise, you can select the latest automatic restore point.



Azure PowerShell

Run the following PowerShell script to restore the workspace. This script uses the latest restore point from the source workspace dedicated SQL pool to restore the SQL pool on the target workspace. Before you run the script, update the performance level from DW100c to the required value.

> **IMPORTANT**
> The dedicated SQL pool name should be the same on both the workspaces.

Get the restore points:

```
$restorePoint=Get-AzSynapseSqlPoolRestorePoint -WorkspaceName $sourceRegionWSName -Name $sqlPoolName|Sort-
Object  -Property RestorePointCreationDate -Descending `
                                                                                | SELECT
RestorePointCreationDate -ExpandProperty  RestorePointCreationDate -First 1
```

Transform the Azure Synapse SQL pool resource ID to SQL database ID because currently the command only

accepts the SQL database ID. For example:

```
/subscriptions/<SubscriptionId>/resourceGroups/<ResourceGroupName>/providers/Microsoft.Sql/servers/<WorkspaceName>/databases/<Datal
```

```
$pool = Get-AzSynapseSqlPool -ResourceGroupName $sourceRegionRGName -WorkspaceName $sourcRegionWSName -Name
$sqlPoolName
$databaseId = $pool.Id `
    -replace "Microsoft.Synapse", "Microsoft.Sql" `
    -replace "workspaces", "servers" `
    -replace "sqlPools", "databases"

$restoredPool = Restore-AzSynapseSqlPool -FromRestorePoint `
                                         -RestorePoint $restorePoint `
                                         -TargetSqlPoolName $sqlPoolName `
                                         -ResourceGroupName $resourceGroupName `
                                         -WorkspaceName $workspaceName `
                                         -ResourceId $databaseId `
                                         -PerformanceLevel DW100c -AsJob
```

The following tracks the status of the restore operation:

```
Get-Job | Where-Object Command -In ("Restore-AzSynapseSqlPool") | `
Select-Object Id,Command,JobStateInfo,PSBeginTime,PSEndTime,PSJobTypeName,Error |Format-Table
```

After the dedicated SQL pool is restored, create all the SQL logins in Azure Synapse. To create all the logins, follow the steps in Create login.

Step 5: Create a serverless SQL pool, Spark pool database, and objects

You can't back up and restore serverless SQL pool databases and Spark pools. As a possible workaround, you could:

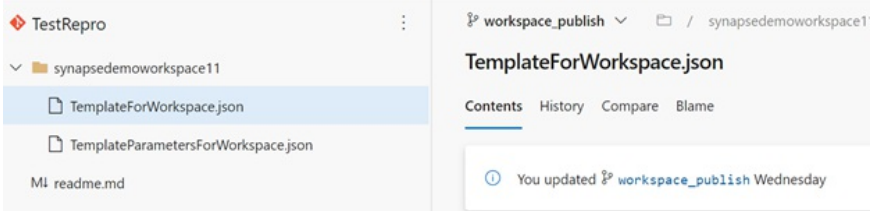
1. Create notebooks and SQL scripts, which have the code to re-create all the required Spark pool, serverless SQL pool databases, tables, roles, and users with all the role assignments. Check in these artifacts to Azure DevOps or GitHub.
2. If the Storage account name is changed, make sure the code artifacts are pointing to the correct storage account name.
3. Create pipelines, which invoke these code artifacts in a specific sequence. When these pipelines are executed on the target region workspace, the Spark SQL databases, serverless SQL pool databases, external data sources, views, roles, and users and permissions will be created on the target region workspace.
4. When you integrate the source region workspace with Azure DevOps, these code artifacts will be part of the repo. Later, you can deploy these code artifacts to the target region workspace by using the DevOps Release pipeline as mentioned in step 6.
5. On the target region workspace, trigger these pipelines manually.

Step 6: Deploy artifacts and pipelines by using CI/CD

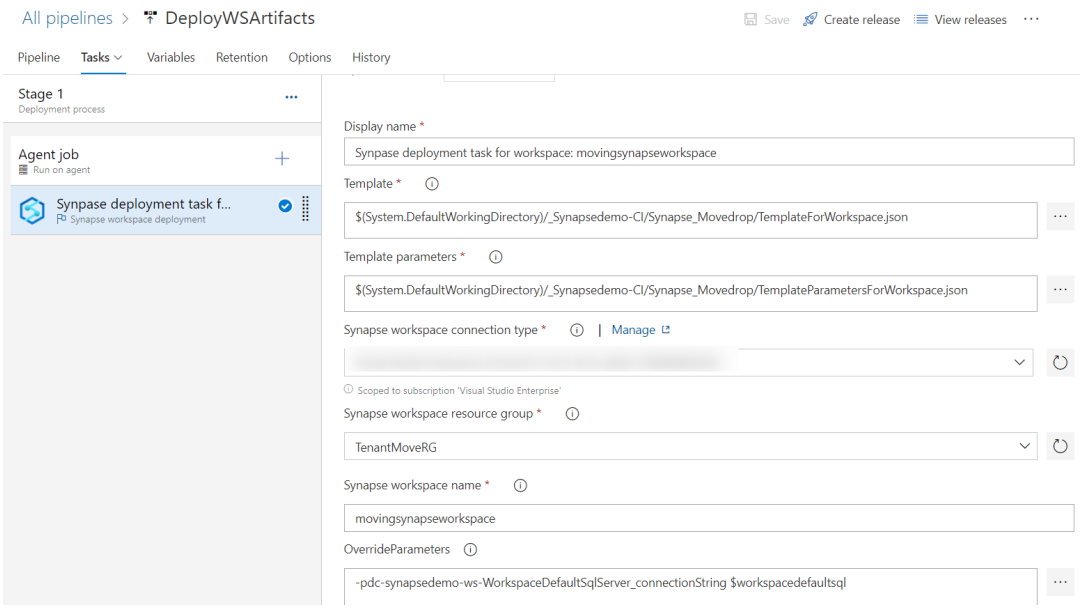
To learn how to integrate an Azure Synapse workspace with Azure DevOps or GitHub and how to deploy the artifacts to a target region workspace, follow the steps in Continuous integration and continuous delivery (CI/CD) for an Azure Synapse workspace.

After the workspace is integrated with Azure DevOps, you'll find a branch with the name workspace_publish. This branch contains the workspace template that includes definitions for the artifacts like Notebooks, SQL Scripts, Datasets, Linked Services, Pipelines, Triggers, and Spark job definition.

This screenshot from the Azure DevOps repo shows the workspace template files for the artifacts and other components.



You can use the workspace template to deploy artifacts and pipelines to a workspace by using the Azure DevOps release pipeline as shown in the following screenshot.



If the workspace isn't integrated with GitHub or Azure DevOps, you'll have to manually re-create or write custom PowerShell or Azure CLI scripts to deploy all the artifacts, pipelines, linked services, credentials, triggers, and Spark definitions on the target region workspace.

> **NOTE**
> This process requires you to keep updating the pipelines and code artifacts to include any changes made to Spark and serverless SQL pools, objects, and roles in the source region workspaces.

Step 7: Create a shared integration runtime

To create a SHIR, follow the steps in Create and configure a self-hosted integration runtime.

Step 8: Assign an Azure role to managed identity

Assign `Storage Blob Contributor` access to the managed identity of the new workspace on the default attached Data Lake Storage Gen2 account. Also assign access on other storage accounts where SA-MI is used for authentication. Assign `Storage Blob Contributor` or `Storage Blob Reader` access to Azure AD users and groups for all the required storage accounts.

Azure portal

Follow the steps in Grant permissions to workspace managed identity to assign a Storage Blob Data Contributor role to the managed identity of the workspace.

Azure PowerShell

Assign a Storage Blob Data Contributor role to the managed identity of the workspace.

Adding Storage Blob Data Contributor to the workspace managed identity on the storage account. The execution of `New-AzRoleAssignment` errors out with the message `Exception of type 'Microsoft.Rest.Azure.CloudException' was thrown.` however it creates the required permissions on the storage account.

```
$workSpaceIdentityObjectID= (Get-AzSynapseWorkspace -ResourceGroupName $resourceGroupName -Name
$workspaceName).Identity.PrincipalId
$scope =
"/subscriptions/$($subscriptionId)/resourceGroups/$($resourceGroupName)/providers/Microsoft.Storage/storageA
ccounts/$($storageAccountName)"

$roleAssignedforManagedIdentity=New-AzRoleAssignment -ObjectId $workSpaceIdentityObjectID `
    -RoleDefinitionName "Storage Blob Data Contributor" `
    -Scope $scope -ErrorAction SilentlyContinue
```

Azure CLI

Get the role name, resource ID, and principal ID for the workspace managed identity, then add the Storage Blob Data Contributor Azure role to the SA-MI.

```
# Getting Role name
$roleName =az role definition list --query "[?contains(roleName, 'Storage Blob Data Contributor')].
{roleName:roleName}" --output tsv

#Getting resource id for storage account
$scope= (az storage account show --name $storageAccountName|ConvertFrom-Json).id

#Getting principal ID for workspace managed identity
$workSpaceIdentityObjectID=(az synapse workspace show --name $workspaceName --resource-group
$resourceGroupName|ConvertFrom-Json).Identity.PrincipalId

# Adding Storage Blob Data Contributor Azure role to SA-MI
az role assignment create --assignee $workSpaceIdentityObjectID `
--role $roleName `
--scope $scope
```

Step 9: Assign Azure Synapse RBAC roles

Add all the users who need access to the target workspace with separate roles and permissions. The following PowerShell and CLI script adds an Azure AD user to the Synapse Administrator role in the target region workspace.

To get all the Azure Synapse RBAC role names, see Azure Synapse RBAC roles.

Synapse Studio

To add or delete Azure Synapse RBAC assignments from Synapse Studio, follow the steps in How to manage Azure Synapse RBAC role assignments in Synapse Studio.

Azure PowerShell

The following PowerShell script adds the Synapse Administrator role assignment to an Azure AD user or group. You can use -RoleDefinitionId instead of -RoleDefinitionName with the following command to add the users to the workspace:

```
New-AzSynapseRoleAssignment `
   -WorkspaceName $workspaceName  `
   -RoleDefinitionName "Synapse Administrator" `
   -ObjectId 1c02d2a6-ed3d-46ec-b578-6f36da5819c6

Get-AzSynapseRoleAssignment -WorkspaceName $workspaceName
```

To get the ObjectIds and RoleIds in the source region workspace, run the `Get-AzSynapseRoleAssignment` command. Assign the same Azure Synapse RBAC roles to the Azure AD users or groups in the target region workspace.

Instead of using `-ObjectId` as the parameter, you can also use `-SignInName`, where you provide the email address or the user principal name of the user. To find out more about the available options, see Azure Synapse RBAC - PowerShell cmdlet.

Azure CLI

Get the Object ID of the user and assign the required Azure Synapse RBAC permissions to the Azure AD user. You can provide the email address of the user (username@contoso.com) for the `--assignee` parameter.

```
az synapse role assignment create `
--workspace-name $workspaceName `
--role "Synapse Administrator" --assignee adasdasdd42-0000-000-xxx-xxxxxxx

az synapse role assignment create `
--workspace-name $workspaceName `
--role "Synapse Contributor" --assignee "user1@contoso.com"
```

To learn more about available options, see Azure Synapse RBAC - CLI.

Step 10: Upload workspace packages

Upload all required workspace packages to the new workspace. To automate the process of uploading the workspace packages, see the Microsoft Azure Synapse Analytics Artifacts client library.

Step 11: Permissions

To set up the access control for the target region Azure Synapse workspace, follow the steps in How to set up access control for your Azure Synapse workspace.

Step 12: Create managed private endpoints

To re-create the managed private endpoints from the source region workspace in your target region workspace, see Create a managed private endpoint to your data source.

Discard

If you wish to discard the target region workspace, delete the target region workspace. To do so, go to the resource group from your dashboard in the portal and select the workspace and select Delete at the top of the Resource group page.

Clean up

To commit the changes and complete the move of the workspace, delete the source region workspace after testing the workspace in the target region. To do so, go to the resource group that has the source region workspace from your dashboard in the portal and select the workspace and select Delete at the top of the Resource group page.

Next steps

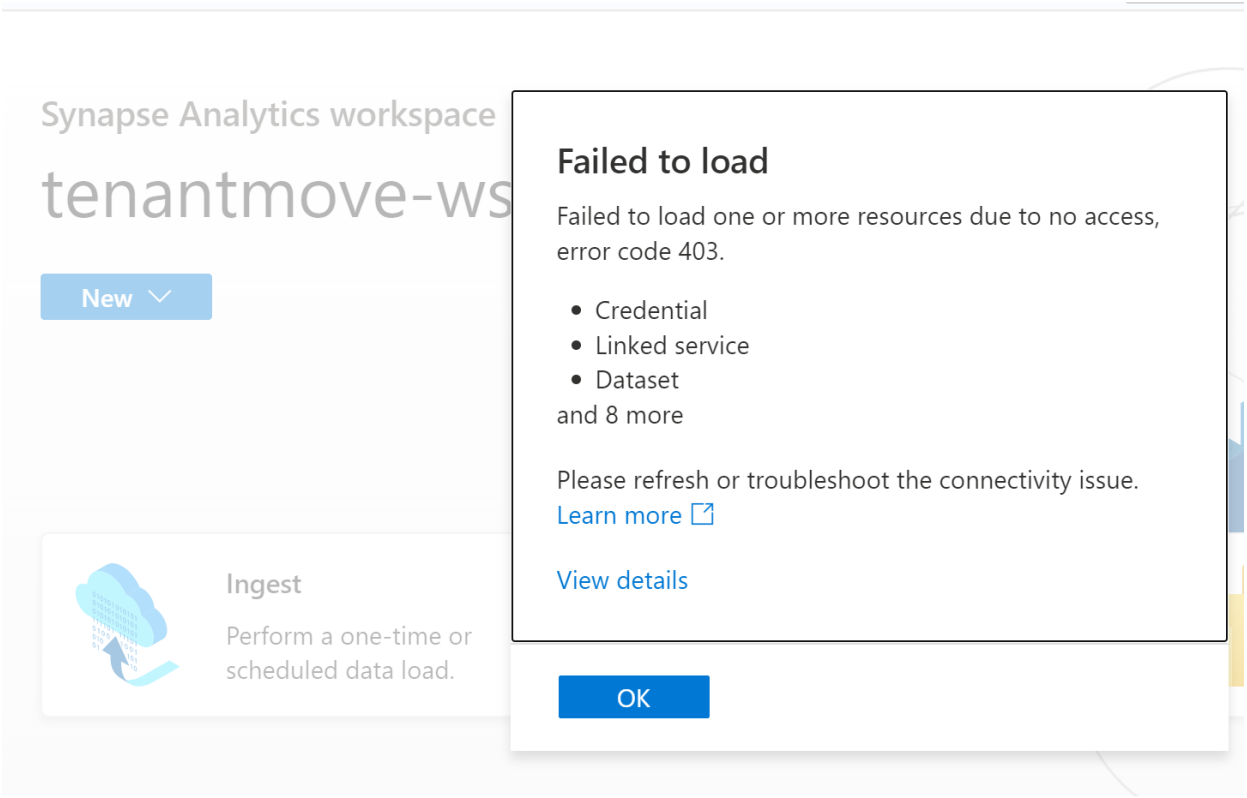
- Learn more about Azure Synapse managed virtual networks.
- Learn more about Azure Synapse managed private endpoints.
- Learn more about how to connect to workspace resources from a restricted network.

Recovering Synapse Analytics workspace after transferring a subscription to a different Azure AD directory (tenant)

8/19/2022 • 5 minutes to read • Edit Online

This article describes how to recover the Synapse Analytics workspace after transferring its subscription to a different Azure AD directory. The Synapse Analytics workspace will not be accessible after transferring a subscription to a different Azure AD directory (tenant).

When you try to launch the Synapse studio after the move, you will see the error: "Failed to load one or more resources due to no access, error code 403."



Follow the steps in this article after transferring a subscription across tenant to recover the Synapse Analytics workspace.

Transferring a subscription to a different Azure AD directory (tenant) is a complex process that must be carefully planned and executed. Azure Synapse Analytics require security principals (identities) to operate normally. When a subscription is moved to a different tenant, all principal IDs change, role assignments are deleted from Azure resource, and system assigned managed identities are dropped.

To understand the impact of transferring a subscription to another tenant see Transfer an Azure subscription to a different Azure AD directory

This article covers the steps involved in recovering a Synapse Analytics workspace after moving the subscription across tenants.

Pre-requisites

- To know more about service or resources impacted by tenant move see Transfer an Azure subscription to a different Azure AD directory.
- Save all the role assignment for Azure Active Directory (Azure AD) users, groups, and managed identities. This information can be used to assign the required permissions on Azure resources like Azure Synapse Analytics and ADLS Gen2 after tenant move. See Step 1: Prepare for the transfer
- Save all the permissions necessary for Azure AD users in dedicated and serverless SQL pool. Azure AD users will be deleted from the dedicated and serverless SQL pools after tenant move.

Steps for recovering Synapse Analytics workspace

After transferring the subscription to another tenant, follow the below steps to recover the Azure Synapse Analytics workspace.

1. Disable and re-enable the system Assigned Managed Identity. More information later in this article.
2. Assign Azure RBAC (role based access control) permissions to the required Azure AD users, groups, and managed identities on the Synapse Analytics workspace and required Azure resources.
3. Set the SQL Active Directory admin.
4. Re-create Azure AD users and groups based on their equivalent users and groups in the new Azure AD tenant for the dedicated and serverless SQL pools.
5. Assign Azure RBAC to Azure AD users, groups to Synapse Analytics workspace. This step should be first step after recovering the workspace. Without this step, launching Synapse Studio will throw 403 messages, due to Azure AD users not having permissions on the workspace:

   ```
   {"error":{"code":"Unauthorized","message":"The principal '<subscriptionid>' does not    have the
   required Synapse RBAC permission to perform this action. Required permission:    Action:
   Microsoft.Synapse/workspaces/read, Scope: workspaces/tenantmove-ws-1/*."}}
   ```

6. Assign Azure RBAC roles to Azure AD users, groups, service principals to all the resources used in the workspace artifacts, such as ADLS Gen2. For more information on Azure RBAC in ADLS Gen2, see Role-based access control (Azure RBAC).
7. Add Synapse RBAC role assignments to Azure AD users and groups. For more information, see How to manage Synapse RBAC role assignments in Synapse Studio
8. Recreate all the Azure AD logins and users in dedicated and serverless SQL pool. For more information, see SQL Authentication in Azure Synapse Analytics
9. Recreate all user assigned managed identity and assign user-assigned managed identity to the Synapse Analytics workspace. For more information, see Credentials in Azure Data Factory and Azure Synapse

> **NOTE**
> Ensure the following steps are executed only after confirming subscription is successfully moved to another tenant.

Disable and re-enable the system assigned managed identity for the Synapse Analytics workspace

This section shows you how to use Azure CLI or Azure PowerShell to disable and re-enable the System-assigned Managed Identity for your Azure Synapse Analytics workspace. Consider the following steps in either Azure CLI or Azure PowerShell.

- Azure CLI
- Azure PowerShell

```
$resourceGroupName="Provide the Resource group name"
$workspaceName="Provide the workspace name"
$subscriptionId="Provide the subscription Id"

$url =
"https://management.azure.com/subscriptions/$subscriptionId/resourceGroups/$resourceGroupName/providers/Micr
osoft.Synapse/workspaces/$workspaceName\?api-version=2021-06-01"
```

This next sample disables System Assigned Managed Identity for the workspace.

```
az rest --method patch --headers  Content-Type=application/json   `
--url  $url `
--body '{ \"identity\":{\"type\":\"None\"}}'
```

Workspace `provisioningState` should be **Succeeded** and the identity type should **None** after preceding command is executed. If you execute the following command, `provisioningState` value might be shown as Provisioning and will take few minutes to change the status to Succeeded. Value of the `provisioningState` should be Succeeded before re-enabling the System Assigned Managed Identity for the workspace.

To get the status of the workspace to get the provisioning status and identity type, use the following code snippet:

```
az rest --method GET --uri $uri
```

The resulting JSON should be similar to:

```
   {
  "id": "/subscriptions/<subscriptionid>/resourceGroups/TenantMove-RG/providers/Microsoft
Synapse/workspaces/tenantmove-ws",
  "identity": {
    "type": "None"
  },
  "location": "eastus",
  "name": "tenantmove-ws",
  "properties": {
    "connectivityEndpoints": {
      "dev": "https://tenantmove-ws.dev.azuresynapse.net",
      "sql": "tenantmove-ws.sql.azuresynapse.net",
      "sqlOnDemand": "tenantmove-ws-ondemand.sql.azuresynapse.net",
      "web": "https://web.azuresynapse.net?
workspace=%2fsubscriptions%2<subscriptionid>b%2fresourceGroups%2fTenantMove-
RG%2fproviders%2fMicrosoft.Synapse%2fworkspaces%2ftenantmove-ws"
    },
    "cspWorkspaceAdminProperties": {
      "initialWorkspaceAdminObjectId": "<object id>"
    },
    "defaultDataLakeStorage": {
      "accountUrl": "https://tenantmovedemowsstorage.dfs.core.windows.net",
      "filesystem": "demo",
      "resourceId": "/subscriptions/<subscriptionid>/resourceGroups/TenantMove-
RG/providers/Microsoft.Storage/storageAccounts/tenantmovedemowsstorage"
    },
    "encryption": {
      "doubleEncryptionEnabled": false
    },
    "extraProperties": {
      "WorkspaceType": "Normal"
    },
    "managedResourceGroupName": "tenantmove-ws-managed-rg",
    "privateEndpointConnections": [],
    "provisioningState": "Succeeded",
    "publicNetworkAccess": "Enabled",
    "sqlAdministratorLogin": "sqladminuser",
    "trustedServiceBypassEnabled": false,
    "workspaceUID": "<workspace UID>"
  },
  "resourceGroup": "TenantMove-RG",
  "tags": {},
  "type": "Microsoft.Synapse/workspaces"
}
```

The next command will re-enable the System Assigned Managed Identity for the workspace:

```
az rest --method patch --headers  Content-Type=application/json   `
--url  $url `
--body '{ \"identity\":{\"type\":\"SystemAssigned\"}}'
```

The next command will get you workspace status. The `provisioningState` value should be Succeeded. The `provisioningState` value will change from Provisioning to Succeeded. Identity type will be changed to **SystemAssigned**.

```
az rest --method GET --uri $uri
```

Next steps

- Transfer an Azure subscription to a different Azure AD directory
- Move an Azure Synapse Analytics workspace from one region to another

- Assign Azure RBAC (role based access control) permissions to the required Azure AD users, groups, and managed identities

What are Azure Synapse database templates?

8/19/2022 • 2 minutes to read • Edit Online

Data takes many forms as it moves from source systems to data warehouses and data marts with the intent to solve business problems. Database templates can help with the transformation of data into insights.

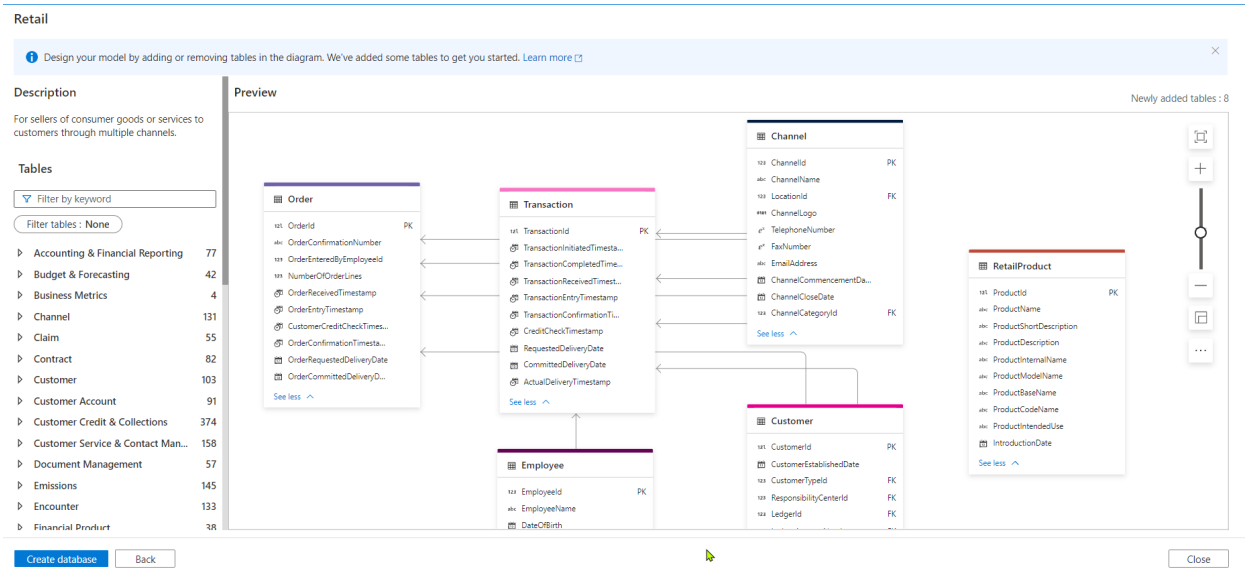
Database templates are a set of business and technical data definitions that are pre-designed to meet the needs of a particular industry. They act as blueprints that provide common elements derived from best practices, government regulations, and the complex data and analytic needs of an industry-specific organization.

These schema blueprints can be used by organizations to plan, architect, and design data solutions for data governance, reporting, business intelligence, and advanced analytics. The data models provide integrated business-wide information architectures that can help you implement, in a timely and predictable way, a proven industry data architecture.

For example, if you're building a product recommendation solution for your retail customers, you'll need to understand what the customer purchased and the transaction that led to the purchase. You may also need information about the store where the purchase was made, and whether the customer is part of a loyalty program. Just to accomplish this use case, consider the following schemas:

- Product
- Transaction
- TransactionLineItem
- Customer
- CustomerLoyalty
- Store

You can set up this use case by selecting the six tables in the **Retail** database template.



A typical database template addresses the core requirements of a specific industry and consists of:

- One or more enterprise templates.
- Tables grouped by **business areas**.

Available database templates

Currently, you can choose from the following database templates in Azure Synapse Studio to start creating your lake database:

- **Agriculture** - For companies engaged in growing crops, raising livestock, and dairy production.
- **Automotive** - For companies manufacturing automobiles, heavy vehicles, tires, and other automotive components.
- **Banking** - For companies providing a wide range of banking and related financial services.
- **Consumer Goods** - For manufacturers or producers of goods bought and used by consumers.
- **Energy & Commodity Trading** - For traders of energy, commodities, or carbon credits.
- **Freight & Logistics** - For companies that provide freight and logistics services.
- **Fund Management** - For companies that manage investment funds for investors.
- **Genomics** - For companies acquiring and analyzing genomic data about human beings or other species.
- **Healthcare Insurance** - For organizations providing insurance to cover healthcare needs (sometimes know as Payors).
- **Healthcare Provider** - For organizations providing healthcare services.
- **Life Insurance & Annuities** - For companies that provide life insurance, sell annuities, or both.
- **Manufacturing** - For companies engaged in discrete manufacturing of a wide range of products.
- **Oil & Gas** - For companies that are involved in various phases of the Oil & Gas value chain.
- **Pharmaceuticals** - For companies engaged in creating, manufacturing, and marketing pharmaceutical and bio-pharmaceutical products and medical devices.
- **Property & Casualty Insurance** - For companies that provide insurance against risks to property and various forms of liability coverage.
- **R&D and Clinical Trials** - For companies involved in research and development and clinical trials of pharmaceutical products or devices.
- **Retail** - For sellers of consumer goods or services to customers through multiple channels.
- **Utilities** - For gas, electric, and water utilities; power generators; and water desalinators.

As emission and carbon management is an important discussion in all industries, so we've included those components in all the available database templates. These components make it easy for companies who need to track and report their direct and indirect greenhouse gas emissions.

Map Data in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

What is the Map data tool?

The Map Data tool is a guided process to help users create ETL mappings and mapping data flows from their source data to Synapse lake database tables without writing code. This process starts with the user choosing the destination tables in Synapse lake databases and then mapping their source data into these tables.

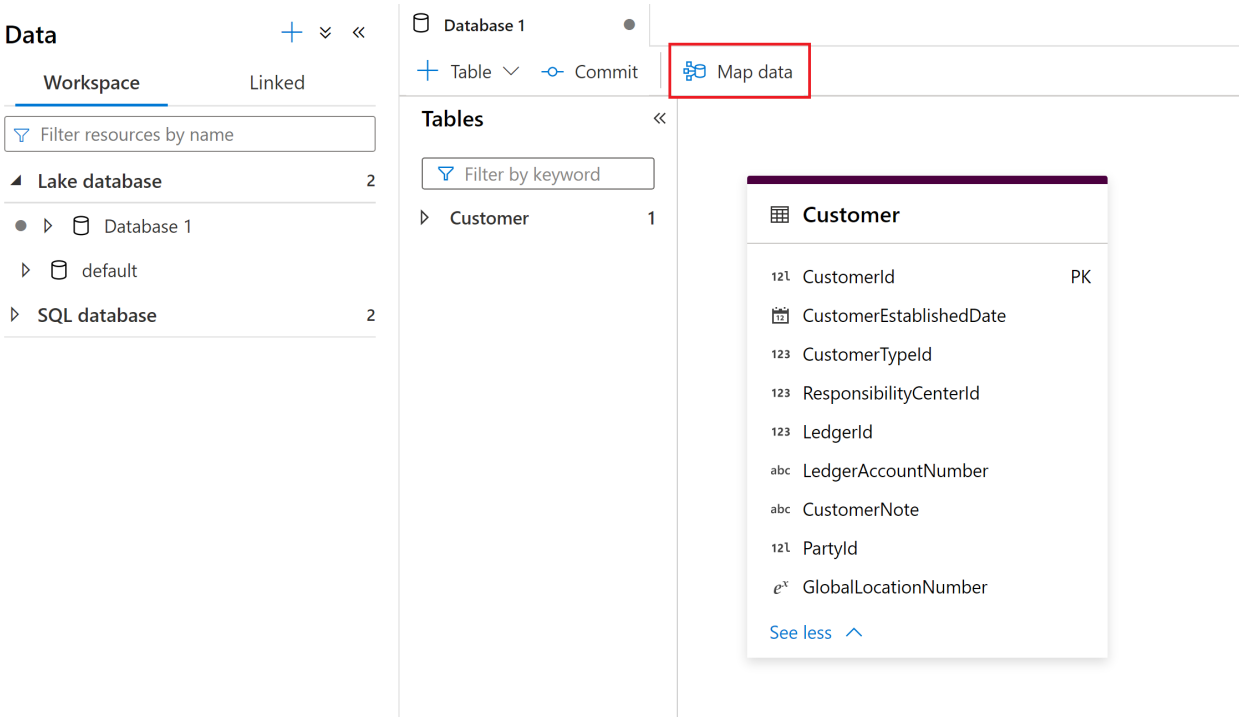
For more information on Synapse lake databases see Overview of Azure Synapse database templates - Azure Synapse Analytics | Microsoft Docs

Map Data provides for a guided experience where the user can generate a mapping data flow without having to start with a blank canvas and quickly generate a scalable mapping data flow runnable in Synapse pipelines.

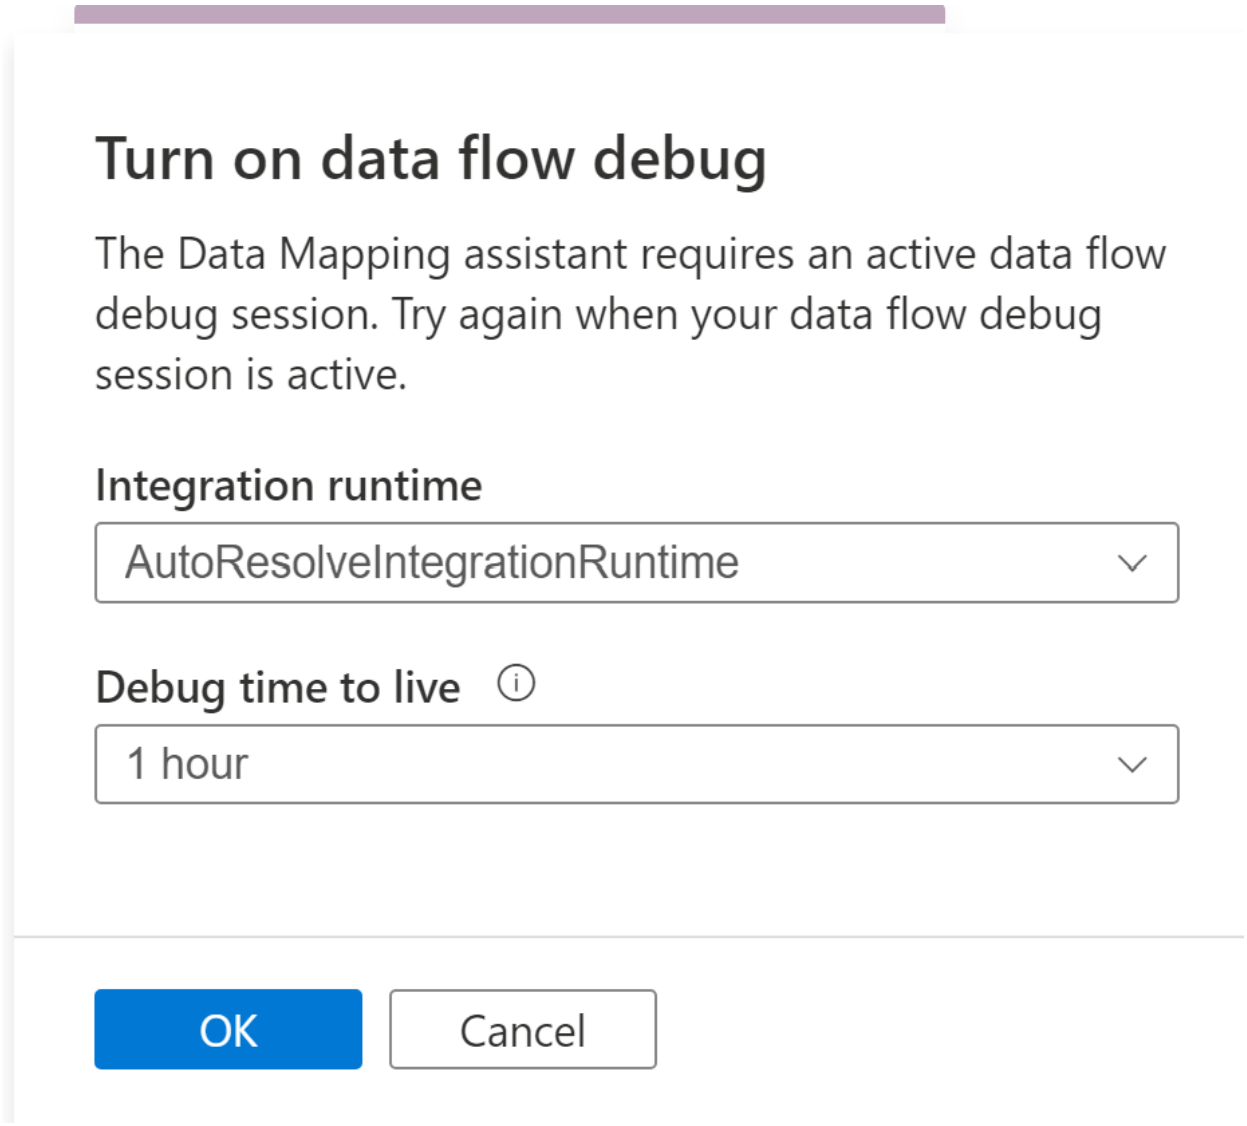
> **NOTE**
> The Map Data feature in Synapse Analytics pipelines is currently in public preview

Getting started

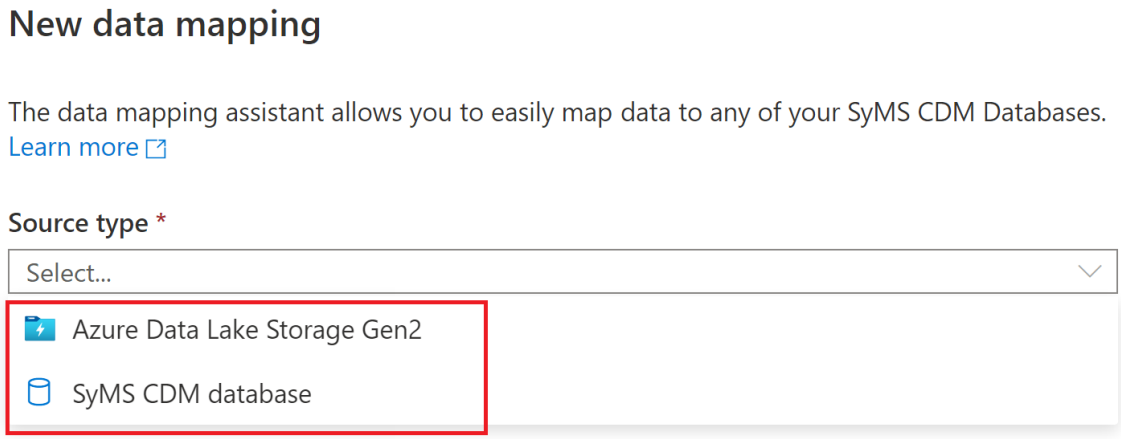
The Map Data tool is started from within the Synapse lake database experience. From here, you can select the Map Data tool to begin the process.



Map Data needs compute available to assist users with previewing data and reading schema of their source files. Upon using Map Data for the first time in a session you will need to warm up a cluster.



To begin, choose your data source that you want to map to your lake database tables. Currently supported data sources are Azure Data Lake Storage Gen 2 and Synapse lake databases.



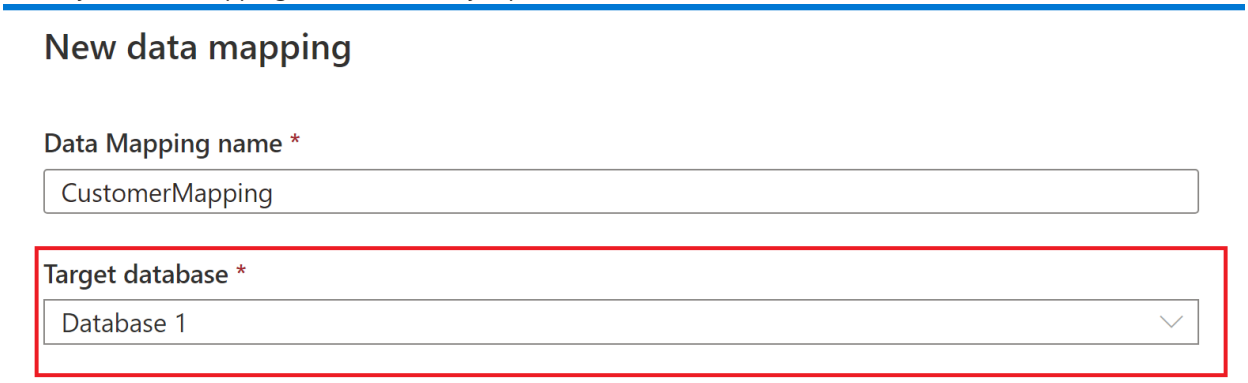
File type options

When choosing a file store such as Azure Data Lake Storage Gen 2 the following file types are supported:

- Common Data Model
- Delimited Text
- Parquet

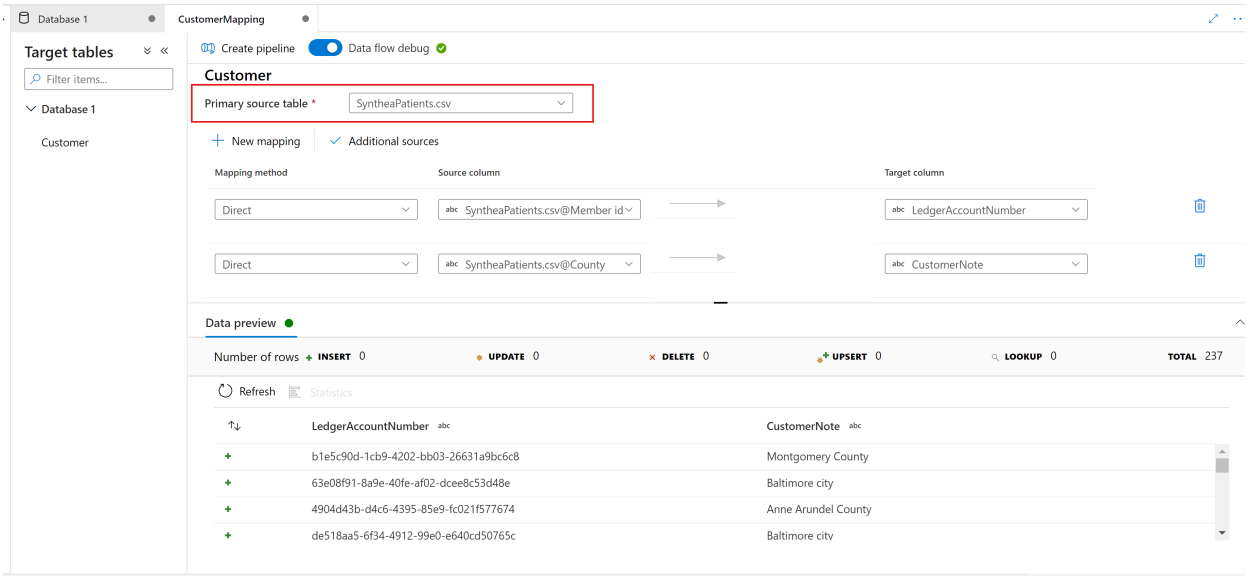
Create data mapping

Name your data mapping and select the Synapse lake database destination.



Source to target mapping

Choose a Primary source table to map to the Synapse lake database destination table.



New mapping

Use the New Mapping button to add a mapping method to create a mapping or transformation.

Additional source

Use the Additional source button to join to and add another source to your mapping.

Preview data

The **Data Preview** tab gives you an interactive snapshot of the data of each transform. For more information, see Data preview in debug mode.

Mapping methods

The following mapping methods are supported:

- Direct
- Surrogate Key
- Lookup
- Unpivot
- Aggregate

    - Sum
    - Minimum
    - Maximum
    - First
    - Last
    - Standard Deviation
    - Average
    - Mean
- Derived Column
    - Trim
    - Upper
    - Lower
    - Advanced

Create pipeline

Once you are done with your Map Data transformations select the Create pipeline button to generate a mapping data flow and pipeline to debug and run your transformation.

Quickstart: Create a new lake database leveraging database templates

8/19/2022 • 2 minutes to read • Edit Online

This quick start gives you a complete sample scenario on how you can apply database templates to create a lake database, align data to your new model, and use the integrated experience to analyze the data.

Prerequisites

- At least **Synapse User** role permissions are required for exploring a lake database template from Gallery.
- **Synapse Administrator**, or **Synapse Contributor** permissions are required on the Azure Synapse workspace for creating a lake database.
- **Storage Blob Data Contributor** permissions are required on data lake when using create table **From data lake** option.

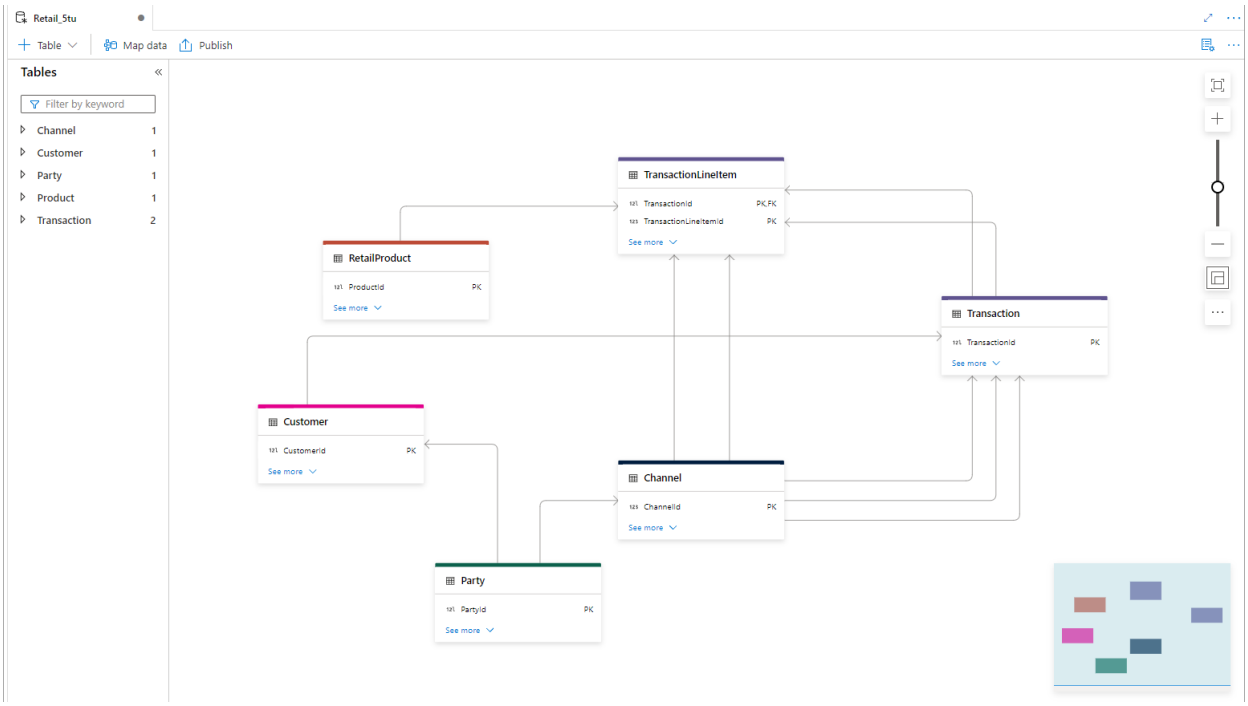
Create a lake database from database templates

Use the new database templates functionality to create a lake database that you can use to configure your data model for the database.

For our scenario we will use the `Retail` database template and select the following entities:

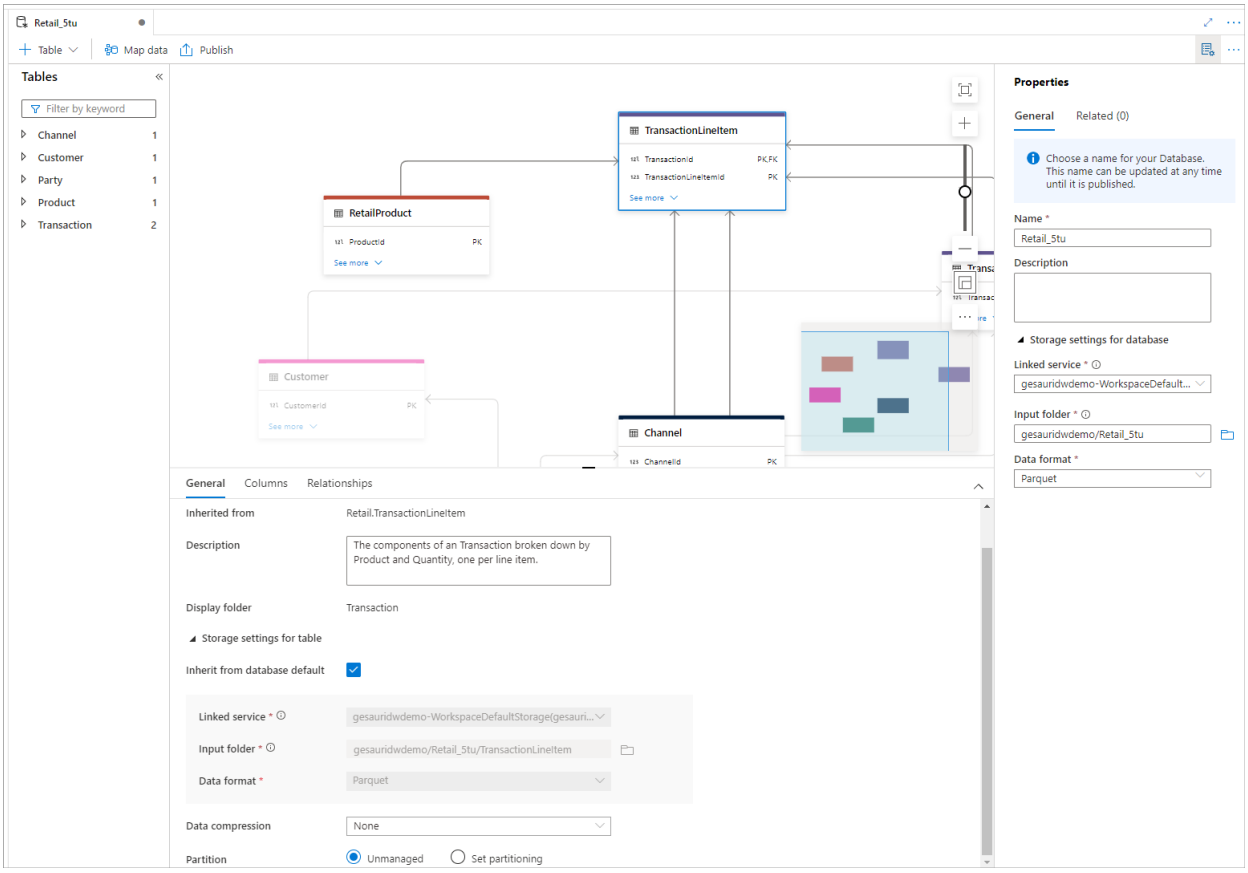
- **RetailProduct** - A product is anything that can be offered to a market that might satisfy a need by potential customers. That product is the sum of all physical, psychological, symbolic, and service attributes associated with it.
- **Transaction** - The lowest level of executable work or customer activity. A transaction consists of one or more discrete events.
- **TransactionLineItem** - The components of a Transaction broken down by Product and Quantity, one per line item.
- **Party** - A party is an individual, organization, legal entity, social organization, or business unit of interest to the business.
- **Customer** - A customer is an individual or legal entity that has or has purchased a product or service.
- **Channel** - A channel is a means by which products or services are sold and/or distributed.

The easiest way to find entities is by using the search box above the different business areas that contain the tables.



Configure lake database

After you have created the database, make sure the storage account and the filepath is set to a location where you wish to store the data. The path will default to the primary storage account within Azure Synapse Analytics but can be changed to your needs.



To save your layout and make it available within Azure Synapse, **Publish** all changes. This step completes the setup of the lake database and makes it available to all components within Azure Synapse Analytics and outside.

Ingest data to lake database

To ingest data to the lake database, you can execute pipelines with code free data flow mappings, which have a

Workspace DB connector to load data directly to the database table. You can also use the interactive Spark notebooks to ingest data to the lake database tables:

```
%%sql
INSERT INTO `retail_mil`.`customer` VALUES (1,'2021-02-18',1022,557,101,'Tailspin Toys (Head
Office)','Waldemar Fisar',90410,466);
```

Query the data

After the lake database is created, there are different ways to query the data. Currently, SQL databases in serverless SQL pools are supported and automatically understand the newly created lake database format.

```
SELECT TOP (100) [ProductId]
,[ProductName]
,[ProductDescription]
,[ProductInternalName]
,[ItemSku]
,[PrimaryBrandId]
FROM [Retail_mil].[dbo].[RetailProduct]
```

The other way to access the data within Azure Synapse is to open a new Spark notebook and use the integrated experience there:

```
df = spark.sql("SELECT * FROM `Retail_mil`.`RetailProduct`")
df.show(10)
```

Train machine learning models

You can use lake database to train your machine learning models and score the data. For more details Train machine learning models

- Lake database concept
- How to create a lake database

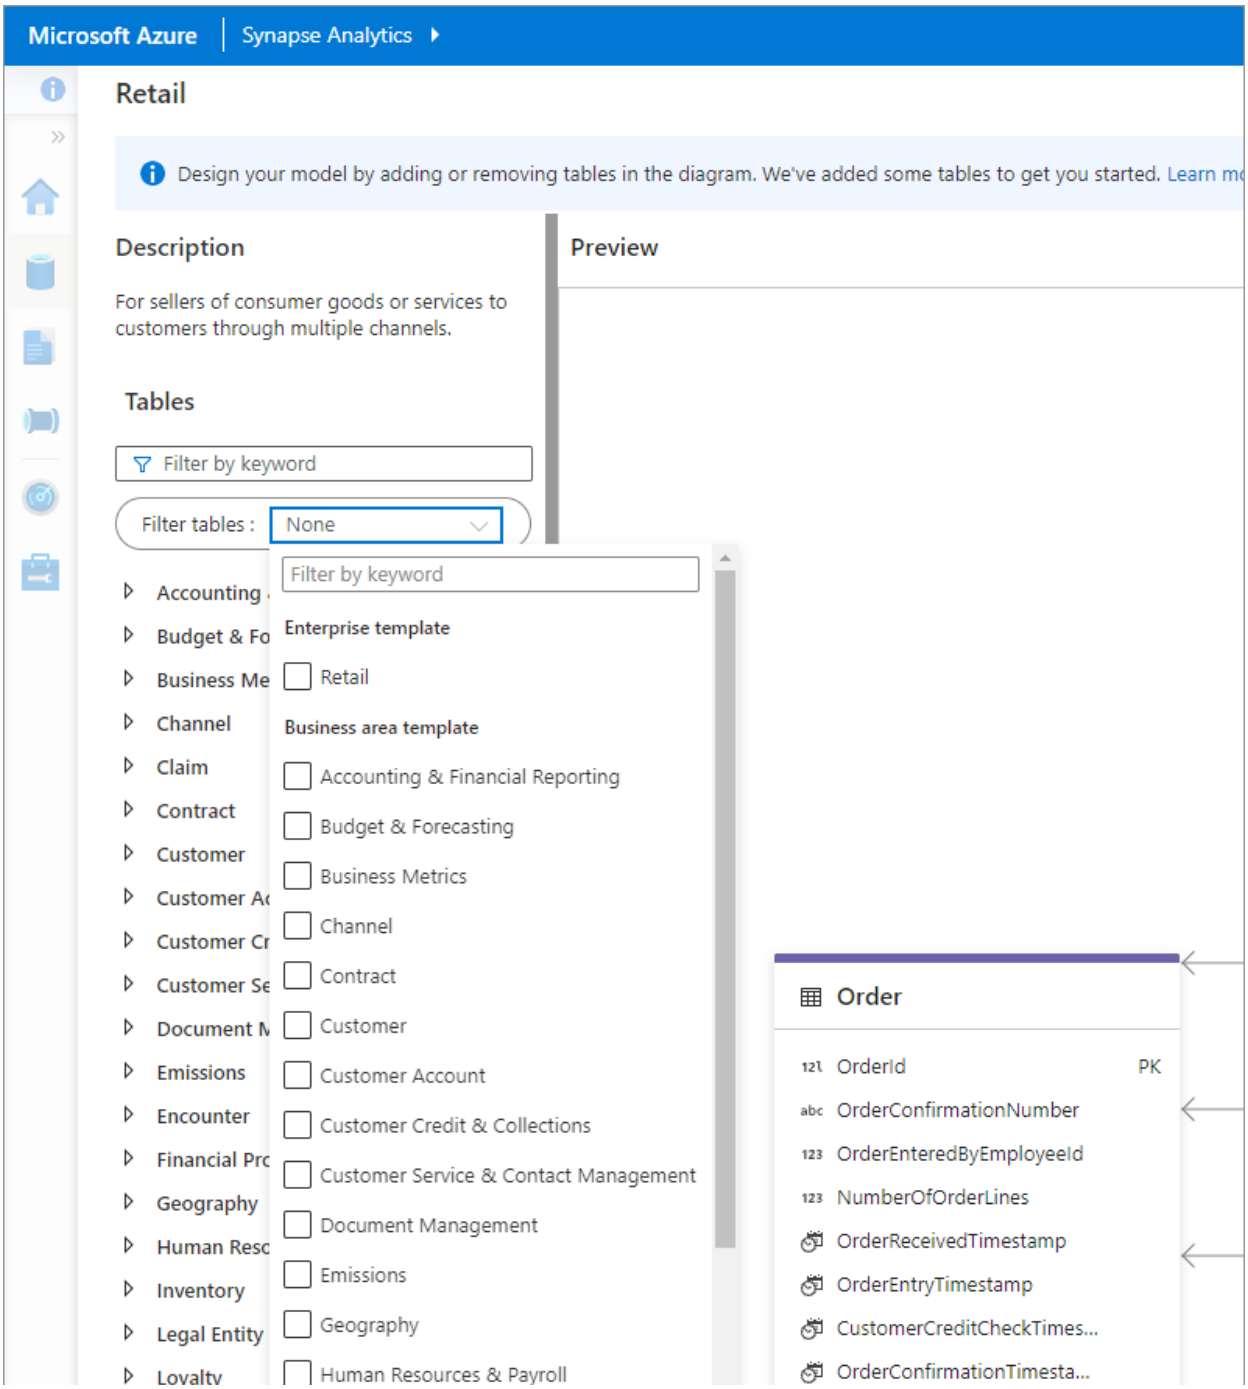
Lake database templates

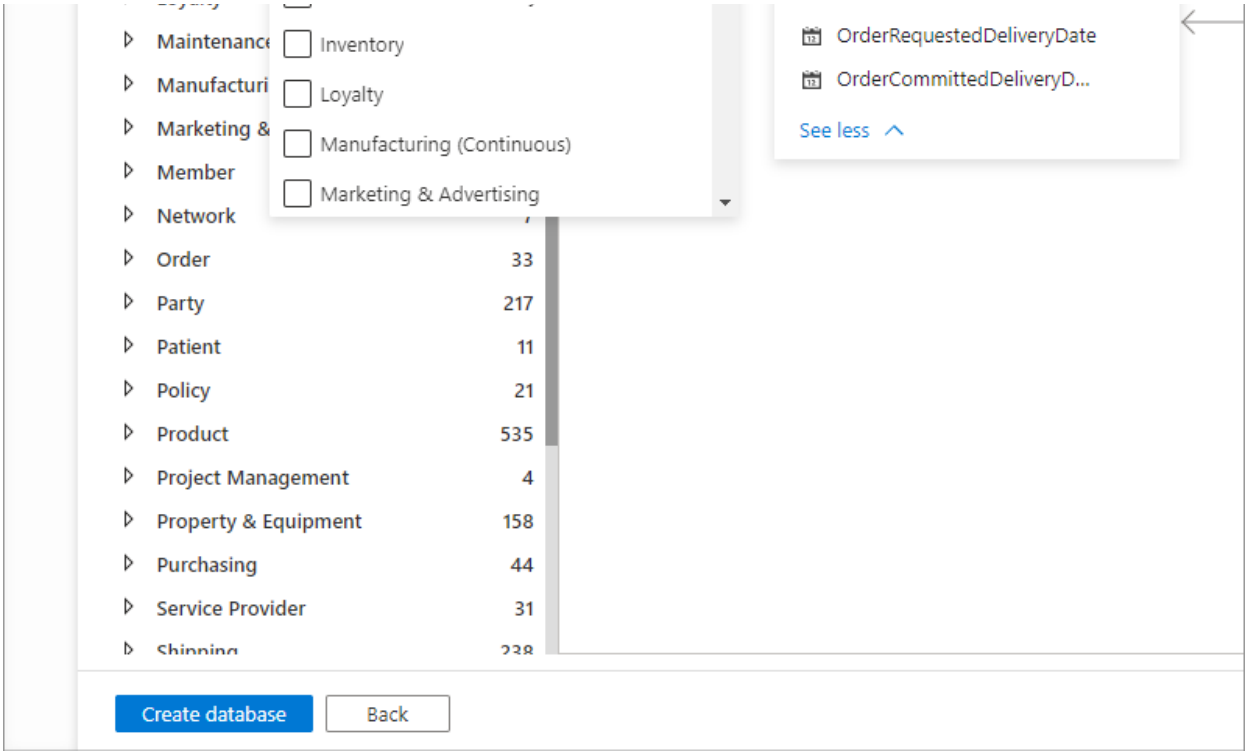
8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics provides industry specific database templates to help standardize data in the lake. These templates provide schemas for predefined business areas, enabling data to be loaded into a lake database in a structured way. Use these templates to create your lake database and use Azure Synapse analytical runtime to provide insights to business users.

Enterprise templates

Enterprise database templates contain a subset of tables that are most likely to be of interest to an organization within a specific industry. It provides a high-level overview and describes the connectivity between the related business areas. These templates serve as an accelerator for many types of large projects. For example, the retail template has one enterprise template called "Retail".





Table

A table is an object with an independent existence that can be differentiated from other objects. For example, Customer, Store, Channel, and so on.

Column

Each table is described by a set of columns that represent the values and data that make up the table. Each column has a name, description, data type and is associated with a table. There are around 30,000 columns in the database templates. For example, CustomerId is a column in the table Customer.

Primary key

The primary key helps to uniquely identify the whole table. It must uniquely identify tuples in a table. For example, a key on the CustomerId column enforces uniqueness, to identify each customer in the table Customer.

Foreign key

A foreign key is a column or a combination of columns whose values match a primary key in a different table. It helps to establish a link between two tables. For example, CustomerId in Transaction table represents a customer who has completed a transaction. A foreign key always has a relationship to a primary key, for example, to the CustomerId primary key in the Customer table.

Composite key

A composite key is one that is composed of two or more columns that are together required to uniquely identify a record in a table. For example, in an Order table, both OrderNumber and ProductId may be required to uniquely identify a record.

Relationships

Relationships are associations or interactions between any two tables. For example, the tables Customer and CustomerEmail are related to each other. There are two tables involved in a relationship. There's a parent table

and a child table, often connected by a foreign key. You might say that the relationship is From table To table.

Table partitions

Lake database allows for the underlying data to be partitioned for a table for better performance. You can set partition configuration in the storage settings of a table in database editor.

Next steps

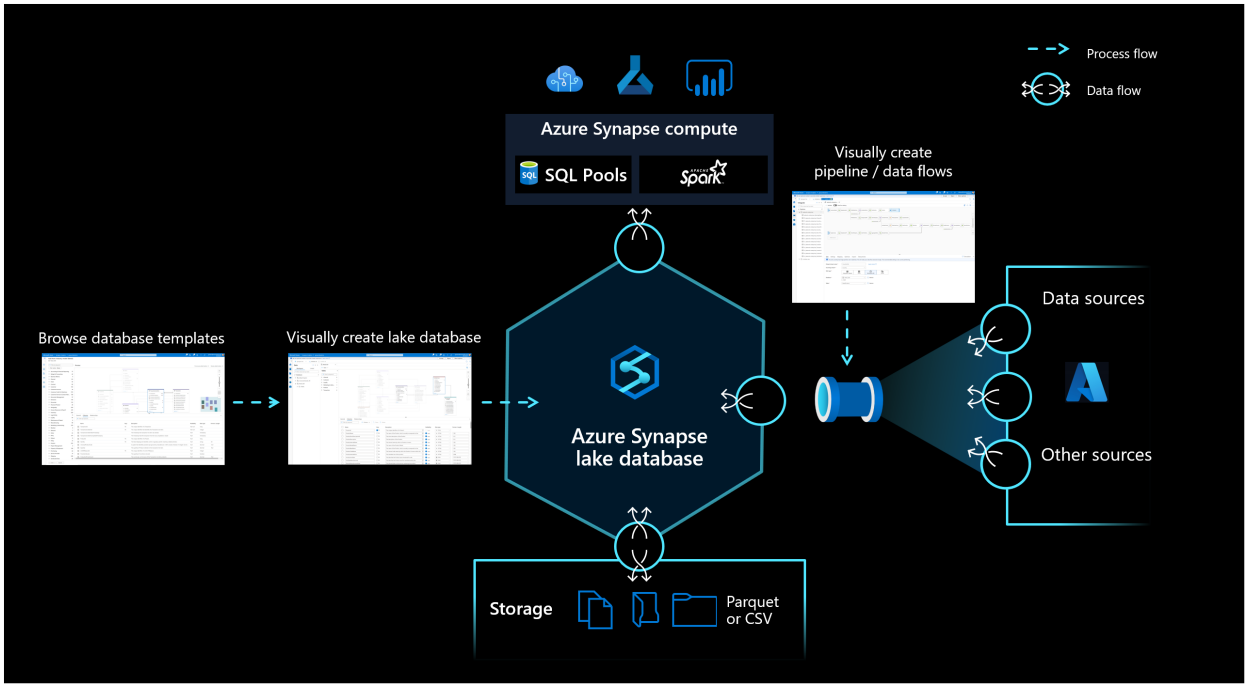
Continue to explore the capabilities of the database designer using the links below.

- Quick start
- Lake database Concept

Lake database

8/19/2022 • 2 minutes to read • Edit Online

The lake database in Azure Synapse Analytics enables customers to bring together database design, meta information about the data that is stored and a possibility to describe how and where the data should be stored. Lake database addresses the challenge of today's data lakes where it is hard to understand how data is structured.



Database designer

The new database designer gives you the possibility to create a data model for your lake database and add additional information to it. Every Entity and Attribute can be described to provide more information about the model, which not only contains Entities but relationships as well. In particular, the inability to model relationships has been a challenge for the interaction on the data lake. This challenge is now addressed with an integrated designer that provides possibilities that have been available in databases but not on the lake. Also the capability to add descriptions and possible demo values to the model allows people who are interacting with it in the future to have information where they need it to get a better understanding about the data.

Data storage

Lake databases use a data lake on the Azure Storage account to store the data of the database. The data can be stored in Parquet or CSV format and different settings can be used to optimize the storage. Every lake database uses a linked service to define the location of the root data folder. For every entity, separate folders are created by default within this database folder on the data lake. By default all tables within a lake database use the same format but the formats and location of the data can be changed per entity if that is requested.

Database compute

The lake database is exposed in Synapse SQL serverless SQL pool and Apache Spark providing users with the capability to decouple storage from compute. The metadata that is associated with the lake database makes it easy for different compute engines to not only provide an integrated experience but also use additional

information (for example, relationships) that was not originally supported on the data lake.

Next steps

Continue to explore the capabilities of the database designer using the links below.

- Create lake database quick start
- Database templates Concept

How-to: Create an empty lake database

8/19/2022 • 4 minutes to read • Edit Online

In this article, you'll learn how to create an empty lake database in Azure Synapse Analytics using the database designer. The database designer allows you to easily create and deploy a database without writing any code.

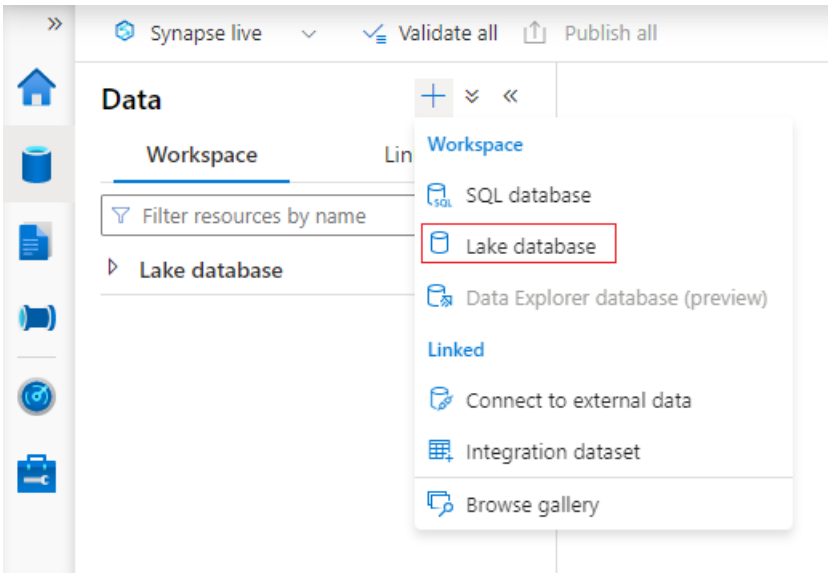
Prerequisites

- At least Synapse User role permissions are required for exploring a lake database template from Gallery.
- Synapse Administrator, Synapse Contributor, or Synapse Artifact Publisher permissions are required on the Synapse workspace for creating a lake database.
- Storage Blob Data Contributor permissions are required on data lake when using the create table **From data lake** option.

Create lake database from database template

1. From your Azure Synapse Analytics workspace **Home** hub, select the **Data** tab on the left. The **Data** tab will open and you will see the list of databases that already exist in your workspace.

2. Hover over the **+** button and select, then choose **Lake database**.



3. The database designer tab will open with an empty database.

4. The database designer has **Properties** on the right that need to be configured.

   - **Name** - Give your database a name. Names cannot be edited after the database is published, so make sure the name you choose is correct.
   - **Description** - Giving your database a description is optional, but it allows users to understand the purpose of the database.
   - **Storage settings for database** - This section contains the default storage information for tables in the database. This default is applied to each table in the database unless it's overridden on the table itself.
   - **Linked service** - It's the default linked service used to store your data in Azure Data Lake Storage. The default linked service associated with the Synapse workspace will be shown, but you can change the **Linked Service** to any ADLS storage account you like.

- **Input folder** - Used to set the default container and folder path within that linked service using the file browser.
- **Data format** - Lake databases in Azure Synapse support parquet and delimited text as the storage formats for data.

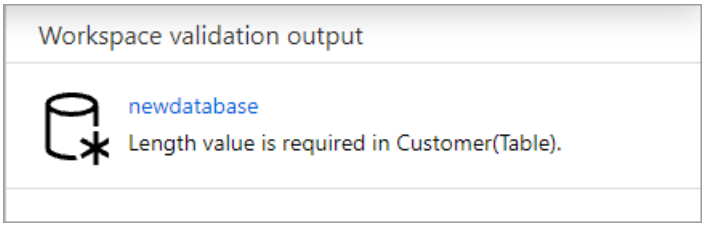
> **NOTE**
> You can always override the default storage settings on a table by table basis, and the default remains customizable. If you are not sure what to choose, you can revisit this later.

5. To add a table to the database, select the **+ Table** button.
   - **Custom** will add a new table to the canvas.
   - **From template** will open the gallery and let you select a database template to use when adding a new table. For more information, see Create lake database from database template.
   - **From data lake** lets you import a table schema using data already in your lake.
6. Select **Custom**. A new table will appear on the canvas called Table_1.
7. You can then customize Table_1, including the table name, description, storage settings, columns, and relationships. For more information, see Modify a lake database.
8. Add a new table from the data lake by selecting **+ Table** and then **From data lake**.
9. The **Create external table from data lake** pane will appear. Fill out the pane with the below details and select **Continue**.
   - **External table name** the name you want to give the table you're creating.
   - **Linked service** the linked service containing the Azure Data Lake Storage location where your data file lives.
   - **Input file or folder** use the file browser to navigate to and select a file on your lake you want to create a table using.

   - On the next screen, Azure Synapse will preview the file and detect the schema.
   - You'll land on the **New external table** page where you can update any settings related to the data format, and **Preview Data** to check if Synapse identified the file correctly.
   - When you're happy with the settings, select **Create**.
   - A new table with the name you selected will be added to the canvas, and the **Storage settings for table** section will show the file that you specified.
10. With the database customized, it's now time to publish it. If you're using Git integration with your Synapse workspace, you must commit your changes and merge them into the collaboration branch. Learn more about source control in Azure Synapse. If you're using Synapse Live mode, you can select

"publish".

- Your database will be validated for errors before it's published. Any errors found will be showing in the notifications tab with instructions on how to remedy the error.



- Publishing will create your database schema in the Azure Synapse Metastore. After publishing, the database and table objects will be visible to other Azure services and allow the metadata from your database to flow into apps like Power BI or Microsoft Purview.

11. You've now created an empty lake database in Azure Synapse, and added tables to it using the **Custom** and **From data lake** options.

Next steps

Continue to explore the capabilities of the database designer using the links below.

- Modify a lake database
- Learn more about lake databases
- Create a lake database from lake database template

How-to: Create a lake database from database templates

8/19/2022 • 5 minutes to read • Edit Online

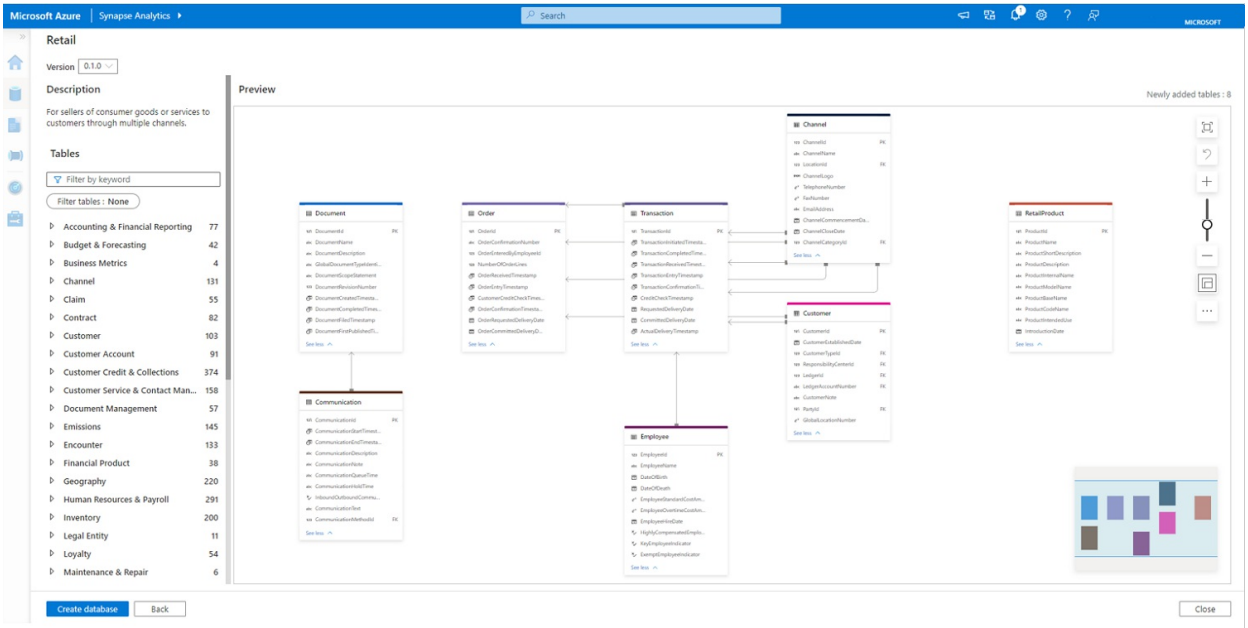
In this article, you'll learn how to use the Azure Synapse database templates to simplify the creation of a lake database. Using database templates provides your database with rich semantic information, allowing end users of the data to more easily understand what data is available and how to use it.

Prerequisites

- At least Synapse User role permissions are required for exploring a lake database template from Gallery.
- Synapse Administrator, or Synapse Contributor permissions are required on the Synapse workspace for creating a lake database.
- Storage Blob Data Contributor permissions are required on data lake when using the create table **From data lake** option.

Create lake database from database template

1. From your Azure Synapse Analytics workspace **Home** hub, select **Knowledge center** and then **Browse gallery**. You'll land on the **Lake database templates** tab.
2. **Lake database templates** category lists standardized database templates available for a specific industry.
   a. You can also visit the **Lake database templates** tab from **Data** hub, **+** Add new resource, **Browse gallery** menu.
3. Select the industry you're interested in (for example, **Retail**) and select **Continue** to navigate to the exploration of the data model.
4. You'll land on the database canvas and can explore the tables available in the template. By default, the canvas will show a selection of the most used tables in that template. The canvas has various tools to help you navigate the entity-relationship diagram.
   - **Zoom to fit** to fit all tables on the canvas in the viewing area
   - **Undo last action** to undo **one** recent change
   - **Increase zoom** to zoom in to the canvas
   - **Decrease zoom** to zoom out of the canvas
   - **Zoom slider** to control the zoom level
   - **Zoom preview** to provide a preview of the canvas
   - **Expand all/Collapse all** to view more or less columns within a table on the canvas
   - **Clear canvas** to clear-off all the tables on the canvas

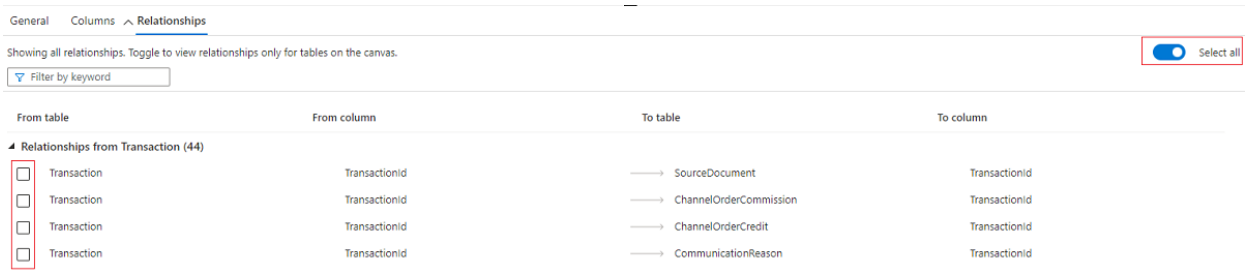


5. On the left, you'll see list of folders containing the items of the template you can add to the canvas. There are several controls to help.

   - **Search box** to search for tables based on a term. The term will be searched across the template tables, columns, and descriptions.
   - **Filter tables** to select whole sections of the model to explore
     - **Enterprise templates** select tables from each **Business area** to show a "best-of".
     - **Business area templates** select tables primarily from a single **Business area** but also include related tables from other **Business areas**.
   - **Business areas** are folders containing tables related to that business construct. For example, Budget & Forecasting contains tables related to managing budgets.
   - You can expand business area folders to view the tables, and select the checkbox to add them to the canvas.
   - Selected tables can be removed via the checkbox.
   - You can also click on the ellipses next to the business area folder and **Select All** or **UnSelect All** to add/remove all tables under that business area to the canvas.

6. You can select a table on the canvas. It opens the table properties pane with the tabs General, Columns, and Relationships.

   - The General tab has information on the table such as its name and description.
   - The Columns tab has the details about all the columns that make up the table such as column names and datatypes.
   - The Relationships tab lists the incoming and outgoing relationships of the table with other tables on the canvas.
     - Use the **Select all** toggle to view all the 'from' & 'to' relationships to that table.
     - Using the check boxes next to each relationship in the relationship tab, add the required table - relationship to the canvas.



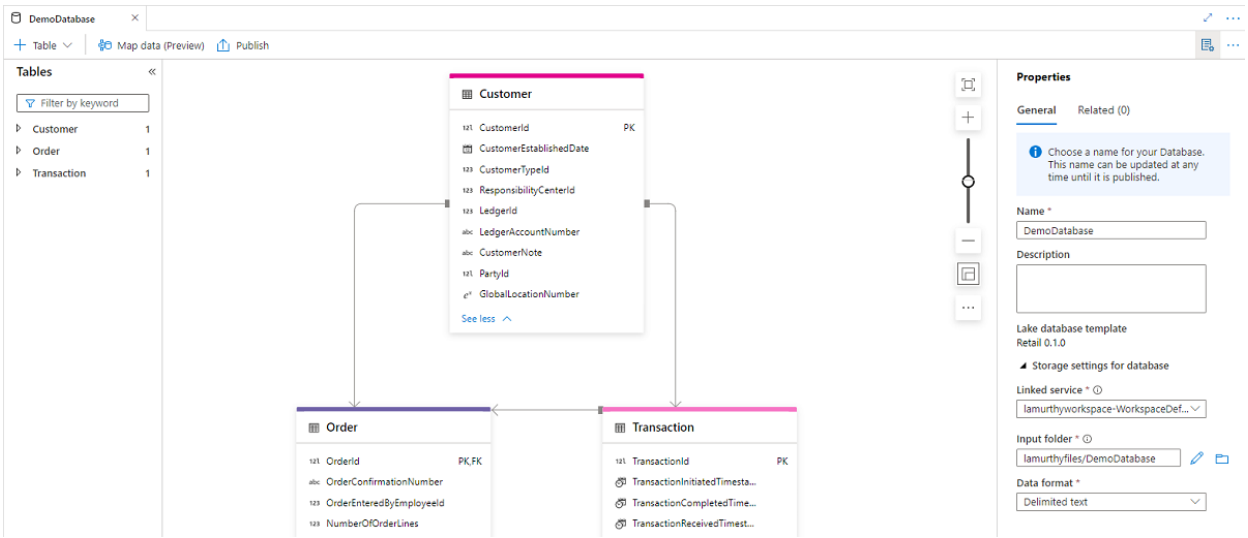
7. To quickly add tables that are related to the tables on canvas, select the ellipses to the right of the table name and then select **Add related tables**. All tables with existing relationships are added to the canvas. If this adds too many tables to the canvas, use the **Undo Last Action** to undo this change.

8. Once the canvas has all the tables that meet your requirements, select **Create database** to continue with creation of lake database. The new database will show up in the database designer and you can customize it per your business needs.

9. The database designer has more **Properties** on the right that need to be configured.

   - **Name** give your database a name. Names cannot be edited after the database is published, so make sure the name you choose is correct.
   - **Description** Giving your database a description is optional, but it allows users to understand the purpose of the database.
   - **Storage settings for database** is a section containing the default storage information for tables in the database. This default is applied to each table in the database unless it's overridden on the table itself.
   - **Linked service** is the default linked service used to store your data in Azure Data Lake Storage. The default linked service associated with the Synapse workspace will be shown, but you can change the **Linked Service** to any ADLS storage account you like.
   - **Input folder** used to set the default container and folder path within that linked service using the file browser or manually editing the path with the pencil icon.
   - **Data format** lake databases in Azure Synapse support parquet and delimited text as the storage formats for data.

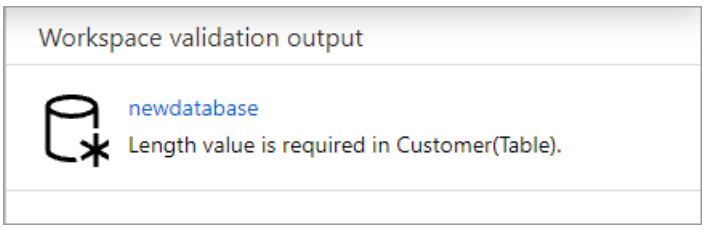
> **NOTE**
>
> You can always override the default storage settings on a table by table basis, and the default remains customizable. If you are not sure what to choose, you can revisit this later. If you are unsure of the folder hierarchy in the data lake, you can also specify wildcards to traverse the directory structure.



10. You can begin to customize tables, columns, and relationships inherited from the database template. You can also add custom tables, columns, relationships as needed in the database. For more information on modifying a lake database, see Modify a lake database.

11. With the database customized, it's now time to publish it. If you're using Git integration with your Synapse workspace, you must commit your changes and merge them into the collaboration branch. Learn more about source control in Azure Synapse. If you're using Synapse Live mode, you can select **Publish**.

- Your database will be validated for errors before it's published. Any errors found will be showing in the notifications tab with instructions on how to remedy the error.



- Publishing will create your database schema in the Azure Synapse Metastore. After publishing, the database and table objects will be visible to other Azure services and allow the metadata from your database to flow into apps like Power BI or Microsoft Purview.

12. You've now created a lake database using a lake database template in Azure Synapse.

- Modify a lake database
- Learn more about lake databases

How-to: Modify a lake database

8/19/2022 • 10 minutes to read • Edit Online

In this article, you'll learn how to modify an existing lake database in Azure Synapse using the database designer. The database designer allows you to easily create and deploy a database without writing any code.

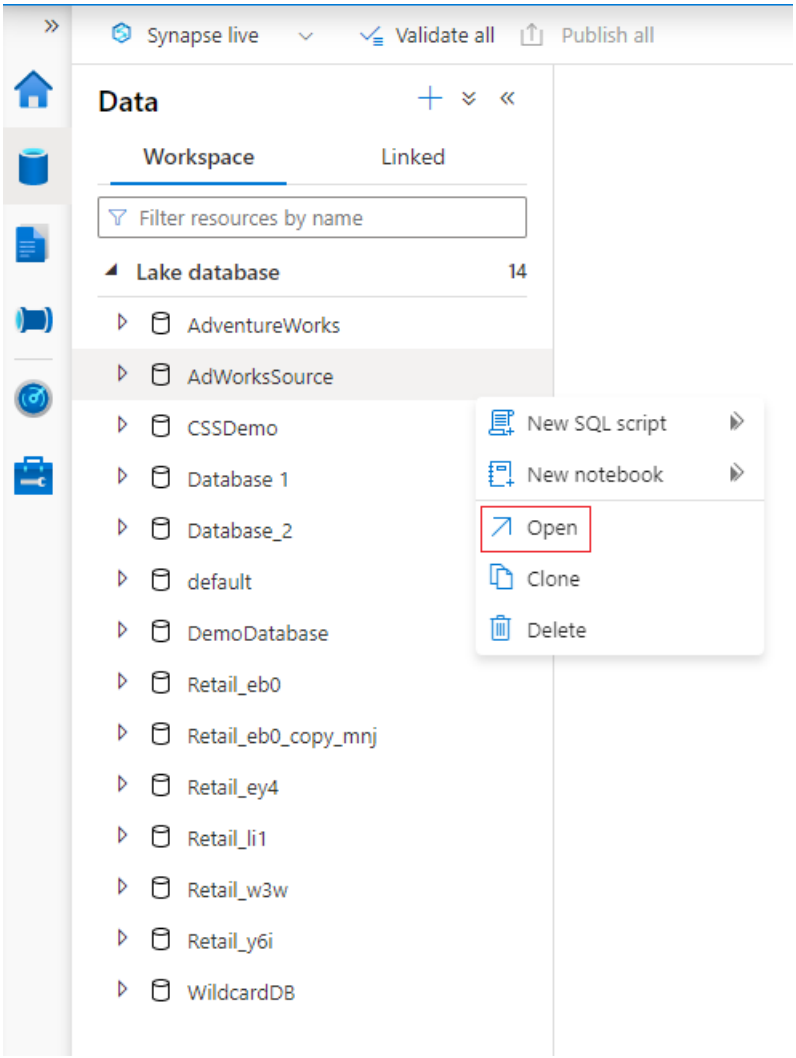
Prerequisites

- Synapse Administrator, or Synapse Contributor permissions are required on the Synapse workspace for creating a lake database.
- Storage Blob Data Contributor permissions are required on data lake when using the create table **From data lake** option.

Modify database properties

1. From your Azure Synapse Analytics workspace **Home** hub, select the **Data** tab on the left. The **Data** tab will open you'll see the list of databases that already exist in your workspace.

2. Hover over the **Databases** section and select the ellipsis **...** next to the database you want to modify, then choose **Open**.



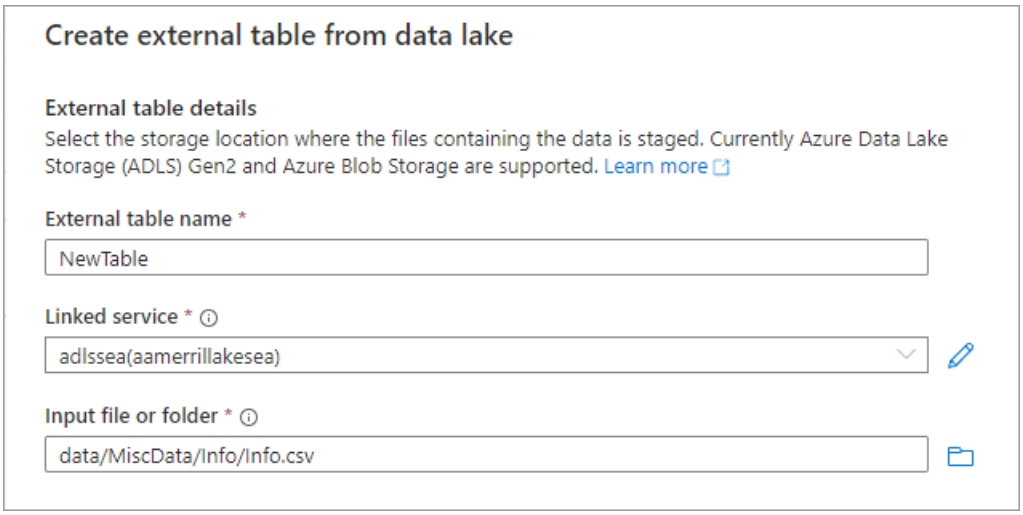
3. The database designer tab will open with your selected database loaded on the canvas.

4. The database designer has **Properties** pane that can be opened by selecting the **Properties** icon in the upper right of the tab.

   - **Name** Names cannot be edited after the database is published, so make sure the name you choose is correct.
   - **Description** Giving your database a description is optional, but it allows users to understand the purpose of the database.
   - **Storage settings for database** is a section containing the default storage information for tables in the database. The default settings are applied to each table in the database unless it's overridden on the table itself.
   - **Linked service** is the default linked service used to store your data in Azure Data Lake Storage. The default linked service associated with the Synapse workspace will be shown, but you can change the **Linked Service** to any ADLS storage account you like.
   - **Input folder** used to set the default container and folder path within that linked service using the file browser or manually editing the path with the pencil icon.
   - **Data format** lake databases in Azure Synapse support parquet and delimited text as the storage formats for data.
5. To add a table to the database, select the **+ Table** button.

   - **Custom** will add a new table to the canvas.
   - **From template** will open the gallery and let you select a database template to use when adding a new table. For more information, see Create lake database from database template.
   - **From data lake** lets you import a table schema using data already in your lake.
6. Select **Custom**. A new table will appear on the canvas called Table_1.
7. You can then customize Table_1, including the table name, description, storage settings, columns, and relationships. See the Customize tables within a database section below.
8. Add a new table from the data lake by selecting **+ Table** and then **From data lake**.
9. The **Create external table from data lake** pane will appear. Fill out the pane with the below details and select **Continue**.

   - **External table name** the name you want to give the table you're creating.
   - **Linked service** the linked service containing the Azure Data Lake Storage location where your data file lives.
   - **Input file or folder** use the file browser to navigate to and select a file on your lake you want to create a table using.



- On the next screen, Azure Synapse will preview the file and detect the schema.
- You'll land on the **New external table** page where you can update any settings related to the data format, and **Preview Data** to check if Azure Synapse identified the file correctly.
- When you're happy with the settings, select **Create**.
- A new table with the name you selected will be added to the canvas, and the **Storage settings for table** section will show the file that you specified.

10. With the database customized, it's now time to publish it. If you're using Git integration with your Synapse workspace, you must commit your changes and merge them into the collaboration branch. Learn more about source control in Azure Synapse. If you're using Synapse Live mode, you can select "publish".

    - Your database will be validated for errors before it's published. Any errors found will be showing in the notifications tab with instructions on how to remedy the error.

    - Publishing will create your database schema in the Azure Synapse Metastore. After publishing, the database and table objects will be visible to other Azure services and allow the metadata from your database to flow into apps like Power BI or Microsoft Purview.

Customize tables within a database

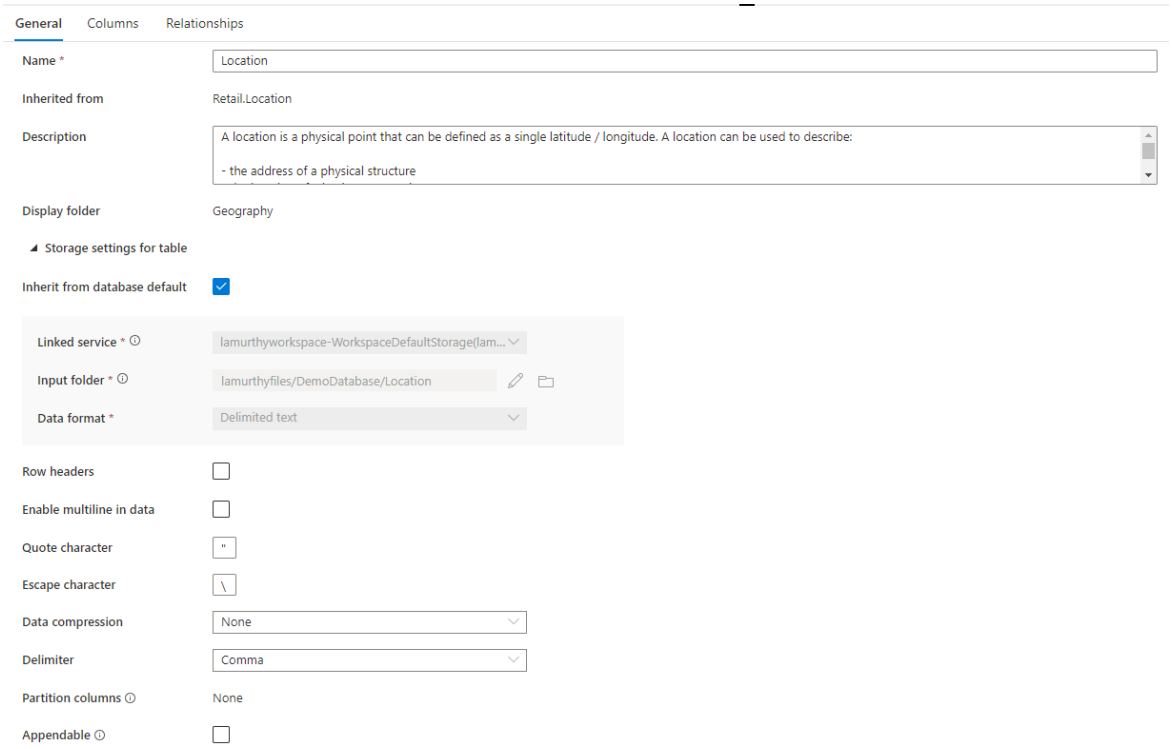
The database designer allows you to fully customize any of the tables in your database. When you select a table there are three tabs available, each containing settings related to the table's schema or metadata.

General

The **General** tab contains information specific to the table itself.

- **Name** the name of the table. The table name can be customized to any unique value within the database. Multiple tables with the same name aren't allowed.
- **Inherited from** (optional) this value will be present if the table was created from a database template. It cannot be edited and tells the user which template table it was derived from.
- **Description** a description of the table. If the table was created from a database template, this will contain a description of the concept represented by this table. This field is editable and can be changed to match the description that matches your business requirements.

- **Display folder** provides the name of the business area folder this table was grouped under as part of the database template. For custom tables, this value will be "Other".

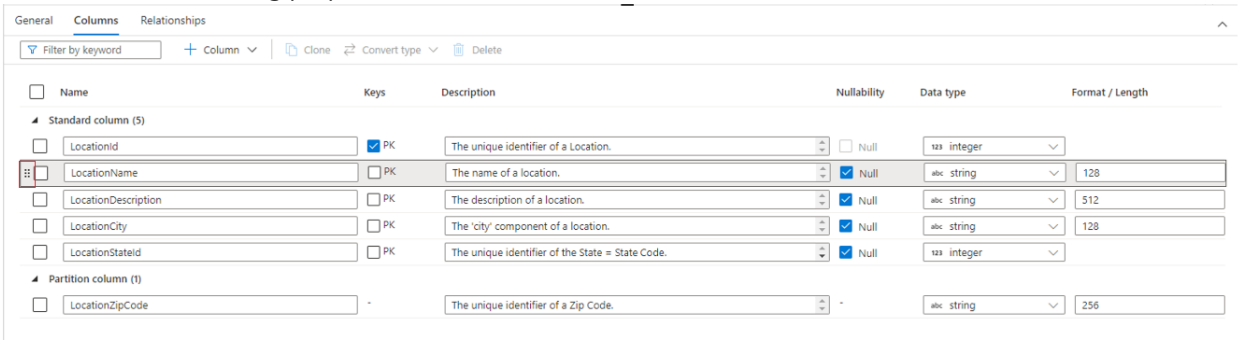


- In addition, there is a collapsible section called **Storage settings for table** that provides settings for the underlying storage information used by the table.
- **Inherit from database default** a checkbox that determines whether the storage settings below are inherited from the values set in the database **Properties** tab, or are set individually. If you want to customize the storage values, uncheck this box.
    - **Linked service** is the default linked service used to store your data in Azure Data Lake Storage. Change this to pick a different ADLS account.
    - **Input folder** the folder in ADLS where the data loaded to this table will live. You can either browse the folder location or edit it manually using the pencil icon.
    - **Data format** the data format of the data in the **Input folder** Lake databases in Azure Synapse support parquet and delimited text as the storage formats for data. If the data format doesn't match the data in the folder, queries to the table will fail.
- For a **Data format** of Delimited text, there are further settings:
    - **Row headers** check this box if the data has row headers.
    - **Enable multiline in data** check this box if the data has multiple lines in a string column.
    - **Quote Character** specify the custom quote character for a delimited text file.
    - **Escape Character** specify the custom escape character for a delimited text file.
    - **Data compression** the compression type used on the data.
    - **Delimiter** the field delimiter used in the data files. Supported values are: Comma (,), tab (\t), and pipe (|).
    - **Partition columns** the list of partition columns will be displayed here.
    - **Appendable** check this box if you are querying Dataverse data from SQL Serverless.
- For Parquet data, there's the following setting:
    - **Data compression** the compression type used on the data.

Columns

The **Columns** tab is where the columns for the table are listed and can be modified. On this tab are two lists of

columns: **Standard columns** and **Partition columns**. **Standard columns** are any column that stores data, is a primary key, and otherwise isn't used for the partitioning of the data. **Partition columns** store data as well, but are used to partition the underlying data into folders based on the values contained in the column. Each column has the following properties.

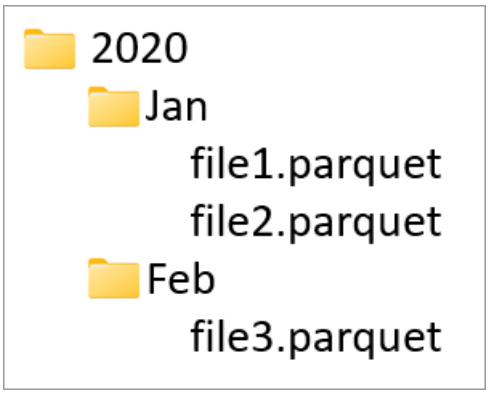


- **Name** the name of the column. Must be unique within the table.
- **Keys** indicates whether the column is a primary key (PK) and/or foreign key (FK) for the table. Not applicable to partition columns.
- **Description** a description of the column. If the column was created from a database template, the description of the concept represented by this column will be seen. This field is editable and can be changed to match the description that matches your business requirements.
- **Nullability** indicates whether there can be null values in this column. Not applicable to partition columns.
- **Data type** sets the data type for the Column based on the available list of Spark data types.
- **Format / Length** allows for customizing the format or maximum length of the column, depending on the data type. Date and timestamp data types have format dropdowns, and other types like string have a maximum length field. Not all data types have a value as some types are fixed length. At the top of the **Columns** tab is a command bar that can be used to interact with the columns.
- **Filter by keyword** filters the list of columns to items that match the keyword specified.
- **+ Column** lets you add a new column. There are three possible options.
  - **New column** creates a new custom standard column.
  - **From template** opens the exploration pane and lets you identify columns from a database template to include on your table. If your database wasn't created using a database template, this option will not appear.
  - **Partition column** adds a new custom partition column.
- **Clone** duplicates the selected column. Cloned columns are always of the same type as the selected column.
- **Convert type** is used to change the selected **standard column** to a **partition column** and the other way around. This option will be grayed out if you have selected multiple columns of different types or the selected column is ineligible to be converted because of a **PK** or **Nullability** flag set on the column.
- **Delete** deletes the selected columns from the table. This action is irreversible.

You can also re-arrange the order of the columns by drag and drop using the double vertical ellipses that show up on the left of the column name when you hover over or click on the column as shown in the image above.

Partition Columns

Partition columns are used to partition the physical data in your database based on values in those columns. Partition columns allow an easy way to distribute data on disk into more performant chunks. Partition columns in Azure Synapse are always at the end of the table schema. In addition, they are used from top to bottom when creating the partition folders. For example, if your partition columns were Year and Month, you would end up with a structure in ADLS like this:

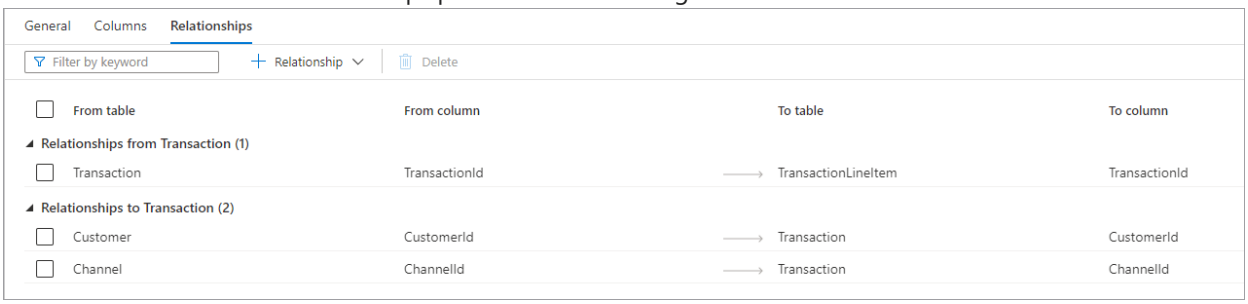


Where file1 and file2 contained all the rows where the values of Year and Month were 2020 and Jan respectively. As more partition columns are added to a table, the more files are added to this hierarchy, making the overall file size of the partitions smaller.

Azure Synapse doesn't enforce or create this hierarchy by adding partition columns to a table. Data must be loaded into the table using either Synapse Pipelines or a Spark notebook in order for the partition structure to be created.

Relationships

The relationships tab lets you specify relationships between tables in the database. Relationships in the database designer are informational, and don't enforce any constraints on the underlying data. They're read by other Microsoft applications can be used to accelerate transformations or provide business users insight into how tables are connected. The relationships pane has the following info.



- **Relationships from (Table)** is when one or more tables have foreign keys connected to this table. This is sometimes called a parent relationship.
- **Relationships to (Table)** is when a table that has foreign key and is connected to other table. This is sometimes called a child relationship.
- Both relationship types have the following properties.
  - **From table** the parent table in the relationship, or the "one" side.
  - **From column** the column in the parent table the relationship is based on.
  - **To table** the child table in the relationship, or the "many" side.
  - **To column** the column in the child table the relationship is based on. At the top of the **Relationships** tab, is the command bar that can be used to interact with the relationships
- **Filter by keyword** filters the list of columns to items that match the keyword specified.
- **+ Relationship** lets you add a new relationship. There are two options.
  - **From table** creates a new relationship from the table you're working on to a different table.
  - **To table** creates a new relationship from a different table to the one you're working on.
  - **From template** opens the exploration pane and lets you pick from relationships in the database template to include in your database. If your database wasn't created using a database template, this option won't appear.

- Create an empty lake database
- Clone a lake database
- Create a lake database from lake database template

How-to: Clone a lake database

8/19/2022 • 2 minutes to read • Edit Online

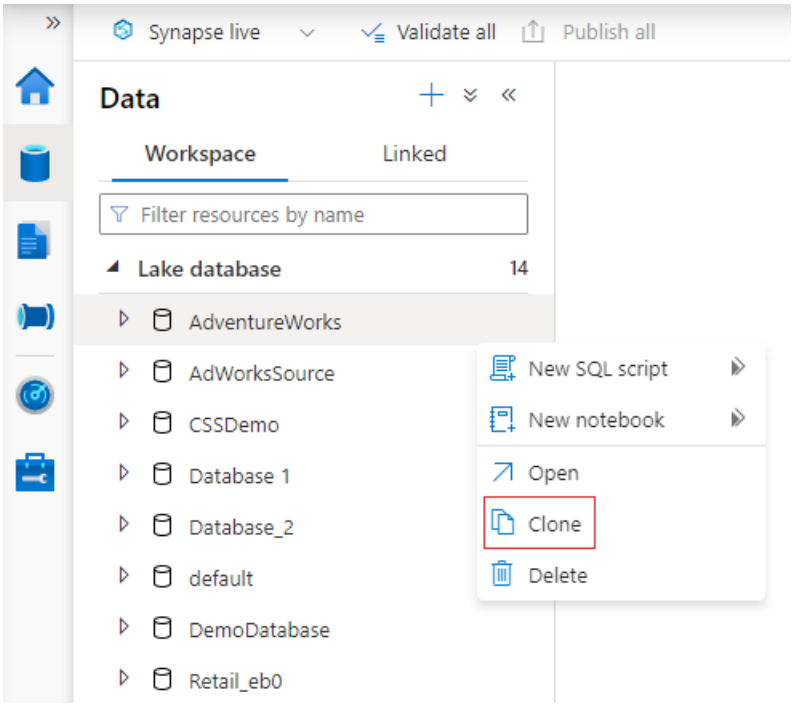
In this article, you'll learn how to clone an existing lake database in Azure Synapse using the database designer. The database designer allows you to easily create and deploy a database without writing any code.

Prerequisites

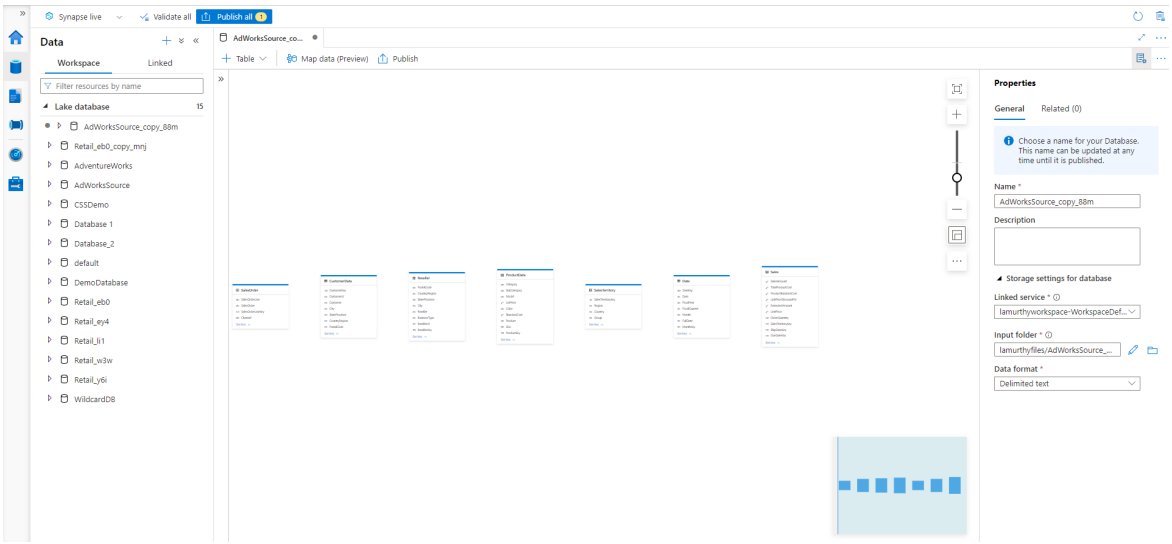
- Synapse Administrator, or Synapse Contributor permissions are required on the Synapse workspace for creating a lake database.

Clone database

1. From your Azure Synapse Analytics workspace **Home** hub, select the **Data** tab on the left. The **Data** tab will open. You'll see the list of databases that already exist in your workspace.
2. Hover over the **Databases** section and select the ellipsis **...** next to the database you want to clone, then choose **Clone**.



3. The database designer tab will open with a copy of the selected database loaded on the canvas.
4. The database designer opens the **Properties** pane by default. Update the details for this cloned lake database.



- **Name** Provide a new name for this database. Note that this name cannot be changed once the lake database is published.
- **Description** Give your database a description (optional).
- **Storage settings for database** provide the default storage information for tables in the database. The default settings are applied to each table in the database unless it's overridden on the table itself.
- **Linked service** provide the default linked service used to store your data in Azure Data Lake Storage. The default linked service associated with the Synapse workspace will be shown, but you can change the **Linked Service** to any ADLS storage account you like.
- **Input folder** set the default container and folder path within that linked service using the file browser or manually editing the path with the pencil icon.
- **Data format** select the data format. Lake databases in Azure Synapse support parquet and delimited text as the storage formats for data.

5. You can add additional tables to this cloned database by selecting the **+ Table** button. For more information, see Modify lake database.

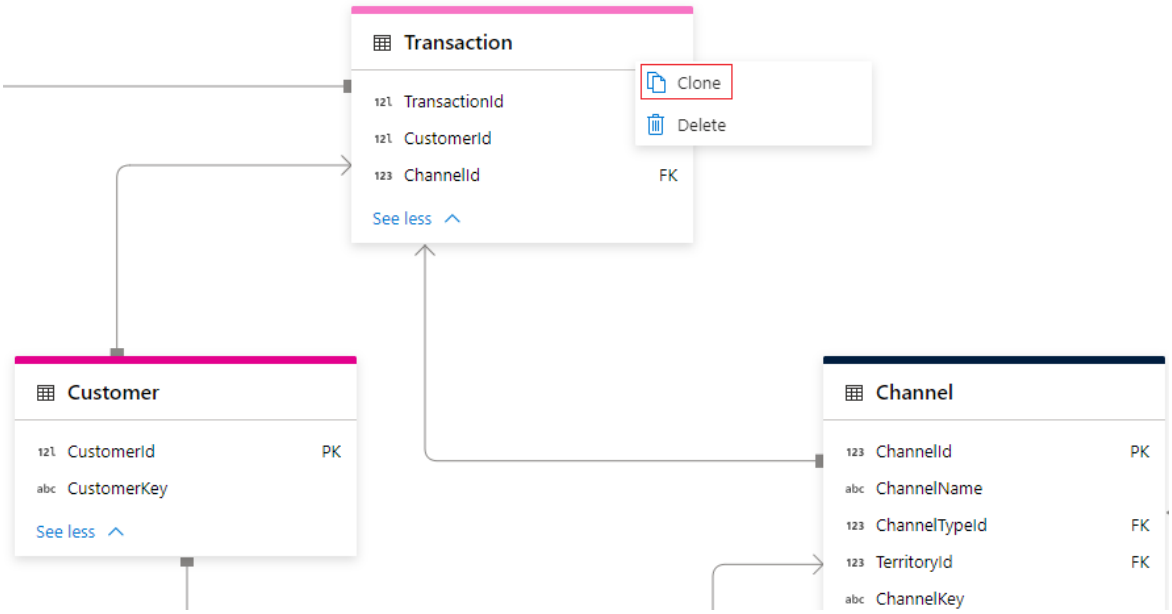
6. Once you have completed all the changes to your cloned database, it's now time to publish it. If you're using Git integration with your Synapse workspace, you must commit your changes and merge them into the collaboration branch. Learn more about source control in Azure Synapse. If you're using Synapse Live mode, you can select "publish".

Clone tables within a lake database

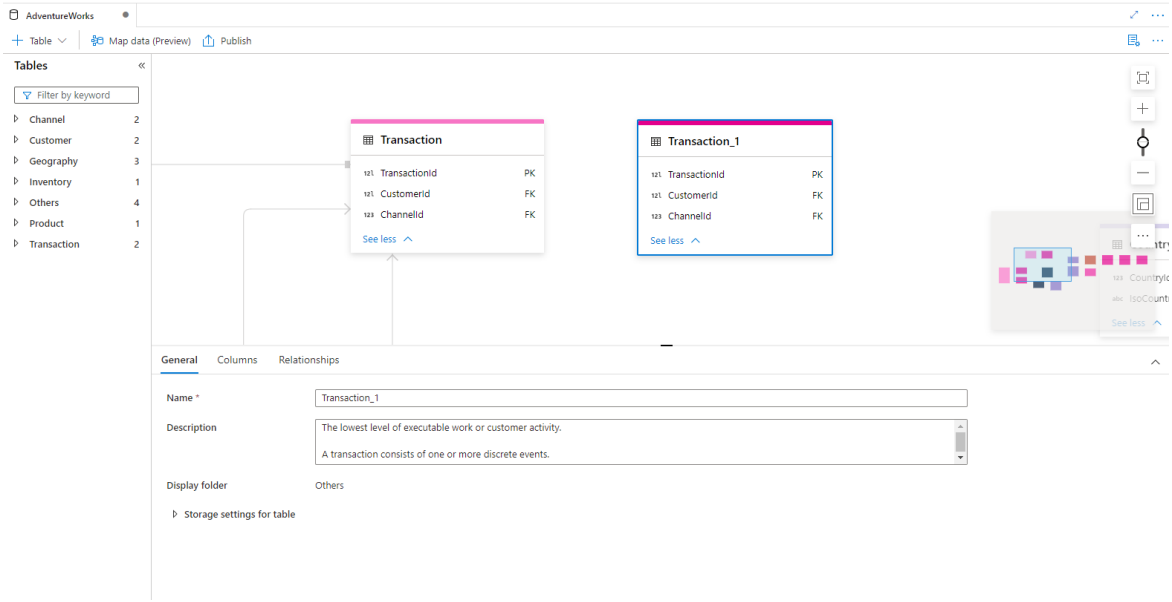
The database designer allows you to clone any of the tables in your database.

1. Select a table within your lake database and click on the ellipsis ... next to the table name.

2. Click **Clone**.



3. The database designer will create a copy of the table and opens the **General** tab by default.



4. Update the **Name**, **Description** and **Storage settings for table** as needed. For more information, see Modify lake database.

5. Similarly update the **Columns** tab and **Relationships** tab as needed.

6. Once you have completed all the changes to your cloned database, it's now time to publish it. If you're using Git integration with your Synapse workspace, you must commit your changes and merge them into the collaboration branch. Learn more about source control in Azure Synapse. If you're using Synapse Live mode, you can select "publish".

Azure Synapse SQL architecture

8/19/2022 • 6 minutes to read • Edit Online

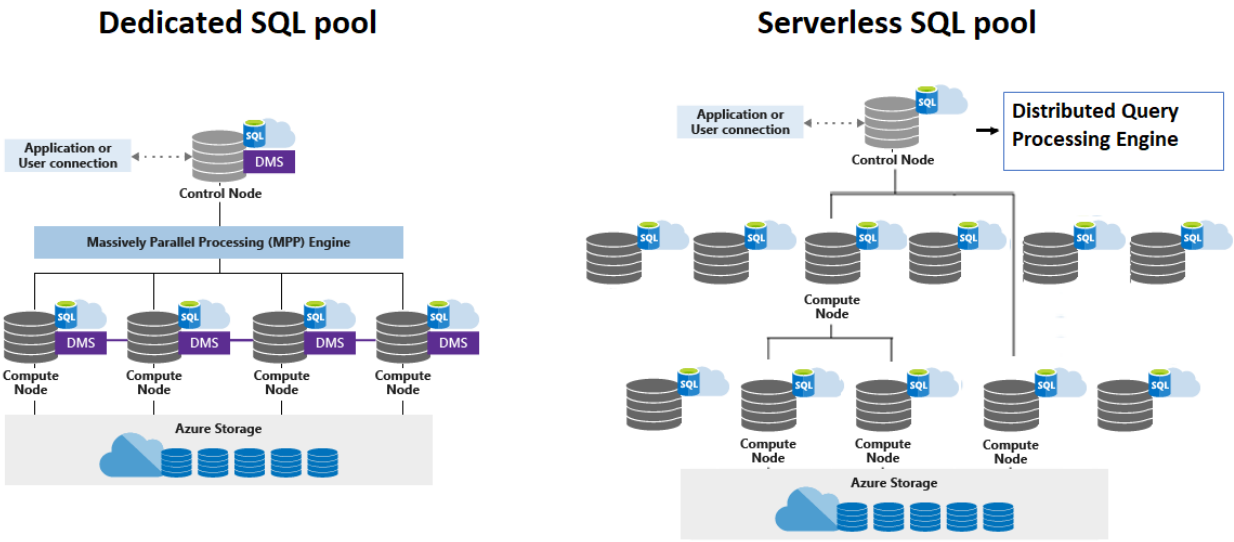
This article describes the architecture components of Synapse SQL.

Synapse SQL architecture components

Synapse SQL leverages a scale out architecture to distribute computational processing of data across multiple nodes. Compute is separate from storage, which enables you to scale compute independently of the data in your system.

For dedicated SQL pool, the unit of scale is an abstraction of compute power that is known as a data warehouse unit.

For serverless SQL pool, being serverless, scaling is done automatically to accommodate query resource requirements. As topology changes over time by adding, removing nodes or failovers, it adapts to changes and makes sure your query has enough resources and finishes successfully. For example, the image below shows serverless SQL pool utilizing 4 compute nodes to execute a query.



Synapse SQL uses a node-based architecture. Applications connect and issue T-SQL commands to a Control node, which is the single point of entry for Synapse SQL.

The Azure Synapse SQL Control node utilizes a distributed query engine to optimize queries for parallel processing, and then passes operations to Compute nodes to do their work in parallel.

The serverless SQL pool Control node utilizes Distributed Query Processing (DQP) engine to optimize and orchestrate distributed execution of user query by splitting it into smaller queries that will be executed on Compute nodes. Each small query is called task and represents distributed execution unit. It reads file(s) from storage, joins results from other tasks, groups, or orders data retrieved from other tasks.

The Compute nodes store all user data in Azure Storage and run the parallel queries. The Data Movement Service (DMS) is a system-level internal service that moves data across the nodes as necessary to run queries in parallel and return accurate results.

With decoupled storage and compute, when using Synapse SQL one can benefit from independent sizing of compute power irrespective of your storage needs. For serverless SQL pool scaling is done automatically, while for dedicated SQL pool one can:

- Grow or shrink compute power, within a dedicated SQL pool, without moving data.
- Pause compute capacity while leaving data intact, so you only pay for storage.
- Resume compute capacity during operational hours.

Azure Storage

Synapse SQL leverages Azure Storage to keep your user data safe. Since your data is stored and managed by Azure Storage, there is a separate charge for your storage consumption.

Serverless SQL pool allows you to query your data lake files, while dedicated SQL pool allows you to query and ingest data from your data lake files. When data is ingested into dedicated SQL pool, the data is sharded into **distributions** to optimize the performance of the system. You can choose which sharding pattern to use to distribute the data when you define the table. These sharding patterns are supported:

- Hash
- Round Robin
- Replicate

Control node

The Control node is the brain of the architecture. It is the front end that interacts with all applications and connections.

In Synapse SQL, the distributed query engine runs on the Control node to optimize and coordinate parallel queries. When you submit a T-SQL query to dedicated SQL pool, the Control node transforms it into queries that run against each distribution in parallel.

In serverless SQL pool, the DQP engine runs on Control node to optimize and coordinate distributed execution of user query by splitting it into smaller queries that will be executed on Compute nodes. It also assigns sets of files to be processed by each node.

Compute nodes

The Compute nodes provide the computational power.

In dedicated SQL pool, distributions map to Compute nodes for processing. As you pay for more compute resources, pool remaps the distributions to the available Compute nodes. The number of compute nodes ranges from 1 to 60, and is determined by the service level for the dedicated SQL pool. Each Compute node has a node ID that is visible in system views. You can see the Compute node ID by looking for the node_id column in system views whose names begin with sys.pdw_nodes. For a list of these system views, see Synapse SQL system views.

In serverless SQL pool, each Compute node is assigned task and set of files to execute task on. Task is distributed query execution unit, which is actually part of query user submitted. Automatic scaling is in effect to make sure enough Compute nodes are utilized to execute user query.

Data Movement Service

Data Movement Service (DMS) is the data transport technology in dedicated SQL pool that coordinates data movement between the Compute nodes. Some queries require data movement to ensure the parallel queries return accurate results. When data movement is required, DMS ensures the right data gets to the right location.

Distributions

A distribution is the basic unit of storage and processing for parallel queries that run on distributed data in

dedicated SQL pool. When dedicated SQL pool runs a query, the work is divided into 60 smaller queries that run in parallel.

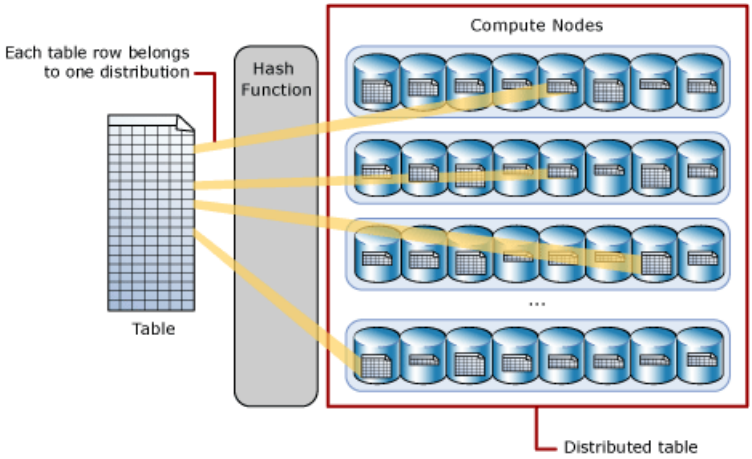
Each of the 60 smaller queries runs on one of the data distributions. Each Compute node manages one or more of the 60 distributions. A dedicated SQL pool with maximum compute resources has one distribution per Compute node. A dedicated SQL pool with minimum compute resources has all the distributions on one compute node.

Hash-distributed tables

A hash distributed table can deliver the highest query performance for joins and aggregations on large tables.

To shard data into a hash-distributed table, dedicated SQL pool uses a hash function to deterministically assign each row to one distribution. In the table definition, one of the columns is designated as the distribution column. The hash function uses the values in the distribution column to assign each row to a distribution.

The following diagram illustrates how a full (non-distributed table) gets stored as a hash-distributed table.



- Each row belongs to one distribution.
- A deterministic hash algorithm assigns each row to one distribution.
- The number of table rows per distribution varies as shown by the different sizes of tables.

There are performance considerations for the selection of a distribution column, such as distinctness, data skew, and the types of queries that run on the system.

Round-robin distributed tables

A round-robin table is the simplest table to create and delivers fast performance when used as a staging table for loads.

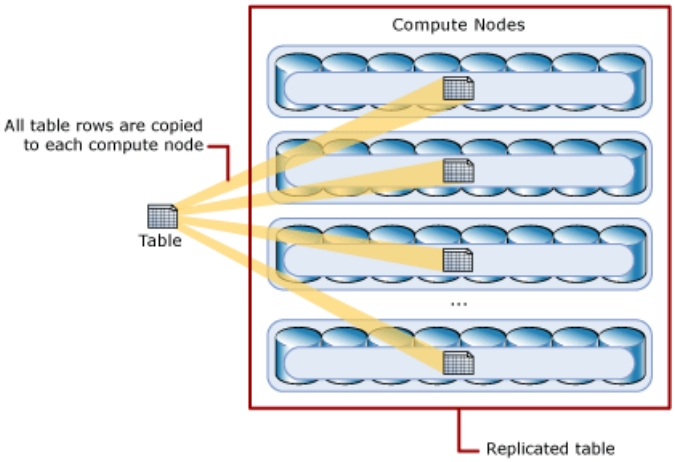
A round-robin distributed table distributes data evenly across the table but without any further optimization. A distribution is first chosen at random and then buffers of rows are assigned to distributions sequentially. It is quick to load data into a round-robin table, but query performance can often be better with hash distributed tables. Joins on round-robin tables require reshuffling data, which takes additional time.

Replicated tables

A replicated table provides the fastest query performance for small tables.

A table that is replicated caches a full copy of the table on each compute node. So, replicating a table removes the need to transfer data among compute nodes before a join or aggregation. Replicated tables are best utilized with small tables. Extra storage is required and there is additional overhead that is incurred when writing data, which make large tables impractical.

The diagram below shows a replicated table that is cached on the first distribution on each compute node.



Next steps

Now that you know a bit about Synapse SQL, learn how to quickly create a dedicated SQL pool and load sample data. Or start using serverless SQL pool. If you are new to Azure, you may find the Azure glossary helpful as you encounter new terminology.

Serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

Every Azure Synapse Analytics workspace comes with serverless SQL pool endpoints that you can use to query data in the Azure Data Lake (Parquet, Delta Lake, delimited text formats), Cosmos DB, or Dataverse.

Serverless SQL pool is a query service over the data in your data lake. It enables you to access your data through the following functionalities:

- A familiar T-SQL syntax to query data in place without the need to copy or load data into a specialized store.
- Integrated connectivity via the T-SQL interface that offers a wide range of business intelligence and ad-hoc querying tools, including the most popular drivers.

Serverless SQL pool is a distributed data processing system, built for large-scale data and computational functions. Serverless SQL pool enables you to analyze your Big Data in seconds to minutes, depending on the workload. Thanks to built-in query execution fault-tolerance, the system provides high reliability and success rates even for long-running queries involving large data sets.

Serverless SQL pool is serverless, hence there's no infrastructure to setup or clusters to maintain. A default endpoint for this service is provided within every Azure Synapse workspace, so you can start querying data as soon as the workspace is created.

There is no charge for resources reserved, you are only being charged for the data processed by queries you run, hence this model is a true pay-per-use model.

If you use Apache Spark for Azure Synapse in your data pipeline, for data preparation, cleansing or enrichment, you can query external Spark tables you've created in the process, directly from serverless SQL pool. Use Private Link to bring your serverless SQL pool endpoint into your managed workspace VNet.

Serverless SQL pool benefits

If you need to explore data in the data lake, gain insights from it or optimize your existing data transformation pipeline, you can benefit from using serverless SQL pool. It is suitable for the following scenarios:

- Basic discovery and exploration - Quickly reason about the data in various formats (Parquet, CSV, JSON) in your data lake, so you can plan how to extract insights from it.
- Logical data warehouse – Provide a relational abstraction on top of raw or disparate data without relocating and transforming data, allowing always up-to-date view of your data. Learn more about creating logical data warehouse.
- Data transformation - Simple, scalable, and performant way to transform data in the lake using T-SQL, so it can be fed to BI and other tools, or loaded into a relational data store (Synapse SQL databases, Azure SQL Database, etc.).

Different professional roles can benefit from serverless SQL pool:

- Data Engineers can explore the lake, transform and prepare data using this service, and simplify their data transformation pipelines. For more information, check this tutorial.
- Data Scientists can quickly reason about the contents and structure of the data in the lake, thanks to features such as OPENROWSET and automatic schema inference.
- Data Analysts can explore data and Spark external tables created by Data Scientists or Data Engineers using familiar T-SQL language or their favorite tools, which can connect to serverless SQL pool.
- BI Professionals can quickly create Power BI reports on top of data in the lake and Spark tables.

How to start using serverless SQL pool

Serverless SQL pool endpoint is provided within every Azure Synapse workspace. You can create a workspace and start querying data instantly using tools you are familiar with.

Make sure that you are applying the best practices to get the best performance.

Client tools

Serverless SQL pool enables existing SQL ad-hoc querying and business intelligence tools to tap into the data lake. As it provides familiar T-SQL syntax, any tool capable to establish TDS connection to SQL offerings can connect to and query Synapse SQL. You can connect with Azure Data Studio and run ad-hoc queries or connect with Power BI to gain insights in a matter of minutes.

T-SQL support

Serverless SQL pool offers T-SQL querying surface area, which is slightly enhanced/extended in some aspects to accommodate for experiences around querying semi-structured and unstructured data. Furthermore, some aspects of the T-SQL language aren't supported due to the design of serverless SQL pool, as an example, DML functionality is currently not supported.

- Workload can be organized using familiar concepts:
- Databases - serverless SQL pool endpoint can have multiple databases.
- Schemas - Within a database, there can be one or many object ownership groups called schemas.
- Views, stored procedures, inline table value functions
- External resources – data sources, file formats, and tables

Security can be enforced using:

- Logins and users
- Credentials to control access to storage accounts
- Grant, deny, and revoke permissions per object level
- Azure Active Directory integration

Supported T-SQL:

- Full SELECT surface area is supported, including a majority of SQL functions
- CETAS - CREATE EXTERNAL TABLE AS SELECT
- DDL statements related to views and security only

Serverless SQL pool has no local storage, only metadata objects are stored in databases. Therefore, T-SQL related to the following concepts isn't supported:

- Tables
- Triggers
- Materialized views
- DDL statements other than ones related to views and security
- DML statements

> **NOTE**
>
> Serverless SQL pool queries have a timeout. For more information on query timeout that may affect your workload, see serverless SQL pool system constraints. Currently you can't change the timeout.

Extensions

In order to enable smooth experience for in place querying of data residing in files in data lake, serverless SQL pool extends the existing OPENROWSET function by adding following capabilities:

Query multiple files or folders

Query PARQUET file format

Query DELTA format

Various delimited text formats (with custom field terminator, row terminator, escape char)

Cosmos DB analytical store

Read a chosen subset of columns

Schema inference

filename function

filepath function

Work with complex types and nested or repeated data structures

Security

Serverless SQL pool offers mechanisms to secure access to your data.

Azure Active Directory integration and multi-factor authentication

Serverless SQL pool enables you to centrally manage identities of database user and other Microsoft services with Azure Active Directory integration. This capability simplifies permission management and enhances security. Azure Active Directory (Azure AD) supports multi-factor authentication (MFA) to increase data and application security while supporting a single sign-on process.

Authentication

Serverless SQL pool authentication refers to how users prove their identity when connecting to the endpoint. Two types of authentication are supported:

- SQL Authentication

  This authentication method uses a username and password.

- Azure Active Directory Authentication:

  This authentication method uses identities managed by Azure Active Directory. For Azure AD users, multi-factor authentication can be enabled. Use Active Directory authentication (integrated security) whenever possible.

Authorization

Authorization refers to what a user can do within a serverless SQL pool database, and is controlled by your user account's database role memberships and object-level permissions.

If SQL Authentication is used, the SQL user exists only in serverless SQL pool and permissions are scoped to the objects in serverless SQL pool. Access to securable objects in other services (such as Azure Storage) can't be granted to SQL user directly since it only exists in scope of serverless SQL pool. The SQL user needs to use one of the supported authorization types to access the files.

If Azure AD authentication is used, a user can sign in to serverless SQL pool and other services, like Azure Storage, and can grant permissions to the Azure AD user.

Access to storage accounts

A user that is logged into the serverless SQL pool service must be authorized to access and query the files in Azure Storage. serverless SQL pool supports the following authorization types:

- **Shared access signature (SAS)** provides delegated access to resources in storage account. With a SAS, you can grant clients access to resources in storage account, without sharing account keys. A SAS gives you granular control over the type of access you grant to clients who have the SAS: validity interval, granted permissions, acceptable IP address range, acceptable protocol (https/http).
- **User Identity** (also known as "pass-through") is an authorization type where the identity of the Azure AD user that logged into serverless SQL pool is used to authorize access to the data. Before accessing the data, Azure Storage administrator must grant permissions to Azure AD user for accessing the data. This authorization type uses the Azure AD user that logged into serverless SQL pool, therefore it's not supported for SQL user types.
- **Workspace Identity** is an authorization type where the identity of the Synapse workspace is used to authorize access to the data. Before accessing the data, Azure Storage administrator must grant permissions to workspace identity for accessing the data.

Access to Cosmos DB

You need to create server-level or database-scoped credential with the Cosmos DB account read-only key to access Cosmos DB analytical store.

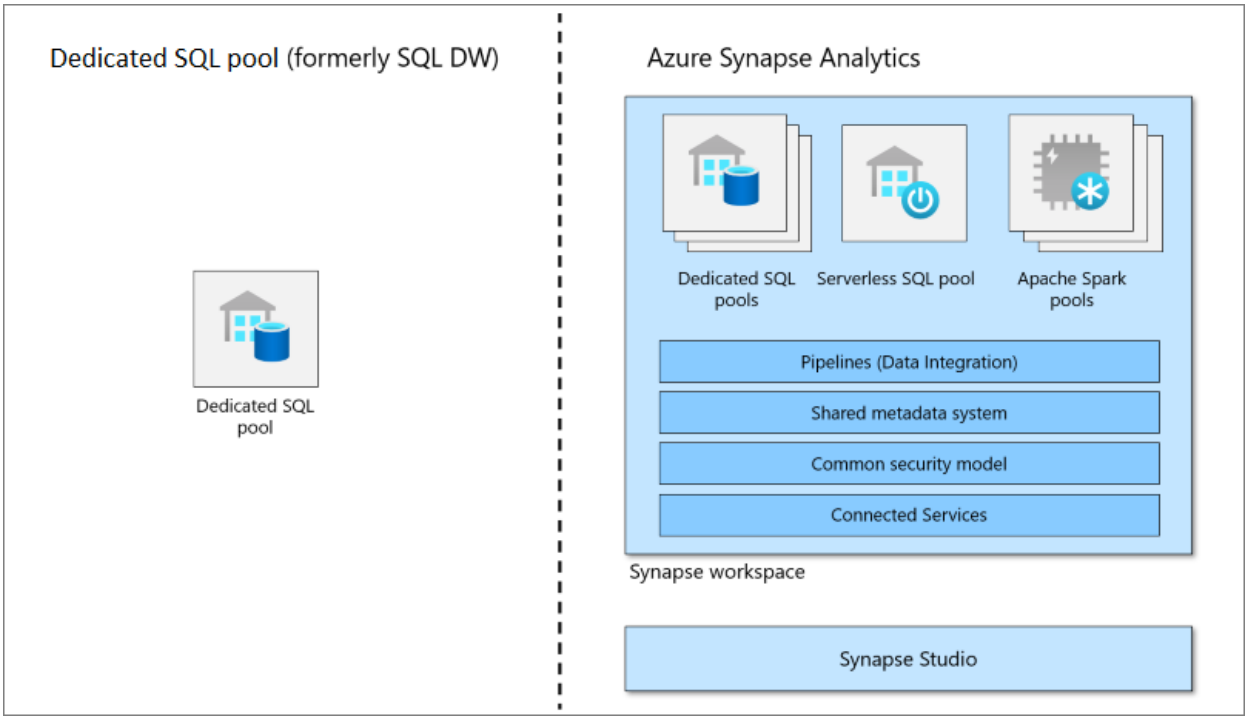
Additional information on endpoint connection and querying files can be found in the following articles:

- Connect to your endpoint
- Query your files

What is dedicated SQL pool (formerly SQL DW) in Azure Synapse Analytics?

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics is an analytics service that brings together enterprise data warehousing and Big Data analytics. Dedicated SQL pool (formerly SQL DW) refers to the enterprise data warehousing features that are available in Azure Synapse Analytics.



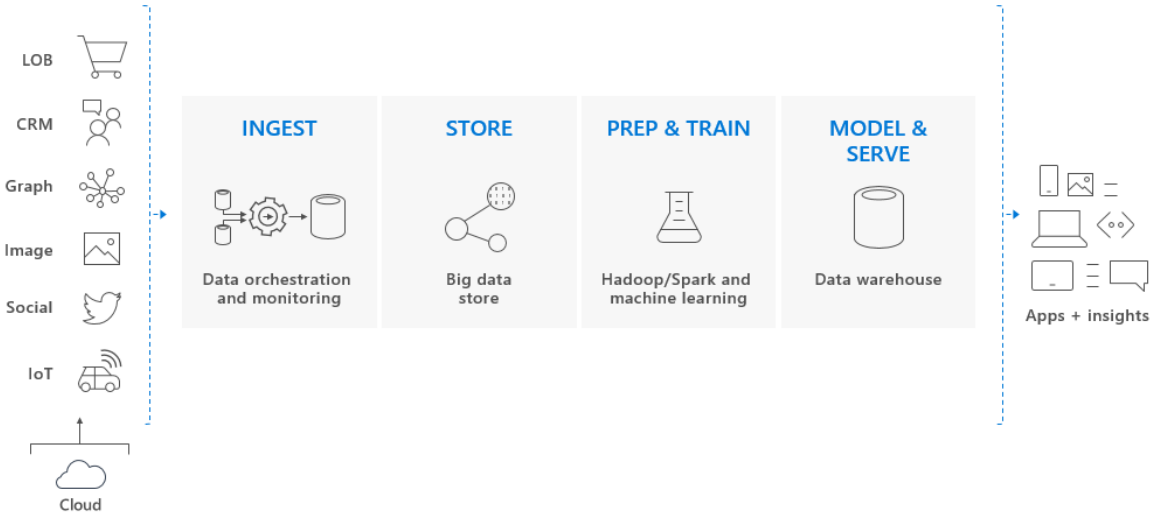
Dedicated SQL pool (formerly SQL DW) represents a collection of analytic resources that are provisioned when using Synapse SQL. The size of a dedicated SQL pool (formerly SQL DW) is determined by Data Warehousing Units (DWU).

Once your dedicated SQL pool is created, you can import big data with simple PolyBase T-SQL queries, and then use the power of the distributed query engine to run high-performance analytics. As you integrate and analyze the data, dedicated SQL pool (formerly SQL DW) will become the single version of truth your business can count on for faster and more robust insights.

> **NOTE**
> Not all features of the dedicated SQL pool in Azure Synapse workspaces apply to dedicated SQL pool (formerly SQL DW), and vice versa. To enable workspace features for an existing dedicated SQL pool (formerly SQL DW) refer to How to enable a workspace for your dedicated SQL pool (formerly SQL DW). Explore the Azure Synapse Analytics documentation and Get Started with Azure Synapse.

Key component of a big data solution

Data warehousing is a key component of a cloud-based, end-to-end big data solution.



In a cloud data solution, data is ingested into big data stores from a variety of sources. Once in a big data store, Hadoop, Spark, and machine learning algorithms prepare and train the data. When the data is ready for complex analysis, dedicated SQL pool uses PolyBase to query the big data stores. PolyBase uses standard T-SQL queries to bring the data into dedicated SQL pool (formerly SQL DW) tables.

Dedicated SQL pool (formerly SQL DW) stores data in relational tables with columnar storage. This format significantly reduces the data storage costs, and improves query performance. Once data is stored, you can run analytics at massive scale. Compared to traditional database systems, analysis queries finish in seconds instead of minutes, or hours instead of days.

The analysis results can go to worldwide reporting databases or applications. Business analysts can then gain insights to make well-informed business decisions.

Transact-SQL features supported in Azure Synapse SQL

8/19/2022 • 13 minutes to read • Edit Online

Azure Synapse SQL is a big data analytic service that enables you to query and analyze your data using the T-SQL language. You can use standard ANSI-compliant dialect of SQL language used on SQL Server and Azure SQL Database for data analysis.

Transact-SQL language is used in serverless SQL pool and dedicated model can reference different objects and has some differences in the set of supported features. In this page, you can find high-level Transact-SQL language differences between consumption models of Synapse SQL.

Database objects

Consumption models in Synapse SQL enable you to use different database objects. The comparison of supported object types is shown in the following table:

	DEDICATED	SERVERLESS
Tables	Yes	No, the in-database tables are not supported. Serverless SQL pool can query only external tables that reference data stored in Azure Data Lake storage or Dataverse.
Views	Yes. Views can use query language elements that are available in dedicated model.	Yes, you can create views over external tables, the queries with the OPENROWSET function, and other views. Views can use query language elements that are available in serverless model.
Schemas	Yes	Yes, schemas are supported. Use schemas to isolate different tenants and place their tables per schemas.
Temporary tables	Yes	Temporary tables might be used just to store some information from the system views, literals, or other temporary tables. UPDATE/DELETE on temp table is also supported. You can join temporary tables with the system views. You cannot select data from an external table to insert it into temporary table or join a temporary table with an external table - these operations will fail because external data and temporary tables cannot be mixed in the same query.

	DEDICATED	SERVERLESS
User defined procedures	Yes	Yes, stored procedures can be placed in any user databases (not `master` database). Procedures can just read external data and use query language elements that are available in serverless pool.
User defined functions	Yes	Yes, only inline table-valued functions are supported. Scalar user-defined functions are not supported.
Triggers	No	No, serverless SQL pools do not allow changing data, so the triggers cannot react on data changes.
External tables	Yes. See supported data formats.	Yes, external tables are available and can be used to read data from Azure Data Lake storage or Dataverse. See the supported data formats.
Caching queries	Yes, multiple forms (SSD-based caching, in-memory, resultset caching). In addition, Materialized View are supported.	No, only the file statistics are cached.
Result set caching	Yes	No, the query results are not cached. Only the file statistics are cached.
Materialized views	Yes	No, the Materialized views are not supported in the serverless SQL pools.
Table variables	No, use temporary tables	No, table variables are not supported.
Table distribution	Yes	No, table distributions are not supported.
Table indexes	Yes	No, indexes are not supported.
Table partitioning	Yes.	External tables do not support partitioning. You can partition files using Hive-partition folder structure and create partitioned tables in Spark. The Spark partitioning will be synchronized with the serverless pool. If you are not using Spark, you can partition your files in folder structure and can create partitioned views on folder partition structure, but the external tables cannot be created on partitioned folders.
Statistics	Yes	Yes, statistics are created on external files.

	DEDICATED	SERVERLESS
Workload management, resource classes, and concurrency control	Yes, see workload management, resource classes, and concurrency control.	No, you cannot manage the resources that are assigned to the queries. The serverless SQL pool automatically manages the resources.
Cost control	Yes, using scale-up and scale-down actions.	Yes, you can limit daily, weekly, or monthly usage of serverless pool using the Azure portal or T-SQL procedure.

Query language

Query languages used in Synapse SQL can have different supported features depending on consumption model. The following table outlines the most important query language differences in Transact-SQL dialects:

	DEDICATED	SERVERLESS
SELECT statement	Yes. `SELECT` statement is supported, but some Transact-SQL query clauses, such as FOR XML/FOR JSON, MATCH, OFFSET/FETCH are not supported.	Yes, `SELECT` statement is supported, but some Transact-SQL query clauses like FOR XML, MATCH, PREDICT, GROUPNG SETS, and the query hints are not supported.
INSERT statement	Yes	No. Upload new data to Data lake using Spark or other tools. Use Cosmos DB with the analytical storage for highly transactional workloads. You can use CETAS to create an external table and insert data.
UPDATE statement	Yes	No, update Parquet/CSV data using Spark and the changes will be automatically available in serverless pool. Use Cosmos DB with the analytical storage for highly transactional workloads.
DELETE statement	Yes	No, delete Parquet/CSV data using Spark and the changes will be automatically available in serverless pool. Use Cosmos DB with the analytical storage for highly transactional workloads.
MERGE statement	Yes (preview)	No, merge Parquet/CSV data using Spark and the changes will be automatically available in serverless pool.
CTAS statement	Yes	No, CREATE TABLE AS SELECT statement is not supported in the serverless SQL pool.
CETAS statement	Yes, you can perform initial load into an external table using CETAS.	Yes, you can perform initial load into an external table using CETAS. CETAS supports Parquet and CSV output formats.

	DEDICATED	SERVERLESS
Transactions	Yes	Yes, transactions are applicable only on the meta-data objects.
Labels	Yes	No, labels are not supported in serverless SQL pools.
Data load	Yes. Preferred utility is COPY statement, but the system supports both BULK load (BCP) and CETAS for data loading.	No, you cannot load data into the serverless SQL pool because data is stored on external storage. You can initially load data into an external table using CETAS statement.
Data export	Yes. Using CETAS.	Yes. You can export data from external storage (Azure data lake, Dataverse, Cosmos DB) into Azure data lake using CETAS.
Types	Yes, all Transact-SQL types except cursor, hierarchyid, ntext, text, and image, rowversion, Spatial Types, sql_variant, and xml	Yes, all Transact-SQL types are supported, except cursor, hierarchyid, ntext, text, and image, rowversion, Spatial Types, sql_variant, xml, and Table type. See how to map Parquet column types to SQL types here.
Cross-database queries	No	Yes, the cross-database queries and the 3-part-name references are supported including USE statement. The queries can reference the serverless SQL databases or the Lake databases in the same workspace. Cross-workspace queries are not supported.
Built-in/system functions (analysis)	Yes, all Transact-SQL Analytic, Conversion, Date and Time, Logical, Mathematical functions, except CHOOSE and PARSE	Yes, all Transact-SQL Analytic, Conversion, Date and Time, Logical, and Mathematical functions are supported.
Built-in/system functions (string)	Yes. All Transact-SQL String, JSON, and Collation functions, except STRING_ESCAPE and TRANSLATE	Yes. All Transact-SQL String, JSON, and Collation functions are supported.
Built-in/system functions (Cryptographic)	Some	`HASHBYTES` is the only supported cryptographic function in serverless SQL pools.
Built-in/system table-value functions	Yes, Transact-SQL Rowset functions, except OPENXML, OPENDATASOURCE, OPENQUERY, and OPENROWSET	Yes, all Transact-SQL Rowset functions are supported, except OPENXML, OPENDATASOURCE, and OPENQUERY.
Built-in/system aggregates	Transact-SQL built-in aggregates, except CHECKSUM_AGG and GROUPING_ID	Yes, all Transact-SQL built-in aggregates are supported.
Operators	Yes, all Transact-SQL operators except !> and !<	Yes, all Transact-SQL operators are supported.

	DEDICATED	SERVERLESS
Control of flow	Yes. All Transact-SQL Control-of-flow statement except CONTINUE, GOTO, RETURN, USE, and WAITFOR	Yes. All Transact-SQL Control-of-flow statements are supported. SELECT query in `WHILE (...)` condition is not supported.
DDL statements (CREATE, ALTER, DROP)	Yes. All Transact-SQL DDL statement applicable to the supported object types	Yes, all Transact-SQL DDL statement applicable to the supported object types are supported.

Security

Synapse SQL pools enable you to use built-in security features to secure your data and control access. The following table compares high-level differences between Synapse SQL consumption models.

	DEDICATED	SERVERLESS
Logins	N/A (only contained users are supported in databases)	Yes, server-level Azure AD and SQL logins are supported.
Users	N/A (only contained users are supported in databases)	Yes, database users are supported.
Contained users	Yes. **Note:** only one Azure AD user can be unrestricted admin	No, the contained users are not supported.
SQL username/password authentication	Yes	Yes, users can access serverless SQL pool using their usernames and passwords.
Azure Active Directory (Azure AD) authentication	Yes, Azure AD users	Yes, Azure AD logins and users can access serverless SQL pools using their Azure AD identities.
Storage Azure Active Directory (Azure AD) passthrough authentication	Yes	Yes, Azure AD passthrough authentication is applicable to Azure AD logins. The identity of the Azure AD user is passed to the storage if a credential is not specified. Azure AD passthrough authentication is not available for the SQL users.
Storage shared access signature (SAS) token authentication	No	Yes, using DATABASE SCOPED CREDENTIAL with shared access signature token in EXTERNAL DATA SOURCE or instance-level CREDENTIAL with shared access signature.
Storage Access Key authentication	Yes, using DATABASE SCOPED CREDENTIAL in EXTERNAL DATA SOURCE	No, use SAS token instead of storage access key.
Storage Managed Identity authentication	Yes, using Managed Service Identity Credential	Yes, The query can access the storage using the workspace Managed Identity credential.

	DEDICATED	SERVERLESS
Storage Application identity/Service principal (SPN) authentication	Yes	Yes, you can create a credential with a service principal application ID that will be used to authenticate on the storage.
Server roles	No	Yes, sysadmin, public, and other server-roles are supported.
SERVER SCOPED CREDENTIAL	No	Yes, the server scoped credentials are used by the `OPENROWSET` function that do not uses explicit data source.
Permissions - Server-level	No	Yes, for example, `CONNECT ANY DATABASE` and `SELECT ALL USER SECURABLES` enable a user to read data from any databases.
Database roles	Yes	Yes, you can use `db_owner`, `db_datareader` and `db_ddladmin` roles.
DATABASE SCOPED CREDENTIAL	Yes, used in external data sources.	Yes, database scoped credentials can be used in external data sources to define storage authentication method.
Permissions - Database-level	Yes	Yes, you can grant, deny, or revoke permissions on the database objects.
Permissions - Schema-level	Yes, including ability to GRANT, DENY, and REVOKE permissions to users/logins on the schema	Yes, you can specify schema-level permissions including ability to GRANT, DENY, and REVOKE permissions to users/logins on the schema.
Permissions - Object-level	Yes, including ability to GRANT, DENY, and REVOKE permissions to users	Yes, you can GRANT, DENY, and REVOKE permissions to users/logins on the system objects that are supported.
Permissions - Column-level security	Yes	Yes, column-level security is supported in serverless SQL pools. Column level encryption is also generally available, see Encrypt a column of data.
Row-level security	Yes	No, there is no built-in support for the row-level security. Use custom views as a workaround.
Data masking	Yes	No, built-in data masking is not supported in the serverless SQL pools. Use wrapper SQL views that explicitly mask some columns as a workaround.

	DEDICATED	SERVERLESS
Built-in/system security & identity functions	Some Transact-SQL security functions and operators: `CURRENT_USER`, `HAS_DBACCESS`, `IS_MEMBER`, `IS_ROLEMEMBER`, `SESSION_USER`, `SUSER_NAME`, `SUSER_SNAME`, `SYSTEM_USER`, `USER`, `USER_NAME`, `EXECUTE AS`, `OPEN/CLOSE MASTER KEY`	Some Transact-SQL security functions and operators are supported: `CURRENT_USER`, `HAS_DBACCESS`, `HAS_PERMS_BY_NAME`, `IS_MEMBER`, `IS_ROLEMEMBER`, `IS_SRVROLEMEMBER`, `SESSION_USER`, `SESSION_CONTEXT`, `SUSER_NAME`, `SUSER_SNAME`, `SYSTEM_USER`, `USER`, `USER_NAME`, `EXECUTE AS`, and `REVERT`. Security functions cannot be used to query external data (store the result in variable that can be used in the query).
Transparent Data Encryption (TDE)	Yes	No, Transparent Data Encryption is not supported.
Data Discovery & Classification	Yes	No, Data Discovery & Classification is not supported.
Vulnerability Assessment	Yes	No, Vulnerability Assessment is not available.
Advanced Threat Protection	Yes	No, Advanced Threat Protection is not supported.
Auditing	Yes	Yes, auditing is supported in serverless SQL pools.
Firewall rules	Yes	Yes, the firewall rules can be set on the serverless SQL endpoint.
Private endpoint	Yes	Yes, the private endpoint can be set on the serverless SQL pool.

Dedicated SQL pool and serverless SQL pool use standard Transact-SQL language to query data. For detailed differences, look at the Transact-SQL language reference.

Tools

You can use various tools to connect to Synapse SQL to query data.

	DEDICATED	SERVERLESS
Synapse Studio	Yes, SQL scripts	Yes, SQL scripts can be used in Synapse Studio. Use SSMS or ADS instead of Synapse Studio if you are returning a large amount of data as a result.
Power BI	Yes	Yes, you can use Power BI to create reports on serverless SQL pool. Import mode is recommended for reporting.

	DEDICATED	SERVERLESS
Azure Analysis Service	Yes	Yes, you can load data in Azure Analysis Service using the serverless SQL pool.
Azure Data Studio (ADS)	Yes	Yes, you can use Azure Data Studio (version 1.18.0 or higher) to query a serverless SQL pool. SQL scripts and SQL notebooks are supported.
SQL Server Management Studio (SSMS)	Yes	Yes, you can use SQL Server Management Studio (version 18.5 or higher) to query a serverless SQL pool. SSMS shows only the objects that are available in the serverless SQL pools.

> **NOTE**
> You can use SSMS to connect to serverless SQL pool and query. It is partially supported starting from version 18.5, you can use it to connect and query only.

Most of the applications use standard Transact-SQL language can query both dedicated and serverless consumption models of Synapse SQL.

Data access

Data that is analyzed can be stored on various storage types. The following table lists all available storage options:

	DEDICATED	SERVERLESS
Internal storage	Yes	No, data is placed in Azure Data Lake or Cosmos DB analytical storage.
Azure Data Lake v2	Yes	Yes, you can use external tables and the `OPENROWSET` function to read data from ADLS. Learn here how to setup access control.
Azure Blob Storage	Yes	Yes, you can use external tables and the `OPENROWSET` function to read data from Azure Blob Storage. Learn here how to setup access control.
Azure SQL/SQL Server (remote)	No	No, serverless SQL pool cannot reference Azure SQL database. You can reference serverless SQL pools from Azure SQL using elastic queries or linked servers.
Dataverse	No, you can load CosmosDB data into a dedicated pool using Azure Synapse Link in serverless SQL pool (via ADLS) or Spark.	Yes, you can read Dataverse tables using Azure Synapse link for Dataverse with Azure Data Lake.

	DEDICATED	SERVERLESS
Azure Cosmos DB transactional storage	No	No, you cannot access Cosmos DB containers to update data or read data from the Cosmos DB transactional storage. Use Spark pools to update the Cosmos DB transactional storage.
Azure Cosmos DB analytical storage	No, you can load CosmosDB data into a dedicated pool using Azure Synapse Link in serverless SQL pool (via ADLS), ADF, Spark or some other load tool.	Yes, you can query Cosmos DB analytical storage using Azure Synapse Link.
Apache Spark tables (in workspace)	No	Yes, serverless pool can read PARQUET and CSV tables using metadata synchronization.
Apache Spark tables (remote)	No	No, serverless pool can access only the PARQUET and CSV tables that are created in Apache Spark pools in the same Synapse workspace. However, you can manually create an external table that reference external Spark table location.
Databricks tables (remote)	No	No, serverless pool can access only the PARQUET and CSV tables that are created in Apache Spark pools in the same Synapse workspace. However, you can manually create an external table that reference Databricks table location.

Data formats

Data that is analyzed can be stored in various storage formats. The following table lists all available data formats that can be analyzed:

	DEDICATED	SERVERLESS
Delimited	Yes	Yes, you can query delimited files.
CSV	Yes (multi-character delimiters not supported)	Yes, you can query CSV files. For better performance use PARSER_VERSION 2.0 that provides faster parsing. If you are appending rows to your CSV files, make sure that you query the files as appendable.
Parquet	Yes	Yes, you can query Parquet files, including the files with nested types.
Hive ORC	Yes	No, serverless SQL pools cannot read Hive ORC format.
Hive RC	Yes	No, serverless SQL pools cannot read Hive RC format.

	DEDICATED	SERVERLESS
JSON	Yes	Yes, you can query JSON files using delimited text format and the T-SQL JSON functions.
Avro	No	No, serverless SQL pools cannot read Avro format.
Delta Lake	No	Yes, you can query delta lake files, including the files with nested types.
Common Data Model (CDM)	No	No, serverless SQL pool cannot read data stored using Common Data Model.

Next steps

Additional information on best practices for dedicated SQL pool and serverless SQL pool can be found in the following articles:

- Best practices for dedicated SQL pool
- Best practices for serverless SQL pool

Synapse SQL resource consumption

8/19/2022 • 7 minutes to read • Edit Online

This article describes resource consumption models of Synapse SQL.

Serverless SQL pool

Serverless SQL pool is a pay per query service that doesn't require you to pick the right size. The system automatically adjusts based on your requirements, freeing you up from managing your infrastructure and picking the right size for your solution.

Dedicated SQL pool - Data Warehouse Units (DWUs) and compute Data Warehouse Units (cDWUs)

Recommendations on choosing the ideal number of data warehouse units (DWUs) to optimize price and performance, and how to change the number of units.

Data Warehouse Units

A Synapse SQL pool represents a collection of analytic resources that are being provisioned. Analytic resources are defined as a combination of CPU, memory, and IO. These three resources are bundled into units of compute scale called Data Warehouse Units (DWUs). A DWU represents an abstract, normalized measure of compute resources and performance. A change to your service level alters the number of DWUs that are available to the system. In turn, this change adjusts the performance and cost of your system.

For higher performance, you can increase the number of data warehouse units. For less performance, reduce data warehouse units. Storage and compute costs are billed separately, so changing data warehouse units does not affect storage costs.

Performance for data warehouse units is based on these data warehouse workload metrics:

- How fast a standard data warehousing query can scan a large number of rows and then perform a complex aggregation. This operation is I/O and CPU intensive.
- How fast the data warehouse can ingest data from Azure Storage Blobs or Azure Data Lake. This operation is network and CPU intensive.
- How fast the `CREATE TABLE AS SELECT` T-SQL command can copy a table. This operation involves reading data from storage, distributing it across the nodes of the appliance and writing to storage again. This operation is CPU, IO, and network intensive.

Increasing DWUs:

- Linearly changes performance of the system for scans, aggregations, and CTAS statements
- Increases the number of readers and writers for PolyBase load operations
- Increases the maximum number of concurrent queries and concurrency slots.

Service Level Objective

The Service Level Objective (SLO) is the scalability setting that determines the cost and performance level of your data warehouse. The service levels for Gen2 are measured in compute data warehouse units (cDWU), for example DW2000c. Gen1 service levels are measured in DWUs, for example DW2000.

The Service Level Objective (SLO) is the scalability setting that determines the cost and performance level of your data warehouse. The service levels for Gen2 dedicated SQL pool are measured in data warehouse units

(DWU), for example DW2000c.

> **NOTE**
> Azure Synapse Analytics Gen2 recently added additional scale capabilities to support compute tiers as low as 100 cDWU. Existing data warehouses currently on Gen1 that require the lower compute tiers can now upgrade to Gen2 in the regions that are currently available for no additional cost. If your region is not yet supported, you can still upgrade to a supported region. For more information, see Upgrade to Gen2.

In T-SQL, the SERVICE_OBJECTIVE setting determines the service level and the performance tier for your dedicated SQL pool.

```
CREATE DATABASE mySQLDW
(Edition = 'Datawarehouse'
 ,SERVICE_OBJECTIVE = 'DW1000c'
)
;
```

Performance Tiers and Data Warehouse Units

Each performance tier uses a slightly different unit of measure for their data warehouse units. This difference is reflected on the invoice as the unit of scale directly translates to billing.

- Gen1 data warehouses are measured in Data Warehouse Units (DWUs).
- Gen2 data warehouses are measured in compute Data Warehouse Units (cDWUs).

Both DWUs and cDWUs support scaling compute up or down, and pausing compute when you don't need to use the data warehouse. These operations are all on-demand. Gen2 uses a local disk-based cache on the compute nodes to improve performance. When you scale or pause the system, the cache is invalidated and so a period of cache warming is required before optimal performance is achieved.

As you increase data warehouse units, you're linearly increasing computing resources. Gen2 provides the best query performance and highest scale. Gen2 systems also make the most use of the cache.

Capacity limits

Each SQL server (for example, myserver.database.windows.net) has a Database Transaction Unit (DTU) quota that allows a specific number of data warehouse units. For more information, see the workload management capacity limits.

Assess the number of data warehouse units you need

The ideal number of data warehouse units depends very much on your workload and the amount of data you've loaded into the system.

Steps for finding the best DWU for your workload:

1. Begin by selecting a smaller DWU.
2. Monitor your application performance as you test data loads into the system, observing the number of DWUs selected compared to the performance you observe.
3. Identify any additional requirements for periodic periods of peak activity. Workloads that show significant peaks and troughs in activity may need to be scaled frequently.

SQL pool is a scale-out system that can provision vast amounts of compute and query sizeable quantities of data. To see its true capabilities for scaling, especially at larger DWUs, we recommend scaling the data set as you scale to ensure that you have enough data to feed the CPUs. For scale testing, we recommend using at least 1 TB.

> **NOTE**
> Query performance only increases with more parallelization if the work can be split between compute nodes. If you find that scaling is not changing your performance, you may need to tune your table design and/or your queries. For query tuning guidance, see Manage user queries.

Permissions

Changing the data warehouse units requires the permissions described in ALTER DATABASE.

Azure built-in roles such as SQL DB Contributor and SQL Server Contributor can change DWU settings.

View current DWU settings

To view the current DWU setting:

1. Open SQL Server Object Explorer in Visual Studio.
2. Connect to the master database associated with the logical SQL server.
3. Select from the sys.database_service_objectives dynamic management view. Here is an example:

```
SELECT  db.name [Database]
,        ds.edition [Edition]
,        ds.service_objective [Service Objective]
FROM    sys.database_service_objectives   AS ds
JOIN    sys.databases                     AS db ON ds.database_id = db.database_id
;
```

Change data warehouse units

Azure portal

To change DWUs:

1. Open the Azure portal, open your database, and select **Scale**.
2. Under **Scale**, move the slider left or right to change the DWU setting.
3. Select **Save**. A confirmation message appears. Select **yes** to confirm or **no** to cancel.

PowerShell

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

To change the DWUs, use the Set-AzSqlDatabase PowerShell cmdlet. The following example sets the service level objective to DW1000 for the database MySQLDW that is hosted on server MyServer.

```
Set-AzSqlDatabase -DatabaseName "MySQLDW" -ServerName "MyServer" -RequestedServiceObjectiveName "DW1000c"
```

For more information, see PowerShell cmdlets for Azure Synapse Analytics

T-SQL

With T-SQL you can view the current DWUsettings, change the settings, and check the progress.

To change the DWUs:

1. Connect to the master database associated with your server.

2. Use the ALTER DATABASE TSQL statement. The following example sets the service level objective to DW1000c for the database MySQLDW.

```
ALTER DATABASE MySQLDW
MODIFY (SERVICE_OBJECTIVE = 'DW1000c')
;
```

REST APIs

To change the DWUs, use the Create or Update Database REST API. The following example sets the service level objective to DW1000c for the database MySQLDW, which is hosted on server MyServer. The server is in an Azure resource group named ResourceGroup1.

```
PUT https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-
name}/providers/Microsoft.Sql/servers/{server-name}/databases/{database-name}?api-version=2014-04-01-preview
HTTP/1.1
Content-Type: application/json; charset=UTF-8

{
    "properties": {
        "requestedServiceObjectiveName": DW1000
    }
}
```

For more REST API examples, see REST APIs for Azure Synapse Analytics.

Check status of DWU changes

DWU changes may take several minutes to complete. If you're scaling automatically, consider implementing logic to ensure that certain operations have been completed before proceeding with another action.

Checking the database state through various endpoints allows you to correctly implement automation. The portal provides notification upon completion of an operation and the databases current state but doesn't allow for programmatic checking of state.

You can't check the database state for scale-out operations with the Azure portal.

To check the status of DWU changes:

1. Connect to the master database associated with your server.
2. Submit the following query to check database state.

```
SELECT    *
FROM      sys.databases
;
```

1. Submit the following query to check status of operation

```
SELECT    *
FROM      sys.dm_operation_status
WHERE     resource_type_desc = 'Database'
AND       major_resource_id = 'MySQLDW'
;
```

This DMV returns information about various management operations on your dedicated SQL pool such as the operation and the state of the operation, which is either IN_PROGRESS or COMPLETED.

The scaling workflow

When you start a scale operation, the system first kills all open sessions, rolling back any open transactions to ensure a consistent state. For scale operations, scaling only occurs after this transactional rollback has completed.

- For a scale-up operation, the system detaches all compute nodes, provisions the additional compute nodes, and then reattaches to the storage layer.
- For a scale-down operation, the system detaches all compute nodes and then reattaches only the needed nodes to the storage layer.

Next steps

To learn more about managing performance, see Resource classes for workload management and Memory and concurrency limits.

Capacity limits for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

Maximum values allowed for various components of dedicated SQL pool in Azure Synapse Analytics.

Workload management

CATEGORY	DESCRIPTION	MAXIMUM
Data Warehouse Units (DWU)	Max DWU for a single dedicated SQL pool	Gen1: DW6000 Gen2: DW30000c
Data Warehouse Units (DWU)	Default DTU per server	54,000 By default, each SQL server (for example, myserver.database.windows.net) has a DTU Quota of 54,000, which allows up to DW6000c. This quota is simply a safety limit. You can increase your quota by creating a support ticket and selecting *Quota* as the request type. To calculate your DTU needs, multiply the 7.5 by the total DWU needed, or multiply 9 by the total cDWU needed. For example: DW6000 x 7.5 = 45,000 DTUs DW7500c x 9 = 67,500 DTUs. You can view your current DTU consumption from the SQL server option in the portal. Both paused and unpaused databases count toward the DTU quota.
Database connection	Maximum Concurrent open sessions	1024 The number of concurrent open sessions will vary based on the selected DWU. DWU1000c and above support a maximum of 1024 open sessions. DWU500c and below, support a maximum concurrent open session limit of 512. Note, there are limits on the number of queries that can execute concurrently. When the concurrency limit is exceeded, the request goes into an internal queue where it waits to be processed.

CATEGORY	DESCRIPTION	MAXIMUM
Database connection	Maximum memory for prepared statements	20 MB
Workload management	Maximum concurrent queries	128 A maximum of 128 concurrent queries will execute and remaining queries will be queued. The number of concurrent queries can decrease when users are assigned to higher resource classes or when the data warehouse unit setting is lowered. Some queries, like DMV queries, are always allowed to run and do not impact the concurrent query limit. For more information on concurrent query execution, see the concurrency maximums article.
tempdb	Maximum GB	399 GB per DW100c. At DWU1000c, tempdb is sized to 3.99 TB.

Database objects

CATEGORY	DESCRIPTION	MAXIMUM
Database	Max size	Gen1: 240 TB compressed on disk. This space is independent of tempdb or log space, and therefore this space is dedicated to permanent tables. Clustered columnstore compression is estimated at 5X. This compression allows the database to grow to approximately 1 PB when all tables are clustered columnstore (the default table type). Gen2: Unlimited storage for columnstore tables. Rowstore portion of the database is still limited to 240 TB compressed on disk.
Table	Max size	Unlimited size for columnstore tables. 60 TB for rowstore tables compressed on disk.
Table	Tables per database	100,000
Table	Columns per table	1024 columns
Table	Bytes per column	Dependent on column data type. Limit is 8000 for char data types, 4000 for nvarchar, or 2 GB for MAX data types.

CATEGORY	DESCRIPTION	MAXIMUM
Table	Bytes per row, defined size	8060 bytes The number of bytes per row is calculated in the same manner as it is for SQL Server with page compression. Like SQL Server, row-overflow storage is supported, which enables **variable length columns** to be pushed off-row. When variable length rows are pushed off-row, only 24-byte root is stored in the main record. For more information, see Row-Overflow Data Exceeding 8 KB.
Table	Partitions per table	15,000 For high performance, we recommend minimizing the number of partitions you need while still supporting your business requirements. As the number of partitions grows, the overhead for Data Definition Language (DDL) and Data Manipulation Language (DML) operations grows and causes slower performance.
Table	Characters per partition boundary value.	4000
Index	Non-clustered indexes per table.	50 Applies to rowstore tables only.
Index	Clustered indexes per table.	1 Applies to both rowstore and columnstore tables.
Index	Index key size.	900 bytes. Applies to rowstore indexes only. Indexes on varchar columns with a maximum size of more than 900 bytes can be created if the existing data in the columns does not exceed 900 bytes when the index is created. However, later INSERT or UPDATE actions on the columns that cause the total size to exceed 900 bytes will fail.
Index	Key columns per index.	16 Applies to rowstore indexes only. Clustered columnstore indexes include all columns.
Statistics	Size of the combined column values.	900 bytes.

CATEGORY	DESCRIPTION	MAXIMUM
Statistics	Columns per statistics object.	32
Statistics	Statistics created on columns per table.	30,000
Stored Procedures	Maximum levels of nesting.	8
View	Columns per view	1,024

Loads

CATEGORY	DESCRIPTION	MAXIMUM
Polybase Loads	MB per row	1 Polybase loads rows that are smaller than 1 MB. Loading LOB data types into tables with a Clustered Columnstore Index (CCI) is not supported.
Polybase Loads	Total number of files	1,000,000 Polybase loads can not exceed more than 1M files. You may experience the following error: **Operation failed as split count exceeding upper bound of 1000000**.

Queries

CATEGORY	DESCRIPTION	MAXIMUM
Query	Queued queries on user tables.	1000
Query	Concurrent queries on system views.	100
Query	Queued queries on system views	1000
Query	Maximum parameters	2098
Batch	Maximum size	65,536*4096
SELECT results	Columns per row	4096 You can never have more than 4096 columns per row in the SELECT result. There is no guarantee that you can always have 4096. If the query plan requires a temporary table, the 1024 columns per table maximum might apply.

CATEGORY	DESCRIPTION	MAXIMUM
SELECT	Nested subqueries	32 You can never have more than 32 nested subqueries in a SELECT statement. There is no guarantee that you can always have 32. For example, a JOIN can introduce a subquery into the query plan. The number of subqueries can also be limited by available memory.
SELECT	Columns per JOIN	1024 columns You can never have more than 1024 columns in the JOIN. There is no guarantee that you can always have 1024. If the JOIN plan requires a temporary table with more columns than the JOIN result, the 1024 limit applies to the temporary table.
SELECT	Bytes per GROUP BY columns.	8060 The columns in the GROUP BY clause can have a maximum of 8060 bytes.
SELECT	Bytes per ORDER BY columns	8060 bytes The columns in the ORDER BY clause can have a maximum of 8060 bytes
Identifiers per statement	Number of referenced identifiers	65,535 The number of identifiers that can be contained in a single expression of a query is limited. Exceeding this number results in SQL Server error 8632. For more information, see Internal error: An expression services limit has been reached.
String literals	Number of string literals in a statement	20,000 The number of string constants in a single expression of a query is limited. Exceeding this number results in SQL Server error 8632.

Metadata

DMV's will reset when a dedicated SQL pool is paused or when it is scaled.

SYSTEM VIEW	MAXIMUM ROWS
sys.dm_pdw_dms_cores	100
sys.dm_pdw_dms_workers	Total number of DMS workers for the most recent 1000 SQL requests.
sys.dm_pdw_errors	10,000
sys.dm_pdw_exec_requests	10,000
sys.dm_pdw_exec_sessions	10,000
sys.dm_pdw_request_steps	Total number of steps for the most recent 1000 SQL requests that are stored in sys.dm_pdw_exec_requests.
sys.dm_pdw_sql_requests	The most recent 1000 SQL requests that are stored in sys.dm_pdw_exec_requests.

Cost management for serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

This article explains how you can estimate and manage costs for serverless SQL pool in Azure Synapse Analytics:

- Estimate amount of data processed before issuing a query
- Use cost control feature to set the budget

Understand that the costs for serverless SQL pool in Azure Synapse Analytics are only a portion of the monthly costs in your Azure bill. If you are using other Azure services, you're billed for all the Azure services and resources used in your Azure subscription, including the third-party services. This article explains how to plan for and manage costs for serverless SQL pool in Azure Synapse Analytics.

Data processed

Data processed is the amount of data that the system temporarily stores while a query is run. Data processed consists of the following quantities:

- Amount of data read from storage. This amount includes:
  - Data read while reading data.
  - Data read while reading metadata (for file formats that contain metadata, like Parquet).
- Amount of data in intermediate results. This data is transferred among nodes while the query runs. It includes the data transfer to your endpoint, in an uncompressed format.
- Amount of data written to storage. If you use CETAS to export your result set to storage, then the amount of data written out is added to the amount of data processed for the SELECT part of CETAS.

Reading files from storage is highly optimized. The process uses:

- Prefetching, which might add some overhead to the amount of data read. If a query reads a whole file, then there's no overhead. If a file is read partially, like in TOP N queries, then a bit more data is read by using prefetching.
- An optimized comma-separated value (CSV) parser. If you use PARSER_VERSION='2.0' to read CSV files, then the amounts of data read from storage slightly increase. An optimized CSV parser reads files in parallel, in chunks of equal size. Chunks don't necessarily contain whole rows. To ensure all rows are parsed, the optimized CSV parser also reads small fragments of adjacent chunks. This process adds a small amount of overhead.

Statistics

The serverless SQL pool query optimizer relies on statistics to generate optimal query execution plans. You can create statistics manually. Otherwise, serverless SQL pool creates them automatically. Either way, statistics are created by running a separate query that returns a specific column at a provided sample rate. This query has an associated amount of data processed.

If you run the same or any other query that would benefit from created statistics, then statistics are reused if possible. There's no additional data processed for statistics creation.

When statistics are created for a Parquet column, only the relevant column is read from files. When statistics are

created for a CSV column, whole files are read and parsed.

Rounding

The amount of data processed is rounded up to the nearest MB per query. Each query has a minimum of 10 MB of data processed.

What data processed doesn't include

- Server-level metadata (like logins, roles, and server-level credentials).
- Databases you create in your endpoint. Those databases contain only metadata (like users, roles, schemas, views, inline table-valued functions [TVFs], stored procedures, database-scoped credentials, external data sources, external file formats, and external tables).
  - If you use schema inference, then file fragments are read to infer column names and data types, and the amount of data read is added to the amount of data processed.
- Data definition language (DDL) statements, except for the CREATE STATISTICS statement because it processes data from storage based on the specified sample percentage.
- Metadata-only queries.

Reducing the amount of data processed

You can optimize your per-query amount of data processed and improve performance by partitioning and converting your data to a compressed column-based format like Parquet.

Examples

Imagine three tables.

- The population_csv table is backed by 5 TB of CSV files. The files are organized in five equally sized columns.
- The population_parquet table has the same data as the population_csv table. It's backed by 1 TB of Parquet files. This table is smaller than the previous one because data is compressed in Parquet format.
- The very_small_csv table is backed by 100 KB of CSV files.

Query 1: SELECT SUM(population) FROM population_csv

This query reads and parses whole files to get values for the population column. Nodes process fragments of this table, and the population sum for each fragment is transferred among nodes. The final sum is transferred to your endpoint.

This query processes 5 TB of data plus a small amount overhead for transferring sums of fragments.

Query 2: SELECT SUM(population) FROM population_parquet

When you query compressed and column-based formats like Parquet, less data is read than in query 1. You see this result because serverless SQL pool reads a single compressed column instead of the whole file. In this case, 0.2 TB is read. (Five equally sized columns are 0.2 TB each.) Nodes process fragments of this table, and the population sum for each fragment is transferred among nodes. The final sum is transferred to your endpoint.

This query processes 0.2 TB plus a small amount of overhead for transferring sums of fragments.

Query 3: SELECT * FROM population_parquet

This query reads all columns and transfers all data in an uncompressed format. If the compression format is 5:1, then the query processes 6 TB because it reads 1 TB and transfers 5 TB of uncompressed data.

Query 4: SELECT COUNT(*) FROM very_small_csv

This query reads whole files. The total size of files in storage for this table is 100 KB. Nodes process fragments of this table, and the sum for each fragment is transferred among nodes. The final sum is transferred to your endpoint.

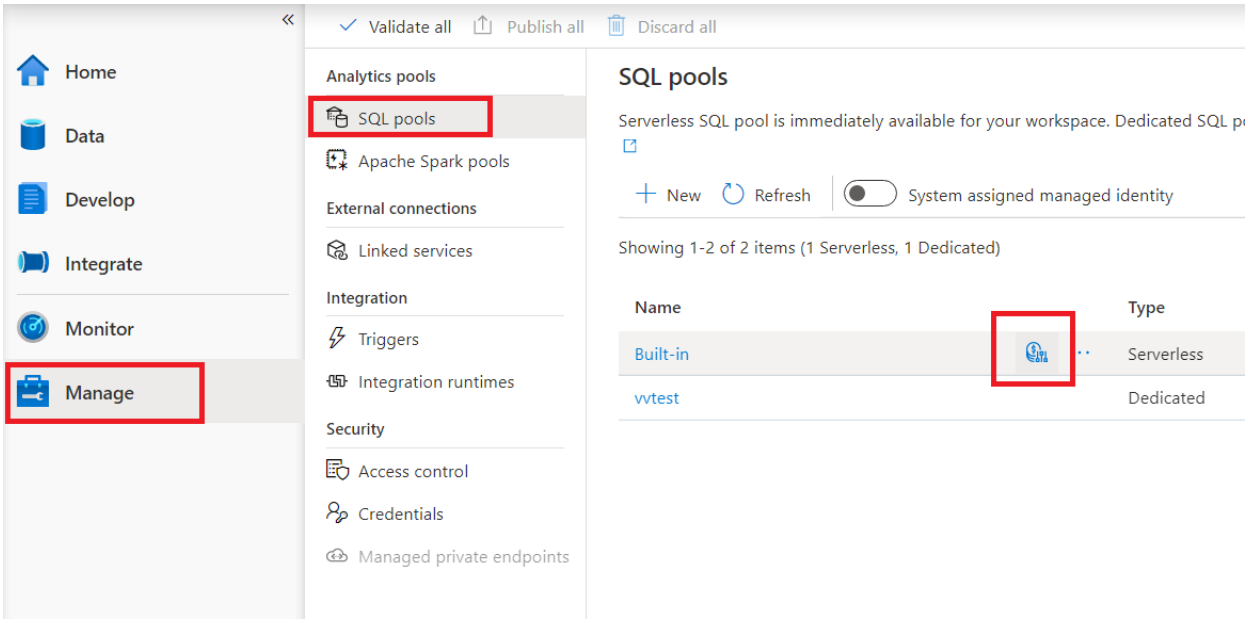
This query processes slightly more than 100 KB of data. The amount of data processed for this query is rounded up to 10 MB, as specified in the Rounding section of this article.

Cost control

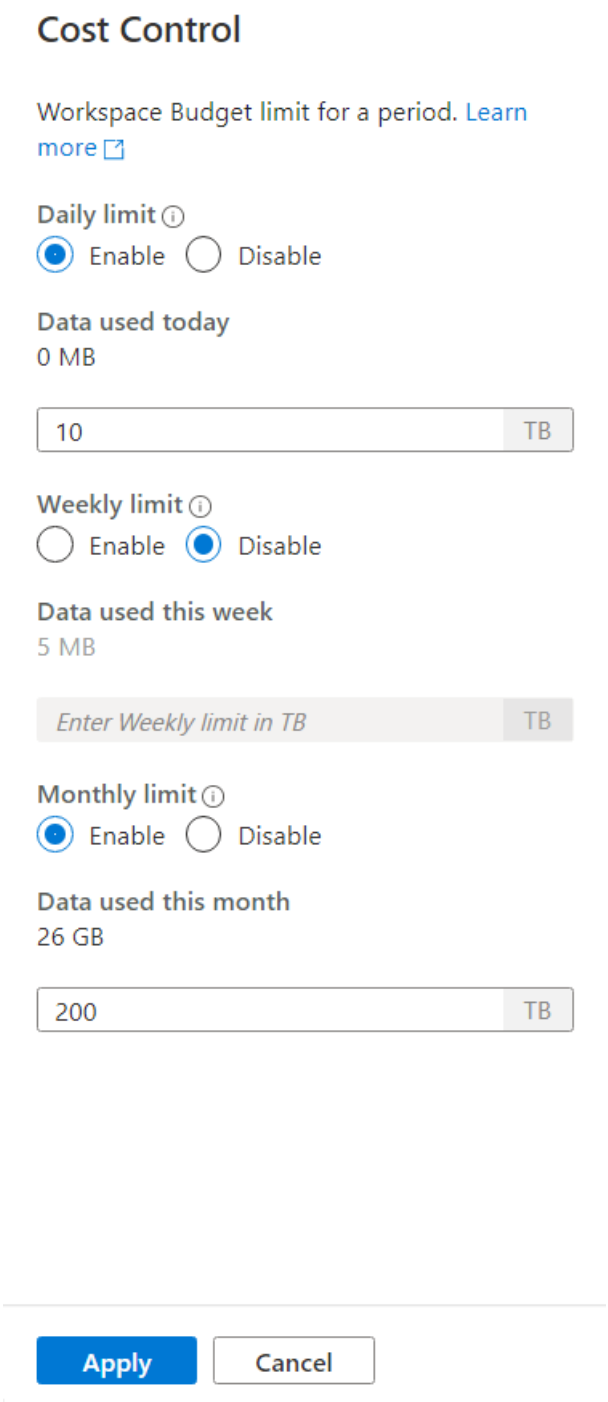
Cost control feature in serverless SQL pool enables you to set the budget for amount of data processed. You can set the budget in TB of data processed for a day, week, and month. At the same time you can have one or more budgets set. To configure cost control for serverless SQL pool, you can use Synapse Studio or T-SQL.

Configure cost control for serverless SQL pool in Synapse Studio

To configure cost control for serverless SQL pool in Synapse Studio navigate to Manage item in the menu on the left, than select SQL pool item under Analytics pools. As you hover of serverless SQL pool, you will notice an icon for cost control - click on this icon.



Once you click on the cost control icon, a side bar will appear:



To set one or more budgets, first click on Enable radio button for a budget you want to set, than enter the integer value in the text box. Unit for the value is TBs. Once you have configured the budgets you wanted click on apply button at the bottom of the side bar. That's it, you budget is now set.

Configure cost control for serverless SQL pool in T-SQL

To configure cost control for serverless SQL pool in T-SQL, you need to execute one or more of the following stored procedures.

```
sp_set_data_processed_limit
 @type = N'daily',
 @limit_tb = 1

sp_set_data_processed_limit
 @type= N'weekly',
 @limit_tb = 2

sp_set_data_processed_limit
 @type= N'monthly',
 @limit_tb = 3334
```

To see the current configuration execute the following T-SQL statement:

```
SELECT * FROM sys.configurations
WHERE name like 'Data processed %';
```

To see how much data was processed during the current day, week, or month, execute the following T-SQL statement:

```
SELECT * FROM sys.dm_external_data_processed
```

Exceeding the limits defined in the cost control

In case any limit is exceeded during the query execution, query won't be terminated.

When limit is exceeded, new query will be rejected with the error message which contains details regarding the period, defined limit for that period and data processed for that period. For example, in case new query is executed, where weekly limit is set to 1 TB and it was exceeded, the error message will be:

```
Query is rejected because SQL Serverless budget limit for a period is exceeded. (Period = Weekly: Limit = 1
TB, Data processed = 1 TB))
```

Next steps

To learn how to optimize your queries for performance, see Best practices for serverless SQL pool.

Quickstart: Create a dedicated SQL pool using Synapse Studio

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics offers various analytics engines to help you ingest, transform, model, and analyze your data. A dedicated SQL pool offers T-SQL based compute and storage capabilities. After creating a dedicated SQL pool in your Synapse workspace, data can be loaded, modeled, processed, and delivered for faster analytic insight.

This quickstart describes the steps to create a dedicated SQL pool in a Synapse workspace using Synapse Studio.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

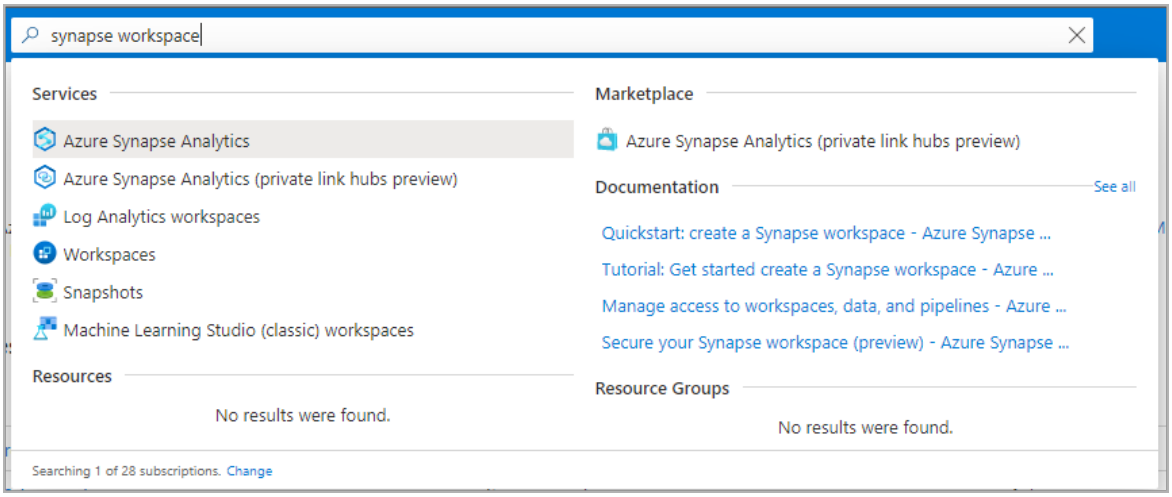
- Azure subscription - create one for free
- Synapse workspace

Sign in to the Azure portal

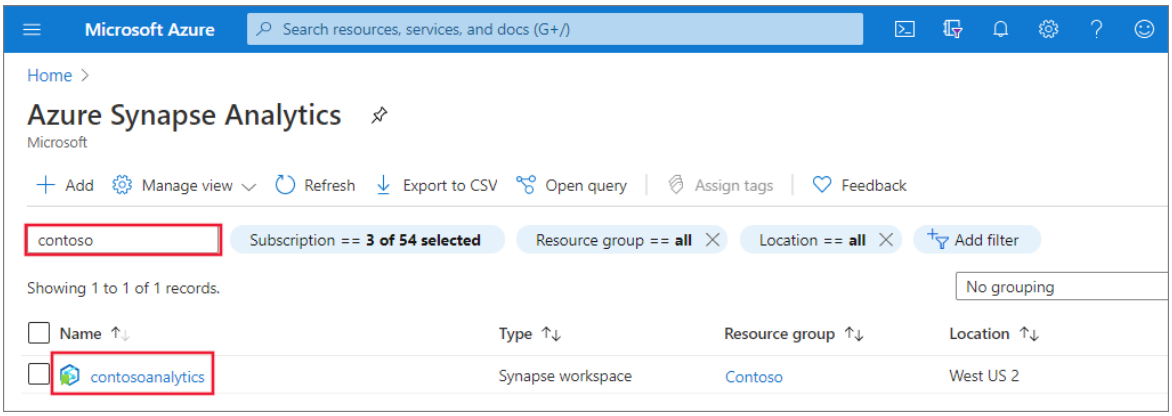
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the dedicated SQL pool will be created by typing the service name (or resource name directly) into the search bar.

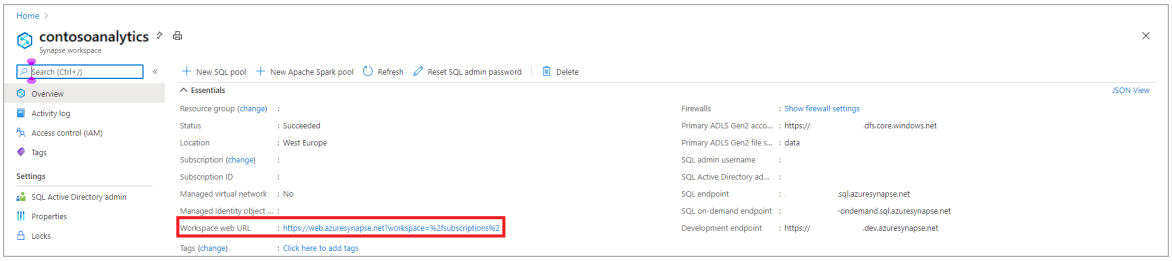


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



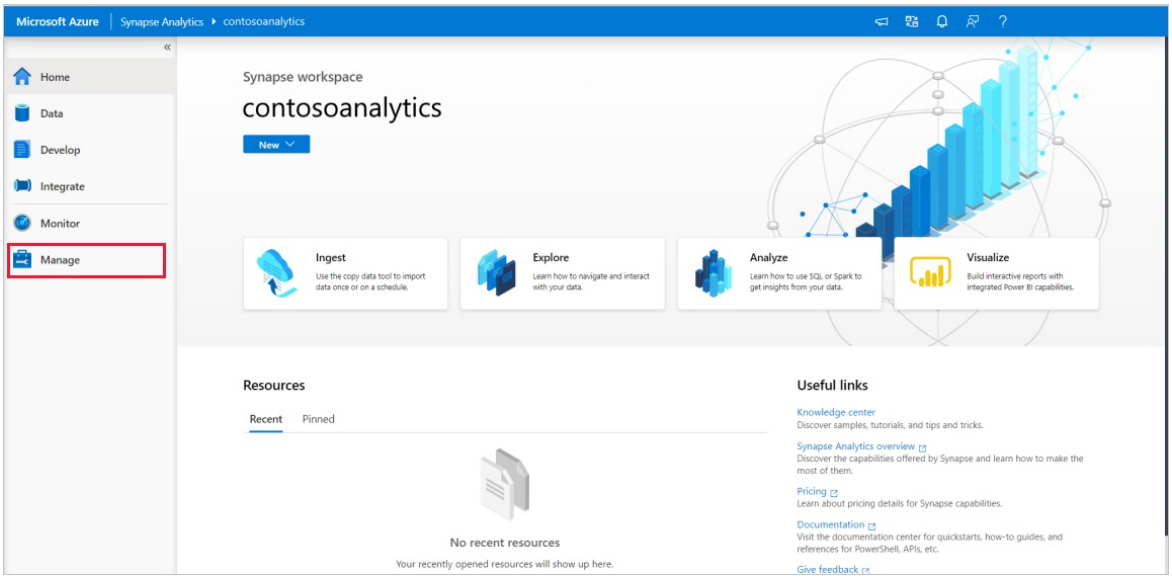
Launch Synapse Studio

1. From the workspace overview, select the **Workspace web URL** to launch Synapse Studio.

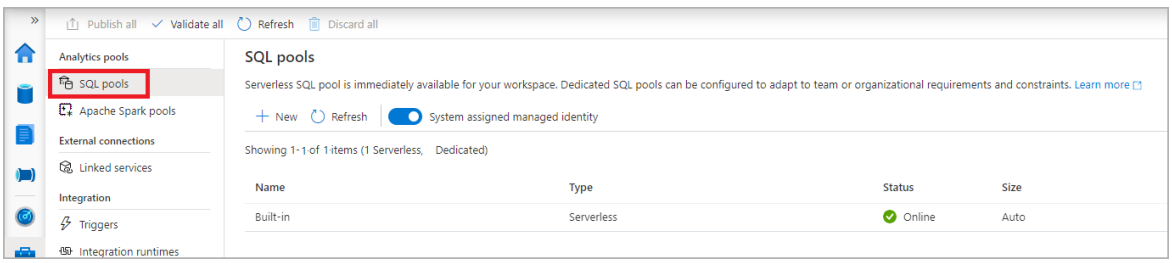


Create a dedicated SQL pool in Synapse Studio

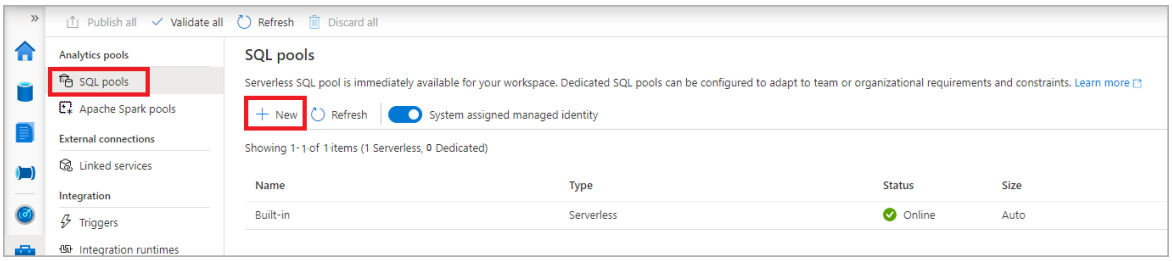
1. On the Synapse Studio home page, navigate to the **Management Hub** in the left navigation by selecting the **Manage** icon.



2. Once in the Management Hub, navigate to the **SQL pools** section to see the current list of SQL pools that are available in the workspace.

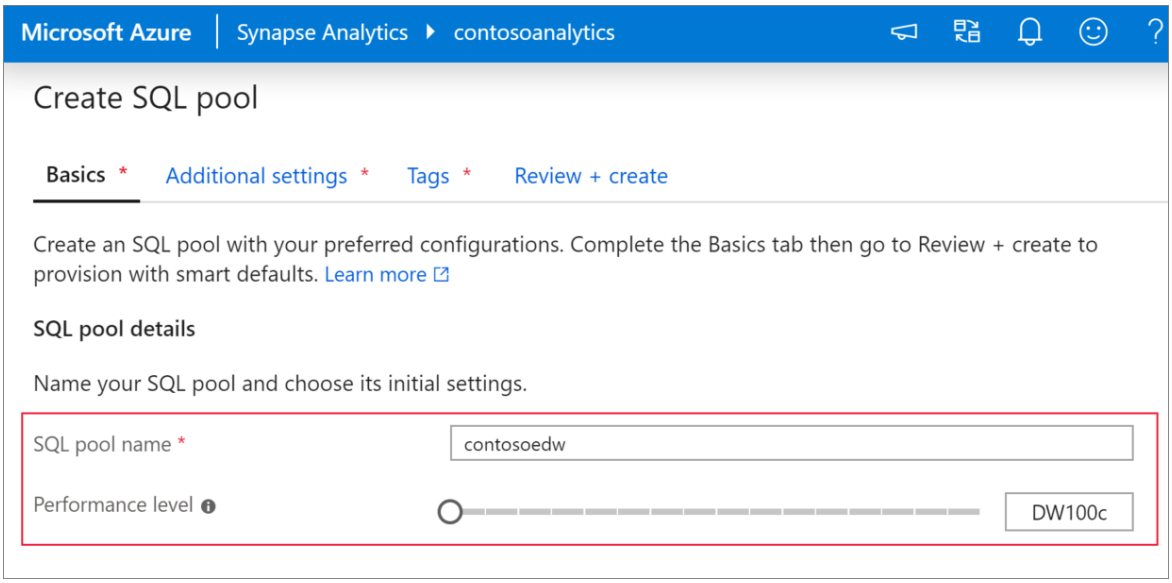


3. Select **+ New** command and the new SQL pool create wizard will appear.



4. Enter the following details in the **Basics** tab:

SETTING	SUGGESTED VALUE	DESCRIPTION
SQL pool name	contosoedw	This is the name that the dedicated SQL pool will have.
Performance level	DW100c	Set this to the smallest size to reduce costs for this quickstart

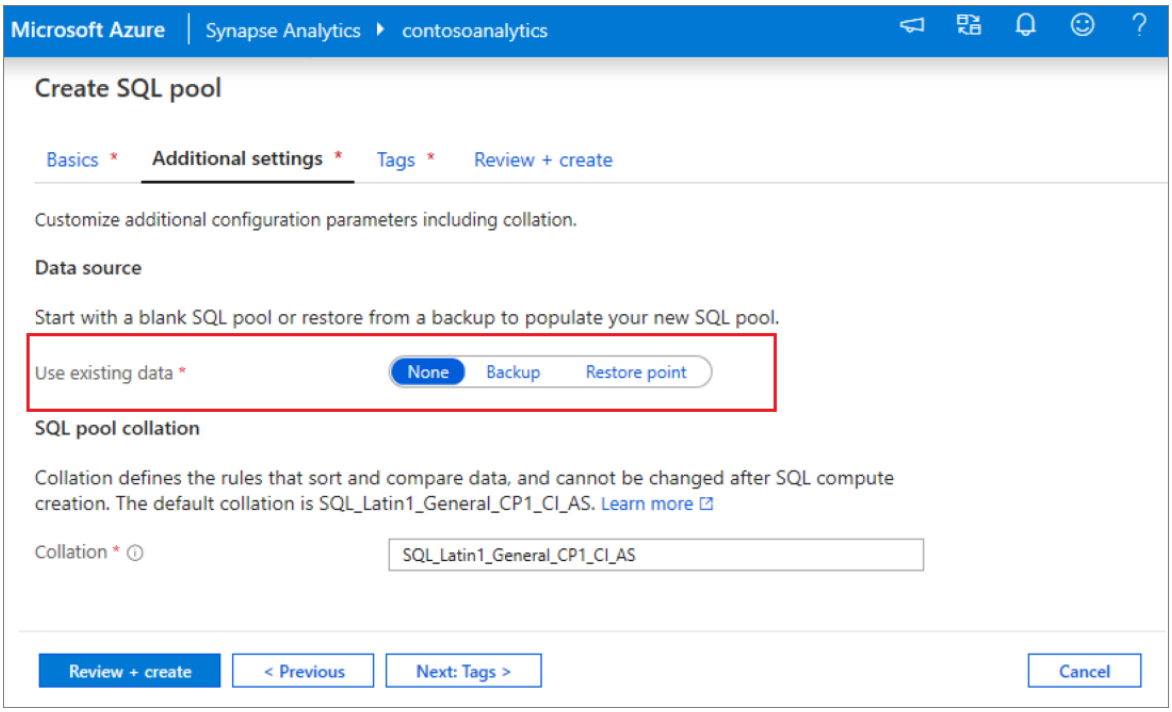


IMPORTANT

Note that there are specific limitations for the names that dedicated SQL pools can use. Names can't contain special characters, must be 60 or less characters, not contain reserved words, and be unique in the workspace.

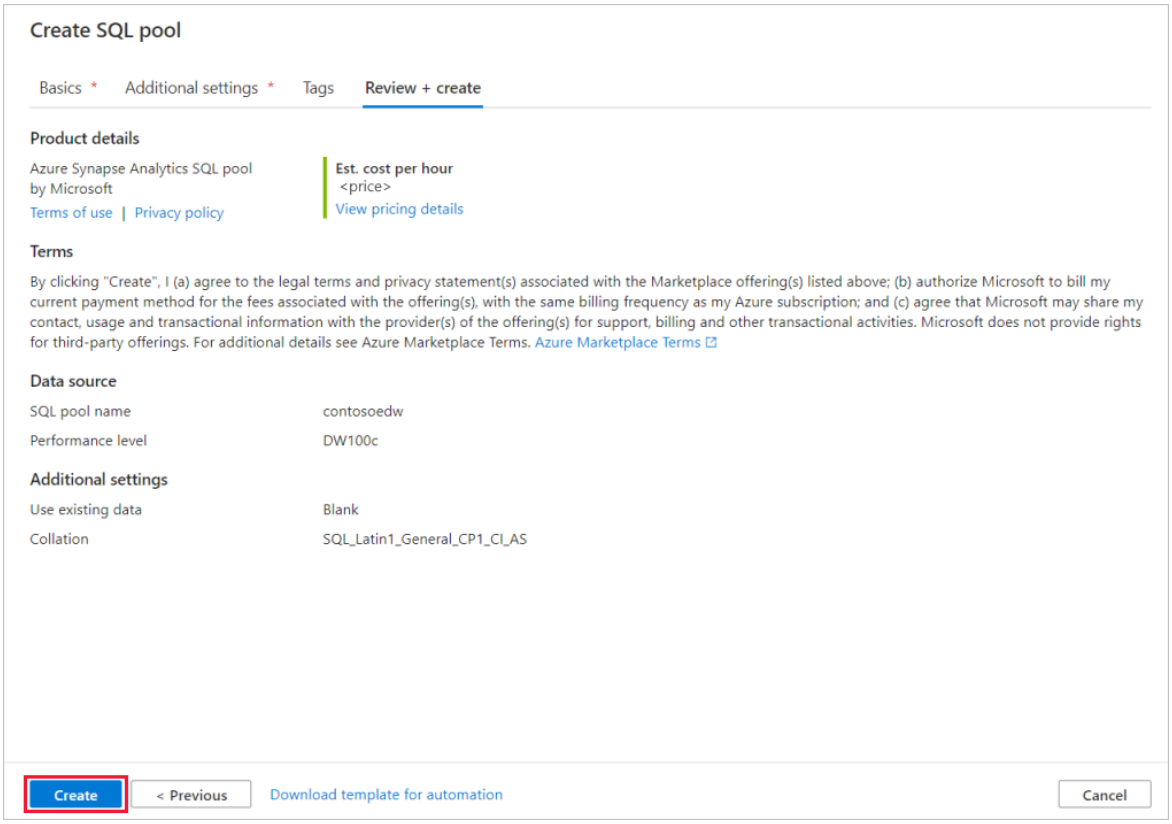
5. In the next tab, **Additional settings**, select **none** to provision the SQL pool without data. Leave the default collation as selected.

   If you want to restore your dedicated SQL pool from a restore point, select **Restore point**. For more information on how to perform a restore, see How-to: Restore an existing dedicated SQL pool



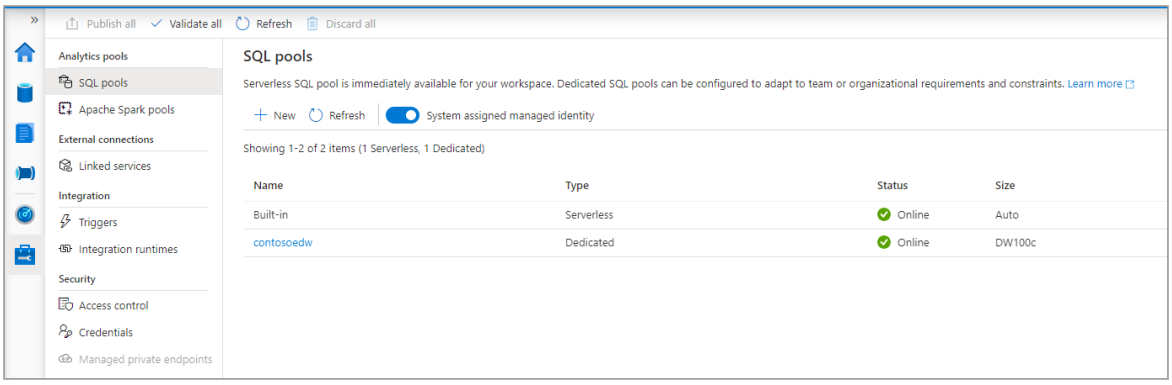
6. We won't add any tags for now, so next select **Review + create**.

7. In the **Review + create** tab, make sure that the details look correct based on what was previously entered, and press **create**.



8. At this point, the resource provisioning flow will start.

9. After the provisioning completes, navigating back to the workspace will show a new entry for the newly created SQL pool.



10. Once the dedicated SQL pool is created, it will be available in the workspace for loading data, processing streams, reading from the lake, etc.

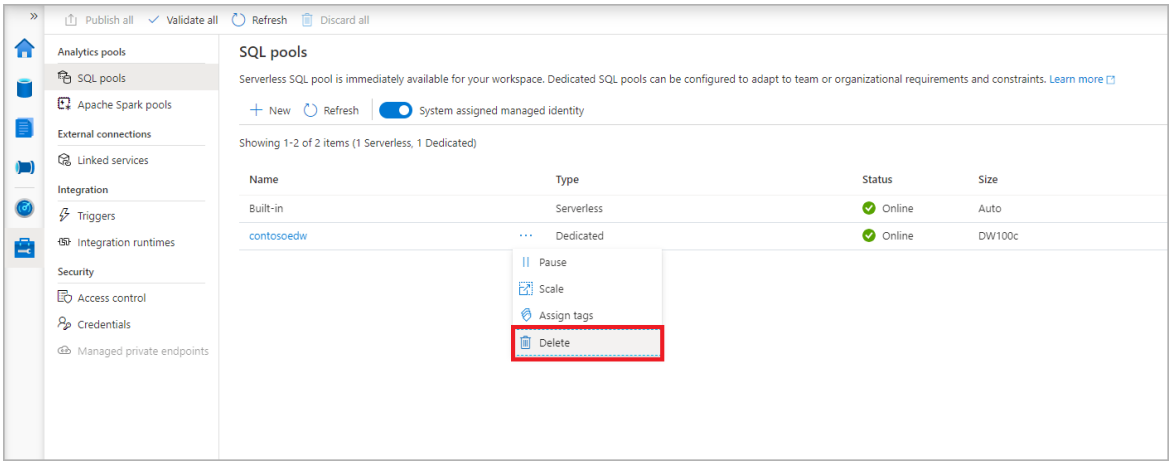
Clean up dedicated SQL pool using Synapse Studio

Follow the steps below to delete the dedicated SQL pool from the workspace using Synapse Studio.

> **WARNING**
> Deleting a dedicated SQL pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, scripts that use this dedicated SQL pool will no longer work.

If you want to delete the dedicated SQL pool, do the following:

1. Navigate to the SQL pools in the Management Hub in Synapse Studio.
2. Select the ellipsis in the dedicated SQL pool to be deleted (in this case, **contosoedw**) to show the commands for the dedicated SQL pool:



3. Press **delete**.
4. Confirm the deletion, and press **Delete** button.
5. When the process completes successfully, the dedicated SQL pool will no longer be listed in the workspace resources.

Next steps

- See Quickstart: Create a dedicated SQL pool using the Azure portal.

Quickstart: Create a dedicated SQL pool using the Azure portal

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics offers various analytics engines to help you ingest, transform, model, and analyze your data. A dedicated SQL pool offers T-SQL based compute and storage capabilities. After creating a dedicated SQL pool in your Synapse workspace, data can be loaded, modeled, processed, and delivered for faster analytic insight.

In this quickstart, you learn how to create a dedicated SQL pool in a Synapse workspace by using the Azure portal.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

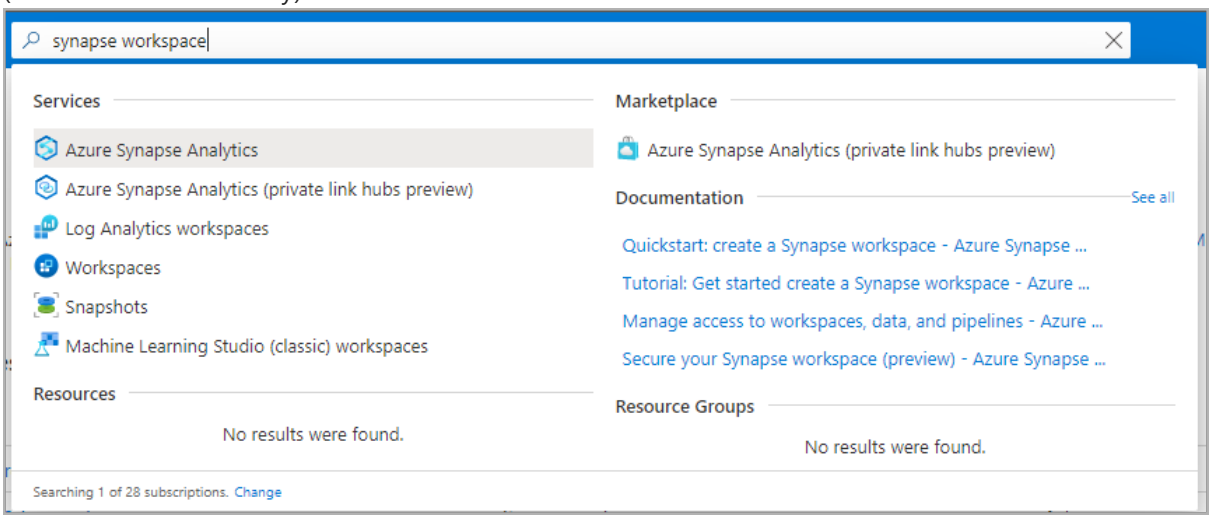
- Azure subscription - create one for free
- Synapse workspace

Sign in to the Azure portal

Sign in to the Azure portal

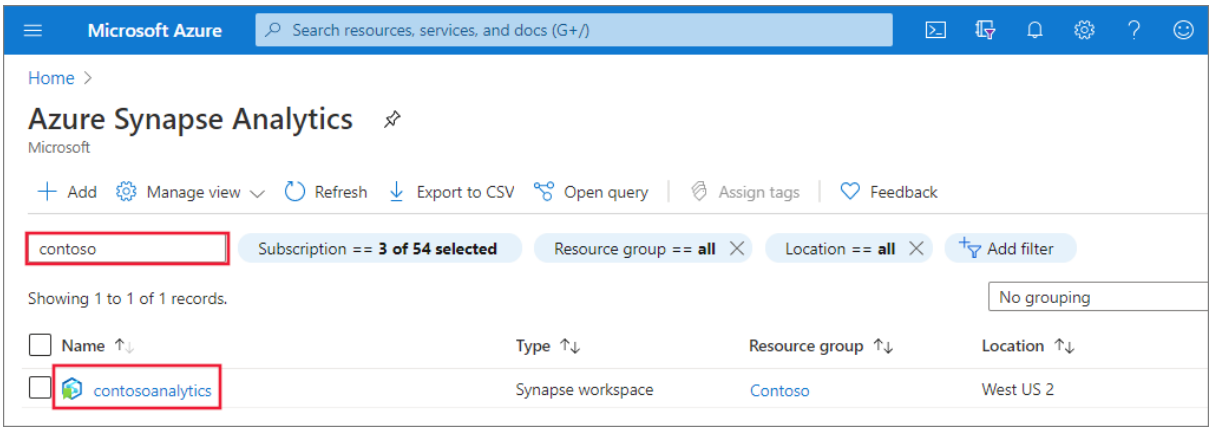
Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the dedicated SQL pool will be created by typing the service name (or resource name directly) into the search bar.



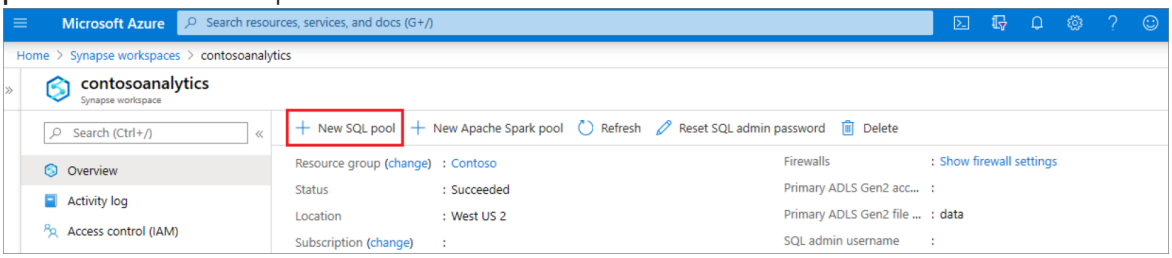
.

2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



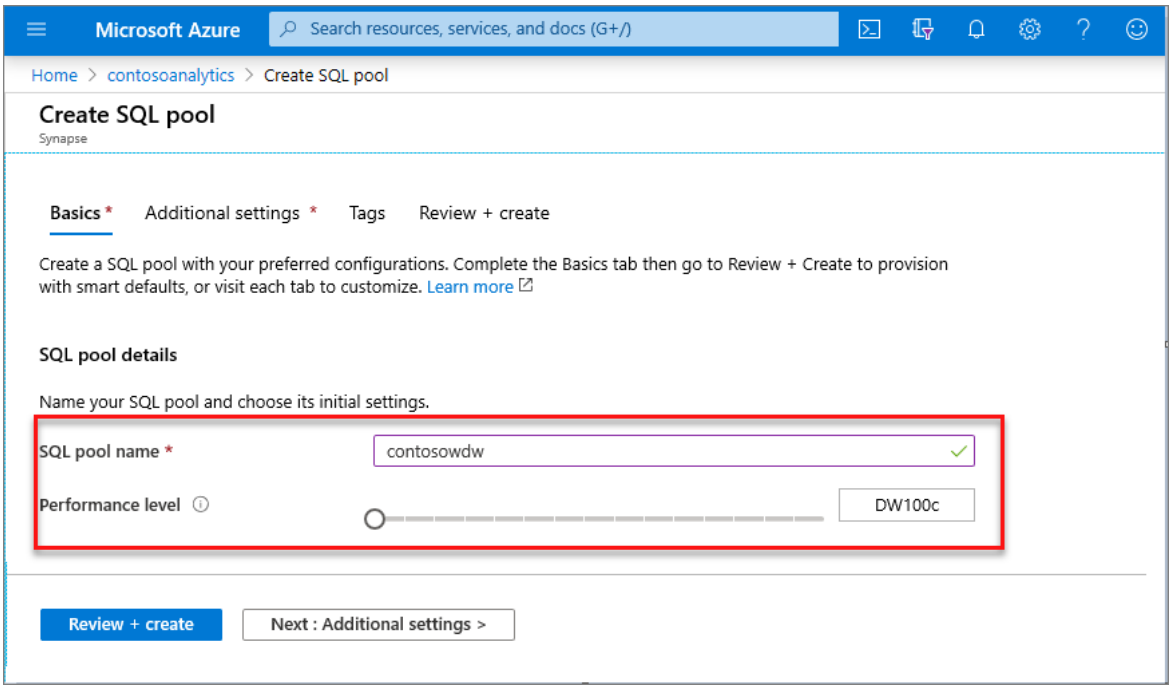
Create new dedicated SQL pool

1. In the Synapse workspace where you want to create the dedicated SQL pool, select **New dedicated SQL pool** command in the top bar.



2. Enter the following details in the **Basics** tab:

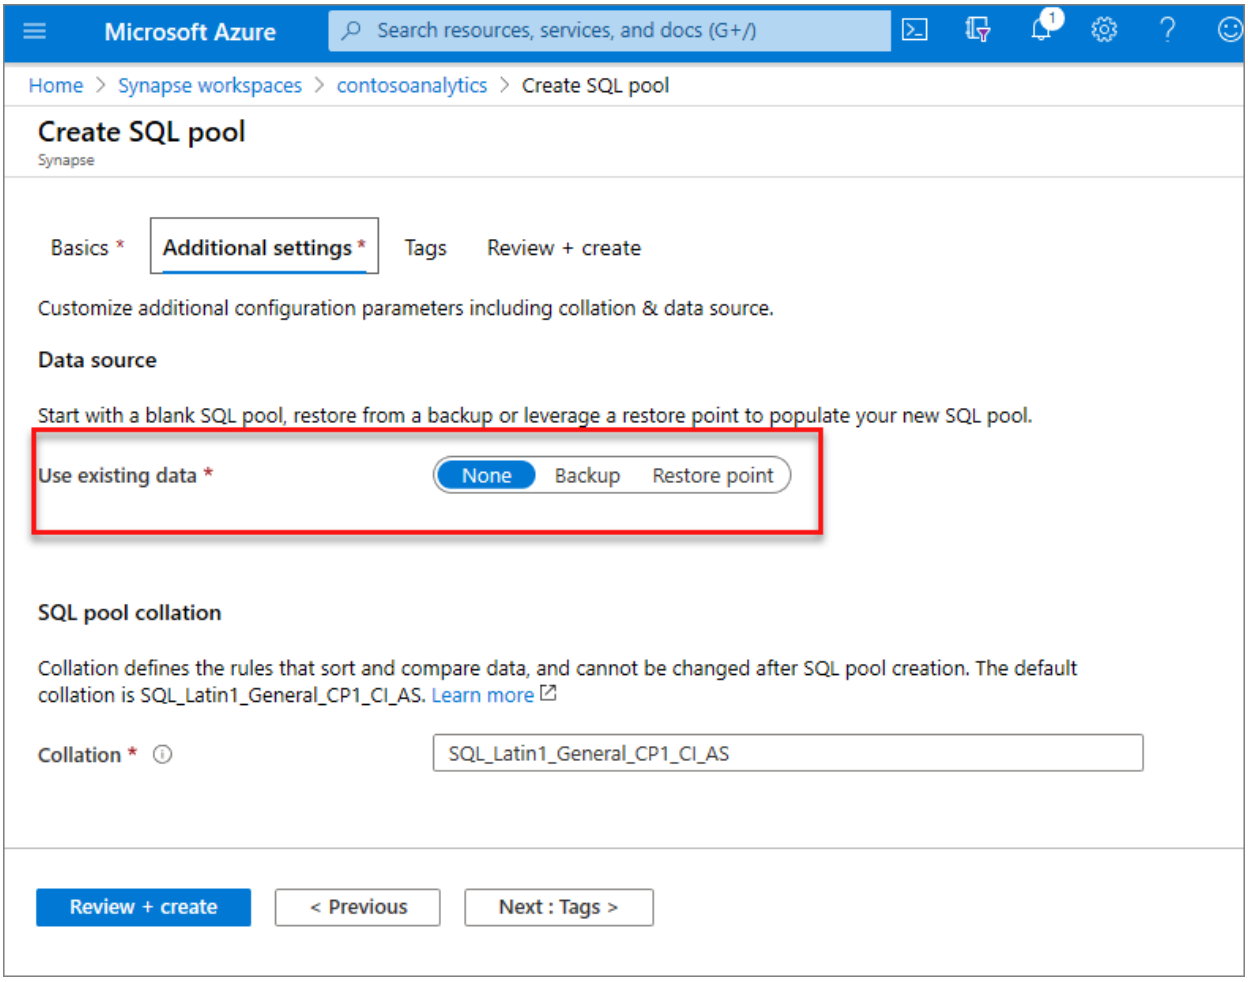
SETTING	SUGGESTED VALUE	DESCRIPTION
Dedicated SQL pool name	Any valid name	Name of the dedicated SQL pool.
Performance level	DW100c	Set to the smallest size to reduce costs for this quickstart



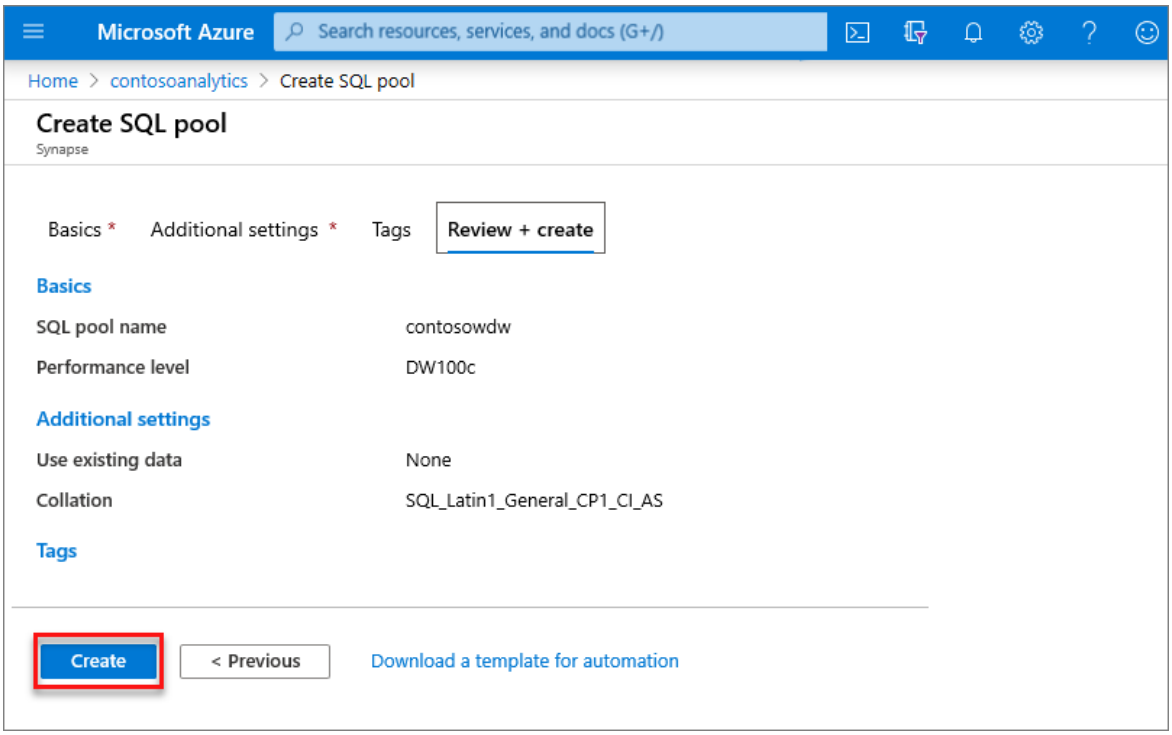
> **IMPORTANT**
>
> Note that there are specific limitations for the names that dedicated SQL pools can use. Names can't contain special characters, must be 60 or less characters, not contain reserved words, and be unique in the workspace.

3. Select **Next: Additional settings**.
4. Select **None** to provision the dedicated SQL pool without data. Leave the default collation selected.

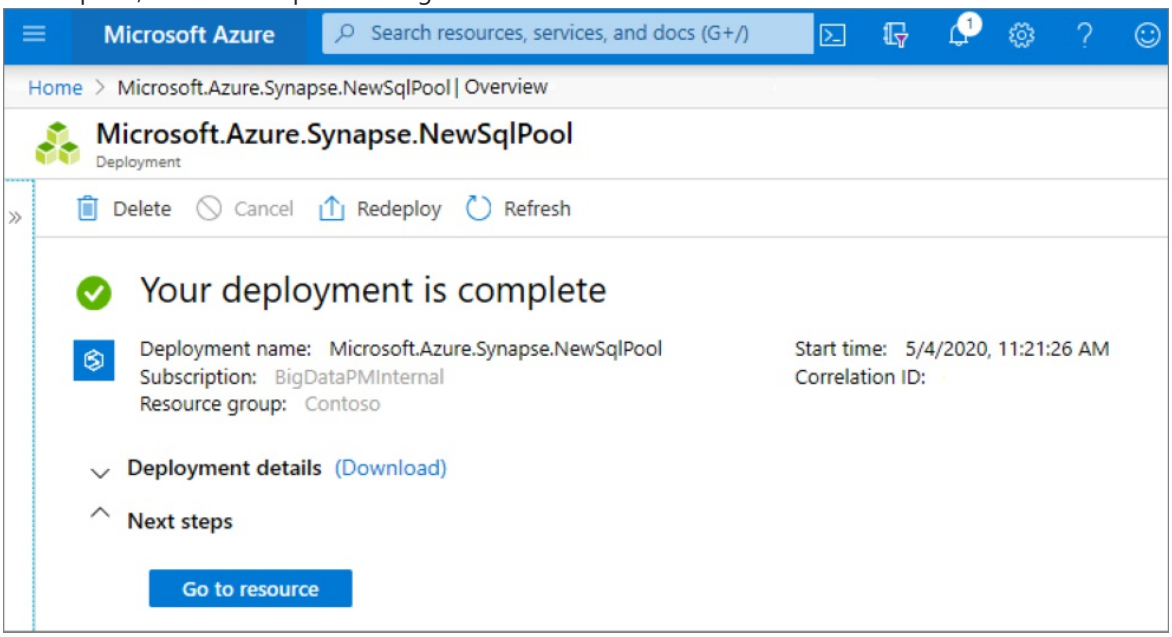
   If you want to restore your dedicated SQL pool from a restore point, select **Restore point**. For more information on how to perform a restore, see How-to: Restore an existing dedicated SQL pool



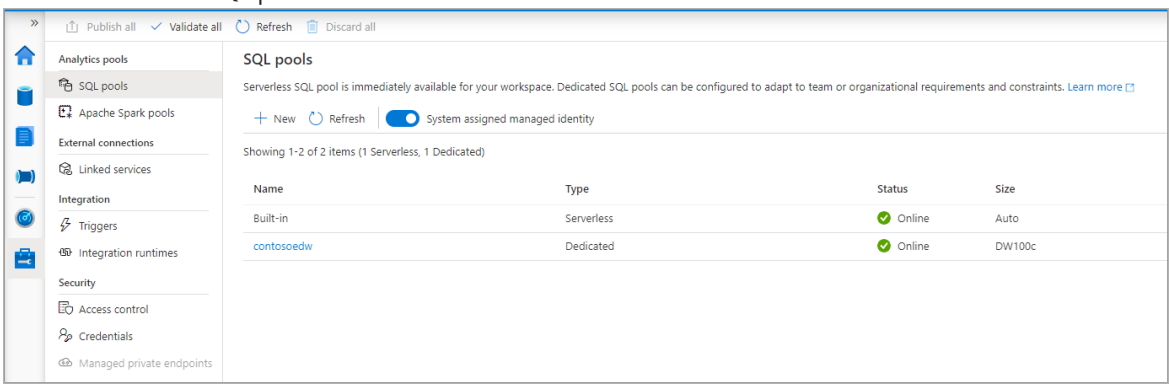
5. Select **Review + create**.
6. Make sure that the details look correct based on what was previously entered. Select **Create**.



7. At this point, the resource provisioning flow will start.



8. After the provisioning completes, navigating back to the workspace will show a new entry for the newly created dedicated SQL pool.



After the dedicated SQL pool is created, it will be available in the workspace for loading data, processing streams, reading from the lake, etc.

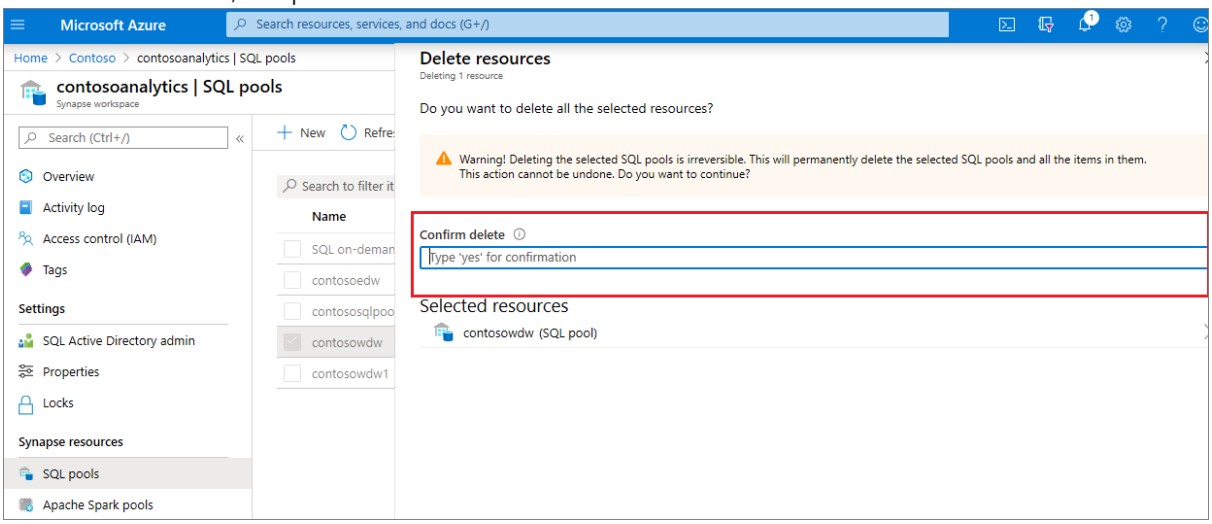
Clean up resources

Follow the steps below to delete the dedicated SQL pool from the workspace.

> **WARNING**
> Deleting a dedicated SQL pool will both remove the analytics engine and the data stored in the database of the deleted dedicated SQL pool from the workspace. It will no longer be possible to connect to the dedicated SQL pool, and all queries, pipelines, and notebooks that read or write to this dedicated SQL pool will no longer work.

If you want to delete the dedicated SQL pool, complete the following steps:

1. Navigate to the SQL pools blade in the workspace blade
2. Select the dedicated SQL pool to be deleted (in this case, **contosowdw**)
3. Once selected, press **delete**
4. Confirm the deletion, and press **Delete** button



5. When the process completes successfully, the dedicated SQL pool will no longer be listed in the workspace resources.

Next steps

- See Quickstart: Create a serverless Apache Spark pool in Synapse Studio using web tools.
- See Quickstart: Create a serverless Apache Spark pool using the Azure portal.

Quickstart: Pause and resume compute in dedicated SQL pool via the Azure portal

8/19/2022 • 2 minutes to read • Edit Online

You can use the Azure portal to pause and resume the dedicated SQL pool compute resources. If you don't have an Azure subscription, create a free account before you begin.

Sign in to the Azure portal

Sign in to the Azure portal.

Before you begin

Use Create and Connect - portal to create a dedicated SQL pool called **mySampleDataWarehouse**.

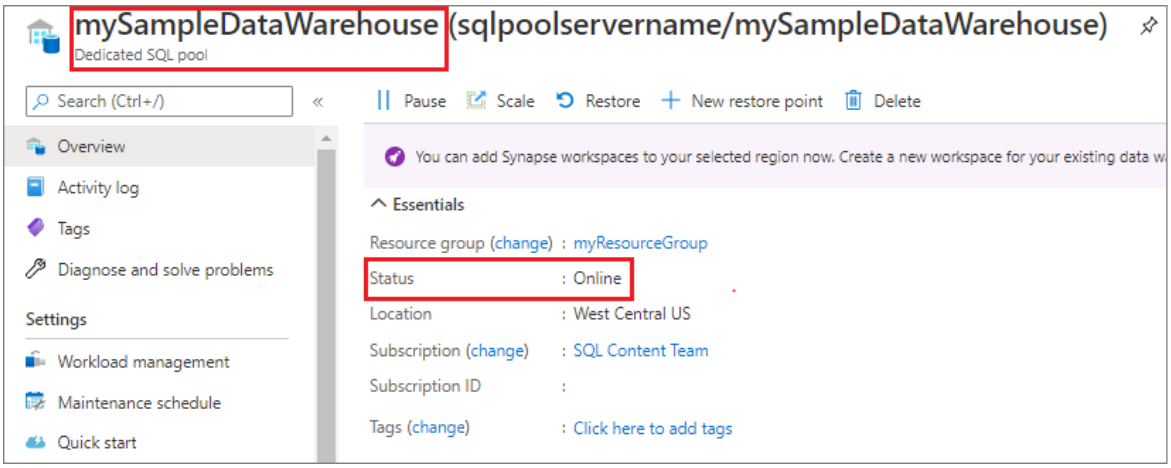
Pause compute

To reduce costs, you can pause and resume compute resources on-demand. For example, if you won't be using the database during the night and on weekends, you can pause it during those times, and resume it during the day.

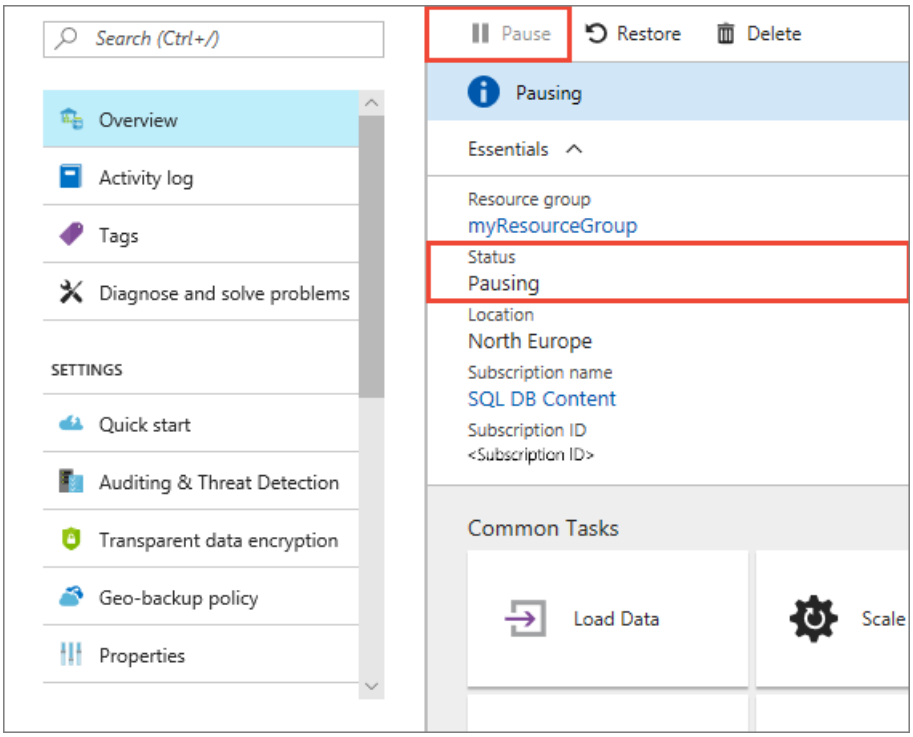
> **NOTE**
> You won't be charged for compute resources while the database is paused. However, you will continue to be charged for storage.

Follow these steps to pause a dedicated SQL pool:

1. Sign in to the Azure portal.
2. Navigate to your the **Dedicated SQL pool** page to open the SQL pool.
3. Notice **Status** is **Online**.

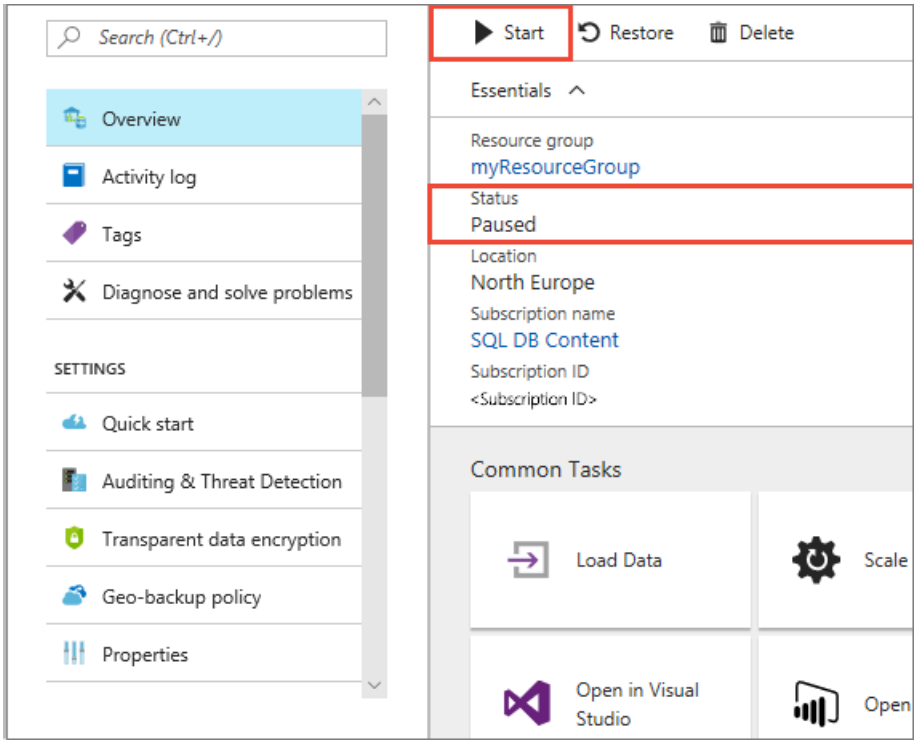


4. To pause the dedicated SQL pool, click the **Pause** button.
5. A confirmation question appears asking if you want to continue. Click **Yes**.
6. Wait a few moments, and then notice the **Status** is **Pausing**.



7. When the pause operation is complete, the status is **Paused** and the option button is **Resume**.

8. The compute resources for the dedicated SQL pool are now offline. You won't be charged for compute until you resume the service.

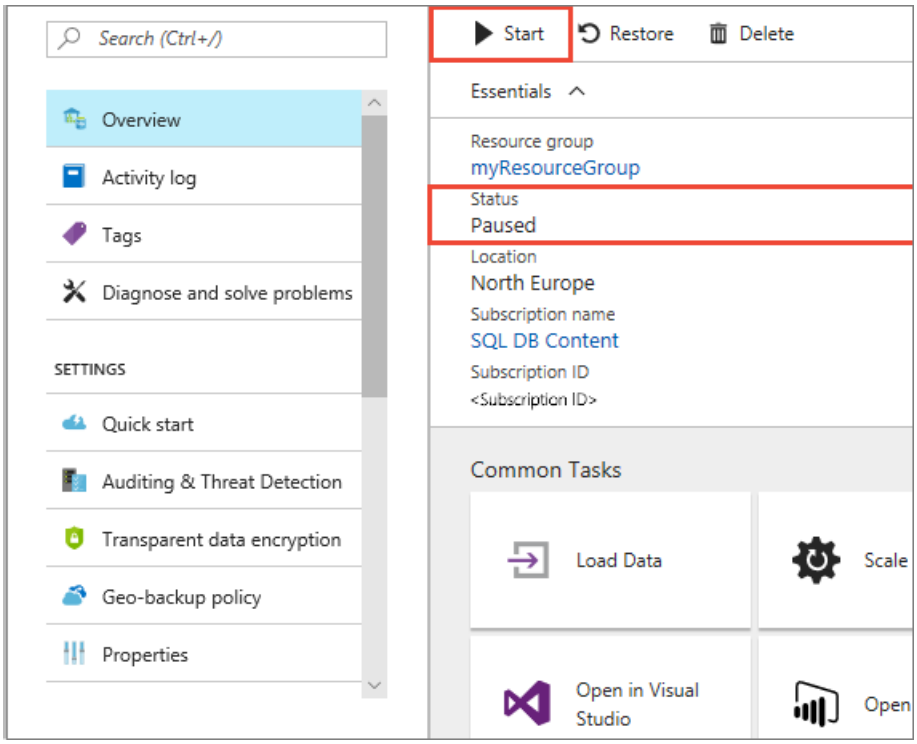


Resume compute

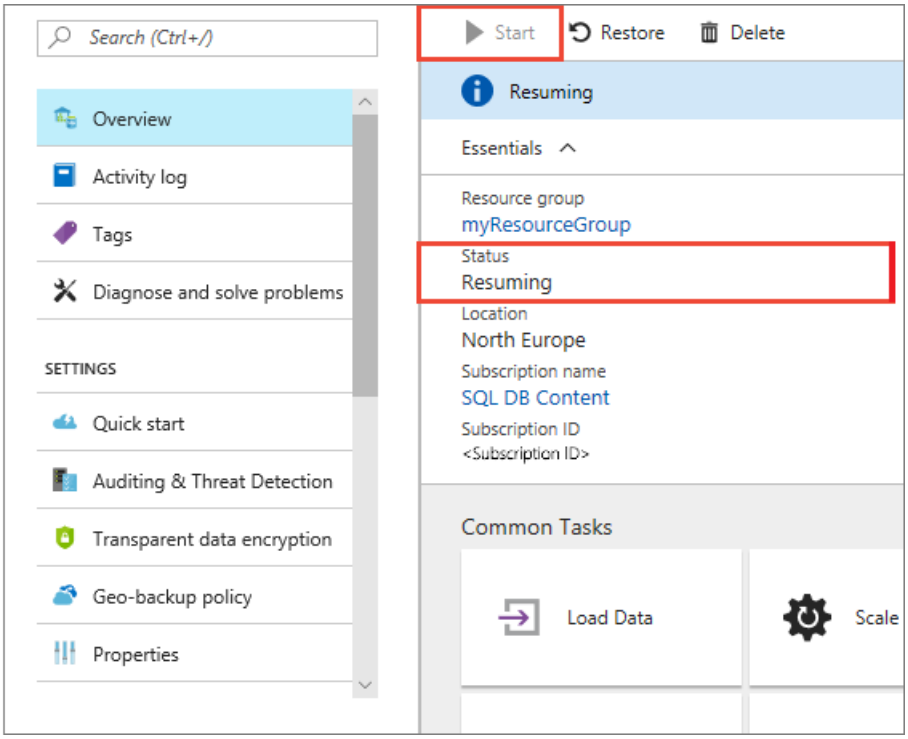
Follow these steps to resume a dedicated SQL pool.

1. Navigate to your the **Dedicated SQL pool** page to open the SQL pool.

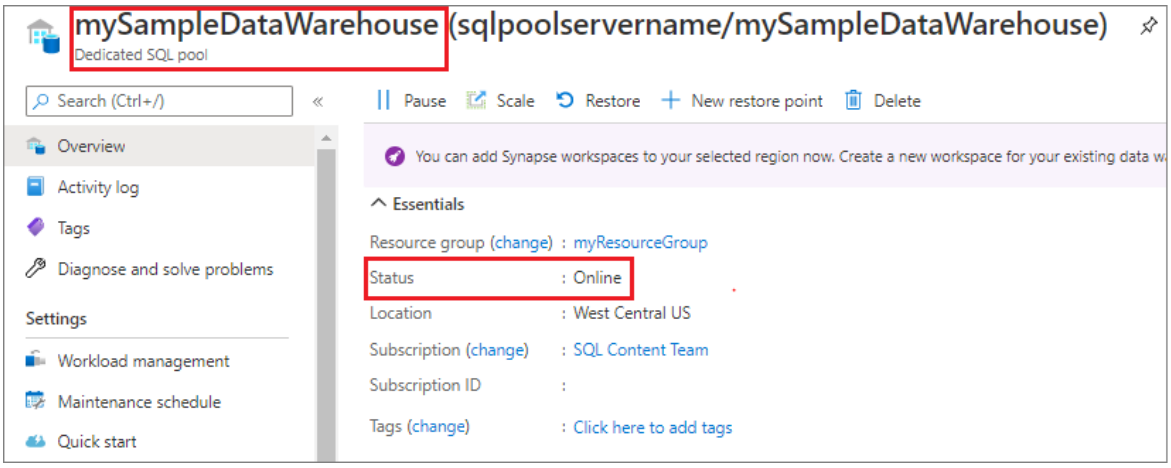
2. On the **mySampleDataWarehouse** page, notice **Status** is **Paused**.



3. To resume SQL pool, click **Resume**.
4. A confirmation question appears asking if you want to start. Click **Yes**.
5. Notice the **Status** is **Resuming**.



6. When the SQL pool is back online, the status is **Online** and the option button is **Pause**.
7. The compute resources for SQL pool are now online and you can use the service. Charges for compute have resumed.



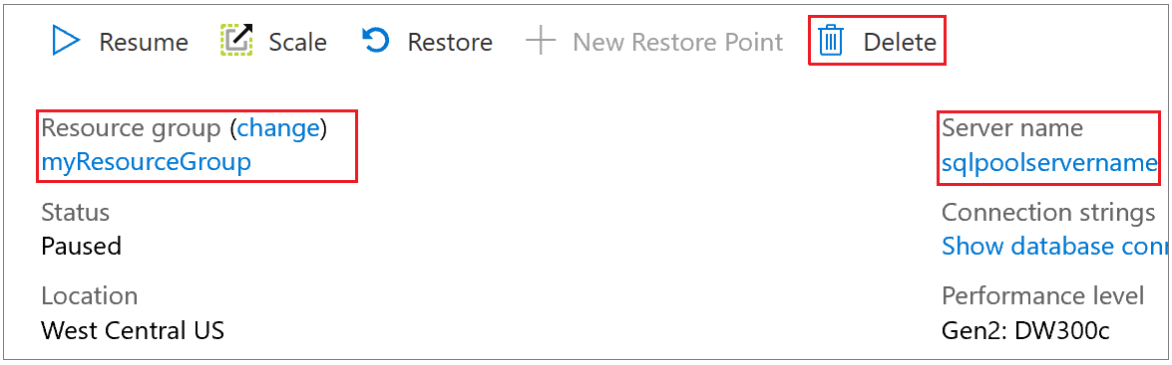
Clean up resources

You are being charged for data warehouse units and the data stored in your dedicated SQL pool. These compute and storage resources are billed separately.

- If you want to keep the data in storage, pause compute.
- If you want to remove future charges, you can delete the dedicated SQL pool.

Follow these steps to clean up resources as you desire.

1. Sign in to the Azure portal, and select your dedicated SQL pool.



2. To pause compute, click the **Pause** button.
3. To remove the dedicated SQL pool so you are not charged for compute or storage, click **Delete**.

Next steps

You have now paused and resumed compute for your dedicated SQL pool. Continue to the next article to learn more about how to Load data into a dedicated SQL pool. For additional information about managing compute capabilities, see the Manage compute overview article.

Quickstart: Bulk load data using the COPY statement

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you'll bulk load data into your dedicated SQL pool using the simple and flexible COPY statement for high-throughput data ingestion. The COPY statement is the recommended loading utility as it enables you to seamlessly and flexibly load data by providing functionality to:

- Allow lower privileged users to load without needing strict CONTROL permissions on the data warehouse
- Leverage only a single T-SQL statement without having to create any additional database objects
- Leverage a finer permission model without exposing storage account keys using Share Access Signatures (SAS)
- Specify a different storage account for the ERRORFILE location (REJECTED_ROW_LOCATION)
- Customize default values for each target column and specify source data fields to load into specific target columns
- Specify a custom row terminator for CSV files
- Escape string, field, and row delimiters for CSV files
- Leverage SQL Server Date formats for CSV files
- Specify wildcards and multiple files in the storage location path

Prerequisites

This quickstart assumes you already have a dedicated SQL pool. If a dedicated SQL pool hasn't been created, use the Create and Connect - portal quickstart.

Set up the required permissions

```
-- List the permissions for your user
select  princ.name
,       princ.type_desc
,       perm.permission_name
,       perm.state_desc
,       perm.class_desc
,       object_name(perm.major_id)
from    sys.database_principals princ
left join
        sys.database_permissions perm
on      perm.grantee_principal_id = princ.principal_id
where name = '<yourusername>';

--Make sure your user has the permissions to CREATE tables in the [dbo] schema
GRANT CREATE TABLE TO <yourusername>;
GRANT ALTER ON SCHEMA::dbo TO <yourusername>;

--Make sure your user has ADMINISTER DATABASE BULK OPERATIONS permissions
GRANT ADMINISTER DATABASE BULK OPERATIONS TO <yourusername>

--Make sure your user has INSERT permissions on the target table
GRANT INSERT ON <yourtable> TO <yourusername>
```

Create the target table

In this example, we'll be loading data from the New York taxi dataset. We'll load a table called Trip that represents taxi trips taken within a single year. Run the following to create the table:

```
CREATE TABLE [dbo].[Trip]
(
    [DateID] int NOT NULL,
    [MedallionID] int NOT NULL,
    [HackneyLicenseID] int NOT NULL,
    [PickupTimeID] int NOT NULL,
    [DropoffTimeID] int NOT NULL,
    [PickupGeographyID] int NULL,
    [DropoffGeographyID] int NULL,
    [PickupLatitude] float NULL,
    [PickupLongitude] float NULL,
    [PickupLatLong] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DropoffLatitude] float NULL,
    [DropoffLongitude] float NULL,
    [DropoffLatLong] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [PassengerCount] int NULL,
    [TripDurationSeconds] int NULL,
    [TripDistanceMiles] float NULL,
    [PaymentType] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [FareAmount] money NULL,
    [SurchargeAmount] money NULL,
    [TaxAmount] money NULL,
    [TipAmount] money NULL,
    [TollsAmount] money NULL,
    [TotalAmount] money NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);
```

Run the COPY statement

Run the following COPY statement that will load data from the Azure blob storage account into the Trip table.

```
COPY INTO [dbo].[Trip] FROM 'https://nytaxiblob.blob.core.windows.net/2013/Trip2013/'
WITH (
   FIELDTERMINATOR='|',
   ROWTERMINATOR='0x0A'
) OPTION (LABEL = 'COPY: dbo.trip');
```

Monitor the load

Check whether your load is making progress by periodically running the following query:

```
SELECT  r.[request_id]
,       r.[status]
,       r.resource_class
,       r.command
,       sum(bytes_processed) AS bytes_processed
,       sum(rows_processed) AS rows_processed
FROM    sys.dm_pdw_exec_requests r
              JOIN sys.dm_pdw_dms_workers w
                     ON r.[request_id] = w.request_id
WHERE [label] = 'COPY: dbo.trip' and session_id <> session_id() and type = 'WRITER'
GROUP BY r.[request_id]
,       r.[status]
,       r.resource_class
,       r.command;
```

Next steps

- For best practices on data loading, see Best Practices for Loading Data.
- For information on how to manage the resources for your data loads, see Workload Isolation.

Securely load data using Synapse SQL

8/19/2022 • 4 minutes to read • Edit Online

This article highlights and provides examples on the secure authentication mechanisms for the COPY statement. The COPY statement is the most flexible and secure way of bulk loading data in Synapse SQL.

Supported authentication mechanisms

The following matrix describes the supported authentication methods for each file type and storage account. This applies to the source storage location and the error file location.

	CSV	PARQUET	ORC
Azure blob storage	SAS/MSI/SERVICE PRINCIPAL/KEY/AAD	SAS/KEY	SAS/KEY
Azure Data Lake Gen2	SAS/MSI/SERVICE PRINCIPAL/KEY/AAD	SAS (blob[1])/MSI (dfs[2])/SERVICE PRINCIPAL/KEY/AAD	SAS (blob[1])/MSI (dfs[2])/SERVICE PRINCIPAL/KEY/AAD

1: The .blob endpoint (`.blob.core.windows.net`) in your external location path is required for this authentication method.

2: The .dfs endpoint (`.dfs.core.windows.net`) in your external location path is required for this authentication method.

A. Storage account key with LF as the row terminator (Unix-style new line)

```
--Note when specifying the column list, input field numbers start from 1
COPY INTO target_table (Col_one default 'myStringDefault' 1, Col_two default 1 3)
FROM 'https://adlsgen2account.dfs.core.windows.net/myblobcontainer/folder1/'
WITH (
    FILE_TYPE = 'CSV'
    ,CREDENTIAL=(IDENTITY= 'Storage Account Key', SECRET='<Your_Account_Key>')
    --CREDENTIAL should look something like this:
    --CREDENTIAL=(IDENTITY= 'Storage Account Key', SECRET='<secret>'),
    ,ROWTERMINATOR='0x0A' --0x0A specifies to use the Line Feed character (Unix based systems)
)
```

IMPORTANT

- Use the hexadecimal value (0x0A) to specify the Line Feed/Newline character. Note the COPY statement will interpret the `\n` string as `\r\n` (carriage return newline).

B. Shared Access Signatures (SAS) with CRLF as the row terminator (Windows style new line)

```
COPY INTO target_table
FROM 'https://adlsgen2account.dfs.core.windows.net/myblobcontainer/folder1/'
WITH (
    FILE_TYPE = 'CSV'
    ,CREDENTIAL=(IDENTITY= 'Shared Access Signature', SECRET='<Your_SAS_Token>')
    --CREDENTIAL should look something like this:
    --CREDENTIAL=(IDENTITY= 'Shared Access Signature', SECRET='?sv=2018-03-28&ss=bfqt&srt=sco&sp=rl&st=2016-
10-17T20%3A14%3A55Z&se=2021-10-18T20%3A19%3A00Z&sig=IEoOdmeYnE9%2FKiJDSFSYsz4AkN'),
    ,ROWTERMINATOR='\n'-- COPY command automatically prefixes the \r character when \n (newline) is
specified. This results in carriage return newline (\r\n) for Windows based systems.
)
```

IMPORTANT

Do not specify the `ROWTERMINATOR` as '\r\n' which will be interpreted as '\r\r\n' and can result in parsing issues. The COPY command automatically prefixes the \r character when \n (newline) is specified. This results in carriage return newline (\r\n) for Windows based systems.

C. Managed Identity

Managed Identity authentication is required when your storage account is attached to a VNet.

Prerequisites

1. Install Azure PowerShell. Refer to Install PowerShell.
2. If you have a general-purpose v1 or blob storage account, you must first upgrade to general-purpose v2. Refer to Upgrade to a general-purpose v2 storage account.
3. You must have **Allow trusted Microsoft services to access this storage account** turned on under Azure Storage account **Firewalls and Virtual networks** settings menu. Refer to Configure Azure Storage firewalls and virtual networks.

Steps

1. If you have a standalone dedicated SQL pool, register your SQL server with Azure Active Directory (Azure AD) using PowerShell:

   ```
   Connect-AzAccount
   Select-AzSubscription -SubscriptionId <subscriptionId>
   Set-AzSqlServer -ResourceGroupName your-database-server-resourceGroup -ServerName your-SQL-servername
   -AssignIdentity
   ```

   This step is not required for dedicated SQL pools within a Synapse workspace. The system assigned managed identity (SA-MI) of the workspace is a member of the Synapse Administrator role and thus has elevated privileges on the dedicated SQL pools of the workspace.

2. Create a **general-purpose v2 Storage Account**. For more information, see Create a storage account.

   NOTE

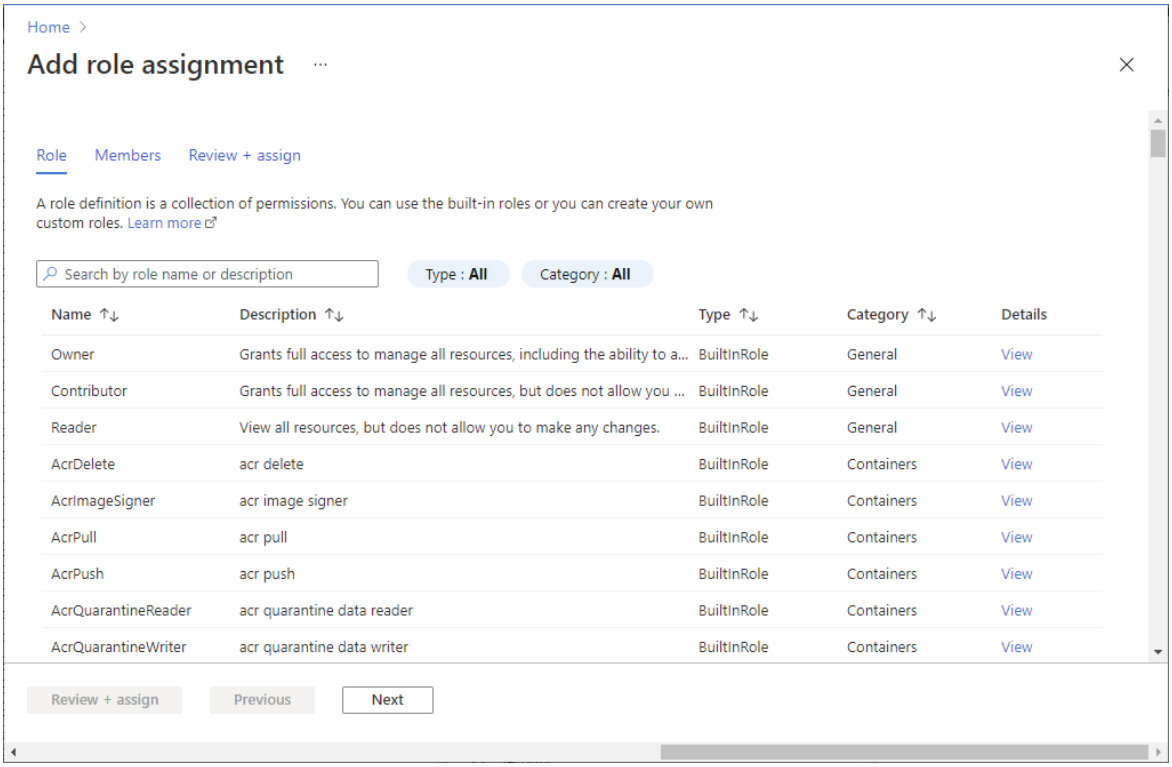
   - If you have a general-purpose v1 or blob storage account, you must **first upgrade to v2**. For more information, see Upgrade to a general-purpose v2 storage account.
   - For known issues with Azure Data Lake Storage Gen2, refer to Known issues with Azure Data Lake Storage Gen2.

3. Under your storage account, select **Access control (IAM)**.

4. Select **Add** > **Add role assignment** to open the Add role assignment page.

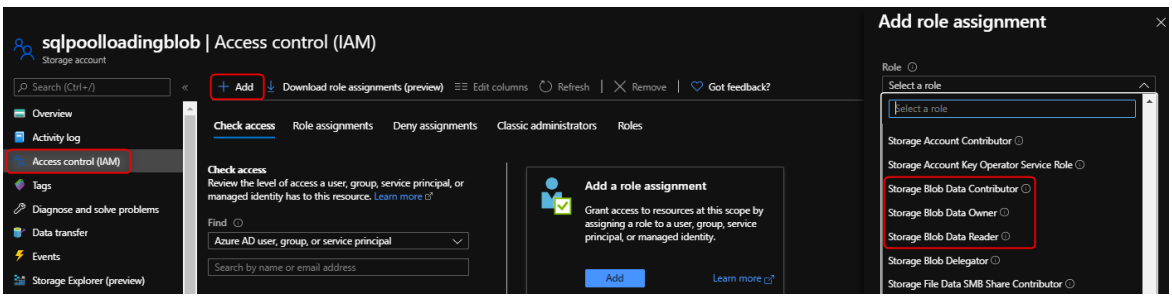
5. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Contributor
Assign access to	SERVICEPRINCIPAL
Members	server or workspace hosting your dedicated SQL pool that you've registered with Azure Active Directory (Azure AD)



> **NOTE**
>
> Only members with Owner privilege can perform this step. For various Azure built-in roles, refer to Azure built-in roles.

> **IMPORTANT**
>
> Specify the **Storage Blob Data** Owner, Contributor, or Reader Azure role. These roles are different than the Azure built-in roles of Owner, Contributor, and Reader.



6. You can now run the COPY statement specifying "Managed Identity":

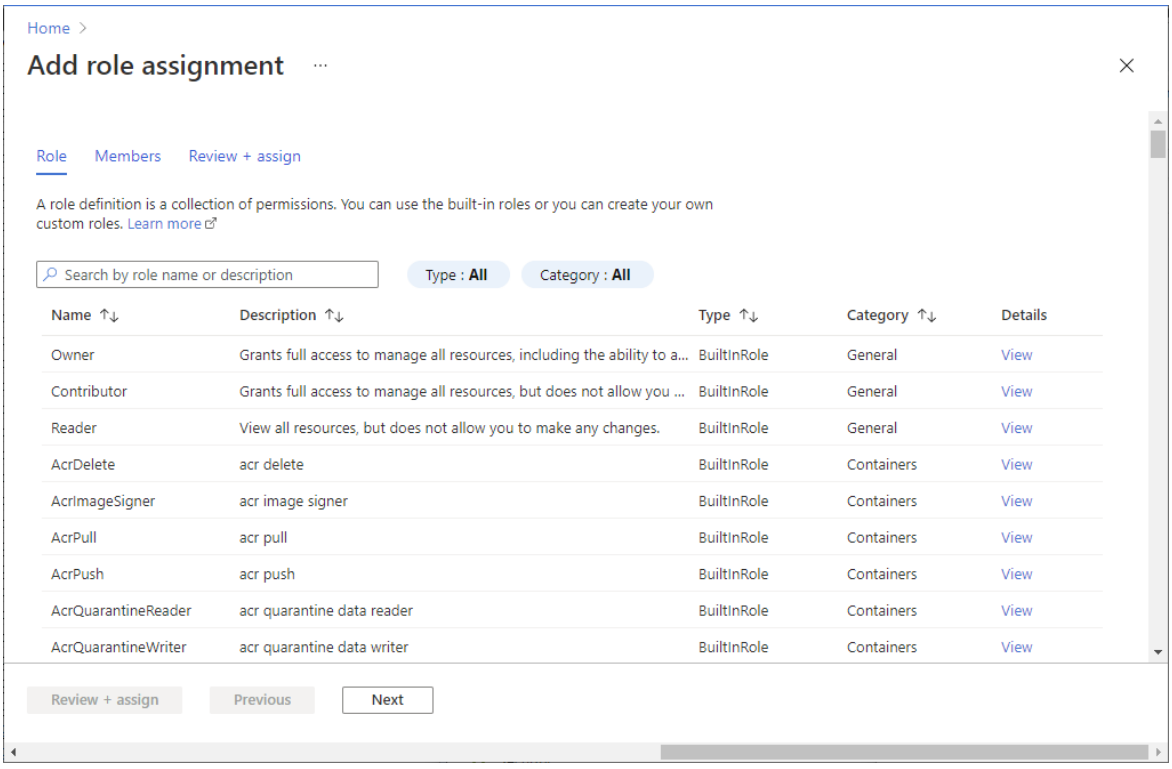
```
COPY INTO dbo.target_table
FROM 'https://myaccount.blob.core.windows.net/myblobcontainer/folder1/*.txt'
WITH (
    FILE_TYPE = 'CSV',
    CREDENTIAL = (IDENTITY = 'Managed Identity'),
)
```

D. Azure Active Directory Authentication

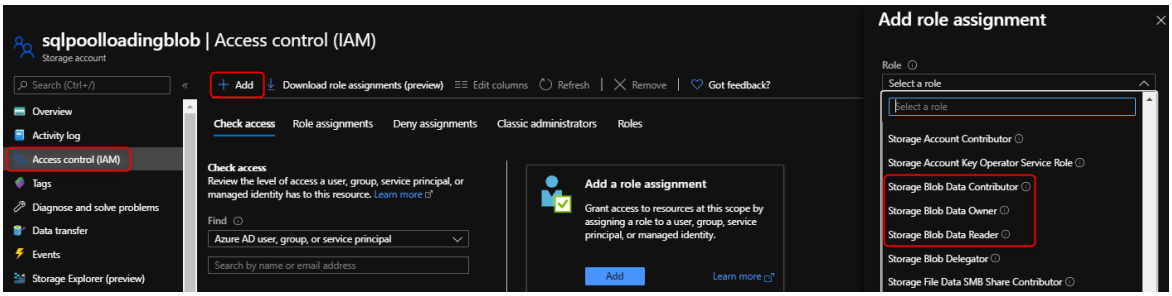
Steps

1. Under your storage account, select **Access control (IAM)**.
2. Select **Add** > **Add role assignment** to open the Add role assignment page.
3. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Owner, Contributor, or Reader
Assign access to	USER
Members	Azure AD user



> **IMPORTANT**
>
> Specify the **Storage Blob Data** Owner, Contributor, or Reader Azure role. These roles are different than the Azure built-in roles of Owner, Contributor, and Reader.



4. Configure Azure AD authentication. Refer to Configure and manage Azure AD authentication with Azure SQL.

5. Connect to your SQL pool using Active Directory where you can now run the COPY statement without specifying any credentials:

```
COPY INTO dbo.target_table
FROM 'https://myaccount.blob.core.windows.net/myblobcontainer/folder1/*.txt'
WITH (
    FILE_TYPE = 'CSV'
)
```

E. Service Principal Authentication

Steps

1. Create an Azure Active Directory application.
2. Get application ID.
3. Get the authentication key.
4. Get the V1 OAuth 2.0 token endpoint.
5. Assign read, write, and execution permissions to your Azure AD application on your storage account.
6. You can now run the COPY statement:

```
COPY INTO dbo.target_table
FROM 'https://myaccount.blob.core.windows.net/myblobcontainer/folder0/*.txt'
WITH (
    FILE_TYPE = 'CSV'
    ,CREDENTIAL=(IDENTITY= '<application_ID>@<OAuth_2.0_Token_EndPoint>' , SECRET=
'<authentication_key>')
    --CREDENTIAL should look something like this:
    --,CREDENTIAL=(IDENTITY= '92761aac-12a9-4ec3-89b8-
7149aef4c35b@https://login.microsoftonline.com/72f714bf-86f1-41af-91ab-2d7cd011db47/oauth2/token',
SECRET='juXi12sZ6gse]woKQNgqwSywYv]7A.M')
)
```

> **IMPORTANT**
>
> Use the **V1** version of the OAuth 2.0 token endpoint

Next steps

- Check the COPY statement article article for the detailed syntax
- Check the data loading overview article for loading best practices

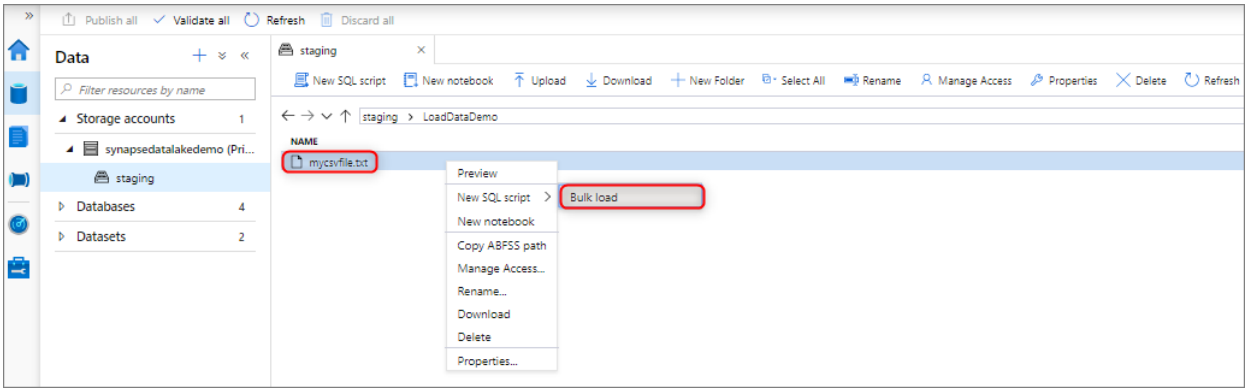
Quickstart: Bulk loading with Synapse Studio

8/19/2022 • 2 minutes to read • Edit Online

Loading data is easy with the Bulk Load wizard in Synapse Studio. Synapse Studio is a feature of Azure Synapse Analytics. The Bulk Load wizard guides you through creating a T-SQL script with the COPY statement to bulk load data into a dedicated SQL pool.

Entry points to the Bulk Load wizard

You can bulk load data by right-clicking the following area within Synapse Studio: a file or folder from an Azure storage account that's attached to your workspace.

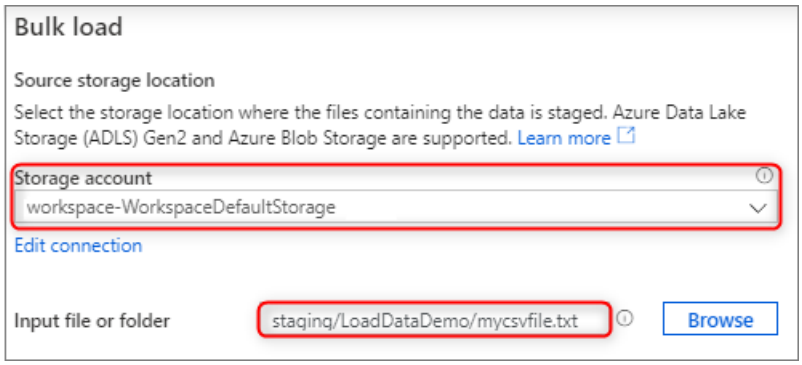


Prerequisites

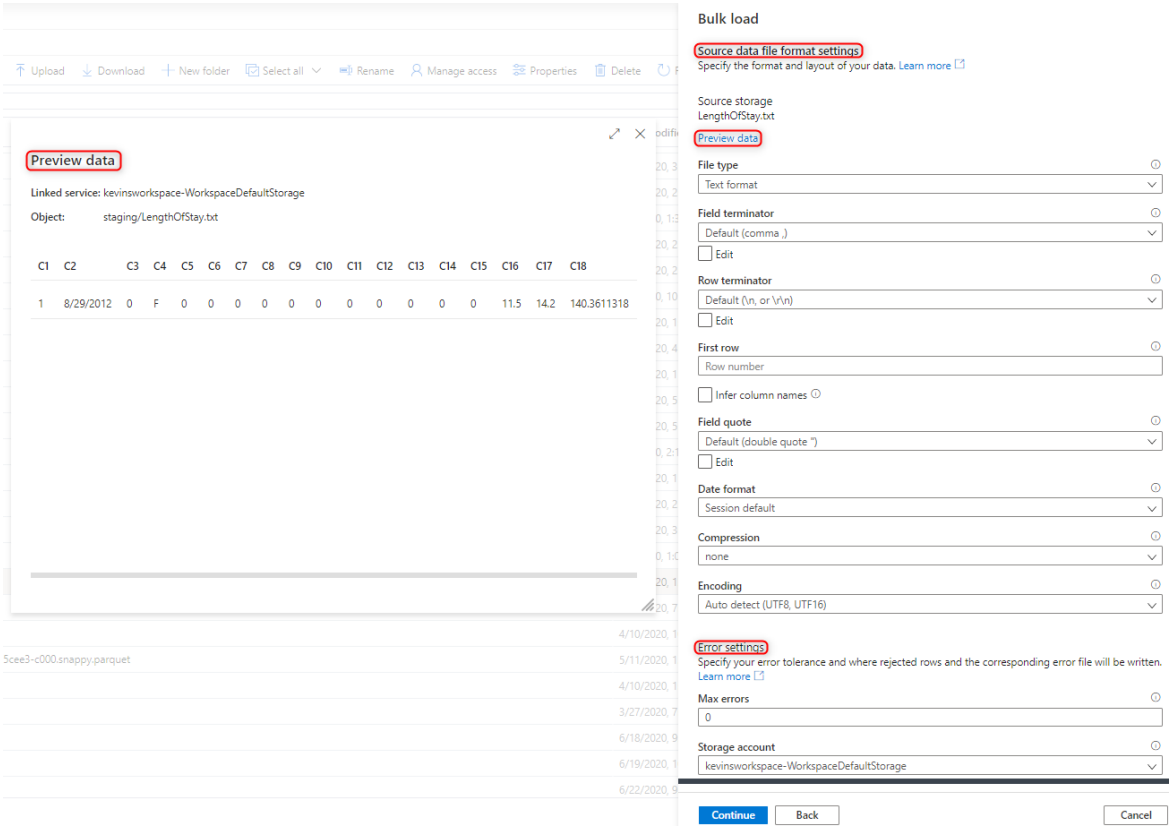
- The wizard generates a COPY statement, which uses Azure Active Directory (Azure AD) pass-through for authentication. Your Azure AD user must have access to the workspace with at least the Storage Blob Data Contributor Azure role for the Azure Data Lake Storage Gen2 account.
- You must have the required permissions to use the COPY statement and Create Table permissions if you're creating a new table to load to.
- The linked service associated with the Data Lake Storage Gen2 account *must have access to the file or folder* to load. For example, if the authentication mechanism for the linked service is a managed identity, the workspace's managed identity must have at least Storage Blob Data Reader permission on the storage account.
- If a virtual network is enabled on your workspace, make sure the integrated runtime associated with the Data Lake Storage Gen2 account's linked services for the source data and error file location has interactive authoring enabled. Interactive authoring is required for autoschema detection, previewing the source file contents, and browsing Data Lake Storage Gen2 storage accounts within the wizard.

Steps

1. On the **Source storage location** panel, select the storage account and the file or folder you're loading from. The wizard automatically tries to detect Parquet files and delimited text (CSV) files, including mapping the source fields from the file to the appropriate target SQL data types.



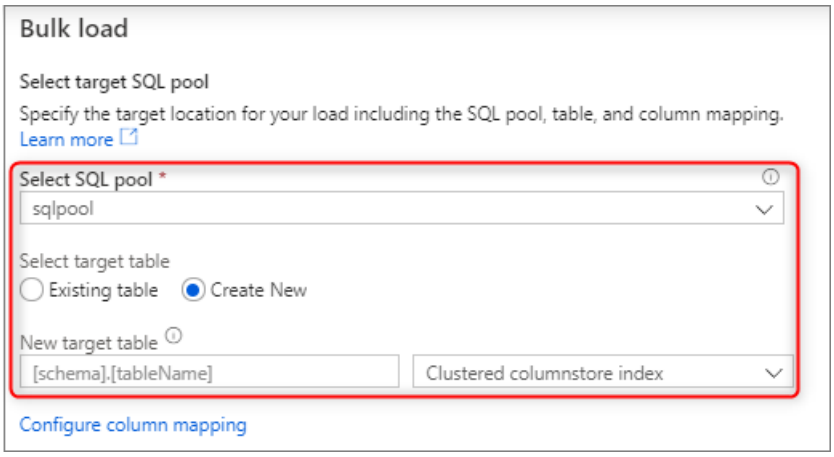
2. Select the file format settings, including your error settings for when there are rejected rows during the bulk load process. You can also select **Preview data** to see how the COPY statement will parse the file to help you configure the file format settings. Select **Preview data** every time you change a file format setting, to see how the COPY statement will parse the file with the updated setting.



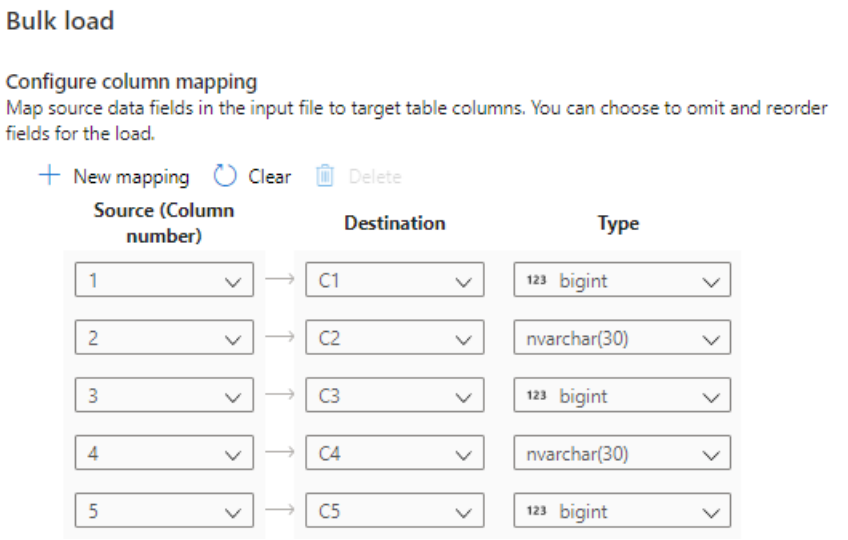
> **NOTE**
>
> - The Bulk Load wizard doesn't support previewing the data with multi-character field terminators. When you specify a multi-character field terminator, the wizard will preview the data within a single column.
> - When you select **Infer column names**, the Bulk Load wizard will parse the columns names from the first row specified by the **First row** field. The Bulk Load wizard will automatically increment the `FIRSTROW` value in the COPY statement by 1 to ignore this header row.
> - Specifying multi-character row terminators is supported in the COPY statement. However, the Bulk Load wizard doesn't support it and will throw an error.

3. Select the dedicated SQL pool that you're using to load, including whether the load will be for an existing

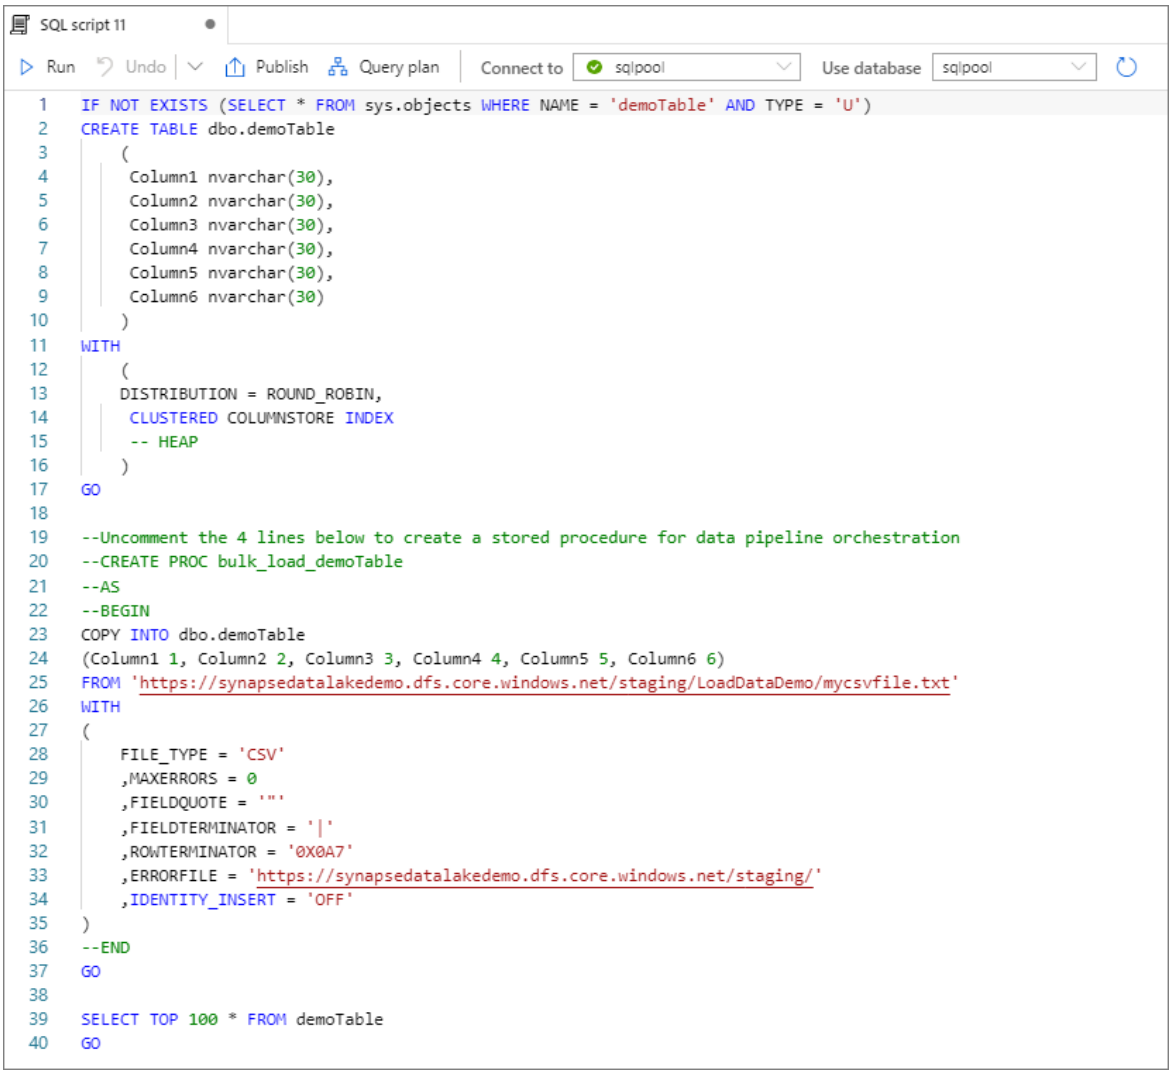
table or a new table.



4. Select **Configure column mapping** to make sure you have the appropriate column mapping. Note columns names will be detected automatically if you enabled **Infer column names**. For new tables, configuring the column mapping is critical for updating the target column data types.



5. Select **Open script**. A T-SQL script is generated with the COPY statement to load from your data lake.



Next steps

- Check the COPY statement article for more information on COPY capabilities.
- Check the data loading overview article for information about using an extract, transform, and load (ETL) process.

Quickstart: Create a dedicated SQL pool workload classifier using the Azure portal

8/19/2022 • 3 minutes to read • Edit Online

In this quickstart, you will create a workload classifier for assigning queries to a workload group. The classifier will assign requests from the `ELTLogin` SQL user to the `DataLoads` workload group. Follow the Quickstart: Configure workload isolation tutorial to create the `DataLoads` workload group. This tutorial will create a workload classifier with the WLM_LABEL option to help further classify requests correctly. The classifier will assign `HIGH` workload importance to these requests as well.

If you don't have an Azure subscription, create a free account before you begin.

Sign in to the Azure portal

Sign in to the Azure portal.

> **NOTE**
> Creating a dedicated SQL pool instance in Azure Synapse Analytics may result in a new billable service. For more information, see Azure Synapse Analytics pricing.

Prerequisites

This quickstart assumes you already have a dedicated SQL pool instance that you have CONTROL DATABASE permissions. If you need to create one, use Create and Connect - portal to create a dedicated SQL pool called **mySampleDataWarehouse**.

A workload group `DataLoads` exists. See the Quickstart: Configure workload isolation tutorial to create the workload group.

> **IMPORTANT**
> Your dedicated SQL pool must be online to configure workload management.

Create a login for ELTLogin

Create a SQL Server authentication login in the `master` database using CREATE LOGIN for `ELTLogin`.

```
IF NOT EXISTS (SELECT * FROM sys.sql_logins WHERE name = 'ELTLogin')
BEGIN
CREATE LOGIN [ELTLogin] WITH PASSWORD='<strongpassword>'
END
;
```

Create user and grant permissions

After the login is created, a user needs to be created in the database. Use CREATE USER to create the SQL user

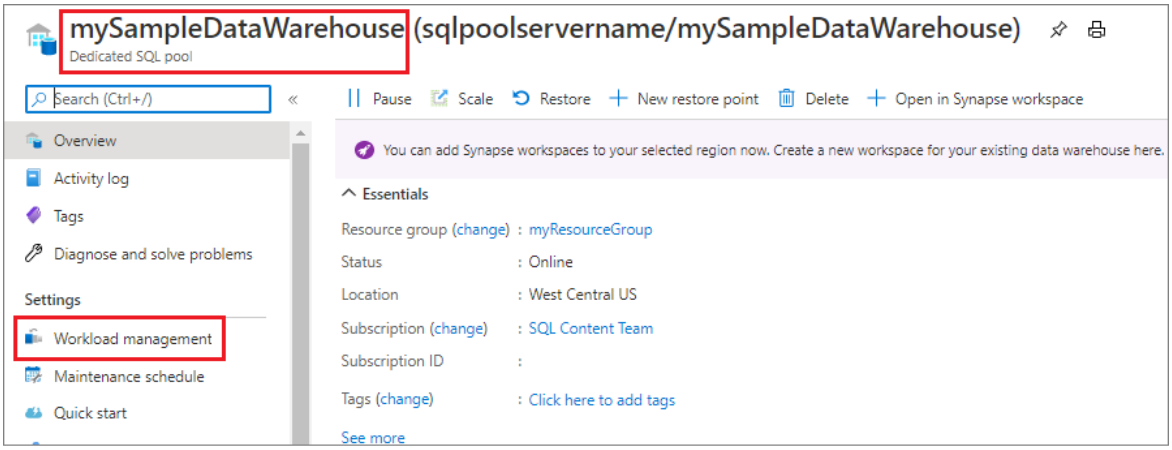
`ELTRole` in the **mySampleDataWarehouse**. Since we will test the classification during this tutorial, grant `ELTLogin` permissions to **mySampleDataWarehouse**.

```
IF NOT EXISTS (SELECT * FROM sys.database_principals WHERE name = 'ELTLogin')
BEGIN
CREATE USER [ELTLogin] FOR LOGIN [ELTLogin]
GRANT CONTROL ON DATABASE::mySampleDataWarehouse TO ELTLogin
END
;
```

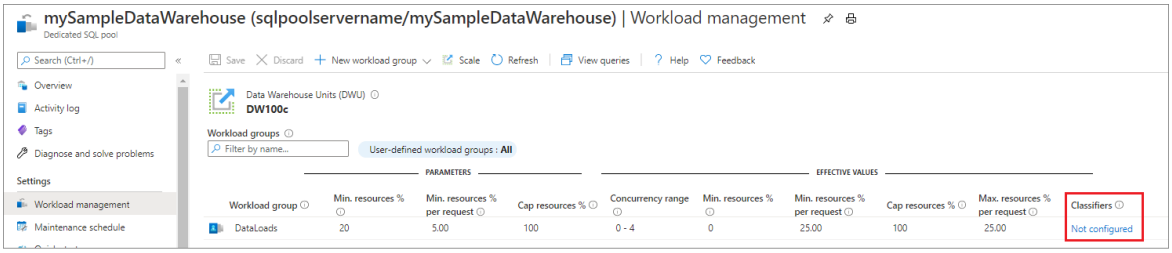
Configure workload classification

Classification allows you to route requests, based on a set of rules, to a workload group. In the Quickstart: Configure workload isolation tutorial we created the `DataLoads` workload group. Now you will create a workload classifier to route queries to the `DataLoads` workload group.

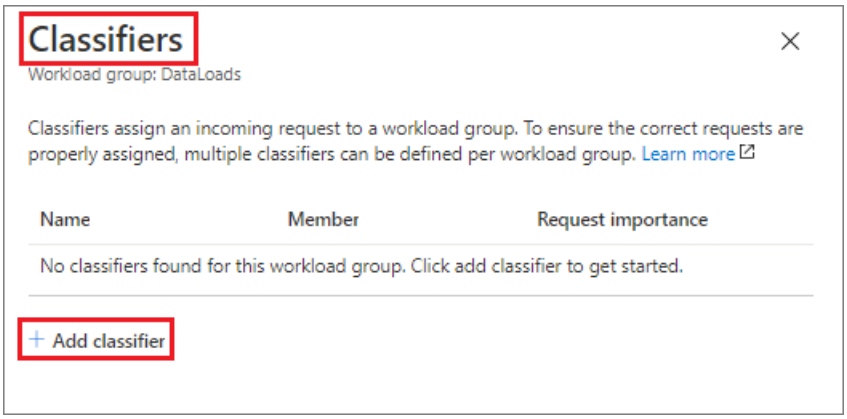
1. Navigate to your **mySampleDataWarehouse** dedicated SQL pool page.
2. Select **Workload management**.



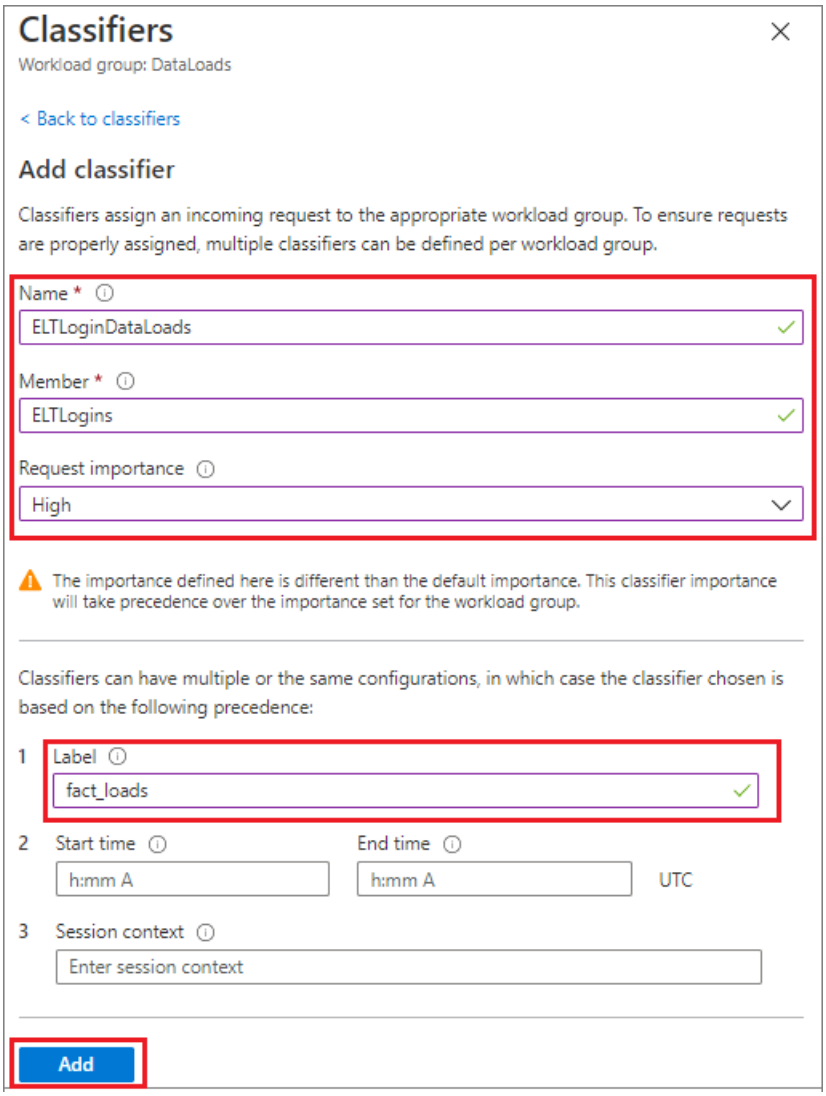
3. Select **Settings & classifiers** on the right-hand side of the `DataLoads` workload group.



4. Select **Not configured** under the Classifiers column.
5. Select **+ Add classifier**.



6. Enter `ELTLoginDataLoads` for **Name**.
7. Enter `ELTLogin` for **Member**.
8. Choose `High` for **Request Importance**. *Optional*, normal importance is default.
9. Enter `fact_loads` for **Label**.
10. Select **Add**.
11. Select **Save**.



Verify and test classification

Check the sys.workload_management_workload_classifiers catalog view to verify existence of the

`ELTLoginDataLoads` classifier.

```
SELECT * FROM sys.workload_management_workload_classifiers WHERE name = 'ELTLoginDataLoads'
```

Check the sys.workload_management_workload_classifier_details catalog view to verify classifier details.

```
SELECT c.[name], c.group_name, c.importance, cd.classifier_type, cd.classifier_value
  FROM sys.workload_management_workload_classifiers c
  JOIN sys.workload_management_workload_classifier_details cd
    ON cd.classifier_id = c.classifier_id
  WHERE c.name = 'ELTLoginDataLoads'
```

Run the following statements to test classification. Ensure you are connected as `ELTLogin` and `Label` is used in query.

```
CREATE TABLE factstaging (ColA int)
INSERT INTO factstaging VALUES(0)
INSERT INTO factstaging VALUES(1)
INSERT INTO factstaging VALUES(2)
GO

CREATE TABLE testclassifierfact WITH (DISTRIBUTION = ROUND_ROBIN)
AS
SELECT * FROM factstaging
OPTION (LABEL='fact_loads')
```

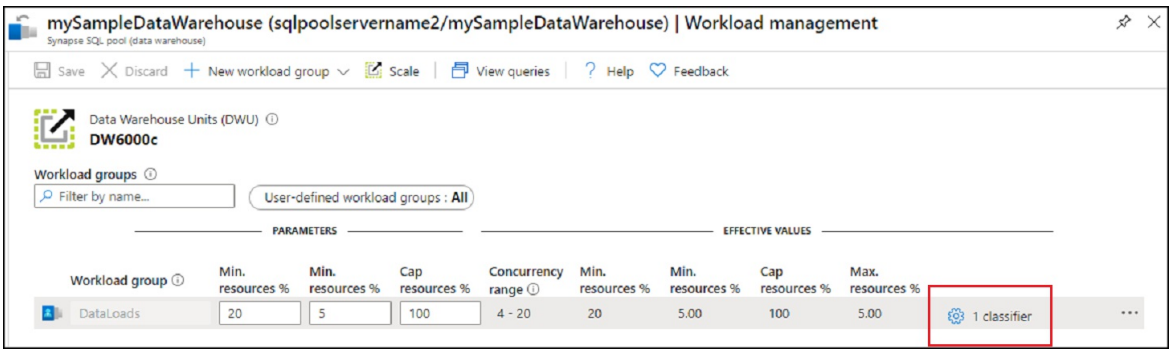
Verify the `CREATE TABLE` statement classified to the `DataLoads` workload group using the `ELTLoginDataLoads` workload classifier.

```
SELECT TOP 1 request_id, classifier_name, group_name, resource_allocation_percentage, submit_time, [status],
[label], command
FROM sys.dm_pdw_exec_requests
WHERE [label] = 'fact_loads'
ORDER BY submit_time DESC
```

Clean up resources

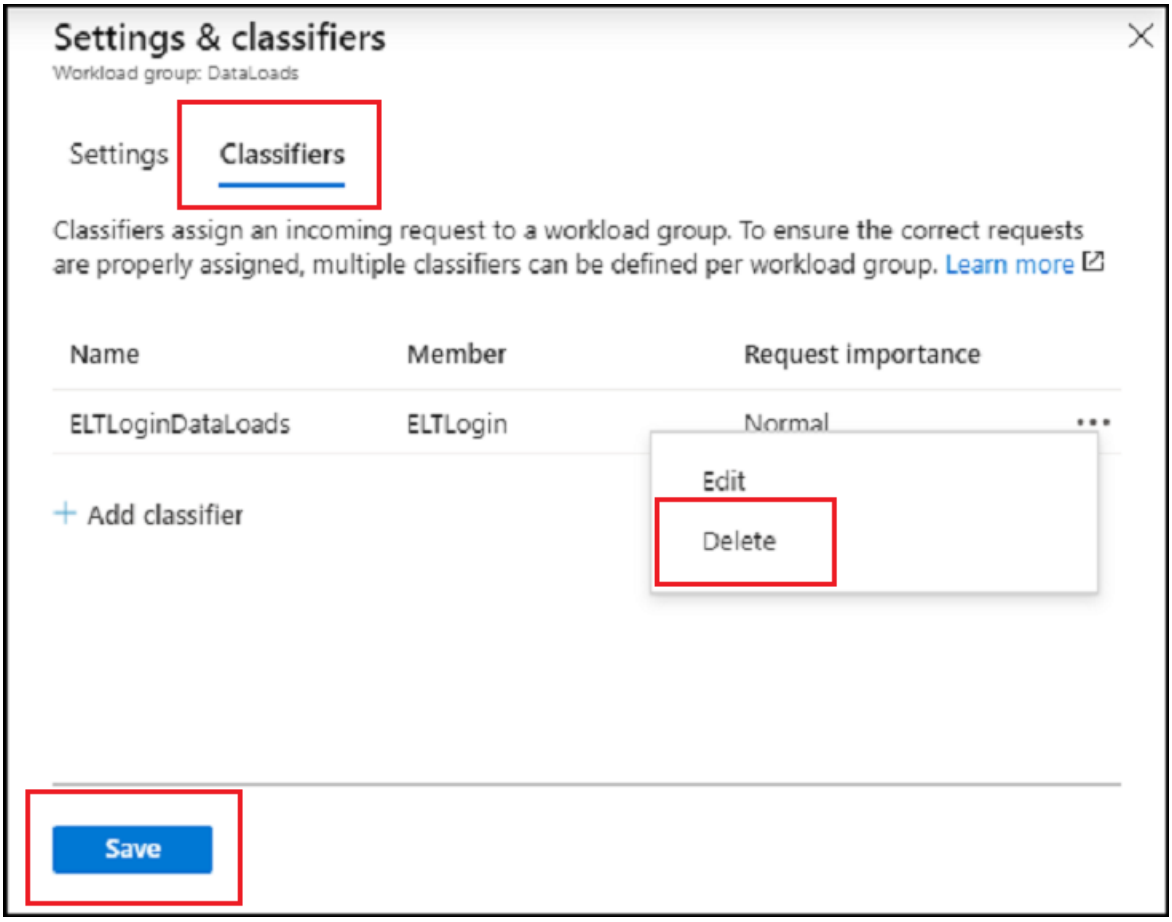
To delete the `ELTLoginDataLoads` workload classifier created in this tutorial:

1. Click on **1 Classifier** on the right-hand side of the `DataLoads` workload group.



2. Click on **Classifiers**.
3. Click on the `...` to the right of the `ELTLoginDataLoads` workload classifier.
4. Click on **Delete**.

5. Click on **Save**.

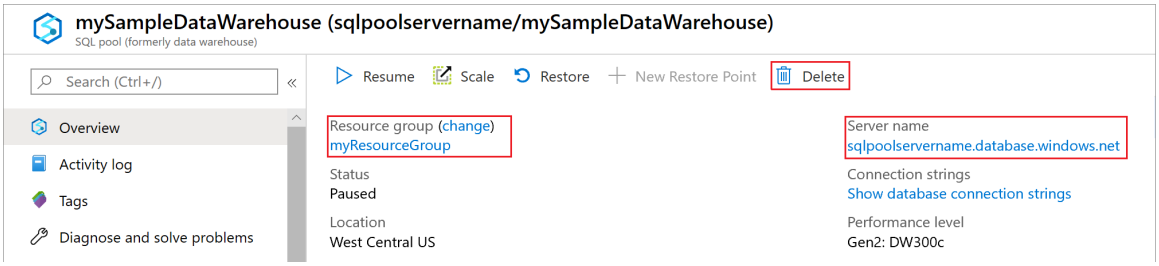


You're being charged for data warehouse units and data stored in your dedicated SQL pool. These compute and storage resources are billed separately.

- If you want to keep the data in storage, you can pause compute when you aren't using your dedicated SQL pool. By pausing compute, you're only charged for data storage. When you're ready to work with the data, resume compute.
- If you want to remove future charges, you can delete your dedicated SQL pool.

Follow these steps to clean up resources.

1. Sign in to the Azure portal, select your dedicated SQL pool.



2. To pause compute, select the **Pause** button. When the dedicated SQL pool is paused, you see a **Start** button. To resume compute, select **Start**.

3. To remove your dedicated SQL pool so you're not charged for compute or storage, select **Delete**.

Next steps

Monitor your workload using the Azure portal monitoring metrics. See Manage and monitor Workload Management for details.

Quickstart: Create a workload classifier using T-SQL

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you'll quickly create a workload classifier with high importance for the CEO of your organization. This workload classifier will allow CEO queries to take precedence over other queries with lower importance in the queue.

If you don't have an Azure subscription, create a free account before you begin.

> **NOTE**
> Creating a dedicated SQL pool instance in Azure Synapse Analytics may result in a new billable service. For more information, see Azure Synapse Analytics pricing.

Prerequisites

This quickstart assumes you have already provisioned a dedicated SQL pool in Azure Synapse Analytics and that you have CONTROL DATABASE permissions. If you need to create one, use Create and Connect - portal to create a dedicated SQL pool called **mySampleDataWarehouse**.

Sign in to the Azure portal

Sign in to the Azure portal.

Create login for TheCEO

Create a SQL Server authentication login in the `master` database using CREATE LOGIN for 'TheCEO'.

```
IF NOT EXISTS (SELECT * FROM sys.sql_logins WHERE name = 'TheCEO')
BEGIN
CREATE LOGIN [TheCEO] WITH PASSWORD='<strongpassword>'
END
;
```

Create user

Create user, "TheCEO", in mySampleDataWarehouse

```
IF NOT EXISTS (SELECT * FROM sys.database_principals WHERE name = 'THECEO')
BEGIN
CREATE USER [TheCEO] FOR LOGIN [TheCEO]
END
;
```

Create a workload classifier

Create a workload classifier for "TheCEO" with high importance.

```
DROP WORKLOAD CLASSIFIER [wgcTheCEO];
CREATE WORKLOAD CLASSIFIER [wgcTheCEO]
WITH (WORKLOAD_GROUP = 'xlargerc'
      ,MEMBERNAME = 'TheCEO'
      ,IMPORTANCE = HIGH);
```

View existing classifiers

```
SELECT * FROM sys.workload_management_workload_classifiers
```

Clean up resources

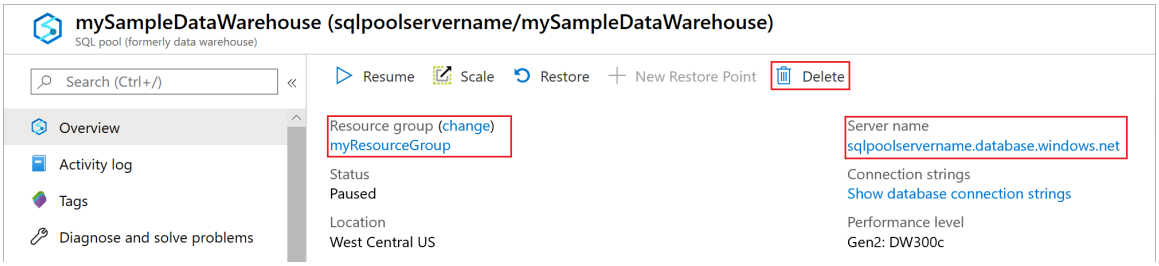
```
DROP WORKLOAD CLASSIFIER [wgcTheCEO]
DROP USER [TheCEO]
;
```

You're being charged for data warehouse units and data stored in your dedicated SQL pool. These compute and storage resources are billed separately.

- If you want to keep the data in storage, you can pause compute when you aren't using the dedicated SQL pool. By pausing compute, you're only charged for data storage. When you're ready to work with the data, resume compute.
- If you want to remove future charges, you can delete the dedicated SQL pool.

Follow these steps to clean up resources.

1. Sign in to the Azure portal, select your dedicated SQL pool.



2. To pause compute, select the **Pause** button. When the dedicated SQL pool is paused, you see a **Start** button. To resume compute, select **Start**.

3. To remove the dedicated SQL pool so you're not charged for compute or storage, select **Delete**.

Next steps

- You've now created a workload classifier. Run a few queries as TheCEO to see how they perform. See sys.dm_pdw_exec_requests to view queries and the importance assigned.
- For more information about dedicated SQL pool workload management, see Workload Importance and Workload Classification.
- See the how-to articles to Configure Workload Importance and how to Manage and monitor Workload Management.

Quickstart: Configure dedicated SQL pool workload isolation using a workload group in the Azure portal

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you will configure workload isolation by creating a workload group for reserving resources. For purposes of this tutorial, we will create the workload group for data loading called `DataLoads`. The workload group will reserve 20% of the system resources. With 20% isolation for data loads, they are guaranteed resources that allow them to hit SLAs. After creating the workload group, create a workload classifier to assign queries to this workload group.

If you don't have an Azure subscription, create a free account before you begin.

Sign in to the Azure portal

Sign in to the Azure portal.

> **NOTE**
> Creating a dedicated SQL pool instance in Azure Synapse Analytics may result in a new billable service. For more information, see Azure Synapse Analytics pricing.

Prerequisites

This quickstart assumes you already have a dedicated SQL pool instance in Synapse SQL and that you have CONTROL DATABASE permissions. If you need to create one, use Quickstart: Create dedicated SQL pool - portal to create a data warehouse called **mySampleDataWarehouse**.

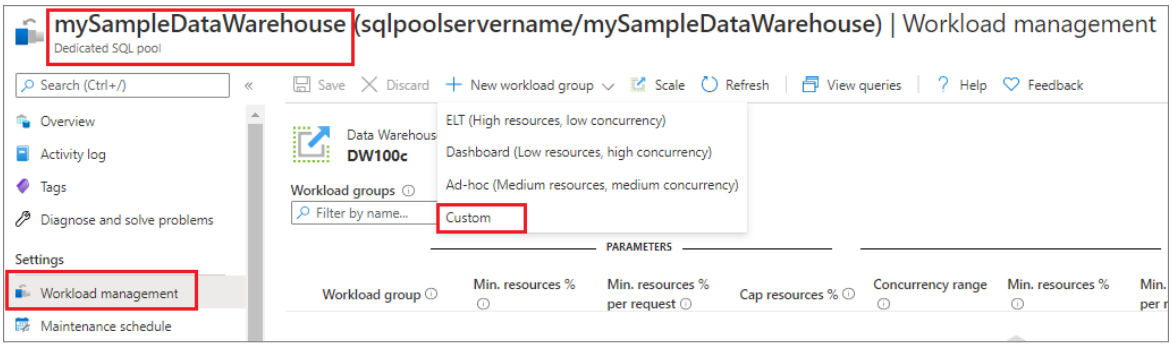
> **IMPORTANT**
> Your dedicated SQL pool must be online to configure workload management.

Configure workload isolation

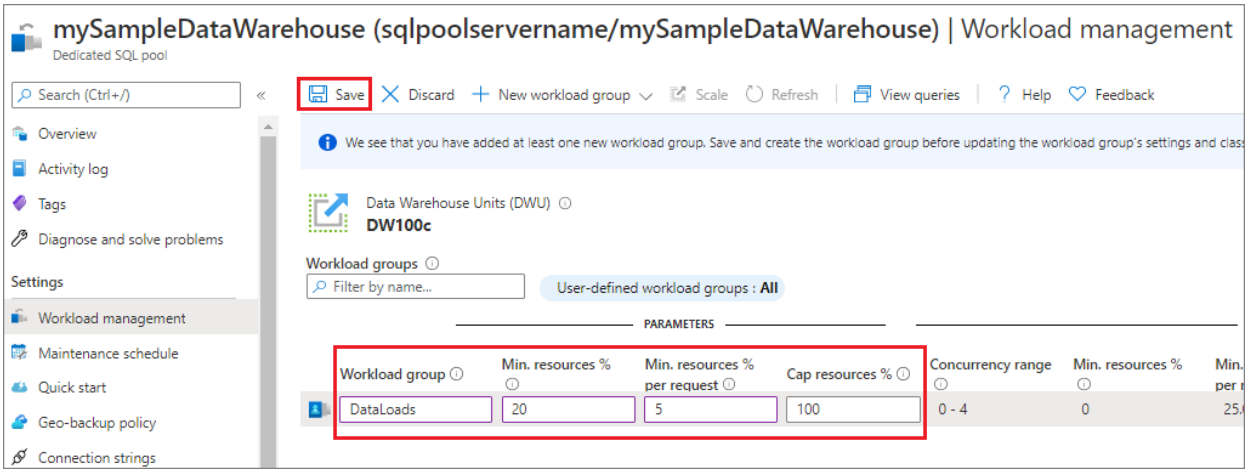
Dedicated SQL pool resources can be isolated and reserved for specific workloads by creating workload groups. See the Workload Isolation concept documentation for more details on how workload groups help you achieve managing your workload. The Create and Connect - portal quickstart created **mySampleDataWarehouse** and initialized it at DW100c. The following steps create a workload group in **mySampleDataWarehouse**.

To create a workload group with 20% isolation:

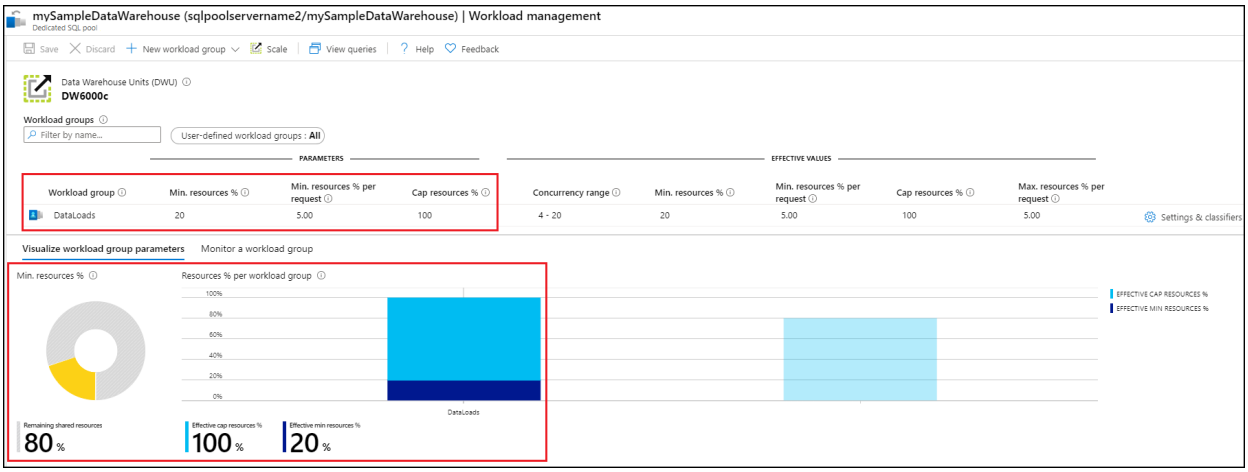
1. Navigate to your **mySampleDataWarehouse** dedicated SQL pool page..
2. Select **Workload management**.
3. Select **New workload group**.
4. Select **Custom**.



5. Enter `DataLoads` for the **Workload group**.
6. Enter `20` for **Min. resources %**.
7. Enter `5` for **Min. resources % per request**.
8. Enter `100` for **Cap resources %**.
9. Enter **Save**.



A portal notification appears when the workload group is created. The workload group resources are displayed in the charts below the configured values.



Clean up resources

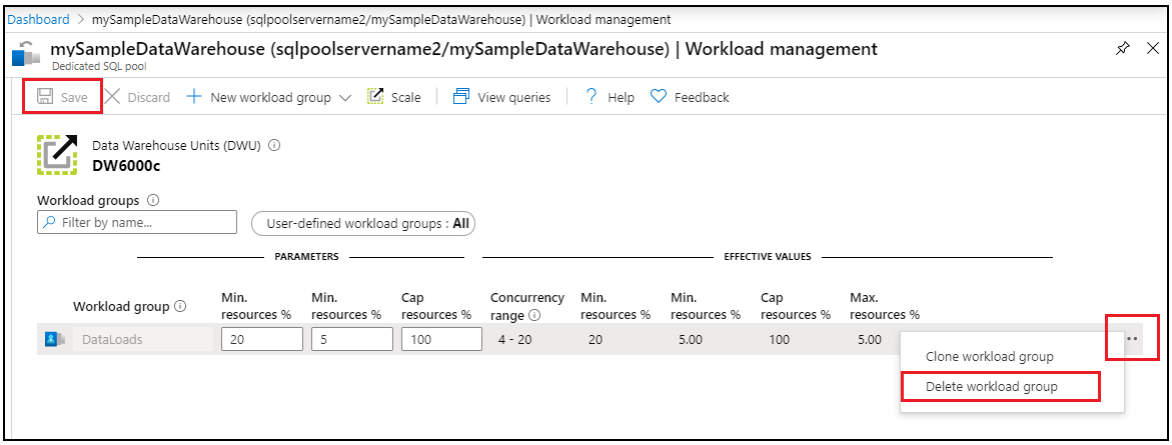
To delete the `DataLoads` workload group created in this tutorial:

1. Click on the `...` to the right of the `DataLoads` workload group.

2. Click on **Delete workload group**.

3. Click on **Yes** when prompted to confirm deletion of the workload group.

4. Click on **Save**.

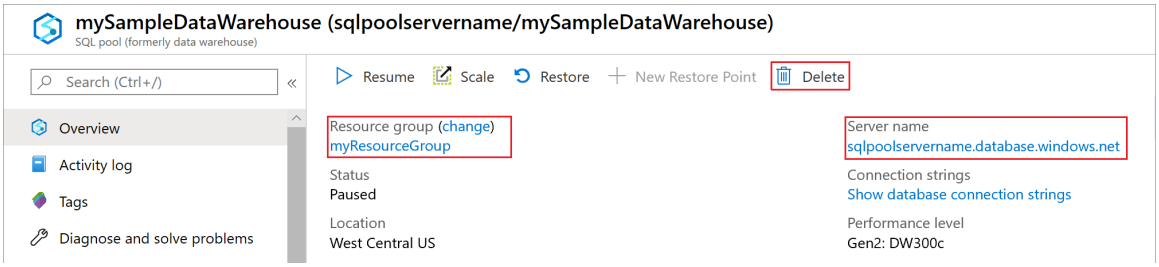


You're being charged for data warehouse units and data stored in your data warehouse. These compute and storage resources are billed separately.

- If you want to keep the data in storage, you can pause compute when you aren't using the data warehouse. By pausing compute, you're only charged for data storage. When you're ready to work with the data, resume compute.
- If you want to remove future charges, you can delete the data warehouse.

Follow these steps to clean up resources.

1. Sign in to the Azure portal, select your dedicated SQL pool.



2. To pause compute, select the **Pause** button. When the data warehouse is paused, you see a **Start** button. To resume compute, select **Start**.

3. To remove the data warehouse so you're not charged for compute or storage, select **Delete**.

Next steps

To use the `DataLoads` workload group, a workload classifier needs to be created to route requests to the workload group. Continue to the create workload classifier tutorial to create a workload classifier for `DataLoads`.

See also

See the how-to article Manage and monitor Workload Management for details on how to monitor workloads for workload management.

Quickstart: Configure workload isolation in a dedicated SQL pool using T-SQL

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you'll quickly create a workload group and classifier for reserving resources for data loading. The workload group will allocate 20% of the system resources to the data loads. The workload classifier will assign requests to the data loads workload group. With 20% isolation for data loads, they are guaranteed resources to hit SLAs.

If you don't have an Azure subscription, create a free account before you begin.

> **NOTE**
> Creating a Synapse SQL instance in Azure Synapse Analytics may result in a new billable service. For more information, see Azure Synapse Analytics pricing.

Prerequisites

This quickstart assumes you already have a Synapse SQL instance in Azure Synapse and that you have CONTROL DATABASE permissions. If you need to create one, use Create and Connect - portal to create a dedicated SQL pool called **mySampleDataWarehouse**.

Create login for DataLoads

Create a SQL Server authentication login in the `master` database using CREATE LOGIN for 'ELTLogin'.

```
IF NOT EXISTS (SELECT * FROM sys.sql_logins WHERE name = 'ELTLogin')
BEGIN
CREATE LOGIN [ELTLogin] WITH PASSWORD='<strongpassword>'
END
;
```

Create user

Create user, "ELTLogin", in mySampleDataWarehouse

```
IF NOT EXISTS (SELECT * FROM sys.database_principals WHERE name = 'ELTLogin')
BEGIN
CREATE USER [ELTLogin] FOR LOGIN [ELTLogin]
END
;
```

Create a workload group

Create a workload group for DataLoads with 20% isolation.

```
CREATE WORKLOAD GROUP DataLoads
WITH ( MIN_PERCENTAGE_RESOURCE = 20
      ,CAP_PERCENTAGE_RESOURCE = 100
      ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 5)
;
```

Create a workload classifier

Create a workload classifier to map ELTLogin to the DataLoads workload group.

```
CREATE WORKLOAD CLASSIFIER [wgcELTLogin]
WITH (WORKLOAD_GROUP = 'DataLoads'
      ,MEMBERNAME = 'ELTLogin')
;
```

View existing workload groups and classifiers and run-time values

```
--Workload groups
SELECT * FROM
sys.workload_management_workload_groups

--Workload classifiers
SELECT * FROM
sys.workload_management_workload_classifiers

--Run-time values
SELECT * FROM
sys.dm_workload_management_workload_groups_stats
```

Clean up resources

```
DROP WORKLOAD CLASSIFIER [wgcELTLogin]
DROP WORKLOAD GROUP [DataLoads]
DROP USER [ELTLogin]
;
```

You're being charged for data warehouse units and data stored in your dedicated SQL pool. These compute and storage resources are billed separately.

- If you want to keep the data in storage, you can pause compute when you aren't using the dedicated SQL pool. By pausing compute, you're only charged for data storage. When you're ready to work with the data, resume compute.
- If you want to remove future charges, you can delete the dedicated SQL pool.

Next steps

- You've now created a workload group. Run a few queries as ELTLogin to see how they perform. See sys.dm_pdw_exec_requests to view queries and the workload group assigned.
- For more information about Synapse SQL workload management, see Workload Management and Workload Isolation.

Tutorial: Explore and Analyze data lakes with serverless SQL pool

8/19/2022 • 4 minutes to read • Edit Online

In this tutorial, you learn how to perform exploratory data analysis. You combine different Azure Open Datasets using serverless SQL pool. You then visualize the results in Synapse Studio for Azure Synapse Analytics.

The `OPENROWSET(BULK...)` function allows you to access files in Azure Storage. `[OPENROWSET](develop-openrowset.md)` reads content of a remote data source, such as a file, and returns the content as a set of rows.

Automatic schema inference

Since data is stored in the Parquet file format, automatic schema inference is available. You can query the data without listing the data types of all columns in the files. You also can use the virtual column mechanism and the `filepath` function to filter out a certain subset of files.

> **NOTE**
>
> The default collation is `SQL_Latin1_General_CP1_CI_ASIf`. For a non-default collation, take into account case sensitivity.
>
> If you create a database with case sensitive collation when you specify columns, make sure to use correct name of the column.
>
> A column name `tpepPickupDateTime` would be correct while `tpeppickupdatetime` wouldn't work in a non-default collation.

This tutorial uses a dataset about New York City (NYC) Taxi:

- Pick-up and drop-off dates and times
- Pick-up and drop-off locations
- Trip distances
- Itemized fares
- Rate types
- Payment types
- Driver-reported passenger counts

To get familiar with the NYC Taxi data, run the following query:

```
SELECT TOP 100 * FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/puYear=*/puMonth=*/*.parquet',
        FORMAT='PARQUET'
    ) AS [nyc]
```

Similarly, you can query the Public Holidays dataset by using the following query:

```
SELECT TOP 100 * FROM
    OPENROWSET(
        BULK 'https://azureopendatastorage.blob.core.windows.net/holidaydatacontainer/Processed/*.parquet',
        FORMAT='PARQUET'
    ) AS [holidays]
```

You can also query the Weather Data dataset by using the following query:

```
SELECT
    TOP 100 *
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/isdweatherdatacontainer/ISDWeather/year=*/month=*/*.parq
uet',
        FORMAT='PARQUET'
    ) AS [weather]
```

You can learn more about the meaning of the individual columns in the descriptions of the data sets:

- NYC Taxi
- Public Holidays
- Weather Data

Time series, seasonality, and outlier analysis

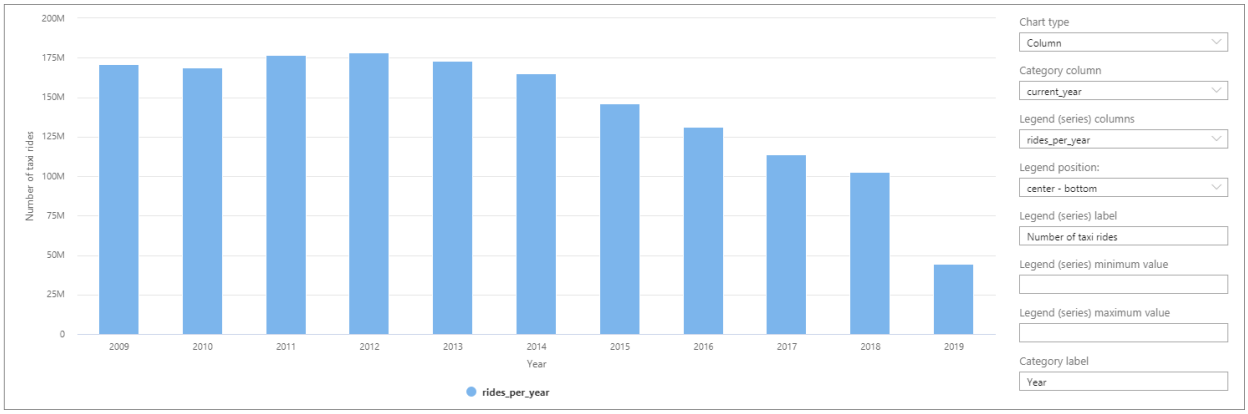
You can summarize the yearly number of taxi rides by using the following query:

```
SELECT
    YEAR(tpepPickupDateTime) AS current_year,
    COUNT(*) AS rides_per_year
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/puYear=*/puMonth=*/*.parquet',
        FORMAT='PARQUET'
    ) AS [nyc]
WHERE nyc.filepath(1) >= '2009' AND nyc.filepath(1) <= '2019'
GROUP BY YEAR(tpepPickupDateTime)
ORDER BY 1 ASC
```

The following snippet shows the result for the yearly number of taxi rides:

CURRENT_YEAR	RIDES_PER_YEAR
2009	170896844
2010	169001153
2011	176897208
2012	178544324
2013	173179759
2014	165114361
2015	146112989
2016	131165043
2017	113496933
2018	102803387
2019	44458570

The data can be visualized in Synapse Studio by switching from the **Table** to the **Chart** view. You can choose among different chart types, such as **Area**, **Bar**, **Column**, **Line**, **Pie**, and **Scatter**. In this case, plot the **Column** chart with the **Category** column set to **current_year**:



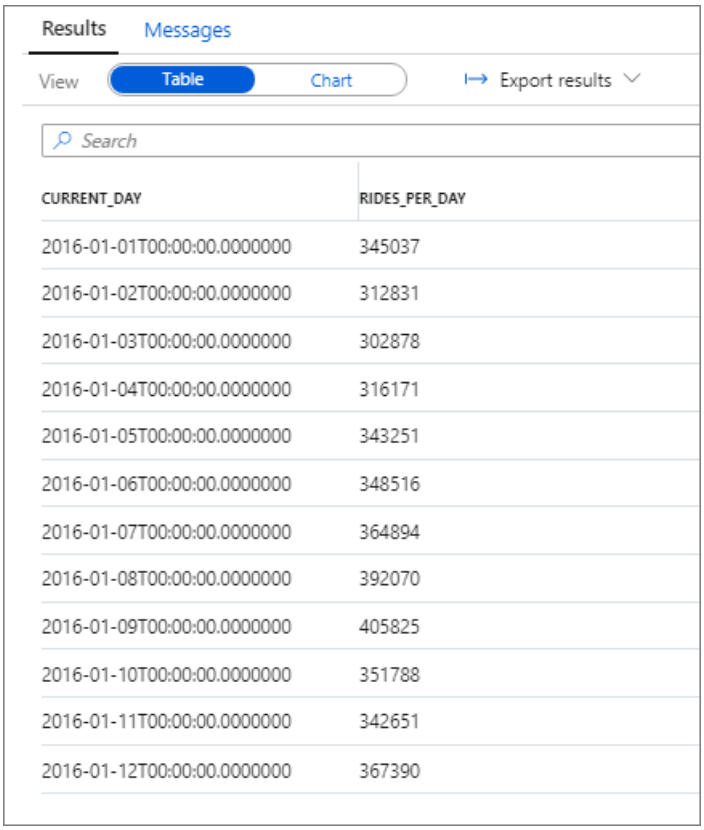
From this visualization, you can see a trend of decreasing ride numbers over the years. Presumably, this decrease is due to the recent increased popularity of ride-sharing companies.

> **NOTE**
>
> At the time of writing this tutorial, data for 2019 is incomplete. As a result, there's a huge drop in the number of rides for that year.

You can focus the analysis on a single year, for example, 2016. The following query returns the daily number of rides during that year:

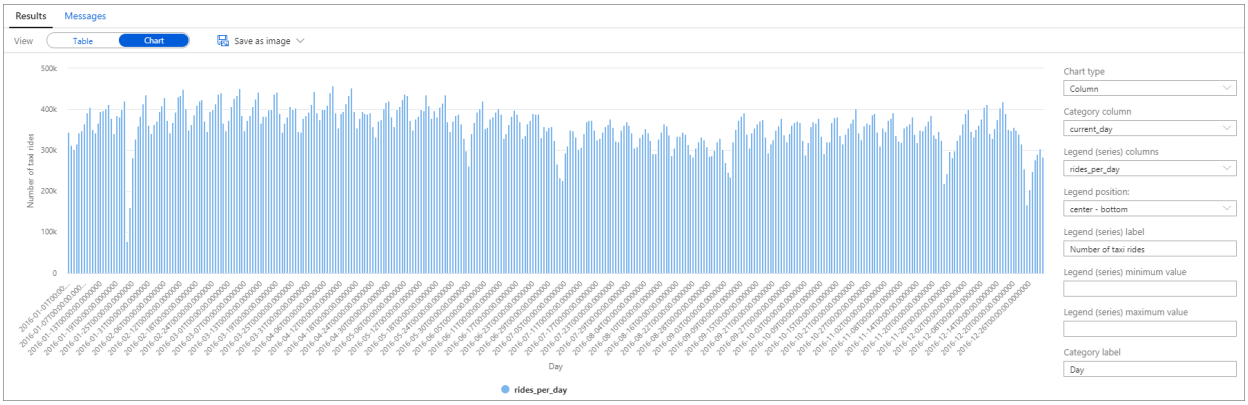
```
SELECT
    CAST([tpepPickupDateTime] AS DATE) AS [current_day],
    COUNT(*) as rides_per_day
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/puYear=*/puMonth=*/*.parquet',
        FORMAT='PARQUET'
    ) AS [nyc]
WHERE nyc.filepath(1) = '2016'
GROUP BY CAST([tpepPickupDateTime] AS DATE)
ORDER BY 1 ASC
```

The following snippet shows the result for this query:



CURRENT_DAY	RIDES_PER_DAY
2016-01-01T00:00:00.0000000	345037
2016-01-02T00:00:00.0000000	312831
2016-01-03T00:00:00.0000000	302878
2016-01-04T00:00:00.0000000	316171
2016-01-05T00:00:00.0000000	343251
2016-01-06T00:00:00.0000000	348516
2016-01-07T00:00:00.0000000	364894
2016-01-08T00:00:00.0000000	392070
2016-01-09T00:00:00.0000000	405825
2016-01-10T00:00:00.0000000	351788
2016-01-11T00:00:00.0000000	342651
2016-01-12T00:00:00.0000000	367390

Again, you can visualize data by plotting the **Column** chart with the **Category** column set to **current_day** and the **Legend (series)** column set to **rides_per_day**.



From the plot chart, you can see there's a weekly pattern, with Saturdays as the peak day. During Summer months, there are fewer taxi rides because of vacations. Also, notice some significant drops in the number of taxi rides without a clear pattern of when and why they occur.

Next, see if the drop in rides correlates with public holidays. Check if there's a correlation by joining the NYC Taxi

rides dataset with the Public Holidays dataset:

```
WITH taxi_rides AS (
SELECT
    CAST([tpepPickupDateTime] AS DATE) AS [current_day],
    COUNT(*) as rides_per_day
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/puYear=*/puMonth=*/*.parquet',
        FORMAT='PARQUET'
    ) AS [nyc]
WHERE nyc.filepath(1) = '2016'
GROUP BY CAST([tpepPickupDateTime] AS DATE)
),
public_holidays AS (
SELECT
    holidayname as holiday,
    date
FROM
    OPENROWSET(
        BULK 'https://azureopendatastorage.blob.core.windows.net/holidaydatacontainer/Processed/*.parquet',
        FORMAT='PARQUET'
    ) AS [holidays]
WHERE countryorregion = 'United States' AND YEAR(date) = 2016
),
joined_data AS (
SELECT
    *
FROM taxi_rides t
LEFT OUTER JOIN public_holidays p on t.current_day = p.date
)

SELECT
    *,
    holiday_rides =
    CASE
      WHEN holiday is null THEN 0
      WHEN holiday is not null THEN rides_per_day
    END
FROM joined_data
ORDER BY current_day ASC
```

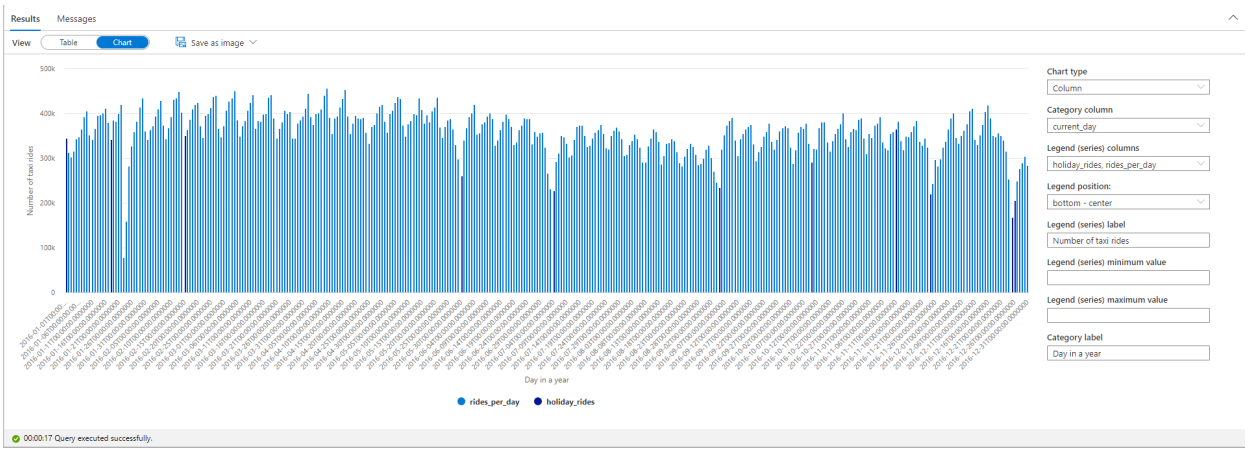
2016-01-15T00:00:00.0000000	401289	(NULL)	(NULL)	0

00:00:17 Query executed successfully.

Highlight the number of taxi rides during public holidays. For that purpose, choose **current_day** for the **Category** column and **rides_per_day** and **holiday_rides** as the **Legend (series)** columns.



From the plot chart, you can see that during public holidays the number of taxi rides is lower. There's still one unexplained large drop on January 23. Let's check the weather in NYC on that day by querying the Weather Data dataset:

```
SELECT
    AVG(windspeed) AS avg_windspeed,
    MIN(windspeed) AS min_windspeed,
    MAX(windspeed) AS max_windspeed,
    AVG(temperature) AS avg_temperature,
    MIN(temperature) AS min_temperature,
    MAX(temperature) AS max_temperature,
    AVG(sealvlpressure) AS avg_sealvlpressure,
    MIN(sealvlpressure) AS min_sealvlpressure,
    MAX(sealvlpressure) AS max_sealvlpressure,
    AVG(precipdepth) AS avg_precipdepth,
    MIN(precipdepth) AS min_precipdepth,
    MAX(precipdepth) AS max_precipdepth,
    AVG(snowdepth) AS avg_snowdepth,
    MIN(snowdepth) AS min_snowdepth,
    MAX(snowdepth) AS max_snowdepth
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/isdweatherdatacontainer/ISDWeather/year=*/month=*/*.parq
uet',
        FORMAT='PARQUET'
    ) AS [weather]
WHERE countryorregion = 'US' AND CAST([datetime] AS DATE) = '2016-01-23' AND stationname = 'JOHN F KENNEDY
INTERNATIONAL AIRPORT'
```

The results of the query indicate that the drop in the number of taxi rides occurred because:

- There was a blizzard on that day in NYC with heavy snow (~30 cm).
- It was cold (temperature was below zero degrees Celsius).
- It was windy (~10 m/s).

This tutorial has shown how a data analyst can quickly perform exploratory data analysis. You can combine different datasets by using serverless SQL pool and visualize the results by using Azure Synapse Studio.

To learn how to use External tables in serverless SQL pool see Use external tables with Synapse SQL

Tutorial: Create Logical Data Warehouse with serverless SQL pool

8/19/2022 • 6 minutes to read • Edit Online

In this tutorial, you will learn how to create a Logical Data Warehouse (LDW) on top of Azure storage and Azure Cosmos DB.

LDW is a relational layer built on top of Azure data sources such as Azure Data Lake storage (ADLS), Azure Cosmos DB analytical storage, or Azure Blob storage.

Create an LDW database

You need to create a custom database where you will store your external tables and views that are referencing external data sources.

```
CREATE DATABASE Ldw
      COLLATE Latin1_General_100_BIN2_UTF8;
```

This collation will provide the optimal performance while reading Parquet and Cosmos DB. If you don't want to specify the database collation, make sure that you specify this collation in the column definition.

Configure data sources and formats

As a first step, you need to configure data source and specify file format of remotely stored data.

Create data source

Data sources represent connection string information that describes where your data is placed and how to authenticate to your data source.

One example of data source definition that references public ECDC COVID 19 Azure Open Data Set is shown in the following example:

```
CREATE EXTERNAL DATA SOURCE ecdc_cases WITH (
    LOCATION = 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-19/ecdc_cases/'
);
```

A caller may access data source without credential if an owner of data source allowed anonymous access or give explicit access to Azure AD identity of the caller.

You can explicitly define a custom credential that will be used while accessing data on external data source.

- Managed Identity of the Synapse workspace
- Shared Access Signature of the Azure storage
- Custom Service Principal Name or Azure Application identity.
- Read-only Cosmos Db account key that enables you to read Cosmos DB analytical storage.

As a prerequisite, you will need to create a master key in the database:

```
CREATE MASTER KEY ENCRYPTION BY PASSWORD = 'Setup you password - you need to create master key only once';
```

In the following external data source, Synapse SQL pool should use a managed identity of the workspace to access data in the storage.

```
CREATE DATABASE SCOPED CREDENTIAL WorkspaceIdentity
WITH IDENTITY = 'Managed Identity';
GO
CREATE EXTERNAL DATA SOURCE ecdc_cases WITH (
    LOCATION = 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-19/ecdc_cases/',
    CREDENTIAL = WorkspaceIdentity
);
```

In order to access Cosmos DB analytical storage, you need to define a credential containing a read-only Cosmos DB account key.

```
CREATE DATABASE SCOPED CREDENTIAL MyCosmosDbAccountCredential
WITH IDENTITY = 'SHARED ACCESS SIGNATURE',
     SECRET = 's5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtFpJjC8Hg==';
```

Any user with the Synapse Administrator role can use these credentials to access Azure Data Lake storage or Cosmos DB analytical storage. If you have low privileged users that do not have Synapse Administrator role, you would need to give them an explicit permission to reference these database scoped credentials:

```
GRANT REFERENCES ON DATABASE SCOPED CREDENTIAL::WorkspaceIdentity TO <user>
GO
GRANT REFERENCES ON DATABASE SCOPED CREDENTIAL::MyCosmosDbAccountCredential TO <user>
GO
```

Find more details in grant DATABASE SCOPED CREDENTIAL permissions page.

Define external file formats

External file formats define the structure of the files stored on external data source. You can define Parquet and CSV external file formats:

```
CREATE EXTERNAL FILE FORMAT ParquetFormat WITH (  FORMAT_TYPE = PARQUET );
GO
CREATE EXTERNAL FILE FORMAT CsvFormat WITH (  FORMAT_TYPE = DELIMITEDTEXT );
```

Find more information in this article

Explore your data

Once you set up your data sources, you can use the `OPENROWSET` function to explore your data. The OPENROWSET function reads content of a remote data source (for example file) and returns the content as a set of rows.

```
select top 10  *
from openrowset(bulk 'latest/ecdc_cases.parquet',
                data_source = 'ecdc_cases',
                format='parquet') as a
```

The `OPENROWSET` function will give you information about the columns in the external files or containers and enable you to define a schema of your external tables and views.

Create external tables on Azure storage

Once you discover the schema, you can create external tables and views on top of your external data sources. The good practice is to organize your tables and views in databases schemas. In the following query you can create a schema where you will place all objects that are accessing ECDC COVID data set in Azure data Lake storage:

```
create schema ecdc_adls;
```

The database schemas are useful for grouping the objects and defining permissions per schema.

Once you define the schemas, you can create external tables that are referencing the files. The following external table is referencing the ECDC COVID parquet file placed in the Azure storage:

```
create external table ecdc_adls.cases (
    date_rep                  date,
    day                       smallint,
    month                     smallint,
    year                      smallint,
    cases                     smallint,
    deaths                    smallint,
    countries_and_territories  varchar(256),
    geo_id                    varchar(60),
    country_territory_code    varchar(16),
    pop_data_2018             int,
    continent_exp             varchar(32),
    load_date                 datetime2(7),
    iso_country               varchar(16)
) with (
    data_source= ecdc_cases,
    location = 'latest/ecdc_cases.parquet',
    file_format = ParquetFormat
);
```

Make sure that you use the smallest possible types for string and number columns to optimize performance of your queries.

Create views on Azure Cosmos DB

As an alternative to external tables, you can create views on top of your external data.

Similar to the tables shown in the previous example, you should place the views in separate schemas:

```
create schema ecdc_cosmosdb;
```

Now you are able to create a view in the schema that is referencing a Cosmos DB container:

```
CREATE OR ALTER VIEW ecdc_cosmosdb.Ecdc
AS SELECT *
FROM OPENROWSET(
      PROVIDER = 'CosmosDB',
      CONNECTION = 'Account=synapselink-cosmosdb-sqlsample;Database=covid',
      OBJECT = 'Ecdc',
      CREDENTIAL = 'MyCosmosDbAccountCredential'
    ) WITH
     ( date_rep varchar(20),
       cases bigint,
       geo_id varchar(6)
     ) as rows
```

To optimize performance, you should use the smallest possible types in the `WITH` schema definition.

> **NOTE**
> You should place your Azure Cosmos DB account key in a separate credential and reference this credential from the `OPENROWSET` function. Do not keep your account key in the view definition.

Access and permissions

As a final step, you should create database users that should be able to access your LDW, and give them permissions to select data from the external tables and views. In the following script you can see how to add a new user that will be authenticated using Azure AD identity:

```
CREATE USER [jovan@contoso.com] FROM EXTERNAL PROVIDER;
GO
```

Instead of Azure AD principals, you can create SQL principals that authenticate with the login name and password.

```
CREATE LOGIN [jovan] WITH PASSWORD = 'My Very strong Password ! 1234';
CREATE USER [jovan] FROM LOGIN [jovan];
```

In both cases, you can assign permissions to the users.

```
DENY ADMINISTER DATABASE BULK OPERATIONS TO [jovan@contoso.com]
GO
GRANT SELECT ON SCHEMA::ecdc_adls TO [jovan@contoso.com]
GO
GRANT SELECT ON OBJECT::ecdc_cosmosDB.cases TO [jovan@contoso.com]
GO
GRANT REFERENCES ON DATABASE SCOPED CREDENTIAL::MyCosmosDbAccountCredential TO [jovan@contoso.com]
GO
```

The security rules depend on your security policies. Some generic guidelines are:

- You should deny `ADMINISTER DATABASE BULK OPERATIONS` permission to the new users because they should be able to read data only using the external tables and views that you prepared.
- You should provide `SELECT` permission only to the tables that some user should be able to use.
- If you are providing access to data using the views, you should grant `REFERENCES` permission to the credential that will be used to access external data source.

This user has minimal permissions needed to query external data. If you want to create a power-user who can set up permissions, external tables and views, you can give `CONTROL` permission to the user:

```
GRANT CONTROL TO [jovan@contoso.com]
```

Role-based security

Instead of assigning permissions to the individual uses, a good practice it to organize the users into roles and manage permission at role-level. The following code sample creates a new role representing the people who can analyze COVID-19 cases, and adds three users to this role:

```
CREATE ROLE CovidAnalyst;

ALTER ROLE CovidAnalyst ADD MEMBER [jovan@contoso.com];
ALTER ROLE CovidAnalyst ADD MEMBER [milan@contoso.com];
ALTER ROLE CovidAnalyst ADD MEMBER [petar@contoso.com];
```

You can assign the permissions to all users that belong to the group:

```
GRANT SELECT ON SCHEMA::ecdc_cosmosdb TO [CovidAnalyst];
GO
DENY SELECT ON SCHEMA::ecdc_adls TO [CovidAnalyst];
GO
DENY ADMINISTER DATABASE BULK OPERATIONS TO [CovidAnalyst];
```

This role-based security access control might simplify management of your security rules.

Tutorial: Use serverless SQL pool with Power BI Desktop & create a report

8/19/2022 • 3 minutes to read • Edit Online

In this tutorial, you'll learn how to:

- Create demo database
- Create view used for report
- Connect Power BI Desktop to serverless SQL pool
- Create report based on view

Prerequisites

To complete this tutorial, you need the following prerequisites:

- Power BI Desktop - needed to visualize the data and create a report.
- Azure Synapse workspace - needed to create database, external data source, and view.

Optional:

- A SQL query tool, such as Azure Data Studio, or SQL Server Management Studio (SSMS).

Values for the following parameters:

PARAMETER	DESCRIPTION
Serverless SQL pool service endpoint address	Used as server name
Serverless SQL pool service endpoint region	Used to determine the storage used in the samples
Username and password for endpoint access	Used to access endpoint
Database you'll use to create views	The database used as starting point in the samples

1 - Create database

For the demo environment, create your own demo database. You use this database to view metadata, not to store actual data.

Create the demo database (and drop an existing database if necessary) by running the following Transact-SQL (T-SQL) script:

```
-- Drop database if it exists
DROP DATABASE IF EXISTS Demo
GO

-- Create new database
CREATE DATABASE [Demo];
GO
```

2 - Create data source

A data source is necessary for the serverless SQL pool service to access files in storage. Create the data source for a storage account that is located in the same region as your endpoint. Although serverless SQL pool can access storage accounts from different regions, having the storage and endpoint in the same region provides better performance.

Create the data source by running the following Transact-SQL (T-SQL) script:

```
-- There is no credential in data surce. We are using public storage account which doesn't need a secret.
CREATE EXTERNAL DATA SOURCE AzureOpenData
WITH ( LOCATION = 'https://azureopendatastorage.blob.core.windows.net/')
```

3 - Prepare view

Create the view based on the external demo data for Power BI to consume by running the following Transact-SQL (T-SQL) script:

Create the view `usPopulationView` inside the database `Demo` with the following query:

```
DROP VIEW IF EXISTS usPopulationView;
GO

CREATE VIEW usPopulationView AS
SELECT
    *
FROM
    OPENROWSET(
        BULK 'censusdatacontainer/release/us_population_county/year=20*/*.parquet',
        DATA_SOURCE = 'AzureOpenData',
        FORMAT='PARQUET'
    ) AS uspv;
```

The demo data contains the following data sets:

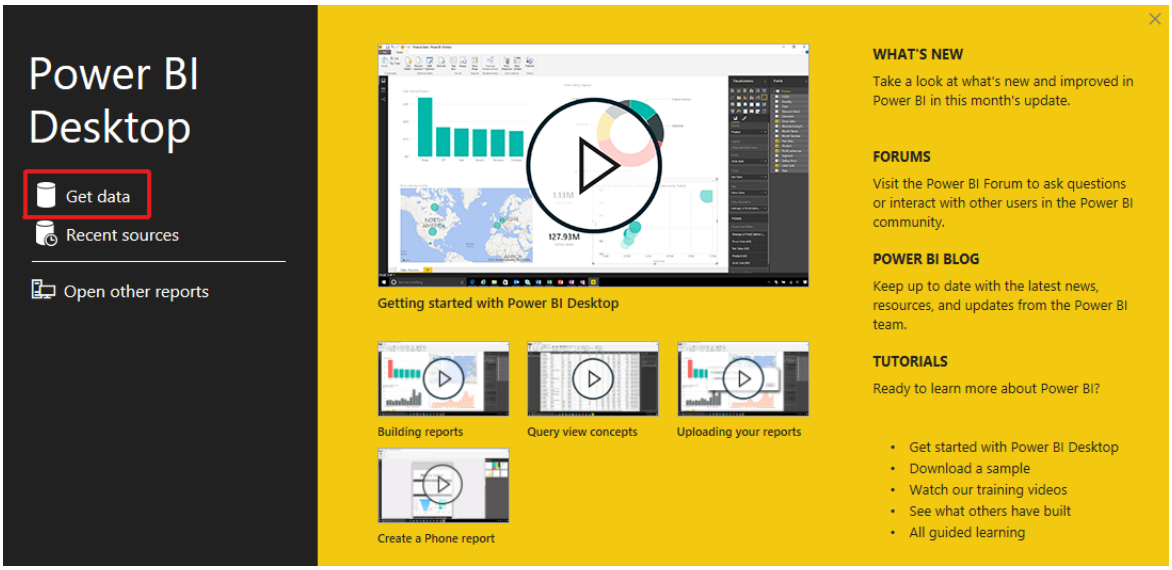
US population by gender and race for each US county sourced from 2000 and 2010 Decennial Census in parquet format.

FOLDER PATH	DESCRIPTION
/release/	Parent folder for data in demo storage account
/release/us_population_county/	US population data files in Parquet format, partitioned by year using Hive/Hadoop partitioning scheme.

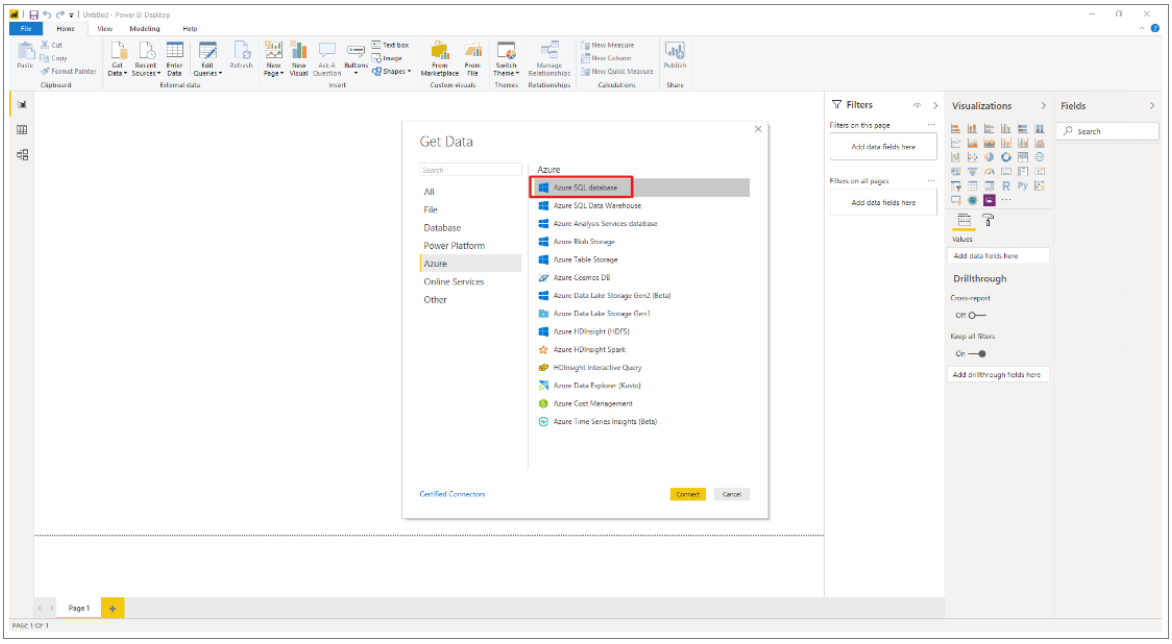
4 - Create Power BI report

Create the report for Power BI Desktop using the following steps:

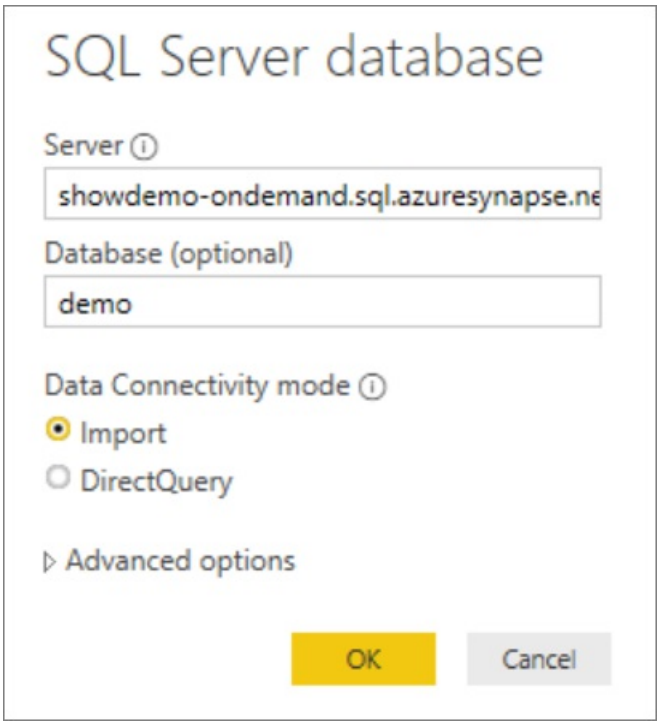
1. Open the Power BI Desktop application and select **Get data**.



2. Select **Azure** > **Azure SQL Database**.



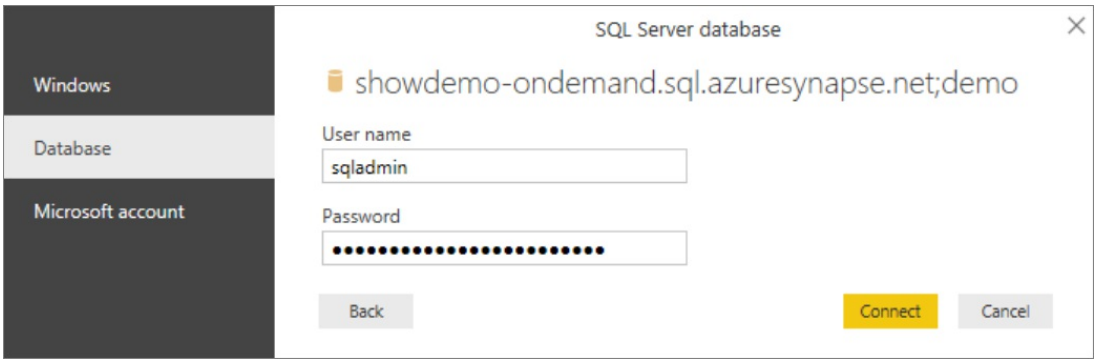
3. Type the name of the server where the database is located in the **Server** field, and then type `Demo` in the database name. Select the **Import** option and then select **OK**.



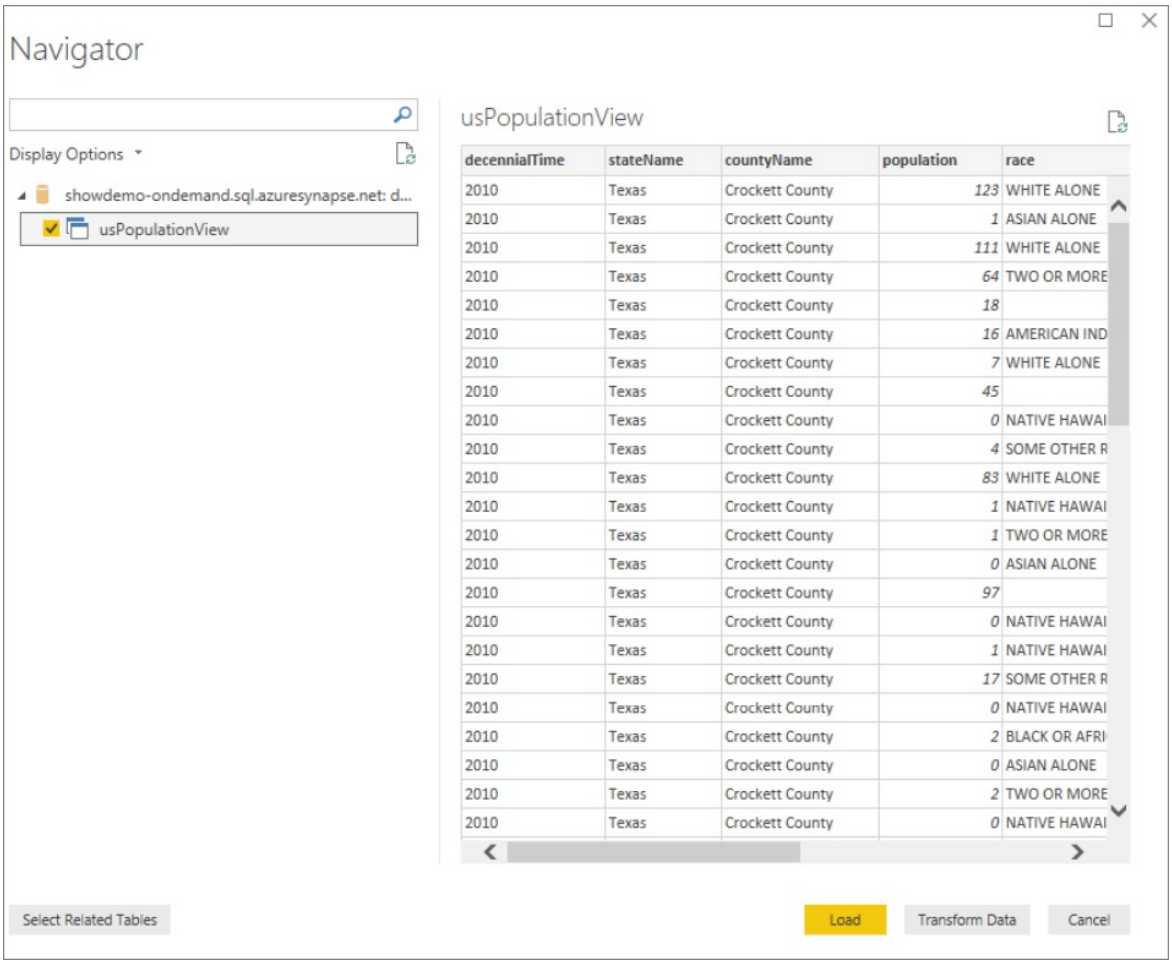
4. Select preferred authentication method:

   - Example for AAD

   - Example for SQL Login - Type your User name and password.

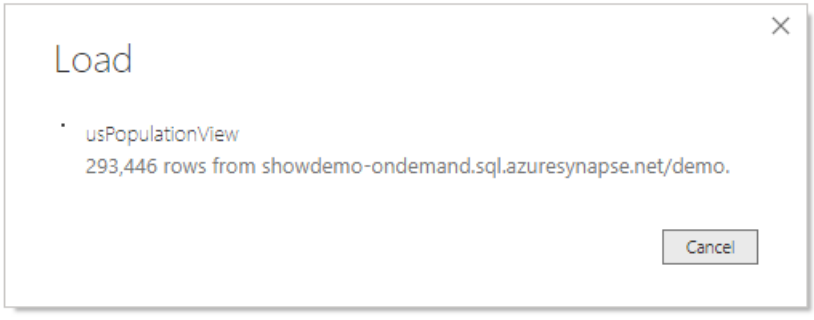


5. Select the view `usPopulationView`, and then select **Load**.



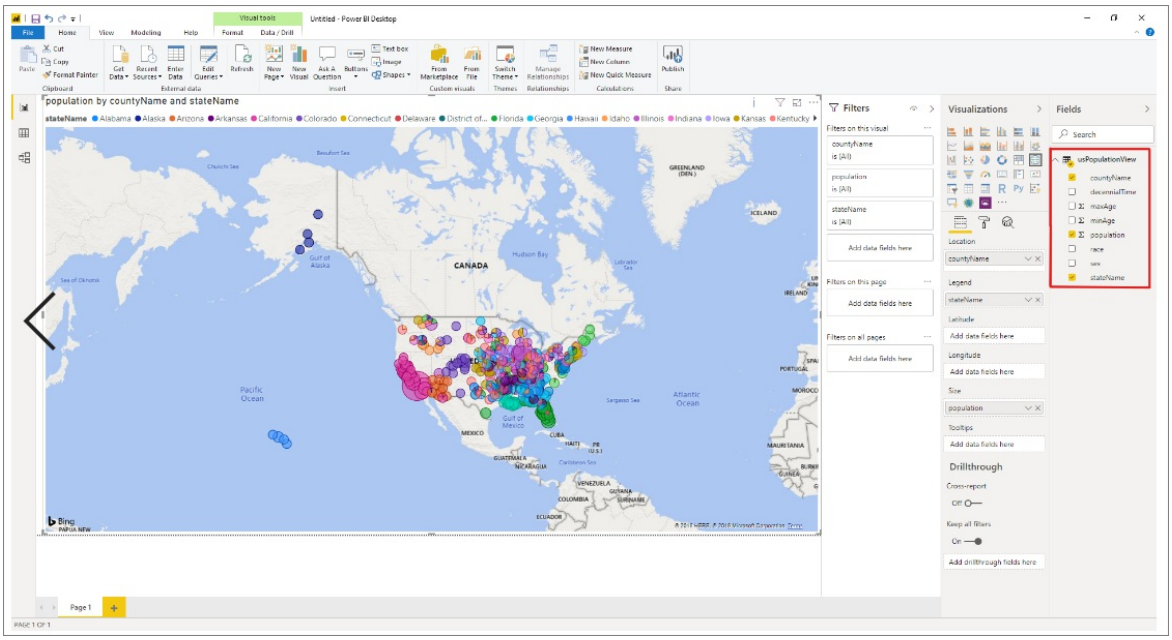
6. Wait for the operation to complete, and then a pop-up will appear stating `There are pending changes in your queries that haven't been applied`. Select **Apply changes**.

7. Wait for the **Apply query changes** dialog box to disappear, which may take a few minutes.



8. Once the load completes, select the following columns in this order to create the report:

- countyName
- population
- stateName



Clean up resources

Once you're done using this report, delete the resources with the following steps:

1. Delete the credential for the storage account

```
DROP EXTERNAL DATA SOURCE AzureOpenData
```

2. Delete the view

```
DROP VIEW usPopulationView;
```

3. Drop the database

```
DROP DATABASE Demo;
```

Advance to the Query storage files to learn how to query storage files using Synapse SQL.

Backup and restore in Azure Synapse Dedicated SQL pool

8/19/2022 • 8 minutes to read • Edit Online

Learn how to use backup and restore in Azure Synapse Dedicated SQL pool. Use dedicated SQL pool restore points to recover or copy your data warehouse to a previous state in the primary region. Use data warehouse geo-redundant backups to restore to a different geographical region.

What is a data warehouse snapshot

A *data warehouse snapshot* creates a restore point you can leverage to recover or copy your data warehouse to a previous state. Since dedicated SQL pool is a distributed system, a data warehouse snapshot consists of many files that are located in Azure storage. Snapshots capture incremental changes from the data stored in your data warehouse.

A *data warehouse restore* is a new data warehouse that is created from a restore point of an existing or deleted data warehouse. Restoring your data warehouse is an essential part of any business continuity and disaster recovery strategy because it re-creates your data after accidental corruption or deletion. Data warehouse snapshot is also a powerful mechanism to create copies of your data warehouse for test or development purposes. Dedicated SQL pool restore rates can vary depending on the database size and location of the source and target data warehouse.

Automatic Restore Points

Snapshots are a built-in feature that creates restore points. You do not have to enable this capability. However, the dedicated SQL pool should be in an active state for restore point creation. If it is paused frequently, automatic restore points may not be created so make sure to create user-defined restore point before pausing the dedicated SQL pool. Automatic restore points currently cannot be deleted by users as the service uses these restore points to maintain SLAs for recovery.

Snapshots of your data warehouse are taken throughout the day creating restore points that are available for seven days. This retention period cannot be changed. Dedicated SQL pool supports an eight-hour recovery point objective (RPO). You can restore your data warehouse in the primary region from any one of the snapshots taken in the past seven days.

To see when the last snapshot started, run this query on your online dedicated SQL pool.

```
select   top 1 *
from     sys.pdw_loader_backup_runs
order by run_id desc
;
```

User-Defined Restore Points

This feature enables you to manually trigger snapshots to create restore points of your data warehouse before and after large modifications. This capability ensures that restore points are logically consistent, which provides additional data protection in case of any workload interruptions or user errors for quick recovery time. User-defined restore points are available for seven days and are automatically deleted on your behalf. You cannot change the retention period of user-defined restore points. **42 user-defined restore points** are guaranteed at

any point in time so they must be deleted before creating another restore point. You can trigger snapshots to create user-defined restore points through PowerShell or the Azure portal.

> **NOTE**
>
> If you require restore points longer than 7 days, please vote for this capability here. You can also create a user-defined restore point and restore from the newly created restore point to a new data warehouse. Once you have restored, you have the dedicated SQL pool online and can pause it indefinitely to save compute costs. The paused database incurs storage charges at the Azure Synapse storage rate. If you need an active copy of the restored data warehouse, you can resume which should take only a few minutes.

Restore point retention

The following lists details for restore point retention periods:

1. Dedicated SQL pool deletes a restore point when it hits the 7-day retention period **and** when there are at least 42 total restore points (including both user-defined and automatic).
2. Snapshots are not taken when a dedicated SQL pool is paused.
3. The age of a restore point is measured by the absolute calendar days from the time the restore point is taken including when the SQL pool is paused.
4. At any point in time, a dedicated SQL pool is guaranteed to be able to store up to 42 user-defined restore points or 42 automatic restore points as long as these restore points have not reached the 7-day retention period
5. If a snapshot is taken, the dedicated SQL pool is then paused for greater than 7 days, and then resumed, the restore point will persist until there are 42 total restore points (including both user-defined and automatic)

Snapshot retention when a SQL pool is dropped

When you drop a dedicated SQL pool, a final snapshot is created and saved for seven days. You can restore the dedicated SQL pool to the final restore point created at deletion. If the dedicated SQL pool is dropped in a paused state, no snapshot is taken. In that scenario, make sure to create a user-defined restore point before dropping the dedicated SQL pool.

Geo-backups and disaster recovery

A geo-backup is created once per day to a paired data center. The RPO for a geo-restore is 24 hours. A geo-restore is always a data movement operation and the RTO will depend on the data size. Only the latest geo-backup is retained. You can restore the geo-backup to a server in any other region where dedicated SQL pool is supported. A geo-backup ensures you can restore data warehouse in case you cannot access the restore points in your primary region.

If you do not require geo-backups for your dedicated SQL pool, you can disable them and save on disaster recovery storage costs. To do so, refer to How to guide: Disable geo-backups for a dedicated SQL pool (formerly SQL DW). Note that if you disable geo-backups, you will not be able to recover your dedicated SQL pool to your paired Azure region if your primary Azure data center is unavailable.

NOTE

If you require a shorter RPO for geo-backups, vote for this capability here. You can also create a user-defined restore point and restore from the newly created restore point to a new data warehouse in a different region. After you have restored, you have the data warehouse online and can pause it indefinitely to save compute costs. The paused database incurs storage charges at the Azure Premium Storage rate. Another common pattern for a shorter recovery point is to ingest data into primary and secondary instances of a data warehouse in parallel. In this scenario, data is ingested from a source (or sources) and persisted to two separate instances of the data warehouse (primary and secondary). To save on compute costs, you can pause the secondary instance of the warehouse. If you need an active copy of the data warehouse, you can resume, which should take only a few minutes.

Data residency

If your paired data center is located outside of your country, you can ensure that your data stays within your region by provisioning your database on locally redundant storage (LRS). If your database has already been provisioned on RA-GRS (Read Only Geographically Redundant Storage, the current default) then you can opt out of geo-backups, however your database will continue to reside on storage that is replicated to a regional pair. To ensure that customer data stays within your region, you can provision or restore your dedicated SQL pool to locally redundant storage. For more information on how to provision or restore to local redundant storage, see How-to guide for configuring single region residency for a dedicated SQL pool (formerly SQL DW) in Azure Synapse Analytics

To confirm that your paired data center is in a different country, refer to Azure Paired Regions.

Backup and restore costs

You will notice the Azure bill has a line item for Storage and a line item for Disaster Recovery Storage. The storage charge is the total cost for storing your data in the primary region along with the incremental changes captured by snapshots. For a more detailed explanation of how snapshots are charged, refer to Understanding how Snapshots Accrue Charges. The geo-redundant charge covers the cost for storing the geo-backups.

The total cost for your primary data warehouse and seven days of snapshot changes is rounded to the nearest TB. For example, if your data warehouse is 1.5 TB and the snapshots captures 100 GB, you are billed for 2 TB of data at Azure standard storage rates.

If you are using geo-redundant storage, you receive a separate storage charge. The geo-redundant storage is billed at the standard Read-Access Geographically Redundant Storage (RA-GRS) rate.

For more information about Azure Synapse pricing, see Azure Synapse pricing. You are not charged for data egress when restoring across regions.

Restoring from restore points

Each snapshot creates a restore point that represents the time the snapshot started. To restore a data warehouse, you choose a restore point and issue a restore command.

You can either keep the restored data warehouse and the current one, or delete one of them. If you want to replace the current data warehouse with the restored data warehouse, you can rename it using ALTER DATABASE with the MODIFY NAME option.

To restore a data warehouse, see Restore a dedicated SQL pool.

To restore a deleted data warehouse, see Restore a deleted database, or if the entire server was deleted, see Restore a data warehouse from a deleted server.

Cross subscription restore

You can perform a cross-subscription restore by follow the guidance here.

Geo-redundant restore

You can restore your dedicated SQL pool to any region supporting dedicated SQL pool at your chosen performance level.

> **NOTE**
> To perform a geo-redundant restore you must not have opted out of this feature.

Support Process

You can submit a support ticket through the Azure portal for Azure Synapse Analytics.

Data loading strategies for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

Traditional SMP dedicated SQL pools use an Extract, Transform, and Load (ETL) process for loading data. Synapse SQL, within Azure Synapse Analytics, uses distributed query processing architecture that takes advantage of the scalability and flexibility of compute and storage resources.

Using an Extract, Load, and Transform (ELT) process leverages built-in distributed query processing capabilities and eliminates the resources needed for data transformation prior to loading.

While dedicated SQL pools support many loading methods, including popular SQL Server options such as bcp and the SqlBulkCopy API, the fastest and most scalable way to load data is through PolyBase external tables and the COPY statement.

With PolyBase and the COPY statement, you can access external data stored in Azure Blob storage or Azure Data Lake Store via the T-SQL language. For the most flexibility when loading, we recommend using the COPY statement.

What is ELT?

Extract, Load, and Transform (ELT) is a process by which data is extracted from a source system, loaded into a dedicated SQL pool, and then transformed.

The basic steps for implementing ELT are:

1. Extract the source data into text files.
2. Land the data into Azure Blob storage or Azure Data Lake Store.
3. Prepare the data for loading.
4. Load the data into staging tables with PolyBase or the COPY command.
5. Transform the data.
6. Insert the data into production tables.

For a loading tutorial, see loading data from Azure blob storage.

1. Extract the source data into text files

Getting data out of your source system depends on the storage location. The goal is to move the data into supported delimited text or CSV files.

Supported file formats

With PolyBase and the COPY statement, you can load data from UTF-8 and UTF-16 encoded delimited text or CSV files. In addition to delimited text or CSV files, it loads from the Hadoop file formats such as ORC and Parquet. PolyBase and the COPY statement can also load data from Gzip and Snappy compressed files.

Extended ASCII, fixed-width format, and nested formats such as WinZip or XML aren't supported. If you're exporting from SQL Server, you can use the bcp command-line tool to export the data into delimited text files.

2. Land the data into Azure Blob storage or Azure Data Lake Store

To land the data in Azure storage, you can move it to Azure Blob storage or Azure Data Lake Store Gen2. In

either location, the data should be stored in text files. PolyBase and the COPY statement can load from either location.

Tools and services you can use to move data to Azure Storage:

- Azure ExpressRoute service enhances network throughput, performance, and predictability. ExpressRoute is a service that routes your data through a dedicated private connection to Azure. ExpressRoute connections do not route data through the public internet. The connections offer more reliability, faster speeds, lower latencies, and higher security than typical connections over the public internet.
- AzCopy utility moves data to Azure Storage over the public internet. This works if your data sizes are less than 10 TB. To perform loads on a regular basis with AzCopy, test the network speed to see if it is acceptable.
- Azure Data Factory (ADF) has a gateway that you can install on your local server. Then you can create a pipeline to move data from your local server up to Azure Storage. To use Data Factory with dedicated SQL pools, see Loading data for dedicated SQL pools.

3. Prepare the data for loading

You might need to prepare and clean the data in your storage account before loading. Data preparation can be performed while your data is in the source, as you export the data to text files, or after the data is in Azure Storage. It is easiest to work with the data as early in the process as possible.

Define the tables

You must first define the table(s) you are loading to in your dedicated SQL pool when using the COPY statement.

If you are using PolyBase, you need to define external tables in your dedicated SQL pool before loading. PolyBase uses external tables to define and access the data in Azure Storage. An external table is similar to a database view. The external table contains the table schema and points to data that is stored outside the dedicated SQL pool.

Defining external tables involves specifying the data source, the format of the text files, and the table definitions. T-SQL syntax reference articles that you will need are:

- CREATE EXTERNAL DATA SOURCE
- CREATE EXTERNAL FILE FORMAT
- CREATE EXTERNAL TABLE

Use the following SQL data type mapping when loading Parquet files:

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
BOOLEAN		bit
BINARY / BYTE_ARRAY		varbinary
DOUBLE		float
FLOAT		real
INT32		int
INT64		bigint
INT96		datetime2

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
FIXED_LEN_BYTE_ARRAY		binary
BINARY	UTF8	nvarchar
BINARY	STRING	nvarchar
BINARY	ENUM	nvarchar
BINARY	UUID	uniqueidentifier
BINARY	DECIMAL	decimal
BINARY	JSON	nvarchar(MAX)
BINARY	BSON	varbinary(max)
FIXED_LEN_BYTE_ARRAY	DECIMAL	decimal
BYTE_ARRAY	INTERVAL	varchar(max),
INT32	INT(8, true)	smallint
INT32	INT(16, true)	smallint
INT32	INT(32, true)	int
INT32	INT(8, false)	tinyint
INT32	INT(16, false)	int
INT32	INT(32, false)	bigint
INT32	DATE	date
INT32	DECIMAL	decimal
INT32	TIME (MILLIS)	time
INT64	INT(64, true)	bigint
INT64	INT(64, false)	decimal(20,0)
INT64	DECIMAL	decimal
INT64	TIME (MILLIS)	time
INT64	TIMESTAMP (MILLIS)	datetime2
Complex type	LIST	varchar(max)

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
[Complex type] (https://github.com/apache/parquet-format/blob/master/LogicalTypes.md	MAP	varchar(max)

IMPORTANT

- SQL dedicated pools do not currently support Parquet data types with MICROS and NANOS precision.
- You may experience the following error if types are mismatched between Parquet and SQL or if you have unsupported Parquet data types: **"HdfsBridge::recordReaderFillBuffer - Unexpected error encountered filling record reader buffer: ClassCastException: ..."**
- Loading a value outside the range of 0-127 into a tinyint column for Parquet and ORC file format is not supported.

For an example of creating external objects, see Create external tables.

Format text files

If you are using PolyBase, the external objects defined need to align the rows of the text files with the external table and file format definition. The data in each row of the text file must align with the table definition. To format the text files:

- If your data is coming from a non-relational source, you need to transform it into rows and columns. Whether the data is from a relational or non-relational source, the data must be transformed to align with the column definitions for the table into which you plan to load the data.
- Format data in the text file to align with the columns and data types in the destination table. Misalignment between data types in the external text files and the dedicated SQL pool table causes rows to be rejected during the load.
- Separate fields in the text file with a terminator. Be sure to use a character or a character sequence that isn't found in your source data. Use the terminator you specified with CREATE EXTERNAL FILE FORMAT.

4. Load the data using PolyBase or the COPY statement

It is best practice to load data into a staging table. Staging tables allow you to handle errors without interfering with the production tables. A staging table also gives you the opportunity to use the dedicated SQL pool parallel processing architecture for data transformations before inserting the data into production tables.

Options for loading

To load data, you can use any of these loading options:

- The COPY statement is the recommended loading utility as it enables you to seamlessly and flexibly load data. The statement has many additional loading capabilities that PolyBase does not provide. See the NY taxi cab COPY tutorial to run through a sample tutorial.
- PolyBase with T-SQL requires you to define external data objects.
- PolyBase and COPY statement with Azure Data Factory (ADF) is another orchestration tool. It defines a pipeline and schedules jobs.
- PolyBase with SSIS works well when your source data is in SQL Server. SSIS defines the source to destination table mappings, and also orchestrates the load. If you already have SSIS packages, you can modify the packages to work with the new data warehouse destination.
- PolyBase with Azure Databricks transfers data from a table to a Databricks dataframe and/or writes data from a Databricks dataframe to a table using PolyBase.

Other loading options

In addition to PolyBase and the COPY statement, you can use bcp or the SqlBulkCopy API. bcp loads directly to the database without going through Azure Blob storage, and is intended only for small loads.

> **NOTE**
> The load performance of these options is slower than PolyBase and the COPY statement.

5. Transform the data

While data is in the staging table, perform transformations that your workload requires. Then move the data into a production table.

6. Insert the data into production tables

The INSERT INTO ... SELECT statement moves the data from the staging table to the permanent table.

As you design an ETL process, try running the process on a small test sample. Try extracting 1000 rows from the table to a file, move it to Azure, and then try loading it into a staging table.

Partner loading solutions

Many of our partners have loading solutions. To find out more, see a list of our solution partners.

Best practices for loading data into a dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

In this article, you'll find recommendations and performance optimizations for loading data.

Prepare data in Azure Storage

To minimize latency, colocate your storage layer and your dedicated SQL pool.

When exporting data into an ORC File Format, you might get Java out-of-memory errors when there are large text columns. To work around this limitation, export only a subset of the columns.

PolyBase can't load rows that have more than 1,000,000 bytes of data. When you put data into the text files in Azure Blob storage or Azure Data Lake Store, they must have fewer than 1,000,000 bytes of data. This byte limitation is true regardless of the table schema.

All file formats have different performance characteristics. For the fastest load, use compressed delimited text files. The difference between UTF-8 and UTF-16 performance is minimal.

Split large compressed files into smaller compressed files.

Run loads with enough compute

For fastest loading speed, run only one load job at a time. If that is not feasible, run a minimal number of loads concurrently. If you expect a large loading job, consider scaling up your dedicated SQL pool before the load.

To run loads with appropriate compute resources, create loading users designated for running loads. Assign each loading user to a specific resource class or workload group. To run a load, sign in as one of the loading users, and then run the load. The load runs with the user's resource class. This method is simpler than trying to change a user's resource class to fit the current resource class need.

Create a loading user

This example creates a loading user classified to a specific workload group. The first step is to **connect to master** and create a login.

```
-- Connect to master
CREATE LOGIN loader WITH PASSWORD = 'a123STRONGpassword!';
```

Connect to the dedicated SQL pool and create a user. The following code assumes you're connected to the database called mySampleDataWarehouse. It shows how to create a user called loader and gives the user permissions to create tables and load using the COPY statement. Then it classifies the user to the DataLoads workload group with maximum resources.

```
-- Connect to the dedicated SQL pool
CREATE USER loader FOR LOGIN loader;
GRANT ADMINISTER DATABASE BULK OPERATIONS TO loader;
GRANT INSERT ON <yourtablename> TO loader;
GRANT SELECT ON <yourtablename> TO loader;
GRANT CREATE TABLE TO loader;
GRANT ALTER ON SCHEMA::dbo TO loader;

CREATE WORKLOAD GROUP DataLoads
WITH (
    MIN_PERCENTAGE_RESOURCE = 0
    ,CAP_PERCENTAGE_RESOURCE = 100
    ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 100
);

CREATE WORKLOAD CLASSIFIER [wgcELTLogin]
WITH (
   WORKLOAD_GROUP = 'DataLoads'
    ,MEMBERNAME = 'loader'
);
```

IMPORTANT

This is an extreme example of allocating 100% resources of the SQL pool to a single load. This will give you a maximum concurrency of 1. Be aware that this should be used only for the initial load where you will need to create additional workload groups with their own configurations to balance resources across your workloads.

To run a load with resources for the loading workload group, sign in as loader and run the load.

Allow multiple users to load

There is often a need to have multiple users load data into a data warehouse. Loading with the CREATE TABLE AS SELECT (Transact-SQL) requires CONTROL permissions of the database. The CONTROL permission gives control access to all schemas. You might not want all loading users to have control access on all schemas. To limit permissions, use the DENY CONTROL statement.

For example, consider database schemas, schema_A for dept A, and schema_B for dept B. Let database users user_A and user_B be users for PolyBase loading in dept A and B, respectively. They both have been granted CONTROL database permissions. The creators of schema A and B now lock down their schemas using DENY:

```
DENY CONTROL ON SCHEMA :: schema_A TO user_B;
DENY CONTROL ON SCHEMA :: schema_B TO user_A;
```

User_A and user_B are now locked out from the other dept's schema.

Load to a staging table

To achieve the fastest loading speed for moving data into a data warehouse table, load data into a staging table. Define the staging table as a heap and use round-robin for the distribution option.

Consider that loading is usually a two-step process in which you first load to a staging table and then insert the data into a production data warehouse table. If the production table uses a hash distribution, the total time to load and insert might be faster if you define the staging table with the hash distribution. Loading to the staging table takes longer, but the second step of inserting the rows to the production table does not incur data

movement across the distributions.

Load to a columnstore index

Columnstore indexes require large amounts of memory to compress data into high-quality rowgroups. For best compression and index efficiency, the columnstore index needs to compress the maximum of 1,048,576 rows into each rowgroup. When there is memory pressure, the columnstore index might not be able to achieve maximum compression rates. This effects query performance. For a deep dive, see Columnstore memory optimizations.

- To ensure the loading user has enough memory to achieve maximum compression rates, use loading users that are a member of a medium or large resource class.
- Load enough rows to completely fill new rowgroups. During a bulk-load, every 1,048,576 rows get compressed directly into the columnstore as a full rowgroup. Loads with fewer than 102,400 rows send the rows to the deltastore where rows are held in a b-tree index. If you load too few rows, they might all go to the deltastore and not get compressed immediately into columnstore format.

Increase batch size when using SQLBulkCopy API or BCP

Loading with the COPY statement will provide the highest throughput with dedicated SQL pools. If you cannot use the COPY to load and must use the SqLBulkCopy API or bcp, you should consider increasing batch size for better throughput.

> **TIP**
> A batch size between 100 K to 1M rows is the recommended baseline for determining optimal batch size capacity.

Manage loading failures

A load using an external table can fail with the error *"Query aborted-- the maximum reject threshold was reached while reading from an external source"*. This message indicates that your external data contains dirty records. A data record is considered dirty if the data types and number of columns do not match the column definitions of the external table, or if the data doesn't conform to the specified external file format.

To fix the dirty records, ensure that your external table and external file format definitions are correct and your external data conforms to these definitions. In case a subset of external data records are dirty, you can choose to reject these records for your queries by using the reject options in 'CREATE EXTERNAL TABLE' .

Insert data into a production table

A one-time load to a small table with an INSERT statement, or even a periodic reload of a look-up might perform good enough with a statement like `INSERT INTO MyLookup VALUES (1, 'Type 1')`. However, singleton inserts are not as efficient as performing a bulk-load.

If you have thousands or more single inserts throughout the day, batch the inserts so you can bulk load them. Develop your processes to append the single inserts to a file, and then create another process that periodically loads the file.

Create statistics after the load

To improve query performance, it's important to create statistics on all columns of all tables after the first load, or major changes occur in the data. Create statistics can be done manually or you can enable auto-create statistics.

For a detailed explanation of statistics, see Statistics. The following example shows how to manually create statistics on five columns of the Customer_Speed table.

```
create statistics [SensorKey] on [Customer_Speed] ([SensorKey]);
create statistics [CustomerKey] on [Customer_Speed] ([CustomerKey]);
create statistics [GeographyKey] on [Customer_Speed] ([GeographyKey]);
create statistics [Speed] on [Customer_Speed] ([Speed]);
create statistics [YearMeasured] on [Customer_Speed] ([YearMeasured]);
```

Rotate storage keys

It is good security practice to change the access key to your blob storage on a regular basis. You have two storage keys for your blob storage account, which enables you to transition the keys.

To rotate Azure Storage account keys:

For each storage account whose key has changed, issue ALTER DATABASE SCOPED CREDENTIAL.

Example:

Original key is created

```
CREATE DATABASE SCOPED CREDENTIAL my_credential WITH IDENTITY = 'my_identity', SECRET = 'key1'
```

Rotate key from key 1 to key 2

```
ALTER DATABASE SCOPED CREDENTIAL my_credential WITH IDENTITY = 'my_identity', SECRET = 'key2'
```

No other changes to underlying external data sources are needed.

Next steps

- To learn more about PolyBase and designing an Extract, Load, and Transform (ELT) process, see Design ELT for Azure Synapse Analytics.
- For a loading tutorial, Use PolyBase to load data from Azure blob storage to Azure Synapse Analytics.

Maximize rowgroup quality for columnstore index performance

8/19/2022 • 6 minutes to read • Edit Online

Rowgroup quality is determined by the number of rows in a rowgroup. Increasing the available memory can maximize the number of rows a columnstore index compresses into each rowgroup. Use these methods to improve compression rates and query performance for columnstore indexes.

Why the rowgroup size matters

Since a columnstore index scans a table by scanning column segments of individual rowgroups, maximizing the number of rows in each rowgroup enhances query performance. When rowgroups have a high number of rows, data compression improves which means there is less data to read from disk.

For more information about rowgroups, see Columnstore Indexes Guide.

Target size for rowgroups

For best query performance, the goal is to maximize the number of rows per rowgroup in a columnstore index. A rowgroup can have a maximum of 1,048,576 rows. It's okay to not have the maximum number of rows per rowgroup. Columnstore indexes achieve good performance when rowgroups have at least 100,000 rows.

Rowgroups can get trimmed during compression

During a bulk load or columnstore index rebuild, sometimes there's not enough memory available to compress all the rows designated for each rowgroup. When there is memory pressure, columnstore indexes trim the rowgroup sizes so compression into the columnstore can succeed.

When there is insufficient memory to compress at least 10,000 rows into each rowgroup, an error will be generated.

For more information on bulk loading, see Bulk load into a clustered columnstore index.

How to monitor rowgroup quality

The dynamic management view (DMV) (sys.dm_db_column_store_row_group_physical_stats contains the view definition matching SQL DB) that exposes useful information such as number of rows in rowgroups and the reason for trimming if there was trimming. You can create the following view as a handy way to query this DMV to get information on rowgroup trimming.

```
CREATE VIEW dbo.vCS_rg_physical_stats
AS
WITH cte
AS
(
select   tb.[name]                    AS [logical_table_name]
,        rg.[row_group_id]            AS [row_group_id]
,        rg.[state]                   AS [state]
,        rg.[state_desc]              AS [state_desc]
,        rg.[total_rows]              AS [total_rows]
,        rg.[trim_reason_desc]        AS trim_reason_desc
,        mp.[physical_name]           AS physical_name
FROM    sys.[schemas] sm
JOIN    sys.[tables] tb               ON  sm.[schema_id]          = tb.[schema_id]
JOIN    sys.[pdw_table_mappings] mp   ON  tb.[object_id]          = mp.[object_id]
JOIN    sys.[pdw_nodes_tables] nt     ON  nt.[name]               = mp.[physical_name]
JOIN    sys.[dm_pdw_nodes_db_column_store_row_group_physical_stats] rg      ON  rg.[object_id]     = nt.
[object_id]
                                                                            AND rg.[pdw_node_id]   = nt.
[pdw_node_id]
                                      AND rg.[distribution_id]    = nt.[distribution_id]
)
SELECT *
FROM cte;
```

The `trim_reason_desc` column indicates whether the rowgroup was trimmed (trim_reason_desc = NO_TRIM implies there was no trimming and row group is of optimal quality). The following trim reasons indicate premature trimming of the rowgroup:

- BULKLOAD: This trim reason is used when the incoming batch of rows for the load had less than 1 million rows. The engine will create compressed row groups if there are greater than 100,000 rows being inserted (as opposed to inserting into the delta store) but sets the trim reason to BULKLOAD. In this scenario, consider increasing your batch load to include more rows. Also, reevaluate your partitioning scheme to ensure it is not too granular as row groups cannot span partition boundaries.
- MEMORY_LIMITATION: To create row groups with 1 million rows, a certain amount of working memory is required by the engine. When available memory of the loading session is less than the required working memory, row groups get prematurely trimmed. The following sections explain how to estimate memory required and allocate more memory.
- DICTIONARY_SIZE: This trim reason indicates that rowgroup trimming occurred because there was at least one string column with wide and/or high cardinality strings. The dictionary size is limited to 16 MB in memory and once this limit is reached the row group is compressed. If you do run into this situation, consider isolating the problematic column into a separate table.

How to estimate memory requirements

The maximum required memory to compress one rowgroup is, approximately, as follows:

- 72 MB +
- #rows * #columns * 8 bytes +
- #rows * #short-string-columns * 32 bytes +
- #long-string-columns * 16 MB for compression dictionary

> **NOTE**
> Where short-string-columns use string data types of <= 32 bytes and long-string-columns use string data types of > 32 bytes.

Long strings are compressed with a compression method designed for compressing text. This compression method uses a *dictionary* to store text patterns. The maximum size of a dictionary is 16 MB. There is only one dictionary for each long string column in the rowgroup.

Ways to reduce memory requirements

Use the following techniques to reduce the memory requirements for compressing rowgroups into columnstore indexes.

Use fewer columns

If possible, design the table with fewer columns. When a rowgroup is compressed into the columnstore, the columnstore index compresses each column segment separately. Therefore the memory requirements to compress a rowgroup increase as the number of columns increases.

Use fewer string columns

Columns of string data types require more memory than numeric and date data types. To reduce memory requirements, consider removing string columns from fact tables and putting them in smaller dimension tables.

Additional memory requirements for string compression:

- String data types up to 32 characters can require 32 additional bytes per value.
- String data types with more than 32 characters are compressed using dictionary methods. Each column in the rowgroup can require up to an additional 16 MB to build the dictionary.

Avoid over-partitioning

Columnstore indexes create one or more rowgroups per partition. For data warehousing in Azure Synapse Analytics, the number of partitions grows quickly because the data is distributed and each distribution is partitioned. If the table has too many partitions, there might not be enough rows to fill the rowgroups. The lack of rows does not create memory pressure during compression, but it leads to rowgroups that do not achieve the best columnstore query performance.

Another reason to avoid over-partitioning is there is a memory overhead for loading rows into a columnstore index on a partitioned table. During a load, many partitions could receive the incoming rows, which are held in memory until each partition has enough rows to be compressed. Having too many partitions creates additional memory pressure.

Simplify the load query

The database shares the memory grant for a query among all the operators in the query. When a load query has complex sorts and joins, the memory available for compression is reduced.

Design the load query to focus only on loading the query. If you need to run transformations on the data, run them separate from the load query. For example, stage the data in a heap table, run the transformations, and then load the staging table into the columnstore index.

Adjust MAXDOP

Each distribution compresses rowgroups into the columnstore in parallel when there's more than one CPU core available per distribution. The parallelism requires additional memory resources, which can lead to memory pressure and rowgroup trimming.

To reduce memory pressure, you can use the MAXDOP query hint to force the load operation to run in serial mode within each distribution.

```
CREATE TABLE MyFactSalesQuota
WITH (DISTRIBUTION = ROUND_ROBIN)
AS SELECT * FROM FactSalesQuota
OPTION (MAXDOP 1);
```

Ways to allocate more memory

DWU size and the user resource class together determine how much memory is available for a user query. To increase the memory grant for a load query, you can either increase the number of DWUs or increase the resource class.

- To increase the DWUs, see How do I scale performance?
- To change the resource class for a query, see Change a user resource class example.

Design a PolyBase data loading strategy for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

Traditional SMP data warehouses use an Extract, Transform, and Load (ETL) process for loading data. Azure SQL pool is a massively parallel processing (MPP) architecture that takes advantage of the scalability and flexibility of compute and storage resources. An Extract, Load, and Transform (ELT) process can take advantage of built-in distributed query processing capabilities and eliminate resources needed to transform the data before loading.

While SQL pool supports many loading methods including non-Polybase options such as BCP and SQL BulkCopy API, the fastest and most scalable way to load data is through PolyBase. PolyBase is a technology that accesses external data stored in Azure Blob storage or Azure Data Lake Store via the T-SQL language.

Extract, Load, and Transform (ELT)

Extract, Load, and Transform (ELT) is a process by which data is extracted from a source system, loaded into a data warehouse, and then transformed.

The basic steps for implementing a PolyBase ELT for dedicated SQL pool are:

1. Extract the source data into text files.
2. Land the data into Azure Blob storage or Azure Data Lake Store.
3. Prepare the data for loading.
4. Load the data into dedicated SQL pool staging tables using PolyBase.
5. Transform the data.
6. Insert the data into production tables.

For a loading tutorial, see Use PolyBase to load data from Azure blob storage to Azure Synapse Analytics.

For more information, see Loading patterns blog.

1. Extract the source data into text files

Getting data out of your source system depends on the storage location. The goal is to move the data into PolyBase supported delimited text files.

PolyBase external file formats

PolyBase loads data from UTF-8 and UTF-16 encoded delimited text files. PolyBase also loads from the Hadoop file formats RC File, ORC, and Parquet. PolyBase can also load data from Gzip and Snappy compressed files. PolyBase currently does not support extended ASCII, fixed-width format, and nested formats such as WinZip, JSON, and XML.

If you're exporting from SQL Server, you can use bcp command-line tool to export the data into delimited text files. The Parquet to Azure Synapse Analytics data type mapping is as follows:

PARQUET DATA TYPE	SQL DATA TYPE
tinyint	tinyint

PARQUET DATA TYPE	SQL DATA TYPE
smallint	smallint
int	int
bigint	bigint
boolean	bit
double	float
float	real
double	money
double	smallmoney
string	nchar
string	nvarchar
string	char
string	varchar
binary	binary
binary	varbinary
timestamp	date
timestamp	smalldatetime
timestamp	datetime2
timestamp	datetime
timestamp	time
date	date
decimal	decimal

2. Land the data into Azure Blob storage or Azure Data Lake Store

To land the data in Azure storage, you can move it to Azure Blob storage or Azure Data Lake Store. In either location, the data should be stored in text files. PolyBase can load from either location.

Tools and services you can use to move data to Azure Storage:

- Azure ExpressRoute service enhances network throughput, performance, and predictability. ExpressRoute is a service that routes your data through a dedicated private connection to Azure. ExpressRoute connections do

not route data through the public internet. The connections offer more reliability, faster speeds, lower latencies, and higher security than typical connections over the public internet.

- AzCopy utility moves data to Azure Storage over the public internet. This works if your data sizes are less than 10 TB. To perform loads on a regular basis with AzCopy, test the network speed to see if it is acceptable.
- Azure Data Factory (ADF) has a gateway that you can install on your local server. Then you can create a pipeline to move data from your local server up to Azure Storage. To use Data Factory with dedicated SQL pool, see Load data into dedicated SQL pool.

3. Prepare the data for loading

You might need to prepare and clean the data in your storage account before loading it into dedicated SQL pool. Data preparation can be performed while your data is in the source, as you export the data to text files, or after the data is in Azure Storage. It is easiest to work with the data as early in the process as possible.

Define external tables

Before you can load data, you need to define external tables in your data warehouse. PolyBase uses external tables to define and access the data in Azure Storage. An external table is similar to a database view. The external table contains the table schema and points to data that is stored outside the data warehouse.

Defining external tables involves specifying the data source, the format of the text files, and the table definitions. What follows are the T-SQL syntax topics that you'll need:

- CREATE EXTERNAL DATA SOURCE
- CREATE EXTERNAL FILE FORMAT
- CREATE EXTERNAL TABLE

Format text files

Once the external objects are defined, you need to align the rows of the text files with the external table and file format definition. The data in each row of the text file must align with the table definition. To format the text files:

- If your data is coming from a non-relational source, you need to transform it into rows and columns. Whether the data is from a relational or non-relational source, the data must be transformed to align with the column definitions for the table into which you plan to load the data.
- Format data in the text file to align with the columns and data types in the SQL pool destination table. Misalignment between data types in the external text files and the data warehouse table causes rows to be rejected during the load.
- Separate fields in the text file with a terminator. Be sure to use a character or a character sequence that is not found in your source data. Use the terminator you specified with CREATE EXTERNAL FILE FORMAT.

4. Load the data into dedicated SQL pool staging tables using PolyBase

It is best practice to load data into a staging table. Staging tables allow you to handle errors without interfering with the production tables. A staging table also gives you the opportunity to use SQL pool built-in distributed query processing capabilities for data transformations before inserting the data into production tables.

Options for loading with PolyBase

To load data with PolyBase, you can use any of these loading options:

- PolyBase with T-SQL works well when your data is in Azure Blob storage or Azure Data Lake Store. It gives you the most control over the loading process, but also requires you to define external data objects. The other methods define these objects behind the scenes as you map source tables to destination tables. To orchestrate T-SQL loads, you can use Azure Data Factory, SSIS, or Azure functions.
- PolyBase with SSIS works well when your source data is in SQL Server. SSIS defines the source to destination

table mappings, and also orchestrates the load. If you already have SSIS packages, you can modify the packages to work with the new data warehouse destination.

- PolyBase with Azure Data Factory (ADF) is another orchestration tool. It defines a pipeline and schedules jobs.
- PolyBase with Azure Databricks transfers data from an Azure Synapse Analytics table to a Databricks dataframe and/or writes data from a Databricks dataframe to an Azure Synapse Analytics table using PolyBase.

Non-PolyBase loading options

If your data is not compatible with PolyBase, you can use bcp or the SQLBulkCopy API. BCP loads directly to dedicated SQL pool without going through Azure Blob storage, and is intended only for small loads. Note, the load performance of these options is slower than PolyBase.

5. Transform the data

While data is in the staging table, perform transformations that your workload requires. Then move the data into a production table.

6. Insert the data into production tables

The INSERT INTO ... SELECT statement moves the data from the staging table to the permanent table.

As you design an ETL process, try running the process on a small test sample. Try extracting 1000 rows from the table to a file, move it to Azure, and then try loading it into a staging table.

Partner loading solutions

Many of our partners have loading solutions. To find out more, see a list of our solution partners.

Design decisions and coding techniques for Synapse SQL features in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll find a list of resources for dedicated SQL pool and serverless SQL pool functions of Synapse SQL. The recommended articles are split up into two sections: Key design decisions and development and coding techniques.

The goal of these articles is to help you develop the optimal technical approach for the Synapse SQL components within Azure Synapse Analytics.

Key design decisions

The articles below highlight concepts and design decisions for Synapse SQL development:

ARTICLE	DEDICATED SQL POOL	SERVERLESS SQL POOL
Connections	Yes	Yes
Resource classes and concurrency	Yes	No
Transactions	Yes	No
User-defined schemas	Yes	Yes
Table distribution	Yes	No
Table indexes	Yes	No
Table partitions	Yes	No
Statistics	Yes	Yes
CTAS	Yes	No
External tables	Yes	Yes
CETAS	Yes	Yes

Recommendations

Below you'll find essential articles that emphasize specific coding techniques, tips, and recommendations for development:

ARTICLE	DEDICATED SQL POOL	SERVERLESS SQL POOL
Stored procedures	Yes	Yes

ARTICLE	DEDICATED SQL POOL	SERVERLESS SQL POOL
Labels	Yes	No
Views	Yes	Yes
Temporary tables	Yes	Yes
Dynamic SQL	Yes	Yes
Looping	Yes	Yes
Group by options	Yes	No
Variable assignment	Yes	Yes

Benefits & best practices

- To learn more on which scenarios are suited for Serverless SQL pool, see Serverless SQL pool benefits article.
- Best practices for using serverless SQL pool
- Best practices for optimal performance using dedicated SQL pools

T-SQL feature support

Transact-SQL language is used in serverless SQL pool and dedicated model can reference different objects and has some differences in the set of supported features. For more information, see Transact-SQL features supported in Azure Synapse SQL article.

Next steps

For more reference information, see SQL pool T-SQL statements.

Best practices for serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

In this article, you'll find a collection of best practices for using serverless SQL pool. Serverless SQL pool is a resource in Azure Synapse Analytics. If you're working with a dedicated SQL pool, see Best practices for dedicated SQL pools for specific guidance.

Serverless SQL pool allows you to query files in your Azure Storage accounts. It doesn't have local storage or ingestion capabilities. All files that the queries target are external to serverless SQL pool. Everything related to reading files from storage might affect query performance.

Some generic guidelines are:

- Make sure your client applications are collocated with serverless SQL pool.
  - If you're using client applications outside Azure, make sure you're using serverless SQL pool in a region that's close to your client computer. Client application examples include Power BI Desktop, SQL Server Management Studio, and Azure Data Studio.
- Make sure the storage and serverless SQL pool are in the same region. Storage examples include Azure Data Lake Storage and Azure Cosmos DB.
- Try to optimize storage layout by using partitioning and keeping your files in the range between 100 MB and 10 GB.
- If you're returning a large number of results, make sure you're using SQL Server Management Studio or Azure Data Studio and not Azure Synapse Studio. Azure Synapse Studio is a web tool that isn't designed for large result sets.
- If you're filtering results by string column, try to use a `BIN2_UTF8` collation.
- Consider caching the results on the client side by using Power BI import mode or Azure Analysis Services, and periodically refresh them. Serverless SQL pools can't provide an interactive experience in Power BI Direct Query mode if you're using complex queries or processing a large amount of data.

Client applications and network connections

Make sure your client application is connected to the closest possible Azure Synapse workspace with the optimal connection.

- Colocate a client application with the Azure Synapse workspace. If you're using applications such as Power BI or Azure Analysis Service, make sure they're in the same region where you placed your Azure Synapse workspace. If needed, create the separate workspaces that are paired with your client applications. Placing a client application and the Azure Synapse workspace in different regions could cause bigger latency and slower streaming of results.
- If you're reading data from your on-premises application, make sure the Azure Synapse workspace is in the region that's close to your location.
- Make sure you don't have network bandwidth issues while reading a large amount of data.
- Don't use Azure Synapse Studio to return a large amount of data. Azure Synapse Studio is a web tool that uses the HTTPS protocol to transfer data. Use Azure Data Studio or SQL Server Management Studio to read a large amount of data.

Storage and content layout

Here are best practices for storage and content layout in serverless SQL pool.

Colocate your storage and serverless SQL pool

To minimize latency, colocate your Azure Storage account or Azure Cosmos DB analytic storage and your serverless SQL pool endpoint. Storage accounts and endpoints provisioned during workspace creation are located in the same region.

For optimal performance, if you access other storage accounts with serverless SQL pool, make sure they're in the same region. If they aren't in the same region, there will be increased latency for the data's network transfer between the remote region and the endpoint's region.

Azure Storage throttling

Multiple applications and services might access your storage account. Storage throttling occurs when the combined IOPS or throughput generated by applications, services, and serverless SQL pool workloads exceeds the limits of the storage account. As a result, you'll experience a significant negative effect on query performance.

When throttling is detected, serverless SQL pool has built-in handling to resolve it. Serverless SQL pool makes requests to storage at a slower pace until throttling is resolved.

> **TIP**
> For optimal query execution, don't stress the storage account with other workloads during query execution.

Prepare files for querying

If possible, you can prepare files for better performance:

- Convert large CSV and JSON files to Parquet. Parquet is a columnar format. Because it's compressed, its file sizes are smaller than CSV or JSON files that contain the same data. Serverless SQL pool skips the columns and rows that aren't needed in a query if you're reading Parquet files. Serverless SQL pool needs less time and fewer storage requests to read it.
- If a query targets a single large file, you'll benefit from splitting it into multiple smaller files.
- Try to keep your CSV file size between 100 MB and 10 GB.
- It's better to have equally sized files for a single OPENROWSET path or an external table LOCATION.
- Partition your data by storing partitions to different folders or file names. See Use filename and filepath functions to target specific partitions.

Colocate your Azure Cosmos DB analytical storage and serverless SQL pool

Make sure your Azure Cosmos DB analytical storage is placed in the same region as an Azure Synapse workspace. Cross-region queries might cause huge latencies. Use the region property in the connection string to explicitly specify the region where the analytical store is placed (see Query Azure Cosmos DB by using serverless SQL pool):

```
'account=<database account name>;database=<database name>;region=<region name>'
```

CSV optimizations

Here are best practices for using CSV files in serverless SQL pool.

Use PARSER_VERSION 2.0 to query CSV files

You can use a performance-optimized parser when you query CSV files. For details, see PARSER_VERSION.

Manually create statistics for CSV files

Serverless SQL pool relies on statistics to generate optimal query execution plans. Statistics are automatically created for columns in Parquet files when needed. At this moment, statistics aren't automatically created for columns in CSV files. Create statistics manually for columns that you use in queries, particularly those used in DISTINCT, JOIN, WHERE, ORDER BY, and GROUP BY. Check statistics in serverless SQL pool for details.

Data types

Here are best practices for using data types in serverless SQL pool.

Use appropriate data types

The data types you use in your query affect performance and concurrency. You can get better performance if you follow these guidelines:

- Use the smallest data size that can accommodate the largest possible value.
  - If the maximum character value length is 30 characters, use a character data type of length 30.
  - If all character column values are of a fixed size, use **char** or **nchar**. Otherwise, use **varchar** or **nvarchar**.
  - If the maximum integer column value is 500, use **smallint** because it's the smallest data type that can accommodate this value. You can find integer data type ranges in this article.
- If possible, use **varchar** and **char** instead of **nvarchar** and **nchar**.
  - Use the **varchar** type with some UTF8 collation if you're reading data from Parquet, Azure Cosmos DB, Delta Lake, or CSV with UTF-8 encoding.
  - Use the **varchar** type without UTF8 collation if you're reading data from CSV non-Unicode files (for example, ASCII).
  - Use the **nvarchar** type if you're reading data from a CSV UTF-16 file.
- Use integer-based data types if possible. SORT, JOIN, and GROUP BY operations complete faster on integers than on character data.
- If you're using schema inference, check inferred data types and override them explicitly with the smaller types if possible.

Check inferred data types

Schema inference helps you quickly write queries and explore data without knowing file schemas. The cost of this convenience is that inferred data types might be larger than the actual data types. This discrepancy happens when there isn't enough information in the source files to make sure the appropriate data type is used. For example, Parquet files don't contain metadata about maximum character column length. So serverless SQL pool infers it as varchar(8000).

You can use sp_describe_first_results_set to check the resulting data types of your query.

The following example shows how you can optimize inferred data types. This procedure is used to show the inferred data types:

```
EXEC sp_describe_first_result_set N'
 SELECT
        vendor_id, pickup_datetime, passenger_count
 FROM
  OPENROWSET(
         BULK ''https://sqlondemandstorage.blob.core.windows.net/parquet/taxi/*/*/*'',
         FORMAT=''PARQUET''
     ) AS nyc';
```

Here's the result set:

IS_HIDDEN	COLUMN_ORDINAL	NAME	SYSTEM_TYPE_NAME	MAX_LENGTH
0	1	vendor_id	varchar(8000)	8000
0	2	pickup_datetime	datetime2(7)	8
0	3	passenger_count	int	4

After you know the inferred data types for the query, you can specify appropriate data types:

```
SELECT
    vendorID, tpepPickupDateTime, passengerCount
FROM
 OPENROWSET(
  BULK
'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/puYear=2018/puMonth=*/*.snappy.parquet',
  FORMAT='PARQUET'
    )
 WITH (
  vendorID varchar(4), -- we used length of 4 instead of the inferred 8000
  tpepPickupDateTime datetime2,
  passengerCount int
 ) AS nyc;
```

Filter optimization

Here are best practices for using queries in serverless SQL pool.

Push wildcards to lower levels in the path

You can use wildcards in your path to query multiple files and folders. Serverless SQL pool lists files in your storage account, starting from the first asterisk (*), by using the storage API. It eliminates files that don't match the specified path. Reducing the initial list of files can improve performance if there are many files that match the specified path up to the first wildcard.

Use filename and filepath functions to target specific partitions

Data is often organized in partitions. You can instruct serverless SQL pool to query particular folders and files. Doing so reduces the number of files and the amount of data the query needs to read and process. An added bonus is that you'll achieve better performance.

For more information, read about the filename and filepath functions and see the examples for querying specific files.

> **TIP**
> Always cast the results of the filepath and filename functions to appropriate data types. If you use character data types, be sure to use the appropriate length.

Functions used for partition elimination, filepath and filename, aren't currently supported for external tables, other than those created automatically for each table created in Apache Spark for Azure Synapse Analytics.

If your stored data isn't partitioned, consider partitioning it. That way you can use these functions to optimize queries that target those files. When you query partitioned Apache Spark for Azure Synapse tables from serverless SQL pool, the query automatically targets only the necessary files.

Use proper collation to utilize predicate pushdown for character columns

Data in a Parquet file is organized in row groups. Serverless SQL pool skips row groups based on the specified predicate in the WHERE clause, which reduces IO. The result is increased query performance.

Predicate pushdown for character columns in Parquet files is supported for Latin1_General_100_BIN2_UTF8 collation only. You can specify collation for a particular column by using a WITH clause. If you don't specify this collation by using a WITH clause, the database collation is used.

Optimize repeating queries

Here are best practices for using CETAS in serverless SQL pool.

Use CETAS to enhance query performance and joins

CETAS is one of the most important features available in serverless SQL pool. CETAS is a parallel operation that creates external table metadata and exports the SELECT query results to a set of files in your storage account.

You can use CETAS to materialize frequently used parts of queries, like joined reference tables, to a new set of files. You can then join to this single external table instead of repeating common joins in multiple queries.

As CETAS generates Parquet files, statistics are automatically created when the first query targets this external table. The result is improved performance for subsequent queries targeting table generated with CETAS.

Review the troubleshooting article for solutions to common problems. If you're working with a dedicated SQL pool rather than serverless SQL pool, see Best practices for dedicated SQL pools for specific guidance.

Best practices for dedicated SQL pools in Azure Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

This article provides a collection of best practices to help you achieve optimal performance for dedicated SQL pools in Azure Synapse Analytics. If you're working with serverless SQL pool, see Best practices for serverless SQL pools for specific guidance. Below, you'll find basic guidance and important areas to focus on as you build your solution. Each section introduces you to a concept and then points you to more detailed articles that cover the concept in more depth.

Dedicated SQL pools loading

For dedicated SQL pools loading guidance, see Guidance for loading data.

Reduce cost with pause and scale

For more information about reducing costs through pausing and scaling, see Manage compute.

Maintain statistics

Dedicated SQL pool can be configured to automatically detect and create statistics on columns. The query plans created by the optimizer are only as good as the available statistics.

We recommend that you enable AUTO_CREATE_STATISTICS for your databases and keep the statistics updated daily or after each load to ensure that statistics on columns used in your queries are always up-to-date.

To shorten statistics maintenance time, be selective about which columns have statistics, or need the most frequent updating. For example, you might want to update date columns where new values may be added daily. Focus on having statistics for columns involved in joins, columns used in the WHERE clause, and columns found in GROUP BY.

Additional information on statistics can be found in the Manage table statistics, CREATE STATISTICS, and UPDATE STATISTICS articles.

Tune query performance

- Performance tuning with materialized views
- Performance tuning with ordered clustered columnstore index
- Performance tuning with result set caching

Group INSERT statements into batches

A one-time load to a small table with an INSERT statement such as `INSERT INTO MyLookup VALUES (1, 'Type 1')` may be the best approach depending on your needs. However, if you need to load thousands or millions of rows throughout the day, it's likely that singleton INSERTS aren't optimal.

One way to solve this issue is to develop one process that writes to a file, and then another process to periodically load this file. Refer to the INSERT article for more information.

Use PolyBase to load and export data quickly

Dedicated SQL pool supports loading and exporting data through several tools including Azure Data Factory, PolyBase, and BCP. For small amounts of data where performance isn't critical, any tool may be sufficient for your needs.

> **NOTE**
> PolyBase is the best choice when you are loading or exporting large volumes of data, or you need faster performance.

PolyBase loads can be run using CTAS or INSERT INTO. CTAS will minimize transaction logging and is the fastest way to load your data. Azure Data Factory also supports PolyBase loads and can achieve performance similar to CTAS. PolyBase supports various file formats including Gzip files.

To maximize throughput when using Gzip text files, break up files into 60 or more files to maximize parallelism of your load. For faster total throughput, consider loading data concurrently. Additional information relevant to this section is included in the following articles:

- Load data
- Guide for using PolyBase
- Dedicated SQL pool loading patterns and strategies
- Load Data with Azure Data Factory
- Move data with Azure Data Factory
- CREATE EXTERNAL FILE FORMAT
- Create table as select (CTAS)

Load then query external tables

PolyBase isn't optimal for queries. PolyBase tables for dedicated SQL pools currently only support Azure blob files and Azure Data Lake storage. These files don't have any compute resources backing them. As a result, dedicated SQL pools cannot offload this work and must read the entire file by loading it to `tempdb` so it can read the data.

If you have several queries for querying this data, it's better to load this data once and have queries use the local table. Further PolyBase guidance is included in the Guide for using PolyBase article.

Hash distribute large tables

By default, tables are Round Robin distributed. This default makes it easy for users to start creating tables without having to decide how their tables should be distributed. Round Robin tables may perform sufficiently for some workloads. But, in most cases, a distribution column provides better performance.

The most common example of a table distributed by a column outperforming a round robin table is when two large fact tables are joined.

For example, if you have an orders table distributed by order_id, and a transactions table also distributed by order_id, when you join your orders table to your transactions table on order_id, this query becomes a pass-through query. Data movement operations are then eliminated. Fewer steps mean a faster query. Less data movement also makes for faster queries.

> **TIP**
> When loading a distributed table, your incoming data shouldn't be sorted on the distribution key. Doing so will slow down your loads.

The article links provided below will give you additional details about improving performance via selecting a

distribution column. Also, you'll find information about how to define a distributed table in the WITH clause of your CREATE TABLE statement:

- Table overview
- Table distribution
- Selecting table distribution
- CREATE TABLE
- CREATE TABLE AS SELECT

Do not over-partition

While partitioning data can be effective for maintaining your data through partition switching or optimizing scans by with partition elimination, having too many partitions can slow down your queries. Often a high granularity partitioning strategy that may work well on SQL Server may not work well on dedicated SQL pool.

Having too many partitions can reduce the effectiveness of clustered columnstore indexes if each partition has fewer than 1 million rows. Dedicated SQL pools automatically partition your data into 60 databases. So, if you create a table with 100 partitions, the result will be 6000 partitions. Each workload is different, so the best advice is to experiment with partitioning to see what works best for your workload.

One option to consider is using a granularity that is lower than what you've implemented using SQL Server. For example, consider using weekly or monthly partitions instead of daily partitions.

More information about partitioning is detailed in the Table partitioning article.

Minimize transaction sizes

INSERT, UPDATE, and DELETE statements run in a transaction. When they fail, they must be rolled back. To reduce the potential for a long rollback, minimize transaction sizes whenever possible. Minimizing transaction sizes can be done by dividing INSERT, UPDATE, and DELETE statements into parts. For example, if you have an INSERT that you expect to take 1 hour, you can break up the INSERT into four parts. Each run will then be shortened to 15 minutes.

> **TIP**
> Leverage special Minimal Logging cases, like CTAS, TRUNCATE, DROP TABLE, or INSERT to empty tables to reduce rollback risk.

Another way to eliminate rollbacks is to use Metadata Only operations like partition switching for data management. For example, rather than execute a DELETE statement to delete all rows in a table where the order_date was in October of 2001, you could partition your data monthly. Then you can switch out the partition with data for an empty partition from another table (see ALTER TABLE examples).

For tables that are not partitioned, consider using a CTAS to write the data you want to keep in a table rather than using DELETE. If a CTAS takes the same amount of time, it's much safer to run since it has minimal transaction logging and can be canceled quickly if needed.

Further information on content related to this section is included in the articles below:

- Create table as select (CTAS)
- Understanding transactions
- Optimizing transactions
- Table partitioning
- TRUNCATE TABLE

- ALTER TABLE

Reduce query result sizes

Reducing query results sizes helps you avoid client-side issues caused by large query results. You can edit your query to reduce the number of rows returned. Some query generation tools allow you to add "top N" syntax to each query. You can also CETAS the query result to a temporary table and then use PolyBase export for the downlevel processing.

Use the smallest possible column size

When defining your DDL, use the smallest data type that will support your data as doing so will improve query performance. This recommendation is particularly important for CHAR and VARCHAR columns. If the longest value in a column is 25 characters, then define your column as VARCHAR(25). Avoid defining all character columns to a large default length. Additionally, define columns as VARCHAR when that is all that is needed rather than using NVARCHAR.

Please see the Table overview, Table data types, and CREATE TABLE articles for a more detailed review of essential concepts relevant to the above information.

Use temporary heap tables for transient data

When you're temporarily landing data on dedicated SQL pools, heap tables will generally make the overall process faster. If you're loading data only to stage it before running more transformations, loading the table to a heap table will be quicker than loading the data to a clustered columnstore table.

Loading data to a temp table will also load much faster than loading a table to permanent storage. Temporary tables start with a "#" and are only accessible by the session that created it. Consequently, they may only work in limited scenarios. Heap tables are defined in the WITH clause of a CREATE TABLE. If you do use a temporary table, remember to create statistics on that temporary table too.

For more information, see the Temporary tables, CREATE TABLE, and CREATE TABLE AS SELECT articles.

Optimize clustered columnstore tables

Clustered columnstore indexes are one of the most efficient ways you can store your data in dedicated SQL pool. By default, tables in dedicated SQL pool are created as Clustered ColumnStore. To get the best performance for queries on columnstore tables, having good segment quality is important. When rows are written to columnstore tables under memory pressure, columnstore segment quality may suffer.

Segment quality can be measured by the number of rows in a compressed Row Group. See the Causes of poor columnstore index quality in the Table indexes article for step-by-step instructions on detecting and improving segment quality for clustered columnstore tables.

Because high-quality columnstore segments are important, it's a good idea to use users IDs that are in the medium or large resource class for loading data. Using lower data warehouse units means you want to assign a larger resource class to your loading user.

Columnstore tables generally won't push data into a compressed columnstore segment until there are more than 1 million rows per table. Each dedicated SQL pool table is partitioned into 60 tables. As such, columnstore tables won't benefit a query unless the table has more than 60 million rows.

> **TIP**
> For tables with less than 60 million rows, having a columnstore index may not be the optimal solution.

If you partition your data, each partition will need to have 1 million rows to benefit from a clustered columnstore index. For a table with 100 partitions, it needs to have at least 6 billion rows to benefit from a clustered columns store (60 distributions *100 partitions* 1 million rows).

If your table doesn't have 6 billion rows, you have two main options. Either reduce the number of partitions or consider using a heap table instead. It also may be worth experimenting to see if better performance can be gained by using a heap table with secondary indexes rather than a columnstore table.

When querying a columnstore table, queries will run faster if you select only the columns you need. Further information on table and columnstore indexes and can be found in the articles below:

- Table indexes
- Columnstore indexes guide
- Rebuilding columnstore indexes
- Performance tuning with ordered clustered columnstore index

Use larger resource class to improve query performance

SQL pools use resource groups as a way to allocate memory to queries. Initially, all users are assigned to the small resource class, which grants 100 MB of memory per distribution. There are always 60 distributions. Each distribution is given a minimum of 100 MB. The total system-wide memory allocation is 6,000 MB, or just under 6 GB.

Certain queries, like large joins or loads to clustered columnstore tables, will benefit from larger memory allocations. Some queries, such as pure scans, will see no benefit. Utilizing larger resource classes impacts concurrency. So, you'll want to keep these facts in mind before moving all of your users to a large resource class.

For additional information on resource classes, refer to the Resource classes for workload management article.

Use smaller resource class to increase concurrency

If you notice a long delay in user queries, your users might be running in larger resource classes. This scenario promotes the consumption of concurrency slots, which can cause other queries to queue up. To determine if users queries are queued, run `SELECT * FROM sys.dm_pdw_waits` to see if any rows are returned.

The Resource classes for workload management and sys.dm_pdw_waits articles will provide you with more information.

Use DMVs to monitor and optimize your queries

Dedicated SQL pools have several DMVs that can be used to monitor query execution. The monitoring article below walks you through step-by-step instructions on how to view details of an executing query. To quickly find queries in these DMVs, using the LABEL option with your queries can help. For additional detailed information, please see the articles included in the list below:

- Monitor your workload using DMVs
- LABEL
- OPTION
- sys.dm_exec_sessions
- sys.dm_pdw_exec_requests
- sys.dm_pdw_request_steps
- sys.dm_pdw_sql_requests

- sys.dm_pdw_dms_workers
- DBCC PDW_SHOWEXECUTIONPLAN
- sys.dm_pdw_waits

Distribution Advisor in Azure Synapse SQL

8/19/2022 • 4 minutes to read • Edit Online

Applies to: Azure Synapse Analytics dedicated SQL pools (formerly SQL DW)

In Azure Synapse SQL, each table is distributed using the strategy chosen by the customer (Round Robin, Hash Distributed, Replicated). The chosen distribution strategy can affect query performance substantially.

The Distribution Advisor (DA) feature of Azure Synapse SQL analyzes customer queries and recommends the best distribution strategies for tables to improve query performance. Queries to be considered by the advisor can be provided by the customer or pulled from historic queries available in DMV.

> **NOTE**
> Distribution Advisor is currently in preview for Azure Synapse Analytics. Preview features are meant for testing only and should not be used on production instances or production data. As a preview feature, Distribution Advisor is subject to undergo changes in behavior or functionality. Please also keep a copy of your test data if the data is important. Distribution Advisor does not support Multi-Column distributed tables.

Prerequisites

- Execute the T-SQL statement `SELECT @@version` to ensure that your Azure Synapse Analytics dedicated SQL pool is version 10.0.15669 or higher. If your version is lower, a new version should automatically reach your provisioned dedicated SQL pools during their maintenance cycle.
- Ensure that statistics are available and up-to-date before running the advisor. For more details, Manage table statistics, CREATE STATISTICS, and UPDATE STATISTICS articles for more details on statistics.

Analyze workload and generate distribution recommendations

The follow tutorial explains the sample use case for using the Distribution Advisor feature to analyze customer queries and recommend the best distribution strategies.

Distribution Advisor only analyzes queries run on user tables.

1. Create Distribution Advisor stored procedures

To run the advisor easily, create two new stored procedures in the database. Run the CreateDistributionAdvisor_PublicPreview script available for download from GitHub:

COMMAND	DESCRIPTION
`dbo.write_dist_recommendation`	Defines queries that DA will analyze on. You can provide queries manually, or read from up to 100 past queries from the actual workloads in sys.dm_pdw_exec_requests.
`dbo.read_dist_recommendation`	Runs the advisor and generates recommendations.

Here is an example of how you could run the advisor.

2a. Run the advisor on past workload in DMV

Run the following commands to read up to the last 100 queries in the workload for analysis and distribution

recommendations:

```
EXEC dbo.write_dist_recommendation <Number of Queries max 100>, NULL
go
EXEC dbo.read_dist_recommendation;
go
```

To see which queries were analyzed by DA, run the e2e_queries_used_for_recommendations.sql script available for download from GitHub.

2b. Run the advisor on selected queries

The first parameter in `dbo.write_dist_recommendation` should be set to `0`, and the second parameter is a semi-colon separated list of up to 100 queries that DA will analyze. In the below example, we want to see the distribution recommendation for two statements separated by semicolons, `select count (*) from t1;` and `select * from t1 join t2 on t1.a1 = t2.a1;`.

```
EXEC dbo.write_dist_recommendation 0, 'select count (*) from t1; select * from t1 join t2 on t1.a1 = t2.a1;'
go
EXEC dbo.read_dist_recommendation;
go
```

3. View recommendations

The `dbo.read_dist_recommendation` system stored procedure will return recommendations in the following format when execution is completed:

COLUMN NAME	DESCRIPTION
Table_name	The table that DA analyzed. One line per table regardless of change in recommendation.
Current_Distribution	Current table distribution strategy.
Recommended_Distribution	Recommended distribution. This can be the same as `Current_Distribution` if there is no change recommended.
Distribution_Change_Command	A CTAS T-SQL command to implement the recommendation.

4. Implement the advice

- Run the CTAS command provided by Distribution Advisor to create new tables with the recommended distribution strategy.
- Modify queries to run on new tables.
- Execute queries on old and new tables to compare for performance improvements.

Troubleshooting

This section contains common troubleshooting scenarios and common mistakes that you may encounter.

1. Stale state from a previous run of the advisor

1a. Symptom:

You see this error message upon running the advisor:

```
Msg 110813, Level 16, State 1, Line 1
Calling GetLastScalarResult() before executing scalar subquery.
```

1b. Mitigation:

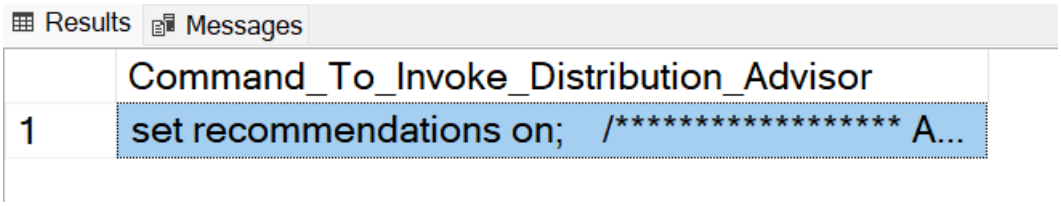
- Verify that you are using single quotes '' to run the advisor on select queries.
- Start a new session in SSMS and run the advisor.

2. Errors during running the advisor

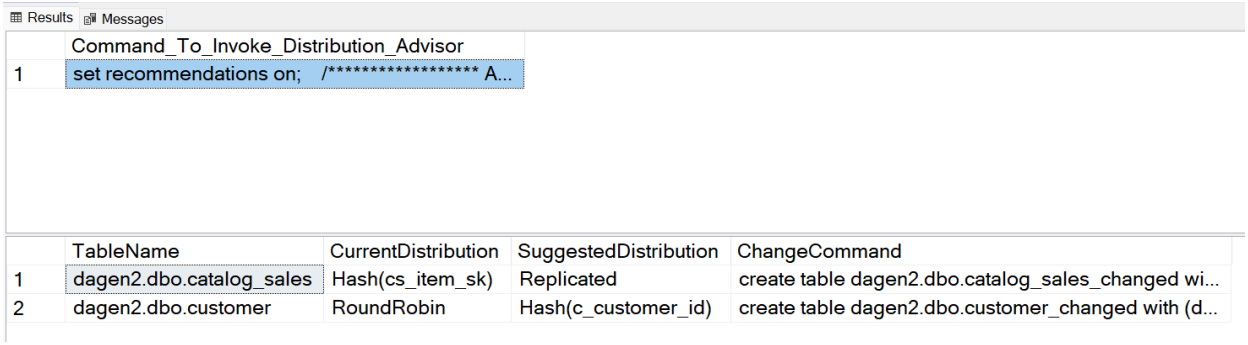
2a. Symptom:

The 'result' pane shows `CommandToInvokeAdvisorString` below but does not show the `RecommendationOutput` below.

For example, you see only the `Command_to_Invoke_Distribution_Advisor` resultset.



But not the second resultset containing the table change T-SQL commands:



2b. Mitigation:

- Check the output of `CommandToInvokeAdvisorString` above.
- Remove queries that may not be valid anymore which may have been added here from either the hand-selected queries or from the DMV by editing `WHERE` clause in: Queries Considered by DA.

3. Error during post-processing of recommendation output

3a. Symptom:

You see the following error message.

```
Invalid length parameter passed to the LEFT or SUBSTRING function.
```

3b. Mitigation:

Ensure that you have the most up to date version of the stored procedure from GitHub:

- e2e_queries_used_for_recommendations.sql script available for download from GitHub
- CreateDistributionAdvisor_PublicPreview.sql script available for download from GitHub

Performance tuning with materialized views using dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

In dedicated SQL pool, materialized views provide a low maintenance method for complex analytical queries to get fast performance without any query change. This article discusses the general guidance on using materialized views.

Materialized views vs. standard views

SQL pool supports both standard and materialized views. Both are virtual tables created with SELECT expressions and presented to queries as logical tables. Views reveal the complexity of common data computation and add an abstraction layer to computation changes so there's no need to rewrite queries.

A standard view computes its data each time when the view is used. There's no data stored on disk. People typically use standard views as a tool that helps organize the logical objects and queries in a database. To use a standard view, a query needs to make direct reference to it.

A materialized view pre-computes, stores, and maintains its data in dedicated SQL pool just like a table. Recomputation isn't needed each time a materialized view is used. That's why queries that use all or a subset of the data in materialized views can gain faster performance. Even better, queries can use a materialized view without making direct reference to it, so there's no need to change application code.

Most of the standard view requirements still apply to a materialized view. For details on the materialized view syntax and other requirements, refer to CREATE MATERIALIZED VIEW AS SELECT.

COMPARISON	VIEW	MATERIALIZED VIEW
View definition	Stored in Azure data warehouse.	Stored in Azure data warehouse.
View content	Generated each time when the view is used.	Pre-processed and stored in Azure data warehouse during view creation. Updated as data is added to the underlying tables.
Data refresh	Always updated	Always updated
Speed to retrieve view data from complex queries	Slow	Fast
Extra storage	No	Yes
Syntax	CREATE VIEW	CREATE MATERIALIZED VIEW AS SELECT

Benefits of materialized views

A properly designed materialized view provides the following benefits:

- Reduced execution time for complex queries with JOINs and aggregate functions. The more complex the query, the higher the potential for execution-time saving. The most benefit is gained when a query's

computation cost is high and the resulting data set is small.

- The query optimizer in dedicated SQL pool can automatically use deployed materialized views to improve query execution plans. This process is transparent to users providing faster query performance and doesn't require queries to make direct reference to the materialized views.
- Requires low maintenance on the views. A materialized view stores data in two places, a clustered columnstore index for the initial data at the view creation time, and a delta store for the incremental data changes. All data changes from the base tables are automatically added to the delta store in a synchronous manner. A background process (tuple mover) periodically moves the data from the delta store to the view's columnstore index. This design allows querying materialized views to return the same data as directly querying the base tables.
- The data in a materialized view can be distributed differently from the base tables.
- Data in materialized views gets the same high availability and resiliency benefits as data in regular tables.

As compared to other data warehouse providers, the materialized views implemented in dedicated SQL pool also provide the following additional benefits:

- Automatic and synchronous data refresh with data changes in base tables. No user action is required.
- Broad aggregate function support. See CREATE MATERIALIZED VIEW AS SELECT (Transact-SQL).
- The support for query-specific materialized view recommendation. See EXPLAIN (Transact-SQL).

Common scenarios

Materialized views are typically used in following scenarios:

Need to improve the performance of complex analytical queries against large data in size

Complex analytical queries typically use more aggregation functions and table joins, causing more compute-heavy operations such as shuffles and joins in query execution. That's why those queries take longer to complete, particularly on large tables.

Users can create materialized views for the data returned from the common computations of queries, so there's no recomputation required when this data is needed by queries, allowing lower compute cost and faster query response.

Need faster performance with no or minimum query changes

Schema and query changes in data warehouses are typically kept to a minimum to support regular ETL operations and reporting. People can use materialized views for query performance tuning if the cost incurred by the views can be offset by the gain in query performance.

In comparison to other tuning options, such as scaling and statistics management, it's a much less impactful production change to create and maintain a materialized view and its potential performance gain is also higher.

- Creating or maintaining materialized views does not impact the queries running against the base tables.
- The query optimizer can automatically use the deployed materialized views without direct view reference in a query. This capability reduces the need for query change in performance tuning.

Need different data distribution strategy for faster query performance

Azure data warehouse is a distributed and massively parallel processing (MPP) system.

Synapse SQL is a distributed query system that enables enterprises to implement data warehousing and data virtualization scenarios using standard T-SQL experiences familiar to data engineers. It also expands the capabilities of SQL to address streaming and machine learning scenarios. Data in a data warehouse table is distributed across 60 nodes using one of three distribution strategies (hash, round_robin, or replicated).

The data distribution is specified at the table creation time and remains unchanged until the table is dropped. Materialized view being a virtual table on disk supports hash and round_robin data distributions. Users can choose a data distribution that's different from the base tables but optimal for the performance of queries that frequently use the views.

Design guidance

Here is the general guidance on using materialized views to improve query performance:

Design for your workload

Before you begin to create materialized views, it's important to have a deep understanding of your workload in terms of query patterns, importance, frequency, and the size of resulting data.

Users can run EXPLAIN WITH_RECOMMENDATIONS <SQL_statement> for the materialized views recommended by the query optimizer. Since these recommendations are query-specific, a materialized view that benefits a single query may not be optimal for other queries in the same workload.

Evaluate these recommendations with your workload needs in mind. The ideal materialized views are those that benefit the workload's performance.

Be aware of the tradeoff between faster queries and the cost

For each materialized view, there's a data storage cost and a cost for maintaining the view. As data changes in the base tables, the size of the materialized view increases and its physical structure also changes.

To avoid query performance degradation, each materialized view is maintained separately by the data warehouse engine, including moving rows from delta store to the columnstore index segments and consolidating data changes.

The maintenance workload climbs higher when the number of materialized views and base table changes increase. Users should check if the cost incurred from all materialized views can be offset by the query performance gain.

You can run this query for the list of materialized view in a database:

```
SELECT V.name as materialized_view, V.object_id
FROM sys.views V
JOIN sys.indexes I ON V.object_id= I.object_id AND I.index_id < 2;
```

Options to reduce the number of materialized views:

- Identify common data sets frequently used by the complex queries in your workload. Create materialized views to store those data sets so the optimizer can use them as building blocks when creating execution plans.
- Drop the materialized views that have low usage or are no longer needed. A disabled materialized view is not maintained but it still incurs storage cost.
- Combine materialized views created on the same or similar base tables even if their data doesn't overlap. Combining materialized views could result in a larger view in size than the sum of the separate views, however the view maintenance cost should reduce. For example:

```
-- Query 1 would benefit from having a materialized view created with this SELECT statement
SELECT A, SUM(B)
FROM T
GROUP BY A

-- Query 2 would benefit from having a materialized view created with this SELECT statement
SELECT C, SUM(D)
FROM T
GROUP BY C

-- You could create a single mateiralized view of this form
SELECT A, C, SUM(B), SUM(D)
FROM T
GROUP BY A, C
```

Not all performance tuning requires query change

The data warehouse optimizer can automatically use deployed materialized views to improve query performance. This support is applied transparently to queries that don't reference the views and to queries that use aggregates unsupported in materialized views creation. No query change is needed. You can check a query's estimated execution plan to confirm if a materialized view is used.

Monitor materialized views

A materialized view is stored in the data warehouse just like a table with clustered columnstore index (CCI). Reading data from a materialized view includes scanning the index and applying changes from the delta store. When the number of rows in the delta store is too high, resolving a query from a materialized view can take longer than directly querying the base tables.

To avoid query performance degradation, it's a good practice to run DBCC PDW_SHOWMATERIALIZEDVIEWOVERHEAD to monitor the view's overhead_ratio (total_rows / base_view_row). If the overhead_ratio is too high, consider rebuilding the materialized view so all rows in the delta store are moved to the columnstore index.

Materialized view and result set caching

These two features are introduced in dedicated SQL pool around the same time for query performance tuning. Result set caching is used for achieving high concurrency and fast response times from repetitive queries against static data.

To use the cached result, the form of the cache requesting query must match with the query that produced the cache. Additionally, the cached result must apply to the entire query.

Materialized views allow data changes in the base tables. Data in materialized views can be applied to a piece of a query. This support allows the same materialized views to be used by different queries that share some computation for faster performance.

Example

This example uses a TPCDS-like query that finds customers who spend more money via catalog than in stores. It also identifies the preferred customers and their country/region of origin. The query involves selecting TOP 100 records from the UNION of three sub-SELECT statements involving SUM() and GROUP BY.

```
WITH year_total AS (
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
```

```
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(ss_ext_list_price-ss_ext_wholesale_cost-ss_ext_discount_amt+ss_ext_sales_price, 0)/2)
year_total
       ,'s' sale_type
FROM customer
     ,store_sales
     ,date_dim
WHERE c_customer_sk = ss_customer_sk
   AND ss_sold_date_sk = d_date_sk
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
         ,d_year
UNION ALL
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(cs_ext_list_price-cs_ext_wholesale_cost-cs_ext_discount_amt+cs_ext_sales_price, 0)/2)
year_total
       ,'c' sale_type
FROM customer
     ,catalog_sales
     ,date_dim
WHERE c_customer_sk = cs_bill_customer_sk
   AND cs_sold_date_sk = d_date_sk
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
         ,d_year
UNION ALL
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(ws_ext_list_price-ws_ext_wholesale_cost-ws_ext_discount_amt+ws_ext_sales_price, 0)/2)
year_total
       ,'w' sale_type
FROM customer
     ,web_sales
     ,date_dim
WHERE c_customer_sk = ws_bill_customer_sk
   AND ws_sold_date_sk = d_date_sk
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
```

```
         ,d_year
         )
  SELECT TOP 100
                  t_s_secyear.customer_id
                 ,t_s_secyear.customer_first_name
                 ,t_s_secyear.customer_last_name
                 ,t_s_secyear.customer_birth_country
FROM year_total t_s_firstyear
     ,year_total t_s_secyear
     ,year_total t_c_firstyear
     ,year_total t_c_secyear
     ,year_total t_w_firstyear
     ,year_total t_w_secyear
WHERE t_s_secyear.customer_id = t_s_firstyear.customer_id
   AND t_s_firstyear.customer_id = t_c_secyear.customer_id
   AND t_s_firstyear.customer_id = t_c_firstyear.customer_id
   AND t_s_firstyear.customer_id = t_w_firstyear.customer_id
   AND t_s_firstyear.customer_id = t_w_secyear.customer_id
   AND t_s_firstyear.sale_type = 's'
   AND t_c_firstyear.sale_type = 'c'
   AND t_w_firstyear.sale_type = 'w'
   AND t_s_secyear.sale_type = 's'
   AND t_c_secyear.sale_type = 'c'
   AND t_w_secyear.sale_type = 'w'
   AND t_s_firstyear.dyear+0 =  1999
   AND t_s_secyear.dyear+0 = 1999+1
   AND t_c_firstyear.dyear+0 =  1999
   AND t_c_secyear.dyear+0 =  1999+1
   AND t_w_firstyear.dyear+0 = 1999
   AND t_w_secyear.dyear+0 = 1999+1
   AND t_s_firstyear.year_total > 0
   AND t_c_firstyear.year_total > 0
   AND t_w_firstyear.year_total > 0
   AND CASE WHEN t_c_firstyear.year_total > 0 THEN t_c_secyear.year_total / t_c_firstyear.year_total ELSE
NULL END
           > CASE WHEN t_s_firstyear.year_total > 0 THEN t_s_secyear.year_total / t_s_firstyear.year_total
ELSE NULL END
   AND CASE WHEN t_c_firstyear.year_total > 0 THEN t_c_secyear.year_total / t_c_firstyear.year_total ELSE
NULL END
           > CASE WHEN t_w_firstyear.year_total > 0 THEN t_w_secyear.year_total / t_w_firstyear.year_total
ELSE NULL END
ORDER BY t_s_secyear.customer_id
         ,t_s_secyear.customer_first_name
         ,t_s_secyear.customer_last_name
         ,t_s_secyear.customer_birth_country
OPTION ( LABEL = 'Query04-af359846-253-3');
```

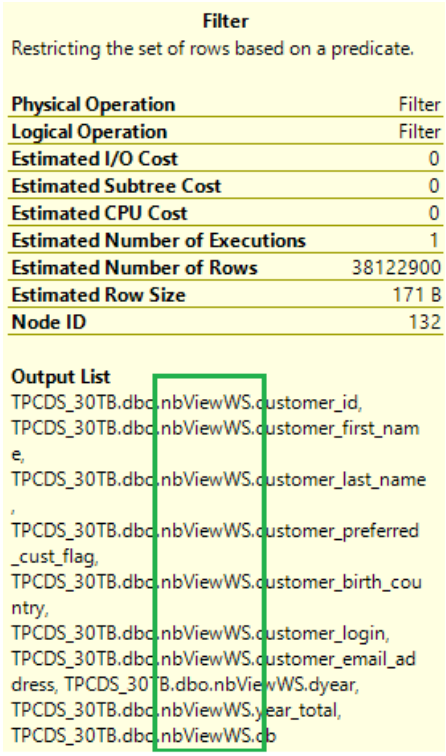
Check the query's estimated execution plan. There are 18 shuffles and 17 joins operations, which take more time to execute. Now let's create one materialized view for each of the three sub-SELECT statements.

```
CREATE materialized view nbViewSS WITH (DISTRIBUTION=HASH(customer_id)) AS
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(ss_ext_list_price-ss_ext_wholesale_cost-ss_ext_discount_amt+ss_ext_sales_price, 0)/2)
year_total
          , count_big(*) AS cb
FROM dbo.customer
     ,dbo.store_sales
     ,dbo.date_dim
WHERE c_customer_sk = ss_customer_sk
   AND ss_sold_date_sk = d_date_sk
```

```
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
         ,d_year
GO
CREATE materialized view nbViewCS WITH (DISTRIBUTION=HASH(customer_id)) AS
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(cs_ext_list_price-cs_ext_wholesale_cost-cs_ext_discount_amt+cs_ext_sales_price, 0)/2)
year_total
          , count_big(*) as cb
FROM dbo.customer
     ,dbo.catalog_sales
     ,dbo.date_dim
WHERE c_customer_sk = cs_bill_customer_sk
   AND cs_sold_date_sk = d_date_sk
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
         ,d_year

GO
CREATE materialized view nbViewWS WITH (DISTRIBUTION=HASH(customer_id)) AS
SELECT c_customer_id customer_id
       ,c_first_name customer_first_name
       ,c_last_name customer_last_name
       ,c_preferred_cust_flag customer_preferred_cust_flag
       ,c_birth_country customer_birth_country
       ,c_login customer_login
       ,c_email_address customer_email_address
       ,d_year dyear
       ,sum(isnull(ws_ext_list_price-ws_ext_wholesale_cost-ws_ext_discount_amt+ws_ext_sales_price, 0)/2)
year_total
          , count_big(*) AS cb
FROM dbo.customer
     ,dbo.web_sales
     ,dbo.date_dim
WHERE c_customer_sk = ws_bill_customer_sk
   AND ws_sold_date_sk = d_date_sk
GROUP BY c_customer_id
         ,c_first_name
         ,c_last_name
         ,c_preferred_cust_flag
         ,c_birth_country
         ,c_login
         ,c_email_address
         ,d_year
```

Check the execution plan of the original query again. Now the number of joins changes from 17 to 5 and there's no shuffle anymore. Select the Filter operation icon in the plan. Its Output List shows the data is read from the materialized views instead of base tables.



With materialized views, the same query runs much faster without any code change.

Performance tuning with ordered clustered columnstore index

8/19/2022 • 7 minutes to read • Edit Online

Applies to: Azure Synapse Analytics dedicated SQL pools, SQL Server 2022 (16.x) and later

When users query a columnstore table in dedicated SQL pool, the optimizer checks the minimum and maximum values stored in each segment. Segments that are outside the bounds of the query predicate aren't read from disk to memory. A query can finish faster if the number of segments to read and their total size are small.

Ordered vs. non-ordered clustered columnstore index

By default, for each table created without an index option, an internal component (index builder) creates a non-ordered clustered columnstore index (CCI) on it. Data in each column is compressed into a separate CCI rowgroup segment. There's metadata on each segment's value range, so segments that are outside the bounds of the query predicate aren't read from disk during query execution. CCI offers the highest level of data compression and reduces the size of segments to read so queries can run faster. However, because the index builder doesn't sort data before compressing them into segments, segments with overlapping value ranges could occur, causing queries to read more segments from disk and take longer to finish.

When creating an ordered CCI, the dedicated SQL pool engine sorts the existing data in memory by the order key(s) before the index builder compresses them into index segments. With sorted data, segment overlapping is reduced allowing queries to have a more efficient segment elimination and thus faster performance because the number of segments to read from disk is smaller. If all data can be sorted in memory at once, then segment overlapping can be avoided. Due to large tables in data warehouses, this scenario doesn't happen often.

To check the segment ranges for a column, run the following command with your table name and column name:

```
SELECT o.name, pnp.index_id,
cls.row_count, pnp.data_compression_desc,
pnp.pdw_node_id, pnp.distribution_id, cls.segment_id,
cls.column_id,
cls.min_data_id, cls.max_data_id,
cls.max_data_id-cls.min_data_id as difference
FROM sys.pdw_nodes_partitions AS pnp
   JOIN sys.pdw_nodes_tables AS Ntables ON pnp.object_id = NTables.object_id AND pnp.pdw_node_id =
NTables.pdw_node_id
   JOIN sys.pdw_table_mappings AS Tmap  ON NTables.name = TMap.physical_name AND
substring(TMap.physical_name,40, 10) = pnp.distribution_id
   JOIN sys.objects AS o ON TMap.object_id = o.object_id
   JOIN sys.pdw_nodes_column_store_segments AS cls ON pnp.partition_id = cls.partition_id AND
pnp.distribution_id  = cls.distribution_id
JOIN sys.columns as cols ON o.object_id = cols.object_id AND cls.column_id = cols.column_id
WHERE o.name = '<Table Name>' and cols.name = '<Column Name>'  and TMap.physical_name  not like '%HdTable%'
ORDER BY o.name, pnp.distribution_id, cls.min_data_id;
```

> **NOTE**
> In an ordered CCI table, the new data resulting from the same batch of DML or data loading operations are sorted within that batch, there is no global sorting across all data in the table. Users can REBUILD the ordered CCI to sort all data in the table. In dedicated SQL pool, the columnstore index REBUILD is an offline operation. For a partitioned table, the REBUILD is done one partition at a time. Data in the partition that is being rebuilt is "offline" and unavailable until the REBUILD is complete for that partition.

Query performance

A query's performance gain from an ordered CCI depends on the query patterns, the size of data, how well the data is sorted, the physical structure of segments, and the DWU and resource class chosen for the query execution. Users should review all these factors before choosing the ordering columns when designing an ordered CCI table.

Queries with all these patterns typically run faster with ordered CCI.

1. The queries have equality, inequality, or range predicates
2. The predicate columns and the ordered CCI columns are the same.

In this example, table T1 has a clustered columnstore index ordered in the sequence of Col_C, Col_B, and Col_A.

```
CREATE CLUSTERED COLUMNSTORE INDEX MyOrderedCCI ON  T1
ORDER (Col_C, Col_B, Col_A);
```

The performance of query 1 and query 2 can benefit most from ordered CCI than the other queries as they reference all the ordered CCI columns.

```
-- Query #1:

SELECT * FROM T1 WHERE Col_C = 'c' AND Col_B = 'b' AND Col_A = 'a';

-- Query #2

SELECT * FROM T1 WHERE Col_B = 'b' AND Col_C = 'c' AND Col_A = 'a';

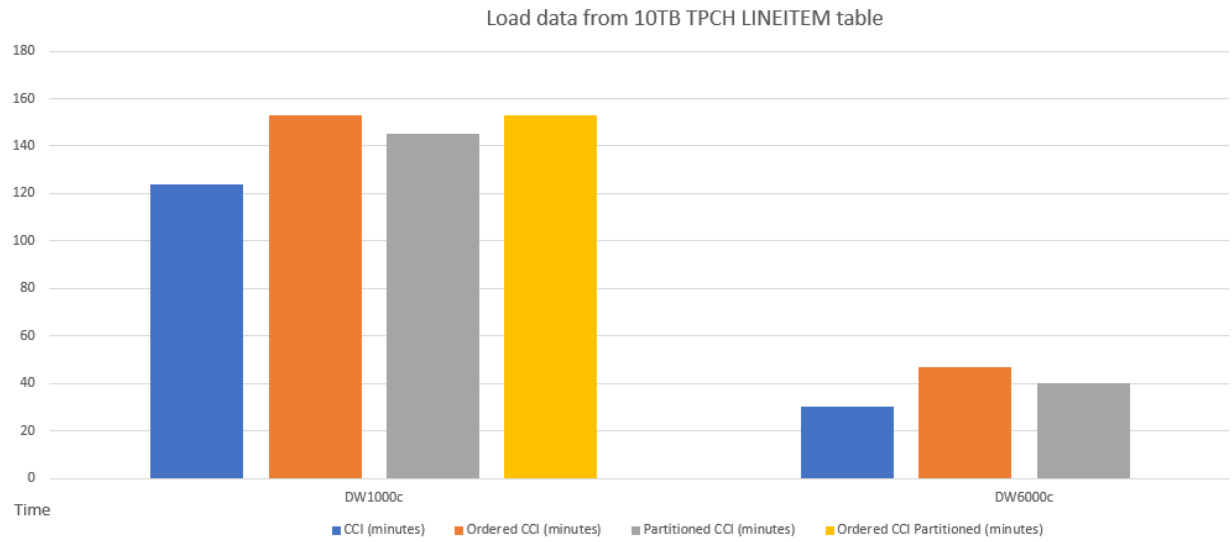
-- Query #3
SELECT * FROM T1 WHERE Col_B = 'b' AND Col_A = 'a';

-- Query #4
SELECT * FROM T1 WHERE Col_A = 'a' AND Col_C = 'c';
```

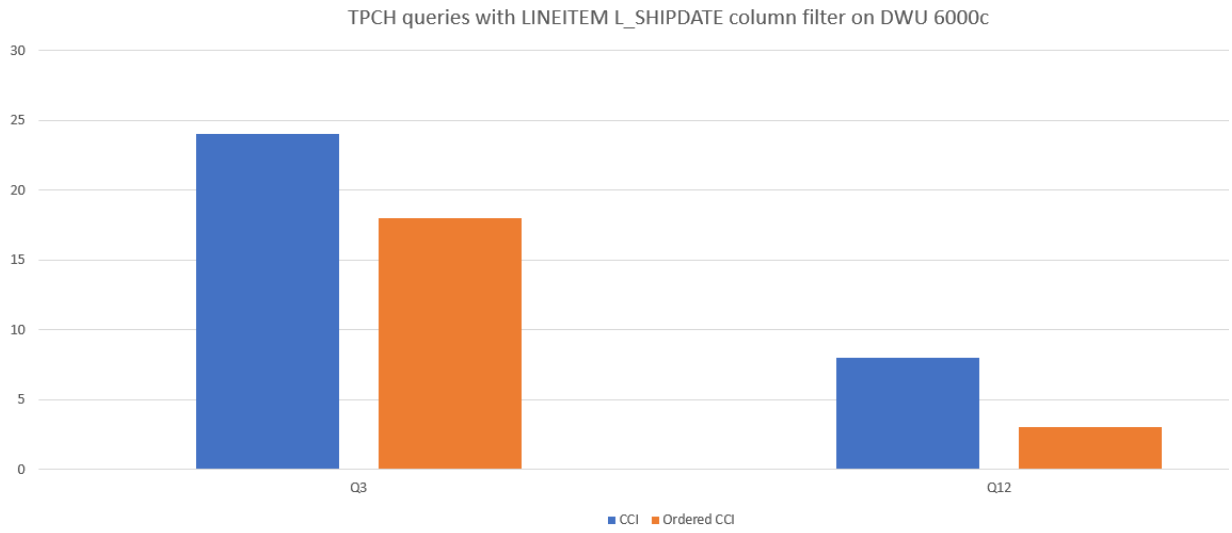
Data loading performance

The performance of data loading into an ordered CCI table is similar to a partitioned table. Loading data into an ordered CCI table can take longer than a non-ordered CCI table because of the data sorting operation, however queries can run faster afterwards with ordered CCI.

Here is an example performance comparison of loading data into tables with different schemas.



Here is an example query performance comparison between CCI and ordered CCI.



Reduce segment overlapping

The number of overlapping segments depends on the size of data to sort, the available memory, and the maximum degree of parallelism (MAXDOP) setting during ordered CCI creation. Below are options to reduce segment overlapping when creating ordered CCI.

- Use `xlargerc` resource class on a higher DWU to allow more memory for data sorting before the index builder compresses the data into segments. Once in an index segment, the physical location of the data cannot be changed. There's no data sorting within a segment or across segments.
- Create ordered CCI with `OPTION (MAXDOP = 1)`. Each thread used for ordered CCI creation works on a subset of data and sorts it locally. There's no global sorting across data sorted by different threads. Using parallel threads can reduce the time to create an ordered CCI but will generate more overlapping segments than using a single thread. Currently, the MAXDOP option is only supported in creating an ordered CCI table using CREATE TABLE AS SELECT command. Creating an ordered CCI via CREATE INDEX or CREATE TABLE commands does not support the MAXDOP option. For example:

```
CREATE TABLE Table1 WITH (DISTRIBUTION = HASH(c1), CLUSTERED COLUMNSTORE INDEX ORDER(c1) )
AS SELECT * FROM ExampleTable
OPTION (MAXDOP 1);
```

- Pre-sort the data by the sort key(s) before loading them into tables.

Here is an example of an ordered CCI table distribution that has zero segment overlapping following above recommendations. The ordered CCI table is created in a DWU1000c database via CTAS from a 20-GB heap table using MAXDOP 1 and `xlargerc`. The CCI is ordered on a BIGINT column with no duplicates.

Distribution_id	Segment_id	Min_data_id	Max_data_id	Min_Max_Difference	Row_count
1	0	10241	57382203	57371962	1048576
1	1	57382204	118528606	61146402	1048576
1	2	118528607	177460494	58931887	1048576
1	3	177460495	243567533	66107038	1048576
1	4	243567534	306639061	63071527	1048576
1	5	306639062	368575285	61936223	1048576
1	6	368575286	430037457	61462171	1048576
1	7	430037458	499756489	69719031	1048576
1	8	499756490	560819016	61062526	1048576
1	9	560819017	629362726	68543709	1048576
1	10	629362727	693056367	63693640	1048576
1	11	693056368	755671165	62614797	1048576
1	12	755671166	818307227	62636061	1048576
1	13	818307228	880813709	62506481	1048576
1	14	880813710	941012631	60198921	1048576
1	15	941012632	1009551689	68539057	1048576
1	16	1009551690	1048530944	38979254	704512

Create ordered CCI on large tables

Creating an ordered CCI is an offline operation. For tables with no partitions, the data won't be accessible to users until the ordered CCI creation process completes. For partitioned tables, since the engine creates the ordered CCI partition by partition, users can still access the data in partitions where ordered CCI creation isn't in process. You can use this option to minimize the downtime during ordered CCI creation on large tables:

1. Create partitions on the target large table (called `Table_A`).
2. Create an empty ordered CCI table (called `Table_B`) with the same table and partition schema as `Table_A`.
3. Switch one partition from `Table_A` to `Table_B`.
4. Run `ALTER INDEX <Ordered_CCI_Index> ON <Table_B> REBUILD PARTITION = <Partition_ID>` to rebuild the switched-in partition on `Table_B`.
5. Repeat step 3 and 4 for each partition in `Table_A`.
6. Once all partitions are switched from `Table_A` to `Table_B` and have been rebuilt, drop `Table_A`, and rename `Table_B` to `Table_A`.

> **TIP**
>
> For a dedicated SQL pool table with an ordered CCI, ALTER INDEX REBUILD will re-sort the data using `tempdb`. Monitor `tempdb` during rebuild operations. If you need more `tempdb` space, scale up the pool. Scale back down once the index rebuild is complete.
>
> For a dedicated SQL pool table with an ordered CCI, ALTER INDEX REORGANIZE does not re-sort the data. To resort data, use ALTER INDEX REBUILD.
>
> For more information on ordered CCI maintenance, see Optimizing clustered columnstore indexes.

Feature differences in SQL Server 2022 capabilities

SQL Server 2022 (16.x) introduced ordered clustered columnstore indexes similar to the feature in Azure Synapse dedicated SQL pools.

- Currently, only SQL Server 2022 (16.x) and later support clustered columnstore enhanced rowgroup elimination capabilities for string, binary, and guid data types, and the datetimeoffset data type for scale greater than two.
- Currently, only SQL Server 2022 (16.x) supports clustered columnstore rowgroup elimination for the prefix

of `LIKE` predicates.

For more information, see What's New in Columnstore Indexes.

Examples

A. To check for ordered columns and order ordinal:

```
SELECT object_name(c.object_id) table_name, c.name column_name, i.column_store_order_ordinal
FROM sys.index_columns i
JOIN sys.columns c ON i.object_id = c.object_id AND c.column_id = i.column_id
WHERE column_store_order_ordinal <>0;
```

B. To change column ordinal, add or remove columns from the order list, or to change from CCI to ordered CCI:

```
CREATE CLUSTERED COLUMNSTORE INDEX InternetSales ON dbo.InternetSales
ORDER (ProductKey, SalesAmount)
WITH (DROP_EXISTING = ON);
```

Performance tuning with result set caching

8/19/2022 • 3 minutes to read • Edit Online

When result set caching is enabled, dedicated SQL pool automatically caches query results in the user database for repetitive use. This allows subsequent query executions to get results directly from the persisted cache so recomputation is not needed. Result set caching improves query performance and reduces compute resource usage. In addition, queries using cached results set do not use any concurrency slots and thus do not count against existing concurrency limits. For security, users can only access the cached results if they have the same data access permissions as the users creating the cached results. Result set caching is OFF by default at the database and session levels.

> **NOTE**
> Result set caching should not be used in conjunction with DECRYPTBYKEY. If this cryptographic function must be used, ensure you have result set caching disabled (either at session-level or database-level) at the time of execution.

Key commands

Turn ON/OFF result set caching for a user database

Turn ON/OFF result set caching for a session

Check the size of cached result set

Clean up the cache

What's not cached

Once result set caching is turned ON for a database, results are cached for all queries until the cache is full, except for these queries:

- Queries with built-in functions or runtime expressions that are non-deterministic even when there's no change in base tables' data or query. For example, DateTime.Now(), GetDate().
- Queries using user defined functions
- Queries using tables with row level security or column level security enabled
- Queries returning data with row size larger than 64KB
- Queries returning large data in size (>10GB)

> **NOTE**
> - Some non-deterministic functions and runtime expressions can be deterministic to repetitive queries against the same data. For example, ROW_NUMBER().
> - Use ORDER BY in your query if the order/sequence of rows in the query result set is important to your application logic.
> - If data in the ORDER BY columns are not unique, there's no guaranteed row order for rows with the same values in the ORDER BY columns, regardless if result set caching is enabled or disabled.

> **IMPORTANT**
> The operations to create result set cache and retrieve data from the cache happen on the control node of a dedicated SQL pool instance. When result set caching is turned ON, running queries that return large result set (for example, >1GB) can cause high throttling on the control node and slow down the overall query response on the instance. Those queries are commonly used during data exploration or ETL operations. To avoid stressing the control node and cause performance issue, users should turn OFF result set caching on the database before running those types of queries.

Run this query for the time taken by result set caching operations for a query:

```
SELECT step_index, operation_type, location_type, status, total_elapsed_time, command
FROM sys.dm_pdw_request_steps
WHERE request_id  = <'request_id'>;
```

Here is an example output for a query executed with result set caching disabled.

	step_index	operation_type	location_type	status	total_elapsed_time	command
1	0	ReturnOperation	Compute	Complete	143	SELECT [T1_1].[C1] AS [C1] FROM (SELECT TOP (CAST ((200) AS BIGINT)) [T2_1].[C1] AS [C1] FROM [XL-DWDemo].[dbo].[SampleDataTable] AS T2_1) AS T1_1 OPTION (MAXDOP 2)

Here is an example output for a query executed with result set caching enabled.

	step_index	operation_type	location_type	status	total_elapsed_time	command
1	0	OnOperation	Control	Complete	15	CREATE TABLE [tempdb].[QTables].[QTable_502ba3603e54461f9779f9d635c81b7f] ([C1] BIGINT NOT NULL) WITH(DISTRIBUTED_MOVE_FILE='');
2	1	PartitionMoveOperation	Compute	Complete	156	SELECT [T1_1].[C1] AS [C1] FROM (SELECT TOP (CAST ((200) AS BIGINT)) [T2_1].[C1] AS [C1] FROM [XL-DWDemo].[dbo].[SampleDataTable] AS T2_1) AS T1_1 OPTION (MAXDOP 2, MIN_GRANT_PERCENT = 25, DISTRIBUTED_MOVE(N''))
3	2	PartitionMoveOperation	Control	Complete	109	SELECT TOP (200) [T1_1].[C1] AS [C1] FROM [tempdb].[QTables].[QTable_502ba3603e54461f9779f9d635c81b7f] AS T1_1 OPTION (MIN_GRANT_PERCENT = 25, DISTRIBUTED_MOVE(N''))
4	3	ReturnOperation	Control	Complete	125	select * from [DWResultCacheDb].[dbo].[x_{00F969EF-5EA7-4D30-BF6D-CCEF6A59B1BF}] OPTION(MAXDOP 1, MIN_GRANT_PERCENT = 25)
5	4	OnOperation	Control	Complete	15	DROP TABLE [tempdb].[QTables].[QTable_502ba3603e54461f9779f9d635c81b7f]

When cached results are used

Cached result set is reused for a query if all of the following requirements are all met:

- The user who's running the query has access to all the tables referenced in the query.
- There is an exact match between the new query and the previous query that generated the result set cache.
- There is no data or schema changes in the tables where the cached result set was generated from.

Run this command to check if a query was executed with a result cache hit or miss. The result_cache_hit column returns 1 for cache hit, 0 for cache miss, and negative values for reasons why result set caching was not used. Check sys.dm_pdw_exec_requests for details.

```
SELECT request_id, command, result_cache_hit FROM sys.dm_pdw_exec_requests
WHERE request_id = <'Your_Query_Request_ID'>
```

Manage cached results

The maximum size of result set cache is 1 TB per database. The cached results are automatically invalidated when the underlying query data change.

The cache eviction is managed by dedicated SQL pool automatically following this schedule:

- Every 48 hours if the result set hasn't been used or has been invalidated.
- When the result set cache approaches the maximum size.

Users can manually empty the entire result set cache by using one of these options:

- Turn OFF the result set cache feature for the database
- Run DBCC DROPRESULTSETCACHE while connected to the database

Pausing a database won't empty cached result set.

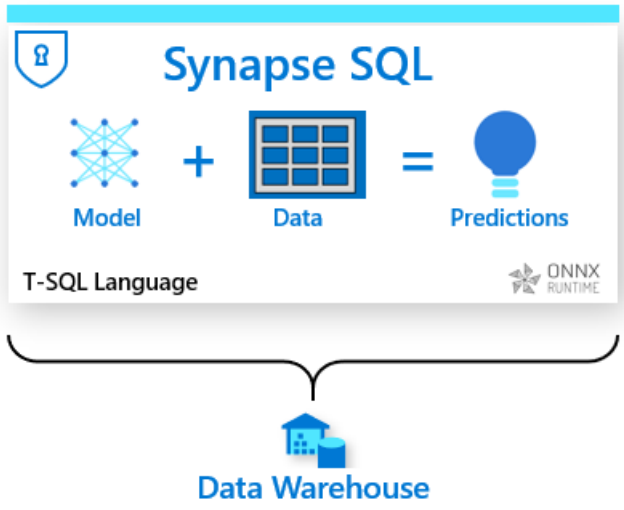
Score machine learning models with PREDICT

8/19/2022 • 3 minutes to read • Edit Online

Dedicated SQL pool provides you the capability to score machine learning models using the familiar T-SQL language. With T-SQL PREDICT, you can bring your existing machine learning models trained with historical data and score them within the secure boundaries of your data warehouse. PREDICT function takes an ONNX (Open Neural Network Exchange) model and data as inputs. This feature eliminates the step of moving valuable data outside the data warehouse for scoring. It aims to empower data professionals to easily deploy machine learning models with the familiar T-SQL interface as well as collaborate seamlessly with data scientists working with the right framework for their task.

> **NOTE**
> This functionality is currently not supported in serverless SQL pool.

The functionality requires that the model is trained outside of Synapse SQL. After building the model, load it into the data warehouse and score it with the T-SQL Predict syntax to get insights from the data.



Training the Model

Dedicated SQL pool expects a pre-trained model. Keep the following factors in mind when training a machine learning model that is used for performing predictions in dedicated SQL pool.

- Dedicated SQL pool only supports ONNX format models. ONNX is an open-source model format that allows you to exchange models between various frameworks to enable interoperability. You can convert your existing models to ONNX format using frameworks that either support it natively or have converting packages available. For example, sklearn-onnx package convert scikit-learn models to ONNX. ONNX GitHub repository provides a list of supported frameworks and examples.

  If you are using Automated ML for training, make sure to set the *enable_onnx_compatible_models* parameter to TRUE to produce an ONNX format model. Automated Machine Learning Notebook shows an example of how to use automated ML to create a machine learning model of ONNX format.

- The following data types are supported for the input data:

    - int, bigint, real, float
    - char, varchar, nvarchar
- The scoring data needs to be in the same format as the training data. Complex data types such as multi-dimensional arrays are not supported by PREDICT. So, for training make sure that each input of the model corresponds to a single column of the scoring table instead of passing a single array containing all inputs.
- Make sure that the names and data types of the model inputs match the column names and data types of the new prediction data. Visualizing an ONNX model using various open-source tools available online can further help with debugging.

Loading the model

The model is stored in a dedicated SQL pool user table as a hexadecimal string. Additional columns such as ID and description may be added in the model table to identify the model. Use varbinary(max) as the data type of the model column. Here is a code example for a table that can be used for storing models:

```
-- Sample table schema for storing a model and related data
CREATE TABLE [dbo].[Models]
(
    [Id] [int] IDENTITY(1,1) NOT NULL,
    [Model] [varbinary](max) NULL,
    [Description] [varchar](200) NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    HEAP
)
GO
```

Once the model is converted to a hexadecimal string and the table definition specified, use the COPY command or Polybase to load the model in the dedicated SQL pool table. The following code sample uses the Copy command to load the model.

```
-- Copy command to load hexadecimal string of the model from Azure Data Lake storage location
COPY INTO [Models] (Model)
FROM '<enter your storage location>'
WITH (
    FILE_TYPE = 'CSV',
    CREDENTIAL=(IDENTITY= 'Shared Access Signature', SECRET='<enter your storage key here>')
)
```

Scoring the model

Once the model and data are loaded in the data warehouse, use the **T-SQL PREDICT** function to score the model. Make sure that the new input data is in the same format as the training data used for building the model. T-SQL PREDICT takes two inputs: model and new scoring input data, and generates new columns for the output.The model can be specified as a variable, a literal or a scalar sub_query. Use WITH common_table_expression to specify a named result set for the data parameter.

The example below shows a sample query using prediction function. An additional column with name *Score* and data type *float* is created containing the prediction results. All the input data columns as well as output prediction columns are available to display with the select statement. For more details, see PREDICT (Transact-SQL).

```
-- Query for ML predictions
SELECT d.*, p.Score
FROM PREDICT(MODEL = (SELECT Model FROM Models WHERE Id = 1),
DATA = dbo.mytable AS d, RUNTIME = ONNX) WITH (Score float) AS p;
```

Next steps

To learn more about the PREDICT function, see PREDICT (Transact-SQL).

Design tables using Synapse SQL in Azure Synapse Analytics

8/19/2022 • 12 minutes to read • Edit Online

This document includes key concepts for designing tables with dedicated SQL pool and serverless SQL pool.

Serverless SQL pool is a query service over the data in your data lake. It doesn't have local storage for data ingestion. Dedicated SQL pool represents a collection of analytic resources that are being provisioned when using Synapse SQL. The size of a dedicated SQL pool is determined by Data Warehousing Units (DWU).

The following table lists the topics that are relevant to dedicated SQL pool vs. serverless SQL pool:

TOPIC	DEDICATED SQL POOL	SERVERLESS SQL POOL
Determine table category	Yes	No
Schema names	Yes	Yes
Table names	Yes	No
Table persistence	Yes	No
Regular table	Yes	No
Temporary table	Yes	Yes
External table	Yes	Yes
Data types	Yes	Yes
Distributed tables	Yes	No
Hash-distributed tables	Yes	No
Replicated tables	Yes	No
Round-robin tables	Yes	No
Common distribution methods for tables	Yes	No
Partitions	Yes	Yes
Columnstore indexes	Yes	No
Statistics	Yes	Yes
Primary key and unique key	Yes	No

TOPIC	DEDICATED SQL POOL	SERVERLESS SQL POOL
Commands for creating tables	Yes	No
Aligning source data with the data warehouse	Yes	No
Unsupported table features	Yes	No
Table size queries	Yes	No

Determine table category

A star schema organizes data into fact and dimension tables. Some tables are used for integration or staging data before moving to a fact or dimension table. As you design a table, decide whether the table data belongs in a fact, dimension, or integration table. This decision informs the appropriate table structure and distribution.

- **Fact tables** contain quantitative data that are commonly generated in a transactional system, and then loaded into the data warehouse. For example, a retail business generates sales transactions every day, and then loads the data into a data warehouse fact table for analysis.
- **Dimension tables** contain attribute data that might change but usually changes infrequently. For example, a customer's name and address are stored in a dimension table and updated only when the customer's profile changes. To minimize the size of a large fact table, the customer's name and address don't need to be in every row of a fact table. Instead, the fact table and the dimension table can share a customer ID. A query can join the two tables to associate a customer's profile and transactions.
- **Integration tables** provide a place for integrating or staging data. You can create an integration table as a regular table, an external table, or a temporary table. For example, you can load data to a staging table, perform transformations on the data in staging, and then insert the data into a production table.

Schema names

Schemas are a good way to group together objects that are used in a similar fashion. The following code creates a user-defined schema called wwi.

```
CREATE SCHEMA wwi;
```

Table names

If you're migrating multiple databases from an on-prem solution to dedicated SQL pool, the best practice is to migrate all of the fact, dimension, and integration tables to one SQL pool schema. For example, you could store all the tables in the WideWorldImportersDW sample data warehouse within one schema called wwi.

To show the organization of the tables in dedicated SQL pool, you could use fact, dim, and int as prefixes to the table names. The table below shows some of the schema and table names for WideWorldImportersDW.

WIDEWORLDIMPORTERSDW TABLE	TABLE TYPE	DEDICATED SQL POOL
City	Dimension	wwi.DimCity
Order	Fact	wwi.FactOrder

Table persistence

Tables store data either permanently in Azure Storage, temporarily in Azure Storage, or in a data store external to the data warehouse.

Regular table

A regular table stores data in Azure Storage as part of the data warehouse. The table and the data persist whether or not a session is open. The example below creates a regular table with two columns.

```
CREATE TABLE MyTable (col1 int, col2 int );
```

Temporary table

A temporary table only exists for the duration of the session. You can use a temporary table to prevent other users from seeing temporary results. Using temporary tables also reduces the need for cleanup. Temporary tables utilize local storage and, in dedicated SQL pools, can offer faster performance.

Serverless SQL pool supports temporary tables. But, its usage is limited since you can select from a temporary table but cannot join it with files in storage.

For more information, see Temporary tables.

External table

External tables point to data located in Azure Storage blob or Azure Data Lake Storage.

Import data from external tables into dedicated SQL pools using the CREATE TABLE AS SELECT statement. For a loading tutorial, see Use PolyBase to load data from Azure blob storage.

For serverless SQL pool, you can use CETAS to save the query result to an external table in Azure Storage.

Data types

Dedicated SQL pool supports the most commonly used data types. For a list of the supported data types, see data types in CREATE TABLE reference in the CREATE TABLE statement. For more information on using data types, see Data types.

Distributed tables

A fundamental feature of dedicated SQL pool is the way it can store and operate on tables across distributions. Dedicated SQL pool supports three methods for distributing data:

- Round-robin (default)
- Hash
- Replicated

Hash-distributed tables

A hash distributed table distributes rows based on the value in the distribution column. A hash distributed table is designed to achieve high performance for queries on large tables. There are several factors to consider when choosing a distribution column.

For more information, see Design guidance for distributed tables.

Replicated tables

A replicated table has a full copy of the table available on every Compute node. Queries run fast on replicated tables because joins on replicated tables don't require data movement. Replication requires extra storage, though, and isn't practical for large tables.

For more information, see Design guidance for replicated tables.

Round-robin tables

A round-robin table distributes table rows evenly across all distributions. The rows are distributed randomly. Loading data into a round-robin table is fast. But, queries can require more data movement than the other distribution methods.

For more information, see Design guidance for distributed tables.

Common distribution methods for tables

The table category often determines the optimal option for table distribution.

TABLE CATEGORY	RECOMMENDED DISTRIBUTION OPTION
Fact	Use hash-distribution with clustered columnstore index. Performance improves when two hash tables are joined on the same distribution column.
Dimension	Use replicated for smaller tables. If tables are too large to store on each Compute node, use hash-distributed.
Staging	Use round-robin for the staging table. The load with CTAS is fast. Once the data is in the staging table, use INSERT...SELECT to move the data to production tables.

Partitions

In dedicated SQL pools, a partitioned table stores and executes operations on the table rows according to data ranges. For example, a table could be partitioned by day, month, or year. You can improve query performance through partition elimination, which limits a query scan to data within a partition.

You can also maintain the data through partition switching. Since the data in a dedicated SQL pool is already distributed, too many partitions can slow query performance. For more information, see Partitioning guidance.

> **TIP**
> When partition switching into table partitions that are not empty, consider using the TRUNCATE_TARGET option in your ALTER TABLE statement if the existing data is to be truncated.

The code below switches the transformed daily data into a SalesFact partition and overwrites any existing data.

```
ALTER TABLE SalesFact_DailyFinalLoad SWITCH PARTITION 256 TO SalesFact PARTITION 256 WITH (TRUNCATE_TARGET =
ON);
```

In serverless SQL pool, you can limit the files/folders (partitions) that will be read by your query. Partitioning by path is supported using the filepath and fileinfo functions described in Querying storage files. The following example reads a folder with data for year 2017:

```
SELECT
    nyc.filepath(1) AS [year],
    payment_type,
    SUM(fare_amount) AS fare_total
FROM
    OPENROWSET(
        BULK 'https://sqlondemandstorage.blob.core.windows.net/parquet/taxi/year=*/month=*/*.parquet',
        FORMAT='PARQUET'
    ) AS nyc
WHERE
    nyc.filepath(1) = 2017
GROUP BY
    nyc.filepath(1),
    payment_type
ORDER BY
    nyc.filepath(1),
    payment_type
```

Columnstore indexes

By default, dedicated SQL pool stores a table as a clustered columnstore index. This form of data storage achieves high data compression and query performance on large tables. The clustered columnstore index is usually the best choice, but in some cases a clustered index or a heap is the appropriate storage structure.

> **TIP**
> A heap table can be especially useful for loading transient data, such as a staging table, which is transformed into a final table.

For a list of columnstore features, see What's new for columnstore indexes. To improve columnstore index performance, see Maximizing rowgroup quality for columnstore indexes.

Statistics

The query optimizer uses column-level statistics when it creates the plan for executing a query. To improve query performance, it's important to have statistics on individual columns, especially columns used in query joins. Synapse SQL supports automatic creation of statistics.

Statistical updating doesn't happen automatically. Update statistics after a significant number of rows are added or changed. For instance, update statistics after a load. Additional information is provided in the Statistics guidance article.

Primary key and unique key

For dedicated SQL pool, PRIMARY KEY is only supported when NONCLUSTERED and NOT ENFORCED are both used. UNIQUE constraint is only supported when NOT ENFORCED is used. For more information, see the dedicated SQL pool table constraints article.

Commands for creating tables

For dedicated SQL pool, you can create a table as a new empty table. You can also create and populate a table with the results of a select statement. The following are the T-SQL commands for creating a table.

T-SQL STATEMENT	DESCRIPTION
CREATE TABLE	Creates an empty table by defining all the table columns and options.
CREATE EXTERNAL TABLE	Creates an external table. The definition of the table is stored in dedicated SQL pool. The table data is stored in Azure Blob storage or Azure Data Lake Storage.
CREATE TABLE AS SELECT	Populates a new table with the results of a select statement. The table columns and data types are based on the select statement results. To import data, this statement can select from an external table.
CREATE EXTERNAL TABLE AS SELECT	Creates a new external table by exporting the results of a select statement to an external location. The location is either Azure Blob storage or Azure Data Lake Storage.

Align source data with the data warehouse

Dedicated SQL pool tables are populated by loading data from another data source. To achieve a successful load, the number and data types of the columns in the source data must align with the table definition in the data warehouse.

> **NOTE**
> Getting the data to align might be the hardest part of designing your tables.

If data is coming from multiple data stores, you can port the data into the data warehouse and store it in an integration table. Once data is in the integration table, you can use the power of dedicated SQL pool to implement transformation operations. Once the data is prepared, you can insert it into production tables.

Unsupported table features

Dedicated SQL pool supports many, but not all, of the table features offered by other databases. The following list shows some of the table features that aren't supported in dedicated SQL pool.

- Foreign key, check Table Constraints
- Computed Columns
- Indexed Views
- Sequence
- Sparse Columns
- Surrogate Keys, implement with Identity
- Synonyms
- Triggers
- Unique Indexes
- User-Defined Types

Table size queries

In dedicated SQL pool, one simple way to identify space and rows consumed by a table in each of the 60 distributions is to use DBCC PDW_SHOWSPACEUSED.

```
DBCC PDW_SHOWSPACEUSED('dbo.FactInternetSales');
```

Keep in mind that using DBCC commands can be quite limiting. Dynamic management views (DMVs) show more detail than DBCC commands. Start by creating the view below.

```
CREATE VIEW dbo.vTableSizes
AS
WITH base
AS
(
SELECT
 GETDATE()                                                              AS  [execution_time]
, DB_NAME()                                                             AS  [database_name]
, s.name                                                                AS  [schema_name]
, t.name                                                                AS  [table_name]
, QUOTENAME(s.name)+'.'+QUOTENAME(t.name)                               AS  [two_part_name]
, nt.[name]                                                             AS  [node_table_name]
, ROW_NUMBER() OVER(PARTITION BY nt.[name] ORDER BY (SELECT NULL))      AS  [node_table_name_seq]
, tp.[distribution_policy_desc]                                         AS  [distribution_policy_name]
, c.[name]                                                              AS  [distribution_column]
, nt.[distribution_id]                                                  AS  [distribution_id]
, i.[type]                                                              AS  [index_type]
, i.[type_desc]                                                         AS  [index_type_desc]
, nt.[pdw_node_id]                                                      AS  [pdw_node_id]
, pn.[type]                                                             AS  [pdw_node_type]
, pn.[name]                                                             AS  [pdw_node_name]
, di.name                                                               AS  [dist_name]
, di.position                                                           AS  [dist_position]

Table space summary

This query returns the rows and space by table. Table space summary allows you to see which tables are your largest tables. You'll also see whether they're round-robin, replicated, or hash-distributed. For hash-distributed tables, the query shows the distribution column.

```
SELECT
     database_name
,    schema_name
,    table_name
,    distribution_policy_name
,      distribution_column
,    index_type_desc
,    COUNT(distinct partition_nmbr) as nbr_partitions
,    SUM(row_count)                 as table_row_count
,    SUM(reserved_space_GB)         as table_reserved_space_GB
,    SUM(data_space_GB)             as table_data_space_GB
,    SUM(index_space_GB)            as table_index_space_GB
,    SUM(unused_space_GB)           as table_unused_space_GB
FROM
    dbo.vTableSizes
GROUP BY
     database_name
,    schema_name
,    table_name
,    distribution_policy_name
,      distribution_column
,    index_type_desc
ORDER BY
    table_reserved_space_GB desc

GROUP BY     distribution_id
ORDER BY    distribution_id
;
```

Next steps

After creating the tables for your data warehouse, the next step is to load data into the table. For a loading tutorial, see Loading data into dedicated SQL pool.

CETAS with Synapse SQL

8/19/2022 • 3 minutes to read • Edit Online

You can use CREATE EXTERNAL TABLE AS SELECT (CETAS) in dedicated SQL pool or serverless SQL pool to complete the following tasks:

- Create an external table
- Export, in parallel, the results of a Transact-SQL SELECT statement to:
  - Hadoop
  - Azure Storage Blob
  - Azure Data Lake Storage Gen2

CETAS in dedicated SQL pool

For dedicated SQL pool, CETAS usage and syntax, check the CREATE EXTERNAL TABLE AS SELECT article. Additionally, for guidance on CTAS using dedicated SQL pool, see the CREATE TABLE AS SELECT article.

CETAS in serverless SQL pool

When using serverless SQL pool, CETAS is used to create an external table and export query results to Azure Storage Blob or Azure Data Lake Storage Gen2.

Syntax

```
CREATE EXTERNAL TABLE [ [database_name  . [ schema_name ] . ] | schema_name . ] table_name
    WITH (
        LOCATION = 'path_to_folder',
        DATA_SOURCE = external_data_source_name,
        FILE_FORMAT = external_file_format_name
)
    AS <select_statement>
[;]

<select_statement> ::=
    [ WITH <common_table_expression> [ ,...n ] ]
    SELECT <select_criteria>
```

Arguments

[[database_name . [schema_name] .] | schema_name .] table_name

The one to three-part name of the table to create. For an external table, serverless SQL pool stores only the table metadata. No actual data is moved or stored in serverless SQL pool.

LOCATION = *'path_to_folder'*

Specifies where to write the results of the SELECT statement on the external data source. The root folder is the data location specified in the external data source. LOCATION must point to a folder and have a trailing /. Example: aggregated_data/

DATA_SOURCE = *external_data_source_name*

Specifies the name of the external data source object that contains the location where the external data will be stored. To create an external data source, use CREATE EXTERNAL DATA SOURCE (Transact-SQL).

FILE_FORMAT = *external_file_format_name*

Specifies the name of the external file format object that contains the format for the external data file. To create an external file format, use CREATE EXTERNAL FILE FORMAT (Transact-SQL). Only external file formats with FORMAT_TYPE=PARQUET and FORMAT_TYPE=DELIMITEDTEXT are currently supported. GZip compression for DELIMITEDTEXT format is not supported.

WITH *<common_table_expression>*

Specifies a temporary named result set, known as a common table expression (CTE). For more information, see WITH common_table_expression (Transact-SQL).

SELECT <select_criteria>

Populates the new table with the results from a SELECT statement. *select_criteria* is the body of the SELECT statement that determines which data to copy to the new table. For information about SELECT statements, see SELECT (Transact-SQL).

> **NOTE**
> ORDER BY clause in SELECT is not supported for CETAS.

Permissions

You need to have permissions to list folder content and write to the LOCATION folder for CETAS to work.

Examples

These examples use CETAS to save total population aggregated by year and state to an aggregated_data folder that is located in the population_ds datasource.

This sample relies on the credential, data source, and external file format created previously. Refer to the external tables document. To save query results to a different folder in the same data source, change the LOCATION argument.

To save results to a different storage account, create and use a different data source for DATA_SOURCE argument.

> **NOTE**
> The samples that follow use a public Azure Open Data storage account. It is read-only. To execute these queries, you need to provide the data source for which you have write permissions.

```
-- use CETAS to export select statement with OPENROWSET result to  storage
CREATE EXTERNAL TABLE population_by_year_state
WITH (
    LOCATION = 'aggregated_data/',
    DATA_SOURCE = population_ds,
    FILE_FORMAT = census_file_format
)
AS
SELECT decennialTime, stateName, SUM(population) AS population
FROM
    OPENROWSET(BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=*/
*.parquet',
    FORMAT='PARQUET') AS [r]
GROUP BY decennialTime, stateName
GO

-- you can query the newly created external table
SELECT * FROM population_by_year_state
```

The following sample uses an external table as the source for CETAS. It relies on the credential, data source, external file format, and external table created previously. Refer to the external tables document.

```
-- use CETAS with select from external table
CREATE EXTERNAL TABLE population_by_year_state
WITH (
    LOCATION = 'aggregated_data/',
    DATA_SOURCE = population_ds,
    FILE_FORMAT = census_file_format
)
AS
SELECT decennialTime, stateName, SUM(population) AS population
FROM census_external_table
GROUP BY decennialTime, stateName
GO

-- you can query the newly created external table
SELECT * FROM population_by_year_state
```

Supported data types

CETAS can be used to store result sets with following SQL data types:

- binary
- varbinary
- char
- varchar
- nchar
- nvarchar
- smalldate
- date
- datetime
- datetime2
- datetimeoffset
- time
- decimal
- numeric

- float
- real
- bigint
- tinyint
- smallint
- int
- bigint
- bit
- money
- smallmoney
- uniqueidentifier

> **NOTE**
> LOBs larger than 1MB can't be used with CETAS.

Next steps

Try querying Apache Spark for Azure Synapse external tables.

CREATE TABLE AS SELECT (CTAS)

8/19/2022 • 9 minutes to read • Edit Online

This article explains the CREATE TABLE AS SELECT (CTAS) T-SQL statement in Synapse SQL for developing solutions. The article also provides code examples.

CREATE TABLE AS SELECT

The CREATE TABLE AS SELECT (CTAS) statement is one of the most important T-SQL features available. CTAS is a parallel operation that creates a new table based on the output of a SELECT statement. CTAS is the simplest and fastest way to create and insert data into a table with a single command.

SELECT...INTO vs. CTAS

CTAS is a more customizable version of the SELECT...INTO statement.

The following is an example of a simple SELECT...INTO:

```
SELECT *
INTO    [dbo].[FactInternetSales_new]
FROM    [dbo].[FactInternetSales]
```

SELECT...INTO doesn't allow you to change either the distribution method or the index type as part of the operation. You create `[dbo].[FactInternetSales_new]` by using the default distribution type of ROUND_ROBIN, and the default table structure of CLUSTERED COLUMNSTORE INDEX.

With CTAS, on the other hand, you can specify both the distribution of the table data as well as the table structure type. To convert the previous example to CTAS:

```
CREATE TABLE [dbo].[FactInternetSales_new]
WITH
(
 DISTRIBUTION = ROUND_ROBIN
 ,CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT  *
FROM    [dbo].[FactInternetSales];
```

> **NOTE**
>
> If you're only trying to change the index in your CTAS operation, and the source table is hash distributed, maintain the same distribution column and data type. This avoids cross-distribution data movement during the operation, which is more efficient.

Use CTAS to copy a table

Perhaps one of the most common uses of CTAS is creating a copy of a table in order to change the DDL. Let's say you originally created your table as `ROUND_ROBIN`, and now want to change it to a table distributed on a column. CTAS is how you would change the distribution column. You can also use CTAS to change partitioning, indexing, or column types.

Let's say you created this table by using the default distribution type of `ROUND_ROBIN`, not specifying a distribution column in the `CREATE TABLE`.

```
CREATE TABLE FactInternetSales
(
    ProductKey int NOT NULL,
    OrderDateKey int NOT NULL,
    DueDateKey int NOT NULL,
    ShipDateKey int NOT NULL,
    CustomerKey int NOT NULL,
    PromotionKey int NOT NULL,
    CurrencyKey int NOT NULL,
    SalesTerritoryKey int NOT NULL,
    SalesOrderNumber nvarchar(20) NOT NULL,
    SalesOrderLineNumber tinyint NOT NULL,
    RevisionNumber tinyint NOT NULL,
    OrderQuantity smallint NOT NULL,
    UnitPrice money NOT NULL,
    ExtendedAmount money NOT NULL,
    UnitPriceDiscountPct float NOT NULL,
    DiscountAmount float NOT NULL,
    ProductStandardCost money NOT NULL,
    TotalProductCost money NOT NULL,
    SalesAmount money NOT NULL,
    TaxAmt money NOT NULL,
    Freight money NOT NULL,
    CarrierTrackingNumber nvarchar(25),
    CustomerPONumber nvarchar(25));
```

Now you want to create a new copy of this table, with a `Clustered Columnstore Index`, so you can take advantage of the performance of Clustered Columnstore tables. You also want to distribute this table on `ProductKey`, because you're anticipating joins on this column and want to avoid data movement during joins on `ProductKey`. Lastly, you also want to add partitioning on `OrderDateKey`, so you can quickly delete old data by dropping old partitions. Here is the CTAS statement, which copies your old table into a new table.

```
CREATE TABLE FactInternetSales_new
WITH
(
    CLUSTERED COLUMNSTORE INDEX,
    DISTRIBUTION = HASH(ProductKey),
    PARTITION
    (
        OrderDateKey RANGE RIGHT FOR VALUES
        (
        20000101,20010101,20020101,20030101,20040101,20050101,20060101,20070101,20080101,20090101,
        20100101,20110101,20120101,20130101,20140101,20150101,20160101,20170101,20180101,20190101,
        20200101,20210101,20220101,20230101,20240101,20250101,20260101,20270101,20280101,20290101
        )
    )
)
AS SELECT * FROM FactInternetSales;
```

Finally, you can rename your tables, to swap in your new table and then drop your old table.

```
RENAME OBJECT FactInternetSales TO FactInternetSales_old;
RENAME OBJECT FactInternetSales_new TO FactInternetSales;

DROP TABLE FactInternetSales_old;
```

Use CTAS to work around unsupported features

You can also use CTAS to work around a number of the unsupported features listed below. This method can often prove helpful, because not only will your code be compliant, but it will often run faster on Synapse SQL. This performance is a result of its fully parallelized design. Scenarios include:

- ANSI JOINS on UPDATEs
- ANSI JOINs on DELETEs
- MERGE statement

> **TIP**
> Try to think "CTAS first." Solving a problem by using CTAS is generally a good approach, even if you're writing more data as a result.

ANSI join replacement for update statements

You might find that you have a complex update. The update joins more than two tables together by using ANSI join syntax to perform the UPDATE or DELETE.

Imagine you had to update this table:

```
CREATE TABLE [dbo].[AnnualCategorySales]
( [EnglishProductCategoryName]    NVARCHAR(50)    NOT NULL
, [CalendarYear]                    SMALLINT        NOT NULL
, [TotalSalesAmount]                MONEY            NOT NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN
);
```

The original query might have looked something like this example:

```
UPDATE    acs
SET        [TotalSalesAmount] = [fis].[TotalSalesAmount]
FROM    [dbo].[AnnualCategorySales]     AS acs
JOIN    (
        SELECT [EnglishProductCategoryName]
        , [CalendarYear]
        , SUM([SalesAmount])                AS [TotalSalesAmount]
        FROM    [dbo].[FactInternetSales]        AS s
        JOIN    [dbo].[DimDate]                    AS d    ON s.[OrderDateKey]                = d.[DateKey]
        JOIN    [dbo].[DimProduct]                AS p    ON s.[ProductKey]                = p.[ProductKey]
        JOIN    [dbo].[DimProductSubCategory]    AS u    ON p.[ProductSubcategoryKey]    = u.
[ProductSubcategoryKey]
        JOIN    [dbo].[DimProductCategory]        AS c    ON u.[ProductCategoryKey]        = c.
[ProductCategoryKey]
        WHERE     [CalendarYear] = 2004
        GROUP BY
                [EnglishProductCategoryName]
        ,        [CalendarYear]
        ) AS fis
ON    [acs].[EnglishProductCategoryName]    = [fis].[EnglishProductCategoryName]
AND    [acs].[CalendarYear]                = [fis].[CalendarYear];
```

Synapse SQL doesn't support ANSI joins in the `FROM` clause of an `UPDATE` statement, so you can't use the previous example without modifying it.

You can use a combination of a CTAS and an implicit join to replace the previous example:

```
-- Create an interim table
CREATE TABLE CTAS_acs
WITH (DISTRIBUTION = ROUND_ROBIN)
AS
SELECT    ISNULL(CAST([EnglishProductCategoryName] AS NVARCHAR(50)),0) AS [EnglishProductCategoryName]
, ISNULL(CAST([CalendarYear] AS SMALLINT),0)  AS [CalendarYear]
, ISNULL(CAST(SUM([SalesAmount]) AS MONEY),0)  AS [TotalSalesAmount]
FROM    [dbo].[FactInternetSales]        AS s
JOIN    [dbo].[DimDate]                    AS d    ON s.[OrderDateKey]                = d.[DateKey]
JOIN    [dbo].[DimProduct]                 AS p    ON s.[ProductKey]                = p.[ProductKey]
JOIN    [dbo].[DimProductSubCategory]    AS u    ON p.[ProductSubcategoryKey]    = u.[ProductSubcategoryKey]
JOIN    [dbo].[DimProductCategory]         AS c    ON u.[ProductCategoryKey]        = c.[ProductCategoryKey]
WHERE     [CalendarYear] = 2004
GROUP BY [EnglishProductCategoryName]
, [CalendarYear];

-- Use an implicit join to perform the update
UPDATE  AnnualCategorySales
SET     AnnualCategorySales.TotalSalesAmount = CTAS_ACS.TotalSalesAmount
FROM    CTAS_acs
WHERE   CTAS_acs.[EnglishProductCategoryName] = AnnualCategorySales.[EnglishProductCategoryName]
AND     CTAS_acs.[CalendarYear]  = AnnualCategorySales.[CalendarYear] ;

--Drop the interim table
DROP TABLE CTAS_acs;
```

ANSI join replacement for MERGE

In Azure Synapse Analytics, MERGE (preview) with NOT MATCHED BY TARGET requires the target to be a HASH distributed table. Users can use the ANSI JOIN with UPDATE or DELETE as a workaround to modify target table data based on the result from joining with another table. Here is an example.

```
CREATE TABLE dbo.Table1
    (ColA INT NOT NULL, ColB DECIMAL(10,3) NOT NULL);
GO
CREATE TABLE dbo.Table2
    (ColA INT NOT NULL, ColB DECIMAL(10,3) NOT NULL);
GO
INSERT INTO dbo.Table1 VALUES(1, 10.0);
INSERT INTO dbo.Table2 VALUES(1, 0.0);
GO
UPDATE dbo.Table2
SET dbo.Table2.ColB = dbo.Table2.ColB + dbo.Table1.ColB
FROM dbo.Table2
    INNER JOIN dbo.Table1
    ON (dbo.Table2.ColA = dbo.Table1.ColA);
GO
SELECT ColA, ColB
FROM dbo.Table2;
```

Explicitly state data type and nullability of output

When migrating code, you might find you run across this type of coding pattern:

```
DECLARE @d decimal(7,2) = 85.455
,       @f float(24)    = 85.455

CREATE TABLE result
(result DECIMAL(7,2) NOT NULL
)
WITH (DISTRIBUTION = ROUND_ROBIN)

INSERT INTO result
SELECT @d*@f;
```

You might think you should migrate this code to CTAS, and you'd be correct. However, there's a hidden issue here.

The following code doesn't yield the same result:

```
DECLARE @d decimal(7,2) = 85.455
, @f float(24)    = 85.455;

CREATE TABLE ctas_r
WITH (DISTRIBUTION = ROUND_ROBIN)
AS
SELECT @d*@f as result;
```

Notice that the column "result" carries forward the data type and nullability values of the expression. Carrying the data type forward can lead to subtle variances in values if you aren't careful.

Try this example:

```
SELECT result,result*@d
from result;

SELECT result,result*@d
from ctas_r;
```

The value stored for result is different. As the persisted value in the result column is used in other expressions, the error becomes even more significant.

	result	second_result
1	7302.98	624112.6708

	result	second_result
1	7302.984	624113.1

This is important for data migrations. Even though the second query is arguably more accurate, there's a problem. The data would be different compared to the source system, and that leads to questions of integrity in the migration. This is one of those rare cases where the "wrong" answer is actually the right one!

The reason we see a disparity between the two results is due to implicit type casting. In the first example, the table defines the column definition. When the row is inserted, an implicit type conversion occurs. In the second example, there is no implicit type conversion as the expression defines the data type of the column.

Notice also that the column in the second example has been defined as a NULLable column, whereas in the first example it has not. When the table was created in the first example, column nullability was explicitly defined. In the second example, it was left to the expression, and by default would result in a NULL definition.

To resolve these issues, you must explicitly set the type conversion and nullability in the SELECT portion of the

CTAS statement. You can't set these properties in 'CREATE TABLE'. The following example demonstrates how to fix the code:

```
DECLARE @d decimal(7,2) = 85.455
, @f float(24)    = 85.455

CREATE TABLE ctas_r
WITH (DISTRIBUTION = ROUND_ROBIN)
AS
SELECT ISNULL(CAST(@d*@f AS DECIMAL(7,2)),0) as result
```

Note the following:

- You can use CAST or CONVERT.
- Use ISNULL, not COALESCE, to force NULLability. See the following note.
- ISNULL is the outermost function.
- The second part of the ISNULL is a constant, 0.

> **NOTE**
>
> For the nullability to be correctly set, it's vital to use ISNULL and not COALESCE. COALESCE is not a deterministic function, and so the result of the expression will always be NULLable. ISNULL is different. It's deterministic. Therefore, when the second part of the ISNULL function is a constant or a literal, the resulting value will be NOT NULL.

Ensuring the integrity of your calculations is also important for table partition switching. Imagine you have this table defined as a fact table:

```
CREATE TABLE [dbo].[Sales]
(
    [date]      INT     NOT NULL
, [product]   INT     NOT NULL
, [store]     INT     NOT NULL
, [quantity]  INT     NOT NULL
, [price]     MONEY   NOT NULL
, [amount]    MONEY   NOT NULL
)
WITH
(   DISTRIBUTION = HASH([product])
,   PARTITION   (   [date] RANGE RIGHT FOR VALUES
                    (20000101,20010101,20020101
                    ,20030101,20040101,20050101
                    )
                )
);
```

However, the amount field is a calculated expression. It isn't part of the source data.

To create your partitioned dataset, you might want to use the following code:

```
CREATE TABLE [dbo].[Sales_in]
WITH
( DISTRIBUTION = HASH([product])
, PARTITION   (   [date] RANGE RIGHT FOR VALUES
                    (20000101,20010101
                    )
                )
)
AS
SELECT
    [date]
,   [product]
,   [store]
,   [quantity]
,   [price]
,   [quantity]*[price]  AS [amount]
FROM [stg].[source]
OPTION (LABEL = 'CTAS : Partition IN table : Create');
```

The query would run perfectly well. The problem comes when you try to do the partition switch. The table definitions don't match. To make the table definitions match, modify the CTAS to add an `ISNULL` function to preserve the column's nullability attribute.

```
CREATE TABLE [dbo].[Sales_in]
WITH
( DISTRIBUTION = HASH([product])
, PARTITION   (   [date] RANGE RIGHT FOR VALUES
                    (20000101,20010101
                    )
                )
)
AS
SELECT
  [date]
, [product]
, [store]
, [quantity]
, [price]
, ISNULL(CAST([quantity]*[price] AS MONEY),0) AS [amount]
FROM [stg].[source]
OPTION (LABEL = 'CTAS : Partition IN table : Create');
```

You can see that type consistency and maintaining nullability properties on a CTAS is an engineering best practice. It helps to maintain integrity in your calculations, and also ensures that partition switching is possible.

CTAS is one of the most important statements in Synapse SQL. Make sure you thoroughly understand it. See the CTAS documentation.

Table data types in Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll find recommendations for defining table data types in Synapse SQL Dedicated Pool.

Data types

Synapse SQL Dedicated Pool supports the most commonly used data types. For a list of the supported data types, see data types in the CREATE TABLE statement. For Synapse SQL Serverless please refer to article Query storage files with serverless SQL pool in Azure Synapse Analytics and How to use OPENROWSET using serverless SQL pool in Azure Synapse Analytics

Minimize row length

Minimizing the size of data types shortens the row length, which leads to better query performance. Use the smallest data type that works for your data.

- Avoid defining character columns with a large default length. For example, if the longest value is 25 characters, then define your column as VARCHAR(25).
- Avoid using [NVARCHAR][NVARCHAR] when you only need VARCHAR.
- When possible, use NVARCHAR(4000) or VARCHAR(8000) instead of NVARCHAR(MAX) or VARCHAR(MAX).
- Avoid using floats and decimals with 0 (zero) scale. These should be TINYINT, SMALLINT, INT or BIGINT.

> **NOTE**
> If you are using PolyBase external tables to load your Synapse SQL tables, the defined length of the table row cannot exceed 1 MB. When a row with variable-length data exceeds 1 MB, you can load the row with BCP, but not with PolyBase.

Identify unsupported data types

If you are migrating your database from another SQL database, you might encounter data types that are not supported in Synapse SQL. Use this query to discover unsupported data types in your existing SQL schema.

```
SELECT  t.[name], c.[name], c.[system_type_id], c.[user_type_id], y.[is_user_defined], y.[name]
FROM sys.tables  t
JOIN sys.columns c on t.[object_id]    = c.[object_id]
JOIN sys.types   y on c.[user_type_id] = y.[user_type_id]
WHERE y.[name] IN ('geography','geometry','hierarchyid','image','text','ntext','sql_variant','xml')
 OR  y.[is_user_defined] = 1;
```

Workarounds for unsupported data types

The following list shows the data types that Synapse SQL does not support and gives alternatives that you can use instead of the unsupported data types.

UNSUPPORTED DATA TYPE	WORKAROUND
geometry	varbinary

UNSUPPORTED DATA TYPE	WORKAROUND
geography	varbinary
hierarchyid	nvarchar(4000)
image	varbinary
text	varchar
ntext	nvarchar
sql_variant	Split column into several strongly typed columns.
table	Convert to temporary tables or consider storing data to storage using CETAS.
timestamp	Rework code to use datetime2 and the CURRENT_TIMESTAMP function. Only constants are supported as defaults, therefore current_timestamp cannot be defined as a default constraint. If you need to migrate row version values from a timestamp typed column, then use BINARY(8) or VARBINARY(8) for NOT NULL or NULL row version values.
xml	varchar
user-defined type	Convert back to the native data type when possible.
default values	Default values support literals and constants only.

Guidance for designing distributed tables using dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

This article contains recommendations for designing hash-distributed and round-robin distributed tables in dedicated SQL pools.

This article assumes you are familiar with data distribution and data movement concepts in dedicated SQL pool. For more information, see Azure Synapse Analytics architecture.

What is a distributed table?

A distributed table appears as a single table, but the rows are actually stored across 60 distributions. The rows are distributed with a hash or round-robin algorithm.

Hash-distribution improves query performance on large fact tables, and is the focus of this article. **Round-robin distribution** is useful for improving loading speed. These design choices have a significant impact on improving query and loading performance.

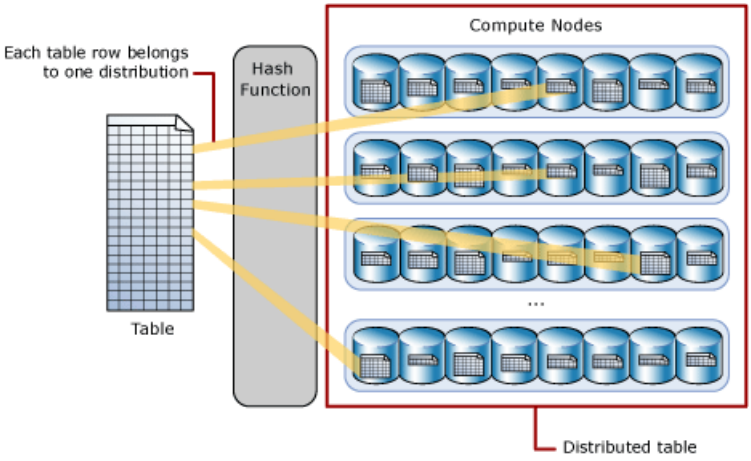
Another table storage option is to replicate a small table across all the Compute nodes. For more information, see Design guidance for replicated tables. To quickly choose among the three options, see Distributed tables in the tables overview.

As part of table design, understand as much as possible about your data and how the data is queried. For example, consider these questions:

- How large is the table?
- How often is the table refreshed?
- Do I have fact and dimension tables in a dedicated SQL pool?

Hash distributed

A hash-distributed table distributes table rows across the Compute nodes by using a deterministic hash function to assign each row to one distribution.



Since identical values always hash to the same distribution, SQL Analytics has built-in knowledge of the row locations. In dedicated SQL pool this knowledge is used to minimize data movement during queries, which improves query performance.

Hash-distributed tables work well for large fact tables in a star schema. They can have very large numbers of

rows and still achieve high performance. There are some design considerations that help you to get the performance the distributed system is designed to provide. Choosing a good distribution column is one such consideration that is described in this article.

Consider using a hash-distributed table when:

- The table size on disk is more than 2 GB.
- The table has frequent insert, update, and delete operations.

Round-robin distributed

A round-robin distributed table distributes table rows evenly across all distributions. The assignment of rows to distributions is random. Unlike hash-distributed tables, rows with equal values are not guaranteed to be assigned to the same distribution.

As a result, the system sometimes needs to invoke a data movement operation to better organize your data before it can resolve a query. This extra step can slow down your queries. For example, joining a round-robin table usually requires reshuffling the rows, which is a performance hit.

Consider using the round-robin distribution for your table in the following scenarios:

- When getting started as a simple starting point since it is the default
- If there is no obvious joining key
- If there is no good candidate column for hash distributing the table
- If the table does not share a common join key with other tables
- If the join is less significant than other joins in the query
- When the table is a temporary staging table

The tutorial Load New York taxicab data gives an example of loading data into a round-robin staging table.

Choose a distribution column

A hash-distributed table has a distribution column that is the hash key. For example, the following code creates a hash-distributed table with ProductKey as the distribution column.

```
CREATE TABLE [dbo].[FactInternetSales]
(   [ProductKey]            int          NOT NULL
,   [OrderDateKey]          int          NOT NULL
,   [CustomerKey]           int          NOT NULL
,   [PromotionKey]          int          NOT NULL
,   [SalesOrderNumber]      nvarchar(20) NOT NULL
,   [OrderQuantity]         smallint     NOT NULL
,   [UnitPrice]             money        NOT NULL
,   [SalesAmount]           money        NOT NULL
)
WITH
(   CLUSTERED COLUMNSTORE INDEX
,  DISTRIBUTION = HASH([ProductKey])
);
```

Data stored in the distribution column can be updated. Updates to data in the distribution column could result in data shuffle operation.

Choosing a distribution column is an important design decision since the values in this column determine how the rows are distributed. The best choice depends on several factors, and usually involves tradeoffs. Once a distribution column is chosen, you cannot change it.

If you didn't choose the best column the first time, you can use CREATE TABLE AS SELECT (CTAS) to re-create the table with a different distribution column.

Choose a distribution column with data that distributes evenly

For best performance, all of the distributions should have approximately the same number of rows. When one or more distributions have a disproportionate number of rows, some distributions finish their portion of a parallel query before others. Since the query can't complete until all distributions have finished processing, each query is only as fast as the slowest distribution.

- Data skew means the data is not distributed evenly across the distributions
- Processing skew means that some distributions take longer than others when running parallel queries. This can happen when the data is skewed.

To balance the parallel processing, select a distribution column that:

- **Has many unique values.** The column can have duplicate values. All rows with the same value are assigned to the same distribution. Since there are 60 distributions, some distributions can have > 1 unique values while others may end with zero values.
- **Does not have NULLs, or has only a few NULLs.** For an extreme example, if all values in the column are NULL, all the rows are assigned to the same distribution. As a result, query processing is skewed to one distribution, and does not benefit from parallel processing.
- **Is not a date column**. All data for the same date lands in the same distribution. If several users are all filtering on the same date, then only 1 of the 60 distributions do all the processing work.

Choose a distribution column that minimizes data movement

To get the correct query result queries might move data from one Compute node to another. Data movement commonly happens when queries have joins and aggregations on distributed tables. Choosing a distribution column that helps minimize data movement is one of the most important strategies for optimizing performance of your dedicated SQL pool.

To minimize data movement, select a distribution column that:

- Is used in `JOIN`, `GROUP BY`, `DISTINCT`, `OVER`, and `HAVING` clauses. When two large fact tables have frequent joins, query performance improves when you distribute both tables on one of the join columns. When a table is not used in joins, consider distributing the table on a column that is frequently in the `GROUP BY` clause.
- Is *not* used in `WHERE` clauses. This could narrow the query to not run on all the distributions.
- Is *not* a date column. `WHERE` clauses often filter by date. When this happens, all the processing could run on only a few distributions.

What to do when none of the columns are a good distribution column

If none of your columns have enough distinct values for a distribution column, you can create a new column as a composite of one or more values. To avoid data movement during query execution, use the composite distribution column as a join column in queries.

Once you design a hash-distributed table, the next step is to load data into the table. For loading guidance, see Loading overview.

How to tell if your distribution column is a good choice

After data is loaded into a hash-distributed table, check to see how evenly the rows are distributed across the 60 distributions. The rows per distribution can vary up to 10% without a noticeable impact on performance.

Determine if the table has data skew

A quick way to check for data skew is to use DBCC PDW_SHOWSPACEUSED. The following SQL code returns the number of table rows that are stored in each of the 60 distributions. For balanced performance, the rows in your distributed table should be spread evenly across all the distributions.

```
-- Find data skew for a distributed table
DBCC PDW_SHOWSPACEUSED('dbo.FactInternetSales');
```

To identify which tables have more than 10% data skew:

1. Create the view `dbo.vTableSizes` that is shown in the Tables overview article.
2. Run the following query:

```
select *
from dbo.vTableSizes
where two_part_name in
    (
    select two_part_name
    from dbo.vTableSizes
    where row_count > 0
    group by two_part_name
    having (max(row_count * 1.000) - min(row_count * 1.000))/max(row_count * 1.000) >= .10
    )
order by two_part_name, row_count
;
```

Check query plans for data movement

A good distribution column enables joins and aggregations to have minimal data movement. This affects the way joins should be written. To get minimal data movement for a join on two hash-distributed tables, one of the join columns needs to be the distribution column. When two hash-distributed tables join on a distribution column of the same data type, the join does not require data movement. Joins can use additional columns without incurring data movement.

To avoid data movement during a join:

- The tables involved in the join must be hash distributed on **one** of the columns participating in the join.
- The data types of the join columns must match between both tables.
- The columns must be joined with an equals operator.
- The join type may not be a `CROSS JOIN`.

To see if queries are experiencing data movement, you can look at the query plan.

Resolve a distribution column problem

It is not necessary to resolve all cases of data skew. Distributing data is a matter of finding the right balance between minimizing data skew and data movement. It is not always possible to minimize both data skew and data movement. Sometimes the benefit of having the minimal data movement might outweigh the impact of having data skew.

To decide if you should resolve data skew in a table, you should understand as much as possible about the data volumes and queries in your workload. You can use the steps in the Query monitoring article to monitor the impact of skew on query performance. Specifically, look for how long it takes large queries to complete on individual distributions.

Since you cannot change the distribution column on an existing table, the typical way to resolve data skew is to re-create the table with a different distribution column.

Re-create the table with a new distribution column

This example uses CREATE TABLE AS SELECT to re-create a table with a different hash distribution column.

```
CREATE TABLE [dbo].[FactInternetSales_CustomerKey]
WITH (  CLUSTERED COLUMNSTORE INDEX
     ,  DISTRIBUTION =  HASH([CustomerKey])
     ,  PARTITION       ( [OrderDateKey] RANGE RIGHT FOR VALUES (   20000101, 20010101, 20020101, 20030101
                                                                ,   20040101, 20050101, 20060101, 20070101
                                                                ,   20080101, 20090101, 20100101, 20110101
                                                                ,   20120101, 20130101, 20140101, 20150101
                                                                ,   20160101, 20170101, 20180101, 20190101
                                                                ,   20200101, 20210101, 20220101, 20230101
                                                                ,   20240101, 20250101, 20260101, 20270101
                                                                ,   20280101, 20290101
                                                                )
                          )
    )
AS
SELECT  *
FROM    [dbo].[FactInternetSales]
OPTION  (LABEL  = 'CTAS : FactInternetSales_CustomerKey')
;

--Create statistics on new table
CREATE STATISTICS [ProductKey] ON [FactInternetSales_CustomerKey] ([ProductKey]);
CREATE STATISTICS [OrderDateKey] ON [FactInternetSales_CustomerKey] ([OrderDateKey]);
CREATE STATISTICS [CustomerKey] ON [FactInternetSales_CustomerKey] ([CustomerKey]);
CREATE STATISTICS [PromotionKey] ON [FactInternetSales_CustomerKey] ([PromotionKey]);
CREATE STATISTICS [SalesOrderNumber] ON [FactInternetSales_CustomerKey] ([SalesOrderNumber]);
CREATE STATISTICS [OrderQuantity] ON [FactInternetSales_CustomerKey] ([OrderQuantity]);
CREATE STATISTICS [UnitPrice] ON [FactInternetSales_CustomerKey] ([UnitPrice]);
CREATE STATISTICS [SalesAmount] ON [FactInternetSales_CustomerKey] ([SalesAmount]);

--Rename the tables
RENAME OBJECT [dbo].[FactInternetSales] TO [FactInternetSales_ProductKey];
RENAME OBJECT [dbo].[FactInternetSales_CustomerKey] TO [FactInternetSales];
```

Next steps

To create a distributed table, use one of these statements:

- CREATE TABLE (dedicated SQL pool)
- CREATE TABLE AS SELECT (dedicated SQL pool)

Primary key, foreign key, and unique key using dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

Learn about table constraints in dedicated SQL pool, including primary key, foreign key, and unique key.

Table constraints

Dedicated SQL pool supports these table constraints:

- PRIMARY KEY is only supported when NONCLUSTERED and NOT ENFORCED are both used.
- UNIQUE constraint is only supported when NOT ENFORCED is used.

For syntax, check ALTER TABLE and CREATE TABLE.

FOREIGN KEY constraint is not supported in dedicated SQL pool.

Remarks

Having primary key and/or unique key allows dedicated SQL pool engine to generate an optimal execution plan for a query. All values in a primary key column or a unique constraint column should be unique.

> **IMPORTANT**
> After creating a table with primary key or unique constraint in dedicated SQL pool, users need to make sure all values in those columns are unique. A violation of that may cause the query to return inaccurate result.

This example shows how a query may return inaccurate result if the primary key or unique constraint column includes duplicate values.

```
 -- Create table t1
CREATE TABLE t1 (a1 INT NOT NULL, b1 INT) WITH (DISTRIBUTION = ROUND_ROBIN)

-- Insert values to table t1 with duplicate values in column a1.
INSERT INTO t1 VALUES (1, 100)
INSERT INTO t1 VALUES (1, 1000)
INSERT INTO t1 VALUES (2, 200)
INSERT INTO t1 VALUES (3, 300)
INSERT INTO t1 VALUES (4, 400)

0           1
1           1

(5 rows affected)
*/
```

Examples

Create a dedicated SQL pool table with a primary key:

```
CREATE TABLE mytable (c1 INT PRIMARY KEY NONCLUSTERED NOT ENFORCED, c2 INT);
```

Create a dedicated SQL pool table with a unique constraint:

```
CREATE TABLE t6 (c1 INT UNIQUE NOT ENFORCED, c2 INT);
```

Next steps

After creating the tables for your dedicated SQL pool, the next step is to load data into the table. For a loading tutorial, see Loading data to dedicated SQL pool.

Use external tables with Synapse SQL

8/19/2022 • 17 minutes to read • Edit Online

An external table points to data located in Hadoop, Azure Storage blob, or Azure Data Lake Storage. External tables are used to read data from files or write data to files in Azure Storage. With Synapse SQL, you can use external tables to read external data using dedicated SQL pool or serverless SQL pool.

Depending on the type of the external data source, you can use two types of external tables:

- Hadoop external tables that you can use to read and export data in various data formats such as CSV, Parquet, and ORC. Hadoop external tables are available in dedicated SQL pools, but they aren't available in serverless SQL pools.
- Native external tables that you can use to read and export data in various data formats such as CSV and Parquet. Native external tables are available in serverless SQL pools, and they are in **public preview** in dedicated SQL pools.

The key differences between Hadoop and native external tables are presented in the following table:

EXTERNAL TABLE TYPE	HADOOP	NATIVE
Dedicated SQL pool	Available	Only Parquet tables are available in **public preview**.
Serverless SQL pool	Not available	Available
Supported formats	Delimited/CSV, Parquet, ORC, Hive RC, and RC	Serverless SQL pool: Delimited/CSV, Parquet, and Delta Lake Dedicated SQL pool: Parquet (preview)
Folder partition elimination	No	Partition elimination is available only in the partitioned tables created on Parquet or CSV formats that are synchronized from Apache Spark pools. You might create external tables on Parquet partitioned folders, but the partitioning columns will be inaccessible and ignored, while the partition elimination will not be applied. Do not create external tables on Delta Lake folders because they are not supported. Use Delta partitioned views if you need to query partitioned Delta Lake data.
File elimination (predicate pushdown)	No	Yes in serverless SQL pool. For the string pushdown, you need to use `Latin1_General_100_BIN2_UTF8` collation on the `VARCHAR` columns to enable pushdown.
Custom format for location	No	Yes, using wildcards like `/year=*/month=*/day=*` for Parquet or CSV formats. Custom folder paths are not available in Delta Lake. In the serverless SQL pool you can also use recursive wildcards `/logs/**` to reference Parquet or CSV files in any sub-folder beneath the referenced folder.
Recursive folder scan	Yes	Yes. In serverless SQL pools must be specified `/**` at the end of the location path. In Dedicated pool the folders are alwasy scanned recursively.

EXTERNAL TABLE TYPE	HADOOP	NATIVE
Storage authentication	Storage Access Key(SAK), AAD passthrough, Managed identity, Custom application Azure AD identity	Shared Access Signature(SAS), AAD passthrough, Managed identity, Custom application Azure AD identity.
Column mapping	Ordinal - the columns in the external table definition are mapped to the columns in the underlying Parquet files by position.	Serverless pool: by name. The columns in the external table definition are mapped to the columns in the underlying Parquet files by column name matching. Dedicated pool: ordinal matching. The columns in the external table definition are mapped to the columns in the underlying Parquet files by position.

> **NOTE**
> The native external tables are the recommended solution in the pools where they are generally available. If you need to access external data, always use the native tables in serverless pools. In dedicated pools, you should switch to the native tables for reading Parquet files once they are in GA. Use the Hadoop tables only if you need to access some types that are not supported in native external tables (for example - ORC, RC), or if the native version is not available.

External tables in dedicated SQL pool and serverless SQL pool

You can use external tables to:

- Query Azure Blob Storage and Azure Data Lake Gen2 with Transact-SQL statements.
- Store query results to files in Azure Blob Storage or Azure Data Lake Storage using CETAS.
- Import data from Azure Blob Storage and Azure Data Lake Storage and store it in a dedicated SQL pool (only Hadoop tables in dedicated pool).

> **NOTE**
> When used in conjunction with the CREATE TABLE AS SELECT statement, selecting from an external table imports data into a table within the **dedicated** SQL pool.
>
> If performance of Hadoop external tables in the dedicated pools do not satisfy your performance goals, consider loading external data into the Datawarehouse tables using the COPY statement.
>
> For a loading tutorial, see Use PolyBase to load data from Azure Blob Storage.

You can create external tables in Synapse SQL pools via the following steps:

1. CREATE EXTERNAL DATA SOURCE to reference an external Azure storage and specify the credential that should be used to access the storage.
2. CREATE EXTERNAL FILE FORMAT to describe format of CSV or Parquet files.
3. CREATE EXTERNAL TABLE on top of the files placed on the data source with the same file format.

Folder partition elimination

The native external tables in Synapse pools are able to ignore the files placed in the folders that are not relevant for the queries. If your files are stored in a folder hierarchy (for example - **/year=2020/month=03/day=16**) and the values for **year**, **month**, and **day** are exposed as the columns, the queries that contain filters like `year=2020` will read the files only from the subfolders placed within the **year=2020** folder. The files and folders placed in other folders (**year=2021** or **year=2022**) will be ignored in this query. This elimination is known as **partition elimination**.

The folder partition elimination is available in the native external tables that are synchronized from the Synapse Spark pools. If you have partitioned data set and you would like to leverage the partition elimination with the external tables that you create, use the partitioned views instead of the external tables.

File elimination

Some data formats such as Parquet and Delta contain file statistics for each column (for example, min/max values for each column). The queries that filter data will not read the files where the required column values do

not exist. The query will first explore min/max values for the columns used in the query predicate to find the files that do not contain the required data. These files will be ignored and eliminated from the query plan. This technique is also known as filter predicate pushdown and it can improve the performance of your queries. Filter pushdown is available in the serverless SQL pools on Parquet and Delta formats. To leverage filter pushdown for the string types, use the VARCHAR type with the `Latin1_General_100_BIN2_UTF8` collation.

Security

User must have `SELECT` permission on an external table to read the data. External tables access underlying Azure storage using the database scoped credential defined in data source using the following rules:

- Data source without credential enables external tables to access publicly available files on Azure storage.
- Data source can have a credential that enables external tables to access only the files on Azure storage using SAS token or workspace Managed Identity - For examples, see the Develop storage files storage access control article.

CREATE EXTERNAL DATA SOURCE

External data sources are used to connect to storage accounts. The complete documentation is outlined here.

Syntax for CREATE EXTERNAL DATA SOURCE

- Hadoop
- Native

External data sources with `TYPE=HADOOP` are available only in dedicated SQL pools.

```
CREATE EXTERNAL DATA SOURCE <data_source_name>
WITH
(    LOCATION         = '<prefix>://<path>'
     [, CREDENTIAL = <database scoped credential> ]
     , TYPE = HADOOP
)
[;]
```

Arguments for CREATE EXTERNAL DATA SOURCE

data_source_name

Specifies the user-defined name for the data source. The name must be unique within the database.

Location

LOCATION = `'<prefix>://<path>'` - Provides the connectivity protocol and path to the external data source. The following patterns can be used in location:

EXTERNAL DATA SOURCE	LOCATION PREFIX	LOCATION PATH
Azure Blob Storage	`wasb[s]`	`<container>@<storage_account>.blob.core.windows.net`
Azure Blob Storage	`http[s]`	`<storage_account>.blob.core.windows.net/<container>/s`
Azure Data Lake Store Gen 1	`http[s]`	`<storage_account>.azuredatalakestore.net/webhdfs/v1`
Azure Data Lake Store Gen 2	`http[s]`	`<storage_account>.dfs.core.windows.net/<container>/su`

`https:` prefix enables you to use subfolder in the path.

Credential

CREDENTIAL = `<database scoped credential>` is optional credential that will be used to authenticate on Azure storage. External data source without credential can access public storage account or use the caller's Azure AD identity to access files on storage.

- In dedicated SQL pool, database scoped credential can specify custom application identity, workspace Managed Identity, or SAK key.
- In serverless SQL pool, database scoped credential can specify workspace Managed Identity, or SAS key.

TYPE

TYPE = `HADOOP` is the option that specifies that Java-based technology should be used to access underlying files.

This parameter can't be used in serverless SQL pool that uses built-in native reader.

Example for CREATE EXTERNAL DATA SOURCE

- Hadoop
- Native

The following example creates a Hadoop external data source in dedicated SQL pool for Azure Data Lake Gen2 pointing to the New York data set:

```
CREATE DATABASE SCOPED CREDENTIAL [ADLS_credential]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = 'sv=2018-03-28&ss=bf&srt=sco&sp=rl&st=2019-10-14T12%3A10%3A25Z&se=2061-12-
31T12%3A10%3A00Z&sig=KlSU2ullCscyTS0An0nozEpo4tO5JAgGBvw%2FJX2lguw%3D'
GO

CREATE EXTERNAL DATA SOURCE AzureDataLakeStore
WITH
  -- Please note the abfss endpoint when your account has secure transfer enabled
  ( LOCATION = 'abfss://data@newyorktaxidataset.dfs.core.windows.net' ,
    CREDENTIAL = ADLS_credential ,
    TYPE = HADOOP
  ) ;
```

The following example creates an external data source for Azure Data Lake Gen2 pointing to the publicly available New York data set:

```
CREATE EXTERNAL DATA SOURCE YellowTaxi
WITH ( LOCATION = 'https://azureopendatastorage.blob.core.windows.net/nyctlc/yellow/',
       TYPE = HADOOP)
```

CREATE EXTERNAL FILE FORMAT

Creates an external file format object that defines external data stored in Azure Blob Storage or Azure Data Lake Storage. Creating an external file format is a prerequisite for creating an external table. The complete documentation is here.

By creating an external file format, you specify the actual layout of the data referenced by an external table.

Syntax for CREATE EXTERNAL FILE FORMAT

```
-- Create an external file format for PARQUET files.
CREATE EXTERNAL FILE FORMAT file_format_name
WITH (
    FORMAT_TYPE = PARQUET
    [ , DATA_COMPRESSION = {
        'org.apache.hadoop.io.compress.SnappyCodec'
      | 'org.apache.hadoop.io.compress.GzipCodec'      }
    ]);

--Create an external file format for DELIMITED TEXT files
CREATE EXTERNAL FILE FORMAT file_format_name
WITH (
    FORMAT_TYPE = DELIMITEDTEXT
    [ , DATA_COMPRESSION = 'org.apache.hadoop.io.compress.GzipCodec' ]
    [ , FORMAT_OPTIONS ( <format_options> [ ,...n  ] ) ]
    );

<format_options> ::=
{
    FIELD_TERMINATOR = field_terminator
    | STRING_DELIMITER = string_delimiter
    | FIRST_ROW = integer
    | USE_TYPE_DEFAULT = { TRUE | FALSE }
    | ENCODING = {'UTF8' | 'UTF16'}
    | PARSER_VERSION = {'parser_version'}
}
```

Arguments for CREATE EXTERNAL FILE FORMAT

file_format_name- Specifies a name for the external file format.

FORMAT_TYPE = [PARQUET | DELIMITEDTEXT]- Specifies the format of the external data.

- PARQUET - Specifies a Parquet format.
- DELIMITEDTEXT - Specifies a text format with column delimiters, also called field terminators.

FIELD_TERMINATOR = *field_terminator* - Applies only to delimited text files. The field terminator specifies one or more characters that mark the end of each field (column) in the text-delimited file. The default is the pipe character ('|').

Examples:

- FIELD_TERMINATOR = '|'
- FIELD_TERMINATOR = ' '
- FIELD_TERMINATOR = '\t'

STRING_DELIMITER = *string_delimiter* - Specifies the field terminator for data of type string in the text-delimited file. The string delimiter is one or more characters in length and is enclosed with single quotes. The default is the empty string ("").

Examples:

- STRING_DELIMITER = '""'
- STRING_DELIMITER = '*'
- STRING_DELIMITER = ','

FIRST_ROW = *First_row_int* - Specifies the row number that is read first and applies to all files. Setting the value to two causes the first row in every file (header row) to be skipped when the data is loaded. Rows are skipped based on the existence of row terminators (/r/n, /r, /n).

USE_TYPE_DEFAULT = { TRUE | **FALSE** } - Specifies how to handle missing values in delimited text files when retrieving data from the text file.

> **NOTE**
> Please note that USE_TYPE_DEFAULT=true is not supported for FORMAT_TYPE = DELIMITEDTEXT, PARSER_VERSION = '2.0'.

TRUE - If you're retrieving data from the text file, store each missing value by using the default value's data type for the corresponding column in the external table definition. For example, replace a missing value with:

- 0 if the column is defined as a numeric column. Decimal columns aren't supported and will cause an error.
- Empty string ("") if the column is a string column.
- 1900-01-01 if the column is a date column.

FALSE - Store all missing values as NULL. Any NULL values that are stored by using the word NULL in the delimited text file are imported as the string 'NULL'.

Encoding = {'UTF8' | 'UTF16'} - Serverless SQL pool can read UTF8 and UTF16 encoded delimited text files.

DATA_COMPRESSION = *data_compression_method* - This argument specifies the data compression method for the external data.

The PARQUET file format type supports the following compression methods:

- DATA_COMPRESSION = 'org.apache.hadoop.io.compress.GzipCodec'
- DATA_COMPRESSION = 'org.apache.hadoop.io.compress.SnappyCodec'

When reading from PARQUET external tables, this argument is ignored, but is used when writing to external tables using CETAS.

The DELIMITEDTEXT file format type supports the following compression method:

- DATA_COMPRESSION = 'org.apache.hadoop.io.compress.GzipCodec'

PARSER_VERSION = 'parser_version' Specifies parser version to be used when reading CSV files. The available parser versions are `1.0` and `2.0`. This option is available only in serverless SQL pools.

Example for CREATE EXTERNAL FILE FORMAT

The following example creates an external file format for census files:

```
CREATE EXTERNAL FILE FORMAT census_file_format
WITH
(
    FORMAT_TYPE = PARQUET,
    DATA_COMPRESSION = 'org.apache.hadoop.io.compress.SnappyCodec'
)
```

CREATE EXTERNAL TABLE

The CREATE EXTERNAL TABLE command creates an external table for Synapse SQL to access data stored in Azure Blob Storage or Azure Data Lake Storage.

Syntax for CREATE EXTERNAL TABLE

```
CREATE EXTERNAL TABLE { database_name.schema_name.table_name | schema_name.table_name | table_name }
    ( <column_definition> [ ,...n ] )
    WITH (
        LOCATION = 'folder_or_filepath',
        DATA_SOURCE = external_data_source_name,
        FILE_FORMAT = external_file_format_name
        [, TABLE_OPTIONS = N'{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}' ]
        [, <reject_options> [ ,...n ] ]
    )
[;]

<column_definition> ::=
column_name <data_type>
    [ COLLATE collation_name ]

<reject_options> ::=
{
    | REJECT_TYPE = value,
    | REJECT_VALUE = reject_value,
    | REJECT_SAMPLE_VALUE = reject_sample_value,
    | REJECTED_ROW_LOCATION = '/REJECT_Directory'
}
```

Arguments CREATE EXTERNAL TABLE

{ database_name.schema_name.table_name | schema_name.table_name | table_name }

The one to three-part name of the table to create. For an external table, Synapse SQL pool stores only the table metadata. No actual data is moved or stored in Synapse SQL database.

<column_definition>, *...n*]

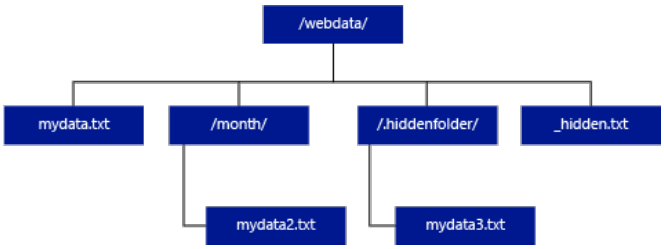
CREATE EXTERNAL TABLE supports the ability to configure column name, data type, and collation. You can't use the DEFAULT CONSTRAINT on external tables.

> **IMPORTANT**
> The column definitions, including the data types and number of columns, must match the data in the external files. If there's a mismatch, the file rows will be rejected when querying the actual data. See reject options to control rejected rows behavior.

When reading from Parquet files, you can specify only the columns you want to read and skip the rest.

LOCATION = '*folder_or_filepath*'

Specifies the folder or the file path and file name for the actual data in Azure Blob Storage. The location starts from the root folder. The root folder is the data location specified in the external data source.



Unlike Hadoop external tables, native external tables don't return subfolders unless you specify /** at the end of path. In this example, if LOCATION='/webdata/', a serverless SQL pool query, will return rows from mydata.txt. It won't return mydata2.txt and mydata3.txt because they're located in a subfolder. Hadoop tables will return all files within any sub-folder.

Both Hadoop and native external tables will skip the files with the names that begin with an underline (_) or a period (.).

DATA_SOURCE = *external_data_source_name*

Specifies the name of the external data source that contains the location of the external data. To create an external data source, use CREATE EXTERNAL DATA SOURCE.

FILE_FORMAT = *external_file_format_name*

Specifies the name of the external file format object that stores the file type and compression method for the external data. To create an external file format, use CREATE EXTERNAL FILE FORMAT.

Reject Options

> **NOTE**
> Rejected rows feature is in Public Preview. Please note that rejected rows feature works for delimited text files and PARSER_VERSION 1.0.

You can specify reject parameters that determine how service will handle *dirty* records it retrieves from the external data source. A data record is considered 'dirty' if actual data types don't match the column definitions of the external table.

When you don't specify or change reject options, service uses default values. This information about the reject parameters is stored as additional metadata when you create an external table with CREATE EXTERNAL TABLE statement. When a future SELECT statement or SELECT INTO SELECT statement selects data from the external table, service will use the reject options to determine the number of rows that can be rejected before the actual query fails. The query will return (partial) results until the reject threshold is exceeded. It then fails with the appropriate error message.

REJECT_TYPE = **value**

This is the only supported value at the moment. Clarifies that the REJECT_VALUE option is specified as a literal value.

value

REJECT_VALUE is a literal value. The query will fail when the number of rejected rows exceeds *reject_value*.

For example, if REJECT_VALUE = 5 and REJECT_TYPE = value, the SELECT query will fail after five rows have been rejected.

REJECT_VALUE = *reject_value*

Specifies the number of rows that can be rejected before the query fails.

For REJECT_TYPE = value, *reject_value* must be an integer between 0 and 2,147,483,647.

REJECTED_ROW_LOCATION = *Directory Location*

Specifies the directory within the External Data Source that the rejected rows and the corresponding error file should be written. If the specified path doesn't exist, service will create one on your behalf. A child directory is created with the name "*rejectedrows*". *The* '" character ensures that the directory is escaped for other data processing unless explicitly named in the location parameter. Within this directory, there's a folder created based

on the time of load submission in the format YearMonthDay_HourMinuteSecond_StatementID (Ex. 20180330-173205-559EE7D2-196D-400A-806D-3BF5D007F891). You can use statement id to correlate folder with query that generated it. In this folder, two files are written: error.json file and the data file.

error.json file contains json array with encountered errors related to rejected rows. Each element representing error contains following attributes:

ATTRIBUTE	DESCRIPTION
Error	Reason why row is rejected.
Row	Rejected row ordinal number in file.
Column	Rejected column ordinal number.
Value	Rejected column value. If the value is larger than 100 characters, only the first 100 characters will be displayed.
File	Path to file that row belongs to.

TABLE_OPTIONS

TABLE_OPTIONS = *json options* - Specifies the set of options that describe how to read the underlying files. Currently, the only option that is available is `"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]` that instructs the external table to ignore the updates that are made on the underlying files, even if this might cause some inconsistent read operations. Use this option only in special cases where you have frequently appended files. This option is available in serverless SQL pool for CSV format.

Permissions CREATE EXTERNAL TABLE

To select from an external table, you need proper credentials with list and read permissions.

Example CREATE EXTERNAL TABLE

The following example creates an external table. It returns the first row:

```
CREATE EXTERNAL TABLE census_external_table
(
    decennialTime varchar(20),
    stateName varchar(100),
    countyName varchar(100),
    population int,
    race varchar(50),
    sex    varchar(10),
    minAge int,
    maxAge int
)
WITH (
    LOCATION = '/parquet/',
    DATA_SOURCE = population_ds,
    FILE_FORMAT = census_file_format
)
GO

SELECT TOP 1 * FROM census_external_table
```

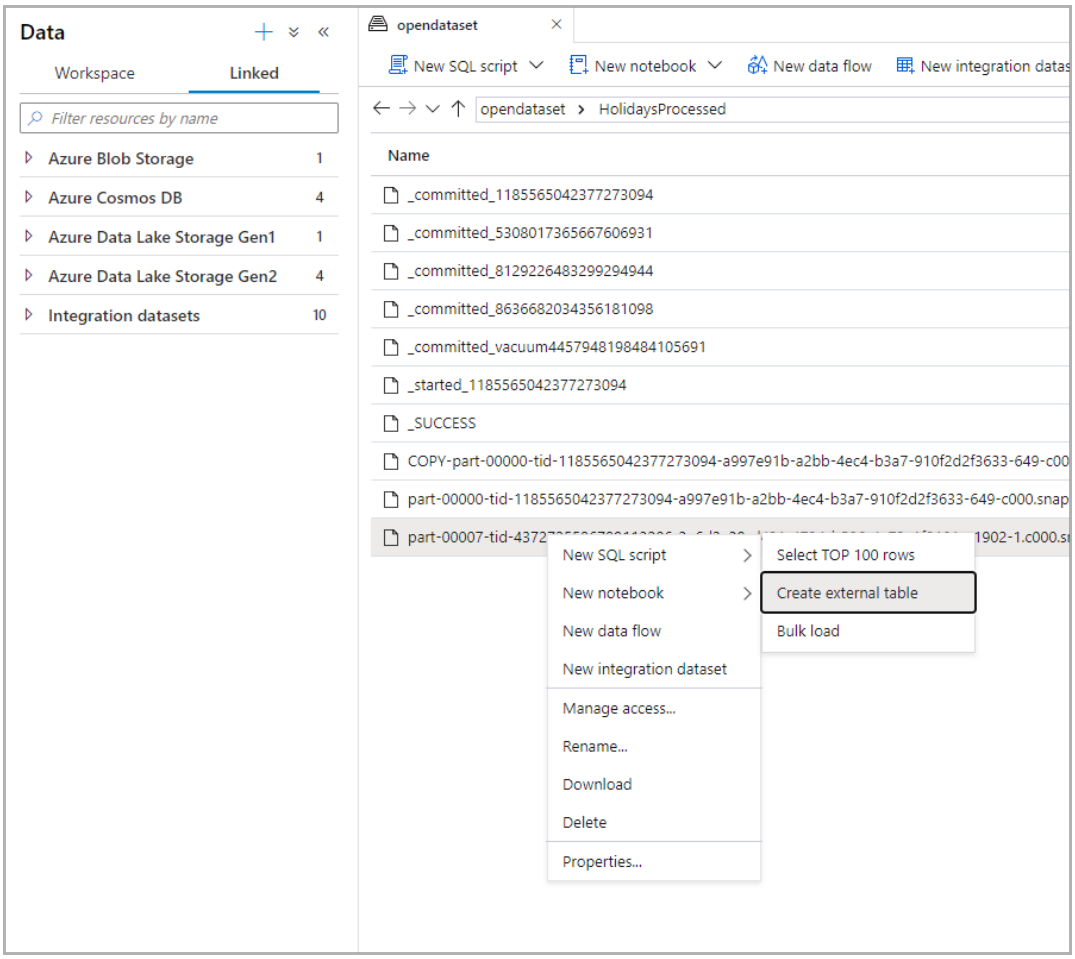
Create and query external tables from a file in Azure Data Lake

Using Data Lake exploration capabilities of Synapse Studio you can now create and query an external table using Synapse SQL pool with a simple right-click on the file. The one-click gesture to create external tables from the ADLS Gen2 storage account is only supported for Parquet files.

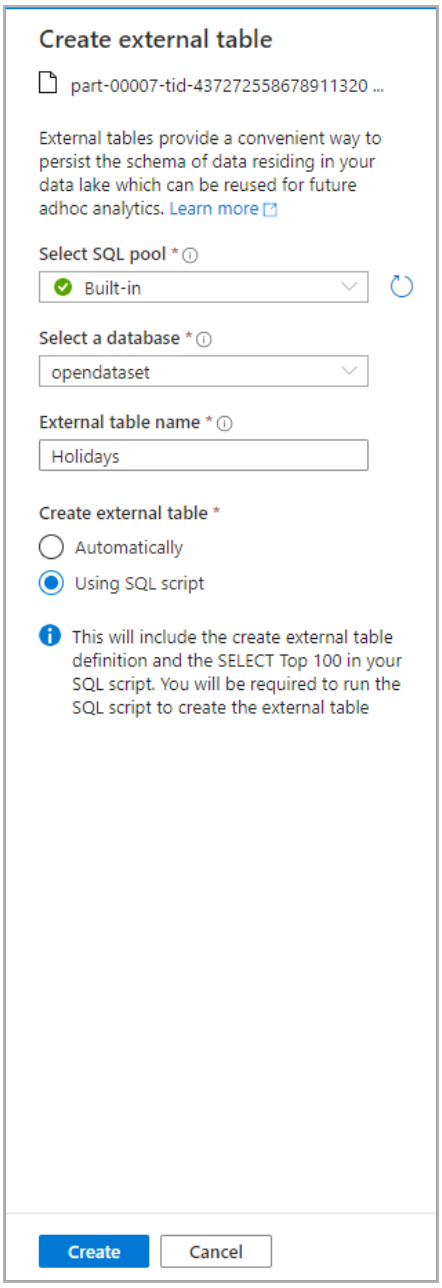
Prerequisites

- You must have access to the workspace with at least the `Storage Blob Data Contributor` access role to the ADLS Gen2 Account or Access Control Lists (ACL) that enable you to query the files.
- You must have at least permissions to create and query external tables on the Synapse SQL pool (dedicated or serverless).

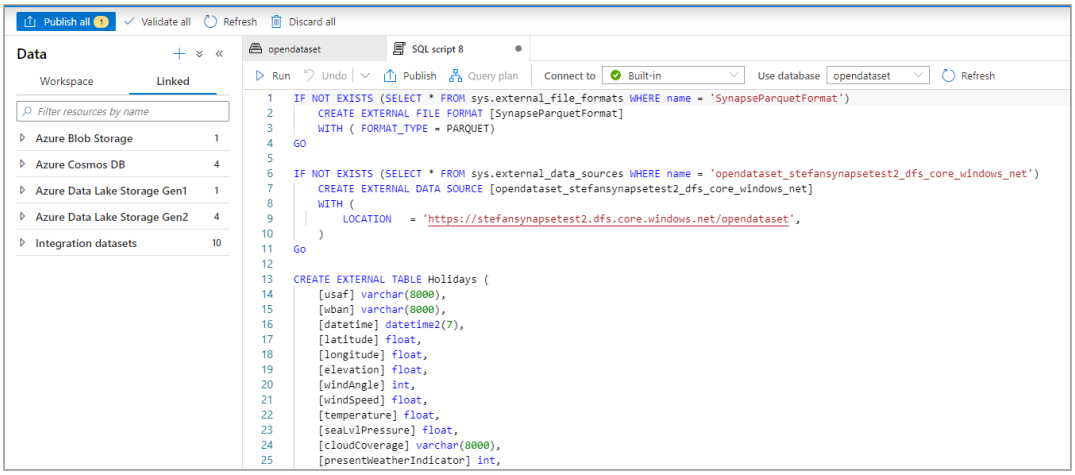
From the Data panel, select the file that you would like to create the external table from:



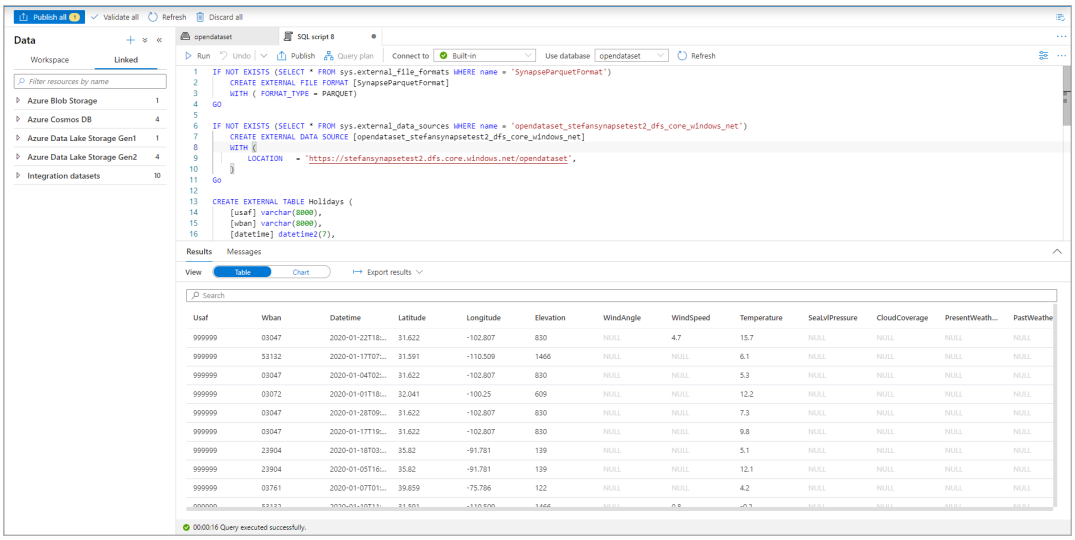
A dialog window will open. Select dedicated SQL pool or serverless SQL pool, give a name to the table and select open script:



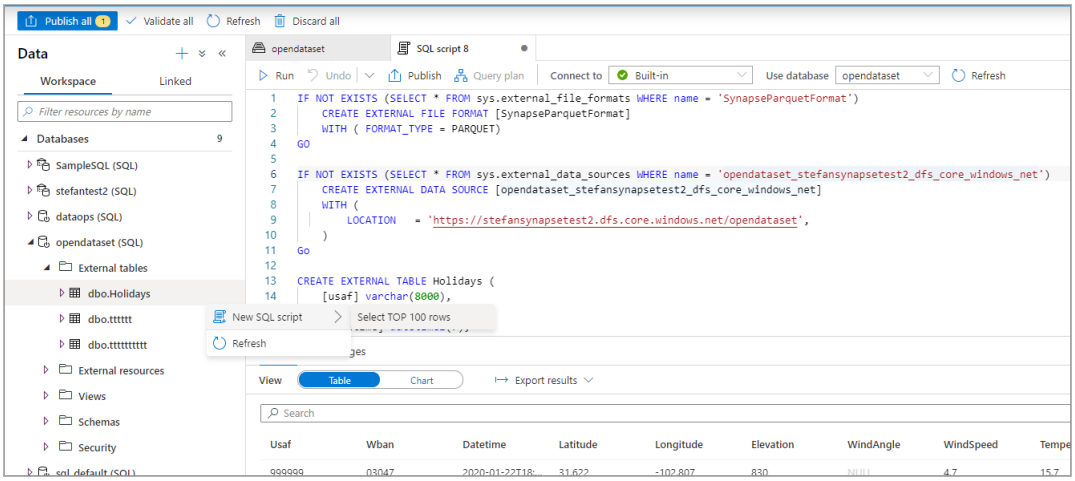
The SQL Script is autogenerated inferring the schema from the file:



Run the script. The script will automatically run a Select Top 100 *.:



The external table is now created, for future exploration of the content of this external table the user can query it directly from the Data pane:



Next steps

See the CETAS article for how to save query results to an external table in Azure Storage. Or you can start querying Apache Spark for Azure Synapse external tables.

Indexes on dedicated SQL pool tables in Azure Synapse Analytics

8/19/2022 • 14 minutes to read • Edit Online

Recommendations and examples for indexing tables in dedicated SQL pool in Azure Synapse Analytics.

Index types

Dedicated SQL pool offers several indexing options including clustered columnstore indexes, clustered indexes and nonclustered indexes, and a non-index option also known as heap.

To create a table with an index, see the CREATE TABLE (dedicated SQL pool) documentation.

Clustered columnstore indexes

By default, dedicated SQL pool creates a clustered columnstore index when no index options are specified on a table. Clustered columnstore tables offer both the highest level of data compression and the best overall query performance. Clustered columnstore tables will generally outperform clustered index or heap tables and are usually the best choice for large tables. For these reasons, clustered columnstore is the best place to start when you are unsure of how to index your table.

To create a clustered columnstore table, simply specify `CLUSTERED COLUMNSTORE INDEX` in the WITH clause, or leave the WITH clause off:

```
CREATE TABLE myTable
  (
    id int NOT NULL,
    lastName varchar(20),
    zipCode varchar(6)
  )
WITH ( CLUSTERED COLUMNSTORE INDEX );
```

There are a few scenarios where clustered columnstore may not be a good option:

- Columnstore tables do not support varchar(max), nvarchar(max), and varbinary(max). Consider heap or clustered index instead.
- Columnstore tables may be less efficient for transient data. Consider heap and perhaps even temporary tables.
- Small tables with less than 60 million rows. Consider heap tables.

Heap tables

When you are temporarily landing data in dedicated SQL pool, you may find that using a heap table makes the overall process faster. This is because loads to heaps are faster than to index tables and in some cases the subsequent read can be done from cache. If you are loading data only to stage it before running more transformations, loading the table to heap table is much faster than loading the data to a clustered columnstore table. In addition, loading data to a temporary table loads faster than loading a table to permanent storage. After data loading, you can create indexes in the table for faster query performance.

Cluster columnstore tables begin to achieve optimal compression once there is more than 60 million rows. For small lookup tables, less than 60 million rows, consider using HEAP or clustered index for faster query

performance.

To create a heap table, simply specify HEAP in the WITH clause:

```
CREATE TABLE myTable
  (
    id int NOT NULL,
    lastName varchar(20),
    zipCode varchar(6)
  )
WITH ( HEAP );
```

Clustered and nonclustered indexes

Clustered indexes may outperform clustered columnstore tables when a single row needs to be quickly retrieved. For queries where a single or very few row lookup is required to perform with extreme speed, consider a clustered index or nonclustered secondary index. The disadvantage to using a clustered index is that only queries that benefit are the ones that use a highly selective filter on the clustered index column. To improve filter on other columns, a nonclustered index can be added to other columns. However, each index that is added to a table adds both space and processing time to loads.

To create a clustered index table, simply specify CLUSTERED INDEX in the WITH clause:

```
CREATE TABLE myTable
  (
    id int NOT NULL,
    lastName varchar(20),
    zipCode varchar(6)
  )
WITH ( CLUSTERED INDEX (id) );
```

To add a non-clustered index on a table, use the following syntax:

```
CREATE INDEX zipCodeIndex ON myTable (zipCode);
```

Optimizing clustered columnstore indexes

Clustered columnstore tables organize data into segments. Having high segment quality is critical to achieving optimal query performance on a columnstore table. Segment quality can be measured by the number of rows in a compressed row group. Segment quality is most optimal where there are at least 100 K rows per compressed row group and gain in performance as the number of rows per row group approach 1,048,576 rows, which is the most rows a row group can contain.

The below view can be created and used on your system to compute the average rows per row group and identify any suboptimal cluster columnstore indexes. The last column on this view generates a SQL statement that can be used to rebuild your indexes.

```
CREATE VIEW dbo.vColumnstoreDensity
AS
SELECT
        GETDATE()                                                                   AS [execution_date]
,       DB_Name()                                                                   AS [database_name]
,       s.name                                                                      AS [schema_name]
,       t.name                                                                      AS [table_name]
,    COUNT(DISTINCT rg.[partition_number])                    AS [table_partition_count]
,       SUM(rg.[total_rows])                                                        AS [row_count_total]
,       SUM(rg.[total_rows])/COUNT(DISTINCT rg.[distribution_id])                   AS
[row_count_per_distribution_MAX]
,    CEILING    ((SUM(rg.[total_rows])*1.0/COUNT(DISTINCT rg.[distribution_id]))/1048576) AS
[rowgroup_per_distribution_MAX]
,       SUM(CASE WHEN rg.[State] = 0 THEN 1                   ELSE 0    END)    AS
[INVISIBLE_rowgroup_count]
,       SUM(CASE WHEN rg.[State] = 0 THEN rg.[total_rows]     ELSE 0    END)    AS [INVISIBLE_rowgroup_rows]
,       MIN(CASE WHEN rg.[State] = 0 THEN rg.[total_rows]     ELSE NULL END)    AS
[INVISIBLE_rowgroup_rows_MIN]
,       MAX(CASE WHEN rg.[State] = 0 THEN rg.[total_rows]     ELSE NULL END)    AS
[INVISIBLE_rowgroup_rows_MAX]
,       AVG(CASE WHEN rg.[State] = 0 THEN rg.[total_rows]     ELSE NULL END)    AS
[INVISIBLE_rowgroup_rows_AVG]
,       SUM(CASE WHEN rg.[State] = 1 THEN 1                   ELSE 0    END)    AS [OPEN_rowgroup_count]
,       SUM(CASE WHEN rg.[State] = 1 THEN rg.[total_rows]     ELSE 0    END)    AS [OPEN_rowgroup_rows]
,       MIN(CASE WHEN rg.[State] = 1 THEN rg.[total_rows]     ELSE NULL END)    AS [OPEN_rowgroup_rows_MIN]
,       MAX(CASE WHEN rg.[State] = 1 THEN rg.[total_rows]     ELSE NULL END)    AS [OPEN_rowgroup_rows_MAX]
,       AVG(CASE WHEN rg.[State] = 1 THEN rg.[total_rows]     ELSE NULL END)    AS [OPEN_rowgroup_rows_AVG]
,       SUM(CASE WHEN rg.[State] = 2 THEN 1                   ELSE 0    END)    AS [CLOSED_rowgroup_count]
,       SUM(CASE WHEN rg.[State] = 2 THEN rg.[total_rows]     ELSE 0    END)    AS [CLOSED_rowgroup_rows]
,       MIN(CASE WHEN rg.[State] = 2 THEN rg.[total_rows]     ELSE NULL END)    AS
[CLOSED_rowgroup_rows_MIN]
,       MAX(CASE WHEN rg.[State] = 2 THEN rg.[total_rows]     ELSE NULL END)    AS
[CLOSED_rowgroup_rows_MAX]
,       AVG(CASE WHEN rg.[State] = 2 THEN rg.[total_rows]     ELSE NULL END)    AS
[CLOSED_rowgroup_rows_AVG]
,       SUM(CASE WHEN rg.[State] = 3 THEN 1                   ELSE 0    END)    AS
[COMPRESSED_rowgroup_count]
,       SUM(CASE WHEN rg.[State] = 3 THEN rg.[total_rows]     ELSE 0    END)    AS
[COMPRESSED_rowgroup_rows]
,       SUM(CASE WHEN rg.[State] = 3 THEN rg.[deleted_rows]   ELSE 0    END)    AS
[COMPRESSED_rowgroup_rows_DELETED]
,       MIN(CASE WHEN rg.[State] = 3 THEN rg.[total_rows]     ELSE NULL END)    AS
[COMPRESSED_rowgroup_rows_MIN]
,       MAX(CASE WHEN rg.[State] = 3 THEN rg.[total_rows]     ELSE NULL END)    AS
[COMPRESSED_rowgroup_rows_MAX]
,       AVG(CASE WHEN rg.[State] = 3 THEN rg.[total_rows]     ELSE NULL END)    AS
[COMPRESSED_rowgroup_rows_AVG]
,       'ALTER INDEX ALL ON ' + s.name + '.' + t.NAME + ' REBUILD;'               AS [Rebuild_Index_SQL]
FROM    sys.[pdw_nodes_column_store_row_groups] rg
JOIN    sys.[pdw_nodes_tables] nt                   ON  rg.[object_id]          = nt.[object_id]
                                                    AND rg.[pdw_node_id]        = nt.[pdw_node_id]
                                                    AND rg.[distribution_id]    = nt.[distribution_id]
JOIN    sys.[pdw_table_mappings] mp                 ON  nt.[name]               = mp.[physical_name]
JOIN    sys.[tables] t                              ON  mp.[object_id]          = t.[object_id]
JOIN    sys.[schemas] s                             ON t.[schema_id]            = s.[schema_id]
GROUP BY
        s.[name]
,       t.[name];
```

Now that you have created the view, run this query to identify tables with row groups with less than 100 K rows. You may want to increase the threshold of 100 K if you are looking for more optimal segment quality.

```
SELECT    *
FROM    [dbo].[vColumnstoreDensity]
WHERE    COMPRESSED_rowgroup_rows_AVG < 100000
        OR INVISIBLE_rowgroup_rows_AVG < 100000;
```

Once you have run the query, you can begin to look at the data and analyze your results. This table explains what to look for in your row group analysis.

COLUMN	HOW TO USE THIS DATA
[table_partition_count]	If the table is partitioned, then you may expect to see higher Open row group counts. Each partition in the distribution could in theory have an open row group associated with it. Factor this into your analysis. A small table that has been partitioned could be optimized by removing the partitioning altogether as this would improve compression.
[row_count_total]	Total row count for the table. For example, you can use this value to calculate percentage of rows in the compressed state.
[row_count_per_distribution_MAX]	If all rows are evenly distributed this value would be the target number of rows per distribution. Compare this value with the compressed_rowgroup_count.
[COMPRESSED_rowgroup_rows]	Total number of rows in columnstore format for the table.
[COMPRESSED_rowgroup_rows_AVG]	If the average number of rows is significantly less than the maximum # of rows for a row group, then consider using CTAS or ALTER INDEX REBUILD to recompress the data
[COMPRESSED_rowgroup_count]	Number of row groups in columnstore format. If this number is very high in relation to the table, it is an indicator that the columnstore density is low.
[COMPRESSED_rowgroup_rows_DELETED]	Rows are logically deleted in columnstore format. If the number is high relative to table size, consider recreating the partition or rebuilding the index as this removes them physically.
[COMPRESSED_rowgroup_rows_MIN]	Use this with the AVG and MAX columns to understand the range of values for the row groups in your columnstore. A low number over the load threshold (102,400 per partition aligned distribution) suggests that optimizations are available in the data load
[COMPRESSED_rowgroup_rows_MAX]	As above
[OPEN_rowgroup_count]	Open row groups are normal. One would reasonably expect one OPEN row group per table distribution (60). Excessive numbers suggest data loading across partitions. Double check the partitioning strategy to make sure it is sound
[OPEN_rowgroup_rows]	Each row group can have 1,048,576 rows in it as a maximum. Use this value to see how full the open row groups are currently

COLUMN	HOW TO USE THIS DATA
[OPEN_rowgroup_rows_MIN]	Open groups indicate that data is either being trickle loaded into the table or that the previous load spilled over remaining rows into this row group. Use the MIN, MAX, AVG columns to see how much data is sat in OPEN row groups. For small tables, it could be 100% of all the data! In which case ALTER INDEX REBUILD to force the data to columnstore.
[OPEN_rowgroup_rows_MAX]	As above
[OPEN_rowgroup_rows_AVG]	As above
[CLOSED_rowgroup_rows]	Look at the closed row group rows as a sanity check.
[CLOSED_rowgroup_count]	The number of closed row groups should be low if any are seen at all. Closed row groups can be converted to compressed row groups using the ALTER INDEX ... REORGANIZE command. However, this is not normally required. Closed groups are automatically converted to columnstore row groups by the background "tuple mover" process.
[CLOSED_rowgroup_rows_MIN]	Closed row groups should have a very high fill rate. If the fill rate for a closed row group is low, then further analysis of the columnstore is required.
[CLOSED_rowgroup_rows_MAX]	As above
[CLOSED_rowgroup_rows_AVG]	As above
[Rebuild_Index_SQL]	SQL to rebuild columnstore index for a table

Impact of index maintenance

The column `Rebuild_Index_SQL` in the `vColumnstoreDensity` view contains an `ALTER INDEX REBUILD` statement that can be used to rebuild your indexes. When rebuilding your indexes, be sure that you allocate enough memory to the session that rebuilds your index. To do this, increase the resource class of a user that has permissions to rebuild the index on this table to the recommended minimum. For an example, see Rebuilding indexes to improve segment quality later in this article.

For a table with an ordered clustered columnstore index, `ALTER INDEX REBUILD` will re-sort the data using tempdb. Monitor tempdb during rebuild operations. If you need more tempdb space, scale up the database pool. Scale back down once the index rebuild is complete.

For a table with an ordered clustered columnstore index, `ALTER INDEX REORGANIZE` does not re-sort the data. To re-sort data, use `ALTER INDEX REBUILD`.

For more information on ordered clustered columnstore indexes, see Performance tuning with ordered clustered columnstore index.

Causes of poor columnstore index quality

If you have identified tables with poor segment quality, you want to identify the root cause. Below are some other common causes of poor segment quality:

1. Memory pressure when index was built
2. High volume of DML operations
3. Small or trickle load operations
4. Too many partitions

These factors can cause a columnstore index to have significantly less than the optimal 1 million rows per row group. They can also cause rows to go to the delta row group instead of a compressed row group.

Memory pressure when index was built

The number of rows per compressed row group are directly related to the width of the row and the amount of memory available to process the row group. When rows are written to columnstore tables under memory pressure, columnstore segment quality may suffer. Therefore, the best practice is to give the session that is writing to your columnstore index tables access to as much memory as possible. Since there is a trade-off between memory and concurrency, the guidance on the right memory allocation depends on the data in each row of your table, the data warehouse units allocated to your system, and the number of concurrency slots you can give to the session that is writing data to your table.

High volume of DML operations

A high volume of DML operations that update and delete rows can introduce inefficiency into the columnstore. This is especially true when most the rows in a row group are modified.

- Deleting a row from a compressed row group only logically marks the row as deleted. The row remains in the compressed row group until the partition or table is rebuilt.
- Inserting a row adds the row to an internal rowstore table called a delta row group. The inserted row is not converted to columnstore until the delta row group is full and is marked as closed. Row groups are closed once they reach the maximum capacity of 1,048,576 rows.
- Updating a row in columnstore format is processed as a logical delete and then an insert. The inserted row may be stored in the delta store.

Batched update and insert operations that exceed the bulk threshold of 102,400 rows per partition-aligned distribution go directly to the columnstore format. However, assuming an even distribution, you would need to be modifying more than 6.144 million rows in a single operation for this to occur. If the number of rows for a given partition-aligned distribution is less than 102,400, the rows go to the delta store and stay there until sufficient rows have been inserted or modified to close the row group or the index has been rebuilt.

Small or trickle load operations

Small loads that flow into dedicated SQL pool are also sometimes known as trickle loads. They typically represent a near constant stream of data being ingested by the system. However, as this stream is near continuous the volume of rows is not particularly large. More often than not the data is significantly under the threshold required for a direct load to columnstore format.

In these situations, it is often better to land the data first in Azure blob storage and let it accumulate prior to loading. This technique is often known as *micro-batching*.

Too many partitions

Another thing to consider is the impact of partitioning on your clustered columnstore tables. Before partitioning, dedicated SQL pool already divides your data into 60 databases. Partitioning further divides your data. If you partition your data, then consider that **each** partition needs at least 1 million rows to benefit from a clustered columnstore index. If you partition your table into 100 partitions, then your table needs at least 6 billion rows to benefit from a clustered columnstore index (60 distributions *100 partitions* 1 million rows). If your 100-partition table does not have 6 billion rows, either reduce the number of partitions or consider using a heap table instead.

Once your tables have been loaded with some data, follow the below steps to identify and rebuild tables with sub-optimal clustered columnstore indexes.

Rebuild indexes to improve segment quality

Step 1: Identify or create user which uses the right resource class

One quick way to immediately improve segment quality is to rebuild the index. The SQL returned by the above view contains an ALTER INDEX REBUILD statement, which can be used to rebuild your indexes. When rebuilding your indexes, be sure that you allocate enough memory to the session that rebuilds your index. To do this, increase the resource class of a user that has permissions to rebuild the index on this table to the recommended minimum.

Below is an example of how to allocate more memory to a user by increasing their resource class. To work with resource classes, see Resource classes for workload management.

```
EXEC sp_addrolemember 'xlargerc', 'LoadUser';
```

Step 2: Rebuild clustered columnstore indexes with higher resource class user

Sign in as the user from step 1 (`LoadUser`), which is now using a higher resource class, and execute the ALTER INDEX statements. Be sure that this user has ALTER permission to the tables where the index is being rebuilt. These examples show how to rebuild the entire columnstore index or how to rebuild a single partition. On large tables, it is more practical to rebuild indexes a single partition at a time.

Alternatively, instead of rebuilding the index, you could copy the table to a new table using CTAS. Which way is best? For large volumes of data, CTAS is usually faster than ALTER INDEX. For smaller volumes of data, ALTER INDEX is easier to use and won't require you to swap out the table.

```
-- Rebuild the entire clustered index
ALTER INDEX ALL ON [dbo].[DimProduct] REBUILD;
```

```
-- Rebuild a single partition
ALTER INDEX ALL ON [dbo].[FactInternetSales] REBUILD Partition = 5;
```

```
-- Rebuild a single partition with archival compression
ALTER INDEX ALL ON [dbo].[FactInternetSales] REBUILD Partition = 5 WITH (DATA_COMPRESSION =
COLUMNSTORE_ARCHIVE);
```

```
-- Rebuild a single partition with columnstore compression
ALTER INDEX ALL ON [dbo].[FactInternetSales] REBUILD Partition = 5 WITH (DATA_COMPRESSION = COLUMNSTORE);
```

Rebuilding an index in dedicated SQL pool is an offline operation. For more information about rebuilding indexes, see the ALTER INDEX REBUILD section in Columnstore Indexes Defragmentation, and ALTER INDEX.

Step 3: Verify clustered columnstore segment quality has improved

Rerun the query which identified table with poor segment quality and verify segment quality has improved. If segment quality did not improve, it could be that the rows in your table are extra wide. Consider using a higher resource class or DWU when rebuilding your indexes.

Rebuild indexes with CTAS and partition switching

This example uses the CREATE TABLE AS SELECT (CTAS) statement and partition switching to rebuild a table partition.

```
-- Step 1: Select the partition of data and write it out to a new table using CTAS
CREATE TABLE [dbo].[FactInternetSales_20000101_20010101]
    WITH    (   DISTRIBUTION = HASH([ProductKey])
            ,   CLUSTERED COLUMNSTORE INDEX
            ,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                                (20000101,20010101
                                )
                            )
            )
AS
SELECT  *
FROM    [dbo].[FactInternetSales]
WHERE   [OrderDateKey] >= 20000101
AND     [OrderDateKey] <  20010101
;

-- Step 2: Switch IN the rebuilt data with TRUNCATE_TARGET option
ALTER TABLE [dbo].[FactInternetSales_20000101_20010101] SWITCH PARTITION 2 TO  [dbo].[FactInternetSales]
PARTITION 2 WITH (TRUNCATE_TARGET = ON);
```

For more information about re-creating partitions using CTAS, see Using partitions in dedicated SQL pool.

Using IDENTITY to create surrogate keys using dedicated SQL pool in AzureSynapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

In this article, you'll find recommendations and examples for using the IDENTITY property to create surrogate keys on tables in dedicated SQL pool.

What is a surrogate key

A surrogate key on a table is a column with a unique identifier for each row. The key is not generated from the table data. Data modelers like to create surrogate keys on their tables when they design data warehouse models. You can use the IDENTITY property to achieve this goal simply and effectively without affecting load performance.

> **NOTE**
>
> In Azure Synapse Analytics, the IDENTITY value increases on its own in each distribution and does not overlap with IDENTITY values in other distributions. The IDENTITY value in Synapse is not guaranteed to be unique if the user explicitly inserts a duplicate value with "SET IDENTITY_INSERT ON" or reseeds IDENTITY. For details, see CREATE TABLE (Transact-SQL) IDENTITY (Property).

Creating a table with an IDENTITY column

The IDENTITY property is designed to scale out across all the distributions in the dedicated SQL pool without affecting load performance. Therefore, the implementation of IDENTITY is oriented toward achieving these goals.

You can define a table as having the IDENTITY property when you first create the table by using syntax that is similar to the following statement:

```
CREATE TABLE dbo.T1
(    C1 INT IDENTITY(1,1) NOT NULL
,    C2 INT NULL
)
WITH
(   DISTRIBUTION = HASH(C2)
,   CLUSTERED COLUMNSTORE INDEX
)
;
```

You can then use `INSERT..SELECT` to populate the table.

This remainder of this section highlights the nuances of the implementation to help you understand them more fully.

Allocation of values

The IDENTITY property doesn't guarantee the order in which the surrogate values are allocated due to the distributed architecture of the data warehouse. The IDENTITY property is designed to scale out across all the distributions in the dedicated SQL pool without affecting load performance.

The following example is an illustration:

```
CREATE TABLE dbo.T1
(    C1 INT IDENTITY(1,1)    NOT NULL
,    C2 VARCHAR(30)                NULL
)
WITH
(   DISTRIBUTION = HASH(C2)
,   CLUSTERED COLUMNSTORE INDEX
)
;

INSERT INTO dbo.T1
VALUES (NULL);

INSERT INTO dbo.T1
VALUES (NULL);

SELECT *
FROM dbo.T1;

DBCC PDW_SHOWSPACEUSED('dbo.T1');
```

In the preceding example, two rows landed in distribution 1. The first row has the surrogate value of 1 in column `C1`, and the second row has the surrogate value of 61. Both of these values were generated by the IDENTITY property. However, the allocation of the values is not contiguous. This behavior is by design.

Skewed data

The range of values for the data type are spread evenly across the distributions. If a distributed table suffers from skewed data, then the range of values available to the datatype can be exhausted prematurely. For example, if all the data ends up in a single distribution, then effectively the table has access to only one-sixtieth of the values of the data type. For this reason, the IDENTITY property is limited to `INT` and `BIGINT` data types only.

SELECT..INTO

When an existing IDENTITY column is selected into a new table, the new column inherits the IDENTITY property, unless one of the following conditions is true:

- The SELECT statement contains a join.
- Multiple SELECT statements are joined by using UNION.
- The IDENTITY column is listed more than one time in the SELECT list.
- The IDENTITY column is part of an expression.

If any one of these conditions is true, the column is created NOT NULL instead of inheriting the IDENTITY property.

CREATE TABLE AS SELECT

CREATE TABLE AS SELECT (CTAS) follows the same SQL Server behavior that's documented for SELECT..INTO. However, you can't specify an IDENTITY property in the column definition of the `CREATE TABLE` part of the statement. You also can't use the IDENTITY function in the `SELECT` part of the CTAS. To populate a table, you need to use `CREATE TABLE` to define the table followed by `INSERT..SELECT` to populate it.

Explicitly inserting values into an IDENTITY column

Dedicated SQL pool supports `SET IDENTITY_INSERT <your table> ON|OFF` syntax. You can use this syntax to explicitly insert values into the IDENTITY column.

Many data modelers like to use predefined negative values for certain rows in their dimensions. An example is the -1 or "unknown member" row.

The next script shows how to explicitly add this row by using SET IDENTITY_INSERT:

```
SET IDENTITY_INSERT dbo.T1 ON;

INSERT INTO dbo.T1
(   C1
,   C2
)
VALUES (-1,'UNKNOWN')
;

SET IDENTITY_INSERT dbo.T1 OFF;

SELECT     *
FROM    dbo.T1
;
```

Loading data

The presence of the IDENTITY property has some implications to your data-loading code. This section highlights some basic patterns for loading data into tables by using IDENTITY.

To load data into a table and generate a surrogate key by using IDENTITY, create the table and then use INSERT..SELECT or INSERT..VALUES to perform the load.

The following example highlights the basic pattern:

```
--CREATE TABLE with IDENTITY
CREATE TABLE dbo.T1
(    C1 INT IDENTITY(1,1)
,    C2 VARCHAR(30)
)
WITH
(   DISTRIBUTION = HASH(C2)
,   CLUSTERED COLUMNSTORE INDEX
)
;

--Use INSERT..SELECT to populate the table from an external table
INSERT INTO dbo.T1
(C2)
SELECT     C2
FROM    ext.T1
;

SELECT *
FROM   dbo.T1
;

DBCC PDW_SHOWSPACEUSED('dbo.T1');
```

> **NOTE**
>
> It's not possible to use `CREATE TABLE AS SELECT` currently when loading data into a table with an IDENTITY column.

For more information on loading data, see Designing Extract, Load, and Transform (ELT) for dedicated SQL pool and Loading best practices.

System views

You can use the sys.identity_columns catalog view to identify a column that has the IDENTITY property.

To help you better understand the database schema, this example shows how to integrate sys.identity_column` with other system catalog views:

```
SELECT  sm.name
,       tb.name
,       co.name
,       CASE WHEN ic.column_id IS NOT NULL
             THEN 1
        ELSE 0
        END AS is_identity
FROM        sys.schemas AS sm
JOIN        sys.tables  AS tb           ON  sm.schema_id = tb.schema_id
JOIN        sys.columns AS co           ON  tb.object_id = co.object_id
LEFT JOIN   sys.identity_columns AS ic  ON  co.object_id = ic.object_id
                                        AND co.column_id = ic.column_id
WHERE   sm.name = 'dbo'
AND     tb.name = 'T1'
;
```

Limitations

The IDENTITY property can't be used:

- When the column data type is not INT or BIGINT
- When the column is also the distribution key
- When the table is an external table

The following related functions are not supported in dedicated SQL pool:

- IDENTITY()
- @@IDENTITY
- SCOPE_IDENTITY
- IDENT_CURRENT
- IDENT_INCR
- IDENT_SEED

Common tasks

This section provides some sample code you can use to perform common tasks when you work with IDENTITY columns.

Column C1 is the IDENTITY in all the following tasks.

Find the highest allocated value for a table

Use the `MAX()` function to determine the highest value allocated for a distributed table:

```
SELECT MAX(C1)
FROM dbo.T1
```

Find the seed and increment for the IDENTITY property

You can use the catalog views to discover the identity increment and seed configuration values for a table by using the following query:

```
SELECT  sm.name
,       tb.name
,       co.name
,       ic.seed_value
,       ic.increment_value
FROM        sys.schemas AS sm
JOIN        sys.tables  AS tb           ON  sm.schema_id = tb.schema_id
JOIN        sys.columns AS co           ON  tb.object_id = co.object_id
JOIN        sys.identity_columns AS ic  ON  co.object_id = ic.object_id
                                        AND co.column_id = ic.column_id
WHERE   sm.name = 'dbo'
AND     tb.name = 'T1'
;
```

How to use OPENROWSET using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 17 minutes to read • Edit Online

The `OPENROWSET(BULK...)` function allows you to access files in Azure Storage. `OPENROWSET` function reads content of a remote data source (for example file) and returns the content as a set of rows. Within the serverless SQL pool resource, the OPENROWSET bulk rowset provider is accessed by calling the OPENROWSET function and specifying the BULK option.

The `OPENROWSET` function can be referenced in the `FROM` clause of a query as if it were a table name `OPENROWSET`. It supports bulk operations through a built-in BULK provider that enables data from a file to be read and returned as a rowset.

> **NOTE**
> The OPENROWSET function is not supported in dedicated SQL pool.

Data source

OPENROWSET function in Synapse SQL reads the content of the file(s) from a data source. The data source is an Azure storage account and it can be explicitly referenced in the `OPENROWSET` function or can be dynamically inferred from URL of the files that you want to read. The `OPENROWSET` function can optionally contain a `DATA_SOURCE` parameter to specify the data source that contains files.

- `OPENROWSET` without `DATA_SOURCE` can be used to directly read the contents of the files from the URL location specified as `BULK` option:

```
SELECT *
FROM OPENROWSET(BULK 'http://<storage account>.dfs.core.windows.net/container/folder/*.parquet',
                FORMAT = 'PARQUET') AS [file]
```

This is a quick and easy way to read the content of the files without pre-configuration. This option enables you to use the basic authentication option to access the storage (Azure AD passthrough for Azure AD logins and SAS token for SQL logins).

- `OPENROWSET` with `DATA_SOURCE` can be used to access files on specified storage account:

```
SELECT *
FROM OPENROWSET(BULK '/folder/*.parquet',
                DATA_SOURCE='storage', --> Root URL is in LOCATION of DATA SOURCE
                FORMAT = 'PARQUET') AS [file]
```

  This option enables you to configure location of the storage account in the data source and specify the authentication method that should be used to access storage.

> **IMPORTANT**
>
> `OPENROWSET` without `DATA_SOURCE` provides quick and easy way to access the storage files but offers limited authentication options. As an example, Azure AD principals can access files only using their Azure AD identity or publicly available files. If you need more powerful authentication options, use `DATA_SOURCE` option and define credential that you want to use to access storage.

Security

A database user must have `ADMINISTER BULK OPERATIONS` permission to use the `OPENROWSET` function.

The storage administrator must also enable a user to access the files by providing valid SAS token or enabling Azure AD principal to access storage files. Learn more about storage access control in this article.

`OPENROWSET` use the following rules to determine how to authenticate to storage:

- In `OPENROWSET` without `DATA_SOURCE` authentication mechanism depends on caller type.
  - Any user can use `OPENROWSET` without `DATA_SOURCE` to read publicly available files on Azure storage.
  - Azure AD logins can access protected files using their own Azure AD identity if Azure storage allows the Azure AD user to access underlying files (for example, if the caller has `Storage Reader` permission on Azure storage).
  - SQL logins can also use `OPENROWSET` without `DATA_SOURCE` to access publicly available files, files protected using SAS token, or Managed Identity of Synapse workspace. You would need to create server-scoped credential to allow access to storage files.
- In `OPENROWSET` with `DATA_SOURCE` authentication mechanism is defined in database scoped credential assigned to the referenced data source. This option enables you to access publicly available storage, or access storage using SAS token, Managed Identity of workspace, or Azure AD identity of caller (if caller is Azure AD principal). If `DATA_SOURCE` references Azure storage that isn't public, you would need to create database-scoped credential and reference it in `DATA SOURCE` to allow access to storage files.

Caller must have `REFERENCES` permission on credential to use it to authenticate to storage.

Syntax

```
--OPENROWSET syntax for reading Parquet or Delta Lake (preview) files
OPENROWSET
( { BULK 'unstructured_data_path' , [DATA_SOURCE = <data source name>, ]
    FORMAT= ['PARQUET' | 'DELTA'] }
)
[WITH ({'column_name' 'column_type' }) ]
[AS] table_alias(column_alias,...n)

--OPENROWSET syntax for reading delimited text files
OPENROWSET
( { BULK 'unstructured_data_path' , [DATA_SOURCE = <data source name>, ]
    FORMAT = 'CSV'
    [ <bulk_options> ]
    [ , <reject_options> ] }
)
WITH ({'column_name' 'column_type' [ 'column_ordinal' | 'json_path'] })
[AS] table_alias(column_alias,...n)

<bulk_options> ::=
[ , FIELDTERMINATOR = 'char' ]
[ , ROWTERMINATOR = 'char' ]
[ , ESCAPECHAR = 'char' ]
[ , FIRSTROW = 'first_row' ]
[ , FIELDQUOTE = 'quote_characters' ]
[ , DATA_COMPRESSION = 'data_compression_method' ]
[ , PARSER_VERSION = 'parser_version' ]
[ , HEADER_ROW = { TRUE | FALSE } ]
[ , DATAFILETYPE = { 'char' | 'widechar' } ]
[ , CODEPAGE = { 'ACP' | 'OEM' | 'RAW' | 'code_page' } ]
[ , ROWSET_OPTIONS = '{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}' ]

<reject_options> ::=
{
    | MAXERRORS = reject_value,
    | ERRORFILE_DATA_SOURCE = <data source name>,
    | ERRORFILE_LOCATION = '/REJECT_Directory'
}
```

Arguments

You have two choices for input files that contain the target data for querying. Valid values are:

- 'CSV' - Includes any delimited text file with row/column separators. Any character can be used as a field separator, such as TSV: FIELDTERMINATOR = tab.
- 'PARQUET' - Binary file in Parquet format
- 'DELTA' - A set of Parquet files organized in Delta Lake (preview) format

'unstructured_data_path'

The unstructured_data_path that establishes a path to the data may be an absolute or relative path:

- Absolute path in the format `\<prefix>://\<storage_account_path>/\<storage_path>` enables a user to directly read the files.
- Relative path in the format `<storage_path>` that must be used with the `DATA_SOURCE` parameter and describes the file pattern within the <storage_account_path> location defined in `EXTERNAL DATA SOURCE`.

Below you'll find the relevant <storage account path> values that will link to your particular external data source.

EXTERNAL DATA SOURCE	PREFIX	STORAGE ACCOUNT PATH
Azure Blob Storage	http[s]	<storage_account>.blob.core.windows.net/path/file
Azure Blob Storage	wasb[s]	<container>@<storage_account>.blob.core.windows.net/path/file
Azure Data Lake Store Gen1	http[s]	<storage_account>.azuredatalakestore.net/webhdfs/v1
Azure Data Lake Store Gen2	http[s]	<storage_account>.dfs.core.windows.net /path/file
Azure Data Lake Store Gen2	abfs[s]	<file_system>@<account_name>.dfs.core.windows.net/path/file

'<storage_path>'

Specifies a path within your storage that points to the folder or file you want to read. If the path points to a container or folder, all files will be read from that particular container or folder. Files in subfolders won't be included.

You can use wildcards to target multiple files or folders. Usage of multiple nonconsecutive wildcards is allowed. Below is an example that reads all *csv* files starting with *population* from all folders starting with */csv/population*:

```
https://sqlondemandstorage.blob.core.windows.net/csv/population*/population*.csv
```

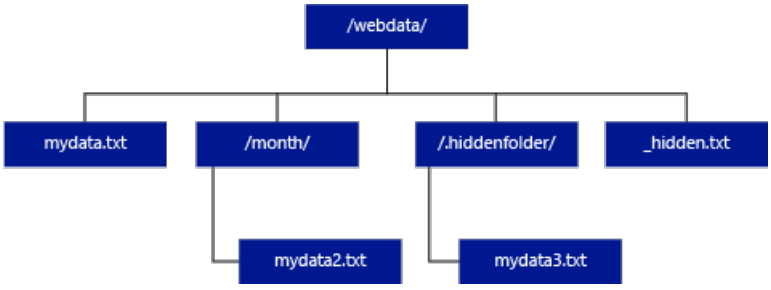
If you specify the unstructured_data_path to be a folder, a serverless SQL pool query will retrieve files from that folder.

You can instruct serverless SQL pool to traverse folders by specifying /* at the end of path as in example:

```
https://sqlondemandstorage.blob.core.windows.net/csv/population/**
```

> **NOTE**
> Unlike Hadoop and PolyBase, serverless SQL pool doesn't return subfolders unless you specify /** at the end of path. Just like Hadoop and PolyBase, it doesn't return files for which the file name begins with an underline (_) or a period (.).

In the example below, if the unstructured_data_path= `https://mystorageaccount.dfs.core.windows.net/webdata/`, a serverless SQL pool query will return rows from mydata.txt. It won't return mydata2.txt and mydata3.txt because they're located in a subfolder.



```
[WITH ({'column_name' 'column_type' [ 'column_ordinal'] }) ]
```

The WITH clause allows you to specify columns that you want to read from files.

- For CSV data files, to read all the columns, provide column names and their data types. If you want a subset of columns, use ordinal numbers to pick the columns from the originating data files by ordinal. Columns will be bound by the ordinal designation. If HEADER_ROW = TRUE is used, then column binding is done by column name instead of ordinal position.

  > **TIP**
  > You can omit WITH clause for CSV files also. Data types will be automatically inferred from file content. You can use HEADER_ROW argument to specify existence of header row in which case column names will be read from header row. For details check automatic schema discovery.

- For Parquet or Delta Lake files, provide column names that match the column names in the originating data files. Columns will be bound by name and is case-sensitive. If the WITH clause is omitted, all columns from Parquet files will be returned.

  > **IMPORTANT**
  > Column names in Parquet and Delta Lake files are case sensitive. If you specify column name with casing different from column name casing in the files, the `NULL` values will be returned for that column.

column_name = Name for the output column. If provided, this name overrides the column name in the source file and column name provided in JSON path if there is one. If json_path is not provided, it will be automatically added as '$.column_name'. Check json_path argument for behavior.

column_type = Data type for the output column. The implicit data type conversion will take place here.

column_ordinal = Ordinal number of the column in the source file(s). This argument is ignored for Parquet files since binding is done by name. The following example would return a second column only from a CSV file:

```
WITH (
    --[country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2 2
    --[year] smallint,
    --[population] bigint
)
```

json_path = JSON path expression to column or nested property. Default path mode is lax.

> **NOTE**
> In strict mode query will fail with error if provided path does not exist. In lax mode query will succeed and JSON path expression will evaluate to NULL.

<bulk_options>

FIELDTERMINATOR='field_terminator'

Specifies the field terminator to be used. The default field terminator is a comma (",").

ROWTERMINATOR='row_terminator'`

Specifies the row terminator to be used. If row terminator is not specified, one of default terminators will be used. Default terminators for PARSER_VERSION = '1.0' are \r\n, \n and \r. Default terminators for PARSER_VERSION = '2.0' are \r\n and \n.

> **NOTE**
> When you use PARSER_VERSION='1.0' and specify \n (newline) as the row terminator, it will be automatically prefixed with a \r (carriage return) character, which results in a row terminator of \r\n.

ESCAPE_CHAR = 'char'

Specifies the character in the file that is used to escape itself and all delimiter values in the file. If the escape character is followed by a value other than itself, or any of the delimiter values, the escape character is dropped when reading the value.

The ESCAPECHAR parameter will be applied regardless of whether the FIELDQUOTE is or isn't enabled. It won't be used to escape the quoting character. The quoting character must be escaped with another quoting character. Quoting character can appear within column value only if value is encapsulated with quoting characters.

FIRSTROW = 'first_row'

Specifies the number of the first row to load. The default is 1 and indicates the first row in the specified data file. The row numbers are determined by counting the row terminators. FIRSTROW is 1-based.

FIELDQUOTE = 'field_quote'

Specifies a character that will be used as the quote character in the CSV file. If not specified, the quote character (") will be used.

DATA_COMPRESSION = 'data_compression_method'

Specifies compression method. Supported in PARSER_VERSION='1.0' only. Following compression method is supported:

- GZIP

PARSER_VERSION = 'parser_version'

Specifies parser version to be used when reading files. Currently supported CSV parser versions are 1.0 and 2.0:

- PARSER_VERSION = '1.0'
- PARSER_VERSION = '2.0'

CSV parser version 1.0 is default and feature rich. Version 2.0 is built for performance and does not support all options and encodings.

CSV parser version 1.0 specifics:

- Following options aren't supported: HEADER_ROW.
- Default terminators are \r\n, \n and \r.
- If you specify \n (newline) as the row terminator, it will be automatically prefixed with a \r (carriage return) character, which results in a row terminator of \r\n.

CSV parser version 2.0 specifics:

- Not all data types are supported.
- Maximum character column length is 8000.
- Maximum row size limit is 8 MB.
- Following options aren't supported: DATA_COMPRESSION.
- Quoted empty string ("") is interpreted as empty string.
- DATEFORMAT SET option is not honored.
- Supported format for DATE data type: YYYY-MM-DD

- Supported format for TIME data type: HH:MM:SS[.fractional seconds]
- Supported format for DATETIME2 data type: YYYY-MM-DD HH:MM:SS[.fractional seconds]
- Default terminators are \r\n and \n.

HEADER_ROW = { TRUE | FALSE }

Specifies whether a CSV file contains header row. Default is `FALSE`. Supported in PARSER_VERSION='2.0'. If TRUE, the column names will be read from the first row according to FIRSTROW argument. If TRUE and schema is specified using WITH, binding of column names will be done by column name, not ordinal positions.

DATAFILETYPE = { 'char' | 'widechar' }

Specifies encoding: `char` is used for UTF8, `widechar` is used for UTF16 files.

CODEPAGE = { 'ACP' | 'OEM' | 'RAW' | 'code_page' }

Specifies the code page of the data in the data file. The default value is 65001 (UTF-8 encoding). See more details about this option here.

ROWSET_OPTIONS = '{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}'

This option will disable the file modification check during the query execution, and read the files that are updated while the query is running. This is useful option when you need to read append-only files that are appended while the query is running. In the appendable files, the existing content is not updated, and only new rows are added. Therefore, the probability of wrong results is minimized compared to the updateable files. This option might enable you to read the frequently appended files without handling the errors. See more information in querying appendable CSV files section.

Reject Options

> **NOTE**
> Rejected rows feature is in Public Preview. Please note that rejected rows feature works for delimited text files and PARSER_VERSION 1.0.

You can specify reject parameters that determine how service will handle *dirty* records it retrieves from the external data source. A data record is considered 'dirty' if actual data types don't match the column definitions of the external table.

When you don't specify or change reject options, service uses default values. Service will use the reject options to determine the number of rows that can be rejected before the actual query fails. The query will return (partial) results until the reject threshold is exceeded. It then fails with the appropriate error message.

MAXERRORS = *reject_value*

Specifies the number of rows that can be rejected before the query fails. MAXERRORS must be an integer between 0 and 2,147,483,647.

ERRORFILE_DATA_SOURCE = *data source*

Specifies data source where rejected rows and the corresponding error file should be written.

ERRORFILE_LOCATION = *Directory Location*

Specifies the directory within the DATA_SOURCE, or ERROR_FILE_DATASOURCE if specified, that the rejected rows and the corresponding error file should be written. If the specified path doesn't exist, service will create one on your behalf. A child directory is created with the name "*rejectedrows". The* '" character ensures that the directory is escaped for other data processing unless explicitly named in the location parameter. Within this

directory, there's a folder created based on the time of load submission in the format YearMonthDay_HourMinuteSecond_StatementID (Ex. 20180330-173205-559EE7D2-196D-400A-806D-3BF5D007F891). You can use statement id to correlate folder with query that generated it. In this folder, two files are written: error.json file and the data file.

error.json file contains json array with encountered errors related to rejected rows. Each element representing error contains following attributes:

ATTRIBUTE	DESCRIPTION
Error	Reason why row is rejected.
Row	Rejected row ordinal number in file.
Column	Rejected column ordinal number.
Value	Rejected column value. If the value is larger than 100 characters, only the first 100 characters will be displayed.
File	Path to file that row belongs to.

Fast delimited text parsing

There are two delimited text parser versions you can use. CSV parser version 1.0 is default and feature rich while parser version 2.0 is built for performance. Performance improvement in parser 2.0 comes from advanced parsing techniques and multi-threading. Difference in speed will be bigger as the file size grows.

Automatic schema discovery

You can easily query both CSV and Parquet files without knowing or specifying schema by omitting WITH clause. Column names and data types will be inferred from files.

Parquet files contain column metadata, which will be read, type mappings can be found in type mappings for Parquet. Check reading Parquet files without specifying schema for samples.

For the CSV files, column names can be read from header row. You can specify whether header row exists using HEADER_ROW argument. If HEADER_ROW = FALSE, generic column names will be used: C1, C2, ... Cn where n is number of columns in file. Data types will be inferred from first 100 data rows. Check reading CSV files without specifying schema for samples.

> **IMPORTANT**
> There are cases when appropriate data type cannot be inferred due to lack of information and larger data type will be used instead. This brings performance overhead and is particularly important for character columns which will be inferred as varchar(8000). For optimal performance, please check inferred data types and use appropriate data types.

Type mapping for Parquet

Parquet and Delta Lake files contain type descriptions for every column. The following table describes how Parquet types are mapped to SQL native types.

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
BOOLEAN		bit

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
BINARY / BYTE_ARRAY		varbinary
DOUBLE		float
FLOAT		real
INT32		int
INT64		bigint
INT96		datetime2
FIXED_LEN_BYTE_ARRAY		binary
BINARY	UTF8	varchar *(UTF8 collation)
BINARY	STRING	varchar *(UTF8 collation)
BINARY	ENUM	varchar *(UTF8 collation)
FIXED_LEN_BYTE_ARRAY	UUID	uniqueidentifier
BINARY	DECIMAL	decimal
BINARY	JSON	varchar(8000) *(UTF8 collation)
BINARY	BSON	Not supported
FIXED_LEN_BYTE_ARRAY	DECIMAL	decimal
BYTE_ARRAY	INTERVAL	Not supported
INT32	INT(8, true)	smallint
INT32	INT(16, true)	smallint
INT32	INT(32, true)	int
INT32	INT(8, false)	tinyint
INT32	INT(16, false)	int
INT32	INT(32, false)	bigint
INT32	DATE	date
INT32	DECIMAL	decimal
INT32	TIME (MILLIS)	time

PARQUET TYPE	PARQUET LOGICAL TYPE (ANNOTATION)	SQL DATA TYPE
INT64	INT(64, true)	bigint
INT64	INT(64, false)	decimal(20,0)
INT64	DECIMAL	decimal
INT64	TIME (MICROS)	time
INT64	TIME (NANOS)	Not supported
INT64	TIMESTAMP (normalized to utc) (MILLIS / MICROS)	datetime2
INT64	TIMESTAMP (not normalized to utc) (MILLIS / MICROS)	bigint - make sure that you explicitly adjust `bigint` value with the timezone offset before converting it to a datetime value.
INT64	TIMESTAMP (NANOS)	Not supported
Complex type	LIST	varchar(8000), serialized into JSON
Complex type	MAP	varchar(8000), serialized into JSON

Examples

Read CSV files without specifying schema

The following example reads CSV file that contains header row without specifying column names and data types:

```
SELECT
    *
FROM OPENROWSET(
    BULK 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.csv',
    FORMAT = 'CSV',
    PARSER_VERSION = '2.0',
    HEADER_ROW = TRUE) as [r]
```

The following example reads CSV file that doesn't contain header row without specifying column names and data types:

```
SELECT
    *
FROM OPENROWSET(
    BULK 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.csv',
    FORMAT = 'CSV',
    PARSER_VERSION = '2.0') as [r]
```

Read Parquet files without specifying schema

The following example returns all columns of the first row from the census data set, in Parquet format, and

without specifying column names and data types:

```
SELECT
    TOP 1 *
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet',
        FORMAT='PARQUET'
    ) AS [r]
```

Read Delta Lake files without specifying schema

The following example returns all columns of the first row from the census data set, in Delta Lake format, and without specifying column names and data types:

```
SELECT
    TOP 1 *
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet',
        FORMAT='DELTA'
    ) AS [r]
```

Read specific columns from CSV file

The following example returns only two columns with ordinal numbers 1 and 4 from the population*.csv files. Since there's no header row in the files, it starts reading from the first line:

```
SELECT
    *
FROM OPENROWSET(
        BULK 'https://sqlondemandstorage.blob.core.windows.net/csv/population/population*.csv',
        FORMAT = 'CSV',
        FIRSTROW = 1
    )
WITH (
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2 1,
    [population] bigint 4
) AS [r]
```

Read specific columns from Parquet file

The following example returns only two columns of the first row from the census data set, in Parquet format:

```
SELECT
    TOP 1 *
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet',
        FORMAT='PARQUET'
    )
WITH (
    [stateName] VARCHAR (50),
    [population] bigint
) AS [r]
```

Specify columns using JSON paths

The following example shows how you can use JSON path expressions in WITH clause and demonstrates difference between strict and lax path modes:

```
SELECT
    TOP 1 *
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet',
        FORMAT='PARQUET'
    )
WITH (
    --lax path mode samples
    [stateName] VARCHAR (50), -- this one works as column name casing is valid - it targets the same column
as the next one
    [stateName_explicit_path] VARCHAR (50) '$.stateName', -- this one works as column name casing is valid
    [COUNTYNAME] VARCHAR (50), -- STATEname column will contain NULLs only because of wrong casing - it
targets the same column as the next one
    [countyName_explicit_path] VARCHAR (50) '$.COUNTYNAME', -- STATEname column will contain NULLS only
because of wrong casing and default path mode being lax

    --strict path mode samples
    [population] bigint 'strict $.population' -- this one works as column name casing is valid
    --,[population2] bigint 'strict $.POPULATION' -- this one fails because of wrong casing and strict path
mode
)
AS [r]
```

Specify multiple files/folders in BULK path

The following example shows how you can use multiple file/folder paths in BULK parameter:

```
SELECT
    TOP 10 *
FROM
    OPENROWSET(
        BULK (

'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
00/*.parquet',

'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
10/*.parquet',
        ),
        FORMAT='PARQUET'
    )
AS [r]
```

Next steps

For more samples, see the query data storage quickstart to learn how to use `OPENROWSET` to read CSV, PARQUET, DELTA LAKE, and JSON file formats. Check best practices for achieving optimal performance. You can also learn how to save the results of your query to Azure Storage using CETAS.

Partitioning tables in dedicated SQL pool

8/19/2022 • 11 minutes to read • Edit Online

Recommendations and examples for using table partitions in dedicated SQL pool.

What are table partitions?

Table partitions enable you to divide your data into smaller groups of data. In most cases, table partitions are created on a date column. Partitioning is supported on all dedicated SQL pool table types; including clustered columnstore, clustered index, and heap. Partitioning is also supported on all distribution types, including both hash or round robin distributed.

Partitioning can benefit data maintenance and query performance. Whether it benefits both or just one is dependent on how data is loaded and whether the same column can be used for both purposes, since partitioning can only be done on one column.

Benefits to loads

The primary benefit of partitioning in dedicated SQL pool is to improve the efficiency and performance of loading data by use of partition deletion, switching and merging. In most cases data is partitioned on a date column that is closely tied to the order in which the data is loaded into the SQL pool. One of the greatest benefits of using partitions to maintain data is the avoidance of transaction logging. While simply inserting, updating, or deleting data can be the most straightforward approach, with a little thought and effort, using partitioning during your load process can substantially improve performance.

Partition switching can be used to quickly remove or replace a section of a table. For example, a sales fact table might contain just data for the past 36 months. At the end of every month, the oldest month of sales data is deleted from the table. This data could be deleted by using a delete statement to delete the data for the oldest month.

However, deleting a large amount of data row-by-row with a delete statement can take too much time, as well as create the risk of large transactions that take a long time to rollback if something goes wrong. A more optimal approach is to drop the oldest partition of data. Where deleting the individual rows could take hours, deleting an entire partition could take seconds.

Benefits to queries

Partitioning can also be used to improve query performance. A query that applies a filter to partitioned data can limit the scan to only the qualifying partitions. This method of filtering can avoid a full table scan and only scan a smaller subset of data. With the introduction of clustered columnstore indexes, the predicate elimination performance benefits are less beneficial, but in some cases there can be a benefit to queries.

For example, if the sales fact table is partitioned into 36 months using the sales date field, then queries that filter on the sale date can skip searching in partitions that don't match the filter.

Partition sizing

While partitioning can be used to improve performance some scenarios, creating a table with **too many** partitions can hurt performance under some circumstances. These concerns are especially true for clustered columnstore tables.

For partitioning to be helpful, it is important to understand when to use partitioning and the number of partitions to create. There is no hard fast rule as to how many partitions are too many, it depends on your data

and how many partitions you are loading simultaneously. A successful partitioning scheme usually has tens to hundreds of partitions, not thousands.

When creating partitions on **clustered columnstore** tables, it is important to consider how many rows belong to each partition. For optimal compression and performance of clustered columnstore tables, a minimum of 1 million rows per distribution and partition is needed. Before partitions are created, dedicated SQL pool already divides each table into 60 distributions.

Any partitioning added to a table is in addition to the distributions created behind the scenes. Using this example, if the sales fact table contained 36 monthly partitions, and given that a dedicated SQL pool has 60 distributions, then the sales fact table should contain 60 million rows per month, or 2.1 billion rows when all months are populated. If a table contains fewer than the recommended minimum number of rows per partition, consider using fewer partitions in order to increase the number of rows per partition.

For more information, see the Indexing article, which includes queries that can assess the quality of cluster columnstore indexes.

Syntax differences from SQL Server

Dedicated SQL pool introduces a way to define partitions that is simpler than SQL Server. Partitioning functions and schemes are not used in dedicated SQL pool as they are in SQL Server. Instead, all you need to do is identify partitioned column and the boundary points.

While the syntax of partitioning may be slightly different from SQL Server, the basic concepts are the same. SQL Server and dedicated SQL pool support one partition column per table, which can be ranged partition. To learn more about partitioning, see Partitioned Tables and Indexes.

The following example uses the CREATE TABLE statement to partition the `FactInternetSales` table on the `OrderDateKey` column:

```
CREATE TABLE [dbo].[FactInternetSales]
(
    [ProductKey]            int          NOT NULL
,   [OrderDateKey]          int          NOT NULL
,   [CustomerKey]           int          NOT NULL
,   [PromotionKey]          int          NOT NULL
,   [SalesOrderNumber]      nvarchar(20) NOT NULL
,   [OrderQuantity]         smallint     NOT NULL
,   [UnitPrice]             money        NOT NULL
,   [SalesAmount]           money        NOT NULL
)
WITH
(   CLUSTERED COLUMNSTORE INDEX
,   DISTRIBUTION = HASH([ProductKey])
,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                    (20000101,20010101,20020101
                    ,20030101,20040101,20050101
                    )
                )
);
```

Migrate partitions from SQL Server

To migrate SQL Server partition definitions to dedicated SQL pool simply:

- Eliminate the SQL Server partition scheme.
- Add the partition function definition to your CREATE TABLE.

If you are migrating a partitioned table from a SQL Server instance, the following SQL can help you to figure out

the number of rows in each partition. Keep in mind that if the same partitioning granularity is used in dedicated SQL pool, the number of rows per partition decreases by a factor of 60.

```
-- Partition information for a SQL Server Database
SELECT      s.[name]                        AS      [schema_name]
,           t.[name]                        AS      [table_name]
,           i.[name]                        AS      [index_name]
,           p.[partition_number]            AS      [partition_number]
,           SUM(a.[used_pages]*8.0)         AS      [partition_size_kb]
,           SUM(a.[used_pages]*8.0)/1024    AS      [partition_size_mb]
,           SUM(a.[used_pages]*8.0)/1048576 AS      [partition_size_gb]
,           p.[rows]                        AS      [partition_row_count]
,           rv.[value]                      AS      [partition_boundary_value]
,           p.[data_compression_desc]       AS      [partition_compression_desc]
FROM        sys.schemas s
JOIN        sys.tables t                    ON      t.[schema_id]         = s.[schema_id]
JOIN        sys.partitions p                ON      p.[object_id]         = t.[object_id]
JOIN        sys.allocation_units a          ON      a.[container_id]      = p.[partition_id]
JOIN        sys.indexes i                   ON      i.[object_id]         = p.[object_id]
                                            AND     i.[index_id]          = p.[index_id]
JOIN        sys.data_spaces ds              ON      ds.[data_space_id]    = i.[data_space_id]
LEFT JOIN   sys.partition_schemes ps        ON      ps.[data_space_id]    = ds.[data_space_id]
LEFT JOIN   sys.partition_functions pf      ON      pf.[function_id]      = ps.[function_id]
LEFT JOIN   sys.partition_range_values rv   ON      rv.[function_id]      = pf.[function_id]
                                            AND     rv.[boundary_id]      = p.[partition_number]
WHERE       p.[index_id] <=1
GROUP BY    s.[name]
,           t.[name]
,           i.[name]
,           p.[partition_number]
,           p.[rows]
,           rv.[value]
,           p.[data_compression_desc];
```

Partition switching

Dedicated SQL pool supports partition splitting, merging, and switching. Each of these functions is executed using the ALTER TABLE statement.

To switch partitions between two tables, you must ensure that the partitions align on their respective boundaries and that the table definitions match. As check constraints are not available to enforce the range of values in a table, the source table must contain the same partition boundaries as the target table. If the partition boundaries are not the same, then the partition switch will fail as the partition metadata will not be synchronized.

A partition split requires the respective partition (not necessarily the whole table) to be empty if the table has a clustered columnstore index (CCI). Other partitions in the same table can contain data. A partition that contains data cannot be split, it will result in error:

```
ALTER PARTITION statement failed because the partition is not empty. Only empty partitions can be split in
when a columnstore index exists on the table. Consider disabling the columnstore index before issuing the
ALTER PARTITION statement, then rebuilding the columnstore index after ALTER PARTITION is complete.
```

As a workaround to split a partition containing data, see How to split a partition that contains data.

How to split a partition that contains data

The most efficient method to split a partition that already contains data is to use a `CTAS` statement. If the partitioned table is a clustered columnstore, then the table partition must be empty before it can be split.

The following example creates a partitioned columnstore table. It inserts one row into each partition:

```
CREATE TABLE [dbo].[FactInternetSales]
(
        [ProductKey]            int          NOT NULL
    ,   [OrderDateKey]          int          NOT NULL
    ,   [CustomerKey]           int          NOT NULL
    ,   [PromotionKey]          int          NOT NULL
    ,   [SalesOrderNumber]      nvarchar(20) NOT NULL
    ,   [OrderQuantity]         smallint     NOT NULL
    ,   [UnitPrice]             money        NOT NULL
    ,   [SalesAmount]           money        NOT NULL
)
WITH
(   CLUSTERED COLUMNSTORE INDEX
,   DISTRIBUTION = HASH([ProductKey])
,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                    (20000101
                    )
                )
);

INSERT INTO dbo.FactInternetSales
VALUES (1,19990101,1,1,1,1,1,1);

INSERT INTO dbo.FactInternetSales
VALUES (1,20000101,1,1,1,1,1,1);
```

The following query finds the row count by using the `sys.partitions` catalog view:

```
SELECT  QUOTENAME(s.[name])+'.'+QUOTENAME(t.[name]) as Table_name
,       i.[name] as Index_name
,       p.partition_number as Partition_nmbr
,       p.[rows] as Row_count
,       p.[data_compression_desc] as Data_Compression_desc
FROM    sys.partitions p
JOIN    sys.tables     t    ON    p.[object_id]   = t.[object_id]
JOIN    sys.schemas    s    ON    t.[schema_id]   = s.[schema_id]
JOIN    sys.indexes    i    ON    p.[object_id]   = i.[object_Id]
                            AND   p.[index_Id]    = i.[index_Id]
WHERE t.[name] = 'FactInternetSales';
```

The following split command receives an error message:

```
ALTER TABLE FactInternetSales SPLIT RANGE (20010101);
```

```
Msg 35346, Level 15, State 1, Line 44
SPLIT clause of ALTER PARTITION statement failed because the partition is not empty. Only empty partitions
can be split in when a columnstore index exists on the table. Consider disabling the columnstore index
before issuing the ALTER PARTITION statement, then rebuilding the columnstore index after ALTER PARTITION is
complete.
```

However, you can use `CTAS` to create a new table to hold the data.

```
CREATE TABLE dbo.FactInternetSales_20000101
    WITH    (   DISTRIBUTION = HASH(ProductKey)
            ,   CLUSTERED COLUMNSTORE INDEX
            ,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                                (20000101
                                )
                            )
)
AS
SELECT *
FROM    FactInternetSales
WHERE   1=2;
```

As the partition boundaries are aligned, a switch is permitted. This will leave the source table with an empty partition that you can subsequently split.

```
ALTER TABLE FactInternetSales SWITCH PARTITION 2 TO FactInternetSales_20000101 PARTITION 2;

ALTER TABLE FactInternetSales SPLIT RANGE (20010101);
```

All that is left is to align the data to the new partition boundaries using `CTAS`, and then switch the data back into the main table.

```
CREATE TABLE [dbo].[FactInternetSales_20000101_20010101]
    WITH    (   DISTRIBUTION = HASH([ProductKey])
            ,   CLUSTERED COLUMNSTORE INDEX
            ,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                                (20000101,20010101
                                )
                            )
            )
AS
SELECT  *
FROM    [dbo].[FactInternetSales_20000101]
WHERE   [OrderDateKey] >= 20000101
AND     [OrderDateKey] <  20010101;

ALTER TABLE dbo.FactInternetSales_20000101_20010101 SWITCH PARTITION 2 TO dbo.FactInternetSales PARTITION 2;
```

Once you have completed the movement of the data, it is a good idea to refresh the statistics on the target table. Updating statistics ensures the statistics accurately reflect the new distribution of the data in their respective partitions.

```
UPDATE STATISTICS [dbo].[FactInternetSales];
```

Finally, in the case of a one-time partition switch to move data, you could drop the tables created for the partition switch, `FactInternetSales_20000101_20010101` and `FactInternetSales_20000101`. Alternatively, you may want to keep empty tables for regular, automated partition switches.

Load new data into partitions that contain data in one step

Loading data into partitions with partition switching is a convenient way to stage new data in a table that is not visible to users. It can be challenging on busy systems to deal with the locking contention associated with partition switching.

To clear out the existing data in a partition, an `ALTER TABLE` used to be required to switch out the data. Then another `ALTER TABLE` was required to switch in the new data.

In dedicated SQL pool, the `TRUNCATE_TARGET` option is supported in the `ALTER TABLE` command. With `TRUNCATE_TARGET` the `ALTER TABLE` command overwrites existing data in the partition with new data. Below is an example that uses `CTAS` to create a new table with the existing data, inserts new data, then switches all the data back into the target table, overwriting the existing data.

```
CREATE TABLE [dbo].[FactInternetSales_NewSales]
    WITH    (   DISTRIBUTION = HASH([ProductKey])
            ,   CLUSTERED COLUMNSTORE INDEX
            ,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES
                                (20000101,20010101
                                )
                            )
            )
AS
SELECT  *
FROM    [dbo].[FactInternetSales]
WHERE   [OrderDateKey] >= 20000101
AND     [OrderDateKey] <  20010101
;

INSERT INTO dbo.FactInternetSales_NewSales
VALUES (1,20000101,2,2,2,2,2,2);

ALTER TABLE dbo.FactInternetSales_NewSales SWITCH PARTITION 2 TO dbo.FactInternetSales PARTITION 2 WITH
(TRUNCATE_TARGET = ON);
```

Table partitioning source control

> **NOTE**
> If your source control tool is not configured to ignore partition schemas, altering a table's schema to update partitions may cause a table to be dropped and recreated as part of the deployment, which may be unfeasible. A custom solution to implement such a change, as described below, may be necessary. Check that your continuous integration/continuous deployment (CI/CD) tool allows for this. In SQL Server Data Tools (SSDT), look for the Advanced Publish Settings "Ignore partition schemes" to avoid a generated script that cause a table to be dropped and recreated.

This example is useful when updating partition schemas of an empty table. To continuously deploy partition changes on a table with data, follow the steps in How to split a partition that contains data alongside deployment to temporarily move data out of each partition before applying the partition SPLIT RANGE. This is necessary since the CI/CD tool isn't aware of which partitions have data.

To avoid your table definition from **rusting** in your source control system, you may want to consider the following approach:

1. Create the table as a partitioned table but with no partition values

```
CREATE TABLE [dbo].[FactInternetSales]
(
    [ProductKey]            int          NOT NULL
,   [OrderDateKey]          int          NOT NULL
,   [CustomerKey]           int          NOT NULL
,   [PromotionKey]          int          NOT NULL
,   [SalesOrderNumber]      nvarchar(20) NOT NULL
,   [OrderQuantity]         smallint     NOT NULL
,   [UnitPrice]             money        NOT NULL
,   [SalesAmount]           money        NOT NULL
)
WITH
(   CLUSTERED COLUMNSTORE INDEX
,   DISTRIBUTION = HASH([ProductKey])
,   PARTITION   (   [OrderDateKey] RANGE RIGHT FOR VALUES () )
);
```

2. `SPLIT` the table as part of the deployment process:

```
 -- Create a table containing the partition boundaries

CREATE TABLE #partitions
WITH
(
    LOCATION = USER_DB
,   DISTRIBUTION = HASH(ptn_no)
)
AS
SELECT  ptn_no
,       ROW_NUMBER() OVER (ORDER BY (ptn_no)) as seq_no
FROM    (
    SELECT CAST(20000101 AS INT) ptn_no
    UNION ALL
    SELECT CAST(20010101 AS INT)
    UNION ALL
    SELECT CAST(20020101 AS INT)
    UNION ALL
    SELECT CAST(20030101 AS INT)
    UNION ALL
    SELECT CAST(20040101 AS INT)
) a;

 -- Iterate over the partition boundaries and split the table

DECLARE @c INT = (SELECT COUNT(*) FROM #partitions)
,       @i INT = 1                              --iterator for while loop
,       @q NVARCHAR(4000)                       --query
,       @p NVARCHAR(20)     = N''               --partition_number
,       @s NVARCHAR(128)    = N'dbo'            --schema
,       @t NVARCHAR(128)    = N'FactInternetSales' --table;

WHILE @i <= @c
BEGIN
    SET @p = (SELECT ptn_no FROM #partitions WHERE seq_no = @i);
    SET @q = (SELECT N'ALTER TABLE '+@s+N'.'+@t+N' SPLIT RANGE ('+@p+N');');

    -- PRINT @q;
    EXECUTE sp_executesql @q;
    SET @i+=1;
END

 -- Code clean-up

DROP TABLE #partitions;
```

With this approach, the code in source control remains static and the partitioning boundary values are allowed to be dynamic; evolving with the SQL pool over time.

For more information about developing tables, see the articles on Table Overview.

Design guidance for using replicated tables in Synapse SQL pool

8/19/2022 • 7 minutes to read • Edit Online

This article gives recommendations for designing replicated tables in your Synapse SQL pool schema. Use these recommendations to improve query performance by reducing data movement and query complexity.

Prerequisites

This article assumes you are familiar with data distribution and data movement concepts in SQL pool. For more information, see the architecture article.

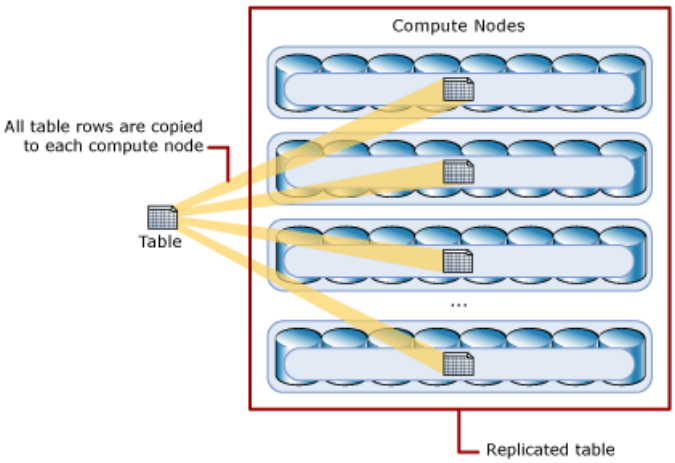
As part of table design, understand as much as possible about your data and how the data is queried. For example, consider these questions:

- How large is the table?
- How often is the table refreshed?
- Do I have fact and dimension tables in a SQL pool?

What is a replicated table?

A replicated table has a full copy of the table accessible on each Compute node. Replicating a table removes the need to transfer data among Compute nodes before a join or aggregation. Since the table has multiple copies, replicated tables work best when the table size is less than 2 GB compressed. 2 GB is not a hard limit. If the data is static and does not change, you can replicate larger tables.

The following diagram shows a replicated table that is accessible on each Compute node. In SQL pool, the replicated table is fully copied to a distribution database on each compute node.



Replicated tables work well for dimension tables in a star schema. Dimension tables are typically joined to fact tables, which are distributed differently than the dimension table. Dimensions are usually of a size that makes it feasible to store and maintain multiple copies. Dimensions store descriptive data that changes slowly, such as customer name and address, and product details. The slowly changing nature of the data leads to less maintenance of the replicated table.

Consider using a replicated table when:

- The table size on disk is less than 2 GB, regardless of the number of rows. To find the size of a table, you can

use the DBCC PDW_SHOWSPACEUSED command: `DBCC PDW_SHOWSPACEUSED('ReplTableCandidate')`.

- The table is used in joins that would otherwise require data movement. When joining tables that are not distributed on the same column, such as a hash-distributed table to a round-robin table, data movement is required to complete the query. If one of the tables is small, consider a replicated table. We recommend using replicated tables instead of round-robin tables in most cases. To view data movement operations in query plans, use sys.dm_pdw_request_steps. The BroadcastMoveOperation is the typical data movement operation that can be eliminated by using a replicated table.

Replicated tables may not yield the best query performance when:

- The table has frequent insert, update, and delete operations. The data manipulation language (DML) operations require a rebuild of the replicated table. Rebuilding frequently can cause slower performance.
- The SQL pool is scaled frequently. Scaling a SQL pool changes the number of Compute nodes, which incurs rebuilding the replicated table.
- The table has a large number of columns, but data operations typically access only a small number of columns. In this scenario, instead of replicating the entire table, it might be more effective to distribute the table, and then create an index on the frequently accessed columns. When a query requires data movement, SQL pool only moves data for the requested columns.

Use replicated tables with simple query predicates

Before you choose to distribute or replicate a table, think about the types of queries you plan to run against the table. Whenever possible,

- Use replicated tables for queries with simple query predicates, such as equality or inequality.
- Use distributed tables for queries with complex query predicates, such as LIKE or NOT LIKE.

CPU-intensive queries perform best when the work is distributed across all of the Compute nodes. For example, queries that run computations on each row of a table perform better on distributed tables than replicated tables. Since a replicated table is stored in full on each Compute node, a CPU-intensive query against a replicated table runs against the entire table on every Compute node. The extra computation can slow query performance.

For example, this query has a complex predicate. It runs faster when the data is in a distributed table instead of a replicated table. In this example, the data can be round-robin distributed.

```
SELECT EnglishProductName
FROM DimProduct
WHERE EnglishDescription LIKE '%frame%comfortable%';
```

Convert existing round-robin tables to replicated tables

If you already have round-robin tables, we recommend converting them to replicated tables if they meet the criteria outlined in this article. Replicated tables improve performance over round-robin tables because they eliminate the need for data movement. A round-robin table always requires data movement for joins.

This example uses CTAS to change the `DimSalesTerritory` table to a replicated table. This example works regardless of whether `DimSalesTerritory` is hash-distributed or round-robin.

```
CREATE TABLE [dbo].[DimSalesTerritory_REPLICATE]
WITH
  (
    HEAP,
    DISTRIBUTION = REPLICATE
  )
AS SELECT * FROM [dbo].[DimSalesTerritory]
OPTION  (LABEL  = 'CTAS : DimSalesTerritory_REPLICATE')

-- Switch table names
RENAME OBJECT [dbo].[DimSalesTerritory] to [DimSalesTerritory_old];
RENAME OBJECT [dbo].[DimSalesTerritory_REPLICATE] TO [DimSalesTerritory];

DROP TABLE [dbo].[DimSalesTerritory_old];
```

Query performance example for round-robin versus replicated

A replicated table does not require any data movement for joins because the entire table is already present on each Compute node. If the dimension tables are round-robin distributed, a join copies the dimension table in full to each Compute node. To move the data, the query plan contains an operation called BroadcastMoveOperation. This type of data movement operation slows query performance and is eliminated by using replicated tables. To view query plan steps, use the sys.dm_pdw_request_steps system catalog view.

For example, in following query against the `AdventureWorks` schema, the `FactInternetSales` table is hash-distributed. The `DimDate` and `DimSalesTerritory` tables are smaller dimension tables. This query returns the total sales in North America for fiscal year 2004:

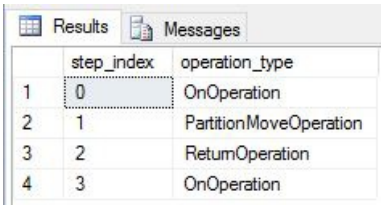
```
SELECT [TotalSalesAmount] = SUM(SalesAmount)
FROM dbo.FactInternetSales s
INNER JOIN dbo.DimDate d
  ON d.DateKey = s.OrderDateKey
INNER JOIN dbo.DimSalesTerritory t
  ON t.SalesTerritoryKey = s.SalesTerritoryKey
WHERE d.FiscalYear = 2004
  AND t.SalesTerritoryGroup = 'North America'
```

We re-created `DimDate` and `DimSalesTerritory` as round-robin tables. As a result, the query showed the following query plan, which has multiple broadcast move operations:

Results | Messages

	step_index	operation_type
1	0	RandomIDOperation
2	1	OnOperation
3	2	BroadcastMoveOperation
4	3	RandomIDOperation
5	4	OnOperation
6	5	BroadcastMoveOperation
7	6	OnOperation
8	7	PartitionMoveOperation
9	8	OnOperation
10	9	OnOperation
11	10	ReturnOperation
12	11	OnOperation

We re-created `DimDate` and `DimSalesTerritory` as replicated tables, and ran the query again. The resulting query plan is much shorter and does not have any broadcast moves.



Results | Messages

	step_index	operation_type
1	0	OnOperation
2	1	PartitionMoveOperation
3	2	ReturnOperation
4	3	OnOperation

Performance considerations for modifying replicated tables

SQL pool implements a replicated table by maintaining a master version of the table. It copies the master version to the first distribution database on each Compute node. When there is a change, the master version is updated first, then the tables on each Compute node are rebuilt. A rebuild of a replicated table includes copying the table to each Compute node and then building the indexes. For example, a replicated table on a DW2000c has five copies of the data. A master copy and a full copy on each Compute node. All data is stored in distribution databases. SQL pool uses this model to support faster data modification statements and flexible scaling operations.

Asynchronous rebuilds are triggered by the first query against the replicated table after:

- Data is loaded or modified
- The Synapse SQL instance is scaled to a different level
- Table definition is updated

Rebuilds are not required after:

- Pause operation
- Resume operation

The rebuild does not happen immediately after data is modified. Instead, the rebuild is triggered the first time a query selects from the table. The query that triggered the rebuild reads immediately from the master version of the table while the data is asynchronously copied to each Compute node. Until the data copy is complete, subsequent queries will continue to use the master version of the table. If any activity happens against the replicated table that forces another rebuild, the data copy is invalidated and the next select statement will trigger data to be copied again.

Use indexes conservatively

Standard indexing practices apply to replicated tables. SQL pool rebuilds each replicated table index as part of the rebuild. Only use indexes when the performance gain outweighs the cost of rebuilding the indexes.

Batch data load

When loading data into replicated tables, try to minimize rebuilds by batching loads together. Perform all the batched loads before running select statements.

For example, this load pattern loads data from four sources and invokes four rebuilds.

- Load from source 1.
- Select statement triggers rebuild 1.
- Load from source 2.
- Select statement triggers rebuild 2.
- Load from source 3.
- Select statement triggers rebuild 3.
- Load from source 4.
- Select statement triggers rebuild 4.

For example, this load pattern loads data from four sources, but only invokes one rebuild.

- Load from source 1.
- Load from source 2.
- Load from source 3.
- Load from source 4.
- Select statement triggers rebuild.

Rebuild a replicated table after a batch load

To ensure consistent query execution times, consider forcing the build of the replicated tables after a batch load. Otherwise, the first query will still use data movement to complete the query.

This query uses the sys.pdw_replicated_table_cache_state DMV to list the replicated tables that have been modified, but not rebuilt.

```
SELECT SchemaName = SCHEMA_NAME(t.schema_id)
 , [ReplicatedTable] = t.[name]
 , [RebuildStatement] = 'SELECT TOP 1 * FROM ' + '[' + SCHEMA_NAME(t.schema_id) + '].[' + t.[name] +']'
FROM sys.tables t
JOIN sys.pdw_replicated_table_cache_state c
  ON c.object_id = t.object_id
JOIN sys.pdw_table_distribution_properties p
  ON p.object_id = t.object_id
WHERE c.[state] = 'NotReady'
AND p.[distribution_policy_desc] = 'REPLICATE'
```

To trigger a rebuild, run the following statement on each table in the preceding output.

```
SELECT TOP 1 * FROM [ReplicatedTable]
```

Next steps

To create a replicated table, use one of these statements:

- CREATE TABLE (SQL pool)
- CREATE TABLE AS SELECT (SQL pool)

For an overview of distributed tables, see distributed tables.

Statistics in Synapse SQL

8/19/2022 • 23 minutes to read • Edit Online

Provided in this article are recommendations and examples for creating and updating query-optimization statistics using the Synapse SQL resources: dedicated SQL pool and serverless SQL pool.

Statistics in dedicated SQL pool

Why use statistics

The more dedicated SQL pool knows about your data, the faster it can execute queries. After loading data into a dedicated SQL pool, collecting statistics on your data is one of the most important things you can do for query optimization.

The dedicated SQL pool query optimizer is a cost-based optimizer. It compares the cost of various query plans, and then chooses the plan with the lowest cost. In most cases, it chooses the plan that will execute the fastest.

For example, if the optimizer estimates that the date your query is filtering on will return one row, it will choose one plan. If it estimates that the selected date will return 1 million rows, it will return a different plan.

Automatic creation of statistics

The dedicated SQL pool engine will analyze incoming user queries for missing statistics when the database AUTO_CREATE_STATISTICS option is set to `ON`. If statistics are missing, the query optimizer creates statistics on individual columns in the query predicate or join condition.

This function is used to improve cardinality estimates for the query plan.

> **IMPORTANT**
> Automatic creation of statistics is currently turned on by default.

You can check if your data warehouse has AUTO_CREATE_STATISTICS configured by running the following command:

```
SELECT name, is_auto_create_stats_on
FROM sys.databases
```

If your data warehouse doesn't have AUTO_CREATE_STATISTICS enabled, we recommend you enable this property by running the following command:

```
ALTER DATABASE <yourdatawarehousename>
SET AUTO_CREATE_STATISTICS ON
```

These statements will trigger the automatic creation of statistics:

- SELECT
- INSERT-SELECT
- CTAS
- UPDATE
- DELETE

- EXPLAIN when containing a join or the presence of a predicate is detected

> **NOTE**
> The automatic creation of statistics is not generated on temporary or external tables.

Automatic creation of statistics is done synchronously. So, you may incur slightly degraded query performance if your columns are missing statistics. The time to create statistics for a single column depends on the size of the table.

To avoid measurable performance degradation, you should ensure stats have been created first by executing the benchmark workload before profiling the system.

> **NOTE**
> The creation of stats is logged in sys.dm_pdw_exec_requests under a different user context.

When automatic statistics are created, they'll take the form: *WA_Sys*<8 digit column id in Hex>_<8 digit table id in Hex>. You can view already created stats by running the DBCC SHOW_STATISTICS command:

```
DBCC SHOW_STATISTICS (<table_name>, <target>)
```

The table_name is the name of the table that contains the statistics to display, which can't be an external table. The target is the name of the target index, statistics, or column for which to display statistics information.

Update statistics

One best practice is to update statistics on date columns each day as new dates are added. Each time new rows are loaded into the data warehouse, new load dates or transaction dates are added. These additions change the data distribution and make the statistics out of date.

Statistics on a country or region column in a customer table might never need to be updated because the distribution of values doesn't usually change. Assuming the distribution is constant between customers, adding new rows to the table variation isn't going to change the data distribution.

However, when your data warehouse only contains one country or region and you bring in data from a new country or region, then you need to update statistics on the country or region column.

The following are recommendations for updating statistics:

TYPE	RECOMMENDATION
Frequency of stats updates	Conservative: Daily After loading or transforming your data
Sampling	Less than 1 billion rows, use default sampling (20 percent). With more than 1 billion rows, use sampling of two percent.

Determine last statistics update

One of the first questions to ask when you're troubleshooting a query is, **"Are the statistics up to date?"**

This question isn't one that can be answered by the age of the data. An up-to-date statistics object might be old if there's been no material change to the underlying data. When the number of rows has changed substantially, or a material change in the distribution of values for a column occurs, *then* it's time to update statistics.

There isn't a dynamic management view available to determine if data within the table has changed since the last time statistics were updated. Knowing the age of your statistics can provide you with part of the picture.

You can use the following query to determine the last time your statistics were updated on each table.

> **NOTE**
> If there is a material change in the distribution of values for a column, you should update statistics regardless of the last time they were updated.

```
SELECT
    sm.[name] AS [schema_name],
    tb.[name] AS [table_name],
    co.[name] AS [stats_column_name],
    st.[name] AS [stats_name],
    STATS_DATE(st.[object_id],st.[stats_id]) AS [stats_last_updated_date]
FROM
    sys.objects ob
    JOIN sys.stats st
        ON  ob.[object_id] = st.[object_id]
    JOIN sys.stats_columns sc
        ON  st.[stats_id] = sc.[stats_id]
        AND st.[object_id] = sc.[object_id]
    JOIN sys.columns co
        ON  sc.[column_id] = co.[column_id]
        AND sc.[object_id] = co.[object_id]
    JOIN sys.types  ty
        ON  co.[user_type_id] = ty.[user_type_id]
    JOIN sys.tables tb
        ON  co.[object_id] = tb.[object_id]
    JOIN sys.schemas sm
        ON  tb.[schema_id] = sm.[schema_id]
WHERE
    st.[user_created] = 1;
```

Date columns in a data warehouse, for example, usually need frequent statistics updates. Each time new rows are loaded into the data warehouse, new load dates or transaction dates are added. These additions change the data distribution and make the statistics out of date.

Statistics on a gender column in a customer table might never need to be updated. Assuming the distribution is constant between customers, adding new rows to the table variation isn't going to change the data distribution.

But, if your data warehouse contains only one gender and a new requirement results in multiple genders, then you need to update statistics on the gender column.

For further information, review the Statistics article.

Implement statistics management

It's often a good idea to extend your data-loading process to ensure that statistics are updated at the end of the load. The data load is when tables most frequently change their size, distribution of values, or both. As such, the load process is a logical place to implement some management processes.

The following guiding principles are provided for updating your statistics during the load process:

- Ensure that each loaded table has at least one statistics object updated. This process updates the table size (row count and page count) information as part of the statistics update.
- Focus on columns participating in JOIN, GROUP BY, ORDER BY, and DISTINCT clauses.
- Consider updating "ascending key" columns such as transaction dates more frequently because these values won't be included in the statistics histogram.

- Consider updating static distribution columns less frequently.
- Remember, each statistic object is updated in sequence. Simply implementing `UPDATE STATISTICS <TABLE_NAME>` isn't always ideal, especially for wide tables with lots of statistics objects.

For more information, see Cardinality Estimation.

Examples: Create statistics

These examples show how to use various options for creating statistics. The options that you use for each column depend on the characteristics of your data and how the column will be used in queries.

Create single-column statistics with default options

To create statistics on a column, provide a name for the statistics object and the name of the column. This syntax uses all of the default options. By default, dedicated SQL pool samples **20 percent** of the table when it creates statistics.

```
CREATE STATISTICS [statistics_name]
    ON [schema_name].[table_name]([column_name]);
```

For example:

```
CREATE STATISTICS col1_stats
    ON dbo.table1 (col1);
```

Create single-column statistics by examining every row

The default sampling rate of 20 percent is sufficient for most situations. However, you can adjust the sampling rate. To sample the full table, use this syntax:

```
CREATE STATISTICS [statistics_name]
    ON [schema_name].[table_name]([column_name])
    WITH FULLSCAN;
```

For example:

```
CREATE STATISTICS col1_stats
    ON dbo.table1 (col1)
    WITH FULLSCAN;
```

Create single-column statistics by specifying the sample size

Another option you have is to specify the sample size as a percent:

```
CREATE STATISTICS col1_stats
    ON dbo.table1 (col1)
    WITH SAMPLE 50 PERCENT;
```

Create single-column statistics on only some of the rows

You can also create statistics on a portion of the rows in your table, which is called a filtered statistic.

For example, you can use filtered statistics when you plan to query a specific partition of a large partitioned table. By creating statistics on only the partition values, the accuracy of the statistics will improve. You'll also experience an improvement in query performance.

This example creates statistics on a range of values. The values can easily be defined to match the range of values in a partition.

```
CREATE STATISTICS stats_col1
    ON table1(col1)
    WHERE col1 > '2000101' AND col1 < '20001231';
```

> **NOTE**
>
> For the query optimizer to consider using filtered statistics when it chooses the distributed query plan, the query must fit inside the definition of the statistics object. Using the previous example, the query's WHERE clause needs to specify col1 values between 2000101 and 20001231.

Create single-column statistics with all the options

You can also combine the options together. The following example creates a filtered statistics object with a custom sample size:

```
CREATE STATISTICS stats_col1
    ON table1 (col1)
    WHERE col1 > '2000101' AND col1 < '20001231'
    WITH SAMPLE 50 PERCENT;
```

For the full reference, see CREATE STATISTICS.

Create multi-column statistics

To create a multi-column statistics object, use the previous examples, but specify more columns.

> **NOTE**
>
> The histogram, which is used to estimate the number of rows in the query result, is only available for the first column listed in the statistics object definition.

In this example, the histogram is on *product_category*. Cross-column statistics are calculated on *product_category* and *product_sub_category*.

```
CREATE STATISTICS stats_2cols
    ON table1 (product_category, product_sub_category)
    WHERE product_category > '2000101' AND product_category < '20001231'
    WITH SAMPLE 50 PERCENT;
```

Because a correlation exists between *product_category* and *product_sub_category*, a multi-column statistics object can be useful if these columns are accessed at the same time. When querying this table, the multi-column statistics will improve cardinality estimations for joins, GROUP BY aggregations, distinct counts, and WHERE filters (so long as the primary statistics column is a part of the filter).

Create statistics on all columns in a table

One way to create statistics is to issue CREATE STATISTICS commands after creating the table:

```
CREATE TABLE dbo.table1
(
   col1 int
,  col2 int
,  col3 int
)
WITH
  (
    CLUSTERED COLUMNSTORE INDEX
  )
;

CREATE STATISTICS stats_col1 on dbo.table1 (col1);
CREATE STATISTICS stats_col2 on dbo.table2 (col2);
CREATE STATISTICS stats_col3 on dbo.table3 (col3);
```

Use a stored procedure to create statistics on all columns in a database

SQL pool doesn't have a system stored procedure equivalent to `sp_create_stats` in SQL Server. This stored procedure creates a single column statistics object on every column of the database that doesn't already have statistics.

The following example will help you get started with your database design. Feel free to adapt it to your needs:

```
CREATE PROCEDURE    [dbo].[prc_sqldw_create_stats]
(   @create_type    tinyint -- 1 default, 2 Fullscan, 3 Sample
,   @sample_pct     tinyint
)
AS

IF @create_type IS NULL
BEGIN
    SET @create_type = 1;
END;

IF @create_type NOT IN (1,2,3)
BEGIN
    THROW 151000,'Invalid value for @stats_type parameter. Valid range 1 (default), 2 (fullscan) or 3
(sample).',1;
END;

IF @sample_pct IS NULL
BEGIN;
    SET @sample_pct = 20;
END;

IF OBJECT_ID('tempdb..#stats_ddl') IS NOT NULL
BEGIN;
    DROP TABLE #stats_ddl;
END;

CREATE TABLE #stats_ddl
WITH    (   DISTRIBUTION    = HASH([seq_nmbr])
        ,   LOCATION        = USER_DB
        )
AS
WITH T
AS
(
SELECT      t.[name]                        AS [table_name]
,           s.[name]                        AS [table_schema_name]
,           c.[name]                        AS [column_name]
,           c.[column_id]                   AS [column_id]
,           t.[object_id]                   AS [object_id]
,           ROW_NUMBER()
            OVER(ORDER BY (SELECT NULL))    AS [seq_nmbr]
```

```
FROM        sys.[tables] t
JOIN        sys.[schemas] s         ON  t.[schema_id]       = s.[schema_id]
JOIN        sys.[columns] c         ON  t.[object_id]       = c.[object_id]
LEFT JOIN   sys.[stats_columns] l   ON  l.[object_id]       = c.[object_id]
                                    AND l.[column_id]       = c.[column_id]
                                    AND l.[stats_column_id] = 1
LEFT JOIN    sys.[external_tables] e    ON    e.[object_id]        = t.[object_id]
WHERE       l.[object_id] IS NULL
AND            e.[object_id] IS NULL -- not an external table
)
SELECT  [table_schema_name]
,       [table_name]
,       [column_name]
,       [column_id]
,       [object_id]
,       [seq_nmbr]
,       CASE @create_type
        WHEN 1
        THEN    CAST('CREATE STATISTICS '+QUOTENAME('stat_'+table_schema_name+ '_' + table_name +
'_'+column_name)+' ON
'+QUOTENAME(table_schema_name)+'.'+QUOTENAME(table_name)+'('+QUOTENAME(column_name)+')' AS VARCHAR(8000))
        WHEN 2
        THEN    CAST('CREATE STATISTICS '+QUOTENAME('stat_'+table_schema_name+ '_' + table_name +
'_'+column_name)+' ON '+QUOTENAME(table_schema_name)+'.'+QUOTENAME(table_name)+'('+QUOTENAME(column_name)+')
WITH FULLSCAN' AS VARCHAR(8000))
        WHEN 3
        THEN    CAST('CREATE STATISTICS '+QUOTENAME('stat_'+table_schema_name+ '_' + table_name +
'_'+column_name)+' ON '+QUOTENAME(table_schema_name)+'.'+QUOTENAME(table_name)+'('+QUOTENAME(column_name)+')
WITH SAMPLE '+CONVERT(varchar(4),@sample_pct)+' PERCENT' AS VARCHAR(8000))
        END AS create_stat_ddl
FROM T
;

DECLARE @i INT              = 1
,       @t INT              = (SELECT COUNT(*) FROM #stats_ddl)
,       @s NVARCHAR(4000)   = N''
;

WHILE @i <= @t
BEGIN
    SET @s=(SELECT create_stat_ddl FROM #stats_ddl WHERE seq_nmbr = @i);

    PRINT @s
    EXEC sp_executesql @s
    SET @i+=1;
END

DROP TABLE #stats_ddl;
```

To create statistics on all columns in the table using the defaults, execute the stored procedure.

```
EXEC [dbo].[prc_sqldw_create_stats] 1, NULL;
```

To create statistics on all columns in the table using a fullscan, call this procedure:

```
EXEC [dbo].[prc_sqldw_create_stats] 2, NULL;
```

To create sampled statistics on all columns in the table, enter 3, and the sample percent. The procedure below uses a 20 percent sample rate.

```
EXEC [dbo].[prc_sqldw_create_stats] 3, 20;
```

Examples: Update statistics

To update statistics, you can:

- Update one statistics object. Specify the name of the statistics object you want to update.
- Update all statistics objects on a table. Specify the name of the table instead of one specific statistics object.

Update one specific statistics object

Use the following syntax to update a specific statistics object:

```
UPDATE STATISTICS [schema_name].[table_name]([stat_name]);
```

For example:

```
UPDATE STATISTICS [dbo].[table1] ([stats_col1]);
```

By updating specific statistics objects, you can minimize the time and resources required to manage statistics. This action requires some thought for selecting the best statistics objects to update.

Update all statistics on a table

A simple method for updating all the statistics objects on a table is:

```
UPDATE STATISTICS [schema_name].[table_name];
```

For example:

```
UPDATE STATISTICS dbo.table1;
```

The UPDATE STATISTICS statement is easy to use. Just remember that it updates *all* statistics on the table, prompting more work than is necessary.

If performance isn't an issue, this method is the easiest and most complete way to guarantee that statistics are up to date.

> **NOTE**
> When updating all statistics on a table, dedicated SQL pool does a scan to sample the table for each statistics object. If the table is large and has many columns and many statistics, it might be more efficient to update individual statistics based on need.

For an implementation of an `UPDATE STATISTICS` procedure, see Temporary tables. The implementation method is slightly different from the preceding `CREATE STATISTICS` procedure, but the result is the same. For the full syntax, see Update statistics.

Statistics metadata

There are several system views and functions that you can use to find information about statistics. For example, you can see if a statistics object might be out of date by using the STATS_DATE() function. STATS_DATE() allows you to see when statistics were last created or updated.

Catalog views for statistics

These system views provide information about statistics:

CATALOG VIEW	DESCRIPTION
sys.columns	One row for each column.
sys.objects	One row for each object in the database.
sys.schemas	One row for each schema in the database.
sys.stats	One row for each statistics object.
sys.stats_columns	One row for each column in the statistics object. Links back to sys.columns.
sys.tables	One row for each table (includes external tables).
sys.table_types	One row for each data type.

System functions for statistics

These system functions are useful for working with statistics:

SYSTEM FUNCTION	DESCRIPTION
STATS_DATE	Date the statistics object was last updated.
DBCC SHOW_STATISTICS	Summary level and detailed information about the distribution of values as understood by the statistics object.

Combine statistics columns and functions into one view

This view brings columns that relate to statistics and results from the STATS_DATE() function together.

```
CREATE VIEW dbo.vstats_columns
AS
SELECT
        sm.[name]                           AS [schema_name]
,       tb.[name]                           AS [table_name]
,       st.[name]                           AS [stats_name]
,       st.[filter_definition]              AS [stats_filter_definition]
,       st.[has_filter]                     AS [stats_is_filtered]
,       STATS_DATE(st.[object_id],st.[stats_id])
                                            AS [stats_last_updated_date]
,       co.[name]                           AS [stats_column_name]
,       ty.[name]                           AS [column_type]
,       co.[max_length]                     AS [column_max_length]
,       co.[precision]                      AS [column_precision]
,       co.[scale]                          AS [column_scale]
,       co.[is_nullable]                    AS [column_is_nullable]
,       co.[collation_name]                 AS [column_collation_name]
,       QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])
                                            AS two_part_name
,       QUOTENAME(DB_NAME())+'.'+QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])
                                            AS three_part_name
FROM    sys.objects                         AS ob
JOIN    sys.stats           AS st ON    ob.[object_id]      = st.[object_id]
JOIN    sys.stats_columns   AS sc ON    st.[stats_id]       = sc.[stats_id]
                            AND         st.[object_id]      = sc.[object_id]
JOIN    sys.columns         AS co ON    sc.[column_id]      = co.[column_id]
                            AND         sc.[object_id]      = co.[object_id]
JOIN    sys.types           AS ty ON    co.[user_type_id]   = ty.[user_type_id]
JOIN    sys.tables          AS tb ON    co.[object_id]      = tb.[object_id]
JOIN    sys.schemas         AS sm ON    tb.[schema_id]      = sm.[schema_id]
WHERE   1=1
AND     st.[user_created] = 1
;
```

DBCC SHOW_STATISTICS() examples

DBCC SHOW_STATISTICS() shows the data held within a statistics object. This data comes in three parts:

- Header
- Density vector
- Histogram

The header is the metadata about the statistics. The histogram displays the distribution of values in the first key column of the statistics object.

The density vector measures cross-column correlation. Dedicated SQL pool computes cardinality estimates with any of the data in the statistics object.

Show header, density, and histogram

This simple example shows all three parts of a statistics object:

```
DBCC SHOW_STATISTICS([<schema_name>.<table_name>],<stats_name>)
```

For example:

```
DBCC SHOW_STATISTICS (dbo.table1, stats_col1);
```

Show one or more parts of DBCC SHOW_STATISTICS()

If you're only interested in viewing specific parts, use the `WITH` clause and specify which parts you want to see:

```
DBCC SHOW_STATISTICS([<schema_name>.<table_name>],<stats_name>)
    WITH stat_header, histogram, density_vector
```

For example:

```
DBCC SHOW_STATISTICS (dbo.table1, stats_col1)
    WITH histogram, density_vector
```

DBCC SHOW_STATISTICS() differences

`DBCC SHOW_STATISTICS()` is more strictly implemented in dedicated SQL pool compared to SQL Server:

- Undocumented features aren't supported.
- Can't use Stats_stream.
- Can't join results for specific subsets of statistics data. For example, STAT_HEADER JOIN DENSITY_VECTOR.
- NO_INFOMSGS can't be set for message suppression.
- Square brackets around statistics names can't be used.
- Can't use column names to identify statistics objects.
- Custom error 2767 isn't supported.

Statistics in serverless SQL pool

Statistics are created per particular column for particular dataset (storage path).

> **NOTE**
> Statistics cannot be created for LOB columns.

Why use statistics

The more serverless SQL pool knows about your data, the faster it can execute queries against it. Collecting statistics on your data is one of the most important things you can do to optimize your queries.

The serverless SQL pool query optimizer is a cost-based optimizer. It compares the cost of various query plans, and then chooses the plan with the lowest cost. In most cases, it chooses the plan that will execute the fastest.

For example, if the optimizer estimates that the date your query is filtering on will return one row it will choose one plan. If it estimates that the selected date will return 1 million rows, it will return a different plan.

Automatic creation of statistics

Serverless SQL pool analyzes incoming user queries for missing statistics. If statistics are missing, the query optimizer creates statistics on individual columns in the query predicate or join condition to improve cardinality estimates for the query plan.

The SELECT statement will trigger automatic creation of statistics.

> **NOTE**
> Automatic creation of statistics is turned on for Parquet files. For CSV files, you need to create statistics manually until automatic creation of CSV files statistics is supported.

Automatic creation of statistics is done synchronously so you may incur slightly degraded query performance if your columns are missing statistics. The time to create statistics for a single column depends on the size of the files targeted.

Manual creation of statistics

Serverless SQL pool lets you create statistics manually. For CSV files, you have to create statistics manually because automatic creation of statistics isn't turned on for CSV files.

See the following examples for instructions on how to manually create statistics.

Update statistics

Changes to data in files, deleting, and adding files result in data distribution changes and makes statistics out of date. In that case, statistics needs to be updated.

Serverless SQL pool automatically recreates statistics if data is changed significantly. Every time statistics are automatically created, the current state of the dataset is also saved: file paths, sizes, last modification dates.

When statistics are stale, new ones will be created. The algorithm goes through the data and compares it to the current state of the dataset. If the size of the changes is greater than the specific threshold, then old stats are deleted and will be re-created over the new dataset.

Manual stats are never declared stale.

> **NOTE**
> Automatic recreation of statistics is turned on for Parquet files. For CSV files, you need to drop and create statistics manually until automatic creation of CSV files statistics is supported. Check the examples below on how to drop and create statistics.

One of the first questions to ask when you're troubleshooting a query is, **"Are the statistics up to date?"**

When the number of rows has changed substantially, or there's a material change in the distribution of values for a column, *then* it's time to update statistics.

> **NOTE**
> If there is a material change in the distribution of values for a column, you should update statistics regardless of the last time they were updated.

Implement statistics management

You may want to extend your data pipeline to ensure that statistics are updated when data is significantly changed through addition, deletion, or change of files.

The following guiding principles are provided for updating your statistics:

- Ensure that the dataset has at least one statistics object updated. This updates size (row count and page count) information as part of the statistics update.
- Focus on columns participating in WHERE, JOIN, GROUP BY, ORDER BY, and DISTINCT clauses.
- Update "ascending key" columns such as transaction dates more frequently because these values won't be included in the statistics histogram.
- Update static distribution columns less frequently.

For more information, see Cardinality Estimation.

Examples: Create statistics for column in OPENROWSET path

The following examples show you how to use various options for creating statistics in Azure Synapse serverless SQL pools. The options that you use for each column depend on the characteristics of your data and how the column will be used in queries. For more information on the stored procedures used in these examples, review sys.sp_create_openrowset_statistics and sys.sp_drop_openrowset_statistics, which apply to serverless SQL pools

only.

> **NOTE**
>
> You can create single-column statistics only at this moment.
>
> Following permissions are required to execute `sp_create_openrowset_statistics` and `sp_drop_openrowset_statistics`: ADMINISTER BULK OPERATIONS or ADMINISTER DATABASE BULK OPERATIONS.

The following stored procedure is used to create statistics:

```
sys.sp_create_openrowset_statistics [ @stmt = ] N'statement_text'
```

Arguments: [@stmt =] N'statement_text' - Specifies a Transact-SQL statement that will return column values to be used for statistics. You can use TABLESAMPLE to specify samples of data to be used. If TABLESAMPLE isn't specified, FULLSCAN will be used.

```
<tablesample_clause> ::= TABLESAMPLE ( sample_number PERCENT )
```

> **NOTE**
>
> CSV sampling does not work at this time, only FULLSCAN is supported for CSV.

Create single-column statistics by examining every row

To create statistics on a column, provide a query that returns the column for which you need statistics.

By default, if you don't specify otherwise, serverless SQL pool uses 100% of the data provided in the dataset when it creates statistics.

For example, to create statistics with default options (FULLSCAN) for a year column of the dataset based on the population.csv file:

```
/* make sure you have credentials for storage account access created
IF EXISTS (SELECT * FROM sys.credentials WHERE name =
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer')
DROP CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
GO

CREATE CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = ''
GO
*/

EXEC sys.sp_create_openrowset_statistics N'SELECT year
FROM OPENROWSET(
        BULK ''https://sqlondemandstorage.blob.core.windows.net/csv/population/population.csv'',
        FORMAT = ''CSV'',
        FIELDTERMINATOR ='','',
        ROWTERMINATOR = ''\n''
    )
WITH (
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
) AS [r]
'
```

Create single-column statistics by specifying the sample size

You can specify the sample size as a percent:

```
/* make sure you have credentials for storage account access created
IF EXISTS (SELECT * FROM sys.credentials WHERE name =
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer')
DROP CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
GO

CREATE CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = ''
GO
*/

EXEC sys.sp_create_openrowset_statistics N'SELECT payment_type
FROM OPENROWSET(
        BULK ''https://sqlondemandstorage.blob.core.windows.net/parquet/taxi/year=2018/month=6/*.parquet'',
         FORMAT = ''PARQUET''
    ) AS [nyc]
    TABLESAMPLE(5 PERCENT)
'
```

Examples: Update statistics

To update statistics, you need to drop and create statistics. For more information, review sys.sp_create_openrowset_statistics and sys.sp_drop_openrowset_statistics.

The `sys.sp_drop_openrowset_statistics` stored procedure is used to drop statistics:

```
sys.sp_drop_openrowset_statistics [ @stmt = ] N'statement_text'
```

> **NOTE**
>
> Following permissions are required to execute `sp_create_openrowset_statistics` and `sp_drop_openrowset_statistics`: ADMINISTER BULK OPERATIONS or ADMINISTER DATABASE BULK OPERATIONS.

Arguments: [@stmt =] N'statement_text' - Specifies the same Transact-SQL statement used when the statistics were created.

To update the statistics for the year column in the dataset, which is based on the `population.csv` file, you need to drop and create statistics:

```
EXEC sys.sp_drop_openrowset_statistics N'SELECT payment_type
FROM OPENROWSET(
        BULK ''https://sqlondemandstorage.blob.core.windows.net/parquet/taxi/year=2018/month=6/*.parquet'',
         FORMAT = ''PARQUET''
    ) AS [nyc]
    TABLESAMPLE(5 PERCENT)
'
GO

/* make sure you have credentials for storage account access created
IF EXISTS (SELECT * FROM sys.credentials WHERE name =
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer')
DROP CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
GO

CREATE CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = ''
GO
*/

EXEC sys.sp_create_openrowset_statistics N'SELECT payment_type
FROM OPENROWSET(
        BULK ''https://sqlondemandstorage.blob.core.windows.net/parquet/taxi/year=2018/month=6/*.parquet'',
         FORMAT = ''PARQUET''
    ) AS [nyc]
    TABLESAMPLE(5 PERCENT)
'
```

Examples: Create statistics for external table column

The following examples show you how to use various options for creating statistics. The options that you use for each column depend on the characteristics of your data and how the column will be used in queries.

> **NOTE**
>
> You can create single-column statistics only at this moment.

To create statistics on a column, provide a name for the statistics object and the name of the column.

```
CREATE STATISTICS statistics_name
ON { external_table } ( column )
    WITH
        { FULLSCAN
          | [ SAMPLE number PERCENT ] }
        , { NORECOMPUTE }
```

Arguments: external_table Specifies external table that statistics should be created.

FULLSCAN Compute statistics by scanning all rows. FULLSCAN and SAMPLE 100 PERCENT have the same results. FULLSCAN can't be used with the SAMPLE option.

SAMPLE number PERCENT Specifies the approximate percentage or number of rows in the table or indexed view for the query optimizer to use when it creates statistics. Number can be from 0 through 100.

SAMPLE can't be used with the FULLSCAN option.

> **NOTE**
> CSV sampling does not work at this time, only FULLSCAN is supported for CSV.

Create single-column statistics by examining every row

```
CREATE STATISTICS sState
    on census_external_table (STATENAME)
    WITH FULLSCAN, NORECOMPUTE
```

Create single-column statistics by specifying the sample size

```
-- following sample creates statistics with sampling 20%
CREATE STATISTICS sState
    on census_external_table (STATENAME)
    WITH SAMPLE 5 percent, NORECOMPUTE
```

Examples: Update statistics

To update statistics, you need to drop and create statistics. Drop statistics first:

```
DROP STATISTICS census_external_table.sState
```

And create statistics:

```
CREATE STATISTICS sState
    on census_external_table (STATENAME)
    WITH FULLSCAN, NORECOMPUTE
```

Statistics metadata

There are several system views and functions that you can use to find information about statistics. For example, you can see if a statistics object might be out of date by using the STATS_DATE() function. STATS_DATE() allows you to see when statistics were last created or updated.

> **NOTE**
> Statistics metadata is available for external table columns only. Statistics metadata is not available for OPENROWSET columns.

Catalog views for statistics

These system views provide information about statistics:

CATALOG VIEW	DESCRIPTION
sys.columns	One row for each column.

CATALOG VIEW	DESCRIPTION
sys.objects	One row for each object in the database.
sys.schemas	One row for each schema in the database.
sys.stats	One row for each statistics object.
sys.stats_columns	One row for each column in the statistics object. Links back to sys.columns.
sys.tables	One row for each table (includes external tables).
sys.table_types	One row for each data type.

System functions for statistics

These system functions are useful for working with statistics:

SYSTEM FUNCTION	DESCRIPTION
STATS_DATE	Date the statistics object was last updated.

Combine statistics columns and functions into one view

This view brings columns that relate to statistics and results from the STATS_DATE() function together.

```
CREATE VIEW dbo.vstats_columns
AS
SELECT
        sm.[name]                           AS [schema_name]
,       tb.[name]                           AS [table_name]
,       st.[name]                           AS [stats_name]
,       st.[filter_definition]              AS [stats_filter_definition]
,       st.[has_filter]                     AS [stats_is_filtered]
,       STATS_DATE(st.[object_id],st.[stats_id])
                                            AS [stats_last_updated_date]
,       co.[name]                           AS [stats_column_name]
,       ty.[name]                           AS [column_type]
,       co.[max_length]                     AS [column_max_length]
,       co.[precision]                      AS [column_precision]
,       co.[scale]                          AS [column_scale]
,       co.[is_nullable]                    AS [column_is_nullable]
,       co.[collation_name]                 AS [column_collation_name]
,       QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])
                                            AS two_part_name
,       QUOTENAME(DB_NAME())+'.'+QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])
                                            AS three_part_name
FROM    sys.objects                         AS ob
JOIN    sys.stats           AS st ON    ob.[object_id]      = st.[object_id]
JOIN    sys.stats_columns   AS sc ON    st.[stats_id]       = sc.[stats_id]
                            AND         st.[object_id]      = sc.[object_id]
JOIN    sys.columns         AS co ON    sc.[column_id]      = co.[column_id]
                            AND         sc.[object_id]      = co.[object_id]
JOIN    sys.types           AS ty ON    co.[user_type_id]   = ty.[user_type_id]
JOIN    sys.tables          AS tb ON    co.[object_id]      = tb.[object_id]
JOIN    sys.schemas         AS sm ON    tb.[schema_id]      = sm.[schema_id]
WHERE   st.[user_created] = 1
;
```

Temporary tables in Synapse SQL

8/19/2022 • 4 minutes to read • Edit Online

This article contains essential guidance for using temporary tables and highlights the principles of session level temporary tables within Synapse SQL.

Both the dedicated SQL pool and serverless SQL pool resources can utilize temporary tables. Serverless SQL pool has limitations that are discussed at the end of this article.

Temporary tables

Temporary tables are useful when processing data, especially during transformation where the intermediate results are transient. With Synapse SQL, temporary tables exist at the session level. They're only visible to the session in which they were created. As such, they're automatically dropped when that session ends.

Temporary tables in dedicated SQL pool

In the dedicated SQL pool resource, temporary tables offer a performance benefit because their results are written to local rather than remote storage.

Create a temporary table

Temporary tables are created by prefixing your table name with a `#`. For example:

```
CREATE TABLE #stats_ddl
(
    [schema_name]        NVARCHAR(128) NOT NULL
,    [table_name]            NVARCHAR(128) NOT NULL
,    [stats_name]            NVARCHAR(128) NOT NULL
,    [stats_is_filtered]     BIT           NOT NULL
,    [seq_nmbr]              BIGINT        NOT NULL
,    [two_part_name]         NVARCHAR(260) NOT NULL
,    [three_part_name]       NVARCHAR(400) NOT NULL
)
WITH
(
    DISTRIBUTION = HASH([seq_nmbr])
,    HEAP
)
```

Temporary tables can also be created with a `CTAS` using exactly the same approach:

```
CREATE TABLE #stats_ddl
WITH
(
    DISTRIBUTION = HASH([seq_nmbr])
,    HEAP
)
AS
(
SELECT
        sm.[name]                                                                   AS [schema_name]
,        tb.[name]                                                                   AS [table_name]
,        st.[name]                                                                   AS [stats_name]
,        st.[has_filter]                                                               AS [stats_is_filtered]
,       ROW_NUMBER()
        OVER(ORDER BY (SELECT NULL))                                               AS [seq_nmbr]
,                               QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])  AS [two_part_name]
,        QUOTENAME(DB_NAME())+'.'+QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])  AS [three_part_name]
FROM    sys.objects            AS ob
JOIN    sys.stats           AS st    ON    ob.[object_id]        = st.[object_id]
JOIN    sys.stats_columns    AS sc    ON    st.[stats_id]        = sc.[stats_id]
                                AND st.[object_id]        = sc.[object_id]
JOIN    sys.columns            AS co    ON    sc.[column_id]        = co.[column_id]
                                AND    sc.[object_id]        = co.[object_id]
JOIN    sys.tables            AS tb    ON    co.[object_id]        = tb.[object_id]
JOIN    sys.schemas            AS sm    ON    tb.[schema_id]        = sm.[schema_id]
WHERE    1=1
AND        st.[user_created]   = 1
GROUP BY
        sm.[name]
,        tb.[name]
,        st.[name]
,        st.[filter_definition]
,        st.[has_filter]
)
;
```

NOTE

`CTAS` is a powerful command and has the added advantage of being efficient in its use of transaction log space.

Drop temporary tables

When a new session is created, no temporary tables should exist. However, if you're calling the same stored procedure that creates a temporary with the same name, to ensure that your `CREATE TABLE` statements are successful, use a simple pre-existence check with `DROP`:

```
IF OBJECT_ID('tempdb..#stats_ddl') IS NOT NULL
BEGIN
    DROP TABLE #stats_ddl
END
```

For coding consistency, it's a good practice to use this pattern for both tables and temporary tables. It's also a good idea to use `DROP TABLE` to remove temporary tables when you're finished with them.

In stored procedure development, it's common to see the drop commands bundled together at the end of a procedure to ensure these objects are cleaned up.

```
DROP TABLE #stats_ddl
```

Modularize code

Temporary tables can be used anywhere in a user session. This capability can then be exploited to help you modularize your application code. To demonstrate, the following stored procedure generates DDL to update all statistics in the database by statistic name:

```
CREATE PROCEDURE    [dbo].[prc_sqldw_update_stats]
(   @update_type    tinyint -- 1 default 2 fullscan 3 sample 4 resample
    ,@sample_pct     tinyint
)
AS

IF @update_type NOT IN (1,2,3,4)
BEGIN;
    THROW 151000,'Invalid value for @update_type parameter. Valid range 1 (default), 2 (fullscan), 3
(sample) or 4 (resample).',1;
END;

IF @sample_pct IS NULL
BEGIN;
    SET @sample_pct = 20;
END;

IF OBJECT_ID('tempdb..#stats_ddl') IS NOT NULL
BEGIN
    DROP TABLE #stats_ddl
END

CREATE TABLE #stats_ddl
WITH
(
    DISTRIBUTION = HASH([seq_nmbr])
)
AS
(
SELECT
        sm.[name]                                                                   AS [schema_name]
,        tb.[name]                                                                   AS [table_name]
,        st.[name]                                                                   AS [stats_name]
,        st.[has_filter]                                                               AS [stats_is_filtered]
,       ROW_NUMBER()
        OVER(ORDER BY (SELECT NULL))                                               AS [seq_nmbr]
,                                QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])  AS [two_part_name]
,        QUOTENAME(DB_NAME())+'.'+QUOTENAME(sm.[name])+'.'+QUOTENAME(tb.[name])  AS [three_part_name]
FROM    sys.objects            AS ob
JOIN    sys.stats            AS st    ON    ob.[object_id]        = st.[object_id]
JOIN    sys.stats_columns    AS sc    ON    st.[stats_id]        = sc.[stats_id]
                                AND st.[object_id]        = sc.[object_id]
JOIN    sys.columns            AS co    ON    sc.[column_id]        = co.[column_id]
                                AND    sc.[object_id]        = co.[object_id]
JOIN    sys.tables            AS tb    ON    co.[object_id]        = tb.[object_id]
JOIN    sys.schemas            AS sm    ON    tb.[schema_id]        = sm.[schema_id]
WHERE    1=1
AND        st.[user_created]   = 1
GROUP BY
        sm.[name]
,        tb.[name]
,        st.[name]
,        st.[filter_definition]
,        st.[has_filter]
)
SELECT
    CASE @update_type
    WHEN 1
    THEN 'UPDATE STATISTICS '+[two_part_name]+'('+[stats_name]+');'
    WHEN 2
    THEN 'UPDATE STATISTICS '+[two_part_name]+'('+[stats_name]+') WITH FULLSCAN;'
    WHEN 3
    THEN 'UPDATE STATISTICS '+[two_part_name]+'('+[stats_name]+') WITH SAMPLE '+CAST(@sample_pct AS
```

```
VARCHAR(20))+' PERCENT;'
    WHEN 4
    THEN 'UPDATE STATISTICS '+[two_part_name]+'('+[stats_name]+') WITH RESAMPLE;'
    END AS [update_stats_ddl]
,   [seq_nmbr]
FROM    #stats_ddl
;
GO
```

At this stage, the only action that has occurred is the creation of a stored procedure that generates the #stats_ddl temporary table. The stored procedure drops #stats_ddl if it already exists. This drop ensures it doesn't fail if run more than once within a session.

Since there isn't a `DROP TABLE` at the end of the stored procedure, when the stored procedure completes, the created table remains and can be read outside of the stored procedure.

In contrast to other SQL Server databases, Synapse SQL allows you to use the temporary table outside of the procedure that created it. The temporary tables created via dedicated SQL pool can be used **anywhere** inside the session. As a result, you'll have more modular and manageable code, as demonstrated in the sample below:

```
EXEC [dbo].[prc_sqldw_update_stats] @update_type = 1, @sample_pct = NULL;

DECLARE @i INT              = 1
,       @t INT              = (SELECT COUNT(*) FROM #stats_ddl)
,       @s NVARCHAR(4000)   = N''

WHILE @i <= @t
BEGIN
    SET @s=(SELECT update_stats_ddl FROM #stats_ddl WHERE seq_nmbr = @i);

    PRINT @s
    EXEC sp_executesql @s
    SET @i+=1;
END

DROP TABLE #stats_ddl;
```

Temporary table limitations

Dedicated SQL pool does have a few implementation limitations for temporary tables:

- Only session scoped temporary tables are supported. Global Temporary Tables aren't supported.
- Views can't be created on temporary tables.
- Temporary tables can only be created with hash or round robin distribution. Replicated temporary table distribution isn't supported.

Temporary tables in serverless SQL pool

Temporary tables in serverless SQL pool are supported but their usage is limited. They can't be used in queries which target files.

For example, you can't join a temporary table with data from files in storage. The number of temporary tables is limited to 100, and their total size is limited to 100 MB.

Next steps

To learn more about developing tables, see the Designing tables using the Synapse SQL resources article.

Use T-SQL loops with Synapse SQL in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

This article provides you with essential tips for using T-SQL loops, replacing cursors, and developing related solutions with Synapse SQL.

Purpose of WHILE loops

Synapse SQL supports the WHILE loop for repeatedly executing statement blocks. This WHILE loop continues for as long as the specified conditions are true or until the code specifically terminates the loop using the BREAK keyword.

Loops in Synapse SQL are useful for replacing cursors defined in SQL code. Fortunately, almost all cursors that are written in SQL code are of the fast forward, read-only variety. So, WHILE loops are a great alternative for replacing cursors.

Replace cursors in Synapse SQL

Before diving in, the following question should be considered: "Could this cursor be rewritten to use set-based operations?" In many cases, the answer is yes and is frequently the best approach. A set-based operation often executes faster than an iterative, row by row approach.

Fast forward read-only cursors are easily replaced with a looping construct. The following code is a simple example. This code example updates the statistics for every table in the database. By iterating over the tables in the loop, each command executes in sequence.

First, create a temporary table containing a unique row number used to identify the individual statements:

```
CREATE TABLE #tbl
WITH
( DISTRIBUTION = ROUND_ROBIN
)
AS
SELECT  ROW_NUMBER() OVER(ORDER BY (SELECT NULL)) AS Sequence
,       [name]
,       'UPDATE STATISTICS '+QUOTENAME([name]) AS sql_code
FROM    sys.tables
;
```

Second, initialize the variables required to execute the loop:

```
DECLARE @nbr_statements INT = (SELECT COUNT(*) FROM #tbl)
,       @i INT = 1
;
```

Now loop over statements executing them one at a time:

```
WHILE   @i <= @nbr_statements
BEGIN
    DECLARE @sql_code NVARCHAR(4000) = (SELECT sql_code FROM #tbl WHERE Sequence = @i);
    EXEC    sp_executesql @sql_code;
    SET     @i +=1;
END
```

Finally drop the temporary table created in the first step

```
DROP TABLE #tbl;
```

Next steps

For more development tips, see development overview.

Stored procedures using Synapse SQL in Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

Synapse SQL provisioned and serverless pools enable you to place complex data processing logic into SQL stored procedures. Stored procedures are a great way for encapsulating your SQL code and storing it close to your data in the data warehouse. Stored procedures help developers modularize their solutions by encapsulating the code into manageable units, and facilitating greater reusability of code. Each stored procedure can also accept parameters to make them even more flexible. In this article you will find some tips for implementing stored procedures in Synapse SQL pool for developing solutions.

What to expect

Synapse SQL supports many of the T-SQL features that are used in SQL Server. More importantly, there are scale-out specific features that you can use to maximize the performance of your solution. In this article, you will learn about the features that you can place in stored procedures.

> **NOTE**
>
> In the procedure body you can use only the features that are supported in Synapse SQL surface area. Review this article to identify objects, statement that can be used in stored procedures. The examples in these articles use generic features that are available both in serverless and dedicated surface area. See additional limitations in provisioned and serverless Synapse SQL pools at the end of this article.

To maintain the scale and performance of SQL pool, there are also some features and functionality that have behavioral differences and others that aren't supported.

Stored procedures in Synapse SQL

In the following example, you can see the procedures that drop external objects if they exist in the database:

```
CREATE PROCEDURE drop_external_table_if_exists @name SYSNAME
AS BEGIN
    IF (0 <> (SELECT COUNT(*) FROM sys.external_tables WHERE name = @name))
    BEGIN
        DECLARE @drop_stmt NVARCHAR(200) = N'DROP EXTERNAL TABLE ' + @name;
        EXEC sp_executesql @tsql = @drop_stmt;
    END
END
GO
CREATE PROCEDURE drop_external_file_format_if_exists @name SYSNAME
AS BEGIN
    IF (0 <> (SELECT COUNT(*) FROM sys.external_file_formats WHERE name = @name))
    BEGIN
        DECLARE @drop_stmt NVARCHAR(200) = N'DROP EXTERNAL FILE FORMAT ' + @name;
        EXEC sp_executesql @tsql = @drop_stmt;
    END
END
GO
CREATE PROCEDURE drop_external_data_source_if_exists @name SYSNAME
AS BEGIN
    IF (0 <> (SELECT COUNT(*) FROM sys.external_data_sources WHERE name = @name))
    BEGIN
        DECLARE @drop_stmt NVARCHAR(200) = N'DROP EXTERNAL DATA SOURCE ' + @name;
        EXEC sp_executesql @tsql = @drop_stmt;
    END
END
```

These procedures can be executed using `EXEC` statement where you can specify the procedure name and parameters:

```
EXEC drop_external_table_if_exists 'mytest';
EXEC drop_external_file_format_if_exists 'mytest';
EXEC drop_external_data_source_if_exists 'mytest';
```

Synapse SQL provides a simplified and streamlined stored procedure implementation. The biggest difference compared to SQL Server is that the stored procedure is not pre-compiled code. In data warehouses, the compilation time is small in comparison to the time it takes to run queries against large data volumes. It is more important to ensure the stored procedure code is correctly optimized for large queries. The goal is to save hours, minutes, and seconds, not milliseconds. It is therefore more helpful to think of stored procedures as containers for SQL logic.

When Synapse SQL executes your stored procedure, the SQL statements are parsed, translated, and optimized at run time. During this process, each statement is converted into distributed queries. The SQL code that is executed against the data is different than the query submitted.

Encapsulate validation rules

Stored procedures enable you to locate validation logic in a single module stored in SQL database. In the following example, you can see how to validate the values of parameters and change their default values.

```
CREATE PROCEDURE count_objects_by_date_created
                            @start_date DATETIME2,
                            @end_date DATETIME2
AS BEGIN

    IF( @start_date >= GETUTCDATE() )
    BEGIN
        THROW 51000, 'Invalid argument @start_date. Value should be in past.', 1;
    END

    IF( @end_date IS NULL )
    BEGIN
        SET @end_date = GETUTCDATE();
    END

    IF( @start_date >= @end_date )
    BEGIN
        THROW 51000, 'Invalid argument @end_date. Value should be greater than @start_date.', 2;
    END

    SELECT
         year = YEAR(create_date),
         month = MONTH(create_date),
         objects_created = COUNT(*)
    FROM
        sys.objects
    WHERE
        create_date BETWEEN @start_date AND @end_date
    GROUP BY
        YEAR(create_date), MONTH(create_date);
END
```

The logic in the sql procedure will validate the input parameters when the procedure is called.

```
EXEC count_objects_by_date_created '2020-08-01', '2020-09-01'

EXEC count_objects_by_date_created '2020-08-01', NULL

EXEC count_objects_by_date_created '2020-09-01', '2020-08-01'
-- Error
-- Invalid argument @end_date. Value should be greater than @start_date.

EXEC count_objects_by_date_created '2120-09-01', NULL
-- Error
-- Invalid argument @start_date. Value should be in past.
```

Nesting stored procedures

When stored procedures call other stored procedures, or execute dynamic SQL, then the inner stored procedure or code invocation is said to be nested. An example of nested procedure is shown in the following code:

```
CREATE PROCEDURE clean_up @name SYSNAME
AS BEGIN
    EXEC drop_external_table_if_exists @name;
    EXEC drop_external_file_format_if_exists @name;
    EXEC drop_external_data_source_if_exists @name;
END
```

This procedure accepts a parameter that represents some name and then calls other procedures to drop the objects with this name. Synapse SQL pool supports a maximum of eight nesting levels. This capability is slightly

different than SQL Server. The nest level in SQL Server is 32.

The top-level stored procedure call equates to nest level 1.

```
EXEC clean_up 'mytest'
```

If the stored procedure also makes another EXEC call, the nest level increases to two.

```
CREATE PROCEDURE clean_up @name SYSNAME
AS
    EXEC drop_external_table_if_exists @name  -- This call is nest level 2
GO
EXEC clean_up 'mytest'  -- This call is nest level 1
```

If the second procedure then executes some dynamic SQL, the nest level increases to three.

```
CREATE PROCEDURE drop_external_table_if_exists @name SYSNAME
AS BEGIN
    /* See full code in the previous example */
    EXEC sp_executesql @tsql = @drop_stmt;  -- This call is nest level 3
END
GO
CREATE PROCEDURE clean_up @name SYSNAME
AS
    EXEC drop_external_table_if_exists @name  -- This call is nest level 2
GO
EXEC clean_up 'mytest'  -- This call is nest level 1
```

> **NOTE**
> Synapse SQL does not currently support @@NESTLEVEL. You need to track the nest level. It is unlikely for you to exceed the eight nest level limit, but if you do, you need to rework your code to fit the nesting levels within this limit.

INSERT..EXECUTE

Provisioned Synapse SQL pool doesn't permit you to consume the result set of a stored procedure with an INSERT statement. There's an alternative approach you can use. For an example, see the article on temporary tables for provisioned Synapse SQL pool.

Limitations

There are some aspects of Transact-SQL stored procedures that aren't implemented in Synapse SQL, such as:

FEATURE/OPTION	PROVISIONED	SERVERLESS
Temporary stored procedures	No	Yes
Numbered stored procedures	No	No
Extended stored procedures	No	No
CLR stored procedures	No	No
Encryption option	No	Yes

FEATURE/OPTION	PROVISIONED	SERVERLESS
Replication option	No	No
Table-valued parameters	No	No
Read-only parameters	No	No
Default parameters	No	Yes
Execution contexts	No	No
Return statement	No	Yes
INSERT INTO .. EXEC	No	Yes

Use transactions with dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

Tips for implementing transactions with dedicated SQL pool in Azure Synapse Analytics for developing solutions.

What to expect

As you would expect, dedicated SQL pool supports transactions as part of the data warehouse workload. However, to ensure the performance of dedicated SQL pool is maintained at scale some features are limited when compared to SQL Server. This article highlights the differences and lists the others.

Transaction isolation levels

Dedicated SQL pool implements ACID transactions. The isolation level of the transactional support is default to READ UNCOMMITTED. You can change it to READ COMMITTED SNAPSHOT ISOLATION by turning ON the READ_COMMITTED_SNAPSHOT database option for a user database when connected to the master database.

Once enabled, all transactions in this database are executed under READ COMMITTED SNAPSHOT ISOLATION and setting READ UNCOMMITTED on session level will not be honored. Check ALTER DATABASE SET options (Transact-SQL) for details.

Transaction size

A single data modification transaction is limited in size. The limit is applied per distribution. As such, the total allocation can be calculated by multiplying the limit by the distribution count.

To approximate the maximum number of rows in the transaction divide the distribution cap by the total size of each row. For variable length columns, consider taking an average column length rather than using the maximum size.

In the table below the following assumptions have been made:

- An even distribution of data has occurred
- The average row length is 250 bytes

Gen2

DWU	CAP PER DISTRIBUTION (GB)	NUMBER OF DISTRIBUTIONS	MAX TRANSACTION SIZE (GB)	# ROWS PER DISTRIBUTION	MAX ROWS PER TRANSACTION
DW100c	1	60	60	4,000,000	240,000,000

DW6000	45	60	2,700	180,000,000	10,800,000,000

The transaction size limit is applied per transaction or operation. It is not applied across all concurrent transactions. Therefore each transaction is permitted to write this amount of data to the log.

To optimize and minimize the amount of data written to the log, refer to the Transactions best practices article.

> **WARNING**
> The maximum transaction size can only be achieved for HASH or ROUND_ROBIN distributed tables where the spread of the data is even. If the transaction is writing data in a skewed fashion to the distributions then the limit is likely to be reached prior to the maximum transaction size.

Transaction state

Dedicated SQL pool uses the XACT_STATE() function to report a failed transaction using the value -2. This value means the transaction has failed and is marked for rollback only.

> **NOTE**
> The use of -2 by the XACT_STATE function to denote a failed transaction represents different behavior to SQL Server. SQL Server uses the value -1 to represent an uncommittable transaction. SQL Server can tolerate some errors inside a transaction without it having to be marked as uncommittable. For example `SELECT 1/0` would cause an error but not force a transaction into an uncommittable state. SQL Server also permits reads in the uncommittable transaction. However, dedicated SQL pool does not let you do this. If an error occurs inside a dedicated SQL pool transaction it will automatically enter the -2 state and you will not be able to make any further select statements until the statement has been rolled back. It is therefore important to check that your application code to see if it uses XACT_STATE() as you may need to make code modifications.

For example, in SQL Server you might see a transaction that looks like the following:

```
SET NOCOUNT ON;
DECLARE @xact_state smallint = 0;

BEGIN TRAN
    BEGIN TRY
        DECLARE @i INT;
        SET     @i = CONVERT(INT,'ABC');
    END TRY
    BEGIN CATCH
        SET @xact_state = XACT_STATE();

        SELECT  ERROR_NUMBER()    AS ErrNumber
        ,       ERROR_SEVERITY()  AS ErrSeverity
        ,       ERROR_STATE()     AS ErrState
        ,       ERROR_PROCEDURE() AS ErrProcedure
        ,       ERROR_MESSAGE()   AS ErrMessage
        ;

        IF @@TRANCOUNT > 0
        BEGIN
            ROLLBACK TRAN;
            PRINT 'ROLLBACK';
        END

    END CATCH;

IF @@TRANCOUNT >0
BEGIN
    PRINT 'COMMIT';
    COMMIT TRAN;
END

SELECT @xact_state AS TransactionState;
```

The preceding code gives the following error message:

Msg 111233, Level 16, State 1, Line 1 111233; The current transaction has aborted, and any pending changes have been rolled back. Cause: A transaction in a rollback-only state wasn't explicitly rolled back before a DDL, DML, or SELECT statement.

You won't get the output of the ERROR_* functions.

In dedicated SQL pool, the code needs to be slightly altered:

```
SET NOCOUNT ON;
DECLARE @xact_state smallint = 0;

BEGIN TRAN
    BEGIN TRY
        DECLARE @i INT;
        SET     @i = CONVERT(INT,'ABC');
    END TRY
    BEGIN CATCH
        SET @xact_state = XACT_STATE();

        IF @@TRANCOUNT > 0
        BEGIN
            ROLLBACK TRAN;
            PRINT 'ROLLBACK';
        END

        SELECT  ERROR_NUMBER()    AS ErrNumber
        ,       ERROR_SEVERITY()  AS ErrSeverity
        ,       ERROR_STATE()     AS ErrState
        ,       ERROR_PROCEDURE() AS ErrProcedure
        ,       ERROR_MESSAGE()   AS ErrMessage
        ;
    END CATCH;

IF @@TRANCOUNT >0
BEGIN
    PRINT 'COMMIT';
    COMMIT TRAN;
END

SELECT @xact_state AS TransactionState;
```

The expected behavior is now observed. The error in the transaction is managed and the ERROR_* functions provide values as expected.

All that has changed is that the ROLLBACK of the transaction had to happen before the read of the error information in the CATCH block.

Error_Line() function

It is also worth noting that dedicated SQL pool does not implement or support the ERROR_LINE() function. If you have this function in your code, you need to remove it to be compliant with dedicated SQL pool. Use query labels in your code instead to implement equivalent functionality. For more information, see the LABEL article.

Use of THROW and RAISERROR

THROW is the more modern implementation for raising exceptions in dedicated SQL pool but RAISERROR is also supported. There are a few differences that are worth paying attention to however.

- User-defined error messages numbers can't be in the 100,000 - 150,000 range for THROW
- RAISERROR error messages are fixed at 50,000
- Use of sys.messages is not supported

Limitations

Dedicated SQL pool does have a few other restrictions that relate to transactions. They are as follows:

- No distributed transactions
- No nested transactions permitted

- No save points allowed
- No named transactions
- No marked transactions
- No support for DDL such as CREATE TABLE inside a user-defined transaction

Next steps

To learn more about optimizing transactions, see Transactions best practices. Additional best practices guides are also provided for Dedicated SQL pool and serverless SQL pool.

Optimize transactions with dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

Learn how to optimize the performance of your transactional code in dedicated SQL pool while minimizing risk for long rollbacks.

Transactions and logging

Transactions are an important component of a relational database engine. Dedicated SQL pool uses transactions during data modification. These transactions can be explicit or implicit. Single INSERT, UPDATE, and DELETE statements are all examples of implicit transactions. Explicit transactions use BEGIN TRAN, COMMIT TRAN, or ROLLBACK TRAN. Explicit transactions are typically used when multiple modification statements need to be tied together into a single atomic unit.

Dedicated SQL pool commits changes to the database using transaction logs. Each distribution has its own transaction log. Transaction log writes are automatic. There is no configuration required. However, while this process guarantees the write it does introduce an overhead in the system. You can minimize this impact by writing transactionally efficient code. Transactionally efficient code broadly falls into two categories.

- Use minimal logging constructs whenever possible
- Process data using scoped batches to avoid singular long running transactions
- Adopt a partition switching pattern for large modifications to a given partition

Minimal vs. full logging

Unlike fully logged operations, which use the transaction log to keep track of every row change, minimally logged operations keep track of extent allocations and meta-data changes only. Therefore, minimal logging involves logging only the information that is required to roll back the transaction after a failure, or for an explicit request (ROLLBACK TRAN). As much less information is tracked in the transaction log, a minimally logged operation performs better than a similarly sized fully logged operation. Furthermore, because fewer writes go the transaction log, a much smaller amount of log data is generated and so is more I/O efficient.

The transaction safety limits only apply to fully logged operations.

> **NOTE**
> Minimally logged operations can participate in explicit transactions. As all changes in allocation structures are tracked, it is possible to roll back minimally logged operations.

Minimally logged operations

The following operations are capable of being minimally logged:

- CREATE TABLE AS SELECT (CTAS)
- INSERT..SELECT
- CREATE INDEX
- ALTER INDEX REBUILD
- DROP INDEX

- TRUNCATE TABLE
- DROP TABLE
- ALTER TABLE SWITCH PARTITION

> **NOTE**
> Internal data movement operations (such as BROADCAST and SHUFFLE) are not affected by the transaction safety limit.

Minimal logging with bulk load

CTAS and INSERT...SELECT are both bulk load operations. However, both are influenced by the target table definition and depend on the load scenario. The following table explains when bulk operations are fully or minimally logged:

PRIMARY INDEX	LOAD SCENARIO	LOGGING MODE
Heap	Any	**Minimal**
Clustered Index	Empty target table	**Minimal**
Clustered Index	Loaded rows do not overlap with existing pages in target	**Minimal**
Clustered Index	Loaded rows overlap with existing pages in target	Full
Clustered Columnstore Index	Batch size >= 102,400 per partition aligned distribution	**Minimal**
Clustered Columnstore Index	Batch size < 102,400 per partition aligned distribution	Full

It is worth noting that any writes to update secondary or non-clustered indexes will always be fully logged operations.

> **IMPORTANT**
> Dedicated SQL pool has 60 distributions. Therefore, assuming all rows are evenly distributed and landing in a single partition, your batch will need to contain 6,144,000 rows or larger to be minimally logged when writing to a Clustered Columnstore Index. If the table is partitioned and the rows being inserted span partition boundaries, then you will need 6,144,000 rows per partition boundary assuming even data distribution. Each partition in each distribution must independently exceed the 102,400 row threshold for the insert to be minimally logged into the distribution.

Loading data into a non-empty table with a clustered index can often contain a mixture of fully logged and minimally logged rows. A clustered index is a balanced tree (b-tree) of pages. If the page being written to already contains rows from another transaction, then these writes will be fully logged. However, if the page is empty then the write to that page will be minimally logged.

Optimize deletes

DELETE is a fully logged operation. If you need to delete a large amount of data in a table or a partition, it often makes more sense to `SELECT` the data you wish to keep, which can be run as a minimally logged operation. To select the data, create a new table with CTAS. Once created, use RENAME to swap out your old table with the

newly created table.

```
-- Delete all sales transactions for Promotions except PromotionKey 2.

--Step 01. Create a new table select only the records we want to kep (PromotionKey 2)
CREATE TABLE [dbo].[FactInternetSales_d]
WITH
(    CLUSTERED COLUMNSTORE INDEX
,    DISTRIBUTION = HASH([ProductKey])
,     PARTITION     (    [OrderDateKey] RANGE RIGHT
                                    FOR VALUES    (    20000101, 20010101, 20020101, 20030101, 20040101,
20050101
                                                ,    20060101, 20070101, 20080101, 20090101, 20100101,
20110101
                                                ,    20120101, 20130101, 20140101, 20150101, 20160101,
20170101
                                                ,    20180101, 20190101, 20200101, 20210101, 20220101,
20230101
                                                ,    20240101, 20250101, 20260101, 20270101, 20280101,
20290101
                                                )
)
AS
SELECT     *
FROM     [dbo].[FactInternetSales]
WHERE    [PromotionKey] = 2
OPTION (LABEL = 'CTAS : Delete')
;

--Step 02. Rename the Tables to replace the
RENAME OBJECT [dbo].[FactInternetSales]   TO [FactInternetSales_old];
RENAME OBJECT [dbo].[FactInternetSales_d] TO [FactInternetSales];
```

Optimize updates

UPDATE is a fully logged operation. If you need to update a large number of rows in a table or a partition, it can often be far more efficient to use a minimally logged operation such as CTAS to do so.

In the example below a full table update has been converted to a CTAS so that minimal logging is possible.

In this case, we are retrospectively adding a discount amount to the sales in the table:

```
--Step 01. Create a new table containing the "Update".
CREATE TABLE [dbo].[FactInternetSales_u]
WITH
(    CLUSTERED INDEX
,    DISTRIBUTION = HASH([ProductKey])
,     PARTITION     (    [OrderDateKey] RANGE RIGHT
                                    FOR VALUES    (    20000101, 20010101, 20020101, 20030101, 20040101,
20050101
                                                ,    20060101, 20070101, 20080101, 20090101, 20100101,
20110101
                                                ,    20120101, 20130101, 20140101, 20150101, 20160101,
20170101
                                                ,    20180101, 20190101, 20200101, 20210101, 20220101,
20230101
                                                ,    20240101, 20250101, 20260101, 20270101, 20280101,
20290101
                                                )
                )
)
AS
SELECT
    [ProductKey]
,    [OrderDateKey]
,    [DueDateKey]
,    [ShipDateKey]
,    [CustomerKey]
,    [PromotionKey]
,    [CurrencyKey]
,    [SalesTerritoryKey]
,    [SalesOrderNumber]
,    [SalesOrderLineNumber]
,    [RevisionNumber]
,    [OrderQuantity]
,    [UnitPrice]
,    [ExtendedAmount]
,    [UnitPriceDiscountPct]
,    ISNULL(CAST(5 as float),0) AS [DiscountAmount]
,    [ProductStandardCost]
,    [TotalProductCost]
,    ISNULL(CAST(CASE WHEN [SalesAmount] <=5 THEN 0
         ELSE [SalesAmount] - 5
         END AS MONEY),0) AS [SalesAmount]
,    [TaxAmt]
,    [Freight]
,    [CarrierTrackingNumber]
,    [CustomerPONumber]
FROM    [dbo].[FactInternetSales]
OPTION (LABEL = 'CTAS : Update')
;

--Step 02. Rename the tables
RENAME OBJECT [dbo].[FactInternetSales]   TO [FactInternetSales_old];
RENAME OBJECT [dbo].[FactInternetSales_u] TO [FactInternetSales];

--Step 03. Drop the old table
DROP TABLE [dbo].[FactInternetSales_old]
```

NOTE

Re-creating large tables can benefit from using dedicated SQL pool workload management features. For more information, see Resource classes for workload management.

Optimize with partition switching

If faced with large-scale modifications inside a table partition, then a partition switching pattern makes sense. If the data modification is significant and spans multiple partitions, then iterating over the partitions achieves the same result.

The steps to perform a partition switch are as follows:

1. Create an empty out partition
2. Perform the 'update' as a CTAS
3. Switch out the existing data to the out table
4. Switch in the new data
5. Clean up the data

However, to help identify the partitions to switch, create the following helper procedure.

```
CREATE PROCEDURE dbo.partition_data_get
    @schema_name           NVARCHAR(128)
,    @table_name               NVARCHAR(128)
,    @boundary_value           INT
AS
IF OBJECT_ID('tempdb..#ptn_data') IS NOT NULL
BEGIN
    DROP TABLE #ptn_data
END
CREATE TABLE #ptn_data
WITH    (    DISTRIBUTION = ROUND_ROBIN
        ,    HEAP
        )
AS
WITH CTE
AS
(
SELECT     s.name                            AS [schema_name]
,        t.name                              AS [table_name]
,         p.partition_number                 AS [ptn_nmbr]
,        p.[rows]                          AS [ptn_rows]
,        CAST(r.[value] AS INT)              AS [boundary_value]
FROM        sys.schemas                      AS s
JOIN        sys.tables                      AS t    ON  s.[schema_id]        = t.[schema_id]
JOIN        sys.indexes                      AS i    ON     t.[object_id]        = i.[object_id]
JOIN        sys.partitions                  AS p    ON     i.[object_id]        = p.[object_id]
                                                AND i.[index_id]        = p.[index_id]
JOIN        sys.partition_schemes        AS h    ON     i.[data_space_id]    = h.[data_space_id]
JOIN        sys.partition_functions        AS f    ON     h.[function_id]        = f.[function_id]
LEFT JOIN    sys.partition_range_values    AS r     ON     f.[function_id]        = r.[function_id]
                                                AND r.[boundary_id]        = p.[partition_number]
WHERE i.[index_id] <= 1
)
SELECT    *
FROM    CTE
WHERE    [schema_name]        = @schema_name
AND        [table_name]        = @table_name
AND        [boundary_value]    = @boundary_value
OPTION (LABEL = 'dbo.partition_data_get : CTAS : #ptn_data')
;
GO
```

This procedure maximizes code reuse and keeps the partition switching example more compact.

The following code demonstrates the steps mentioned previously to achieve a full partition switching routine.

```
--Create a partitioned aligned empty table to switch out the data
IF OBJECT_ID('[dbo].[FactInternetSales_out]') IS NOT NULL
BEGIN
```

```
    DROP TABLE [dbo].[FactInternetSales_out]
END

CREATE TABLE [dbo].[FactInternetSales_out]
WITH
(    DISTRIBUTION = HASH([ProductKey])
,    CLUSTERED COLUMNSTORE INDEX
,     PARTITION     (    [OrderDateKey] RANGE RIGHT
                                    FOR VALUES    (    20020101, 20030101
                                                )
                )
)
AS
SELECT *
FROM    [dbo].[FactInternetSales]
WHERE 1=2
OPTION (LABEL = 'CTAS : Partition Switch IN : UPDATE')
;

--Create a partitioned aligned table and update the data in the select portion of the CTAS
IF OBJECT_ID('[dbo].[FactInternetSales_in]') IS NOT NULL
BEGIN
    DROP TABLE [dbo].[FactInternetSales_in]
END

CREATE TABLE [dbo].[FactInternetSales_in]
WITH
(    DISTRIBUTION = HASH([ProductKey])
,    CLUSTERED COLUMNSTORE INDEX
,     PARTITION     (    [OrderDateKey] RANGE RIGHT
                                    FOR VALUES    (    20020101, 20030101
                                                )
                )
)
AS
SELECT
    [ProductKey]
,    [OrderDateKey]
,    [DueDateKey]
,    [ShipDateKey]
,    [CustomerKey]
,    [PromotionKey]
,    [CurrencyKey]
,    [SalesTerritoryKey]
,    [SalesOrderNumber]
,    [SalesOrderLineNumber]
,    [RevisionNumber]
,    [OrderQuantity]
,    [UnitPrice]
,    [ExtendedAmount]
,    [UnitPriceDiscountPct]
,    ISNULL(CAST(5 as float),0) AS [DiscountAmount]
,    [ProductStandardCost]
,    [TotalProductCost]
,    ISNULL(CAST(CASE WHEN [SalesAmount] <=5 THEN 0
         ELSE [SalesAmount] - 5
         END AS MONEY),0) AS [SalesAmount]
,    [TaxAmt]
,    [Freight]
,    [CarrierTrackingNumber]
,    [CustomerPONumber]
FROM    [dbo].[FactInternetSales]
WHERE    OrderDateKey BETWEEN 20020101 AND 20021231
OPTION (LABEL = 'CTAS : Partition Switch IN : UPDATE')
;

--Use the helper procedure to identify the partitions
--The source table
EXEC dbo.partition_data_get 'dbo','FactInternetSales',20030101
```

```
DECLARE @ptn_nmbr_src INT = (SELECT ptn_nmbr FROM #ptn_data)
SELECT @ptn_nmbr_src

--The "in" table
EXEC dbo.partition_data_get 'dbo','FactInternetSales_in',20030101
DECLARE @ptn_nmbr_in INT = (SELECT ptn_nmbr FROM #ptn_data)
SELECT @ptn_nmbr_in

--The "out" table
EXEC dbo.partition_data_get 'dbo','FactInternetSales_out',20030101
DECLARE @ptn_nmbr_out INT = (SELECT ptn_nmbr FROM #ptn_data)
SELECT @ptn_nmbr_out

--Switch the partitions over
DECLARE @SQL NVARCHAR(4000) = '
ALTER TABLE [dbo].[FactInternetSales]    SWITCH PARTITION '+CAST(@ptn_nmbr_src AS VARCHAR(20))    +' TO
[dbo].[FactInternetSales_out] PARTITION '    +CAST(@ptn_nmbr_out AS VARCHAR(20))+';
ALTER TABLE [dbo].[FactInternetSales_in] SWITCH PARTITION '+CAST(@ptn_nmbr_in AS VARCHAR(20))    +' TO
[dbo].[FactInternetSales] PARTITION '        +CAST(@ptn_nmbr_src AS VARCHAR(20))+';'
EXEC sp_executesql @SQL

--Perform the clean-up
TRUNCATE TABLE dbo.FactInternetSales_out;
TRUNCATE TABLE dbo.FactInternetSales_in;

DROP TABLE dbo.FactInternetSales_out
DROP TABLE dbo.FactInternetSales_in
DROP TABLE #ptn_data
```

Minimize logging with small batches

For large data modification operations, it may make sense to divide the operation into chunks or batches to scope the unit of work.

A following code is a working example. The batch size has been set to a trivial number to highlight the technique. In reality, the batch size would be significantly larger.

```
SET NO_COUNT ON;
IF OBJECT_ID('tempdb..#t') IS NOT NULL
BEGIN
    DROP TABLE #t;
    PRINT '#t dropped';
END

CREATE TABLE #t
WITH    (    DISTRIBUTION = ROUND_ROBIN
        ,    HEAP
        )
AS
SELECT    ROW_NUMBER() OVER(ORDER BY (SELECT NULL)) AS seq_nmbr
,        SalesOrderNumber
,        SalesOrderLineNumber
FROM    dbo.FactInternetSales
WHERE    [OrderDateKey] BETWEEN 20010101 and 20011231
;

DECLARE    @seq_start        INT = 1
,        @batch_iterator    INT = 1
,        @batch_size        INT = 50
,        @max_seq_nmbr    INT = (SELECT MAX(seq_nmbr) FROM dbo.#t)
;

DECLARE    @batch_count    INT = (SELECT CEILING((@max_seq_nmbr*1.0)/@batch_size))
,        @seq_end        INT = @batch_size
;

SELECT COUNT(*)
FROM    dbo.FactInternetSales f

PRINT 'MAX_seq_nmbr '+CAST(@max_seq_nmbr AS VARCHAR(20))
PRINT 'MAX_Batch_count '+CAST(@batch_count AS VARCHAR(20))

WHILE    @batch_iterator <= @batch_count
BEGIN
    DELETE
    FROM    dbo.FactInternetSales
    WHERE EXISTS
    (
            SELECT    1
            FROM    #t t
            WHERE    seq_nmbr BETWEEN  @seq_start AND @seq_end
            AND        FactInternetSales.SalesOrderNumber        = t.SalesOrderNumber
            AND        FactInternetSales.SalesOrderLineNumber    = t.SalesOrderLineNumber
    )
    ;

    SET @seq_start = @seq_end
    SET @seq_end = (@seq_start+@batch_size);
    SET @batch_iterator +=1;
END
```

Pause and scaling guidance

Azure Synapse Analytics lets you pause, resume, and scale your dedicated SQL pool on demand.

When you pause or scale your dedicated SQL pool, it is important to understand that any in-flight transactions are terminated immediately; causing any open transactions to be rolled back.

If your workload had issued a long running and incomplete data modification prior to the pause or scale operation, then this work will need to be undone. This undoing might impact the time it takes to pause or scale your dedicated SQL pool.

> **IMPORTANT**
> Both `UPDATE` and `DELETE` are fully logged operations and so these undo/redo operations can take significantly longer than equivalent minimally logged operations.

The best scenario is to let in flight data modification transactions complete prior to pausing or scaling your dedicated SQL pool. However, this scenario might not always be practical. To mitigate the risk of a long rollback, consider one of the following options:

- Rewrite long running operations using CTAS
- Break the operation into chunks; operating on a subset of the rows

Next steps

See Transactions in dedicated SQL pool to learn more about isolation levels and transactional limits. For an overview of other best practices, see Dedicated SQL pool best practices.

User-defined schemas within Synapse SQL

8/19/2022 • 3 minutes to read • Edit Online

In the sections below, you'll find various tips for using T-SQL user-defined schemas to develop solutions within Synapse SQL.

Schemas for application boundaries

Traditional analytics architecture often uses separate databases to create application boundaries based on workload, domain, or security. For example, a traditional SQL Server analytics infrastructure might include a staging database, an analytics database, and data mart databases. In this topology, each database operates as a workload and security boundary in the architecture.

Instead, Synapse SQL runs the entire analytics workload within one database. Cross database joins aren't permitted. Synapse SQL expects all tables used by the warehouse to be stored within the one database.

> **NOTE**
> Dedicated SQL pools do not support cross database queries of any kind. Consequently, analytics implementations that leverage this pattern will need to be revised. Serverless SQL pool supports cross database queries.

User-defined schema recommendations

Included are recommendations for consolidating workloads, security, domain, and functional boundaries by using user-defined schemas:

- Use one database to run your entire analytics workload.
- Consolidate your existing analytics environment to use one database.
- Leverage **user-defined schemas** to provide the boundary previously implemented using databases.

If user-defined schemas haven't been used previously, then you have a clean slate. Use the old database name as the basis for your user-defined schemas in the Synapse SQL database.

If schemas have already been used, then you have a few options:

- Remove the legacy schema names and start fresh
- Keep the legacy schema names by pre-pending the legacy schema name to the table name
- Retain the legacy schema names by implementing views over the table in an extra schema, which re-creates the old schema structure.

> **NOTE**
> On first inspection, option 3 may seem like the most appealing choice. Views are read only in Synapse SQL. Any data or table modification would need to be performed against the base table. Option 3 also introduces a layer of views into your system. You might want to give this some additional thought if you are already using views in your architecture.

Examples

Implement user-defined schemas based on database names.

```
CREATE SCHEMA [stg]; -- stg previously database name for staging database
GO
CREATE SCHEMA [edw]; -- edw previously database name for the analytics
GO
CREATE TABLE [stg].[customer] -- create staging tables in the stg schema
(       CustKey BIGINT NOT NULL
,       ...
);
GO
CREATE TABLE [edw].[customer] -- create analytics tables in the edw schema
(       CustKey BIGINT NOT NULL
,       ...
);
```

Keep the legacy schema names by pre-pending them to the table name. Use schemas for the workload boundary.

```
CREATE SCHEMA [stg]; -- stg defines the staging boundary
GO
CREATE SCHEMA [edw]; -- edw defines the analytics boundary
GO
CREATE TABLE [stg].[dim_customer] --pre-pend the old schema name to the table and create in the staging
boundary
(       CustKey BIGINT NOT NULL
,       ...
);
GO
CREATE TABLE [edw].[dim_customer] --pre-pend the old schema name to the table and create in the analytics
boundary
(       CustKey BIGINT NOT NULL
,       ...
);
```

Retain the legacy schema names using views.

```
CREATE SCHEMA [stg]; -- stg defines the staging boundary
GO
CREATE SCHEMA [edw]; -- stg defines the analytics boundary
GO
CREATE SCHEMA [dim]; -- edw defines the legacy schema name boundary
GO
CREATE TABLE [stg].[customer] -- create the base staging tables in the staging boundary
(       CustKey    BIGINT NOT NULL
,       ...
)
GO
CREATE TABLE [edw].[customer] -- create the base analytics tables in the analytics boundary
(       CustKey    BIGINT NOT NULL
,       ...
)
GO
CREATE VIEW [dim].[customer] -- create a view in the legacy schema name boundary for presentation
consistency purposes only
AS
SELECT  CustKey
,       ...
FROM    [edw].customer
;
```

> **NOTE**
>
> Any change in schema strategy requires a review of the security model for the database. In many cases, you might be able to simplify the security model by assigning permissions at the schema level.

If more granular permissions are required, you can use database roles. For more information about database roles, see the Manage database roles and users article.

For more development tips, see Synapse SQL development overview.

Assign variables with Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll find tips for assigning T-SQL variables with Synapse SQL.

Set variables with DECLARE

Variables in Synapse SQL are set using the `DECLARE` statement or the `SET` statement. Initializing variables with DECLARE is one of the most flexible ways to set a variable value in Synapse SQL.

```
DECLARE @v  int = 0
;
```

You can also use DECLARE to set more than one variable at a time. You can't use SELECT or UPDATE to do the following:

```
DECLARE @v  INT = (SELECT TOP 1 c_customer_sk FROM Customer where c_last_name = 'Smith')
,       @v1 INT = (SELECT TOP 1 c_customer_sk FROM Customer where c_last_name = 'Jones')
;
```

You can't initialize and use a variable in the same DECLARE statement. To illustrate, the following example isn't allowed since *@p1* is both initialized and used in the same DECLARE statement. The following example gives an error.

```
DECLARE @p1 int = 0
,       @p2 int = (SELECT COUNT (*) FROM sys.types where is_user_defined = @p1 )
;
```

Set values with SET

SET is a common method for setting a single variable.

The following statements are all valid ways to set a variable with SET:

```
SET     @v = (Select max(database_id) from sys.databases);
SET     @v = 1;
SET     @v = @v+1;
SET     @v +=1;
```

You can only set one variable at a time with SET. However, compound operators are permissible.

Limitations

You can't use UPDATE for variable assignment.

Next steps

For more development tips, see the Synapse SQL development overview article.

T-SQL views with dedicated SQL pool and serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll find tips for using T-SQL views and developing solutions with dedicated SQL pool and serverless SQL pool in Azure Synapse Analytics.

Why use views

Views can be used in a number of different ways to improve the quality of your solution. This article highlights a few examples of how to enrich your solution with views and includes the limitations that need to be considered.

SQL pool - create view

> **NOTE**
> Syntax for CREATE VIEW is not discussed in this article. For more information, see the CREATE VIEW documentation.

Architectural abstraction

A common application pattern is to re-create tables using CREATE TABLE AS SELECT (CTAS), which is followed by an object renaming pattern while loading data.

The following example adds new date records to a date dimension. Note how a new table, DimDate_New, is first created and then renamed to replace the original version of the table.

```
CREATE TABLE dbo.DimDate_New
WITH (DISTRIBUTION = ROUND_ROBIN
, CLUSTERED INDEX (DateKey ASC)
)
AS
SELECT *
FROM   dbo.DimDate  AS prod
UNION ALL
SELECT *
FROM   dbo.DimDate_stg AS stg
;

RENAME OBJECT DimDate TO DimDate_Old;
RENAME OBJECT DimDate_New TO DimDate;
```

Keep in mind that this approach can result in tables appearing and disappearing from a user's view, and prompts "table does not exist" error messages. Views can be used to provide users with a consistent presentation layer while the underlying objects are renamed.

By providing access to data through views, users don't need visibility to the underlying tables. In addition to a consistent user experience, this layer ensures that analytics designers can evolve the data model. The ability to evolve the underlying tables means designers can use CTAS to maximize performance during the data loading process.

Performance optimization

Views can also be used to enforce performance optimized joins between tables. For example, a view can incorporate a redundant distribution key as part of the joining criteria to minimize data movement.

Forcing a specific query or joining hint is another benefit of using T-SQL views. As such, the views capability ensures that joins are always performed in an optimal fashion. You'll avoid the need for users to remember the correct construct for their joins.

Limitations

Views in Synapse SQL are only stored as metadata. Consequently, the following options aren't available:

- There isn't a schema binding option
- Base tables can't be updated through the view
- Views can't be created over temporary tables
- There's no support for the EXPAND / NOEXPAND hints
- There are no indexed views in Synapse SQL

Next steps

For more development tips, see Synapse SQL development overview.

Dynamic SQL in Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll find tips for using dynamic SQL and developing solutions using Synapse SQL.

Dynamic SQL Example

When developing application code, you may need to use dynamic SQL to help deliver flexible, generic, and modular solutions.

> **NOTE**
>
> Dedicated SQL pool does not support blob data types at this time. Not supporting blob data types might limit the size of your strings since blob data types include both varchar(max) and nvarchar(max) types. If you have used these types in your application code to build large strings, you need to break the code into chunks and use the EXEC statement instead.

A simple example:

```
DECLARE @sql_fragment1 VARCHAR(8000)=' SELECT name '
,       @sql_fragment2 VARCHAR(8000)=' FROM sys.system_views '
,       @sql_fragment3 VARCHAR(8000)=' WHERE name like ''%table%''';

EXEC( @sql_fragment1 + @sql_fragment2 + @sql_fragment3);
```

If the string is short, you can use sp_executesql as normal.

> **NOTE**
>
> Statements executed as dynamic SQL will still be subject to all T-SQL validation rules.

Next steps

For more development tips, see development overview.

GROUP BY options in Synapse SQL

8/19/2022 • 3 minutes to read • Edit Online

Synapse SQL allows for developing solutions by implementing different GROUP BY options.

What GROUP BY does

The GROUP BY T-SQL clause aggregates data to a summary set of rows.

Serverless SQL pool doesn't support GROUP BY options. Dedicated SQL pool supports a limited number of GROUP BY options.

GROUP BY options supported in dedicated SQL pool

GROUP BY has some options that dedicated SQL pool doesn't support. These options have workarounds, which are as follows:

- GROUP BY with ROLLUP
- GROUPING SETS
- GROUP BY with CUBE

Rollup and grouping sets options

The simplest option here is to use UNION ALL to execute the rollup rather than relying on the explicit syntax. The result is exactly the same

The following example uses the GROUP BY statement with the ROLLUP option:

```
SELECT [SalesTerritoryCountry]
,      [SalesTerritoryRegion]
,      SUM(SalesAmount)             AS TotalSalesAmount
FROM  dbo.factInternetSales s
JOIN  dbo.DimSalesTerritory t       ON s.SalesTerritoryKey       = t.SalesTerritoryKey
GROUP BY ROLLUP (
                        [SalesTerritoryCountry]
                ,       [SalesTerritoryRegion]
                )
;
```

By using ROLLUP, the preceding example requests the following aggregations:

- Country and Region
- Country
- Grand Total

To replace ROLLUP and return the same results, you can use UNION ALL and explicitly specify the required aggregations:

```
SELECT [SalesTerritoryCountry]
,      [SalesTerritoryRegion]
,      SUM(SalesAmount) AS TotalSalesAmount
FROM  dbo.factInternetSales s
JOIN  dbo.DimSalesTerritory t     ON s.SalesTerritoryKey       = t.SalesTerritoryKey
GROUP BY
       [SalesTerritoryCountry]
,      [SalesTerritoryRegion]
UNION ALL
SELECT [SalesTerritoryCountry]
,      NULL
,      SUM(SalesAmount) AS TotalSalesAmount
FROM  dbo.factInternetSales s
JOIN  dbo.DimSalesTerritory t     ON s.SalesTerritoryKey       = t.SalesTerritoryKey
GROUP BY
       [SalesTerritoryCountry]
UNION ALL
SELECT NULL
,      NULL
,      SUM(SalesAmount) AS TotalSalesAmount
FROM  dbo.factInternetSales s
JOIN  dbo.DimSalesTerritory t     ON s.SalesTerritoryKey       = t.SalesTerritoryKey;
```

To replace GROUPING SETS, the sample principle applies. You only need to create UNION ALL sections for the aggregation levels you want to see.

Cube options

It's possible to create a GROUP BY WITH CUBE using the UNION ALL approach. The problem is that the code can quickly become cumbersome and unwieldy. To mitigate this issue, you can use this more advanced approach.

The first step is to define the 'cube' that defines all the levels of aggregation that we want to create. Take note of the CROSS JOIN of the two derived tables as it generates all levels. The rest of the code is there for formatting.

```
CREATE TABLE #Cube
WITH
(   DISTRIBUTION = ROUND_ROBIN
,   LOCATION = USER_DB
)
AS
WITH GrpCube AS
(SELECT    CAST(ISNULL(Country,'NULL')+','+ISNULL(Region,'NULL') AS NVARCHAR(50)) as 'Cols'
,          CAST(ISNULL(Country+',','')+ISNULL(Region,'') AS NVARCHAR(50))  as 'GroupBy'
,          ROW_NUMBER() OVER (ORDER BY Country) as 'Seq'
FROM       ( SELECT 'SalesTerritoryCountry' as Country
             UNION ALL
             SELECT NULL
           ) c
CROSS JOIN ( SELECT 'SalesTerritoryRegion' as Region
             UNION ALL
             SELECT NULL
           ) r
)
SELECT Cols
,      CASE WHEN SUBSTRING(GroupBy,LEN(GroupBy),1) = ','
            THEN SUBSTRING(GroupBy,1,LEN(GroupBy)-1)
            ELSE GroupBy
       END AS GroupBy  --Remove Trailing Comma
,Seq
FROM GrpCube;
```

The following image shows the results of CREATE TABLE AS SELECT:

	Cols	GroupBy	Seq
1	NULL,SalesTerritoryRegion	SalesTerritoryRegion	1
2	NULL,NULL		2
3	SalesTerritoryCountry,SalesTerritoryRegion	SalesTerritoryCountry,SalesTerritoryRegion	3
4	SalesTerritoryCountry,NULL	SalesTerritoryCountry	4

The second step is to specify a target table for storing interim results:

```
DECLARE
 @SQL NVARCHAR(4000)
,@Columns NVARCHAR(4000)
,@GroupBy NVARCHAR(4000)
,@i INT = 1
,@nbr INT = 0
;
CREATE TABLE #Results
(
 [SalesTerritoryCountry] NVARCHAR(50)
,[SalesTerritoryRegion]  NVARCHAR(50)
,[TotalSalesAmount]      MONEY
)
WITH
(   DISTRIBUTION = ROUND_ROBIN
,   LOCATION = USER_DB
)
;
```

The third step is to loop over the cube of columns performing the aggregation. The query will run once for every row in the #Cube temporary table. Results are stored in the #Results temp table:

```
SET @nbr =(SELECT MAX(Seq) FROM #Cube);

WHILE @i<=@nbr
BEGIN
    SET @Columns = (SELECT Cols    FROM #Cube where seq = @i);
    SET @GroupBy = (SELECT GroupBy FROM #Cube where seq = @i);

    SET @SQL ='INSERT INTO #Results
               SELECT '+@Columns+'
               ,      SUM(SalesAmount) AS TotalSalesAmount
               FROM  dbo.factInternetSales s
               JOIN  dbo.DimSalesTerritory t
               ON s.SalesTerritoryKey = t.SalesTerritoryKey
               '+CASE WHEN @GroupBy <>''
                      THEN 'GROUP BY '+@GroupBy ELSE '' END

    EXEC sp_executesql @SQL;
    SET @i +=1;
END
```

Lastly, you can return the results by reading from the #Results temporary table:

```
SELECT *
FROM #Results
ORDER BY 1,2,3
;
```

By breaking up the code into sections and generating a looping construct, the code becomes more manageable and maintainable.

Use query labels in Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

Included in this article are essential tips for using query labels in Synapse SQL.

> **NOTE**
> Serverless SQL pool doesn't support labelling queries.

What are query labels

Dedicated SQL pool supports a concept called query labels. Before going into any depth, let's look at an example:

```
SELECT *
FROM sys.tables
OPTION (LABEL = 'My Query Label')
;
```

The last line tags the string 'My Query Label' to the query. This tag is helpful since the label is query-able through the DMVs. Querying for labels provides a mechanism for locating problem queries and helps to identify progress through an ELT run.

Good naming conventions are most helpful. For example, starting the label with PROJECT, PROCEDURE, STATEMENT, or COMMENT uniquely identifies the query among all the code in source control.

The following query uses a dynamic management view to search by label:

```
SELECT  *
FROM    sys.dm_pdw_exec_requests r
WHERE   r.[label] = 'My Query Label'
;
```

> **NOTE**
> It is essential to put square brackets or double quotes around the word label when querying. Label is a reserved word and causes an error when it is not delimited.

For more development tips, see development overview.

Access external storage using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

This article describes how users can read data from the files stored on Azure Storage in serverless SQL pool. Users have the following options to access storage:

- OPENROWSET function that enables ad-hoc queries over the files in Azure Storage.
- External table that is a predefined data structure built on top of set of external files.

User can use different authentication methods such as Azure AD passthrough authentication (default for Azure AD principals) and SAS authentication (default for SQL principals).

Query files using OPENROWSET

OPENROWSET enables users to query external files on Azure storage if they have access to the storage. A user who is connected to serverless SQL pool should use the following query to read the content of the files on Azure storage:

```
SELECT * FROM
 OPENROWSET(BULK 'https://<storage_account>.dfs.core.windows.net/<container>/<path>/*.parquet', format=
'parquet') as rows
```

User can access storage using the following access rules:

- Azure AD user - `OPENROWSET` will use Azure AD identity of caller to access Azure Storage or access storage with anonymous access.
- SQL user – `OPENROWSET` will access storage with anonymous access or can be impersonated using SAS token or Managed identity of workspace.

- Impersonation
- Direct access

SQL principals can also use OPENROWSET to directly query files protected with SAS tokens or Managed Identity of the workspace. If a SQL user executes this function, a power user with `ALTER ANY CREDENTIAL` permission must create a server-scoped credential that matches URL in the function (using storage name and container) and granted REFERENCES permission for this credential to the caller of OPENROWSET function:

```
EXECUTE AS somepoweruser

CREATE CREDENTIAL [https://<storage_account>.dfs.core.windows.net/<container>]
 WITH IDENTITY = 'SHARED ACCESS SIGNATURE', SECRET = 'sas token';

GRANT REFERENCES ON CREDENTIAL::[https://<storage_account>.dfs.core.windows.net/<container>] TO sqluser
```

If there's no server-level CREDENTIAL that matches the URL, or the SQL user doesn't have references permission for this credential, the error will be returned. SQL principals can't impersonate using some Azure AD identity.

> **NOTE**
> This version of OPENROWSET is designed for quick-and-easy data exploration using default authentication. To leverage impersonation or Managed Identity, use OPENROWSET with DATA_SOURCE described in the next section.

Query data sources using OPENROWSET

OPENROWSET enables user to query the files placed on some external data source:

```
SELECT * FROM
 OPENROWSET(BULK 'file/path/*.parquet',
 DATA_SOURCE = MyAzureInvoices,
 FORMAT= 'parquet') as rows
```

The user that executes this query must be able to access the files. The users must be impersonated using SAS token or Managed Identity of workspace if they can't directly access the files using their Azure AD identity or anonymous access.

- Impersonation
- Direct access

`DATABASE SCOPED CREDENTIAL` specifies how to access files on the referenced data source (currently SAS and Managed Identity). Power user with `CONTROL DATABASE` permission would need to create `DATABASE SCOPED CREDENTIAL` that will be used to access storage and `EXTERNAL DATA SOURCE` that specifies URL of data source and credential that should be used:

```
EXECUTE AS somepoweruser;

-- Create MASTER KEY if it doesn't exists in database
CREATE MASTER KEY ENCRYPTION BY PASSWORD = 'some very strong password';

CREATE DATABASE SCOPED CREDENTIAL AccessAzureInvoices
 WITH IDENTITY = 'SHARED ACCESS SIGNATURE',
 SECRET = '******srt=sco&amp;sp=rwac&amp;se=2017-02-01T00:55:34Z&amp;st=201********' ;

CREATE EXTERNAL DATA SOURCE MyAzureInvoices
 WITH ( LOCATION = 'https://<storage_account>.dfs.core.windows.net/<container>/<path>/' ,
 CREDENTIAL = AccessAzureInvoices) ;
```

Caller must have one of the following permissions to execute OPENROWSET function:

- One of the permissions to execute OPENROWSET:
  - `ADMINISTER BULK OPERATIONS` enables login to execute OPENROWSET function.
  - `ADMINISTER DATABASE BULK OPERATIONS` enables database scoped user to execute OPENROWSET function.
- `REFERENCES DATABASE SCOPED CREDENTIAL` to the credential that is referenced in `EXTERNAL DATA SOURCE`.

EXTERNAL TABLE

User with the permissions to read table can access external files using an EXTERNAL TABLE created on top of set of Azure Storage folders and files.

User that has permissions to create external table (for example CREATE TABLE and ALTER ANY CREDENTIAL or REFERENCES DATABASE SCOPED CREDENTIAL) can use the following script to create a table on top of Azure Storage data source:

```
CREATE EXTERNAL TABLE [dbo].[DimProductexternal]
( ProductKey int, ProductLabel nvarchar, ProductName nvarchar )
WITH
(
LOCATION='/DimProduct/year=*/month=*' ,
DATA_SOURCE = AzureDataLakeStore ,
FILE_FORMAT = TextFileFormat
) ;
```

User that reads data from this table must be able to access the files. The users must be impersonated using SAS token or Managed Identity of workspace if they cannot directly access the files using their Azure AD identity or anonymous access.

- Impersonation
- Direct access

DATABASE SCOPED CREDENTIAL specifies how to access files on the referenced data source. User with CONTROL DATABASE permission would need to create DATABASE SCOPED CREDENTIAL that will be used to access storage and EXTERNAL DATA SOURCE that specifies URL of data source and credential that should be used:

```
EXECUTE AS somepoweruser;

-- Create MASTER KEY if it doesn't exists in database
CREATE MASTER KEY ENCRYPTION BY PASSWORD = 'some very strong password';

CREATE DATABASE SCOPED CREDENTIAL cred
 WITH IDENTITY = 'SHARED ACCESS SIGNATURE',
 SECRET = '******srt=sco&sp=rwac&se=2017-02-01T00:55:34Z&st=201********' ;

CREATE EXTERNAL DATA SOURCE AzureDataLakeStore
 WITH ( LOCATION = 'https://<storage_account>.dfs.core.windows.net/<container>/<path>' ,
 CREDENTIAL = cred
 ) ;
```

Read external files with EXTERNAL TABLE

EXTERNAL TABLE enables you to read data from the files that are referenced via data source using standard SQL SELECT statement:

```
SELECT *
FROM dbo.DimProductsExternal
```

Caller must have the following permissions to read data:

- `SELECT` permission ON external table
- `REFERENCES DATABASE SCOPED CREDENTIAL` permission if `DATA SOURCE` has `CREDENTIAL`

Permissions

The following table lists required permissions for the operations listed above.

QUERY	REQUIRED PERMISSIONS

QUERY	REQUIRED PERMISSIONS
OPENROWSET(BULK) without datasource	`ADMINISTER BULK OPERATIONS`, `ADMINISTER DATABASE BULK OPERATIONS`, or SQL login must have REFERENCES CREDENTIAL::<URL> for SAS-protected storage
OPENROWSET(BULK) with datasource without credential	`ADMINISTER BULK OPERATIONS` or `ADMINISTER DATABASE BULK OPERATIONS`,
OPENROWSET(BULK) with datasource with credential	`REFERENCES DATABASE SCOPED CREDENTIAL` and one of `ADMINISTER BULK OPERATIONS` or `ADMINISTER DATABASE BULK OPERATIONS`
CREATE EXTERNAL DATA SOURCE	`ALTER ANY EXTERNAL DATA SOURCE` and `REFERENCES DATABASE SCOPED CREDENTIAL`
CREATE EXTERNAL TABLE	`CREATE TABLE`, `ALTER ANY SCHEMA`, `ALTER ANY EXTERNAL FILE FORMAT`, and `ALTER ANY EXTERNAL DATA SOURCE`
SELECT FROM EXTERNAL TABLE	`SELECT TABLE` and `REFERENCES DATABASE SCOPED CREDENTIAL`
CETAS	To create table - `CREATE TABLE`, `ALTER ANY SCHEMA`, `ALTER ANY DATA SOURCE`, and `ALTER ANY EXTERNAL FILE FORMAT`. To read data: `ADMINISTER BULK OPERATIONS` or `REFERENCES CREDENTIAL` or `SELECT TABLE` per each table/view/function in query + R/W permission on storage

Next steps

You're now ready to continue on with the following How To articles:

- Query data on storage
- Query CSV file
- Query Parquet files
- Query JSON files
- Query folders and multiple files
- Use partitioning and metadata functions
- Query nested types
- Creating and using views

Control storage account access for serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 16 minutes to read • Edit Online

A serverless SQL pool query reads files directly from Azure Storage. Permissions to access the files on Azure storage are controlled at two levels:

- **Storage level** - User should have permission to access underlying storage files. Your storage administrator should allow Azure AD principal to read/write files, or generate SAS key that will be used to access storage.
- **SQL service level** - User should have granted permission to read data using external table or to execute the `OPENROWSET` function. Read more about the required permissions in this section.

This article describes the types of credentials you can use and how credential lookup is enacted for SQL and Azure AD users.

Storage permissions

A serverless SQL pool in Synapse Analytics workspace can read the content of files stored in Azure Data Lake storage. You need to configure permissions on storage to enable a user who executes a SQL query to read the files. There are three methods for enabling the access to the files:

- **Role based access control (RBAC)** enables you to assign a role to some Azure AD user in the tenant where your storage is placed. A reader must have `Storage Blob Data Reader`, `Storage Blob Data Contributor`, or `Storage Blob Data Owner` RBAC role on storage account. A user who writes data in the Azure storage must have `Storage Blob Data Contributor` or `Storage Blob Data Owner` role. Note that `Storage Owner` role does not imply that a user is also `Storage Data Owner`.
- **Access Control Lists (ACL)** enable you to define a fine grained Read(R), Write(W), and Execute(X) permissions on the files and directories in Azure storage. ACL can be assigned to Azure AD users. If readers want to read a file on a path in Azure Storage, they must have Execute(X) ACL on every folder in the file path, and Read(R) ACL on the file. Learn more how to set ACL permissions in storage layer.
- **Shared access signature (SAS)** enables a reader to access the files on the Azure Data Lake storage using the time-limited token. The reader doesn't even need to be authenticated as Azure AD user. SAS token contains the permissions granted to the reader as well as the period when the token is valid. SAS token is good choice for time-constrained access to any user that doesn't even need to be in the same Azure AD tenant. SAS token can be defined on the storage account or on specific directories. Learn more about granting limited access to Azure Storage resources using shared access signatures.

As an alternative, you can make your files publicly available by allowing anonymous access. This approach should NOT be used if you have non-public data.

Supported storage authorization types

A user that has logged into a serverless SQL pool must be authorized to access and query the files in Azure Storage if the files aren't publicly available. You can use four authorization types to access non-public storage - User Identity, Shared access signature, Service Principal and Managed Identity.

> **NOTE**
> **Azure AD pass-through** is the default behavior when you create a workspace.

- User Identity
- Shared access signature
- Service Principal
- Managed Identity
- Anonymous access

User Identity, also known as "Azure AD pass-through", is an authorization type where the identity of the Azure AD user that logged into serverless SQL pool is used to authorize data access. Before accessing the data, the Azure Storage administrator must grant permissions to the Azure AD user. As indicated in the table below, it's not supported for the SQL user type.

> **IMPORTANT**
> AAD authentication token might be cached by the client applications. For example PowerBI caches AAD token and reuses the same token for an hour. The long running queries might fail if the token expires in the middle of the query execution. If you are experiencing query failures caused by the AAD access token that expires in the middle of the query, consider switching to Service Principal, Managed identity or Shared access signature.

You need to have a Storage Blob Data Owner/Contributor/Reader role to use your identity to access the data. As an alternative, you can specify fine-grained ACL rules to access files and folders. Even if you are an Owner of a Storage Account, you still need to add yourself into one of the Storage Blob Data roles. To learn more about access control in Azure Data Lake Store Gen2, review the Access control in Azure Data Lake Storage Gen2 article.

Cross-tenant scenarios

In cases when Azure Storage is in a different tenant from the Synapse serverless SQL pool, authorization via **Service Principal** is the recommended method. **SAS** authorization is also possible, while **Managed Identity** is not supported.

Supported authorization types for databases users

In the table below you can find the available authorization types for different login methods into Synapse Serverless SQL endpoint:

AUTHORIZATION TYPE	*SQL USER*	*AZURE AD USER*	*SERVICE PRINCIPAL*
User Identity	Not Supported	Supported	Supported
SAS	Supported	Supported	Supported
Service Principal	Supported	Supported	Supported
Managed Identity	Supported	Supported	Supported

Supported storages and authorization types

You can use the following combinations of authorization and Azure Storage types:

AUTHORIZATION TYPE	BLOB STORAGE	ADLS GEN1	ADLS GEN2
SAS	Supported	Not supported	Supported

AUTHORIZATION TYPE	BLOB STORAGE	ADLS GEN1	ADLS GEN2
Service Principal	Supported	Supported	Supported
Managed Identity	Supported	Supported	Supported
User Identity	Supported	Supported	Supported

Firewall protected storage

You can configure storage accounts to allow access to specific serverless SQL pool by creating a resource instance rule. When accessing storage that is protected with the firewall, you can use **User Identity** or **Managed Identity**.

> **NOTE**
> The firewall feature on Storage is in public preview and is available in all public cloud regions.

In the table below you can find the available authorization types for different login methods into Synapse Serverless SQL endpoint:

AUTHORIZATION TYPE	*SQL USER*	*AZURE AD USER*	*SERVICE PRINCIPAL*
User Identity	Not Supported	Supported	Supported
SAS	Not Supported	Not Supported	Not Supported
Service Principal	Not Supported	Not Supported	Not Supported
Managed Identity	Supported	Supported	Supported

- User Identity
- Shared access signature
- Service Principal
- Managed Identity
- Anonymous access

To access storage that is protected with the firewall via User Identity, you can use Azure portal UI or PowerShell module Az.Storage.

Configuration via Azure portal

1. Search for your Storage Account in Azure portal.
2. Go to Networking under section Settings.
3. In Section "Resource instances" add an exception for your Synapse workspace.
4. Select Microsoft.Synapse/workspaces as a Resource type.
5. Select name of your workspace as an Instance name.
6. Click Save.

Configuration via PowerShell

Follow these steps to configure your storage account firewall and add an exception for Synapse workspace.

1. Open PowerShell or install PowerShell

2. Install the Az.Storage 3.4.0 module and Az.Synapse 0.7.0:

```
Install-Module -Name Az.Storage -RequiredVersion 3.4.0
Install-Module -Name Az.Synapse -RequiredVersion 0.7.0
```

> **IMPORTANT**
>
> Make sure that you use **version 3.4.0**. You can check your Az.Storage version by running this command:
>
> ```
> Get-Module -ListAvailable -Name  Az.Storage | select Version
> ```

3. Connect to your Azure Tenant:

```
Connect-AzAccount
```

4. Define variables in PowerShell:

   - Resource group name - you can find this in Azure portal in overview of Storage account.
   - Account Name - name of storage account that is protected by firewall rules.
   - Tenant ID - you can find this in Azure portal in Azure Active Directory in tenant information.
   - Workspace Name - Name of the Synapse workspace.

```
    $resourceGroupName = "<resource group name>"
    $accountName = "<storage account name>"
    $tenantId = "<tenant id>"
    $workspaceName = "<synapse workspace name>"

    $workspace = Get-AzSynapseWorkspace -Name $workspaceName
    $resourceId = $workspace.Id
    $index = $resourceId.IndexOf("/resourceGroups/", 0)
    # Replace G with g - /resourceGroups/ to /resourcegroups/
    $resourceId = $resourceId.Substring(0,$index) + "/resourcegroups/" + $resourceId.Substring($index
+ "/resourceGroups/".Length)
    $resourceId
```

> **IMPORTANT**
>
> Make sure that resource id matches this template in the print of the resourceId variable.
>
> It's important to write **resourcegroups** in lower case. Example of one resource id:
>
> ```
> /subscriptions/{subscription-id}/resourcegroups/{resource-
> group}/providers/Microsoft.Synapse/workspaces/{name-of-workspace}
> ```

5. Add Storage Network rule:

```
    Add-AzStorageAccountNetworkRule -ResourceGroupName $resourceGroupName -Name $accountName -
TenantId $tenantId -ResourceId $resourceId
```

6. Verify that rule was applied in your storage account:

```
    $rule = Get-AzStorageAccountNetworkRuleSet -ResourceGroupName $resourceGroupName -Name
$accountName
    $rule.ResourceAccessRules | ForEach-Object {
        if ($_.ResourceId -cmatch "\/subscriptions\/(\w\-*)+\/resourcegroups\/(.)+") {
            Write-Host "Storage account network rule is successfully configured." -ForegroundColor
Green
            $rule.ResourceAccessRules
        } else {
            Write-Host "Storage account network rule is not configured correctly. Remove this rule
and follow the steps in detail." -ForegroundColor Red
            $rule.ResourceAccessRules
        }
    }
```

Credentials

To query a file located in Azure Storage, your serverless SQL pool end point needs a credential that contains the authentication information. Two types of credentials are used:

- Server-level CREDENTIAL is used for ad-hoc queries executed using `OPENROWSET` function. Credential name must match the storage URL.
- DATABASE SCOPED CREDENTIAL is used for external tables. External table references `DATA SOURCE` with the credential that should be used to access storage.

To allow a user to create or drop a credential, admin can GRANT/DENY ALTER ANY CREDENTIAL permission to a user:

```
GRANT ALTER ANY CREDENTIAL TO [user_name];
```

Database users who access external storage must have permission to use credentials.

Grant permissions to use credential

To use the credential, a user must have `REFERENCES` permission on a specific credential. To grant a `REFERENCES` permission ON a storage_credential for a specific_user, execute:

```
GRANT REFERENCES ON CREDENTIAL::[storage_credential] TO [specific_user];
```

Server-scoped credential

Server-scoped credentials are used when SQL login calls `OPENROWSET` function without `DATA_SOURCE` to read files on some storage account. The name of server-scoped credential **must** match the base URL of Azure storage (optionally followed by a container name). A credential is added by running CREATE CREDENTIAL. You'll need to provide a CREDENTIAL NAME argument.

> **NOTE**
> The `FOR CRYPTOGRAPHIC PROVIDER` argument is not supported.

Server-level CREDENTIAL name must match the full path to the storage account (and optionally container) in the following format: `<prefix>://<storage_account_path>[/<container_name>]`. Storage account paths are described in the following table:

EXTERNAL DATA SOURCE	PREFIX	STORAGE ACCOUNT PATH
Azure Blob Storage	https	<storage_account>.blob.core.windows.net
Azure Data Lake Storage Gen1	https	<storage_account>.azuredatalakestore.net/webhdfs/v1
Azure Data Lake Storage Gen2	https	<storage_account>.dfs.core.windows.net

Server-scoped credentials enable access to Azure storage using the following authentication types:

- User Identity
- Shared access signature
- Service Principal
- Managed Identity
- Public access

Azure AD users can access any file on Azure storage if they have `Storage Blob Data Owner`, `Storage Blob Data Contributor`, or `Storage Blob Data Reader` role. Azure AD users don't need credentials to access storage.

SQL users can't use Azure AD authentication to access storage.

Database-scoped credential

Database-scoped credentials are used when any principal calls `OPENROWSET` function with `DATA_SOURCE` or selects data from external table that don't access public files. The database scoped credential doesn't need to match the name of storage account. It will be explicitly used in DATA SOURCE that defines the location of storage.

Database-scoped credentials enable access to Azure storage using the following authentication types:

- Azure AD Identity
- Shared access signature
- Service Principal
- Managed Identity
- Public access

Azure AD users can access any file on Azure storage if they have at least `Storage Blob Data Owner`, `Storage Blob Data Contributor`, or `Storage Blob Data Reader` role. Azure AD users don't need credentials to access storage.

```
CREATE EXTERNAL DATA SOURCE mysample
WITH (    LOCATION   = 'https://<storage_account>.dfs.core.windows.net/<container>/<path>'
)
```

SQL users can't use Azure AD authentication to access storage.

Database scoped credentials are used in external data sources to specify what authentication method will be used to access this storage:

```
CREATE EXTERNAL DATA SOURCE mysample
WITH (    LOCATION   = 'https://<storage_account>.dfs.core.windows.net/<container>/<path>',
          CREDENTIAL = <name of database scoped credential>
)
```

Examples

Access a publicly available data source

Use the following script to create a table that accesses publicly available data source.

```
CREATE EXTERNAL FILE FORMAT [SynapseParquetFormat]
       WITH ( FORMAT_TYPE = PARQUET)
GO
CREATE EXTERNAL DATA SOURCE publicData
WITH (    LOCATION   = 'https://<storage_account>.dfs.core.windows.net/<public_container>/<path>' )
GO

CREATE EXTERNAL TABLE dbo.userPublicData ( [id] int, [first_name] varchar(8000), [last_name] varchar(8000) )
WITH ( LOCATION = 'parquet/user-data/*.parquet',
       DATA_SOURCE = [publicData],
       FILE_FORMAT = [SynapseParquetFormat] )
```

Database user can read the content of the files from the data source using external table or OPENROWSET function that references the data source:

```
SELECT TOP 10 * FROM dbo.userPublicData;
GO
SELECT TOP 10 * FROM OPENROWSET(BULK 'parquet/user-data/*.parquet',
                                DATA_SOURCE = 'mysample',
                                FORMAT='PARQUET') as rows;
GO
```

Access a data source using credentials

Modify the following script to create an external table that accesses Azure storage using SAS token, Azure AD identity of user, or managed identity of workspace.

```
-- Create master key in databases with some password (one-off per database)
CREATE MASTER KEY ENCRYPTION BY PASSWORD = 'Y*********0'
GO

-- Create databases scoped credential that use Managed Identity, SAS token or Service Principal. User needs
to create only database-scoped credentials that should be used to access data source:

CREATE DATABASE SCOPED CREDENTIAL WorkspaceIdentity
WITH IDENTITY = 'Managed Identity'
GO
CREATE DATABASE SCOPED CREDENTIAL SasCredential
WITH IDENTITY = 'SHARED ACCESS SIGNATURE', SECRET = 'sv=2019-10-1********ZVsTOL0ltEGhf54N8KhDCRfLRI%3D'
GO
CREATE DATABASE SCOPED CREDENTIAL SPNCredential WITH
IDENTITY = '**44e*****8f6-ag44-1890-34u4-22r23r771098@https://login.microsoftonline.com/**do99dd-87f3-33da-
33gf-3d3rh133ee33/oauth2/token'
, SECRET = '.7OaaU_454azar9WWzLL.Ea9ePPZWzQee~'
GO
-- Create data source that one of the credentials above, external file format, and external tables that
reference this data source and file format:

CREATE EXTERNAL FILE FORMAT [SynapseParquetFormat] WITH ( FORMAT_TYPE = PARQUET)
GO

CREATE EXTERNAL DATA SOURCE mysample
WITH (    LOCATION   = 'https://<storage_account>.dfs.core.windows.net/<container>/<path>'
-- Uncomment one of these options depending on authentication method that you want to use to access data
source:
--,CREDENTIAL = WorkspaceIdentity
--,CREDENTIAL = SasCredential
--,CREDENTIAL = SPNCredential
)

CREATE EXTERNAL TABLE dbo.userData ( [id] int, [first_name] varchar(8000), [last_name] varchar(8000) )
WITH ( LOCATION = 'parquet/user-data/*.parquet',
       DATA_SOURCE = [mysample],
       FILE_FORMAT = [SynapseParquetFormat] );
```

Database user can read the content of the files from the data source using external table or OPENROWSET function that references the data source:

```
SELECT TOP 10 * FROM dbo.userdata;
GO
SELECT TOP 10 * FROM OPENROWSET(BULK 'parquet/user-data/*.parquet', DATA_SOURCE = 'mysample',
FORMAT='PARQUET') as rows;
GO
```

- Query Parquet nested types

Synchronize Apache Spark for Azure Synapse external table definitions in serverless SQL pool

8/19/2022 • 2 minutes to read • Edit Online

Serverless SQL pool can automatically synchronize metadata from Apache Spark. A serverless SQL pool database will be created for each database existing in serverless Apache Spark pools.

For each Spark external table based on Parquet or CSV and located in Azure Storage, an external table is created in a serverless SQL pool database. As such, you can shut down your Spark pools and still query Spark external tables from serverless SQL pool.

When a table is partitioned in Spark, files in storage are organized by folders. Serverless SQL pool will use partition metadata and only target relevant folders and files for your query.

Metadata synchronization is automatically configured for each serverless Apache Spark pool provisioned in the Azure Synapse workspace. You can start querying Spark external tables instantly.

Each Spark Parquet or CSV external table located in Azure Storage is represented with an external table in a dbo schema that corresponds to a serverless SQL pool database.

For Spark external table queries, run a query that targets an external [spark_table]. Before running the following example, make sure you have correct access to the storage account where the files are located.

```
SELECT * FROM [db].dbo.[spark_table]
```

Apache Spark data types to SQL data types mapping

For more information on mapping Apache Spark data types to SQL data types, see Azure Synapse Analytics shared metadata tables.

Manageability and monitoring with dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Synapse SQL allows you to provision a data warehouse via dedicated SQL pool. The articles that follow will help you to manage and monitor your data warehouse. You'll also learn ways to optimize the data warehouse's usage and performance.

Overview

- Learn about compute management and elasticity
- Understand what metrics and logs are available in the Azure portal
- Learn about backup and restore capabilities
- Learn about built-in intelligence and recommendations
- Learn about maintenance periods and what is available to minimize downtime of your data warehouse
- Find common troubleshooting guidance

Next steps

For How-to guides, see Monitor and tune your dedicated SQL pool.

Monitoring resource utilization and query activity in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics provides a rich monitoring experience within the Azure portal to surface insights regarding your data warehouse workload. The Azure portal is the recommended tool when monitoring your data warehouse as it provides configurable retention periods, alerts, recommendations, and customizable charts and dashboards for metrics and logs. The portal also enables you to integrate with other Azure monitoring services such as Azure Monitor (logs) with Log analytics to provide a holistic monitoring experience for not only your data warehouse but also your entire Azure analytics platform for an integrated monitoring experience. This documentation describes what monitoring capabilities are available to optimize and manage your analytics platform with Synapse SQL.

Resource utilization

The following metrics are available in the Azure portal for Synapse SQL. These metrics are surfaced through Azure Monitor.

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
CPU percentage	CPU utilization across all nodes for the data warehouse	Avg, Min, Max
Data IO percentage	IO Utilization across all nodes for the data warehouse	Avg, Min, Max
Memory percentage	Memory utilization (SQL Server) across all nodes for the data warehouse	Avg, Min, Max
Active Queries	Number of active queries executing on the system	Sum
Queued Queries	Number of queued queries waiting to start executing	Sum
Successful Connections	Number of successful connections (logins) against the database	Sum, Count
Failed Connections	Number of failed connections (logins) against the database	Sum, Count
Blocked by Firewall	Number of logins to the data warehouse which was blocked	Sum, Count
DWU limit	Service level objective of the data warehouse	Avg, Min, Max
DWU percentage	Maximum between CPU percentage and Data IO percentage	Avg, Min, Max

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
DWU used	DWU limit * DWU percentage	Avg, Min, Max
Cache hit percentage	(cache hits / (cache hits + cache miss)) * 100, where cache hits are the sum of all columnstore segments hits in the local SSD cache and cache miss is the columnstore segments misses in the local SSD cache summed across all nodes	Avg, Min, Max
Cache used percentage	(cache used / cache capacity) * 100 where cache used is the sum of all bytes in the local SSD cache across all nodes and cache capacity is the sum of the storage capacity of the local SSD cache across all nodes	Avg, Min, Max
Local tempdb percentage	Local tempdb utilization across all compute nodes - values are emitted every five minutes	Avg, Min, Max

Things to consider when viewing metrics and setting alerts:

- DWU used represents only a **high-level representation of usage** across the SQL pool and is not meant to be a comprehensive indicator of utilization. To determine whether to scale up or down, consider all factors which can be impacted by DWU such as concurrency, memory, tempdb, and adaptive cache capacity. We recommend running your workload at different DWU settings to determine what works best to meet your business objectives.
- Failed and successful connections are reported for a particular data warehouse - not for the server itself.
- Memory percentage reflects utilization even if the data warehouse is in idle state - it does not reflect active workload memory consumption. Use and track this metric along with others (`tempdb`, gen2 cache) to make a holistic decision on if scaling for additional cache capacity will increase workload performance to meet your requirements.

Query activity

For a programmatic experience when monitoring Synapse SQL via T-SQL, the service provides a set of Dynamic Management Views (DMVs). These views are useful when actively troubleshooting and identifying performance bottlenecks with your workload.

To view the list of DMVs that apply to Synapse SQL, review dedicated SQL pool DMVs.

Metrics and diagnostics logging

Both metrics and logs can be exported to Azure Monitor, specifically the Azure Monitor logs component and can be programmatically accessed through log queries. The log latency for Synapse SQL is about 10-15 minutes.

Next steps

The following How-to guide describes common scenarios and use cases when monitoring and managing your data warehouse:

- Monitor your data warehouse workload with DMVs
- Use Azure Monitor with your Azure Synapse Analytics workspace

Azure Advisor recommendations for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

This article describes the dedicated SQL pool recommendations available in Azure Advisor.

Dedicated SQL pool provides recommendations to ensure your data warehouse workload is consistently optimized for performance. Recommendations are tightly integrated with Azure Advisor to provide you with best practices directly within the Azure portal. Dedicated SQL pool collects telemetry and surfaces recommendations for your active workload on a daily cadence. The supported recommendation scenarios are outlined below along with how to apply recommended actions.

You can check your recommendations today!

Data skew

Data skew can cause additional data movement or resource bottlenecks when running your workload. The following documentation describes show to identify data skew and prevent it from happening by selecting an optimal distribution key.

- Identify and remove skew

No or outdated statistics

Having suboptimal statistics can severely impact query performance as it can cause the SQL query optimizer to generate suboptimal query plans. The following documentation describes the best practices around creating and updating statistics:

- Creating and updating table statistics

To see the list of impacted tables by these recommendations, run the following T-SQL script. Advisor continuously runs the same T-SQL script to generate these recommendations.

Replicate tables

For replicated table recommendations, Advisor detects table candidates based on the following physical characteristics:

- Replicated table size
- Number of columns
- Table distribution type
- Number of partitions

Advisor continuously leverages workload-based heuristics such as table access frequency, rows returned on average, and thresholds around data warehouse size and activity to ensure high-quality recommendations are generated.

The following section describes workload-based heuristics you may find in the Azure portal for each replicated table recommendation:

- Scan avg- the average percent of rows that were returned from the table for each table access over the past seven days

- Frequent read, no update - indicates that the table has not been updated in the past seven days while showing access activity
- Read/update ratio - the ratio of how frequent the table was accessed relative to when it gets updated over the past seven days
- Activity - measures the usage based on access activity. This activity compares the table access activity relative to the average table access activity across the data warehouse over the past seven days.

Currently Advisor will only show at most four replicated table candidates at once with clustered columnstore indexes prioritizing the highest activity.

> **IMPORTANT**
> The replicated table recommendation is not full proof and does not take into account data movement operations. We are working on adding this as a heuristic but in the meantime, you should always validate your workload after applying the recommendation. To learn more about replicated tables, visit the following documentation.

Adaptive (Gen2) cache utilization

When you have a large working set, you can experience a low cache hit percentage and high cache utilization. For this scenario, you should scale up to increase cache capacity and rerun your workload. For more information visit the following documentation.

Tempdb contention

Query performance can degrade when there is high tempdb contention. Tempdb contention can occur via user-defined temporary tables or when there is a large amount of data movement. For this scenario, you can scale for more tempdb allocation and configure resource classes and workload management to provide more memory to your queries.

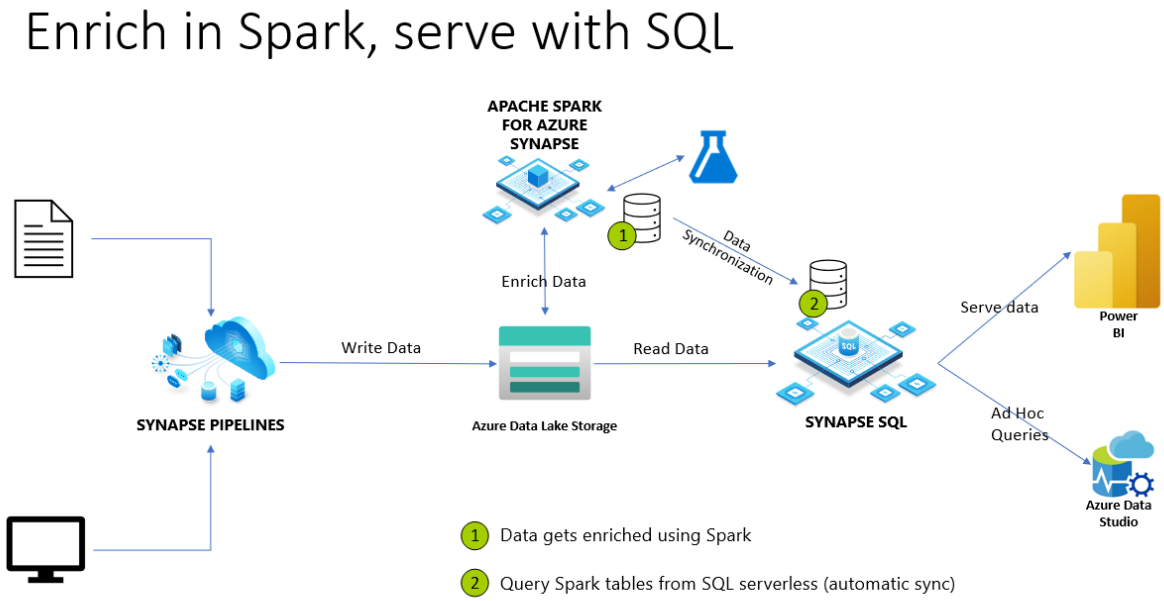
Data loading misconfiguration

You should always load data from a storage account in the same region as your dedicated SQL pool to minimize latency. Use the COPY statement for high throughput data ingestion and split your staged files in your storage account to maximize throughput. If you can't use the COPY statement, you can use the SqlBulkCopy API or bcp with a high batch size for better throughput. See Best practices for data loading for additional data loading guidance.

How to set up access control on synchronized objects in serverless SQL pool

8/19/2022 • 3 minutes to read • Edit Online

In Azure Synapse Analytics, Spark databases and tables are shared with serverless SQL pool. Lake databases, Parquet, and CSV backed tables created with Spark are automatically available in serverless SQL pool. This feature allows using serverless SQL pool to explore and query data prepared by using Spark pools. On below diagram, you can see a high-level architecture overview to utilize this feature. First, Azure Synapse Pipelines are moving data from on-premise (or other) storage to Azure Data Lake Storage. Spark can now enrich the data, and create databases, and tables that are getting synchronized to serverless Synapse SQL. Later, user can execute ad-hoc queries on top of the enriched data or serve it to Power BI for example.



Full administrator access(sysadmin)

Once these databases and tables are synchronized from Spark to serverless SQL pool, these external tables in serverless SQL pool can be used to access the same data. However, objects in serverless SQL pool are read-only because of keeping consistency with the Spark pools objects. The limitation makes only users with Synapse SQL Administrator or Synapse Administrator roles can access these objects in serverless SQL pool. If a non-admin user tries to execute a query on the synchronized database/table, they'll receive error like: `External table '<table>' is not accessible because content of directory cannot be listed.` despite them having access to data on the underlying storage account(s).

Since synchronized databases in serverless SQL pool are read-only, they can't be modified. Creating a user, or giving other permissions will fail if attempted. To read synchronized databases, one must have privileged server-level permissions (like sysadmin). This limitation is also present on external tables in serverless SQL pool when using Azure Synapse Link for Dataverse and lake databases tables.

Non-admin access to synchronized databases

A user who needs to read data and create reports usually doesn't have full administrator access (sysadmin). This

user is usually data analyst who just needs to read and analyze data using the existing tables. They don't need to create new objects.

A user with minimal permission should be able to:

- Connect to a database that is replicated from Spark
- Select data via external tables and access the underlying ADLS data.

After executing the code script below, it will allow non-admin users to have server-level permissions to connect to any database. It will also allow users to view data from all schema-level objects, such as tables or views. Data access security can be managed on the storage layer.

```
-- Creating Azure AD login (same can be achieved for Azure AD app)
    CREATE LOGIN [login@contoso.com] FROM EXTERNAL PROVIDER;
    go;

    GRANT CONNECT ANY DATABASE to [login@contoso.com];
    GRANT SELECT ALL USER SECURABLES to [login@contoso.com];
    GO;
```

`CONNECT ANY DATABASE` permission will allow a user to access connection to any database, but it doesn't grant any permission in any database beyond connect. When `SELECT ALL USER SECURABLES` permission is granted, a login can view data from all schema-level objects, such as external tables and views (any schema except sys and INFORMATION_SCHEMA). This permission has effect in all databases that the user can connect to. Read more about GRANT SERVER permissions.

After creating a login and granting permissions, users can run queries on top of the synchronized external tables. This mitigation can also be applied to Azure AD security groups.

More security on the objects can be managed through specific schemas and lock access to a specific schema. The workaround requires extra DDL. For this scenario, you can create new serverless database, schemas, and views that will point to the Spark tables data on ADLS.

Access to the data on storage account can be managed via ACL or regular Storage Blob Data Owner/Reader/Contributor roles for Azure AD users/groups. For Service Principals (Azure AD apps), make sure you use ACL setup.

> **NOTE**
>
> - If you want to forbid using OPENROWSET on top of the data, you can use `DENY ADMINISTER BULK OPERATIONS to [login@contoso.com];` For more information, visit DENY Server permissions.
> - If you want to forbid using specific schemas, you can use `DENY SELECT ON SCHEMA::[schema_name] TO [login@contoso.com];` For more information, visit DENY Schema Permissions.

Column-level security

8/19/2022 • 2 minutes to read • Edit Online

Column-Level security allows customers to control access to table columns based on the user's execution context or group membership.

Since this video was posted Row level Security became available for dedicated SQL pool in Azure Synapse.

Column-level security simplifies the design and coding of security in your application, allowing you to restrict column access to protect sensitive data. For example, ensuring that specific users can access only certain columns of a table pertinent to their department. The access restriction logic is located in the database tier rather than away from the data in another application tier. The database applies the access restrictions every time data access is attempted from any tier. This restriction makes your security more reliable and robust by reducing the surface area of your overall security system. In addition, column-level security also eliminates the need for introducing views to filter out columns for imposing access restrictions on the users.

You can implement column-level security with the GRANT T-SQL statement. With this mechanism, both SQL and Azure Active Directory (Azure AD) authentication are supported.

Syntax

```
GRANT <permission> [ ,...n ] ON
    [ OBJECT :: ][ schema_name ]. object_name [ ( column [ ,...n ] ) ]
    TO <database_principal> [ ,...n ]
    [ WITH GRANT OPTION ]
    [ AS <database_principal> ]
<permission> ::=
    SELECT
  | UPDATE
<database_principal> ::=
      Database_user
    | Database_role
    | Database_user_mapped_to_Windows_User
    | Database_user_mapped_to_Windows_Group
```

Example

The following example shows how to restrict `TestUser` from accessing the `SSN` column of the `Membership` table:

Create `Membership` table with SSN column used to store social security numbers:

```
CREATE TABLE Membership
  (MemberID int IDENTITY,
   FirstName varchar(100) NULL,
   SSN char(9) NOT NULL,
   LastName varchar(100) NOT NULL,
   Phone varchar(12) NULL,
   Email varchar(100) NULL);
```

Allow `TestUser` to access all columns except for the SSN column, which has the sensitive data:

```
GRANT SELECT ON Membership(MemberID, FirstName, LastName, Phone, Email) TO TestUser;
```

Queries executed as `TestUser` will fail if they include the SSN column:

```
SELECT * FROM Membership;

-- Msg 230, Level 14, State 1, Line 12
-- The SELECT permission was denied on the column 'SSN' of the object 'Membership', database 'CLS_TestDW',
schema 'dbo'.
```

Use Cases

Some examples of how column-level security is being used today:

- A financial services firm allows only account managers to have access to customer social security numbers (SSN), phone numbers, and other personal data.
- A health care provider allows only doctors and nurses to have access to sensitive medical records while preventing members of the billing department from viewing this data.

What is workload management?

8/19/2022 • 2 minutes to read • Edit Online

Running mixed workloads can pose resource challenges on busy systems. Solution Architects seek ways to separate classic data warehousing activities (such as loading, transforming, and querying data) to ensure that enough resources exist to hit SLAs.

Physical server isolation can lead to pockets of infrastructure that are underutilized, overbooked or in a state where caches are constantly being primed with hardware starting and stopping. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI).

A data warehouse workload refers to all operations that transpire in relation to a data warehouse. The depth and breadth of these components depend on the maturity level of the data warehouse. The data warehouse workload encompasses:

- The entire process of loading data into the warehouse
- Performing data warehouse analysis and reporting
- Managing data in the data warehouse
- Exporting data from the data warehouse

The performance capacity of a data warehouse is determined by the data warehouse units.

- To view the resources allocated for all the performance profiles, see Memory and concurrency limits.
- To adjust capacity, you can scale up or down.

Workload management concepts

In the past, for Synapse SQL in Azure Synapse you managed the query performance through resource classes. Resource classes allowed for assigning memory to a query based on role membership. The primary challenge with resources classes is that, once configured, there was no governance or ability to control the workload.

For example, granting an ad-hoc user role membership to smallrc allowed that user to consume 100% of the memory on the system. With resource classes, there is no way to reserve and ensure resources are available for critical workloads.

Dedicated SQL pool workload management in Azure Synapse consists of three high-level concepts: Workload Classification, Workload Importance, and Workload Isolation. These capabilities give you more control over how your workload utilizes system resources.

Workload classification is the concept of assigning a request to a workload group and setting importance levels. Historically, this assignment was done via role membership using sp_addrolemember. This action can now be done via the CREATE WORKLOAD CLASSIFER. The classification capability provides a richer set of options such as label, session, and time to classify requests.

Workload importance influences the order in which a request gets access to resources. On a busy system, a request with higher importance has first access to resources. Importance can also ensure ordered access to locks.

Workload isolation reserves resources for a workload group. Resources reserved in a workload group are held exclusively for that workload group to ensure execution. Workload groups also allow you to define the amount of resources that are assigned per request, much like resource classes do. Workload groups give you the ability

to reserve or cap the amount of resources a set of requests can consume. Finally, workload groups are a mechanism to apply rules, such as query timeout, to requests.

Next steps

Workload classification for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

This article explains the workload classification process of assigning a workload group and importance to incoming requests with dedicated SQL pools in Azure Synapse.

Classification

Workload management classification allows workload policies to be applied to requests through assigning resource classes and importance.

While there are many ways to classify data warehousing workloads, the simplest and most common classification is load and query. You load data with insert, update, and delete statements. You query the data using selects. A data warehousing solution will often have a workload policy for load activity, such as assigning a higher resource class with more resources. A different workload policy could apply to queries, such as lower importance compared to load activities.

You can also subclassify your load and query workloads. Subclassification gives you more control of your workloads. For example, query workloads can consist of cube refreshes, dashboard queries or ad-hoc queries. You can classify each of these query workloads with different resource classes or importance settings. Load can also benefit from subclassification. Large transformations can be assigned to larger resource classes. Higher importance can be used to ensure key sales data is loader before weather data or a social data feed.

Not all statements are classified as they do not require resources or need importance to influence execution. DBCC commands, BEGIN, COMMIT, and ROLLBACK TRANSACTION statements are not classified.

Classification process

Classification for dedicated SQL pool is achieved today by assigning users to a role that has a corresponding resource class assigned to it using sp_addrolemember. The ability to characterize requests beyond a login to a resource class is limited with this capability. A richer method for classification is now available with the CREATE WORKLOAD CLASSIFIER syntax. With this syntax, dedicated SQL pool users can assign importance and how much system resources are assigned to a request via the `workload_group` parameter.

Classification weighting

As part of the classification process, weighting is in place to determine which workload group is assigned. The weighting goes as follows:

CLASSIFIER PARAMETER	WEIGHT
MEMBERNAME:USER	64
MEMBERNAME:ROLE	32
WLM_LABEL	16

CLASSIFIER PARAMETER	WEIGHT
WLM_CONTEXT	8
START_TIME/END_TIME	4

The `membername` parameter is mandatory. However, if the membername specified is a database user instead of a database role, the weighting for user is higher and thus that classifier is chosen.

If a user is a member of multiple roles with different resource classes assigned or matched in multiple classifiers, the user is given the highest resource class assignment. This behavior is consistent with existing resource class assignment behavior.

> **NOTE**
> Classifying managed identities (MI) behavior differs between the dedicated SQL pool in Azure Synapse workspaces and the standalone dedicated SQL pool (formerly SQL DW). While the standalone dedicated SQL pool MI maintains the assigned identity, for Azure Synapse workspaces the MI runs as **dbo**. This cannot be changed. The dbo role, by default, is classified to smallrc. Creating a classifier for the dbo role allows for assigning requests to a workload group other than smallrc. If dbo alone is too generic for classification and has broader impacts, consider using label, session or time-based classification in conjunction with the dbo role classification.

System classifiers

Workload classification has system workload classifiers. The system classifiers map existing resource class role memberships to resource class resource allocations with normal importance. System classifiers can't be dropped. To view system classifiers, you can run the below query:

```
SELECT * FROM sys.workload_management_workload_classifiers where classifier_id <= 12
```

Mixing resource class assignments with classifiers

System classifiers created on your behalf provide an easy path to migrate to workload classification. Using resource class role mappings with classification precedence, can lead to misclassification as you start to create new classifiers with importance.

Consider the following scenario:

- An existing data warehouse has a database user DBAUser assigned to the largerc resource class role. The resource class assignment was done with sp_addrolemember.
- The data warehouse is now updated with workload management.
- To test the new classification syntax, the database role DBARole (which DBAUser is a member of), has a classifier created for them mapping them to mediumrc and high importance.
- When DBAUser logs in and runs a query, the query will be assigned to largerc. Because a user takes precedence over a role membership.

To simplify troubleshooting misclassification, we recommended you remove resource class role mappings as you create workload classifiers. The code below returns existing resource class role memberships. Run sp_droprolemember for each member name returned from the corresponding resource class.

```
SELECT  r.name AS [Resource Class]
,       m.name AS membername
FROM    sys.database_role_members rm
JOIN    sys.database_principals AS r ON rm.role_principal_id = r.principal_id
JOIN    sys.database_principals AS m ON rm.member_principal_id = m.principal_id
WHERE   r.name IN
('mediumrc','largerc','xlargerc','staticrc10','staticrc20','staticrc30','staticrc40','staticrc50','staticrc6
0','staticrc70','staticrc80');

--for each row returned run
sp_droprolemember '[Resource Class]', membername
```

Next steps

- For more information on creating a classifier, see the CREATE WORKLOAD CLASSIFIER (Transact-SQL).
- See the Quickstart on how to create a workload classifier Create a workload classifier.
- See the how-to articles to Configure Workload Importance and how to manage and monitor Workload Management.
- See sys.dm_pdw_exec_requests to view queries and the importance assigned.

Azure Synapse Analytics workload importance

8/19/2022 • 2 minutes to read • Edit Online

This article explains how workload importance can influence the order of execution for dedicated SQL pool requests in Azure Synapse.

Importance

Business needs can require data warehousing workloads to be more important than others. Consider a scenario where mission critical sales data is loaded before the fiscal period close. Data loads for other sources such as weather data don't have strict SLAs. Setting high importance for a request to load sales data and low importance to a request to load weather data ensures the sales data load gets first access to resources and completes quicker.

Importance levels

There are five levels of importance: low, below_normal, normal, above_normal, and high. Requests that don't set importance are assigned the default level of normal. Requests that have the same importance level have the same scheduling behavior that exists today.

Importance scenarios

Beyond the basic importance scenario described above with sales and weather data, there are other scenarios where workload importance helps meet data processing and querying needs.

Locking

Access to locks for read and write activity is one area of natural contention. Activities such as partition switching or RENAME OBJECT require elevated locks. Without workload importance, dedicated SQL pool in Azure Synapse optimizes for throughput. Optimizing for throughput means that when running and queued requests have the same locking needs and resources are available, the queued requests can bypass requests with higher locking needs that arrived in the request queue earlier. Once workload importance is applied to requests with higher locking needs. Request with higher importance will be run before request with lower importance.

Consider the following example:

- Q1 is actively running and selecting data from SalesFact.
- Q2 is queued waiting for Q1 to complete. It was submitted at 9am and is attempting to partition switch new data into SalesFact.
- Q3 is submitted at 9:01am and wants to select data from SalesFact.

If Q2 and Q3 have the same importance and Q1 is still executing, Q3 will begin executing. Q2 will continue to wait for an exclusive lock on SalesFact. If Q2 has higher importance than Q3, Q3 will wait until Q2 is finished before it can begin execution.

Non-uniform requests

Another scenario where importance can help meet querying demands is when requests with different resource classes are submitted. As was previously mentioned, under the same importance, dedicated SQL pool in Azure Synapse optimizes for throughput. When mixed size requests (such as smallrc or mediumrc) are queued, dedicated SQL pool will choose the earliest arriving request that fits within the available resources. If workload

importance is applied, the highest importance request is scheduled next.

Consider the following example on DW500c:

- Q1, Q2, Q3, and Q4 are running smallrc queries.
- Q5 is submitted with the mediumrc resource class at 9am.
- Q6 is submitted with smallrc resource class at 9:01am.

Because Q5 is mediumrc, it requires two concurrency slots. Q5 needs to wait for two of the running queries to complete. However, when one of the running queries (Q1-Q4) completes, Q6 is scheduled immediately because the resources exist to execute the query. If Q5 has higher importance than Q6, Q6 waits until Q5 is running before it can begin executing.

Azure Synapse Analytics workload group isolation

8/19/2022 • 6 minutes to read • Edit Online

This article explains how workload groups can be used to configure workload isolation, contain resources, and apply runtime rules for query execution.

Workload groups

Workload groups are containers for a set of requests and are the basis for how workload management, including workload isolation, is configured on a system. Workload groups are created using the CREATE WORKLOAD GROUP syntax. A simple workload management configuration can manage data loads and user queries. For example, a workload group named `wgDataLoads` will define workload aspects for data being loaded into the system. Also, a workload group named `wgUserQueries` will define workload aspects for users running queries to read data from the system.

The following sections will highlight how workload groups provide the ability to define isolation, containment, request resource definition, and adhere to execution rules.

Resource governance

Workload groups govern memory and CPU resources. Disk and network IO as well as tempdb are not governed. Resource governance for memory and CPU is as follows:

Memory is governed at the request level and held throughout the duration of the request. See Resources per request definition for further details on how to configure the amount of memory per request. The MIN_PERCENTAGE_RESOURCE parameter for the workload group dedicates memory to that workload group exclusively. The CAP_PERCENTAGE_RESOURCE parameter for the workload group is a hard limit on the memory a workload group can consume.

CPU resources are governed at the workload group level and shared by all requests within a workload group. CPU resources are fluid compared to memory which is dedicated to a request for the duration of execution. Given CPU is a fluid resource, unused CPU resources can be consumed by all workload groups. This means that CPU utilization can exceed the CAP_PERCENTAGE_RESOURCE parameter for the workload group. This also means that the MIN_PERCENTAGE_RESOURCE parameter for the workload group is not a hard reservation like memory is. When CPU resources are under contention, utilization will align to the CAP_PERCENTAGE_RESOURCE definition for workload groups.

Workload isolation

Workload isolation means resources are reserved, exclusively, for a workload group. Workload isolation is achieved by configuring the MIN_PERCENTAGE_RESOURCE parameter to greater than zero in the CREATE WORKLOAD GROUP syntax. For continuous execution workloads that need to adhere to tight SLAs, isolation ensures resources are always available for the workload group.

Configuring workload isolation implicitly defines a guaranteed level of concurrency. For example, a workload group with a MIN_PERCENTAGE_RESOURCE set to 30% and REQUEST_MIN_RESOURCE_GRANT_PERCENT set to 2% is guaranteed 15 concurrency. The level of concurrency is guaranteed because 15-2% slots of resources are reserved within the workload group at all times (regardless of how REQUEST_*MAX*_RESOURCE_GRANT_PERCENT is configured). If REQUEST_MAX_RESOURCE_GRANT_PERCENT is greater than REQUEST_MIN_RESOURCE_GRANT_PERCENT and CAP_PERCENTAGE_RESOURCE is greater than MIN_PERCENTAGE_RESOURCE additional resources can be added per request (based on resource availability). If

REQUEST_MAX_RESOURCE_GRANT_PERCENT and REQUEST_MIN_RESOURCE_GRANT_PERCENT are equal and CAP_PERCENTAGE_RESOURCE is greater than MIN_PERCENTAGE_RESOURCE, additional concurrency is possible. Consider the below method for determining guaranteed concurrency:

[Guaranteed Concurrency] = [`MIN_PERCENTAGE_RESOURCE`] / [`REQUEST_MIN_RESOURCE_GRANT_PERCENT`]

> **NOTE**
> There are specific service level minimum values for min_percentage_resource. For more information, see Effective Values for further details.

In the absence of workload isolation, requests operate in the shared pool of resources. Access to resources in the shared pool is not guaranteed and is assigned on an importance basis.

Configuring workload isolation should be done with caution as the resources are allocated to the workload group even if there are no active requests in the workload group. Over-configuring isolation can lead to diminished overall system utilization.

Users should avoid a workload management solution that configures 100% workload isolation: 100% isolation is achieved when the sum of min_percentage_resource configured across all workload groups equals 100%. This type of configuration is overly restrictive and rigid, leaving little room for resource requests that are accidentally mis-classified. There is a provision to allow one request to execute from workload groups not configured for isolation. The resources allocated to this request will show up as a zero in the systems DMVs and borrow a smallrc level of resource grant from system reserved resources.

> **NOTE**
> To ensure optimal resource utilization, consider a workload management solution that leverages some isolation to ensure SLAs are met and mixed with shared resources that are accessed based on workload importance.

Workload containment

Workload containment refers to limiting the amount of resources a workload group can consume. Workload containment is achieved by configuring the CAP_PERCENTAGE_RESOURCE parameter to less than 100 in the CREATE WORKLOAD GROUP syntax. Consider the scenario whereby users need read access to the system so they can run a what-if analysis via ad-hoc queries. These types of requests could have a negative impact on other workloads that are running on the system. Configuring containment ensures the amount of resources is limited.

Configuring workload containment implicitly defines a maximum level of concurrency. With a CAP_PERCENTAGE_RESOURCE set to 60% and a REQUEST_MIN_RESOURCE_GRANT_PERCENT set to 1%, up to a 60-concurrency level is allowed for the workload group. Consider the method included below for determining the maximum concurrency:

[Max Concurrency] = [`CAP_PERCENTAGE_RESOURCE`] / [`REQUEST_MIN_RESOURCE_GRANT_PERCENT`]

> **NOTE**
> The effective CAP_PERCENTAGE_RESOURCE of a workload group will not reach 100% when workload groups with MIN_PERCENTAGE_RESOURCE at a level greater than zero are created. See sys.dm_workload_management_workload_groups_stats for effective runtime values.

Resources per request definition

Workload groups provide a mechanism to define the min and max amount of resources that are allocated per request with the REQUEST_MIN_RESOURCE_GRANT_PERCENT and REQUEST_MAX_RESOURCE_GRANT_PERCENT parameters in the CREATE WORKLOAD GROUP syntax. Resource in this case is memory. CPU resource governance is covered in the Resource governance section.

> **NOTE**
> REQUEST_MAX_RESOURCE_GRANT_PERCENT is an optional parameter that defaults to the same value that is specified for REQUEST_MIN_RESOURCE_GRANT_PERCENT.

Like choosing a resource class, configuring REQUEST_MIN_RESOURCE_GRANT_PERCENT sets the value for the resources utilized by a request. The amount of resources indicated by the set value is guaranteed for allocation to the request before it begins execution. For customers migrating from resource classes to workload groups, consider following the How To article to map from resources classes to workload groups as a starting point.

Configuring REQUEST_MAX_RESOURCE_GRANT_PERCENT to a value greater than REQUEST_MIN_RESOURCE_GRANT_PERCENT allows the system to allocate more resources per request. While scheduling a request, system determines actual resource allocation to the request, which is between REQUEST_MIN_RESOURCE_GRANT_PERCENT and REQUEST_MAX_RESOURCE_GRANT_PERCENT, based on resource availability in shared pool and current load on the system. The resources must exist in the shared pool of resources when the query is scheduled.

> **NOTE**
> REQUEST_MIN_RESOURCE_GRANT_PERCENT and REQUEST_MAX_RESOURCE_GRANT_PERCENT have effective values that are dependent on the effective MIN_PERCENTAGE_RESOURCE and CAP_PERCENTAGE_RESOURCE values. See sys.dm_workload_management_workload_groups_stats for effective runtime values.

Execution Rules

On ad-hoc reporting systems, customers can accidentally execute runaway queries that severely impact the productivity of others. System admins are forced to spend time killing runaway queries to free up system resources. Workload groups offer the ability to configure a query execution timeout rule to cancel queries that have exceeded the specified value. The rule is configured by setting the QUERY_EXECUTION_TIMEOUT_SEC parameter in the CREATE WORKLOAD GROUP syntax.

Shared pool resources

Shared pool resources are the resources not configured for isolation. Workload groups with a MIN_PERCENTAGE_RESOURCE set to zero leverage resources in the shared pool to execute requests. Workload groups with a CAP_PERCENTAGE_RESOURCE greater than MIN_PERCENTAGE_RESOURCE also used shared resources. The amount of resources available in the shared pool is calculated as follows.

[Shared Pool] = 100 - [sum of `MIN_PERCENTAGE_RESOURCE` across all workload groups]

Access to resources in the shared pool is allocated on an importance basis. Requests with the same importance level will access shared pool resources on a first in/first out basis.

Next steps

- Quickstart: configure workload isolation
- CREATE WORKLOAD GROUP
- Convert resource classes to workload groups.

Azure Synapse Analytics – Workload Management Portal Monitoring

8/19/2022 • 6 minutes to read • Edit Online

This article explains how to monitor workload group resource utilization and query activity. For details on how to configure the Azure Metrics Explorer see the Getting started with Azure Metrics Explorer article. See the Resource utilization section in Azure Synapse Analytics Monitoring documentation for details on how to monitor system resource consumption. There are two different categories of workload group metrics provided for monitoring workload management: resource allocation and query activity. These metrics can be split and filtered by workload group. The metrics can be split and filtered based on if they are system defined (resource class workload groups) or user-defined (created by user with CREATE WORKLOAD GROUP syntax).

Workload management metric definitions

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
Effective cap resource percent	*Effective cap resource percent* is a hard limit on the percentage of resources accessible by the workload group, taking into account *Effective min resource percentage* allocated for other workload groups. The *Effective cap resource percent* metric is configured using the `CAP_PERCENTAGE_RESOURCE` parameter in the CREATE WORKLOAD GROUP syntax. The effective value is described here. For example if a workload group `DataLoads` is created with `CAP_PERCENTAGE_RESOURCE` = 100 and another workload group is created with an Effective min resource percentage of 25%, the *Effective cap resource percent* for the `DataLoads` workload group is 75%. The *Effective cap resource percent* determines the upper bound of concurrency (and thus potential throughput) a workload group can achieve. If additional throughput is needed beyond what is currently reported by the *Effective cap resource percent* metric, either increase the `CAP_PERCENTAGE_RESOURCE`, decrease the `MIN_PERCENTAGE_RESOURCE` of other workload groups or scale up the instance to add more resources. Decreasing the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` can increase concurrency, but may not increase overall throughput.	Min, Avg, Max

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
Effective min resource percent	*Effective min resource percent* is the minimum percentage of resources reserved and isolated for the workload group taking into account the service level minimum. The Effective min resource percent metric is configured using the `MIN_PERCENTAGE_RESOURCE` parameter in the CREATE WORKLOAD GROUP syntax. The effective value is described here. Use the Sum aggregation type when this metric is unfiltered and unsplit to monitor the total workload isolation configured on the system. The *Effective min resource percent* determines the lower bound of guaranteed concurrency (and thus guaranteed throughput) a workload group can achieve. If additional guaranteed resources are needed beyond what is currently reported by the *Effective min resource percent* metric, increase the `MIN_PERCENTAGE_RESOURCE` parameter configured for the workload group. Decreasing the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` can increase concurrency, but may not increase overall throughput.	Min, Avg, Max
Workload group active queries	This metric reports the active queries within the workload group. Using this metric unfiltered and unsplit displays all active queries running on the system.	Sum

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
Workload group allocation by cap resource percent	This metric displays the percentage allocation of resources relative to the *Effective cap resource percent* per workload group. This metric provides the effective utilization of the workload group. Consider a workload group `DataLoads` with an *Effective cap resource percent* of 75% and a `REQUEST_MIN_RESOURCE_GRANT_PERCENT` configured at 25%. The *Workload group allocation by cap resource percent* value filtered to `DataLoads` would be 33% (25% / 75%) if a single query were running in this workload group. Use this metric to identify a workload group's utilization. A value close to 100% indicates all resources available to the workload group are being used. Additionally, the *Workload group queued queries metric* for the same workload group showing a value greater than zero would indicate the workload group would utilize additional resources if allocated. Conversely, if this metric is consistently low and the *Workload group active queries* is low the workload group is not being utilized. This situation is especially problematic if *Effective cap resource percent* is greater than zero as that would indicate underutilized workload isolation.	Min, Avg, Max
Workload group allocation by system percent	This metric displays the percentage allocation of resources relative to the entire system. Consider a workload group `DataLoads` with a `REQUEST_MIN_RESOURCE_GRANT_PERCENT` configured at 25%. *Workload group allocation by system percent* value filtered to `DataLoads` would be 25% (25% / 100%) if a single query were running in this workload group.	Min, Avg, Max

METRIC NAME	DESCRIPTION	AGGREGATION TYPE
Workload group query timeouts	Queries for the workload group that have timed out. Query timeouts reported by this metric are only once the query has started executing (it does not include wait time due to locking or resource waits). Query timeout is configured using the `QUERY_EXECUTION_TIMEOUT_SEC` parameter in the CREATE WORKLOAD GROUP syntax. Increasing the value could reduce the number of query timeouts. Consider increasing the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` parameter for the workload group to reduce the amount of timeouts and allocate more resources per query. Note, increasing `REQUEST_MIN_RESOURCE_GRANT_PERCENT` reduces the amount of concurrency for the workload group.	Sum
Workload group queued queries	Queries for the workload group that are currently queued waiting to start execution. Queries can be queue because they are waiting for resources or locks. Queries could be waiting for numerous reasons. If the system is overloaded and the concurrency demand is greater than what is available, queries will queue. Consider adding more resources to the workload group by increasing the `CAP_PERCENTAGE_RESOURCE` parameter in the CREATE WORKLOAD GROUP statement. If `CAP_PERCENTAGE_RESOURCE` is greater than the *Effective cap resource percent* metric, the configured workload isolation for other workload group is impacting the resources allocated to this workload group. Consider lowering `MIN_PERCENTAGE_RESOURCE` of other workload groups or scale up the instance to add more resources.	Sum

Monitoring scenarios and actions

Below are a series of chart configurations to highlight workload management metric usage for troubleshooting along with associated actions to address the issue.

Underutilized workload isolation

Consider the following workload group and classifier configuration where a workload group named `wgPriority`

is created and *TheCEO* `membername` is mapped to it using the `wcCEOPriority` workload classifier. The `wgPriority` workload group has 25% workload isolation configured for it (`MIN_PERCENTAGE_RESOURCE` = 25). Each query submitted by *TheCEO* is given 5% of system resources (`REQUEST_MIN_RESOURCE_GRANT_PERCENT` = 5).

```
CREATE WORKLOAD GROUP wgPriority
WITH ( MIN_PERCENTAGE_RESOURCE = 25
      ,CAP_PERCENTAGE_RESOURCE = 50
      ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 5);

CREATE WORKLOAD CLASSIFIER wcCEOPriority
WITH ( WORKLOAD_GROUP = 'wgPriority'
      ,MEMBERNAME = 'TheCEO');
```

The below chart is configured as follows:
Metric 1: *Effective min resource percent* (Avg aggregation, `blue line`)
Metric 2: *Workload group allocation by system percent* (Avg aggregation, `purple line`)
Filter: [Workload Group] = `wgPriority`

The chart shows that with 25% workload isolation, only 10% is being used on average. In this case, the `MIN_PERCENTAGE_RESOURCE` parameter value could be lowered to between 10 or 15 and allow for other workloads on the system to consume the resources.

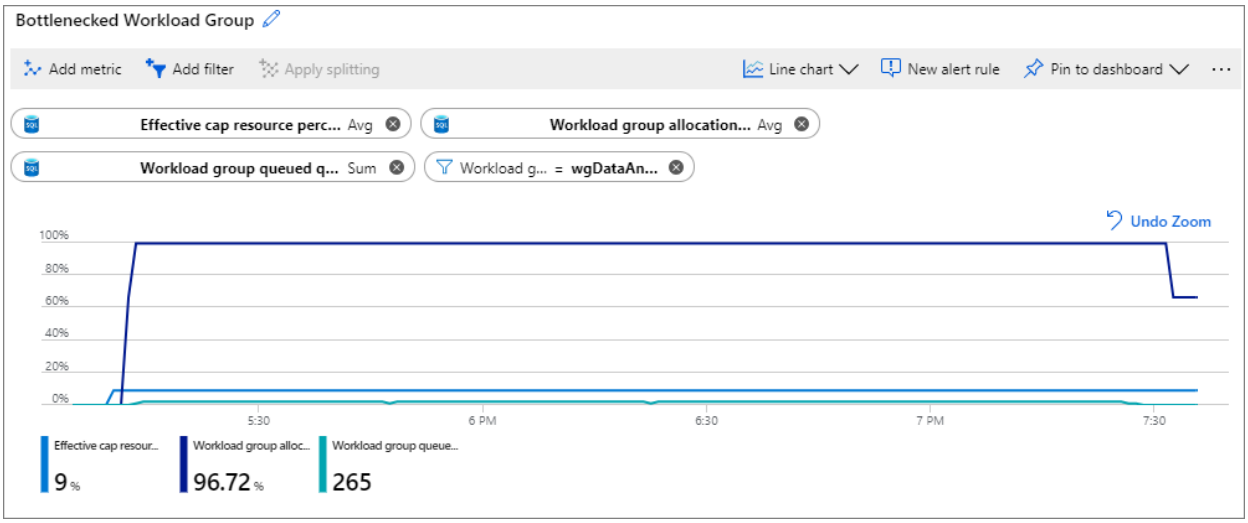
Workload group bottleneck

Consider the following workload group and classifier configuration where a workload group named `wgDataAnalyst` is created and the *DataAnalyst* `membername` is mapped to it using the `wcDataAnalyst` workload classifier. The `wgDataAnalyst` workload group has 6% workload isolation configured for it (`MIN_PERCENTAGE_RESOURCE` = 6) and a resource limit of 9% (`CAP_PERCENTAGE_RESOURCE` = 9). Each query submitted by the *DataAnalyst* is given 3% of system resources (`REQUEST_MIN_RESOURCE_GRANT_PERCENT` = 3).

```
CREATE WORKLOAD GROUP wgDataAnalyst
WITH ( MIN_PERCENTAGE_RESOURCE = 6
      ,CAP_PERCENTAGE_RESOURCE = 9
      ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 3);

CREATE WORKLOAD CLASSIFIER wcDataAnalyst
WITH ( WORKLOAD_GROUP = 'wgDataAnalyst'
      ,MEMBERNAME = 'DataAnalyst');
```

The below chart is configured as follows:
Metric 1: *Effective cap resource percent* (Avg aggregation, `blue line`)
Metric 2: *Workload group allocation by cap resource percent* (Avg aggregation, `purple line`)
Metric 3: *Workload group queued queries* (Sum aggregation, `turquoise line`)
Filter: [Workload Group] = `wgDataAnalyst`



The chart shows that with a 9% cap on resources, the workload group is 90%+ utilized (from the *Workload group allocation by cap resource percent metric*). There is a steady queuing of queries as shown from the *Workload group queued queries metric*. In this case, increasing the `CAP_PERCENTAGE_RESOURCE` to a value higher than 9% will allow more queries to execute concurrently. Increasing the `CAP_PERCENTAGE_RESOURCE` assumes that there are enough resources available and not isolated by other workload groups. Verify the cap increased by checking the *Effective cap resource percent metric*. If more throughput is desired, also consider increasing the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` to a value greater than 3. Increasing the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` could allow queries to run faster.

Memory and concurrency limits for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

View the memory and concurrency limits allocated to the various performance levels and resource classes in Azure Synapse Analytics.

> **NOTE**
> Workload management workload groups provide more flexibility for configuring resources per request and concurrency than dynamic or static resource classes. See Workload Groups and the CREATE WORKLOAD GROUP syntax for further details.

Data warehouse capacity settings

The following tables show the maximum capacity for the data warehouse at different performance levels. To change the performance level, see Scale compute - portal.

Service Levels

The service levels range from DW100c to DW30000c.

PERFORMANCE LEVEL	COMPUTE NODES	DISTRIBUTIONS PER COMPUTE NODE	MEMORY PER DATA WAREHOUSE (GB)
DW100c	1	60	60
DW200c	1	60	120
DW300c	1	60	180
DW400c	1	60	240
DW500c	1	60	300
DW1000c	2	30	600
DW1500c	3	20	900
DW2000c	4	15	1200
DW2500c	5	12	1500
DW3000c	6	10	1800
DW5000c	10	6	3000
DW6000c	12	5	3600

PERFORMANCE LEVEL	COMPUTE NODES	DISTRIBUTIONS PER COMPUTE NODE	MEMORY PER DATA WAREHOUSE (GB)
DW7500c	15	4	4500
DW10000c	20	3	6000
DW15000c	30	2	9000
DW30000c	60	1	18000

The maximum service level is DW30000c, which has 60 Compute nodes and one distribution per Compute node. For example, a 600 TB data warehouse at DW30000c processes approximately 10 TB per Compute node.

Concurrency maximums for workload groups

With the introduction of workload groups, the concept of concurrency slots no longer applies. Resources per request are allocated on a percentage basis and specified in the workload group definition. However, even with the removal of concurrency slots, there are minimum amounts of resources needed per queries based on the service level. The below table defined the minimum amount of resources needed per query across service levels and the associated concurrency that can be achieved.

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	MIN % SUPPORTED FOR REQUEST_MIN_RESOURCE_GRANT_PER CENT
DW100c	4	25%
DW200c	8	12.5%
DW300c	12	8%
DW400c	16	6.25%
DW500c	20	5%
DW1000c	32	3%
DW1500c	32	3%
DW2000c	48	2%
DW2500c	48	2%
DW3000c	64	1.5%
DW5000c	64	1.5%
DW6000c	128	0.75%
DW7500c	128	0.75%
DW10000c	128	0.75%

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	MIN % SUPPORTED FOR REQUEST_MIN_RESOURCE_GRANT_PERCENT
DW15000c	128	0.75%
DW30000c	128	0.75%

Concurrency maximums for resource classes

To ensure each query has enough resources to execute efficiently, Synapse SQL tracks resource utilization by assigning concurrency slots to each query. The system puts queries into a queue based on importance and concurrency slots. Queries wait in the queue until enough concurrency slots are available. Importance and concurrency slots determine CPU prioritization. For more information, see Analyze your workload

Static resource classes

The following table shows the maximum concurrent queries and concurrency slots for each static resource class.

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	CONCURRENCY SLOTS AVAILABLE	SLOTS USED BY STATICRC10	SLOTS USED BY STATICRC20	SLOTS USED BY STATICRC30	SLOTS USED BY STATICRC40	SLOTS USED BY STATICRC50	SLOTS USED BY STATICRC60	SLOTS USED BY STATICRC70	SLOTS USED BY STATICRC80
DW100c	4	4	1	2	4	4	4	4	4	4
DW200c	8	8	1	2	4	8	8	8	8	8
DW300c	12	12	1	2	4	8	8	8	8	8
DW400c	16	16	1	2	4	8	16	16	16	16
DW500c	20	20	1	2	4	8	16	16	16	16
DW1000c	32	40	1	2	4	8	16	32	32	32
DW1500c	32	60	1	2	4	8	16	32	32	32
DW2000c	48	80	1	2	4	8	16	32	64	64
DW2500c	48	100	1	2	4	8	16	32	64	64
DW3000c	64	120	1	2	4	8	16	32	64	64

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	CONCURRENCY SLOTS AVAILABLE	SLOTS USED BY STATICRC10	SLOTS USED BY STATICRC20	SLOTS USED BY STATICRC30	SLOTS USED BY STATICRC40	SLOTS USED BY STATICRC50	SLOTS USED BY STATICRC60	SLOTS USED BY STATICRC70	SLOTS USED BY STATICRC80
DW5000c	64	200	1	2	4	8	16	32	64	128
DW6000c	128	240	1	2	4	8	16	32	64	128
DW7500c	128	300	1	2	4	8	16	32	64	128
DW10000c	128	400	1	2	4	8	16	32	64	128
DW15000c	128	600	1	2	4	8	16	32	64	128
DW30000c	128	1200	1	2	4	8	16	32	64	128

Dynamic resource classes

The following table shows the maximum concurrent queries and concurrency slots for each dynamic resource class. Dynamic resource classes use a 3-10-22-70 memory percentage allocation for small-medium-large-xlarge resource classes across all service levels.

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	CONCURRENCY SLOTS AVAILABLE	SLOTS USED BY SMALLRC	SLOTS USED BY MEDIUMRC	SLOTS USED BY LARGERC	SLOTS USED BY XLARGERC
DW100c	4	4	1	1	1	2
DW200c	8	8	1	1	1	5
DW300c	12	12	1	1	2	8
DW400c	16	16	1	1	3	11
DW500c	20	20	1	2	4	14
DW1000c	32	40	1	4	8	28
DW1500c	32	60	1	6	13	42
DW2000c	32	80	2	8	17	56
DW2500c	32	100	3	10	22	70
DW3000c	32	120	3	12	26	84

SERVICE LEVEL	MAXIMUM CONCURRENT QUERIES	CONCURRENCY SLOTS AVAILABLE	SLOTS USED BY SMALLRC	SLOTS USED BY MEDIUMRC	SLOTS USED BY LARGERC	SLOTS USED BY XLARGERC
DW5000c	32	200	6	20	44	140
DW6000c	32	240	7	24	52	168
DW7500c	32	300	9	30	66	210
DW10000c	32	400	12	40	88	280
DW15000c	32	600	18	60	132	420
DW30000c	32	1200	36	120	264	840

When there are not enough concurrency slots free to start query execution, queries are queued and executed based on importance. If there is equivalent importance, queries are executed on a first-in, first-out basis. As a queries finishes and the number of queries and slots fall below the limits, Azure Synapse Analytics releases queued queries.

Workload management with resource classes in Azure Synapse Analytics

8/19/2022 • 16 minutes to read • Edit Online

Guidance for using resource classes to manage memory and concurrency for Synapse SQL pool queries in Azure Synapse.

What are resource classes

The performance capacity of a query is determined by the user's resource class. Resource classes are pre-determined resource limits in Synapse SQL pool that govern compute resources and concurrency for query execution. Resource classes can help you configure resources for your queries by setting limits on the number of queries that run concurrently and on the compute-resources assigned to each query. There's a trade-off between memory and concurrency.

- Smaller resource classes reduce the maximum memory per query, but increase concurrency.
- Larger resource classes increase the maximum memory per query, but reduce concurrency.

There are two types of resource classes:

- Static resources classes, which are well suited for increased concurrency on a data set size that is fixed.
- Dynamic resource classes, which are well suited for data sets that are growing in size and need increased performance as the service level is scaled up.

Resource classes use concurrency slots to measure resource consumption. Concurrency slots are explained later in this article.

- To view the resource utilization for the resource classes, see Memory and concurrency limits.
- To adjust the resource class, you can run the query under a different user or change the current user's resource class membership.

Static resource classes

Static resource classes allocate the same amount of memory regardless of the current performance level, which is measured in data warehouse units. Since queries get the same memory allocation regardless of the performance level, scaling out the data warehouse allows more queries to run within a resource class. Static resource classes are ideal if the data volume is known and constant.

The static resource classes are implemented with these pre-defined database roles:

- staticrc10
- staticrc20
- staticrc30
- staticrc40
- staticrc50
- staticrc60
- staticrc70
- staticrc80

Dynamic resource classes

Dynamic Resource Classes allocate a variable amount of memory depending on the current service level. While

static resource classes are beneficial for higher concurrency and static data volumes, dynamic resource classes are better suited for a growing or variable amount of data. When you scale up to a larger service level, your queries automatically get more memory.

The dynamic resource classes are implemented with these pre-defined database roles:

- smallrc
- mediumrc
- largerc
- xlargerc

The memory allocation for each resource class is as follows.

SERVICE LEVEL	SMALLRC	MEDIUMRC	LARGERC	XLARGERC
DW100c	25%	25%	25%	70%
DW200c	12.5%	12.5%	22%	70%
DW300c	8%	10%	22%	70%
DW400c	6.25%	10%	22%	70%
DW500c	5%	10%	22%	70%
DW1000c to DW30000c	3%	10%	22%	70%

Default resource class

By default, each user is a member of the dynamic resource class **smallrc**.

The resource class of the service administrator is fixed at smallrc and cannot be changed. The service administrator is the user created during the provisioning process. The service administrator in this context is the login specified for the "Server admin login" when creating a new Synapse SQL pool with a new server.

> **NOTE**
> Users or groups defined as Active Directory admin are also service administrators.

Resource class operations

Resource classes are designed to improve performance for data management and manipulation activities. Complex queries can also benefit from running under a large resource class. For example, query performance for large joins and sorts can improve when the resource class is large enough to enable the query to execute in memory.

Operations governed by resource classes

These operations are governed by resource classes:

- INSERT-SELECT, UPDATE, DELETE
- SELECT (when querying user tables)
- ALTER INDEX - REBUILD or REORGANIZE
- ALTER TABLE REBUILD
- CREATE INDEX

- CREATE CLUSTERED COLUMNSTORE INDEX
- CREATE TABLE AS SELECT (CTAS)
- Data loading
- Data movement operations conducted by the Data Movement Service (DMS)

> **NOTE**
> SELECT statements on dynamic management views (DMVs) or other system views are not governed by any of the concurrency limits. You can monitor the system regardless of the number of queries executing on it.

Operations not governed by resource classes

Some queries always run in the smallrc resource class even though the user is a member of a larger resource class. These exempt queries do not count towards the concurrency limit. For example, if the concurrency limit is 16, many users can be selecting from system views without impacting the available concurrency slots.

The following statements are exempt from resource classes and always run in smallrc:

- CREATE or DROP TABLE
- ALTER TABLE ... SWITCH, SPLIT, or MERGE PARTITION
- ALTER INDEX DISABLE
- DROP INDEX
- CREATE, UPDATE, or DROP STATISTICS
- TRUNCATE TABLE
- ALTER AUTHORIZATION
- CREATE LOGIN
- CREATE, ALTER, or DROP USER
- CREATE, ALTER, or DROP PROCEDURE
- CREATE or DROP VIEW
- INSERT VALUES
- SELECT from system views and DMVs
- EXPLAIN
- DBCC

Concurrency slots

Concurrency slots are a convenient way to track the resources available for query execution. They are like tickets that you purchase to reserve seats at a concert because seating is limited. The total number of concurrency slots per data warehouse is determined by the service level. Before a query can start executing, it must be able to reserve enough concurrency slots. When a query completes, it releases its concurrency slots.

- A query running with 10 concurrency slots can access 5 times more compute resources than a query running with 2 concurrency slots.
- If each query requires 10 concurrency slots and there are 40 concurrency slots, then only 4 queries can run concurrently.

Only resource governed queries consume concurrency slots. System queries and some trivial queries don't consume any slots. The exact number of concurrency slots consumed is determined by the query's resource class.

View the resource classes

Resource classes are implemented as pre-defined database roles. There are two types of resource classes:

dynamic and static. To view a list of the resource classes, use the following query:

```
SELECT name
FROM   sys.database_principals
WHERE  name LIKE '%rc%' AND type_desc = 'DATABASE_ROLE';
```

Change a user's resource class

Resource classes are implemented by assigning users to database roles. When a user runs a query, the query runs with the user's resource class. For example, if a user is a member of the staticrc10 database role, their queries run with small amounts of memory. If a database user is a member of the xlargerc or staticrc80 database roles, their queries run with large amounts of memory.

To increase a user's resource class, use sp_addrolemember to add the user to a database role of a large resource class. The below code adds a user to the largerc database role. Each request gets 22% of the system memory.

```
EXEC sp_addrolemember 'largerc', 'loaduser';
```

To decrease the resource class, use sp_droprolemember. If 'loaduser' is not a member or any other resource classes, they go into the default smallrc resource class with a 3% memory grant.

```
EXEC sp_droprolemember 'largerc', 'loaduser';
```

Resource class precedence

Users can be members of multiple resource classes. When a user belongs to more than one resource class:

- Dynamic resource classes take precedence over static resource classes. For example, if a user is a member of both mediumrc(dynamic) and staticrc80 (static), queries run with mediumrc.
- Larger resource classes take precedence over smaller resource classes. For example, if a user is a member of mediumrc and largerc, queries run with largerc. Likewise, if a user is a member of both staticrc20 and statirc80, queries run with staticrc80 resource allocations.

Recommendations

> **NOTE**
> Consider leveraging workload management capabilities (workload isolation, classification and importance) for more control over your workload and predictable performance.

We recommend creating a user that is dedicated to running a specific type of query or load operation. Give that user a permanent resource class instead of changing the resource class on a frequent basis. Static resource classes afford greater overall control on the workload, so we suggest using static resource classes before considering dynamic resource classes.

Resource classes for load users

`CREATE TABLE` uses clustered columnstore indexes by default. Compressing data into a columnstore index is a memory-intensive operation, and memory pressure can reduce the index quality. Memory pressure can lead to needing a higher resource class when loading data. To ensure loads have enough memory, you can create a user that is designated for running loads and assign that user to a higher resource class.

The memory needed to process loads efficiently depends on the nature of the table loaded and the data size. For

more information on memory requirements, see Maximizing rowgroup quality.

Once you have determined the memory requirement, choose whether to assign the load user to a static or dynamic resource class.

- Use a static resource class when table memory requirements fall within a specific range. Loads run with appropriate memory. When you scale the data warehouse, the loads do not need more memory. By using a static resource class, the memory allocations stay constant. This consistency conserves memory and allows more queries to run concurrently. We recommend that new solutions use the static resource classes first as these provide greater control.
- Use a dynamic resource class when table memory requirements vary widely. Loads might require more memory than the current DWU or cDWU level provides. Scaling the data warehouse adds more memory to load operations, which allows loads to perform faster.

Resource classes for queries

Some queries are compute-intensive and some aren't.

- Choose a dynamic resource class when queries are complex, but don't need high concurrency. For example, generating daily or weekly reports is an occasional need for resources. If the reports are processing large amounts of data, scaling the data warehouse provides more memory to the user's existing resource class.
- Choose a static resource class when resource expectations vary throughout the day. For example, a static resource class works well when the data warehouse is queried by many people. When scaling the data warehouse, the amount of memory allocated to the user doesn't change. Consequently, more queries can be executed in parallel on the system.

Proper memory grants depend on many factors, such as the amount of data queried, the nature of the table schemas, and various joins, select, and group predicates. In general, allocating more memory allows queries to complete faster, but reduces the overall concurrency. If concurrency is not an issue, over-allocating memory does not harm throughput.

To tune performance, use different resource classes. The next section gives a stored procedure that helps you figure out the best resource class.

Example code for finding the best resource class

You can use the following specified stored procedure to figure out concurrency and memory grant per resource class at a given SLO and the best resource class for memory intensive CCI operations on non-partitioned CCI table at a given resource class:

Here's the purpose of this stored procedure:

1. To see the concurrency and memory grant per resource class at a given SLO. User needs to provide NULL for both schema and tablename as shown in this example.
2. To see the best resource class for the memory-intensive CCI operations (load, copy table, rebuild index, etc.) on non-partitioned CCI table at a given resource class. The stored proc uses table schema to find out the required memory grant.

Dependencies & Restrictions

- This stored procedure isn't designed to calculate the memory requirement for a partitioned cci table.
- This stored procedure doesn't take memory requirements into account for the SELECT part of CTAS/INSERT-SELECT and assumes it's a SELECT.
- This stored procedure uses a temp table, which is available in the session where this stored procedure was created.
- This stored procedure depends on the current offerings (for example, hardware configuration, DMS config), and if any of that changes then this stored proc won't work correctly.

- This stored procedure depends on existing concurrency limit offerings and if these change then this stored procedure won't work correctly.
- This stored procedure depends on existing resource class offerings and if these change then this stored procedure won't work correctly.

> **NOTE**
>
> If you are not getting output after executing stored procedure with parameters provided, then there could be two cases.
>
> 1. Either DW Parameter contains an invalid SLO value
> 2. Or, there is no matching resource class for the CCI operation on the table.
>
> For example, at DW100c, the highest memory grant available is 1 GB, and if table schema is wide enough to cross the requirement of 1 GB.

Usage example

Syntax:

```
EXEC dbo.prc_workload_management_by_DWU @DWU VARCHAR(7), @SCHEMA_NAME VARCHAR(128), @TABLE_NAME VARCHAR(128)
```

1. @DWU: Either provide a NULL parameter to extract the current DWU from the DW DB or provide any supported DWU in the form of 'DW100c'
2. @SCHEMA_NAME: Provide a schema name of the table
3. @TABLE_NAME: Provide a table name of the interest

Examples executing this stored proc:

```
EXEC dbo.prc_workload_management_by_DWU 'DW2000c', 'dbo', 'Table1';
EXEC dbo.prc_workload_management_by_DWU NULL, 'dbo', 'Table1';
EXEC dbo.prc_workload_management_by_DWU 'DW6000c', NULL, NULL;
EXEC dbo.prc_workload_management_by_DWU NULL, NULL, NULL;
```

The following statement creates Table1 that is used in the preceding examples.

```
CREATE TABLE Table1 (a int, b varchar(50), c decimal (18,10), d char(10), e varbinary(15), f float, g
datetime, h date);
```

Stored procedure definition

User-defined restore points

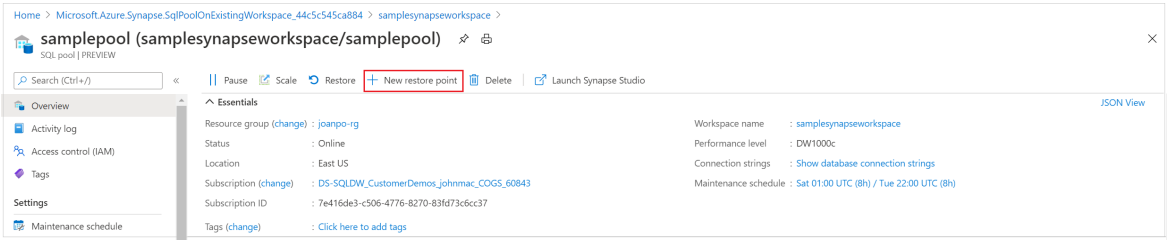
8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll learn to create a new user-defined restore point for a dedicated SQL pool in Azure Synapse Analytics by using the Azure portal.

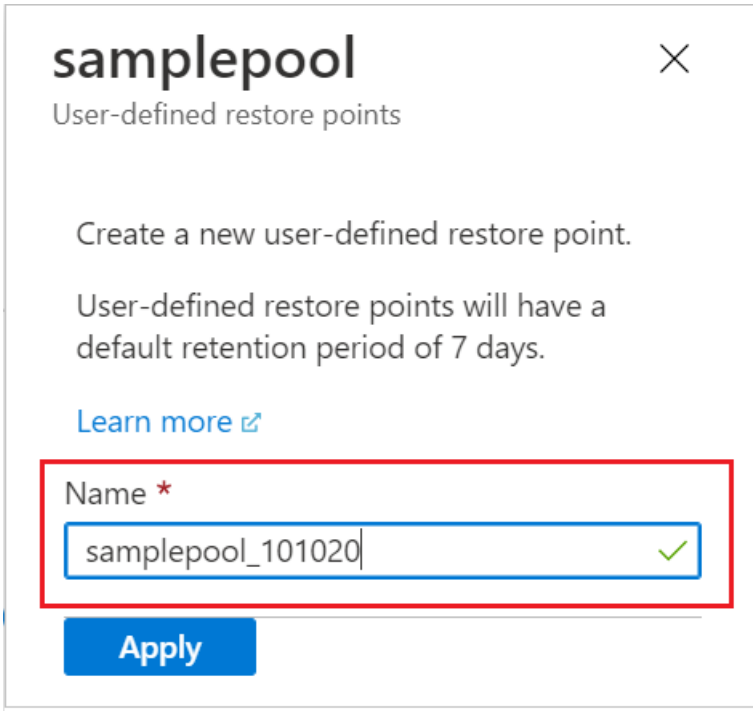
Create user-defined restore points through the Azure portal

User-defined restore points can also be created through Azure portal.

1. Sign in to your Azure portal account.
2. Navigate to the dedicated SQL pool that you want to create a restore point for.
3. Select **Overview** from the left pane, select **+ New restore point**. If the New Restore Point button isn't enabled, make sure that the dedicated SQL pool isn't paused.



4. Specify a name for your user-defined restore point and click **Apply**. User-defined restore points have a default retention period of seven days.



Next steps

- Restore an existing dedicated SQL pool

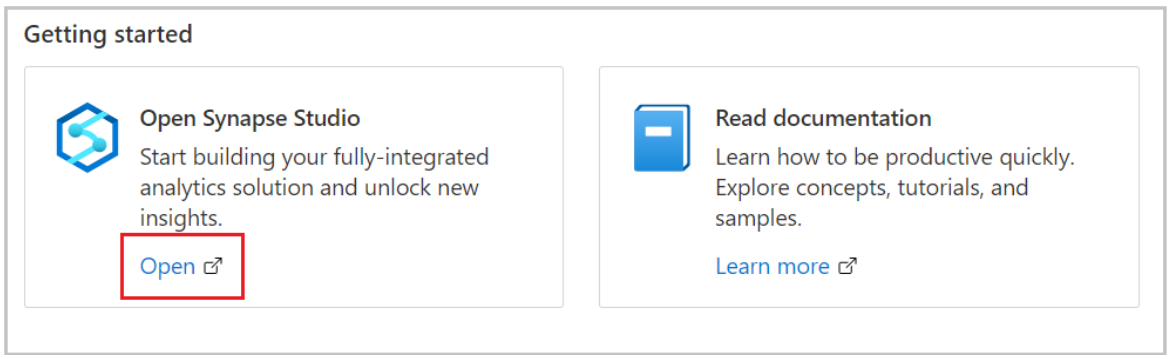
Restore an existing dedicated SQL pool

8/19/2022 • 5 minutes to read • Edit Online

In this article, you learn how to restore an existing dedicated SQL pool in Azure Synapse Analytics using Azure portal, Synapse Studio, and PowerShell. This article applies to both restores and geo-restores.

Restore an existing dedicated SQL pool through the Synapse Studio

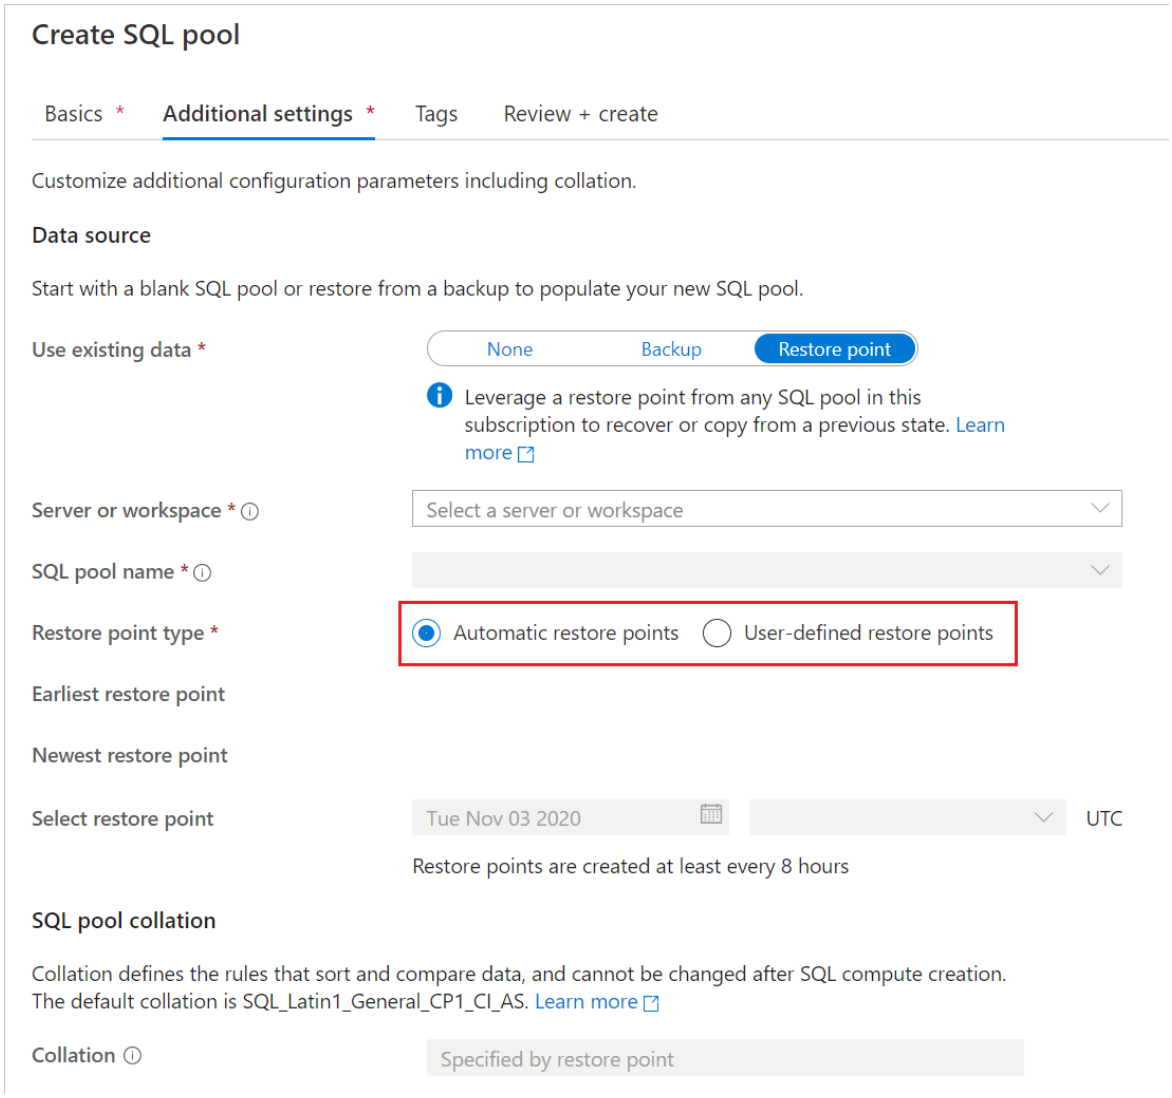
1. Sign in to the Azure portal.
2. Navigate to your Synapse workspace.
3. Under Getting Started -> Open Synapse Studio, select **Open**.



4. On the left hand navigation pane, select **Data**.
5. Select **Manage pools**.
6. Select **+ New** to create a new dedicated SQL pool.
7. In the Additional Settings tab, select a Restore Point to restore from.

   If you want to perform a geo-restore, select the workspace and dedicated SQL pool that you want to recover.

8. Select either **Automatic Restore Points** or **User-Defined Restore Points**.



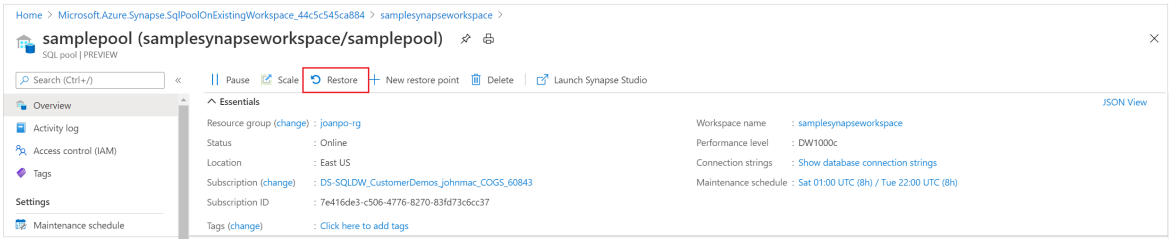
If the dedicated SQL pool doesn't have any automatic restore points, wait a few hours or create a user defined restore point before restoring. For User-Defined Restore Points, select an existing one or create a new one.

If you are restoring a geo-backup, simply select the workspace located in the source region and the dedicated SQL pool you want to restore.

9. Select **Review + Create**.

Restore an existing dedicated SQL pool through the Azure portal

1. Sign in to the Azure portal.
2. Navigate to the dedicated SQL pool that you want to restore from.
3. At the top of the Overview blade, select **Restore**.



4. Select either **Automatic Restore Points** or **User-Defined Restore Points**.

If the dedicated SQL pool doesn't have any automatic restore points, wait a few hours or create a user-

defined restore point before restoring.

If you want to perform a geo-restore, select the workspace and dedicated SQL pool that you want to recover.

5. Select **Review + Create**.

Restore an existing dedicated SQL pool through PowerShell

1. Open PowerShell.
2. Connect to your Azure account and list all the subscriptions associated with your account.
3. Select the subscription that contains the SQL pool to be restored.
4. List the restore points for the dedicated SQL pool.
5. Pick the desired restore point using the RestorePointCreationDate.
6. Restore the dedicated SQL pool to the desired restore point using Restore-AzSynapseSqlPool PowerShell cmdlet.
   a. To restore the dedicated SQL pool to a different workspace, make sure to specify the other workspace name. This workspace can also be in a different resource group and region.
   b. To restore to a different subscription, see the below section.
7. Verify that the restored dedicated SQL pool is online.

```
$SubscriptionName="<YourSubscriptionName>"
$ResourceGroupName="<YourResourceGroupName>"
$WorkspaceName="<YourWorkspaceNameWithoutURLSuffixSeeNote>"  # Without sql.azuresynapse.net
#$TargetResourceGroupName="<YourTargetResourceGroupName>" # uncomment to restore to a different workspace.
#$TargetWorkspaceName="<YourtargetWorkspaceNameWithoutURLSuffixSeeNote>"
$SQLPoolName="<YourDatabaseName>"
$NewSQLPoolName="<YourDatabaseName>"

Connect-AzAccount
Get-AzSubscription
Select-AzSubscription -SubscriptionName $SubscriptionName

# list all restore points
Get-AzSynapseSqlPoolRestorePoint -ResourceGroupName $ResourceGroupName -WorkspaceName $WorkspaceName -Name
$SQLPoolName
# Pick desired restore point using RestorePointCreationDate "xx/xx/xxxx xx:xx:xx xx"
$PointInTime="<RestorePointCreationDate>"

# Get the specific SQL pool to restore
$SQLPool = Get-AzSynapseSqlPool -ResourceGroupName $ResourceGroupName -WorkspaceName $WorkspaceName -Name
$SQLPoolName
# Transform Synapse SQL pool resource ID to SQL database ID because currently the restore command only
accepts the SQL database ID format.
$DatabaseID = $SQLPool.Id -replace "Microsoft.Synapse", "Microsoft.Sql" `
 -replace "workspaces", "servers" `
 -replace "sqlPools", "databases"

# Restore database from a restore point
$RestoredDatabase = Restore-AzSynapseSqlPool –FromRestorePoint -RestorePoint $PointInTime -ResourceGroupName
$SQLPool.ResourceGroupName `
    -WorkspaceName $SQLPool.WorkspaceName -TargetSqlPoolName $NewSQLPoolName –ResourceId $DatabaseID -
PerformanceLevel DW100c

# Use the following command to restore to a different workspace
#$TargetResourceGroupName = $SQLPool.ResourceGroupName # for restoring to different workspace in same
resourcegroup
#$RestoredDatabase = Restore-AzSynapseSqlPool –FromRestorePoint -RestorePoint $PointInTime -
ResourceGroupName $TargetResourceGroupName `
#    -WorkspaceName $TargetWorkspaceName -TargetSqlPoolName $NewSQLPoolName –ResourceId $DatabaseID -
PerformanceLevel DW100c

# Verify the status of restored database
$RestoredDatabase.status
```

Restore an existing dedicated SQL pool to a different subscription through PowerShell

When performing a cross-subscription restore, a synapse workspace dedicated SQL pool can only restore to a standalone dedicated SQL pool (formerly SQL DW). The PowerShell below is similar to the above however there are three main differences:

- After retrieving the SQL Pool object to be restored, the subscription context needs to be switched to the destination (or target) subscription name.
- When performing the restore, use the Az.Sql modules instead of the Az.Synapse modules.
- If it is required to restore the dedicated SQL pool to a Synapse workspace in the destination subscription, an additional restore step is required.

Steps:

1. Open PowerShell.

2. Update Az.Sql Module to 3.8.0 (or greater) if needed
3. Connect to your Azure account and list all the subscriptions associated with your account.
4. Select the subscription that contains the SQL pool to be restored.
5. List the restore points for the dedicated SQL pool.
6. Pick the desired restore point using the RestorePointCreationDate.
7. Select the destination subscription in which the SQL pool should be restored.
8. Restore the dedicated SQL pool to the desired restore point using Restore-AzSqlDatabase PowerShell cmdlet.
9. Verify that the restored dedicated SQL pool (formerly SQL DW) is online.
10. **If the desired destination is a Synapse Workspace, uncomment the code to perform the additional restore step.**
    a. Create a restore point for the newly created data warehouse.
    b. Retrieve the last restore point created by using the "Select -Last 1" syntax.
    c. Perform the restore to the desired Synapse workspace.

```
$SourceSubscriptionName="<YourSubscriptionName>"
$SourceResourceGroupName="<YourResourceGroupName>"
$SourceWorkspaceName="<YourServerNameWithoutURLSuffixSeeNote>"  # Without sql.azuresynapse.net
$SourceSQLPoolName="<YourDatabaseName>"
$TargetSubscriptionName="<YourTargetSubscriptionName>"
$TargetResourceGroupName="<YourTargetResourceGroupName>"
$TargetServerName="<YourTargetServerNameWithoutURLSuffixSeeNote>"  # Without sql.azuresynapse.net
$TargetDatabaseName="<YourDatabaseName>"
#$TargetWorkspaceName="<YourTargetWorkspaceName>" # uncomment if restore to a synapse workspace is required

# Update Az.Sql module to the latest version (3.8.0 or above)
# Update-Module -Name Az.Sql -RequiredVersion 3.8.0

Connect-AzAccount
Get-AzSubscription
Select-AzSubscription -SubscriptionName $SourceSubscriptionName

# list all restore points
Get-AzSynapseSqlPoolRestorePoint -ResourceGroupName $SourceResourceGroupName -WorkspaceName
$SourceWorkspaceName -Name $SourceSQLPoolName
# Pick desired restore point using RestorePointCreationDate "xx/xx/xxxx xx:xx:xx xx"
$PointInTime="<RestorePointCreationDate>"

# Get the specific SQL pool to restore
$SQLPool = Get-AzSynapseSqlPool -ResourceGroupName $SourceResourceGroupName -WorkspaceName
$SourceWorkspaceName -Name $SourceSQLPoolName
# Transform Synapse SQL pool resource ID to SQL database ID because currently the restore command only
accepts the SQL database ID format.
$DatabaseID = $SQLPool.Id -replace "Microsoft.Synapse", "Microsoft.Sql" `
 -replace "workspaces", "servers" `
 -replace "sqlPools", "databases"

# Switch context to the destination subscription
Select-AzSubscription -SubscriptionName $TargetSubscriptionName

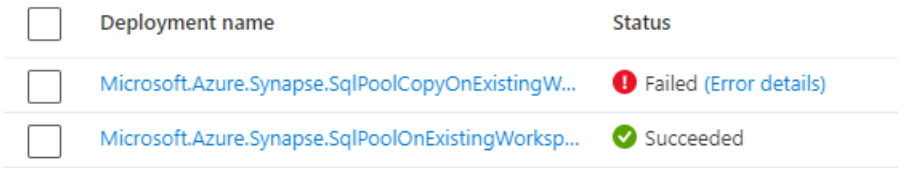
# Restore database from a desired restore point of the source database to the target server in the desired
subscription
$RestoredDatabase = Restore-AzSqlDatabase –FromPointInTimeBackup –PointInTime $PointInTime -
ResourceGroupName $TargetResourceGroupName `
    -ServerName $TargetServerName -TargetDatabaseName $TargetDatabaseName –ResourceId $DatabaseID

# Verify the status of restored database
$RestoredDatabase.status

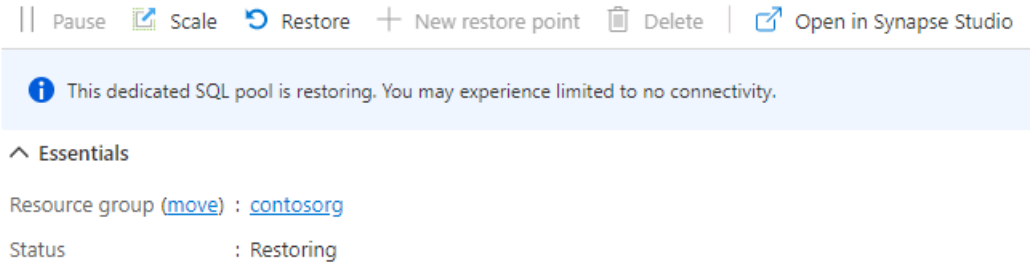
# uncomment below cmdlets to perform one more restore to push the SQL Pool to an existing workspace in the
destination subscription
# # Create restore point
# New-AzSqlDatabaseRestorePoint -ResourceGroupName $RestoredDatabase.ResourceGroupName -ServerName
$RestoredDatabase.ServerName `
#     -DatabaseName $RestoredDatabase.DatabaseName -RestorePointLabel "UD-001"
# # Gets the last restore point of the sql dw (will use the RestorePointCreationDate property)
# $RestorePoint = Get-AzSqlDatabaseRestorePoint -ResourceGroupName $RestoredDatabase.ResourceGroupName -
ServerName $RestoredDatabase.ServerName `
#     -DatabaseName $RestoredDatabase.DatabaseName | Select -Last 1
# # Restore to destination synapse workspace
# $FinalRestore = Restore-AzSynapseSqlPool –FromRestorePoint -RestorePoint
$RestorePoint.RestorePointCreationDate -ResourceGroupName $TargetResourceGroupName `
#     -WorkspaceName $TargetWorkspaceName -TargetSqlPoolName $TargetDatabaseName –ResourceId
$RestoredDatabase.ResourceID -PerformanceLevel DW100c
```

Troubleshooting

A restore operation can result in a deployment failure based on a "RequestTimeout" exception.



This timeout can be ignored. Review the dedicated SQL pool blade in the portal and it may still have status of "Restoring" and eventually will transition to "Online".



Next Steps

- Create a restore point

Restore a dedicated SQL pool from a deleted workspace

8/19/2022 • 2 minutes to read • Edit Online

In this article, you learn how to restore a dedicated SQL pool in Azure Synapse Analytics after an accidental drop of a workspace using PowerShell.

> **NOTE**
> This guidance is for Synapse Workspace dedicated sql pools only. For standalone dedicated sql pool (formerly SQL DW) please follow guidance Restore sql pool from deleted server.

Before you begin

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Restore the SQL pool from the dropped workspace

1. Open PowerShell
2. Connect to your Azure account.
3. Set the context to the subscription that contains the workspace that was dropped.
4. Specify the approximate datetime the workspace was dropped.
5. Construct the resource ID for the database you wish to recover from the dropped workspace.
6. Restore the database from the dropped workspace
7. Verify the status of the recovered database as 'online'.

```
$SubscriptionID="<YourSubscriptionID>"
$ResourceGroupName="<YourResourceGroupName>"
$WorkspaceName="<YourWorkspaceNameWithoutURLSuffixSeeNote>"  # Without sql.azuresynapse.net
$DatabaseName="<YourDatabaseName>"
$TargetResourceGroupName="<YourTargetResourceGroupName>"
$TargetWorkspaceName="<YourtargetServerNameWithoutURLSuffixSeeNote>"
$TargetDatabaseName="<YourDatabaseName>"

Connect-AzAccount
Set-AzContext -SubscriptionID $SubscriptionID

# Define the approximate point in time the workspace was dropped as DroppedDateTime "yyyy-MM-ddThh:mm:ssZ"
(ex. 2022-01-01T16:15:00Z)
$PointInTime=”<DroppedDateTime>”
$DroppedDateTime = Get-Date -Date $PointInTime

# construct the resource ID of the sql pool you wish to recover. The format required Microsoft.Sql. This
includes the approximate date time the server was dropped.
$SourceDatabaseID =
"/subscriptions/"+$SubscriptionID+"/resourceGroups/"+$ResourceGroupName+"/providers/Microsoft.Sql/servers/"+
$WorkspaceName+"/databases/"+$DatabaseName

# Restore to the target workspace with the source SQL pool.
$RestoredDatabase = Restore-AzSynapseSqlPool -FromDroppedSqlPool -DeletionDate $DroppedDateTime -
TargetSqlPoolName $TargetDatabaseName -ResourceGroupName $TargetResourceGroupName -WorkspaceName
$TargetWorkspaceName -ResourceId $SourceDatabaseID

# Verify the status of restored database
$RestoredDatabase.status
```

Troubleshooting

If "An unexpected error occurred while processing the request." message is received, the original database may not have any recovery points available due to the original workspace being short lived. Typically this is when the workspace existed for less than one hour.

Next Steps

- Create a restore point
- Restore a SQL pool

Pause and resume dedicated SQL pools with Synapse Pipelines

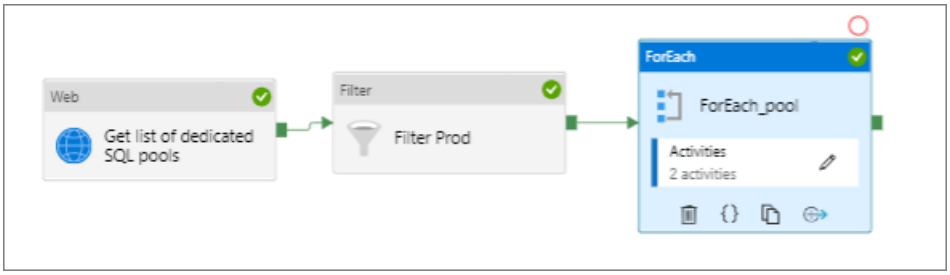
8/19/2022 • 9 minutes to read • Edit Online

Pause and resume for dedicated SQL pools can be automated using Synapse Pipelines in Azure Synapse Analytics. Pause and resume can be used to save costs for a dedicated SQL pool. This solution can easily be included in an existing data orchestration process.

The following steps will guide you through setting up automated pause and resume.

1. Create a pipeline.
2. Set up parameters in your pipeline.
3. Identify the list of dedicated SQL pools in your Azure Synapse workspace.
4. Filter any dedicated SQL pools that you don't want to pause or resume from the list.
5. Loop over each dedicated SQL pool and:
   a. Check the state of the dedicated SQL pool.
   b. Evaluate the state of the dedicated SQL pool.
   c. Pause or resume the dedicated SQL pool.

These steps are laid out in a simple pipeline in Azure Synapse:



Depending upon the nature of your environment, the whole process described here may not apply, and you may just want to choose the appropriate steps. The process described here can be used to pause or resume all instances in a development, test, or PoC environment. For a production environment, you're more likely to schedule pause or resume on an instance by instance basis so will only need Steps 5a through 5c.

The steps above use the REST APIs for Azure Synapse and Azure SQL:

- Dedicated SQL pool operations
- Azure SQL Database REST API

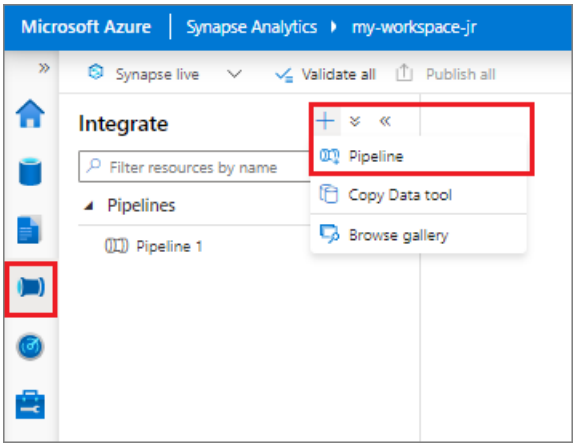
Synapse Pipelines allow for the automation of pause and resume, but you can execute these commands on-demand via the tool or application of your choice.

Prerequisites

- An existing Azure Synapse workspace
- At least one dedicated SQL pool
- Your workspace must be assigned the Azure contributor role to the affected Dedicated SQL Pool(s). See Grant Synapse administrators the Azure Contributor role on the workspace.

Step 1: Create a pipeline in Synapse Studio.

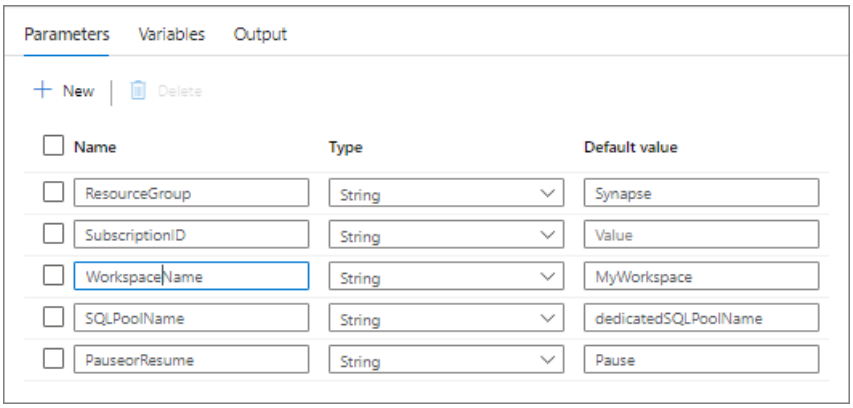
1. Navigate to your workspace and open Synapse Studio.
2. Select the **Integrate** icon, then select the + sign to create a new pipeline.
3. Name your pipeline PauseResume.



Step 2: Create pipeline parameters

The pipeline you'll create will be parameter driven. Parameters allow you to create a generic pipeline that you can use across multiple subscriptions, resource groups, or dedicated SQL pools. Select the **Parameters** tab near the bottom of the pipeline screen. Select **+New** to create each of the following parameters:

NAME	TYPE	DEFAULT VALUE	DESCRIPTION
ResourceGroup	string	Synapse	Name of the resource group for your dedicated SQL pools
SubscriptionID	string	`<SubscriptionID>`	Subscription ID for your resource group
WorkspaceName	string	Synapse	Name of your workspace
SQLPoolName	string	SQLPool1	Name of your dedicated SQL pool
PauseorResume	string	Pause	The state wanted at the end of the pipeline run



Step 3: Create list of dedicated SQL pools

Set up a **Web** activity, you'll use this activity to create the list of dedicated SQL pools by calling the dedicated SQL pools - List By Server REST API request. The output is a JSON string that contains a list of the dedicated SQL pools in your workspace. The JSON string is passed to the next activity.

1. Under **Activities** > **General** drag a **Web** activity to the pipeline canvas as the first stage of your pipeline.
2. In the **General** tab, name this stage GET List.
3. Select the **Settings** tab then click in the **URL** entry space, then select **Add dynamic content**. Copy and paste the GET request that has been parameterized using the @concat string function below into the dynamic content box. Select **Finish**. The following code is a simple Get request:

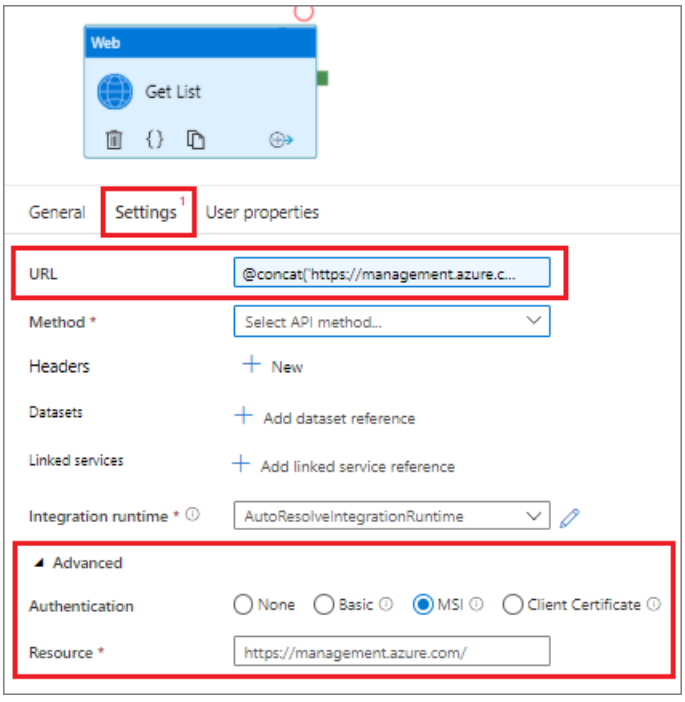
   ```
   GET https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Synapse/workspaces/{workspace-name}/sqlPools?api-version=2019-06-01-preview
   ```

   GET request that has been parameterized using the @concat string function:

   ```
   @concat('https://management.azure.com/subscriptions/',pipeline().parameters.SubscriptionID,'/resourceGroups/',pipeline().parameters.ResourceGroup,'/providers/Microsoft.Synapse/workspaces/',pipeline().parameters.WorkspaceName,'/sqlPools?api-version=2019-06-01-preview')
   ```

4. Select the drop-down for **Method** and select **Get**.
5. Select **Advanced** to expand the content. Select **MSI** as the Authentication type. For Resource enter `https://management.azure.com/`

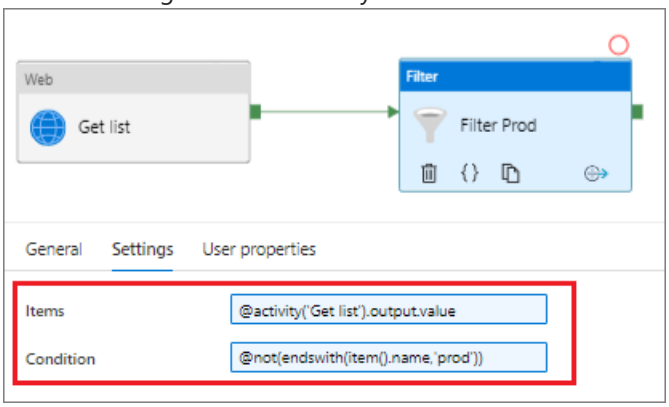
   > **IMPORTANT**
   > For all of the Web Activities / REST API Web calls, you need to ensure that Synapse Pipeline is authenticated against dedicated SQL pool. Managed Identity is required to run these REST API calls.



Step 4: Filter dedicated SQL pools

Remove dedicated SQL pools that you don't want to pause or resume. Use a filter activity that filters the values passed from the Get list activity. In this example, we're extracting the records from the array that don't have "prod" in the name. Apply other conditions as needed. For example, filter on the sku/name of the Synapse workspace to ensure only valid dedicated SQL pools are identified.

1. Select and drag the **Filter** activity under **Iteration & conditionals** to the pipeline canvas.

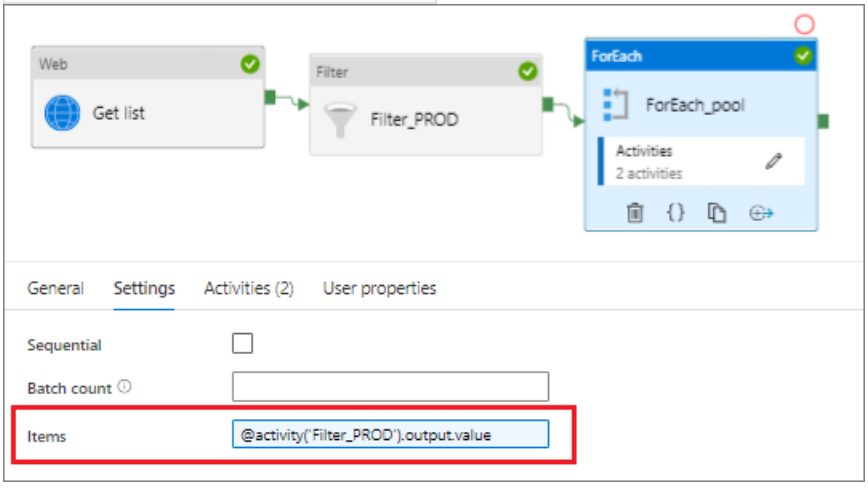


2. Connect the Get List Web activity to the Filter activity. Select the green tab on the Web activity and drag it to the Filter box.
3. Enter `@activity('Get list').output.value` for **Items** where GET List is the name of the preceding Web activity
4. Enter `@not(endswith(item().name,'prod'))` for **Condition**. The remaining records in the array are then passed to the next activity.

Step 5: Create a ForEach loop

Create a ForEach activity to loop over each dedicated SQL pool.

1. Select and drag the **ForEach** activity under **Iteration & conditionals** to the pipeline canvas.
2. On the **General** tab name the activity, we have used 'ForEach_pool'.
3. On the Settings tab, select the **Items** input and select **Add dynamic content**. Scroll to the **Activity outputs** and select the output from your filter activity. Add `.value` to the activity. the value should be similar to `@activity('Filter_PROD').output.value`. Select **finish**.



4. Select the **Activities** tab and select the edit pencil to open the ForEach loop canvas.

Step 5a: Check the state of the dedicated SQL pools

Checking the state of the dedicated SQL pool requires a Web Activity, similar to step 1. This activity calls the Check dedicated SQL pool state REST API for Azure Synapse.

1. Select and drag a **Web** activity under **General** to the pipeline canvas.

2. In the **General** tab, name this stage CheckState.

3. Select the **Settings** tab.

4. Click in the **URL** entry space, then select **Add dynamic content**. Copy and paste the GET request that has been parameterized using the @concat string function from below into the dynamic content box. Select **Finish**. Checking the state again uses a Get request using the following call:

   ```
   GET https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Synapse/workspaces/{workspace-name}/sqlPools/{database-name}?api-version=2019-06-01-preview HTTP/1.1
   ```

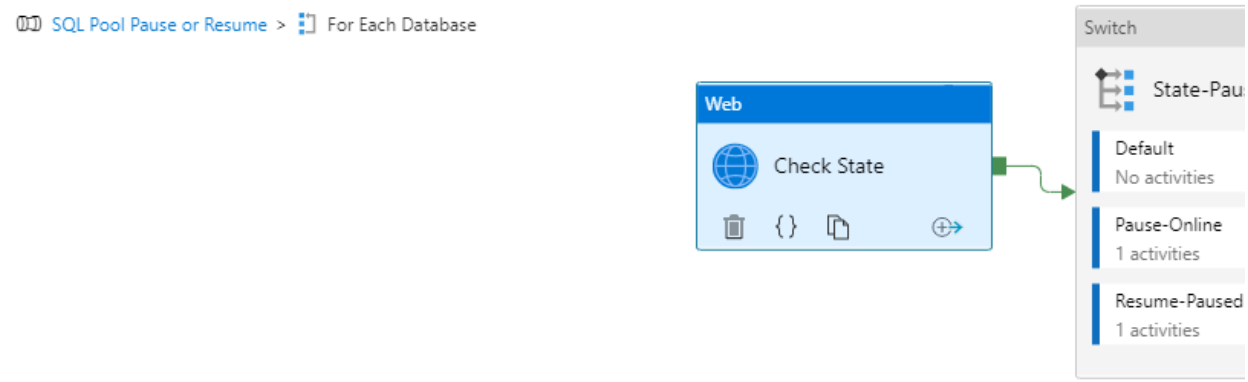
   The parameterize GET request using the @concat string function:

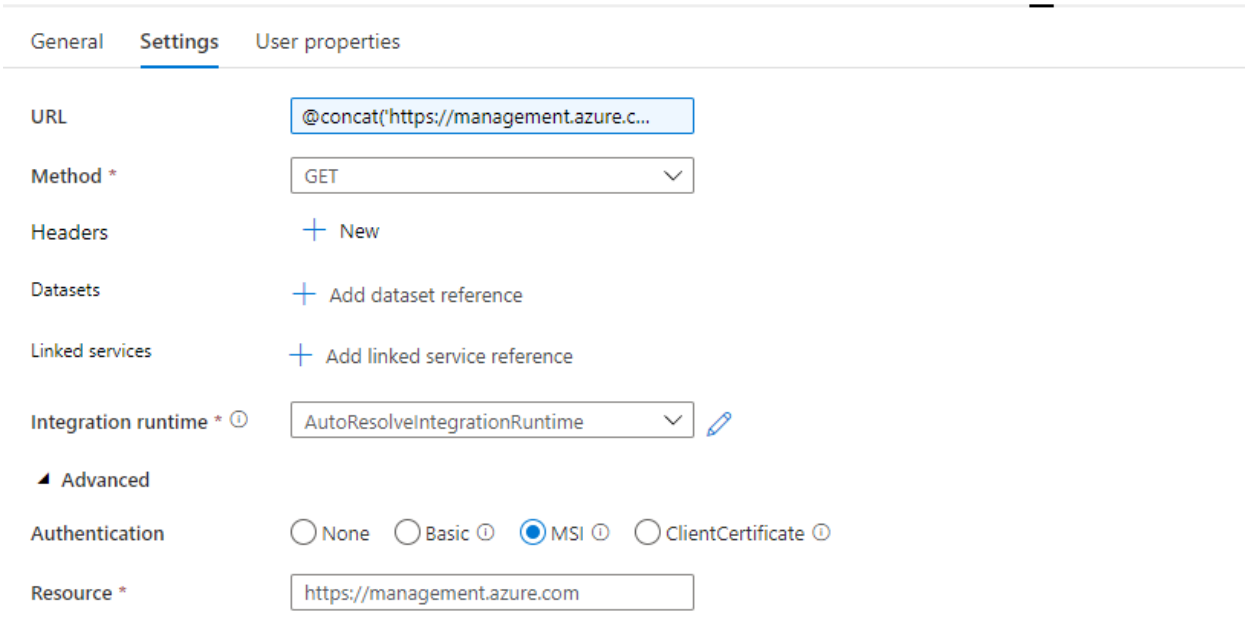
   ```
   @concat('https://management.azure.com/subscriptions/',pipeline().parameters.SubscriptionID,'/resourceGroups/',pipeline().parameters.ResourceGroup,'/providers/Microsoft.Synapse/workspaces/',pipeline().parameters.WorkspaceName,'/sqlPools/',item().name,'?api-version=2019-06-01-preview')
   ```

   In this case, we are using item().name, which is the name of the dedicated SQL pool from Step 1 that was passed to this activity from the ForEach loop. If you are using a pipeline to control a single dedicated SQL pool, you can embed the name of your dedicated SQL pool here, or use a parameter from the pipeline. For example, you could use pipeline().parameters.SQLPoolName.

   The output is a JSON string that contains details of the dedicated SQL pool, including its status (in properties.status). The JSON string is passed to the next activity.

5. Select the drop-down for **Method** and select **Get** Select **Advanced** to expand the content. Select **MSI** as the Authentication type. For Resource enter `https://management.azure.com/`





Step 5b: Evaluate the state of the dedicated SQL pools

Evaluate the desired state, Pause or Resume, and the current status, Online, or Paused, and then initiate Pause or Resume as needed.

1. Select and drag a **Switch** activity, under **Iteration & conditionals**, to the pipeline canvas.
2. Connect the **Switch** activity to the **CheckState** activity. Select the green tab on the Web activity and drag it to the Switch box.
3. In the **General** tab, name this stage State-PauseOrResume.

   Based on the desired state and the current status, only the following two combinations will require a change in state: Paused->Resume or Online->Pause.
4. On the **Activities** tab, copy the code below into the **Expression**.

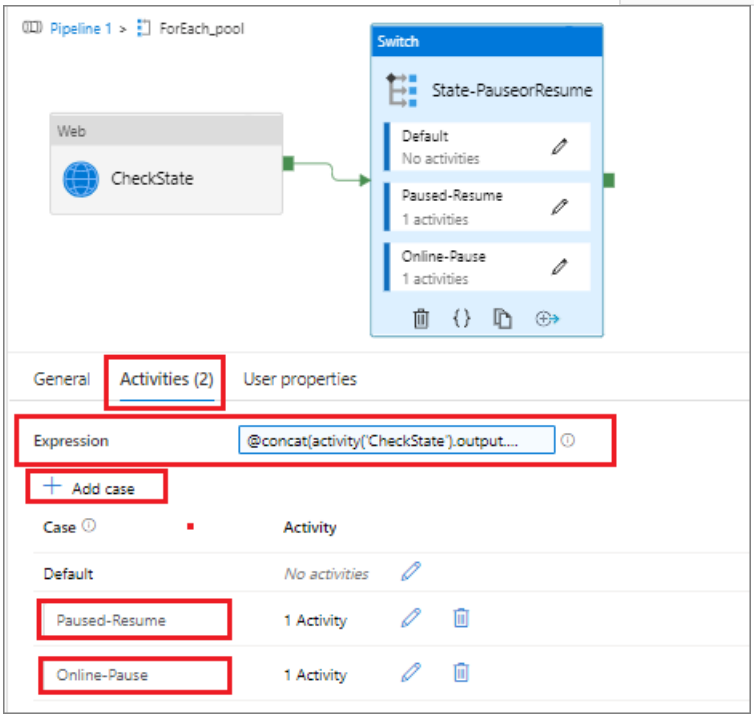
   ```
   @concat(activity('CheckState').output.properties.status,'-',pipeline().parameters.PauseOrResume)
   ```

   Where Check State is the name of the preceding Web activity with output.properties.status defining the current status and pipeline().parameters.PauseOrResume indicates the desired state.

   The check condition does a check of the desired state and the current status. If the desired state is Resume and the current status is Paused, a Resume Activity is invoked within the Paused-Resume Case. If the

desired state is Pause and the current status is Online, a Pause Activity is invoked with the Online-Pause Case. Any other cases, such as a desired state of Pause and a current status of Paused, or a desired state of Resume and a current status of Online, would require no action and be handled by the Default case, which has no activities.

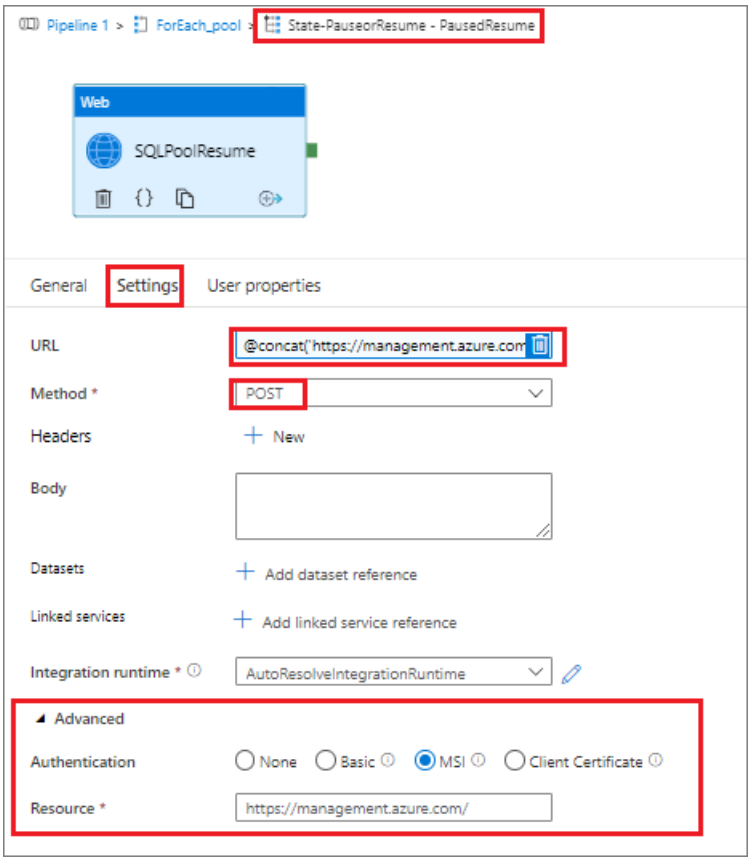
5. On the Activities tab, select **+ Add Case**. Add the cases `Paused-Resume` and `Online-Pause`.



Step 5c: Pause or Resume dedicated SQL pools

The final and only relevant step for some requirements, is to initiate the pause or resume of your dedicated SQL pool. This step again uses a Web activity, calling the Pause or Resume compute REST API for Azure Synapse.

1. Select the activity edit pencil and add a **Web** activity to the State-PauseorResume canvas.
2. Select the **Settings** tab then click in the **URL** entry space, then select **Add dynamic content**. Copy and paste the POST request that has been parameterized using the @concat string function below into the dynamic content box. Select **Finish**.
3. Select the drop-down for **Method** and select **POST**.
4. In the Body section type "Pause and Resume"
5. Select **Advanced** to expand the content. Select **MSI** as the Authentication type. For Resource enter `https://management.azure.com/`
6. Add a second activity for the resume functionality using the parameterized code below.



The example here is to resume a dedicated SQL pool, invoking a POST request using the following call:

```
POST https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Synapse/workspaces/{workspace-name}/sqlPools/{database-name}/resume?api-version=2019-06-01-preview HTTP/1.1
```

You can parameterize the POST statement from above using the @concat string function:

```
@concat('https://management.azure.com/subscriptions/',pipeline().parameters.SubscriptionID,'/resourceGroups/',pipeline().parameters.ResourceGroup,'/providers/Microsoft.Synapse/workspaces/',pipeline().parameters.WorkspaceName,'/sqlPools/',activity('CheckState').output.name,'/resume?api-version=2019-06-01-preview')
```

In this case, we are using the activity 'Check State'.output.name with the names of the dedicated SQL pools from Step 3a that were passed to this activity through the Switch Condition. If you are using a single activity against a single database, you could embed the name of your dedicated SQL pool here, or use a parameter from the pipeline. For example, you could use the pipeline().parameters.DatabaseName.

The POST request to pause a dedicated SQL pool is:

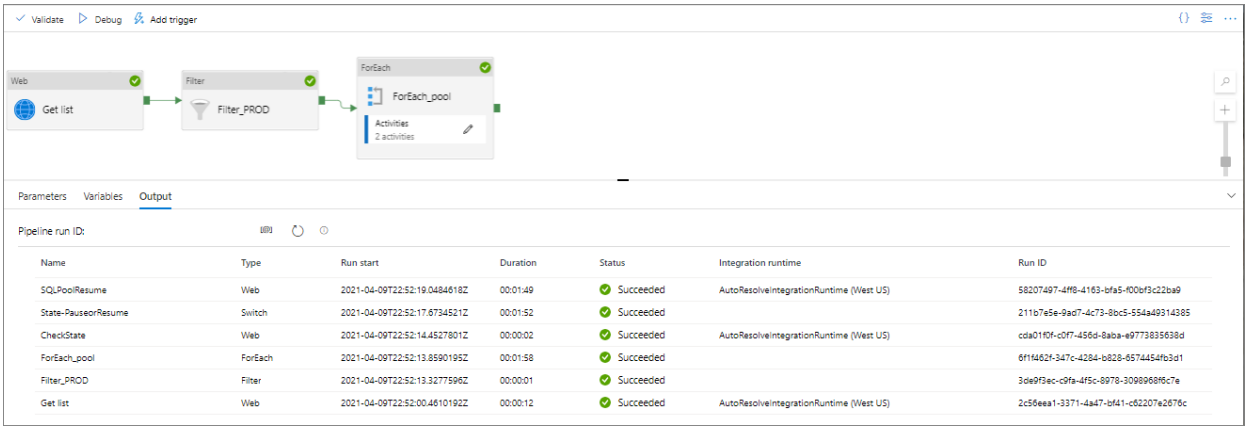
```
POST https://management.azure.com/subscriptions/{subscription-id}/resourceGroups/{resource-group-name}/providers/Microsoft.Synapse/workspaces/{workspace-name}/sqlPools/{database-name}/pause?api-version=2019-06-01-preview HTTP/1.1
```

The POST request can be parameterized using the @concat string function as shown:

```
@concat('https://management.azure.com/subscriptions/',pipeline().parameters.SubscriptionID,'/resourceGroups/',pipeline().parameters.ResourceGroup,'/providers/Microsoft.Synapse/workspaces/',pipeline().parameters.WorkspaceName,'/sqlPools/',activity('CheckState').output.name,'/pause?api-version=2019-06-01-preview')
```

Pipeline run output

When the full pipeline is run, you will see the output listed below. You can run your pipeline by selecting **Debug** mode or by selecting **add trigger**. For the pipeline results below, the pipeline parameter named "ResourceGroup" was set to a single resource group that had two Synapse Workspaces. One was named testprod and was filtered out, the second was named test1. The test1 dedicated SQL pool was paused, so the job initiated a resume.

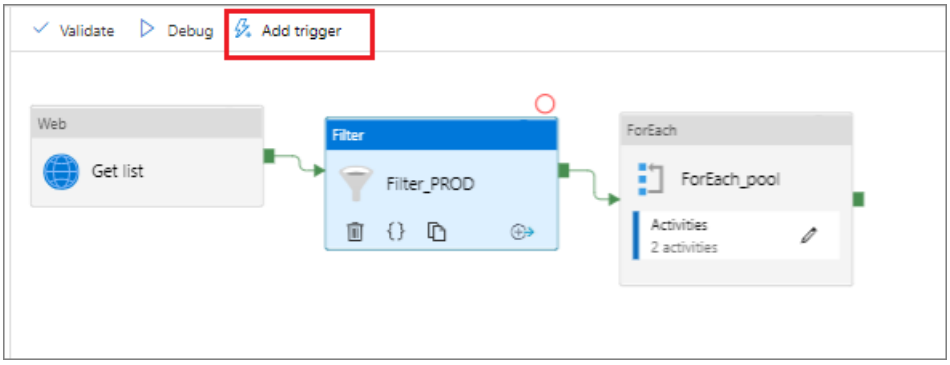


Save your pipeline

To save your pipeline, select **Publish all** above your pipeline.

Schedule your pause or resume pipeline to run

To schedule your pipeline, select **Add trigger** at the top of your pipeline. Follow the screens to schedule your pipeline to run at a specified time.



Next steps

Further details on Managed Identity for Azure Synapse, and how Managed Identity is added to your dedicated SQL pool can be found here:

Azure Synapse workspace managed identity

Grant permissions to workspace managed identity

Use Synapse Studio to monitor your SQL requests

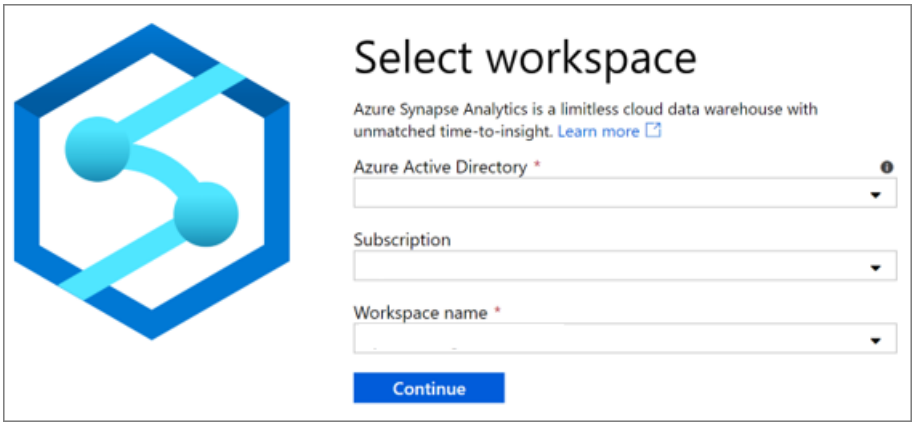
8/19/2022 • 2 minutes to read • Edit Online

With Synapse Studio, you can run SQL scripts on the SQL pools in your workspace.

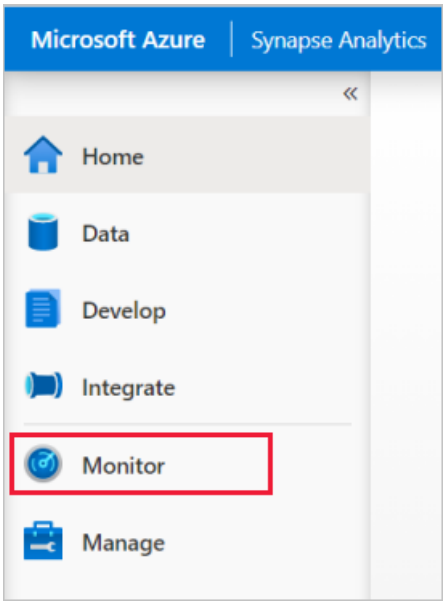
This article explains how to monitor your SQL requests, allowing you to keep an eye on the status of running requests and discover details of historical requests.

Access SQL requests list

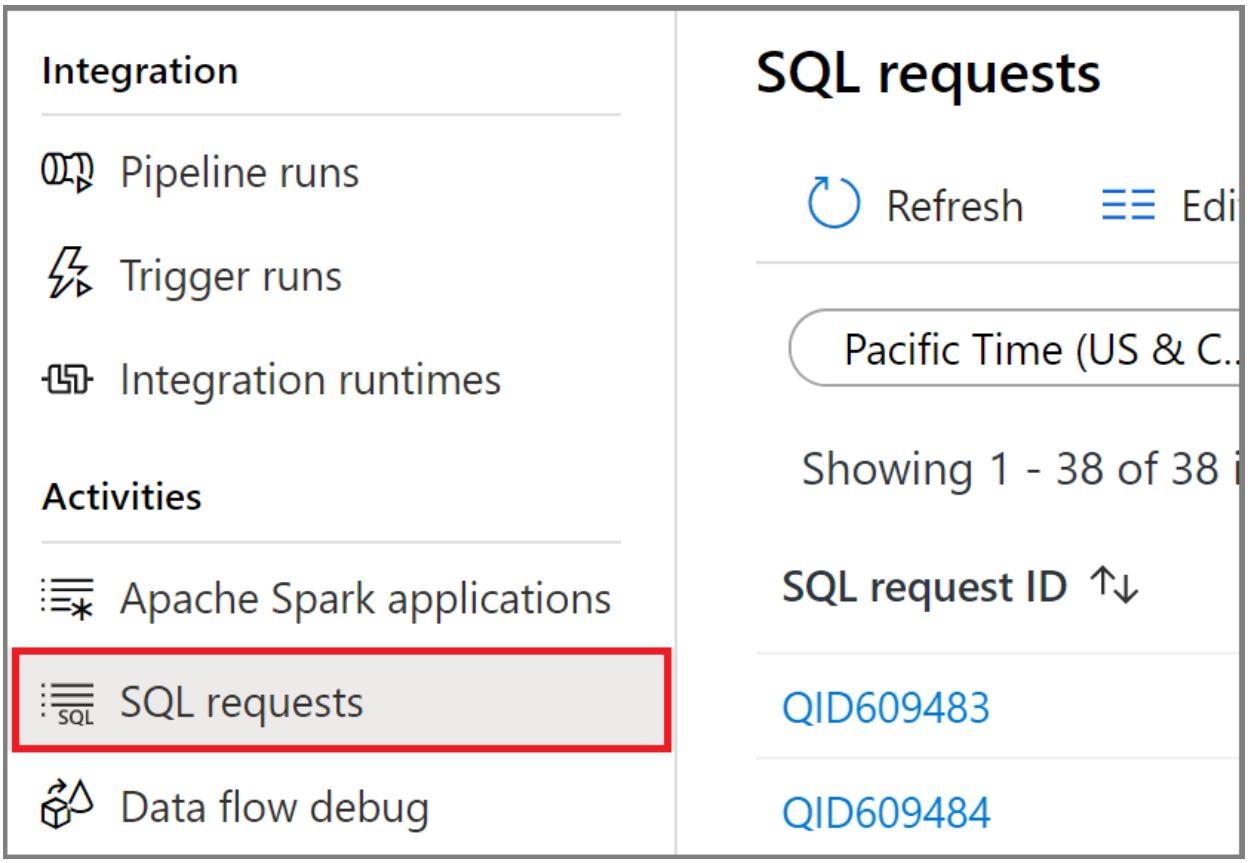
To see the list of SQL requests in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.

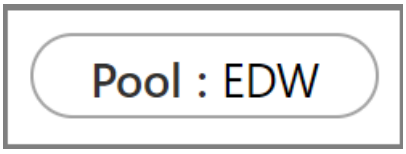


Select **SQL requests** to view the list of SQL requests.



Select a SQL pool

By default, the SQL request history for the built-in serverless SQL pool are shown in this view. You can select one of your dedicated SQL pools to see the SQL request history of that pool.



Filter your SQL requests

You can filter the list of SQL requests to the ones that interest you. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the SQL requests submitted by `maria@contoso.com`:

View details about a specific SQL request

To view the details about one of your SQL requests, open the SQL request to navigate to the details view. For the complex requests running on dedicated SQL pools, you can monitor the progress.

Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs in Synapse Studio article.

For more information on monitoring Apache Spark applications, see the Monitor Apache Spark applications in

Synapse Studio article.

To analyze historical queries, see Historical query storage and analysis in Azure Synapse Analytics.

Use Synapse Studio to monitor your SQL pools

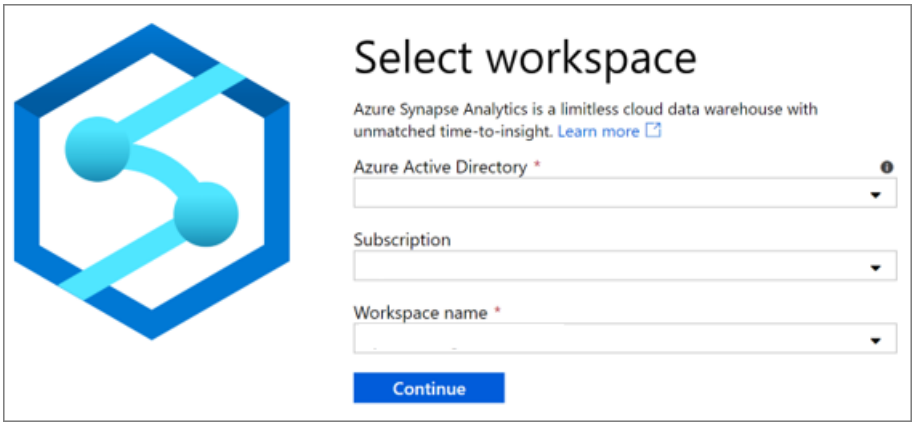
8/19/2022 • 2 minutes to read • Edit Online

With Synapse Studio, you can run SQL scripts on the SQL pools in your workspace.

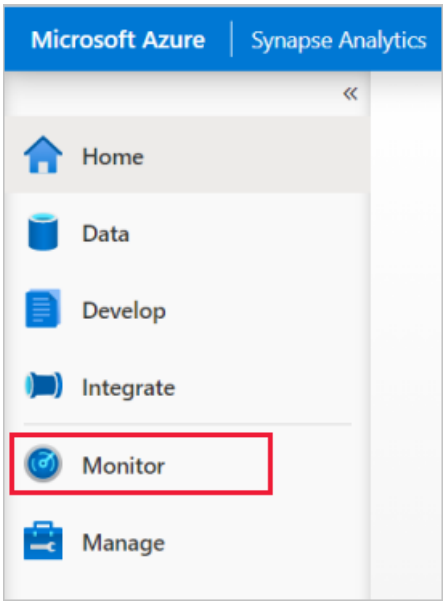
This article explains how to monitor your SQL pools, allowing you to keep an eye on the status and activity of your pools.

Access SQL pools list

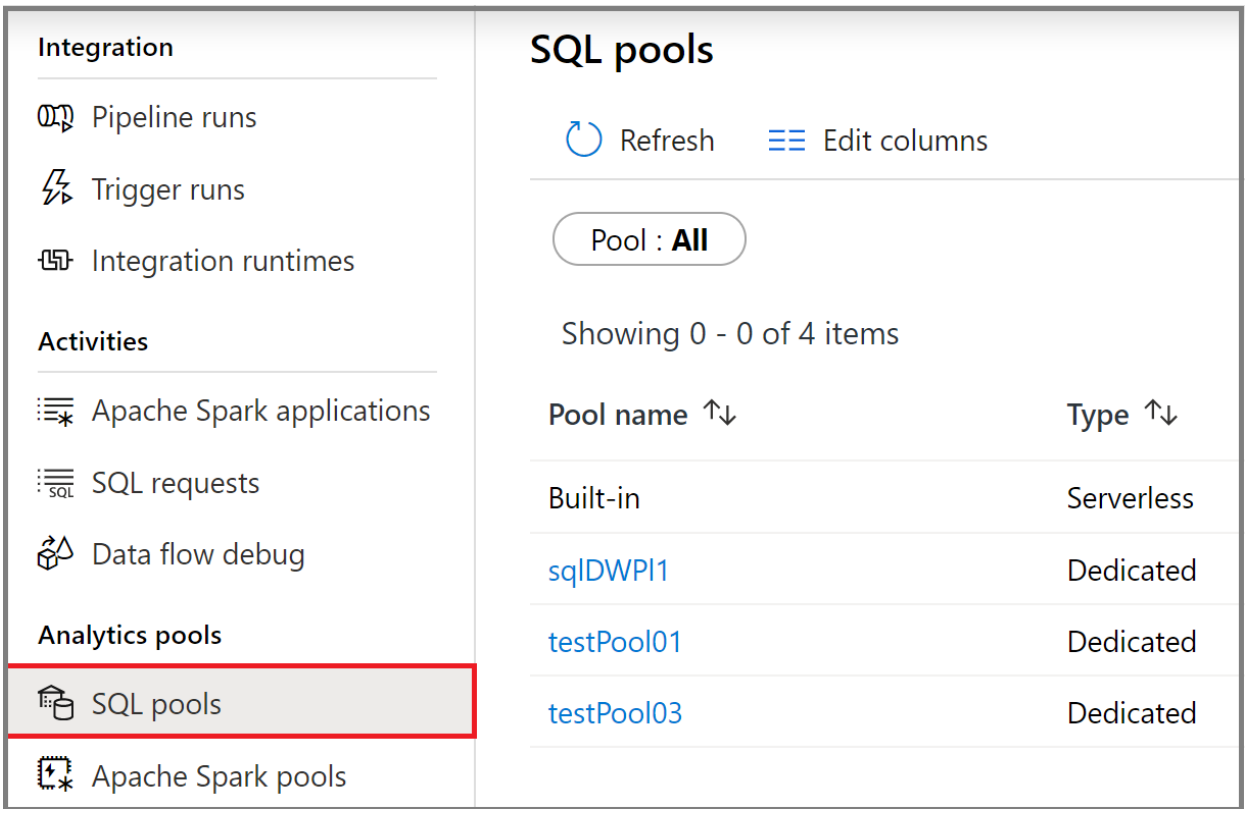
To see the list of SQL pools in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.



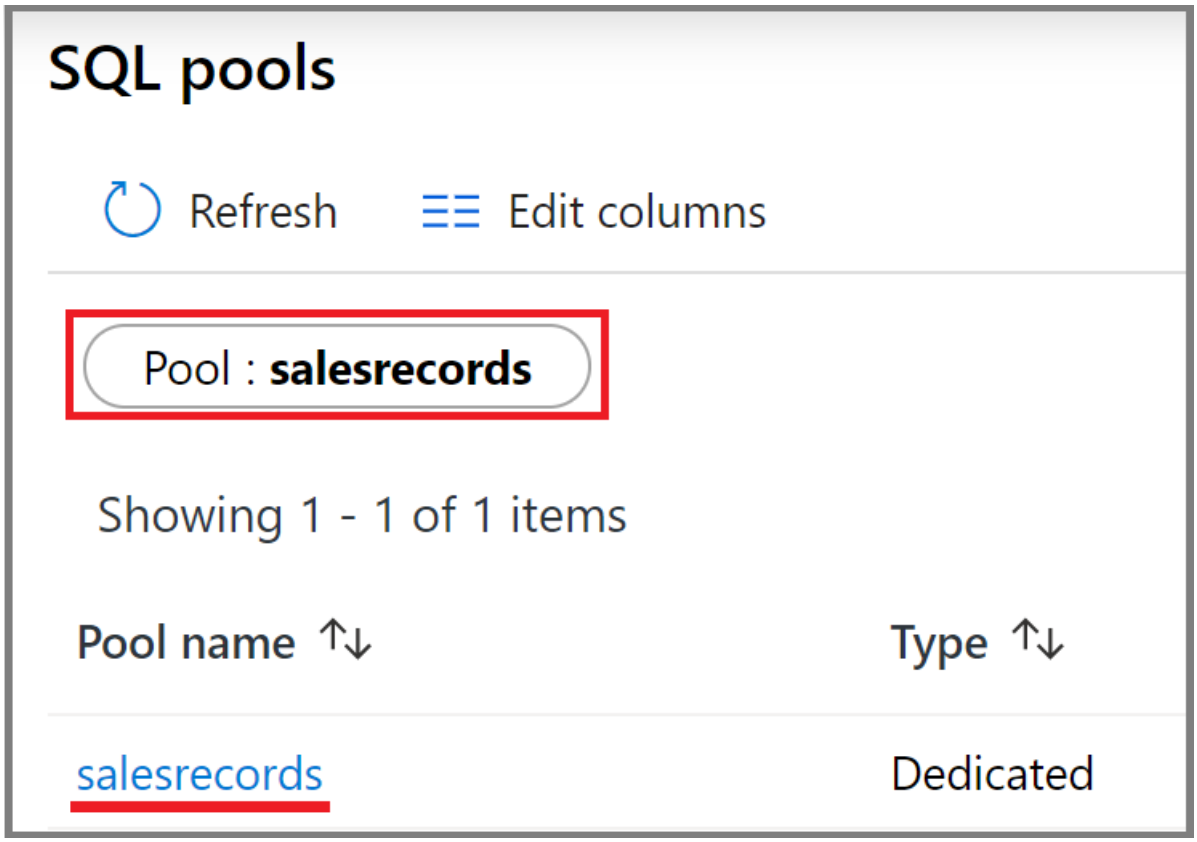
Select **SQL pools** to view the list of SQL pools.



Filter your SQL pools

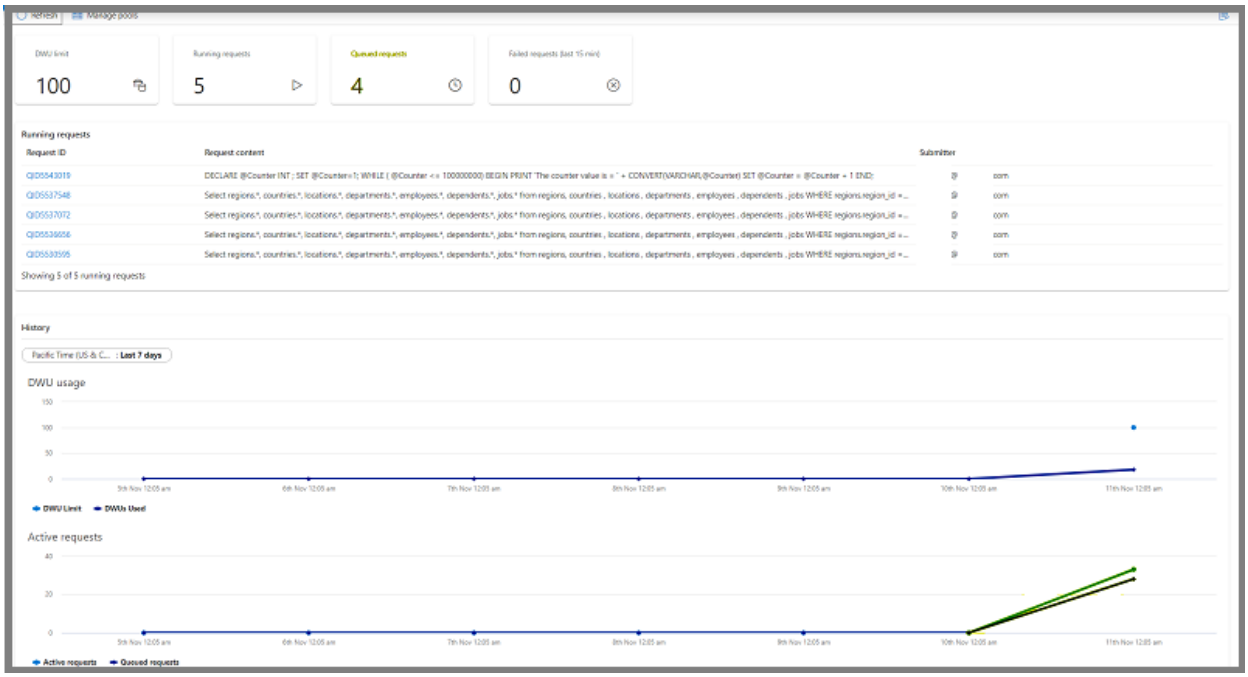
You can filter the list of SQL pools to the ones that interest you. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the SQL pools containing the name "salesrecords":



View details about a specific SQL pool

To view the details about one of your SQL pools, select the SQL pool to view the details.



Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs in Synapse Studio article.

For more information on monitoring SQL requests, see the Monitor SQL requests in Synapse Studio article.

How to monitor the adaptive cache

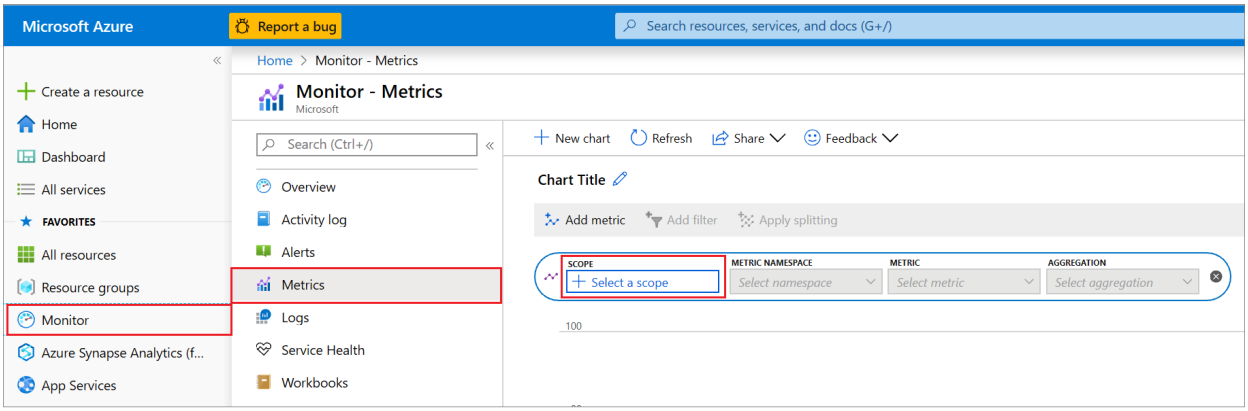
8/19/2022 • 2 minutes to read • Edit Online

This article describes how to monitor and troubleshoot slow query performance by determining whether your workload is optimally leveraging the adaptive cache for dedicated SQL pools.

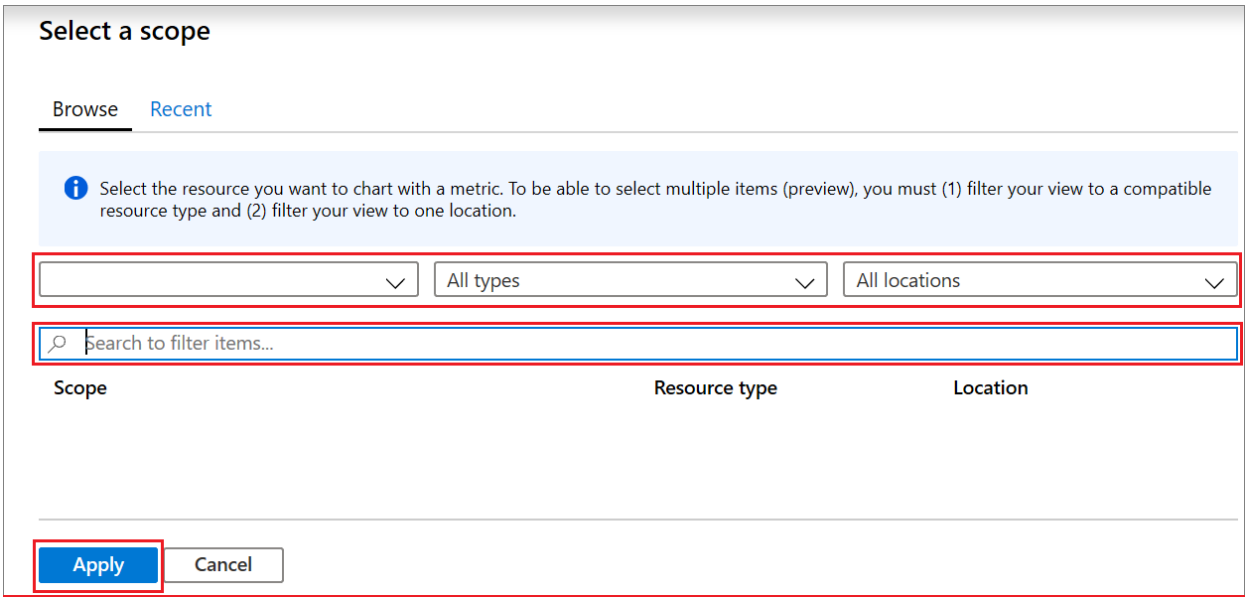
The dedicated SQL pool storage architecture automatically tiers your most frequently queried columnstore segments in a cache residing on NVMe based SSDs. You will have greater performance when your queries retrieve segments that are residing in the cache.

Troubleshoot using the Azure portal

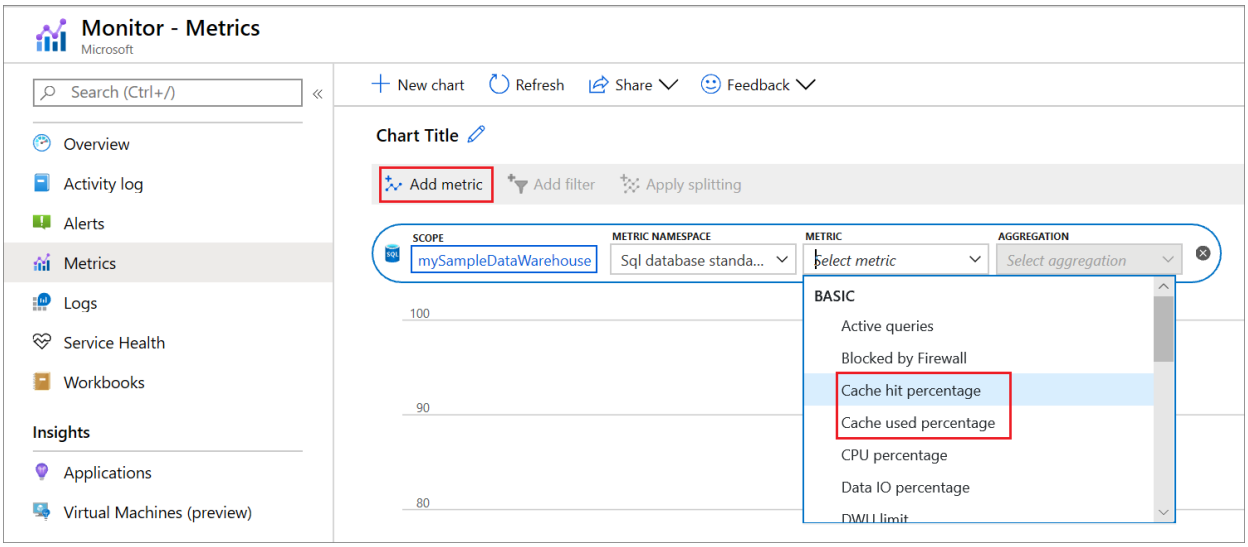
You can use Azure Monitor to view cache metrics to troubleshoot query performance. First go to the Azure portal and click on **Monitor**, **Metrics** and **+ Select a scope**:



Use the search and drop down bars to locate your dedicated SQL pool. Then select apply.



The key metrics for troubleshooting the cache are **Cache hit percentage** and **Cache used percentage**. Select **Cache hit percentage** then use the **add metric** button to add **Cache used percentage**.



Cache hit and used percentage

The matrix below describes scenarios based on the values of the cache metrics:

	HIGH CACHE HIT PERCENTAGE	LOW CACHE HIT PERCENTAGE
High Cache used percentage	Scenario 1	Scenario 2
Low Cache used percentage	Scenario 3	Scenario 4

Scenario 1: You are optimally using your cache. Troubleshoot other areas that may be slowing down your queries.

Scenario 2: Your current working data set cannot fit into the cache which causes a low cache hit percentage due to physical reads. Consider scaling up your performance level and rerun your workload to populate the cache.

Scenario 3: It is likely that your query is running slow due to reasons unrelated to the cache. Troubleshoot other areas that may be slowing down your queries. You can also consider scaling down your instance to reduce your cache size to save costs.

Scenario 4: You had a cold cache which could be the reason why your query was slow. Consider rerunning your query as your working dataset should now be in cached.

> **IMPORTANT**
> If the cache hit percentage or cache used percentage isn't updating after rerunning your workload, your working set can already be residing in memory. Only clustered columnstore tables are cached.

Next steps

For more information on general query performance tuning, see Monitor query execution.

Monitor your Azure Synapse Analytics dedicated SQL pool workload using DMVs

8/19/2022 • 9 minutes to read • Edit Online

This article describes how to use Dynamic Management Views (DMVs) to monitor your workload including investigating query execution in SQL pool.

Permissions

To query the DMVs in this article, you need either **VIEW DATABASE STATE** or **CONTROL** permission. Usually, granting **VIEW DATABASE STATE** is the preferred permission as it is much more restrictive.

```
GRANT VIEW DATABASE STATE TO myuser;
```

Monitor connections

All logins to your data warehouse are logged to sys.dm_pdw_exec_sessions. This DMV contains the last 10,000 logins. The session_id is the primary key and is assigned sequentially for each new logon.

```
-- Other Active Connections
SELECT * FROM sys.dm_pdw_exec_sessions where status <> 'Closed' and session_id <> session_id();
```

Monitor query execution

All queries executed on SQL pool are logged to sys.dm_pdw_exec_requests. This DMV contains the last 10,000 queries executed. The request_id uniquely identifies each query and is the primary key for this DMV. The request_id is assigned sequentially for each new query and is prefixed with QID, which stands for query ID. Querying this DMV for a given session_id shows all queries for a given logon.

> **NOTE**
> Stored procedures use multiple Request IDs. Request IDs are assigned in sequential order.

Here are steps to follow to investigate query execution plans and times for a particular query.

STEP 1: Identify the query you wish to investigate

```
-- Monitor active queries
SELECT *
FROM sys.dm_pdw_exec_requests
WHERE status not in ('Completed','Failed','Cancelled')
  AND session_id <> session_id()
ORDER BY submit_time DESC;

-- Find top 10 queries longest running queries
SELECT TOP 10 *
FROM sys.dm_pdw_exec_requests
ORDER BY total_elapsed_time DESC;
```

From the preceding query results, **note the Request ID** of the query that you would like to investigate.

Queries in the **Suspended** state can be queued due to a large number of active running queries. These queries also appear in the sys.dm_pdw_waits. In that case, look for waits such as UserConcurrencyResourceType. For information on concurrency limits, see Memory and concurrency limits or Resource classes for workload management. Queries can also wait for other reasons such as for object locks. If your query is waiting for a resource, see Investigating queries waiting for resources further down in this article.

To simplify the lookup of a query in the sys.dm_pdw_exec_requests table, use LABEL to assign a comment to your query, which can be looked up in the sys.dm_pdw_exec_requests view.

```
-- Query with Label
SELECT *
FROM sys.tables
OPTION (LABEL = 'My Query')
;

-- Find a query with the Label 'My Query'
-- Use brackets when querying the label column, as it it a key word
SELECT  *
FROM    sys.dm_pdw_exec_requests
WHERE   [label] = 'My Query';
```

STEP 2: Investigate the query plan

Use the Request ID to retrieve the query's distributed SQL (DSQL) plan from sys.dm_pdw_request_steps

```
-- Find the distributed query plan steps for a specific query.
-- Replace request_id with value from Step 1.

SELECT * FROM sys.dm_pdw_request_steps
WHERE request_id = 'QID####'
ORDER BY step_index;
```

When a DSQL plan is taking longer than expected, the cause can be a complex plan with many DSQL steps or just one step taking a long time. If the plan is many steps with several move operations, consider optimizing your table distributions to reduce data movement. The Table distribution article explains why data must be moved to solve a query. The article also explains some distribution strategies to minimize data movement.

To investigate further details about a single step, the *operation_type* column of the long-running query step and note the **Step Index**:

- Proceed with Step 3 for **SQL operations**: OnOperation, RemoteOperation, ReturnOperation.
- Proceed with Step 4 for **Data Movement operations**: ShuffleMoveOperation, BroadcastMoveOperation, TrimMoveOperation, PartitionMoveOperation, MoveOperation, CopyOperation.

STEP 3: Investigate SQL on the distributed databases

Use the Request ID and the Step Index to retrieve details from sys.dm_pdw_sql_requests, which contains execution information of the query step on all of the distributed databases.

```
-- Find the distribution run times for a SQL step.
-- Replace request_id and step_index with values from Step 1 and 3.

SELECT * FROM sys.dm_pdw_sql_requests
WHERE request_id = 'QID####' AND step_index = 2;
```

When the query step is running, DBCC PDW_SHOWEXECUTIONPLAN can be used to retrieve the SQL Server estimated plan from the SQL Server plan cache for the step running on a particular distribution.

```
-- Find the SQL Server execution plan for a query running on a specific SQL pool or control node.
-- Replace distribution_id and spid with values from previous query.

DBCC PDW_SHOWEXECUTIONPLAN(1, 78);
```

STEP 4: Investigate data movement on the distributed databases

Use the Request ID and the Step Index to retrieve information about a data movement step running on each distribution from sys.dm_pdw_dms_workers.

```
-- Find information about all the workers completing a Data Movement Step.
-- Replace request_id and step_index with values from Step 1 and 3.

SELECT * FROM sys.dm_pdw_dms_workers
WHERE request_id = 'QID####' AND step_index = 2;
```

- Check the *total_elapsed_time* column to see if a particular distribution is taking significantly longer than others for data movement.
- For the long-running distribution, check the *rows_processed* column to see if the number of rows being moved from that distribution is significantly larger than others. If so, this finding might indicate skew of your underlying data. One cause for data skew is distributing on a column with many NULL values (whose rows will all land in the same distribution). Prevent slow queries by avoiding distribution on these types of columns or filtering your query to eliminate NULLs when possible.

If the query is running, you can use DBCC PDW_SHOWEXECUTIONPLAN to retrieve the SQL Server estimated plan from the SQL Server plan cache for the currently running SQL Step within a particular distribution.

```
-- Find the SQL Server estimated plan for a query running on a specific SQL pool Compute or control node.
-- Replace distribution_id and spid with values from previous query.

DBCC PDW_SHOWEXECUTIONPLAN(55, 238);
```

Monitor waiting queries

If you discover that your query is not making progress because it is waiting for a resource, here is a query that shows all the resources a query is waiting for.

```
-- Find queries
-- Replace request_id with value from Step 1.

SELECT waits.session_id,
      waits.request_id,
      requests.command,
      requests.status,
      requests.start_time,
      waits.type,
      waits.state,
      waits.object_type,
      waits.object_name
FROM   sys.dm_pdw_waits waits
   JOIN  sys.dm_pdw_exec_requests requests
   ON waits.request_id=requests.request_id
WHERE waits.request_id = 'QID####'
ORDER BY waits.object_name, waits.object_type, waits.state;
```

If the query is actively waiting on resources from another query, then the state will be **AcquireResources**. If the

query has all the required resources, then the state will be **Granted**.

Monitor tempdb

Tempdb is used to hold intermediate results during query execution. High utilization of the tempdb database can lead to slow query performance. For every DW100c configured, 399 GB of tempdb space is allocated (DW1000c would have 3.99 TB of total tempdb space). Below are tips for monitoring tempdb usage and for decreasing tempdb usage in your queries.

Monitoring tempdb with views

To monitor tempdb usage, first install the microsoft.vw_sql_requests view from the Microsoft Toolkit for SQL pool. You can then execute the following query to see the tempdb usage per node for all executed queries:

```
-- Monitor tempdb
SELECT
    sr.request_id,
    ssu.session_id,
    ssu.pdw_node_id,
    sr.command,
    sr.total_elapsed_time,
    exs.login_name AS 'LoginName',
    DB_NAME(ssu.database_id) AS 'DatabaseName',
    (es.memory_usage * 8) AS 'MemoryUsage (in KB)',
    (ssu.user_objects_alloc_page_count * 8) AS 'Space Allocated For User Objects (in KB)',
    (ssu.user_objects_dealloc_page_count * 8) AS 'Space Deallocated For User Objects (in KB)',
    (ssu.internal_objects_alloc_page_count * 8) AS 'Space Allocated For Internal Objects (in KB)',
    (ssu.internal_objects_dealloc_page_count * 8) AS 'Space Deallocated For Internal Objects (in KB)',
    CASE es.is_user_process
    WHEN 1 THEN 'User Session'
    WHEN 0 THEN 'System Session'
    END AS 'SessionType',
    es.row_count AS 'RowCount'
FROM sys.dm_pdw_nodes_db_session_space_usage AS ssu
    INNER JOIN sys.dm_pdw_nodes_exec_sessions AS es ON ssu.session_id = es.session_id AND ssu.pdw_node_id =
es.pdw_node_id
    INNER JOIN sys.dm_pdw_nodes_exec_connections AS er ON ssu.session_id = er.session_id AND ssu.pdw_node_id
= er.pdw_node_id
    INNER JOIN microsoft.vw_sql_requests AS sr ON ssu.session_id = sr.spid AND ssu.pdw_node_id =
sr.pdw_node_id
    LEFT JOIN sys.dm_pdw_exec_requests exr on exr.request_id = sr.request_id
    LEFT JOIN sys.dm_pdw_exec_sessions exs on exr.session_id = exs.session_id
WHERE DB_NAME(ssu.database_id) = 'tempdb'
    AND es.session_id <> @@SPID
    AND es.login_name <> 'sa'
ORDER BY sr.request_id;
```

If you have a query that is consuming a large amount of memory or have received an error message related to the allocation of tempdb, it could be due to a very large CREATE TABLE AS SELECT (CTAS) or INSERT SELECT statement running that is failing in the final data movement operation. This can usually be identified as a ShuffleMove operation in the distributed query plan right before the final INSERT SELECT. Use sys.dm_pdw_request_steps to monitor ShuffleMove operations.

The most common mitigation is to break your CTAS or INSERT SELECT statement into multiple load statements so the data volume will not exceed the 2TB per node tempdb limit (when at or above DW500c). You can also scale your cluster to a larger size which will spread the tempdb size across more nodes reducing the tempdb on each individual node.

In addition to CTAS and INSERT SELECT statements, large, complex queries running with insufficient memory can spill into tempdb causing queries to fail. Consider running with a larger resource class to avoid spilling into tempdb.

Monitor memory

Memory can be the root cause for slow performance and out of memory issues. Consider scaling your data warehouse if you find SQL Server memory usage reaching its limits during query execution.

The following query returns SQL Server memory usage and memory pressure per node:

```
-- Memory consumption
SELECT
  pc1.cntr_value as Curr_Mem_KB,
  pc1.cntr_value/1024.0 as Curr_Mem_MB,
  (pc1.cntr_value/1048576.0) as Curr_Mem_GB,
  pc2.cntr_value as Max_Mem_KB,
  pc2.cntr_value/1024.0 as Max_Mem_MB,
  (pc2.cntr_value/1048576.0) as Max_Mem_GB,
  pc1.cntr_value * 100.0/pc2.cntr_value AS Memory_Utilization_Percentage,
  pc1.pdw_node_id
FROM
-- pc1: current memory
sys.dm_pdw_nodes_os_performance_counters AS pc1
-- pc2: total memory allowed for this SQL instance
JOIN sys.dm_pdw_nodes_os_performance_counters AS pc2
ON pc1.object_name = pc2.object_name AND pc1.pdw_node_id = pc2.pdw_node_id
WHERE
pc1.counter_name = 'Total Server Memory (KB)'
AND pc2.counter_name = 'Target Server Memory (KB)'
```

Monitor transaction log size

The following query returns the transaction log size on each distribution. If one of the log files is reaching 160 GB, you should consider scaling up your instance or limiting your transaction size.

```
-- Transaction log size
SELECT
  instance_name as distribution_db,
  cntr_value*1.0/1048576 as log_file_size_used_GB,
  pdw_node_id
FROM sys.dm_pdw_nodes_os_performance_counters
WHERE
instance_name like 'Distribution_%'
AND counter_name = 'Log File(s) Used Size (KB)'
```

Monitor transaction log rollback

If your queries are failing or taking a long time to proceed, you can check and monitor if you have any transactions rolling back.

```
-- Monitor rollback
SELECT
    SUM(CASE WHEN t.database_transaction_next_undo_lsn IS NOT NULL THEN 1 ELSE 0 END),
    t.pdw_node_id,
    nod.[type]
FROM sys.dm_pdw_nodes_tran_database_transactions t
JOIN sys.dm_pdw_nodes nod ON t.pdw_node_id = nod.pdw_node_id
GROUP BY t.pdw_node_id, nod.[type]
```

Monitor PolyBase load

The following query provides an approximate estimate of the progress of your load. The query only shows files currently being processed.

```
-- To track bytes and files
SELECT
    r.command,
    s.request_id,
    r.status,
    count(distinct input_name) as nbr_files,
    sum(s.bytes_processed)/1024/1024/1024 as gb_processed
FROM
    sys.dm_pdw_exec_requests r
    inner join sys.dm_pdw_dms_external_work s
        on r.request_id = s.request_id
GROUP BY
    r.command,
    s.request_id,
    r.status
ORDER BY
    nbr_files desc,
    gb_processed desc;
```

Monitor query blockings

The following query provides the top 500 blocked queries in the environment.

```
--Collect the top blocking
SELECT
    TOP 500 waiting.request_id AS WaitingRequestId,
    waiting.object_type AS LockRequestType,
    waiting.object_name AS ObjectLockRequestName,
    waiting.request_time AS ObjectLockRequestTime,
    blocking.session_id AS BlockingSessionId,
    blocking.request_id AS BlockingRequestId
FROM
    sys.dm_pdw_waits waiting
    INNER JOIN sys.dm_pdw_waits blocking
    ON waiting.object_type = blocking.object_type
    AND waiting.object_name = blocking.object_name
WHERE
    waiting.state = 'Queued'
    AND blocking.state = 'Granted'
ORDER BY
    ObjectLockRequestTime ASC;
```

Retrieve query text from waiting and blocking queries

The following query provides the query text and identifier for the waiting and blocking queries to easily troubleshoot.

```
-- To retrieve query text from waiting and blocking queries

SELECT waiting.session_id AS WaitingSessionId,
       waiting.request_id AS WaitingRequestId,
       COALESCE(waiting_exec_request.command,waiting_exec_request.command2) AS WaitingExecRequestText,
       blocking.session_id AS BlockingSessionId,
       blocking.request_id AS BlockingRequestId,
       COALESCE(blocking_exec_request.command,blocking_exec_request.command2) AS BlockingExecRequestText,
       waiting.object_name AS Blocking_Object_Name,
       waiting.object_type AS Blocking_Object_Type,
       waiting.type AS Lock_Type,
       waiting.request_time AS Lock_Request_Time,
       datediff(ms, waiting.request_time, getdate())/1000.0 AS Blocking_Time_sec
FROM sys.dm_pdw_waits waiting
       INNER JOIN sys.dm_pdw_waits blocking
       ON waiting.object_type = blocking.object_type
       AND waiting.object_name = blocking.object_name
       INNER JOIN sys.dm_pdw_exec_requests blocking_exec_request
       ON blocking.request_id = blocking_exec_request.request_id
       INNER JOIN sys.dm_pdw_exec_requests waiting_exec_request
       ON waiting.request_id = waiting_exec_request.request_id
WHERE waiting.state = 'Queued'
       AND blocking.state = 'Granted'
ORDER BY Lock_Request_Time DESC;
```

Next steps

For more information about DMVs, see System views.

Monitor workload - Azure portal

8/19/2022 • 2 minutes to read • Edit Online

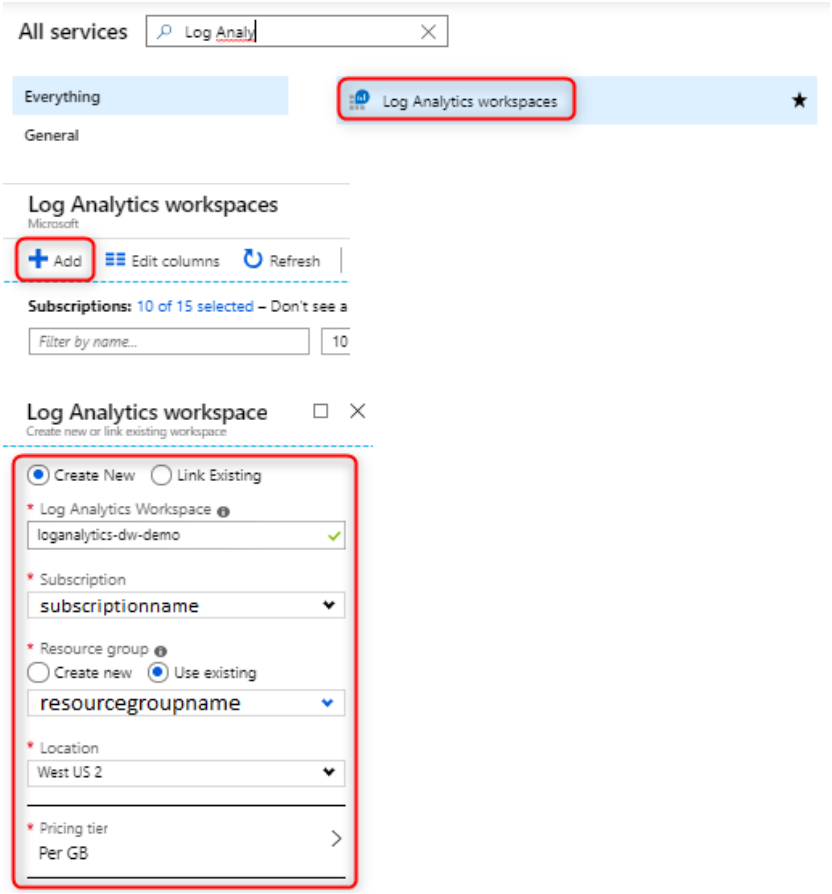
This article describes how to use the Azure portal to monitor your workload. This includes setting up Azure Monitor Logs to investigate query execution and workload trends using log analytics for Synapse SQL.

Prerequisites

- Azure subscription: If you don't have an Azure subscription, create a free account before you begin.
- SQL pool: We will be collecting logs for a SQL pool. If you don't have a SQL pool provisioned, see the instructions in Create a SQL pool.

Create a Log Analytics workspace

Navigate to the browse blade for Log Analytics workspaces and create a workspace



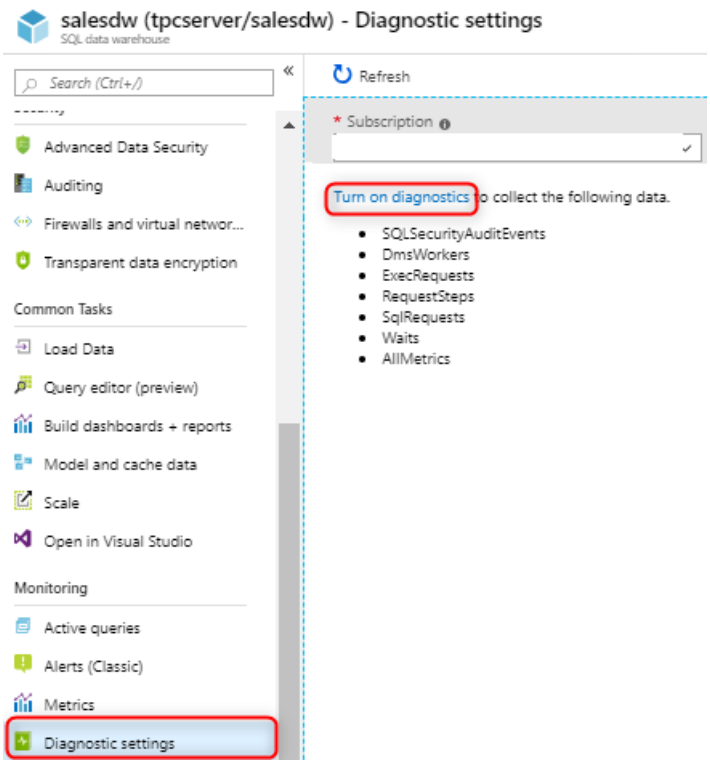
For more details on workspaces, visit the following documentation.

Turn on Resource logs

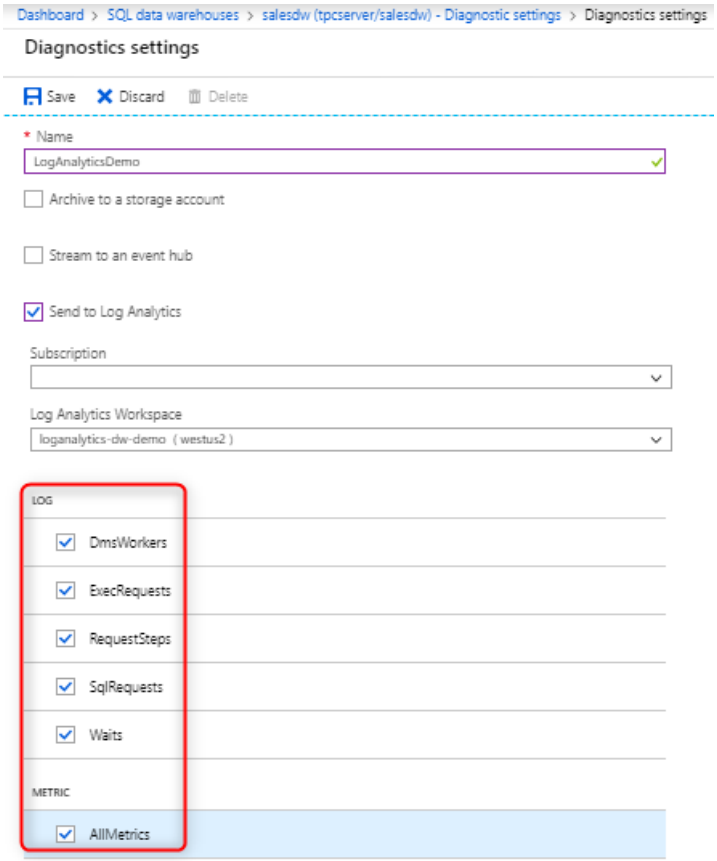
Configure diagnostic settings to emit logs from your SQL pool. Logs consist of telemetry views equivalent to the most commonly used performance troubleshooting DMVs. Currently the following views are supported:

- sys.dm_pdw_exec_requests
- sys.dm_pdw_request_steps
- sys.dm_pdw_dms_workers

- sys.dm_pdw_waits
- sys.dm_pdw_sql_requests



Logs can be emitted to Azure Storage, Stream Analytics, or Log Analytics. For this tutorial, select Log Analytics.



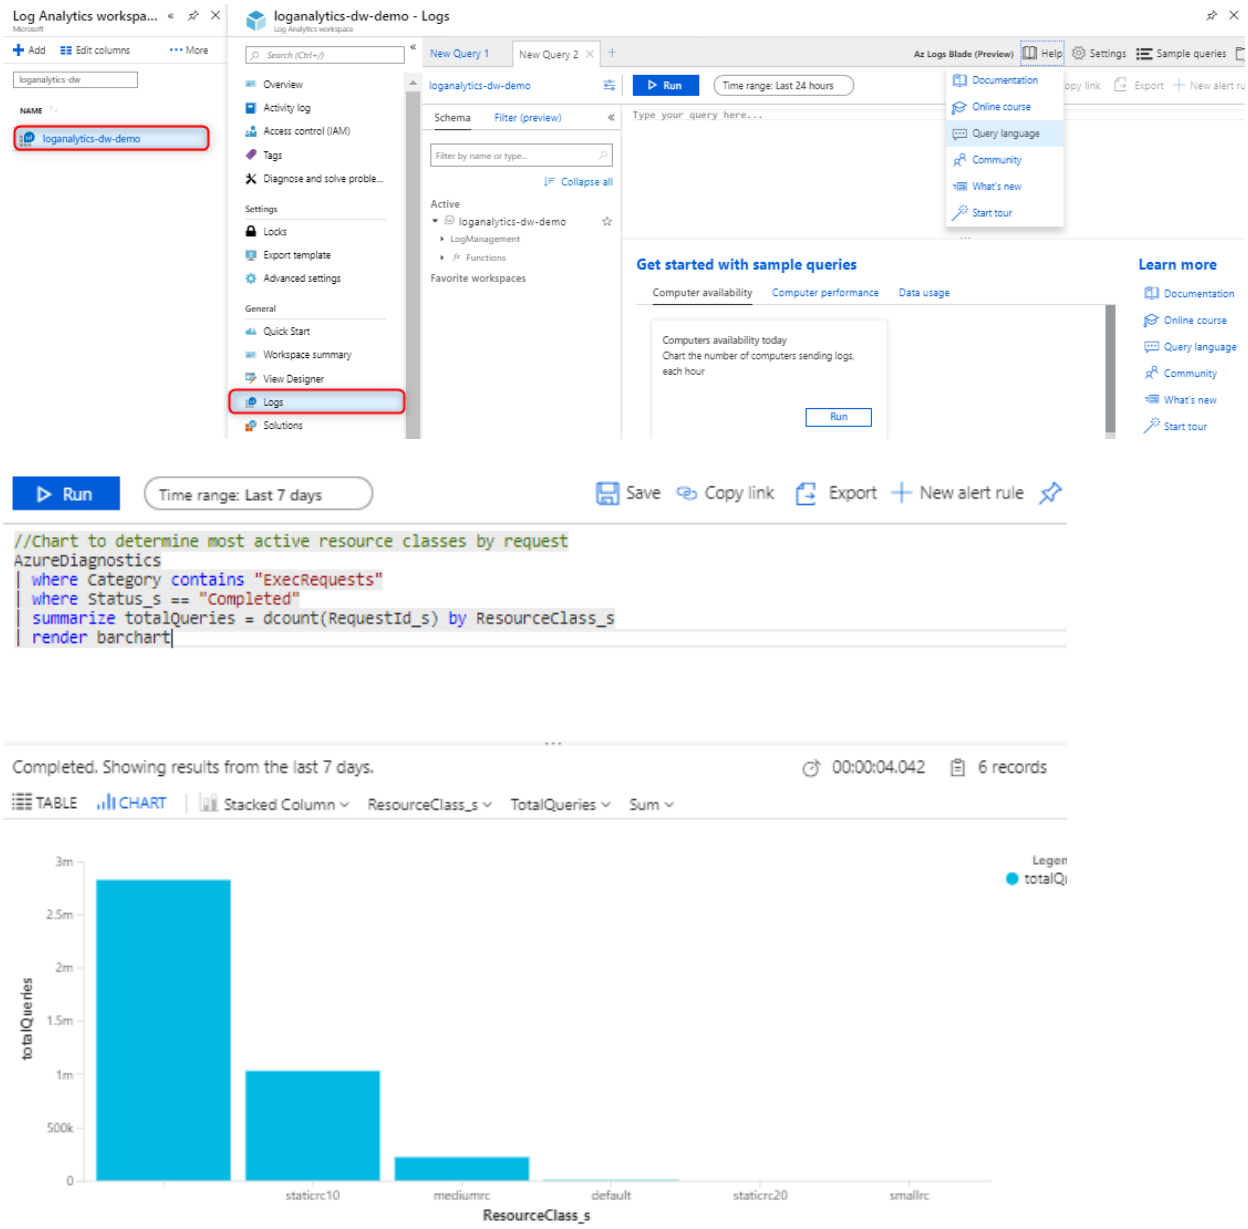
Run queries against Log Analytics

Navigate to your Log Analytics workspace where you can do the following:

- Analyze logs using log queries and save queries for reuse
- Save queries for reuse

- Create log alerts
- Pin query results to a dashboard

For details on the capabilities of log queries, visit the following documentation.



Sample log queries

```
//List all queries
AzureDiagnostics
| where Category contains "ExecRequests"
| project TimeGenerated, StartTime_t, EndTime_t, Status_s, Command_s, ResourceClass_s,
duration=datetime_diff('millisecond',EndTime_t, StartTime_t)
```

```
//Chart the most active resource classes
AzureDiagnostics
| where Category contains "ExecRequests"
| where Status_s == "Completed"
| summarize totalQueries = dcount(RequestId_s) by ResourceClass_s
| render barchart
```

```
//Count of all queued queries
AzureDiagnostics
| where Category contains "waits"
| where Type_s == "UserConcurrencyResourceType"
| summarize totalQueuedQueries = dcount(RequestId_s)
```

Next steps

Now that you have set up and configured Azure monitor logs, customize Azure dashboards to share across your team.

Historical query storage and analysis in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

Historic query analysis is one of the crucial needs of data engineers. Azure Synapse Analytics supports four main ways to analyze query history and performance. These include Query Store, DMVs, Azure Log Analytics, and Azure Data Explorer.

This article will show you how to use each of these options for your needs. Review use cases when it comes to analyzing query history, and the best method for each.

CUSTOMER NEED	QUERY STORE	DMVS	AZURE LOG ANALYTICS	AZURE DATA EXPLORER
Out of the box solution	Needs enabling	✔	Addition service required	Addition service required
Longer analysis periods	30 days	Up to 10000 rows of history	Customizable	Customizable
Crucial metrics availability	Limited	✔	Limited	Customizable
Use SQL for analysis	✔	✔	KQL needed	SQL support is limited

Query Store

The Query Store feature provides insight on query plan choice and performance. It simplifies performance troubleshooting by helping you quickly find performance differences caused by query plan changes.

Query Store is not enabled by default for new Azure Synapse Analytics databases. To enable Query Store to run the following T-SQL command:

```
ALTER DATABASE <database_name>
SET QUERY_STORE = ON;
```

For example:

```
ALTER DATABASE [SQLPOOL1]
SET QUERY_STORE = ON;
```

You can run performance auditing and troubleshooting related tasks by finding last executed queries, execution counts, longest running queries, queries with maximum physical I/O leads. Please refer to Monitoring Performance By Using the Query Store for sample queries.

Advantages:

- Up to 30 days of storage for query data. Default 7 days.

- Data can be consumed in the same tool that you'd run the query in.

Known Limitation:

- Default storage of historic query data is less.
- Scenarios for analysis are limited in Query Store for Azure Synapse when compared to using DMVs.

DMVs

Dynamic Management Views (DMVs) are extremely useful when it comes to gathering information on query wait times, execution plans, memory, etc. It is highly recommended to label your query of interest to track it down later. For example:

```
-- Query with Label
SELECT *
FROM sys.tables
OPTION (LABEL = 'My Query');
```

For more information on labeling your queries in Azure Synapse SQL, see Use query labels in Synapse SQL.

For more information on using DMVs to monitor your Azure Synapse Analytics workload, see Monitor your dedicated SQL pool workload using DMVs. For documentation on catalog views specific to Azure Synapse Analytics, see Azure Synapse Analytics Catalog Views.

Advantages:

- Data can be consumed in the same querying tool.
- DMVs provide extensive options for analysis.

Known Limitations:

- DMVs are limited to 10,000 rows of historic entries.
- Views are reset when pool is paused/resumed.

Log Analytics

Log Analytics workspaces can be created easily in the Azure portal. For further instructions on how to connect Synapse with Log Analytics, see Monitor workload - Azure portal.

Like Azure Data Explorer, Log Analytics uses the Kusto Query Language (KQL). For more information about Kusto syntax, see Kusto query overview.

Along with configurable retention period, you choose the workspace you are specifically targeting to query in Log Analytics. Log Analytics gives you the flexibility to store data, run, and save queries.

Advantages:

- Azure Log Analytics has a customizable log retention policy

Known Limitations:

- Using KQL adds to the learning curve.
- Limited views can be logged out of the box.

Azure Data Explorer (ADX)

Azure Data Explorer (ADX) is a leading data exploration service. This service can be used to analyze historic queries from Azure Synapse Analytics. To setup an Azure Data Factory (ADF) pipeline to copy and store logs to

ADX, see Copy data to or from Azure Data Explorer. In ADX, you can run performant Kusto query to analyze your logs. You can combine other strategies here, for example to query and load DMV output to ADX via ADF.

Advantages:

- ADX provides a customizable log retention policy.
- Performant query execution against large amount of data, especially queries involving string search.

Known Limitation:

- Using KQL adds to the learning curve.

Analyze your workload for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Techniques for analyzing your dedicated SQL pool workload in Azure Synapse Analytics.

Resource Classes

Dedicated SQL pool provides resource classes to assign system resources to queries. For more information on resource classes, see Resource classes & workload management. Queries will wait if the resource class assigned to a query needs more resources than are currently available.

Queued query detection and other DMVs

You can use the `sys.dm_pdw_exec_requests` DMV to identify queries that are waiting in a concurrency queue. Queries waiting for a concurrency slot have a status of **suspended**.

```
SELECT  r.[request_id]                          AS Request_ID
,       r.[status]                              AS Request_Status
,       r.[submit_time]                         AS Request_SubmitTime
,       r.[start_time]                          AS Request_StartTime
,       DATEDIFF(ms,[submit_time],[start_time]) AS Request_InitiateDuration_ms
,       r.resource_class                        AS Request_resource_class
FROM    sys.dm_pdw_exec_requests r
;
```

Workload management roles can be viewed with `sys.database_principals`.

```
SELECT  ro.[name]           AS [db_role_name]
FROM    sys.database_principals ro
WHERE   ro.[type_desc]      = 'DATABASE_ROLE'
AND     ro.[is_fixed_role]  = 0
;
```

The following query shows which role each user is assigned to.

```
SELECT  r.name AS role_principal_name
,       m.name AS member_principal_name
FROM    sys.database_role_members rm
JOIN    sys.database_principals AS r            ON rm.role_principal_id      = r.principal_id
JOIN    sys.database_principals AS m            ON rm.member_principal_id    = m.principal_id
WHERE   r.name IN ('mediumrc','largerc','xlargerc')
;
```

Dedicated SQL pool has the following wait types:

- **LocalQueriesConcurrencyResourceType**: Queries that sit outside of the concurrency slot framework. DMV queries and system functions such as `SELECT @@VERSION` are examples of local queries.
- **UserConcurrencyResourceType**: Queries that sit inside the concurrency slot framework. Queries against end-user tables represent examples that would use this resource type.
- **DmsConcurrencyResourceType**: Waits resulting from data movement operations.

- **BackupConcurrencyResourceType**: This wait indicates that a database is being backed up. The maximum value for this resource type is 1. If multiple backups have been requested at the same time, the others queue. In general, we recommend a minimum time between consecutive snapshots of 10 minutes.

The `sys.dm_pdw_waits` DMV can be used to see which resources a request is waiting for.

```
SELECT  w.[wait_id]
,       w.[session_id]
,       w.[type]                                        AS Wait_type
,       w.[object_type]
,       w.[object_name]
,       w.[request_id]
,       w.[request_time]
,       w.[acquire_time]
,       w.[state]
,       w.[priority]
,       SESSION_ID()                                    AS Current_session
,       s.[status]                                      AS Session_status
,       s.[login_name]
,       s.[query_count]
,       s.[client_id]
,       s.[sql_spid]
,       r.[command]                                     AS Request_command
,       r.[label]
,       r.[status]                                      AS Request_status
,       r.[submit_time]
,       r.[start_time]
,       r.[end_compile_time]
,       r.[end_time]
,       DATEDIFF(ms,r.[submit_time],r.[start_time])     AS Request_queue_time_ms
,       DATEDIFF(ms,r.[start_time],r.[end_compile_time])  AS Request_compile_time_ms
,       DATEDIFF(ms,r.[end_compile_time],r.[end_time])   AS Request_execution_time_ms
,       r.[total_elapsed_time]
FROM    sys.dm_pdw_waits w
JOIN    sys.dm_pdw_exec_sessions s  ON w.[session_id] = s.[session_id]
JOIN    sys.dm_pdw_exec_requests r  ON w.[request_id] = r.[request_id]
WHERE    w.[session_id] <> SESSION_ID();
```

The `sys.dm_pdw_resource_waits` DMV shows the wait information for a given query. Resource wait time measures the time waiting for resources to be provided. Signal wait time is the time it takes for the underlying SQL servers to schedule the query onto the CPU.

```
SELECT  [session_id]
,       [type]
,       [object_type]
,       [object_name]
,       [request_id]
,       [request_time]
,       [acquire_time]
,       DATEDIFF(ms,[request_time],[acquire_time])  AS acquire_duration_ms
,       [concurrency_slots_used]                    AS concurrency_slots_reserved
,       [resource_class]
,       [wait_id]                                   AS queue_position
FROM    sys.dm_pdw_resource_waits
WHERE    [session_id] <> SESSION_ID();
```

You can also use the `sys.dm_pdw_resource_waits` DMV calculate how many concurrency slots have been granted.

```
SELECT  SUM([concurrency_slots_used]) as total_granted_slots
FROM    sys.[dm_pdw_resource_waits]
WHERE   [state]           = 'Granted'
AND     [resource_class] is not null
AND     [session_id]     <> session_id();
```

The `sys.dm_pdw_wait_stats` DMV can be used for historic trend analysis of waits.

```
SELECT   w.[pdw_node_id]
,        w.[wait_name]
,        w.[max_wait_time]
,        w.[request_count]
,        w.[signal_time]
,        w.[completed_count]
,        w.[wait_time]
FROM    sys.dm_pdw_wait_stats w;
```

For more information about managing database users and security, see Secure a dedicated SQL pool (formerly SQL DW). For more information about how larger resource classes can improve clustered columnstore index quality, see Rebuilding indexes to improve segment quality.

Configure workload importance in dedicated SQL pool for Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Setting importance in dedicated SQL pool for Azure Synapse allows you to influence the scheduling of queries. Queries with higher importance will be scheduled to run before queries with lower importance. To assign importance to queries, you need to create a workload classifier.

Create a Workload Classifier with Importance

Often in a data warehouse scenario you have users, on a busy system, who need to run their queries quickly. The user could be executives of the company who need to run reports or the user could be an analyst running an adhoc query. To assign importance, you create a workload classifier and importance is assigned to a query. The examples below use the create workload classifier syntax to create two classifiers. `Membername` can be a single user or a group. To find existing dedicated SQL pool users, run:

```
Select name from sys.sysusers
```

To create a workload classifier, for a user with higher importance run:

```
CREATE WORKLOAD CLASSIFIER ExecReportsClassifier
    WITH (WORKLOAD_GROUP = 'xlargerc'
         ,MEMBERNAME     = 'name'
         ,IMPORTANCE     = above_normal);
```

To create a workload classifier for a user running adhoc queries with lower importance run:

```
CREATE WORKLOAD CLASSIFIER AdhocClassifier
    WITH (WORKLOAD_GROUP = 'xlargerc'
         ,MEMBERNAME     = 'name'
         ,IMPORTANCE     = below_normal);
```

Next Steps

- For more information about workload management, see Workload Classification
- For more information on Importance, see Workload Importance

Go to Manage and monitor Workload Importance

Manage and monitor workload importance in dedicated SQL pool for Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Manage and monitor dedicated SQL pool request level importance in Azure Synapse using DMVs and catalog views.

Monitor importance

Monitor importance using the new importance column in the sys.dm_pdw_exec_requests dynamic management view. The below monitoring query shows submit time and start time for queries. Review the submit time and start time along with importance to see how importance influenced scheduling.

```
SELECT s.login_name, r.status, r.importance, r.submit_time, r.start_time
  FROM sys.dm_pdw_exec_sessions s
  JOIN sys.dm_pdw_exec_requests r ON s.session_id = r.session_id
  WHERE r.resource_class is not null
ORDER BY r.start_time
```

To look further into how queries are being schedule, use the catalog views.

Manage importance with catalog views

The sys.workload_management_workload_classifiers catalog view contains information on classifiers. To exclude the system-defined classifiers that map to resource classes execute the following code:

```
SELECT *
  FROM sys.workload_management_workload_classifiers
  WHERE classifier_id > 12
```

The catalog view, sys.workload_management_workload_classifier_details, contains information on the parameters used in creation of the classifier. The below query shows that ExecReportsClassifier was created on the `membername` parameter for values with ExecutiveReports:

```
SELECT c.name,cd.classifier_type, classifier_value
  FROM sys.workload_management_workload_classifiers c
  JOIN sys.workload_management_workload_classifier_details cd
    ON cd.classifier_id = c.classifier_id
  WHERE c.name = 'ExecReportsClassifier'
```

Results | Messages

	name	classifier_type	classifier_value
1	ExecReportsClassifier	membername	ExecutiveReports

To simplify troubleshooting misclassification, we recommended you remove resource class role mappings as you create workload classifiers. The code below returns existing resource class role memberships. Run sp_droprolemember for each `membername` returned from the corresponding resource class. Below is an example of checking for existence before dropping a workload classifier:

```
IF EXISTS (SELECT 1 FROM sys.workload_management_workload_classifiers WHERE name = 'ExecReportsClassifier')
  DROP WORKLOAD CLASSIFIER ExecReportsClassifier;
GO
```

Next steps

- For more information on Classification, see Workload Classification.
- For more information on Importance, see Workload Importance

Go to Configure Workload Importance

Convert Resource Classes to Workload Groups

8/19/2022 • 2 minutes to read • Edit Online

Workload groups provide a mechanism to isolate and contain system resources. Additionally, workload groups allow you to set execution rules for the requests running in them. A query timeout execution rule allows runaway queries to be canceled without user intervention. This article explains how to take an existing resource class and create a workload group with a similar configuration. In addition, an optional query timeout rule is added.

> **NOTE**
>
> See the Mixing resource class assignments with classifiers section in the Workload Classification concept document for guidance on using workload groups and resource classes at the same time.

Understanding the existing resource class configuration

Workload groups require a parameter called `REQUEST_MIN_RESOURCE_GRANT_PERCENT` that specifies the percentage of overall system resources allocated per request. Resource allocation is done for resource classes by allocating concurrency slots. To determine the value to specify for `REQUEST_MIN_RESOURCE_GRANT_PERCENT`, use the sys.dm_workload_management_workload_groups_stats DMV. For example, the below query query returns a value that can be used for the `REQUEST_MIN_RESOURCE_GRANT_PERCENT` parameter to create a workload group similar to staticrc40.

```
SELECT Request_min_resource_grant_percent = Effective_request_min_resource_grant_percent
  FROM sys.dm_workload_management_workload_groups_stats
  WHERE name = 'staticrc40'
```

> **NOTE**
>
> Workload groups operate based on percentage of overall system resources.

Because workload groups operate based on percentage of overall system resources, as you scale up and down, the percentage of resources allocated to static resource classes relative to the overall system resources changes. For example, staticrc40 at DW1000c allocates 19.2% of the overall system resources. At DW2000c, 9.6% are allocated. This model is similar if you wish to scale up for concurrency versus allocating more resources per request.

Create Workload Group

With the known `REQUEST_MIN_RESOURCE_GRANT_PERCENT`, you can use the CREATE WORKLOAD GROUP syntax to create the workload group. You can optionally specify a `MIN_PERCENTAGE_RESOURCE` that is greater than zero to isolate resources for the workload group. Also, you can optionally specify `CAP_PERCENTAGE_RESOURCE` less than 100 to limit the amount of resources the workload group can consume.

Using mediumrc as a basis for an example, the below code sets the `MIN_PERCENTAGE_RESOURCE` to dedicate 10% of the system resources to `wgDataLoads` and guarantees one query will be able to run all the times. Additionally, `CAP_PERCENTAGE_RESOURCE` is set to 40% and limits this workload group to four concurrent requests. By setting the `QUERY_EXECUTION_TIMEOUT_SEC` parameter to 3600, any query that runs for more than 1 hour will be automatically

canceled.

```
CREATE WORKLOAD GROUP wgDataLoads WITH
( REQUEST_MIN_RESOURCE_GRANT_PERCENT = 10
 ,MIN_PERCENTAGE_RESOURCE = 10
 ,CAP_PERCENTAGE_RESOURCE = 40
 ,QUERY_EXECUTION_TIMEOUT_SEC = 3600)
```

Create the Classifier

Previously, the mapping of queries to resource classes was done with sp_addrolemember. To achieve the same functionality and map requests to workload groups, use the CREATE WORKLOAD CLASSIFIER syntax. Using sp_addrolemember only allowed you to map resources to a request based on a login. A classifier provides additional options besides login, such as: - label - session - time The below example assigns queries from the `AdfLogin` login that also have the OPTION LABEL set to `factloads` to the workload group `wgDataLoads` created above.

```
CREATE WORKLOAD CLASSIFIER wcDataLoads WITH
( WORKLOAD_GROUP = 'wgDataLoads'
 ,MEMBERNAME = 'AdfLogin'
 ,WLM_LABEL = 'factloads')
```

Test with a sample query

Below is a sample query and a DMV query to ensure the workload group and classifier are configured correctly.

```
SELECT SUSER_SNAME() --should be 'AdfLogin'

--change to a valid table AdfLogin has access to
SELECT TOP 10 *
  FROM nation
  OPTION (label='factloads')

SELECT request_id, [label], classifier_name, group_name, command
  FROM sys.dm_pdw_exec_requests
  WHERE [label] = 'factloads'
  ORDER BY submit_time DESC
```

Troubleshooting a misclassified workload in Azure Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

This article covers guidance on how to troubleshoot a misclassified workload, and how to identify the reason behind the classification, for workloads in a dedicated SQL pool.

Azure Synapse Analytics provides workload management capabilities like classifying workloads to appropriate workload groups, assigning importance, and isolating resources to meet SLAs.

However, in some scenarios, a combination of these capabilities can lead to workload classification that doesn't reflect user intent. This article lists such common scenarios and how to troubleshoot them. First, you should query basic information for troubleshooting misclassified workload scenarios.

> **NOTE**
> Classifying managed identities (MI) behavior differs between the dedicated SQL pool in Azure Synapse workspaces and the standalone dedicated SQL pool (formerly SQL DW). While the standalone dedicated SQL pool MI maintains the assigned identity, for Azure Synapse workspaces the MI runs as **dbo**. This cannot be changed. The dbo role, by default, is classified to smallrc. Creating a classifier for the dbo role allows for assigning requests to a workload group other than smallrc. If dbo alone is too generic for classification and has broader impacts, consider using label, session or time-based classification in conjunction with the dbo role classification.

Basic troubleshooting information

To troubleshoot a misclassified workload scenario the following information is needed:

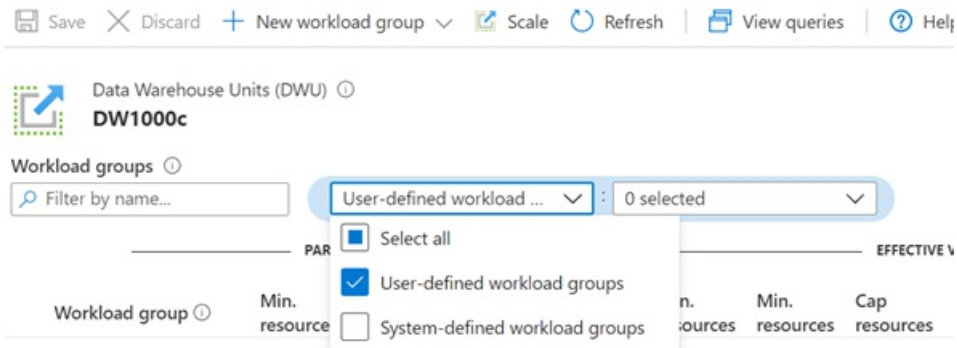
- List of all workload groups
- List of all workload classifiers and associated workload groups
- List of users and mapped workload groups (system and user defined)
- List of workload group and classifier details of a request

Workload groups

Azure portal

To get a list of all workload groups (including system workload groups) and associated details in the Azure portal:

1. Go to the Azure Synapse workspace under which the dedicated SQL Pool of interest has been created.
2. On the left side pane, all pool types created under the workspace are listed. Select **SQL Pools** under **Analytical Pools** section.
3. Select the dedicated SQL pool of interest.
4. In the left side pane, select **Workload management** under **Settings**.
5. Under **Workload groups** section, all workloads are listed. By default only **User-Defined Workload groups** are listed. To view a list of both user-defined and system-defined workload groups, edit the filter and **Select All**.



T-SQL

To view workload groups using T-SQL, connect to the dedicated SQL Pool using SQL Server Management Studio (SSMS) and issue following query:

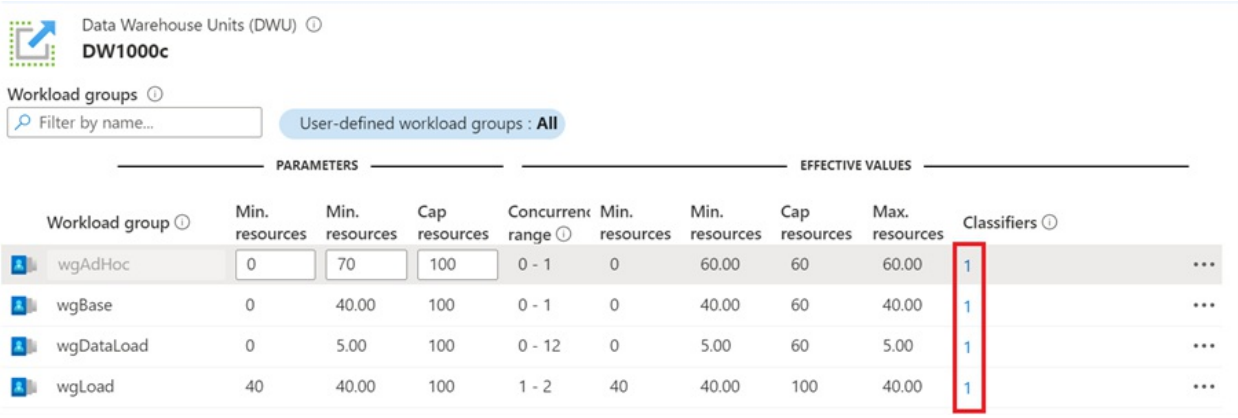
```
SELECT * FROM sys.workload_management_workload_groups;
```

For more information, see sys.workload_management_workload_groups.

Workload classifiers

Azure portal

To list all workload classifiers (including system-defined classifiers) by workload group in the Azure portal, see the numbers listed in **Classifiers** column in Workload group table (see previous section).



T-SQL

To get the list of all workload classifiers (including system-defined classifiers) using T-SQL, use following query:

```
SELECT * FROM sys.workload_management_workload_classifiers;
```

For more information, see sys.workload_management_workload_classifiers.

Users and mapped resource classes

To get a list of system defined resource classes and mapped users in T-SQL, use following query:

```
SELECT  r.name AS [Resource Class]
,       m.name AS [Member Name]
FROM    sys.database_role_members AS rm
JOIN    sys.database_principals AS r ON rm.role_principal_id = r.principal_id
JOIN    sys.database_principals AS m ON rm.member_principal_id = m.principal_id
WHERE   r.name IN
('mediumrc','largerc','xlargerc','staticrc10','staticrc20','staticrc30','staticrc40','staticrc50','staticrc6
0','staticrc70','staticrc80');
```

Workload group and classifier details of a request

The first step in troubleshooting a misclassified workload problem is to identify the workload group and workload classifier for a query. Use the dynamic management view sys.dm_pdw_exec_requests to view submitted queries and their classification:

```
SELECT * FROM sys.dm_pdw_exec_requests;
```

For more information, see sys.dm_pdw_exec_requests.

Common scenarios of misclassified workloads

Here are some common scenarios where unintended misclassified workloads can occur:

Mixed usage of resource classes and user-defined workload management

In scenarios where resource classes and workload groups are used together, user role to resource class mappings can conflict with workload classifier rules, and lead to unintended query classification.

Consider following scenario:

1. A database user, DBAUser, is assigned to largerc resource class role using `sp_addrolemember` procedure.
2. DBAUser has created a new workload group and classifier using workload management.
3. A newly-created workload classifier maps database role DBARole to mediumrc resource class with high importance.
4. DBAUser is a made a member of the DBARole database role.
5. When DBAUser runs a query, the query is expected to run on mediumrc based on workload classifier. Instead it will be assigned to largerc, as **user** mapping takes precedence over **role membership** mapping to a classifier.

It's best to avoid mixing usage of resource classes and workload management groups to do workload management. For more information on steps to convert resource classes to workloads, see Convert Resource Classes to Workload Groups.

However, there can be situations where both resource classes and workload management need to be used together. In such scenarios, to simplify troubleshooting misclassification, we recommend you remove resource class role mappings as you create workload classifiers. The code below returns existing resource class role memberships. Run sp_droprolemember for each member name returned from the corresponding resource class.

```
SELECT  r.name AS [Resource Class]
, m.name AS membername
FROM    sys.database_role_members AS rm
JOIN    sys.database_principals AS r ON rm.role_principal_id = r.principal_id
JOIN    sys.database_principals AS m ON rm.member_principal_id = m.principal_id
WHERE   r.name IN
('mediumrc','largerc','xlargerc','staticrc10','staticrc20','staticrc30','staticrc40','staticrc50','staticrc6
0','staticrc70','staticrc80');

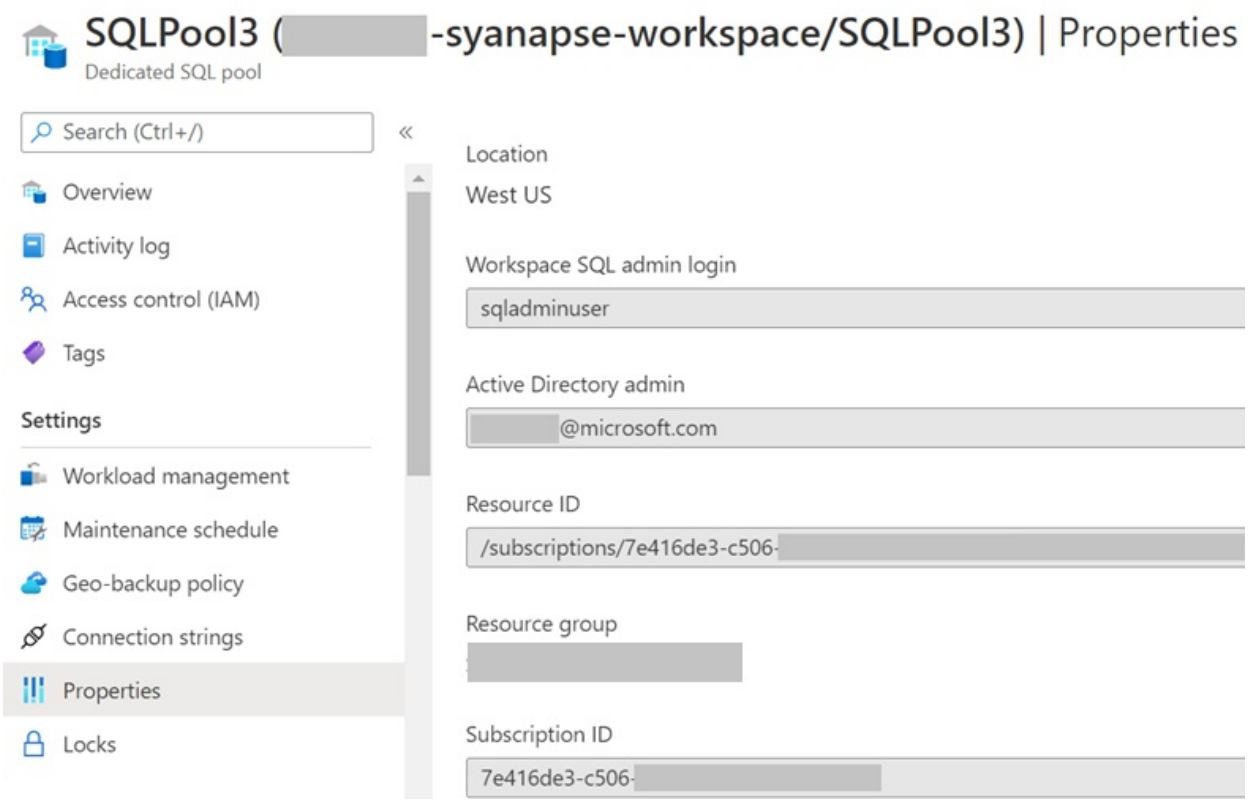
--for each row returned run
EXEC sp_droprolemember '[Resource Class]', membername;
```

Some administrative users are always mapped to smallrc workload group

Consider a scenario for the Azure Synapse Workspace SQL Admin login, the Azure Synapse Azure Active Directory admin (user or group member), or a database owner. These users may still have a workload classifier or have been added to a resource class role other than smallrc. All queries executed by these user will still run on smallrc resource class, even though the user is mapped to a different resource class or workload group.

Recommendation: These administrative users can't change their default workload group. For more information, see workload management with resource classes. It is recommended that critical or performance-sensitive workloads not run as one of these administrative users in the dedicated SQL pool.

The Azure Synapse Workspace SQL Admin login and the Azure Synapse Azure Active Directory admin (user or group member) are specified in the Azure portal:



Similarly, the database owner (dbo) and **db_owner** database roles are not allowed to change their default resource class. If a user is either the database owner or added under **db_owner** database role, all queries executed by the user go to smallrc by default. These roles can't be added to a resource class other than smallrc. However, if a user who is part of this role would like to classify their queries to a different workload group, they can use MEMBERNAME option in workload classifier definition.

Use workload group precedence for better classification

In scenarios where workload classifiers are mapped to multiple workload groups, or a user is mapped to multiple resource classes, precedence order determines chosen workload group and Resource class. List of precedence rules:

> **NOTE**
> As mentioned in Mixing Resource Classes and user-defined Workload Management section, it isn't recommended to combine usage of Resource classes and user-defined workload groups/classes.

If resource classes are being used:

In scenarios where resource classes are being used it's best to create a dedicated user for each type of workload being run. However, if a user is a member of multiple resource classes, then precedence rules documented in Resource Class Precedence take effect:

1. Dynamic resource class takes precedence over static resource class. For example, if a user is member of mediumrc (dynamic) and staticrc80(static), user queries run with mediumrc.
2. Bigger resource classes are preferred over smaller resource classes. For example, if a user is member of staticrc20 and staticrc80, then user queries will run with staticrc80.

If Workload Management Capabilities are used

WLM provides capability to create multiple workload classifiers for same user or workload group. Classifier definition statement has multiple parameters based on which incoming requests are assigned to workloads. These parameters have a **weight** score as shown below and this score determines order of precedence:

CLASSIFIER PARAMETER	WEIGHT
MEMBERNAME:USER	64
MEMBERNAME:ROLE	32
WLM_LABEL	16
WLM_CONTEXT	8
START_TIME/END_TIME	4

Let us see these precedence rules in action using an example. If a user creates two workload classifiers as follows:

```
CREATE WORKLOAD CLASSIFIER CLASSIFIER-1 WITH
( WORKLOAD_GROUP = 'wgDataLoad'
 ,MEMBERNAME     = 'USER-1'
 ,WLM_LABEL      = 'dimension_loads'
 ,IMPORTANCE     = 'High');

CREATE WORKLOAD CLASSIFIER CLASSIFIER-2 WITH
( WORKLOAD_GROUP = 'wgUserqueries'
 ,MEMBERNAME     = 'USER-1'
 ,START_TIME     = '18:00'
 ,END_TIME       = '07:30'
 ,IMPORTANCE     = 'Low')
```

Queries submitted by User-1 can be submitted via both classifiers. Query run by User-1 with the 'dimension_loads' label between 6PM and 7AM UTC will be assigned to `wgDashboards` as weight score of WLM_LABEL is higher than START_TIME/END_TIME. The weighting of `CLASSIFIER-1` is 80 (64 for user, plus 16 for WLM_LABEL). The weighting of `CLASSIFIER-2` is 68 (64 for user, 4 for START_TIME/END_TIME).

For more information on workload classification, see classification weighting and query labels.

What happens if precedence in workload classification leads to a tie?

Even after workload classifier precedence is applied, it is possible for a query to be classified to multiple workload groups. For example, consider following classifiers:

```
CREATE WORKLOAD CLASSIFIER CLASSIFIER-1 WITH
( WORKLOAD_GROUP = 'wgDataLoad'
 ,MEMBERNAME     = 'USER-1'
 ,WLM_LABEL      = 'dimension_loads'
 ,IMPORTANCE     = 'High');

CREATE WORKLOAD CLASSIFIER CLASSIFIER-2 WITH
( WORKLOAD_GROUP = 'wgUserqueries'
 ,MEMBERNAME     = 'USER-1'
 ,WLM_LABEL      = 'dimension_loads'
 ,IMPORTANCE     = 'Low');
```

If a user runs a query with `OPTION (LABEL = 'dimension_loads')`, it can be classified to either `wgDataLoad` or

`wgUserqueries` based on precedence rules. But which workload group is chosen?

Workload group and classifier tie-breakers

If there was a tie in workload groups or classifiers, following precedence takes effect:

1. The workload group with the highest resource allocation is chosen. This behavior optimizes for performance in scenarios where logins are members of multiple resource classes. This behavior also ensures backward compatibility.

Consider the following two workload groups and workload classifiers:

```
-- Workload Groups
CREATE WORKLOAD GROUP wgDataLoad
WITH
( MIN_PERCENTAGE_RESOURCE = 26
,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 2
,CAP_PERCENTAGE_RESOURCE = 100 )

CREATE WORKLOAD GROUP wgUserqueries
WITH
( MIN_PERCENTAGE_RESOURCE = 15
,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 5
,CAP_PERCENTAGE_RESOURCE = 50 );

--Workload Classifiers
CREATE WORKLOAD CLASSIFIER CLASSIFIER-1 WITH
( WORKLOAD_GROUP = 'wgDataLoad'
,MEMBERNAME     = 'USER-1'
,WLM_LABEL      = 'dimension_loads'
,IMPORTANCE     = 'High');

CREATE WORKLOAD CLASSIFIER CLASSIFIER-2 WITH
( WORKLOAD_GROUP = 'wgUserqueries'
,MEMBERNAME     = 'USER-1'
,WLM_LABEL      = 'dimension_loads'
,IMPORTANCE     = 'High');
```

If a user runs a query with `OPTION (LABEL = 'dimension_loads')`, the query meets criteria for both the classifiers. However, the user request will be routed to `wgUserQueries` workload group as it has higher minimum resource allocation per request.

2. Next, concurrency setting and available concurrency for respective workload groups is considered for tie-breakers. The workload group with the highest available concurrency at a time when request arrived will give the query best chance of executing.

Consider following two workload groups and workload classifiers:

```
--Workload Groups
CREATE WORKLOAD GROUP wgDataLoad
WITH
( MIN_PERCENTAGE_RESOURCE = 30
 ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 2 (concurrency of 15)
 ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 2
 ,CAP_PERCENTAGE_RESOURCE = 100 );

CREATE WORKLOAD GROUP wgUserqueries
WITH
( MIN_PERCENTAGE_RESOURCE = 30
 ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 2 (concurrency of 15)
 ,REQUEST_MIN_RESOURCE_GRANT_PERCENT = 2
 ,CAP_PERCENTAGE_RESOURCE = 100 );

-- Workload Classifiers
CREATE WORKLOAD CLASSIFIER CLASSIFIER-1 WITH
( WORKLOAD_GROUP = 'wgDataLoad'
 ,MEMBERNAME     = 'USER-1'
 ,WLM_LABEL      = 'dimension_loads'
 ,IMPORTANCE     = 'High');

CREATE WORKLOAD CLASSIFIER CLASSIFIER-2 WITH
( WORKLOAD_GROUP = 'wgUserqueries'
 ,MEMBERNAME     = 'USER-1'
 ,WLM_LABEL      = 'dimension_loads'
 ,IMPORTANCE     = 'High');
```

If a user runs a query with `OPTION (LABEL = 'dimension_loads')`, both the classifiers have a tie as the query meets criteria for both. When user submits the query, consider the scenario where five concurrent queries are getting executed in the `wgUserqueries` group and ten queries are getting executed in the `wgDataLoad` group. The user request will be routed to `wgUserqueries` group using `CLASSIFIER-2`, as the `wgUserqueries` workload group has higher available concurrency at the time the user submitted a query.

3. Next, the importance setting of the request is considered for tie-breakers. If there was a tie in workload classification using precedence rules, the request will be routed to workload group that has highest importance. For more information, see workload importance.

4. Finally, the creation time of the workload group is considered for tie-breakers. The user request will be routed to the workload group that was created most recently.

Go to Configure Workload Importance

Load data from Azure Data Lake Storage into dedicated SQL pools in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

This guide outlines how to use the COPY statement to load data from Azure Data Lake Storage. For quick examples on using the COPY statement across all authentication methods, visit the following documentation: Securely load data using dedicated SQL pools.

> **NOTE**
>
> To provide feedback or report issues on the COPY statement, send an email to the following distribution list: sqldwcopypreview@service.microsoft.com.

- Create the target table to load data from Azure Data Lake Storage.
- Create the COPY statement to load data into the data warehouse.

If you don't have an Azure subscription, create a free account before you begin.

Before you begin

Before you begin this tutorial, download and install the newest version of SQL Server Management Studio (SSMS).

To run this tutorial, you need:

- A dedicated SQL pool. See Create a dedicated SQL pool and query data.
- A Data Lake Storage account. See Get started with Azure Data Lake Storage. For this storage account, you will need to configure or specify one of the following credentials to load: A storage account key, shared access signature (SAS) key, an Azure Directory Application user, or an AAD user which has the appropriate Azure role to the storage account.

Create the target table

Connect to your dedicated SQL pool and create the target table you will to load to. In this example, we are creating a product dimension table.

```
-- A: Create the target table
-- DimProduct
CREATE TABLE [dbo].[DimProduct]
(
    [ProductKey] [int] NOT NULL,
    [ProductLabel] [nvarchar](255) NULL,
    [ProductName] [nvarchar](500) NULL
)
WITH
(
    DISTRIBUTION = HASH([ProductKey]),
    CLUSTERED COLUMNSTORE INDEX
    --HEAP
);
```

Create the COPY statement

Connect to your SQL dedicated pool and run the COPY statement. For a complete list of examples, visit the following documentation: Securely load data using dedicated SQL pools.

```
-- B: Create and execute the COPY statement

COPY INTO [dbo].[DimProduct]
--The column list allows you map, omit, or reorder input file columns to target table columns.
--You can also specify the default value when there is a NULL value in the file.
--When the column list is not specified, columns will be mapped based on source and target ordinality
(
 ProductKey default -1 1,
 ProductLabel default 'myStringDefaultWhenNull' 2,
 ProductName default 'myStringDefaultWhenNull' 3
)
--The storage account location where you data is staged
FROM 'https://storageaccount.blob.core.windows.net/container/directory/'
WITH
(
   --CREDENTIAL: Specifies the authentication method and credential access your storage account
   CREDENTIAL = (IDENTITY = '', SECRET = ''),
   --FILE_TYPE: Specifies the file type in your storage account location
   FILE_TYPE = 'CSV',
   --FIELD_TERMINATOR: Marks the end of each field (column) in a delimited text (CSV) file
   FIELDTERMINATOR = '|',
   --ROWTERMINATOR: Marks the end of a record in the file
   ROWTERMINATOR = '0x0A',
   --FIELDQUOTE: Specifies the delimiter for data of type string in a delimited text (CSV) file
   FIELDQUOTE = '',
   ENCODING = 'UTF8',
   DATEFORMAT = 'ymd',
   --MAXERRORS: Maximum number of reject rows allowed in the load before the COPY operation is canceled
   MAXERRORS = 10,
   --ERRORFILE: Specifies the directory where the rejected rows and the corresponding error reason should be
written
   ERRORFILE = '/errorsfolder',
) OPTION (LABEL = 'COPY: ADLS tutorial');
```

Optimize columnstore compression

By default, tables are defined as a clustered columnstore index. After a load completes, some of the data rows might not be compressed into the columnstore. There's a variety of reasons why this can happen. To learn more, see manage columnstore indexes.

To optimize query performance and columnstore compression after a load, rebuild the table to force the columnstore index to compress all the rows.

```
ALTER INDEX ALL ON [dbo].[DimProduct] REBUILD;
```

Optimize statistics

It is best to create single-column statistics immediately after a load. There are some choices for statistics. For example, if you create single-column statistics on every column it might take a long time to rebuild all the statistics. If you know certain columns are not going to be in query predicates, you can skip creating statistics on those columns.

If you decide to create single-column statistics on every column of every table, you can use the stored

procedure code sample `prc_sqldw_create_stats` in the statistics article.

The following example is a good starting point for creating statistics. It creates single-column statistics on each column in the dimension table, and on each joining column in the fact tables. You can always add single or multi-column statistics to other fact table columns later on.

Achievement unlocked!

You have successfully loaded data into your data warehouse. Great job!

Next steps

Loading data is the first step to developing a data warehouse solution using Azure Synapse Analytics. Check out our development resources.

Load data into Azure Synapse Analytics using Azure Data Factory or a Synapse pipeline

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Azure Synapse Analytics is a cloud-based, scale-out database that's capable of processing massive volumes of data, both relational and non-relational. Azure Synapse Analytics is built on the massively parallel processing (MPP) architecture that's optimized for enterprise data warehouse workloads. It offers cloud elasticity with the flexibility to scale storage and compute independently.

Getting started with Azure Synapse Analytics is now easier than ever. Azure Data Factory and its equivalent pipelines feature within Azure Synapse itself provide a fully managed cloud-based data integration service. You can use the service to populate an Azure Synapse Analytics with data from your existing system and save time when building your analytics solutions.

Azure Data Factory and Synapse pipelines offer the following benefits for loading data into Azure Synapse Analytics:

- **Easy to set up**: An intuitive 5-step wizard with no scripting required.
- **Rich data store support**: Built-in support for a rich set of on-premises and cloud-based data stores. For a detailed list, see the table of Supported data stores.
- **Secure and compliant**: Data is transferred over HTTPS or ExpressRoute. The global service presence ensures that your data never leaves the geographical boundary.
- **Unparalleled performance by using PolyBase**: Polybase is the most efficient way to move data into Azure Synapse Analytics. Use the staging blob feature to achieve high load speeds from all types of data stores, including Azure Blob storage and Data Lake Store. (Polybase supports Azure Blob storage and Azure Data Lake Store by default.) For details, see Copy activity performance.

This article shows you how to use the Copy Data tool to *load data from Azure SQL Database into Azure Synapse Analytics*. You can follow similar steps to copy data from other types of data stores.

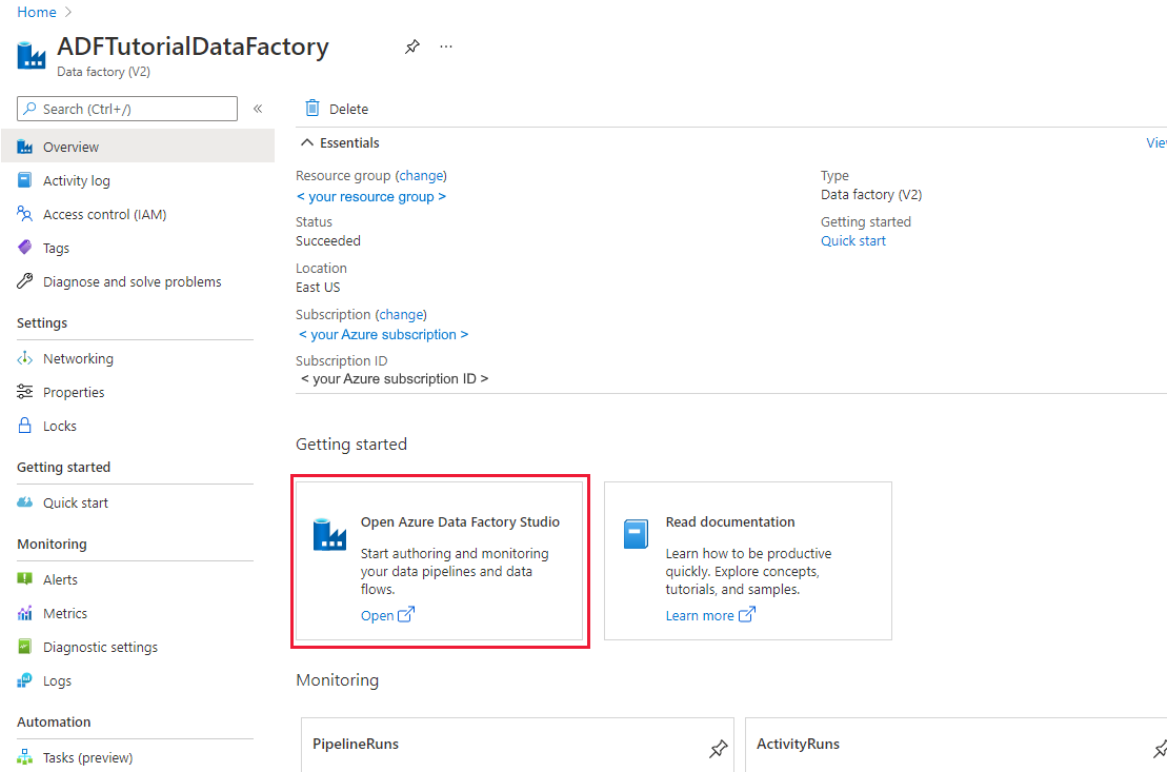
> **NOTE**
> For more information, see Copy data to or from Azure Synapse Analytics.

Prerequisites

- Azure subscription: If you don't have an Azure subscription, create a free account before you begin.
- Azure Synapse Analytics: The data warehouse holds the data that's copied over from the SQL database. If you don't have an Azure Synapse Analytics, see the instructions in Create an Azure Synapse Analytics.
- Azure SQL Database: This tutorial copies data from the Adventure Works LT sample dataset in Azure SQL Database. You can create this sample database in SQL Database by following the instructions in Create a sample database in Azure SQL Database.
- Azure storage account: Azure Storage is used as the *staging* blob in the bulk copy operation. If you don't have an Azure storage account, see the instructions in Create a storage account.

Create a data factory

1. If you have not created your data factory yet, follow the steps in Quickstart: Create a data factory by using the Azure portal and Azure Data Factory Studio to create one. After creating it, browse to the data factory in the Azure portal.

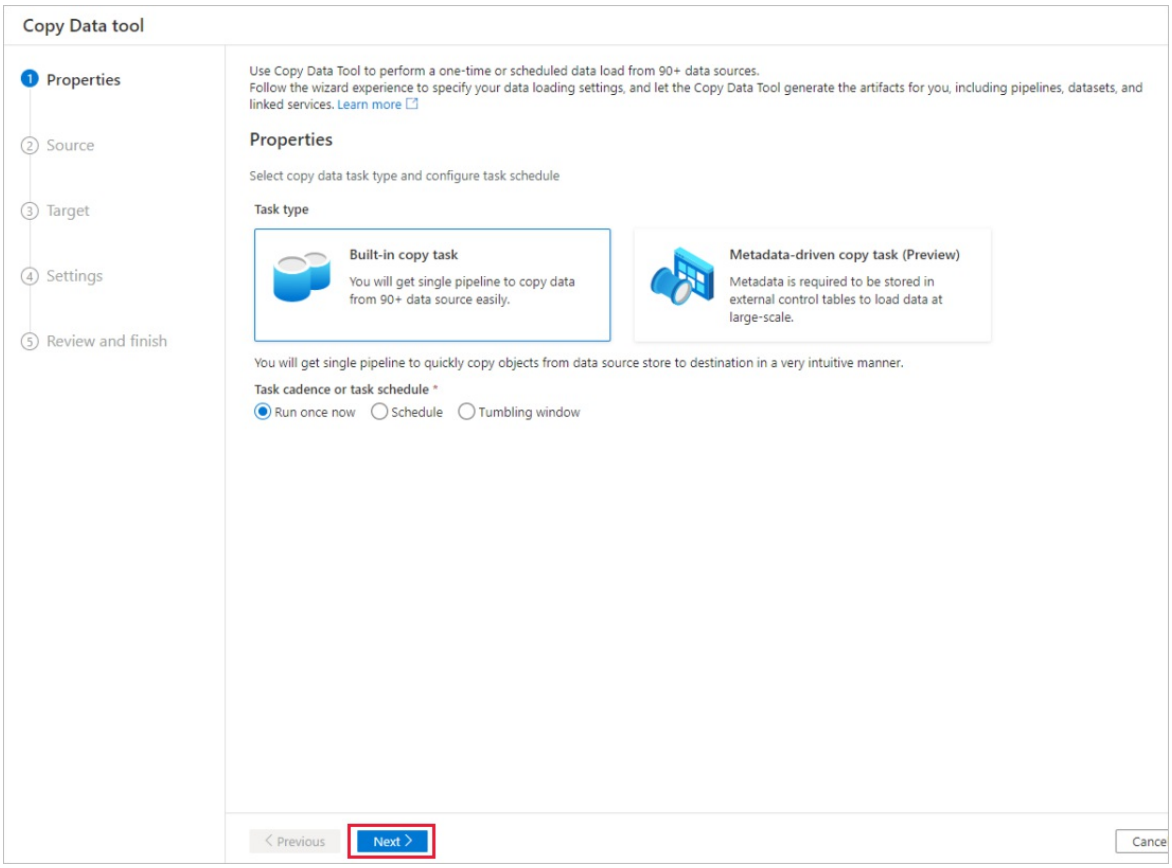


2. Select **Open** on the **Open Azure Data Factory Studio** tile to launch the Data Integration application in a separate tab.

Load data into Azure Synapse Analytics

1. In the home page of Azure Data Factory or Azure Synapse workspace, select the **Ingest** tile to launch the Copy Data tool. Then choose the **Built-in copy task**.

2. In the **Properties** page, choose **Built-in copy task** under **Task type**, then select **Next**.

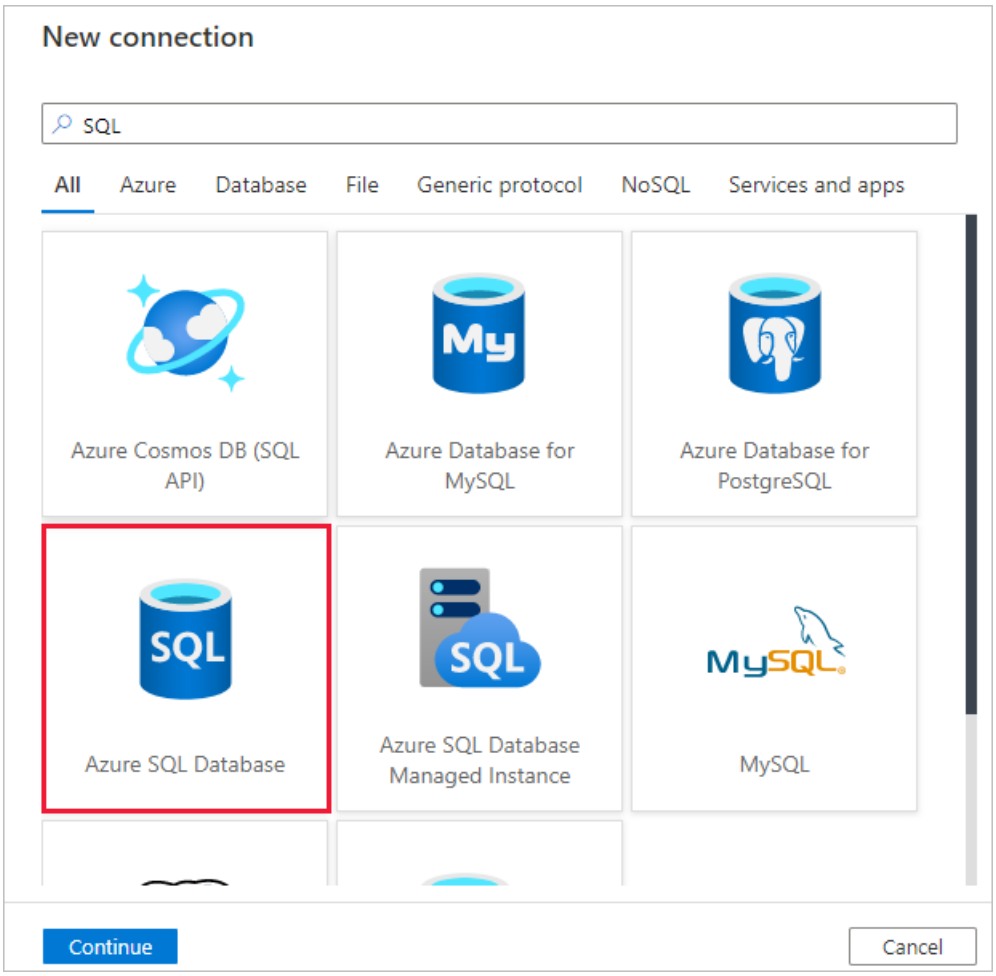


3. In the **Source data store** page, complete the following steps:

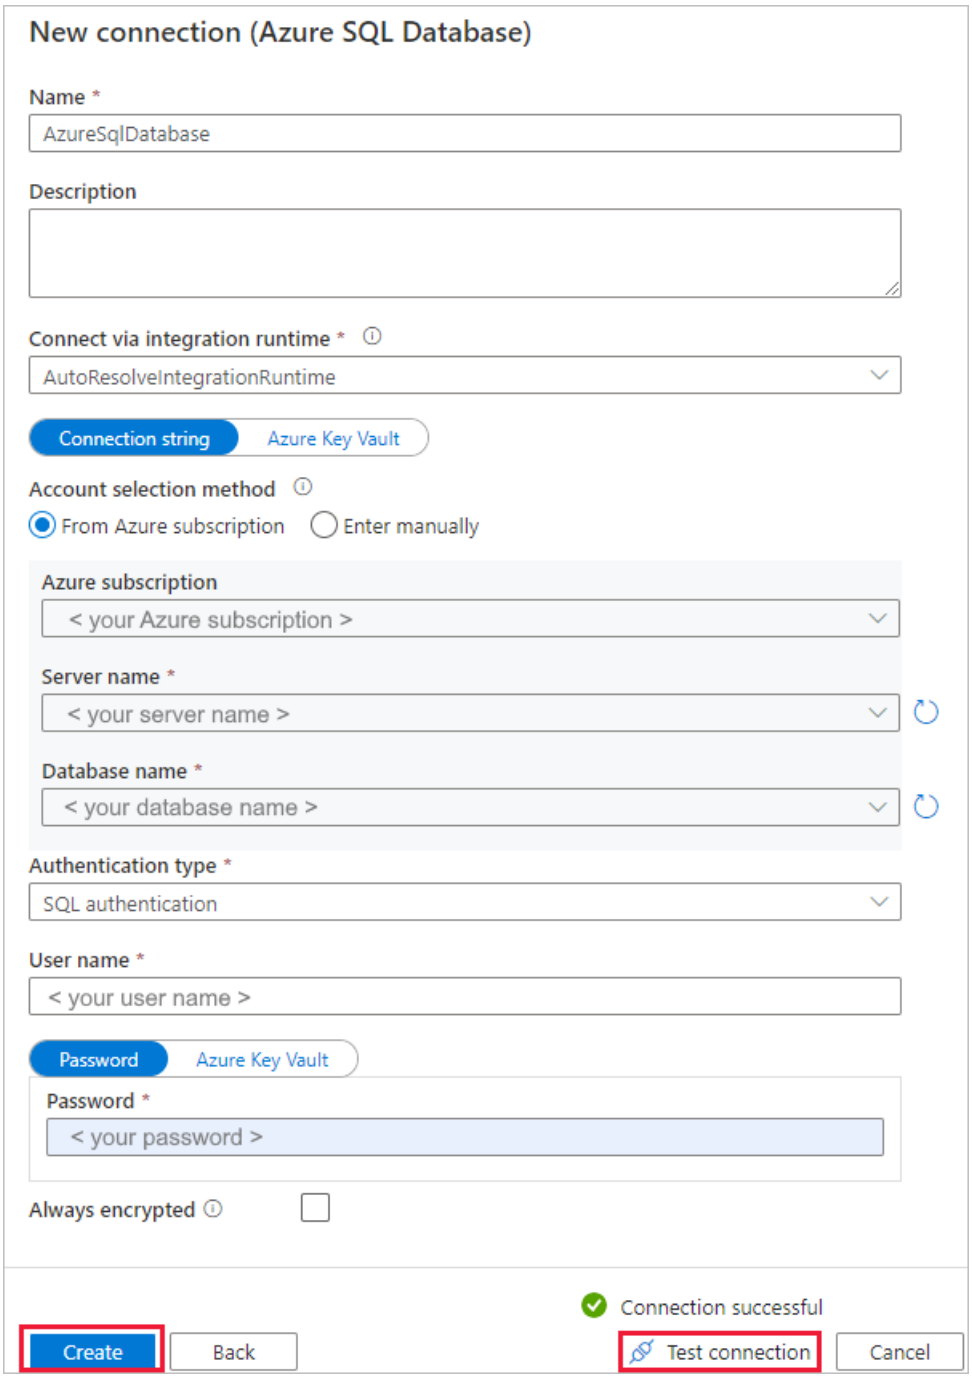
> **TIP**
>
> In this tutorial, you use *SQL authentication* as the authentication type for your source data store, but you can choose other supported authentication methods:*Service Principal* and *Managed Identity* if needed. Refer to corresponding sections in this article for details. To store secrets for data stores securely, it's also recommended to use an Azure Key Vault. Refer to this article for detailed illustrations.

a. Select **+ New connection**.

b. Select **Azure SQL Database** from the gallery, and select **Continue**. You can type "SQL" in the search box to filter the connectors.

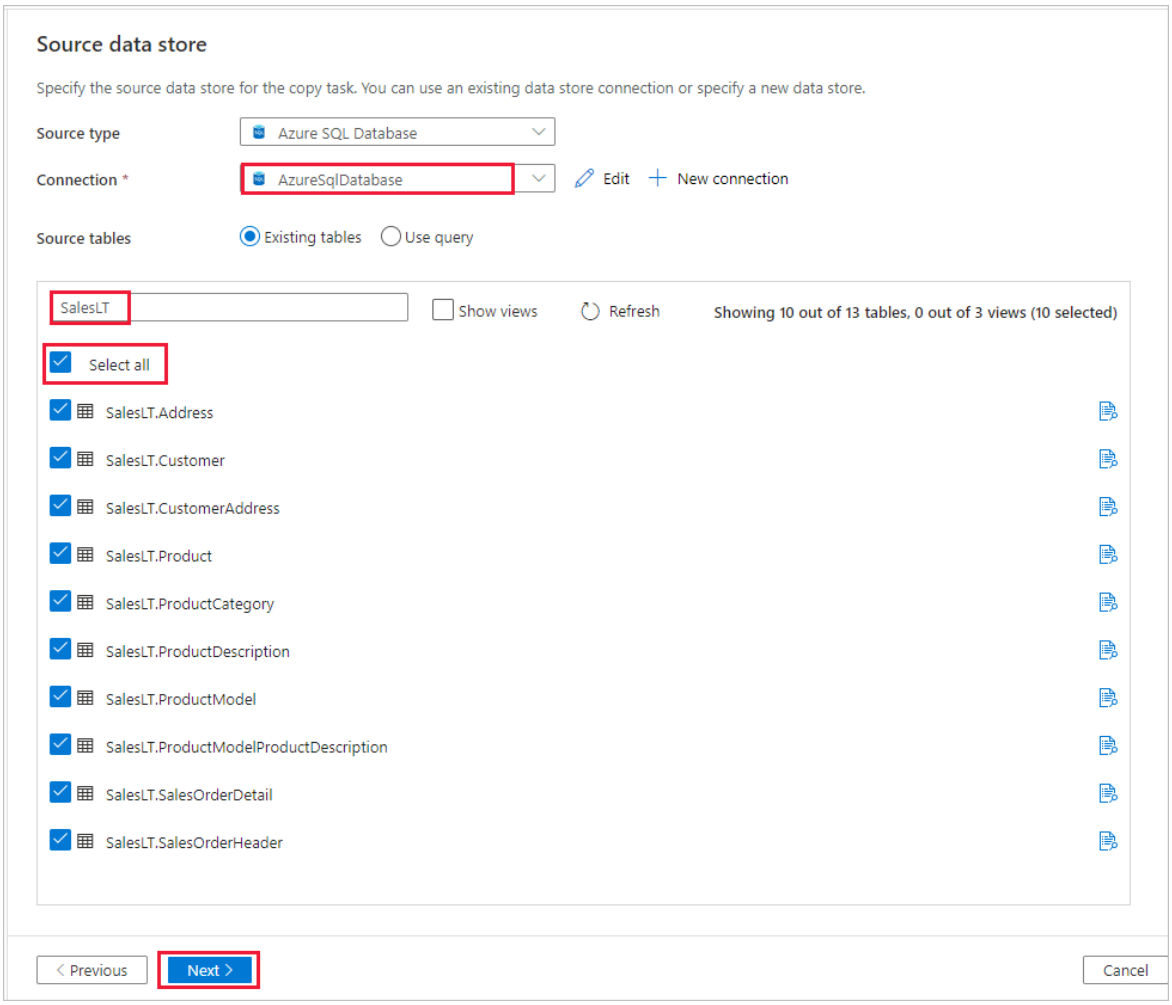


c. In the **New connection (Azure SQL Database)** page, select your server name and DB name from the dropdown list, and specify the username and password. Select **Test connection** to validate the settings, then select **Create**.

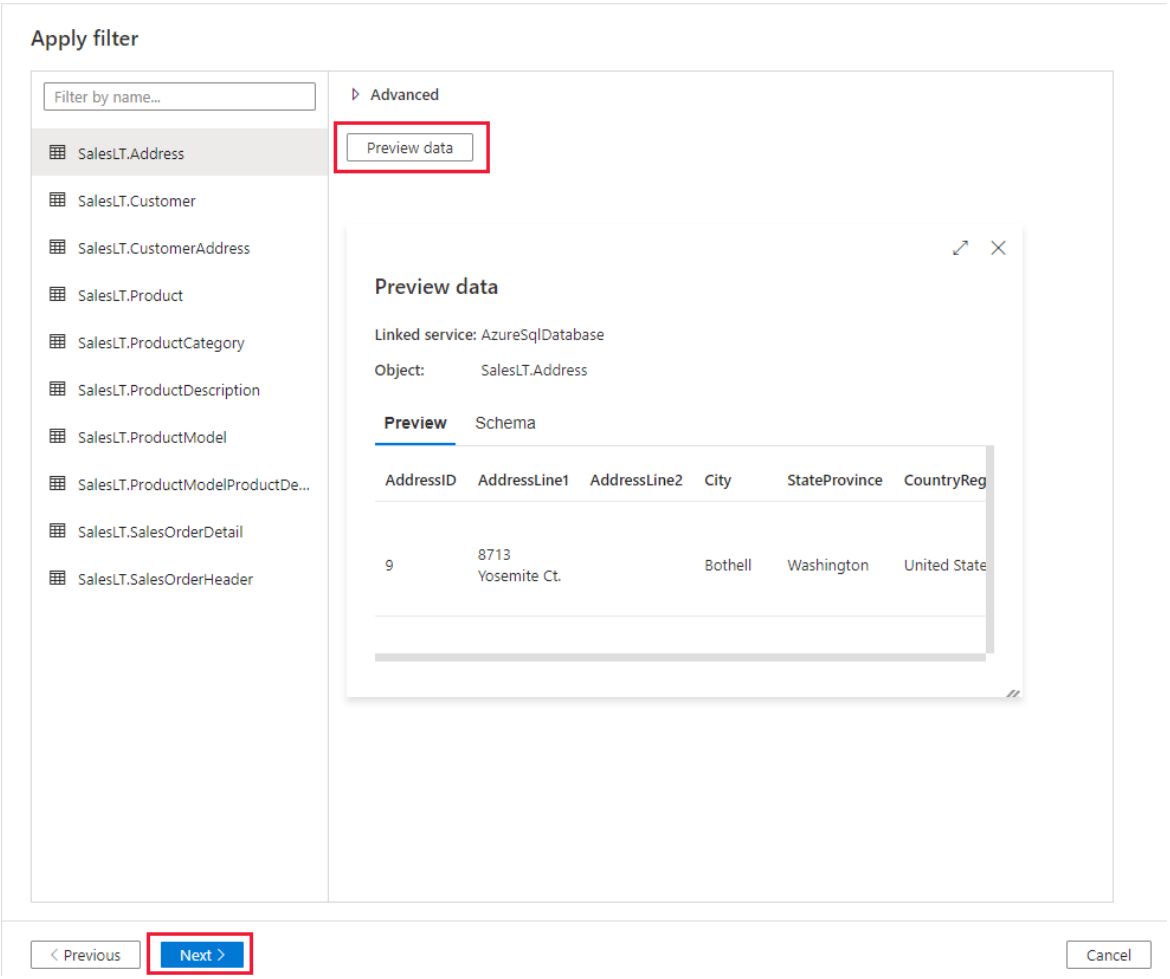


d. In the **Source data store** page, select the newly created connection as source in the **Connection** section.

e. In the **Source tables** section, enter **SalesLT** to filter the tables. Choose the **(Select all)** box to use all of the tables for the copy, and then select **Next**.



4. In the **Apply filter** page, specify your settings or select **Next**. You can preview data and view the schema of the input data by selecting **Preview data** button on this page.

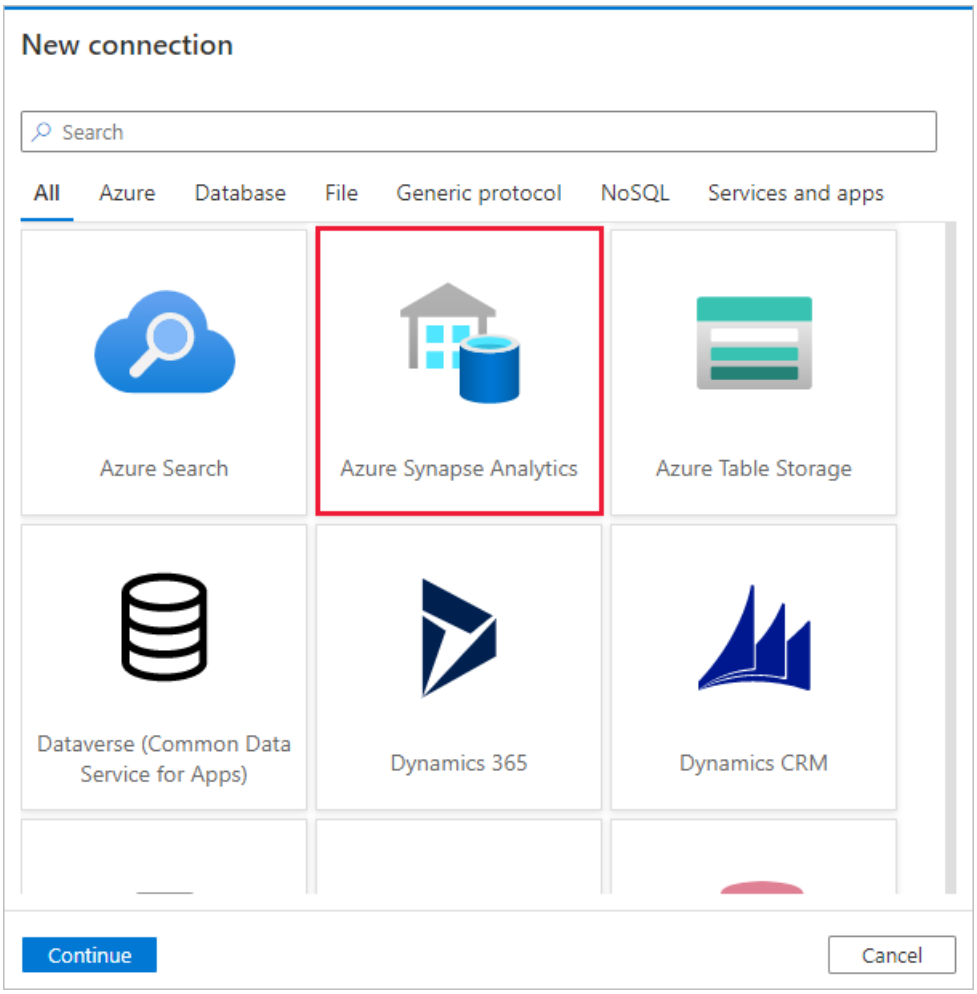


5. In the **Destination data store** page, complete the following steps:

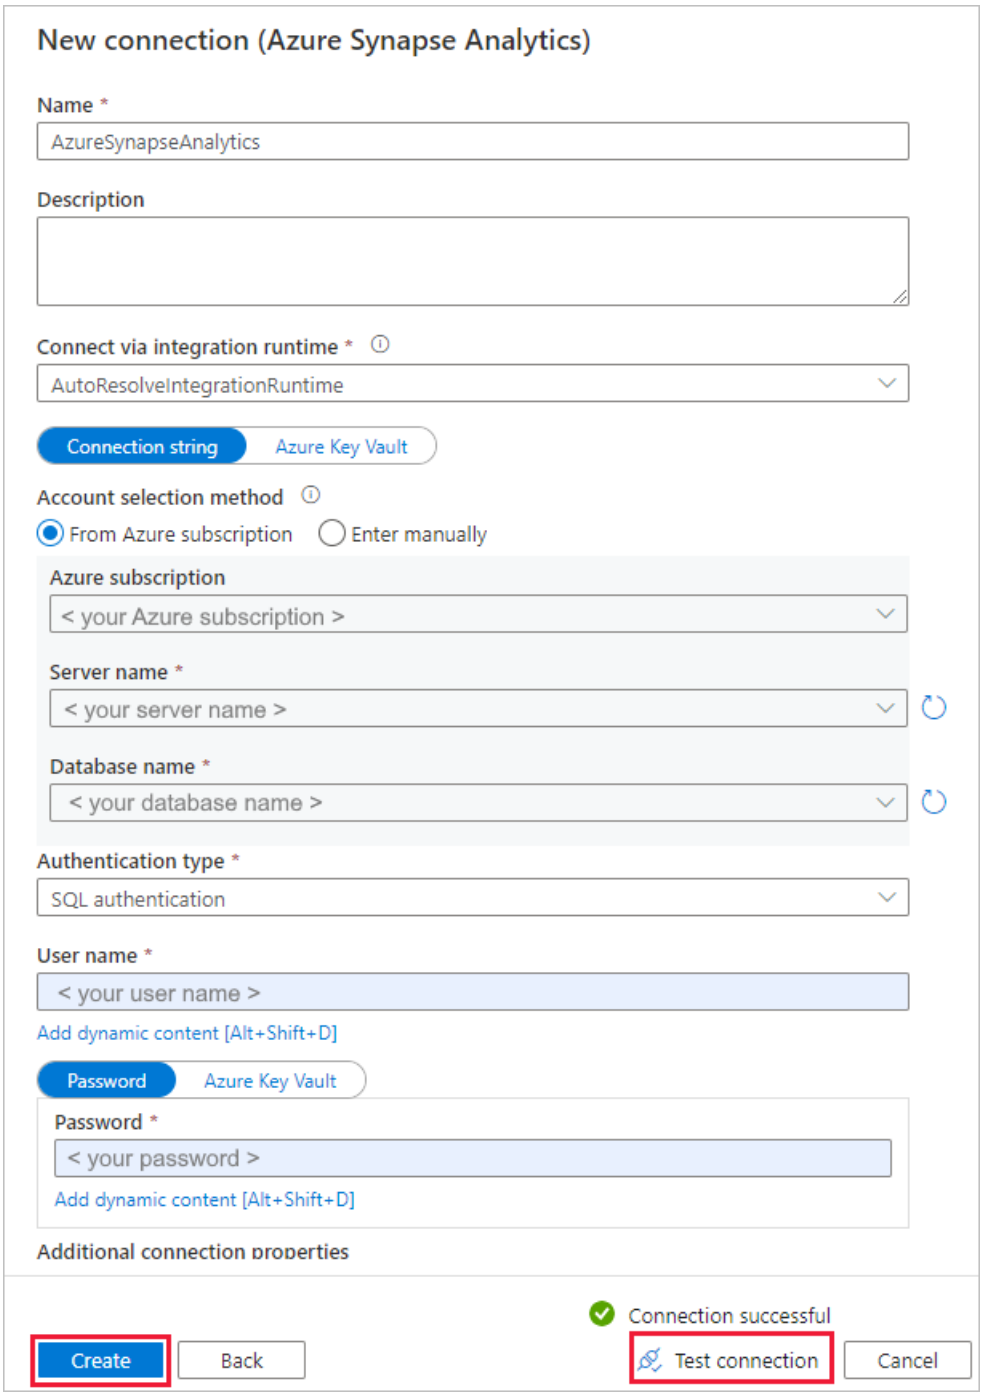
> **TIP**
>
> In this tutorial, you use *SQL authentication* as the authentication type for your destination data store, but you can choose other supported authentication methods:*Service Principal* and *Managed Identity* if needed. Refer to corresponding sections in this article for details. To store secrets for data stores securely, it's also recommended to use an Azure Key Vault. Refer to this article for detailed illustrations.

a. Select **+ New connection** to add a connection.

b. Select **Azure Synapse Analytics** from the gallery, and select **Continue**.

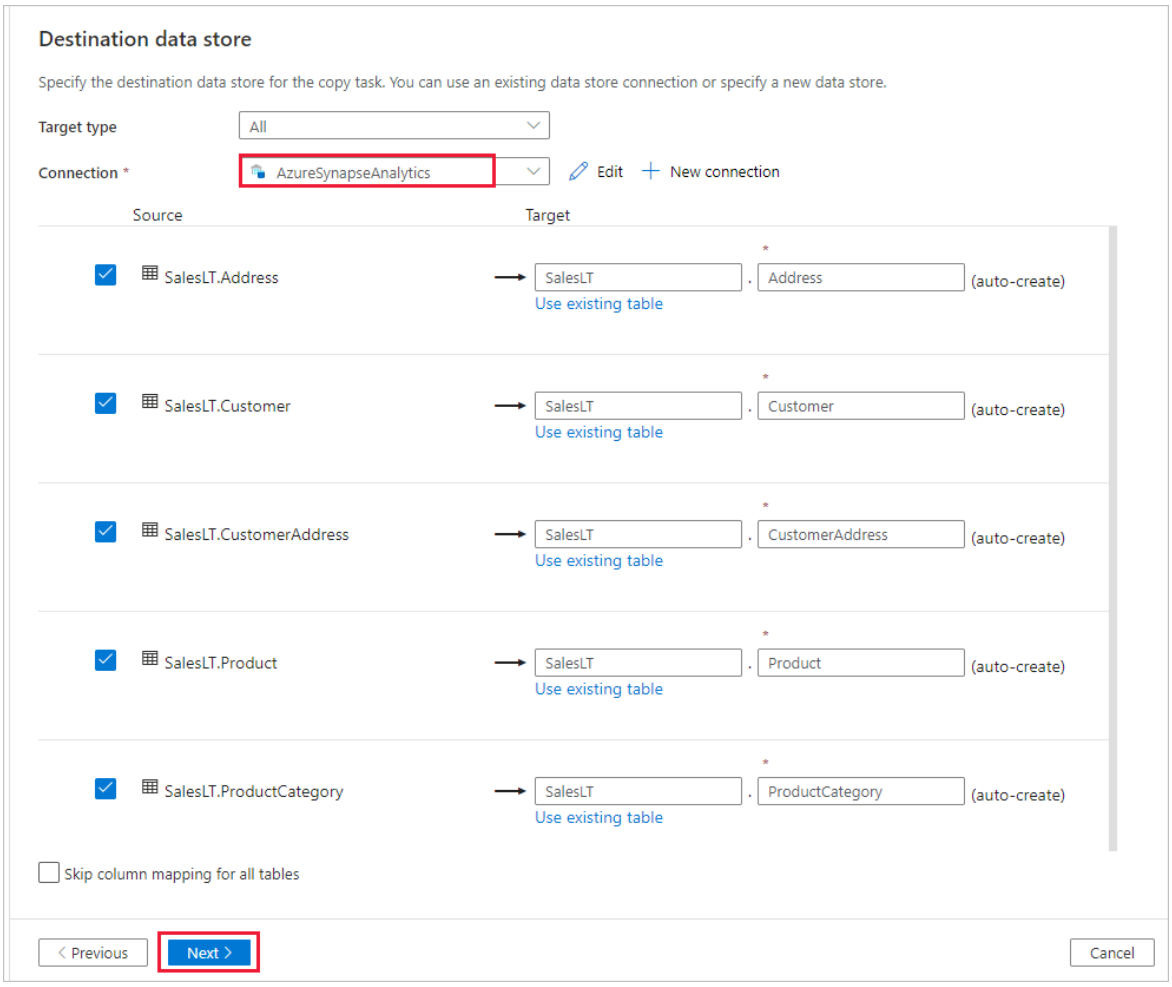


c. In the **New connection (Azure Synapse Analytics)** page, select your server name and DB name from the dropdown list, and specify the username and password. Select **Test connection** to validate the settings, then select **Create**.

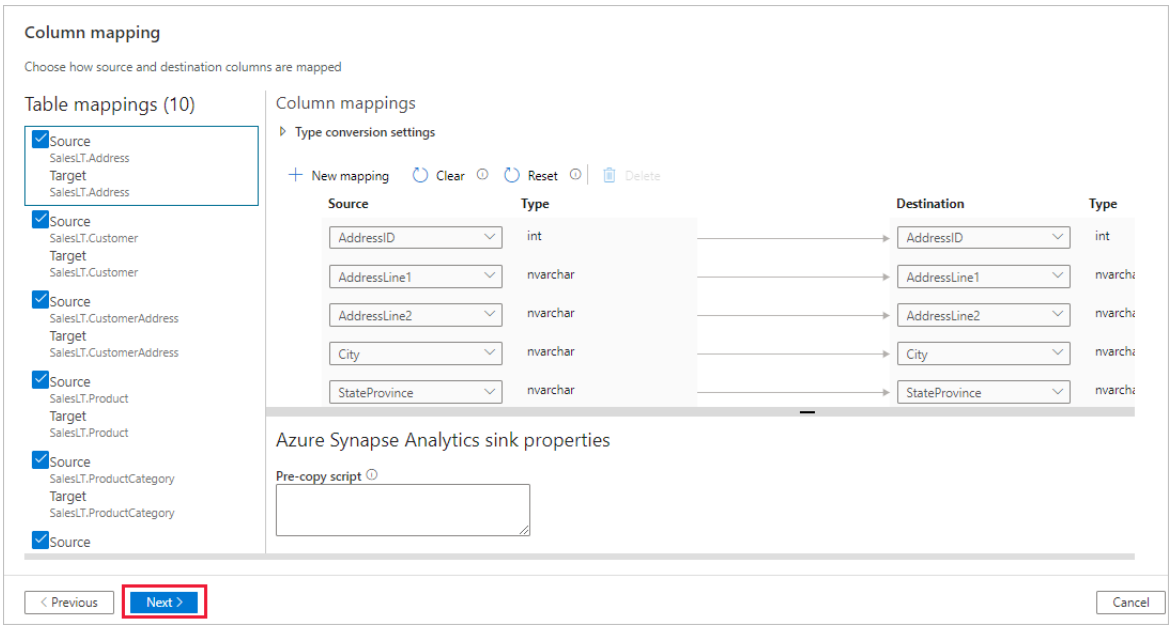


d. In the **Destination data store** page, select the newly created connection as sink in the **Connection** section.

6. In the **Table mapping** section, review the content and select **Next**. An intelligent table mapping displays. The source tables are mapped to the destination tables based on the table names. If a source table doesn't exist in the destination, the service creates a destination table with the same name by default. You can also map a source table to an existing destination table.



7. In the **Column mapping** page, review the content, and select **Next**. The intelligent table mapping is based on the column name. If you let the service automatically create the tables, data type conversion can occur when there are incompatibilities between the source and destination stores. If there's an unsupported data type conversion between the source and destination column, you see an error message next to the corresponding table.



8. In the **Settings** page, complete the following steps:

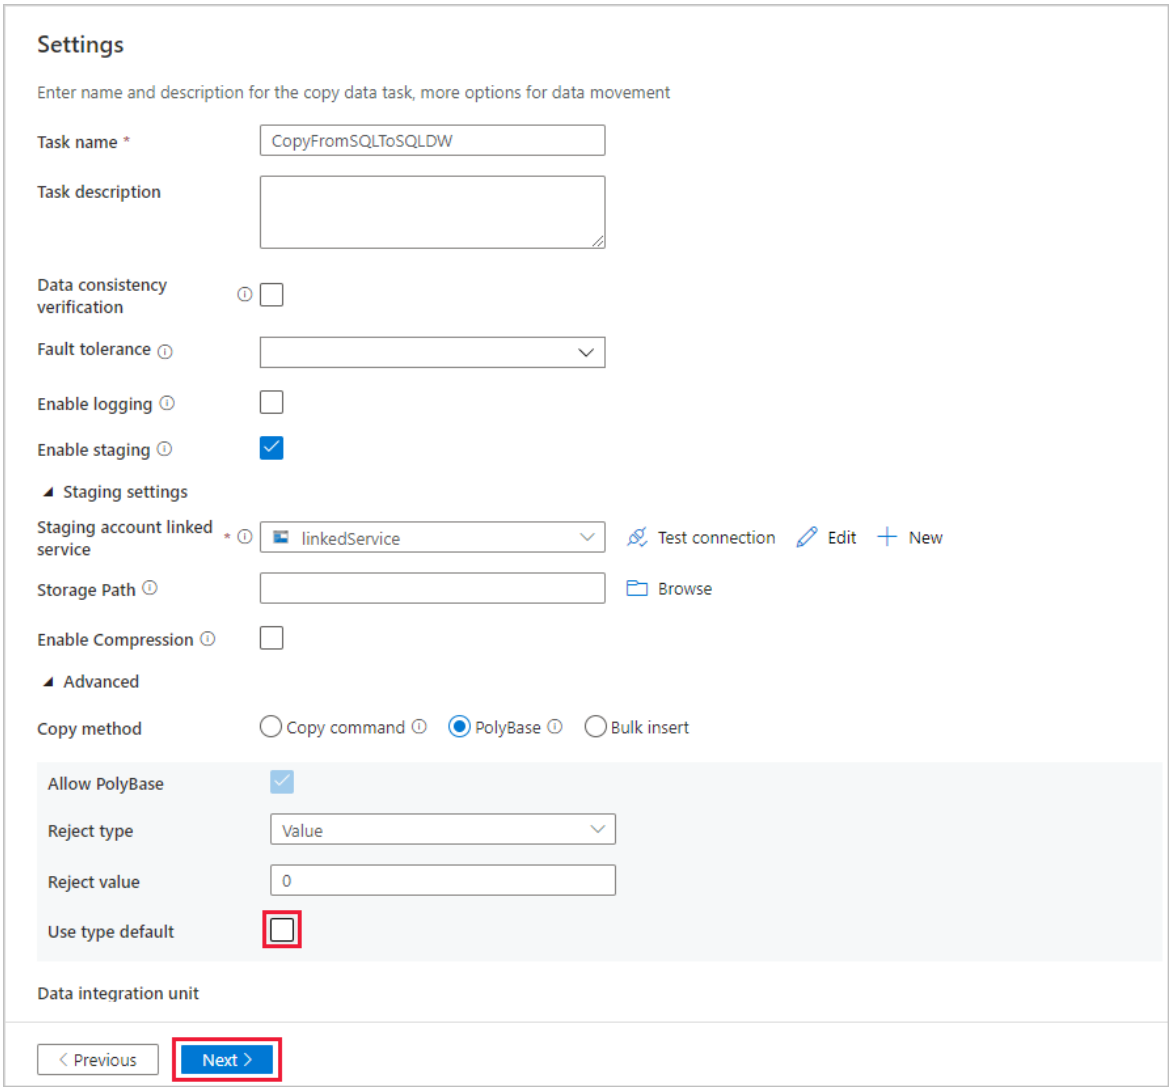
   a. Specify **CopyFromSQLToSQLDW** for the **Task name** field.

   b. In **Staging settings** section, select **+ New** to new a staging storage. The storage is used for staging the data before it loads into Azure Synapse Analytics by using PolyBase. After the copy is

complete, the interim data in Azure Blob Storage is automatically cleaned up.

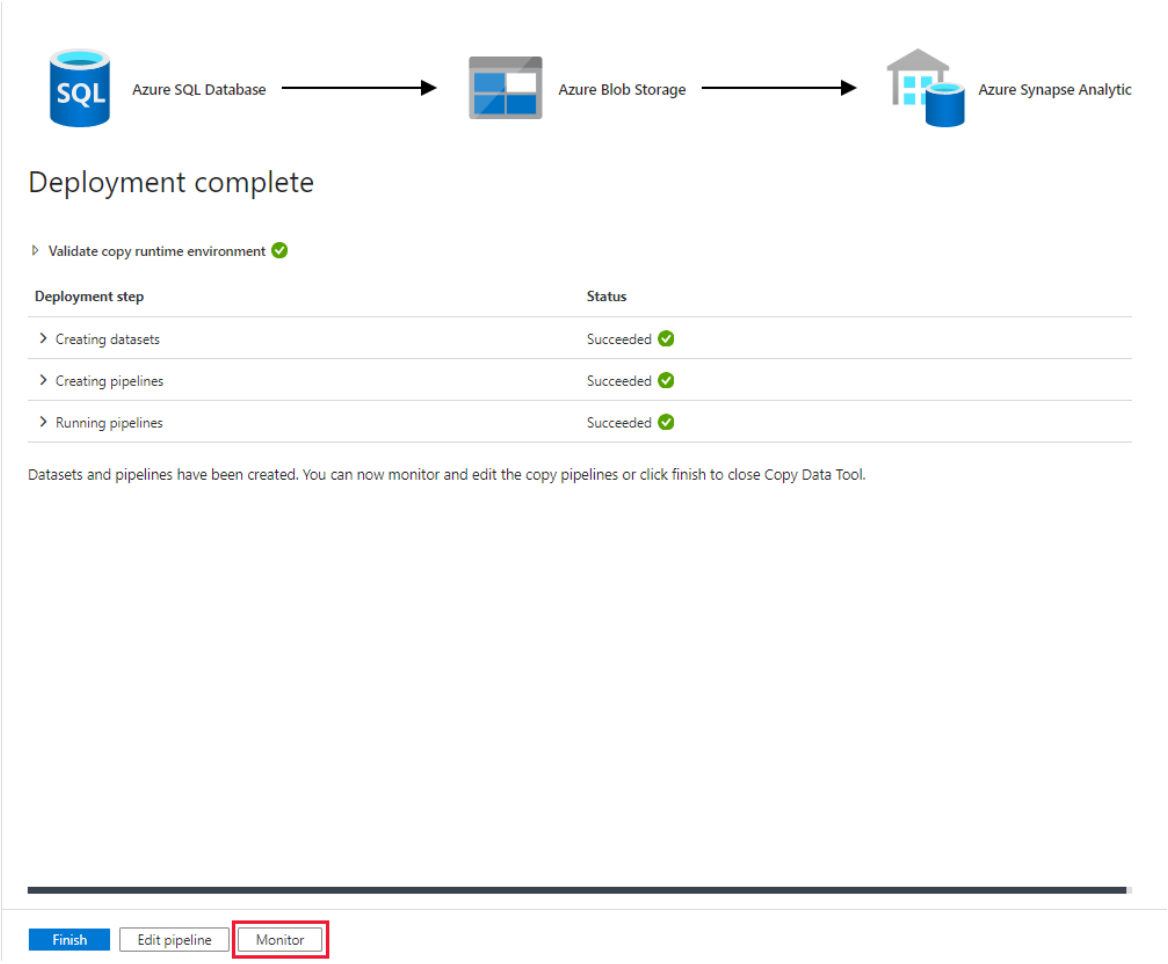
c. In the **New linked service** page, select your storage account, and select **Create** to deploy the linked service.

d. Deselect the **Use type default** option, and then select **Next**.



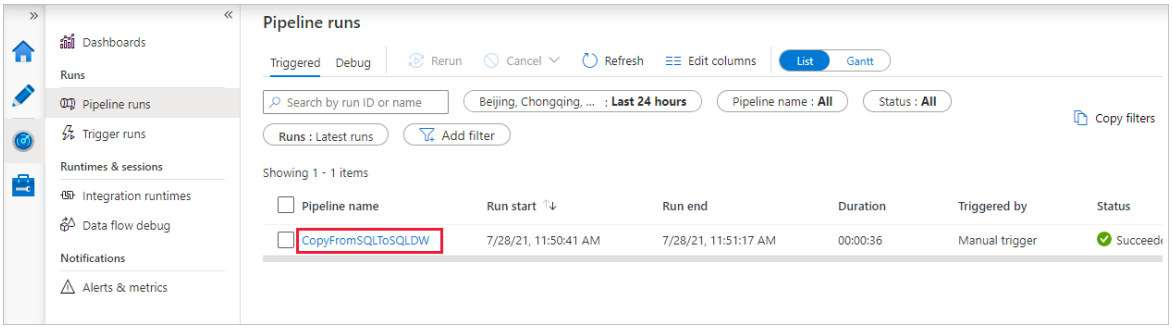
9. In the **Summary** page, review the settings, and select **Next**.

10. On the **Deployment page**, select **Monitor** to monitor the pipeline (task).

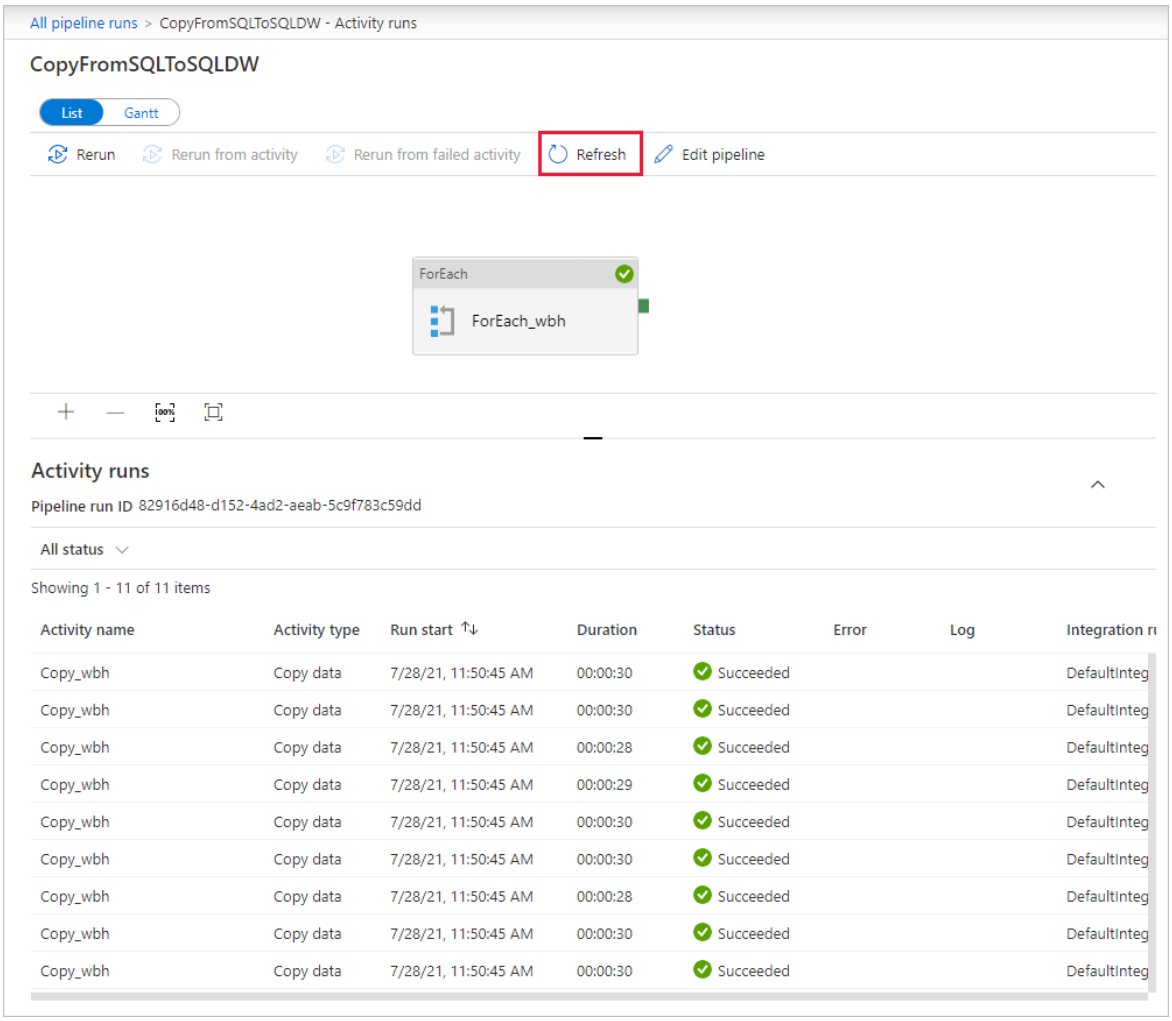


11. Notice that the **Monitor** tab on the left is automatically selected. When the pipeline run completes successfully, select the **CopyFromSQLToSQLDW** link under the **Pipeline name** column to view activity run details or to rerun the pipeline.

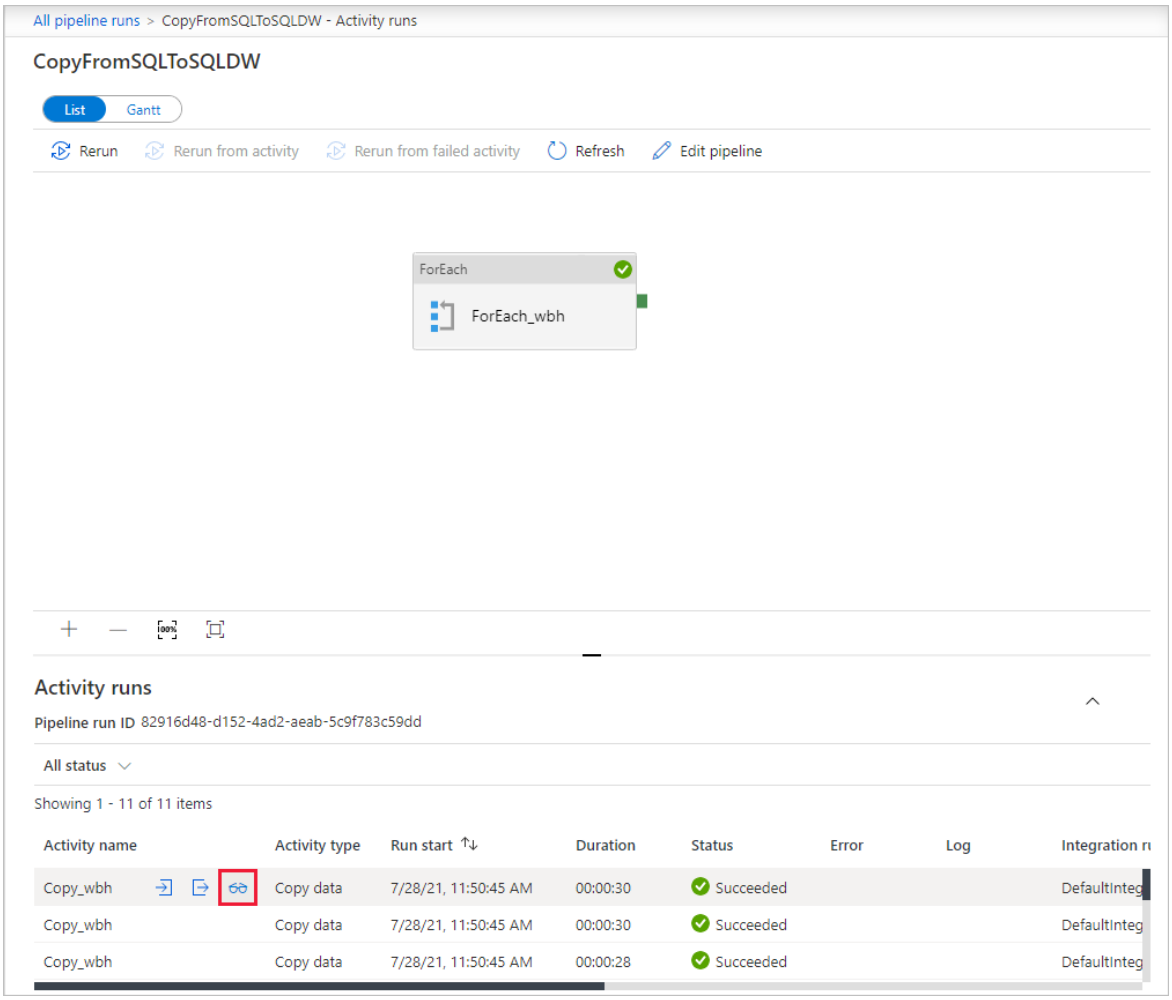
    - Azure Data Factory
    - Azure Synapse

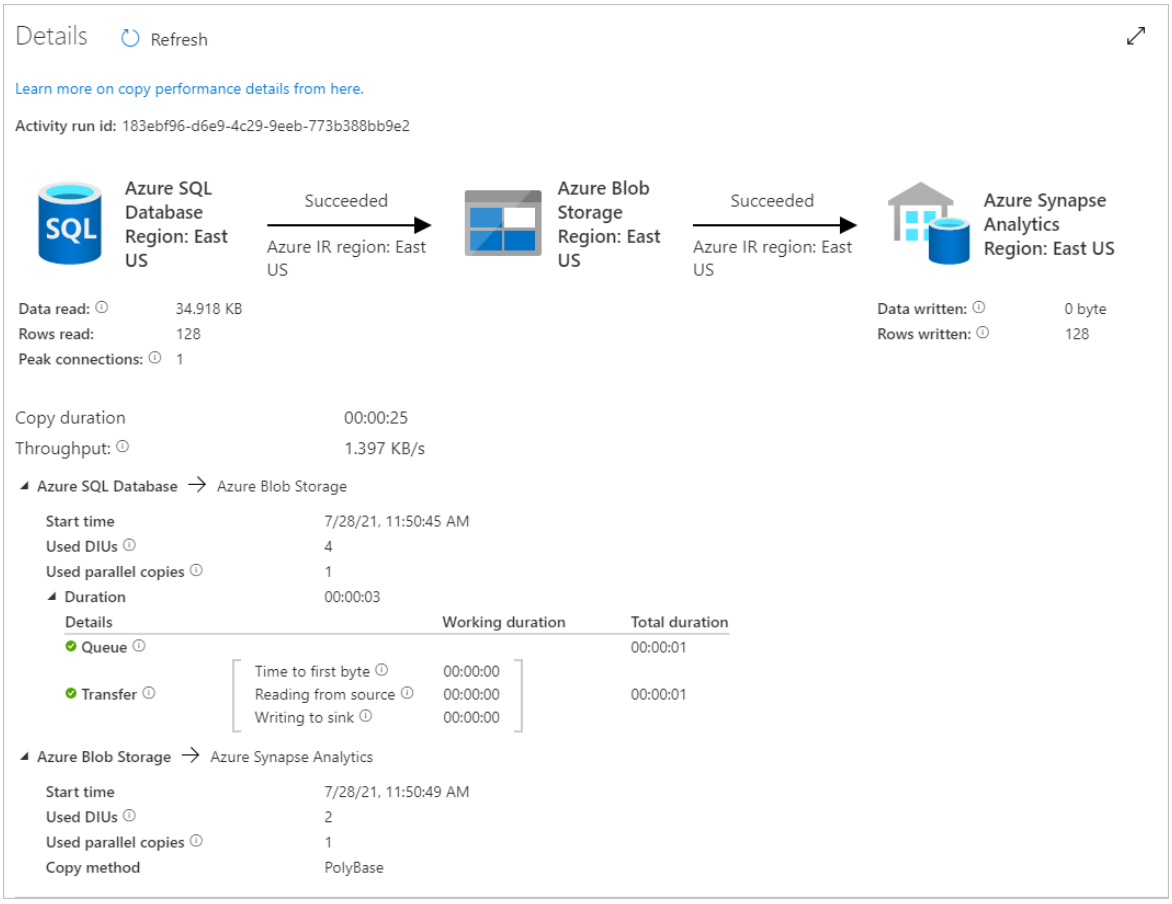


12. To switch back to the pipeline runs view, select the **All pipeline runs** link at the top. Select **Refresh** to refresh the list.



13. To monitor the execution details for each copy activity, select the **Details** link (eyeglasses icon) under **Activity name** in the activity runs view. You can monitor details like the volume of data copied from the source to the sink, data throughput, execution steps with corresponding duration, and used configurations.





Next steps

Advance to the following article to learn about Azure Synapse Analytics support:

Tutorial: Load the New York Taxicab dataset

8/19/2022 • 8 minutes to read • Edit Online

This tutorial uses the COPY statement to load New York Taxicab dataset from an Azure Blob Storage account. The tutorial uses the Azure portal and SQL Server Management Studio (SSMS) to:

- Create a user designated for loading data
- Create the tables for the sample dataset
- Use the COPY T-SQL statement to load data into your data warehouse
- View the progress of data as it is loading

If you don't have an Azure subscription, create a free account before you begin.

Before you begin

Before you begin this tutorial, download and install the newest version of SQL Server Management Studio (SSMS).

This tutorial assumes you have already created a SQL dedicated pool from the following tutorial.

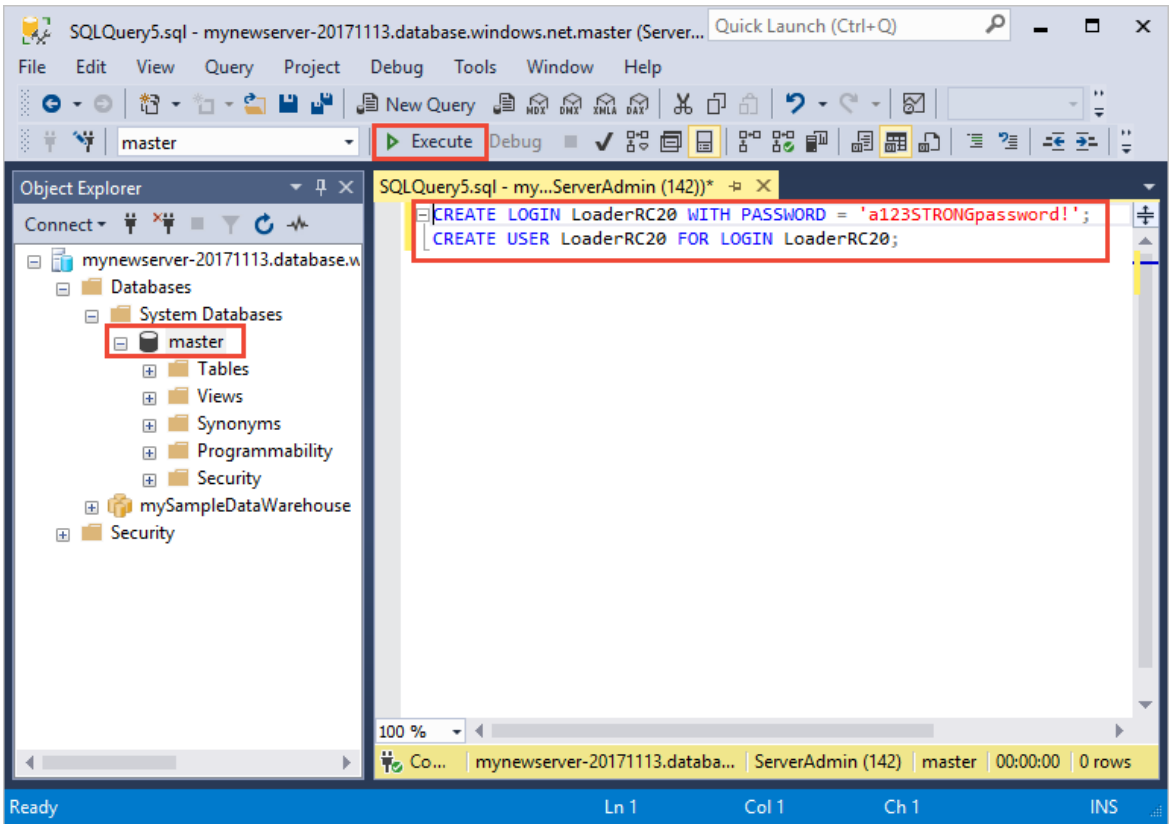
Create a user for loading data

The server admin account is meant to perform management operations, and is not suited for running queries on user data. Loading data is a memory-intensive operation. Memory maximums are defined according to the data warehouse units and resource class configured.

It's best to create a login and user that is dedicated for loading data. Then add the loading user to a resource class that enables an appropriate maximum memory allocation.

Connect as the server admin so you can create logins and users. Use these steps to create a login and user called **LoaderRC20**. Then assign the user to the **staticrc20** resource class.

1. In SSMS, right-select **master** to show a drop-down menu, and choose **New Query**. A new query window opens.

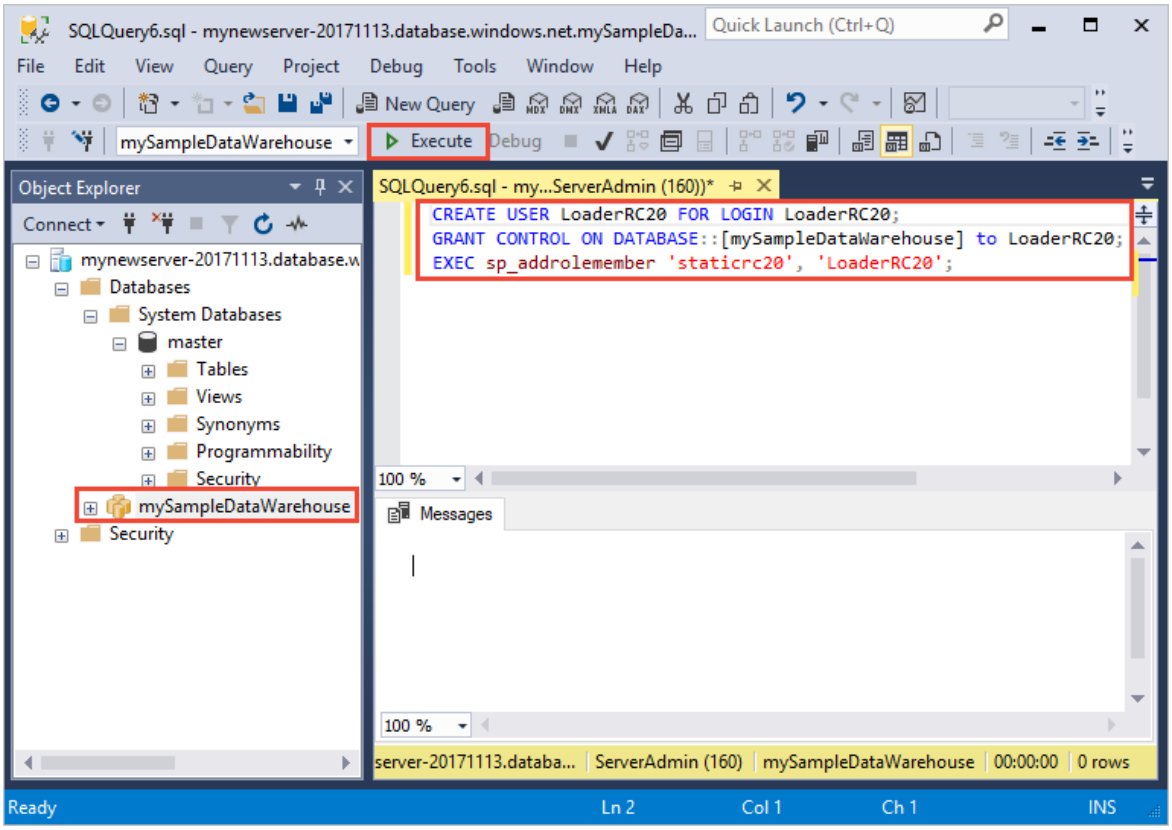


2. In the query window, enter these T-SQL commands to create a login and user named LoaderRC20, substituting your own password for 'a123STRONGpassword!'.

```
CREATE LOGIN LoaderRC20 WITH PASSWORD = 'a123STRONGpassword!';
CREATE USER LoaderRC20 FOR LOGIN LoaderRC20;
```

3. Select **Execute**.

4. Right-click **mySampleDataWarehouse**, and choose **New Query**. A new query Window opens.



5. Enter the following T-SQL commands to create a database user named LoaderRC20 for the LoaderRC20 login. The second line grants the new user CONTROL permissions on the new data warehouse. These permissions are similar to making the user the owner of the database. The third line adds the new user as a member of the staticrc20 resource class.

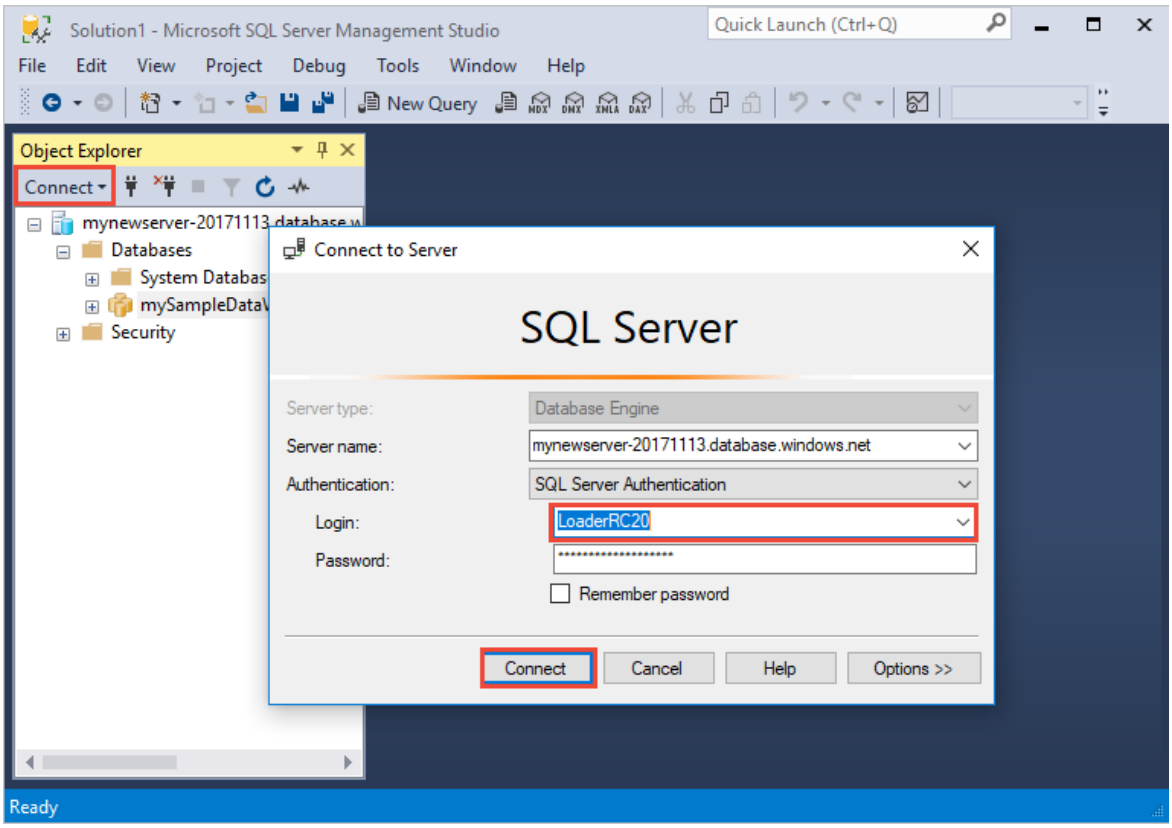
```
CREATE USER LoaderRC20 FOR LOGIN LoaderRC20;
GRANT CONTROL ON DATABASE::[mySampleDataWarehouse] to LoaderRC20;
EXEC sp_addrolemember 'staticrc20', 'LoaderRC20';
```

6. Select **Execute**.

Connect to the server as the loading user

The first step toward loading data is to login as LoaderRC20.

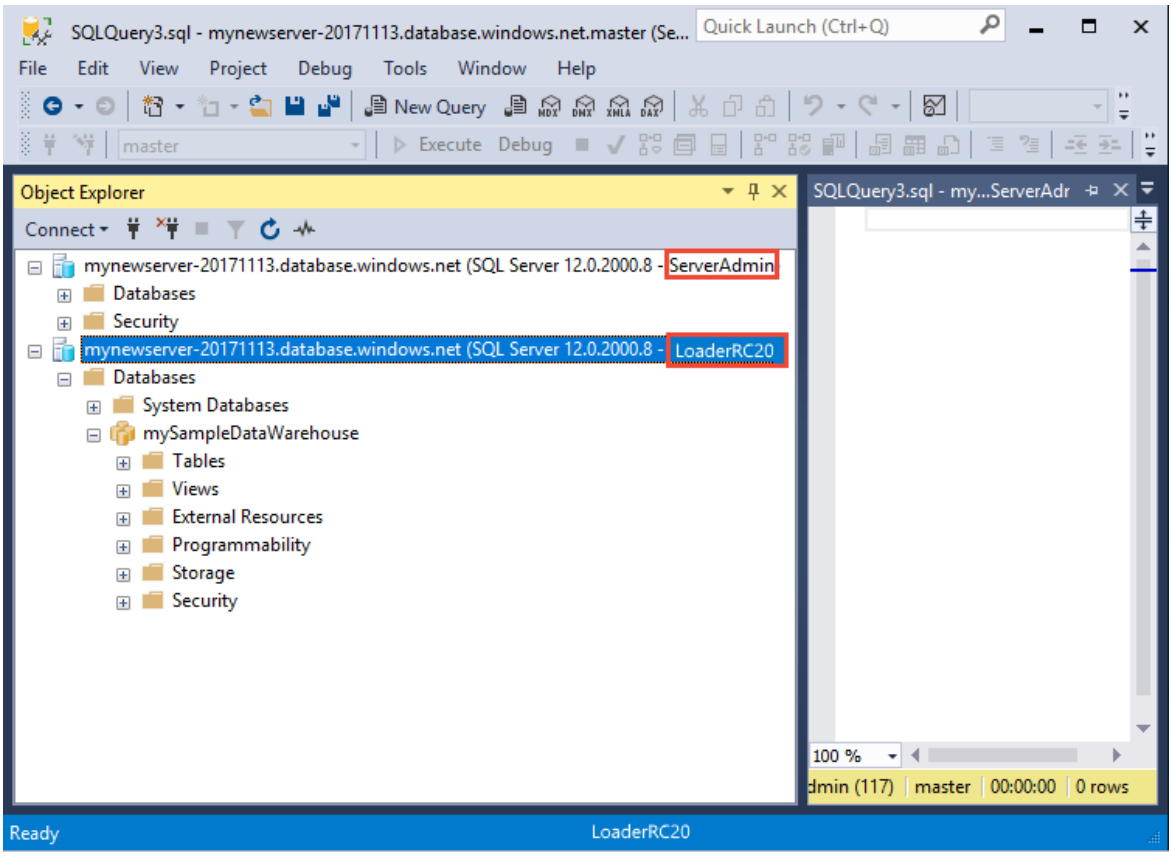
1. In Object Explorer, select the **Connect** drop down menu and select **Database Engine**. The **Connect to Server** dialog box appears.



2. Enter the fully qualified server name, and enter **LoaderRC20** as the Login. Enter your password for LoaderRC20.

3. Select **Connect**.

4. When your connection is ready, you will see two server connections in Object Explorer. One connection as ServerAdmin and one connection as MedRCLogin.

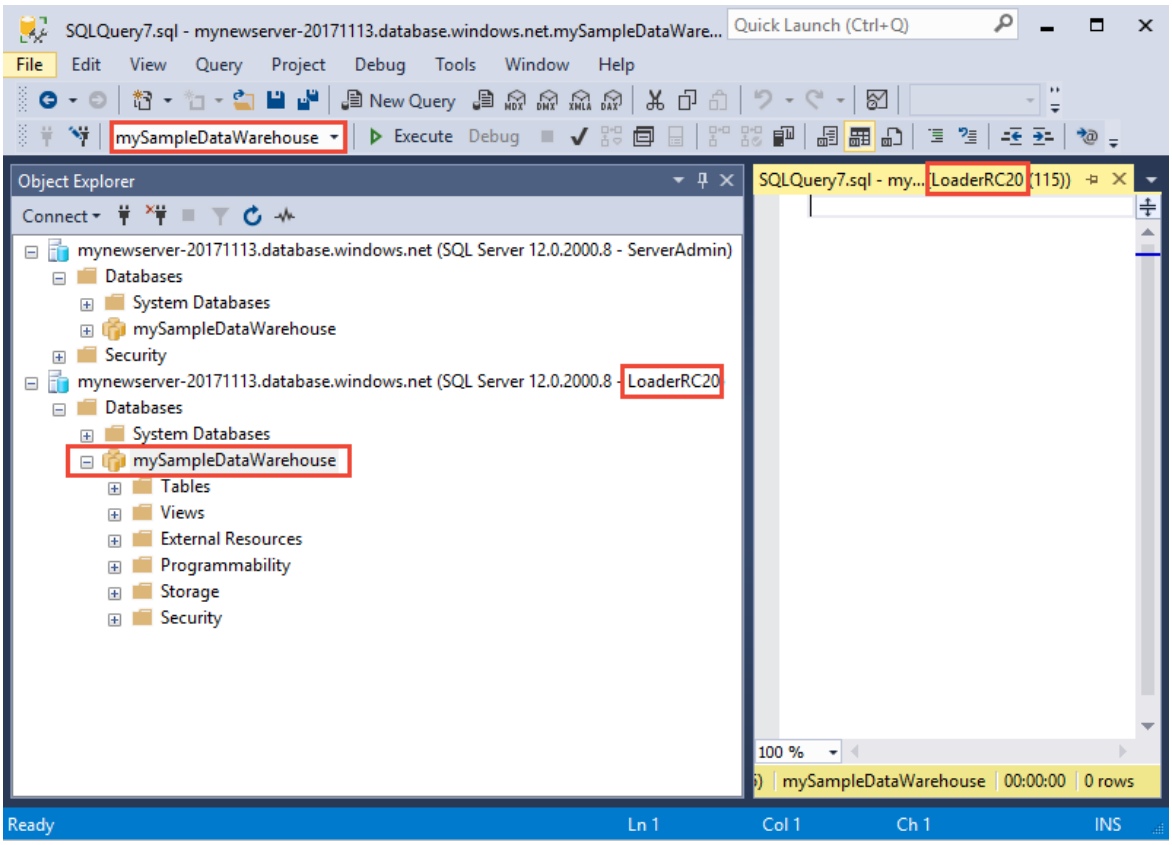


Create tables for the sample data

You are ready to begin the process of loading data into your new data warehouse. This part of the tutorial shows you how to use the COPY statement to load the New York City taxi cab dataset from an Azure Storage blob. For future reference, to learn how to get your data to Azure Blob Storage or to load it directly from your source, see the loading overview.

Run the following SQL scripts and specify information about the data you wish to load. This information includes where the data is located, the format of the contents of the data, and the table definition for the data.

1. In the previous section, you logged into your data warehouse as LoaderRC20. In SSMS, right-click your LoaderRC20 connection and select **New Query**. A new query window appears.



2. Compare your query window to the previous image. Verify your new query window is running as LoaderRC20 and performing queries on your MySampleDataWarehouse database. Use this query window to perform all of the loading steps.

3. Run the following T-SQL statements to create the tables:

```
CREATE TABLE [dbo].[Date]
(
    [DateID] int NOT NULL,
    [Date] datetime NULL,
    [DateBKey] char(10) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfMonth] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DaySuffix] varchar(4) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayName] varchar(9) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfWeek] char(1) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfWeekInMonth] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfWeekInYear] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfQuarter] varchar(3) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [DayOfYear] varchar(3) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [WeekOfMonth] varchar(1) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [WeekOfQuarter] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [WeekOfYear] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [Month] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [MonthName] varchar(9) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [MonthOfQuarter] varchar(2) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [Quarter] char(1) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [QuarterName] varchar(9) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [Year] char(4) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [YearName] char(7) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [MonthYear] char(10) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [MMYYYY] char(6) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [FirstDayOfMonth] date NULL,
    [LastDayOfMonth] date NULL,
    [FirstDayOfQuarter] date NULL,
    [LastDayOfQuarter] date NULL,
    [FirstDayOfYear] date NULL,
    [LastDayOfYear] date NULL,
    [IsHolidayUSA] bit NULL,
    [IsWeekday] bit NULL
```

```
    [IsWeekday] bit NULL,
    [HolidayUSA] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);

CREATE TABLE [dbo].[Geography]
(
    [GeographyID] int NOT NULL,
    [ZipCodeBKey] varchar(10) COLLATE SQL_Latin1_General_CP1_CI_AS NOT NULL,
    [County] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [City] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [State] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [Country] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [ZipCode] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);

CREATE TABLE [dbo].[HackneyLicense]
(
    [HackneyLicenseID] int NOT NULL,
    [HackneyLicenseBKey] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NOT NULL,
    [HackneyLicenseCode] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);

CREATE TABLE [dbo].[Medallion]
(
    [MedallionID] int NOT NULL,
    [MedallionBKey] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NOT NULL,
    [MedallionCode] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL
)
WITH

    [PaymentType] varchar(50) COLLATE SQL_Latin1_General_CP1_CI_AS NULL,
    [FareAmount] money NULL,
    [SurchargeAmount] money NULL,
    [TaxAmount] money NULL,
    [TipAmount] money NULL,
    [TollsAmount] money NULL,
    [TotalAmount] money NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);

CREATE TABLE [dbo].[Weather]
(
    [DateID] int NOT NULL,
    [GeographyID] int NOT NULL,
    [PrecipitationInches] float NOT NULL,
    [AvgTemperatureFahrenheit] float NOT NULL
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
);
```

Load the data into your data warehouse

This section uses the COPY statement to load the sample data from Azure Storage Blob.

> **NOTE**
>
> This tutorial loads the data directly into the final table. You would typically load into a staging table for your production workloads. While data is in the staging table you can perform any necessary transformations.

1. Run the following statements to load the data:

```
COPY INTO [dbo].[Date]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Date'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = ''
)
OPTION (LABEL = 'COPY : Load [dbo].[Date] - Taxi dataset');
```

```
COPY INTO [dbo].[Geography]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Geography'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = ''
)
OPTION (LABEL = 'COPY : Load [dbo].[Geography] - Taxi dataset');

COPY INTO [dbo].[HackneyLicense]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/HackneyLicense'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = ''
)
OPTION (LABEL = 'COPY : Load [dbo].[HackneyLicense] - Taxi dataset');

COPY INTO [dbo].[Medallion]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Medallion'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = ''
)
OPTION (LABEL = 'COPY : Load [dbo].[Medallion] - Taxi dataset');

COPY INTO [dbo].[Time]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Time'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = ''
)
OPTION (LABEL = 'COPY : Load [dbo].[Time] - Taxi dataset');

COPY INTO [dbo].[Weather]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Weather'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = ',',
 FIELDQUOTE = '',
 ROWTERMINATOR='0X0A'
)
OPTION (LABEL = 'COPY : Load [dbo].[Weather] - Taxi dataset');

COPY INTO [dbo].[Trip]
FROM 'https://nytaxiblob.blob.core.windows.net/2013/Trip2013'
WITH
(
    FILE_TYPE = 'CSV',
 FIELDTERMINATOR = '|',
 FIELDQUOTE = '',
 ROWTERMINATOR='0X0A',
 COMPRESSION = 'GZIP'
)
OPTION (LABEL = 'COPY : Load [dbo].[Trip] - Taxi dataset');
```

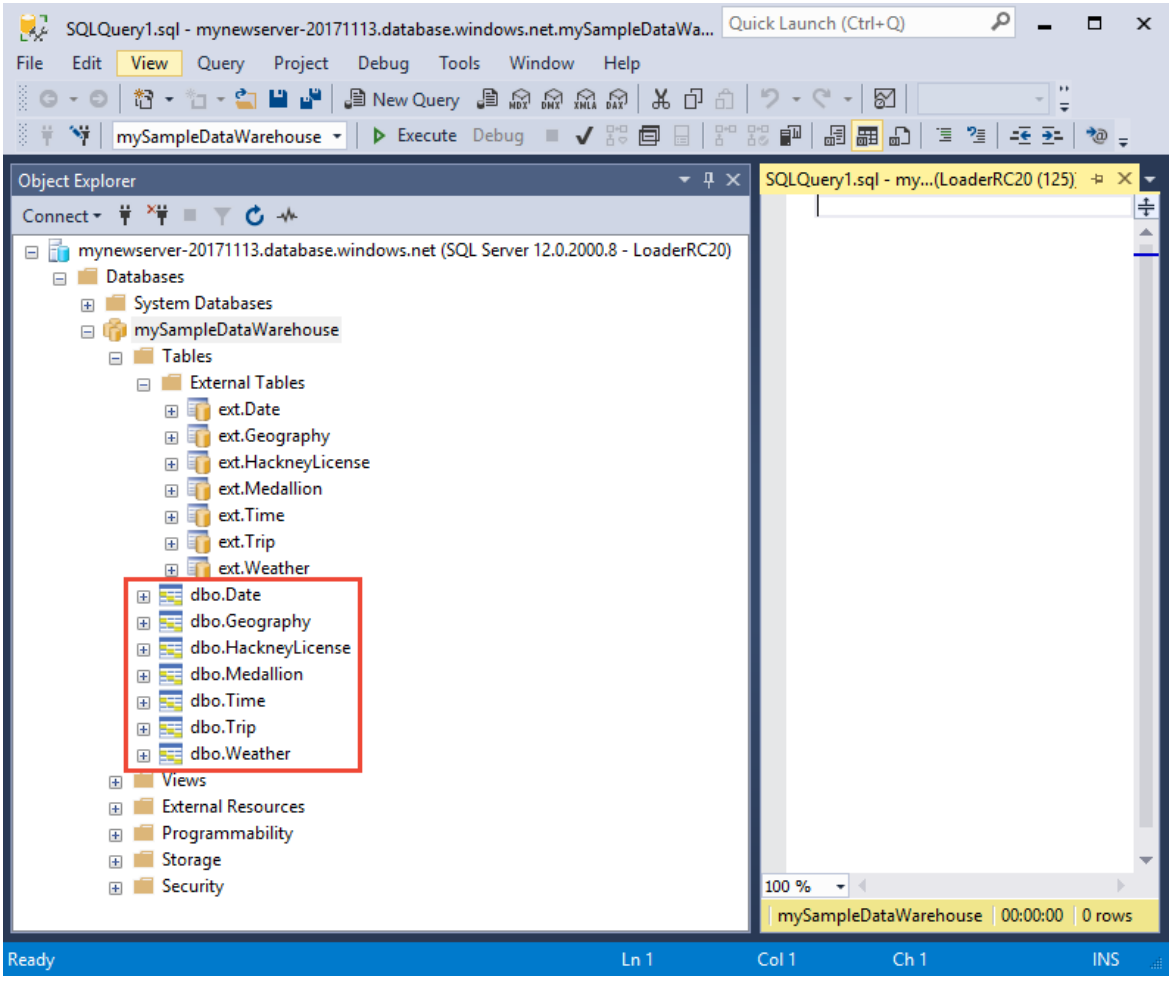
2. View your data as it loads. You're loading several GBs of data and compressing it into highly performant clustered columnstore indexes. Run the following query that uses a dynamic management views (DMVs) to show the status of the load.

```
SELECT  r.[request_id]
,       r.[status]
,       r.resource_class
,       r.command
,       sum(bytes_processed) AS bytes_processed
,       sum(rows_processed) AS rows_processed
FROM    sys.dm_pdw_exec_requests r
              JOIN sys.dm_pdw_dms_workers w
                     ON r.[request_id] = w.request_id
WHERE [label] = 'COPY : Load [dbo].[Date] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[Geography] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[HackneyLicense] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[Medallion] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[Time] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[Weather] - Taxi dataset' OR
    [label] = 'COPY : Load [dbo].[Trip] - Taxi dataset'
and session_id <> session_id() and type = 'WRITER'
GROUP BY r.[request_id]
,       r.[status]
,       r.resource_class
,       r.command;
```

3. View all system queries.

```
SELECT * FROM sys.dm_pdw_exec_requests;
```

4. Enjoy seeing your data nicely loaded into your data warehouse.



Clean up resources

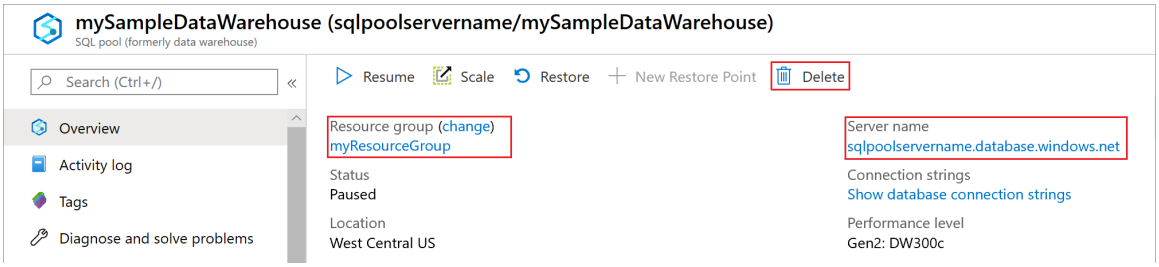
You are being charged for compute resources and data that you loaded into your data warehouse. These are

billed separately.

- If you want to keep the data in storage, you can pause compute when you aren't using the data warehouse. By pausing compute you will only be charge for data storage and you can resume the compute whenever you are ready to work with the data.
- If you want to remove future charges, you can delete the data warehouse.

Follow these steps to clean up resources as you desire.

1. Log in to the Azure portal, select your data warehouse.



2. To pause compute, select the **Pause** button. When the data warehouse is paused, you will see a **Start** button. To resume compute, select **Start**.
3. To remove the data warehouse so you won't be charged for compute or storage, select **Delete**.
4. To remove the server you created, select **mynewserver-20180430.database.windows.net** in the previous image, and then select **Delete**. Be careful with this as deleting the server will delete all databases assigned to the server.
5. To remove the resource group, select **myResourceGroup**, and then select **Delete resource group**.

Next steps

In this tutorial, you learned how to create a data warehouse and create a user for loading data. You used the simple COPY statement to load data into your data warehouse.

You did these things:

- Created a data warehouse in the Azure portal
- Set up a server-level firewall rule in the Azure portal
- Connected to the data warehouse with SSMS
- Created a user designated for loading data
- Created the tables for the sample data
- Used the COPY T-SQL statement to load data into your data warehouse
- Viewed the progress of data as it is loading

Advance to the development overview to learn how to migrate an existing database to Azure Synapse Analytics:

Design decisions to migrate an existing database to Azure Synapse Analytics

For more loading examples and references, view the following documentation:

- COPY statement reference documentation
- COPY examples for each authentication method
- COPY quickstart for a single table

Load Contoso retail data into dedicated SQL pools in Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

In this tutorial, you learn to use PolyBase and T-SQL commands to load two tables from the Contoso retail data into dedicated SQL pools.

In this tutorial you will:

1. Configure PolyBase to load from Azure blob storage
2. Load public data into your database
3. Perform optimizations after the load is finished.

Before you begin

To run this tutorial, you need an Azure account that already has a dedicated SQL pool. If you don't have a data warehouse provisioned, see Create a data warehouse and set server-level firewall rule.

Configure the data source

PolyBase uses T-SQL external objects to define the location and attributes of the external data. The external object definitions are stored in dedicated SQL pools. The data is stored externally.

Create a credential

Skip this step if you're loading the Contoso public data. You don't need secure access to the public data since it's already accessible to anyone.

Don't skip this step if you're using this tutorial as a template for loading your own data. To access data through a credential, use the following script to create a database-scoped credential. Then use it when defining the location of the data source.

```
-- A: Create a master key.
-- Only necessary if one does not already exist.
-- Required to encrypt the credential secret in the next step.

CREATE MASTER KEY;

-- B: Create a database scoped credential
-- IDENTITY: Provide any string, it is not used for authentication to Azure storage.
-- SECRET: Provide your Azure storage account key.

CREATE DATABASE SCOPED CREDENTIAL AzureStorageCredential
WITH
    IDENTITY = 'user',
    SECRET = '<azure_storage_account_key>'
;

-- C: Create an external data source
-- TYPE: HADOOP - PolyBase uses Hadoop APIs to access data in Azure blob storage.
-- LOCATION: Provide Azure storage account name and blob container name.
-- CREDENTIAL: Provide the credential created in the previous step.

CREATE EXTERNAL DATA SOURCE AzureStorage
WITH (
    TYPE = HADOOP,
    LOCATION = 'wasbs://<blob_container_name>@<azure_storage_account_name>.blob.core.windows.net',
    CREDENTIAL = AzureStorageCredential
);
```

Create the external data source

Use this CREATE EXTERNAL DATA SOURCE command to store the location of the data, and the data type.

```
CREATE EXTERNAL DATA SOURCE AzureStorage_west_public
WITH
(
    TYPE = Hadoop
,   LOCATION = 'wasbs://contosoretaildw-tables@contosoretaildw.blob.core.windows.net/'
);
```

> **IMPORTANT**
>
> If you choose to make your azure blob storage containers public, remember that as the data owner you will be charged for data egress charges when data leaves the data center.

Configure the data format

The data is stored in text files in Azure blob storage, and each field is separated with a delimiter. In SSMS, run the following CREATE EXTERNAL FILE FORMAT command to specify the format of the data in the text files. The Contoso data is uncompressed and pipe delimited.

```
CREATE EXTERNAL FILE FORMAT TextFileFormat
WITH
(   FORMAT_TYPE = DELIMITEDTEXT
,    FORMAT_OPTIONS    (   FIELD_TERMINATOR = '|'
                     ,    STRING_DELIMITER = ''
                     ,    DATE_FORMAT         = 'yyyy-MM-dd HH:mm:ss.fff'
                     ,    USE_TYPE_DEFAULT = FALSE
                     )
);
```

Create the schema for the external tables

Now that you've specified the data source and file format, you're ready to create the schema for the external tables.

To create a place to store the Contoso data in your database, create a schema.

```
CREATE SCHEMA [asb]
GO
```

Create the external tables

Run the following script to create the DimProduct and FactOnlineSales external tables. All you're doing here is defining column names and data types, and binding them to the location and format of the Azure blob storage files. The definition is stored in the data warehouse and the data is still in the Azure Storage Blob.

The **LOCATION** parameter is the folder under the root folder in the Azure Storage Blob. Each table is in a different folder.

```
--DimProduct
CREATE EXTERNAL TABLE [asb].DimProduct (
    [ProductKey] [int] NOT NULL,
    [ProductLabel] [nvarchar](255) NULL,
    [ProductName] [nvarchar](500) NULL,
    [ProductDescription] [nvarchar](400) NULL,
    [ProductSubcategoryKey] [int] NULL,
    [Manufacturer] [nvarchar](50) NULL,
    [BrandName] [nvarchar](50) NULL,
    [ClassID] [nvarchar](10) NULL,
    [ClassName] [nvarchar](20) NULL,
    [StyleID] [nvarchar](10) NULL,
    [StyleName] [nvarchar](20) NULL,
    [ColorID] [nvarchar](10) NULL,
    [ColorName] [nvarchar](20) NOT NULL,
    [Size] [nvarchar](50) NULL,
    [SizeRange] [nvarchar](50) NULL,
    [SizeUnitMeasureID] [nvarchar](20) NULL,
    [Weight] [float] NULL,
    [WeightUnitMeasureID] [nvarchar](20) NULL,
    [UnitOfMeasureID] [nvarchar](10) NULL,

```

Load the data

There are different ways to access external data. You can query data directly from the external tables, load the data into new tables in the data warehouse, or add external data to existing data warehouse tables.

Create a new schema

CTAS creates a new table that contains data. First, create a schema for the contoso data.

```
CREATE SCHEMA [cso]
GO
```

Load the data into new tables

To load data from Azure blob storage into the data warehouse table, use the CREATE TABLE AS SELECT (Transact-SQL) statement. Loading with CTAS leverages the strongly typed external tables you've created. To load the data

into new tables, use one CTAS statement per table.

CTAS creates a new table and populates it with the results of a select statement. CTAS defines the new table to have the same columns and data types as the results of the select statement. If you select all the columns from an external table, the new table will be a replica of the columns and data types in the external table.

In this example, we create both the dimension and the fact table as hash distributed tables.

```
SELECT GETDATE();
GO

CREATE TABLE [cso].[DimProduct]            WITH (DISTRIBUTION = HASH([ProductKey]  ) ) AS SELECT * FROM
[asb].[DimProduct]             OPTION (LABEL = 'CTAS : Load [cso].[DimProduct]             ');
CREATE TABLE [cso].[FactOnlineSales]       WITH (DISTRIBUTION = HASH([ProductKey]  ) ) AS SELECT * FROM
[asb].[FactOnlineSales]        OPTION (LABEL = 'CTAS : Load [cso].[FactOnlineSales]        ');
```

Track the load progress

You can track the progress of your load using dynamic management views (DMVs).

```
-- To see all requests
SELECT * FROM sys.dm_pdw_exec_requests;

-- To see a particular request identified by its label
SELECT * FROM sys.dm_pdw_exec_requests as r
WHERE r.[label] = 'CTAS : Load [cso].[DimProduct]             '
      OR r.[label] = 'CTAS : Load [cso].[FactOnlineSales]        '
;

-- To track bytes and files
SELECT
    r.command,
    s.request_id,
    r.status,
    count(distinct input_name) as nbr_files,
    sum(s.bytes_processed)/1024/1024/1024 as gb_processed
FROM
    sys.dm_pdw_exec_requests r
    inner join sys.dm_pdw_dms_external_work s
        on r.request_id = s.request_id
WHERE
    r.[label] = 'CTAS : Load [cso].[DimProduct]             '
    OR r.[label] = 'CTAS : Load [cso].[FactOnlineSales]        '
GROUP BY
    r.command,
    s.request_id,
    r.status
ORDER BY
    nbr_files desc,
    gb_processed desc;
```

Optimize columnstore compression

By default, dedicated SQL pools store the table as a clustered columnstore index. After a load completes, some of the data rows might not be compressed into the columnstore. There are different reasons why this can happen. To learn more, see manage columnstore indexes.

To optimize query performance and columnstore compression after a load, rebuild the table to force the columnstore index to compress all the rows.

```
SELECT GETDATE();
GO

ALTER INDEX ALL ON [cso].[DimProduct]               REBUILD;
ALTER INDEX ALL ON [cso].[FactOnlineSales]          REBUILD;
```

For more information on maintaining columnstore indexes, see the manage columnstore indexes article.

Optimize statistics

It's best to create single-column statistics immediately after a load. If you know certain columns aren't going to be in query predicates, you can skip creating statistics on those columns. If you create single-column statistics on every column, it might take a long time to rebuild all the statistics.

If you decide to create single-column statistics on every column of every table, you can use the stored procedure code sample `prc_sqldw_create_stats` in the statistics article.

The following example is a good starting point for creating statistics. It creates single-column statistics on each column in the dimension table, and on each joining column in the fact tables. You can always add single or multi-column statistics to other fact table columns later on.

```
CREATE STATISTICS [stat_cso_DimProduct_AvailableForSaleDate] ON [cso].[DimProduct]([AvailableForSaleDate]);
CREATE STATISTICS [stat_cso_DimProduct_BrandName] ON [cso].[DimProduct]([BrandName]);
CREATE STATISTICS [stat_cso_DimProduct_ClassID] ON [cso].[DimProduct]([ClassID]);
CREATE STATISTICS [stat_cso_DimProduct_ClassName] ON [cso].[DimProduct]([ClassName]);
CREATE STATISTICS [stat_cso_DimProduct_ColorID] ON [cso].[DimProduct]([ColorID]);
CREATE STATISTICS [stat_cso_DimProduct_ColorName] ON [cso].[DimProduct]([ColorName]);
CREATE STATISTICS [stat_cso_DimProduct_ETLLoadID] ON [cso].[DimProduct]([ETLLoadID]);
CREATE STATISTICS [stat_cso_DimProduct_ImageURL] ON [cso].[DimProduct]([ImageURL]);
CREATE STATISTICS [stat_cso_DimProduct_LoadDate] ON [cso].[DimProduct]([LoadDate]);
CREATE STATISTICS [stat_cso_DimProduct_Manufacturer] ON [cso].[DimProduct]([Manufacturer]);
CREATE STATISTICS [stat_cso_DimProduct_ProductDescription] ON [cso].[DimProduct]([ProductDescription]);
CREATE STATISTICS [stat_cso_DimProduct_ProductKey] ON [cso].[DimProduct]([ProductKey]);
CREATE STATISTICS [stat_cso_DimProduct_ProductLabel] ON [cso].[DimProduct]([ProductLabel]);
CREATE STATISTICS [stat_cso_DimProduct_ProductName] ON [cso].[DimProduct]([ProductName]);
CREATE STATISTICS [stat_cso_DimProduct_ProductSubcategoryKey] ON [cso].[DimProduct]
([ProductSubcategoryKey]);
CREATE STATISTICS [stat_cso_DimProduct_ProductURL] ON [cso].[DimProduct]([ProductURL]);
CREATE STATISTICS [stat_cso_DimProduct_Size] ON [cso].[DimProduct]([Size]);
CREATE STATISTICS [stat_cso_DimProduct_SizeRange] ON [cso].[DimProduct]([SizeRange]);
CREATE STATISTICS [stat_cso_DimProduct_SizeUnitMeasureID] ON [cso].[DimProduct]([SizeUnitMeasureID]);
CREATE STATISTICS [stat_cso_DimProduct_Status] ON [cso].[DimProduct]([Status]);
CREATE STATISTICS [stat_cso_DimProduct_StockTypeID] ON [cso].[DimProduct]([StockTypeID]);
CREATE STATISTICS [stat_cso_DimProduct_StockTypeName] ON [cso].[DimProduct]([StockTypeName]);
CREATE STATISTICS [stat_cso_DimProduct_StopSaleDate] ON [cso].[DimProduct]([StopSaleDate]);
CREATE STATISTICS [stat_cso_DimProduct_StyleID] ON [cso].[DimProduct]([StyleID]);
CREATE STATISTICS [stat_cso_DimProduct_StyleName] ON [cso].[DimProduct]([StyleName]);
CREATE STATISTICS [stat_cso_DimProduct_UnitCost] ON [cso].[DimProduct]([UnitCost]);
CREATE STATISTICS [stat_cso_DimProduct_UnitOfMeasureID] ON [cso].[DimProduct]([UnitOfMeasureID]);
CREATE STATISTICS [stat_cso_DimProduct_UnitOfMeasureName] ON [cso].[DimProduct]([UnitOfMeasureName]);
CREATE STATISTICS [stat_cso_DimProduct_UnitPrice] ON [cso].[DimProduct]([UnitPrice]);
CREATE STATISTICS [stat_cso_DimProduct_UpdateDate] ON [cso].[DimProduct]([UpdateDate]);
CREATE STATISTICS [stat_cso_DimProduct_Weight] ON [cso].[DimProduct]([Weight]);
CREATE STATISTICS [stat_cso_DimProduct_WeightUnitMeasureID] ON [cso].[DimProduct]([WeightUnitMeasureID]);
CREATE STATISTICS [stat_cso_FactOnlineSales_CurrencyKey] ON [cso].[FactOnlineSales]([CurrencyKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_CustomerKey] ON [cso].[FactOnlineSales]([CustomerKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_DateKey] ON [cso].[FactOnlineSales]([DateKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_OnlineSalesKey] ON [cso].[FactOnlineSales]([OnlineSalesKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_ProductKey] ON [cso].[FactOnlineSales]([ProductKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_PromotionKey] ON [cso].[FactOnlineSales]([PromotionKey]);
CREATE STATISTICS [stat_cso_FactOnlineSales_StoreKey] ON [cso].[FactOnlineSales]([StoreKey]);
```

Achievement unlocked!

You have successfully loaded public data into your data warehouse. Great job!

You can now start querying the tables to explore your data. Run the following query to find out total sales per brand:

```
SELECT  SUM(f.[SalesAmount]) AS [sales_by_brand_amount]
,       p.[BrandName]
FROM    [cso].[FactOnlineSales] AS f
JOIN    [cso].[DimProduct]      AS p ON f.[ProductKey] = p.[ProductKey]
GROUP BY p.[BrandName]
```

Next steps

To load the full data set, run the example load the full Contoso retail data warehouse from the Microsoft SQL Server samples repository. For more development tips, see Design decisions and coding techniques for data warehouses.

Tutorial: Load data to Azure Synapse Analytics SQL pool

8/19/2022 • 26 minutes to read • Edit Online

This tutorial uses PolyBase to load the WideWorldImportersDW data warehouse from Azure Blob storage to your data warehouse in Azure Synapse Analytics SQL pool. The tutorial uses the Azure portal and SQL Server Management Studio (SSMS) to:

- Create a user designated for loading data
- Create external tables that use Azure blob as the data source
- Use the CTAS T-SQL statement to load data into your data warehouse
- View the progress of data as it is loading
- Generate a year of data in the date dimension and sales fact tables
- Create statistics on the newly loaded data

If you don't have an Azure subscription, create a free account before you begin.

Before you begin

Before you begin this tutorial, download and install the newest version of SQL Server Management Studio (SSMS).

This tutorial assumes you have already created a SQL dedicated pool from the following tutorial.

> **NOTE**
> It is recommended to use at least a DW1000c for this tutorial.

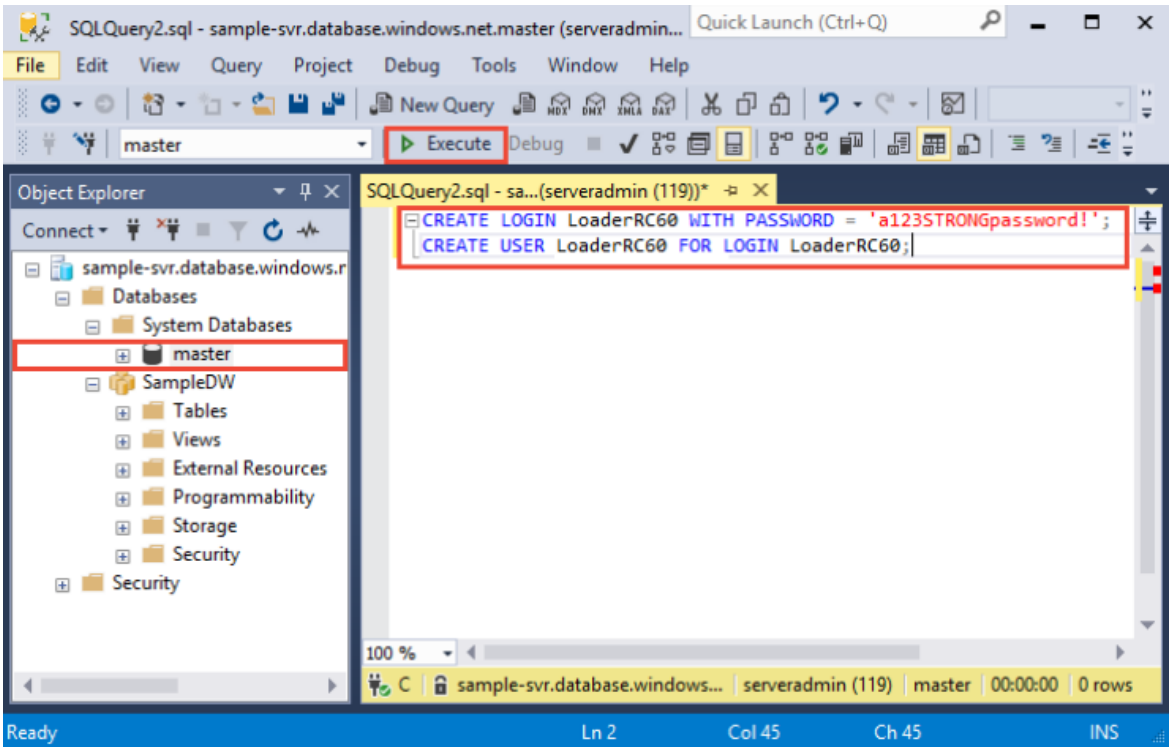
Create a user for loading data

The server admin account is meant to perform management operations, and is not suited for running queries on user data. Loading data is a memory-intensive operation. Memory maximums are defined according to the Generation of SQL pool you're using, data warehouse units, and resource class.

It's best to create a login and user that is dedicated for loading data. Then add the loading user to a resource class that enables an appropriate maximum memory allocation.

Since you are currently connected as the server admin, you can create logins and users. Use these steps to create a login and user called **LoaderRC60**. Then assign the user to the **staticrc60** resource class.

1. In SSMS, right-click **master** to show a drop-down menu, and choose **New Query**. A new query window opens.

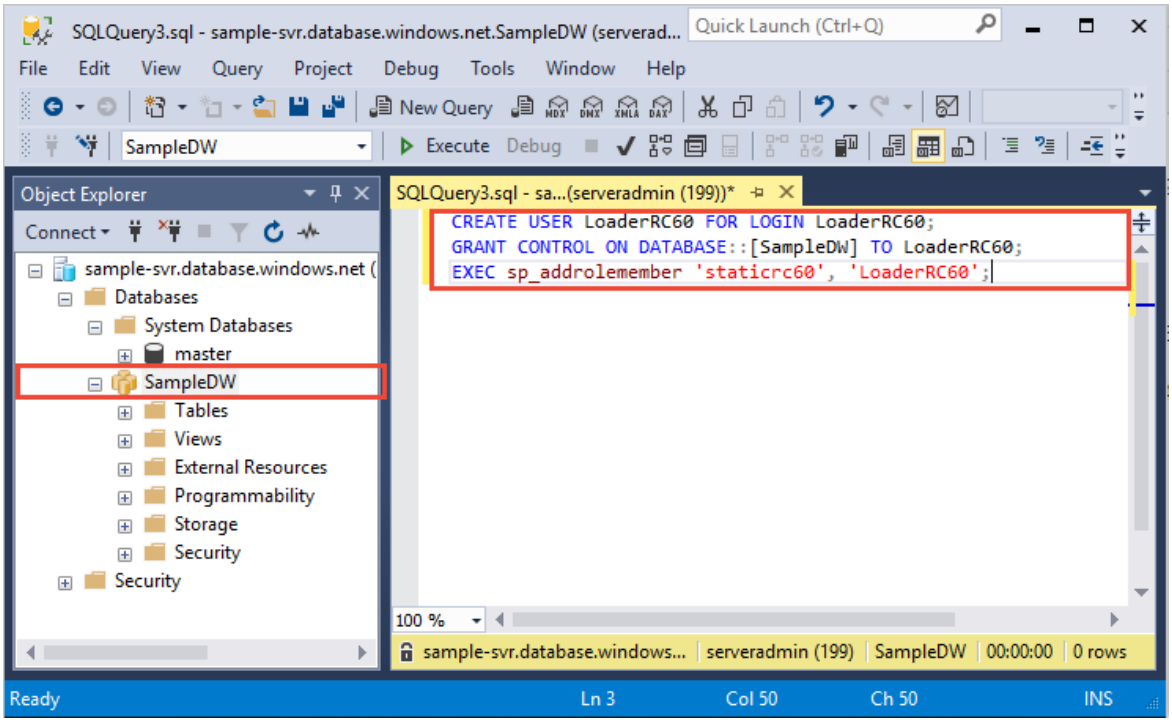


2. In the query window, enter these T-SQL commands to create a login and user named LoaderRC60, substituting your own password for 'a123STRONGpassword!'.

```
CREATE LOGIN LoaderRC60 WITH PASSWORD = 'a123STRONGpassword!';
CREATE USER LoaderRC60 FOR LOGIN LoaderRC60;
```

3. Click **Execute**.

4. Right-click **SampleDW**, and choose **New Query**. A new query Window opens.



5. Enter the following T-SQL commands to create a database user named LoaderRC60 for the LoaderRC60 login. The second line grants the new user CONTROL permissions on the new data warehouse. These permissions are similar to making the user the owner of the database. The third line adds the new user as a member of the `staticrc60` resource class.

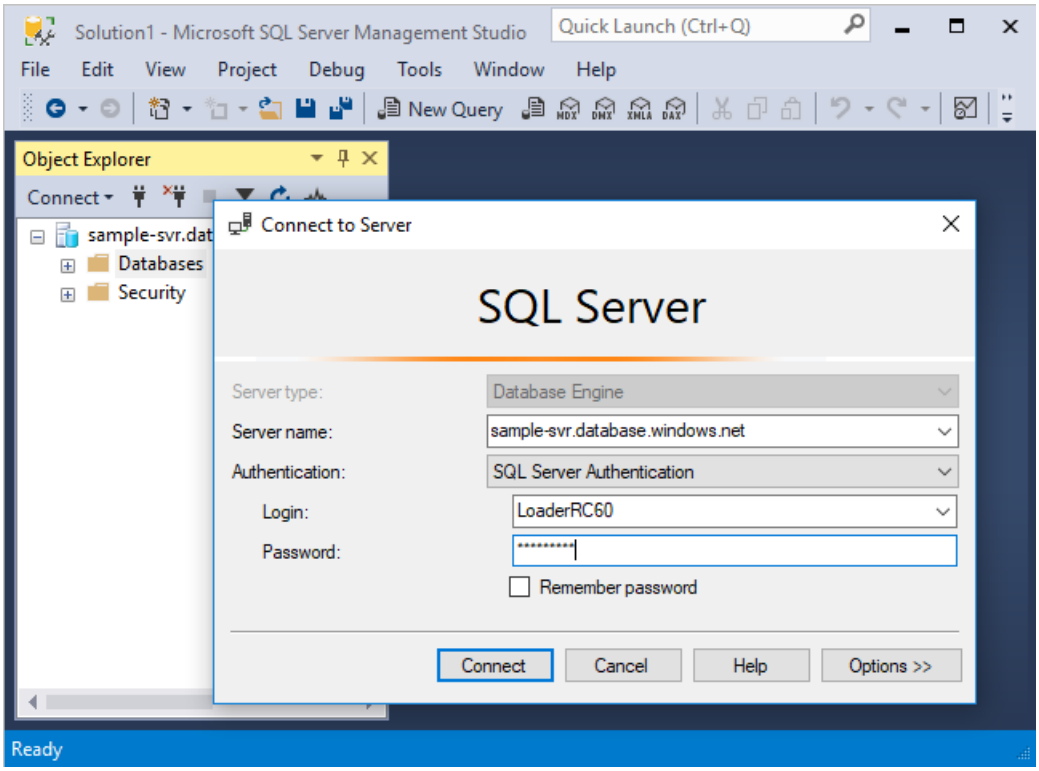
```
CREATE USER LoaderRC60 FOR LOGIN LoaderRC60;
GRANT CONTROL ON DATABASE::[SampleDW] to LoaderRC60;
EXEC sp_addrolemember 'staticrc60', 'LoaderRC60';
```

6. Click **Execute**.

Connect to the server as the loading user

The first step toward loading data is to login as LoaderRC60.

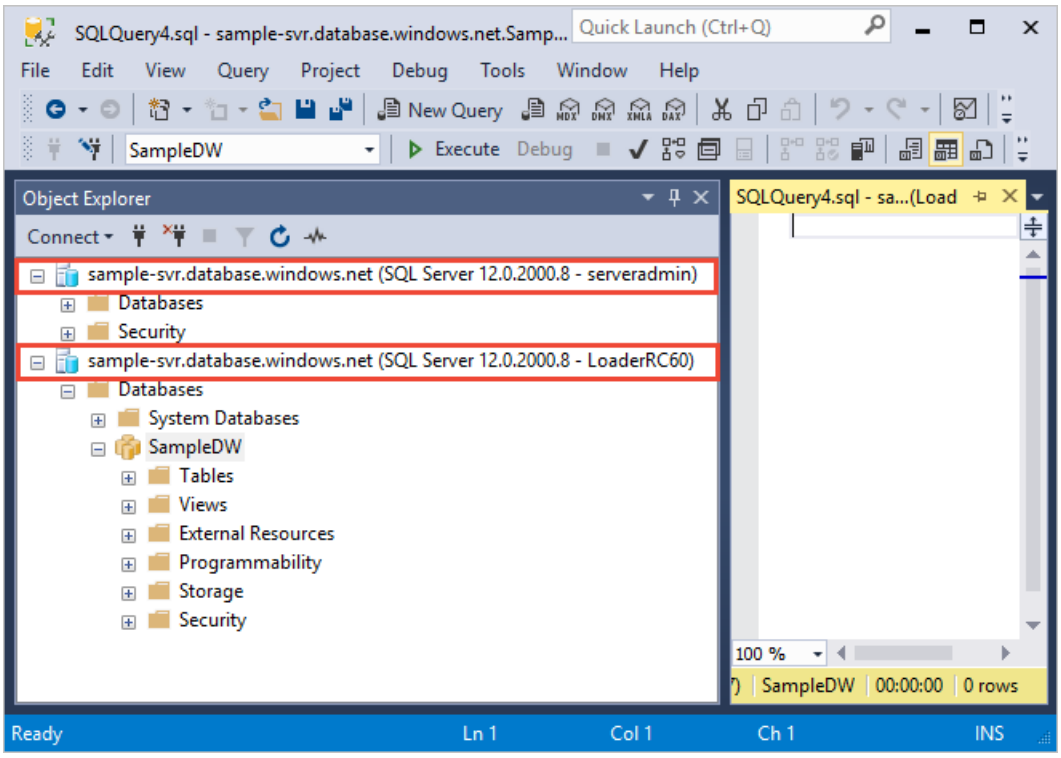
1. In Object Explorer, click the **Connect** drop down menu and select **Database Engine**. The **Connect to Server** dialog box appears.



2. Enter the fully qualified server name, and enter **LoaderRC60** as the Login. Enter your password for LoaderRC60.

3. Click **Connect**.

4. When your connection is ready, you will see two server connections in Object Explorer. One connection as ServerAdmin and one connection as LoaderRC60.

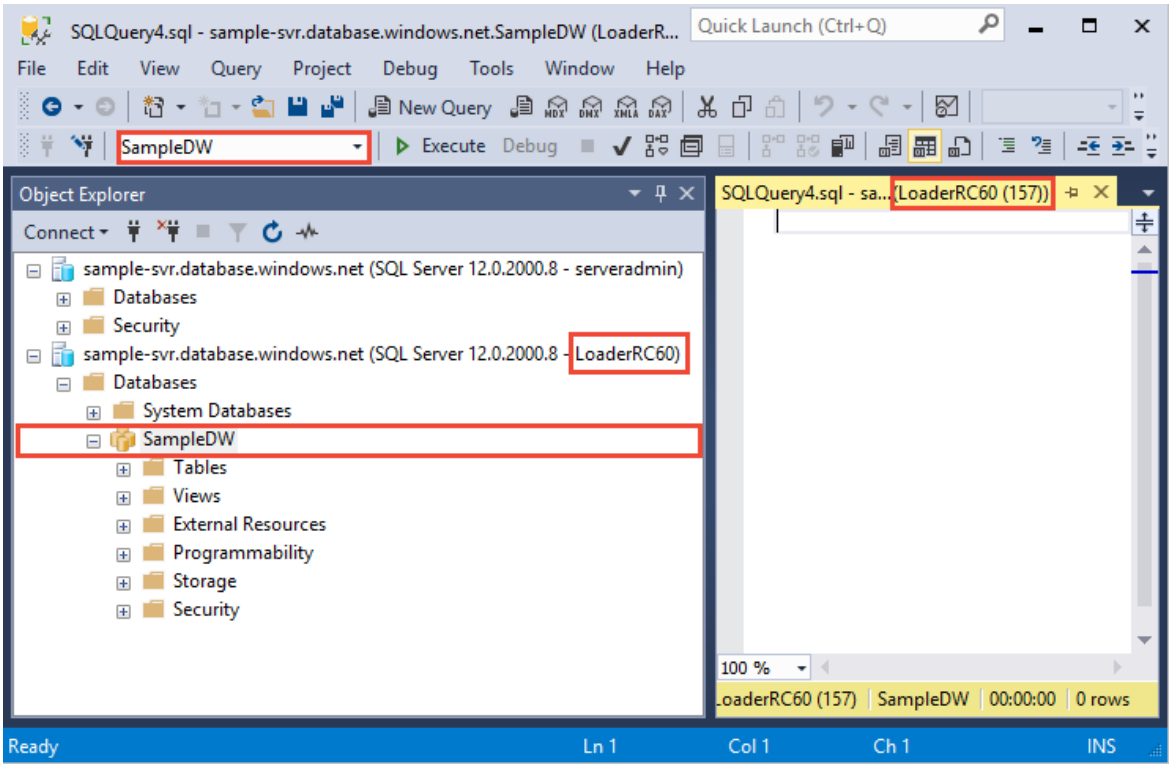


Create external tables and objects

You are ready to begin the process of loading data into your new data warehouse. For future reference, to learn how to get your data to Azure Blob storage or to load it directly from your source into SQL pool, see the loading overview.

Run the following SQL scripts to specify information about the data you wish to load. This information includes where the data is located, the format of the contents of the data, and the table definition for the data. The data is located in a global Azure Blob.

1. In the previous section, you logged into your data warehouse as LoaderRC60. In SSMS, right-click **SampleDW** under your LoaderRC60 connection and select **New Query**. A new query window appears.



2. Compare your query window to the previous image. Verify your new query window is running as

LoaderRC60 and performing queries on your SampleDW database. Use this query window to perform all of the loading steps.

3. Create a master key for the SampleDW database. You only need to create a master key once per database.

```
CREATE MASTER KEY;
```

4. Run the following CREATE EXTERNAL DATA SOURCE statement to define the location of the Azure blob. This is the location of the external worldwide importers data. To run a command that you have appended to the query window, highlight the commands you wish to run and click **Execute**.

```
CREATE EXTERNAL DATA SOURCE WWIStorage
WITH
(
    TYPE = Hadoop,
    LOCATION = 'wasbs://wideworldimporters@sqldwholdata.blob.core.windows.net'
);
```

5. Run the following CREATE EXTERNAL FILE FORMAT T-SQL statement to specify the formatting characteristics and options for the external data file. This statement specifies the external data is stored as text and the values are separated by the pipe ('|') character.

```
CREATE EXTERNAL FILE FORMAT TextFileFormat
WITH
(
    FORMAT_TYPE = DELIMITEDTEXT,
    FORMAT_OPTIONS
    (
        FIELD_TERMINATOR = '|',
        USE_TYPE_DEFAULT = FALSE
    )
);
```

6. Run the following CREATE SCHEMA statements to create a schema for your external file format. The ext schema provides a way to organize the external tables you are about to create. The wwi schema organizes the standard tables that will contain the data.

```
CREATE SCHEMA ext;
GO
CREATE SCHEMA wwi;
```

7. Create the external tables. The table definitions are stored in the database, but the tables reference data that is stored in Azure blob storage. Run the following T-SQL commands to create several external tables that all point to the Azure blob you defined previously in the external data source.

```
CREATE EXTERNAL TABLE [ext].[dimension_City](
    [City Key] [int] NOT NULL,
    [WWI City ID] [int] NOT NULL,
    [City] [nvarchar](50) NOT NULL,
    [State Province] [nvarchar](50) NOT NULL,
    [Country] [nvarchar](60) NOT NULL,
    [Continent] [nvarchar](30) NOT NULL,

    REJECT_VALUE = 0
);
```

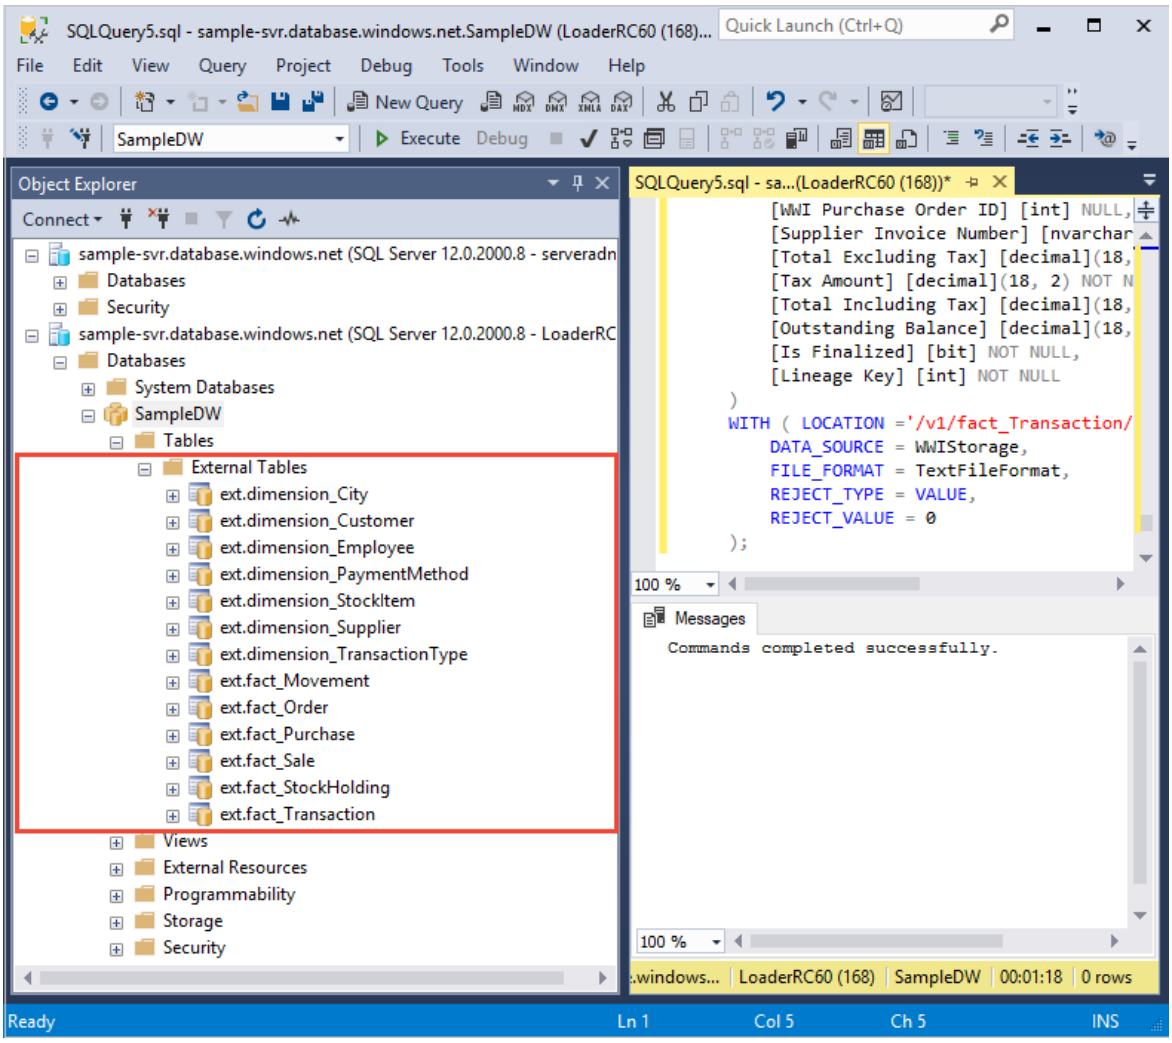
8. In Object Explorer, expand SampleDW to see the list of external tables you created.



Load the data into SQL pool

This section uses the external tables you defined to load the sample data from Azure Blob to SQL pool.

> **NOTE**
>
> This tutorial loads the data directly into the final table. In a production environment, you will usually use CREATE TABLE AS SELECT to load into a staging table. While data is in the staging table you can perform any necessary transformations. To append the data in the staging table to a production table, you can use the INSERT...SELECT statement. For more information, see Inserting data into a production table.

The script uses the CREATE TABLE AS SELECT (CTAS) T-SQL statement to load the data from Azure Storage Blob into new tables in your data warehouse. CTAS creates a new table based on the results of a select statement. The new table has the same columns and data types as the results of the select statement. When the select statement selects from an external table, the data is imported into a relational table in the data warehouse.

This script does not load data into the wwi.dimension_Date and wwi.fact_Sale tables. These tables are generated in a later step in order to make the tables have a sizeable number of rows.

1. Run the following script to load the data into new tables in your data warehouse.

```
CREATE TABLE [wwi].[dimension_City]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
```

```
AS
SELECT * FROM [ext].[dimension_City]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_City]')
;

CREATE TABLE [wwi].[dimension_Customer]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_Customer]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_Customer]')
;

CREATE TABLE [wwi].[dimension_Employee]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_Employee]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_Employee]')
;

CREATE TABLE [wwi].[dimension_PaymentMethod]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_PaymentMethod]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_PaymentMethod]')
;

CREATE TABLE [wwi].[dimension_StockItem]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_StockItem]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_StockItem]')
;

CREATE TABLE [wwi].[dimension_Supplier]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_Supplier]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_Supplier]')
;

CREATE TABLE [wwi].[dimension_TransactionType]
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[dimension_TransactionType]
OPTION (LABEL = 'CTAS : Load [wwi].[dimension_TransactionType]')
;
```

```
;

CREATE TABLE [wwi].[fact_Movement]
WITH
(
    DISTRIBUTION = HASH([Movement Key]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_Movement]
OPTION (LABEL = 'CTAS : Load [wwi].[fact_Movement]')
;

CREATE TABLE [wwi].[fact_Order]
WITH
(
    DISTRIBUTION = HASH([Order Key]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_Order]
OPTION (LABEL = 'CTAS : Load [wwi].[fact_Order]')
;

CREATE TABLE [wwi].[fact_Purchase]
WITH
(
    DISTRIBUTION = HASH([Purchase Key]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_Purchase]
OPTION (LABEL = 'CTAS : Load [wwi].[fact_Purchase]')
;

CREATE TABLE [wwi].[seed_Sale]
WITH
(
    DISTRIBUTION = HASH([WWI Invoice ID]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_Sale]
OPTION (LABEL = 'CTAS : Load [wwi].[seed_Sale]')
;

CREATE TABLE [wwi].[fact_StockHolding]
WITH
(
    DISTRIBUTION = HASH([Stock Holding Key]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_StockHolding]
OPTION (LABEL = 'CTAS : Load [wwi].[fact_StockHolding]')
;

CREATE TABLE [wwi].[fact_Transaction]
WITH
(
    DISTRIBUTION = HASH([Transaction Key]),
    CLUSTERED COLUMNSTORE INDEX
)
AS
SELECT * FROM [ext].[fact_Transaction]
OPTION (LABEL = 'CTAS : Load [wwi].[fact_Transaction]')
;
```

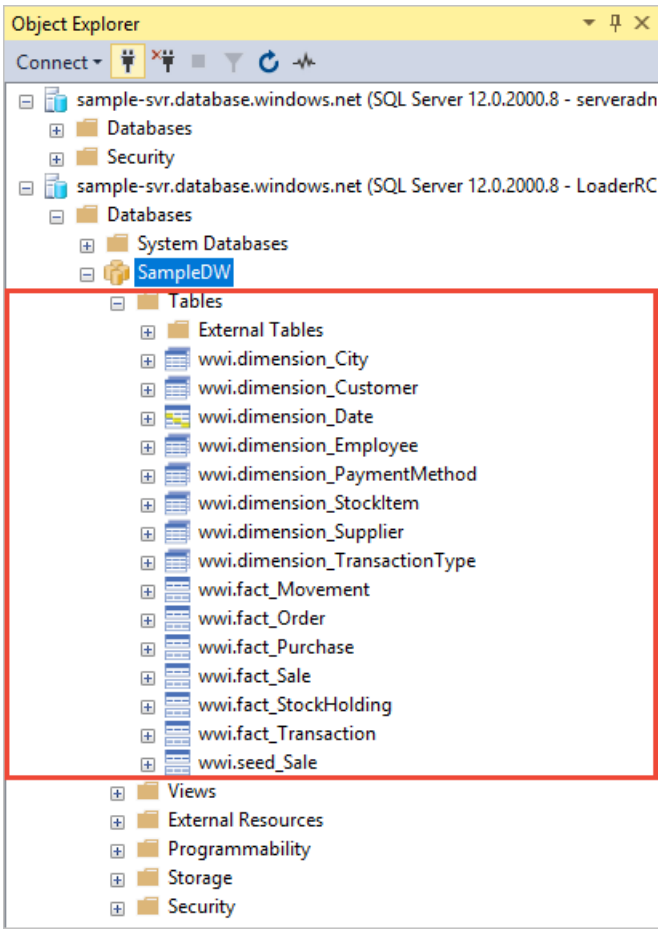
2. View your data as it loads. You're loading several GBs of data and compressing it into highly performant clustered columnstore indexes. Open a new query window on SampleDW, and run the following query to show the status of the load. After starting the query, grab a coffee and a snack while SQL pool does some heavy lifting.

```
SELECT
    r.command,
    s.request_id,
    r.status,
    count(distinct input_name) as nbr_files,
    sum(s.bytes_processed)/1024/1024/1024 as gb_processed
FROM
    sys.dm_pdw_exec_requests r
    INNER JOIN sys.dm_pdw_dms_external_work s
    ON r.request_id = s.request_id
WHERE
    r.[label] = 'CTAS : Load [wwi].[dimension_City]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_Customer]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_Employee]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_PaymentMethod]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_StockItem]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_Supplier]' OR
    r.[label] = 'CTAS : Load [wwi].[dimension_TransactionType]' OR
    r.[label] = 'CTAS : Load [wwi].[fact_Movement]' OR
    r.[label] = 'CTAS : Load [wwi].[fact_Order]' OR
    r.[label] = 'CTAS : Load [wwi].[fact_Purchase]' OR
    r.[label] = 'CTAS : Load [wwi].[fact_StockHolding]' OR
    r.[label] = 'CTAS : Load [wwi].[fact_Transaction]'
GROUP BY
    r.command,
    s.request_id,
    r.status
ORDER BY
    nbr_files desc,
    gb_processed desc;
```

3. View all system queries.

```
SELECT * FROM sys.dm_pdw_exec_requests;
```

4. Enjoy seeing your data nicely loaded into your data warehouse.



Create tables and procedures to generate the Date and Sales tables

This section creates the wwi.dimension_Date and wwi.fact_Sale tables. It also creates stored procedures that can generate millions of rows in the wwi.dimension_Date and wwi.fact_Sale tables.

1. Create the dimension_Date and fact_Sale tables.

```
CREATE TABLE [wwi].[dimension_Date]
(
    [Date] [datetime] NOT NULL,
    [Day Number] [int] NOT NULL,
    [Day] [nvarchar](10) NOT NULL,
    [Month] [nvarchar](10) NOT NULL,
    [Short Month] [nvarchar](3) NOT NULL,
    [Calendar Month Number] [int] NOT NULL,
    [Calendar Month Label] [nvarchar](20) NOT NULL,
    [Calendar Year] [int] NOT NULL,
    [Calendar Year Label] [nvarchar](10) NOT NULL,
    [Fiscal Month Number] [int] NOT NULL,
    [Fiscal Month Label] [nvarchar](20) NOT NULL,
    [Fiscal Year] [int] NOT NULL,
    [Fiscal Year Label] [nvarchar](10) NOT NULL,
    [ISO Week Number] [int] NOT NULL
)
WITH
(
    DISTRIBUTION = REPLICATE,
    CLUSTERED INDEX ([Date])
);
CREATE TABLE [wwi].[fact_Sale]
(
    [Sale Key] [bigint] IDENTITY(1,1) NOT NULL,
    [City Key] [int] NOT NULL,
    [Customer Key] [int] NOT NULL,
    [Bill To Customer Key] [int] NOT NULL,
    [Stock Item Key] [int] NOT NULL,
    [Invoice Date Key] [date] NOT NULL,
    [Delivery Date Key] [date] NULL,
    [Salesperson Key] [int] NOT NULL,
    [WWI Invoice ID] [int] NOT NULL,
    [Description] [nvarchar](100) NOT NULL,
    [Package] [nvarchar](50) NOT NULL,
    [Quantity] [int] NOT NULL,
    [Unit Price] [decimal](18, 2) NOT NULL,
    [Tax Rate] [decimal](18, 3) NOT NULL,
    [Total Excluding Tax] [decimal](18, 2) NOT NULL,
    [Tax Amount] [decimal](18, 2) NOT NULL,
    [Profit] [decimal](18, 2) NOT NULL,
    [Total Including Tax] [decimal](18, 2) NOT NULL,
    [Total Dry Items] [int] NOT NULL,
    [Total Chiller Items] [int] NOT NULL,
    [Lineage Key] [int] NOT NULL
)
WITH
(
    DISTRIBUTION = HASH ( [WWI Invoice ID] ),
    CLUSTERED COLUMNSTORE INDEX
)
```

2. Create [wwi].[InitialSalesDataPopulation] to increase the number of rows in [wwi].[seed_Sale] by a factor of eight.

```
CREATE PROCEDURE [wwi].[InitialSalesDataPopulation] AS
BEGIN
    INSERT INTO [wwi].[seed_Sale] (
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    )
    SELECT
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    FROM [wwi].[seed_Sale]

    INSERT INTO [wwi].[seed_Sale] (
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    )
    SELECT
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    FROM [wwi].[seed_Sale]

    INSERT INTO [wwi].[seed_Sale] (
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    )
    SELECT
        [Sale Key], [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice
Date Key], [Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], [Package],
[Quantity], [Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], [Profit], [Total Including
Tax], [Total Dry Items], [Total Chiller Items], [Lineage Key]
    FROM [wwi].[seed_Sale]
END
```

3. Create this stored procedure that populates rows into wwi.dimension_Date.

```
CREATE PROCEDURE [wwi].[PopulateDateDimensionForYear] @Year [int] AS
BEGIN
    IF OBJECT_ID('tempdb..#month', 'U') IS NOT NULL
        DROP TABLE #month
    CREATE TABLE #month (
        monthnum int,
        numofdays int
    )
    WITH ( DISTRIBUTION = ROUND_ROBIN, heap )
    INSERT INTO #month
        SELECT 1, 31 UNION SELECT 2, CASE WHEN (@YEAR % 4 = 0 AND @YEAR % 100 <> 0) OR @YEAR % 400 =
0 THEN 29 ELSE 28 END UNION SELECT 3,31 UNION SELECT 4,30 UNION SELECT 5,31 UNION SELECT 6,30 UNION
SELECT 7,31 UNION SELECT 8,31 UNION SELECT 9,30 UNION SELECT 10,31 UNION SELECT 11,30 UNION SELECT
12,31

    IF OBJECT_ID('tempdb..#days', 'U') IS NOT NULL
        DROP TABLE #days
    CREATE TABLE #days (days int)
    WITH (DISTRIBUTION = ROUND_ROBIN, HEAP)

    INSERT INTO #days
        SELECT 1 UNION SELECT 2 UNION SELECT 3 UNION SELECT 4 UNION SELECT 5 UNION SELECT 6 UNION
```

```
SELECT 7 UNION SELECT 8 UNION SELECT 9 UNION SELECT 10 UNION SELECT 11 UNION SELECT 12 UNION SELECT
13 UNION SELECT 14 UNION SELECT 15 UNION SELECT 16 UNION SELECT 17 UNION SELECT 18 UNION SELECT 19
UNION SELECT 20    UNION SELECT 21 UNION SELECT 22 UNION SELECT 23 UNION SELECT 24 UNION SELECT 25
UNION SELECT 26 UNION SELECT 27 UNION SELECT 28 UNION SELECT 29 UNION SELECT 30 UNION SELECT 31

    INSERT [wwi].[dimension_Date] (
        [Date], [Day Number], [Day], [Month], [Short Month], [Calendar Month Number], [Calendar Month
Label], [Calendar Year], [Calendar Year Label], [Fiscal Month Number], [Fiscal Month Label], [Fiscal
Year], [Fiscal Year Label], [ISO Week Number]
    )
    SELECT
        CAST(CAST(monthnum AS VARCHAR(2)) + '/' + CAST([days] AS VARCHAR(3)) + '/' + CAST(@year AS
CHAR(4)) AS DATE) AS [Date]
        ,DAY(CAST(CAST(monthnum AS VARCHAR(2)) + '/' + CAST([days] AS VARCHAR(3)) + '/' + CAST(@year
AS CHAR(4)) AS DATE)) AS [Day Number]
        ,CAST(DATENAME(day, CAST(CAST(monthnum AS VARCHAR(2)) + '/' + CAST([days] AS VARCHAR(3)) +
'/' + CAST(@year AS CHAR(4)) AS DATE)) AS NVARCHAR(10)) AS [Day]
        ,CAST(DATENAME(month, CAST(CAST(monthnum AS VARCHAR(2)) + '/' + CAST([days] AS VARCHAR(3)) +
'/' + CAST(@year as char(4)) AS DATE)) AS nvarchar(10)) AS [Month]
        ,CAST(SUBSTRING(DATENAME(month, CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as
varchar(3)) + '/' + CAST(@year as char(4)) AS DATE)), 1, 3) AS nvarchar(3)) AS [Short Month]
        ,MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) AS [Calendar Month Number]
        ,CAST(N'CY' + CAST(YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3))
+ '/' + CAST(@year as char(4)) AS DATE)) AS nvarchar(4)) + N'-' + SUBSTRING(DATENAME(month,
CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' + CAST(@year as char(4))
AS DATE)), 1, 3) AS nvarchar(10)) AS [Calendar Month Label]
        ,YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' + CAST(@year
as char(4)) AS DATE)) AS [Calendar Year]
        ,CAST(N'CY' + CAST(YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3))
+ '/' + CAST(@year as char(4)) AS DATE)) AS nvarchar(4)) AS nvarchar(10)) AS [Calendar Year Label]
        ,CASE WHEN MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) IN (11, 12)
        THEN MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) - 10
        ELSE MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) + 2 END AS [Fiscal Month Number]
        ,CAST(N'FY' + CAST(CASE WHEN MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as
varchar(3)) + '/' + CAST(@year as char(4)) AS DATE)) IN (11, 12)
        THEN YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) + 1
        ELSE YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) END AS nvarchar(4)) + N'-' + SUBSTRING(DATENAME(month,
CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' + CAST(@year as char(4))
AS DATE)), 1, 3) AS nvarchar(20)) AS [Fiscal Month Label]
        ,CASE WHEN MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) IN (11, 12)
        THEN YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) + 1
        ELSE YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) END AS [Fiscal Year]
        ,CAST(N'FY' + CAST(CASE WHEN MONTH(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as
varchar(3)) + '/' + CAST(@year as char(4)) AS DATE)) IN (11, 12)
        THEN YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE)) + 1
        ELSE YEAR(CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) + '/' +
CAST(@year as char(4)) AS DATE))END AS nvarchar(4)) AS nvarchar(10)) AS [Fiscal Year Label]
        , DATEPART(ISO_WEEK, CAST(CAST(monthnum as varchar(2)) + '/' + CAST([days] as varchar(3)) +
'/' + CAST(@year as char(4)) AS DATE)) AS [ISO Week Number]
FROM #month m
    CROSS JOIN #days d
WHERE d.days <= m.numofdays

DROP table #month;
DROP table #days;
END;
```

4. Create this procedure that populates the wwi.dimension_Date and wwi.fact_Sale tables. It calls [wwi].[PopulateDateDimensionForYear] to populate wwi.dimension_Date.

```
CREATE PROCEDURE [wwi].[Configuration_PopulateLargeSaleTable] @EstimatedRowsPerDay [bigint],@Year
[int] AS
BEGIN
    SET NOCOUNT ON;
    SET XACT_ABORT ON;

    EXEC [wwi].[PopulateDateDimensionForYear] @Year;

    DECLARE @OrderCounter bigint = 0;
    DECLARE @NumberOfSalesPerDay bigint = @EstimatedRowsPerDay;
    DECLARE @DateCounter date;
    DECLARE @StartingSaleKey bigint;
    DECLARE @MaximumSaleKey bigint = (SELECT MAX([Sale Key]) FROM wwi.seed_Sale);
    DECLARE @MaxDate date;
    SET @MaxDate = (SELECT MAX([Invoice Date Key]) FROM wwi.fact_Sale)
    IF ( @MaxDate < CAST(@YEAR AS CHAR(4)) + '1231') AND (@MaxDate > CAST(@YEAR AS CHAR(4)) + '0101')
        SET @DateCounter = @MaxDate
    ELSE
        SET @DateCounter= CAST(@Year as char(4)) + '0101';

    PRINT 'Targeting ' + CAST(@NumberOfSalesPerDay AS varchar(20)) + ' sales per day.';

    DECLARE @OutputCounter varchar(20);
    DECLARE @variance DECIMAL(18,10);
    DECLARE @VariantNumberOfSalesPerDay BIGINT;

    WHILE @DateCounter < CAST(@YEAR AS CHAR(4)) + '1231'
    BEGIN
        SET @OutputCounter = CONVERT(varchar(20), @DateCounter, 112);
        RAISERROR(@OutputCounter, 0, 1);
        SET @variance = (SELECT RAND() * 10)*.01 + .95
        SET @VariantNumberOfSalesPerDay = FLOOR(@NumberOfSalesPerDay * @variance)

        SET @StartingSaleKey = @MaximumSaleKey - @VariantNumberOfSalesPerDay - FLOOR(RAND() * 20000);
        SET @OrderCounter = 0;

        INSERT [wwi].[fact_Sale] (
            [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], [Invoice Date Key],
[Delivery Date Key], [Salesperson Key], [WWI Invoice ID], [Description], Package, Quantity, [Unit
Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], Profit, [Total Including Tax], [Total Dry
Items], [Total Chiller Items], [Lineage Key]
        )
        SELECT TOP(@VariantNumberOfSalesPerDay)
            [City Key], [Customer Key], [Bill To Customer Key], [Stock Item Key], @DateCounter,
DATEADD(day, 1, @DateCounter), [Salesperson Key], [WWI Invoice ID], [Description], Package, Quantity,
[Unit Price], [Tax Rate], [Total Excluding Tax], [Tax Amount], Profit, [Total Including Tax], [Total
Dry Items], [Total Chiller Items], [Lineage Key]
        FROM [wwi].[seed_Sale]
        WHERE
             --[Sale Key] > @StartingSaleKey and /* IDENTITY DOES NOT WORK THE SAME IN SQLDW AND
CAN'T USE THIS METHOD FOR VARIANT */
            [Invoice Date Key] >=cast(@YEAR AS CHAR(4)) + '-01-01'
        ORDER BY [Sale Key];

        SET @DateCounter = DATEADD(day, 1, @DateCounter);
    END;

END;
```

Generate millions of rows

Use the stored procedures you created to generate millions of rows in the wwi.fact_Sale table, and

corresponding data in the wwi.dimension_Date table.

1. Run this procedure to seed the [wwi].[seed_Sale] with more rows.

```
EXEC [wwi].[InitialSalesDataPopulation]
```

2. Run this procedure to populate wwi.fact_Sale with 100,000 rows per day for each day in the year 2000.

```
EXEC [wwi].[Configuration_PopulateLargeSaleTable] 100000, 2000
```

3. The data generation in the previous step might take a while as it progresses through the year. To see which day the current process is on, open a new query and run this SQL command:

```
SELECT MAX([Invoice Date Key]) FROM wwi.fact_Sale;
```

4. Run the following command to see the space used.

```
EXEC sp_spaceused N'wwi.fact_Sale';
```

Populate the replicated table cache

SQL pool replicates a table by caching the data to each Compute node. The cache gets populated when a query runs against the table. Therefore, the first query on a replicated table might require extra time to populate the cache. After the cache is populated, queries on replicated tables run faster.

Run these SQL queries to populate the replicated table cache on the Compute nodes.

```
SELECT TOP 1 * FROM [wwi].[dimension_City];
SELECT TOP 1 * FROM [wwi].[dimension_Customer];
SELECT TOP 1 * FROM [wwi].[dimension_Date];
SELECT TOP 1 * FROM [wwi].[dimension_Employee];
SELECT TOP 1 * FROM [wwi].[dimension_PaymentMethod];
SELECT TOP 1 * FROM [wwi].[dimension_StockItem];
SELECT TOP 1 * FROM [wwi].[dimension_Supplier];
SELECT TOP 1 * FROM [wwi].[dimension_TransactionType];
```

Create statistics on newly loaded data

To achieve high query performance, it's important to create statistics on each column of each table after the first load. It's also important to update statistics after substantial changes in the data.

1. Create this stored procedure that updates statistics on all columns of all tables.

```
CREATE PROCEDURE    [dbo].[prc_sqldw_create_stats]
(   @create_type    tinyint -- 1 default 2 Fullscan 3 Sample
,   @sample_pct     tinyint
)
AS

IF @create_type IS NULL
BEGIN
    SET @create_type = 1;
END;

IF @create_type NOT IN (1,2,3)
BEGIN
```

```
BEGIN
    THROW 151000,'Invalid value for @stats_type parameter. Valid range 1 (default), 2 (fullscan) or 3
(sample).',1;
END;

IF @sample_pct IS NULL
BEGIN;
    SET @sample_pct = 20;
END;

IF OBJECT_ID('tempdb..#stats_ddl') IS NOT NULL
BEGIN;
    DROP TABLE #stats_ddl;
END;

CREATE TABLE #stats_ddl

;

DECLARE @i INT              = 1
,       @t INT              = (SELECT COUNT(*) FROM #stats_ddl)
,       @s NVARCHAR(4000)   = N''
```

```
;

WHILE @i <= @t
BEGIN
    SET @s=(SELECT create_stat_ddl FROM #stats_ddl WHERE seq_nmbr = @i);
    PRINT @s
    EXEC sp_executesql @s
    SET @i+=1;
END

DROP TABLE #stats_ddl;
```

2. Run this command to create statistics on all columns of all tables in the data warehouse.

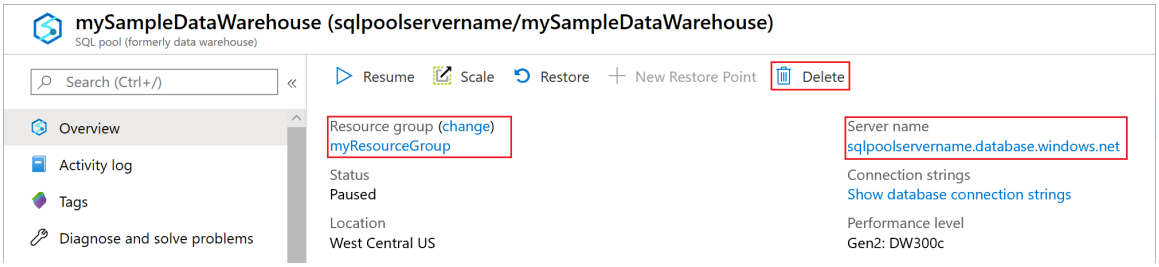
```
EXEC [dbo].[prc_sqldw_create_stats] 1, NULL;
```

Clean up resources

You are being charged for compute resources and data that you loaded into your data warehouse. These are billed separately.

Follow these steps to clean up resources as you desire.

1. Sign in to the Azure portal, click on your data warehouse.



2. If you want to keep the data in storage, you can pause compute when you aren't using the data warehouse. By pausing compute, you will only be charge for data storage and you can resume the compute whenever you are ready to work with the data. To pause compute, click the **Pause** button. When the data warehouse is paused, you will see a **Start** button. To resume compute, click **Start**.

3. If you want to remove future charges, you can delete the data warehouse. To remove the data warehouse so you won't be charged for compute or storage, click **Delete**.

4. To remove the server you created, click **sample-svr.database.windows.net** in the previous image, and then click **Delete**. Be careful with this as deleting the server will delete all databases assigned to the server.

5. To remove the resource group, click **SampleRG**, and then click **Delete resource group**.

Next steps

In this tutorial, you learned how to create a data warehouse and create a user for loading data. You created external tables to define the structure for data stored in Azure Storage Blob, and then used the PolyBase CREATE TABLE AS SELECT statement to load data into your data warehouse.

You did these things:

- Created a data warehouse using SQL pool in the Azure portal
- Set up a server-level firewall rule in the Azure portal
- Connected to the SQL pool with SSMS

- Created a user designated for loading data
- Created external tables for data in Azure Storage Blob
- Used the CTAS T-SQL statement to load data into your data warehouse
- Viewed the progress of data as it is loading
- Created statistics on the newly loaded data

Advance to the development overview to learn how to migrate an existing database to Azure Synapse SQL pool.

Design decisions to migrate an existing database to SQL pool

Ingest data into a dedicated SQL pool

8/19/2022 • 3 minutes to read • Edit Online

In this article, you'll learn how to ingest data from an Azure Data Lake Gen 2 storage account into a dedicated SQL pool in Azure Synapse Analytics.

Prerequisites

- **Azure subscription**: If you don't have an Azure subscription, create a free Azure account before you begin.
- **Azure storage account**: You use Azure Data Lake Storage Gen 2 as a *source* data store. If you don't have a storage account, see Create an Azure Storage account for steps to create one.
- **Azure Synapse Analytics**: You use a dedicated SQL pool as a *sink* data store.
  - If you don't have an existing Synapse workspace, see Creating a Synapse workspace
  - If you don't have an existing dedicated SQL pool. see Create a dedicated SQL pool.

Create linked services

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll add an Azure Synapse Analytics and Azure Data Lake Storage Gen2 linked service.

1. Open the Azure Synapse Analytics UX and go to the **Manage** tab.
2. Under **External connections**, select **Linked services**.
3. To add a linked service, select **New**.
4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
5. Enter your authentication credentials. Account key, service principal, and managed identity are currently supported authentication types. Select test connection to verify your credentials are correct. Select **Create** when finished.
6. Repeat steps 3-5, but instead of Azure Data Lake Storage Gen2, select the Azure Synapse Analytics tile and enter in the corresponding connection credentials. For Azure Synapse Analytics, SQL authentication, managed identity, and service principal are currently supported.

Create pipeline

A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline containing a copy activity that ingests data from ADLS Gen2 into a dedicated SQL pool.

1. Go to the **Integrate** tab. Select on the plus icon next to the pipelines header and select **Pipeline**.
2. Under **Move and Transform** in the activities pane, drag **Copy data** onto the pipeline canvas.
3. Select on the copy activity and go to the **Source** tab. Select **New** to create a new source dataset.
4. Select Azure Data Lake Storage gen2 as your data store and select continue.
5. Select DelimitedText as your format and select continue.
6. In the set properties pane, select the ADLS linked service you created. Specify the file path of your source data and specify whether the first row has a header. You can import the schema from the file store or a sample file. Select OK when finished.
7. Go to the **Sink** tab. Select **New** to create a new sink dataset.
8. Select Azure Synapse Analytics as your data store and select continue.
9. In the set properties pane, select the Azure Synapse Analytics linked service you created. If you're writing to an existing table, select it from the dropdown. Otherwise, check **Edit** and enter in your new table name.

Select OK when finished

10. If you're creating a table, enable **Auto create table** in the table option field.

Debug and publish pipeline

Once you've finished configuring your pipeline, you can execute a debug run before you publish your artifacts to verify everything is correct.

1. To debug the pipeline, select **Debug** on the toolbar. You see the status of the pipeline run in the **Output** tab at the bottom of the window.
2. Once the pipeline can run successfully, in the top toolbar, select **Publish All**. This action publishes entities (datasets, and pipelines) you created to the Synapse Analytics service.
3. Wait until you see the **Successfully published** message. To see notification messages, select the bell button on the top-right.

Trigger and monitor the pipeline

In this step, you manually trigger the pipeline published in the previous step.

1. Select **Add Trigger** on the toolbar, and then select **Trigger Now**. On the **Pipeline Run** page, select **Finish**.
2. Go to the **Monitor** tab located in the left sidebar. You see a pipeline run that is triggered by a manual trigger. You can use links in the **Actions** column to view activity details and to rerun the pipeline.
3. To see activity runs associated with the pipeline run, select the **View Activity Runs** link in the **Actions** column. In this example, there's only one activity, so you see only one entry in the list. For details about the copy operation, select the **Details** link (eyeglasses icon) in the **Actions** column. Select **Pipeline Runs** at the top to go back to the Pipeline Runs view. To refresh the view, select **Refresh**.
4. Verify your data is correctly written in the dedicated SQL pool.

Next steps

For more information on data integration for Azure Synapse Analytics, see the Ingesting data into Azure Data Lake Storage Gen2 article.

Ingest data into Azure Data Lake Storage Gen2

8/19/2022 • 3 minutes to read • Edit Online

In this article, you'll learn how to ingest data from one location to another in an Azure Data Lake Gen 2 (Azure Data Lake Gen 2) storage account using Azure Synapse Analytics.

Prerequisites

- **Azure subscription**: If you don't have an Azure subscription, create a free Azure account before you begin.
- **Azure Storage account**: You use Azure Data Lake Gen 2 as a *source* data store. If you don't have a storage account, see Create an Azure Storage account for steps to create one.

Create linked services

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll add Azure Synapse Analytics and Azure Data Lake Gen 2 as linked services.

1. Open the Azure Synapse Analytics UX and go to the **Manage** tab.
2. Under **External connections**, select **Linked services**.
3. To add a linked service, select **New**.
4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
5. Enter your authentication credentials. Account key, service principal, and managed identity are currently supported authentication types. Select test connection to verify your credentials are correct.
6. Select **Create** when finished.

Create pipeline

A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline containing a copy activity that ingests data from Azure Data Lake Gen 2 into a dedicated SQL pool.

1. Go to the **Orchestrate** tab. Select on the plus icon next to the pipelines header and select **Pipeline**.
2. Under **Move and Transform** in the activities pane, drag **Copy data** onto the pipeline canvas.
3. Select on the copy activity and go to the **Source** tab. Select **New** to create a new source dataset.
4. Select Azure Data Lake Storage Gen2 as your data store and select continue.
5. Select DelimitedText as your format and select continue.
6. In the set properties pane, select the ADLS linked service you created. Specify the file path of your source data and specify whether the first row has a header. You can import the schema from the file store or a sample file. Select OK when finished.
7. Go to the **Sink** tab. Select **New** to create a new sink dataset.
8. Select Azure Data Lake Storage gen2 as your data store and select continue.
9. Select DelimitedText as your format and select continue.
10. In the set properties pane, select the ADLS linked service you created. Specify the path of the folder where you wish to write data. Select OK when finished.

Debug and publish pipeline

Once you've finished configuring your pipeline, you can execute a debug run before you publish your artifacts to verify everything is correct.

1. To debug the pipeline, select **Debug** on the toolbar. You see the status of the pipeline run in the **Output** tab at the bottom of the window.
2. Once the pipeline can run successfully, in the top toolbar, select **Publish All**. This action publishes entities (datasets, and pipelines) you created to the Synapse Analytics service.
3. Wait until you see the **Successfully published** message. To see notification messages, select the bell button on the top-right.

Trigger and monitor the pipeline

In this step, you manually trigger the pipeline published in the previous step.

1. Select **Add Trigger** on the toolbar, and then select **Trigger Now**. On the **Pipeline Run** page, select **Finish**.
2. Go to the **Monitor** tab located in the left sidebar. You see a pipeline run that is triggered by a manual trigger. You can use links in the **Actions** column to view activity details and to rerun the pipeline.
3. To see activity runs associated with the pipeline run, select the **View Activity Runs** link in the **Actions** column. In this example, there's only one activity, so you see only one entry in the list. For details about the copy operation, select the **Details** link (eyeglasses icon) in the **Actions** column. Select **Pipeline Runs** at the top to go back to the Pipeline Runs view. To refresh the view, select **Refresh**.
4. Verify your data is correctly written in the dedicated SQL pool.

Next steps

For more information on data integration for Azure Synapse Analytics, see the Ingesting data into a dedicated SQL pool article.

Getting started with Visual Studio 2019

8/19/2022 • 2 minutes to read • Edit Online

Visual Studio **2019** SQL Server Data Tools (SSDT) is a single tool allowing you to do the following:

- Connect, query, and develop applications
- Leverage an object explorer to visually explore all objects in your data model including tables, views, stored procedures, and etc.
- Generate T-SQL data definition language (DDL) scripts for your objects
- Develop your data warehouse using a state-based approach with SSDT Database Projects
- Integrate your database project with source control systems such as Git with Azure Repos
- Set up continuous integration and deployment pipelines with automation servers such as Azure DevOps

Install Visual Studio 2019

See Download Visual Studio 2019 to download and install Visual Studio **16.3 and above**. During install, select the data storage and processing workload. Standalone SSDT installation is no longer required in Visual Studio 2019.

Unsupported features in SSDT

There are times when feature releases for Synapse SQL may not include support for SSDT. The following features are currently unsupported:

- Workload management - workload groups and classifiers
- Row-level security (including table-valued functions)
  - Submit a support ticket or vote to get the feature supported.
  - Submit a support ticket or vote to get the feature supported.
- Certain T-SQL features, such as:
  - *WITHIN GROUP* clause in the STRING_AGG string function.

Next steps

Now that you have the latest version of SSDT, you're ready to connect to your SQL pool.

Continuous integration and deployment for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

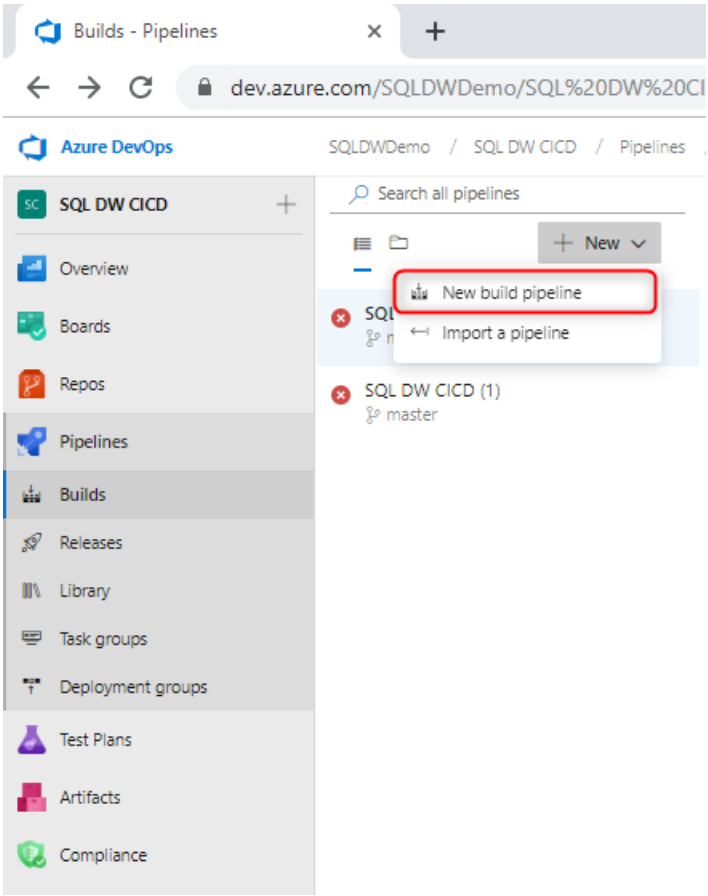
This simple tutorial outlines how to integrate your SQL Server Data tools (SSDT) database project with Azure DevOps and leverage Azure Pipelines to set up continuous integration and deployment. This tutorial is the second step in building your continuous integration and deployment pipeline for data warehousing.

Before you begin

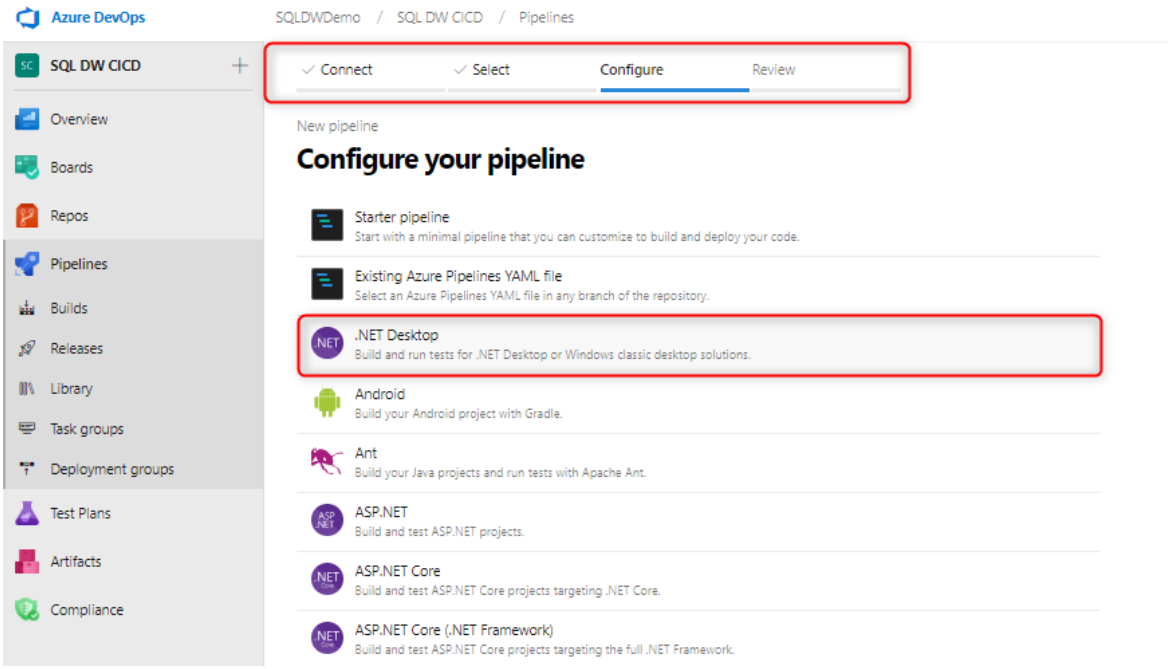
- Go through the source control integration tutorial
- Set up and connect to Azure DevOps

Continuous integration with Visual Studio build

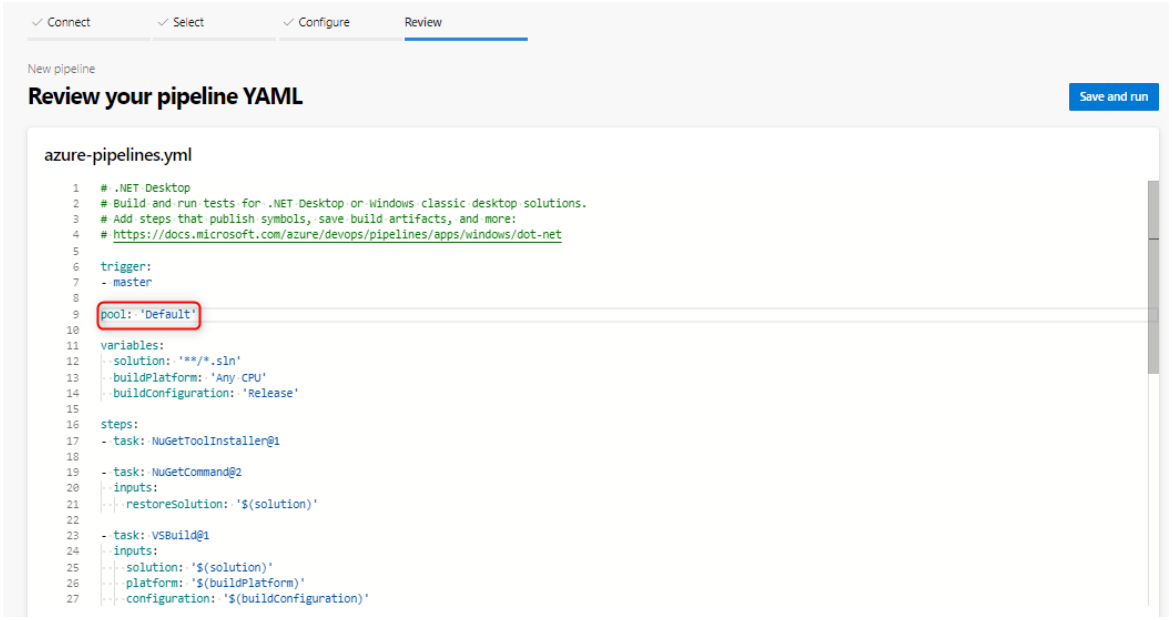
1. Navigate to Azure Pipelines and create a new build pipeline.



2. Select your source code repository (Azure Repos Git) and select the .NET Desktop app template.



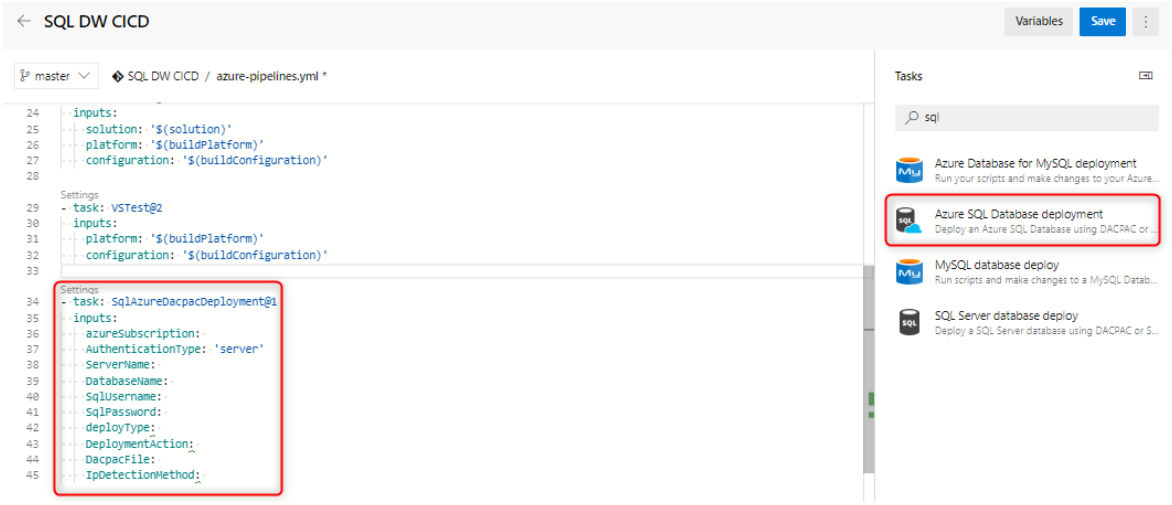
3. Edit your YAML file to use the proper pool of your agent. Your YAML file should look something like this:



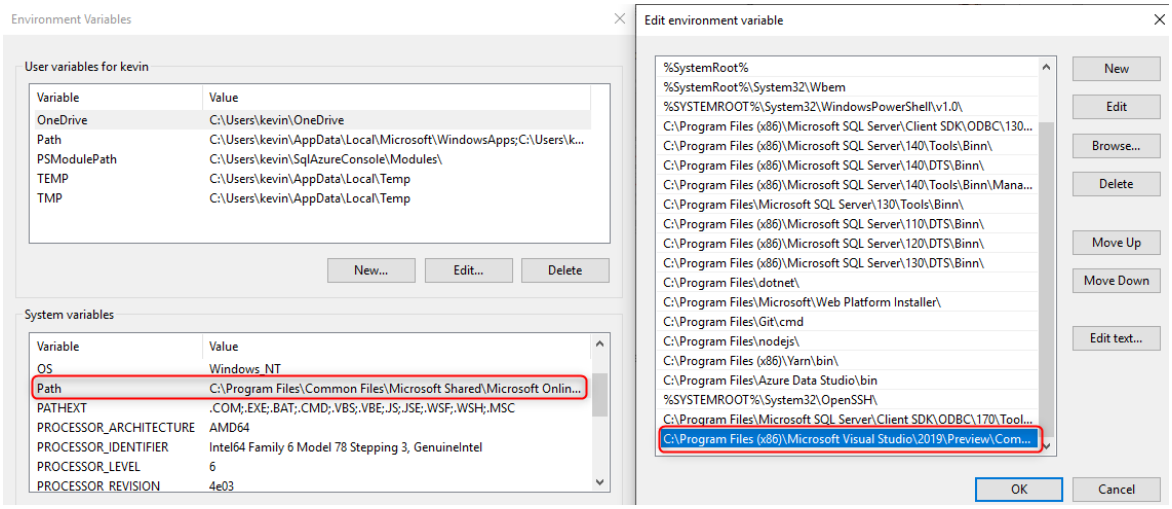
At this point, you have a simple environment where any check-in to your source control repository main branch should automatically trigger a successful Visual Studio build of your database project. Validate the automation is working end to end by making a change in your local database project and checking in that change to your main branch.

Continuous deployment with the Azure Synapse Analytics (or Database) deployment task

1. Add a new task using the Azure SQL Database deployment task and fill in the required fields to connect to your target data warehouse. When this task runs, the DACPAC generated from the previous build process is deployed to the target data warehouse. You can also use the Azure Synapse Analytics deployment task.



2. If you are using a self-hosted agent, make sure you set your environment variable to use the correct SqlPackage.exe for Azure Synapse Analytics. The path should look something like this:



C:\Program Files (x86)\Microsoft Visual Studio\2019\Preview\Common7\IDE\Extensions\Microsoft\SQLDB\DAC\150

Run and validate your pipeline. You can make changes locally and check in changes to your source control that should generate an automatic build and deployment.

Deploy linked ARM templates with VSTS

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes how to deploy linked Azure Resource Manager (ARM) templates with Visual Studio Team Services (VSTS).

Overview

When dealing with deploying many components in Azure, a single ARM template might be challenging to manage and maintain. ARM linked templates allow you to make your deployment more modular and makes the templates easier to manage. When dealing with large deployments, it is highly recommended to consider breaking down your deployment into a main template and multiple linked templates representing different components of your deployment.

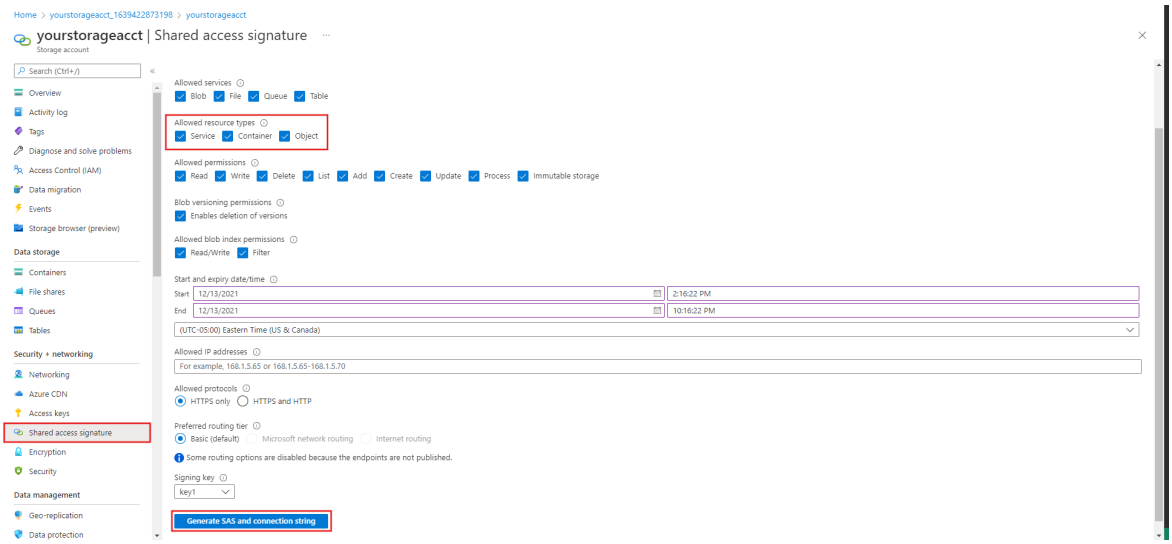
Deploying ARM templates can be performed using several different methods such as using PowerShell, Azure CLI, and Azure portal. A recommended approach however is to adopt one of DevOps practices, namely continuous deployment. VSTS is an application lifecycle management tool hosted in the cloud and offered as a service. One of the capabilities VSTS offers is release management.

This article describes how you can deploy linked ARM templates using the release management feature of VSTS. In order for the linked templates to be deployed properly, they will need to be stored in a location that can be reached by the Azure Resource Manager, such as Azure Storage; so we will show how Azure Storage can be used to stage the ARM template files. We will also show some recommended practices around keeping secrets protected using Azure Key Vault.

The scenario we walk through here is to deploy VNet with a Network Security Group (NSG) structured as linked templates. We will use VSTS to show how continuous deployment can be set up to enable teams to continuously update Azure with new changes each time there is a modification to the template.

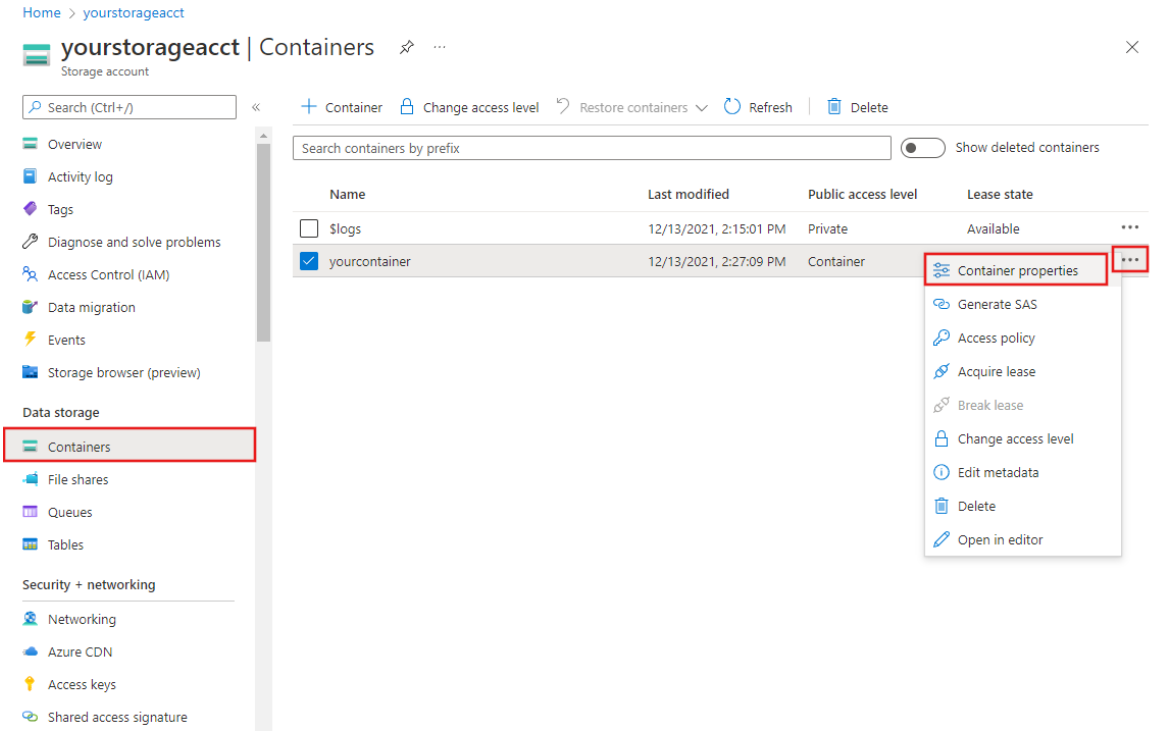
Create an Azure Storage account

1. Log in to the Azure portal and create an Azure Storage account following the steps documented here.
2. Once deployment is complete, navigate to the storage account and select **Shared access signature**. Select Service, Container, and Object for the **Allowed resource types**. Then select **Generate SAS and connection string**. Copy the SAS token and keep it available since we will use it later.



3. Select the storage account Containers page and create a new Container.

4. Select the new Container properties.



5. Copy the URL field and keep it handy. We will need it later along with the SAS token from above.

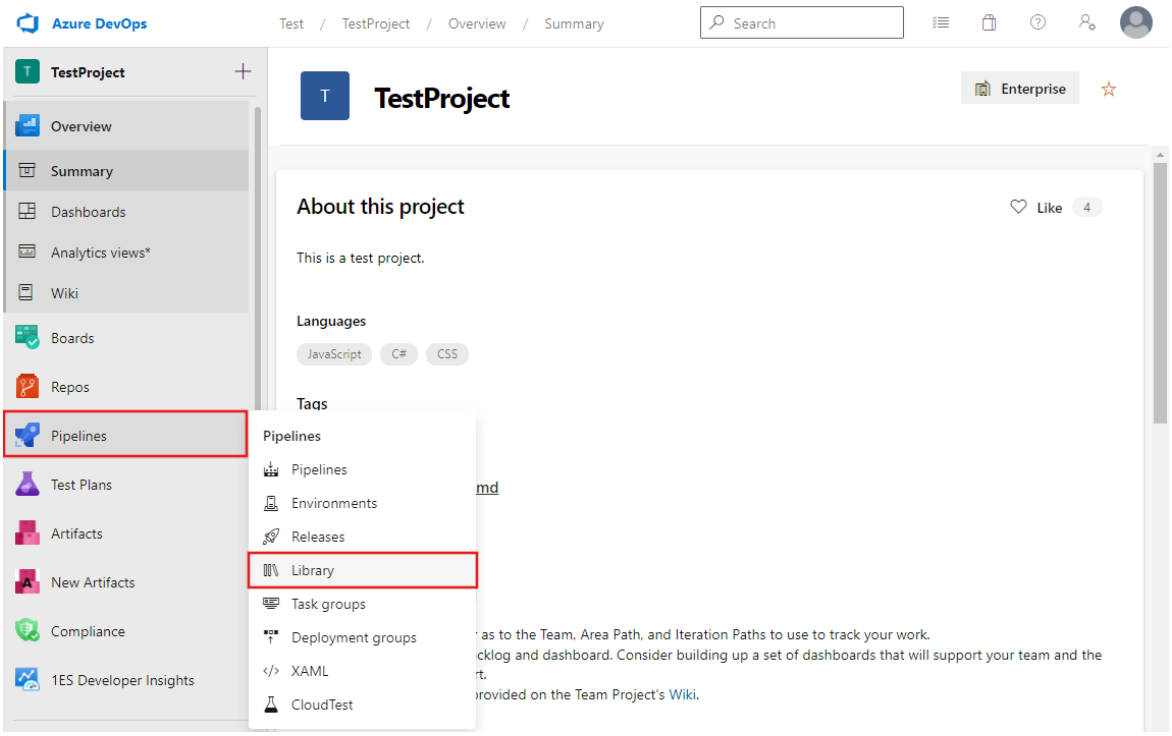
Protect secrets with Azure Key Vault

1. In the Azure portal, create an Azure Key Vault resource.
2. Select the Azure Key Vault you created above and then select Secrets.
3. Select Generate/Import to add the SAS Token.
4. For the Name property, enter `StorageSASToken` and then provide the Azure Storage shared access signature key you copied in a previous step for the Value.
5. Select Create.

Link Azure Key Vault to VSTS

1. Log in to your Azure DevOps organization and navigate to your project.

2. Go to **Library** under **Pipelines** in the navigation pane.



3. Under **Variable group**, create a new group and for **Variable group name** enter `AzureKeyVaultSecrets`.
4. Toggle **Link secrets from an Azure key vault as variables**.
5. Select your Azure subscription and then the Azure Key Vault you created earlier, and then select Authorize.
6. Once authorization is successful, you can add variables by clicking **Add** and will be presented with the option to add references to the secrets in the Azure Key Vault. Add a reference to the `StorageSASToken` created above, and save it.

Setup continuous deployment using VSTS

1. Follow steps listed in the article Automate continuous integration using Azure Pipelines releases.
2. A few changes are required from the above steps in order to use a linked ARM template deployment:
   - Under the release, link the variable group created earlier:

   - Linked ARM template:
     - For Template, point to ArmTemplate_master.json instead of ArmTemplateForFactory.json
     - For Template Parameters, point to 'ArmTemplateParameters_master.json' instead of 'ArmTemplateParametersForFactory.json'
   - Under override Template parameters update two additional parameters
     - **containerUri** – Paste the URL of container created above.
     - **containerSasToken** - If the secret's name is 'StorageSASToken', enter '$(StorageSASToken)' for this value.
3. Save the release pipeline and trigger a release.

Next steps

- Automate continuous integration using Azure Pipelines releases

Query storage files with serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

Serverless SQL pool enables you to query data in your data lake. It offers a T-SQL query surface area that accommodates semi-structured and unstructured data queries. For querying, the following T-SQL aspects are supported:

- Full SELECT surface area, including majority of SQL functions and operators.
- CREATE EXTERNAL TABLE AS SELECT (CETAS) creates an external table and then exports, in parallel, the results of a Transact-SQL SELECT statement to Azure Storage.

For more information on what is vs. what isn't currently supported, read the serverless SQL pool overview article, or the following articles:

- Develop storage access where you can learn how to use External table and OPENROWSET function to read data from storage.
- Control storage access where you can learn how to enable Synapse SQL to access storage using SAS authentication, or Managed Identity of the workspace.

Overview

To support a smooth experience for in place querying of data that's located in Azure Storage files, serverless SQL pool uses the OPENROWSET function with additional capabilities:

- Query multiple files or folders
- PARQUET file format
- Query CSV and delimited text (field terminator, row terminator, escape char)
- DELTA LAKE format
- Read a chosen subset of columns
- Schema inference
- filename function
- filepath function
- Work with complex types and nested or repeated data structures

Query PARQUET files

To query Parquet source data, use FORMAT = 'PARQUET':

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/mycontainer/mysubfolder/data.parquet', FORMAT =
'PARQUET')
WITH (C1 int, C2 varchar(20), C3 varchar(max)) as rows
```

Review the Query Parquet files article for usage examples.

Query CSV files

To query CSV source data, use FORMAT = 'CSV'. You can specify schema of the CSV file as part of `OPENROWSET`

function when you query CSV files:

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/mycontainer/mysubfolder/data.csv', FORMAT = 'CSV',
PARSER_VERSION='2.0')
WITH (C1 int, C2 varchar(20), C3 varchar(max)) as rows
```

There are some additional options that can be used to adjust parsing rules to custom CSv format:

- ESCAPE_CHAR = 'char' Specifies the character in the file that is used to escape itself and all delimiter values in the file. If the escape character is followed by a value other than itself, or any of the delimiter values, the escape character is dropped when reading the value. The ESCAPE_CHAR parameter will be applied whether the FIELDQUOTE is or isn't enabled. It won't be used to escape the quoting character. The quoting character must be escaped with another quoting character. Quoting character can appear within column value only if value is encapsulated with quoting characters.
- FIELDTERMINATOR='field_terminator' Specifies the field terminator to be used. The default field terminator is a comma (",")
- ROWTERMINATOR='row_terminator' Specifies the row terminator to be used. The default row terminator is a newline character:**\r\n**.

Query DELTA LAKE format

To query Delta Lake source data, use FORMAT = 'DELTA' and reference the root folder containing your Delta Lake files.

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/mycontainer/mysubfolder', FORMAT = 'DELTA')
WITH (C1 int, C2 varchar(20), C3 varchar(max)) as rows
```

The root folder must contain a subfolder called `_delta_log`. Review the query Delta Lake format article for usage examples.

File schema

SQL language in Synapse SQL enables you to define schema of the file as part of `OPENROWSET` function and read all or subset of columns, or it tries to automatically determine column types from the file using schema inference.

Read a chosen subset of columns

To specify columns that you want to read, you can provide an optional WITH clause within your `OPENROWSET` statement.

- If there are CSV data files, to read all the columns, provide column names and their data types. If you want a subset of columns, use ordinal numbers to pick the columns from the originating data files by ordinal. Columns will be bound by the ordinal designation.
- If there are Parquet data files, provide column names that match the column names in the originating data files. Columns will be bound by name.

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/mycontainer/mysubfolder/data.parquet', FORMAT =
'PARQUET')
WITH (
      C1 int,
      C2 varchar(20),
      C3 varchar(max)
) as rows
```

For every column, you need to specify column name and type in `WITH` clause. For samples, refer to Read CSV files without specifying all columns.

Schema inference

By omitting the WITH clause from the `OPENROWSET` statement, you can instruct the service to auto detect (infer) the schema from underlying files.

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/mycontainer/mysubfolder/data.parquet', FORMAT =
'PARQUET')
```

Make sure appropriate inferred data types are used for optimal performance.

Query multiple files or folders

To run a T-SQL query over a set of files within a folder or set of folders while treating them as a single entity or rowset, provide a path to a folder or a pattern (using wildcards) over a set of files or folders.

The following rules apply:

- Patterns can appear either in part of a directory path or in a filename.
- Several patterns can appear in the same directory step or file name.
- If there are multiple wildcards, then files within all matching paths will be included in the resulting file set.

```
SELECT * FROM
OPENROWSET( BULK N'https://myaccount.dfs.core.windows.net/myroot/*/mysubfolder/*.parquet', FORMAT =
'PARQUET' ) as rows
```

Refer to Query folders and multiple files for usage examples.

File metadata functions

Filename function

This function returns the file name that the row originates from.

To query specific files, read the Filename section in the Query specific files article.

Return data type is nvarchar(1024). For optimal performance, always cast result of filename function to appropriate data type. If you use character data type, make sure appropriate length is used.

Filepath function

This function returns a full path or a part of path:

- When called without parameter, returns the full file path that a row originates from.
- When called with parameter, it returns part of path that matches the wildcard on position specified in the

parameter. For example, parameter value 1 would return part of path that matches the first wildcard.

For additional information, read the Filepath section of the Query specific files article.

Return data type is nvarchar(1024). For optimal performance, always cast result of filepath function to appropriate data type. If you use character data type, make sure appropriate length is used.

Work with complex types and nested or repeated data structures

To enable a smooth experience with data stored in nested or repeated data types, such as in Parquet files, serverless SQL pool has added the extensions that follow.

Project nested or repeated data

To project data, run a SELECT statement over the Parquet file that contains columns of nested data types. On output, nested values will be serialized into JSON and returned as a varchar(8000) SQL data type.

```
SELECT * FROM
OPENROWSET
(   BULK 'unstructured_data_path' ,
    FORMAT = 'PARQUET' )
[AS alias]
```

For more detailed information, refer to the Project nested or repeated data section of the Query Parquet nested types article.

Access elements from nested columns

To access nested elements from a nested column, such as Struct, use "dot notation" to concatenate field names into the path. Provide the path as column_name in the WITH clause of the `OPENROWSET` function.

The syntax fragment example is as follows:

```
OPENROWSET
(   BULK 'unstructured_data_path' ,
    FORMAT = 'PARQUET' )
WITH ({'column_name' 'column_type',})
[AS alias]
'column_name' ::= '[field_name.] field_name'
```

By default, the `OPENROWSET` function matches the source field name and path with the column names provided in the WITH clause. Elements contained at different nesting levels within the same source Parquet file can be accessed via the WITH clause.

Return values

- Function returns a scalar value, such as int, decimal, and varchar, from the specified element, and on the specified path, for all Parquet types that aren't in the Nested Type group.
- If the path points to an element that is of a Nested Type, the function returns a JSON fragment starting from the top element on the specified path. The JSON fragment is of type varchar(8000).
- If the property can't be found at the specified column_name, the function returns an error.
- If the property can't be found at the specified column_path, depending on Path mode, the function returns an error when in strict mode or null when in lax mode.

For query samples, review the Access elements from nested columns section in the Query Parquet nested types article.

Access elements from repeated columns

To access elements from a repeated column, such as an element of an Array or Map, use the JSON_VALUE

function for every scalar element you need to project and provide:

- Nested or repeated column, as the first parameter
- A JSON path that specifies the element or property to access, as a second parameter

To access non-scalar elements from a repeated column, use the JSON_QUERY function for every non-scalar element you need to project and provide:

- Nested or repeated column, as the first parameter
- A JSON path that specifies the element or property to access, as a second parameter

See syntax fragment below:

```
SELECT
   { JSON_VALUE (column_name, path_to_sub_element), }
   { JSON_QUERY (column_name [ , path_to_sub_element ]), )
FROM
OPENROWSET
(   BULK 'unstructured_data_path' ,
    FORMAT = 'PARQUET' )
[AS alias]
```

You can find query samples for accessing elements from repeated columns in the Query Parquet nested types article.

Query samples

You can learn more about querying various types of data using the sample queries.

Tools

The tools you need to issue queries: - Azure Synapse Studio - Azure Data Studio - SQL Server Management Studio

Demo setup

Your first step is to **create a database** where you'll execute the queries. Then you'll initialize the objects by executing setup script on that database.

This setup script will create the data sources, database scoped credentials, and external file formats that are used to read data in these samples.

> **NOTE**
> Databases are only used for viewing metadata, not for actual data. Write down the database name that you use, you will need it later on.

```
CREATE DATABASE mydbname;
```

Provided demo data

Demo data contains the following data sets:

- NYC Taxi - Yellow Taxi Trip Records - part of public NYC data set in CSV and Parquet format
- Population data set in CSV format
- Sample Parquet files with nested columns
- Books in JSON format

FOLDER PATH	DESCRIPTION
/csv/	Parent folder for data in CSV format
/csv/population/ /csv/population-unix/ /csv/population-unix-hdr/ /csv/population-unix-hdr-escape /csv/population-unix-hdr-quoted	Folders with Population data files in different CSV formats.
/csv/taxi/	Folder with NYC public data files in CSV format
/parquet/	Parent folder for data in Parquet format
/parquet/taxi	NYC public data files in Parquet format, partitioned by year, and month using Hive/Hadoop partitioning scheme.
/parquet/nested/	Sample Parquet files with nested columns
/json/	Parent folder for data in JSON format
/json/books/	JSON files with books data

Next steps

For more information on how to query different file types, and to create and use views, see the following articles:

- Query CSV files
- Query Parquet files
- Query JSON files
- Query nested values
- Query folders and multiple CSV files
- Use file metadata in queries
- Create and use views

Query CSV files

8/19/2022 • 8 minutes to read • Edit Online

In this article, you'll learn how to query a single CSV file using serverless SQL pool in Azure Synapse Analytics. CSV files may have different formats:

- With and without a header row
- Comma and tab-delimited values
- Windows and Unix style line endings
- Non-quoted and quoted values, and escaping characters

All of the above variations will be covered below.

Quickstart example

`OPENROWSET` function enables you to read the content of CSV file by providing the URL to your file.

Read a csv file

The easiest way to see to the content of your `CSV` file is to provide file URL to `OPENROWSET` function, specify csv `FORMAT`, and 2.0 `PARSER_VERSION`. If the file is publicly available or if your Azure AD identity can access this file, you should be able to see the content of the file using the query like the one shown in the following example:

```
select top 10 *
from openrowset(
    bulk 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.csv',
    format = 'csv',
    parser_version = '2.0',
    firstrow = 2 ) as rows
```

Option `firstrow` is used to skip the first row in the CSV file that represents header in this case. Make sure that you can access this file. If your file is protected with SAS key or custom identity, your would need to setup server level credential for sql login.

> **IMPORTANT**
>
> If your CSV file contains UTF-8 characters, make sure that you are using a UTF-8 database collation (for example `Latin1_General_100_CI_AS_SC_UTF8`). A mismatch between text encoding in the file and the collation might cause unexpected conversion errors. You can easily change default collation of the current database using the following T-SQL statement: `alter database current collate Latin1_General_100_CI_AI_SC_UTF8`

Data source usage

Previous example uses full path to the file. As an alternative, you can create an external data source with the location that points to the root folder of the storage:

```
create external data source covid
with ( location = 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-19/ecdc_cases' );
```

Once you create a data source, you can use that data source and the relative path to the file in `OPENROWSET` function:

```
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.csv',
        data_source = 'covid',
        format = 'csv',
        parser_version ='2.0',
        firstrow = 2
    ) as rows
```

If a data source is protected with SAS key or custom identity you can configure data source with database scoped credential.

Explicitly specify schema

`OPENROWSET` enables you to explicitly specify what columns you want to read from the file using `WITH` clause:

```
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.csv',
        data_source = 'covid',
        format = 'csv',
        parser_version ='2.0',
        firstrow = 2
    ) with (
        date_rep date 1,
        cases int 5,
        geo_id varchar(6) 8
    ) as rows
```

The numbers after a data type in the `WITH` clause represent column index in the CSV file.

> **IMPORTANT**
> If your CSV file contains UTF-8 characters, make sure that you are explicilty specifying some UTF-8 collation (for example `Latin1_General_100_CI_AS_SC_UTF8`) for all columns in `WITH` clause or set some UTF-8 collation at database level. Mismatch between text encoding in the file and collation might cause unexpected conversion errors. You can easily change default collation of the current database using the following T-SQL statement: `alter database current collate Latin1_General_100_CI_AI_SC_UTF8` You can easily set collation on the colum types using the following definition: `geo_id varchar(6) collate Latin1_General_100_CI_AI_SC_UTF8 8`

In the following sections you can see how to query various types of CSV files.

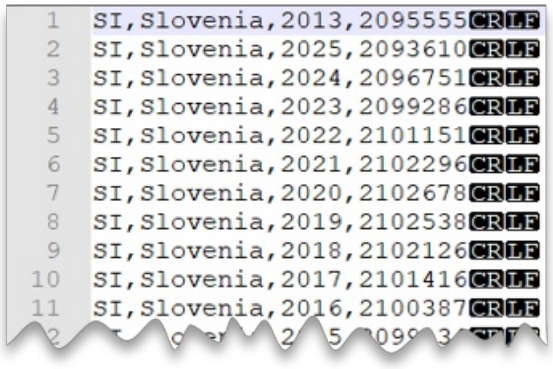
Prerequisites

Your first step is to **create a database** where the tables will be created. Then initialize the objects by executing setup script on that database. This setup script will create the data sources, database scoped credentials, and external file formats that are used in these samples.

Windows style new line

The following query shows how to read a CSV file without a header row, with a Windows-style new line, and comma-delimited columns.

File preview:



```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '\n'
    )
WITH (
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
) AS [r]
WHERE
    country_name = 'Luxembourg'
    AND year = 2017;
```

Unix-style new line

The following query shows how to read a file without a header row, with a Unix-style new line, and comma-delimited columns. Note the different location of the file as compared to the other examples.

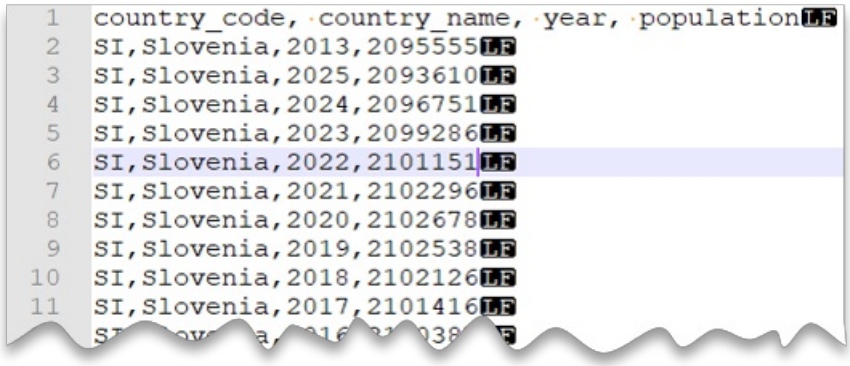
File preview:

```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population-unix/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '0x0a'
    )
WITH (
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
) AS [r]
WHERE
    country_name = 'Luxembourg'
    AND year = 2017;
```

Header row

The following query shows how to a read file with a header row, with a Unix-style new line, and comma-delimited columns. Note the different location of the file as compared to the other examples.

File preview:



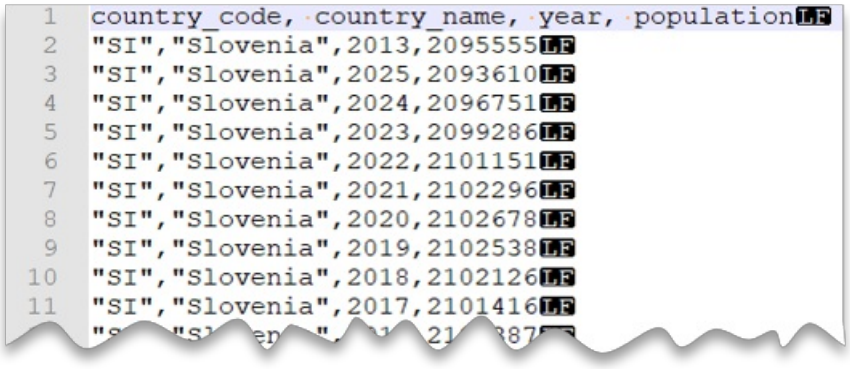
```
SELECT *
FROM OPENROWSET(
    BULK 'csv/population-unix-hdr/population.csv',
    DATA_SOURCE = 'SqlOnDemandDemo',
    FORMAT = 'CSV', PARSER_VERSION = '2.0',
    FIELDTERMINATOR =',',
    HEADER_ROW = TRUE
    ) AS [r]
```

Option `HEADER_ROW = TRUE` will result in reading column names from the header row in file. It is great for exploration purposes when you are not familiar with file content. For best performance see Use appropriate data types section in Best practices. Also, you can read more about OPENROWSET syntax here.

Custom quote character

The following query shows how to read a file with a header row, with a Unix-style new line, comma-delimited columns, and quoted values. Note the different location of the file as compared to the other examples.

File preview:



```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population-unix-hdr-quoted/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '0x0a',
        FIRSTROW = 2,
        FIELDQUOTE = '"'
    )
    WITH (
        [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
        [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
        [year] smallint,
        [population] bigint
    ) AS [r]
WHERE
    country_name = 'Luxembourg'
    AND year = 2017;
```

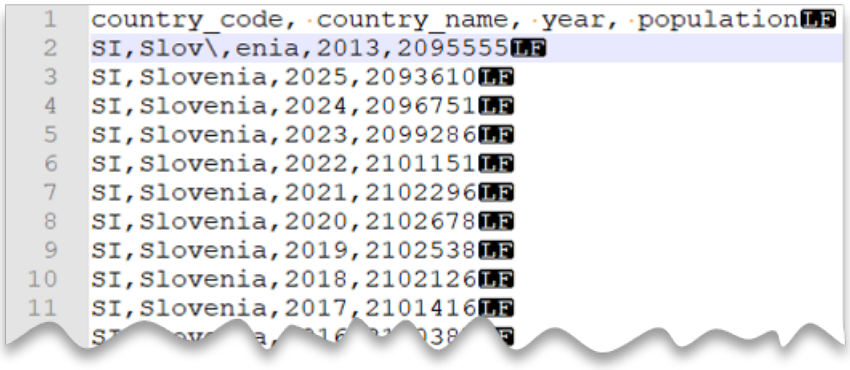
NOTE

This query would return the same results if you omitted the FIELDQUOTE parameter since the default value for FIELDQUOTE is a double-quote.

Escape characters

The following query shows how to read a file with a header row, with a Unix-style new line, comma-delimited columns, and an escape char used for the field delimiter (comma) within values. Note the different location of the file as compared to the other examples.

File preview:



```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population-unix-hdr-escape/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '0x0a',
        FIRSTROW = 2,
        ESCAPECHAR = '\\'
    )
    WITH (
        [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
        [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
        [year] smallint,
        [population] bigint
    ) AS [r]
WHERE
    country_name = 'Slovenia';
```

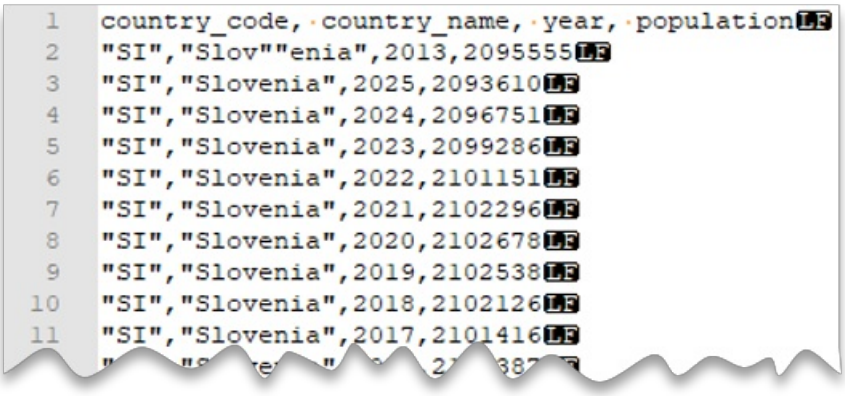
NOTE

This query would fail if ESCAPECHAR is not specified since the comma in "Slov,enia" would be treated as field delimiter instead of part of the country/region name. "Slov,enia" would be treated as two columns. Therefore, the particular row would have one column more than the other rows, and one column more than you defined in the WITH clause.

Escape quoting characters

The following query shows how to read a file with a header row, with a Unix-style new line, comma-delimited columns, and an escaped double quote char within values. Note the different location of the file as compared to the other examples.

File preview:



```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population-unix-hdr-escape-quoted/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '0x0a',
        FIRSTROW = 2
    )
    WITH (
        [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
        [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
        [year] smallint,
        [population] bigint
    ) AS [r]
WHERE
    country_name = 'Slovenia';
```

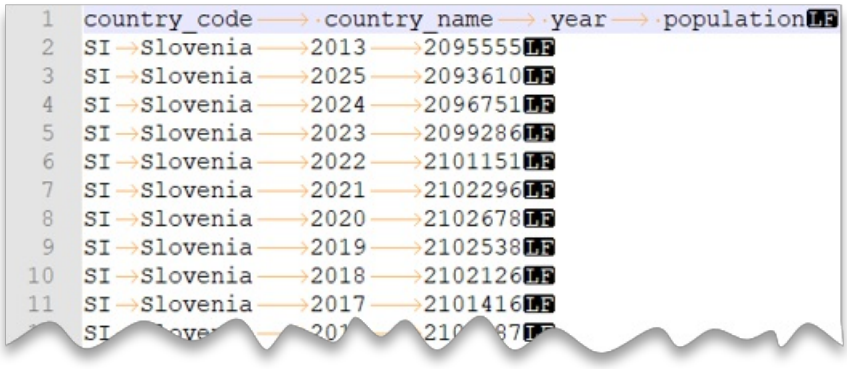
NOTE

The quoting character must be escaped with another quoting character. Quoting character can appear within column value only if value is encapsulated with quoting characters.

Tab-delimited files

The following query shows how to read a file with a header row, with a Unix-style new line, and tab-delimited columns. Note the different location of the file as compared to the other examples.

File preview:



```
SELECT *
FROM OPENROWSET(
        BULK 'csv/population-unix-hdr-tsv/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR ='\t',
        ROWTERMINATOR = '0x0a',
        FIRSTROW = 2
    )
    WITH (
        [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
        [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
        [year] smallint,
        [population] bigint
    ) AS [r]
WHERE
    country_name = 'Luxembourg'
    AND year = 2017
```

Return a subset of columns

So far, you've specified the CSV file schema using WITH and listing all columns. You can only specify columns you actually need in your query by using an ordinal number for each column needed. You'll also omit columns of no interest.

The following query returns the number of distinct country/region names in a file, specifying only the columns that are needed:

> **NOTE**
>
> Take a look at the WITH clause in the query below and note that there is "2" (without quotes) at the end of row where you define the *[country_name]* column. It means that the *[country_name]* column is the second column in the file. The query will ignore all columns in the file except the second one.

```
SELECT
    COUNT(DISTINCT country_name) AS countries
FROM OPENROWSET(
        BULK 'csv/population/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '\n'
    )
WITH (
    --[country_code] VARCHAR (5),
    [country_name] VARCHAR (100) 2
    --[year] smallint,
    --[population] bigint
) AS [r]
```

Querying appendable files

The CSV files that are used in the query should not be changed while the query is running. In the long-running query, SQL pool may retry reads, read parts of the files, or even read the file multiple times. Changes of the file content would cause wrong results. Therefore, SQL pool fails the query if detects that modification time of any file is changed during the query execution.

In some scenarios you might want to read the files that are constantly appended. To avoid the query failures due to constantly appended files, you can allow the `OPENROWSET` function to ignore potentially inconsistent reads using the `ROWSET_OPTIONS` setting.

```
select top 10 *
from openrowset(
    bulk 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.csv',
    format = 'csv',
    parser_version = '2.0',
    firstrow = 2,
    ROWSET_OPTIONS = '{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}') as rows
```

The `ALLOW_INCONSISTENT_READS` read option will disable the file modification time check during the query lifecycle and read whatever is available in the file. In the appendable files, the existing content is not updated, and only new rows are added. Therefore, the probability of wrong results is minimized compared to the updateable files. This option might enable you to read the frequently appended files without handling the errors. Im most of the scenarios, SQL pool will just ignore some rows that are appended to the files during the query execution.

The next articles will show you how to:

- Querying Parquet files
- Querying folders and multiple files

Query Parquet files using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

In this article, you'll learn how to write a query using serverless SQL pool that will read Parquet files.

Quickstart example

`OPENROWSET` function enables you to read the content of parquet file by providing the URL to your file.

Read parquet file

The easiest way to see to the content of your `PARQUET` file is to provide file URL to `OPENROWSET` function and specify parquet `FORMAT`. If the file is publicly available or if your Azure AD identity can access this file, you should be able to see the content of the file using the query like the one shown in the following example:

```
select top 10 *
from openrowset(
    bulk 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.parquet',
    format = 'parquet') as rows
```

Make sure that you can access this file. If your file is protected with SAS key or custom Azure identity, you would need to setup server level credential for sql login.

> **IMPORTANT**
>
> Ensure you are using a UTF-8 database collation (for example `Latin1_General_100_BIN2_UTF8`) because string values in PARQUET files are encoded using UTF-8 encoding. A mismatch between the text encoding in the PARQUET file and the collation may cause unexpected conversion errors. You can easily change the default collation of the current database using the following T-SQL statement: `alter database current collate Latin1_General_100_BIN2_UTF8`

If you use the `Latin1_General_100_BIN2_UTF8` collation you will get an additional performance boost compared to the other collations. The `Latin1_General_100_BIN2_UTF8` collation is compatible with parquet string sorting rules. The SQL pool is able to eliminate some parts of the parquet files that will not contain data needed in the queries (file/column-segment pruning). If you use other collations, all data from the parquet files will be loaded into Synapse SQL and the filtering is happening within the SQL process. The `Latin1_General_100_BIN2_UTF8` collation has additional performance optimization that works only for parquet and CosmosDB. The downside is that you lose fine-grained comparison rules like case insensitivity.

Data source usage

Previous example uses full path to the file. As an alternative, you can create an external data source with the location that points to the root folder of the storage, and use that data source and the relative path to the file in `OPENROWSET` function:

```
create external data source covid
with ( location = 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-19/ecdc_cases' );
go
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.parquet',
        data_source = 'covid',
        format = 'parquet'
    ) as rows
```

If a data source is protected with SAS key or custom identity you can configure data source with database scoped credential.

Explicitly specify schema

`OPENROWSET` enables you to explicitly specify what columns you want to read from the file using `WITH` clause:

```
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.parquet',
        data_source = 'covid',
        format = 'parquet'
    ) with ( date_rep date, cases int, geo_id varchar(6) ) as rows
```

IMPORTANT

Make sure that you are explicilty specifying some UTF-8 collation (for example `Latin1_General_100_BIN2_UTF8`) for all string columns in `WITH` clause or set some UTF-8 collation at database level. Mismatch between text encoding in the file and string column collation might cause unexpected conversion errors. You can easily change default collation of the current database using the following T-SQL statement:
`alter database current collate Latin1_General_100_BIN2_UTF8` You can easily set collation on the colum types using the following definition: `geo_id varchar(6) collate Latin1_General_100_BIN2_UTF8`

In the following sections you can see how to query various types of PARQUET files.

Prerequisites

Your first step is to **create a database** with a datasource that references NYC Yellow Taxi storage account. Then initialize the objects by executing setup script on that database. This setup script will create the data sources, database scoped credentials, and external file formats that are used in these samples.

Dataset

NYC Yellow Taxi dataset is used in this sample. You can query Parquet files the same way you read CSV files. The only difference is that the `FILEFORMAT` parameter should be set to `PARQUET`. Examples in this article show the specifics of reading Parquet files.

Query set of parquet files

You can specify only the columns of interest when you query Parquet files.

```
SELECT
        YEAR(tpepPickupDateTime),
        passengerCount,
        COUNT(*) AS cnt
FROM
    OPENROWSET(
        BULK 'puYear=2018/puMonth=*/*.snappy.parquet',
        DATA_SOURCE = 'YellowTaxi',
        FORMAT='PARQUET'
    ) WITH (
        tpepPickupDateTime DATETIME2,
        passengerCount INT
    ) AS nyc
GROUP BY
    passengerCount,
    YEAR(tpepPickupDateTime)
ORDER BY
    YEAR(tpepPickupDateTime),
    passengerCount;
```

Automatic schema inference

You don't need to use the OPENROWSET WITH clause when reading Parquet files. Column names and data types are automatically read from Parquet files.

The sample below shows the automatic schema inference capabilities for Parquet files. It returns the number of rows in September 2018 without specifying a schema.

> **NOTE**
> You don't have to specify columns in the OPENROWSET WITH clause when reading Parquet files. In that case, serverless SQL pool query service will utilize metadata in the Parquet file and bind columns by name.

```
SELECT TOP 10 *
FROM
    OPENROWSET(
        BULK 'puYear=2018/puMonth=9/*.snappy.parquet',
        DATA_SOURCE = 'YellowTaxi',
        FORMAT='PARQUET'
    ) AS nyc
```

Query partitioned data

The data set provided in this sample is divided (partitioned) into separate subfolders. You can target specific partitions using the filepath function. This example shows fare amounts by year, month, and payment_type for the first three months of 2017.

> **NOTE**
> The serverless SQL pool query is compatible with Hive/Hadoop partitioning scheme.

```
SELECT
        YEAR(tpepPickupDateTime),
        passengerCount,
        COUNT(*) AS cnt
FROM
    OPENROWSET(
        BULK 'puYear=*/puMonth=*/*.snappy.parquet',
        DATA_SOURCE = 'YellowTaxi',
        FORMAT='PARQUET'
    ) nyc
WHERE
    nyc.filepath(1) = 2017
    AND nyc.filepath(2) IN (1, 2, 3)
    AND tpepPickupDateTime BETWEEN CAST('1/1/2017' AS datetime) AND CAST('3/31/2017' AS datetime)
GROUP BY
    passengerCount,
    YEAR(tpepPickupDateTime)
ORDER BY
    YEAR(tpepPickupDateTime),
    passengerCount;
```

Type mapping

For Parquet type mapping to SQL native type check type mapping for Parquet.

Next steps

Advance to the next article to learn how to Query Parquet nested types.

Query JSON files using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

In this article, you'll learn how to write a query using serverless SQL pool in Azure Synapse Analytics. The query's objective is to read JSON files using OPENROWSET.

- Standard JSON files where multiple JSON documents are stored as a JSON array.
- Line-delimited JSON files, where JSON documents are separated with new-line character. Common extensions for these types of files are `jsonl`, `ldjson`, and `ndjson`.

Read JSON documents

The easiest way to see to the content of your JSON file is to provide the file URL to the `OPENROWSET` function, specify csv `FORMAT`, and set values `0x0b` for `fieldterminator` and `fieldquote`. If you need to read line-delimited JSON files, then this is enough. If you have classic JSON file, you would need to set values `0x0b` for `rowterminator`. `OPENROWSET` function will parse JSON and return every document in the following format:

doc
{"date_rep":"2020-07-24","day":24,"month":7,"year":2020,"cases":3,"deaths":0,"geo_id":"AF"}
{"date_rep":"2020-07-25","day":25,"month":7,"year":2020,"cases":7,"deaths":0,"geo_id":"AF"}
{"date_rep":"2020-07-26","day":26,"month":7,"year":2020,"cases":4,"deaths":0,"geo_id":"AF"}
{"date_rep":"2020-07-27","day":27,"month":7,"year":2020,"cases":8,"deaths":0,"geo_id":"AF"}

If the file is publicly available, or if your Azure AD identity can access this file, you should see the content of the file using the query like the one shown in the following examples.

Read JSON files

The following sample query reads JSON and line-delimited JSON files, and returns every document as a separate row.

```
select top 10 *
from openrowset(
        bulk 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.jsonl',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b'
    ) with (doc nvarchar(max)) as rows
go
select top 10 *
from openrowset(
        bulk 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-
19/ecdc_cases/latest/ecdc_cases.json',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b',
        rowterminator = '0x0b' --> You need to override rowterminator to read classic JSON
    ) with (doc nvarchar(max)) as rows
```

The JSON document in the preceding sample query includes an array of objects. The query returns each object as a separate row in the result set. Make sure that you can access this file. If your file is protected with SAS key or custom identity, you would need to set up server level credential for sql login.

Data source usage

The previous example uses full path to the file. As an alternative, you can create an external data source with the location that points to the root folder of the storage, and use that data source and the relative path to the file in the `OPENROWSET` function:

```
create external data source covid
with ( location = 'https://pandemicdatalake.blob.core.windows.net/public/curated/covid-19/ecdc_cases' );
go
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.jsonl',
        data_source = 'covid',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b'
    ) with (doc nvarchar(max)) as rows
go
select top 10 *
from openrowset(
        bulk 'latest/ecdc_cases.json',
        data_source = 'covid',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b',
        rowterminator = '0x0b' --> You need to override rowterminator to read classic JSON
    ) with (doc nvarchar(max)) as rows
```

If a data source is protected with SAS key or custom identity, you can configure data source with database scoped credential.

In the following sections, you can see how to query various types of JSON files.

Parse JSON documents

The queries in the previous examples return every JSON document as a single string in a separate row of the result set. You can use functions `JSON_VALUE` and `OPENJSON` to parse the values in JSON documents and return them as relational values, as it's shown in the following example:

DATE_REP	CASES	GEO_ID
2020-07-24	3	AF
2020-07-25	7	AF
2020-07-26	4	AF
2020-07-27	8	AF

Sample JSON document

The query examples read *json* files containing documents with following structure:

```
{
    "date_rep":"2020-07-24",
    "day":24,"month":7,"year":2020,
    "cases":13,"deaths":0,
    "countries_and_territories":"Afghanistan",
    "geo_id":"AF",
    "country_territory_code":"AFG",
    "continent_exp":"Asia",
    "load_date":"2020-07-25 00:05:14",
    "iso_country":"AF"
}
```

> **NOTE**
>
> If these documents are stored as line-delimited JSON, you need to set `FIELDTERMINATOR` and `FIELDQUOTE` to 0x0b. If you have standard JSON format you need to set `ROWTERMINATOR` to 0x0b.

Query JSON files using JSON_VALUE

The query below shows you how to use JSON_VALUE to retrieve scalar values (`date_rep` , `countries_and_territories` , `cases`) from a JSON documents:

```
select
    JSON_VALUE(doc, '$.date_rep') AS date_reported,
    JSON_VALUE(doc, '$.countries_and_territories') AS country,
    CAST(JSON_VALUE(doc, '$.deaths') AS INT) as fatal,
    JSON_VALUE(doc, '$.cases') as cases,
    doc
from openrowset(
        bulk 'latest/ecdc_cases.jsonl',
        data_source = 'covid',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b'
    ) with (doc nvarchar(max)) as rows
order by JSON_VALUE(doc, '$.geo_id') desc
```

Once you extract JSON properties from a JSON document, you can define column aliases and optionally cast the textual value to some type.

Query JSON files using OPENJSON

The following query uses OPENJSON. It will retrieve COVID statistics reported in Serbia:

```
select
    *
from openrowset(
        bulk 'latest/ecdc_cases.jsonl',
        data_source = 'covid',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b'
    ) with (doc nvarchar(max)) as rows
    cross apply openjson (doc)
        with (  date_rep datetime2,
                cases int,
                fatal int '$.deaths',
                country varchar(100) '$.countries_and_territories')
where country = 'Serbia'
order by country, date_rep desc;
```

The results are functionally same as the results returned using the `JSON_VALUE` function. In some cases, `OPENJSON` might have advantage over `JSON_VALUE`:

- In the `WITH` clause you can explicitly set the column aliases and the types for every property. You don't need to put the `CAST` function in every column in `SELECT` list.
- `OPENJSON` might be faster if you are returning a large number of properties. If you are returning just 1-2 properties, the `OPENJSON` function might be overhead.
- You must use the `OPENJSON` function if you need to parse the array from each document, and join it with the parent row.

Next steps

The next articles in this series will demonstrate how to:

- Querying folders and multiple files
- Create and use views

Query nested types in Parquet and JSON files by using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

In this article, you'll learn how to write a query by using serverless SQL pool in Azure Synapse Analytics. The query will read Parquet nested types. Nested types are complex structures that represent objects or arrays. Nested types can be stored in:

- Parquet, where you can have multiple complex columns that contain arrays and objects.
- Hierarchical JSON files, where you can read a complex JSON document as a single column.
- Azure Cosmos DB collections (currently under gated public preview), where every document can contain complex nested properties.

Serverless SQL pool formats all nested types as JSON objects and arrays. So you can extract or modify complex objects by using JSON functions or parse JSON data by using the OPENJSON function.

Here's an example of a query that extracts scalar and object values from the COVID-19 Open Research Dataset JSON file, which contains nested objects:

```
SELECT
    title = JSON_VALUE(doc, '$.metadata.title'),
    first_author = JSON_QUERY(doc, '$.metadata.authors[0]'),
    first_author_name = JSON_VALUE(doc, '$.metadata.authors[0].first'),
    complex_object = doc
FROM
    OPENROWSET(
        BULK
'https://azureopendatastorage.blob.core.windows.net/covid19temp/comm_use_subset/pdf_json/000b7d1517ceebb34e1
e3e817695b6de03e2fa78.json',
        FORMAT='CSV', FIELDTERMINATOR ='0x0b', FIELDQUOTE = '0x0b', ROWTERMINATOR = '0x0b'
    )
    WITH ( doc varchar(MAX) ) AS docs;
```

The `JSON_VALUE` function returns a scalar value from the field at the specified path. The `JSON_QUERY` function returns an object formatted as JSON from the field at the specified path.

> **IMPORTANT**
>
> This example uses a file from the COVID-19 Open Research Dataset. See the licence and the structure of the data here.

Prerequisites

The first step is to create a database where the datasource will be created. You'll then initialize the objects by running a setup script on the database. The setup script will create the data sources, database-scoped credentials, and external file formats that are used in the samples.

Project nested or repeated data

A Parquet file can have multiple columns with complex types. The values from these columns are formatted as JSON text and returned as VARCHAR columns. The following query reads the structExample.parquet file and shows how to read the values of the nested columns:

```
SELECT
    DateStruct, TimeStruct, TimestampStruct, DecimalStruct, FloatStruct
FROM
    OPENROWSET(
        BULK 'parquet/nested/structExample.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    )
    WITH (
        DateStruct VARCHAR(8000),
        TimeStruct VARCHAR(8000),
        TimestampStruct VARCHAR(8000),
        DecimalStruct VARCHAR(8000),
        FloatStruct VARCHAR(8000)
    ) AS [r];
```

This query returns the following result. The content of every nested object is returned as JSON text.

DATESTRUCT	TIMESTRUCT	TIMESTAMPSTRUCT	DECIMALSTRUCT	FLOATSTRUCT
{"Date":"2009-04-25"}	{"Time":"20:51:54.3598000"}	{"Timestamp":"5501-04-08 12:13:57.4821000"}	{"Decimal":11143412.25350}	{"Float":0.5}
{"Date":"1916-04-29"}	{"Time":"00:16:04.6778000"}	{"Timestamp":"1990-06-30 20:50:52.6828000"}	{"Decimal":1963545.62800}	{"Float":-2.125}

The following query reads the justSimpleArray.parquet file. It projects all columns from the Parquet file, including nested and repeated data.

```
SELECT
    SimpleArray
FROM
    OPENROWSET(
        BULK 'parquet/nested/justSimpleArray.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    ) AS [r];
```

This query will return the following result:

SIMPLEARRAY
[11,12,13]
[21,22,23]

Read properties from nested object columns

The `JSON_VALUE` function enables you to return values from columns formatted as JSON text:

```
SELECT
    title = JSON_VALUE(complex_column, '$.metadata.title'),
    first_author_name = JSON_VALUE(complex_column, '$.metadata.authors[0].first'),
    body_text = JSON_VALUE(complex_column, '$.body_text.text'),
    complex_column
FROM
    OPENROWSET( BULK
'https://azureopendatastorage.blob.core.windows.net/covid19temp/comm_use_subset/pdf_json/000b7d1517ceebb34e1e3e817695b6de03e2fa78.json',
                FORMAT='CSV', FIELDTERMINATOR ='0x0b', FIELDQUOTE = '0x0b', ROWTERMINATOR = '0x0b' ) WITH (
complex_column varchar(MAX) ) AS docs;
```

The result is shown in the following table:

TITLE	FIRST_AUTHOR_NAME	BODY_TEXT	COMPLEX_COLUMN
Supplementary Information An eco-epidemiolo...	Julien	- Figure S1 : Phylogeny of...	{ "paper_id": "000b7d1517ceebb34e1e3e817695b6de03e2fa "metadata": { "title": "Supplementary Information An eco-epidemiological stu Morbilli-related paramyxovirus infecti Madagascar bats reveals host-switching the dominant macro-evolutionary mechan "authors": [{ "first": "Julien"

Unlike JSON files, which in most cases return a single column that contains a complex JSON object, Parquet files can have multiple complex columns. You can read the properties of nested columns by using the `JSON_VALUE` function on each column. `OPENROWSET` enables you to directly specify the paths of the nested properties in a `WITH` clause. You can set the paths as the name of a column, or you can add a JSON path expression after the column type.

The following query reads the structExample.parquet file and shows how to surface elements of a nested column. There are two ways to reference a nested value:

- By specifying the nested value path expression after the type specification.
- By formatting the column name as a nested path by using do "." to reference the fields.

```
SELECT
    *
FROM
    OPENROWSET(
        BULK 'parquet/nested/structExample.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    )
    WITH (
        [DateValue] DATE '$.DateStruct.Date',
        [TimeStruct.Time] TIME,
        [TimestampStruct.Timestamp] DATETIME2,
        DecimalValue DECIMAL(18, 5) '$.DecimalStruct.Decimal',
        [FloatStruct.Float] FLOAT
    ) AS [r];
```

Access elements from repeated columns

The following query reads the justSimpleArray.parquet file and uses JSON_VALUE to retrieve a scalar element from within a repeated column, like an array or map:

```
SELECT
    *,
    JSON_VALUE(SimpleArray, '$[0]') AS FirstElement,
    JSON_VALUE(SimpleArray, '$[1]') AS SecondElement,
    JSON_VALUE(SimpleArray, '$[2]') AS ThirdElement
FROM
    OPENROWSET(
        BULK 'parquet/nested/justSimpleArray.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    ) AS [r];
```

Here's the result:

SIMPLEARRAY	FIRSTELEMENT	SECONDELEMENT	THIRDELEMENT
[11,12,13]	11	12	13

SIMPLEARRAY	FIRSTELEMENT	SECONDELEMENT	THIRDELEMENT
[21,22,23]	21	22	23

Access sub-objects from complex columns

The following query reads the mapExample.parquet file and uses JSON_QUERY to retrieve a non-scalar element from within a repeated column, like an array or map:

```
SELECT
    MapOfPersons,
    JSON_QUERY(MapOfPersons, '$."John Doe"') AS [John]
FROM
    OPENROWSET(
        BULK 'parquet/nested/mapExample.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    ) AS [r];
```

You can also explicitly reference the columns that you want to return in a `WITH` clause:

```
SELECT DocId,
    MapOfPersons,
    JSON_QUERY(MapOfPersons, '$."John Doe"') AS [John]
FROM
    OPENROWSET(
        BULK 'parquet/nested/mapExample.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    )
    WITH (DocId bigint, MapOfPersons VARCHAR(max)) AS [r];
```

The structure `MapOfPersons` is returned as a VARCHAR column and formatted as a JSON string.

Project values from repeated columns

If you have an array of scalar values (for example `[1,2,3]`) in some columns, you can easily expand them and join them with the main row by using this script:

```
SELECT
    SimpleArray, Element
FROM
    OPENROWSET(
        BULK 'parquet/nested/justSimpleArray.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    ) AS arrays
    CROSS APPLY OPENJSON (SimpleArray) WITH (Element int '$') as array_values
```

Next steps

The next article will show you how to Query JSON files.

Query Delta Lake files using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

In this article, you'll learn how to write a query using serverless Synapse SQL pool to read Apache Delta Lake files. Delta Lake is an open-source storage layer that brings ACID (atomicity, consistency, isolation, and durability) transactions to Apache Spark and big data workloads.

The serverless SQL pool in Synapse workspace enables you to read the data stored in Delta Lake format, and serve it to reporting tools. A serverless SQL pool can read Delta Lake files that are created using Apache Spark, Azure Databricks, or any other producer of the Delta Lake format.

Apache Spark pools in Azure Synapse enable data engineers to modify Delta Lake files using Scala, PySpark, and .NET. Serverless SQL pools help data analysts to create reports on Delta Lake files created by data engineers.

Quickstart example

The OPENROWSET function enables you to read the content of Delta Lake files by providing the URL to your root folder.

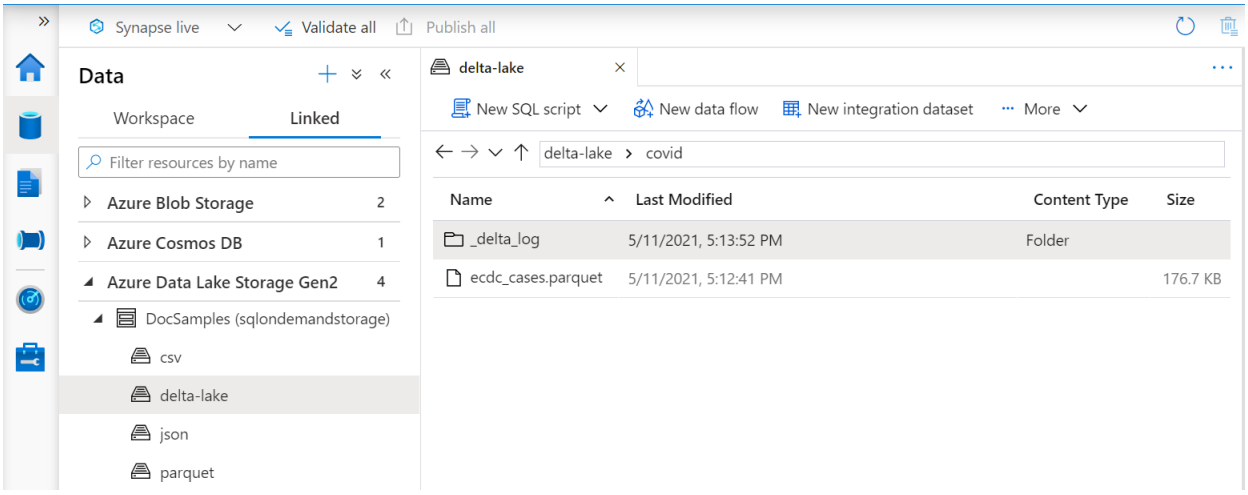
Read Delta Lake folder

The easiest way to see to the content of your `DELTA` file is to provide the file URL to the OPENROWSET function and specify `DELTA` format. If the file is publicly available or if your Azure AD identity can access this file, you should be able to see the content of the file using a query like the one shown in the following example:

```
SELECT TOP 10 *
FROM OPENROWSET(
    BULK 'https://sqlondemandstorage.blob.core.windows.net/delta-lake/covid/',
    FORMAT = 'delta') as rows;
```

Column names and data types are automatically read from Delta Lake files. The `OPENROWSET` function uses best guess types like VARCHAR(1000) for the string columns.

The URI in the `OPENROWSET` function must reference the root Delta Lake folder that contains a subfolder called `_delta_log`.



If you don't have this subfolder, you are not using Delta Lake format. You can convert your plain Parquet files in

the folder to Delta Lake format using the following Apache Spark Python script:

```
%%pyspark
from delta.tables import *
deltaTable = DeltaTable.convertToDelta(spark, "parquet.`abfss://delta-
lake@sqlondemandstorage.dfs.core.windows.net/covid`")
```

To improve the performance of your queries, consider specifying explicit types in the `WITH` clause.

> **NOTE**
> The serverless Synapse SQL pool uses schema inference to automatically determine columns and their types. The rules for schema inference are the same used for Parquet files. For Delta Lake type mapping to SQL native type check type mapping for Parquet.

Make sure you can access your file. If your file is protected with SAS key or custom Azure identity, you will need to set up a server level credential for sql login.

> **IMPORTANT**
> Ensure you are using a UTF-8 database collation (for example `Latin1_General_100_BIN2_UTF8`) because string values in Delta Lake files are encoded using UTF-8 encoding. A mismatch between the text encoding in the Delta Lake file and the collation may cause unexpected conversion errors. You can easily change the default collation of the current database using the following T-SQL statement: `alter database current collate Latin1_General_100_BIN2_UTF8`

Data source usage

The previous examples used the full path to the file. As an alternative, you can create an external data source with the location that points to the root folder of the storage. Once you've created the external data source, use the data source and the relative path to the file in the `OPENROWSET` function. This way you don't need to use the full absolute URI to your files. You can also then define custom credentials to access the storage location.

> **IMPORTANT**
> Data sources can be created only in custom databases (not in the master database or the databases replicated from Apache Spark pools).

To use the samples below, you will need to complete the following step:

1. **Create a database** with a datasource that references NYC Yellow Taxi storage account.
2. Initialize the objects by executing setup script on the database you created in step 1. This setup script will create the data sources, database scoped credentials, and external file formats that are used in these samples.

If you created your database, and switched the context to your database (using `USE database_name` statement or dropdown for selecting database in some query editor), you can create your external data source containing the root URI to your data set and use it to query Delta Lake files:

```
CREATE EXTERNAL DATA SOURCE DeltaLakeStorage
WITH ( LOCATION = 'https://sqlondemandstorage.blob.core.windows.net/delta-lake/' );
GO

SELECT TOP 10 *
FROM OPENROWSET(
        BULK 'covid',
        DATA_SOURCE = 'DeltaLakeStorage',
        FORMAT = 'delta'
    ) as rows;
```

If a data source is protected with SAS key or custom identity, you can configure data source with database scoped credential.

Explicitly specify schema

`OPENROWSET` enables you to explicitly specify what columns you want to read from the file using `WITH` clause:

```
SELECT TOP 10 *
FROM OPENROWSET(
        BULK 'covid',
        DATA_SOURCE = 'DeltaLakeStorage',
        FORMAT = 'delta'
    )
    WITH ( date_rep date,
           cases int,
           geo_id varchar(6)
           ) as rows;
```

With the explicit specification of the result set schema, you can minimize the type sizes and use the more precise types VARCHAR(6) for string columns instead of pessimistic VARCHAR(1000). Minimization of types might significantly improve performance of your queries.

> **IMPORTANT**
> Make sure that you are explicitly specifying a UTF-8 collation (for example `Latin1_General_100_BIN2_UTF8`) for all string columns in `WITH` clause or set a UTF-8 collation at the database level. Mismatch between text encoding in the file and string column collation might cause unexpected conversion errors. You can easily change default collation of the current database using the following T-SQL statement: `alter database current collate Latin1_General_100_BIN2_UTF8` You can easily set collation on the colum types using the following definition:
> `geo_id varchar(6) collate Latin1_General_100_BIN2_UTF8`

Dataset

NYC Yellow Taxi dataset is used in this sample. You can query Parquet files the same way you read CSV files. The only difference is that the `FILEFORMAT` parameter should be set to `PARQUET`. Examples in this article show the specifics of reading Parquet files.

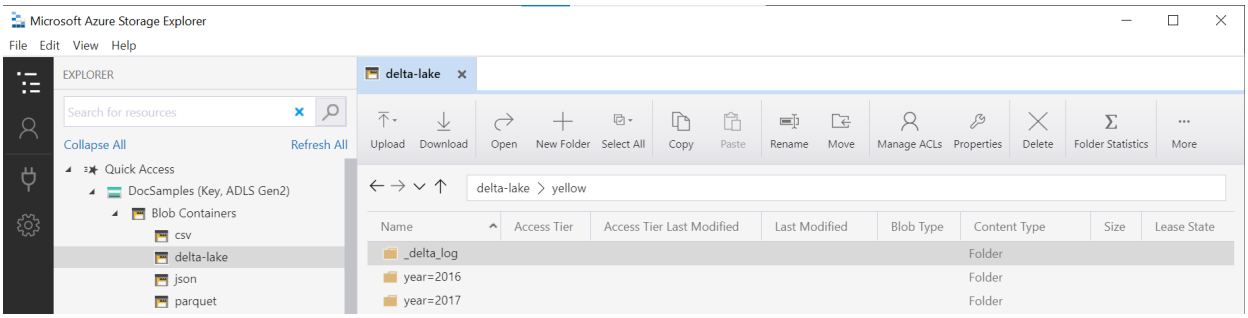
Query partitioned data

The data set provided in this sample is divided (partitioned) into separate subfolders. Unlike Parquet, you don't need to target specific partitions using the `FILEPATH` function. The `OPENROWSET` will identify partitioning columns in your Delta Lake folder structure and enable you to directly query data using these columns. This example shows fare amounts by year, month, and payment_type for the first three months of 2017.

```
SELECT
        YEAR(pickup_datetime) AS year,
        passenger_count,
        COUNT(*) AS cnt
FROM
    OPENROWSET(
        BULK 'yellow',
        DATA_SOURCE = 'DeltaLakeStorage',
        FORMAT='DELTA'
    ) nyc
WHERE
    nyc.year = 2017
    AND nyc.month IN (1, 2, 3)
    AND pickup_datetime BETWEEN CAST('1/1/2017' AS datetime) AND CAST('3/31/2017' AS datetime)
GROUP BY
    passenger_count,
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime),
    passenger_count;
```

The `OPENROWSET` function will eliminate partitions that don't match the `year` and `month` in the where clause. This file/partition pruning technique will significantly reduce your data set, improve performance, and reduce the cost of the query.

The folder name in the `OPENROWSET` function (`yellow` in this example) is concatenated using the `LOCATION` in `DeltaLakeStorage` data source, and must reference the root Delta Lake folder that contains a subfolder called `_delta_log`.



If you don't have this subfolder, you are not using Delta Lake format. You can convert your plain Parquet files in the folder to Delta Lake format using the following Apache Spark Python script:

```
%%pyspark
from delta.tables import *
deltaTable = DeltaTable.convertToDelta(spark, "parquet.`abfss://delta-
lake@sqlondemandstorage.dfs.core.windows.net/yellow`", "year INT, month INT")
```

The second argument of `DeltaTable.convertToDeltaLake` function represents the partitioning columns (year and month) that are a part of folder pattern (`year=*/month=*` in this example) and their types.

Limitations

- Review the limitations and the known issues on Synapse serverless SQL pool self-help page.
- Currently, both the Spark pool and serverless SQL pool in Azure Synapse Analytics support Delta Lake format. Serverless SQL pools do not support updating Delta Lake files. Only tables in Parquet format are shared from Spark pools to a serverless SQL pool. For more information, see Shared Spark tables.

Next steps

Advance to the next article to learn how to Query Parquet nested types. If you want to continue building Delta Lake solution, learn how to create views or external tables on the Delta Lake folder.

Query folders and multiple files

8/19/2022 • 6 minutes to read • Edit Online

In this article, you'll learn how to write a query using serverless SQL pool in Azure Synapse Analytics.

Serverless SQL pool supports reading multiple files/folders by using wildcards, which are similar to the wildcards used in Windows OS. However, greater flexibility is present since multiple wildcards are allowed.

Prerequisites

Your first step is to **create a database** where you'll execute the queries. Then initialize the objects by executing setup script on that database. This setup script will create the data sources, database scoped credentials, and external file formats that are used in these samples.

You'll use the folder *csv/taxi* to follow the sample queries. It contains NYC Taxi - Yellow Taxi Trip Records data from July 2016 to June 2018. Files in *csv/taxi* are named after year and month using the following pattern: yellow_tripdata_<year>-<month>.csv

Read all files in folder

The example below reads all NYC Yellow Taxi data files from the *csv/taxi* folder and returns the total number of passengers and rides per year. It also shows usage of aggregate functions.

```
SELECT
    YEAR(pickup_datetime) as [year],
    SUM(passenger_count) AS passengers_total,
    COUNT(*) AS [rides_total]
FROM OPENROWSET(
        BULK 'csv/taxi/*.csv',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        pickup_datetime DATETIME2 2,
        passenger_count INT 4
    ) AS nyc
GROUP BY
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime);
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Read subset of files in folder

The example below reads the 2017 NYC Yellow Taxi data files from the *csv/taxi* folder using a wildcard and returns the total fare amount per payment type.

```
SELECT
    payment_type,
    SUM(fare_amount) AS fare_total
FROM OPENROWSET(
        BULK 'csv/taxi/yellow_tripdata_2017-*.csv',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        payment_type INT 10,
        fare_amount FLOAT 11
    ) AS nyc
GROUP BY payment_type
ORDER BY payment_type;
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Read subset of files in folder using multiple file paths

The example below reads the 2017 NYC Yellow Taxi data files from the *csv/taxi* folder using 2 file paths first one with full path to the file containing data from month January and second with a wildcard reading months November and December which returns the total fare amount per payment type.

```
SELECT
    payment_type,
    SUM(fare_amount) AS fare_total
FROM OPENROWSET(
        BULK (
            'csv/taxi/yellow_tripdata_2017-01.csv',
            'csv/taxi/yellow_tripdata_2017-1*.csv'
        ),
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        payment_type INT 10,
        fare_amount FLOAT 11
    ) AS nyc
GROUP BY payment_type
ORDER BY payment_type;
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Read folders

The path that you provide to OPENROWSET can also be a path to a folder. The following sections include these query types.

Read all files from specific folder

You can read all the files in a folder using the file level wildcard as shown in Read all files in folder. But, there's a

way to query a folder and consume all files within that folder.

If the path provided in OPENROWSET points to a folder, all files in that folder will be used as a source for your query. The following query will read all files in the *csv/taxi* folder.

> **NOTE**
> Note the existence of the / at the end of the path in the query below. It denotes a folder. If the / is omitted, the query will target a file named *taxi* instead.

```
SELECT
    YEAR(pickup_datetime) as [year],
    SUM(passenger_count) AS passengers_total,
    COUNT(*) AS [rides_total]
FROM OPENROWSET(
        BULK 'csv/taxi/',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        vendor_id VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_datetime DATETIME2,
        dropoff_datetime DATETIME2,
        passenger_count INT,
        trip_distance FLOAT,
        rate_code INT,
        store_and_fwd_flag VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_location_id INT,
        dropoff_location_id INT,
        payment_type INT,
        fare_amount FLOAT,
        extra FLOAT,
        mta_tax FLOAT,
        tip_amount FLOAT,
        tolls_amount FLOAT,
        improvement_surcharge FLOAT,
        total_amount FLOAT
    ) AS nyc
GROUP BY
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime);
```

> **NOTE**
> All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Read all files from multiple folders

It's possible to read files from multiple folders by using a wildcard. The following query will read all files from all folders located in the *csv* folder that have names starting with *t* and ending with *i*.

> **NOTE**
> Note the existence of the / at the end of the path in the query below. It denotes a folder. If the / is omitted, the query will target files named *t*i* instead.

```
SELECT
    YEAR(pickup_datetime) as [year],
    SUM(passenger_count) AS passengers_total,
    COUNT(*) AS [rides_total]
FROM OPENROWSET(
        BULK 'csv/t*i/',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        vendor_id VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_datetime DATETIME2,
        dropoff_datetime DATETIME2,
        passenger_count INT,
        trip_distance FLOAT,
        rate_code INT,
        store_and_fwd_flag VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_location_id INT,
        dropoff_location_id INT,
        payment_type INT,
        fare_amount FLOAT,
        extra FLOAT,
        mta_tax FLOAT,
        tip_amount FLOAT,
        tolls_amount FLOAT,
        improvement_surcharge FLOAT,
        total_amount FLOAT
    ) AS nyc
GROUP BY
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime);
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Since you have only one folder that matches the criteria, the query result is the same as Read all files in folder.

Traverse folders recursively

Serverless SQL pool can recursively traverse folders if you specify /** at the end of path. The following query will read all files from all folders and subfolders located in the *csv/taxi* folder.

```
SELECT
    YEAR(pickup_datetime) as [year],
    SUM(passenger_count) AS passengers_total,
    COUNT(*) AS [rides_total]
FROM OPENROWSET(
        BULK 'csv/taxi/**',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        vendor_id VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_datetime DATETIME2,
        dropoff_datetime DATETIME2,
        passenger_count INT,
        trip_distance FLOAT,
        rate_code INT,
        store_and_fwd_flag VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_location_id INT,
        dropoff_location_id INT,
        payment_type INT,
        fare_amount FLOAT,
        extra FLOAT,
        mta_tax FLOAT,
        tip_amount FLOAT,
        tolls_amount FLOAT,
        improvement_surcharge FLOAT,
        total_amount FLOAT
    ) AS nyc
GROUP BY
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime);
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Multiple wildcards

You can use multiple wildcards on different path levels. For example, you can enrich previous query to read files with 2017 data only, from all folders which names start with *t* and end with *i*.

NOTE

Note the existence of the / at the end of the path in the query below. It denotes a folder. If the / is omitted, the query will target files named *t***i* instead. There is a maximum limit of 10 wildcards per query.

```
SELECT
    YEAR(pickup_datetime) as [year],
    SUM(passenger_count) AS passengers_total,
    COUNT(*) AS [rides_total]
FROM OPENROWSET(
        BULK 'csv/t*i/yellow_tripdata_2017-*.csv',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        vendor_id VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_datetime DATETIME2,
        dropoff_datetime DATETIME2,
        passenger_count INT,
        trip_distance FLOAT,
        rate_code INT,
        store_and_fwd_flag VARCHAR(100) COLLATE Latin1_General_BIN2,
        pickup_location_id INT,
        dropoff_location_id INT,
        payment_type INT,
        fare_amount FLOAT,
        extra FLOAT,
        mta_tax FLOAT,
        tip_amount FLOAT,
        tolls_amount FLOAT,
        improvement_surcharge FLOAT,
        total_amount FLOAT
    ) AS nyc
GROUP BY
    YEAR(pickup_datetime)
ORDER BY
    YEAR(pickup_datetime);
```

NOTE

All files accessed with the single OPENROWSET must have the same structure (i.e., number of columns and their data types).

Since you have only one folder that matches the criteria, the query result is the same as Read subset of files in folder and Read all files from specific folder. More complex wildcard usage scenarios are covered in Query Parquet files.

Use file metadata in serverless SQL pool queries

8/19/2022 • 2 minutes to read • Edit Online

Serverless SQL pool can address multiple files and folders as described in the Query folders and multiple files article. In this article, you learn how to use metadata information about file and folder names in the queries.

Sometimes, you may need to know which file or folder source correlates to a specific row in the result set.

You can use function `filepath` and `filename` to return file names and/or the path in the result set. Or you can use them to filter data based on the file name and/or folder path. These functions are described in the syntax section filename function and filepath function. In the following sections, you'll find short descriptions along samples.

Prerequisites

Your first step is to **create a database** with a datasource that references storage account. Then initialize the objects by executing setup script on that database. This setup script will create the data sources, database scoped credentials, and external file formats that are used in these samples.

Functions

Filename

This function returns the file name that row originates from.

The following sample reads the NYC Yellow Taxi data files for the last three months of 2017 and returns the number of rides per file. The OPENROWSET part of the query specifies which files will be read.

```
SELECT
    nyc.filename() AS [filename]
    ,COUNT_BIG(*) AS [rows]
FROM
    OPENROWSET(
        BULK 'parquet/taxi/year=2017/month=9/*.parquet',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT='PARQUET'
    ) nyc
GROUP BY nyc.filename();
```

The following example shows how *filename()* can be used in the WHERE clause to filter the files to be read. It accesses the entire folder in the OPENROWSET part of the query and filters files in the WHERE clause.

Your results will be the same as the prior example.

```
SELECT
    r.filename() AS [filename]
    ,COUNT_BIG(*) AS [rows]
FROM OPENROWSET(
    BULK 'csv/taxi/yellow_tripdata_2017-*.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV',
        PARSER_VERSION = '2.0',
        FIRSTROW = 2)
        WITH (C1 varchar(200) ) AS [r]
WHERE
    r.filename() IN ('yellow_tripdata_2017-10.csv', 'yellow_tripdata_2017-11.csv', 'yellow_tripdata_2017-
12.csv')
GROUP BY
    r.filename()
ORDER BY
    [filename];
```

Filepath

The filepath function returns a full or partial path:

- When called without a parameter, it returns the full file path that the row originates from. When DATA_SOURCE is used in OPENROWSET, it returns path relative to DATA_SOURCE.
- When called with a parameter, it returns part of the path that matches the wildcard on the position specified in the parameter. For example, parameter value 1 would return part of the path that matches the first wildcard.

The following sample reads NYC Yellow Taxi data files for the last three months of 2017. It returns the number of rides per file path. The OPENROWSET part of the query specifies which files will be read.

```
SELECT
    r.filepath() AS filepath
    ,COUNT_BIG(*) AS [rows]
FROM OPENROWSET(
        BULK 'csv/taxi/yellow_tripdata_2017-1*.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV',
        PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
    WITH (
        vendor_id INT
    ) AS [r]
GROUP BY
    r.filepath()
ORDER BY
    filepath;
```

The following example shows how *filepath()* can be used in the WHERE clause to filter the files to be read.

You can use the wildcards in the OPENROWSET part of the query and filter the files in the WHERE clause. Your results will be the same as the prior example.

```
SELECT
    r.filepath() AS filepath
    ,r.filepath(1) AS [year]
    ,r.filepath(2) AS [month]
    ,COUNT_BIG(*) AS [rows]
FROM OPENROWSET(
        BULK 'csv/taxi/yellow_tripdata_*-*.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV',
        PARSER_VERSION = '2.0',
        FIRSTROW = 2
    )
WITH (
    vendor_id INT
) AS [r]
WHERE
    r.filepath(1) IN ('2017')
    AND r.filepath(2) IN ('10', '11', '12')
GROUP BY
    r.filepath()
    ,r.filepath(1)
    ,r.filepath(2)
ORDER BY
    filepath;
```

Next steps

In the next article, you'll learn how to query Parquet files.

Create and use views using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

In this section, you'll learn how to create and use views to wrap serverless SQL pool queries. Views will allow you to reuse those queries. Views are also needed if you want to use tools, such as Power BI, in conjunction with serverless SQL pool.

Prerequisites

Your first step is to create a database where the view will be created and initialize the objects needed to authenticate on Azure storage by executing setup script on that database. All queries in this article will be executed on your sample database.

Views over external data

You can create views the same way you create regular SQL Server views. The following query creates view that reads *population.csv* file.

> **NOTE**
> Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO

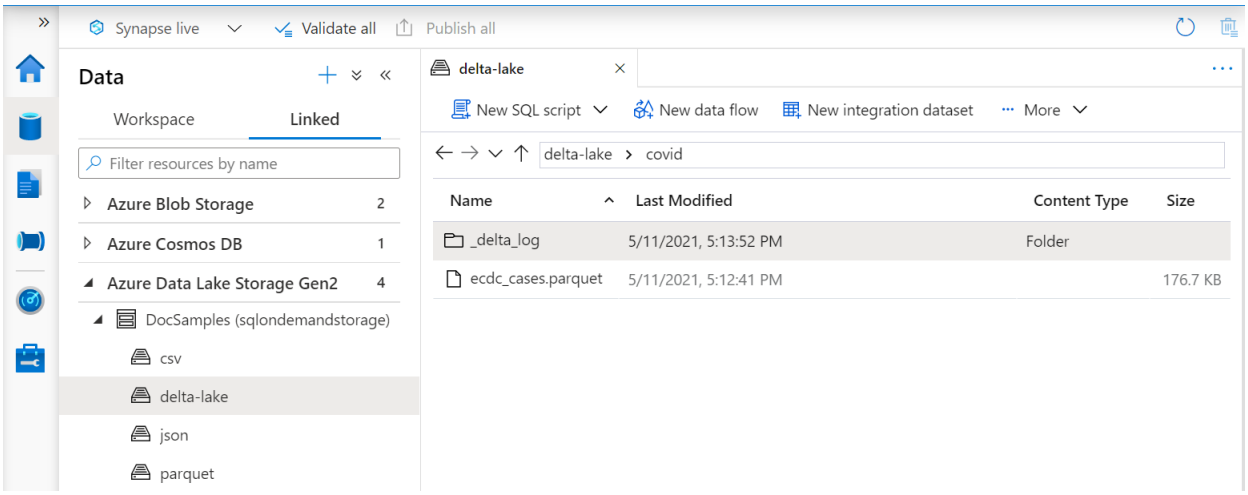
DROP VIEW IF EXISTS populationView;
GO

CREATE VIEW populationView AS
SELECT *
FROM OPENROWSET(
        BULK 'csv/population/population.csv',
        DATA_SOURCE = 'SqlOnDemandDemo',
        FORMAT = 'CSV',
        FIELDTERMINATOR =',',
        ROWTERMINATOR = '\n'
    )
WITH (
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
) AS [r];
```

The view uses an `EXTERNAL DATA SOURCE` with a root URL of your storage, as a `DATA_SOURCE` and adds a relative file path to the files.

Delta Lake views

If you are creating the views on top of Delta Lake folder, you need to specify the location to the root folder after the `BULK` option instead of specifying the file path.



The `OPENROWSET` function that reads data from the Delta Lake folder will examine the folder structure and automatically identify the file locations.

```
create or alter view CovidDeltaLake
as
select *
from openrowset(
           bulk 'covid',
           data_source = 'DeltaLakeStorage',
           format = 'delta'
    ) with (
           date_rep date,
           cases int,
           geo_id varchar(6)
           ) as rows
```

Review the known issues on Synapse serverless SQL pool self-help page.

Partitioned views

If you have a set of files that is partitioned in the hierarchical folder structure, you can describe the partition pattern using the wildcards in the file path. Use the `FILEPATH` function to expose parts of the folder path as partitioning columns.

```
CREATE VIEW TaxiView
AS SELECT *, nyc.filepath(1) AS [year], nyc.filepath(2) AS [month]
FROM
    OPENROWSET(
        BULK 'parquet/taxi/year=*/month=*/*.parquet',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT='PARQUET'
    ) AS nyc
```

The partitioned views will perform folder partition elimination if you query this view with the filters on the partitioning columns. This might improve performance of your queries.

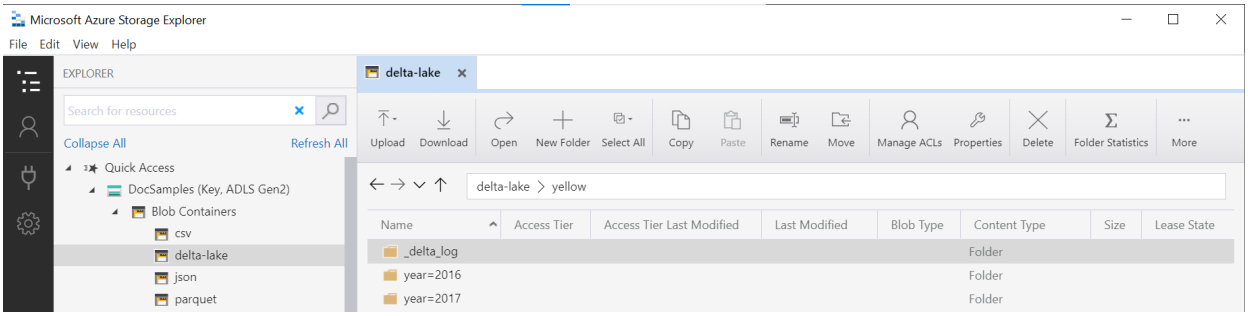
Delta Lake partitioned views

If you are creating the partitioned views on top of Delta Lake storage, you can specify just a root Delta Lake folder and don't need to explicitly expose the partitioning columns using the `FILEPATH` function:

```
CREATE OR ALTER VIEW YellowTaxiView
AS SELECT *
FROM
    OPENROWSET(
        BULK 'yellow',
        DATA_SOURCE = 'DeltaLakeStorage',
        FORMAT='DELTA'
    ) nyc
```

The `OPENROWSET` function will examine the structure of the underlying Delta Lake folder and automatically identify and expose the partitioning columns. The partition elimination will be done automatically if you put the partitioning column in the `WHERE` clause of a query.

The folder name in the `OPENROWSET` function (`yellow` in this example) that is concatenated with the `LOCATION` URI defined in `DeltaLakeStorage` data source must reference the root Delta Lake folder that contains a subfolder called `_delta_log`.



Review the known issues on Synapse serverless SQL pool self-help page.

JSON views

The views are the good choice if you need to do some additional processing on top of the result set that is fetched from the files. One example might be parsing JSON files where we need to apply the JSON functions to extract the values from the JSON documents:

```
CREATE OR ALTER VIEW CovidCases
AS
select
    *
from openrowset(
        bulk 'latest/ecdc_cases.jsonl',
        data_source = 'covid',
        format = 'csv',
        fieldterminator ='0x0b',
        fieldquote = '0x0b'
    ) with (doc nvarchar(max)) as rows
    cross apply openjson (doc)
        with (  date_rep datetime2,
                cases int,
                fatal int '$.deaths',
                country varchar(100) '$.countries_and_territories')
```

The `OPENJSON` function parses each line from the JSONL file containing one JSON document per line in textual format.

Cosmos DB views on containers

The views can be created on top of the Azure Cosmos DB containers if the Cosmos DB analytical storage is enabled on the container. Cosmos DB account name, database name, and container name should be added as a

part of the view, and the read-only access key should be placed in the database scoped credential that the view references.

```
CREATE DATABASE SCOPED CREDENTIAL MyCosmosDbAccountCredential
WITH IDENTITY = 'SHARED ACCESS SIGNATURE', SECRET =
's5zarR2pT0JWH9k8roipnWxUYBegOuFGjJpSjGlR36y86cW0GQ6RaaG8kGjsRAQoWMw1QKTkkX8HQtFpJjC8Hg==';
GO
CREATE OR ALTER VIEW Ecdc
AS SELECT *
FROM OPENROWSET(
      PROVIDER = 'CosmosDB',
      CONNECTION = 'Account=synapselink-cosmosdb-sqlsample;Database=covid',
      OBJECT = 'Ecdc',
      CREDENTIAL = 'MyCosmosDbAccountCredential'
    ) with ( date_rep varchar(20), cases bigint, geo_id varchar(6) ) as rows
```

For more information, see Query Azure Cosmos DB data with a serverless SQL pool in Azure Synapse Link.

Use a view

You can use views in your queries the same way you use views in SQL Server queries.

The following query demonstrates using the *population_csv* view we created in Create a view. It returns country/region names with their population in 2019 in descending order.

> **NOTE**
> Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO

SELECT
    country_name, population
FROM populationView
WHERE
    [year] = 2019
ORDER BY
    [population] DESC;
```

Next steps

For information on how to query different file types, refer to the Query single CSV file, Query Parquet files, and Query JSON files articles.

Create and use native external tables using SQL pools in Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

In this section, you'll learn how to create and use native external tables in Synapse SQL pools. Native external tables have better performance when compared to external tables with `TYPE=HADOOP` in their external data source definition. This is because native external tables use native code to access external data.

External tables are useful when you want to control access to external data in Synapse SQL pool. External tables are also useful if you want to use tools, such as Power BI, in conjunction with Synapse SQL pool. External tables can access two types of storage:

- Public storage where users access public storage files.
- Protected storage where users access storage files using SAS credential, Azure AD identity, or Managed Identity of Synapse workspace.

> **NOTE**
> In dedicated SQL pools you can only use native external tables with a Parquet file type, and this feature is in **public preview**. If you want to use generally available Parquet reader functionality in dedicated SQL pools, or you need to access CSV or ORC files, use Hadoop external tables. Native external tables are generally available in serverless SQL pools. Learn more about the differences between native and Hadoop external tables in Use external tables with Synapse SQL.

The following table lists the data formats supported:

DATA FORMAT (NATIVE EXTERNAL TABLES)	SERVERLESS SQL POOL	DEDICATED SQL POOL
Parquet	Yes (GA)	Yes (public preview)
CSV	Yes	No (Alternatively, use Hadoop external tables)
delta	Yes	No
Spark	Yes	No
Dataverse	Yes	No
Azure Cosmos DB data formats (JSON, BSON etc.)	No (Alternatively, create views)	No

Prerequisites

Your first step is to create a database where the tables will be created. Then create the following objects that are used in this sample:

- DATABASE SCOPED CREDENTIAL `sqlondemand` that enables access to SAS-protected `https://sqlondemandstorage.blob.core.windows.net` Azure storage account.

```
CREATE DATABASE SCOPED CREDENTIAL [sqlondemand]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = 'sv=2018-03-28&ss=bf&srt=sco&sp=rl&st=2019-10-14T12%3A10%3A25Z&se=2061-12-
31T12%3A10%3A00Z&sig=KlSU2ullCscyTS0An0nozEpo4tO5JAgGBvw%2FJX2lguw%3D'
```

- EXTERNAL DATA SOURCE `sqlondemanddemo` that references demo storage account protected with SAS key, and EXTERNAL DATA SOURCE `nyctlc` that references publicly available Azure storage account on location `https://azureopendatastorage.blob.core.windows.net/nyctlc/`.

```
CREATE EXTERNAL DATA SOURCE SqlOnDemandDemo WITH (
    LOCATION = 'https://sqlondemandstorage.blob.core.windows.net',
    CREDENTIAL = sqlondemand
);
GO
CREATE EXTERNAL DATA SOURCE nyctlc
WITH ( LOCATION = 'https://azureopendatastorage.blob.core.windows.net/nyctlc/')
GO
CREATE EXTERNAL DATA SOURCE DeltaLakeStorage
WITH ( location = 'https://sqlondemandstorage.blob.core.windows.net/delta-lake/' );
```

- File formats `QuotedCSVWithHeaderFormat` and `ParquetFormat` that describe CSV and parquet file types.

```
CREATE EXTERNAL FILE FORMAT QuotedCsvWithHeaderFormat
WITH (
    FORMAT_TYPE = DELIMITEDTEXT,
    FORMAT_OPTIONS ( FIELD_TERMINATOR = ',', STRING_DELIMITER = '"', FIRST_ROW = 2   )
);
GO
CREATE EXTERNAL FILE FORMAT ParquetFormat WITH (  FORMAT_TYPE = PARQUET );
GO
CREATE EXTERNAL FILE FORMAT DeltaLakeFormat WITH (  FORMAT_TYPE = DELTA );
GO
```

The queries in this article will be executed on your sample database and use these objects.

External table on a file

You can create external tables that access data on an Azure storage account that allows access to users with some Azure AD identity or SAS key. You can create external tables the same way you create regular SQL Server external tables.

The following query creates an external table that reads *population.csv* file from SynapseSQL demo Azure storage account that is referenced using `sqlondemanddemo` data source and protected with database scoped credential called `sqlondemand`.

Data source and database scoped credential are created in setup script.

> **NOTE**
>
> Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO
CREATE EXTERNAL TABLE populationExternalTable
(
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
)
WITH (
    LOCATION = 'csv/population/population.csv',
    DATA_SOURCE = sqlondemanddemo,
    FILE_FORMAT = QuotedCSVWithHeaderFormat
);
```

Native CSV tables are currently available only in the serverless SQL pools.

External table on a set of files

You can create external tables that read data from a set of files placed on Azure storage:

```
CREATE EXTERNAL TABLE Taxi (
     vendor_id VARCHAR(100) COLLATE Latin1_General_BIN2,
     pickup_datetime DATETIME2,
     dropoff_datetime DATETIME2,
     passenger_count INT,
     trip_distance FLOAT,
     fare_amount FLOAT,
     tip_amount FLOAT,
     tolls_amount FLOAT,
     total_amount FLOAT
) WITH (
         LOCATION = 'yellow/puYear=*/puMonth=*/*.parquet',
         DATA_SOURCE = nyctlc,
         FILE_FORMAT = ParquetFormat
);
```

You can specify the pattern that the files must satisfy in order to be referenced by the external table. The pattern is required only for Parquet and CSV tables. If you are using Delta Lake format, you need to specify just a root folder, and the external table will automatically find the pattern.

> **NOTE**
>
> The table is created on partitioned folder structure, but you cannot leverage some partition elimination. If you want to get better performance by skipping the files that do not satisfy some criterion (like specific year or month in this case), use views on external data.

External table on appendable files

The files that are referenced by an external table should not be changed while the query is running. In the long-running query, SQL pool may retry reads, read parts of the files, or even read the file multiple times. Changes of the file content would cause wrong results. Therefore, the SQL pool fails the query if detects that the modification time of any file is changed during the query execution. In some scenarios you might want to create a table on the files that are constantly appended. To avoid the query failures due to constantly appended files, you can specify that the external table should ignore potentially inconsistent reads using the `TABLE_OPTIONS` setting.

```
CREATE EXTERNAL TABLE populationExternalTable
(
    [country_code] VARCHAR (5) COLLATE Latin1_General_BIN2,
    [country_name] VARCHAR (100) COLLATE Latin1_General_BIN2,
    [year] smallint,
    [population] bigint
)
WITH (
    LOCATION = 'csv/population/population.csv',
    DATA_SOURCE = sqlondemanddemo,
    FILE_FORMAT = QuotedCSVWithHeaderFormat,
    TABLE_OPTIONS = N'{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}'
);
```

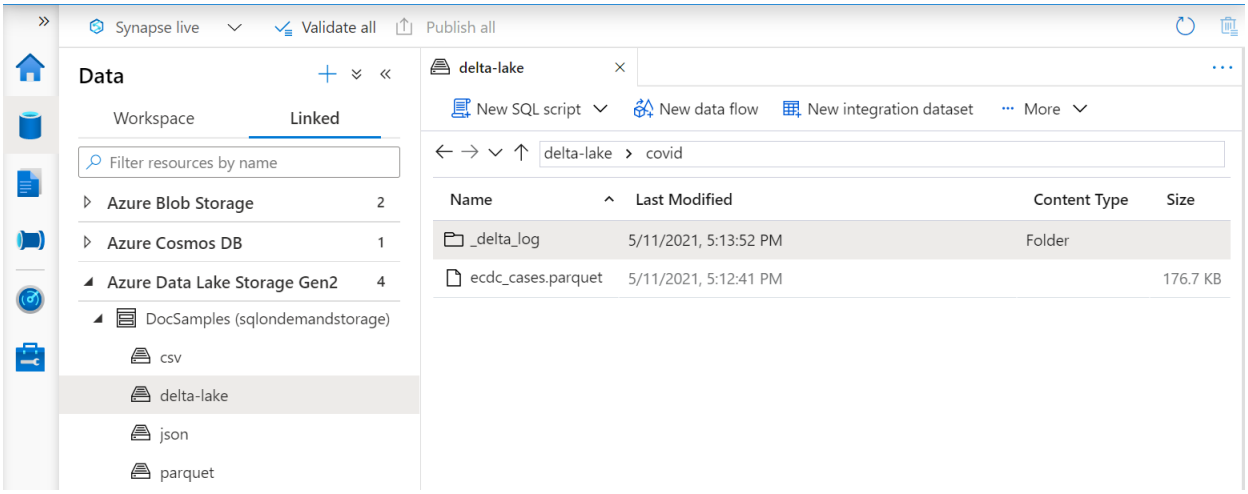
The `ALLOW_INCONSISTENT_READS` read option will disable file modification time check during the query lifecycle and read whatever is available in the files that are referenced by the external table. In appendable files, the existing content is not updated, and only new rows are added. Therefore, the probability of wrong results is minimized compared to the updateable files. This option might enable you to read the frequently appended files without handling the errors.

This option is available only in the external tables created on CSV file format.

> **NOTE**
>
> As the option name implies, the creator of the table accepts a risk that the results might not be consistent. In the appendable files, you might get incorrect results if you force multiple read of the underlying files by self-joining the table. In most of the "classic" queries, the external table will just ignore some rows that are appended while the query was running.

Delta Lake external table

External tables can be created on top of a Delta Lake folder. The only difference between the external tables created on a single file or a file set and the external tables created on a Delta Lake format is that in Delta Lake external table you need to reference a folder containing the Delta Lake structure.



An example of a table definition created on a Delta Lake folder is:

```
CREATE EXTERNAL TABLE Covid (
     date_rep date,
     cases int,
     geo_id varchar(6)
) WITH (
        LOCATION = 'covid', --> the root folder containing the Delta Lake files
        data_source = DeltaLakeStorage,
        FILE_FORMAT = DeltaLakeFormat
);
```

External tables cannot be created on a partitioned folder. Review the other known issues on Synapse serverless SQL pool self-help page.

Delta tables on partitioned folders

External tables in serverless SQL pools do not support partitioning on Delta Lake format. Use Delta partitioned views instead of tables if you have partitioned Delta Lake data sets.

> **IMPORTANT**
> Do not create external tables on partitioned Delta Lake folders even if you see that they might work in some cases. Using unsupported features like external tables on partitioned delta folders might cause issues or instability of the serverless pool. Azure support will not be able to resolve any issue if it is using tables on partitioned folders. You would be asked to transition to Delta partitioned views and rewrite your code to use only the supported feature before proceeding with issue resolution.

Use an external table

You can use external tables in your queries the same way you use them in SQL Server queries.

The following query demonstrates this using the *population* external table we created in previous section. It returns country/region names with their population in 2019 in descending order.

> **NOTE**
> Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO

SELECT
    country_name, population
FROM populationExternalTable
WHERE
    [year] = 2019
ORDER BY
    [population] DESC;
```

Performance of this query might vary depending on region. Your workspace might not be placed in the same region as the Azure storage accounts used in these samples. For production workloads, place your Synapse workspace and Azure storage in the same region.

Next steps

For information on how to store results of a query to storage, refer to Store query results to the storage article.

Store query results to storage using serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

In this article, you'll learn how to store query results to storage using serverless SQL pool.

Prerequisites

Your first step is to **create a database** where you will execute the queries. Then initialize the objects by executing setup script on that database. This setup script will create the data sources, database scoped credentials, and external file formats that are used to read data in these samples.

Follow the instructions in this article to create data sources, database scoped credentials, and external file formats that are used to write data into the output storage.

Create external table as select

You can use the CREATE EXTERNAL TABLE AS SELECT (CETAS) statement to store the query results to storage.

> **NOTE**
> Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO

CREATE DATABASE SCOPED CREDENTIAL [SasTokenWrite]
WITH IDENTITY = 'SHARED ACCESS SIGNATURE',
     SECRET = 'sv=2018-03-28&ss=bfqt&srt=sco&sp=rwdlacup&se=2019-04-18T20:42:12Z&st=2019-04-
18T12:42:12Z&spr=https&sig=lQHczNvrk1KoYLCpFdSsMANd0ef9BrIPBNJ3VYEIq78%3D';
GO

CREATE EXTERNAL DATA SOURCE [MyDataSource] WITH (
    LOCATION = 'https://<storage account name>.blob.core.windows.net/csv', CREDENTIAL = [SasTokenWrite]
);
GO

CREATE EXTERNAL FILE FORMAT [ParquetFF] WITH (
    FORMAT_TYPE = PARQUET,
    DATA_COMPRESSION = 'org.apache.hadoop.io.compress.SnappyCodec'
);
GO

CREATE EXTERNAL TABLE [dbo].[PopulationCETAS] WITH (
        LOCATION = 'populationParquet/',
        DATA_SOURCE = [MyDataSource],
        FILE_FORMAT = [ParquetFF]
) AS
SELECT
    *
FROM
    OPENROWSET(
        BULK 'csv/population-unix/population.csv',
        DATA_SOURCE = 'sqlondemanddemo',
        FORMAT = 'CSV', PARSER_VERSION = '2.0'
    ) WITH (
        CountryCode varchar(4),
        CountryName varchar(64),
        Year int,
        PopulationCount int
    ) AS r;
```

NOTE

You must modify this script and change the target location to execute it again. External tables cannot be created on the location where you already have some data.

Use the external table

You can use the external table created through CETAS like a regular external table.

NOTE

Change the first line in the query, i.e., [mydbname], so you're using the database you created.

```
USE [mydbname];
GO

SELECT
    country_name, population
FROM PopulationCETAS
WHERE
    [year] = 2019
ORDER BY
    [population] DESC;
```

Remarks

Once you store your results, the data in the external table cannot be modified. You cannot repeat this script because CETAS will not overwrite the underlying data created in the previous execution. Vote for the following feedback items if some of these are required in your scenarios, or propose the new ones on Azure feedback site:

- Enable inserting new data into external table
- Enable deleting data from external table
- Specify partitions in CETAS
- Specify file sizes and counts

The only supported output types are Parquet and CSV. You can vote for the other types on Azure feedback site.

Next steps

For more information on how to query different file types, see the Query single CSV file, Query Parquet files, and Query JSON files articles.

Analyze complex data types in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

This article is relevant for Parquet files and containers in Azure Synapse Link for Azure Cosmos DB. You can use Spark or SQL to read or transform data with complex schemas such as arrays or nested structures. The following example is completed with a single document, but it can easily scale to billions of documents with Spark or SQL. The code included in this article uses PySpark (Python).

Use case

Complex data types are increasingly common and represent a challenge for data engineers. Analyzing nested schema and arrays can involve time-consuming and complex SQL queries. Additionally, it can be difficult to rename or cast the nested columns data type. Also, when you're working with deeply nested objects, you can encounter performance problems.

Data engineers need to understand how to efficiently process complex data types and make them easily accessible to everyone. In the following example, you use Spark in Azure Synapse Analytics to read and transform objects into a flat structure through data frames. You use the serverless model of SQL in Azure Synapse Analytics to query such objects directly, and return those results as a regular table.

What are arrays and nested structures?

The following object comes from Application Insights. In this object, there are nested structures and arrays that contain nested structures.

```
{
    "id": "66532691-ab20-11ea-8b1d-936b3ec64e54",
    "context": {
        "data": {
            "eventTime": "2020-06-10T13:43:34.553Z",
            "samplingRate": "100.0",
            "isSynthetic": "false"
        },
        "session": {
            "isFirst": "false",
            "id": "38619c14-7a23-4687-8268-95862c5326b1"
        },
        "custom": {
            "dimensions": [
                {
                    "customerInfo": {
                        "ProfileType": "ExpertUser",
                        "RoomName": "",
                        "CustomerName": "diamond",
                        "UserName": "XXXX@yahoo.com"
                    }
                },
                {
                    "customerInfo": {
                        "ProfileType": "Novice",
                        "RoomName": "",
                        "CustomerName": "topaz",
                        "UserName": "XXXX@outlook.com"
                    }
                }
            ]
        }
    }
}
```

Schema example of arrays and nested structures

When you're printing the schema of the object's data frame (called **df**) with the command `df.printschema`, you see the following representation:

- Yellow represents nested structures.
- Green represents an array with two elements.

```
root
 |-- _rid: string (nullable = true)
 |-- _ts: long (nullable = true)
 |-- id: string (nullable = true)
 |-- context: struct (nullable = true)
 |    |-- data: struct (nullable = true)
 |    |    |-- eventTime: string (nullable = true)
 |    |    |-- samplingRate: string (nullable = true)
 |    |    |-- isSynthetic: string (nullable = true)
 |    |-- session: struct (nullable = true)
 |    |    |-- isFirst: string (nullable = true)
 |    |    |-- id: string (nullable = true)
 |    |-- custom: struct (nullable = true)
 |    |    |-- dimensions: array (nullable = true)
 |    |    |    |-- element: struct (containsNull = true)
 |    |    |    |    |-- customerInfo: struct (nullable = true)
 |    |    |    |    |    |-- ProfileType: string (nullable = true)
 |    |    |    |    |    |-- RoomName: string (nullable = true)
 |    |    |    |    |    |-- CustomerName: string (nullable = true)
 |    |    |    |    |    |-- UserName: string (nullable = true)
 |-- _etag: string (nullable = true)
```

`_rid`, `_ts`, and `_etag` have been added to the system as the document was ingested into the Azure Cosmos DB transactional store.

The preceding data frame counts for 5 columns and 1 row only. After transformation, the curated data frame will have 13 columns and 2 rows, in a tabular format.

Flatten nested structures and explode arrays

With Spark in Azure Synapse Analytics, it's easy to transform nested structures into columns and array elements into multiple rows. Use the following steps for implementation.

Define a function to flatten the nested schema

You can use this function without change. Create a cell in a PySpark notebook with the following function:

```
from pyspark.sql.functions import col

def flatten_df(nested_df):
    stack = [((), nested_df)]
    columns = []

    while len(stack) > 0:
        parents, df = stack.pop()

        flat_cols = [
            col(".".join(parents + (c[0],))).alias("_".join(parents + (c[0],)))
            for c in df.dtypes
            if c[1][:6] != "struct"
        ]

        nested_cols = [
            c[0]
            for c in df.dtypes
            if c[1][:6] == "struct"
        ]

        columns.extend(flat_cols)

        for nested_col in nested_cols:
            projected_df = df.select(nested_col + ".*")
            stack.append((parents + (nested_col,), projected_df))

    return nested_df.select(columns)
```

Use the function to flatten the nested schema

In this step, you flatten the nested schema of the data frame (**df**) into a new data frame (`df_flat`):

```
from pyspark.sql.types import StringType, StructField, StructType
df_flat = flatten_df(df)
display(df_flat.limit(10))
```

The display function should return 10 columns and 1 row. The array and its nested elements are still there.

Transform the array

Here, you transform the array, `context_custom_dimensions`, in the data frame `df_flat`, into a new data frame `df_flat_explode`. In the following code, you also define which column to select:

```
from pyspark.sql.functions import explode
from pyspark.sql.functions import flatten
from pyspark.sql.functions import arrays_zip
df_flat_explode =
df_flat.select("_rid","_ts","id","_etag",explode(df_flat.context_custom_dimensions),"context_session_isFirst
","context_session_id","context_data_eventTime","context_data_samplingRate","context_data_isSynthetic")\
.select("_rid","_ts","id","_etag","col.*","context_session_isFirst","context_session_id","context_data_event
Time","context_data_samplingRate","context_data_isSynthetic")
display(df_flat_explode.limit(10))
```

The display function should return 10 columns and 2 rows. The next step is to flatten nested schemas with the function defined in step 1.

Use the function to flatten the nested schema

Finally, you use the function to flatten the nested schema of the data frame `df_flat_explode`, into a new data frame, `df_flat_explode_flat`:

```
df_flat_explode_flat = flatten_df(df_flat_explode)
display(df_flat_explode_flat.limit(10))
```

The display function should show 13 columns and 2 rows.

The function `printSchema` of the data frame `df_flat_explode_flat` returns the following result:

```
root
 |-- _rid: string (nullable = true)
 |-- _ts: long (nullable = true)
 |-- id: string (nullable = true)
 |-- _etag: string (nullable = true)
 |-- context_session_isFirst: string (nullable = true)
 |-- context_session_id: string (nullable = true)
 |-- context_data_eventTime: string (nullable = true)
 |-- context_data_samplingRate: string (nullable = true)
 |-- context_data_isSynthetic: string (nullable = true)
 |-- customerInfo_ProfileType: string (nullable = true)
 |-- customerInfo_RoomName: string (nullable = true)
 |-- customerInfo_CustomerName: string (nullable = true)
 |-- customerInfo_UserName: string (nullable = true)
```

Read arrays and nested structures directly

With the serverless model of SQL, you can query and create views and tables over such objects.

First, depending how the data has been stored, users should use the following taxonomy. Everything shown in uppercase is specific to your use case:

BULK	FORMAT
'https://ACCOUNTNAME.dfs.core.windows.net/FILESYSTEM/PATH/FINENAME.parquet'	'Parquet' (ADLSg2)

BULK	FORMAT
N'endpoint=https://ACCOUNTNAME.documents-staging.windows-ppe.net:443/;account=ACCOUNTNAME;database=DATABASENAME;collection=COLLECTIONNAME;region=REGIONTOQUERY', SECRET='YOURSECRET'	'CosmosDB' (Azure Synapse Link)

Replace each field as follows:

- 'YOUR BULK ABOVE' is the connection string of the data source you connect to.
- 'YOUR TYPE ABOVE' is the format you use to connect to the source.

```
select *
FROM
openrowset(
    BULK 'YOUR BULK ABOVE',
    FORMAT='YOUR TYPE ABOVE'
)
with (id varchar(50),
        contextdataeventTime varchar(50) '$.context.data.eventTime',
        contextdatasamplingRate varchar(50) '$.context.data.samplingRate',
        contextdataisSynthetic varchar(50) '$.context.data.isSynthetic',
        contextsessionisFirst varchar(50) '$.context.session.isFirst',
        contextsessionid varchar(50) '$.context.session.id',
        contextcustomdimensions varchar(max) '$.context.custom.dimensions'
) as q
cross apply openjson (contextcustomdimensions)
with ( ProfileType varchar(50) '$.customerInfo.ProfileType',
            RoomName varchar(50) '$.customerInfo.RoomName',
            CustomerName varchar(50) '$.customerInfo.CustomerName',
            UserName varchar(50) '$.customerInfo.UserName'
    )
```

There are two different types of operations:

- The first operation type is indicated in the following line of code, which defines the column called `contextdataeventTime` that refers to the nested element, `Context.Data.eventTime`.

  ```
  contextdataeventTime varchar(50) '$.context.data.eventTime'
  ```

  This line defines the column called `contextdataeventTime` that refers to the nested element, `Context>Data>eventTime`.

- The second operation type uses `cross apply` to create new rows for each element under the array. Then it defines each nested object.

  ```
  cross apply openjson (contextcustomdimensions)
  with ( ProfileType varchar(50) '$.customerInfo.ProfileType',
  ```

  If the array had 5 elements with 4 nested structures, the serverless model of SQL returns 5 rows and 4 columns. The serverless model of SQL can query in place, map the array in 2 rows, and display all nested structures into columns.

Use Azure Stream Analytics with dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Azure Stream Analytics is a fully managed service providing low-latency, highly available, scalable complex event processing over streaming data in the cloud. You can learn the basics by reading Introduction to Azure Stream Analytics. You can then learn how to create an end-to-end solution with Stream Analytics by following the Get started using Azure Stream Analytics tutorial.

In this article, you will learn how to use your dedicated SQL pool as an output sink for high throughput data ingestion with Azure Stream Analytics jobs.

Prerequisites

- Azure Stream Analytics Job - To create an Azure Stream Analytics job, follow the steps in the Get started using Azure Stream Analytics tutorial to:
  1. Create an Event Hub input
  2. Configure and start event generator application
  3. Provision a Stream Analytics job
  4. Specify job input and query
- Dedicated SQL pool - To create a new dedicated SQL pool, follow the steps in the Quickstart: Create a dedicated SQL pool.

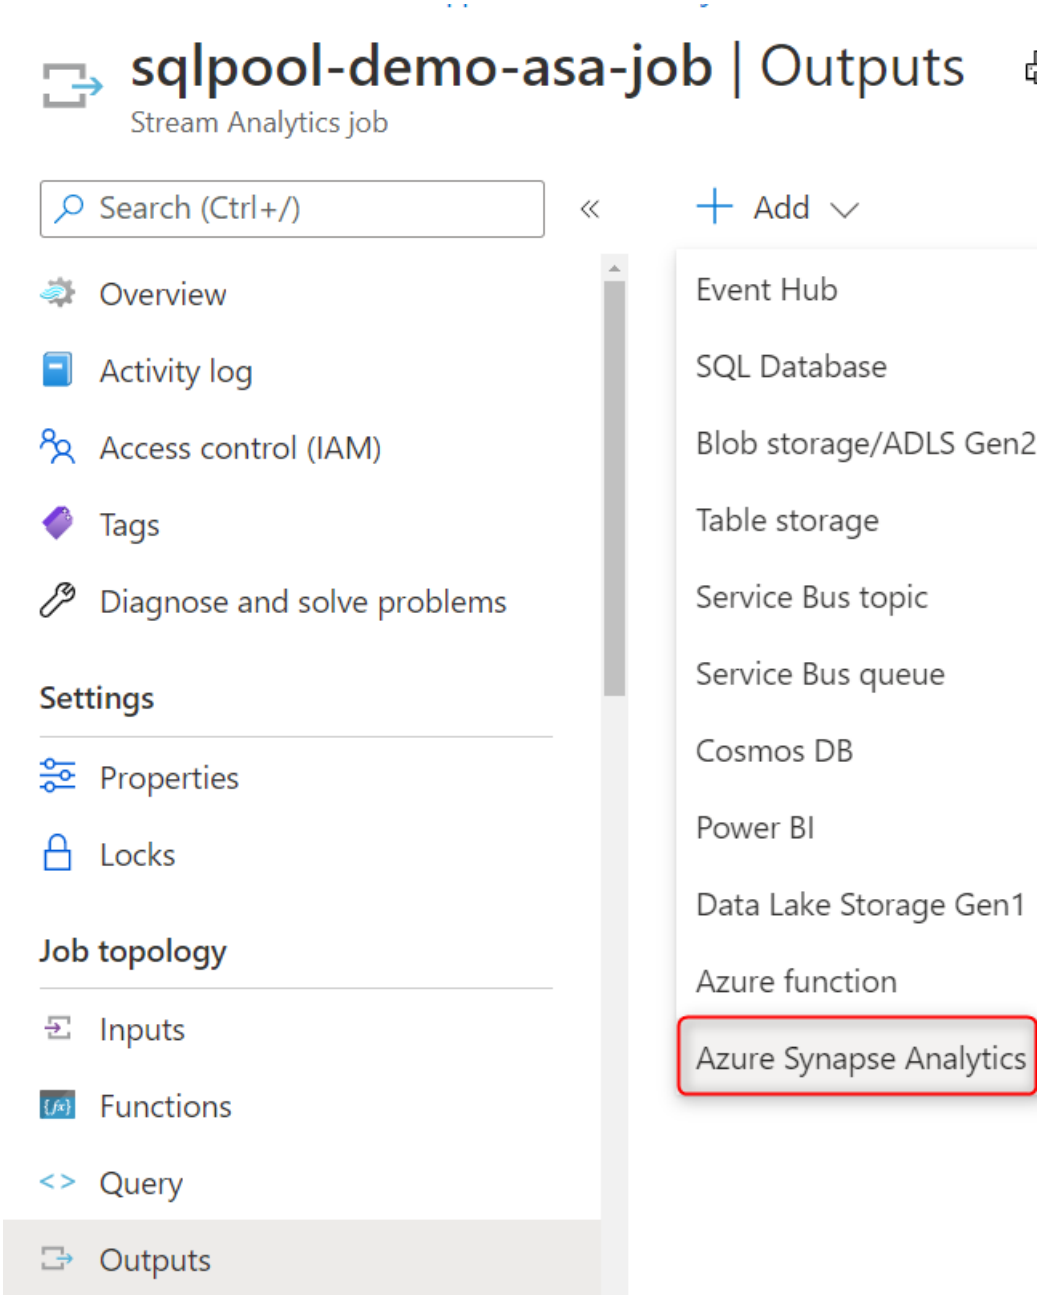
Specify streaming output to point to your dedicated SQL pool

Step 1

From the Azure portal, go to your Stream Analytics job and click on **Outputs** under the **Job topology** menu.

Step 2

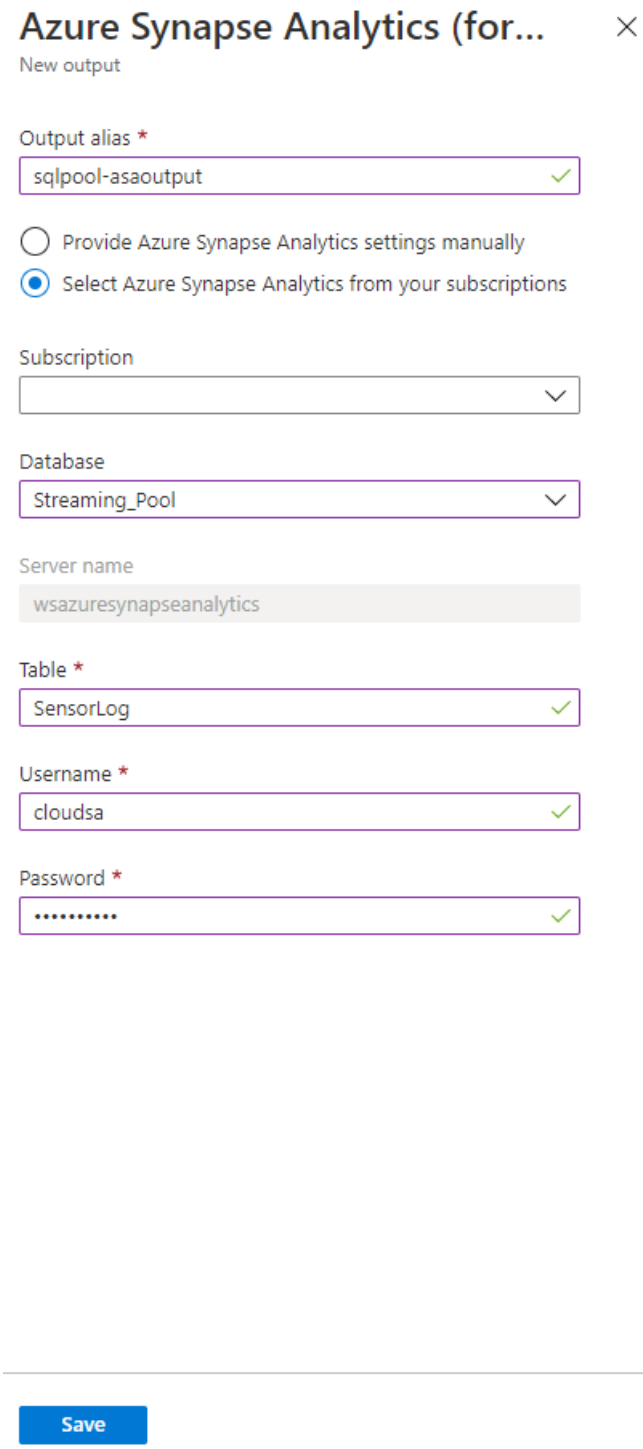
Click on the **Add** button and choose **Azure Synapse Analytics** from the drop down menu.



Step 3

Enter the following values:

- *Output Alias*: Enter a friendly name for this job output.
- *Subscription*:
  - If your dedicated SQL pool is in the same subscription as the Stream Analytics job, click on ***Select Azure Synapse Analytics from your subscriptions***.
  - If your dedicated SQL pool is in a different subscription, click on Provide Azure Synapse Analytics settings manually.
- *Database*: Select the destination database from the drop down list.
- *User Name*: Specify the user name of an account that has write permissions for the database.
- *Password*: Provide the password for the specified user account.
- *Table*: Specify the name of the target table in the database.
- click on the **Save** button



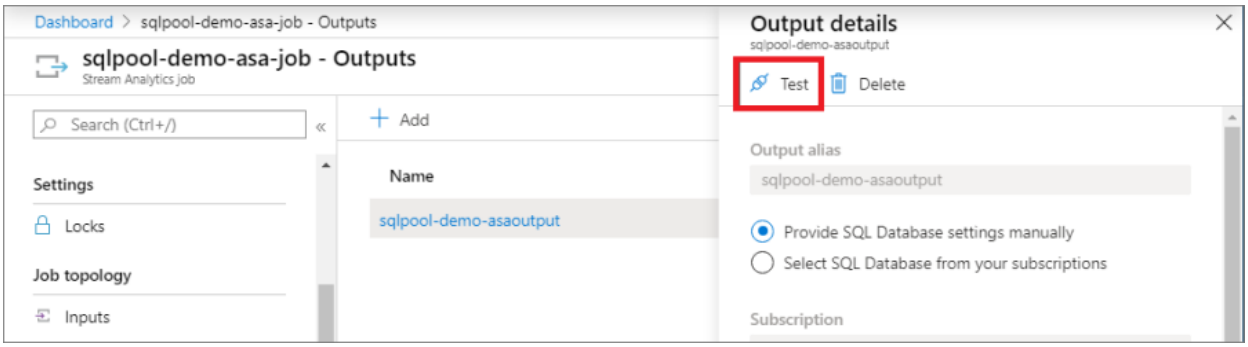
Step 4

Before you can run a test, you will need to create the table in your dedicated SQL pool. Run the following table creation script using SQL Server Management Studio (SSMS) or your choice of query tool.

```
CREATE TABLE SensorLog
(
    RecordType VARCHAR(2)
    , SystemIdentity VARCHAR(2)
    , FileNum INT
    , SwitchNum VARCHAR(50)
    , CallingNum VARCHAR(25)
    , CallingIMSI VARCHAR(25)
    , CalledNum VARCHAR(25)
    , CalledIMSI VARCHAR(25)
    , DateS VARCHAR(25)
    , TimeS VARCHAR(25)
    , TimeType INT
    , CallPeriod INT
    , CallingCellID VARCHAR(25)
    , CalledCellID VARCHAR(25)
    , ServiceType VARCHAR(25)
    , [Transfer] INT
    , IncomingTrunk VARCHAR(25)
    , OutgoingTrunk VARCHAR(25)
    , MSRN VARCHAR(25)
    , CalledNum2 VARCHAR(25)
    , FCIFlag VARCHAR(25)
    , callrecTime VARCHAR(50)
    , EventProcessedUtcTime VARCHAR(50)
    , PartitionId int
    , EventEnqueuedUtcTime VARCHAR(50)
    )
WITH (DISTRIBUTION = ROUND_ROBIN)
```

Step 5

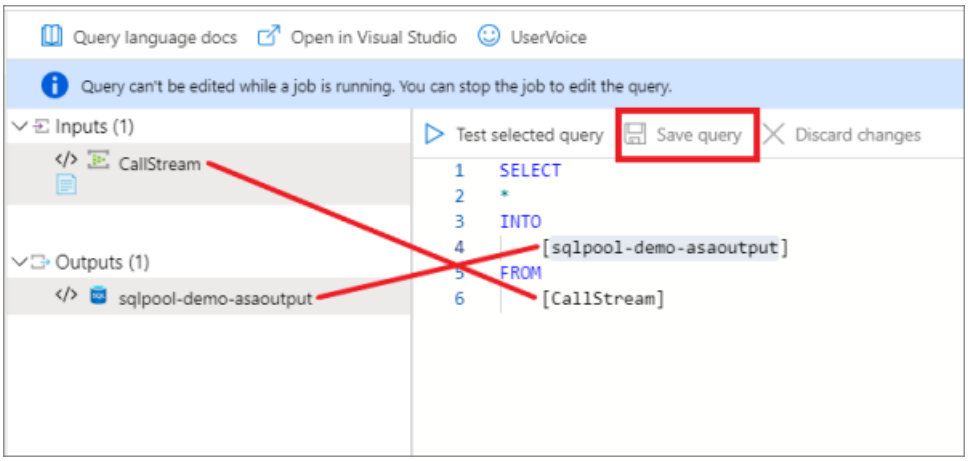
On the Azure portal for Stream Analytics job, click on your job name. Click on the *Test* button in the *Output details* pane.



When the connection to the database succeeds, you will see a notification in the portal.

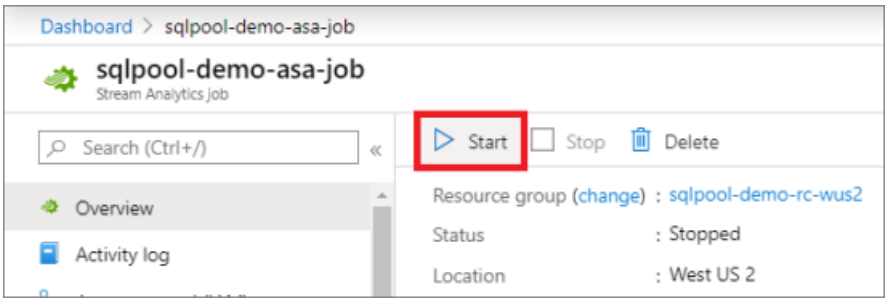
Step 6

Click on the *Query* menu under *Job topology* and change the query to insert data into the Stream output you created. Click on the *Test selected query* button to test your query. Click *Save Query* button when your query test is successful.

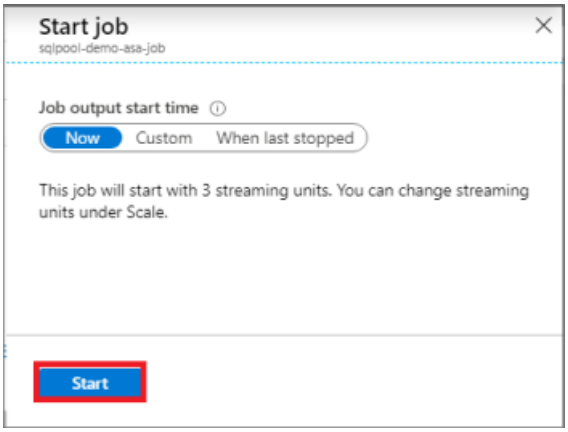


Step 7

Start the Azure Stream Analytics job. Click on the ***Start*** button on the ***Overview*** menu.



Click the ***Start*** button on the start job pane.



Next steps

For an overview of integration, see Integrate other services. For more development tips, see Design decisions and coding techniques for dedicated SQL pool.

Connect to Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

Get connected to the Synapse SQL capability in Azure Synapse Analytics.

Supported tools for serverless SQL pool

Azure Data Studio is fully supported starting from version 1.18.0. SSMS is partially supported starting from version 18.5, you can use it to connect and query only.

> **NOTE**
>
> If an AAD login has a connection open for more than 1 hour at time of query execution, any query that relies on AAD will fail. This includes querying storage using AAD pass-through and statements that interact with AAD (like CREATE EXTERNAL PROVIDER). This affects every tool that keeps connections open, like in query editor in SSMS and ADS. Tools that open new connections to execute a query, like Synapse Studio, are not affected.

> You can restart SSMS or connect and disconnect in ADS to mitigate this issue.

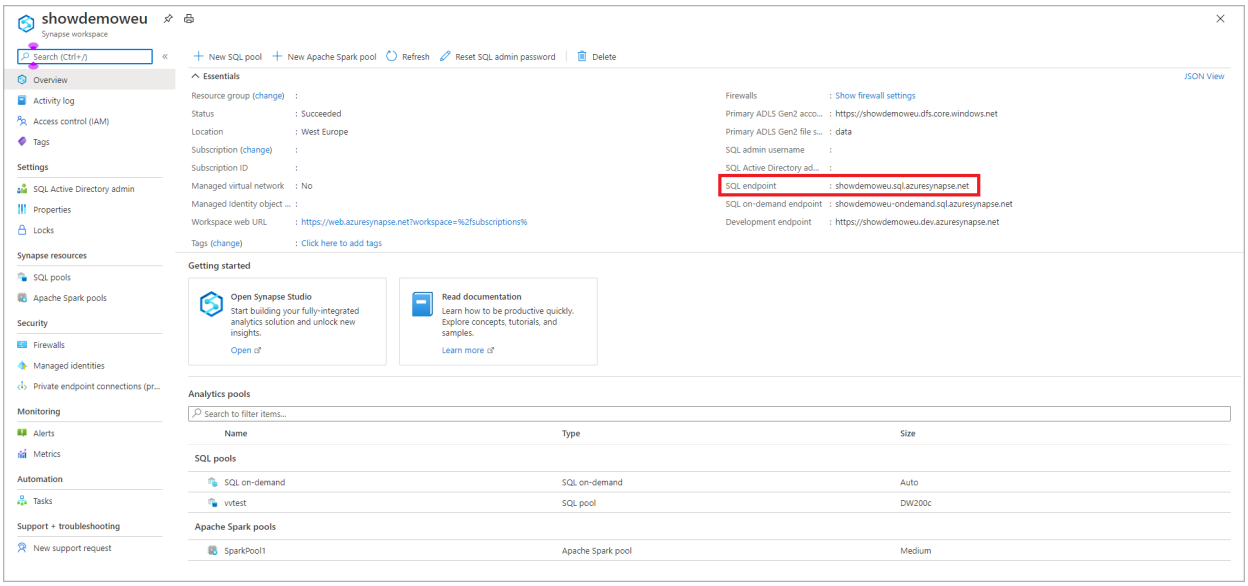
Find your server name

The server name for the dedicated SQL pool in the following example is: showdemoweu.sql.azuresynapse.net. The server name for the serverless SQL pool in the following example is: showdemoweu-ondemand.sql.azuresynapse.net.

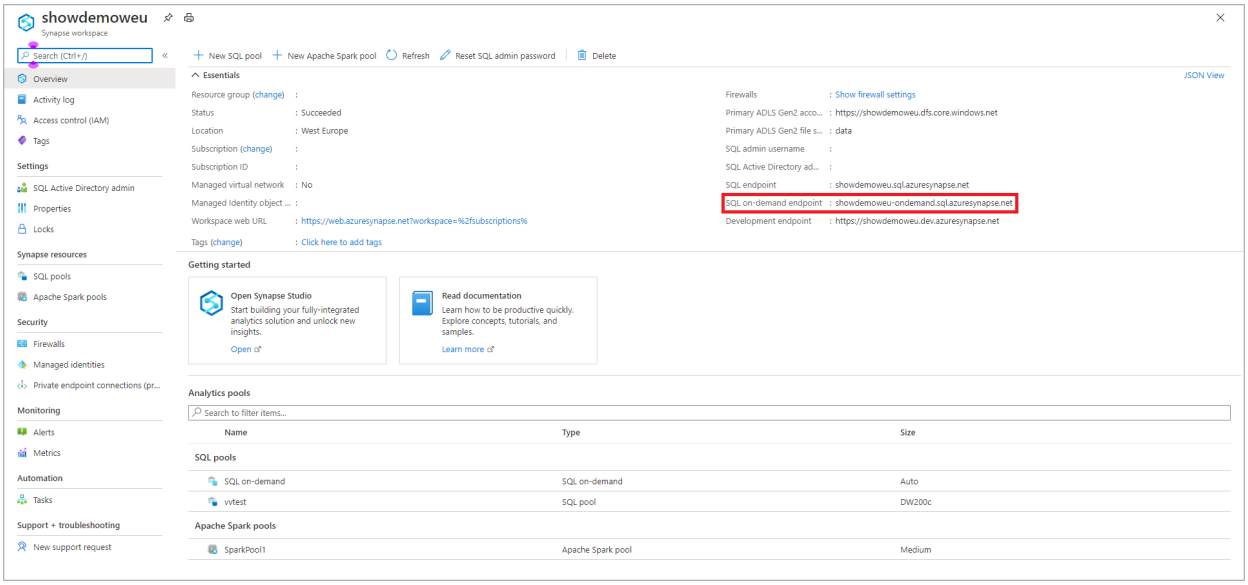
To find the fully qualified server name:

1. Go to the Azure portal.
2. Select on **Synapse workspaces**.
3. Select on the workspace you want to connect to.
4. Go to overview.
5. Locate the full server name.

SQL pool



serverless SQL pool



Supported drivers and connection strings

Synapse SQL supports ADO.NET, ODBC, PHP, and JDBC. To find the latest version and documentation, select one of the preceding drivers. To automatically generate the connection string for the driver that you're using from the Azure portal, select **Show database connection strings** from the preceding example. Following are also some examples of what a connection string looks like for each driver.

> **NOTE**
>
> Consider setting the connection timeout to 300 seconds to allow your connection to survive short periods of unavailability.

ADO.NET connection string example

```
Server=tcp:{your_server}.sql.azuresynapse.net,1433;Database={your_database};User ID=
{your_user_name};Password={your_password_here};Encrypt=True;TrustServerCertificate=False;Connection
Timeout=30;
```

ODBC connection string example

```
Driver={SQL Server Native Client 11.0};Server=tcp:{your_server}.sql.azuresynapse.net,1433;Database=
{your_database};Uid={your_user_name};Pwd=
{your_password_here};Encrypt=yes;TrustServerCertificate=no;Connection Timeout=30;
```

PHP connection string example

```
Server: {your_server}.sql.azuresynapse.net,1433 \r\nSQL Database: {your_database}\r\nUser Name:
{your_user_name}\r\n\r\nPHP Data Objects(PDO) Sample Code:\r\n\r\ntry {\r\n   $conn = new PDO (
\"sqlsrv:server = tcp:{your_server}.sql.azuresynapse.net,1433; Database = {your_database}\", \"
{your_user_name}\", \"{your_password_here}\");\r\n    $conn->setAttribute( PDO::ATTR_ERRMODE,
PDO::ERRMODE_EXCEPTION );\r\n}\r\ncatch ( PDOException $e ) {\r\n   print( \"Error connecting to SQL
Server.\" );\r\n   die(print_r($e));\r\n}\r\n\r\nSQL Server Extension Sample Code:\r\n\r\n$connectionInfo =
array(\"UID\" => \"{your_user_name}\", \"pwd\" => \"{your_password_here}\", \"Database\" => \"
{your_database}\", \"LoginTimeout\" => 30, \"Encrypt\" => 1, \"TrustServerCertificate\" =>
0);\r\n$serverName = \"tcp:{your_server}.sql.azuresynapse.net,1433\";\r\n$conn = sqlsrv_connect($serverName,
$connectionInfo);
```

JDBC connection string example

```
jdbc:sqlserver://yourserver.sql.azuresynapse.net:1433;database=yourdatabase;user={your_user_name};password=
{your_password_here};encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.sql.azuresynapse.net;
loginTimeout=30;
```

Connection settings

Synapse SQL standardizes some settings during connection and object creation. These settings can't be overridden and include:

DATABASE SETTING	VALUE
ANSI_NULLS	ON
QUOTED_IDENTIFIERS	ON
DATEFORMAT	mdy
DATEFIRST	7

Recommendations

For executing **serverless SQL pool** queries, recommended tools are Azure Data Studio and Azure Synapse Studio.

Next steps

To connect and query with Visual Studio, see Query with Visual Studio. To learn more about authentication options, see Authentication to Synapse SQL.

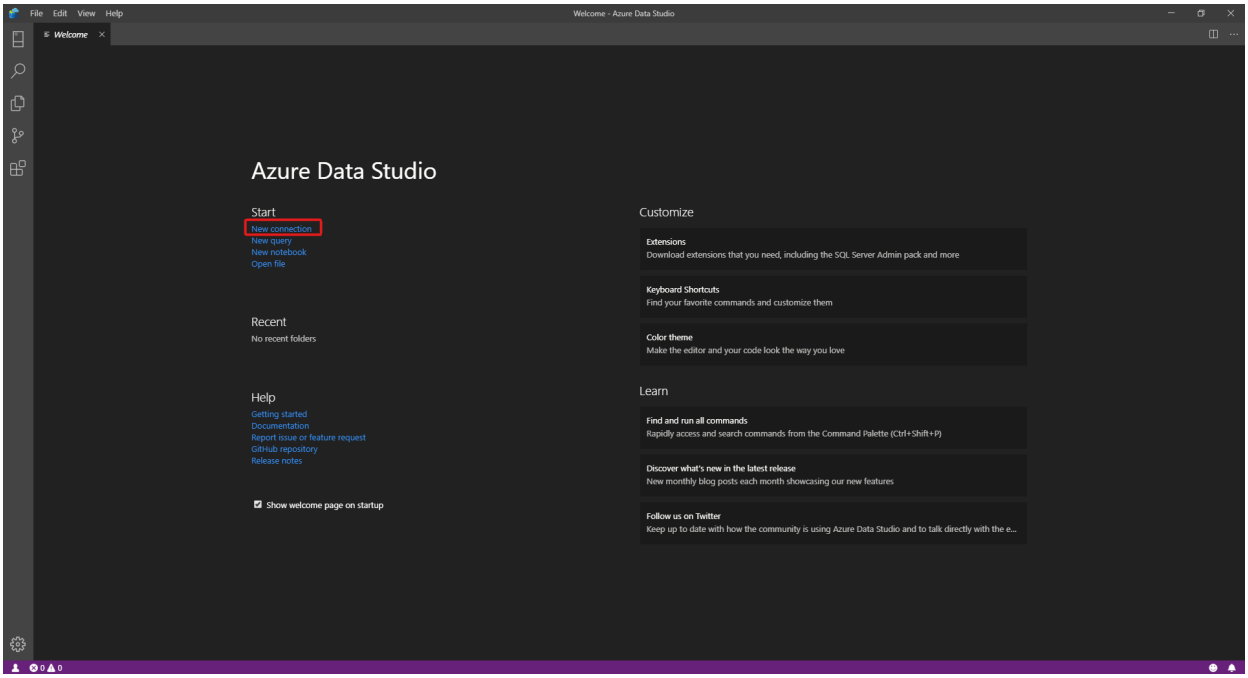
Connect to Synapse SQL with Azure Data Studio

8/19/2022 • 2 minutes to read • Edit Online

You can use Azure Data Studio to connect to and query Synapse SQL in Azure Synapse Analytics.

Connect

To connect to Synapse SQL, open Azure Data Studio and select **New Connection**.



Choose **Microsoft SQL Server** as the **Connection type**.

The connection requires the following parameters:

- **Server**: Server in the form `<Azure Synapse workspace name>`-ondemand.sql.azuresynapse.net
- **Database**: Database name

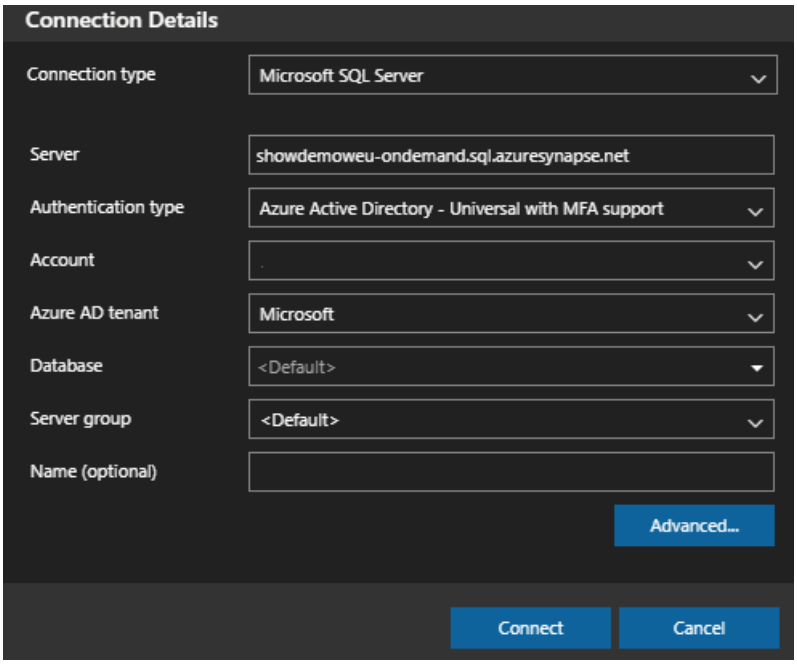
> **NOTE**
>
> If you would like to use **serverless SQL pool** the URL should look like:
>
> - `<Azure Synapse workspace name>`-ondemand.sql.azuresynapse.net.
>
> If you would like to use **dedicated SQL pool** the URL should look like:
>
> - `<Azure Synapse workspace name>`.sql.azuresynapse.net

Choose **Windows Authentication**, **Azure Active Directory**, or **SQL Login** as the **Authentication Type**.

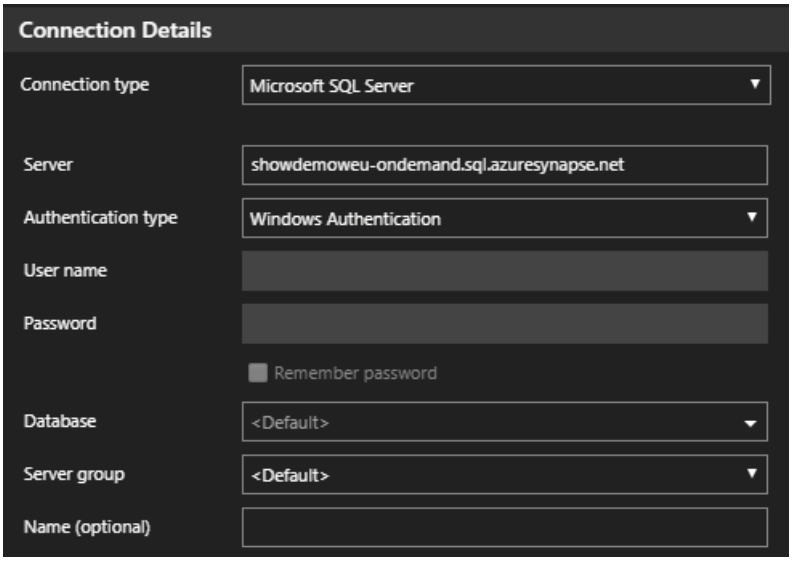
To use **SQL Login** as the authentication type, add the username/password parameters:

- **User**: Server user in the form `<User>`
- **Password**: Password associated with the user

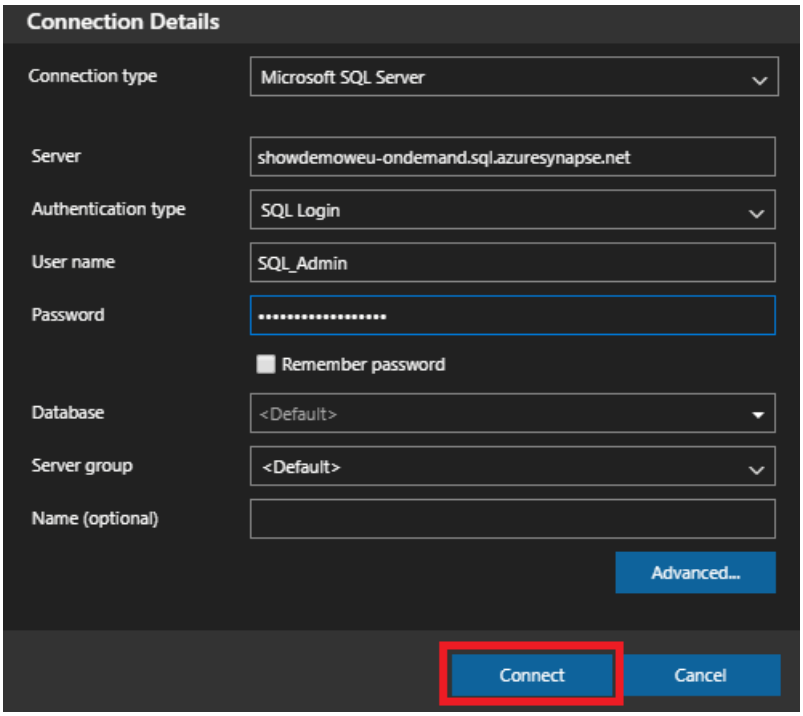
To use Azure Active Directory, you need to choose the needed authentication type.



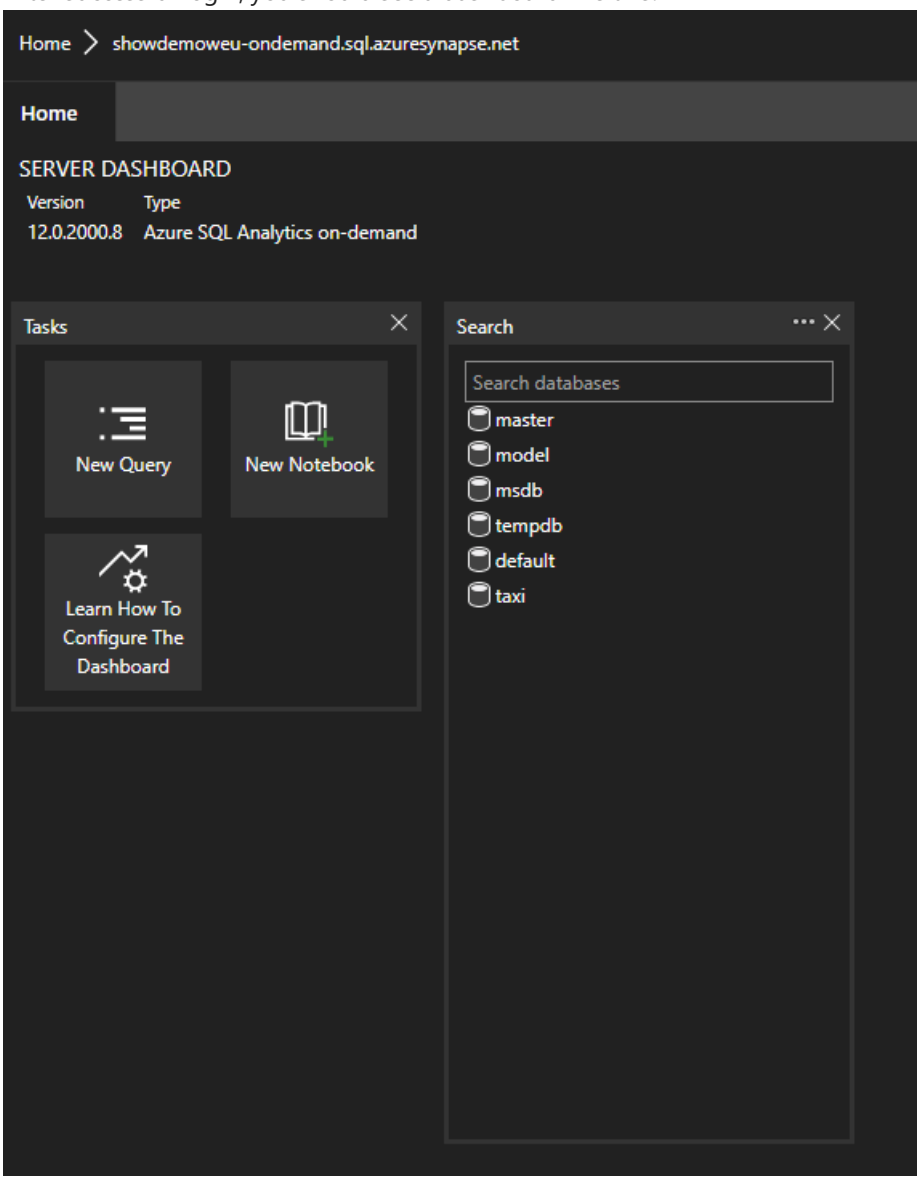
The following screenshot shows the **Connection Details** for **Windows Authentication**:



The following screenshot shows the **Connection Details** using **SQL Login**:

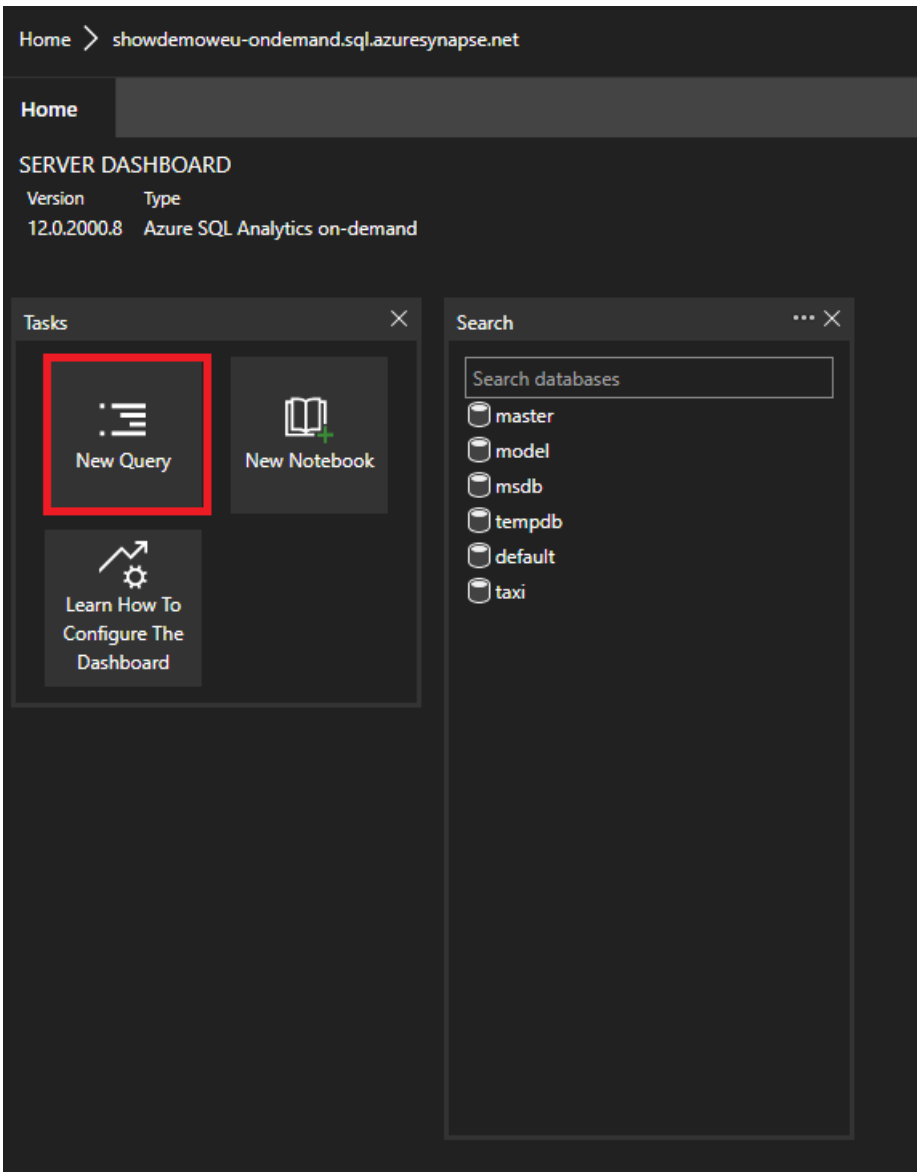


After successful login, you should see a dashboard like this:



Query

Once connected, you can query Synapse SQL using supported Transact-SQL (T-SQL) statements against the instance. Select **New query** from the dashboard view to get started.



For example, you can use the following Transact-SQL statement to query Parquet files using serverless SQL pool:

```
SELECT COUNT(*)
FROM
OPENROWSET(
    BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet',
    FORMAT='PARQUET'
)
```

Connection strings for Synapse SQL

8/19/2022 • 2 minutes to read • Edit Online

You can connect to Synapse SQL with several different application protocols such as, ADO.NET, ODBC, PHP, and JDBC. Below are some examples of connections strings for each protocol.

You can also use the Azure portal to build your connection string. To build your connection string using the Azure portal, navigate to your database blade, under *Essentials* select *Show database connection strings*.

Sample ADO.NET connection string

```
Server=tcp:{your_server}.sql.azuresynapse.net,1433;Database={your_database};User ID=
{your_user_name};Password={your_password_here};Encrypt=True;TrustServerCertificate=False;Connection
Timeout=30;
```

Sample ODBC connection string

```
Driver={SQL Server Native Client 11.0};Server=tcp:{your_server}.sql.azuresynapse.net,1433;Database=
{your_database};Uid={your_user_name};Pwd=
{your_password_here};Encrypt=yes;TrustServerCertificate=no;Connection Timeout=30;
```

Sample PHP connection string

```
Server: {your_server}.sql.azuresynapse.net,1433 \r\nSQL Database: {your_database}\r\nUser Name:
{your_user_name}\r\n\r\nPHP Data Objects(PDO) Sample Code:\r\n\r\ntry {\r\n   $conn = new PDO (
\"sqlsrv:server = tcp:{your_server}.sql.azuresynapse.net,1433; Database = {your_database}\", \"
{your_user_name}\", \"{your_password_here}\");\r\n    $conn->setAttribute( PDO::ATTR_ERRMODE,
PDO::ERRMODE_EXCEPTION );\r\n}\r\ncatch ( PDOException $e ) {\r\n   print( \"Error connecting to SQL
Server.\" );\r\n   die(print_r($e));\r\n}\r\n\r\nSQL Server Extension Sample Code:\r\n\r\n$connectionInfo =
array(\"UID\" => \"{your_user_name}\", \"pwd\" => \"{your_password_here}\", \"Database\" => \"
{your_database}\", \"LoginTimeout\" => 30, \"Encrypt\" => 1, \"TrustServerCertificate\" =>
0);\r\n$serverName = \"tcp:{your_server}.sql.azuresynapse.net,1433\";\r\n$conn = sqlsrv_connect($serverName,
$connectionInfo);
```

Sample JDBC connection string

```
jdbc:sqlserver://yourserver.sql.azuresynapse.net:1433;database=yourdatabase;user={your_user_name};password=
{your_password_here};encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.sql.azuresynapse.net;
loginTimeout=30;
```

NOTE

Consider setting the connection timeout to 300 seconds to allow the connection to survive short periods of unavailability.

Recommendations

For executing **serverless SQL pool** queries, recommended tools are Azure Data Studio and Azure Synapse Studio.

Next steps

To start querying your analytics with Visual Studio and other applications, see Query with Visual Studio.

Connect to Synapse SQL with SQL Server Management Studio (SSMS)

8/19/2022 • 3 minutes to read • Edit Online

You can use SQL Server Management Studio (SSMS) to connect to and query Synapse SQL in Azure Synapse Analytics through either serverless SQL pool or dedicated SQL pool resources.

Supported tools for serverless SQL pool

Azure Data Studio is fully supported starting from version 1.18.0. SSMS is partially supported starting from version 18.5, you can use it to connect and query only.

> **NOTE**
> If AAD login has connection open for more than 1 hour at time of query execution, any query that relies on AAD will fail. This includes querying storage using AAD pass-through and statements that interact with AAD (like CREATE EXTERNAL PROVIDER). This affects every tool that keeps connection open, like in query editor in SSMS and ADS. Tools that open new connection to execute query are not affected, like Synapse Studio. You can restart SSMS or connect and disconnect in ADS to mitigate this issue. .

Prerequisites

Before you begin, make sure you have the following prerequisites:

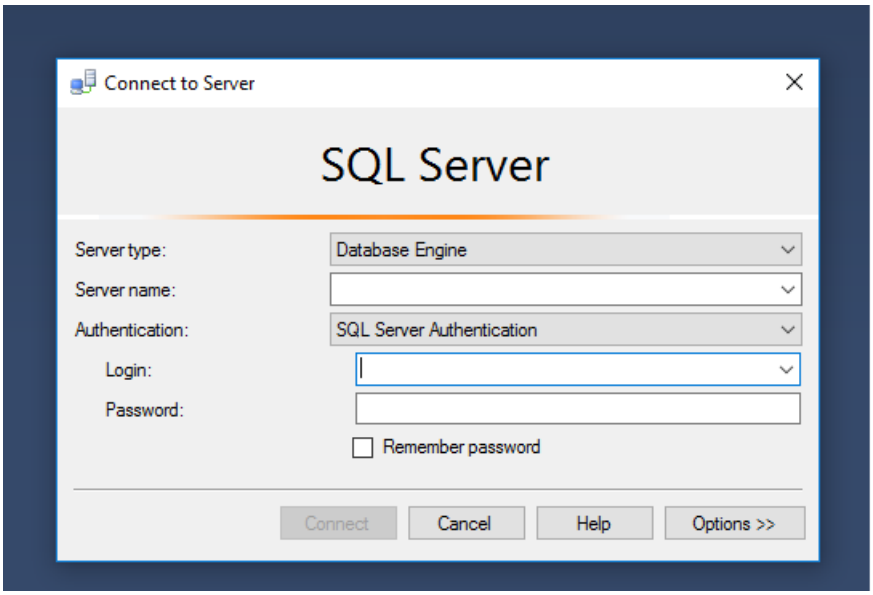
- SQL Server Management Studio (SSMS).
- For dedicated SQL pool, you need an existing data warehouse. To create one, see Create a dedicated SQL pool. For serverless SQL pool one is already provisioned, named Built-in, in your workspace at creation time.
- The fully qualified SQL Server name. To find this name, see Connect to Synapse SQL.

Connect

Dedicated SQL pool

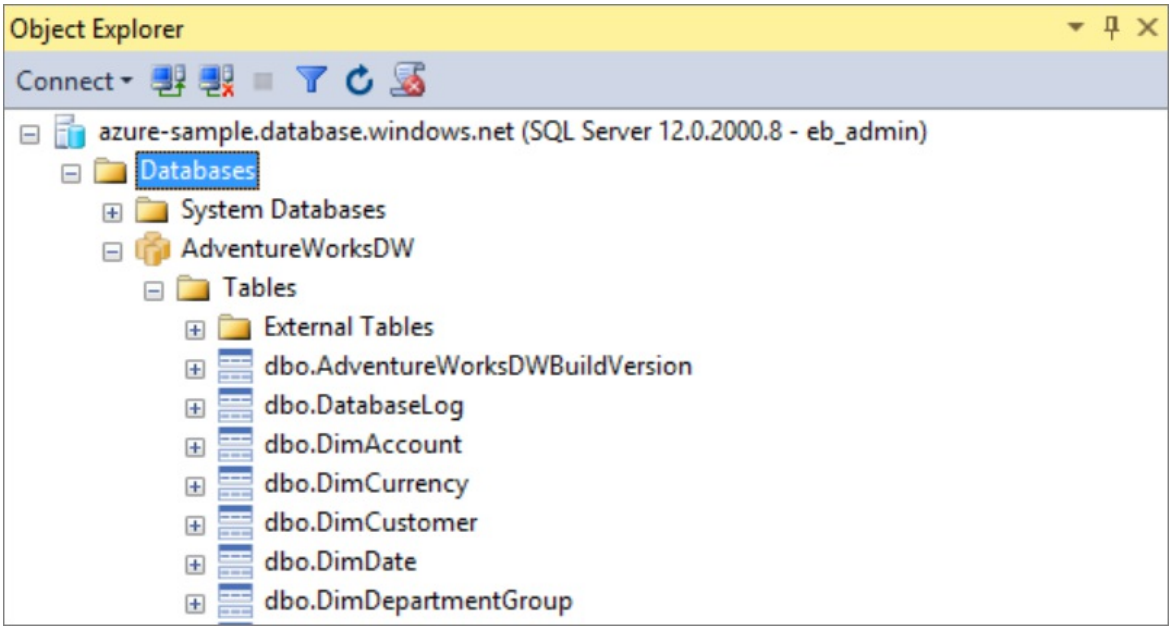
To connect to Synapse SQL using dedicated SQL pool, follow these steps:

1. Open SQL Server Management Studio (SSMS).
2. In the **Connect to Server** dialog box, fill in the fields, and then select **Connect**:



- **Server name**: Enter the **server name** previously identified.
- **Authentication**: Choose an authentication type, such as **SQL Server Authentication** or **Active Directory Integrated Authentication**.
- **User Name** and **Password**: Enter your user name and password if SQL Server Authentication was selected above.

3. Expand your Azure SQL Server in **Object Explorer**. You can view the databases associated with the server, such as the sample AdventureWorksDW database. You can expand the database to see the tables:

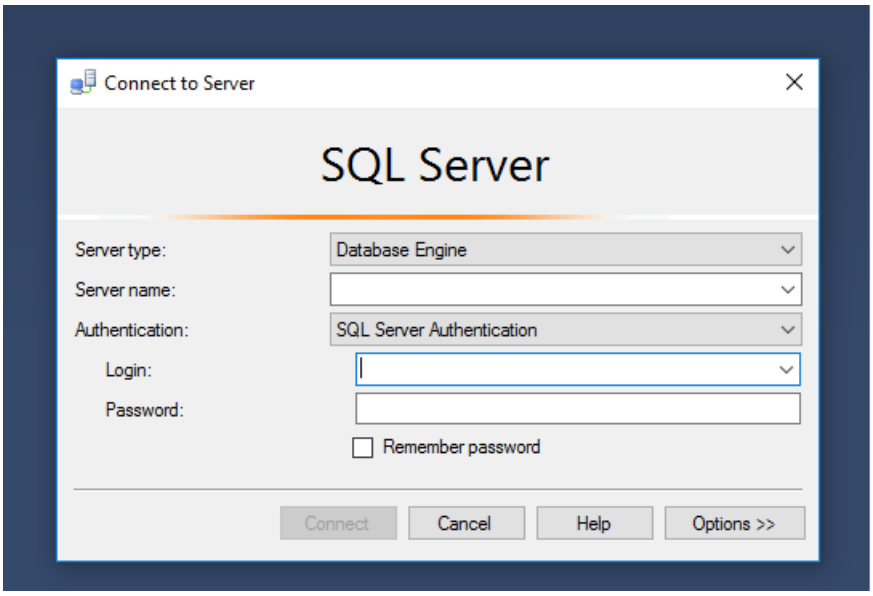


Serverless SQL pool

To connect to Synapse SQL using serverless SQL pool, follow these steps:

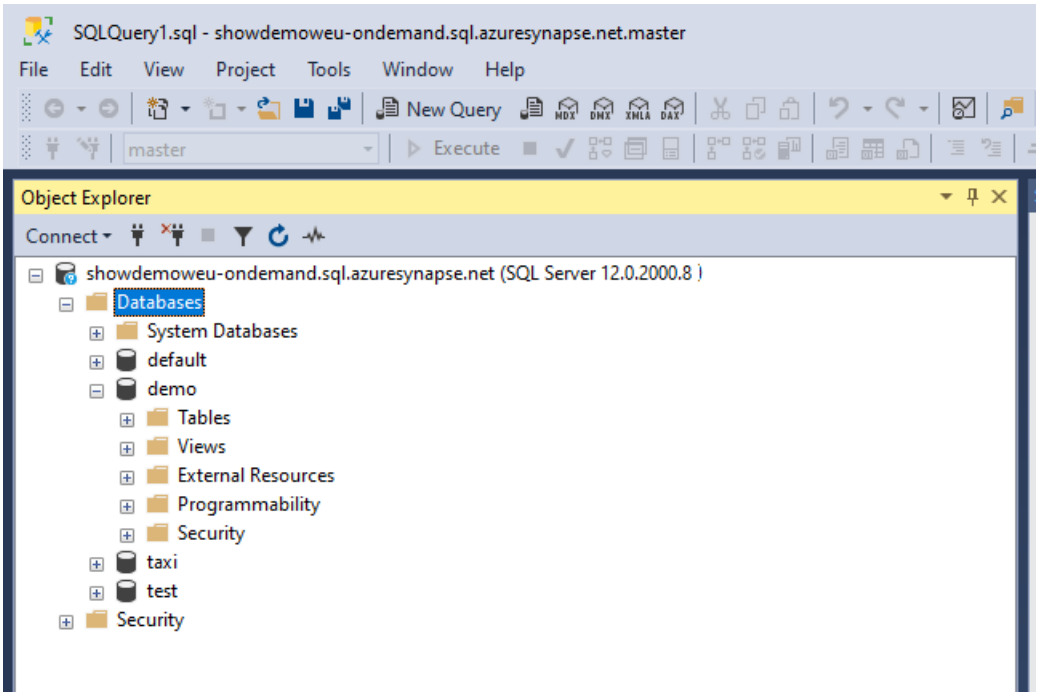
1. Open SQL Server Management Studio (SSMS).

2. In the **Connect to Server** dialog box, fill in the fields, and then select **Connect**:



- **Server name**: Enter the **server name** previously identified.
- **Authentication**: Choose an authentication type, such as **SQL Server Authentication** or **Active Directory Integrated Authentication**:
- **User Name** and **Password**: Enter your user name and password if SQL Server Authentication was selected above.
- Select **Connect**.

3. To explore, expand your Azure SQL server. You can view the databases associated with the server. Expand *demo* to see the content in your sample database.



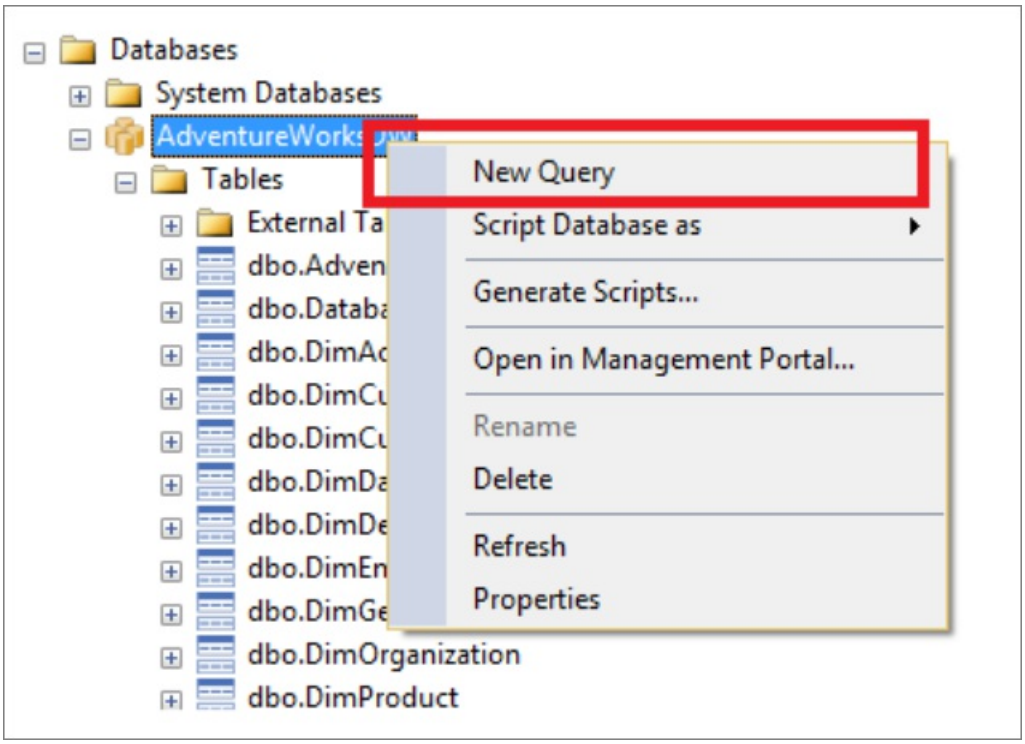
Run a sample query

Dedicated SQL pool

Now that a database connection has been established, you can query the data.

1. Right-click your database in SQL Server Object Explorer.

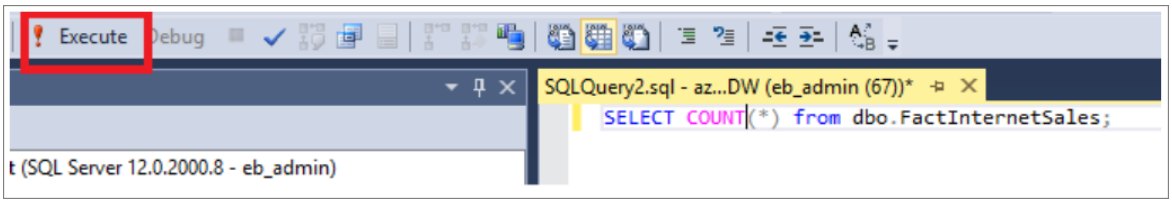
2. Select **New Query**. A new query window opens.



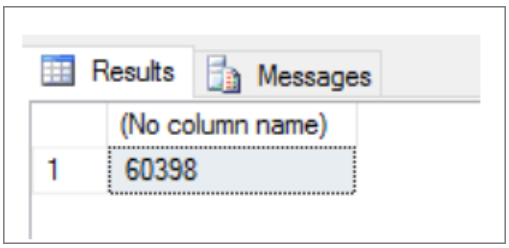
3. Copy the following T-SQL query into the query window:

```
SELECT COUNT(*) FROM dbo.FactInternetSales;
```

4. Run the query by selecting `Execute` or use the following shortcut: `F5`.



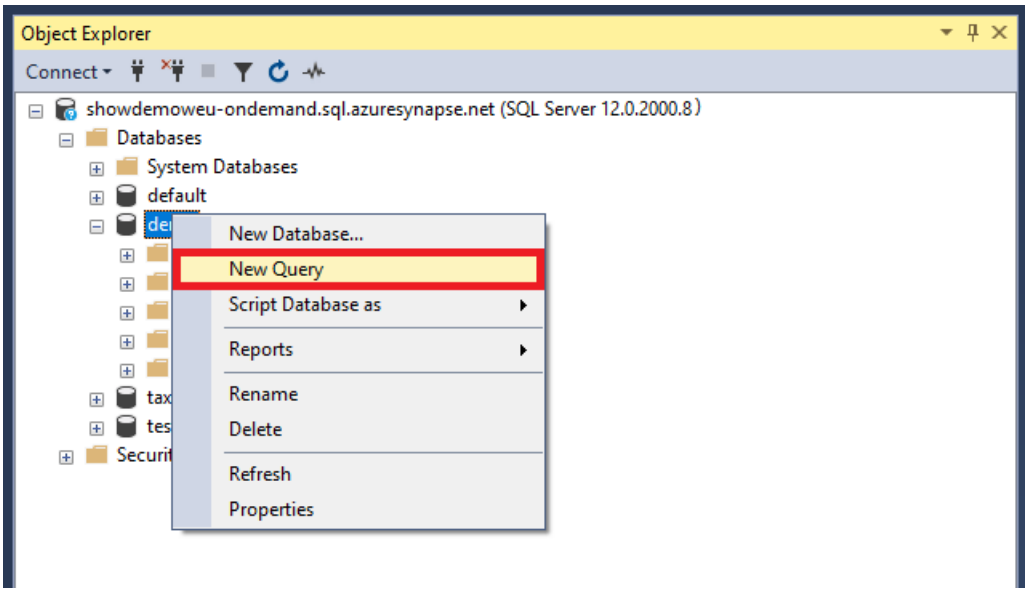
5. Look at the query results. In the following example, the FactInternetSales table has 60398 rows.



Serverless SQL pool

Now that you've established a database connection, you can query the data.

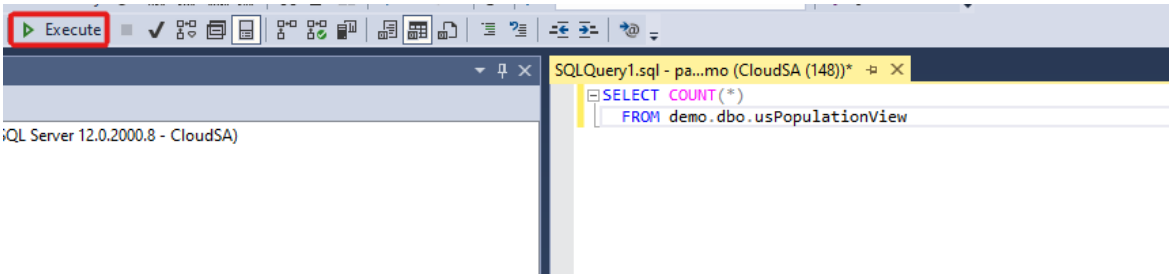
1. Right-click your database in SQL Server Object Explorer.
2. Select **New Query**. A new query window opens.



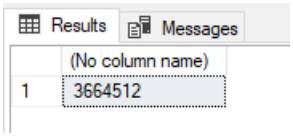
3. Copy the following T-SQL query into the query window:

```
SELECT COUNT(*) FROM demo.dbo.usPopulationView
```

4. Run the query by selecting `Execute` or use the following shortcut: `F5`.



5. Look at the query results. In this example, the usPopulationView view has 3664512 rows.



Next steps

Now that you can connect and query, try visualizing the data with Power BI.

To configure your environment for Azure Active Directory authentication, see Authenticate to Synapse SQL.

Connect to serverless SQL pool with Power BI Professional

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, we will go through the steps for connecting Power BI desktop to serverless SQL pool.

Prerequisites

You need the following tools to issue queries:

- SQL client of your choice:
  - Azure Data Studio
  - SQL Server Management Studio
- Power BI desktop installed

Parameters:

PARAMETER	DESCRIPTION
Serverless SQL pool service endpoint address	Will be used as server name
Serverless SQL pool service endpoint region	Will be used to determine what storage will we use in samples
Username and password for endpoint access	Will be used to access endpoint
Database you'll use to create views	This database will be used as starting point in samples

First-time setup

There are two steps prior to using samples:

1. Create database for your views
2. Create credentials to be used by serverless SQL pool to access files in storage

Create database

For this getting started article, you should create your own database to utilize as a demo. A database is needed for views creation. You'll use this database in some of the sample queries within this documentation.

> **NOTE**
>
> Databases are used only for viewing metadata, not for actual data.
>
> Write down the database name you're using, you'll need it later on.

```
DROP DATABASE IF EXISTS demo;
```

Create credentials

We need to create credentials before you can run queries. This credential will be used by serverless SQL pool service to access files in storage.

> **NOTE**
>
> You need to create credentials for storage account access. Although serverless SQL pool can access storage from different regions, having storage and Azure Synapse workspace in the same region will provide a better performance experience.

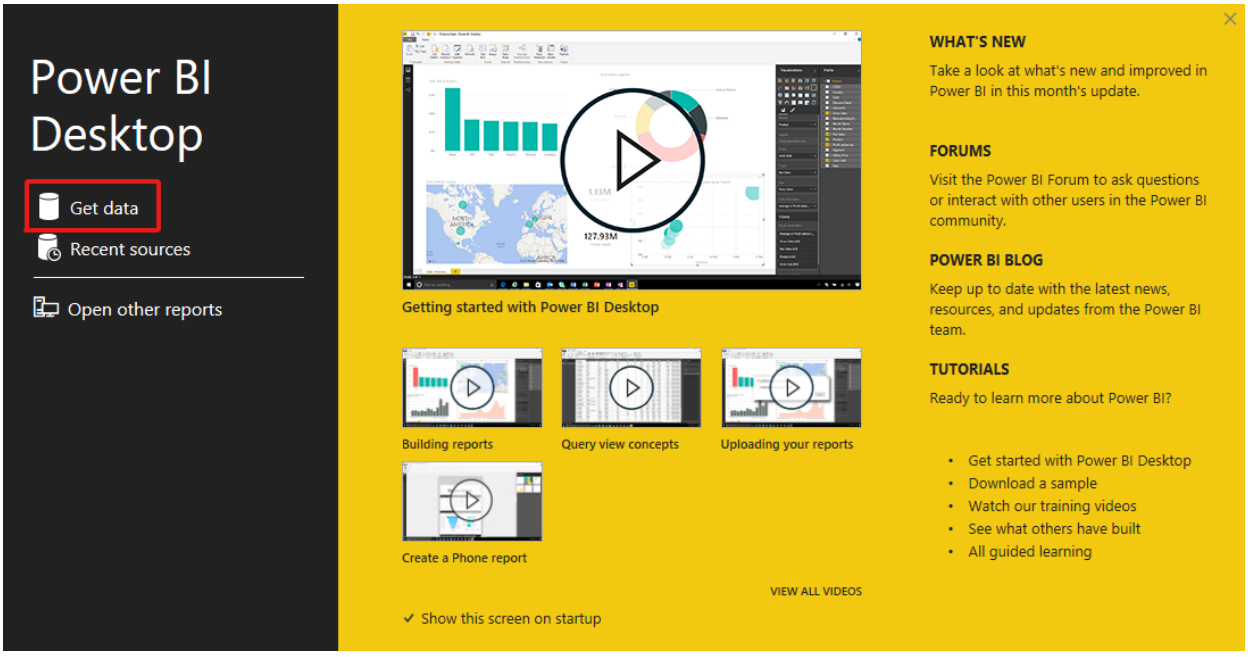
Code snippet on how to create credentials for Census data containers, run:

```
IF EXISTS (SELECT * FROM sys.credentials WHERE name =
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer')
DROP CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer];
GO

-- Create credentials for Census Data container which resides in a azure open data storage account
-- There is no secret. We are using public storage account which doesn't need secret
CREATE CREDENTIAL [https://azureopendatastorage.blob.core.windows.net/censusdatacontainer]
WITH IDENTITY='SHARED ACCESS SIGNATURE',
SECRET = '';
GO
```

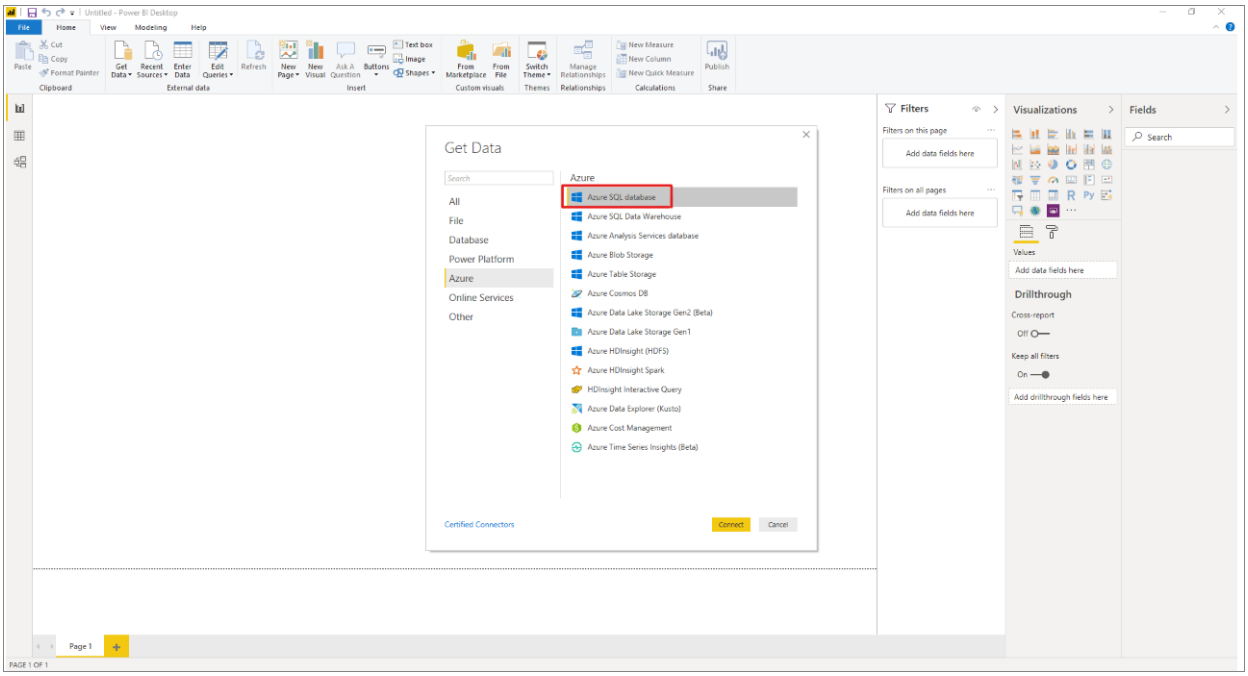
Create a Power BI desktop report

Open the Power BI desktop application and select the **Get data** option.



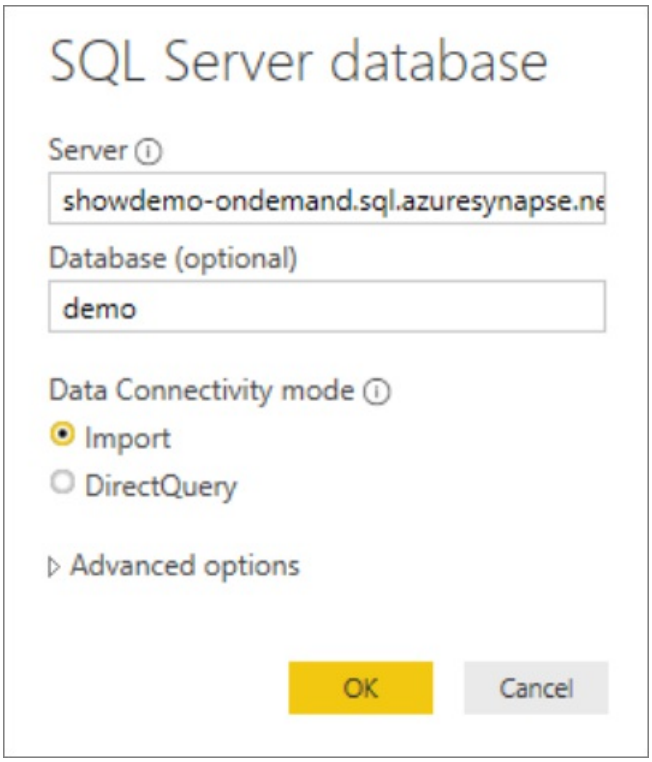
Step 1 - Select data source

Select **Azure** in the menu and then **Azure SQL Database**.



Step 2 - Select database

Write the URL for the database and the name of the database where the view resides.



Next steps

Advance to Query storage files to learn how to connect to serverless SQL pool using Azure Data Studio.

Connect to Synapse SQL with Visual Studio and SSDT

8/19/2022 • 2 minutes to read • Edit Online

Use Visual Studio to query dedicated SQL pool using Azure Synapse Analytics. This method uses the SQL Server Data Tools (SSDT) extension in Visual Studio 2019.

> **NOTE**
> Serverless SQL pool is not supported by SSDT.

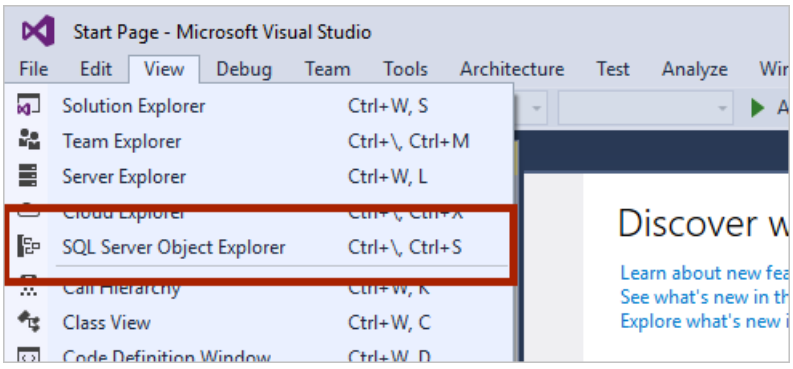
Prerequisites

To use this tutorial, you need to have the following components:

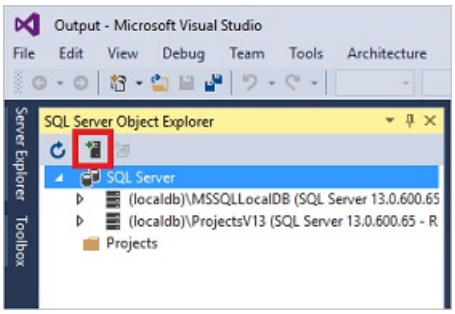
- An existing Synapse workspace, If you need to create one see Creating a Synapse workspace
- A dedicated SQL pool. If you do not have one, see Create a dedicated SQL pool.
- SSDT for Visual Studio. If you have Visual Studio, you probably already have this component. For installation instructions and options, see Installing Visual Studio and SSDT.
- The fully qualified SQL server name. To find this server name, see Connect to a dedicated SQL pool.

1. Connect to a dedicated SQL pool

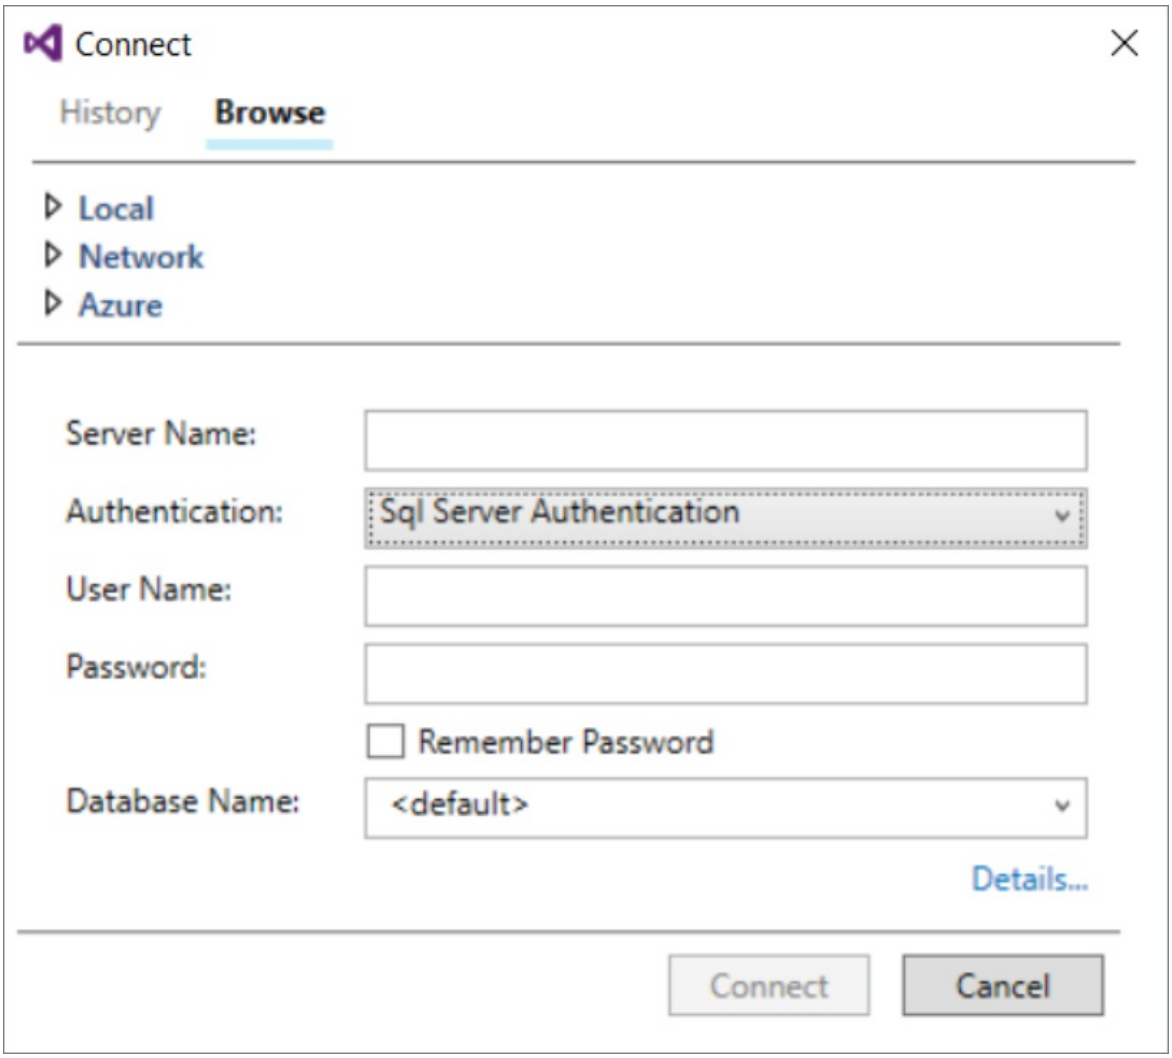
1. Open Visual Studio 2019.
2. Open the SQL Server Object Explorer by selecting **View** > **SQL Server Object Explorer**.



3. Click the **Add SQL Server** icon.

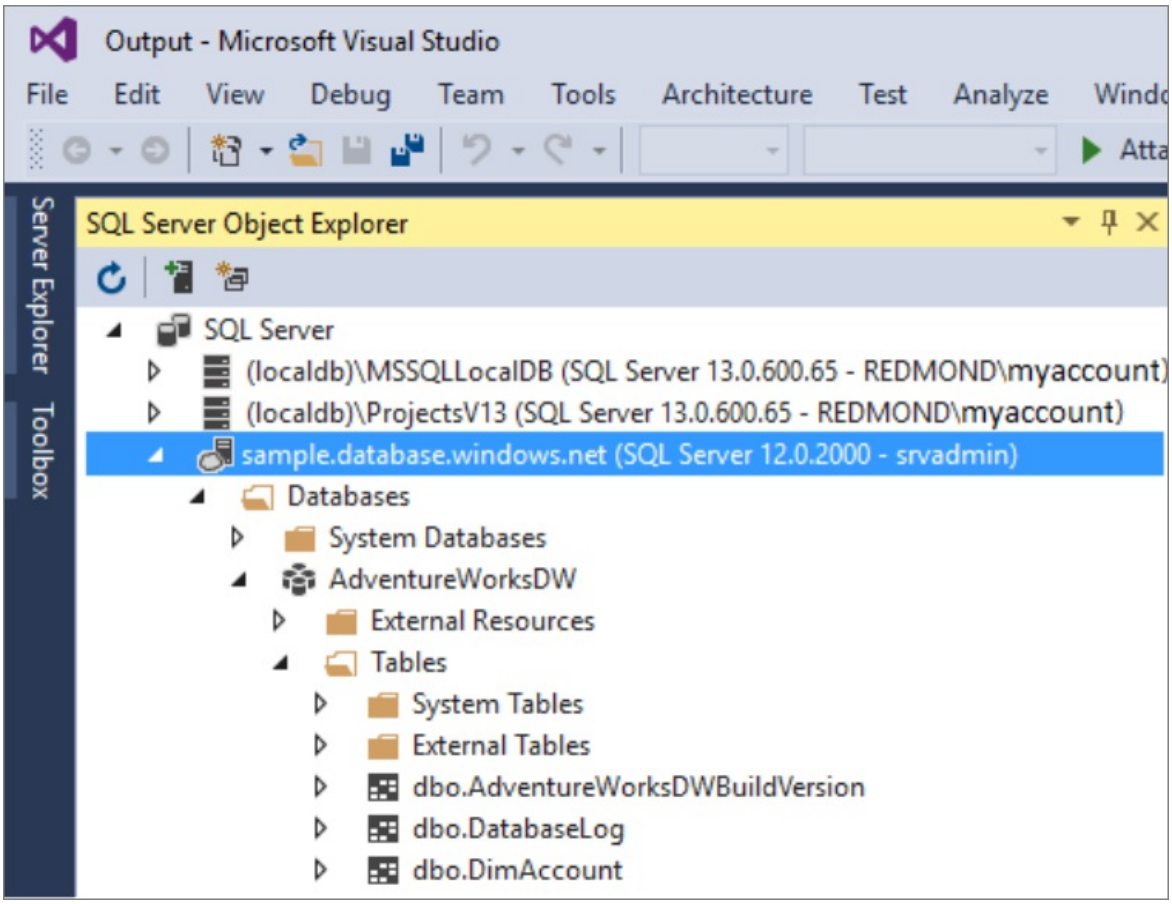


4. Fill in the fields in the Connect to Server window.



- **Server name**: Enter the **server name** previously identified.
- **Authentication**: Select **SQL Server Authentication** or **Active Directory Integrated Authentication**:
- **User Name** and **Password**: Enter your user name and password if SQL Server Authentication was selected above.
- Click **Connect**.

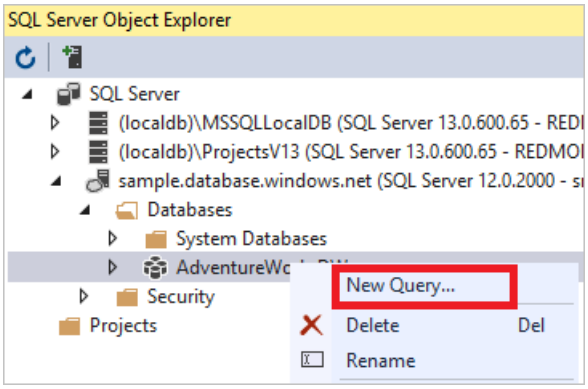
5. To explore, expand your Azure SQL server. You can view the databases associated with the server. Expand AdventureWorksDW to see the tables in your sample database.



2. Run a sample query

Now that a connection has been established to your database, you'll write a query.

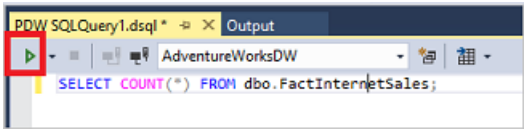
1. Right-click your database in SQL Server Object Explorer.
2. Select **New Query**. A new query window opens.



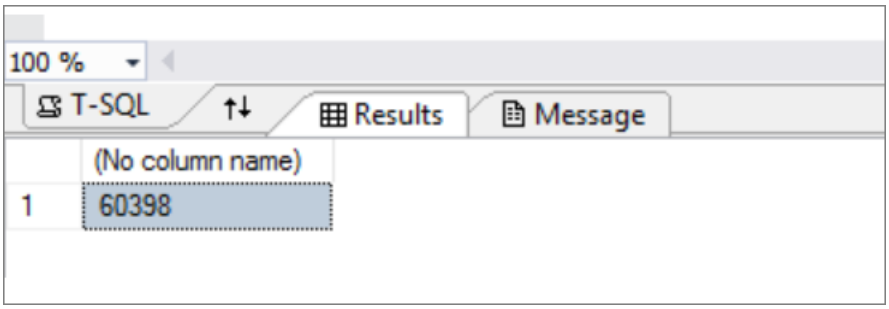
3. Copy the following T-SQL query into the query window:

```
SELECT COUNT(*) FROM dbo.FactInternetSales;
```

4. Run the query by clicking the green arrow or use the following shortcut: `CTRL` + `SHIFT` + `E`.



5. Look at the query results. In this example, the FactInternetSales table has 60398 rows.



Next steps

Now that you can connect and query, try visualizing the data with Power BI. To configure your environment for Azure Active Directory authentication, see Authenticate to dedicated SQL pool.

Connect to Synapse SQL with sqlcmd

8/19/2022 • 2 minutes to read • Edit Online

You can use the sqlcmd command-line utility to connect to and query serverless SQL pool and dedicated SQL pool within Synapse SQL.

1. Connect

To get started with sqlcmd, open the command prompt and enter **sqlcmd** followed by the connection string for your Synapse SQL database. The connection string requires the following parameters:

- **Server (-S):** Server in the form `<Server Name>`.database.windows.net
- **Database (-d):** Database name
- **Enable Quoted Identifiers (-I):** Quoted identifiers must be enabled to connect to a Synapse SQL instance

To use SQL Server Authentication, you need to add the username and password parameters:

- **User (-U):** Server user in the form `<User>`
- **Password (-P):** Password associated with the user

Your connection string might look like the following example:

Serverless SQL pool

```
C:\>sqlcmd -S partyeunrt.database.windows.net -d demo -U Enter_Your_Username_Here -P
Enter_Your_Password_Here -I
```

Dedicated SQL pool

```
C:\>sqlcmd -S MySqlDw.database.windows.net -d Adventure_Works -U myuser -P myP@ssword -I
```

To use Azure Active Directory Integrated authentication, you need to add the Azure Active Directory parameters:

- **Azure Active Directory Authentication (-G):** use Azure Active Directory for authentication

Your connection string might look like on of the following examples:

Serverless SQL pool

```
C:\>sqlcmd -S partyeunrt.database.windows.net -d demo -G -I
```

Dedicated SQL pool

```
C:\>sqlcmd -S MySqlDw.database.windows.net -d Adventure_Works -G -I
```

> **NOTE**
> You need to enable Azure Active Directory Authentication to authenticate using Active Directory.

2. Query

Use dedicated SQL pool

After connection, you can issue any supported Transact-SQL (T-SQL) statements against the instance. In this example, queries are submitted in interactive mode:

```
C:\>sqlcmd -S MySqlDw.database.windows.net -d Adventure_Works -U myuser -P myP@ssword -I
1> SELECT name FROM sys.tables;
2> GO
3> QUIT
```

For dedicated SQL pool, the following examples show you how to run queries in batch mode using the -Q option or piping your SQL to sqlcmd:

```
sqlcmd -S MySqlDw.database.windows.net -d Adventure_Works -U myuser -P myP@ssword -I -Q "SELECT name FROM
sys.tables;"
```

```
"SELECT name FROM sys.tables;" | sqlcmd -S MySqlDw.database.windows.net -d Adventure_Works -U myuser -P
myP@ssword -I > .\tables.out
```

Use serverless SQL pool

After connecting, you can issue any supported Transact-SQL (T-SQL) statements against the instance. In the following example, queries are submitted in interactive mode:

```
C:\>sqlcmd -S partyeunrt.database.windows.net -d demo -U Enter_Your_Username_Here -P
Enter_Your_Password_Here -I
1> SELECT COUNT(*) FROM  OPENROWSET(BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet', FORMAT='PARQUET')
2> GO
3> QUIT
```

For serverless SQL pool, the examples that follow show you how to run queries in batch mode using the -Q option or piping your SQL to sqlcmd:

```
sqlcmd -S partyeunrt.database.windows.net -d demo -U Enter_Your_Username_Here -P 'Enter_Your_Password_Here'
-I -Q "SELECT COUNT(*) FROM  OPENROWSET(BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet', FORMAT='PARQUET')"
```

```
"SELECT COUNT(*) FROM  OPENROWSET(BULK
'https://azureopendatastorage.blob.core.windows.net/censusdatacontainer/release/us_population_county/year=20
*/*.parquet', FORMAT='PARQUET')" | sqlcmd -S partyeunrt.database.windows.net -d demo -U
Enter_Your_Username_Here -P 'Enter_Your_Password_Here' -I > ./tables.out
```

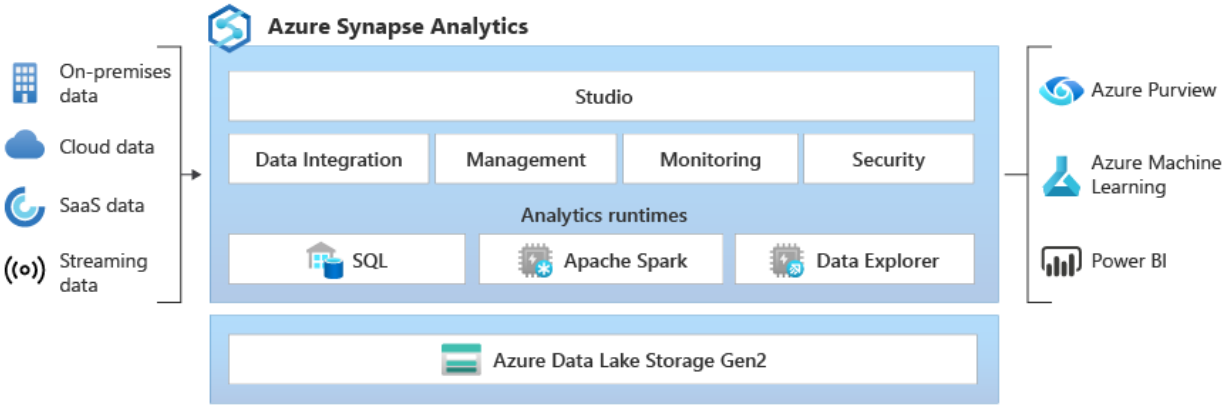
Next steps

For more information about sqlcmd options, see the sqlcmd documentation.

What is Azure Synapse Data Explorer? (Preview)

8/19/2022 • 5 minutes to read • Edit Online

Azure Synapse Data Explorer provides customers with an interactive query experience to unlock insights from log and telemetry data. To complement existing SQL and Apache Spark analytics runtime engines, the Data Explorer analytics runtime is optimized for efficient log analytics using powerful indexing technology to automatically index free-text and semi-structured data commonly found in telemetry data.



To learn more, see the following video:

What makes Azure Synapse Data Explorer unique?

- **Easy ingestion** - Data Explorer offers built-in integrations for no-code/low-code, high-throughput data ingestion, and caching data from real-time sources. Data can be ingested from sources such as Event Hub, Kafka, Azure Data Lake, open source agents such as Fluentd/Fluent Bit, and a wide variety of cloud and on-premises data sources.
- **No complex data modeling** - With Data Explorer, there is no need to build complex data models and no need for complex scripting to transform data before it's consumed.
- **No index maintenance** - There is no need for maintenance tasks to optimize data for query performance and no need for index maintenance. With Data Explorer, all raw data is available immediately, allowing you to run high-performance and high-concurrency queries on your streaming and persistent data. You can use these queries to build near real-time dashboards and alerts, and connect operational analytics data with the rest of data analytics platform.
- **Democratizing data analytics** - Data Explorer democratizes self-service, big data analytics with the intuitive Kusto Query Language (KQL) that provides the expressiveness and power of SQL with the simplicity of Excel. KQL is highly optimized for exploring raw telemetry and time series data by leveraging Data Explorer's best-in-class text indexing technology for efficient free-text and regex search, and comprehensive parsing capabilities for querying traces\text data and JSON semi-structured data including arrays and nested structures. KQL offers advanced time series support for creating, manipulating, and analyzing multiple time series with in-engine Python execution support for model scoring.
- **Proven technology at petabyte scale** - Data Explorer is a distributed system with compute and

storage that can scale independently, enabling analytics on gigabytes or petabytes of data.

- **Integrated** - Azure Synapse Analytics provides interoperability across data between Data Explorer, Apache Spark, and SQL engines empowering data engineers, data scientists, and data analysts to easily, and securely, access and collaborate on the same data in the data lake.

When to use Azure Synapse Data Explorer?

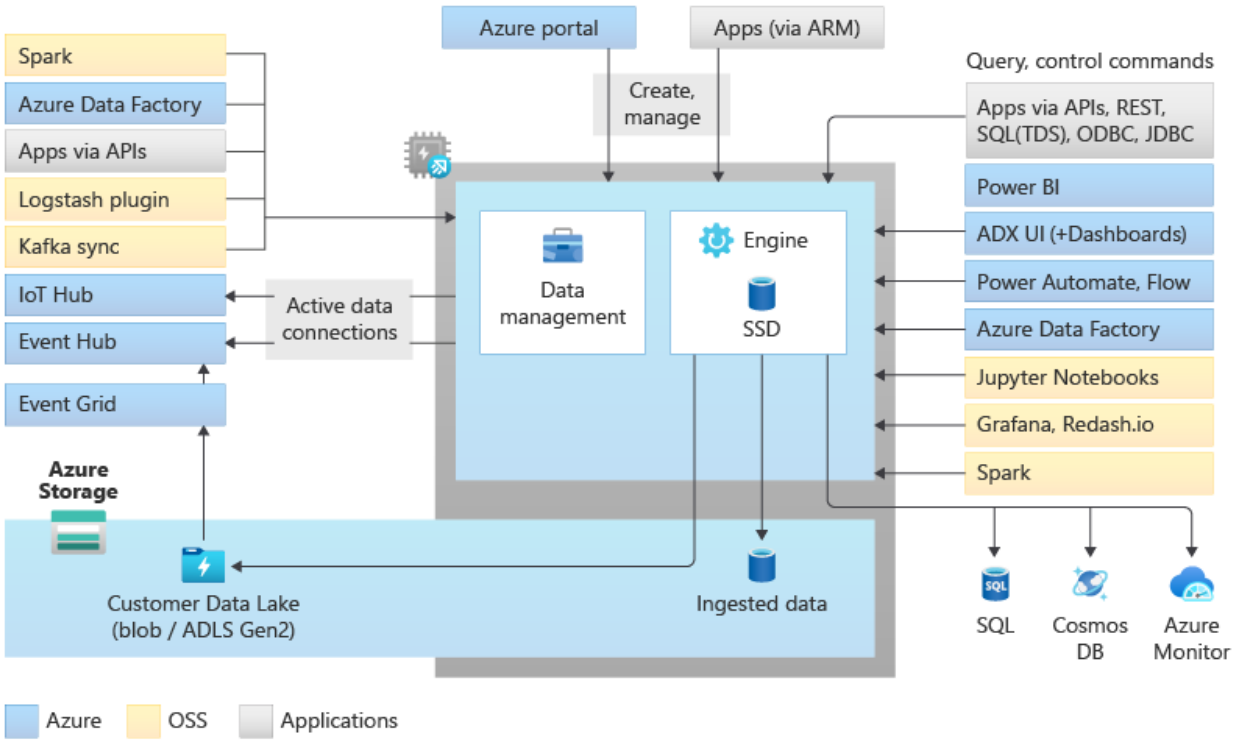
Use Data Explorer as a data platform for building near real-time log analytics and IoT analytics solutions to:

- Consolidate and correlate your logs and events data across on-premises, cloud, and third-party data sources.
- Accelerate your AI Ops journey (pattern recognition, anomaly detection, forecasting, and more).
- Replace infrastructure-based log search solutions to save cost and increase productivity.
- Build IoT analytics solutions for your IoT data.
- Build analytics SaaS solutions to offer services to your internal and external customers.

Data Explorer pool architecture

Data Explorer pools implement a scale out architecture by separating the compute and storage resources. This enables you to independently scale each resource and, for example, run multiple read only computes on the same data. Data Explorer pools consist of a set of computes running the engine that is responsible for automatically indexing, compressing, caching, and serving distributed queries. They also have a second set of computes running the data management service responsible for background system jobs, and managed and queued data ingestion. All data is persisted on managed blob storage accounts using a compressed columnar format.

Data Explorer pools support a rich ecosystem for ingesting data using connectors, SDKs, REST APIs, and other managed capabilities. It offers various ways to consume data for adhoc queries, reports, dashboards, alerts, REST APIs, and SDKs.



There are many unique capabilities that makes Data Explore the best analytical engine for log and time series

analytics on Azure. If you are interested in learning more about how Data Explorer works, see Azure Data Explorer white paper.

The following sections highlight the key differentiators.

Free-text and semi-structured data indexing enables near real time high performance and high concurrent queries

Data Explorer indexes semi-structured data (JSON) and unstructured data (free text) that makes running queries very performant on this type of data. By default, every field is indexed during the data ingestion with the option to use a low-level encoding policy to fine tune or disable the index for specific fields. The scope of the index is a single data shard.

The implementation of the index depends on the type of the field, as follows:

FIELD TYPE	INDEXING IMPLEMENTATION
String	The engine builds an inverted term index for string column values. Each string value is analyzed and split into normalized terms and an ordered list of logical positions, containing record ordinals, is recorded for each term. The resulting sorted list of terms and their associated positions is stored as an immutable B-tree.
Numeric **Datelime** **TimeSpan**	The engine builds a simple range-based forward index. The index records the min/max values for each block, for a group of blocks and for the entire column within the data shard.
Dynamic	The ingestion process enumerates all "atomic" elements within the dynamic value, such as property names, values, and array elements, and forwards them to the index builder. Dynamic fields have the same inverted term index as string fields.

These efficient indexing capabilities enables Data Explore to make the data available in near-real-time for high-performance and high-concurrency queries. The system automatically optimizes data shards to further boost performance.

Kusto Query Language

KQL has a large, growing community with the rapid adoption of Azure Monitor Log Analytics and Application Insights, Microsoft Sentinel, Azure Data Explorer, and other Microsoft offerings. The language is well designed with an easy-to-read syntax and provides a smooth transition from simple one-liner to complex data processing queries. This allows Data Explorer to provide rich Intellisense support and a rich set of language construct and built-in capabilities for aggregations, time series, and user analytics that aren't available in SQL for rapid exploration of telemetry data.

Next Steps

- Create a Data Explorer pool using Synapse Studio
- Create a Data Explorer pool using the Azure portal (Preview)

What is the difference between Azure Synapse Data Explorer and Azure Data Explorer? (Preview)

8/19/2022 • 2 minutes to read • Edit Online

Azure Data Explorer is a stand-alone, fast, and highly scalable data exploration service for log and telemetry data. The same underlying technology that runs the service is available in Azure Synapse as an integrated analytics service to complement its existing SQL and Spark services geared for data warehouse and data engineering machine learning scenarios.

The native integration of Data Explore capabilities brings analytics log and time series workloads to Synapse in the form of Synapse Data Explorer pools. These pools offer close integration with, and easier management of connectivity to, other Synapse capabilities. Having all your machine and user data available and accessible in one place, and by leveraging the near real-time exploratory capabilities of Data Explorer, enables you to build solutions that drive business value.

We recommend starting with Synapse Data Explorer if you are looking for a unified solution that combines big data and analytics capabilities.

Data Explorer in Azure Synapse Analytics

Azure Synapse Data Explorer data ingestion overview (Preview)

8/19/2022 • 5 minutes to read • Edit Online

Data ingestion is the process used to load data records from one or more sources to import data into a table in Azure Synapse Data Explorer pool. Once ingested, the data becomes available for query.

The Azure Synapse Data Explorer data management service, which is responsible for data ingestion, implements the following process:

- Pulls data in batches or streaming from an external source and reads requests from a pending Azure queue.
- Batch data flowing to the same database and table is optimized for ingestion throughput.
- Initial data is validated and the format is converted where necessary.
- Further data manipulation including matching schema, organizing, indexing, encoding, and compressing the data.
- Data is persisted in storage according to the set retention policy.
- Ingested data is committed into the engine, where it's available for query.

Supported data formats, properties, and permissions

- **Supported data formats**
- **Ingestion properties**: The properties that affect how the data will be ingested (for example, tagging, mapping, creation time).
- **Permissions**: To ingest data, the process requires database ingestor level permissions. Other actions, such as query, may require database admin, database user, or table admin permissions.

Batching vs streaming ingestions

- Batching ingestion does data batching and is optimized for high ingestion throughput. This method is the preferred and most performant type of ingestion. Data is batched according to ingestion properties. Small batches of data are merged and optimized for fast query results. The ingestion batching policy can be set on databases or tables. By default, the maximum batching value is 5 minutes, 1000 items, or a total size of 1 GB. The data size limit for a batch ingestion command is 4 GB.
- Streaming ingestion is ongoing data ingestion from a streaming source. Streaming ingestion allows near real-time latency for small sets of data per table. Data is initially ingested to row store, then moved to column store extents.

Ingestion methods and tools

Azure Synapse Data Explorer supports several ingestion methods, each with its own target scenarios. These methods include ingestion tools, connectors and plugins to diverse services, managed pipelines, programmatic ingestion using SDKs, and direct access to ingestion.

Ingestion using managed pipelines

For organizations who wish to have management (throttling, retries, monitors, alerts, and more) done by an external service, using a connector is likely the most appropriate solution. Queued ingestion is appropriate for large data volumes. Azure Synapse Data Explorer supports the following Azure Pipelines:

- **Event Hub**: A pipeline that transfers events from services to Azure Synapse Data Explorer. For more information, see Ingest data from Event Hub into Azure Synapse Data Explorer.

- **Synapse pipelines**: A fully managed data integration service for analytic workloads in Synapse pipelines connects with over 90 supported sources to provide efficient and resilient data transfer. Synapse pipelines prepares, transforms, and enriches data to give insights that can be monitored in different kinds of ways. This service can be used as a one-time solution, on a periodic timeline, or triggered by specific events.

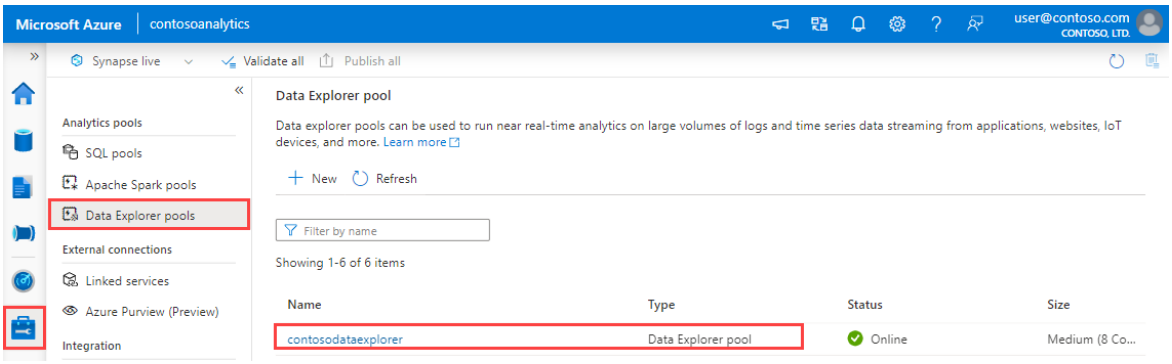
Programmatic ingestion using SDKs

Azure Synapse Data Explorer provides SDKs that can be used for query and data ingestion. Programmatic ingestion is optimized for reducing ingestion costs (COGs), by minimizing storage transactions during and following the ingestion process.

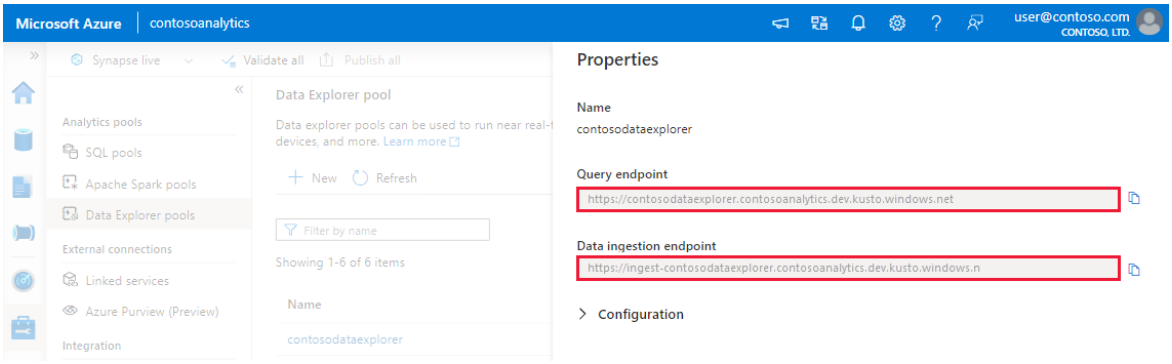
Before you start, use the following steps to get the Data Explorer pool endpoints for configuring programmatic ingestion.

1. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.

2. Select the Data Explorer pool you want to use to view its details.



3. Make a note of the Query and Data Ingestion endpoints. Use the Query endpoint as the cluster when configuring connections to your Data Explorer pool. When configuring SDKs for data ingestion, use the data ingestion endpoint.



Available SDKs and open-source projects

- Python SDK
- .NET SDK
- Java SDK
- Node SDK
- REST API
- GO SDK

Tools

- **One-click ingestion**: Enables you to quickly ingest data by creating and adjusting tables from a wide range of source types. One-click ingestion automatically suggests tables and mapping structures based on the data source in Azure Synapse Data Explorer. One-click ingestion can be used for one-time ingestion, or to define continuous ingestion via Event Grid on the container to which the data was ingested.

Kusto Query Language ingest control commands

There are a number of methods by which data can be ingested directly to the engine by Kusto Query Language (KQL) commands. Because this method bypasses the Data Management services, it's only appropriate for exploration and prototyping. Don't use this method in production or high-volume scenarios.

- **Inline ingestion**: A control command .ingest inline is sent to the engine, with the data to be ingested being a part of the command text itself. This method is intended for improvised testing purposes.
- **Ingest from query**: A control command .set, .append, .set-or-append, or .set-or-replace is sent to the engine, with the data specified indirectly as the results of a query or a command.
- **Ingest from storage (pull)**: A control command .ingest into is sent to the engine, with the data stored in some external storage (for example, Azure Blob Storage) accessible by the engine and pointed-to by the command.

For an example of using ingest control commands, see Analyze with Data Explorer.

Ingestion process

Once you have chosen the most suitable ingestion method for your needs, do the following steps:

1. **Set retention policy**

   Data ingested into a table in Azure Synapse Data Explorer is subject to the table's effective retention policy. Unless set on a table explicitly, the effective retention policy is derived from the database's retention policy. Hot retention is a function of cluster size and your retention policy. Ingesting more data than you have available space will force the first in data to cold retention.

   Make sure that the database's retention policy is appropriate for your needs. If not, explicitly override it at the table level. For more information, see retention policy.

2. **Create a table**

   In order to ingest data, a table needs to be created beforehand. Use one of the following options:

   - Create a table with a command. For an example of using the create a table command, see Analyze with Data Explorer.
   - Create a table using One-click Ingestion.

   > **NOTE**
   > If a record is incomplete or a field cannot be parsed as the required data type, the corresponding table columns will be populated with null values.

3. **Create schema mapping**

   Schema mapping helps bind source data fields to destination table columns. Mapping allows you to take data from different sources into the same table, based on the defined attributes. Different types of mappings are supported, both row-oriented (CSV, JSON and AVRO), and column-oriented (Parquet). In most methods, mappings can also be pre-created on the table and referenced from the ingest command

parameter.

4. **Set update policy** (optional)

   Some of the data format mappings (Parquet, JSON, and Avro) support simple and useful ingest-time transformations. Where the scenario requires more complex processing at ingest time, use update policy, which allows for lightweight processing using Kusto Query Language commands. The update policy automatically runs extractions and transformations on ingested data on the original table, and ingests the resulting data into one or more destination tables. Set your update policy.

Azure Synapse Data Explorer data ingestion properties (Preview)

8/19/2022 • 3 minutes to read • Edit Online

Data ingestion is the process by which data is added to a table and is made available for query in Data Explorer. You add properties to the ingestion command after the `with` keyword.

Ingestion properties

The following table lists the properties supported by Data Explorer, describes them, and provides examples:

PROPERTY	DESCRIPTION	EXAMPLE
`ingestionMapping`	A string value that indicates how to map data from the source file to the actual columns in the table. Define the `format` value with the relevant mapping type. See data mappings.	`with (format="json", ingestionMapping = "[{\"column\":\"rownumber\", \"Properties\": {\"Path\":\"$.RowNumber\"}}, {\"column\":\"rowguid\", \"Properties\": {\"Path\":\"$.RowGuid\"}}]")` (deprecated: `avroMapping`, `csvMapping`, `jsonMapping`)
`ingestionMappingReference`	A string value that indicates how to map data from the source file to the actual columns in the table using a named mapping policy object. Define the `format` value with the relevant mapping type. See data mappings.	`with (format="csv", ingestionMappingReference = "Mapping1")` (deprecated: `avroMappingReference`, `csvMappingReference`, `jsonMappingReference`)
`creationTime`	The datetime value (formatted as an ISO8601 string) to use at the creation time of the ingested data extents. If unspecified, the current value (`now()`) will be used. Overriding the default is useful when ingesting older data, so that the retention policy will be applied correctly. When specified, make sure the `Lookback` property in the target table's effective Extents merge policy is aligned with the specified value.	`with (creationTime="2017-02-13")`
`extend_schema`	A Boolean value that, if specified, instructs the command to extend the schema of the table (defaults to `false`). This option applies only to `.append` and `.set-or-append` commands. The only allowed schema extensions have additional columns added to the table at the end.	If the original table schema is `(a:string, b:int)` , a valid schema extension would be `(a:string, b:int, c:datetime, d:string)` , but `(a:string, c:datetime)` wouldn't be valid

PROPERTY	DESCRIPTION	EXAMPLE
`folder`	For ingest-from-query commands, the folder to assign to the table. If the table already exists, this property will override the table's folder.	`with (folder="Tables/Temporary")`
`format`	The data format (see supported data formats).	`with (format="csv")`
`ingestIfNotExists`	A string value that, if specified, prevents ingestion from succeeding if the table already has data tagged with an `ingest-by:` tag with the same value. This ensures idempotent data ingestion. For more information, see ingest-by: tags.	The properties `with (ingestIfNotExists='["Part0001"]', tags='["ingest-by:Part0001"]')` indicate that if data with the tag `ingest-by:Part0001` already exists, then don't complete the current ingestion. If it doesn't already exist, this new ingestion should have this tag set (in case a future ingestion attempts to ingest the same data again.)
`ignoreFirstRecord`	A Boolean value that, if set to `true`, indicates that ingestion should ignore the first record of every file. This property is useful for files in `csv` and similar formats, if the first record in the file are the column names. By default, `false` is assumed.	`with (ignoreFirstRecord=false)`
`persistDetails`	A Boolean value that, if specified, indicates that the command should persist the detailed results (even if successful) so that the .show operation details command could retrieve them. Defaults to `false`.	`with (persistDetails=true)`
`policy_ingestiontime`	A Boolean value that, if specified, describes whether to enable the Ingestion Time Policy on a table that is created by this command. The default is `true`.	`with (policy_ingestiontime=false)`
`recreate_schema`	A Boolean value that, if specified, describes whether the command may recreate the schema of the table. This property applies only to the `.set-or-replace` command. This property takes precedence over the `extend_schema` property if both are set.	`with (recreate_schema=true)`
`tags`	A list of tags to associate with the ingested data, formatted as a JSON string	`with (tags="['Tag1', 'Tag2']")`
`validationPolicy`	A JSON string that indicates which validations to run during ingestion. See Data ingestion for an explanation of the different options.	`with (validationPolicy='{"ValidationOptions":1, "ValidationImplications":1}')` (this is actually the default policy)

PROPERTY	DESCRIPTION	EXAMPLE
`zipPattern`	Use this property when ingesting data from storage that has a ZIP archive. This is a string value indicating the regular expression to use when selecting which files in the ZIP archive to ingest. All other files in the archive will be ignored.	`with (zipPattern="*.csv")`

Data formats supported by Azure Synapse Data Explorer for ingestion (Preview)

8/19/2022 • 2 minutes to read • Edit Online

Data ingestion is the process by which data is added to a table and is made available for query in Data Explorer. For all ingestion methods, other than ingest-from-query, the data must be in one of the supported formats. The following table lists and describes the formats that Data Explorer supports for data ingestion.

NOTE

Before you ingest data, make sure that your data is properly formatted and defines the expected fields. We recommend using your preferred validator to confirm the format is valid. For example, you may find the following validators useful to check CSV or JSON files:

- CSV: http://csvlint.io/
- JSON: https://jsonlint.com/

For more information about why ingestion might fail, see Ingestion failures and Ingestion error codes in Data Explorer.

FORMAT	EXTENSION	DESCRIPTION
ApacheAvro	`.avro`	An AVRO format with support for logical types. The following compression codecs are supported: `null`, `deflate`, and `snappy`. Reader implementation of the `apacheavro` format is based on the official Apache Avro library.
Avro	`.avro`	A legacy implementation for AVRO format based on .NET library. The following compression codecs are supported: `null`, `deflate` (for `snappy` - use `ApacheAvro` data format).
CSV	`.csv`	A text file with comma-separated values (`,`). See RFC 4180: *Common Format and MIME Type for Comma-Separated Values (CSV) Files*.
JSON	`.json`	A text file with JSON objects delimited by `\n` or `\r\n`. See JSON Lines (JSONL).

FORMAT	EXTENSION	DESCRIPTION
MultiJSON	`.multijson`	A text file with a JSON array of property bags (each representing a record), or any number of property bags delimited by whitespace, `\n` or `\r\n`. Each property bag can be spread on multiple lines. This format is preferred over `JSON`, unless the data is non-property bags.
ORC	`.orc`	An ORC file.
Parquet	`.parquet`	A Parquet file.
PSV	`.psv`	A text file with pipe-separated values (`|`).
RAW	`.raw`	A text file whose entire contents is a single string value.
SCsv	`.scsv`	A text file with semicolon-separated values (`;`).
SOHsv	`.sohsv`	A text file with SOH-separated values. (SOH is ASCII codepoint 1; this format is used by Hive on HDInsight.)
TSV	`.tsv`	A text file with tab-separated values (`\t`).
TSVE	`.tsv`	A text file with tab-separated values (`\t`). A backslash character (`\`) is used for escaping.
TXT	`.txt`	A text file with lines delimited by `\n`. Empty lines are skipped.
W3CLOGFILE	`.log`	Web log file format standardized by the W3C.

Supported data compression formats

Blobs and files can be compressed through any of the following compression algorithms:

COMPRESSION	EXTENSION
GZip	.gz
Zip	.zip

Indicate compression by appending the extension to the name of the blob or file.

For example:

- `MyData.csv.zip` indicates a blob or a file formatted as CSV, compressed with ZIP (archive or a single file)
- `MyData.json.gz` indicates a blob or a file formatted as JSON, compressed with GZip.

Blob or file names that don't include the format extensions but just compression (for example, `MyData.zip`) is also supported. In this case, the file format must be specified as an ingestion property because it cannot be inferred.

> **NOTE**
>
> - Some compression formats keep track of the original file extension as part of the compressed stream. This extension is generally ignored for determining the file format. If the file format can't be determined from the (compressed) blob or file name, it must be specified through the `format` ingestion property.
> - Not to be confused with internal (chunk level) compression codec used by `Parquet`, `AVRO` and `ORC` formats. Internal compression name is usually added to a file name before file format extension, for example: `file1.gz.parquet`, `file1.snappy.avro`, etc.

Quickstart: Create a Data Explorer pool using the Azure portal (Preview)

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast, fully managed data analytics service for real-time analysis on large volumes of data streaming from applications, websites, IoT devices, and more. To use Data Explorer, you first create a Data Explorer pool.

This article describes the steps to create a Data Explorer pool in a Synapse workspace by using the Azure portal.

> **IMPORTANT**
> Billing for Data Explorer instances is prorated per minute, whether you are using them or not. Be sure to shutdown your Data Explorer instance after you have finished using it, or set a short timeout. For more information, see **Clean up resources**.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

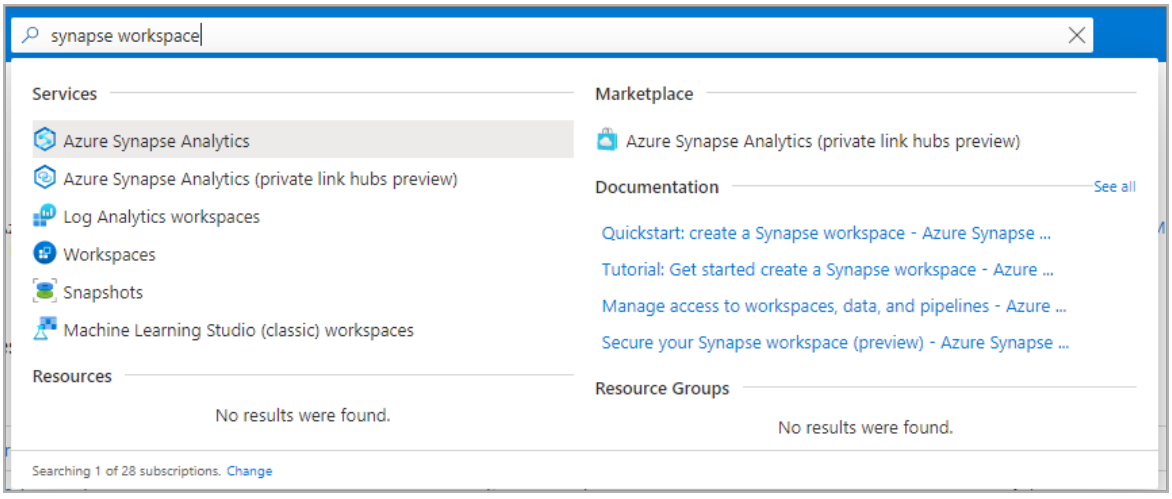
- Azure subscription - create one for free
- Synapse workspace

Sign in to the Azure portal

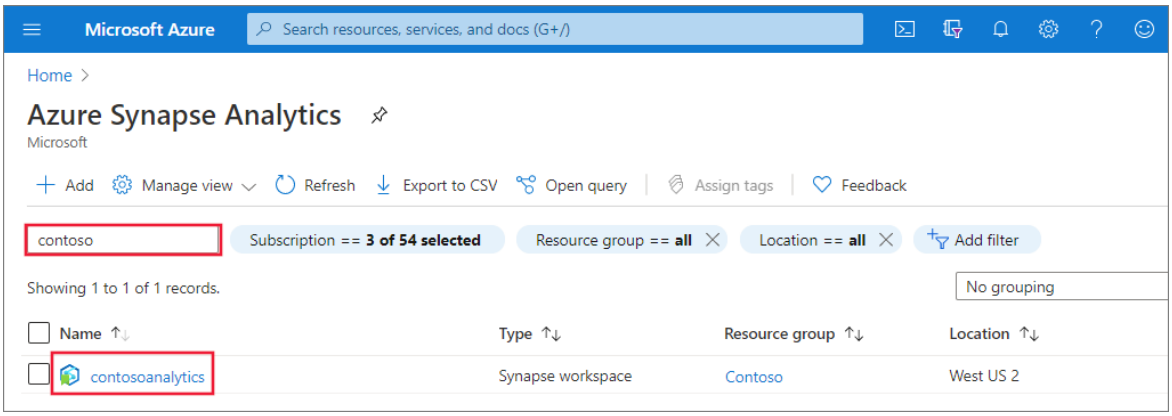
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the Data Explorer pool will be created by typing the service name (or resource name directly) into the search bar.

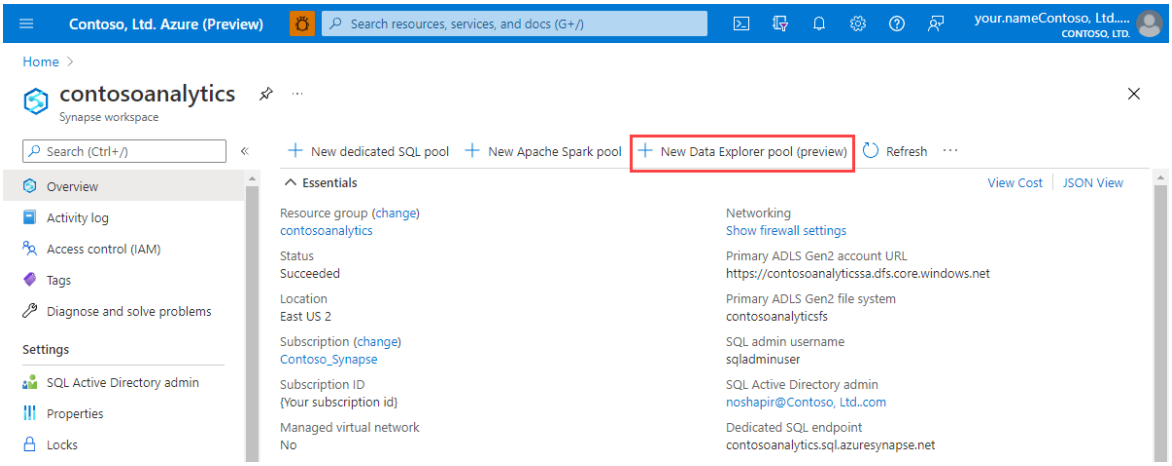


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



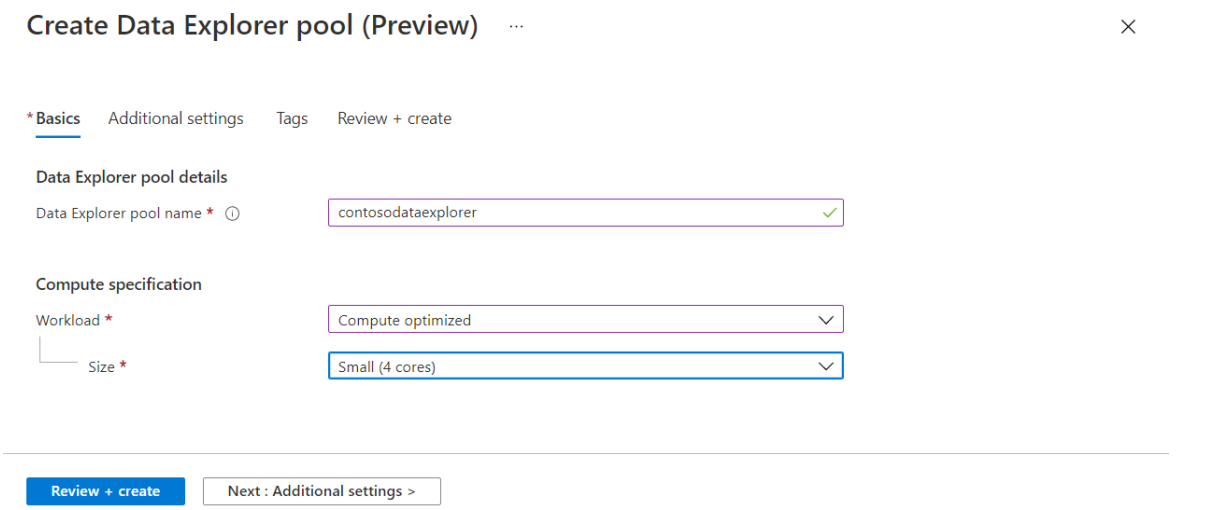
Create a new Data Explorer pool

1. In the Synapse workspace where you want to create the Data Explorer pool, select **New Data Explorer pool**.



2. Enter the following details in the **Basics** tab:

SETTING	SUGGESTED VALUE	DESCRIPTION
Data Explorer pool name	contosodataexplorer	This is the name that the Data Explorer pool will have.
Workload	Compute optimized	This workload provides a higher CPU to SSD storage ratio.
Node size	Small (4 cores)	Set this to the smallest size to reduce costs for this quickstart

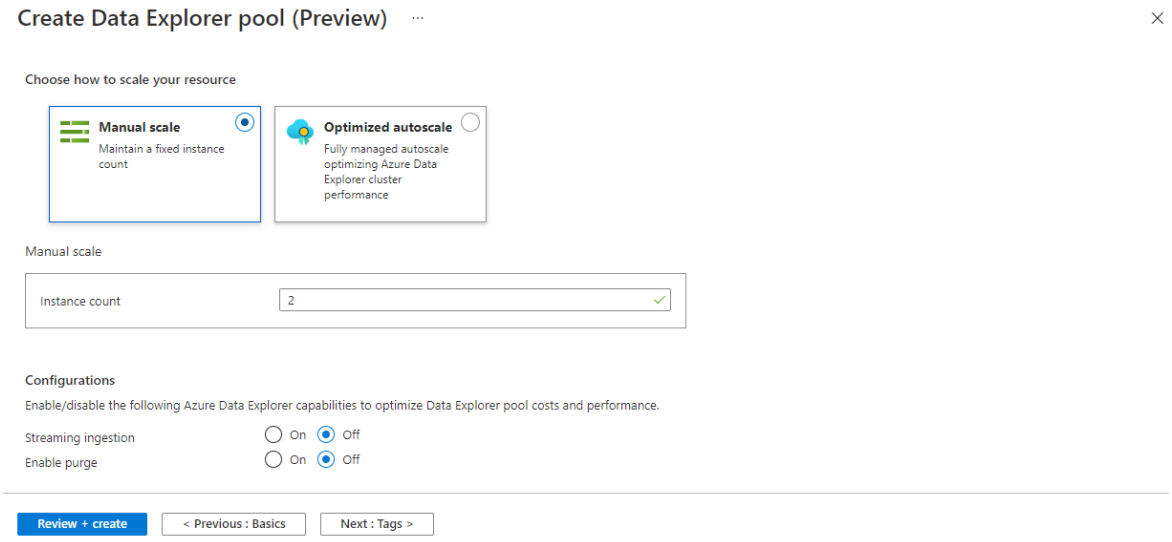


IMPORTANT

Note that there are specific limitations for the names that Data Explorer pools can use. Names must contain lowercase letters and numbers only, must be between 4 and 15 characters, and must start with a letter.

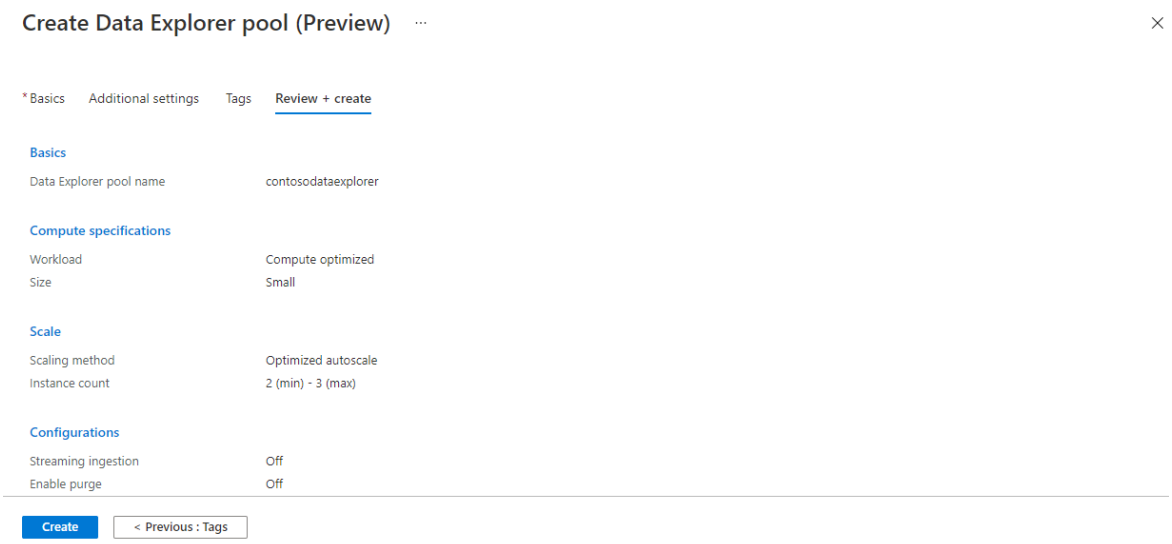
3. Select **Next: Additional settings**. Use the following settings and leave the defaults for the remaining settings.

SETTING	SUGGESTED VALUE	DESCRIPTION
Scaling	Manual scale	We won't need autoscale in this quickstart
Number count	2	Set this to the smallest size to reduce costs for this quickstart

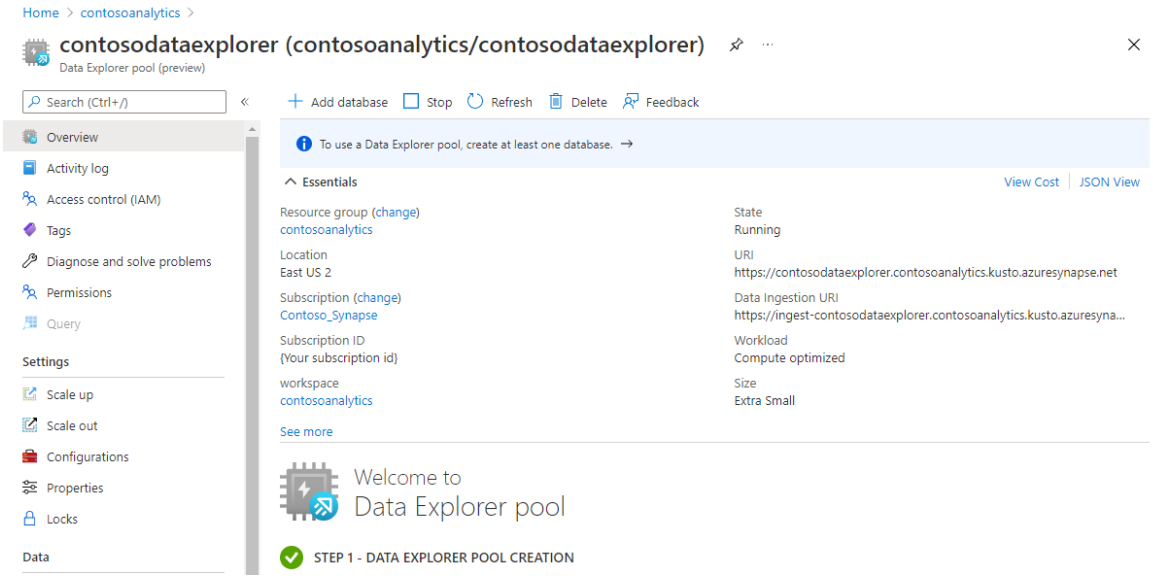


4. Select **Next: tags**. Don't add any tags.
5. Select **Review + create**.
6. Review the detail making sure they are correct, and then select **Create**.

   The Data Explorer pool will start the provisioning process.



7. Once the provisioning is complete, navigate back to the workspace **Overview** page and verify that the new Data Explorer pool welcome page appears.



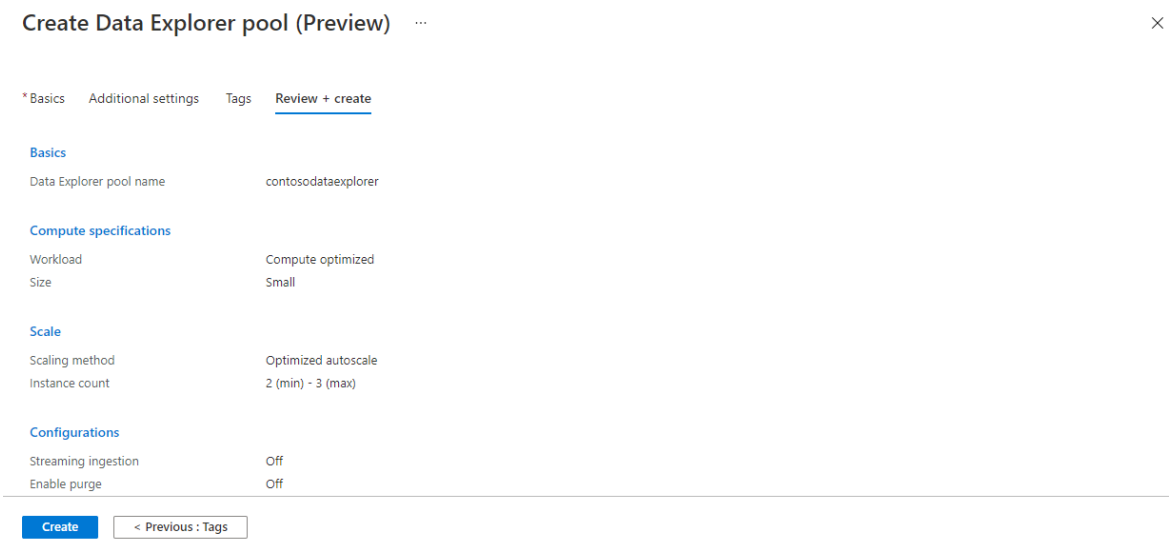
Clean up Data Explorer pool resources using the Azure portal

Use the following steps to delete the Data Explorer pool from the workspace using the Azure portal.

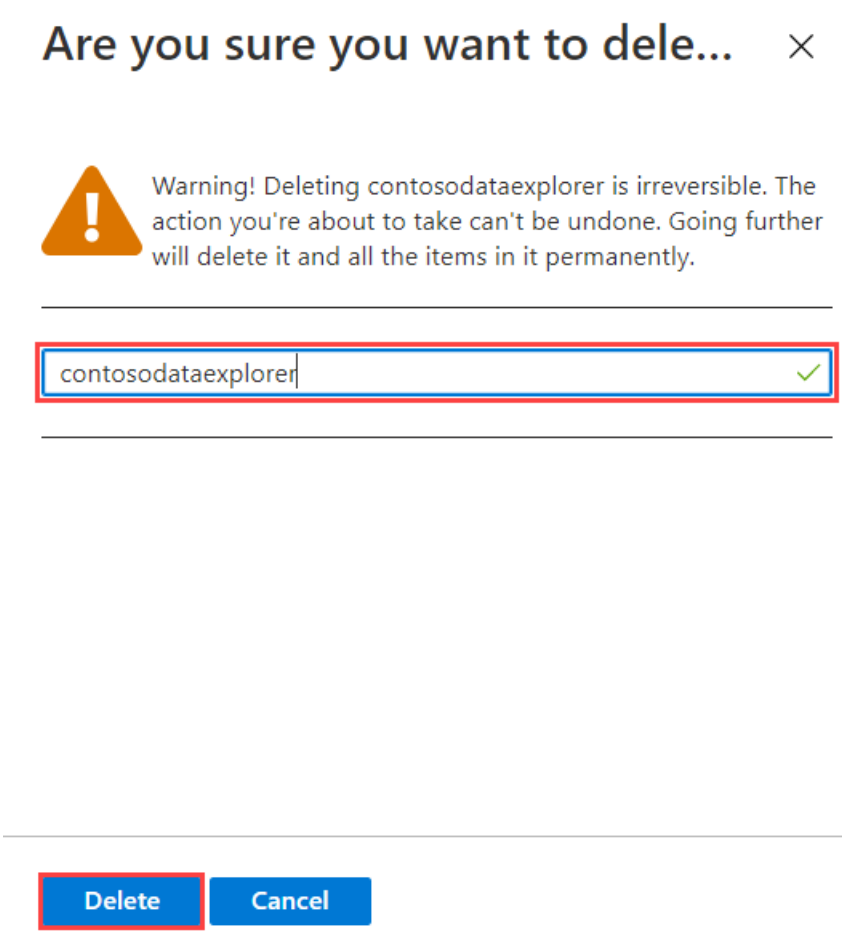
> **WARNING**
> Deleting a data-explorer pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, and notebooks that use the deleted pool will no longer work.

Delete the Data Explorer pool

1. Navigate to the Data Explorer pools in the workspace.
2. To remove the Data Explorer pool (in this case, **contosodataexplorer**), select **More [...]** > **Delete**.



3. To confirm the deletion, enter the name of the pool being deleted and then select **Delete**.



4. Once the process completes successfully, verify that the pool no longer appears in the list.

Next steps

- Ingestion overview
- Analyze with Data Explorer
- Monitor Data Explorer pools

Quickstart: Create a Data Explorer pool using Synapse Studio (Preview)

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast, fully managed data analytics service for real-time analysis on large volumes of data streaming from applications, websites, IoT devices, and more. To use Data Explorer, you first create a Data Explorer pool.

This quickstart describes the steps to create a Data Explorer pool in a Synapse workspace by using Synapse Studio.

> **IMPORTANT**
> Billing for Data Explorer instances is prorated per minute, whether you are using them or not. Be sure to shutdown your Data Explorer instance after you have finished using it, or set a short timeout. For more information, see **Clean up resources**.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

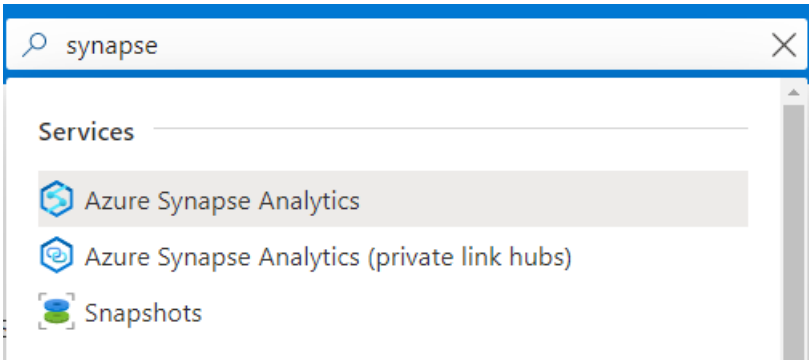
- Azure subscription - create one for free
- Synapse workspace

Sign in to the Azure portal

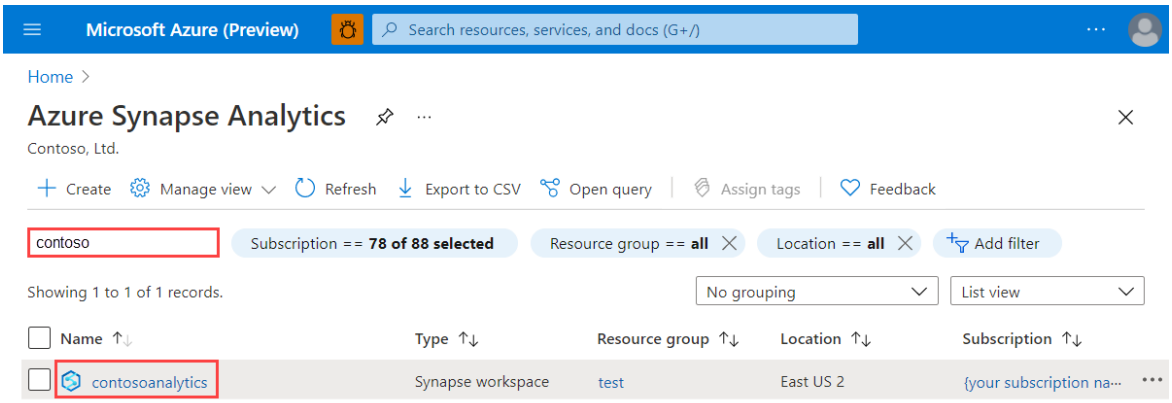
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the Data Explorer pool will be created by typing the service name (or resource name directly) into the search bar.

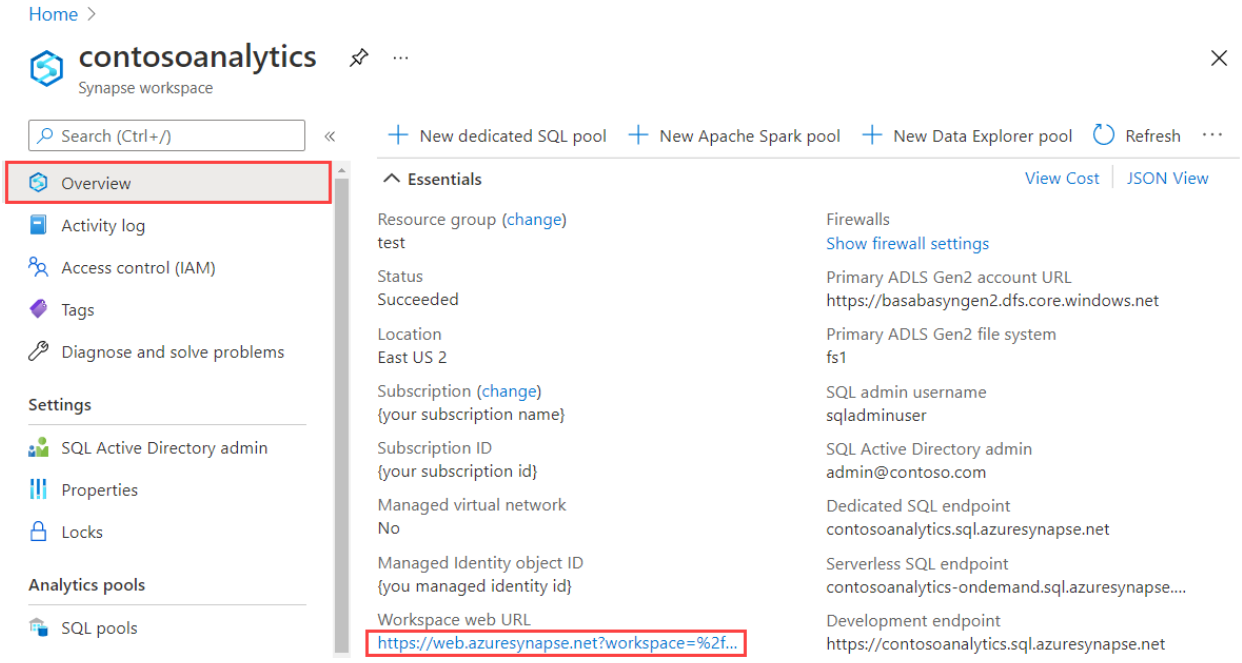


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



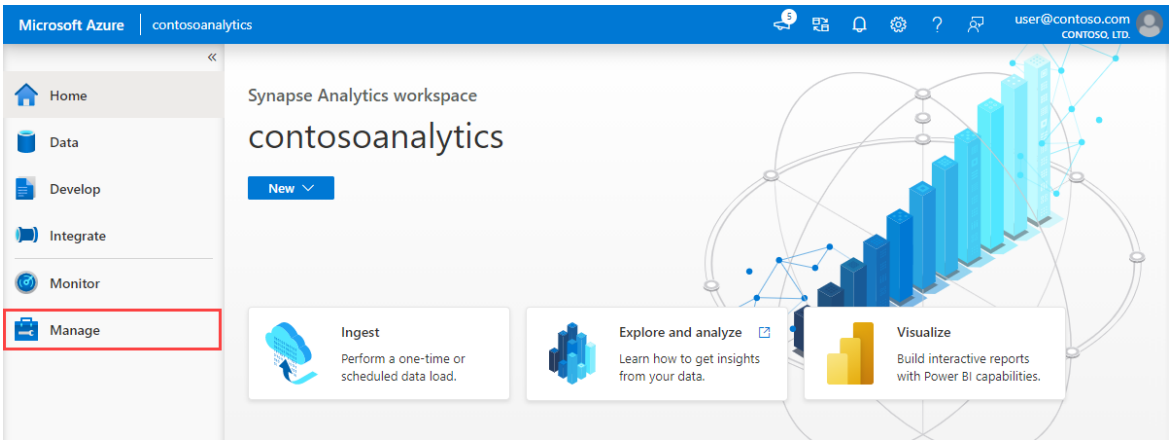
Launch Synapse Studio

From the workspace overview, select the **Workspace web URL** to open Synapse Studio.

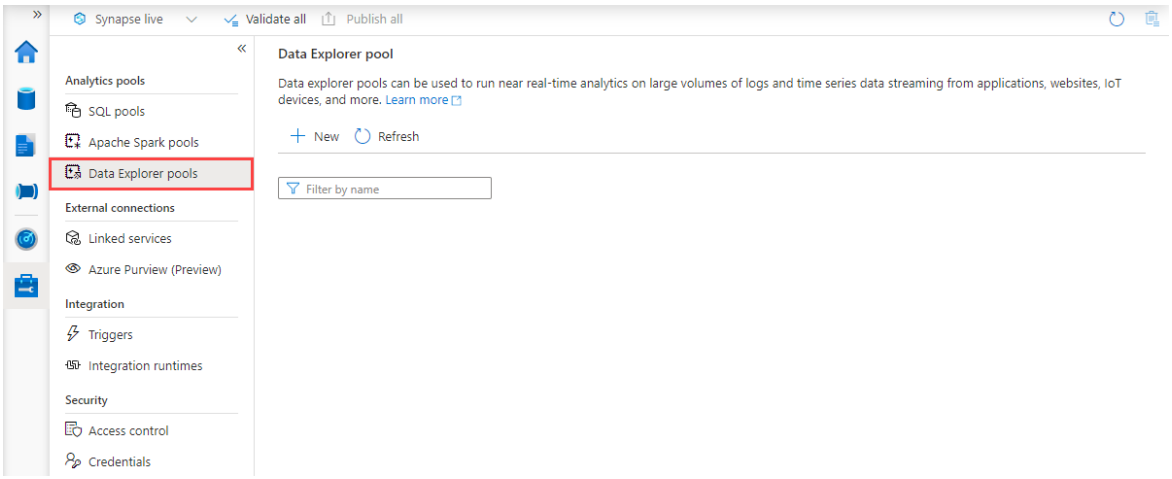


Create a new Data Explorer pool

1. On the Synapse Studio home page, navigate to the **Management Hub** in the left navigation by selecting the **Manage** icon.



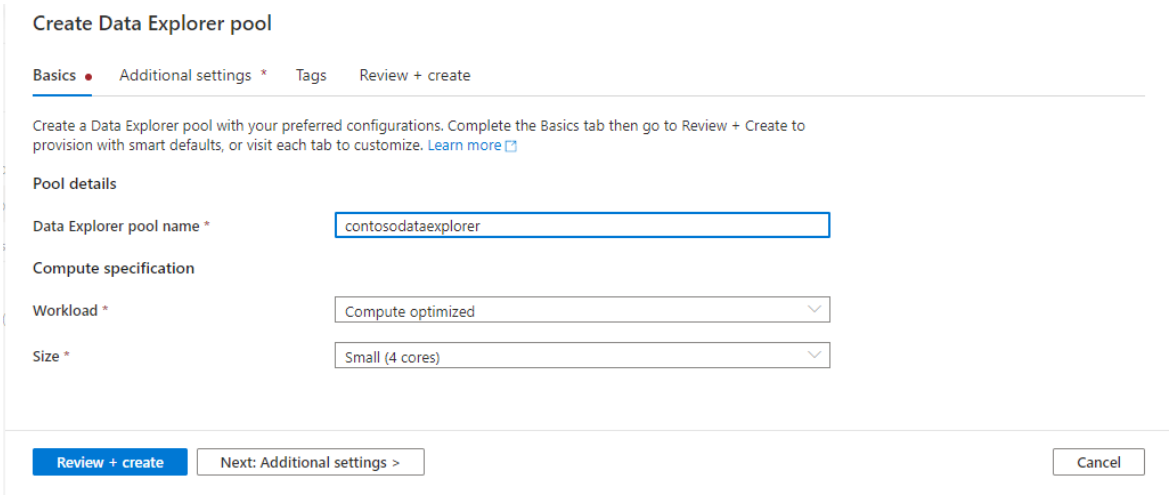
2. Once in the Management Hub, navigate to the **Data Explorer pools** section to see the current list of Data Explorer pools that are available in the workspace.



3. Select **+ New**. The new Data Explorer pool create wizard appears.

4. Enter the following details in the **Basics** tab:

SETTING	SUGGESTED VALUE	DESCRIPTION
Data Explorer pool name	contosodataexplorer	This is the name that the Data Explorer pool will have.
Workload	Compute optimized	This workload provides a higher CPU to SSD storage ratio.
Node size	Small (4 cores)	Set this to the smallest size to reduce costs for this quickstart

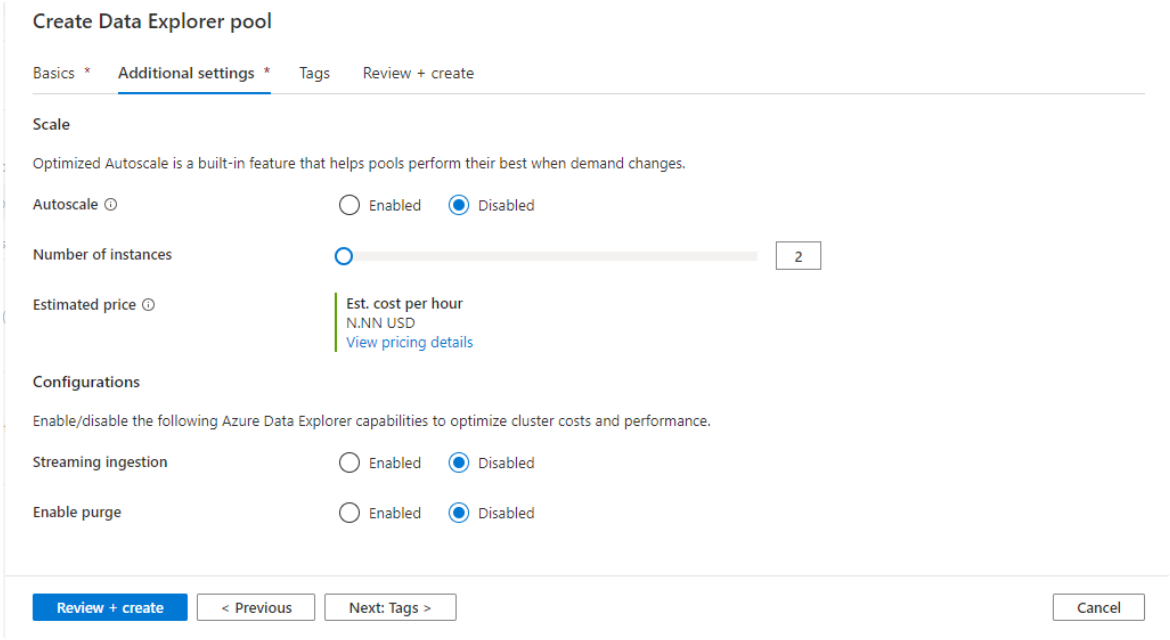


> **IMPORTANT**
> Note that there are specific limitations for the names that Data Explorer pools can use. Names must contain lowercase letters and numbers only, must be between 4 and 15 characters, and must start with a letter.

5. Select **Next: Additional settings**. Use the following settings and leave the defaults for the remaining settings.

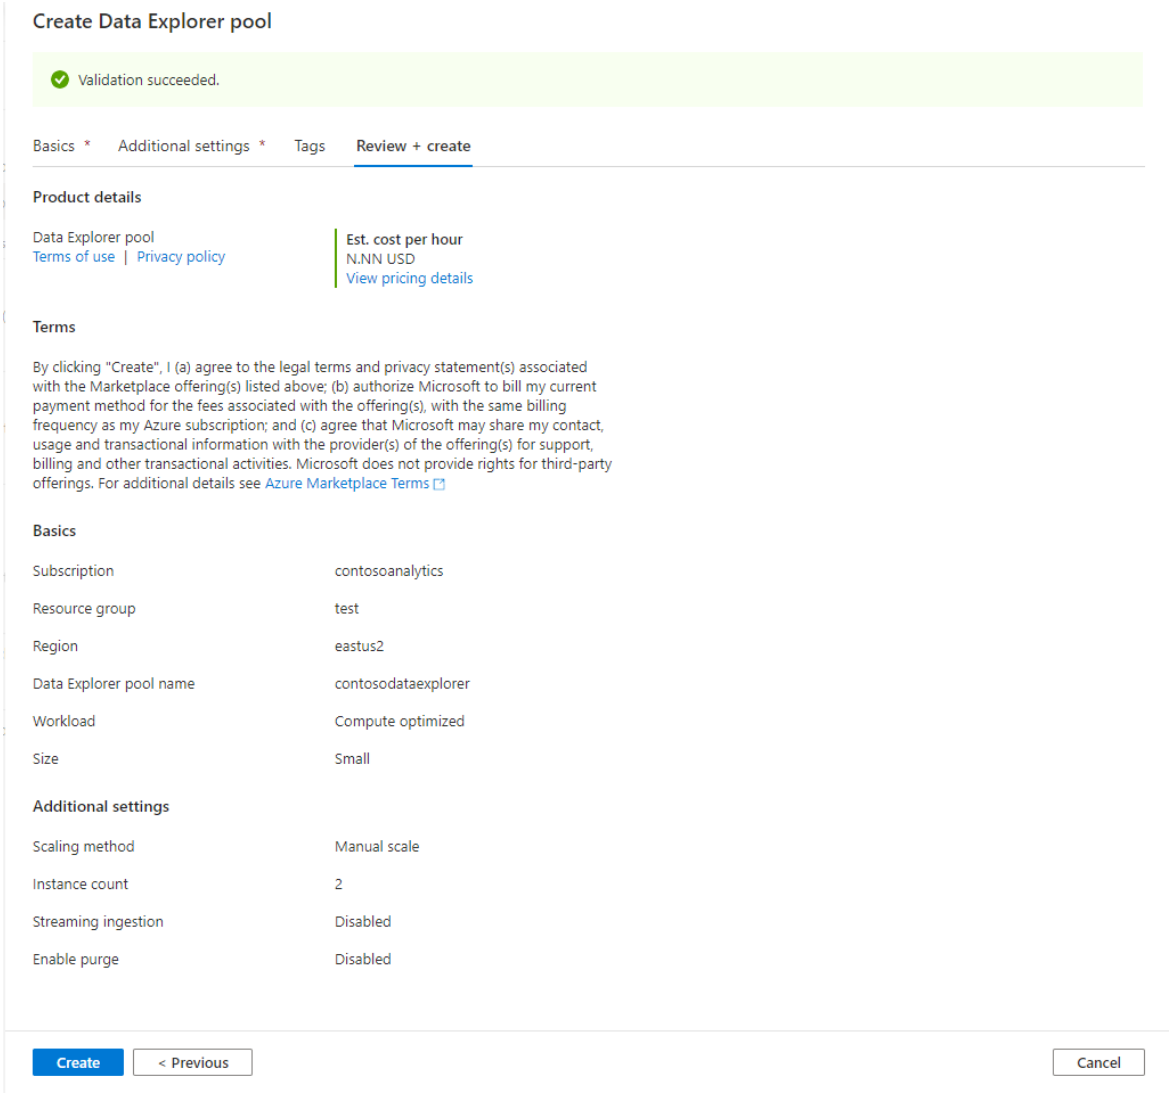
SETTING	SUGGESTED VALUE	DESCRIPTION
Autoscale	Disabled	We won't need autoscale in this quickstart

SETTING	SUGGESTED VALUE	DESCRIPTION
Number of instances	2	Set this to the smallest size to reduce costs for this quickstart

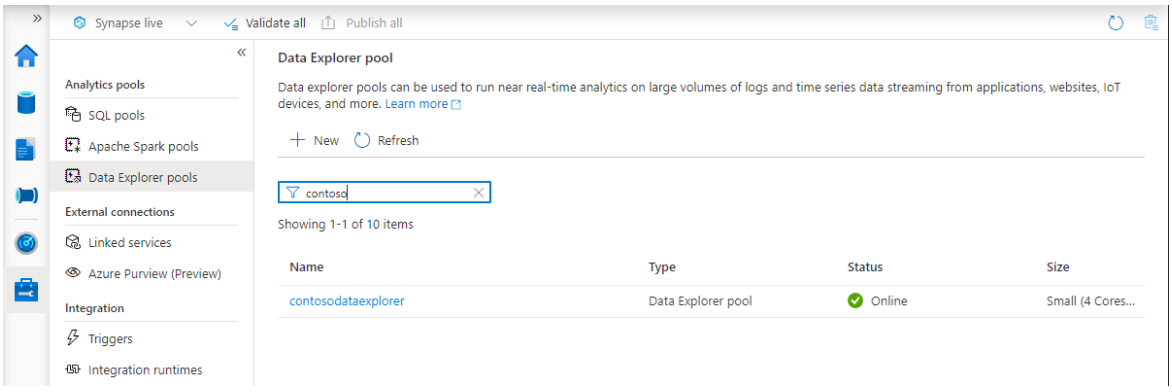


6. Select **Next: tags**. Don't add any tags.
7. Select **Review + create**.
8. Review the detail making sure they are correct, and then select **Create**.

   The Data Explorer pool will start the provisioning process.



9. Once the provisioning is complete, navigate back to the workspace and verify that the new Data Explorer pool appears in the list.



Clean up Data Explorer pool resources using Synapse Studio

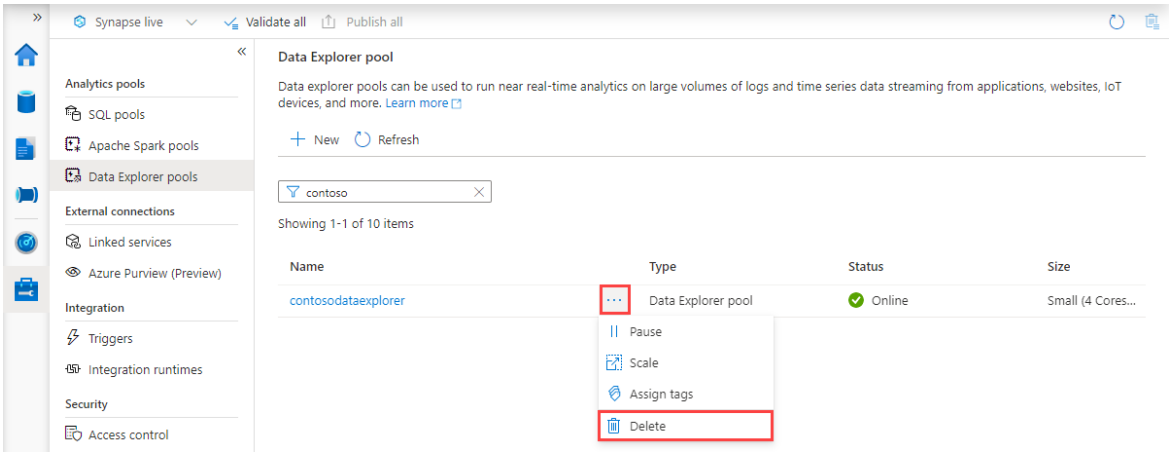
Use the following steps to delete the Data Explorer pool from the workspace using the Synapse Studio.

> **WARNING**
> Deleting a data-explorer pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, and notebooks that use the deleted pool will no longer work.

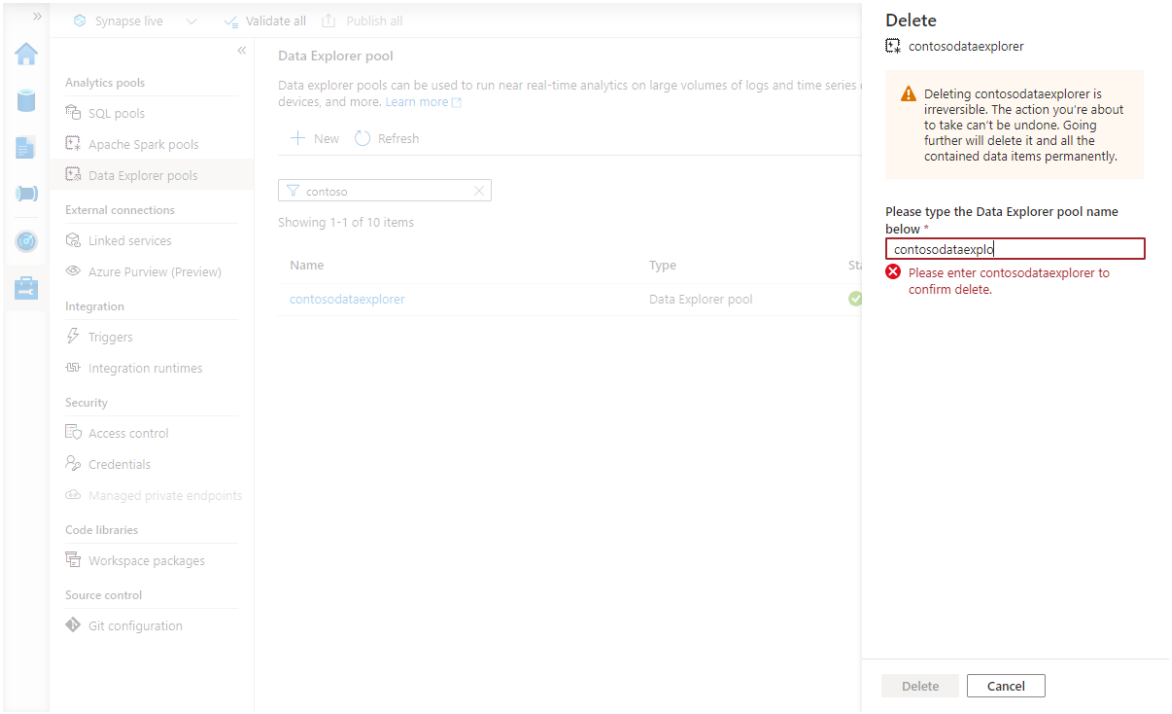
Delete the Data Explorer pool

1. Navigate to the Data Explorer pools in the workspace.

2. To remove the Data Explorer pool (in this case, **contosodataexplorer**), select **More [...]** > **Delete**.



3. To confirm the deletion, enter the name of the pool being deleted and then select **Delete**.



4. Once the process completes successfully, verify that the pool no longer appears in the list.

Azure Synapse Data Explorer data ingestion overview (Preview)

8/19/2022 • 5 minutes to read • Edit Online

Data ingestion is the process used to load data records from one or more sources to import data into a table in Azure Synapse Data Explorer pool. Once ingested, the data becomes available for query.

The Azure Synapse Data Explorer data management service, which is responsible for data ingestion, implements the following process:

- Pulls data in batches or streaming from an external source and reads requests from a pending Azure queue.
- Batch data flowing to the same database and table is optimized for ingestion throughput.
- Initial data is validated and the format is converted where necessary.
- Further data manipulation including matching schema, organizing, indexing, encoding, and compressing the data.
- Data is persisted in storage according to the set retention policy.
- Ingested data is committed into the engine, where it's available for query.

Supported data formats, properties, and permissions

- **Supported data formats**
- **Ingestion properties**: The properties that affect how the data will be ingested (for example, tagging, mapping, creation time).
- **Permissions**: To ingest data, the process requires database ingestor level permissions. Other actions, such as query, may require database admin, database user, or table admin permissions.

Batching vs streaming ingestions

- Batching ingestion does data batching and is optimized for high ingestion throughput. This method is the preferred and most performant type of ingestion. Data is batched according to ingestion properties. Small batches of data are merged and optimized for fast query results. The ingestion batching policy can be set on databases or tables. By default, the maximum batching value is 5 minutes, 1000 items, or a total size of 1 GB. The data size limit for a batch ingestion command is 4 GB.
- Streaming ingestion is ongoing data ingestion from a streaming source. Streaming ingestion allows near real-time latency for small sets of data per table. Data is initially ingested to row store, then moved to column store extents.

Ingestion methods and tools

Azure Synapse Data Explorer supports several ingestion methods, each with its own target scenarios. These methods include ingestion tools, connectors and plugins to diverse services, managed pipelines, programmatic ingestion using SDKs, and direct access to ingestion.

Ingestion using managed pipelines

For organizations who wish to have management (throttling, retries, monitors, alerts, and more) done by an external service, using a connector is likely the most appropriate solution. Queued ingestion is appropriate for large data volumes. Azure Synapse Data Explorer supports the following Azure Pipelines:

- **Event Hub**: A pipeline that transfers events from services to Azure Synapse Data Explorer. For more information, see Ingest data from Event Hub into Azure Synapse Data Explorer.

- **Synapse pipelines**: A fully managed data integration service for analytic workloads in Synapse pipelines connects with over 90 supported sources to provide efficient and resilient data transfer. Synapse pipelines prepares, transforms, and enriches data to give insights that can be monitored in different kinds of ways. This service can be used as a one-time solution, on a periodic timeline, or triggered by specific events.

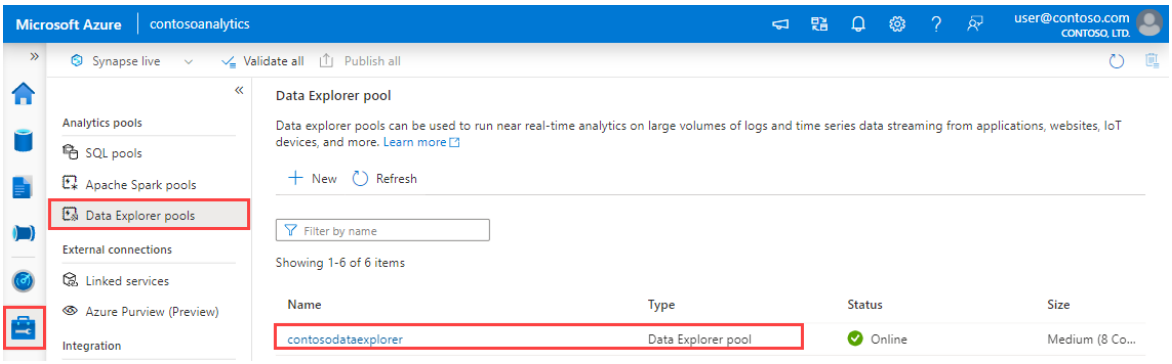
Programmatic ingestion using SDKs

Azure Synapse Data Explorer provides SDKs that can be used for query and data ingestion. Programmatic ingestion is optimized for reducing ingestion costs (COGs), by minimizing storage transactions during and following the ingestion process.

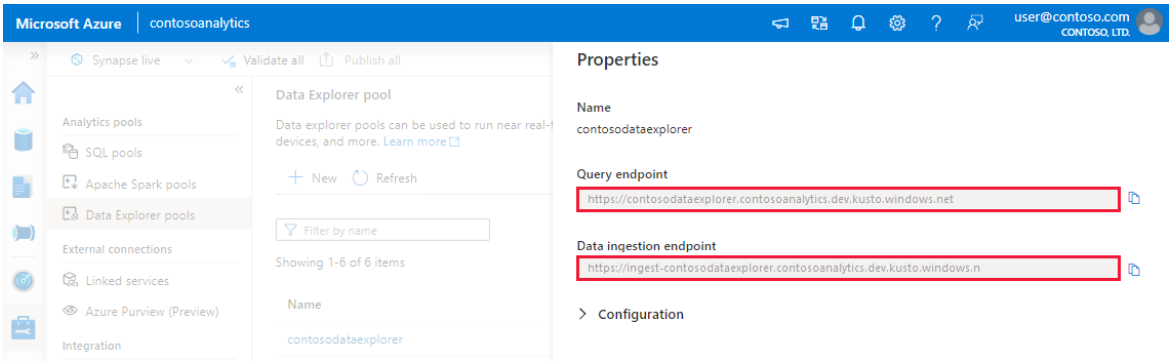
Before you start, use the following steps to get the Data Explorer pool endpoints for configuring programmatic ingestion.

1. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.

2. Select the Data Explorer pool you want to use to view its details.



3. Make a note of the Query and Data Ingestion endpoints. Use the Query endpoint as the cluster when configuring connections to your Data Explorer pool. When configuring SDKs for data ingestion, use the data ingestion endpoint.



Available SDKs and open-source projects

- Python SDK
- .NET SDK
- Java SDK
- Node SDK
- REST API
- GO SDK

Tools

- **One-click ingestion**: Enables you to quickly ingest data by creating and adjusting tables from a wide range of source types. One-click ingestion automatically suggests tables and mapping structures based on the data source in Azure Synapse Data Explorer. One-click ingestion can be used for one-time ingestion, or to define continuous ingestion via Event Grid on the container to which the data was ingested.

Kusto Query Language ingest control commands

There are a number of methods by which data can be ingested directly to the engine by Kusto Query Language (KQL) commands. Because this method bypasses the Data Management services, it's only appropriate for exploration and prototyping. Don't use this method in production or high-volume scenarios.

- **Inline ingestion**: A control command .ingest inline is sent to the engine, with the data to be ingested being a part of the command text itself. This method is intended for improvised testing purposes.
- **Ingest from query**: A control command .set, .append, .set-or-append, or .set-or-replace is sent to the engine, with the data specified indirectly as the results of a query or a command.
- **Ingest from storage (pull)**: A control command .ingest into is sent to the engine, with the data stored in some external storage (for example, Azure Blob Storage) accessible by the engine and pointed-to by the command.

For an example of using ingest control commands, see Analyze with Data Explorer.

Ingestion process

Once you have chosen the most suitable ingestion method for your needs, do the following steps:

1. **Set retention policy**

   Data ingested into a table in Azure Synapse Data Explorer is subject to the table's effective retention policy. Unless set on a table explicitly, the effective retention policy is derived from the database's retention policy. Hot retention is a function of cluster size and your retention policy. Ingesting more data than you have available space will force the first in data to cold retention.

   Make sure that the database's retention policy is appropriate for your needs. If not, explicitly override it at the table level. For more information, see retention policy.

2. **Create a table**

   In order to ingest data, a table needs to be created beforehand. Use one of the following options:

   - Create a table with a command. For an example of using the create a table command, see Analyze with Data Explorer.
   - Create a table using One-click Ingestion.

   > **NOTE**
   > If a record is incomplete or a field cannot be parsed as the required data type, the corresponding table columns will be populated with null values.

3. **Create schema mapping**

   Schema mapping helps bind source data fields to destination table columns. Mapping allows you to take data from different sources into the same table, based on the defined attributes. Different types of mappings are supported, both row-oriented (CSV, JSON and AVRO), and column-oriented (Parquet). In most methods, mappings can also be pre-created on the table and referenced from the ingest command

parameter.

4. **Set update policy** (optional)

   Some of the data format mappings (Parquet, JSON, and Avro) support simple and useful ingest-time transformations. Where the scenario requires more complex processing at ingest time, use update policy, which allows for lightweight processing using Kusto Query Language commands. The update policy automatically runs extractions and transformations on ingested data on the original table, and ingests the resulting data into one or more destination tables. Set your update policy.

Next steps

- Supported data formats
- Supported ingestion properties

Quickstart: Ingest data using One-click (Preview)

8/19/2022 • 5 minutes to read • Edit Online

One-click ingestion makes the data ingestion process easy, fast, and intuitive. One-click ingestion helps you ramp-up quickly to start ingesting data, creating database tables, mapping structures. Select data from different kinds of sources in different data formats, either as a one-time or continuous ingestion process.

The following features make one-click ingestion so useful:

- Intuitive experience guided by the ingestion wizard
- Ingest data in a matter of minutes
- Ingest data from different kinds of sources: local file, blobs, and containers (up to 10,000 blobs)
- Ingest data in a variety of formats
- Ingest data into new or existing tables
- Table mapping and schema are suggested to you and easy to change

One-click ingestion is particularly useful when ingesting data for the first time, or when your data's schema is unfamiliar to you.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Create a table

1. In Synapse Studio, on the left-side pane, select **Develop**.
2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
3. In the **Connect to** menu, select *contosodataexplorer*.
4. In the **Use database** menu, select *TestDatabase*.
5. Paste in the following command, and select **Run** to create the table.

```
.create table StormEvents (StartTime: datetime, EndTime: datetime, EpisodeId: int, EventId: int,
State: string, EventType: string, InjuriesDirect: int, InjuriesIndirect: int, DeathsDirect: int,
DeathsIndirect: int, DamageProperty: int, DamageCrops: int, Source: string, BeginLocation: string,
EndLocation: string, BeginLat: real, BeginLon: real, EndLat: real, EndLon: real, EpisodeNarrative:
string, EventNarrative: string, StormSummary: dynamic)
```

TIP

Verify that the table was successfully created. On the left-side pane, select **Data**, select the *contosodataexplorer* more menu, and then select **Refresh**. Under *contosodataexplorer*, expand **Tables** and make sure that the *StormEvents* table appears in the list.

Access the one-click wizard

The one-click ingestion wizard guides you through the one-click ingestion process.

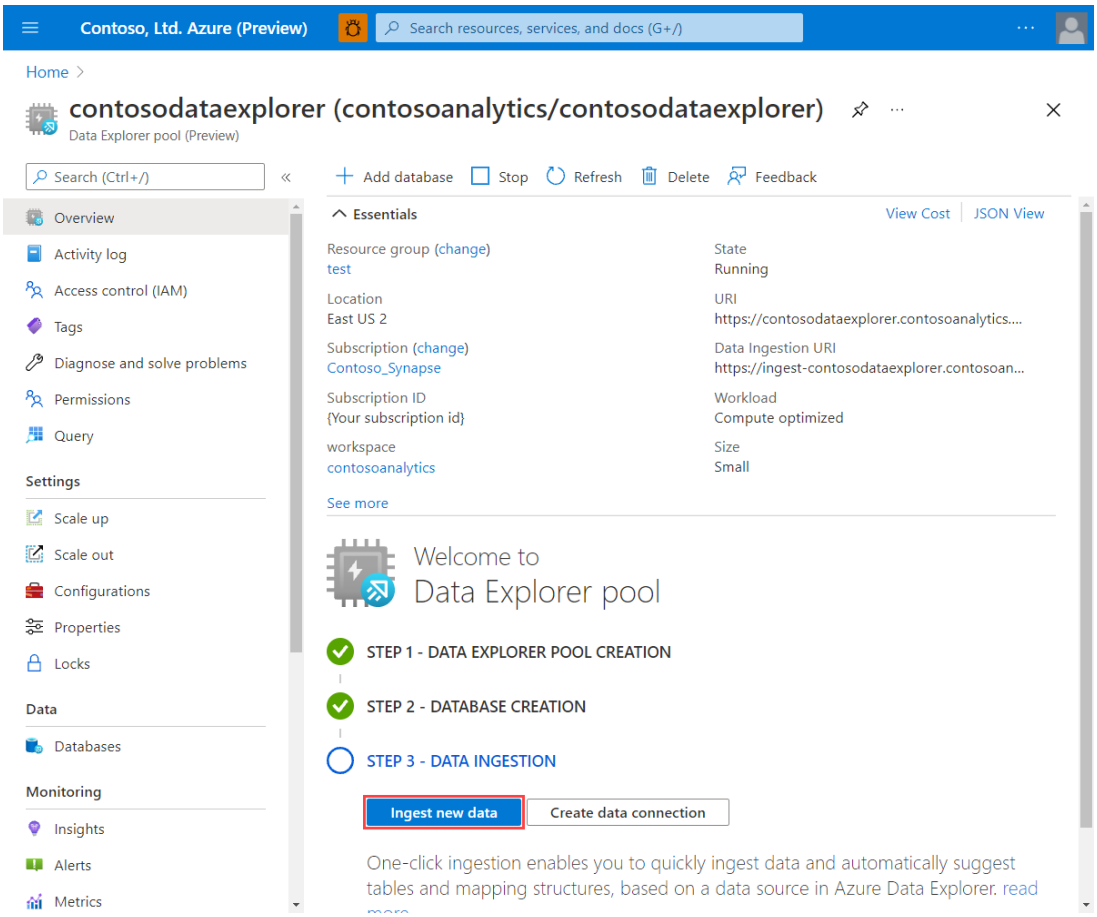
- To access the wizard from Azure Synapse:

  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Under **Data Explorer Databases**, right-click the relevant database, and then select **Open in Azure Data Explorer**.

  3. Right-click the relevant pool, and then select **Ingest new data**.

- To access the wizard from the Azure portal:

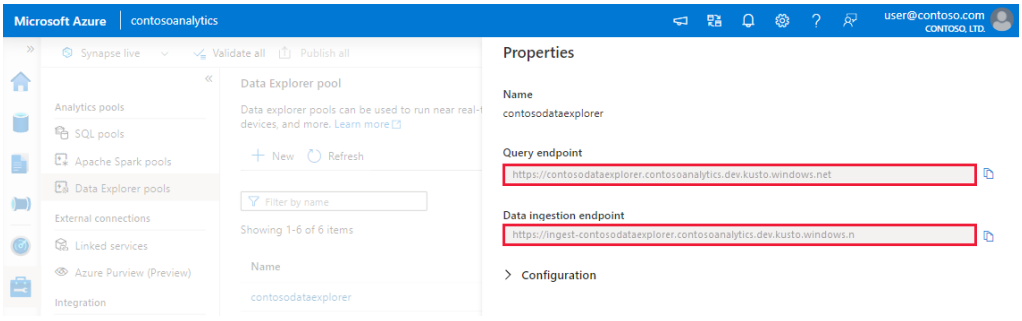
  1. In the Azure portal, search for and select the relevant Synapse workspace.
  2. Under **Data Explorer pools**, select the relevant pool.
  3. On the **Welcome to Data Explorer pool** home screen, select **Ingest new data**.



- To access the wizard from the Azure Data Explorer web ui:

1. Before you start, use the following steps to get the Query and Data Ingestion endpoints.
   a. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.
   b. Select the Data Explorer pool you want to use to view its details.

   c. Make a note of the Query and Data Ingestion endpoints. Use the Query endpoint as the cluster when configuring connections to your Data Explorer pool. When configuring SDKs for data ingestion, use the data ingestion endpoint.

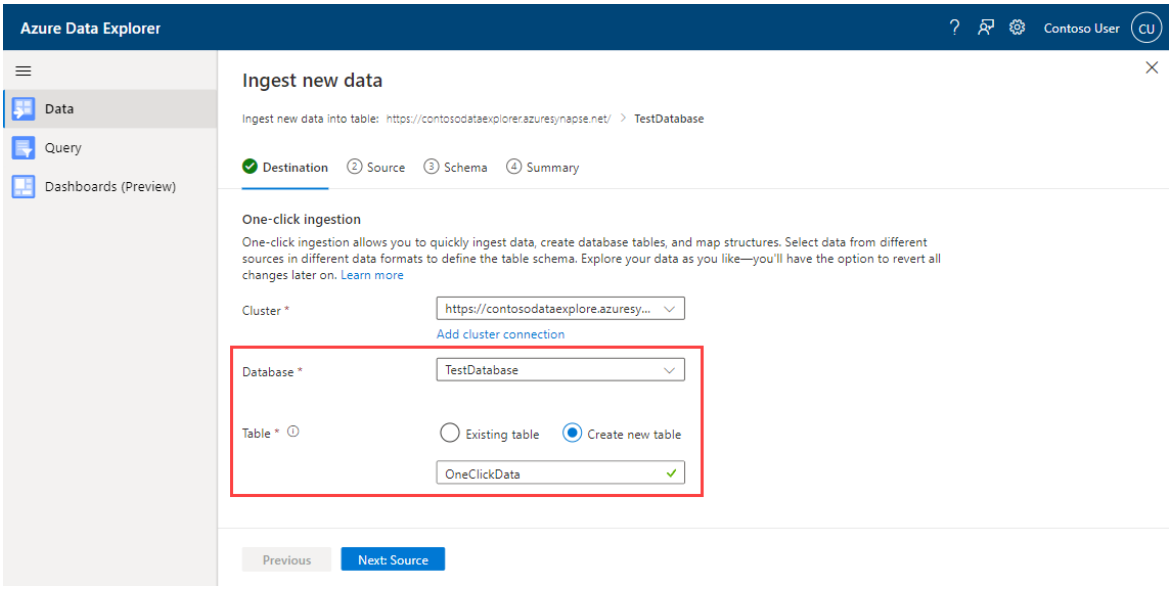


2. In the Azure Data Explorer web ui, add a connection to the *Query endpoint*.
3. Select **Query** from the left menu, right-click on the **database** or **table**, and select **Ingest new data**.

One-click ingestion wizard

> **NOTE**
>
> This section describes the wizard using Event Hub as the data source. You can also use these steps to ingest data from a blob, file, blob container, and a ADLS Gen2 container.
>
> Replace the example values with actual values for your Synapse workspace.

1. On the **Destination** tab, choose the database and table for the ingested data.



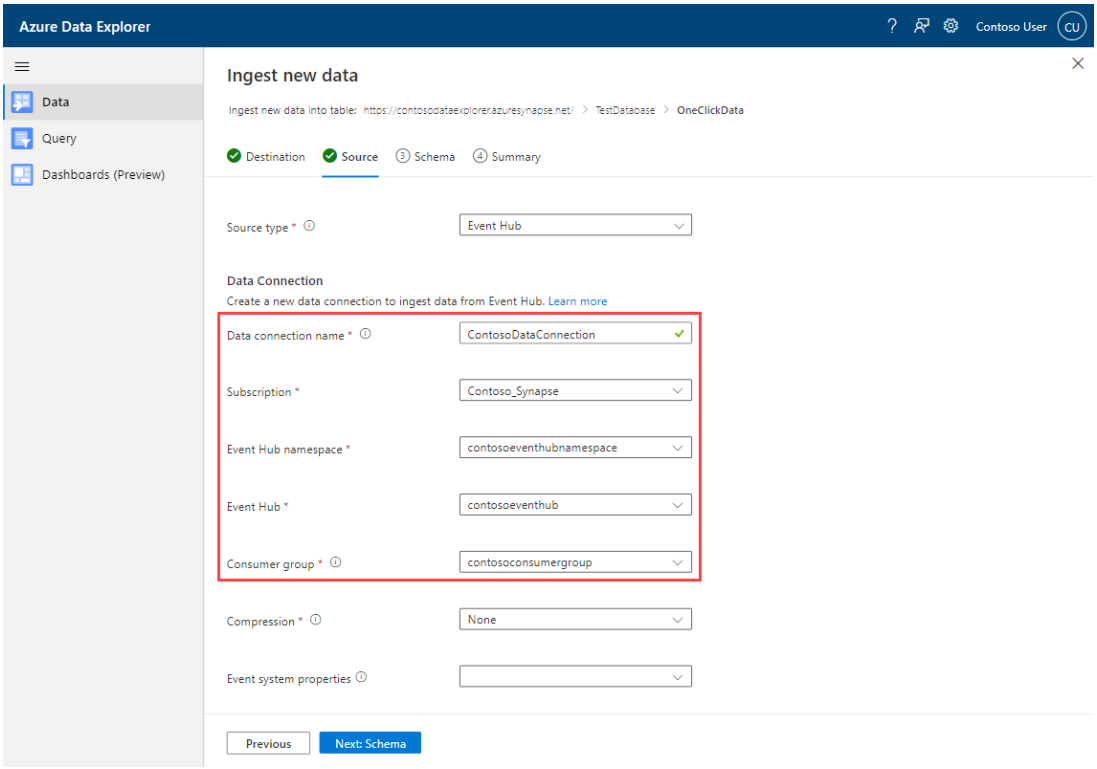
2. On the **Source** tab:

   a. Select *Event Hub* as the **Source type** for the ingestion.

   b. Fill out the Event Hub data connection details using the following information:

SETTING	EXAMPLE VALUE	DESCRIPTION
Data connection name	*ContosoDataConnection*	The name of the Event Hub data connection
Subscription	*Contoso_Synapse*	The subscription where the Event Hub resides.

SETTING	EXAMPLE VALUE	DESCRIPTION
Even Hub namespace	*contosoeventhubnamespace*	The namespace of the Event Hub.
Consumer group	*contosoconsumergroup*	The name of the Even Hub consumer group.



c. Select **Next**.

Schema mapping

The service automatically generates schema and ingestion properties, which you can change. You can use an existing mapping structure or create a new one, depending on if you're ingesting to a new or existing table.

In the **Schema** tab, do the following actions:

1. Confirm the autogenerated compression type.
2. Choose the format of your data. Different formats will allow you to make further changes.
3. Change mapping in the Editor window.

File formats

One-click ingestion supports ingesting from source data in all data formats supported by Data Explorer for ingestion.

Editor window

In the **Editor** window of the **Schema** tab, you can adjust data table columns as necessary.

The changes you can make in a table depend on the following parameters:

- **Table** type is new or existing
- **Mapping** type is new or existing

TABLE TYPE	MAPPING TYPE	AVAILABLE ADJUSTMENTS

TABLE TYPE	MAPPING TYPE	AVAILABLE ADJUSTMENTS
New table	New mapping	Change data type, Rename column, New column, Delete column, Update column, Sort ascending, Sort descending
Existing table	New mapping	New column (on which you can then change data type, rename, and update), Update column, Sort ascending, Sort descending
	Existing mapping	Sort ascending, Sort descending

> **NOTE**
> When adding a new column or updating a column, you can change mapping transformations. For more information, see Mapping transformations

Mapping transformations

Some data format mappings (Parquet, JSON, and Avro) support simple ingest-time transformations. To apply mapping transformations, create or update a column in the Editor window.

Mapping transformations can be performed on a column of **Type** string or datetime, with the **Source** having data type int or long. Supported mapping transformations are:

- DateTimeFromUnixSeconds
- DateTimeFromUnixMilliseconds
- DateTimeFromUnixMicroseconds
- DateTimeFromUnixNanoseconds

Data ingestion

Once you have completed schema mapping and column manipulations, the ingestion wizard will start the data ingestion process.

- When ingesting data from **non-container** sources, the ingestion will take immediate effect.
- If your data source is a **container**:
  - Data Explorer's batching policy will aggregate your data.
  - After ingestion, you can download the ingestion report and review the performance of each blob that was addressed.

Initial data exploration

After ingestion, the wizard gives you options to use **Quick commands** for initial exploration of your data.

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Configure streaming ingestion on your Azure Synapse Data Explorer pool (Preview)

8/19/2022 • 11 minutes to read • Edit Online

Streaming ingestion is useful for loading data when you need low latency between ingestion and query. Consider using streaming ingestion in the following scenarios:

- Latency of less than a second is required.
- To optimize operational processing of many tables where the stream of data into each table is relatively small (a few records per second), but the overall data ingestion volume is high (thousands of records per second).

If the stream of data into each table is high (over 4 GB per hour), consider using batch ingestion.

To learn more about different ingestion methods, see data ingestion overview.

Choose the appropriate streaming ingestion type

Two streaming ingestion types are supported:

INGESTION TYPE	DESCRIPTION
Event Hub or **IoT Hub**	Hubs are configured as table streaming data sources. For information about setting these up, see **Event Hub**.
Custom ingestion	Custom ingestion requires you to write an application that uses one of the Azure Synapse Data Explorer client libraries. Use the information in this topic to configure custom ingestion. You may also find the C# streaming ingestion sample application helpful.

Use the following table to help you choose the ingestion type that's appropriate for your environment:

CRITERION	EVENT HUB / IOT HUB	CUSTOM INGESTION
Data delay between ingestion initiation and the data available for query	Longer delay	Shorter delay
Development overhead	Fast and easy setup, no development overhead	High development overhead to create an application ingest the data, handle errors, and ensure data consistency

> **NOTE**
> Ingesting data from an Event Hub into Data Explorer pools will not work if your Synapse workspace uses a managed virtual network with data exfiltration protection enabled.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal

- Create a Data Explorer database.

  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

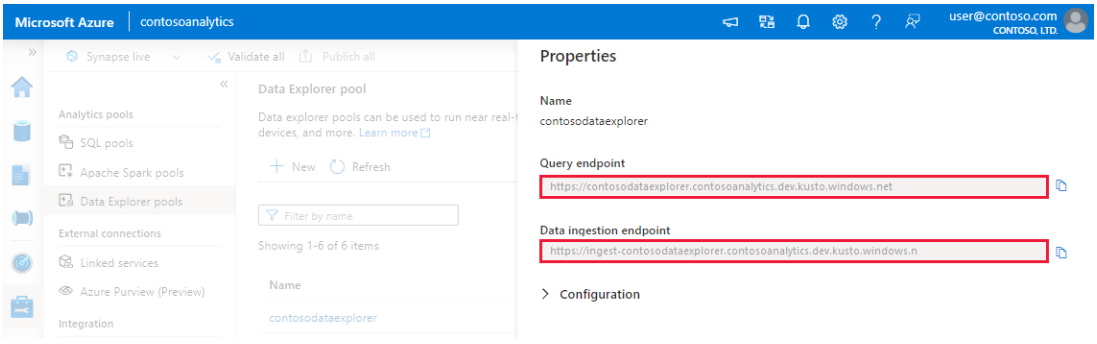
SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.

- Get the Query and Data Ingestion endpoints.

  1. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.
  2. Select the Data Explorer pool you want to use to view its details.

  3. Make a note of the Query and Data Ingestion endpoints. Use the Query endpoint as the cluster when configuring connections to your Data Explorer pool. When configuring SDKs for data ingestion, use the data ingestion endpoint.



Performance and operational considerations

The main contributors that can impact streaming ingestion are:

- **Compute Specification**: Streaming ingestion performance and capacity scales with increased Data Explorer pool sizes. The number of concurrent ingestion requests is limited to six per core. For example, for 16 core workload type, such as Compute Optimized (Large) and Storage Optimized (Large), the maximal supported load is 96 concurrent ingestion requests. For two core workload type, such as Compute Optimized (Extra Small), the maximal supported load is 12 concurrent ingestion requests.
- **Data size limit**: The data size limit for a streaming ingestion request is 4 MB.
- **Schema updates**: Schema updates, such as creation and modification of tables and ingestion mappings, may take up to five minutes for the streaming ingestion service. For more information see Streaming ingestion and schema changes.
- **SSD capacity**: Enabling streaming ingestion on a Data Explorer pool, even when data isn't ingested via streaming, uses part of the local SSD disk of the Data Explorer pool machines for streaming ingestion data and reduces the storage available for hot cache.

Enable streaming ingestion on your Data Explorer pool

Before you can use streaming ingestion, you must enable the capability on your Data Explorer pool and define a streaming ingestion policy. You can enable the capability when creating the Data Explorer pool, or add it to an existing Data Explorer pool.

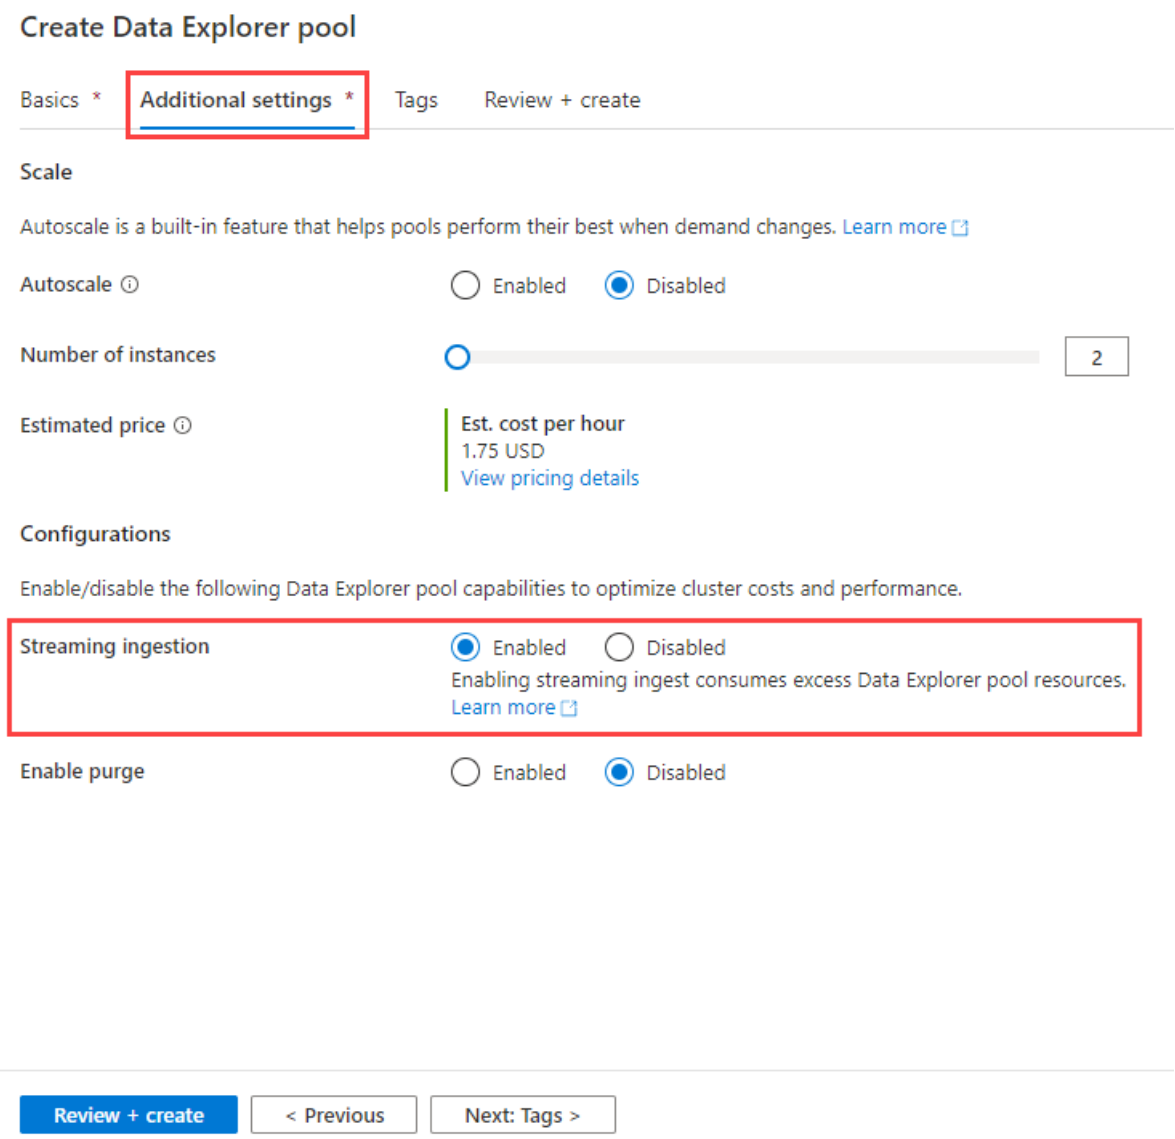
> **WARNING**
> Review the limitations prior to enabling streaming ingestion.

Enable streaming ingestion while creating a new Data Explorer pool

You can enable streaming ingestion while creating a new Data Explorer pool using Azure Synapse Studio or the Azure portal.

- Studio
- Portal

While creating a Data Explorer pool using the steps in Create a Data Explorer pool using Synapse Studio, in the **Additional settings** tab, select **Streaming ingestion** > **Enabled**.



Enable streaming ingestion on an existing Data Explorer pool

If you have an existing Data Explorer pool, you can enable streaming ingestion using the Azure portal.

1. In the Azure portal, go to your Data Explorer pool.
2. In **Settings**, select **Configurations**.
3. In the **Configurations** pane, select **On** to enable **Streaming ingestion**.
4. Select **Save**.

Create a target table and define the policy

Create a table to receive the streaming ingestion data and define its related policy using Azure Synapse Studio or the Azure portal.

- Studio
- Portal

1. In Synapse Studio, on the left-side pane, select **Develop**.
2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
3. In the **Connect to** menu, select *contosodataexplorer*.
4. In the **Use database** menu, select *TestDatabase*.
5. Paste in the following command, and select **Run** to create the table.

```
.create table TestTable (TimeStamp: datetime, Name: string, Metric: int, Source:string)
```

6. Copy one of the following commands into the **Query pane** and select **Run**. This defines the streaming ingestion policy on the table you created or on the database that contains the table.

> **TIP**
> A policy that is defined at the database level applies to all existing and future tables in the database.

- To define the policy on the table you created, use:

```
.alter table TestTable policy streamingingestion enable
```

- To define the policy on the database containing the table you created, use:

```
.alter database StreamingTestDb policy streamingingestion enable
```

Create a streaming ingestion application to ingest data to your Data Explorer pool

Create your application for ingesting data to your Data Explorer pool using your preferred language. For the *poolPath* variable, use the Query endpoint you made a note of in the Prerequisites.

- C#
- Python
- Node.js
- Go
- Java

```
using Kusto.Data;
using Kusto.Ingest;
using System.IO;
using Kusto.Data.Common;

namespace StreamingIngestion
{
    class Program
    {
        static void Main(string[] args)
        {
            string poolPath = "https://<Poolname>.<WorkspaceName>.kusto.windows.net";
            string appId = "<appId>";
            string appKey = "<appKey>";
            string appTenant = "<appTenant>";
            string dbName = "<dbName>";
            string tableName = "<tableName>";

            // Create Kusto connection string with App Authentication
            var csb =
                new KustoConnectionStringBuilder(poolPath)
                    .WithAadApplicationKeyAuthentication(
                        applicationClientId: appId,
                        applicationKey: appKey,
                        authority: appTenant
                    );

            // Create a disposable client that will execute the ingestion
            using (IKustoIngestClient client = KustoIngestFactory.CreateStreamingIngestClient(csb))
            {
                // Initialize client properties
                var ingestionProperties =
                    new KustoIngestionProperties(
                        databaseName: dbName,
                        tableName: tableName
                    );

                // Ingest from a compressed file
                var fileStream = File.Open("MyFile.gz", FileMode.Open);
                // Create source options
                var sourceOptions = new StreamSourceOptions()
                {
                    CompressionType = DataSourceCompressionType.GZip,
                };
                // Ingest from stream
                var status = client.IngestFromStreamAsync(fileStream, ingestionProperties,
sourceOptions).GetAwaiter().GetResult();
            }
        }
    }
}
```

Disable streaming ingestion on your Data Explorer pool

> **WARNING**
> Disabling streaming ingestion may take a few hours.

Before disabling streaming ingestion on your Data Explorer pool, drop the streaming ingestion policy from all relevant tables and databases. The removal of the streaming ingestion policy triggers data rearrangement inside your Data Explorer pool. The streaming ingestion data is moved from the initial storage to permanent storage in the column store (extents or shards). This process can take between a few seconds to a few hours, depending on

the amount of data in the initial storage.

Drop the streaming ingestion policy

You can drop the streaming ingestion policy using Azure Synapse Studio or the Azure portal.

- Studio
- Portal

1. In Synapse Studio, on the left-side pane, select **Develop**.
2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
3. In the **Connect to** menu, select *contosodataexplorer*.
4. In the **Use database** menu, select *TestDatabase*.
5. Paste in the following command, and select **Run** to create the table.

```
.delete table TestTable policy streamingingestion
```

6. In the Azure portal, go to your Data Explorer pool.
7. In **Settings**, select **Configurations**.
8. In the **Configurations** pane, select **On** to enable **Streaming ingestion**.
9. Select **Save**.

Limitations

- Database cursors aren't supported for a database if the database itself or any of its tables have the Streaming ingestion policy defined and enabled.
- Data mappings must be pre-created for use in streaming ingestion. Individual streaming ingestion requests don't accommodate inline data mappings.
- Extent tags can't be set on the streaming ingestion data.
- Update policy. The update policy can reference only the newly-ingested data in the source table and not any other data or tables in the database.
- If streaming ingestion is used on any of the tables of the database, this database cannot be used as leader for follower databases or as a data provider for Azure Synapse Analytics Data Share.

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Event Hub data connection (Preview)

8/19/2022 • 6 minutes to read • Edit Online

Azure Event Hubs is a big data streaming platform and event ingestion service. Azure Synapse Data Explorer offers continuous ingestion from customer-managed Event Hubs.

The Event Hub ingestion pipeline transfers events to Azure Synapse Data Explorer in several steps. You first create an Event Hub in the Azure portal. You then create a target table in Azure Synapse Data Explorer into which the data in a particular format, will be ingested using the given ingestion properties. The Event Hub connection needs to know events routing. Data is embedded with selected properties according to the event system properties mapping. Create a connection to Event Hub to create an Event Hub and send events. This process can be managed through the Azure portal, programmatically with C# or Python, or with the Azure Resource Manager template.

For general information about data ingestion in Azure Synapse Data Explorer, see Azure Synapse Data Explorer data ingestion overview.

Data format

- Data is read from the Event Hub in form of EventData objects.
- See supported formats.

  > **NOTE**
  > Event Hub doesn't support the .raw format.

- Data can be compressed using the `GZip` compression algorithm. Specify `Compression` in ingestion properties.
  - Data compression isn't supported for compressed formats (Avro, Parquet, ORC).
  - Custom encoding and embedded system properties aren't supported on compressed data.

Ingestion properties

Ingestion properties instruct the ingestion process, where to route the data, and how to process it. You can specify ingestion properties of the events ingestion using the EventData.Properties. You can set the following properties:

PROPERTY	DESCRIPTION
Table	Name (case sensitive) of the existing target table. Overrides the `Table` set on the `Data Connection` pane.
Format	Data format. Overrides the `Data format` set on the `Data Connection` pane.
IngestionMappingReference	Name of the existing ingestion mapping to be used. Overrides the `Column mapping` set on the `Data Connection` pane.

PROPERTY	DESCRIPTION
Compression	Data compression, `None` (default), or `GZip` compression.
Encoding	Data encoding, the default is UTF8. Can be any of .NET supported encodings.
Tags	A list of tags to associate with the ingested data, formatted as a JSON array string. There are performance implications when using tags.

> **NOTE**
> Only events enqueued after you create the data connection are ingested.

Events routing

When you set up an Event Hub connection to Azure Synapse Data Explorer cluster, you specify target table properties (table name, data format, compression, and mapping). The default routing for your data is also referred to as `static routing`. You can also specify target table properties for each event, using event properties. The connection will dynamically route the data as specified in the EventData.Properties, overriding the static properties for this event.

In the following example, set Event Hub details and send weather metric data to table `WeatherMetrics`. Data is in `json` format. `mapping1` is pre-defined on the table `WeatherMetrics`.

```
var eventHubNamespaceConnectionString=<connection_string>;
var eventHubName=<event_hub>;

// Create the data
var metric = new Metric { Timestamp = DateTime.UtcNow, MetricName = "Temperature", Value = 32 };
var data = JsonConvert.SerializeObject(metric);

// Create the event and add optional "dynamic routing" properties
var eventData = new EventData(Encoding.UTF8.GetBytes(data));
eventData.Properties.Add("Table", "WeatherMetrics");
eventData.Properties.Add("Format", "json");
eventData.Properties.Add("IngestionMappingReference", "mapping1");
eventData.Properties.Add("Tags", "['mydatatag']");

// Send events
var eventHubClient = EventHubClient.CreateFromConnectionString(eventHubNamespaceConnectionString,
eventHubName);
eventHubClient.Send(eventData);
eventHubClient.Close();
```

Event system properties mapping

System properties store properties that are set by the Event Hubs service, at the time the event is enqueued. The Azure Synapse Data Explorer Event Hub connection will embed the selected properties into the data landing in your table.

NOTE

- System properties are supported for `json` and tabular formats (`csv`, `tsv` etc.) and aren't supported on compressed data. When using a non-supported format, the data will still be ingested, but the properties will be ignored.
- For tabular data, system properties are supported only for single-record event messages.
- For JSON data, system properties are also supported for multiple-record event messages. In such cases, the system properties are added only to the first record of the event message.
- For `csv` mapping, properties are added at the beginning of the record in the order listed in the System properties table.
- For `json` mapping, properties are added according to property names in the System properties table.

System properties

Event Hub exposes the following system properties:

PROPERTY	DATA TYPE	DESCRIPTION
x-opt-enqueued-time	datetime	UTC time when the event was enqueued
x-opt-sequence-number	long	The logical sequence number of the event within the partition stream of the Event Hub
x-opt-offset	string	The offset of the event from the Event Hub partition stream. The offset identifier is unique within a partition of the Event Hub stream
x-opt-publisher	string	The publisher name, if the message was sent to a publisher endpoint
x-opt-partition-key	string	The partition key of the corresponding partition that stored the event

If you selected **Event system properties** in the **Data Source** section of the table, you must include the properties in the table schema and mapping.

Schema mapping examples

Table schema mapping example

If your data includes three columns (`Timespan`, `Metric`, and `Value`) and the properties you include are `x-opt-enqueued-time` and `x-opt-offset`, create or alter the table schema by using this command:

```
    .create-merge table TestTable (TimeStamp: datetime, Metric: string, Value: int,
EventHubEnqueuedTime:datetime, EventHubOffset:string)
```

CSV mapping example

Run the following commands to add data to the beginning of the record. Note ordinal values.

```
.create table TestTable ingestion csv mapping "CsvMapping1"
'['
'   { "column" : "Timespan", "Properties":{"Ordinal":"2"}},'
'   { "column" : "Metric", "Properties":{"Ordinal":"3"}},'
'   { "column" : "Value", "Properties":{"Ordinal":"4"}},'
'   { "column" : "EventHubEnqueuedTime", "Properties":{"Ordinal":"0"}},'
'   { "column" : "EventHubOffset", "Properties":{"Ordinal":"1"}}'
']'
```

JSON mapping example

Data is added by using the system properties mapping. Run these commands:

```
.create table TestTable ingestion json mapping "JsonMapping1"
'['
'    { "column" : "Timespan", "Properties":{"Path":"$.timestamp"}},'
'    { "column" : "Metric", "Properties":{"Path":"$.metric"}},'
'    { "column" : "Value", "Properties":{"Path":"$.value"}},'
'    { "column" : "EventHubEnqueuedTime", "Properties":{"Path":"$.x-opt-enqueued-time"}},'
'    { "column" : "EventHubOffset", "Properties":{"Path":"$.x-opt-offset"}}'
']'
```

Event Hub connection

> **NOTE**
> For best performance, create all resources in the same region as the Azure Synapse Data Explorer cluster.

Create an Event Hub

If you don't already have one, Create an Event Hub. Connecting to Event Hub can be managed through the Azure portal, programmatically with C# or Python, or with the Azure Resource Manager template.

> **NOTE**
> - The partition count isn't changeable, so you should consider long-term scale when setting partition count.
> - Consumer group *must* be unique per consumer. Create a consumer group dedicated to Azure Synapse Data Explorer connection.

Send events

See the sample app that generates data and sends it to an Event Hub.

For an example of how to generate sample data, see Ingest data from Event Hub into Azure Synapse Data Explorer

Set up Geo-disaster recovery solution

Event Hub offers a Geo-disaster recovery solution. Azure Synapse Data Explorer doesn't support `Alias` Event Hub namespaces. To implement the Geo-disaster recovery in your solution, create two Event Hub data connections: one for the primary namespace and one for the secondary namespace. Azure Synapse Data Explorer will listen to both Event Hub connections.

> **NOTE**
>
> It's the user's responsibility to implement a failover from the primary namespace to the secondary namespace.

Next steps

- Ingest data from Event Hub into Azure Synapse Data Explorer
- Create an Event Hub data connection for Azure Synapse Data Explorer using C#
- Create an Event Hub data connection for Azure Synapse Data Explorer using Python
- Create an Event Hub data connection for Azure Synapse Data Explorer using Azure Resource Manager template

Ingest data from Event Hub into Azure Synapse Data Explorer

8/19/2022 • 9 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast and highly scalable data exploration service for log and telemetry data. Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, IoT Hubs, and blobs written to blob containers.

Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, a big data streaming platform and event ingestion service. Event Hubs can process millions of events per second in near real time. In this article, you create an Event Hub, connect to it from Azure Synapse Data Explorer and see data flow through the system.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Create a target table to which Event Hubs will send data
  1. In Synapse Studio, on the left-side pane, select **Develop**.
  2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
  3. In the **Connect to** menu, select *contosodataexplorer*.

4. In the **Use database** menu, select *TestDatabase*.

5. Paste in the following command, and select **Run** to create the table.

```
.create table TestTable (TimeStamp: datetime, Name: string, Metric: int, Source:string)
```

> **TIP**
> Verify that the table was successfully created. On the left-side pane, select **Data**, select the *contosodataexplorer* more menu, and then select **Refresh**. Under *contosodataexplorer*, expand **Tables** and make sure that the *TestTable* table appears in the list.

6. Copy the following command into the window and select **Run** to map the incoming JSON data to the column names and data types of the table (TestTable).

```
.create table TestTable ingestion json mapping 'TestMapping' '[{"column":"TimeStamp",
"Properties": {"Path": "$.timeStamp"}},{"column":"Name", "Properties": {"Path":"$.name"}} ,
{"column":"Metric", "Properties": {"Path":"$.metric"}}, {"column":"Source", "Properties":
{"Path":"$.source"}}]'
```

- We recommend using a user assigned managed identity or system assigned managed identity for the data connection (optional).
- A sample app that generates data and sends it to an Event Hub. Download the sample app to your system.
- Visual Studio 2019 to run the sample app.

Sign in to the Azure portal

Sign in to the Azure portal.

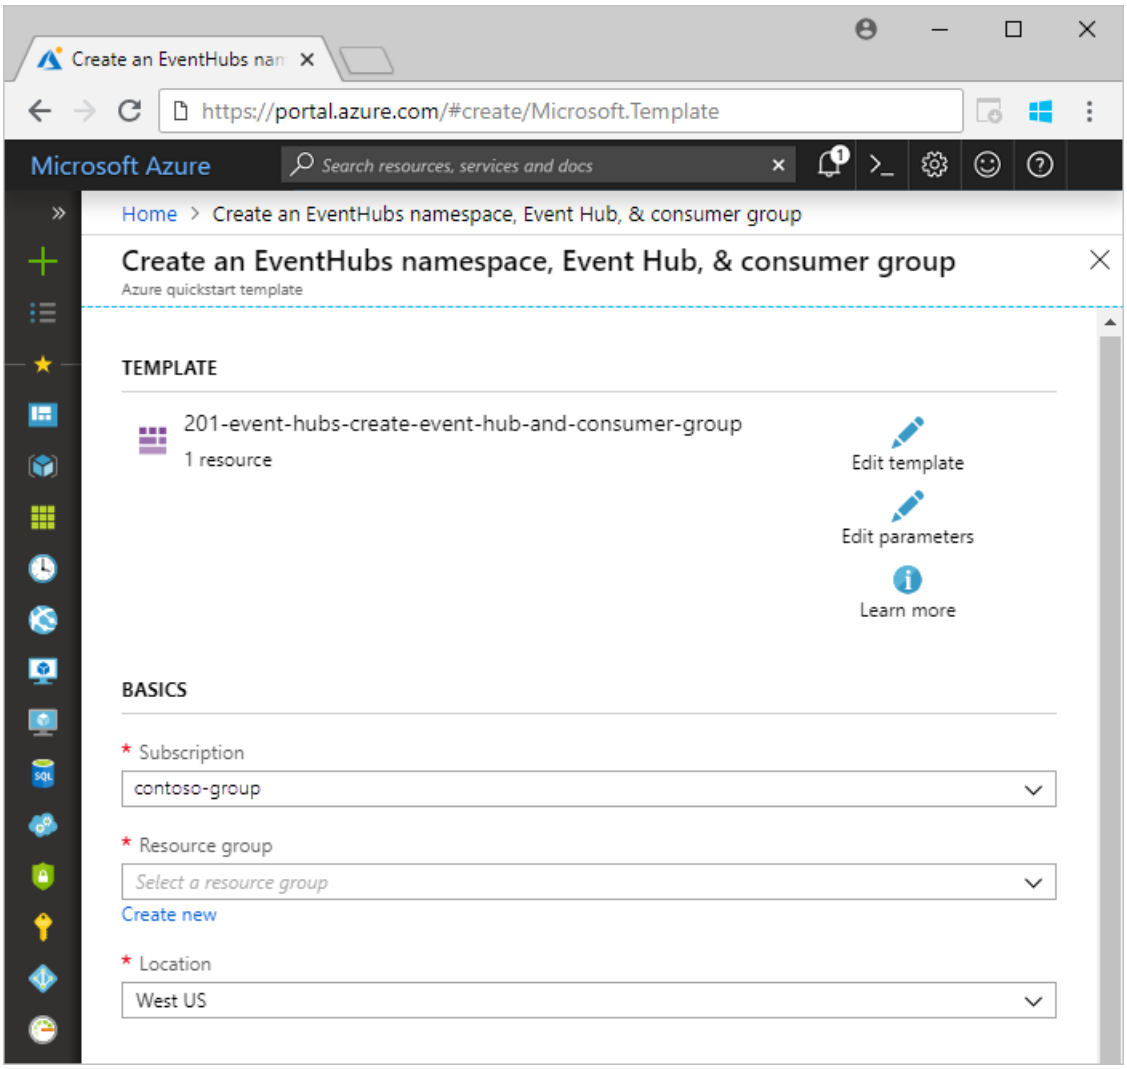
Create an Event Hub

Create an Event Hub by using an Azure Resource Manager template in the Azure portal.

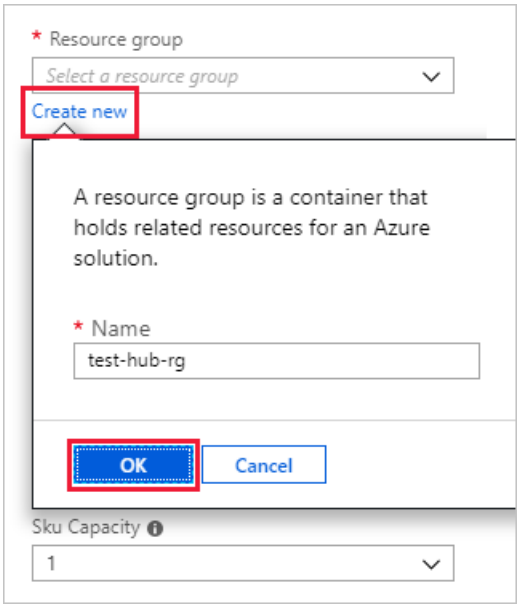
1. To create an Event Hub, use the following button to start the deployment. Right-click and select **Open in new window**, so you can follow the rest of the steps in this article.

   Deploy to Azure

   The **Deploy to Azure** button takes you to the Azure portal.



2. Select the subscription where you want to create the Event Hub, and create a resource group named *test-hub-rg*.

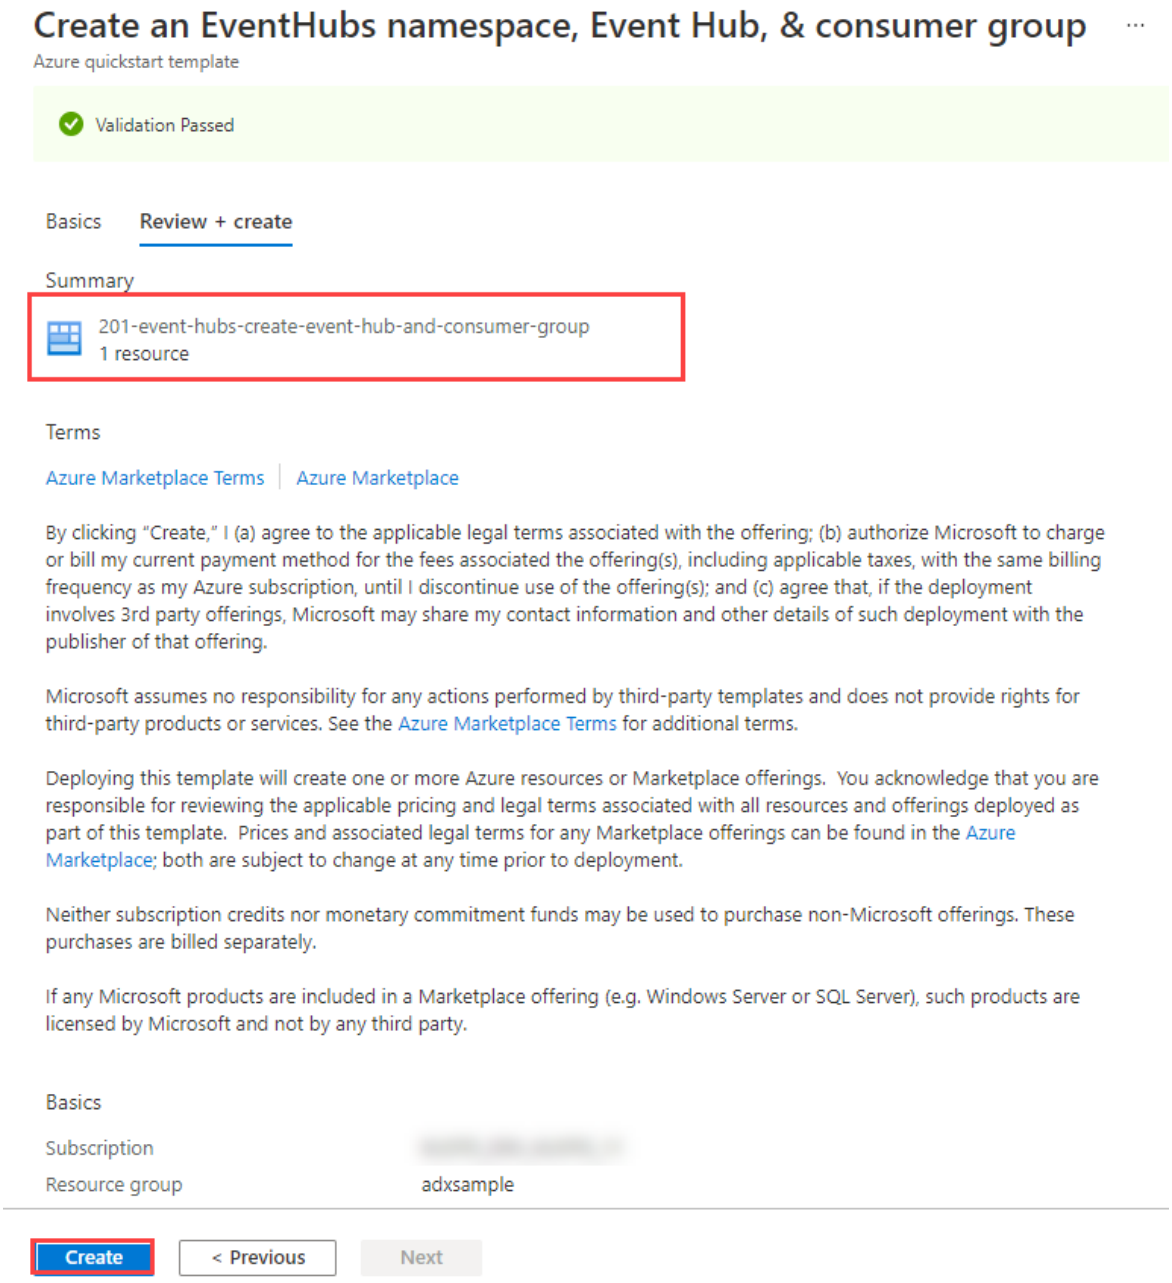


3. Fill out the form with the following information.

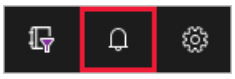
   Use defaults for any settings not listed in the following table.

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Subscription	Your subscription	Select the Azure subscription that you want to use for your Event Hub.
Resource group	*test-hub-rg*	Create a new resource group.
Location	*West US*	Select *West US* for this article. For a production system, select the region that best meets your needs. Create the Event Hub namespace in the same Location as the Azure Synapse Data Explorer cluster for best performance (most important for Event Hub namespaces with high throughput).
Namespace name	A unique namespace name	Choose a unique name that identifies your namespace. For example, *mytestnamespace*. The domain name *servicebus.windows.net* is appended to the name you provide. The name can contain only letters, numbers, and hyphens. The name must start with a letter, and it must end with a letter or number. The value must be between 6 and 50 characters long.
Event Hub name	*test-hub*	The Event Hub sits under the namespace, which provides a unique scoping container. The Event Hub name must be unique within the namespace.
Consumer group name	*test-group*	Consumer groups enable multiple consuming applications to each have a separate view of the event stream.

4. Select **Review + create**.
5. Review the **Summary** of resources created. Select **Create**, which acknowledges that you're creating resources in your subscription.



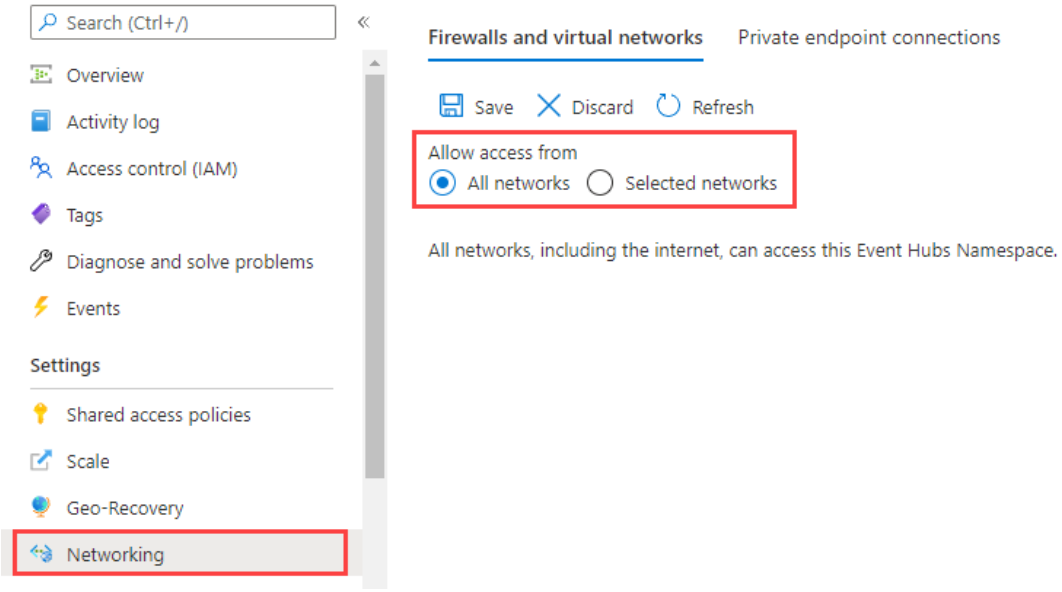
6. Select **Notifications** on the toolbar to monitor the provisioning process. It might take several minutes for the deployment to succeed, but you can move on to the next step now.



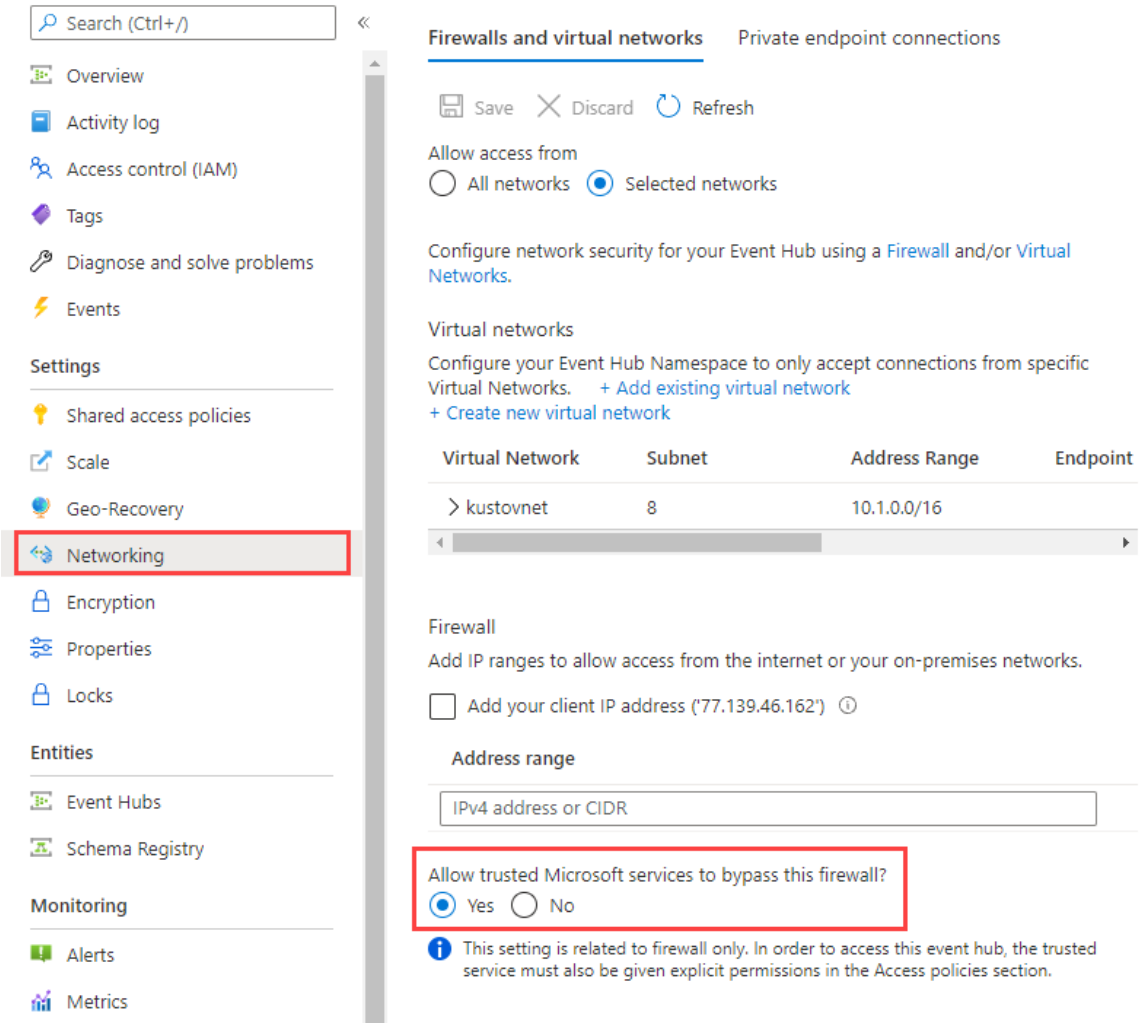
Authentication considerations

Depending on the type of identity, you are using to authenticate with the Event Hub, you may need some additional configurations.

- If you are authenticating with Event Hub using a user assigned managed identity, go to your Event Hub > **Networking**, and then under **Allow access from**, select **All networks** and save the changes.



- If you are authenticating with the Event Hub using a system assigned managed identity, go to your Event Hub > **Networking**, and then either allow access from all networks or under **Allow access from**, select **Selected networks**, select **Allow trusted Microsoft services to bypass this firewall** and save the changes.

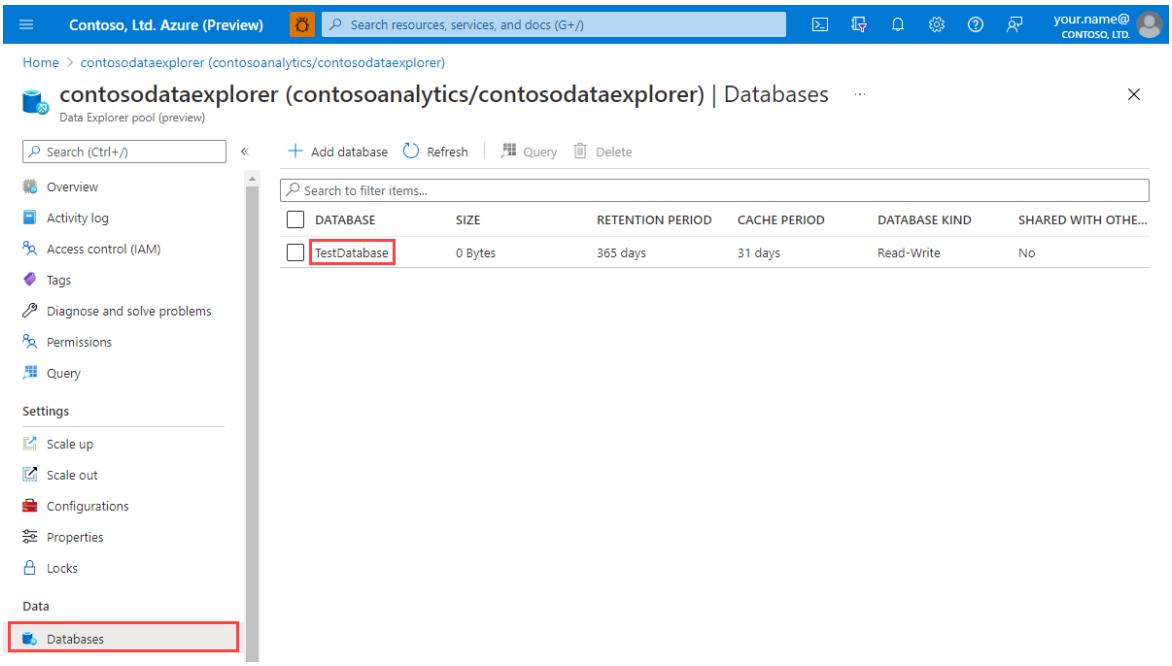


Connect to the Event Hub

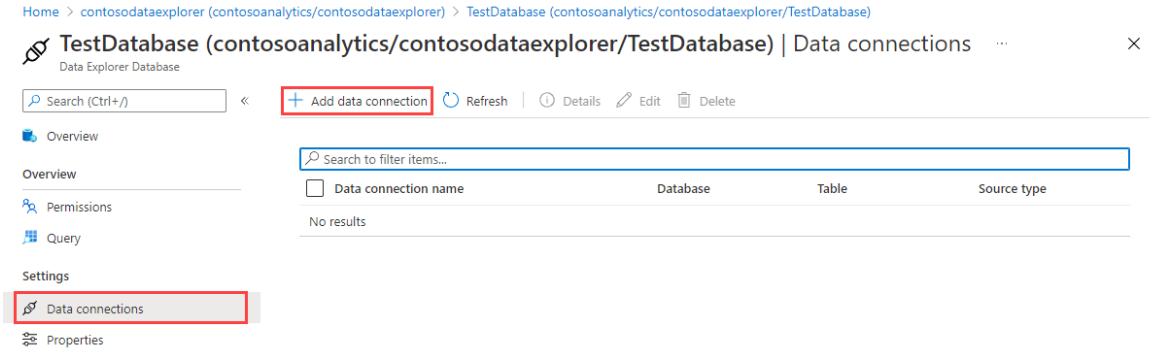
Now you connect to the Event Hub from Data Explorer pool. When this connection is in place, data that flows into the Event Hub streams to the test table you created earlier in this article.

1. Select **Notifications** on the toolbar to verify that the Event Hub deployment was successful.

2. Under the Data Explorer pool you created, select **Databases** > **TestDatabase**.

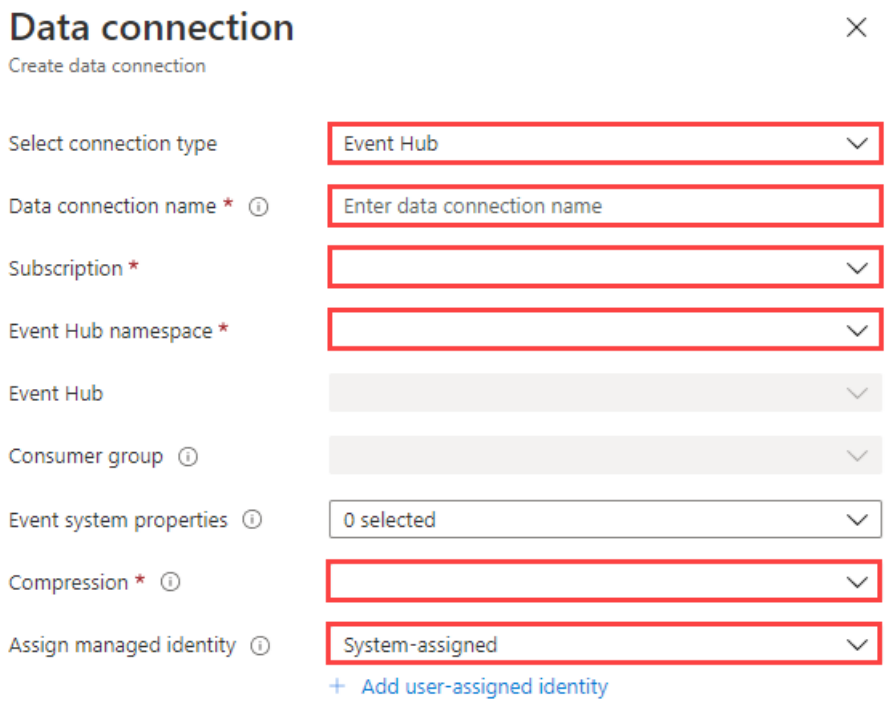


3. Select **Data connections** and **Add data connection**.



Create a data connection (Preview)

Fill out the form with the following information, and then select **Create**.

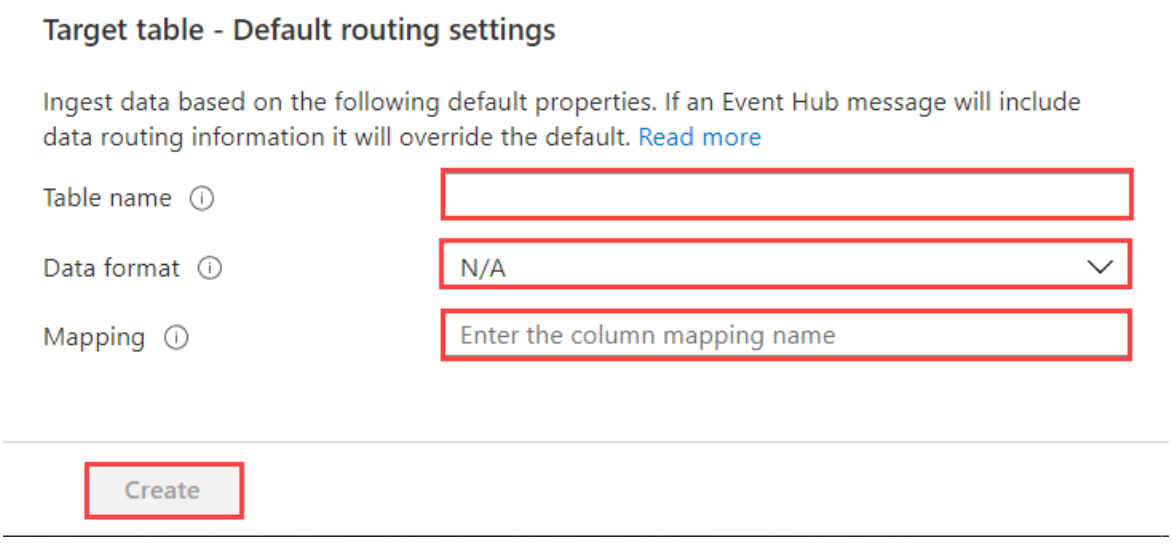


SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Data connection name	*test-hub-connection*	The name of the connection you want to create in Azure Synapse Data Explorer.
Subscription		The subscription ID where the Event Hub resource is located. This field is autopopulated.
Event Hub namespace	A unique namespace name	The name you chose earlier that identifies your namespace.
Event Hub	*test-hub*	The Event Hub you created.
Consumer group	*test-group*	The consumer group defined in the Event Hub you created.
Event system properties	Select relevant properties	The Event Hub system properties. If there are multiple records per event message, the system properties will be added to the first record. When adding system properties, create or update table schema and mapping to include the selected properties.
Compression	*None*	The compression type of the Event Hub messages payload. Supported compression types: *None, Gzip*.
Managed Identity	System-assigned	The managed identity used by the Data Explorer cluster for access to read from the Event Hub. **Note**: When the data connection is created: - *System-assigned* identities are automatically created if they don't exist - The managed identity is automatically assigned the *Azure Event Hubs Data Receiver* role and is added to your Data Explorer cluster. We recommend verifying that the role was assigned and that the identity was added to the cluster.

Target table

There are two options for routing the ingested data: *static* and *dynamic*. For this article, you use static routing, where you specify the table name, data format, and mapping as default values. If the Event Hub message includes data routing information, this routing information will override the default settings.

1. Fill out the following routing settings:



SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Table name	*TestTable*	The table you created in **TestDatabase**.
Data format	*JSON*	Supported formats are Avro, CSV, JSON, MULTILINE JSON, ORC, PARQUET, PSV, SCSV, SOHSV, TSV, TXT, TSVE, APACHEAVRO, and W3CLOG.
Mapping	*TestMapping*	The mapping you created in **TestDatabase**, which maps incoming data to the column names and data types of **TestTable**. Required for JSON, MULTILINE JSON and AVRO, and optional for other formats.

NOTE

- You don't have to specify all **Default routing settings**. Partial settings are also accepted.
- Only events enqueued after you create the data connection are ingested.

2. Select **Create**.

Event system properties mapping

NOTE

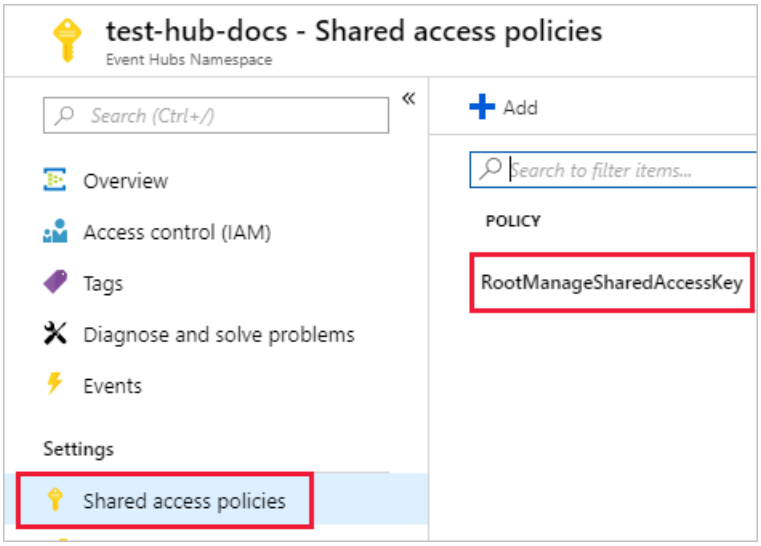
- System properties are supported for `json` and tabular formats (`csv`, `tsv` etc.) and aren't supported on compressed data. When using a non-supported format, the data will still be ingested, but the properties will be ignored.
- For tabular data, system properties are supported only for single-record event messages.
- For JSON data, system properties are also supported for multiple-record event messages. In such cases, the system properties are added only to the first record of the event message.
- For `csv` mapping, properties are added at the beginning of the record in the order listed in the System properties table.
- For `json` mapping, properties are added according to property names in the System properties table.

If you selected **Event system properties** in the **Data Source** section of the table, you must include system properties in the table schema and mapping.

Copy the connection string

When you run the sample app listed in Prerequisites, you need the connection string for the Event Hub namespace.

1. Under the Event Hub namespace you created, select **Shared access policies**, then **RootManageSharedAccessKey**.



2. Copy **Connection string - primary key**. You paste it in the next section.

Generate sample data

Use the sample app you downloaded to generate data.

1. Open the sample app solution in Visual Studio.
2. In the *program.cs* file, update the `eventHubName` constant to the name of your Event Hub and update the `connectionString` constant to the connection string you copied from the Event Hub namespace.

```
const string eventHubName = "test-hub";
// Copy the connection string ("Connection string-primary key") from your Event Hub namespace.
const string connectionString = @"<YourConnectionString>";
```

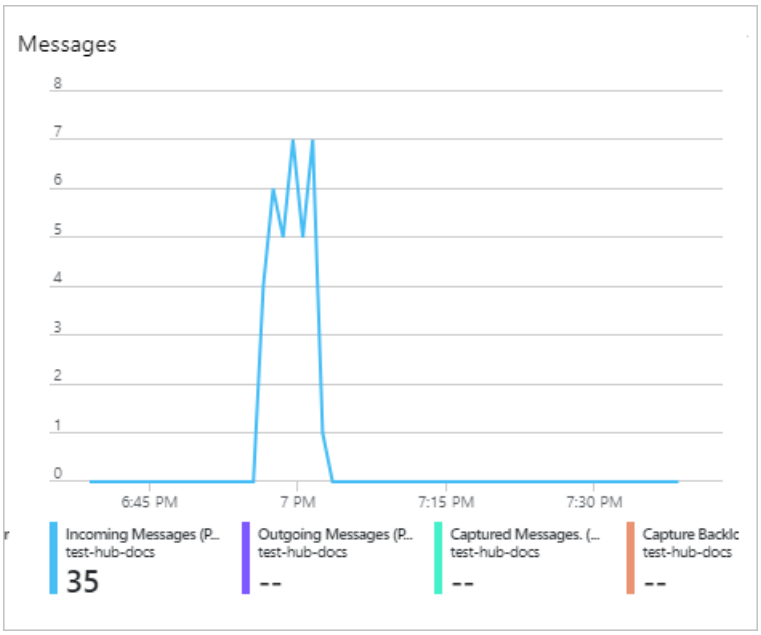
3. Build and run the app. The app sends messages to the Event Hub, and prints its status every 10 seconds.
4. After the app has sent a few messages, move on to the next step: reviewing the flow of data into your

Event Hub and test table.

Review the data flow

With the app generating data, you can now see the flow of that data from the Event Hub to the table in your cluster.

1. In the Azure portal, under your Event Hub, you see the spike in activity while the app is running.



2. To check how many messages have made it to the database so far, run the following query in your test database.

```
TestTable
| count
```

3. To see the content of the messages, run the following query:

```
TestTable
```

The result set should look like the following image:

TestTable | Stats

TimeStamp	Name	Metric	Source
2018-09-18T18:19:17Z	name 0	0	EventHubMessage
2018-09-18T18:19:17Z	name 0	1	EventHubMessage
2018-09-18T18:19:17Z	name 0	2	EventHubMessage
2018-09-18T18:24:29Z	name 3	3	EventHubMessage

2018-09-18T18:24:29Z	name 3	5	EventHubMessage
2018-09-18T18:29:39Z	name 6	6	EventHubMessage
2018-09-18T18:29:39Z	name 6	7	EventHubMessage
2018-09-18T18:29:39Z	name 6	8	EventHubMessage

NOTE

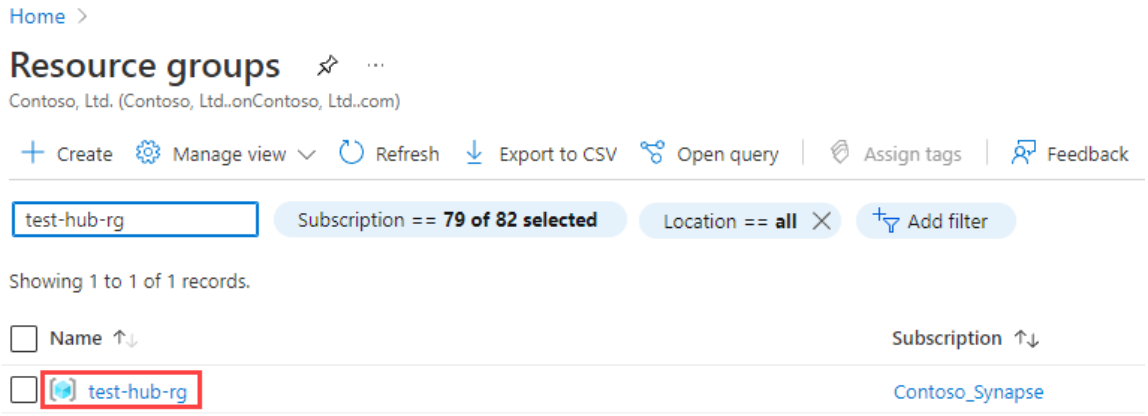
- Azure Synapse Data Explorer has an aggregation (batching) policy for data ingestion, designed to optimize the ingestion process. The default batching policy is configured to seal a batch once one of the following conditions is true for the batch: a maximum delay time of 5 minutes, total size of 1G, or 1000 blobs. Therefore, you may experience a latency. For more information, see batching policy.
- Event Hub ingestion includes Event Hub response time of 10 seconds or 1 MB.
- To reduce response time lag, configure your table to support streaming. See streaming policy.

Clean up resources

If you don't plan to use your Event Hub again, clean up **test-hub-rg**, to avoid incurring costs.

1. In the Azure portal, select **Resource groups** on the far left, and then select the resource group you created.

   If the left menu is collapsed, select » to expand it.



2. Under **test-resource-group**, select **Delete resource group**.
3. In the new window, type the name of the resource group to delete (*test-hub-rg*), and then select **Delete**.

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Use one-click ingestion to create an Event Hub data connection for Azure Synapse Data Explorer (Preview)

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, a big data streaming platform and event ingestion service. Event Hubs can process millions of events per second in near real-time. In this article, you connect an Event Hub to a table in Azure Synapse Data Explorer using the one-click ingestion experience.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

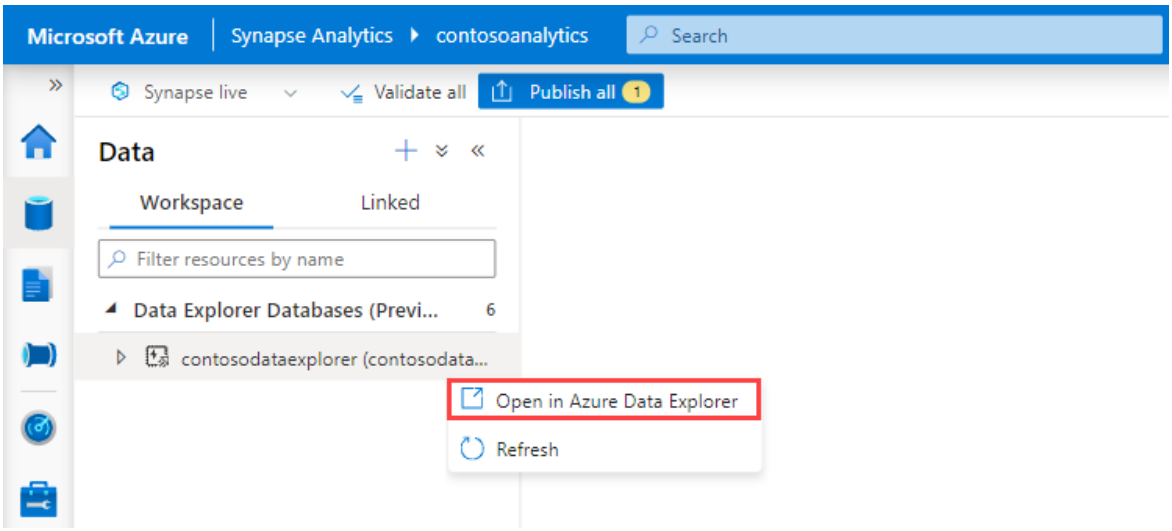
SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Event Hub with data for ingestion.

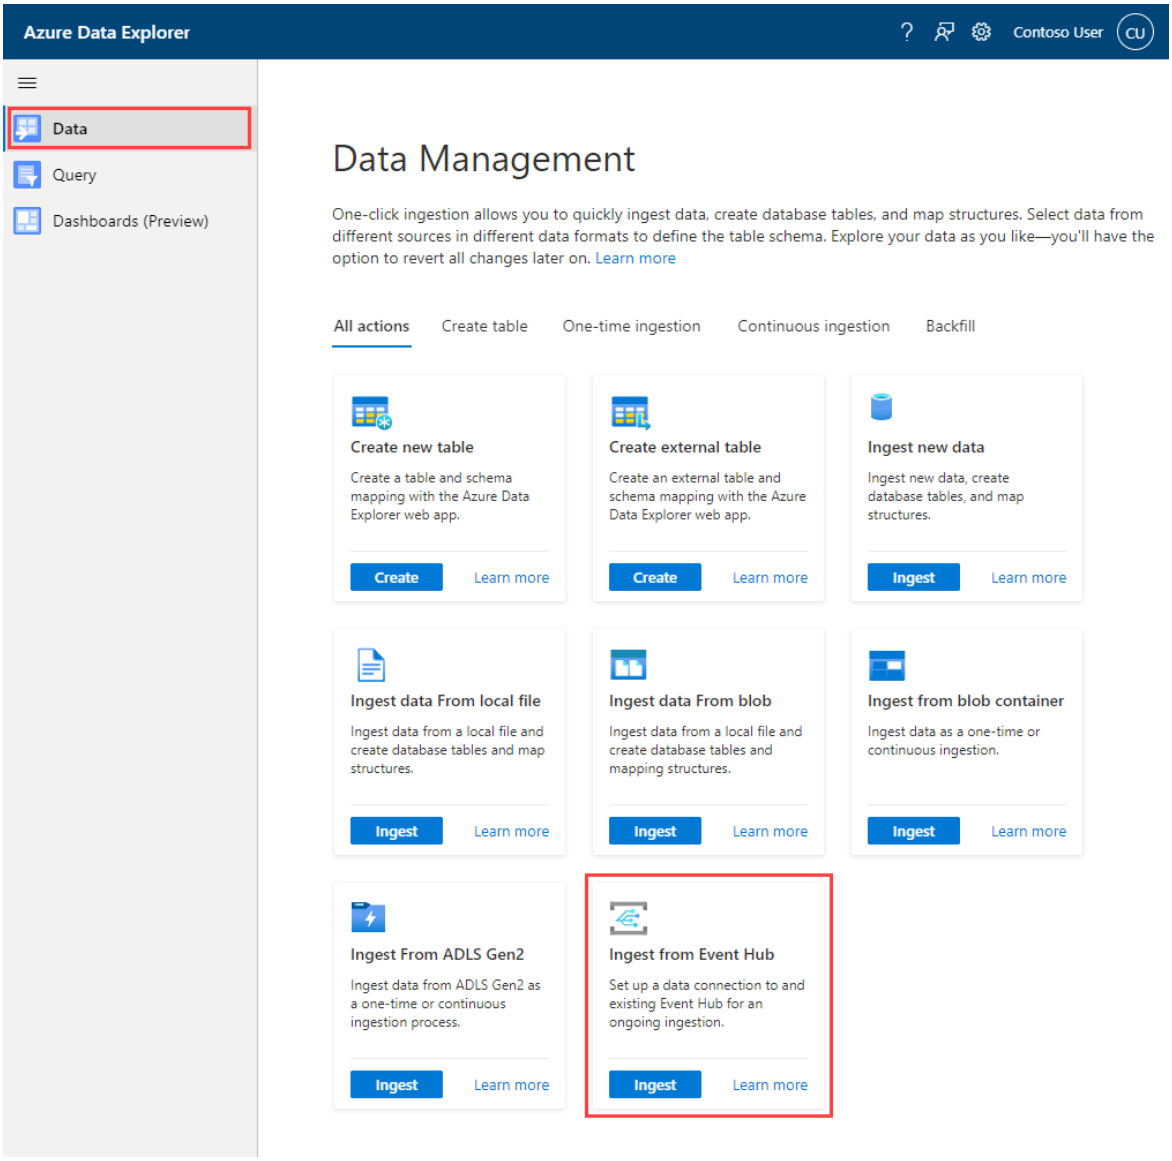
> **NOTE**
> Ingesting data from an Event Hub into Data Explorer pools will not work if your Synapse workspace uses a managed virtual network with data exfiltration protection enabled.

Ingest new data

1. In Synapse Studio, on the left-side pane, select **Data**.
2. Under **Data Explorer Databases**, right-click the relevant database, and then select **Open in Azure Data Explorer**.



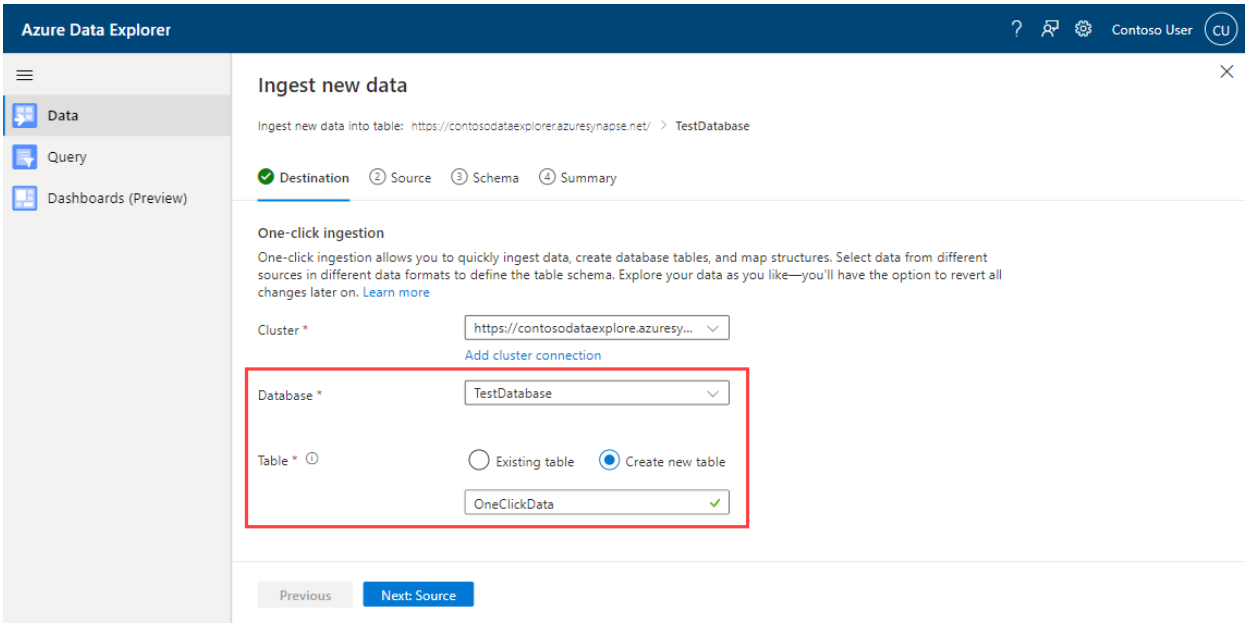
3. In the left menu of the Web UI, select the **Data** tab.



4. In the **Ingest data from Event Hub** card, select **Ingest**.

The **Ingest new data** window opens with the **Destination** tab selected.

Destination tab



1. The **Cluster** and **Database** fields are auto-populated. You may select a different cluster or database from the drop-down menus.

2. Under **Table**, select **Create new table** and enter a name for the new table. Alternatively, use an existing table.

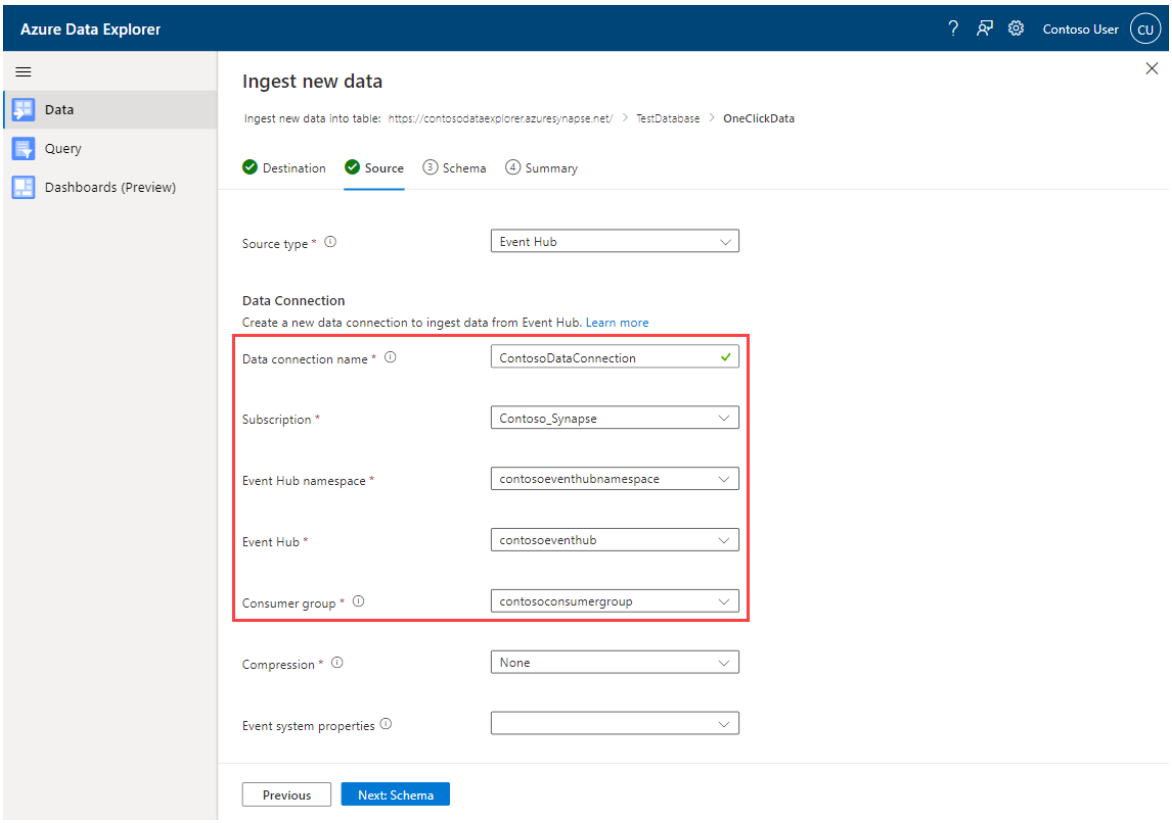
   > **NOTE**
   > Table names must be between 1 and 1024 characters. You can use alphanumeric, hyphens, and underscores. Special characters aren't supported.

3. Select **Next: Source**.

Source tab

1. Under **Source type**, select **Event Hub**.

2. Under **Data Connection**, fill in the following fields:

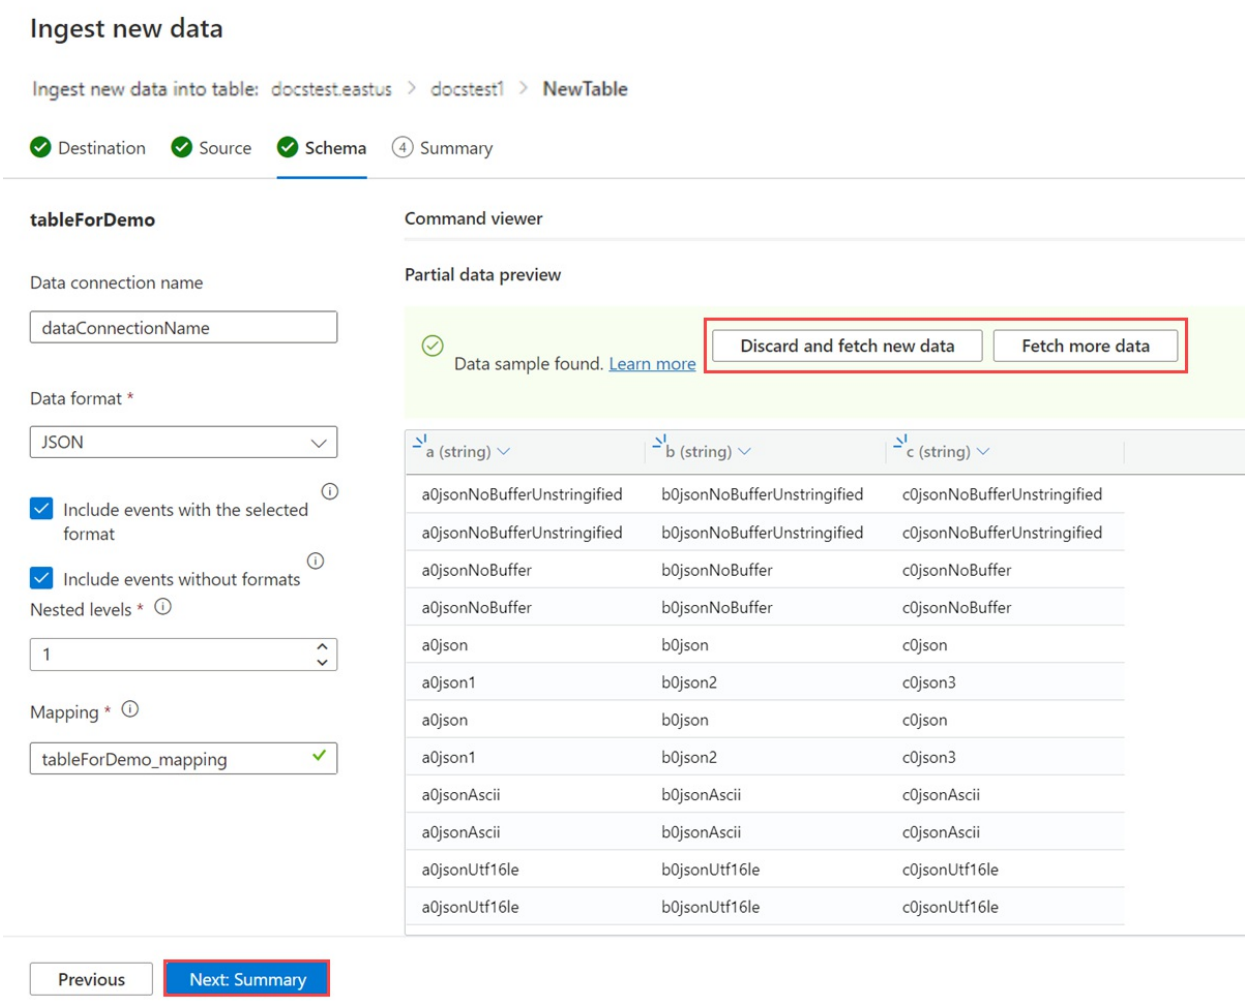


SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Data connection name	*ContosoDataConnection*	The name that identifies your data connection.
Subscription		The subscription ID where the Event Hub resource is located.
Event Hub namespace		The name that identifies your namespace.
Event Hub		The Event Hub you wish to use.
Consumer group		The consumer group defined in your Event Hub.
Event system properties	Select relevant properties	The Event Hub system properties. If there are multiple records per event message, the system properties will be added to the first one. When adding system properties, create or update table schema and mapping to include the selected properties.

3. Select **Next: Schema**.

Schema tab

Data is read from the Event Hub in form of EventData objects. Supported formats are CSV, JSON, PSV, SCsv, SOHsv TSV, TXT, and TSVE.



1. If the data you see in the preview window is not complete, you may need more data to create a table with all necessary data fields. Use the following commands to fetch new data from your Event Hub:

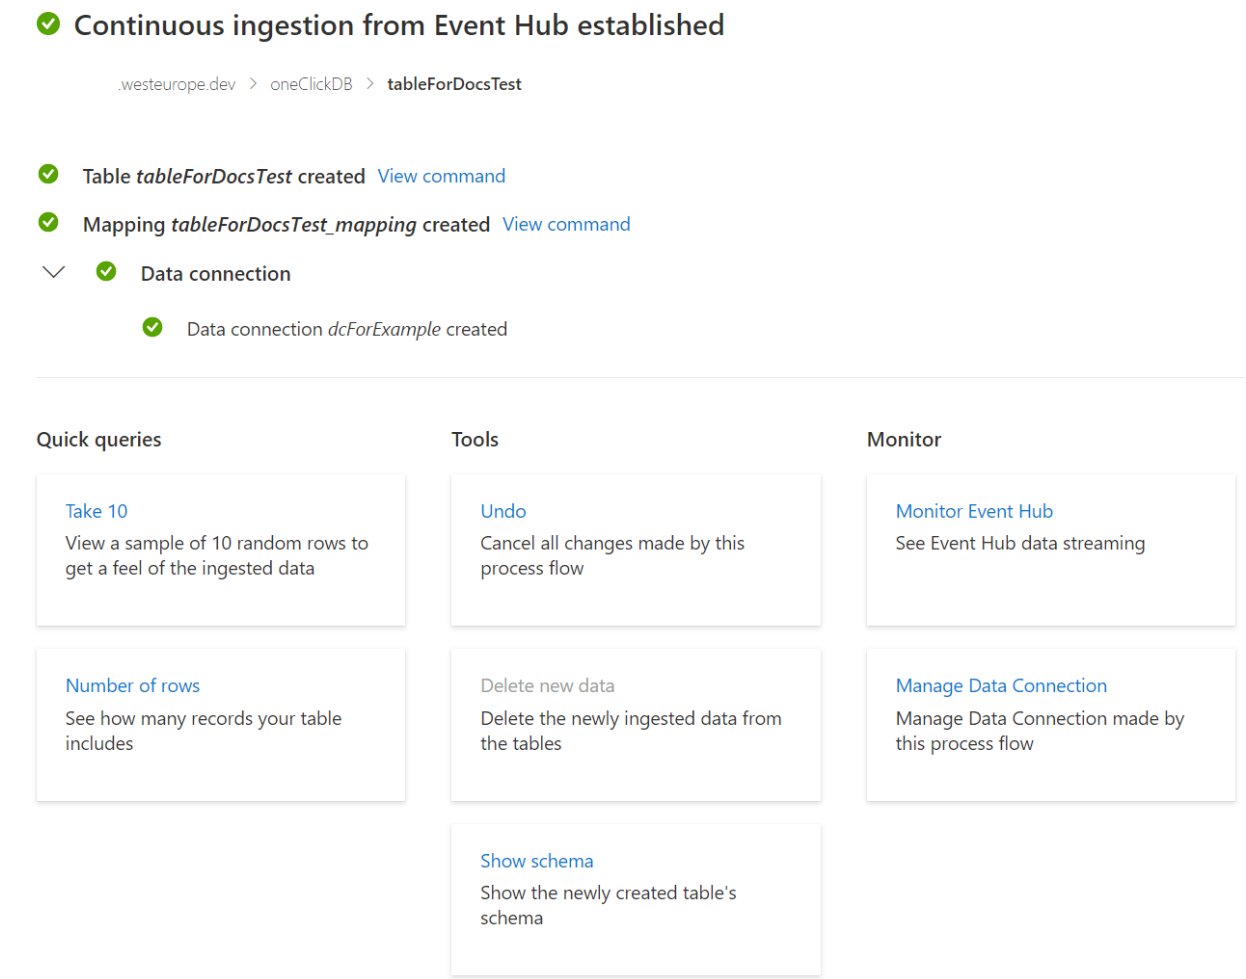
   - **Discard and fetch new data**: discards the data presented and searches for new events.
   - **Fetch more data**: Searches for more events in addition to the events already found.

   > **NOTE**
   > To see a preview of your data, your Event Hub must be sending events.

2. Select **Next: Summary**.

Continuous ingestion from Event Hub

In the **Continuous ingestion from Event Hub established** window, all steps will be marked with green check marks when establishment finishes successfully. The cards below these steps give you options to explore your data with **Quick queries**, undo changes made using **Tools**, or **Monitor** the Event Hub connections and data.



Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Create an Event Hub data connection for Azure Synapse Data Explorer by using C# (Preview)

8/19/2022 • 7 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast and highly scalable data exploration service for log and telemetry data. Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, IoT Hubs, and blobs written to blob containers.

In this article, you create an Event Hub data connection for Azure Synapse Data Explorer by using C#.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Event Hub with data for ingestion.

> **NOTE**
> Ingesting data from an Event Hub into Data Explorer pools will not work if your Synapse workspace uses a managed virtual network with data exfiltration protection enabled.

- Visual Studio 2019, download and use the **free** Visual Studio 2019 Community Edition. Enable **Azure development** during the Visual Studio setup.

Create a table on your test cluster

Create a table named `StormEvents` that matches the schema of the data in the `StormEvents.csv` file.

> **TIP**
> The following code snippets create an instance of a client for almost every call. This is done to make each snippet individually runnable. In production, the client instances are reentrant, and should be kept as long as needed. A single client instance per URI is sufficient, even when working with multiple databases (database can be specified on a command level).

```
var databaseName = "<DatabaseName>";
var table = "StormEvents";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableCreateCommand(
            table,
            new[]
            {
                Tuple.Create("StartTime", "System.DateTime"),
                Tuple.Create("EndTime", "System.DateTime"),
                Tuple.Create("EpisodeId", "System.Int32"),
                Tuple.Create("EventId", "System.Int32"),
                Tuple.Create("State", "System.String"),
                Tuple.Create("EventType", "System.String"),
                Tuple.Create("InjuriesDirect", "System.Int32"),
                Tuple.Create("InjuriesIndirect", "System.Int32"),
                Tuple.Create("DeathsDirect", "System.Int32"),
                Tuple.Create("DeathsIndirect", "System.Int32"),
                Tuple.Create("DamageProperty", "System.Int32"),
                Tuple.Create("DamageCrops", "System.Int32"),
                Tuple.Create("Source", "System.String"),
                Tuple.Create("BeginLocation", "System.String"),
                Tuple.Create("EndLocation", "System.String"),
                Tuple.Create("BeginLat", "System.Double"),
                Tuple.Create("BeginLon", "System.Double"),
                Tuple.Create("EndLat", "System.Double"),
                Tuple.Create("EndLon", "System.Double"),
                Tuple.Create("EpisodeNarrative", "System.String"),
                Tuple.Create("EventNarrative", "System.String"),
                Tuple.Create("StormSummary", "System.Object"),
            });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Define ingestion mapping

Map the incoming CSV data to the column names used when creating the table. Provision a CSV column mapping object on that table.

```
var tableMapping = "StormEvents_CSV_Mapping";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableMappingCreateCommand(
            Data.Ingestion.IngestionMappingKind.Csv,
            table,
            tableMapping,
            new[] {
                new ColumnMapping() { ColumnName = "StartTime", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "0" } } },
                new ColumnMapping() { ColumnName = "EndTime", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "1" } } },
                new ColumnMapping() { ColumnName = "EpisodeId", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "2" } } },
                new ColumnMapping() { ColumnName = "EventId", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "3" } } },
                new ColumnMapping() { ColumnName = "State", Properties =  new Dictionary<string, string>() {
{ MappingConsts.Ordinal, "4" } } },
                new ColumnMapping() { ColumnName = "EventType", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "5" } } },
                new ColumnMapping() { ColumnName = "InjuriesDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "6" } } },
                new ColumnMapping() { ColumnName = "InjuriesIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "7" } } },
                new ColumnMapping() { ColumnName = "DeathsDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "8" } } },
                new ColumnMapping() { ColumnName = "DeathsIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "9" } } },
                new ColumnMapping() { ColumnName = "DamageProperty", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "10" } } },
                new ColumnMapping() { ColumnName = "DamageCrops", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "11" } } },
                new ColumnMapping() { ColumnName = "Source", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "12" } } },
                new ColumnMapping() { ColumnName = "BeginLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "13" } } },
                new ColumnMapping() { ColumnName = "EndLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "14" } } },
                new ColumnMapping() { ColumnName = "BeginLat", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "15" } } },
                new ColumnMapping() { ColumnName = "BeginLon", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "16" } } },
                new ColumnMapping() { ColumnName = "EndLat", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "17" } } },
                new ColumnMapping() { ColumnName = "EndLon", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "18" } } },
                new ColumnMapping() { ColumnName = "EpisodeNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "19" } } },
                new ColumnMapping() { ColumnName = "EventNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "20" } } },
                new ColumnMapping() { ColumnName = "StormSummary", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "21" } } }
        });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Install C# NuGet

- Install the Microsoft.Azure.Management.Kusto NuGet package.

Authentication

To run the following example, you need an Azure Active Directory (Azure AD) application and service principal that can access resources. To create a free Azure AD application and add role assignment at the subscription level, see Create an Azure AD application. You also need the directory (tenant) ID, application ID, and client secret.

Add an Event Hub data connection

The following example shows you how to add an Event Hub data connection programmatically. See connect to the Event Hub for information about adding an Event Hub data connection using the Azure portal.

```
var tenantId = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx";//Directory (tenant) ID
var clientId = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx";//Application ID
var clientSecret = "xxxxxxxxxxxxx";//Client Secret
var subscriptionId = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx";
var authenticationContext = new AuthenticationContext($"https://login.windows.net/{tenantId}");
var credential = new ClientCredential(clientId, clientSecret);
var result = await authenticationContext.AcquireTokenAsync(resource: "https://management.core.windows.net/",
clientCredential: credential);

var credentials = new TokenCredentials(result.AccessToken, result.AccessTokenType);

var kustoManagementClient = new KustoManagementClient(credentials)
{
    SubscriptionId = subscriptionId
};

var resourceGroupName = "testrg";
//The cluster and database that are created as part of the Prerequisites
var clusterName = "mykustocluster";
var databaseName = "mykustodatabase";
var dataConnectionName = "myeventhubconnect";
//The Event Hub that is created as part of the Prerequisites
var eventHubResourceId = "/subscriptions/xxxxxxxx-xxxxx-xxxx-xxxx-
xxxxxxxxx/resourceGroups/xxxxxx/providers/Microsoft.EventHub/namespaces/xxxxxx/eventhubs/xxxxxx";
var consumerGroup = "$Default";
var location = "Central US";
//The table and column mapping are created as part of the Prerequisites
var tableName = "StormEvents";
var mappingRuleName = "StormEvents_CSV_Mapping";
var dataFormat = DataFormat.CSV;
var compression = "None";
await kustoManagementClient.DataConnections.CreateOrUpdateAsync(resourceGroupName, clusterName,
databaseName, dataConnectionName,
    new EventHubDataConnection(eventHubResourceId, consumerGroup, location: location, tableName: tableName,
mappingRuleName: mappingRuleName, dataFormat: dataFormat, compression: compression));
```

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
tenantId	*xxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx*	Your tenant ID. Also known as directory ID.
subscriptionId	*xxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx*	The subscription ID that you use for resource creation.
clientId	*xxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx*	The client ID of the application that can access resources in your tenant.
clientSecret	*xxxxxxxxxxxxx*	The client secret of the application that can access resources in your tenant.

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
resourceGroupName	*testrg*	The name of the resource group containing your cluster.
clusterName	*mykustocluster*	The name of your cluster.
databaseName	*mykustodatabase*	The name of the target database in your cluster.
dataConnectionName	*myeventhubconnect*	The desired name of your data connection.
tableName	*StormEvents*	The name of the target table in the target database.
mappingRuleName	*StormEvents_CSV_Mapping*	The name of your column mapping related to the target table.
dataFormat	*csv*	The data format of the message.
eventHubResourceId	*Resource ID*	The resource ID of your Event Hub that holds the data for ingestion.
consumerGroup	*$Default*	The consumer group of your Event Hub.
location	*Central US*	The location of the data connection resource.
compression	*Gzip* or *None*	The type of data compression.

Generate data

See the sample app that generates data and sends it to an Event Hub.

An event can contain one or more records, up to its size limit. In the following sample we send two events, each has five records appended:

```
var events = new List<EventData>();
var data = string.Empty;
var recordsPerEvent = 5;
var rand = new Random();
var counter = 0;

for (var i = 0; i < 10; i++)
{
    // Create the data
    var metric = new Metric { Timestamp = DateTime.UtcNow, MetricName = "Temperature", Value = rand.Next(-
30, 50) };
    var data += JsonConvert.SerializeObject(metric) + Environment.NewLine;
    counter++;

    // Create the event
    if (counter == recordsPerEvent)
    {
        var eventData = new EventData(Encoding.UTF8.GetBytes(data));
        events.Add(eventData);

        counter = 0;
        data = string.Empty;
    }
}

// Send events
eventHubClient.SendAsync(events).Wait();
```

Clean up resources

To delete the data connection, use the following command:

```
kustoManagementClient.DataConnections.Delete(resourceGroupName, clusterName, databaseName,
dataConnectionName);
```

Create an Event Hub data connection for Azure Synapse Data Explorer by using Python (Preview)

8/19/2022 • 6 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast and highly scalable data exploration service for log and telemetry data. Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, IoT Hubs, and blobs written to blob containers.

In this article, you create an Event Hub data connection for Azure Synapse Data Explorer by using Python.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.

  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.

- Event Hub with data for ingestion.
- Python 3.4+.

Create a table on your test cluster

Create a table named `StormEvents` that matches the schema of the data in the `StormEvents.csv` file.

TIP

The following code snippets create an instance of a client for almost every call. This is done to make each snippet individually runnable. In production, the client instances are reentrant, and should be kept as long as needed. A single client instance per URI is sufficient, even when working with multiple databases (database can be specified on a command level).

```
var databaseName = "<DatabaseName>";
var table = "StormEvents";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableCreateCommand(
            table,
            new[]
            {
                Tuple.Create("StartTime", "System.DateTime"),
                Tuple.Create("EndTime", "System.DateTime"),
                Tuple.Create("EpisodeId", "System.Int32"),
                Tuple.Create("EventId", "System.Int32"),
                Tuple.Create("State", "System.String"),
                Tuple.Create("EventType", "System.String"),
                Tuple.Create("InjuriesDirect", "System.Int32"),
                Tuple.Create("InjuriesIndirect", "System.Int32"),
                Tuple.Create("DeathsDirect", "System.Int32"),
                Tuple.Create("DeathsIndirect", "System.Int32"),
                Tuple.Create("DamageProperty", "System.Int32"),
                Tuple.Create("DamageCrops", "System.Int32"),
                Tuple.Create("Source", "System.String"),
                Tuple.Create("BeginLocation", "System.String"),
                Tuple.Create("EndLocation", "System.String"),
                Tuple.Create("BeginLat", "System.Double"),
                Tuple.Create("BeginLon", "System.Double"),
                Tuple.Create("EndLat", "System.Double"),
                Tuple.Create("EndLon", "System.Double"),
                Tuple.Create("EpisodeNarrative", "System.String"),
                Tuple.Create("EventNarrative", "System.String"),
                Tuple.Create("StormSummary", "System.Object"),
            });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Define ingestion mapping

Map the incoming CSV data to the column names used when creating the table. Provision a CSV column mapping object on that table.

```
var tableMapping = "StormEvents_CSV_Mapping";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableMappingCreateCommand(
            Data.Ingestion.IngestionMappingKind.Csv,
            table,
            tableMapping,
            new[] {
                new ColumnMapping() { ColumnName = "StartTime", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "0" } } },
                new ColumnMapping() { ColumnName = "EndTime", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "1" } } },
                new ColumnMapping() { ColumnName = "EpisodeId", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "2" } } },
                new ColumnMapping() { ColumnName = "EventId", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "3" } } },
                new ColumnMapping() { ColumnName = "State", Properties =  new Dictionary<string, string>() {
{ MappingConsts.Ordinal, "4" } } },
                new ColumnMapping() { ColumnName = "EventType", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "5" } } },
                new ColumnMapping() { ColumnName = "InjuriesDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "6" } } },
                new ColumnMapping() { ColumnName = "InjuriesIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "7" } } },
                new ColumnMapping() { ColumnName = "DeathsDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "8" } } },
                new ColumnMapping() { ColumnName = "DeathsIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "9" } } },
                new ColumnMapping() { ColumnName = "DamageProperty", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "10" } } },
                new ColumnMapping() { ColumnName = "DamageCrops", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "11" } } },
                new ColumnMapping() { ColumnName = "Source", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "12" } } },
                new ColumnMapping() { ColumnName = "BeginLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "13" } } },
                new ColumnMapping() { ColumnName = "EndLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "14" } } },
                new ColumnMapping() { ColumnName = "BeginLat", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "15" } } },
                new ColumnMapping() { ColumnName = "BeginLon", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "16" } } },
                new ColumnMapping() { ColumnName = "EndLat", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "17" } } },
                new ColumnMapping() { ColumnName = "EndLon", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "18" } } },
                new ColumnMapping() { ColumnName = "EpisodeNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "19" } } },
                new ColumnMapping() { ColumnName = "EventNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "20" } } },
                new ColumnMapping() { ColumnName = "StormSummary", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "21" } } }
        });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Install Python package

To install the Python package for Azure Synapse Data Explorer, open a command prompt that has Python in its path. Run the following command:

```
pip install azure-common
pip install azure-mgmt-kusto
```

Authentication

To run the following example, you need an Azure Active Directory (Azure AD) application and service principal that can access resources. To create a free Azure AD application and add role assignment at the subscription level, see Create an Azure AD application. You also need the directory (tenant) ID, application ID, and client secret.

Add an Event Hub data connection

The following example shows you how to add an Event Hub data connection programmatically. See connect to the event hub for adding an Event Hub data connection using the Azure portal.

```
from azure.mgmt.kusto import KustoManagementClient
from azure.mgmt.kusto.models import EventHubDataConnection
from azure.common.credentials import ServicePrincipalCredentials

#Directory (tenant) ID
tenant_id = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx"
#Application ID
client_id = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx"
#Client Secret
client_secret = "xxxxxxxxxxxxx"
subscription_id = "xxxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx"
credentials = ServicePrincipalCredentials(
        client_id=client_id,
        secret=client_secret,
        tenant=tenant_id
    )
kusto_management_client = KustoManagementClient(credentials, subscription_id)

resource_group_name = "testrg"
#The cluster and database that are created as part of the Prerequisites
cluster_name = "mykustocluster"
database_name = "mykustodatabase"
data_connection_name = "myeventhubconnect"
#The event hub that is created as part of the Prerequisites
event_hub_resource_id = "/subscriptions/xxxxxxxx-xxxxx-xxxx-xxxx-
xxxxxxxxx/resourceGroups/xxxxxx/providers/Microsoft.EventHub/namespaces/xxxxxx/eventhubs/xxxxxx";
consumer_group = "$Default"
location = "Central US"
#The table and column mapping that are created as part of the Prerequisites
table_name = "StormEvents"
mapping_rule_name = "StormEvents_CSV_Mapping"
data_format = "csv"
#Returns an instance of LROPoller, check
https://docs.microsoft.com/python/api/msrest/msrest.polling.lropoller?view=azure-python
poller = kusto_management_client.data_connections.create_or_update(resource_group_name=resource_group_name,
cluster_name=cluster_name, database_name=database_name, data_connection_name=data_connection_name,

parameters=EventHubDataConnection(event_hub_resource_id=event_hub_resource_id,
consumer_group=consumer_group, location=location,
                                                                    table_name=table_name,
mapping_rule_name=mapping_rule_name, data_format=data_format))
```

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
tenant_id	*xxxxxxx-xxxxx-xxxx-xxxx-xxxxxxxxx*	Your tenant ID. Also known as directory ID.

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
subscriptionId	*xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxx*	The subscription ID that you use for resource creation.
client_id	*xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxx*	The client ID of the application that can access resources in your tenant.
client_secret	*xxxxxxxxxxxx*	The client secret of the application that can access resources in your tenant.
resource_group_name	*testrg*	The name of the resource group containing your cluster.
cluster_name	*mykustocluster*	The name of your cluster.
database_name	*mykustodatabase*	The name of the target database in your cluster.
data_connection_name	*myeventhubconnect*	The desired name of your data connection.
table_name	*StormEvents*	The name of the target table in the target database.
mapping_rule_name	*StormEvents_CSV_Mapping*	The name of your column mapping related to the target table.
data_format	*csv*	The data format of the message.
event_hub_resource_id	*Resource ID*	The resource ID of your Event Hub that holds the data for ingestion.
consumer_group	*$Default*	The consumer group of your Event Hub.
location	*Central US*	The location of the data connection resource.

Clean up resources

To delete the data connection, use the following command:

```
kusto_management_client.data_connections.delete(resource_group_name=resource_group_name,
cluster_name=kusto_cluster_name, database_name=kusto_database_name,
data_connection_name=kusto_data_connection_name)
```

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Create an Event Hub data connection for Azure Synapse Data Explorer by using Azure Resource Manager template (Preview)

8/19/2022 • 6 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast and highly scalable data exploration service for log and telemetry data. Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, IoT Hubs, and blobs written to blob containers.

In this article, you create an Event Hub data connection for Azure Synapse Data Explorer by using Azure Resource Manager template.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Event Hub with data for ingestion.

Create a table on your test cluster

Create a table named `StormEvents` that matches the schema of the data in the `StormEvents.csv` file.

TIP

The following code snippets create an instance of a client for almost every call. This is done to make each snippet individually runnable. In production, the client instances are reentrant, and should be kept as long as needed. A single client instance per URI is sufficient, even when working with multiple databases (database can be specified on a command level).

```
var databaseName = "<DatabaseName>";
var table = "StormEvents";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableCreateCommand(
            table,
            new[]
            {
                Tuple.Create("StartTime", "System.DateTime"),
                Tuple.Create("EndTime", "System.DateTime"),
                Tuple.Create("EpisodeId", "System.Int32"),
                Tuple.Create("EventId", "System.Int32"),
                Tuple.Create("State", "System.String"),
                Tuple.Create("EventType", "System.String"),
                Tuple.Create("InjuriesDirect", "System.Int32"),
                Tuple.Create("InjuriesIndirect", "System.Int32"),
                Tuple.Create("DeathsDirect", "System.Int32"),
                Tuple.Create("DeathsIndirect", "System.Int32"),
                Tuple.Create("DamageProperty", "System.Int32"),
                Tuple.Create("DamageCrops", "System.Int32"),
                Tuple.Create("Source", "System.String"),
                Tuple.Create("BeginLocation", "System.String"),
                Tuple.Create("EndLocation", "System.String"),
                Tuple.Create("BeginLat", "System.Double"),
                Tuple.Create("BeginLon", "System.Double"),
                Tuple.Create("EndLat", "System.Double"),
                Tuple.Create("EndLon", "System.Double"),
                Tuple.Create("EpisodeNarrative", "System.String"),
                Tuple.Create("EventNarrative", "System.String"),
                Tuple.Create("StormSummary", "System.Object"),
            });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Define ingestion mapping

Map the incoming CSV data to the column names used when creating the table. Provision a CSV column mapping object on that table.

```
var tableMapping = "StormEvents_CSV_Mapping";
using (var kustoClient = KustoClientFactory.CreateCslAdminProvider(kustoConnectionStringBuilder))
{
    var command =
        CslCommandGenerator.GenerateTableMappingCreateCommand(
            Data.Ingestion.IngestionMappingKind.Csv,
            table,
            tableMapping,
            new[] {
                new ColumnMapping() { ColumnName = "StartTime", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "0" } } },
                new ColumnMapping() { ColumnName = "EndTime", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "1" } } },
                new ColumnMapping() { ColumnName = "EpisodeId", Properties = new Dictionary<string, string>
() { { MappingConsts.Ordinal, "2" } } },
                new ColumnMapping() { ColumnName = "EventId", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "3" } } },
                new ColumnMapping() { ColumnName = "State", Properties =  new Dictionary<string, string>() {
{ MappingConsts.Ordinal, "4" } } },
                new ColumnMapping() { ColumnName = "EventType", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "5" } } },
                new ColumnMapping() { ColumnName = "InjuriesDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "6" } } },
                new ColumnMapping() { ColumnName = "InjuriesIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "7" } } },
                new ColumnMapping() { ColumnName = "DeathsDirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "8" } } },
                new ColumnMapping() { ColumnName = "DeathsIndirect", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "9" } } },
                new ColumnMapping() { ColumnName = "DamageProperty", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "10" } } },
                new ColumnMapping() { ColumnName = "DamageCrops", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "11" } } },
                new ColumnMapping() { ColumnName = "Source", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "12" } } },
                new ColumnMapping() { ColumnName = "BeginLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "13" } } },
                new ColumnMapping() { ColumnName = "EndLocation", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "14" } } },
                new ColumnMapping() { ColumnName = "BeginLat", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "15" } } },
                new ColumnMapping() { ColumnName = "BeginLon", Properties =  new Dictionary<string, string>
() { { MappingConsts.Ordinal, "16" } } },
                new ColumnMapping() { ColumnName = "EndLat", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "17" } } },
                new ColumnMapping() { ColumnName = "EndLon", Properties =  new Dictionary<string, string>()
{ { MappingConsts.Ordinal, "18" } } },
                new ColumnMapping() { ColumnName = "EpisodeNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "19" } } },
                new ColumnMapping() { ColumnName = "EventNarrative", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "20" } } },
                new ColumnMapping() { ColumnName = "StormSummary", Properties =  new Dictionary<string,
string>() { { MappingConsts.Ordinal, "21" } } }
        });

    kustoClient.ExecuteControlCommand(databaseName, command);
}
```

Azure Resource Manager template for adding an Event Hub data connection

The following example shows an Azure Resource Manager template for adding an Event Hub data connection. You can edit and deploy the template in the Azure portal by using the form.

```
{
    "$schema": "https://schema.management.azure.com/schemas/2015-01-01/deploymentTemplate.json#",
    "contentVersion": "1.0.0.0",
    "parameters": {
        "namespaces_eventhubns_name": {
            "type": "string",
            "defaultValue": "eventhubns",
            "metadata": {
                "description": "Specifies the Event Hub Namespace name."
            }
        },
        "EventHubs_eventhubdemo_name": {
            "type": "string",
            "defaultValue": "eventhubdemo",
            "metadata": {
                "description": "Specifies the Event Hub name."
            }
        },
        "consumergroup_default_name": {
            "type": "string",
            "defaultValue": "$Default",
            "metadata": {
                "description": "Specifies the consumer group of the Event Hub."
            }
        },
        "Clusters_kustocluster_name": {
            "type": "string",
            "defaultValue": "kustocluster",

                "tableName": "[parameters('tables_kustotable_name')]",
                "mappingRuleName": "[parameters('mapping_kustomapping_name')]",
                "dataFormat": "[parameters('dataformat_type')]"
            }
        }
    ]
}
```

Clean up resources

When the Azure resources are no longer needed, clean up the resources you deployed by deleting the resource group.

Clean up resources using the Azure portal

Delete the resources in the Azure portal by following the steps in clean up resources.

Clean up resources using PowerShell

If the Cloud Shell is still open, you don't need to copy/run the first line (Read-Host).

```
$projectName = Read-Host -Prompt "Enter the same project name that you used in the last procedure"
$resourceGroupName = "${projectName}rg"

Remove-AzResourceGroup -ResourceGroupName $resourceGroupName

Write-Host "Press [ENTER] to continue ..."
```

Next steps

- Monitor Data Explorer pools

Event Grid data connection (Preview)

8/19/2022 • 4 minutes to read • Edit Online

Event Grid ingestion is a pipeline that listens to Azure storage, and updates Azure Data Explorer to pull information when subscribed events occur. Data Explorer offers continuous ingestion from Azure Storage (Blob storage and ADLSv2) with Azure Event Grid subscription for blob created or blob renamed notifications and streaming these notifications to Data Explorer via an Event Hub.

The Event Grid ingestion pipeline goes through several steps. You create a target table in Data Explorer into which the data in a particular format will be ingested. Then you create an Event Grid data connection in Data Explorer. The Event Grid data connection needs to know events routing information, such as what table to send the data to and the table mapping. You also specify ingestion properties, which describe the data to be ingested, the target table, and the mapping. You can generate sample data and upload blobs or rename blobs to test your connection. Delete blobs after ingestion. This process can be managed through the Azure portal.

Data format

- See supported formats.
- See supported compressions.
  - The original uncompressed data size should be part of the blob metadata, or else Data Explorer will estimate it. The ingestion uncompressed size limit per file is 4 GB.

> **NOTE**
> Event Grid notification subscription can be set on Azure Storage accounts for `BlobStorage`, `StorageV2`, or Data Lake Storage Gen2.

Ingestion properties

You can specify ingestion properties of the blob ingestion via the blob metadata. You can set the following properties:

PROPERTY	PROPERTY DESCRIPTION
`rawSizeBytes`	Size of the raw (uncompressed) data. For Avro/ORC/Parquet, that is the size before format-specific compression is applied. Provide the original data size by setting this property to the uncompressed data size in bytes.
`kustoTable`	Name of the existing target table. Overrides the `Table` set on the `Data Connection` blade.
`kustoDataFormat`	Data format. Overrides the `Data format` set on the `Data Connection` blade.
`kustoIngestionMappingReference`	Name of the existing ingestion mapping to be used. Overrides the `Column mapping` set on the `Data Connection` blade.

PROPERTY	PROPERTY DESCRIPTION
`kustoIgnoreFirstRecord`	If set to `true`, Kusto ignores the first row of the blob. Use in tabular format data (CSV, TSV, or similar) to ignore headers.
`kustoExtentTags`	String representing tags that will be attached to resulting extent.
`kustoCreationTime`	Overrides $IngestionTime for the blob, formatted as an ISO 8601 string. Use for backfilling.

Events routing

When setting up a blob storage connection to Data Explorer cluster, specify target table properties:

- table name
- data format
- mapping

This setup is the default routing for your data, sometimes referred to as `static routing`. You can also specify target table properties for each blob, using blob metadata. The data will dynamically route, as specified by ingestion properties.

The following example shows you how to set ingestion properties on the blob metadata before uploading it. Blobs are routed to different tables.

For more information, see upload blobs.

```
// Blob is dynamically routed to table `Events`, ingested using `EventsMapping` data mapping
blob = container.GetBlockBlobReference(blobName2);
blob.Metadata.Add("rawSizeBytes", "4096"); // the uncompressed size is 4096 bytes
blob.Metadata.Add("kustoTable", "Events");
blob.Metadata.Add("kustoDataFormat", "json");
blob.Metadata.Add("kustoIngestionMappingReference", "EventsMapping");
blob.UploadFromFile(jsonCompressedLocalFileName);
```

Upload blobs

You can create a blob from a local file, set ingestion properties to the blob metadata, and upload it. For examples, see Ingest blobs into Data Explorer by subscribing to Event Grid notifications

NOTE

- Use `BlockBlob` to generate data. `AppendBlob` is not supported.
- Using Azure Data Lake Gen2 storage SDK requires using `CreateFile` for uploading files and `Flush` at the end with the close parameter set to "true".

> - When the Event Hub endpoint doesn't acknowledge receipt of an event, Azure Event Grid activates a retry mechanism. If this retry delivery fails, Event Grid can deliver the undelivered events to a storage account using a process of *dead-lettering*. For more information, see Event Grid message delivery and retry.

Rename blobs

When using ADLSv2, you can rename a blob to trigger blob ingestion to Data Explorer. For example, see Ingest blobs into Data Explorer by subscribing to Event Grid notifications.

> **NOTE**
>
> - Directory renaming is possible in ADLSv2, but it doesn't trigger *blob renamed* events and ingestion of blobs inside the directory. To ingest blobs following renaming, directly rename the desired blobs.
> - If you defined filters to track specific subjects while creating the data connection.

Delete blobs using storage lifecycle

Data Explorer won't delete the blobs after ingestion. Use Azure Blob storage lifecycle to manage your blob deletion. It's recommended to keep the blobs for three to five days.

Known Event Grid issues

- When using Data Explorer to export the files used for event grid ingestion, note:
  - Event Grid notifications aren't triggered if the connection string provided to the export command or the connection string provided to an external table is a connecting string in ADLS Gen2 format (for example, `abfss://filesystem@accountname.dfs.core.windows.net`) but the storage account isn't enabled for hierarchical namespace.
  - If the account isn't enabled for hierarchical namespace, connection string must use the Blob Storage format (for example, `https://accountname.blob.core.windows.net`). The export works as expected even when using the ADLS Gen2 connection string, but notifications won't be triggered and Event Grid ingestion won't work.

- Ingest blobs into Data Explorer by subscribing to Event Grid notifications

Ingest blobs into Azure Synapse Data Explorer by subscribing to Event Grid notifications (Preview)

8/19/2022 • 7 minutes to read • Edit Online

Azure Synapse Data Explorer is a fast and highly scalable data exploration service for log and telemetry data. Azure Synapse Data Explorer offers ingestion (data loading) from Event Hubs, IoT Hubs, and blobs written to blob containers.

In this article, you learn how to ingest blobs from your storage account into Azure Synapse Data Explorer using an Event Grid data connection. You'll create an Event Grid data connection that sets an Azure Event Grid subscription. The Event Grid subscription routes events from your storage account to Data Explorer via an Azure Event Hub. Then you'll see an example of the data flow throughout the system.

For general information about ingesting into Data Explorer from Event Grid, see Connect to Event Grid.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Create a target table to which Event Hubs will send data
  1. In Synapse Studio, on the left-side pane, select **Develop**.
  2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can

name your script.

3. In the **Connect to** menu, select *contosodataexplorer*.
4. In the **Use database** menu, select *TestDatabase*.
5. Paste in the following command, and select **Run** to create the table.

```
.create table TestTable (TimeStamp: datetime, Value: string, Source:string)
```

> **TIP**
> Verify that the table was successfully created. On the left-side pane, select **Data**, select the *contosodataexplorer* more menu, and then select **Refresh**. Under *contosodataexplorer*, expand **Tables** and make sure that the *TestTable* table appears in the list.

6. Copy the following command into the window and select **Run** to map the incoming JSON data to the column names and data types of the table (TestTable).

```
.create table TestTable ingestion json mapping 'TestMapping'
'[{"column":"TimeStamp","path":"$.TimeStamp"},{"column":"Value","path":"$.Value"},
{"column":"Source","path":"$.Source"}]'
```

- Create a storage account.
- Event Grid notification subscription can be set on Azure Storage accounts for `BlobStorage`, `StorageV2`, or Data Lake Storage Gen2.

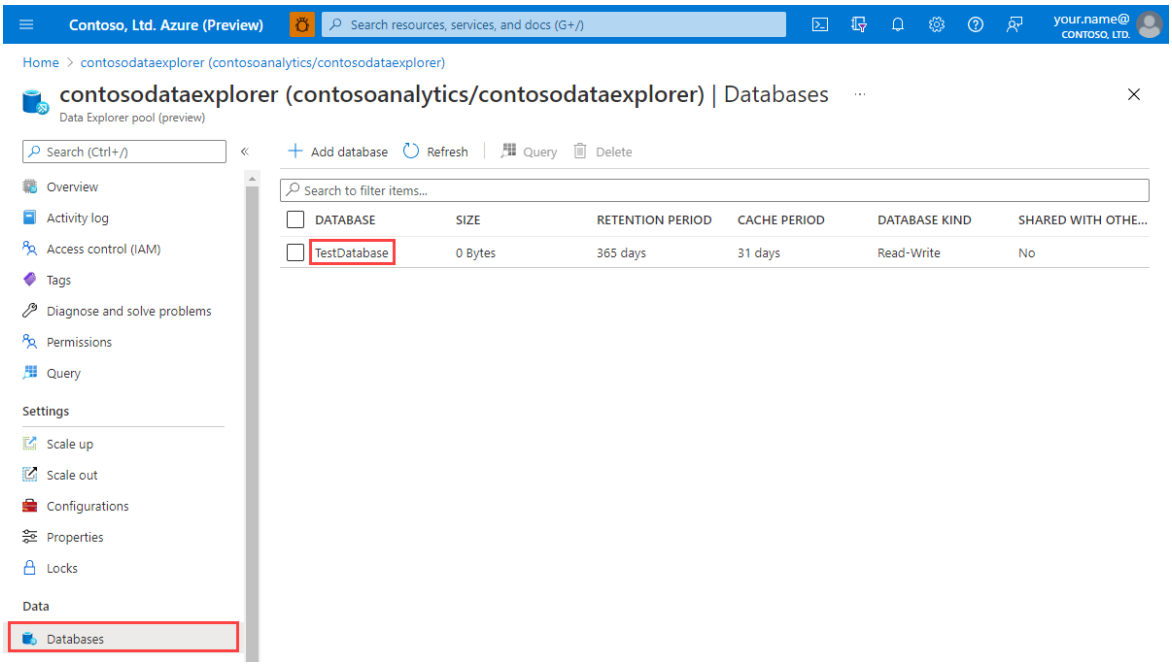
Sign in to the Azure portal

Sign in to the Azure portal.

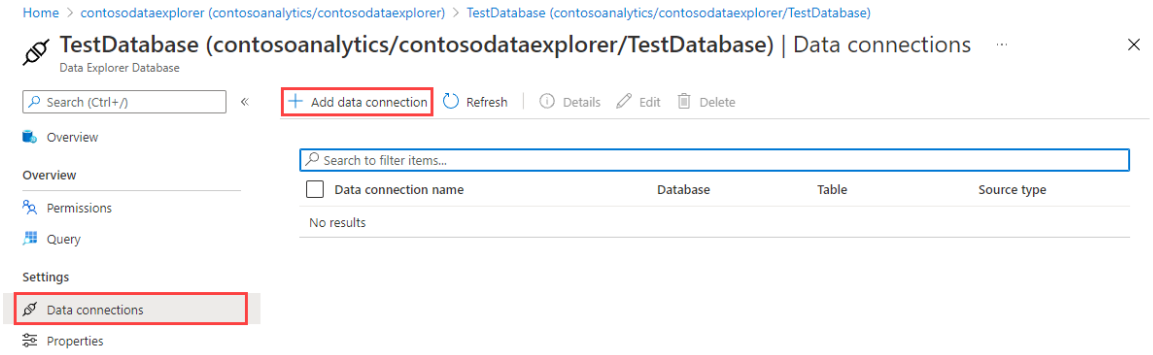
Create an Event Grid data connection

Now connect the storage account to Data Explorer, so that data flowing into the storage is streamed to the test table. This connection can be created in the Azure portal under Data Explorer.

1. Under the Data Explorer pool you created, select **Databases** > **TestDatabase**.



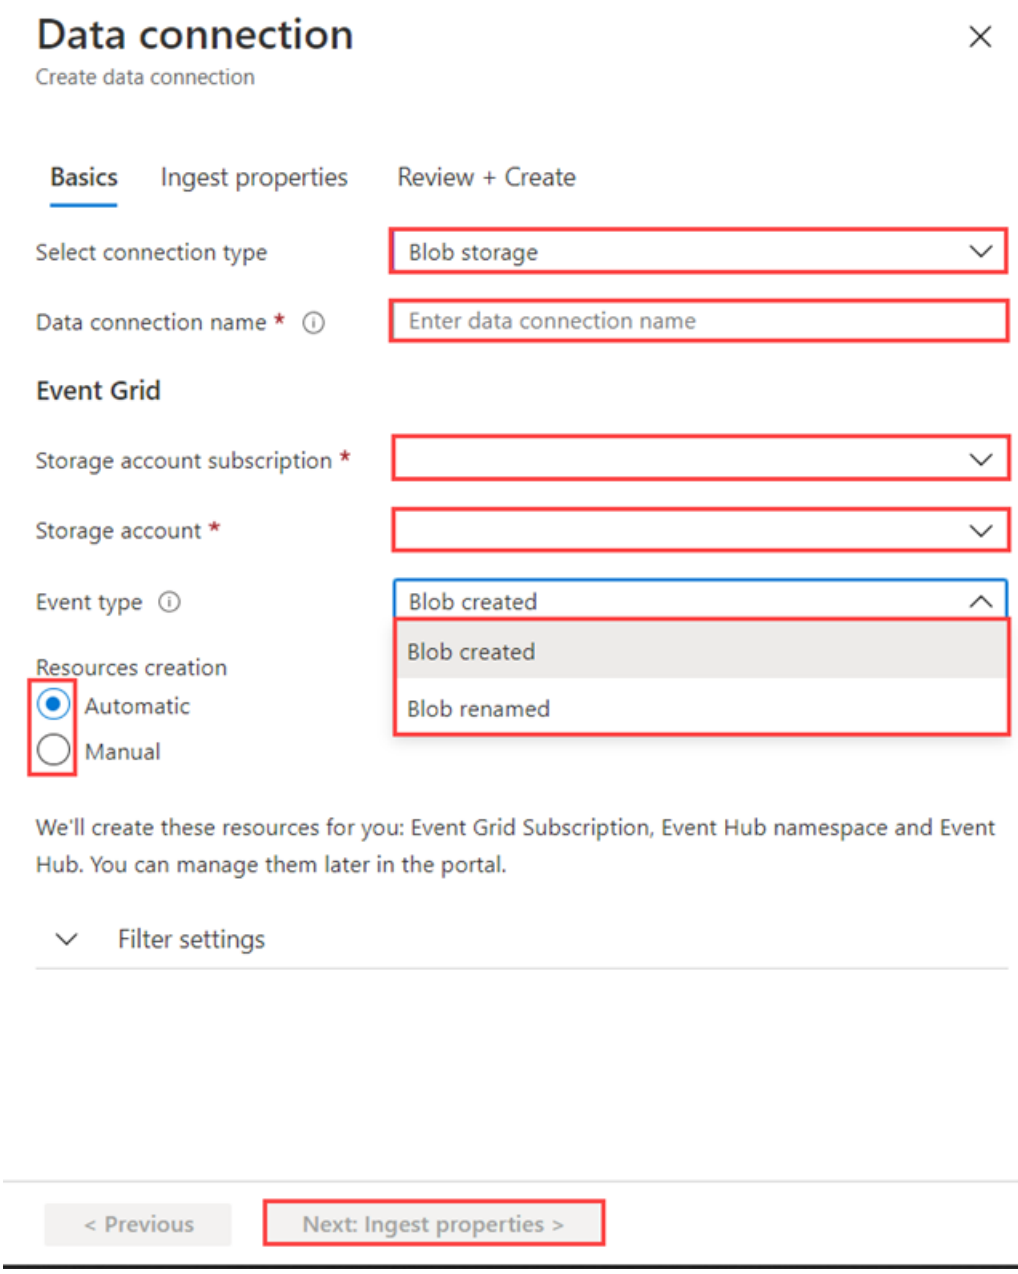
2. Select **Data connections** and **Add data connection**.



Data connection - Basics tab

1. Select the connection type: **Blob storage**.

2. Fill out the form with the following information:

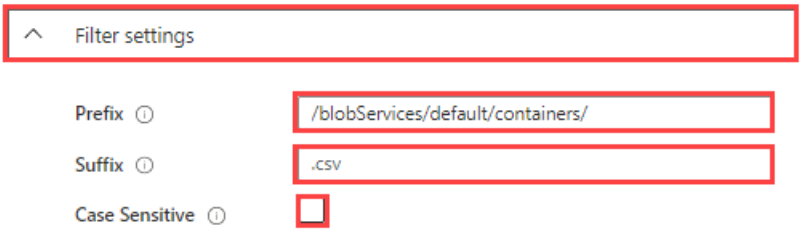


SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Data connection name	*test-grid-connection*	The name of the connection that you want to create in Data Explorer.
Storage account subscription	Your subscription ID	The subscription ID where your storage account is.
Storage account	*gridteststorage1*	The name of the storage account that you created previously.
Event type	*Blob created* or *Blob renamed*	The type of event that triggers ingestion. *Blob renamed* is supported only for ADLSv2 storage. Supported types are: Microsoft.Storage.BlobCreated or Microsoft.Storage.BlobRenamed.

SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Resources creation	*Automatic*	Define whether you want Data Explorer to create an Event Grid Subscription, an Event Hub namespace, and an Event Hub for you.

3. Select **Filter settings** if you want to track specific subjects. Set the filters for the notifications as follows:

   - **Prefix** field is the *literal* prefix of the subject. As the pattern applied is *startswith*, it can span multiple containers, folders, or blobs. No wildcards are allowed.
     - To define a filter on the blob container, the field *must* be set as follows: `/blobServices/default/containers/[container prefix]`.
     - To define a filter on a blob prefix (or a folder in Azure Data Lake Gen2), the field *must* be set as follows: `/blobServices/default/containers/[container name]/blobs/[folder/blob prefix]`.
   - **Suffix** field is the *literal* suffix of the blob. No wildcards are allowed.
   - **Case-Sensitive** field indicates whether the prefix and suffix filters are case-sensitive
   - For more information about filtering events, see Blob storage events.

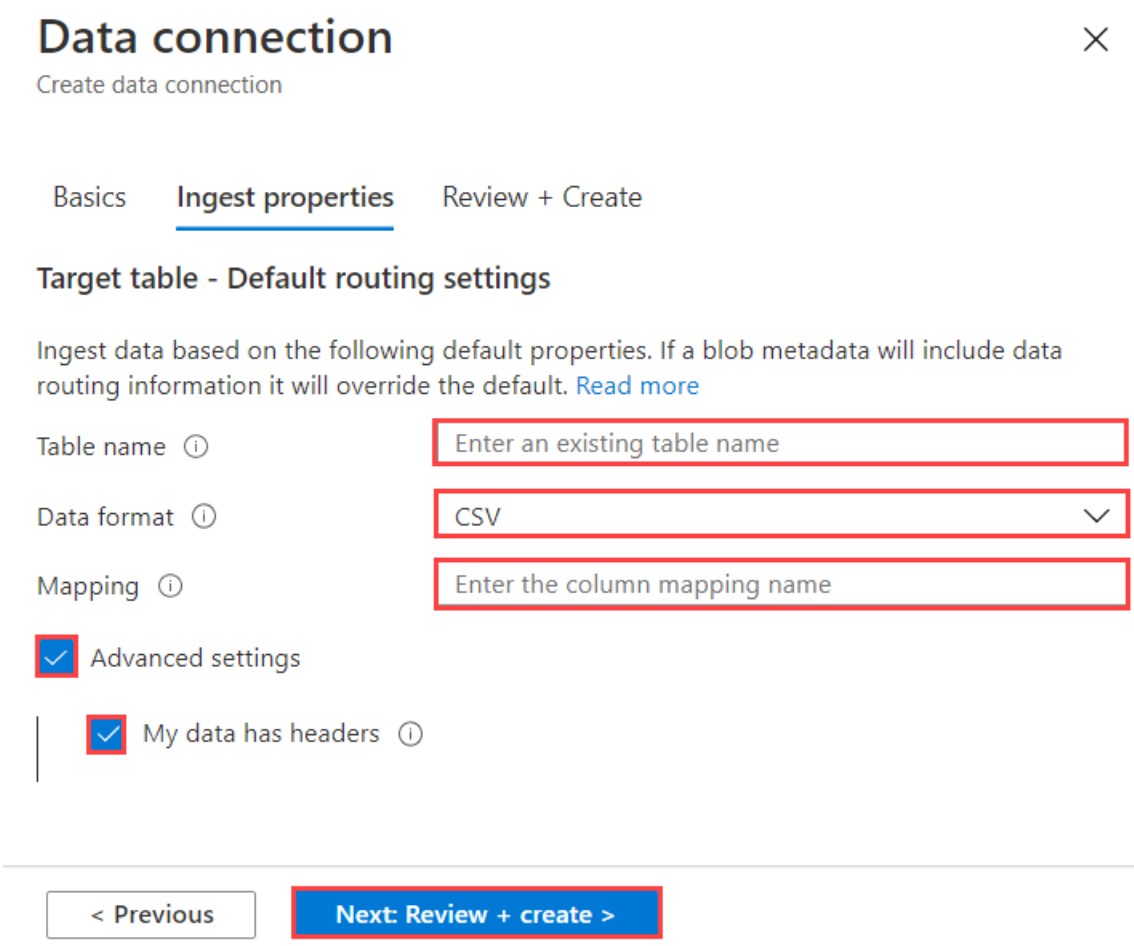


4. Select **Next: Ingest properties**.

> **NOTE**
> We recommend updating the data connection to use managed identities to access the storage account as soon as soon as the option becomes available for your cluster.

Data connection - Ingest properties tab

1. Fill out the form with the following information. Table and mapping names are case-sensitive:



Ingest properties:

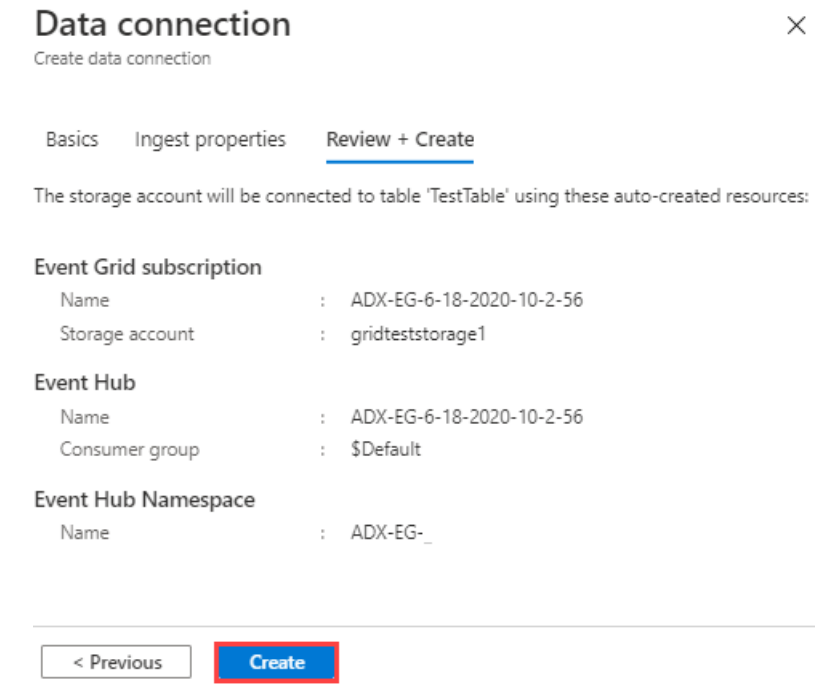
SETTING	SUGGESTED VALUE	FIELD DESCRIPTION
Table name	*TestTable*	The table you created in **TestDatabase**.
Data format	*JSON*	Supported formats are Avro, CSV, JSON, MULTILINE JSON, ORC, PARQUET, PSV, SCSV, SOHSV, TSV, TXT, TSVE, APACHEAVRO, RAW, and W3CLOG. Supported compression options are Zip and Gzip.
Mapping	*TestMapping*	The mapping you created in **TestDatabase**, which maps incoming JSON data to the column names and data types of **TestTable**.
Advanced settings	*My data has headers*	Ignores headers. Supported for *SV type files.

> **NOTE**
> You don't have to specify all **Default routing settings**. Partial settings are also accepted.

2. Select **Next: Review + Create**

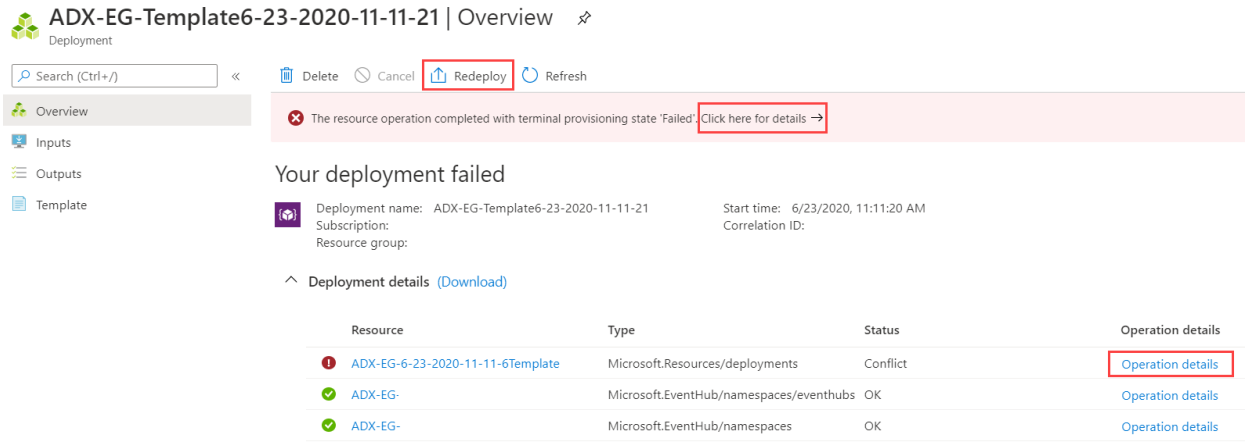
Data connection - Review + Create tab

1. Review the resources that were auto created for you and select **Create**.



Deployment

Wait until the deployment is completed. If your deployment failed, select **Operation details** next to the failed stage to get more information for the failure reason. Select **Redeploy** to try to deploy the resources again. You can alter the parameters before deployment.



Generate sample data

Now that Data Explorer and the storage account are connected, you can create sample data.

Upload blob to the storage container

We'll work with a small shell script that issues a few basic Azure CLI commands to interact with Azure Storage resources. This script does the following actions:

1. Creates a new container in your storage account.
2. Uploads an existing file (as a blob) to that container.
3. Lists the blobs in the container.

You can use Azure Cloud Shell to execute the script directly in the portal.

Save the data into a file and upload it with this script:

```
{"TimeStamp": "1987-11-16 12:00","Value": "Hello World","Source": "TestSource"}
```

```
    #!/bin/bash
    ### A simple Azure Storage example script

    export AZURE_STORAGE_ACCOUNT=<storage_account_name>
    export AZURE_STORAGE_KEY=<storage_account_key>

    export container_name=<container_name>
    export blob_name=<blob_name>
    export file_to_upload=<file_to_upload>
    export destination_file=<destination_file>

    echo "Creating the container..."
    az storage container create --name $container_name

    echo "Uploading the file..."
    az storage blob upload --container-name $container_name --file $file_to_upload --name $blob_name --
metadata "rawSizeBytes=1024"

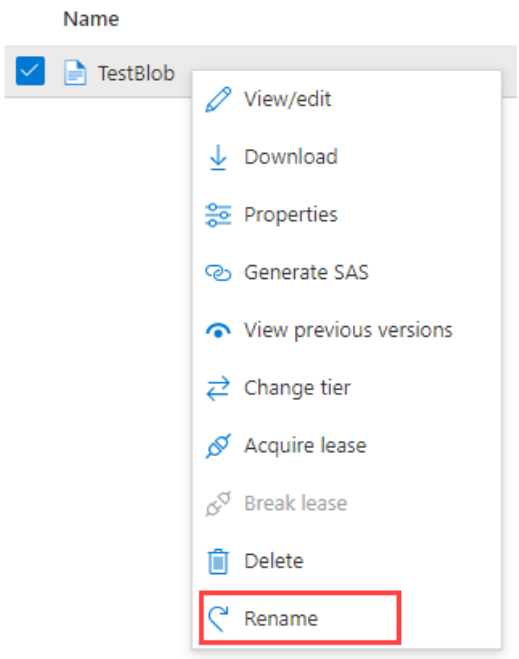
    echo "Listing the blobs..."
    az storage blob list --container-name $container_name --output table

    echo "Done"
```

> **NOTE**
>
> To achieve the best ingestion performance, the *uncompressed* size of the compressed blobs submitted for ingestion must be communicated. Because Event Grid notifications contain only basic details, the size information must be explicitly communicated. The uncompressed size information can be provided by setting the `rawSizeBytes` property on the blob metadata with the *uncompressed* data size in bytes.

Rename blob

If you're ingesting data from ADLSv2 storage and have defined *Blob renamed* as the event type for the data connection, the trigger for blob ingestion is blob renaming. To rename a blob, navigate to the blob in Azure portal, right-click on the blob and select **Rename**:



Ingestion properties

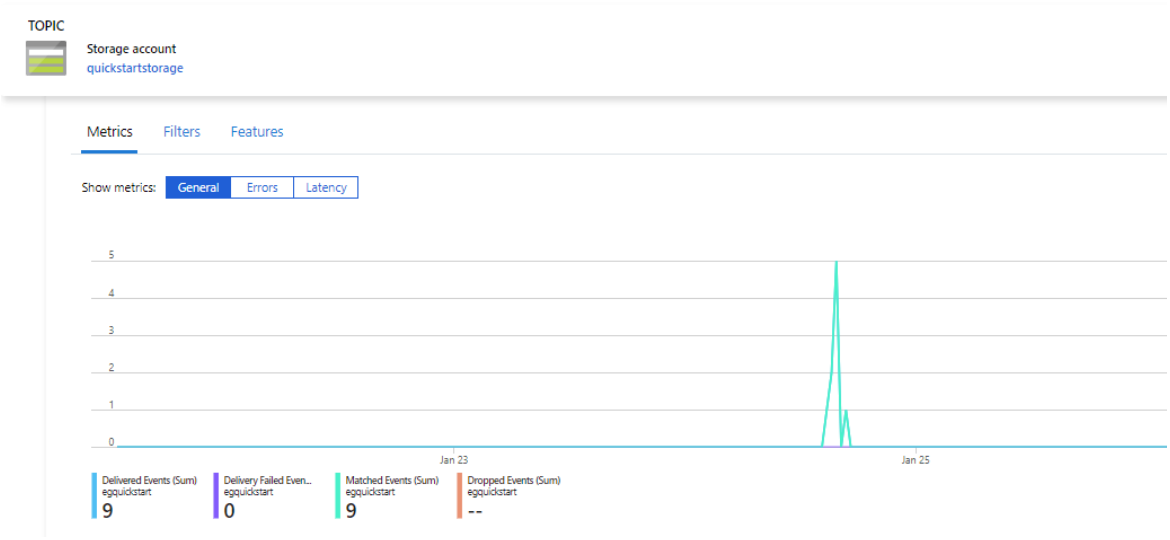
You can specify the ingestion properties of the blob ingestion via the blob metadata.

> **NOTE**
>
> Data Explorer won't delete the blobs post ingestion. Retain the blobs for three to five days. Use Azure Blob storage lifecycle to manage blob deletion.

Review the data flow

> **NOTE**
>
> Data Explorer has an aggregation (batching) policy for data ingestion designed to optimize the ingestion process. By default, the policy is configured to 5 minutes. You'll be able to alter the policy at a later time if needed. In this article you can expect a latency of a few minutes.

1. In the Azure portal, under your Event Grid, you see the spike in activity while the app is running.



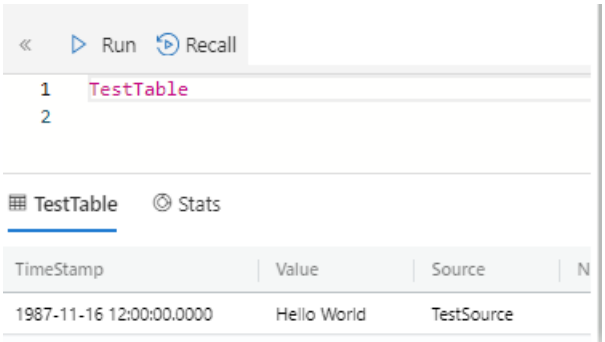
2. To check how many messages have made it to the database so far, run the following query in your test database.

```
TestTable
| count
```

3. To see the content of the messages, run the following query in your test database.

```
TestTable
```

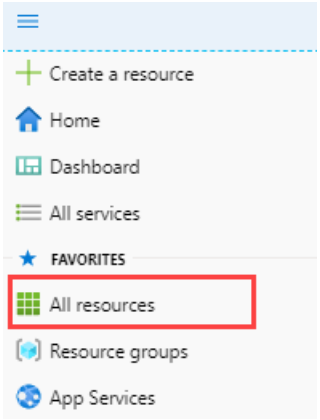
   The result set should look like the following image:



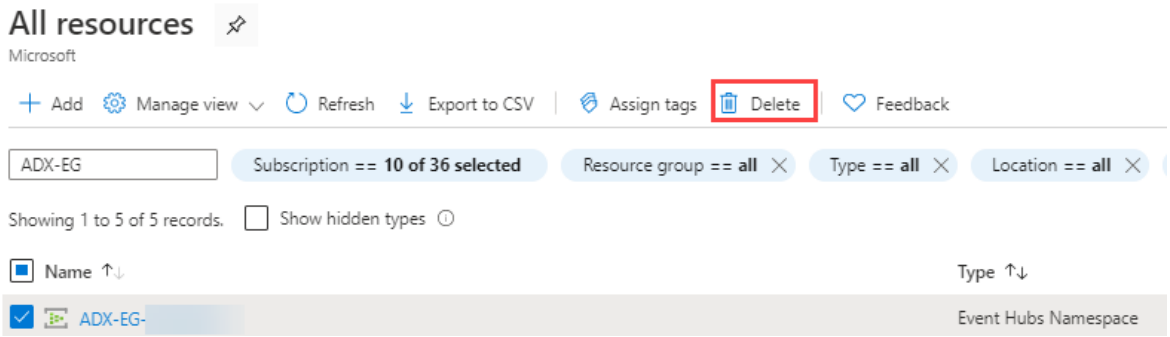
Clean up resources

If you don't plan to use your Event Grid again, clean up the Event Grid Subscription, Event Hub namespace, and Event Hub that were autocreated for you, to avoid incurring costs.

1. In Azure portal, go to the left menu and select **All resources**.

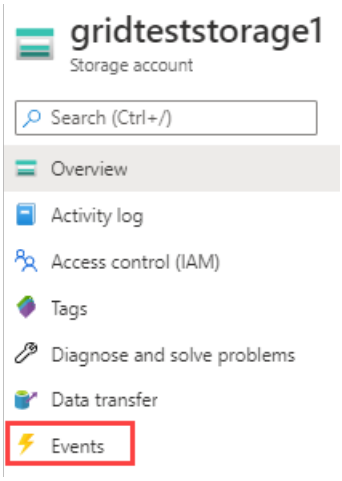


2. Search for your Event Hub Namespace and select **Delete** to delete it:

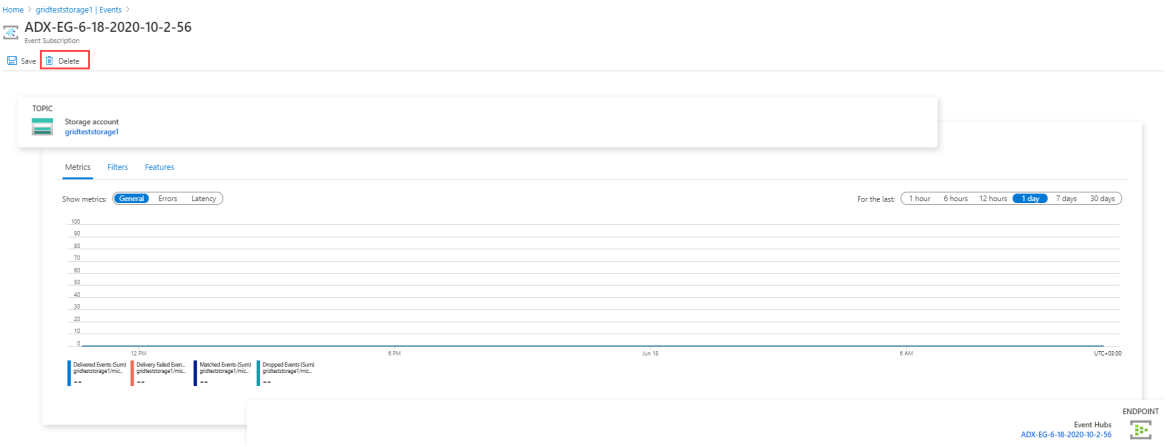


3. In the Delete resources form, confirm the deletion to delete the Event Hub Namespace and Event Hub resources.

4. Go to your storage account. In the left menu, select **Events**:

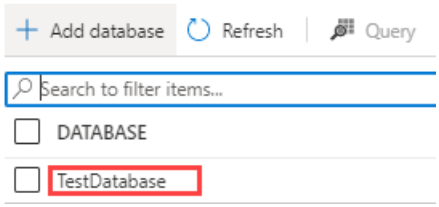


5. Below the graph, Select your Event Grid Subscription and then select **Delete** to delete it:

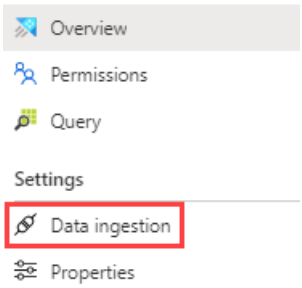


6. To delete your Event Grid data connection, go to your Data Explorer cluster. On the left menu, select **Databases**.

7. Select your database **TestDatabase**:



8. On the left menu, select **Data ingestion**:



9. Select your data connection *test-grid-connection* and then select **Delete** to delete it.

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Quickstart: Ingest data using Azure Synapse Pipelines (Preview)

8/19/2022 • 5 minutes to read • Edit Online

In this quickstart, you learn how to load data from a data source into Azure Synapse Data Explorer pool.

Prerequisites

- An Azure subscription. Create a free Azure account.
- Create a Data Explorer pool using Synapse Studio or the Azure portal
- Create a Data Explorer database.
  1. In Synapse Studio, on the left-side pane, select **Data**.
  2. Select **+** (Add new resource) > **Data Explorer pool**, and use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Pool name	*contosodataexplorer*	The name of the Data Explorer pool to use
Name	*TestDatabase*	The database name must be unique within the cluster.
Default retention period	*365*	The time span (in days) for which it's guaranteed that the data is kept available to query. The time span is measured from the time that data is ingested.
Default cache period	*31*	The time span (in days) for which to keep frequently queried data available in SSD storage or RAM, rather than in longer-term storage.

  3. Select **Create** to create the database. Creation typically takes less than a minute.
- Create a table
  1. In Synapse Studio, on the left-side pane, select **Develop**.
  2. Under **KQL scripts**, Select **+** (Add new resource) > **KQL script**. On the right-side pane, you can name your script.
  3. In the **Connect to** menu, select *contosodataexplorer*.
  4. In the **Use database** menu, select *TestDatabase*.
  5. Paste in the following command, and select **Run** to create the table.

```
.create table StormEvents (StartTime: datetime, EndTime: datetime, EpisodeId: int, EventId: int,
State: string, EventType: string, InjuriesDirect: int, InjuriesIndirect: int, DeathsDirect: int,
DeathsIndirect: int, DamageProperty: int, DamageCrops: int, Source: string, BeginLocation: string,
EndLocation: string, BeginLat: real, BeginLon: real, EndLat: real, EndLon: real, EpisodeNarrative:
string, EventNarrative: string, StormSummary: dynamic)
```

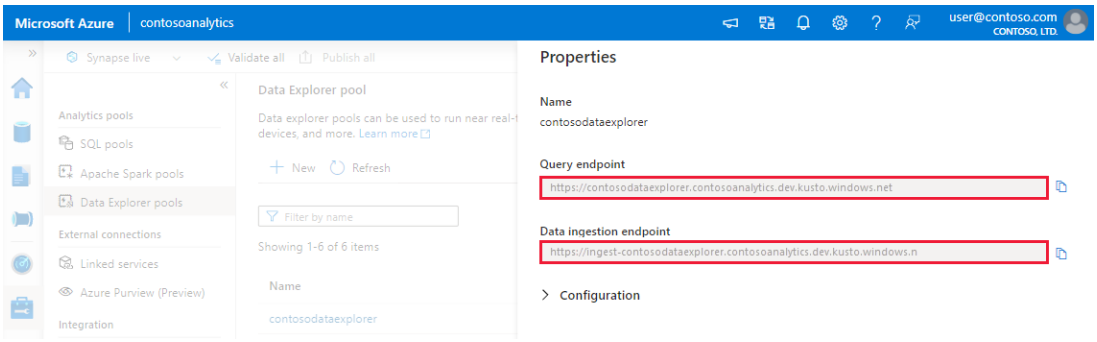
TIP

Verify that the table was successfully created. On the left-side pane, select **Data**, select the *contosodataexplorer* more menu, and then select **Refresh**. Under *contosodataexplorer*, expand **Tables** and make sure that the *StormEvents* table appears in the list.

- Get the Query and Data Ingestion endpoints. You'll need the query endpoint to configure your linked service.

  1. In Synapse Studio, on the left-side pane, select **Manage** > **Data Explorer pools**.
  2. Select the Data Explorer pool you want to use to view its details.

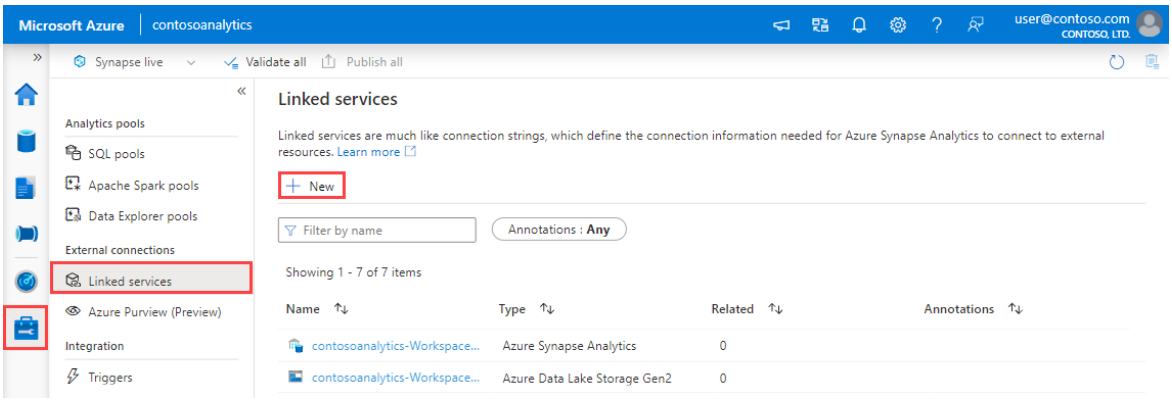
  3. Make a note of the Query and Data Ingestion endpoints. Use the Query endpoint as the cluster when configuring connections to your Data Explorer pool. When configuring SDKs for data ingestion, use the data ingestion endpoint.



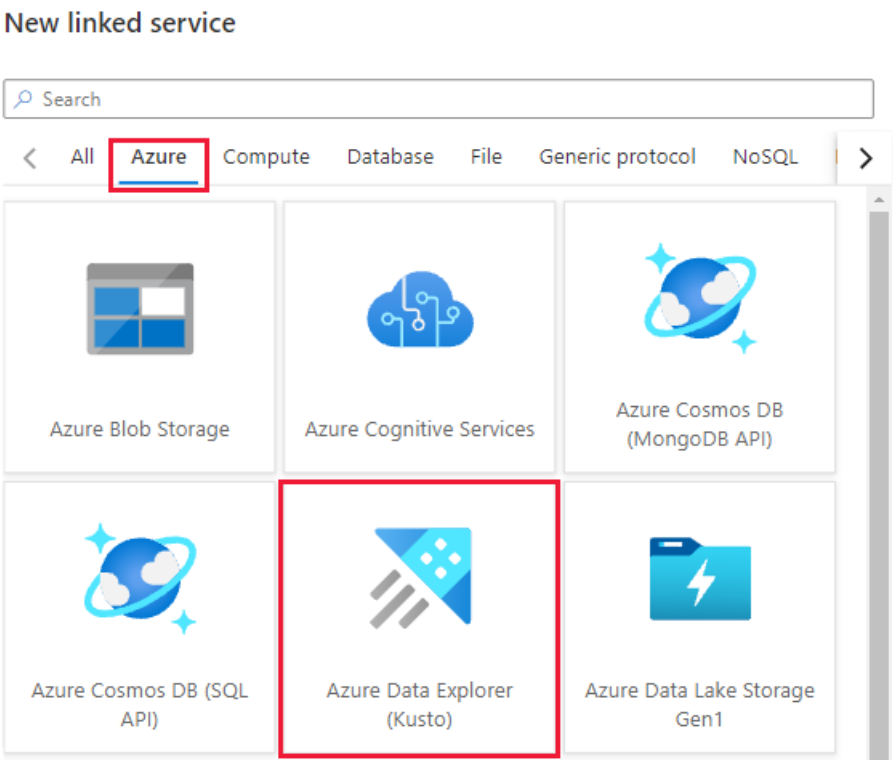
Create a linked service

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll create a linked service for Azure Data Explorer.

1. In Synapse Studio, on the left-side pane, select **Manage** > **Linked services**.
2. Select **+ New**.

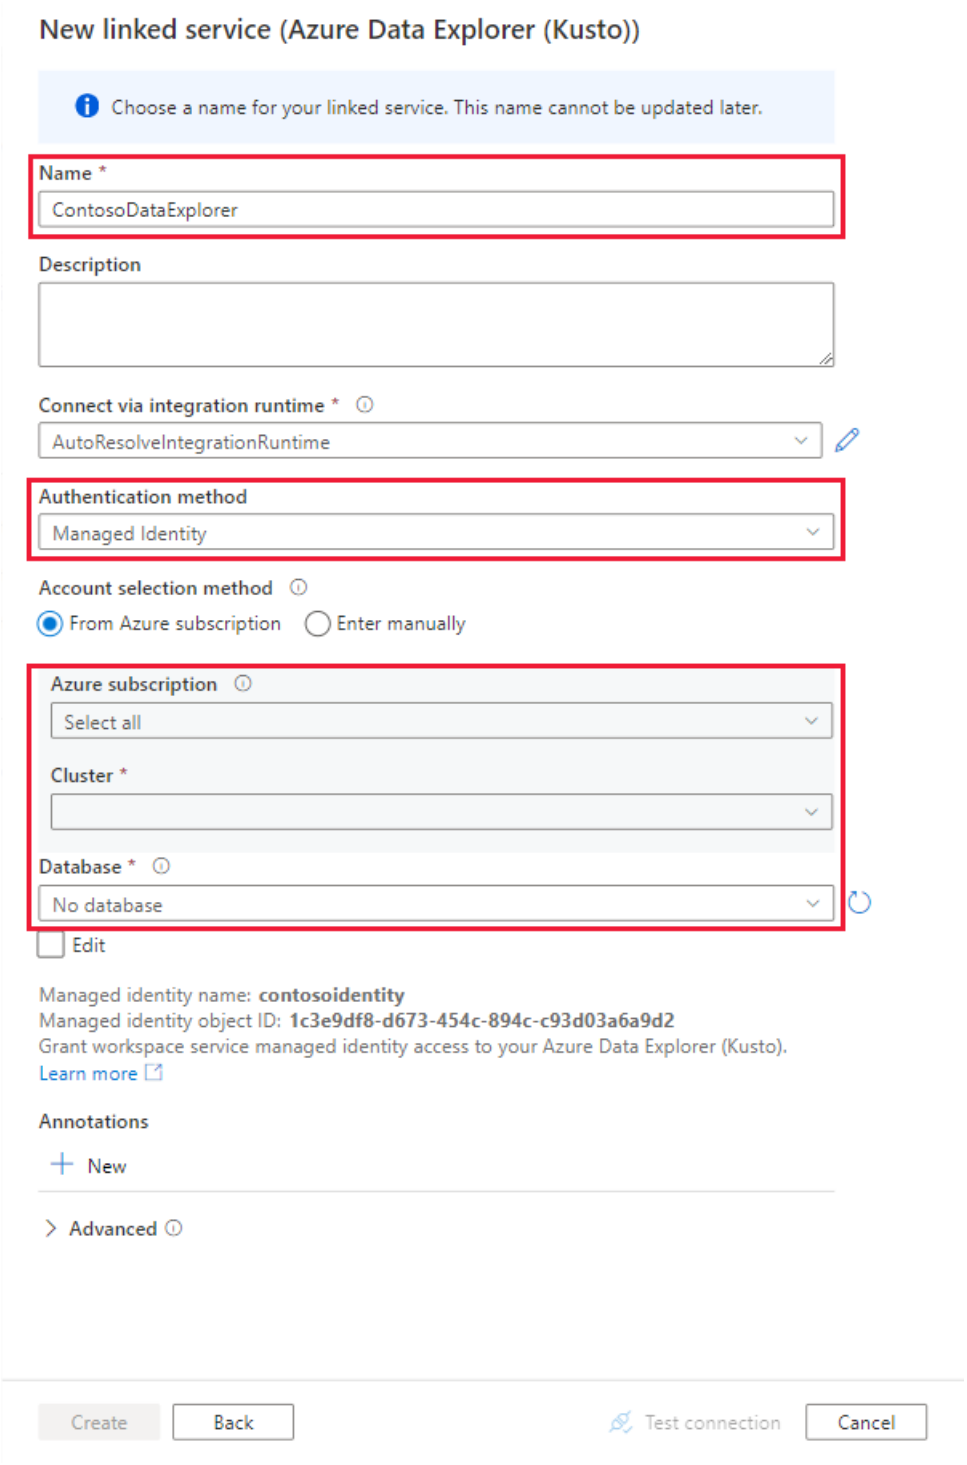


3. Select the **Azure Data Explorer** service from the gallery, and then select **Continue**.



4. In the New Linked Services page, use the following information:

SETTING	SUGGESTED VALUE	DESCRIPTION
Name	*contosodataexplorerlinkedservice*	The name for the new Azure Data Explorer linked service.
Authentication method	*Managed Identity*	The authentication method for the new service.
Account selection method	*Enter manually*	The method for specifying the Query endpoint.
Endpoint	*https://contosodataexplorer.contosoanalytics.dev.kusto.windows.net*	The Query endpoint you made a note of earlier.
Database	*TestDatabase*	The database where you want to ingest data.



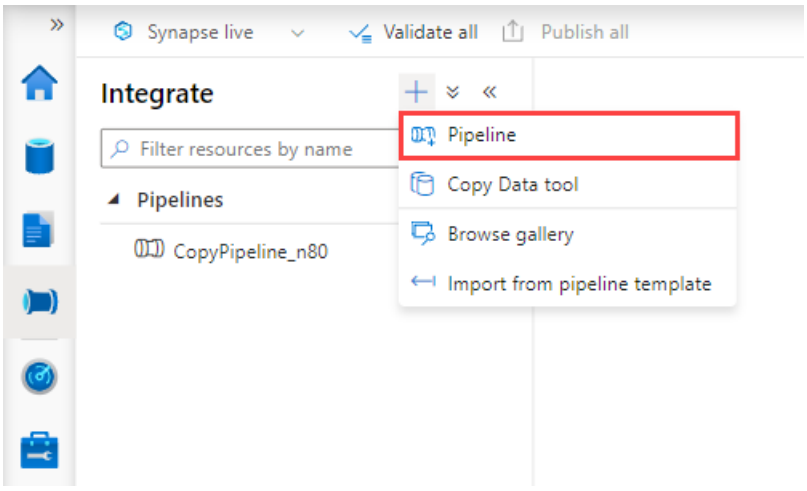
5. Select **Test connection** to validate the settings, and then select **Create**.

Create a pipeline to ingest data

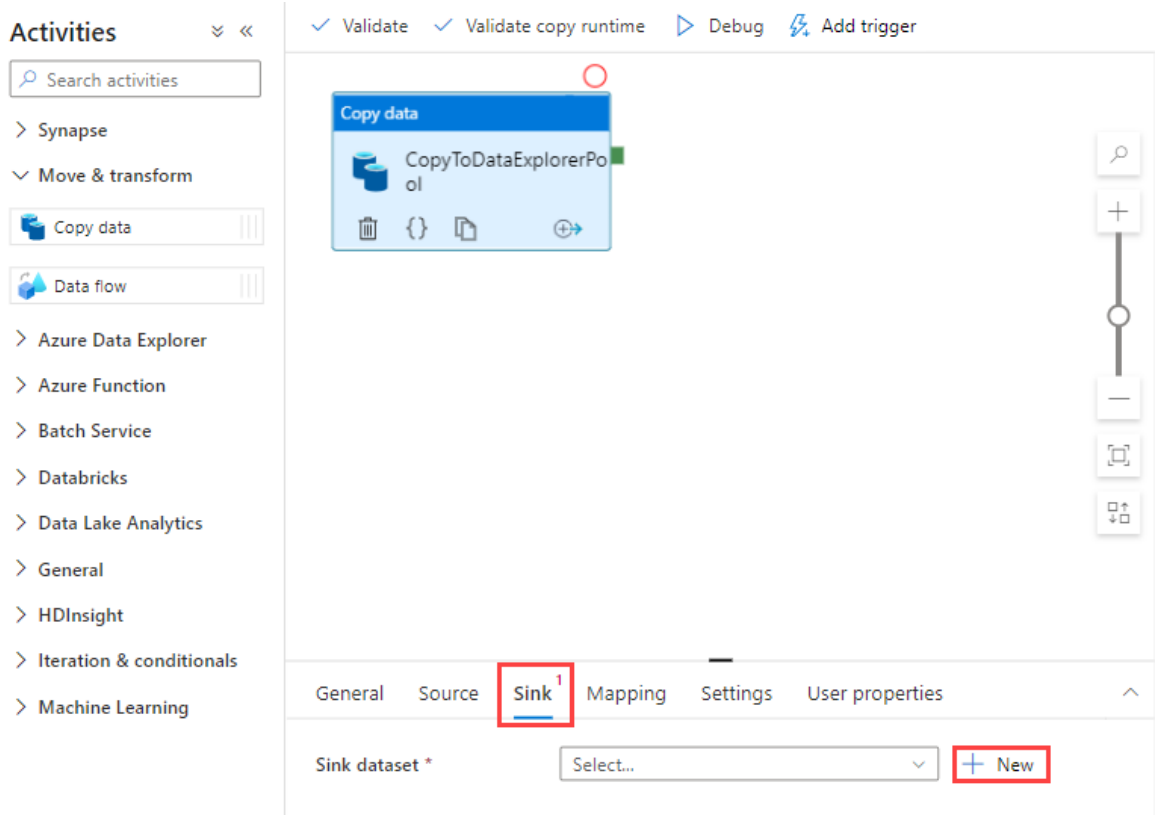
A pipeline contains the logical flow for an execution of a set of activities. In this section, you'll create a pipeline containing a copy activity that ingests data from your preferred source into a Data Explorer pool.

1. In Synapse Studio, on the left-side pane, select **Integrate**.

2. Select **+** > **Pipeline**. On the right-side pane, you can name your pipeline.

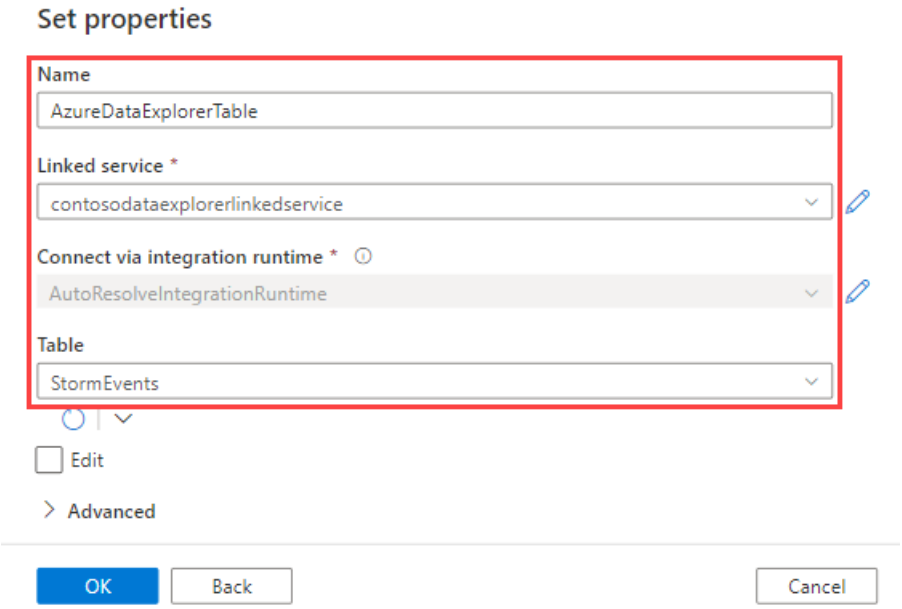


3. Under **Activities** > **Move & transform**, drag **Copy data** onto the pipeline canvas.
4. Select the copy activity and go to the **Source** tab. Select or create a new source dataset as the source to copy data from.
5. Go to the **Sink** tab. Select **New** to create a new sink dataset.



6. Select the **Azure Data Explorer** dataset from the gallery, and then select **Continue**.
7. In the **Set properties** pane, use the following information, and then select **OK**.

SETTING	SUGGESTED VALUE	DESCRIPTION
Name	*AzureDataExplorerTable*	The name for the new pipeline.
Linked service	*contosodataexplorerlinkedservice*	The linked service you created earlier.
Table	*StormEvents*	The table you created earlier.



8. To validate the pipeline, select **Validate** on the toolbar. You see the result of the Pipeline validation output on the right side of the page.

Debug and publish the pipeline

Once you've finished configuring your pipeline, you can execute a debug run before you publish your artifacts to verify everything is correct.

1. Select **Debug** on the toolbar. You see the status of the pipeline run in the **Output** tab at the bottom of the window.
2. Once the pipeline run succeeds, in the top toolbar, select **Publish all**. This action publishes entities (datasets and pipelines) you created to the Synapse Analytics service.
3. Wait until you see the **Successfully published** message. To see notification messages, select the bell button in the top-right.

Trigger and monitor the pipeline

In this section, you manually trigger the pipeline published in the previous step.

1. Select **Add Trigger** on the toolbar, and then select **Trigger Now**. On the **Pipeline Run** page, select **OK**.
2. Go to the **Monitor** tab located in the left sidebar. You see a pipeline run that is triggered by a manual trigger.
3. When the pipeline run completes successfully, select the link under the **Pipeline name** column to view activity run details or to rerun the pipeline. In this example, there's only one activity, so you see only one entry in the list.
4. For details about the copy operation, select the **Details** link (eyeglasses icon) under the **Activity name** column. You can monitor details like the volume of data copied from the source to the sink, data throughput, execution steps with corresponding duration, and used configurations.
5. To switch back to the pipeline runs view, select the **All pipeline runs** link at the top. Select **Refresh** to refresh the list.
6. Verify your data is correctly written in the Data Explorer pool.

Next steps

- Analyze with Data Explorer
- Monitor Data Explorer pools

Quickstart: Use Synapse Studio to monitor your Data Explorer pools (Preview)

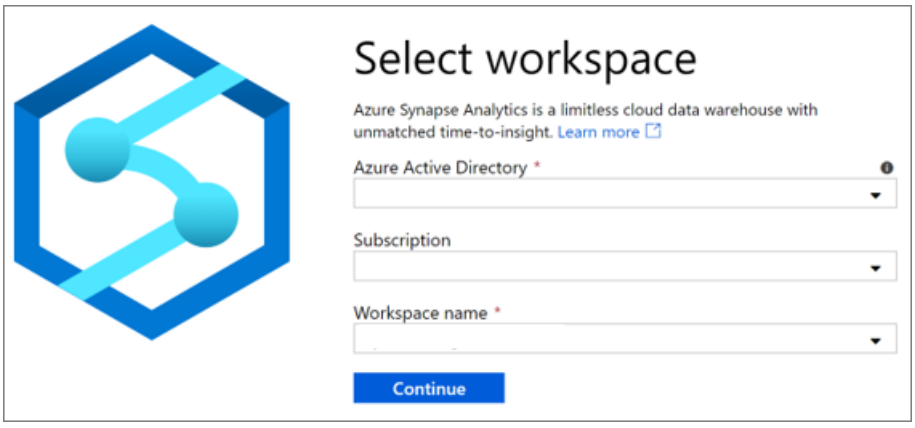
8/19/2022 • 2 minutes to read • Edit Online

With Azure Synapse Analytics, you can use Data Explorer to run queries, dashboards and more on Data Explorer pools in your workspace.

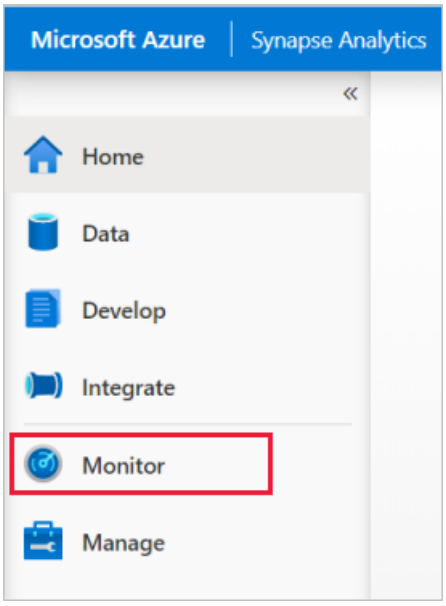
This article explains how to monitor your Data Explorer pools, allowing you to keep an eye on the status of your pools, including how many vCores are in use by different workspace users.

Access Data Explorer pools list

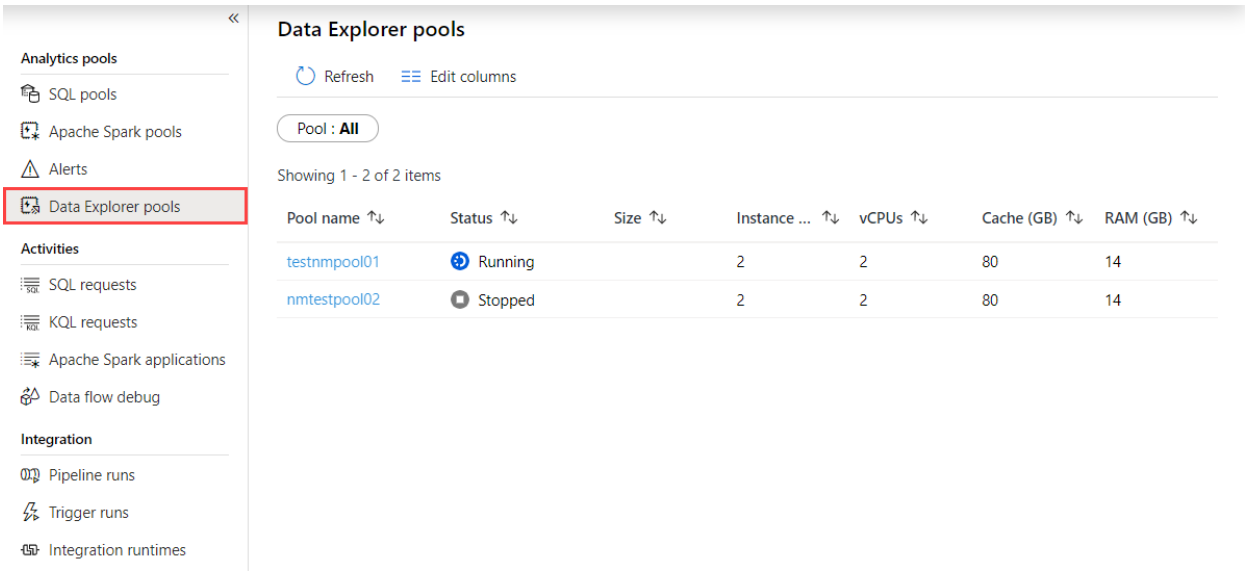
To see the list of Data Explorer pools in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.



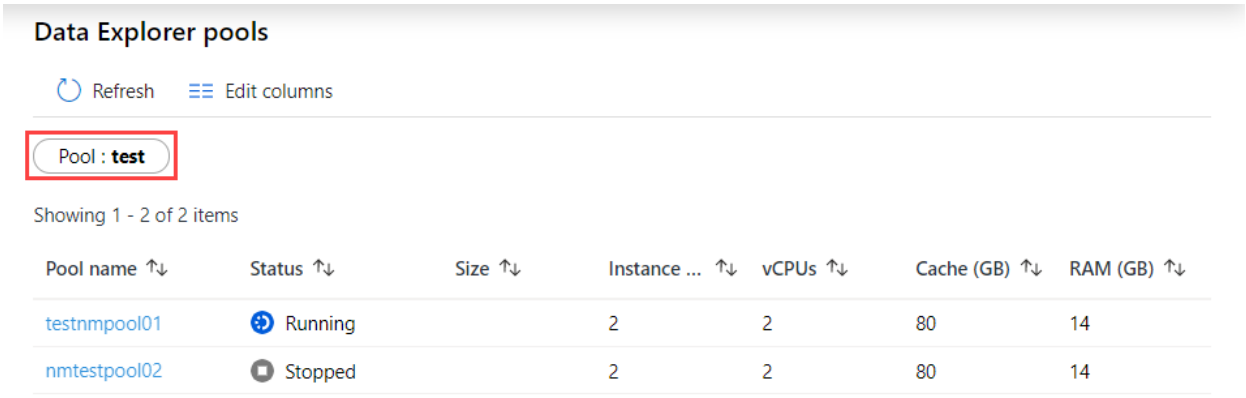
Select **Data Explorer pools** to view the list of Data Explorer pools.



Filter your Data Explorer pools

You can filter the list of Data Explorer pools to the ones that interest you. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the Data Explorer pools containing the name "test":



View details about a specific Data Explorer pool

To view the details about one of your Data Explorer pools, select the Data Explorer pool to view the details.

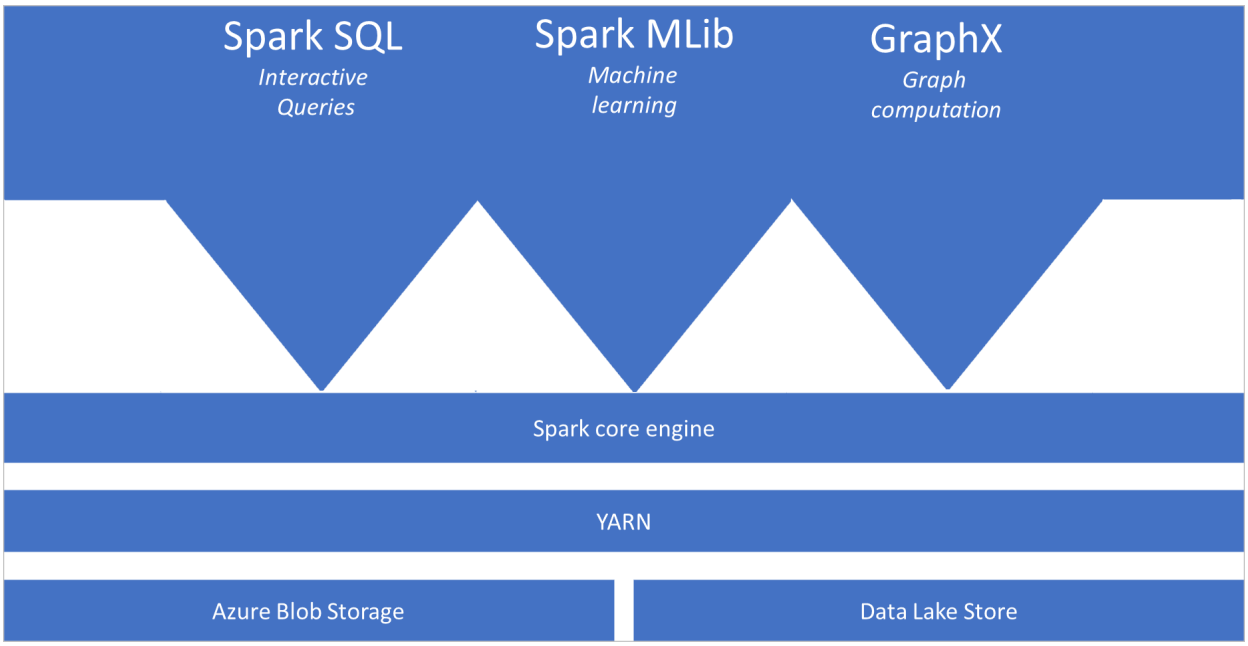
Apache Spark in Azure Synapse Analytics

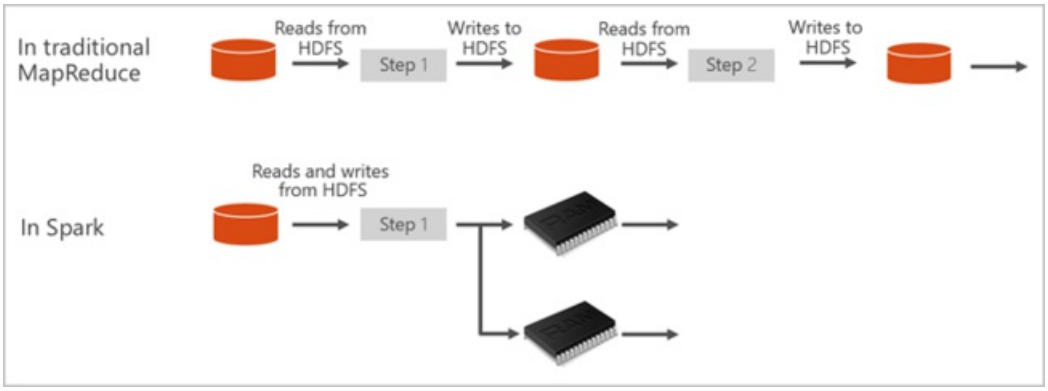
8/19/2022 • 4 minutes to read • Edit Online

Apache Spark is a parallel processing framework that supports in-memory processing to boost the performance of big data analytic applications. Apache Spark in Azure Synapse Analytics is one of Microsoft's implementations of Apache Spark in the cloud. Azure Synapse makes it easy to create and configure a serverless Apache Spark pool in Azure. Spark pools in Azure Synapse are compatible with Azure Storage and Azure Data Lake Generation 2 Storage. So you can use Spark pools to process your data stored in Azure.



What is Apache Spark

Apache Spark provides primitives for in-memory cluster computing. A Spark job can load and cache data into memory and query it repeatedly. In-memory computing is much faster than disk-based applications. Spark also integrates with multiple programming languages to let you manipulate distributed data sets like local collections. There's no need to structure everything as map and reduce operations.



Spark pools in Azure Synapse offer a fully managed Spark service. The benefits of creating a Spark pool in Azure Synapse Analytics are listed here.

FEATURE	DESCRIPTION

FEATURE	DESCRIPTION
Speed and efficiency	Spark instances start in approximately 2 minutes for fewer than 60 nodes and approximately 5 minutes for more than 60 nodes. The instance shuts down, by default, 5 minutes after the last job runs unless it's kept alive by a notebook connection.
Ease of creation	You can create a new Spark pool in Azure Synapse in minutes using the Azure portal, Azure PowerShell, or the Synapse Analytics .NET SDK. See Get started with Spark pools in Azure Synapse Analytics.
Ease of use	Synapse Analytics includes a custom notebook derived from nteract. You can use these notebooks for interactive data processing and visualization.
REST APIs	Spark in Azure Synapse Analytics includes Apache Livy, a REST API-based Spark job server to remotely submit and monitor jobs.
Support for Azure Data Lake Storage Generation 2	Spark pools in Azure Synapse can use Azure Data Lake Storage Generation 2 and BLOB storage. For more information on Data Lake Storage, see Overview of Azure Data Lake Storage.
Integration with third-party IDEs	Azure Synapse provides an IDE plugin for JetBrains' IntelliJ IDEA that is useful to create and submit applications to a Spark pool.
Preloaded Anaconda libraries	Spark pools in Azure Synapse come with Anaconda libraries preinstalled. Anaconda provides close to 200 libraries for machine learning, data analysis, visualization, and other technologies.
Scalability	Apache Spark in Azure Synapse pools can have Auto-Scale enabled, so that pools scale by adding or removing nodes as needed. Also, Spark pools can be shut down with no loss of data since all the data is stored in Azure Storage or Data Lake Storage.

Spark pools in Azure Synapse include the following components that are available on the pools by default:

- Spark Core. Includes Spark Core, Spark SQL, GraphX, and MLlib.
- Anaconda
- Apache Livy
- nteract notebook

Spark pool architecture

Spark applications run as independent sets of processes on a pool, coordinated by the `SparkContext` object in your main program, called the *driver program*.

The `SparkContext` can connect to the cluster manager, which allocates resources across applications. The cluster manager is Apache Hadoop YARN. Once connected, Spark acquires executors on nodes in the pool, which are processes that run computations and store data for your application. Next, it sends your application code, defined by JAR or Python files passed to `SparkContext`, to the executors. Finally, `SparkContext` sends tasks to the

executors to run.

The `SparkContext` runs the user's main function and executes the various parallel operations on the nodes. Then, the `SparkContext` collects the results of the operations. The nodes read and write data from and to the file system. The nodes also cache transformed data in-memory as Resilient Distributed Datasets (RDDs).

The `SparkContext` connects to the Spark pool and is responsible for converting an application to a directed acyclic graph (DAG). The graph consists of individual tasks that run within an executor process on the nodes. Each application gets its own executor processes, which stay up during the whole application and run tasks in multiple threads.

Apache Spark in Azure Synapse Analytics use cases

Spark pools in Azure Synapse Analytics enable the following key scenarios:

- Data Engineering/Data Preparation

  Apache Spark includes language features to support preparation and processing of large volumes of data so that it can be made more valuable and then consumed by other services within Azure Synapse Analytics. This approach is enabled through multiple languages, including C#, Scala, PySpark, and Spark SQL, and supplied libraries for processing and connectivity.

- Machine Learning

  Apache Spark comes with MLlib, a machine learning library built on top of Spark that you can use from a Spark pool in Azure Synapse Analytics. Spark pools in Azure Synapse Analytics also include Anaconda, a Python distribution with various packages for data science including machine learning. When combined with built-in support for notebooks, you have an environment for creating machine learning applications.

Where do I start

Use the following articles to learn more about Apache Spark in Azure Synapse Analytics:

- Quickstart: Create a Spark pool in Azure Synapse
- Quickstart: Create an Apache Spark notebook
- Tutorial: Machine learning using Apache Spark
- Apache Spark official documentation

> **NOTE**
> Some of the official Apache Spark documentation relies on using the Spark console, which is not available on Azure Synapse Spark. Use the notebook or IntelliJ experiences instead.

Next steps

This overview provided a basic understanding of Apache Spark in Azure Synapse Analytics. Advance to the next article to learn how to create a Spark pool in Azure Synapse Analytics:

- Create a Spark pool in Azure Synapse

Quickstart: Create a serverless Apache Spark pool in Azure Synapse Analytics using web tools

8/19/2022 • 5 minutes to read • Edit Online

In this quickstart, you learn how to create a serverless Apache Spark pool in Azure Synapse using web tools. You then learn to connect to the Apache Spark pool and run Spark SQL queries against files and tables. Apache Spark enables fast data analytics and cluster computing using in-memory processing. For information on Spark in Azure Synapse, see Overview: Apache Spark on Azure Synapse.

> **IMPORTANT**
>
> Billing for Spark instances is prorated per minute, whether you are using them or not. Be sure to shutdown your Spark instance after you have finished using it, or set a short timeout. For more information, see the **Clean up resources** section of this article.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure subscription - create one for free
- Synapse Analytics workspace
- Serverless Apache Spark pool

Sign in to the Azure portal

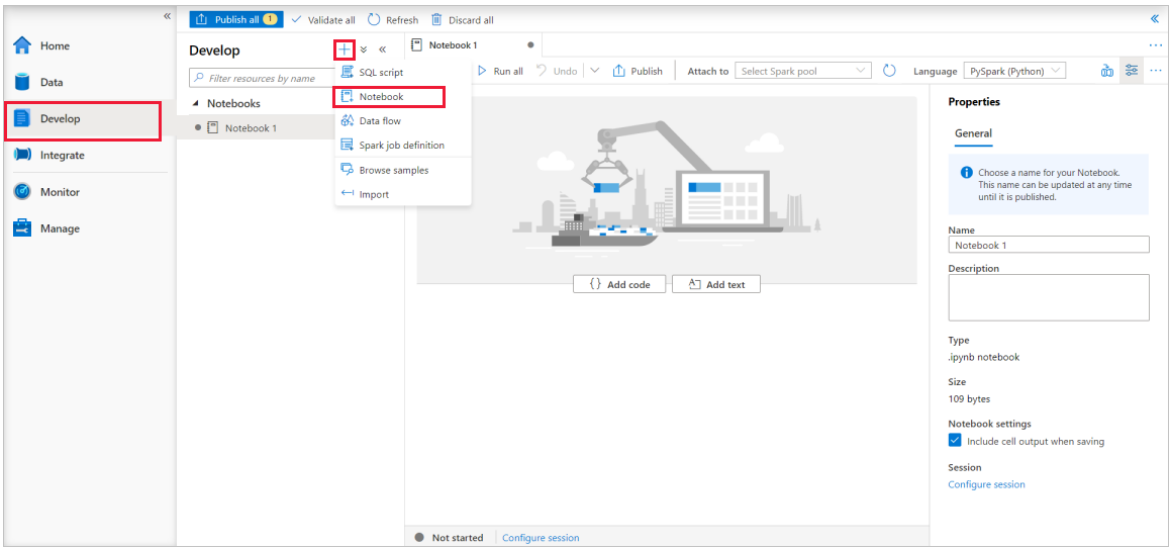
Sign in to the Azure portal.

If you don't have an Azure subscription, create a free account before you begin.

Create a notebook

A notebook is an interactive environment that supports various programming languages. The notebook allows you to interact with your data, combine code with markdown, text, and perform simple visualizations.

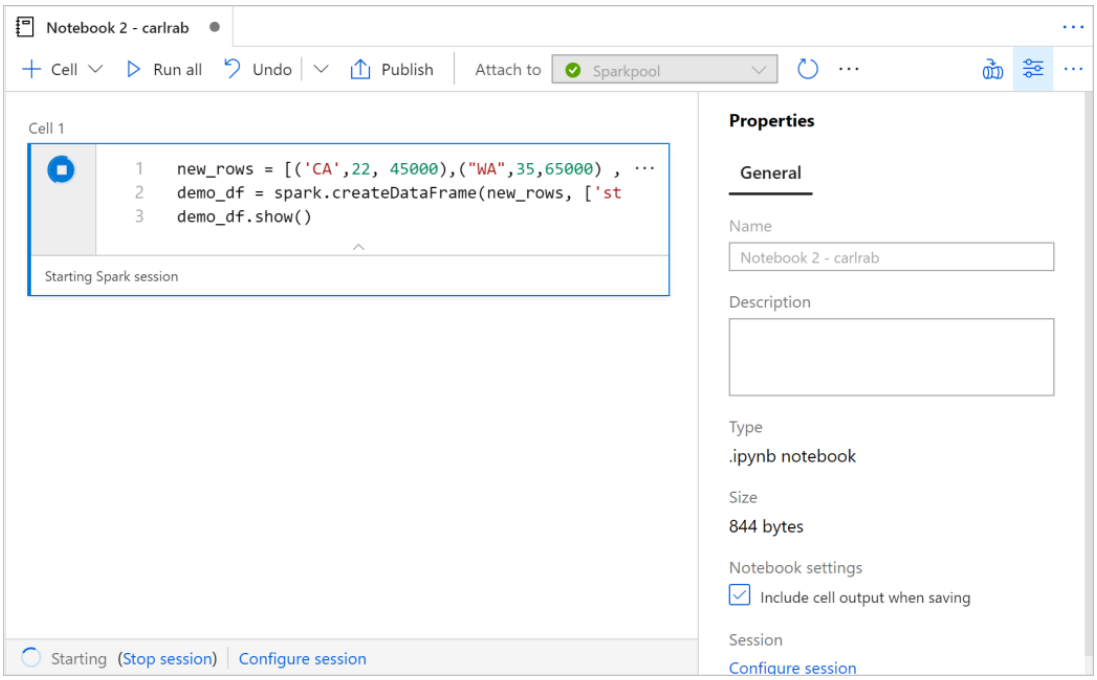
1. From the Azure portal view for the Azure Synapse workspace you want to use, select **Launch Synapse Studio**.
2. Once Synapse Studio has launched, select **Develop**. Then, select the "**+**" icon to add a new resource.
3. From there, select **Notebook**. A new notebook is created and opened with an automatically generated name.



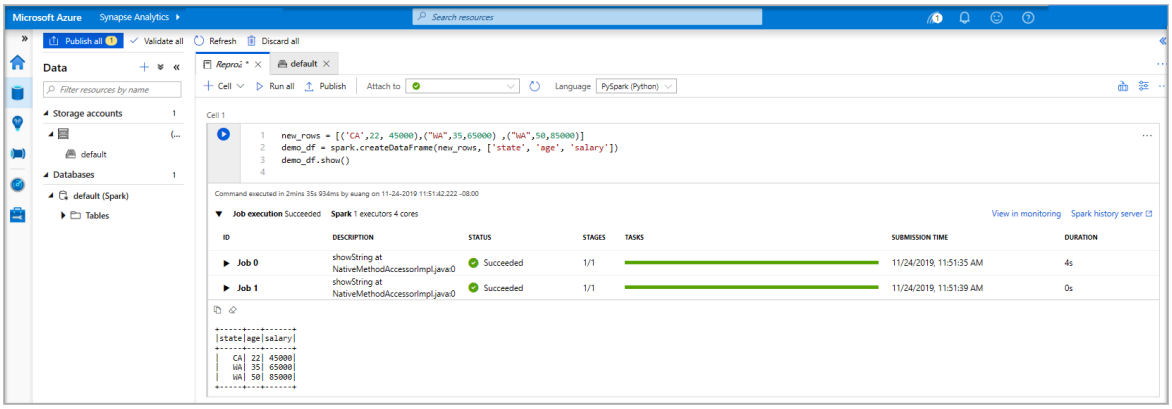
4. In the **Properties** window, provide a name for the notebook.
5. On the toolbar, click **Publish**.
6. If there is only one Apache Spark pool in your workspace, then it's selected by default. Use the drop-down to select the correct Apache Spark pool if none is selected.
7. Click **Add code**. The default language is `Pyspark`. You are going to use a mix of Pyspark and Spark SQL, so the default choice is fine. Other supported languages are Scala and .NET for Spark.
8. Next you create a simple Spark DataFrame object to manipulate. In this case, you create it from code. There are three rows and three columns:

```
new_rows = [('CA',22, 45000),("WA",35,65000) ,("WA",50,85000)]
demo_df = spark.createDataFrame(new_rows, ['state', 'age', 'salary'])
demo_df.show()
```

9. Now run the cell using one of the following methods:
   - Press **SHIFT + ENTER**.
   - Select the blue play icon to the left of the cell.
   - Select the **Run all** button on the toolbar.



10. If the Apache Spark pool instance isn't already running, it is automatically started. You can see the Apache Spark pool instance status below the cell you are running and also on the status panel at the bottom of the notebook. Depending on the size of pool, starting should take 2-5 minutes. Once the code has finished running, information below the cell displays showing how long it took to run and its execution. In the output cell, you see the output.



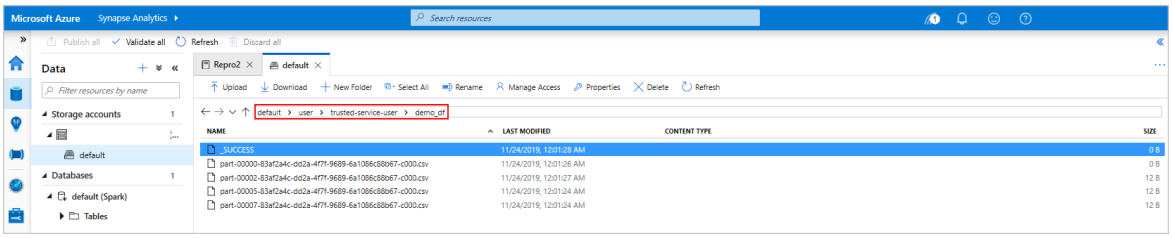
11. The data now exists in a DataFrame from there you can use the data in many different ways. You are going to need it in different formats for the rest of this quickstart.

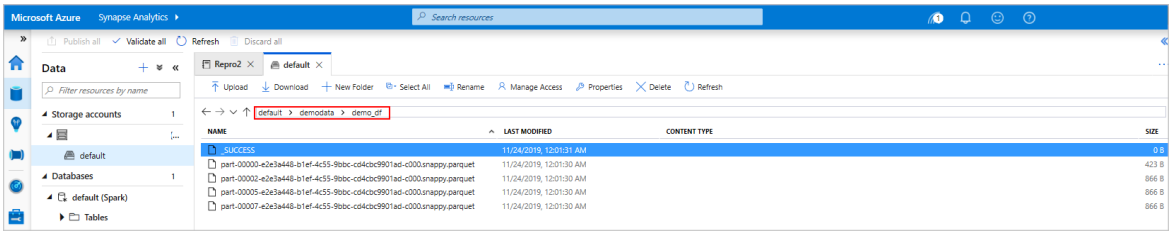
12. Enter the code below in another cell and run it, this creates a Spark table, a CSV, and a Parquet file all with copies of the data:

```
demo_df.createOrReplaceTempView('demo_df')
demo_df.write.csv('demo_df', mode='overwrite')
demo_df.write.parquet('abfss://<<TheNameOfAStorageAccountFileSystem>>@<<TheNameOfAStorageAccount>>.dfs.core.windows.net/demodata/demo_df', mode='overwrite')
```

If you use the storage explorer, it's possible to see the impact of the two different ways of writing a file used above. When no file system is specified then the default is used, in this case `default>user>trusted-service-user>demo_df`. The data is saved to the location of the specified file system.

Notice in both the "csv" and "parquet" formats, write operations a directory is created with many partitioned files.





Run Spark SQL statements

Structured Query Language (SQL) is the most common and widely used language for querying and defining data. Spark SQL functions as an extension to Apache Spark for processing structured data, using the familiar SQL syntax.

1. Paste the following code in an empty cell, and then run the code. The command lists the tables on the pool.

   ```
   %%sql
   SHOW TABLES
   ```

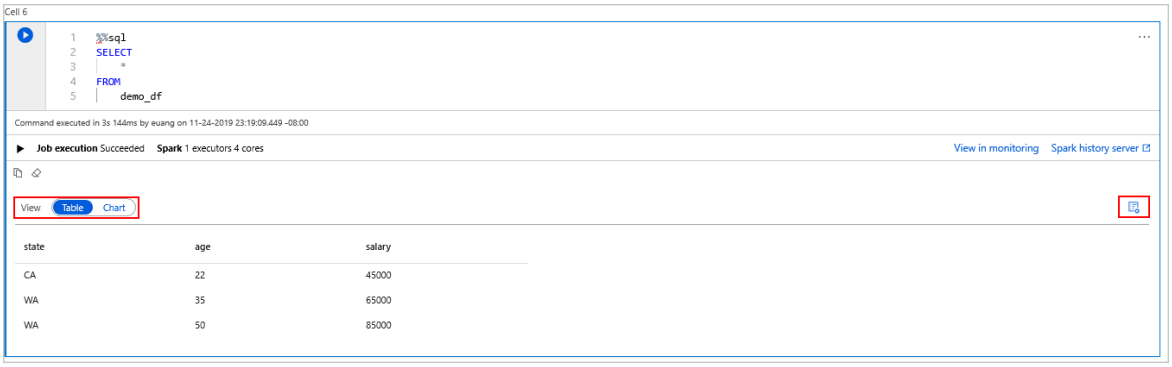
   When you use a Notebook with your Azure Synapse Apache Spark pool, you get a preset `sqlContext` that you can use to run queries using Spark SQL. `%%sql` tells the notebook to use the preset `sqlContext` to run the query. The query retrieves the top 10 rows from a system table that comes with all Azure Synapse Apache Spark pools by default.

2. Run another query to see the data in `demo_df`.

   ```
   %%sql
   SELECT * FROM demo_df
   ```

   The code produces two output cells, one that contains data results the other, which shows the job view.

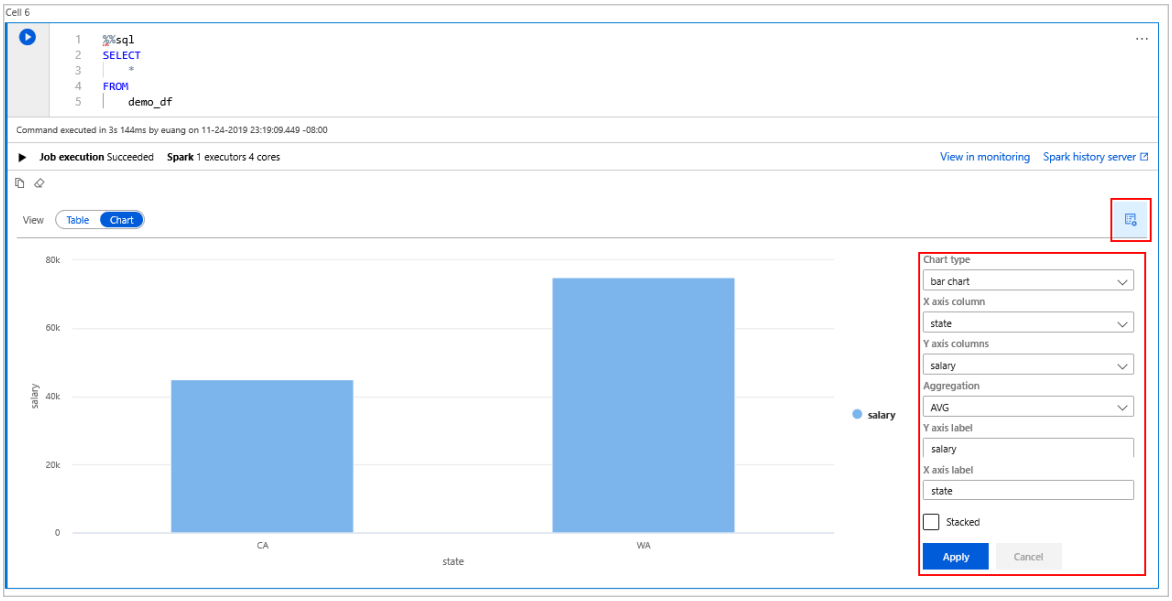
   By default the results view shows a grid. But, there is a view switcher underneath the grid that allows the view to switch between grid and graph views.



3. In the **View** switcher, select **Chart**.

4. Select the **View options** icon from the far right-hand side.

5. In the **Chart type** field, select "bar chart".
6. In the X-axis column field, select "state".
7. In the Y-axis column field, select "salary".
8. In the **Aggregation** field, select to "AVG".
9. Select **Apply**.



10. It is possible to get the same experience of running SQL but without having to switch languages. You can do this by replacing the SQL cell above with this PySpark cell, the output experience is the same because the **display** command is used:

```
display(spark.sql('SELECT * FROM demo_df'))
```

11. Each of the cells that previously executed had the option to go to **History Server** and **Monitoring**. Clicking the links takes you to different parts of the User Experience.

> **NOTE**
> Some of the Apache Spark official documentation relies on using the Spark console, which is not available on Synapse Spark. Use the notebook or IntelliJ experiences instead.

Clean up resources

Azure Synapse saves your data in Azure Data Lake Storage. You can safely let a Spark instance shut down when it is not in use. You are charged for a serverless Apache Spark pool as long as it is running, even when it is not in use.

Since the charges for the pool are many times more than the charges for storage, it makes economic sense to let Spark instances shut down when they are not in use.

To ensure the Spark instance is shut down, end any connected sessions(notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **end session** from the status bar at the bottom of the notebook.

Next steps

In this quickstart, you learned how to create a serverless Apache Spark pool and run a basic Spark SQL query.

Quickstart: Create a new serverless Apache Spark pool using the Azure portal

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics offers various analytics engines to help you ingest, transform, model, analyze, and distribute your data. An Apache Spark pool provides open-source big data compute capabilities. After you've created an Apache Spark pool in your Synapse workspace, data can be loaded, modeled, processed, and distributed for faster analytic insight.

In this quickstart, you learn how to use the Azure portal to create an Apache Spark pool in a Synapse workspace.

> **IMPORTANT**
> Billing for Spark instances is prorated per minute, whether you are using them or not. Be sure to shutdown your Spark instance after you have finished using it, or set a short timeout. For more information, see the **Clean up resources** section of this article.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

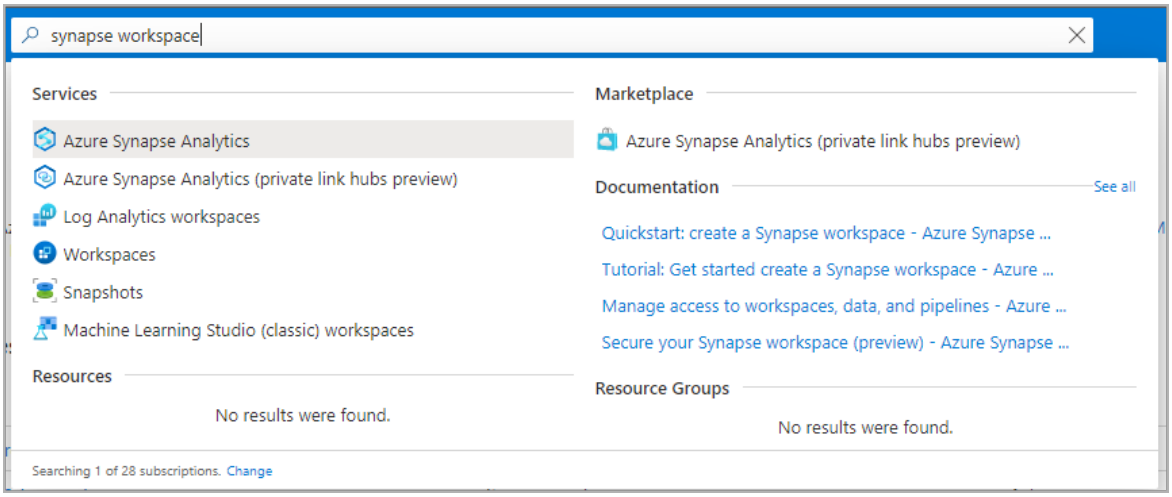
- Azure subscription - create one for free
- Synapse Analytics workspace

Sign in to the Azure portal

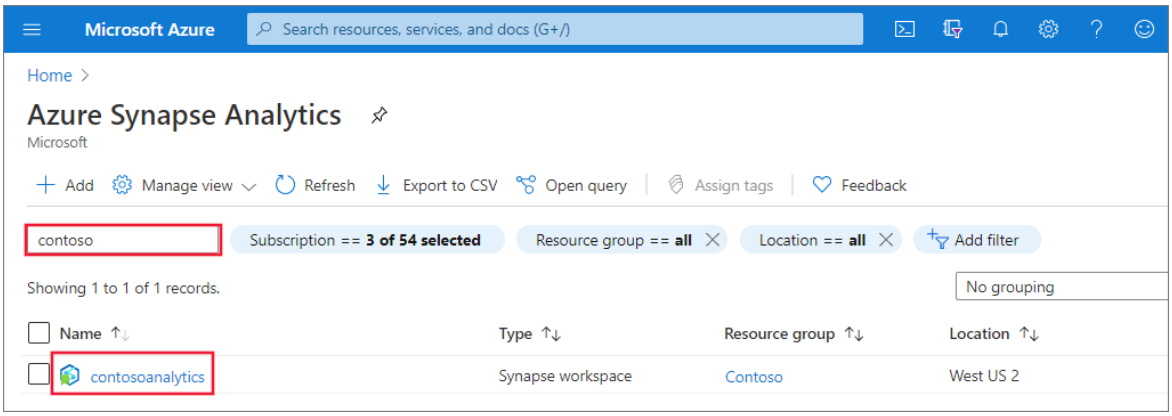
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the Apache Spark pool will be created by typing the service name (or resource name directly) into the search bar.

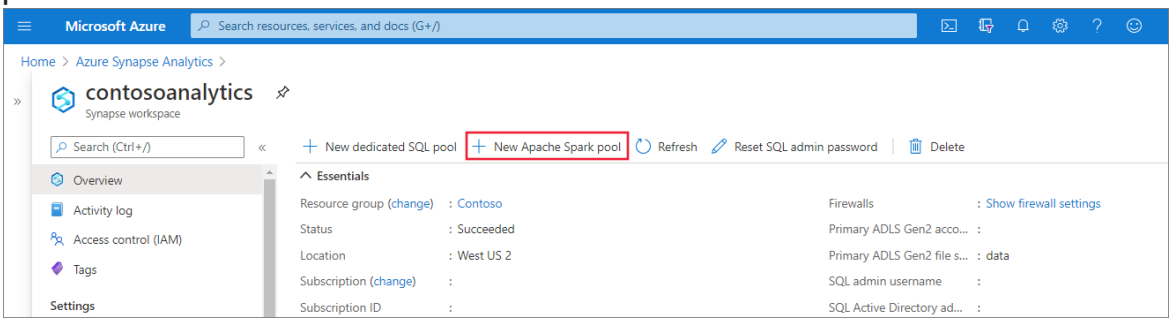


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



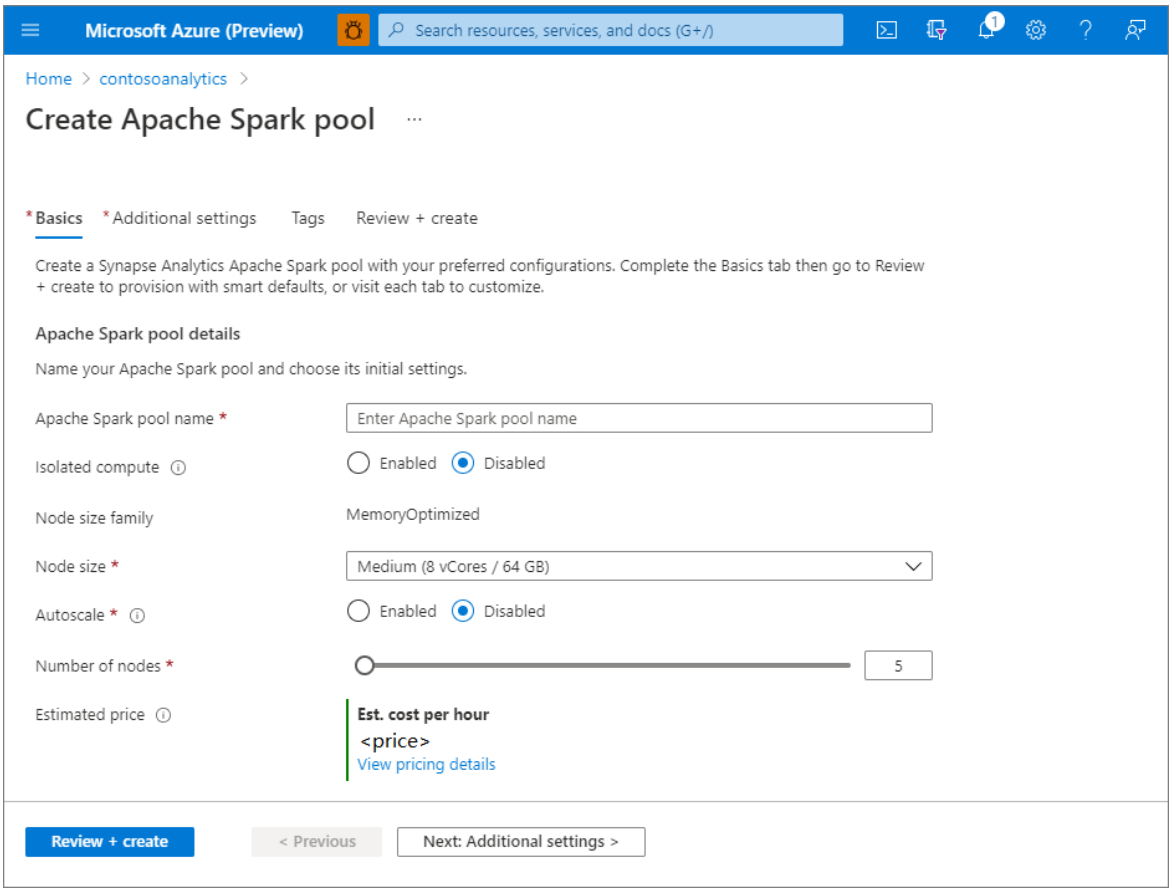
Create new Apache Spark pool

1. In the Synapse workspace where you want to create the Apache Spark pool, select **New Apache Spark pool**.



2. Enter the following details in the **Basics** tab:

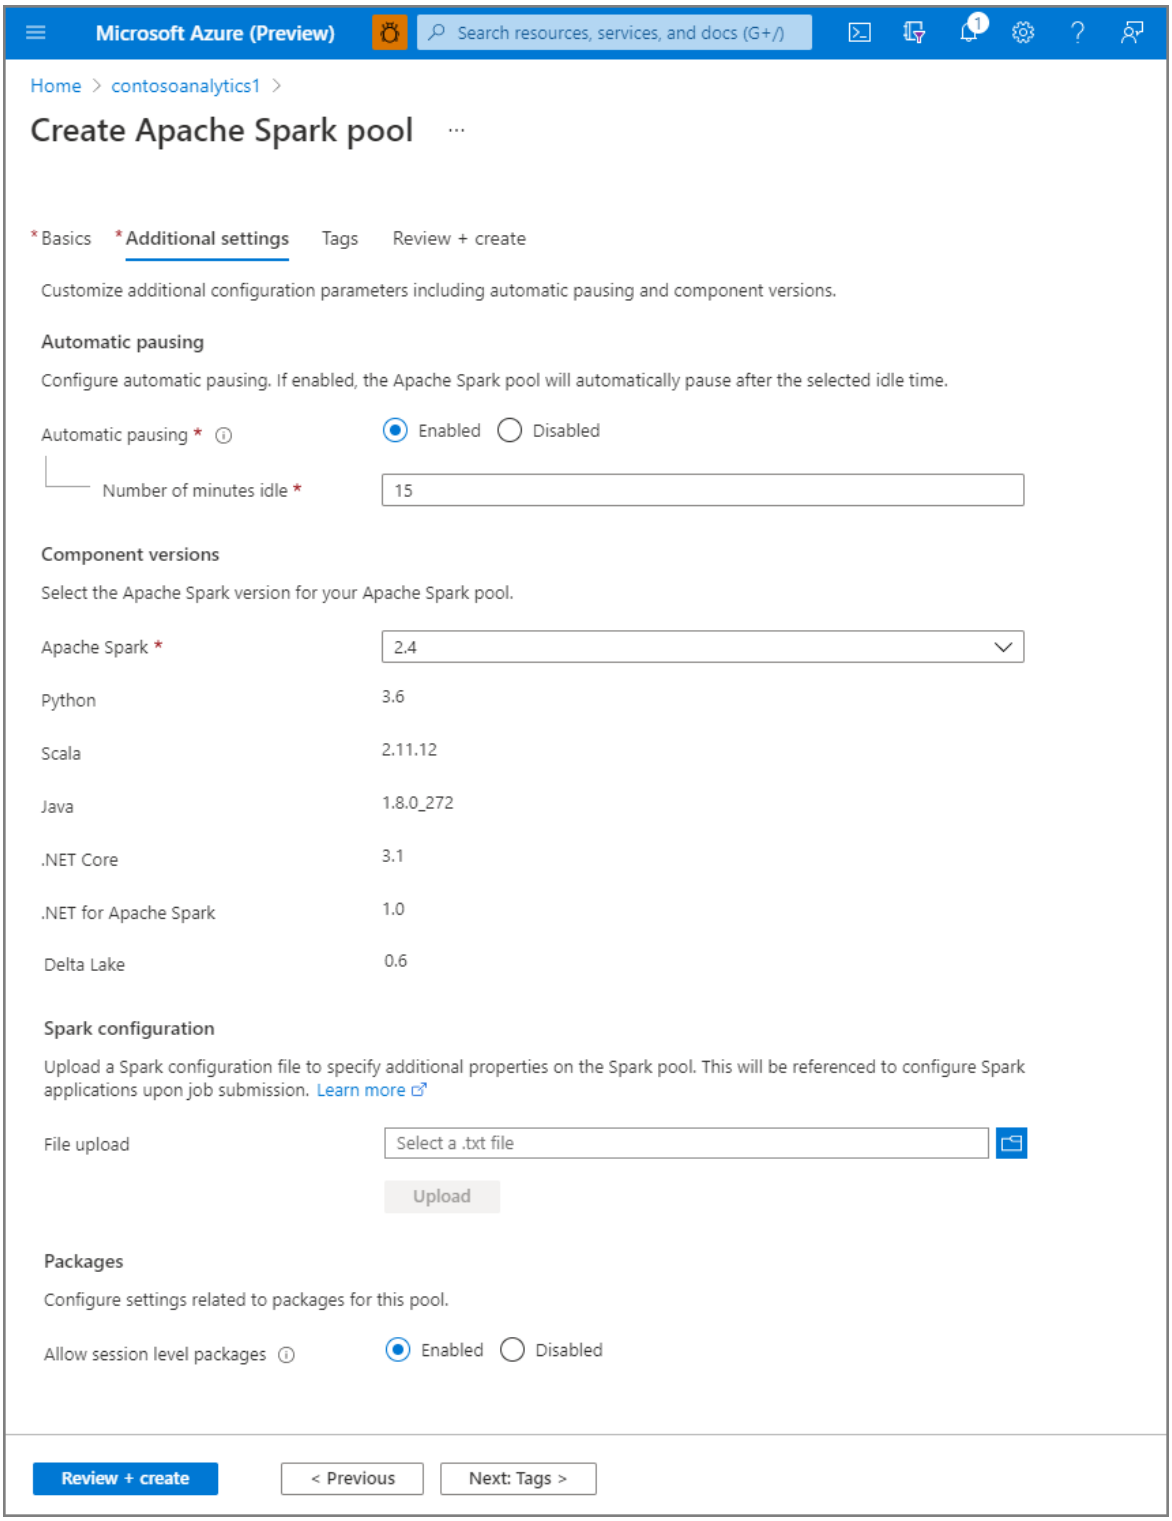
SETTING	SUGGESTED VALUE	DESCRIPTION
Apache Spark pool name	A valid pool name	This is the name that the Apache Spark pool will have.
Node size	Small (4 vCPU / 32 GB)	Set this to the smallest size to reduce costs for this quickstart
Autoscale	Disabled	We don't need autoscale for this quickstart
Number of nodes	5	Use a small size to limit costs for this quickstart



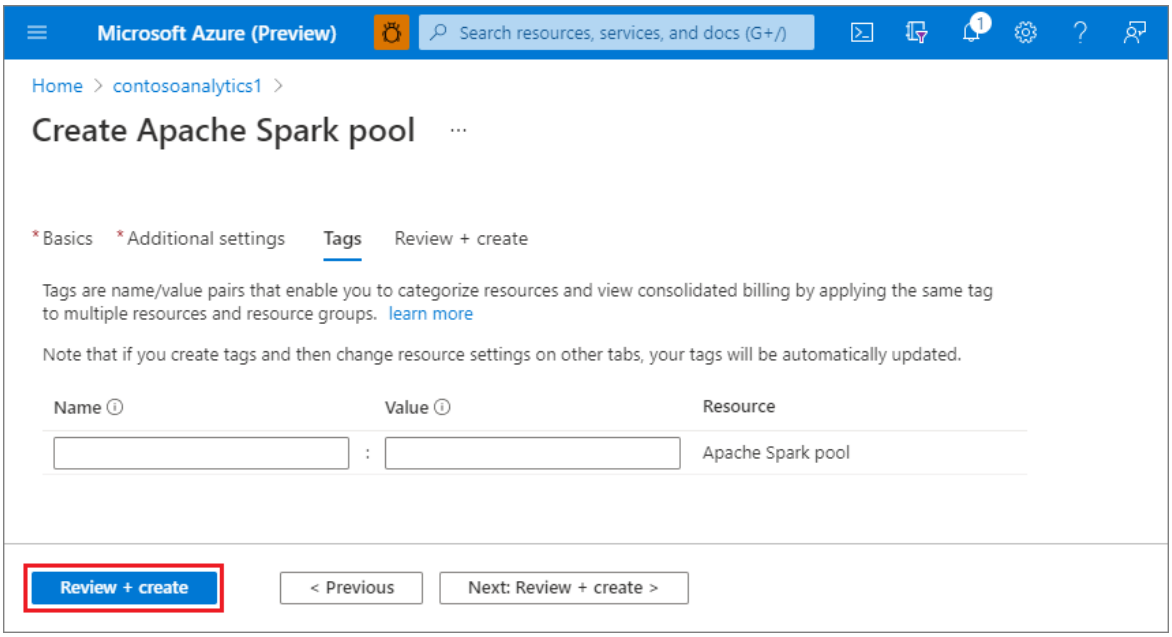
IMPORTANT

Note that there are specific limitations for the names that Apache Spark pools can use. Names must contain letters or numbers only, must be 15 or less characters, must start with a letter, not contain reserved words, and be unique in the workspace.

3. Select **Next: additional settings** and review the default settings. Do not modify any default settings.

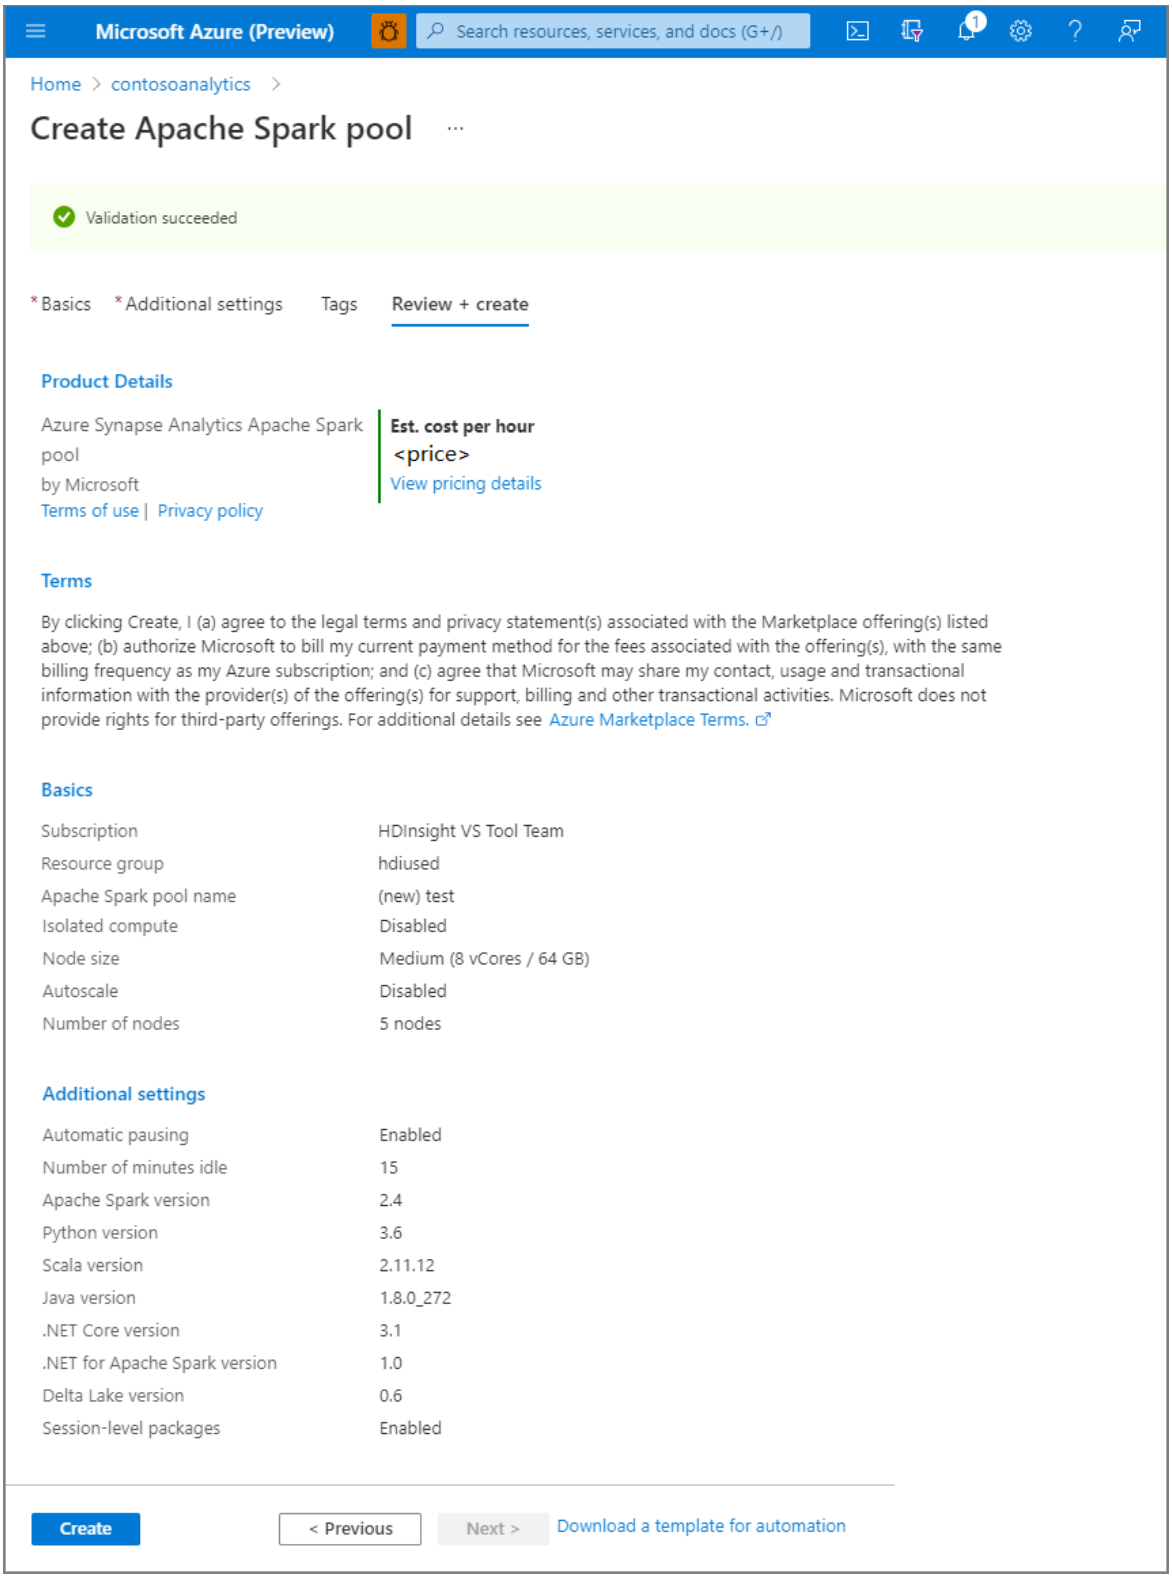


4. Select **Next: tags**. Don't add any tags.

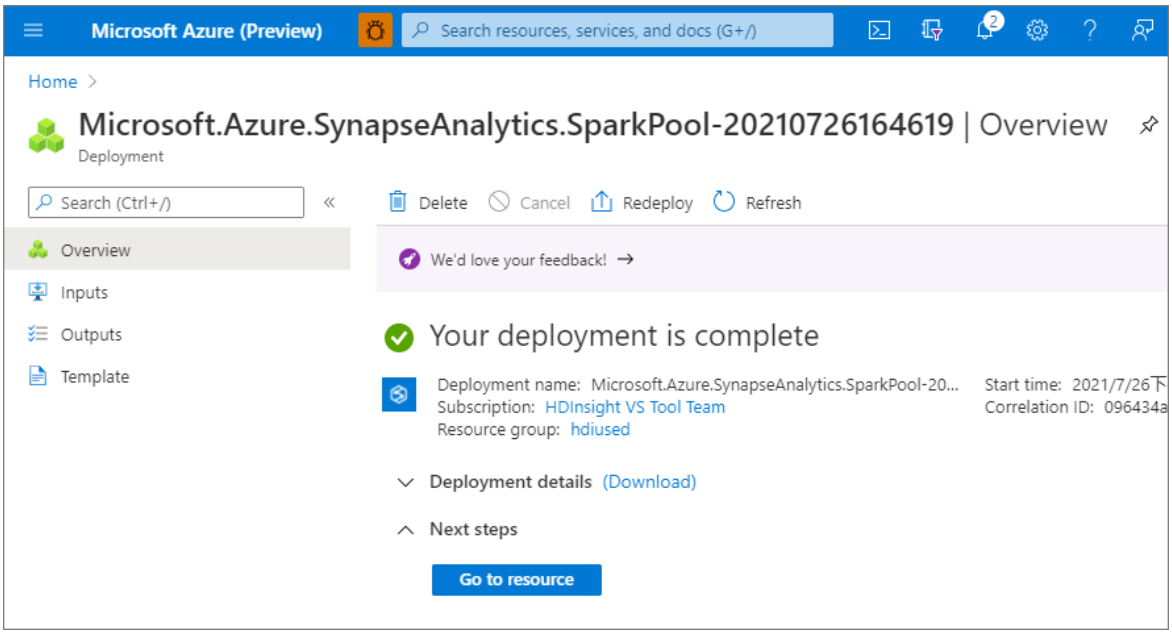


5. Select **Review + create**.

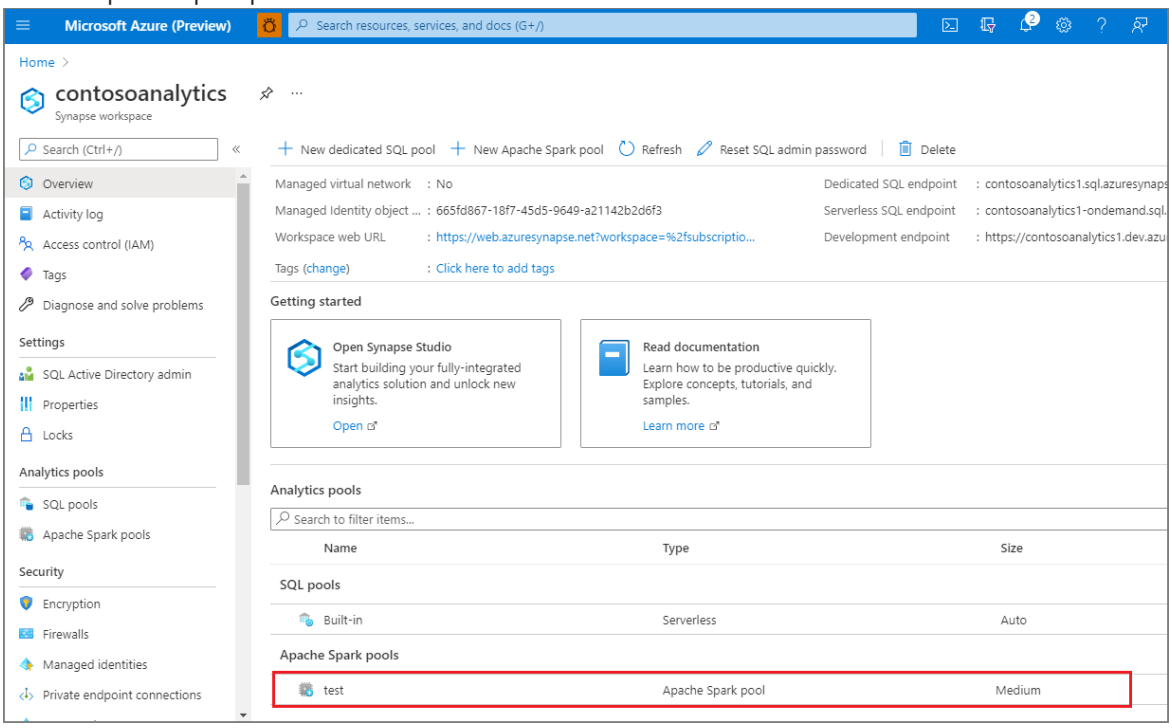
6. Make sure that the details look correct based on what was previously entered, and select **Create**.



7. At this point, the resource provisioning flow will start, indicating once it's complete.



8. After the provisioning completes, navigating back to the workspace will show a new entry for the newly created Apache Spark pool.



9. At this point, there are no resources running, no charges for Spark, you have created metadata about the Spark instances you want to create.

Clean up resources

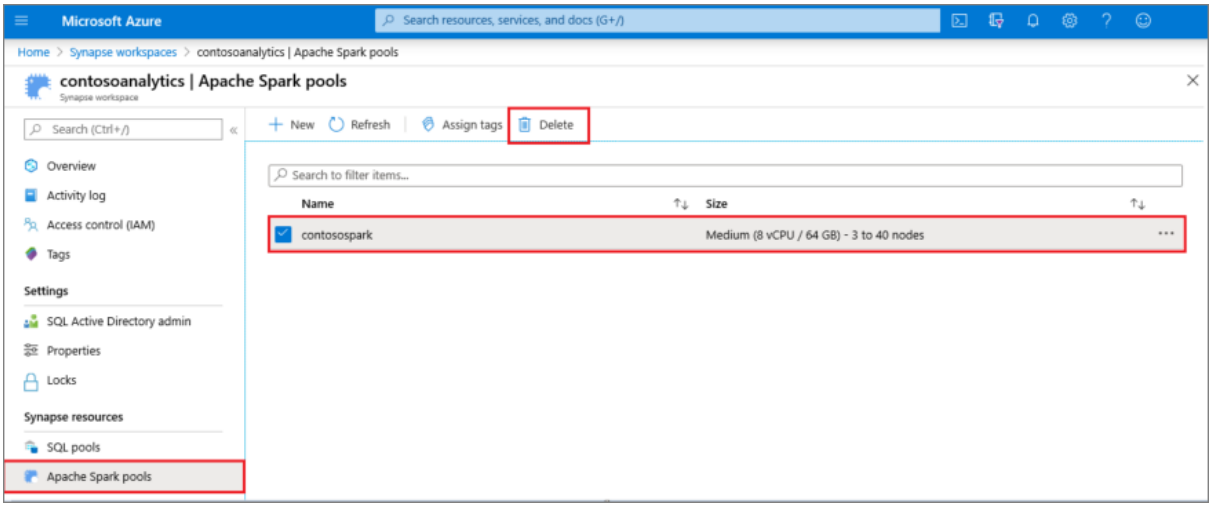
Follow the steps below to delete the Apache Spark pool from the workspace.

> **WARNING**
> Deleting an Apache Spark pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, and notebooks that use this Apache Spark pool will no longer work.

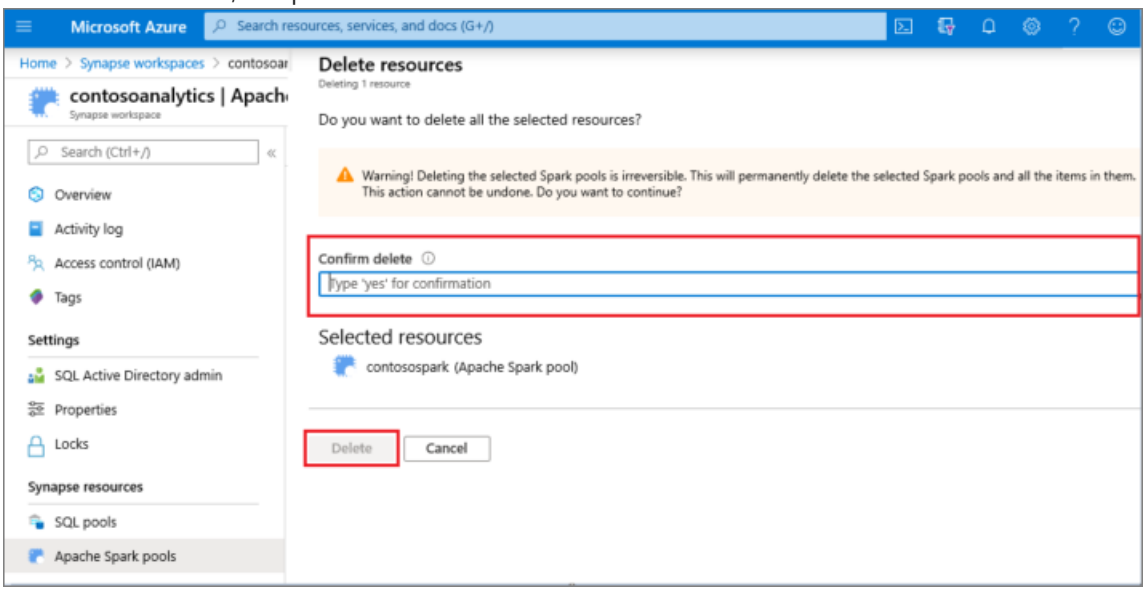
If you want to delete the Apache Spark pool, do the following:

1. Navigate to the Apache Spark pools blade in the workspace.

2. Select the Apache Spark pool to be deleted (in this case, **contosospark**).
3. Press **delete**.



4. Confirm the deletion, and press **Delete** button.



5. When the process completes successfully, the Apache Spark pool will no longer be listed in the workspace resources.

Next steps

- See Quickstart: Create an Apache Spark notebook.
- See Quickstart: Create a dedicated SQL pool using the Azure portal.

Quickstart: Create a serverless Apache Spark pool using Synapse Studio

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics offers various analytics engines to help you ingest, transform, model, analyze, and serve your data. Apache Spark pool offers open-source big data compute capabilities. After creating an Apache Spark pool in your Synapse workspace, data can be loaded, modeled, processed, and served to obtain insights.

This quickstart describes the steps to create an Apache Spark pool in a Synapse workspace by using Synapse Studio.

> **IMPORTANT**
> Billing for Spark instances is prorated per minute, whether you are using them or not. Be sure to shutdown your Spark instance after you have finished using it, or set a short timeout. For more information, see the **Clean up resources** section of this article.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

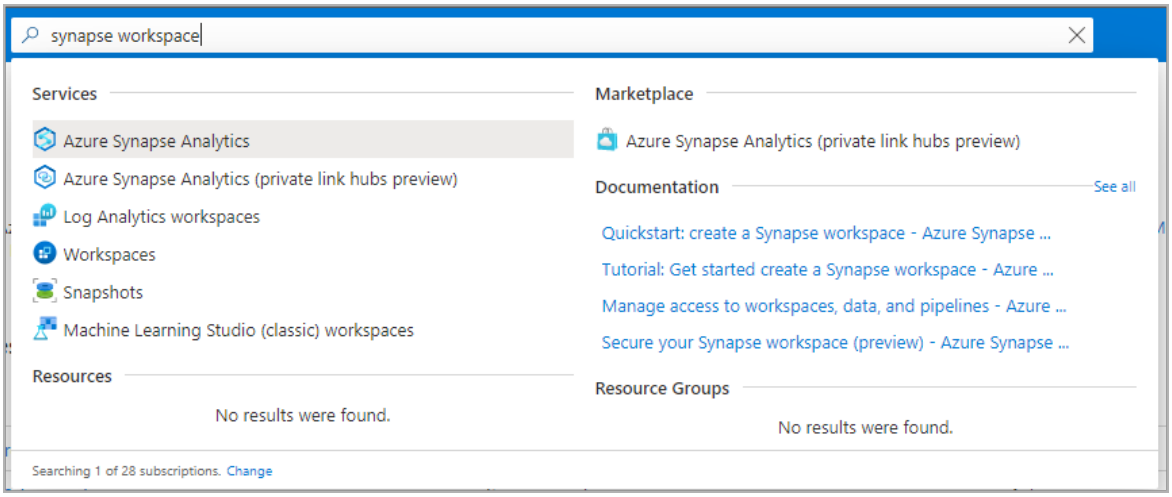
- Azure subscription - create one for free
- Synapse workspace

Sign in to the Azure portal

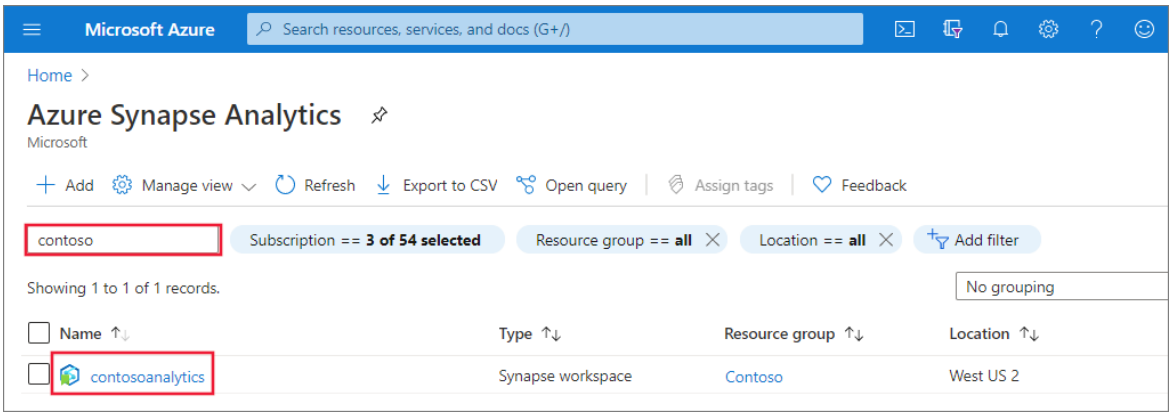
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the Apache Spark pool will be created by typing the service name (or resource name directly) into the search bar.

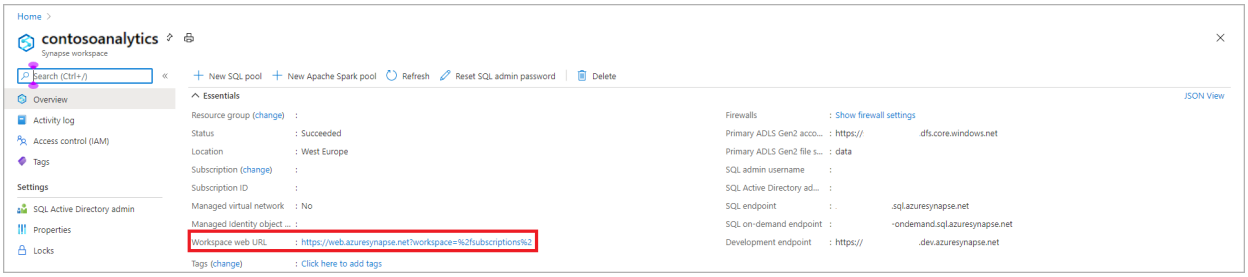


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



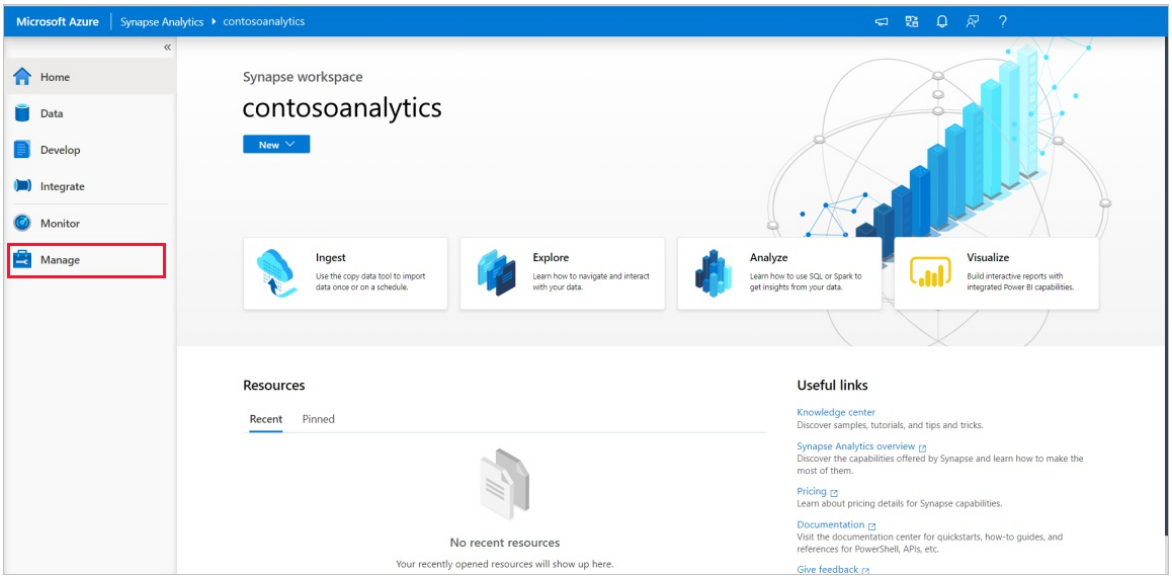
Launch Synapse Studio

From the workspace overview, select the **Workspace web URL** to open Synapse Studio.

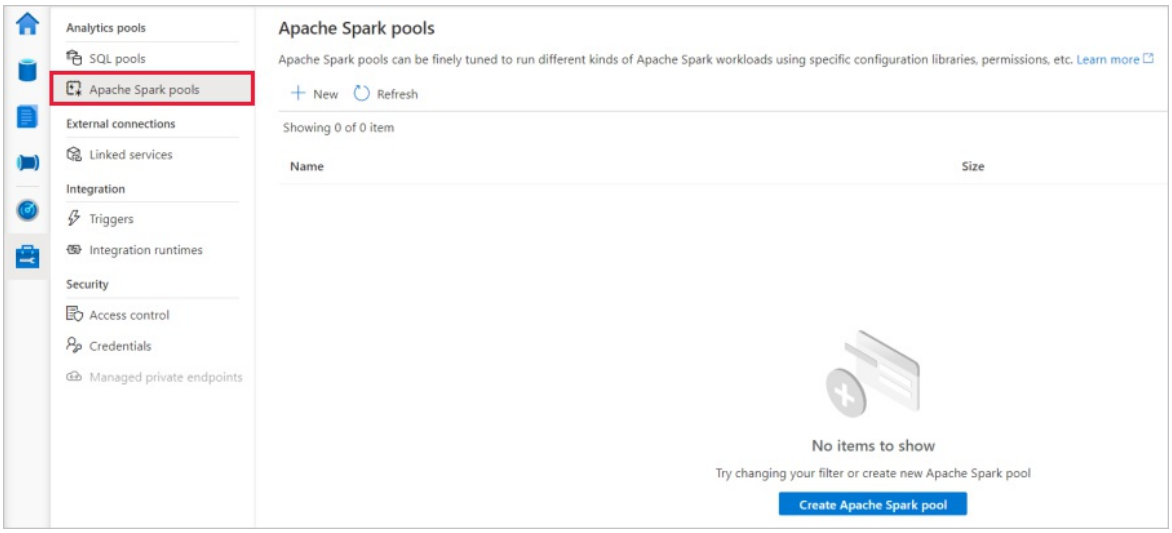


Create the Apache Spark pool in Synapse Studio

1. On the Synapse Studio home page, navigate to the **Management Hub** in the left navigation by selecting the **Manage** icon.



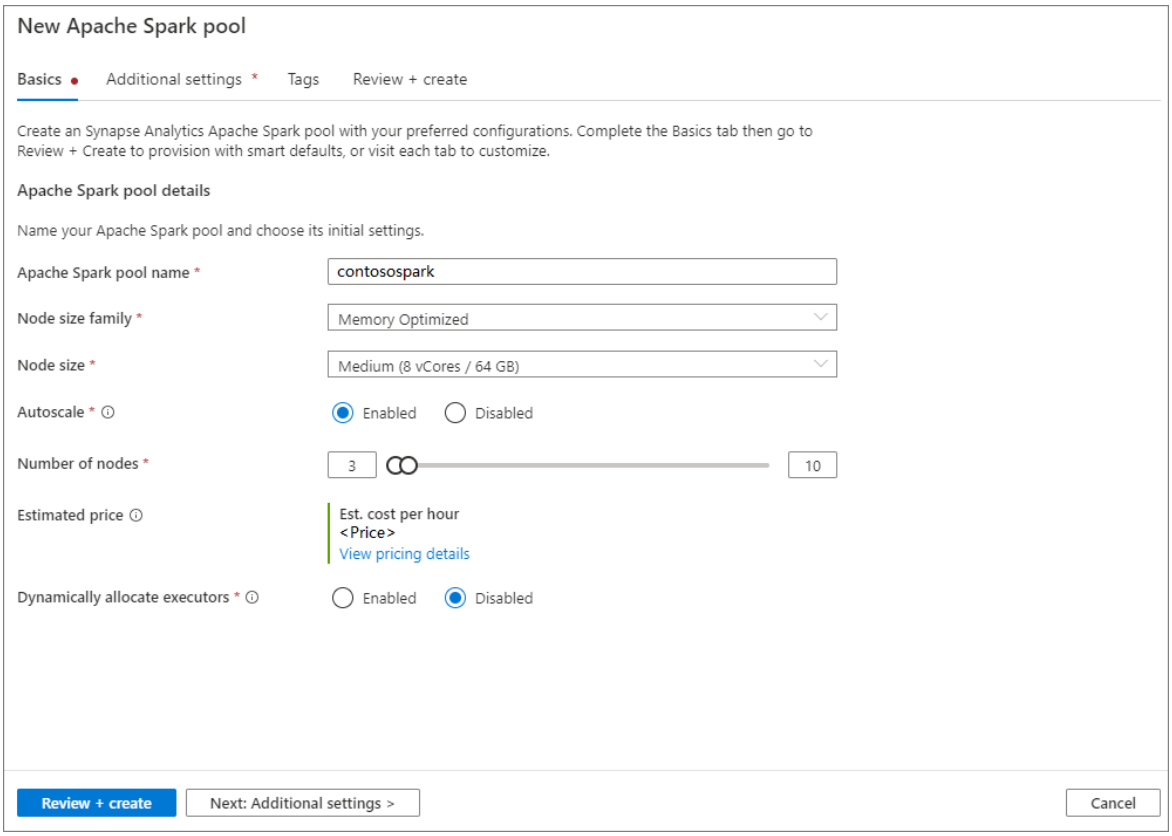
2. Once in the Management Hub, navigate to the **Apache Spark pools** section to see the current list of Apache Spark pools that are available in the workspace.



3. Select **+ New** and the new Apache Spark pool create wizard will appear.

4. Enter the following details in the **Basics** tab:

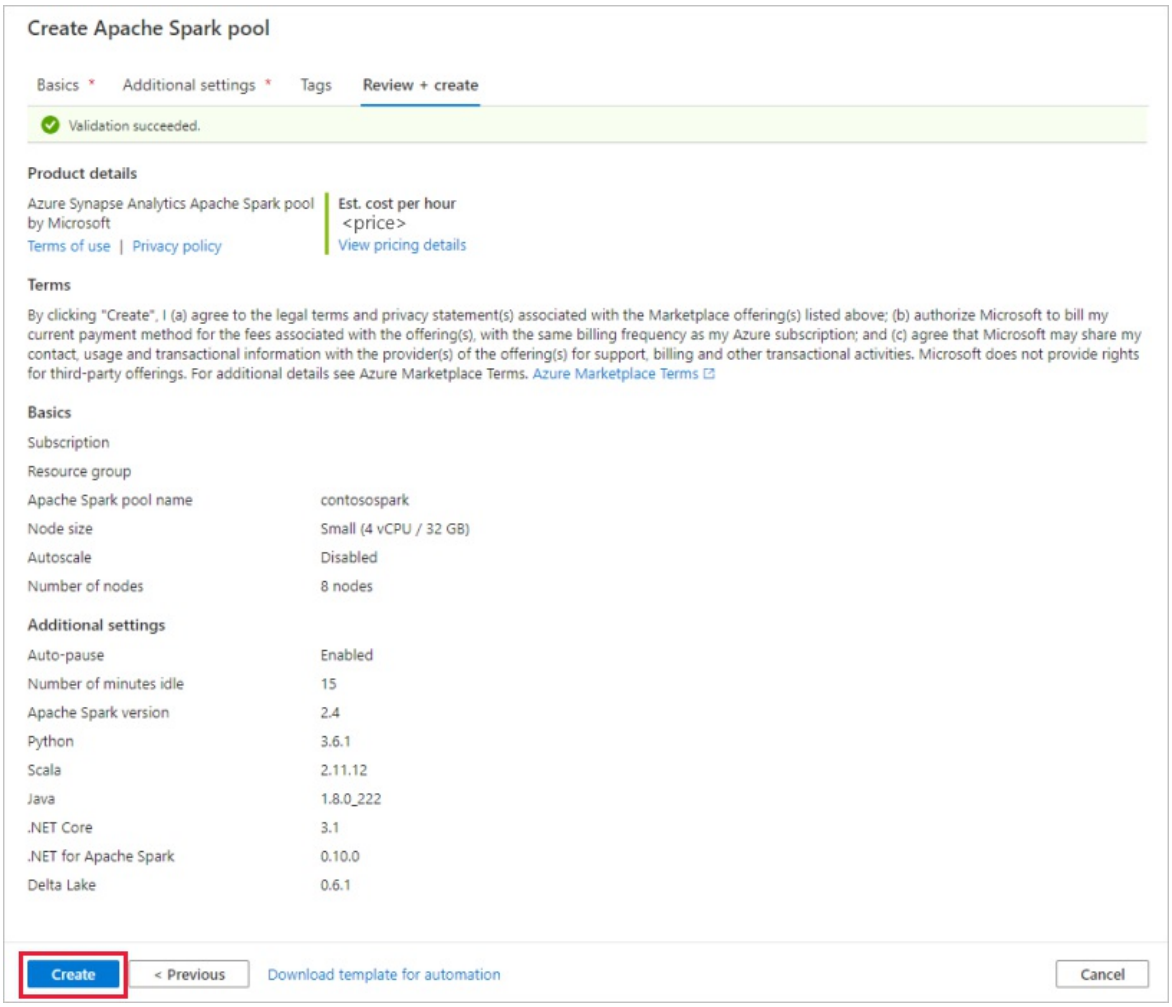
SETTING	SUGGESTED VALUE	DESCRIPTION
Apache Spark pool name	contosospark	This is the name that the Apache Spark pool will have.
Node size	Small (4 vCPU / 32 GB)	Set this to the smallest size to reduce costs for this quickstart
Autoscale	Disabled	We won't need autoscale in this quickstart
Number of nodes	8	Use a small size to limit costs in this quickstart
Dynamically allocate executors	Disabled	This setting maps to the dynamic allocation property in Spark configuration for Spark Application executors allocation. We won't need autoscale in this quickstart.



IMPORTANT

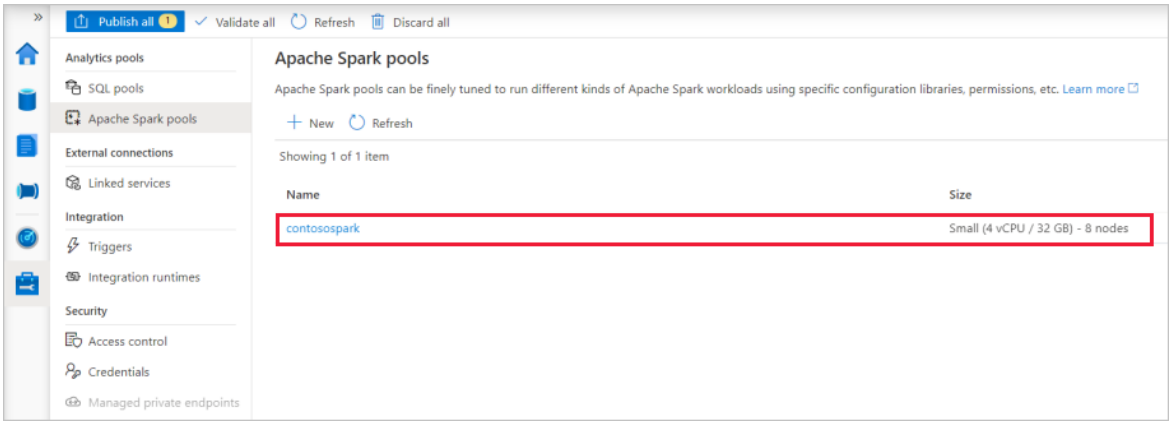
Note that there are specific limitations for the names that Apache Spark pools can use. Names must contain letters or numbers only, must be 15 or less characters, must start with a letter, not contain reserved words, and be unique in the workspace.

5. In the next tab (Additional settings), leave all settings as defaults.
6. We won't add any tags for now, so select **Review + create**.
7. In the **Review + create** tab, make sure that the details look correct based on what was previously entered, and press **Create**.



8. The Apache Spark pool will start the provisioning process.

9. Once the provisioning is complete, the new Apache Spark pool will appear in the list.



Clean up Apache Spark pool resources using Synapse Studio

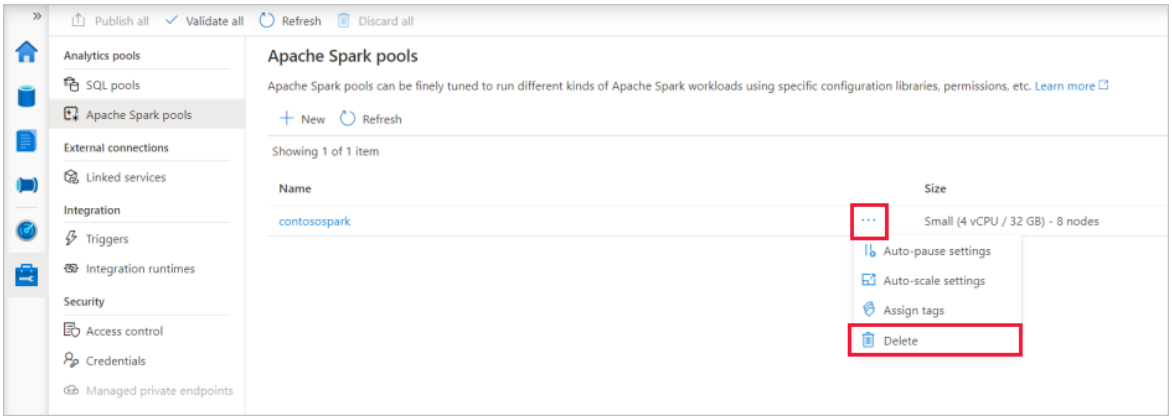
Follow the steps below to delete the Apache Spark pool from the workspace using Synapse Studio.

> **WARNING**
> Deleting a Spark pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, and notebooks that use this Spark pool will no longer work.

If you want to delete the Apache Spark pool, do the following:

1. Navigate to the Apache Spark pools in the Management Hub in Synapse Studio.

2. Select the ellipsis next to the Apache pool to be deleted (in this case, **contosospark**) to show the commands for the Apache Spark pool.



3. Press **delete**.

4. Confirm the deletion, and press **Delete** button.

5. When the process completes successfully, the Apache Spark pool will no longer be listed in the workspace resources.

Next steps

- See Quickstart: Create an Apache Spark pool in Synapse Studio using web tools.
- See Quickstart: Create an Apache Spark pool using the Azure portal.

Quickstart: Create an Apache Spark GPU-enabled Pool in Azure Synapse Analytics using the Azure portal

8/19/2022 • 2 minutes to read • Edit Online

An Apache Spark pool provides open-source big data compute capabilities where data can be loaded, modeled, processed, and distributed for faster analytic insight. Synapse now offers the ability to create Apache Spark pools that use GPUs on the backend to run your Spark workloads on GPUs for accelerated processing.

In this quickstart, you learn how to use the Azure portal to create an Apache Spark GPU-enabled pool in an Azure Synapse Analytics workspace.

> **NOTE**
> Azure Synapse GPU-enabled pools are currently in Public Preview.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

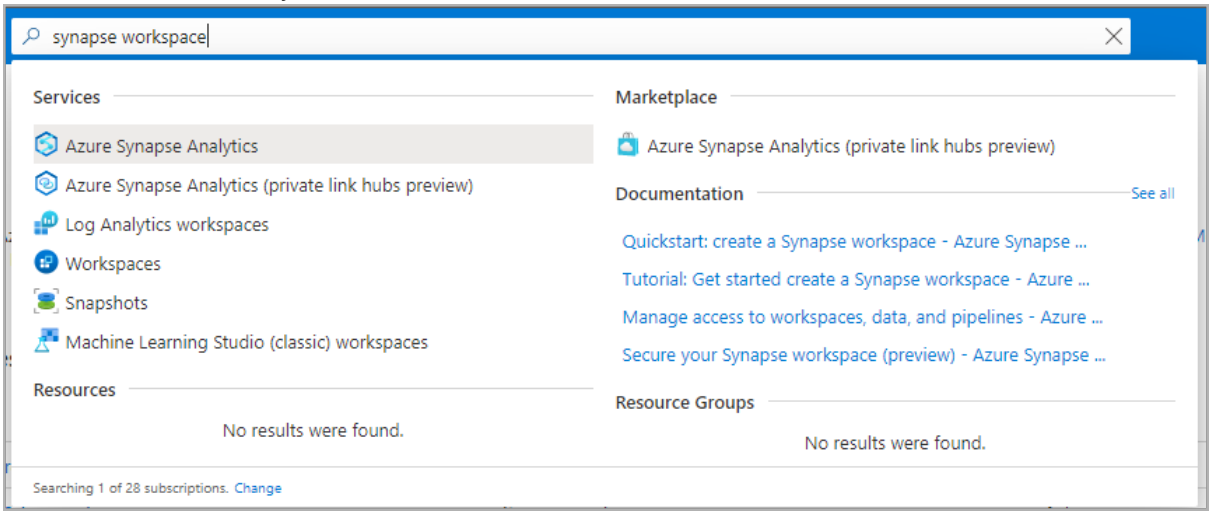
- Azure subscription - create one for free
- Synapse Analytics workspace

Sign in to the Azure portal

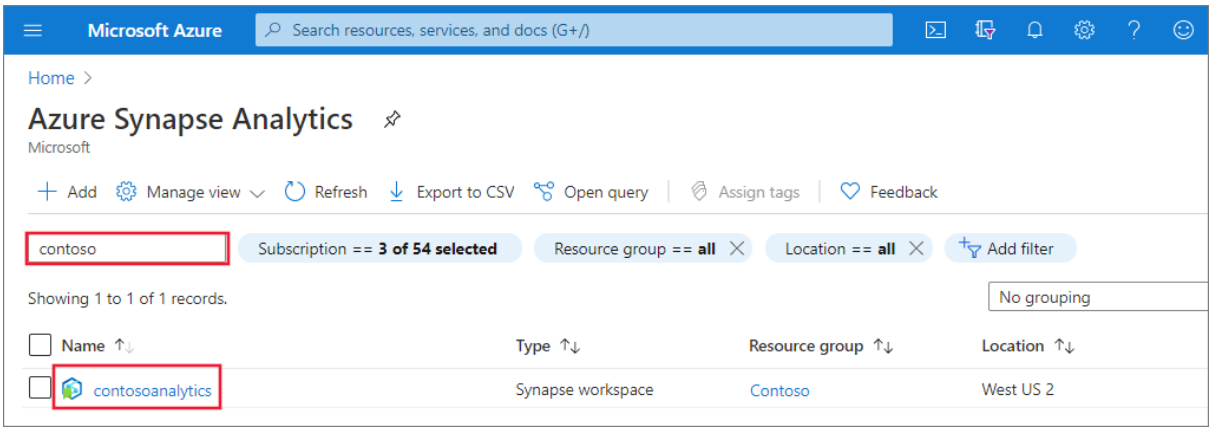
Sign in to the Azure portal

Navigate to the Synapse workspace

1. Navigate to the Synapse workspace where the Apache Spark pool will be created by typing the service name (or resource name directly) into the search bar.

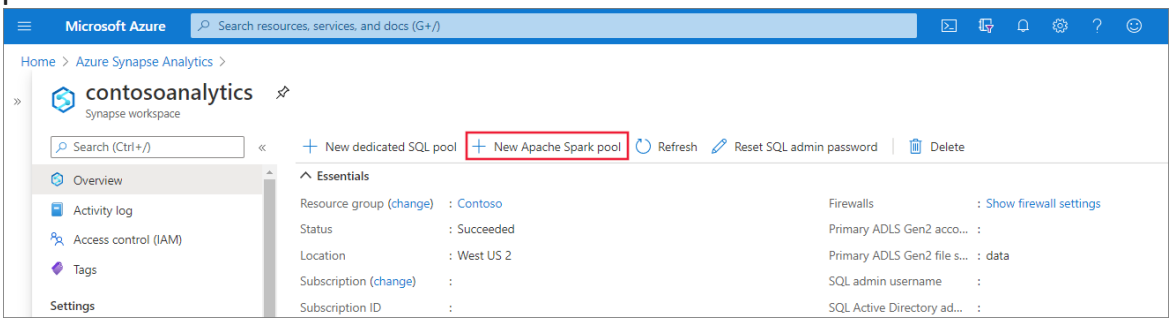


2. From the list of workspaces, type the name (or part of the name) of the workspace to open. For this example, we'll use a workspace named **contosoanalytics**.



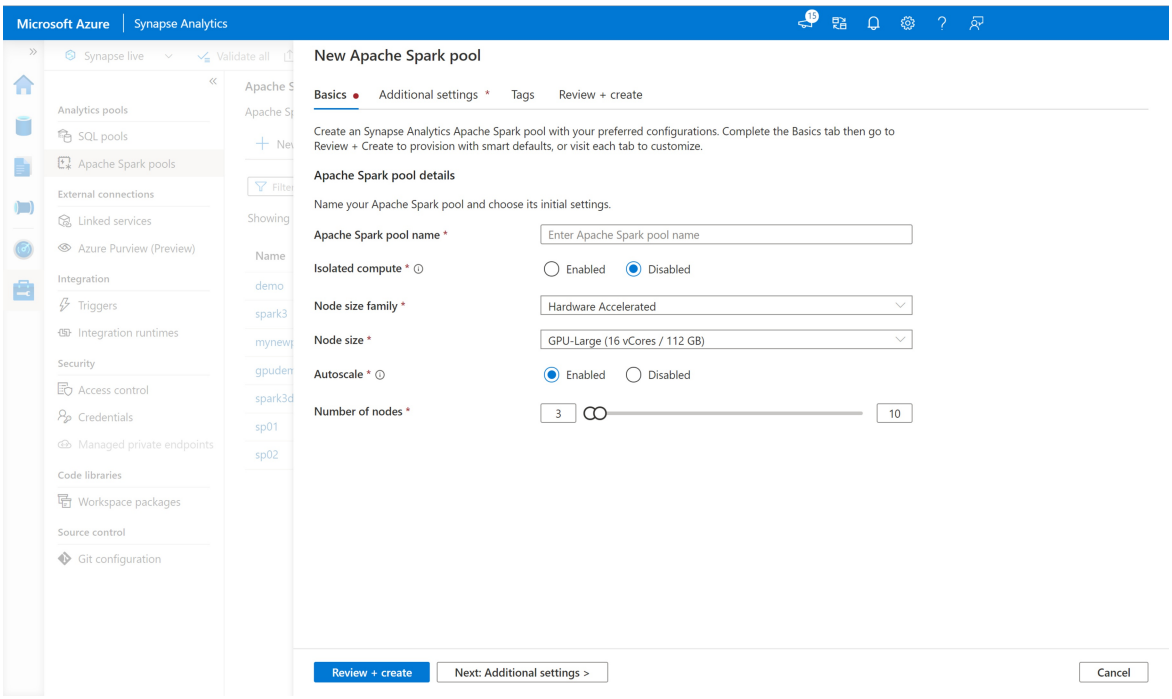
Create new Azure Synapse GPU-enabled pool

1. In the Synapse workspace where you want to create the Apache Spark pool, select **New Apache Spark pool**.



2. Enter the following details in the **Basics** tab:

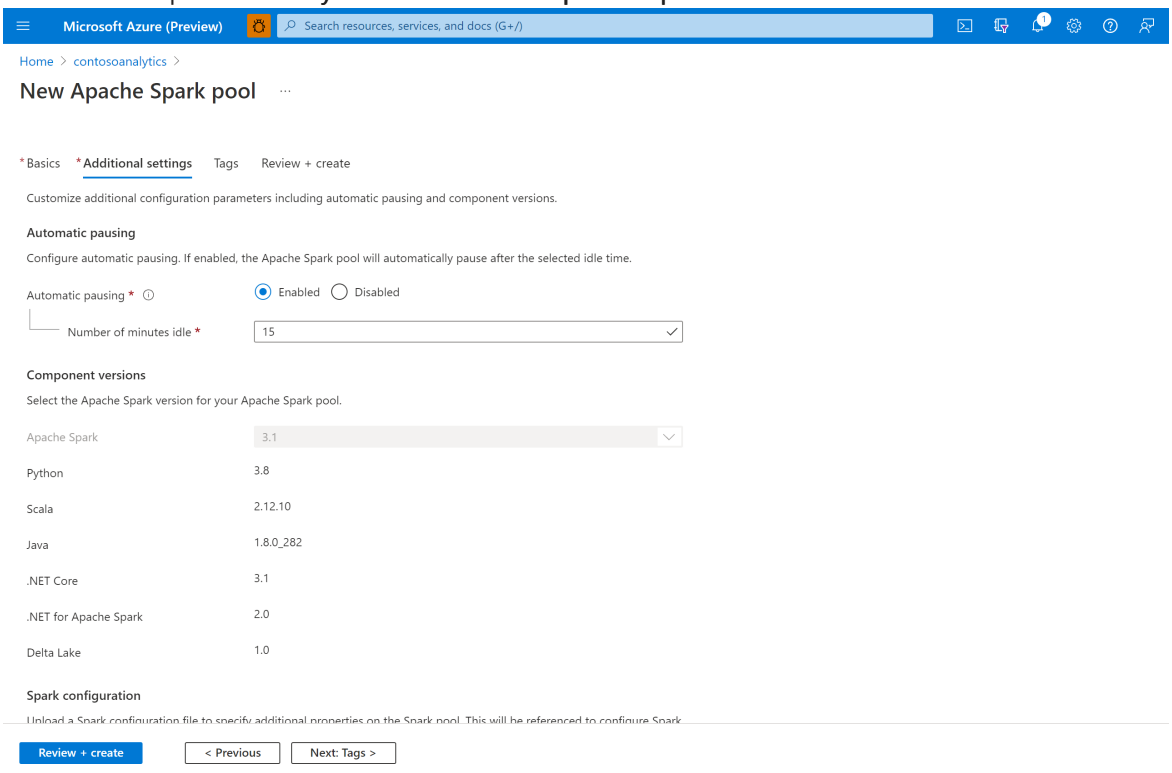
SETTING	SUGGESTED VALUE	DESCRIPTION
Apache Spark pool name	A valid pool name	This is the name that the Apache Spark pool will have.
Node size family	Hardware Accelerated	Choose Hardware Accelerated from the drop down menu
Node size	Large (16 vCPU / 110 GB / 1 GPU)	Set this to the smallest size to reduce costs for this quickstart
Autoscale	Disabled	We don't need autoscale for this quickstart
Number of nodes	3	Use a small size to limit costs for this quickstart



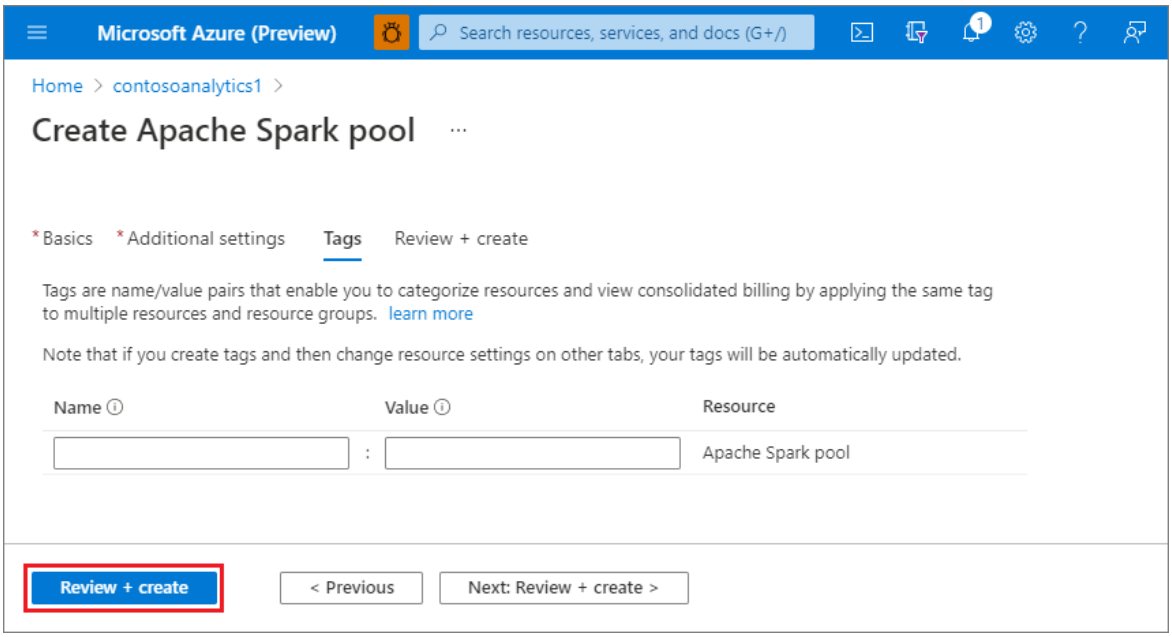
IMPORTANT

Note that there are specific limitations for the names that Apache Spark pools can use. Names must contain letters or numbers only, must be 15 or less characters, must start with a letter, not contain reserved words, and be unique in the workspace.

3. Select **Next: additional settings** and review the default settings. Do not modify any default settings. Note that GPU pools can **only be created with Apache Spark 3.1**.

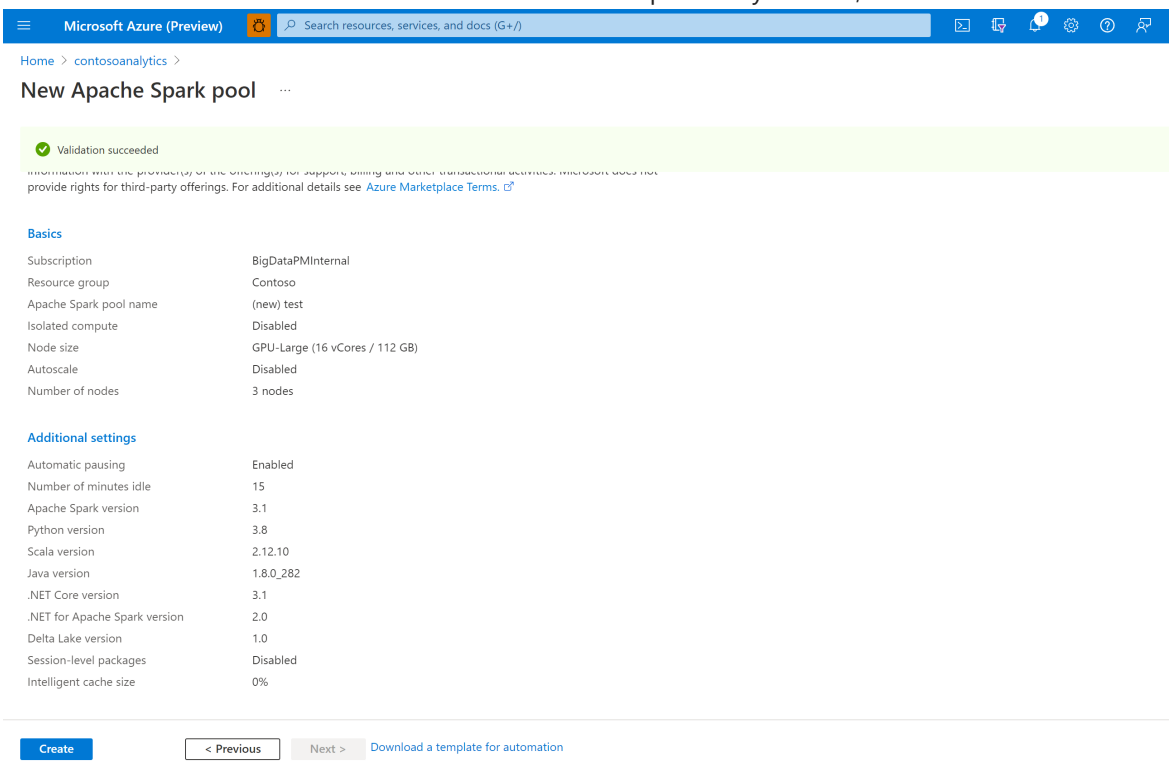


4. Select **Next: tags**. Don't add any tags.

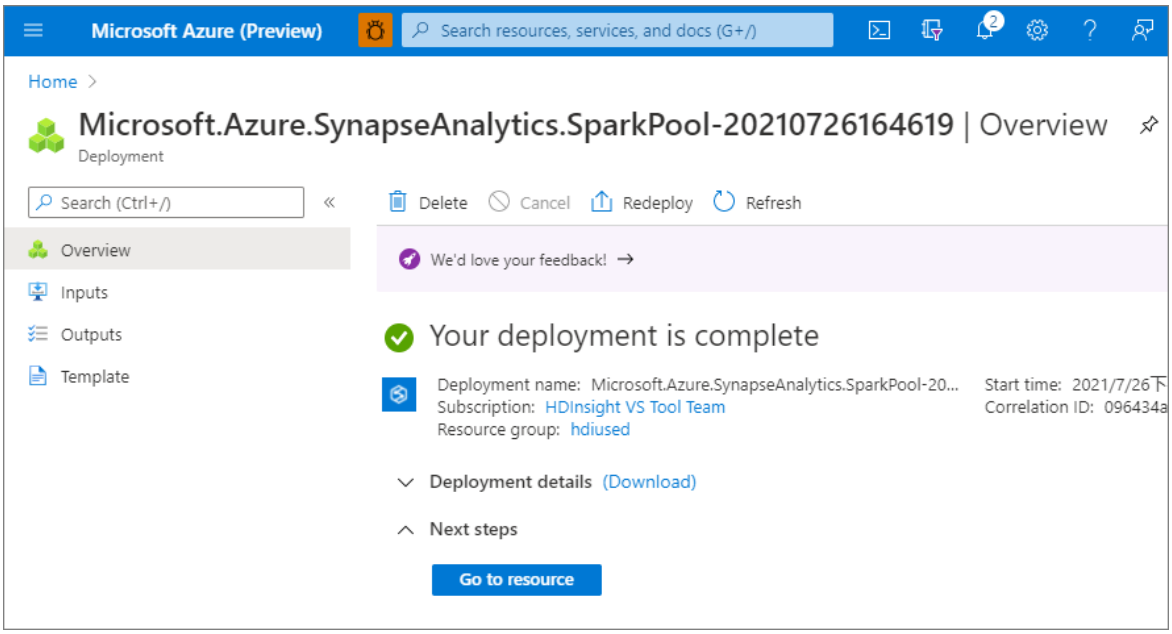


5. Select **Review + create**.

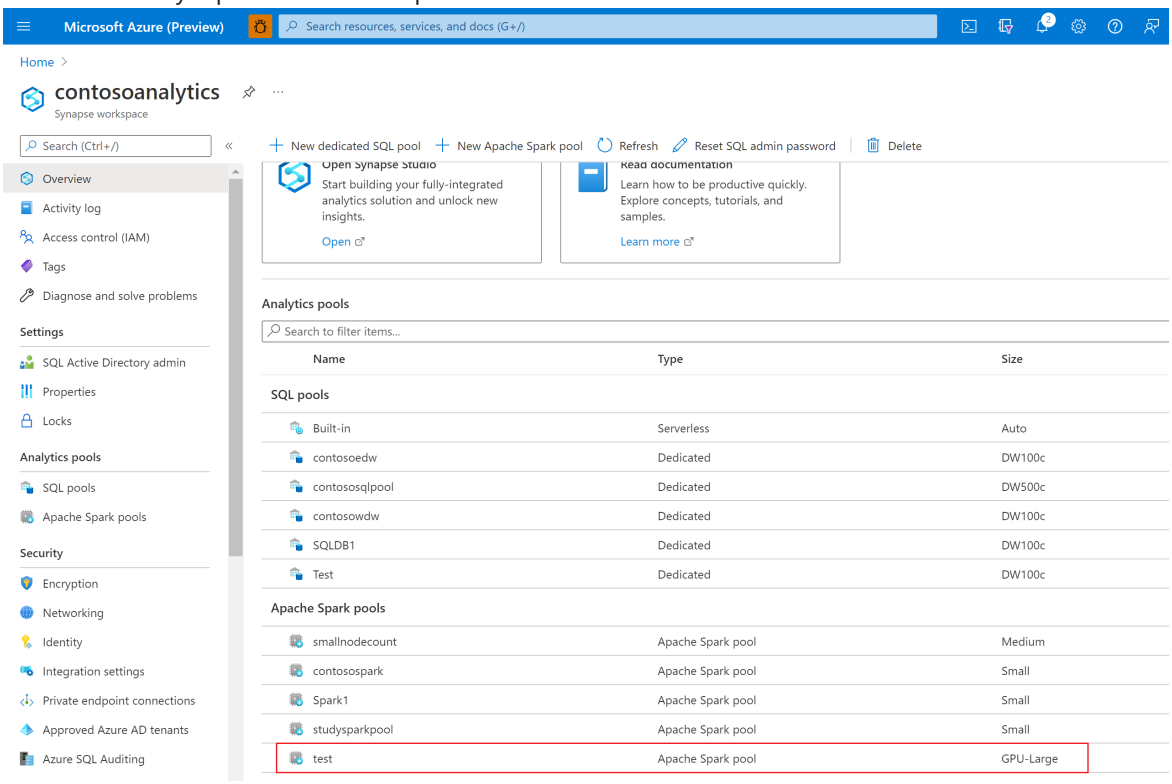
6. Make sure that the details look correct based on what was previously entered, and select **Create**.



7. At this point, the resource provisioning flow will start, indicating once it's complete.



8. After the provisioning completes, navigating back to the workspace will show a new entry for the newly created Azure Synapse GPU-enabled pool.



9. At this point, there are no resources running, no charges for Spark, you have created metadata about the Spark instances you want to create.

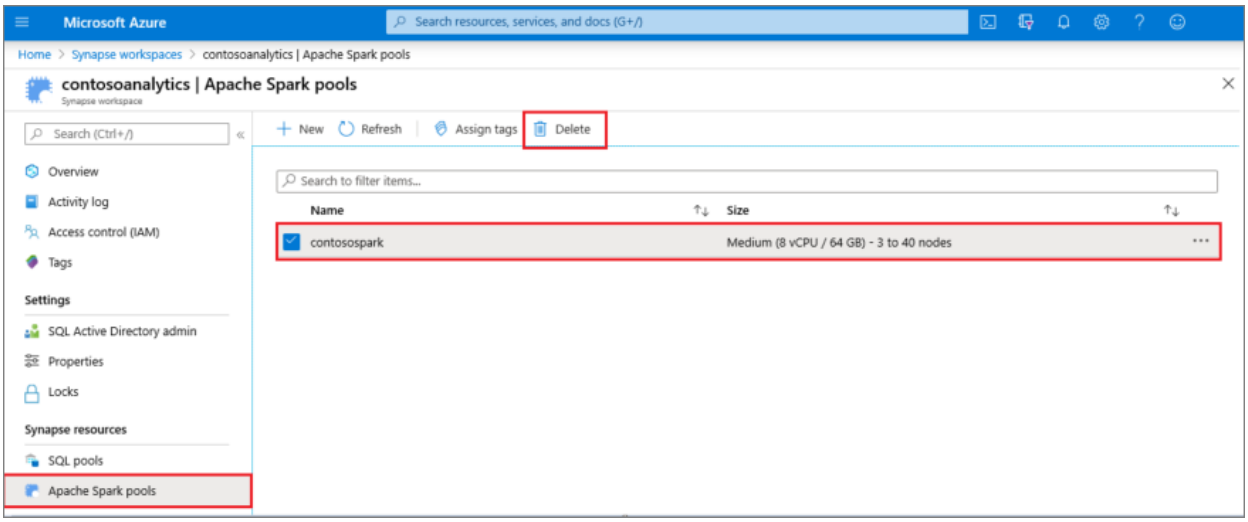
Clean up resources

Follow the steps below to delete the Apache Spark pool from the workspace.

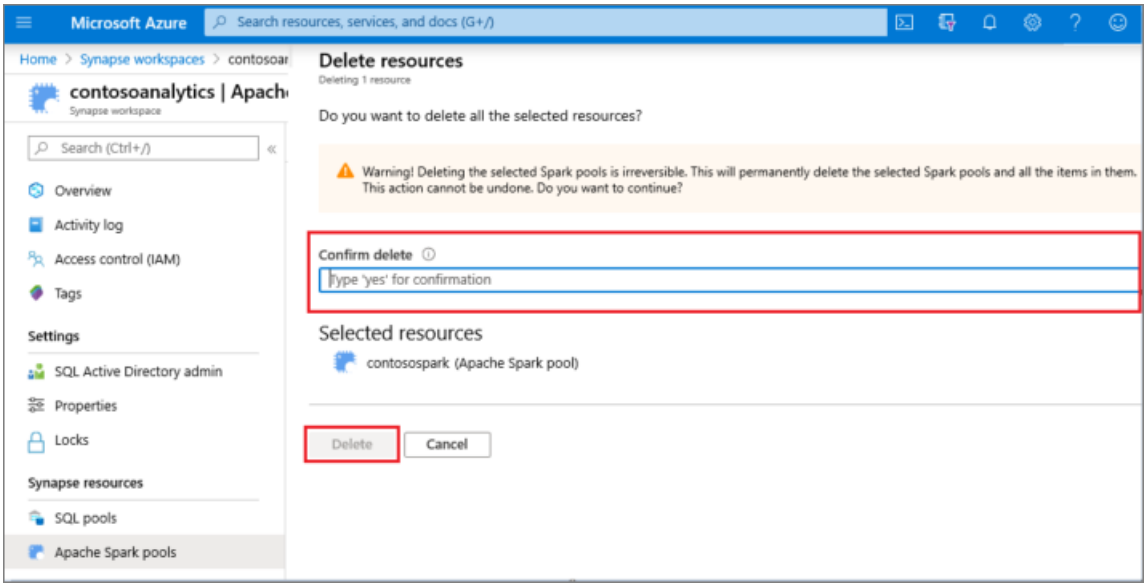
> **WARNING**
>
> Deleting an Apache Spark pool will remove the analytics engine from the workspace. It will no longer be possible to connect to the pool, and all queries, pipelines, and notebooks that use this Apache Spark pool will no longer work.

If you want to delete the Apache Spark pool, do the following:

1. Navigate to the Apache Spark pools blade in the workspace.
2. Select the Apache Spark pool to be deleted (in this case, **contosospark**).
3. Press **delete**.



4. Confirm the deletion, and press **Delete** button.



5. When the process completes successfully, the Apache Spark pool will no longer be listed in the workspace resources.

Next steps

- See Quickstart: Create an Apache Spark notebook to run on a GPU pool.

Analyze data with Apache Spark

8/19/2022 • 5 minutes to read • Edit Online

In this tutorial, you'll learn how to perform exploratory data analysis by using Azure Open Datasets and Apache Spark. You can then visualize the results in a Synapse Studio notebook in Azure Synapse Analytics.

In particular, we'll analyze the New York City (NYC) Taxi dataset. The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips: information about each trip, the start and end time and locations, the cost, and other interesting attributes.

Before you begin

Create an Apache Spark Pool by following the Create an Apache Spark pool tutorial.

Download and prepare the data

1. Create a notebook by using the PySpark kernel. For instructions, see Create a notebook.

   > **NOTE**
   > Because of the PySpark kernel, you don't need to create any contexts explicitly. The Spark context is automatically created for you when you run the first code cell.

2. In this tutorial, we'll use several different libraries to help us visualize the dataset. To do this analysis, import the following libraries:

   ```
   import matplotlib.pyplot as plt
   import seaborn as sns
   import pandas as pd
   ```

3. Because the raw data is in a Parquet format, you can use the Spark context to pull the file into memory as a DataFrame directly. Create a Spark DataFrame by retrieving the data via the Open Datasets API. Here, we use the Spark DataFrame *schema on read* properties to infer the datatypes and schema.

   ```
   from azureml.opendatasets import NycTlcYellow
   from datetime import datetime
   from dateutil import parser

   end_date = parser.parse('2018-06-06')
   start_date = parser.parse('2018-05-01')
   nyc_tlc = NycTlcYellow(start_date=start_date, end_date=end_date)
   df = nyc_tlc.to_spark_dataframe()
   ```

4. After the data is read, we'll want to do some initial filtering to clean the dataset. We might remove unneeded columns and add columns that extract important information. In addition, we'll filter out anomalies within the dataset.

```
# Filter the dataset
from pyspark.sql.functions import *

filtered_df = df.select('vendorID', 'passengerCount', 'tripDistance','paymentType', 'fareAmount',
'tipAmount'\
                                , date_format('tpepPickupDateTime', 'hh').alias('hour_of_day')\
                                , dayofweek('tpepPickupDateTime').alias('day_of_week')\
                                , dayofmonth(col('tpepPickupDateTime')).alias('day_of_month'))\
                            .filter((df.passengerCount > 0)\
                                & (df.tipAmount >= 0)\
                                & (df.fareAmount >= 1) & (df.fareAmount <= 250)\
                                & (df.tripDistance > 0) & (df.tripDistance <= 200))

filtered_df.createOrReplaceTempView("taxi_dataset")
```

Analyze data

As a data analyst, you have a wide range of tools available to help you extract insights from the data. In this part of the tutorial, we'll walk through a few useful tools available within Azure Synapse Analytics notebooks. In this analysis, we want to understand the factors that yield higher taxi tips for our selected period.

Apache Spark SQL Magic

First, we'll perform exploratory data analysis by Apache Spark SQL and magic commands with the Azure Synapse notebook. After we have our query, we'll visualize the results by using the built-in `chart options` capability.

1. Within your notebook, create a new cell and copy the following code. By using this query, we want to understand how the average tip amounts have changed over the period we've selected. This query will also help us identify other useful insights, including the minimum/maximum tip amount per day and the average fare amount.

   ```
   %%sql
   SELECT
       day_of_month
       , MIN(tipAmount) AS minTipAmount
       , MAX(tipAmount) AS maxTipAmount
       , AVG(tipAmount) AS avgTipAmount
       , AVG(fareAmount) as fareAmount
   FROM taxi_dataset
   GROUP BY day_of_month
   ORDER BY day_of_month ASC
   ```

2. After our query finishes running, we can visualize the results by switching to the chart view. This example creates a line chart by specifying the `day_of_month` field as the key and `avgTipAmount` as the value. After you've made the selections, select **Apply** to refresh your chart.

Visualize data

In addition to the built-in notebook charting options, you can use popular open-source libraries to create your own visualizations. In the following examples, we'll use Seaborn and Matplotlib. These are commonly used Python libraries for data visualization.

NOTE

By default, every Apache Spark pool in Azure Synapse Analytics contains a set of commonly used and default libraries. You can view the full list of libraries in the Azure Synapse runtime documentation. In addition, to make third-party or locally built code available to your applications, you can install a library onto one of your Spark pools.

1. To make development easier and less expensive, we'll downsample the dataset. We'll use the built-in Apache Spark sampling capability. In addition, both Seaborn and Matplotlib require a Pandas DataFrame or NumPy array. To get a Pandas DataFrame, use the `toPandas()` command to convert the DataFrame.

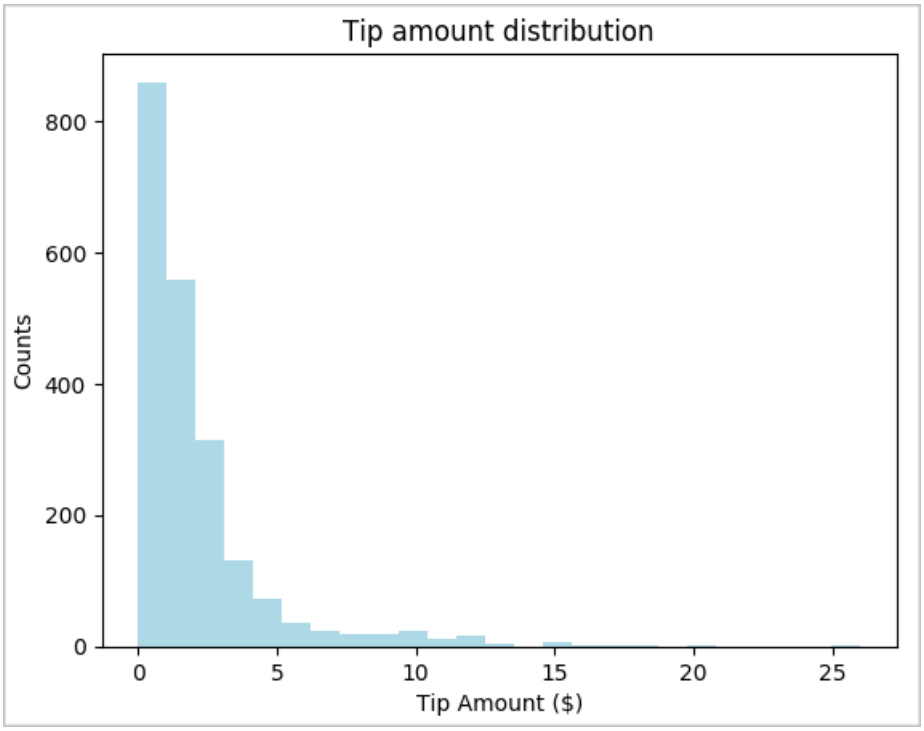
```
# To make development easier, faster, and less expensive, downsample for now
sampled_taxi_df = filtered_df.sample(True, 0.001, seed=1234)

# The charting package needs a Pandas DataFrame or NumPy array to do the conversion
sampled_taxi_pd_df = sampled_taxi_df.toPandas()
```

2. We want to understand the distribution of tips in our dataset. We'll use Matplotlib to create a histogram that shows the distribution of tip amount and count. Based on the distribution, we can see that tips are skewed toward amounts less than or equal to $10.

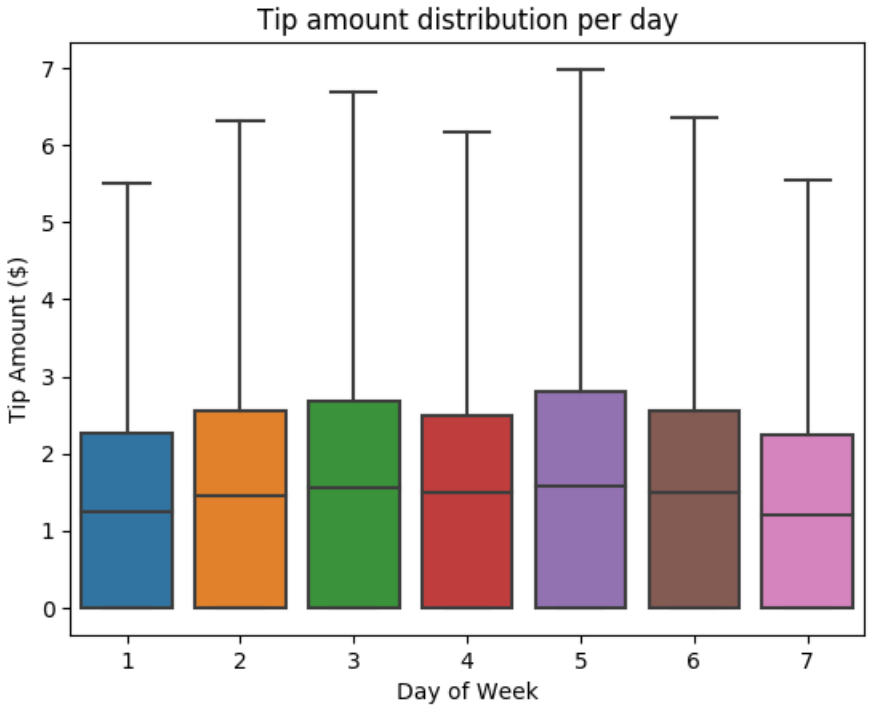
```
# Look at a histogram of tips by count by using Matplotlib

ax1 = sampled_taxi_pd_df['tipAmount'].plot(kind='hist', bins=25, facecolor='lightblue')
ax1.set_title('Tip amount distribution')
ax1.set_xlabel('Tip Amount ($)')
ax1.set_ylabel('Counts')
plt.suptitle('')
plt.show()
```



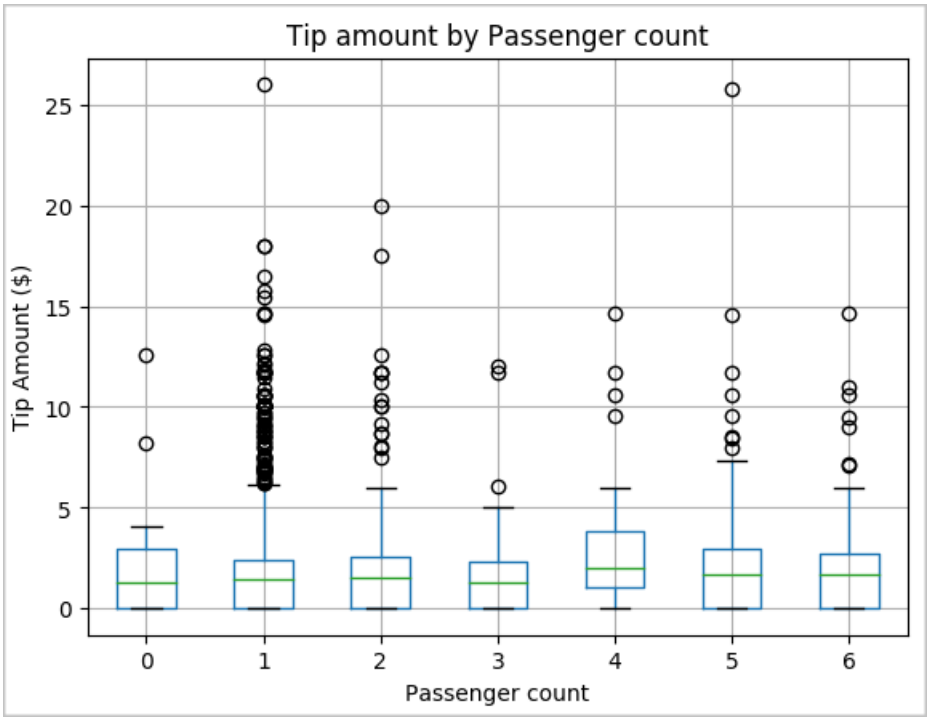
3. Next, we want to understand the relationship between the tips for a given trip and the day of the week. Use Seaborn to create a box plot that summarizes the trends for each day of the week.

```
# View the distribution of tips by day of week using Seaborn
ax = sns.boxplot(x="day_of_week", y="tipAmount",data=sampled_taxi_pd_df, showfliers = False)
ax.set_title('Tip amount distribution per day')
ax.set_xlabel('Day of Week')
ax.set_ylabel('Tip Amount ($)')
plt.show()
```



4. Another hypothesis of ours might be that there's a positive relationship between the number of passengers and the total taxi tip amount. To verify this relationship, run the following code to generate a box plot that illustrates the distribution of tips for each passenger count.

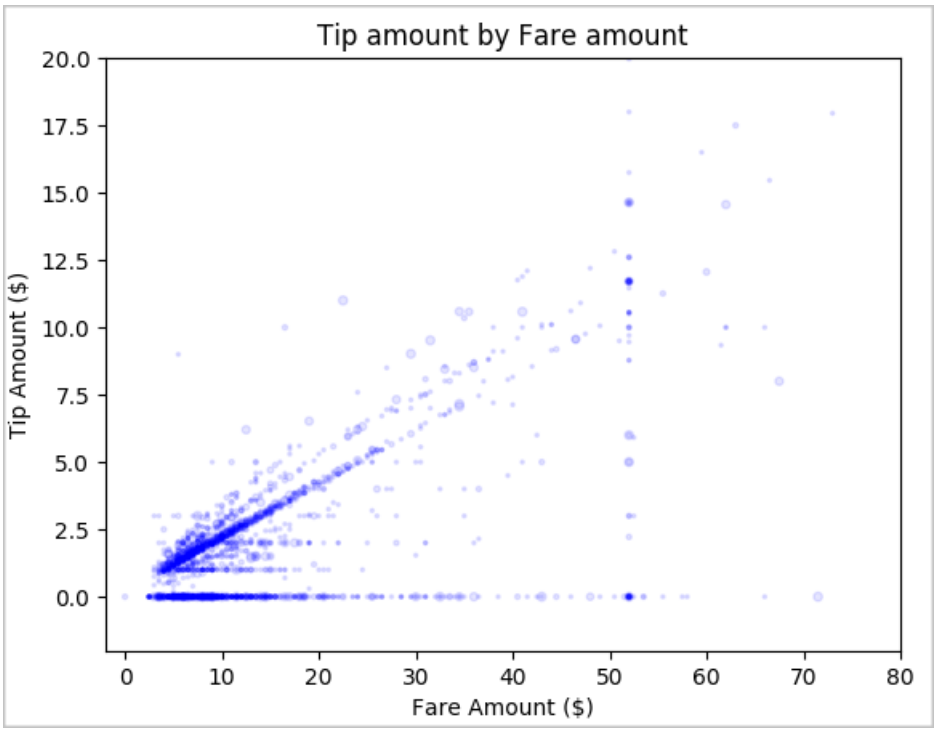
```
# How many passengers tipped by various amounts
ax2 = sampled_taxi_pd_df.boxplot(column=['tipAmount'], by=['passengerCount'])
ax2.set_title('Tip amount by Passenger count')
ax2.set_xlabel('Passenger count')
ax2.set_ylabel('Tip Amount ($)')
ax2.set_ylim(0,30)
plt.suptitle('')
plt.show()
```



5. Last, we want to understand the relationship between the fare amount and the tip amount. Based on the results, we can see that there are several observations where people don't tip. However, we also see a positive relationship between the overall fare and tip amounts.

```
# Look at the relationship between fare and tip amounts

ax = sampled_taxi_pd_df.plot(kind='scatter', x= 'fareAmount', y = 'tipAmount', c='blue', alpha =
0.10, s=2.5*(sampled_taxi_pd_df['passengerCount']))
ax.set_title('Tip amount by Fare amount')
ax.set_xlabel('Fare Amount ($)')
ax.set_ylabel('Tip Amount ($)')
plt.axis([-2, 80, -2, 20])
plt.suptitle('')
plt.show()
```



Shut down the Spark instance

After you finish running the application, shut down the notebook to release the resources. Either close the tab or select **End Session** from the status panel at the bottom of the notebook.

Tutorial: Create a Power BI report using Apache Spark and Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Organizations often need to process large volumes of data before serving to key business stakeholders. In this tutorial, you will learn how to leverage the integrated experiences in Azure Synapse Analytics to process data using Apache Spark and later serve the data to end-users through Power BI and Serverless SQL.

Before you begin

- Azure Synapse Analytics workspace with an ADLS Gen2 storage account configured as the default storage.
- Power BI workspace and Power BI Desktop to visualize data. For details, see create a Power BI workspace and install Power BI desktop
- Linked service to connect your Azure Synapse Analytics and Power BI workspaces. For details, see link to a Power BI workspace
- Serverless Apache Spark pool in your Synapse Analytics workspace. For details, see create a serverless Apache Spark pool

Download and prepare the data

In this example, you will use Apache Spark to perform some analysis on taxi trip tip data from New York. The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips, including information about each trip, the start and end time and locations, the cost, and other interesting attributes.

1. Run the following lines to create a Spark dataframe by pasting the code into a new cell. This retrieves the data via the Open Datasets API. Pulling all of this data generates about 1.5 billion rows. The following code example uses start_date and end_date to apply a filter that returns a single month of data.

```
from azureml.opendatasets import NycTlcYellow
from dateutil import parser
from datetime import datetime

end_date = parser.parse('2018-06-06')
start_date = parser.parse('2018-05-01')
nyc_tlc = NycTlcYellow(start_date=start_date, end_date=end_date)
filtered_df = nyc_tlc.to_spark_dataframe()
```

2. Using Apache Spark SQL, we will create a database called NycTlcTutorial. We will use this database to store the results of our data processing.

```
%%pyspark
 spark.sql("CREATE DATABASE IF NOT EXISTS NycTlcTutorial")
```

3. Next, we will use Spark dataframe operations to process the data. In the following code, we perform the following transformations:

   a. The removal of columns which are not needed.
   b. The removal of outliers/incorrect values through filtering.

c. The creation of new features like `tripTimeSecs` and `tipped` for additional analysis.

```
from pyspark.sql.functions import unix_timestamp, date_format, col, when

taxi_df = filtered_df.select('totalAmount', 'fareAmount', 'tipAmount', 'paymentType', 'rateCodeId',
'passengerCount'\
                                , 'tripDistance', 'tpepPickupDateTime', 'tpepDropoffDateTime'\
                                , date_format('tpepPickupDateTime', 'hh').alias('pickupHour')\
                                , date_format('tpepPickupDateTime', 'EEEE').alias('weekdayString')\
                                , (unix_timestamp(col('tpepDropoffDateTime')) -
unix_timestamp(col('tpepPickupDateTime'))).alias('tripTimeSecs')\
                                , (when(col('tipAmount') > 0, 1).otherwise(0)).alias('tipped')
                                )\
                        .filter((filtered_df.passengerCount > 0) & (filtered_df.passengerCount < 8)\
                                & (filtered_df.tipAmount >= 0) & (filtered_df.tipAmount <= 25)\
                                & (filtered_df.fareAmount >= 1) & (filtered_df.fareAmount <= 250)\
                                & (filtered_df.tipAmount < filtered_df.fareAmount)\
                                & (filtered_df.tripDistance > 0) & (filtered_df.tripDistance <= 100)\
                                & (filtered_df.rateCodeId <= 5)
                                & (filtered_df.paymentType.isin({"1", "2"})))
```

4. Finally, we will save our dataframe using the Apache Spark `saveAsTable` method. This will allow you to later query and connect to the same table using serverless SQL pools.

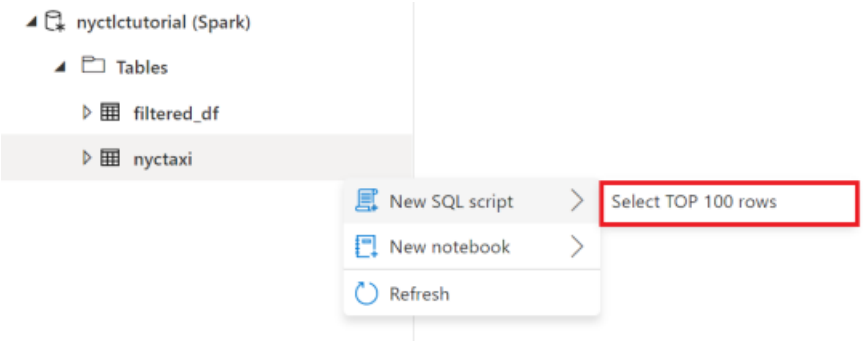
```
taxi_df.write.mode("overwrite").saveAsTable("NycTlcTutorial.nyctaxi")
```

Query data using serverless SQL pools

Azure Synapse Analytics allows the different workspace computational engines to share databases and tables between its serverless Apache Spark pools and serverless SQL pool. This is powered through the Synapse shared metadata management capability. As a result, the Spark created databases and their parquet-backed tables become visible in the workspace serverless SQL pool.

To query your Apache Spark table using your serverless SQL pool:

1. Once you have saved your Apache Spark table, switch over to the **data** tab.
2. Under **Workspaces**, find the Apache Spark table that you just created and select **New SQL script** and then **Select TOP 100 rows**.



3. You can continue to refine your query or even visualize your results using the SQL charting options.

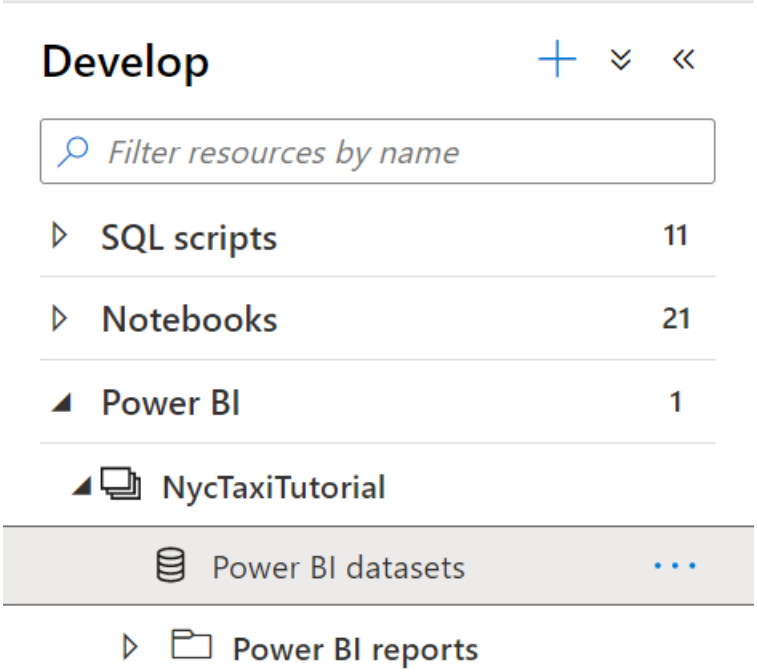
Connect to Power BI

Next, we will connect our serverless SQL pool to our Power BI workspace. Once you have connected your workspace, you will be able to create Power BI reports both directly from Azure Synapse Analytics as well as from Power BI desktop.

> **NOTE**
>
> Before you begin, you will need to set up a linked service to your Power BI workspace and download the Power BI desktop.

To connect our serverless SQL pool to our Power BI workspace:

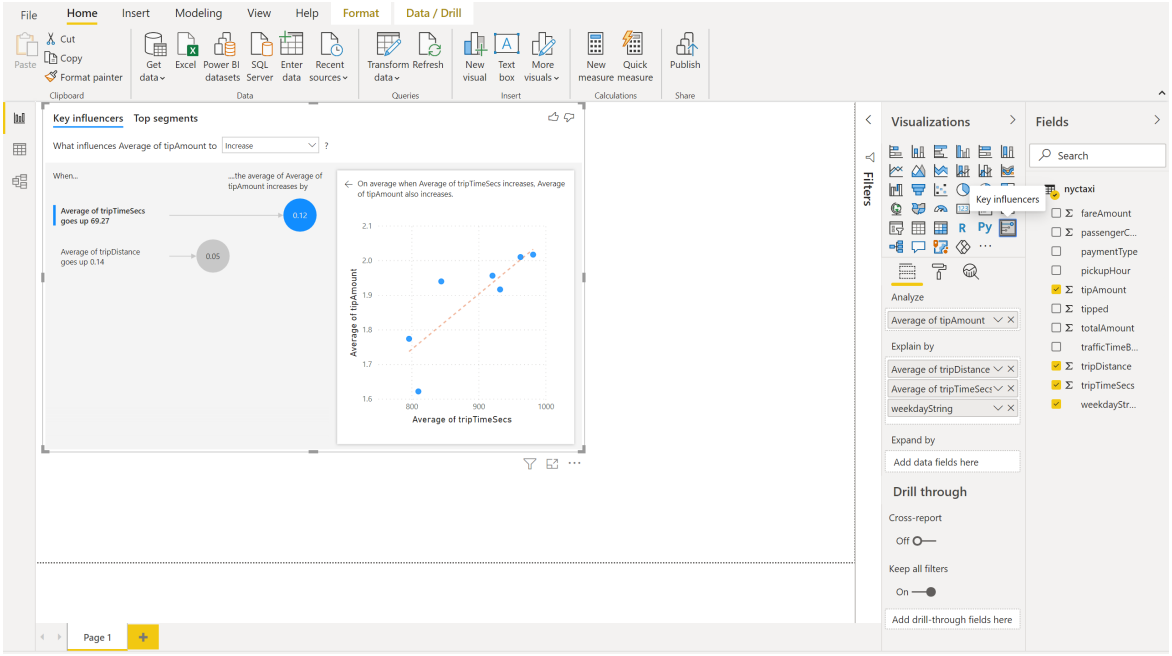
1. Navigate to the **Power BI datasets** tab and select the option to **+ New Dataset**. From the prompt, download the .pbids file from the SQL Analytics database you would like to use as a data source.



2. Open the file with Power BI Desktop to create a dataset. Once you open the file, connect to the SQL server database using the **Microsoft account** and **Import** option.

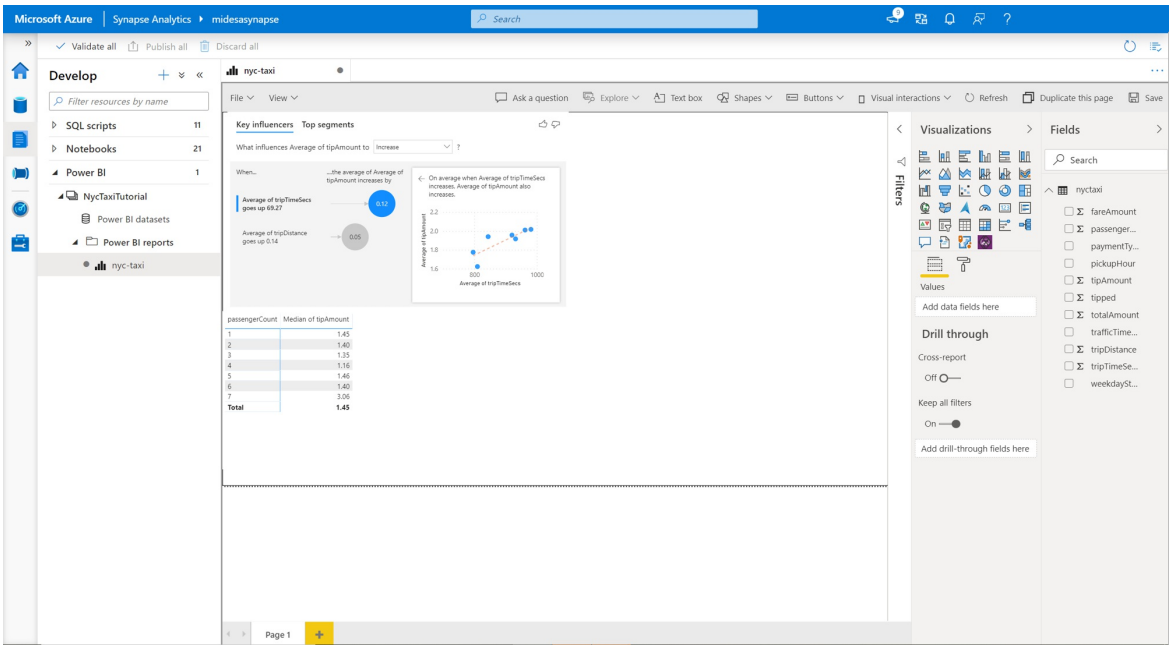
Create a Power BI report

1. From Power BI desktop, you can now add a **key influencers** chart to your report.
   a. Drag the average *tipAmount* column to **Analyze** axis.
   b. Drag the **weekdayString**, average **tripDistance**, and average **tripTimeSecs** columns to the **Explain by** axis.



2. On the Power BI desktop Home tab, select **Publish** and **Save** changes. Enter a file name and save this report to the the *NycTaxiTutorial Workspace*.

3. In addition, you can also create Power BI visualizations from within your Azure Synapse Analytics workspace. To do this, navigate to the **Develop** tab in your Azure Synapse workspace and open the Power BI tab. From here, you can select your report and continue building additional visualizations.



For more details on how to create a dataset through serverless SQL and connect to Power BI, you can visit this tutorial on connecting to Power BI desktop

Tutorial: Use Pandas to read/write Azure Data Lake Storage Gen2 data in serverless Apache Spark pool in Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Learn how to use Pandas to read/write data to Azure Data Lake Storage Gen2 (ADLS) using a serverless Apache Spark pool in Azure Synapse Analytics. Examples in this tutorial show you how to read csv data with Pandas in Synapse, as well as excel and parquet files.

In this tutorial, you'll learn how to:

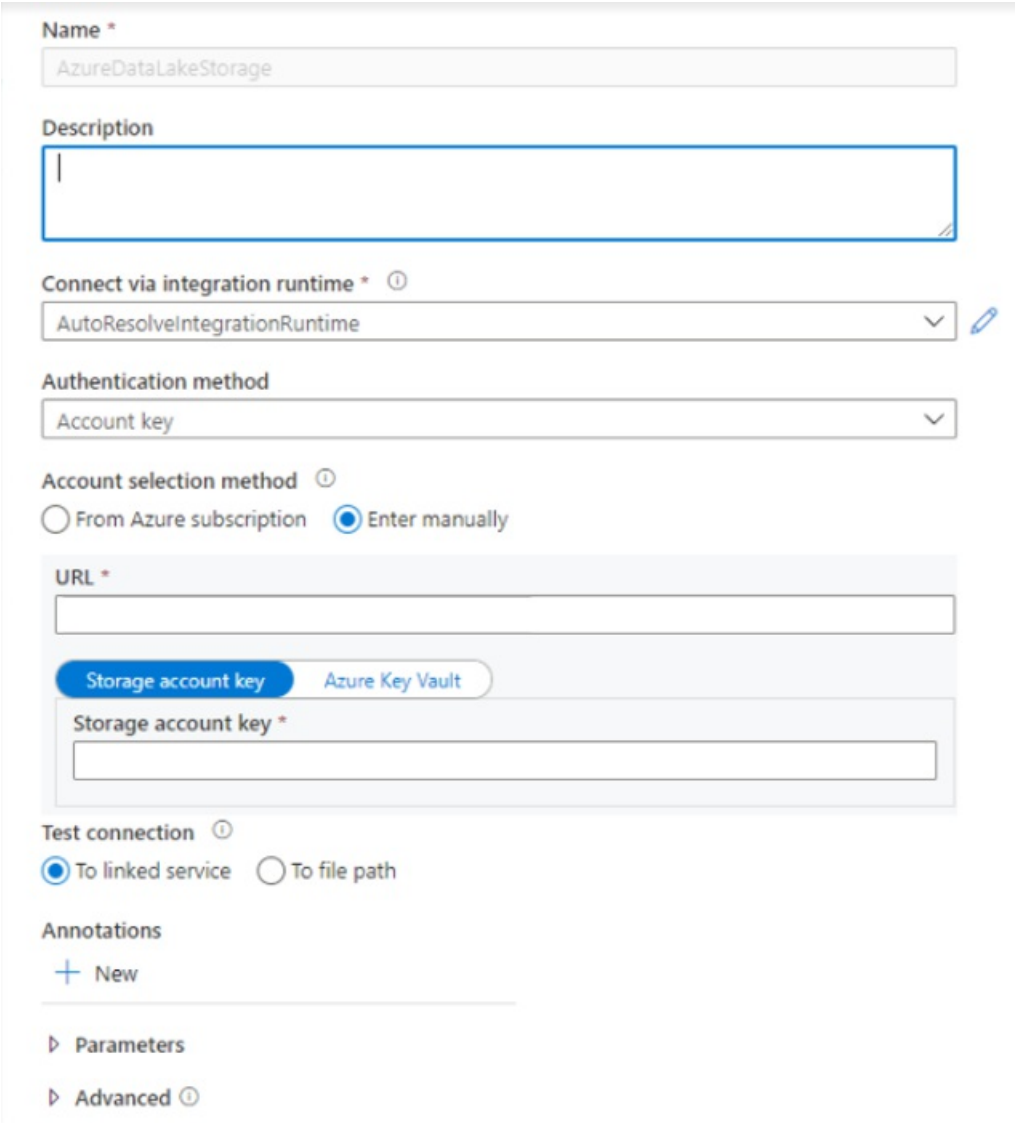
- Read/write ADLS Gen2 data using Pandas in a Spark session.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage (or primary storage). You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Serverless Apache Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Configure Secondary Azure Data Lake Storage Gen2 account (which is not default to Synapse workspace). You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Create linked services - In Azure Synapse Analytics, a linked service defines your connection information to the service. In this tutorial, you'll add an Azure Synapse Analytics and Azure Data Lake Storage Gen2 linked service.

  1. Open the Azure Synapse Studio and select the **Manage** tab.
  2. Under **External connections**, select **Linked services**.
  3. To add a linked service, select **New**.
  4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
  5. Enter your authentication credentials. Account key, service principal (SP), Credentials and Manged service identity (MSI) are currently supported authentication types. Make sure that *Storage Blob Data Contributor* is assigned on storage for SP and MSI before you choose it for authentication. **Test connection** to verify your credentials are correct. Select **Create**.



NOTE

- Pandas feature is supported on **Python 3.8** and **Spark3** serverless Apache Spark pool in Azure Synapse Analytics.
- Support available for following versions: **pandas 1.2.3, fsspec 2021.10.0, adlfs 0.7.7**
- Have capabilities to support both **Azure Data Lake Storage Gen2 URI** (abfs[s]://file_system_name@account_name.dfs.core.windows.net/file_path) and **FSSPEC short URL** (abfs[s]://container_name/file_path).

Sign in to the Azure portal

Sign in to the Azure portal.

Read/Write data to default ADLS storage account of Synapse workspace

Pandas can read/write ADLS data by specifying the file path directly.

Run the following code.

NOTE

Update the file URL in this script before running it.

```
#Read data file from URI of default Azure Data Lake Storage Gen2

import pandas

#read csv file
df = pandas.read_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/file_path')
print(df)

#write csv file
data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
data.to_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/file_path')
```

```
#Read data file from FSSPEC short URL of default Azure Data Lake Storage Gen2

import pandas

#read csv file
df = pandas.read_csv('abfs[s]://container_name/file_path')
print(df)

#write csv file
data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
data.to_csv('abfs[s]://container_name/file_path')
```

Read/Write data using secondary ADLS account

Pandas can read/write secondary ADLS account data:

- using linked service (with authentication options - storage account key, service principal, manages service identity and credentials).
- using storage options to directly pass client ID & Secret, SAS key, storage account key and connection string.

Using linked service

Run the following code.

> **NOTE**
> Update the file URL and linked service name in this script before running it.

```
#Read data file from URI of secondary Azure Data Lake Storage Gen2

import pandas

#read data file
df = pandas.read_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/   file_path',
storage_options = {'linked_service' : 'linked_service_name'})
print(df)

#write data file
data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
data.to_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/file_path',    storage_options
= {'linked_service' : 'linked_service_name'})
```

```
   #Read data file from FSSPEC short URL of default Azure Data Lake Storage Gen2

   import pandas

   #read data file
   df = pandas.read_csv('abfs[s]://container_name/file_path', storage_options =       {'linked_service' :
'linked_service_name'})
   print(df)

   #write data file
   data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
   data.to_csv('abfs[s]://container_name/file_path', storage_options = {'linked_service' :
'linked_service_name'})
```

Using storage options to directly pass client ID & Secret, SAS key, storage account key, and connection string.

Run the following code.

> **NOTE**
>
> Update the file URL and storage_options in this script before running it.

```
   #Read data file from URI of secondary Azure Data Lake Storage Gen2

   import pandas

   #read data file
   df = pandas.read_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/   file_path',
storage_options = {'account_key' : 'account_key_value'})

   ## or storage_options = {'sas_token' : 'sas_token_value'}
   ## or storage_options = {'connection_string' : 'connection_string_value'}
   ## or storage_options = {'tenant_id': 'tenant_id_value', 'client_id' : 'client_id_value',
'client_secret': 'client_secret_value'}

   print(df)

   #write data file
   data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
   data.to_csv('abfs[s]://file_system_name@account_name.dfs.core.windows.net/file_path',    storage_options
= {'account_key' : 'account_key_value'})

   ## or storage_options = {'sas_token' : 'sas_token_value'}
   ## or storage_options = {'connection_string' : 'connection_string_value'}
   ## or storage_options = {'tenant_id': 'tenant_id_value', 'client_id' : 'client_id_value',
'client_secret': 'client_secret_value'}
```

```
   #Read data file from FSSPEC short URL of default Azure Data Lake Storage Gen2

   import pandas

   #read data file
   df = pandas.read_csv('abfs[s]://container_name/file_path', storage_options = {'account_key' :
'account_key_value'})

   ## or storage_options = {'sas_token' : 'sas_token_value'}
   ## or storage_options = {'connection_string' : 'connection_string_value'}
   ## or storage_options = {'tenant_id': 'tenant_id_value', 'client_id' : 'client_id_value',
'client_secret': 'client_secret_value'}

   print(df)

   #write data file
   data = pandas.DataFrame({'Name':['A', 'B', 'C', 'D'], 'ID':[20, 21, 19, 18]})
   data.to_csv('abfs[s]://container_name/file_path', storage_options = {'account_key' :
'account_key_value'})

   ## or storage_options = {'sas_token' : 'sas_token_value'}
   ## or storage_options = {'connection_string' : 'connection_string_value'}
   ## or storage_options = {'tenant_id': 'tenant_id_value', 'client_id' : 'client_id_value',
'client_secret': 'client_secret_value'}
```

Example to read/write parquet file

Run the following code.

> **NOTE**
>
> Update the file URL in this script before running it.

```
   import pandas

   #read parquet file
   df = pandas.read_parquet('abfs[s]://file_system_name@account_name.dfs.core.windows.net/
parquet_file_path')
   print(df)

   #write parquet file
   df.to_parquet('abfs[s]://file_system_name@account_name.dfs.core.windows.net/   parquet_file_path')
```

Example to read/write excel file

Run the following code.

> **NOTE**
>
> Update the file URL in this script before running it.

```
import pandas

#read excel file
df = pandas.read_excel('abfs[s]://file_system_name@account_name.dfs.core.windows.net/   excel_file_path')
print(df)

#write excel file
df.to_excel('abfs[s]://file_system_name@account_name.dfs.core.windows.net/excel_file_path')
```

- Azure Synapse Analytics

Tutorial: Use FSSPEC to read/write ADLS data in serverless Apache Spark pool in Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

Learn how to use Filesystem Spec (FSSPEC) to read/write data to Azure Data Lake Storage (ADLS) using a linked service in a serverless Apache Spark pool in Azure Synapse Analytics.

In this tutorial, you'll learn how to:

- Read/write ADLS data in a dedicated Spark session.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.

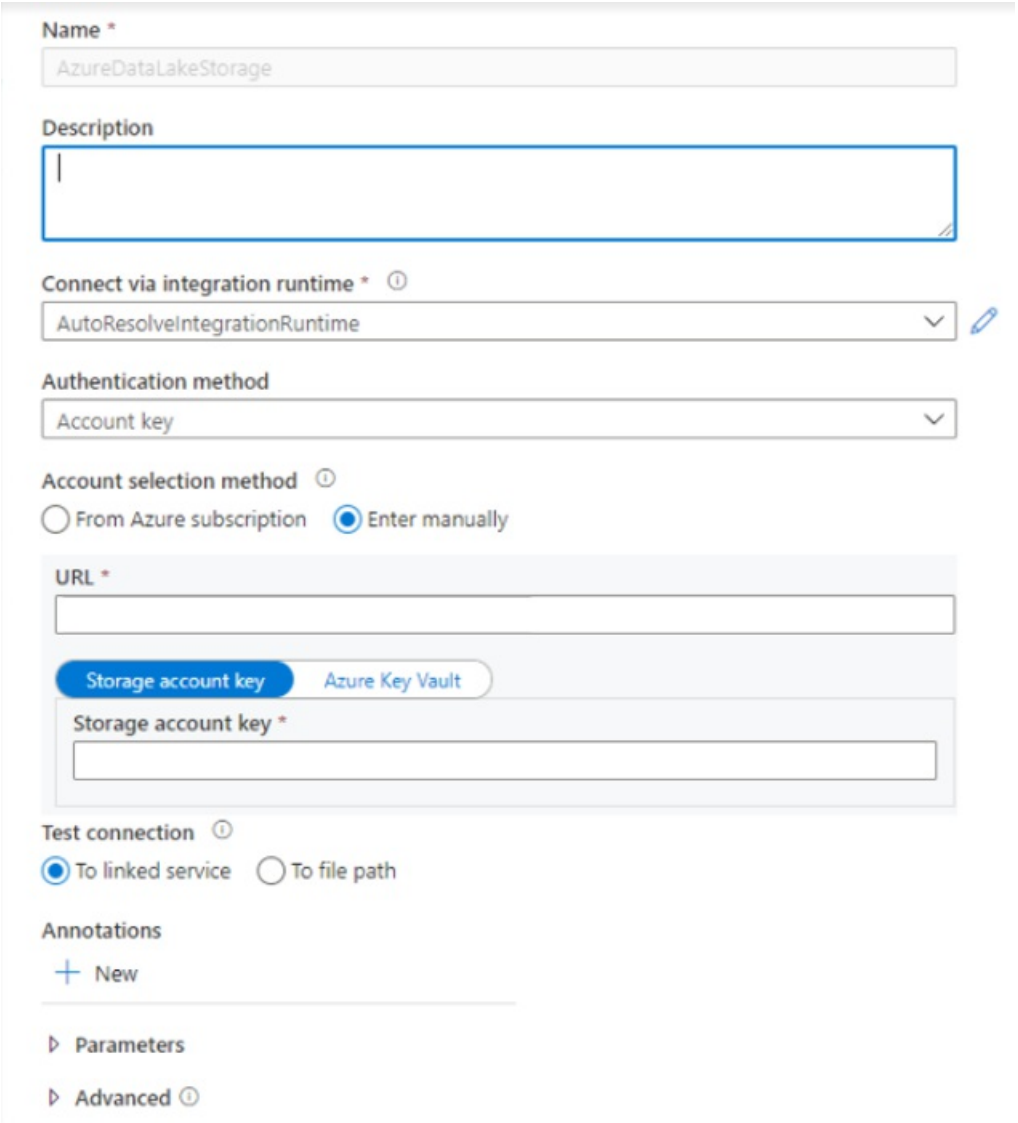
Sign in to the Azure portal

Sign in to the Azure portal.

Create linked services

In Azure Synapse Analytics, a linked service is where you define your connection information to other services. In this section, you'll add an Azure Synapse Analytics and Azure Data Lake Storage Gen2 linked service.

1. Open the Azure Synapse Studio and select the **Manage** tab.
2. Under **External connections**, select **Linked services**.
3. To add a linked service, select **New**.
4. Select the Azure Data Lake Storage Gen2 tile from the list and select **Continue**.
5. Enter your authentication credentials. Account key is currently supported authentication type. Select **Test connection** to verify your credentials are correct. Select **Create**.



Read/Write data using storage account name and key

FSSPEC can read/write ADLS data by specifying the storage account name and key directly.

1. In Synapse studio, open **Data** > **Linked** > **Azure Data Lake Storage Gen2**. Upload data to the default storage account.

2. Run the following code.

> **NOTE**
>
> Update the file URL, ADLS Gen2 storage name and key in this script before running it.

```
# To read data
import fsspec
import pandas

adls_account_name = '' #Provide exact ADLS account name
adls_account_key = '' #Provide exact ADLS account key

fsspec_handle = fsspec.open('abfs[s]://<container>/<path-to-file>', account_name=adls_account_name,
account_key=adls_account_key)

with fsspec_handle.open() as f:
    df = pandas.read_csv(f)

# To write data
import fsspec
import pandas

adls_account_name = '' #Provide exact ADLS account name
adls_account_key = '' #Provide exact ADLS account key

data = pandas.DataFrame({'Name':['Tom', 'nick', 'krish', 'jack'], 'Age':[20, 21, 19, 18]})

fsspec_handle = fsspec.open('abfs[s]://<container>/<path-to-file>', account_name=adls_account_name,
account_key=adls_account_key, mode="wt")

with fsspec_handle.open() as f:
 data.to_csv(f)
```

Read/Write data using linked service

FSSPEC can read/write ADLS data by specifying the linked service name.

1. In Synapse studio, open **Data** > **Linked** > **Azure Data Lake Storage Gen2**. Upload data to the default storage account.
2. Run the following code.

> **NOTE**
> Update the file URL, Linked Service Name and ADLS Gen2 storage name in this script before running it.

```
# To read data
import fsspec
import pandas

adls_account_name = '' #Provide exact ADLS account name
sas_key = TokenLibrary.getConnectionString(<LinkedServiceName>)

fsspec_handle = fsspec.open('abfs[s]://<container>/<path-to-file>', account_name =
adls_account_name, sas_token=sas_key)

with fsspec_handle.open() as f:
    df = pandas.read_csv(f)

# To write data
import fsspec
import pandas

adls_account_name = '' #Provide exact ADLS account name

data = pandas.DataFrame({'Name':['Tom', 'nick', 'krish', 'jack'], 'Age':[20, 21, 19, 18]})
sas_key = TokenLibrary.getConnectionString(<LinkedServiceName>)

fsspec_handle = fsspec.open('abfs[s]://<container>/<path-to-file>', account_name =
adls_account_name, sas_token=sas_key, mode="wt")

with fsspec_handle.open() as f:
    data.to_csv(f)
```

Upload file from local file system to default ADLS storage account of Synapse workspace

FSSPEC can upload a file from the local file system to a Synapse workspace default ADLS storage account.

Run the following code.

> **NOTE**
> Update the file URL in this script before running it.

```
# Import libraries
import fsspec
import os

# Set variables
local_file_name = "<local_file_name>"
ADLS_Store_Path = "abfs[s]://<filesystemname>@<account name>.dfs.windows.cor.net/"+local_file_name

# Generate local file for testing
with open(local_file_name, mode='w') as f:
    for i in range(1000):
        f.write("Testing local file functionality\n")
print("Created: " + local_file_name)

# Upload local file to ADLS
fs = fsspec.filesystem('abfs[s]')
fs.upload(local_file_name, ADLS_Store_Path)
```

Tutorial: Build a machine learning app with Apache Spark MLlib and Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

In this article, you'll learn how to use Apache Spark MLlib to create a machine learning application that does simple predictive analysis on an Azure open dataset. Spark provides built-in machine learning libraries. This example uses *classification* through logistic regression.

SparkML and MLlib are core Spark libraries that provide many utilities that are useful for machine learning tasks, including utilities that are suitable for:

- Classification
- Regression
- Clustering
- Topic modeling
- Singular value decomposition (SVD) and principal component analysis (PCA)
- Hypothesis testing and calculating sample statistics

Understand classification and logistic regression

Classification, a popular machine learning task, is the process of sorting input data into categories. It's the job of a classification algorithm to figure out how to assign *labels* to input data that you provide. For example, you can think of a machine learning algorithm that accepts stock information as input and divide the stock into two categories: stocks that you should sell and stocks that you should keep.

Logistic regression is an algorithm that you can use for classification. Spark's logistic regression API is useful for *binary classification*, or classifying input data into one of two groups. For more information about logistic regression, see Wikipedia.

In summary, the process of logistic regression produces a *logistic function* that you can use to predict the probability that an input vector belongs in one group or the other.

Predictive analysis example on NYC taxi data

In this example, you use Spark to perform some predictive analysis on taxi-trip tip data from New York. The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips, including information about each trip, the start and end time and locations, the cost, and other interesting attributes.

> **IMPORTANT**
> There might be additional charges for pulling this data from its storage location.

In the following steps, you develop a model to predict whether a particular trip includes a tip or not.

Create an Apache Spark machine learning model

1. Create a notebook by using the PySpark kernel. For instructions, see Create a notebook.

2. Import the types required for this application. Copy and paste the following code into an empty cell, and

then press Shift+Enter. Or run the cell by using the blue play icon to the left of the code.

```
import matplotlib.pyplot as plt
from datetime import datetime
from dateutil import parser
from pyspark.sql.functions import unix_timestamp, date_format, col, when
from pyspark.ml import Pipeline
from pyspark.ml import PipelineModel
from pyspark.ml.feature import RFormula
from pyspark.ml.feature import OneHotEncoder, StringIndexer, VectorIndexer
from pyspark.ml.classification import LogisticRegression
from pyspark.mllib.evaluation import BinaryClassificationMetrics
from pyspark.ml.evaluation import BinaryClassificationEvaluator
```

Because of the PySpark kernel, you don't need to create any contexts explicitly. The Spark context is automatically created for you when you run the first code cell.

Construct the input DataFrame

Because the raw data is in a Parquet format, you can use the Spark context to pull the file into memory as a DataFrame directly. Although the code in the following steps uses the default options, it's possible to force mapping of data types and other schema attributes if needed.

1. Run the following lines to create a Spark DataFrame by pasting the code into a new cell. This step retrieves the data via the Open Datasets API. Pulling all of this data generates about 1.5 billion rows.

   Depending on the size of your serverless Apache Spark pool, the raw data might be too large or take too much time to operate on. You can filter this data down to something smaller. The following code example uses `start_date` and `end_date` to apply a filter that returns a single month of data.

   ```
   from azureml.opendatasets import NycTlcYellow

   end_date = parser.parse('2018-06-06')
   start_date = parser.parse('2018-05-01')
   nyc_tlc = NycTlcYellow(start_date=start_date, end_date=end_date)
   filtered_df = nyc_tlc.to_spark_dataframe()
   ```

2. The downside to simple filtering is that, from a statistical perspective, it might introduce bias into the data. Another approach is to use the sampling built into Spark.

   The following code reduces the dataset to about 2,000 rows, if it's applied after the preceding code. You can use this sampling step instead of the simple filter or in conjunction with the simple filter.

   ```
   # To make development easier, faster, and less expensive, downsample for now
   sampled_taxi_df = filtered_df.sample(True, 0.001, seed=1234)
   ```

3. It's now possible to look at the data to see what was read. It's normally better to review data with a subset rather than the full set, depending on the size of the dataset.

   The following code offers two ways to view the data. The first way is basic. The second way provides a much richer grid experience, along with the capability to visualize the data graphically.

   ```
   #sampled_taxi_df.show(5)
   display(sampled_taxi_df)
   ```

4. Depending on the size of the generated dataset, and your need to experiment or run the notebook many

times, you might want to cache the dataset locally in the workspace. There are three ways to perform explicit caching:

- Save the DataFrame locally as a file.
- Save the DataFrame as a temporary table or view.
- Save the DataFrame as a permanent table.

The first two of these approaches are included in the following code examples.

Creating a temporary table or view provides different access paths to the data, but it lasts only for the duration of the Spark instance session.

```
sampled_taxi_df.createOrReplaceTempView("nytaxi")
```

Prepare the data

The data in its raw form is often not suitable for passing directly to a model. You must perform a series of actions on the data to get it into a state where the model can consume it.

In the following code, you perform four classes of operations:

- The removal of outliers or incorrect values through filtering.
- The removal of columns, which are not needed.
- The creation of new columns derived from the raw data to make the model work more effectively. This operation is sometimes called featurization.
- Labeling. Because you're undertaking binary classification (will there be a tip or not on a given trip), there's a need to convert the tip amount into a 0 or 1 value.

```
taxi_df = sampled_taxi_df.select('totalAmount', 'fareAmount', 'tipAmount', 'paymentType', 'rateCodeId',
'passengerCount'\
                                , 'tripDistance', 'tpepPickupDateTime', 'tpepDropoffDateTime'\
                                , date_format('tpepPickupDateTime', 'hh').alias('pickupHour')\
                                , date_format('tpepPickupDateTime', 'EEEE').alias('weekdayString')\
                                , (unix_timestamp(col('tpepDropoffDateTime')) -
unix_timestamp(col('tpepPickupDateTime'))).alias('tripTimeSecs')\
                                , (when(col('tipAmount') > 0, 1).otherwise(0)).alias('tipped')
                                )\
                        .filter((sampled_taxi_df.passengerCount > 0) & (sampled_taxi_df.passengerCount < 8)\
                                & (sampled_taxi_df.tipAmount >= 0) & (sampled_taxi_df.tipAmount <= 25)\
                                & (sampled_taxi_df.fareAmount >= 1) & (sampled_taxi_df.fareAmount <= 250)\
                                & (sampled_taxi_df.tipAmount < sampled_taxi_df.fareAmount)\
                                & (sampled_taxi_df.tripDistance > 0) & (sampled_taxi_df.tripDistance <=
100)\
                                & (sampled_taxi_df.rateCodeId <= 5)
                                & (sampled_taxi_df.paymentType.isin({"1", "2"}))
                                )
```

You then make a second pass over the data to add the final features.

```
taxi_featurised_df = taxi_df.select('totalAmount', 'fareAmount', 'tipAmount', 'paymentType',
'passengerCount'\
                                                , 'tripDistance', 'weekdayString',
'pickupHour','tripTimeSecs','tipped'\
                                                , when((taxi_df.pickupHour <= 6) | (taxi_df.pickupHour >=
20),"Night")\
                                                .when((taxi_df.pickupHour >= 7) & (taxi_df.pickupHour <=
10), "AMRush")\
                                                .when((taxi_df.pickupHour >= 11) & (taxi_df.pickupHour <=
15), "Afternoon")\
                                                .when((taxi_df.pickupHour >= 16) & (taxi_df.pickupHour <=
19), "PMRush")\
                                                .otherwise(0).alias('trafficTimeBins')
                                              )\
                                       .filter((taxi_df.tripTimeSecs >= 30) & (taxi_df.tripTimeSecs <=
7200))
```

Create a logistic regression model

The final task is to convert the labeled data into a format that can be analyzed through logistic regression. The input to a logistic regression algorithm needs to be a set of *label/feature vector pairs*, where the *feature vector* is a vector of numbers that represent the input point.

So, you need to convert the categorical columns into numbers. Specifically, you need to convert the `trafficTimeBins` and `weekdayString` columns into integer representations. There are multiple approaches to performing the conversion. The following example takes the `OneHotEncoder` approach, which is common.

```
# Because the sample uses an algorithm that works only with numeric features, convert them so they can be
consumed
sI1 = StringIndexer(inputCol="trafficTimeBins", outputCol="trafficTimeBinsIndex")
en1 = OneHotEncoder(dropLast=False, inputCol="trafficTimeBinsIndex", outputCol="trafficTimeBinsVec")
sI2 = StringIndexer(inputCol="weekdayString", outputCol="weekdayIndex")
en2 = OneHotEncoder(dropLast=False, inputCol="weekdayIndex", outputCol="weekdayVec")

# Create a new DataFrame that has had the encodings applied
encoded_final_df = Pipeline(stages=[sI1, en1, sI2,
en2]).fit(taxi_featurised_df).transform(taxi_featurised_df)
```

This action results in a new DataFrame with all columns in the right format to train a model.

Train a logistic regression model

The first task is to split the dataset into a training set and a testing or validation set. The split here is arbitrary. Experiment with different split settings to see if they affect the model.

```
# Decide on the split between training and testing data from the DataFrame
trainingFraction = 0.7
testingFraction = (1-trainingFraction)
seed = 1234

# Split the DataFrame into test and training DataFrames
train_data_df, test_data_df = encoded_final_df.randomSplit([trainingFraction, testingFraction], seed=seed)
```

Now that there are two DataFrames, the next task is to create the model formula and run it against the training DataFrame. Then you can validate against the testing DataFrame. Experiment with different versions of the model formula to see the impact of different combinations.

> **NOTE**
>
> To save the model, assign the *Storage Blob Data Contributor* role to the Azure SQL Database server resource scope. For detailed steps, see Assign Azure roles using the Azure portal. Only members with owner privileges can perform this step.

```
## Create a new logistic regression object for the model
logReg = LogisticRegression(maxIter=10, regParam=0.3, labelCol = 'tipped')

## The formula for the model
classFormula = RFormula(formula="tipped ~ pickupHour + weekdayVec + passengerCount + tripTimeSecs +
tripDistance + fareAmount + paymentType+ trafficTimeBinsVec")

## Undertake training and create a logistic regression model
lrModel = Pipeline(stages=[classFormula, logReg]).fit(train_data_df)

## Saving the model is optional, but it's another form of inter-session cache
datestamp = datetime.now().strftime('%m-%d-%Y-%s')
fileName = "lrModel_" + datestamp
logRegDirfilename = fileName
lrModel.save(logRegDirfilename)

## Predict tip 1/0 (yes/no) on the test dataset; evaluation using area under ROC
predictions = lrModel.transform(test_data_df)
predictionAndLabels = predictions.select("label","prediction").rdd
metrics = BinaryClassificationMetrics(predictionAndLabels)
print("Area under ROC = %s" % metrics.areaUnderROC)
```

The output from this cell is:

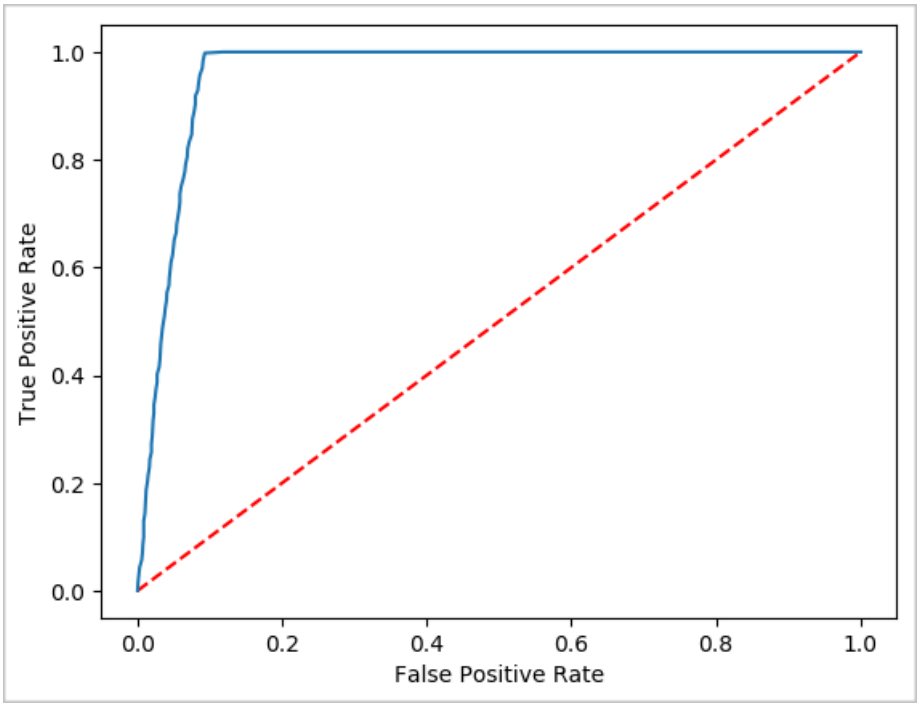
```
Area under ROC = 0.9779470729751403
```

Create a visual representation of the prediction

You can now construct a final visualization to help you reason about the results of this test. An ROC curve is one way to review the result.

```
## Plot the ROC curve; no need for pandas, because this uses the modelSummary object
modelSummary = lrModel.stages[-1].summary

plt.plot([0, 1], [0, 1], 'r--')
plt.plot(modelSummary.roc.select('FPR').collect(),
         modelSummary.roc.select('TPR').collect())
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.show()
```



Shut down the Spark instance

After you finish running the application, shut down the notebook to release the resources by closing the tab. Or select **End Session** from the status panel at the bottom of the notebook.

Tutorial: Create Apache Spark job definition in Synapse Studio

8/19/2022 • 9 minutes to read • Edit Online

This tutorial demonstrates how to use the Synapse Studio to create Apache Spark job definitions, and then submit them to a serverless Apache Spark pool.

This tutorial covers the following tasks:

- Create an Apache Spark job definition for PySpark (Python)
- Create an Apache Spark job definition for Spark (Scala)
- Create an Apache Spark job definition for .NET Spark (C#/F#)
- Create job definition by importing a JSON file
- Exporting an Apache Spark job definition file to local
- Submit an Apache Spark job definition as a batch job
- Add an Apache Spark job definition into pipeline

Prerequisites

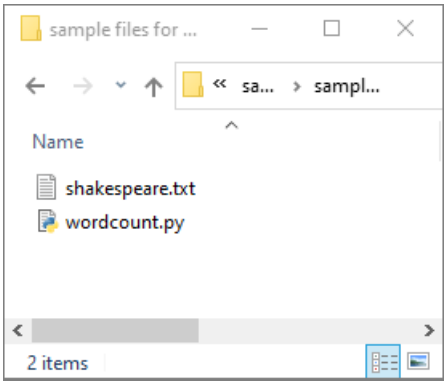
Before you start with this tutorial, make sure to meet the following requirements:

- An Azure Synapse Analytics workspace. For instructions, see Create an Azure Synapse Analytics workspace.
- A serverless Apache Spark pool.
- An ADLS Gen2 storage account. You need to be the **Storage Blob Data Contributor** of the ADLS Gen2 filesystem you want to work with. If you aren't, you need to add the permission manually.
- If you don't want to use the workspace default storage, link the required ADLS Gen2 storage account in Synapse Studio.

Create an Apache Spark job definition for PySpark (Python)

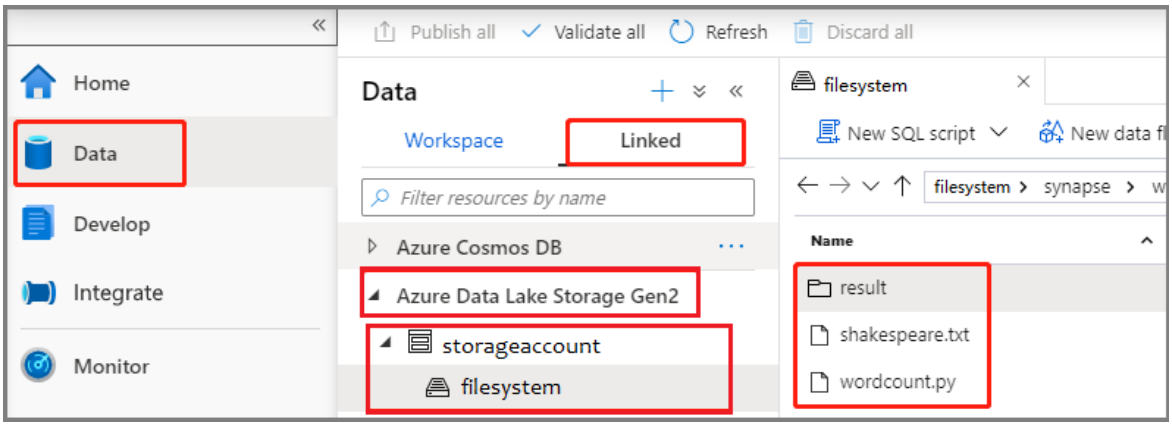
In this section, you create an Apache Spark job definition for PySpark (Python).

1. Open Synapse Studio.
2. You can go to Sample files for creating Apache Spark job definitions to download **sample files for python.zip**, then unzip the compressed package, and extract the **wordcount.py** and **shakespeare.txt** files.

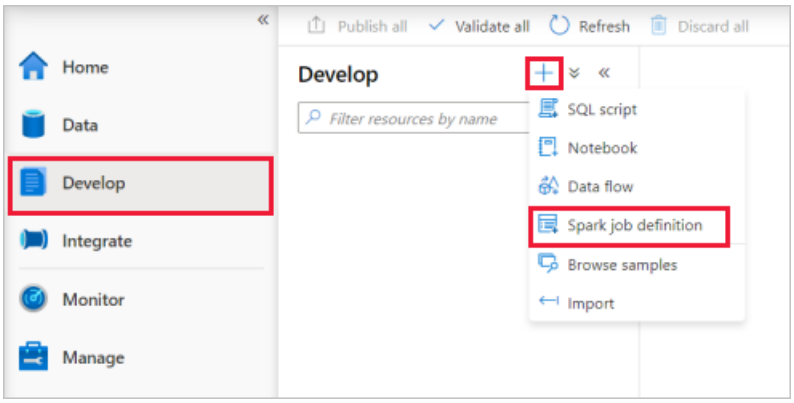


3. Select **Data** -> **Linked** -> **Azure Data Lake Storage Gen2**, and

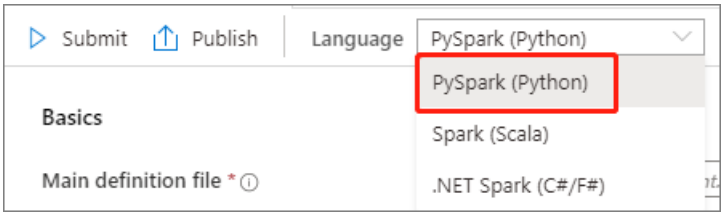
upload **wordcount.py** and **shakespeare.txt** into your ADLS Gen2 filesystem.



4. Select **Develop** hub, select the '+' icon and select **Spark job definition** to create a new Spark job definition.



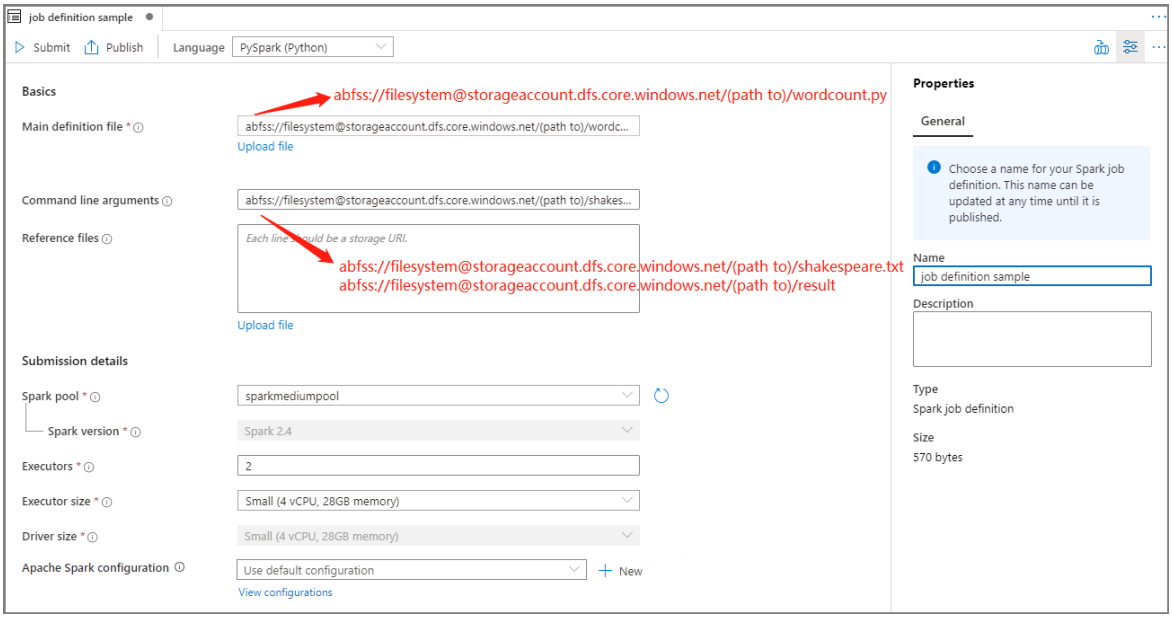
5. Select **PySpark (Python)** from the Language drop down list in the Apache Spark job definition main window.



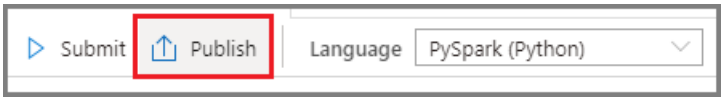
6. Fill in information for Apache Spark job definition.

PROPERTY	DESCRIPTION
Job definition name	Enter a name for your Apache Spark job definition. This name can be updated at any time until it's published. Sample: `job definition sample`
Main definition file	The main file used for the job. Select a PY file from your storage. You can select **Upload file** to upload the file to a storage account. Sample: `abfss://…/path/to/wordcount.py`
Command-line arguments	Optional arguments to the job. Sample: `abfss://…/path/to/shakespeare.txt` `abfss://…/path/to/result` *Note: Two arguments for the sample job definition are separated by a space.*

PROPERTY	DESCRIPTION
Reference files	Additional files used for reference in the main definition file. You can select **Upload file** to upload the file to a storage account.
Spark pool	The job will be submitted to the selected Apache Spark pool.
Spark version	Version of Apache Spark that the Apache Spark pool is running.
Executors	Number of executors to be given in the specified Apache Spark pool for the job.
Executor size	Number of cores and memory to be used for executors given in the specified Apache Spark pool for the job.
Driver size	Number of cores and memory to be used for driver given in the specified Apache Spark pool for the job.
Apache Spark configuration	Customize configurations by adding properties below. If you do not add a property, Azure Synapse will use the default value when applicable.



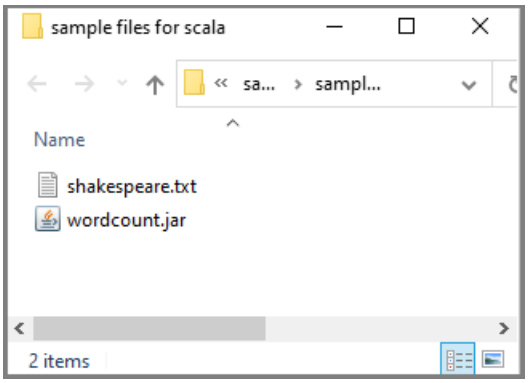
7. Select **Publish** to save the Apache Spark job definition.



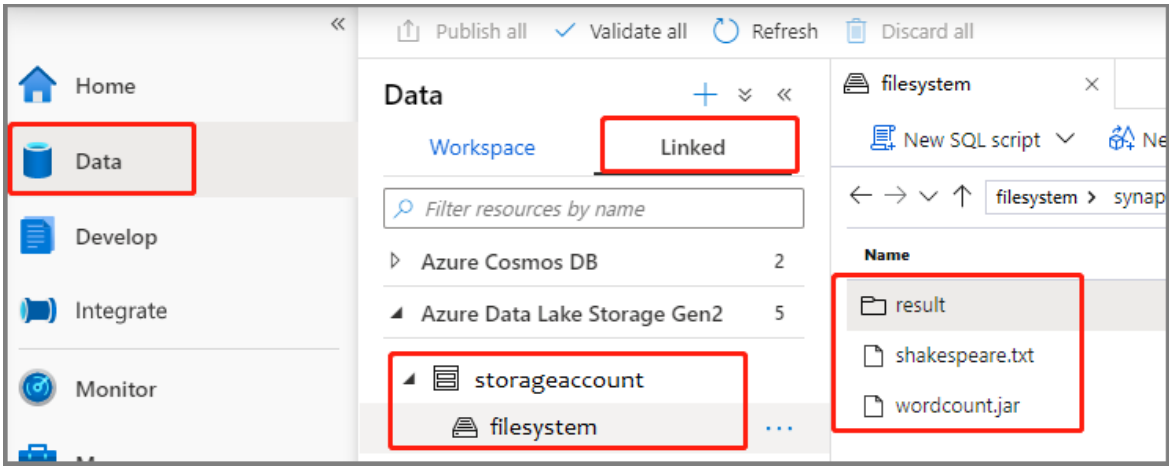
Create an Apache Spark job definition for Apache Spark(Scala)

In this section, you create an Apache Spark job definition for Apache Spark(Scala).

1. Open Azure Synapse Studio.
2. You can go to Sample files for creating Apache Spark job definitions to download **sample files for scala.zip**, then unzip the compressed package, and extract the **wordcount.jar** and **shakespeare.txt** files.

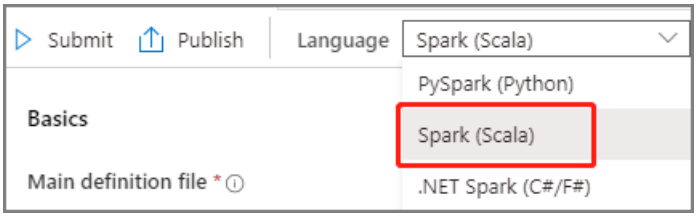


3. Select **Data** -> **Linked** -> **Azure Data Lake Storage Gen2**, and upload **wordcount.jar** and **shakespeare.txt** into your ADLS Gen2 filesystem.



4. Select **Develop** hub, select the '+' icon and select **Spark job definition** to create a new Spark job definition. (The sample image is the same as step 4 of **Create an Apache Spark job definition (Python) for PySpark**.)

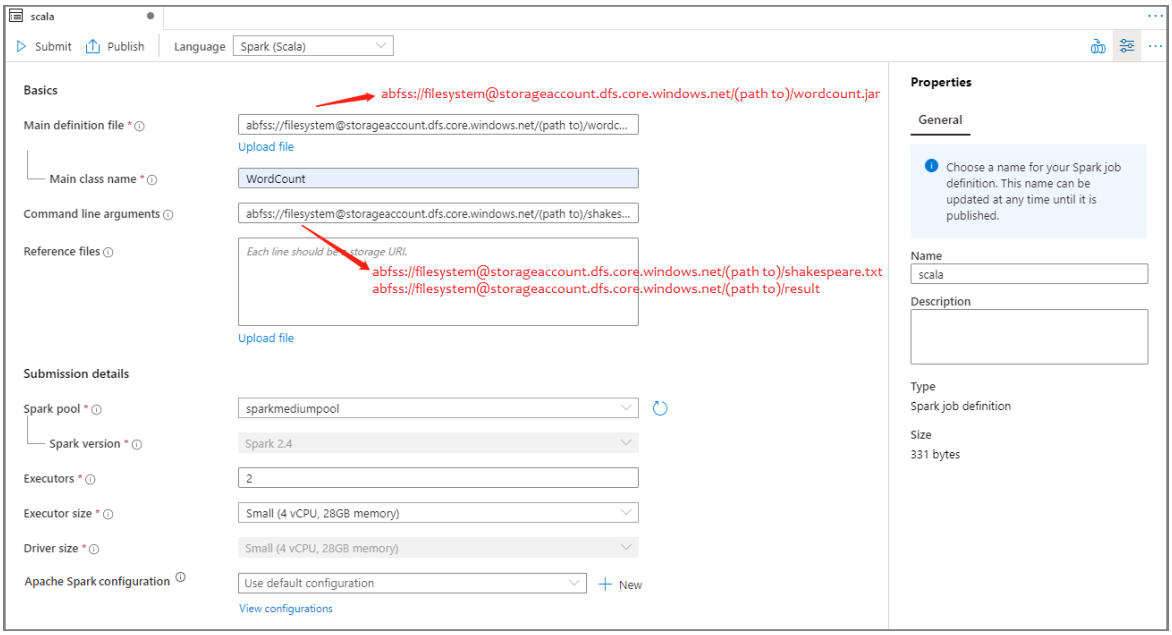
5. Select **Spark(Scala)** from the Language drop down list in the Apache Spark job definition main window.



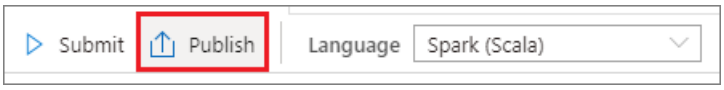
6. Fill in information for Apache Spark job definition. You can copy the sample information.

PROPERTY	DESCRIPTION
Job definition name	Enter a name for your Apache Spark job definition. This name can be updated at any time until it's published. Sample: `scala`
Main definition file	The main file used for the job. Select a JAR file from your storage. You can select **Upload file** to upload the file to a storage account. Sample: `abfss://…/path/to/wordcount.jar`
Main class name	The fully qualified identifier or the main class that is in the main definition file. Sample: `WordCount`

PROPERTY	DESCRIPTION
Command-line arguments	Optional arguments to the job. Sample: `abfss://…/path/to/shakespeare.txt` `abfss://…/path/to/result` *Note: Two arguments for the sample job definition are separated by a space.*
Reference files	Additional files used for reference in the main definition file. You can select **Upload file** to upload the file to a storage account.
Spark pool	The job will be submitted to the selected Apache Spark pool.
Spark version	Version of Apache Spark that the Apache Spark pool is running.
Executors	Number of executors to be given in the specified Apache Spark pool for the job.
Executor size	Number of cores and memory to be used for executors given in the specified Apache Spark pool for the job.
Driver size	Number of cores and memory to be used for driver given in the specified Apache Spark pool for the job.
Apache Spark configuration	Customize configurations by adding properties below. If you do not add a property, Azure Synapse will use the default value when applicable.



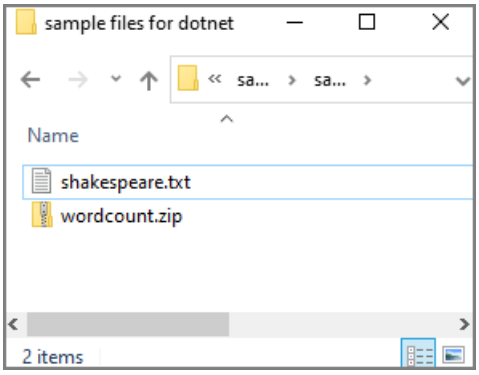
7. Select **Publish** to save the Apache Spark job definition.



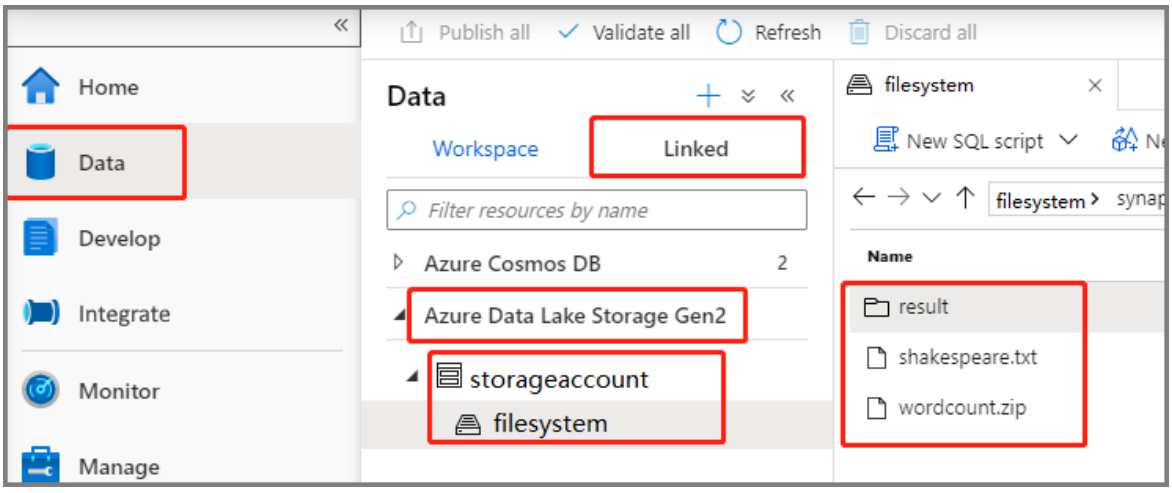
Create an Apache Spark job definition for .NET Spark(C#/F#)

In this section, you create an Apache Spark job definition for .NET Spark(C#/F#).

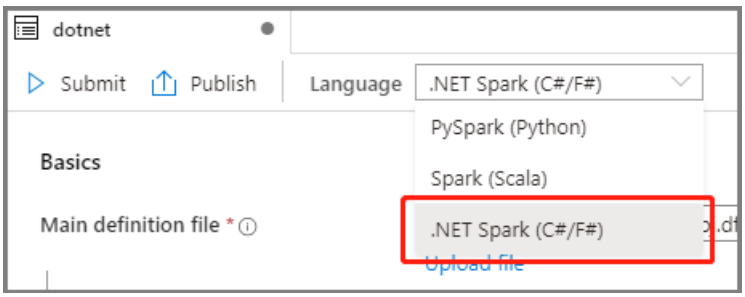
1. Open Azure Synapse Studio.
2. You can go to Sample files for creating Apache Spark job definitions to download **sample files for dotnet.zip**, then unzip the compressed package, and extract the **wordcount.zip** and **shakespeare.txt** files.



3. Select **Data** -> **Linked** -> **Azure Data Lake Storage Gen2**, and upload **wordcount.zip** and **shakespeare.txt** into your ADLS Gen2 filesystem.



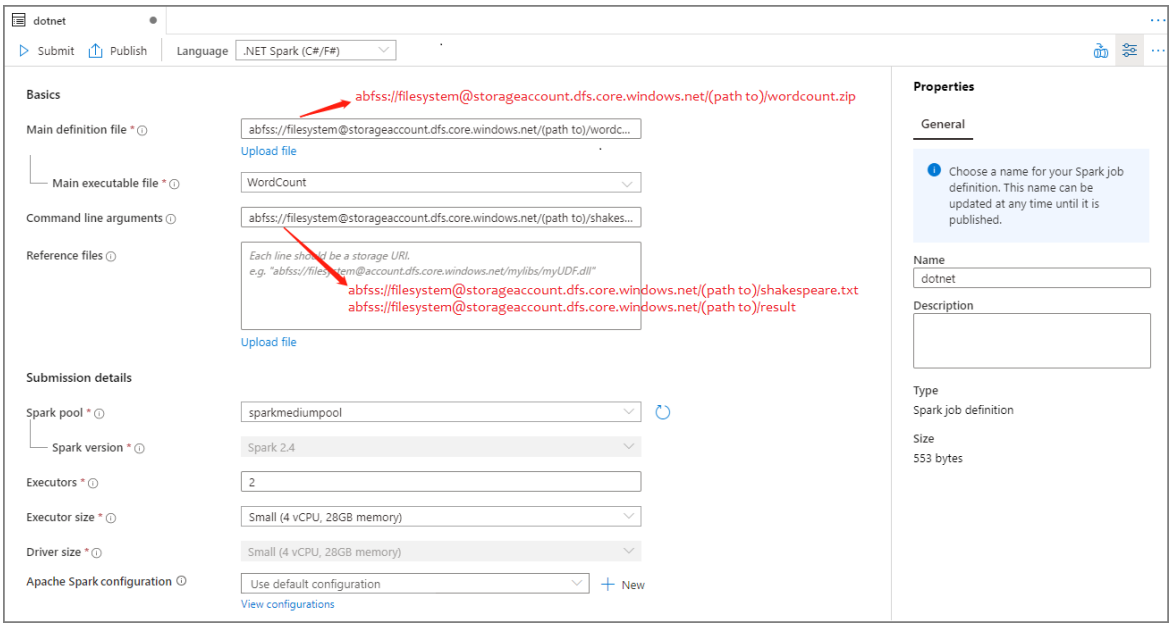
4. Select **Develop** hub, select the '+' icon and select **Spark job definition** to create a new Spark job definition. (The sample image is the same as step 4 of **Create an Apache Spark job definition (Python) for PySpark**.)
5. Select **.NET Spark(C#/F#)** from the Language drop down list in the Apache Spark Job Definition main window.



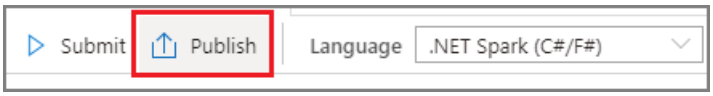
6. Fill in information for Apache Spark Job Definition. You can copy the sample information.

PROPERTY	DESCRIPTION

PROPERTY	DESCRIPTION
Job definition name	Enter a name for your Apache Spark job definition. This name can be updated at any time until it's published. Sample: `dotnet`
Main definition file	The main file used for the job. Select a ZIP file that contains your .NET for Apache Spark application (that is, the main executable file, DLLs containing user-defined functions, and other required files) from your storage. You can select **Upload file** to upload the file to a storage account. Sample: `abfss://…/path/to/wordcount.zip`
Main executable file	The main executable file in the main definition ZIP file. Sample: `WordCount`
Command-line arguments	Optional arguments to the job. Sample: `abfss://…/path/to/shakespeare.txt` `abfss://…/path/to/result` *Note: Two arguments for the sample job definition are separated by a space.*
Reference files	Additional files needed by the worker nodes for executing the .NET for Apache Spark application that isn't included in the main definition ZIP file (that is, dependent jars, additional user-defined function DLLs, and other config files). You can select **Upload file** to upload the file to a storage account.
Spark pool	The job will be submitted to the selected Apache Spark pool.
Spark version	Version of Apache Spark that the Apache Spark pool is running.
Executors	Number of executors to be given in the specified Apache Spark pool for the job.
Executor size	Number of cores and memory to be used for executors given in the specified Apache Spark pool for the job.
Driver size	Number of cores and memory to be used for driver given in the specified Apache Spark pool for the job.
Apache Spark configuration	Customize configurations by adding properties below. If you do not add a property, Azure Synapse will use the default value when applicable.



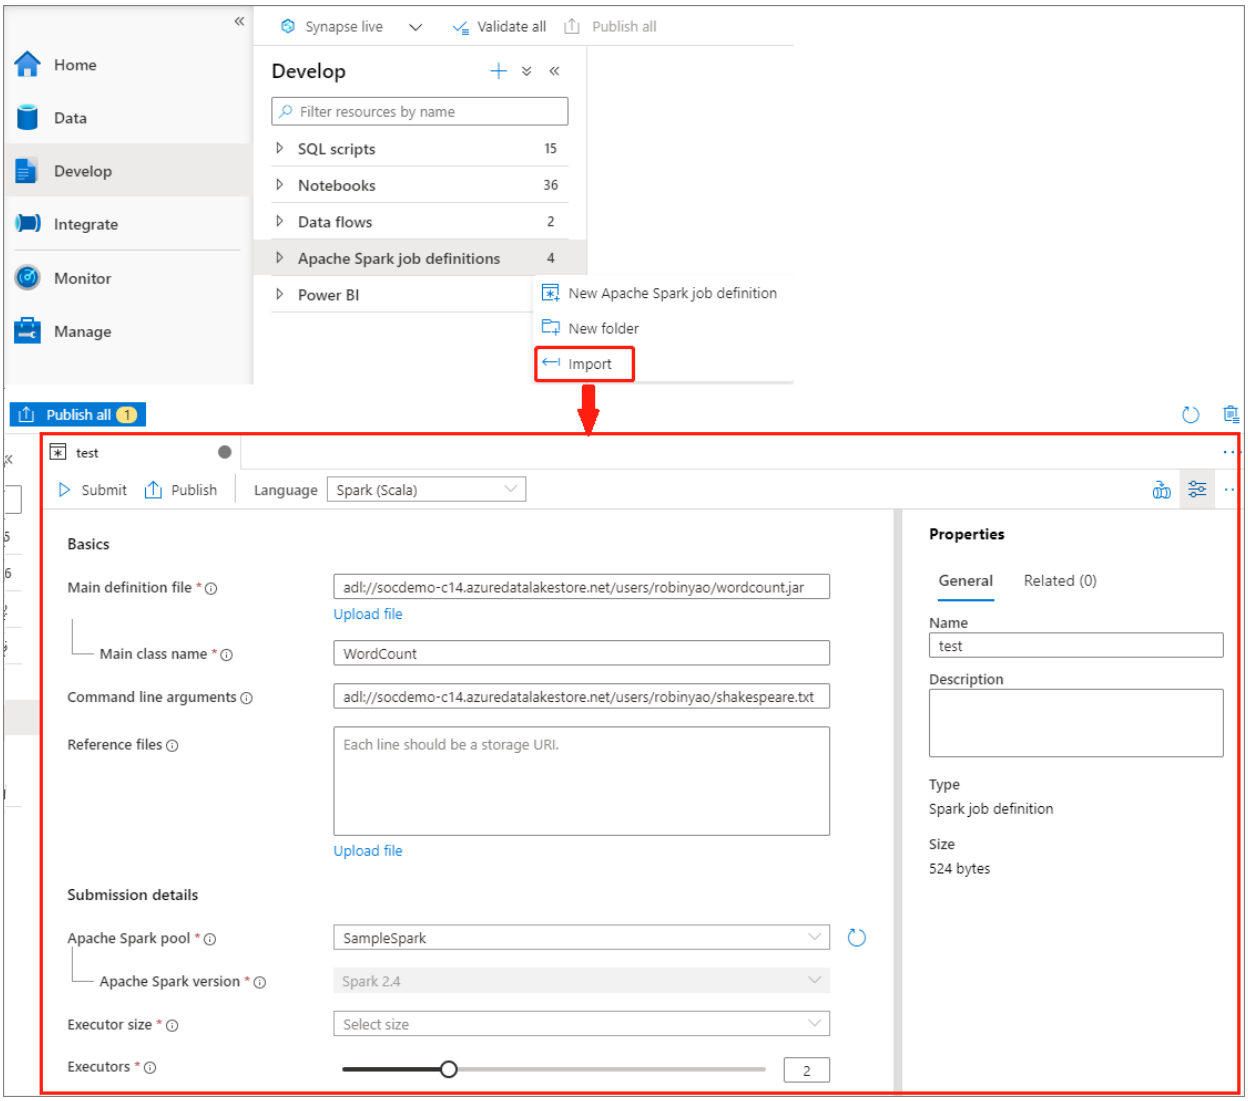
7. Select **Publish** to save the Apache Spark job definition.



> **NOTE**
>
> For Apache Spark configuration, if the Apache Spark configuration Apache Spark job definition does not do anything special, the default configuration will be used when running the job.

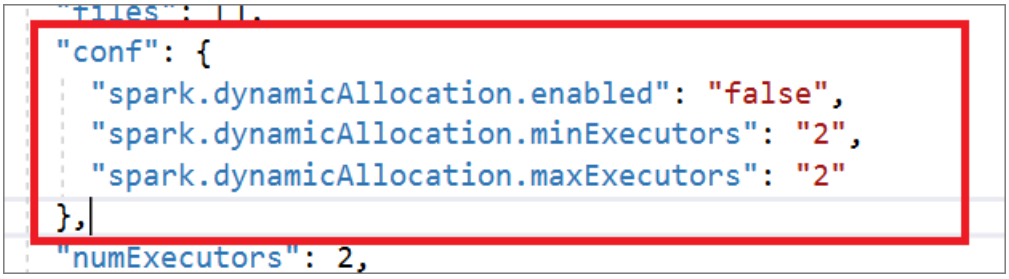
Create Apache Spark job definition by importing a JSON file

You can import an existing local JSON file into Azure Synapse workspace from the **Actions** (...) menu of the Apache Spark job definition Explorer to create a new Apache Spark job definition.



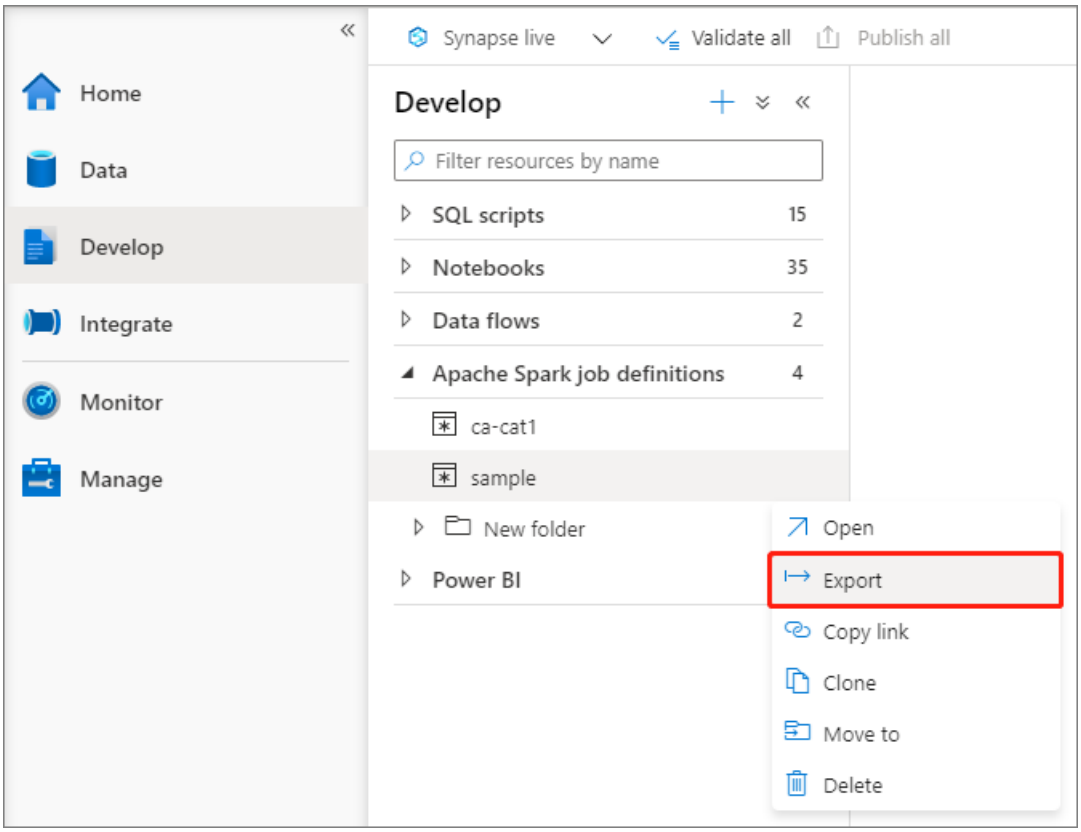
The Spark job definition is fully compatible with Livy API. You can add additional parameters for other Livy properties (Livy Docs - REST API (apache.org) in the local JSON file. You can also specify the Spark configuration related parameters in the config property as shown below. Then, you can import the JSON file back to create a new Apache Spark job definition for your batch job. Example JSON for spark definition import:

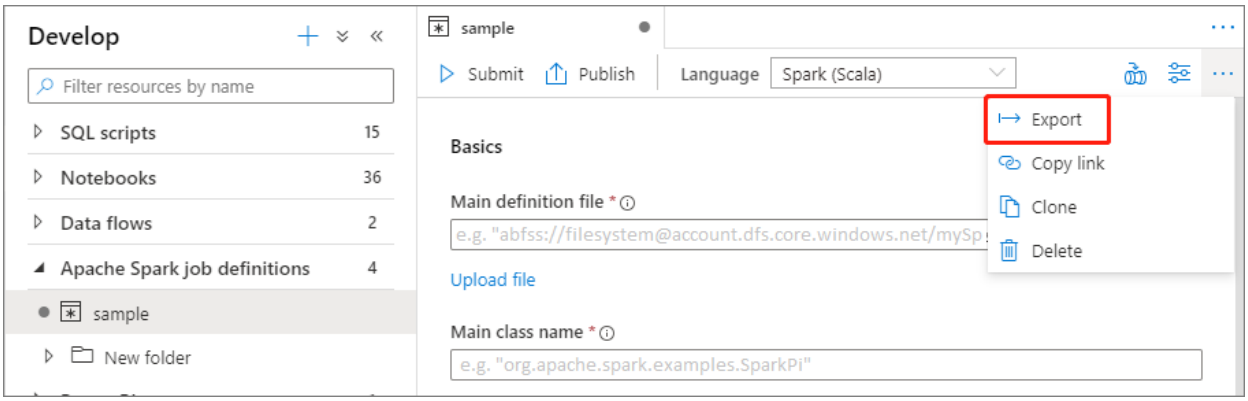
```
 {
"targetBigDataPool": {
  "referenceName": "socdemolarge",
  "type": "BigDataPoolReference"
},
"requiredSparkVersion": "2.3",
"language": "scala",
"jobProperties": {
  "name": "robinSparkDefinitiontest",
  "file": "adl://socdemo-c14.azuredatalakestore.net/users/robinyao/wordcount.jar",
  "className": "WordCount",
  "args": [
    "adl://socdemo-c14.azuredatalakestore.net/users/robinyao/shakespeare.txt"
  ],
  "jars": [],
  "files": [],
  "conf": {
    "spark.dynamicAllocation.enabled": "false",
    "spark.dynamicAllocation.minExecutors": "2",
    "spark.dynamicAllocation.maxExecutors": "2"
  },
  "numExecutors": 2,
  "executorCores": 8,
  "executorMemory": "24g",
  "driverCores": 8,
  "driverMemory": "24g"
}
}
```



Export an existing Apache Spark job definition file

You can export existing Apache Spark job definition files to local from **Actions** (...) menu of the File Explorer. You can further update the JSON file for additional Livy properties, and import it back to create new job definition if necessary.



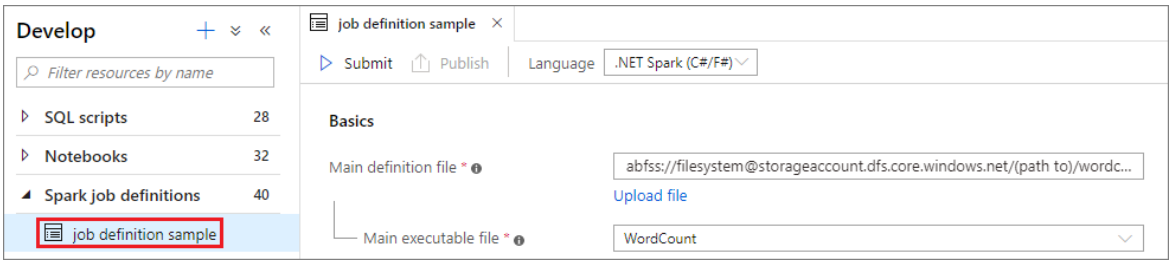


Submit an Apache Spark job definition as a batch job

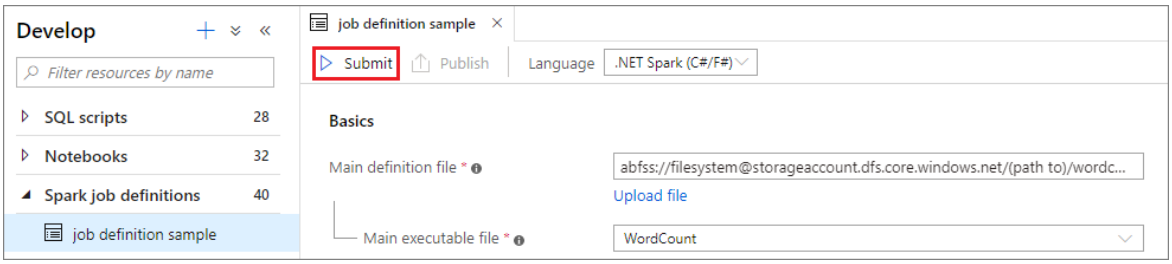
After creating an Apache Spark job definition, you can submit it to an Apache Spark pool. Make sure you are the **Storage Blob Data Contributor** of the ADLS Gen2 filesystem you want to work with. If you aren't, you need to add the permission manually.

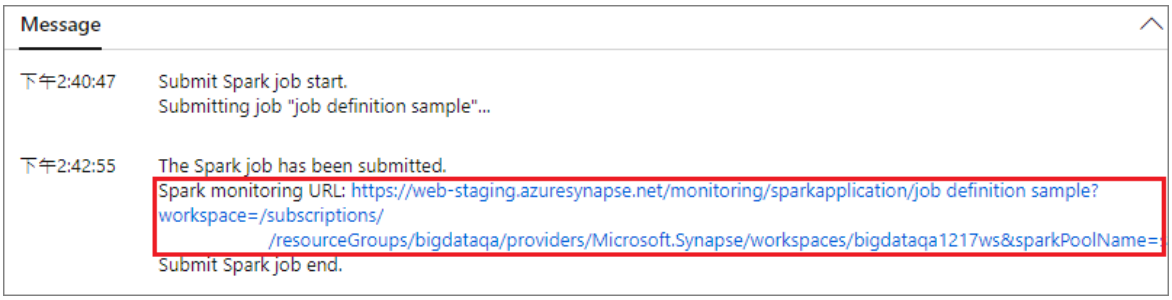
Scenario 1: Submit Apache Spark job definition

1. Open an Apache spark job definition window by selecting it.



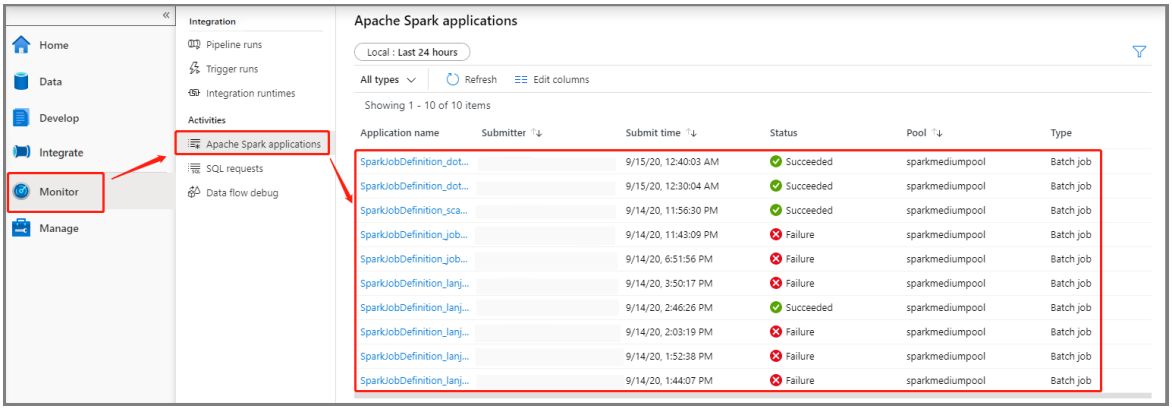
2. Select **Submit** button to submit your project to the selected Apache Spark Pool. You can select **Spark monitoring URL** tab to see the LogQuery of the Apache Spark application.



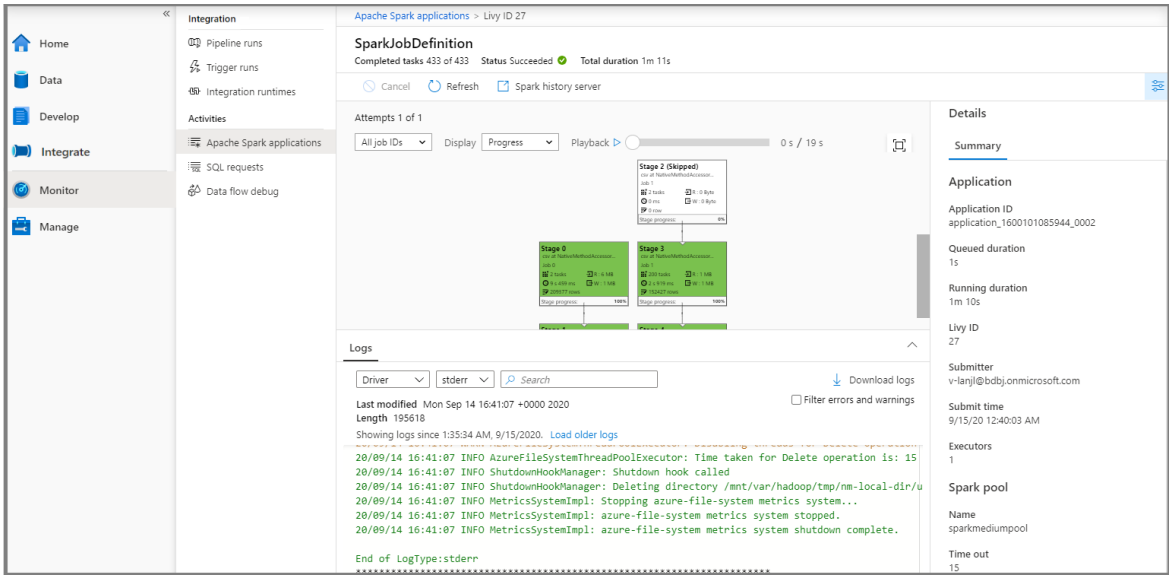


Scenario 2: View Apache Spark job running progress

1. Select **Monitor**, then select the **Apache Spark applications** option. You can find the submitted Apache Spark application.

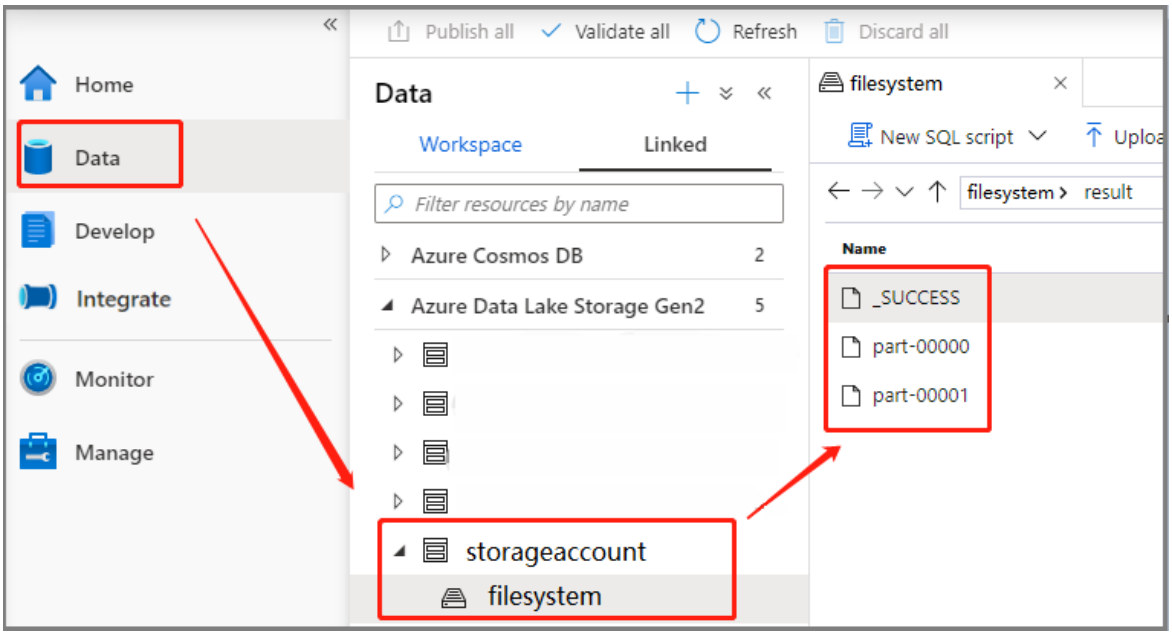


2. Then select an Apache Spark application, the **SparkJobDefinition** job window displays. You can view the job execution progress from here.



Scenario 3: Check output file

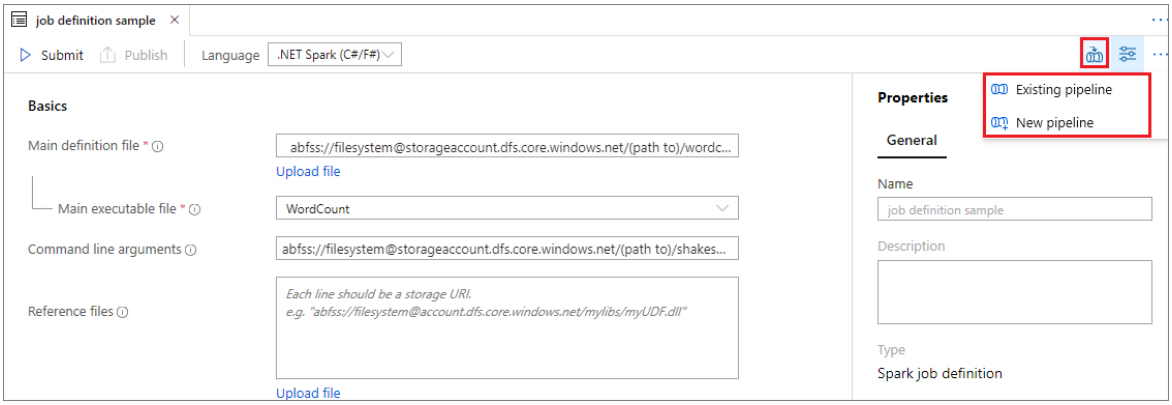
1. Select **Data -> Linked -> Azure Data Lake Storage Gen2** (hozhaobdbj), open the **result** folder created earlier, you can go to the result folder and check if the output is generated.

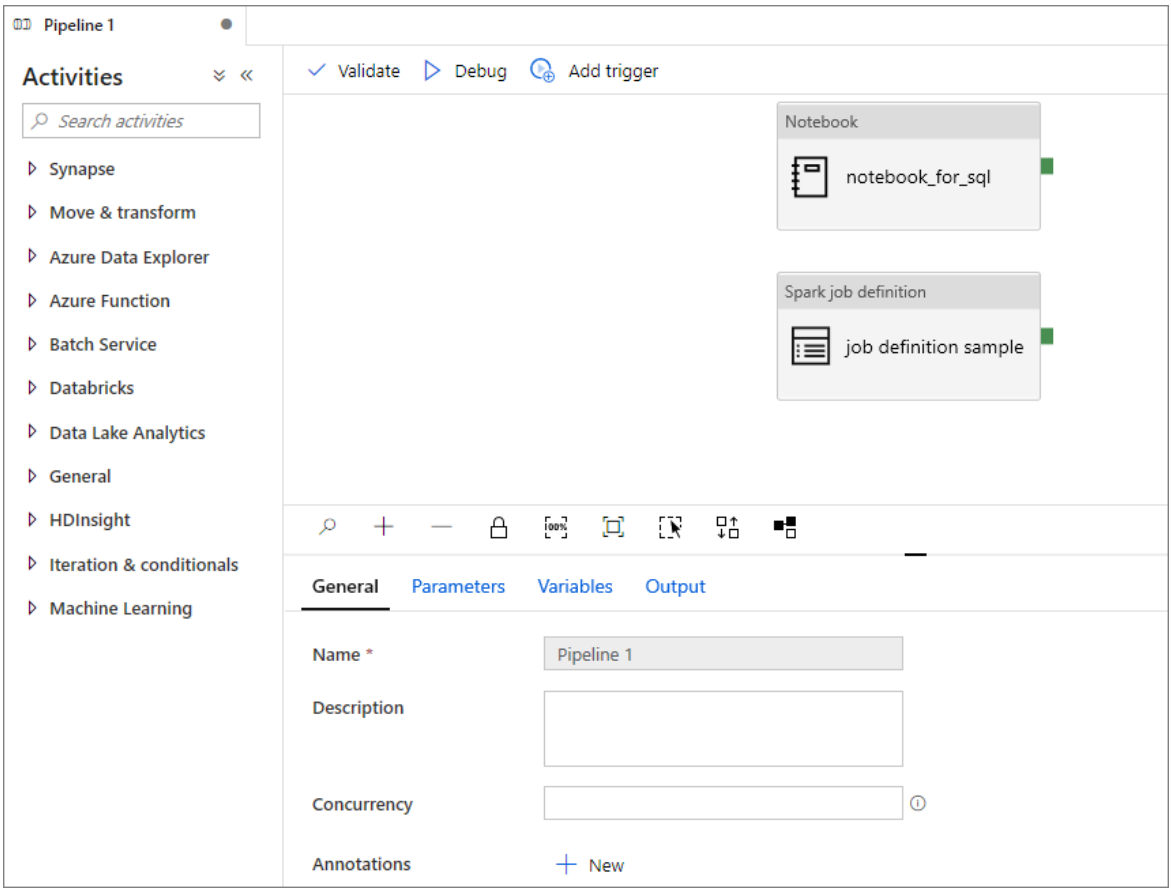


Add an Apache Spark job definition into pipeline

In this section, you add an Apache Spark job definition into pipeline.

1. Open an existing Apache Spark job definition.
2. Select the icon on the top right of Apache Spark job definition, choose **Existing Pipeline**, or **New pipeline**. You can refer to Pipeline page for more information.





Next steps

Next you can use Azure Synapse Studio to create Power BI datasets and manage Power BI data. Advance to the Linking a Power BI workspace to a Synapse workspace article to learn more.

Apache Spark in Azure Synapse Analytics Core Concepts

8/19/2022 • 4 minutes to read • Edit Online

Apache Spark is a parallel processing framework that supports in-memory processing to boost the performance of big-data analytic applications. Apache Spark in Azure Synapse Analytics is one of Microsoft's implementations of Apache Spark in the cloud.

Azure Synapse makes it easy to create and configure Spark capabilities in Azure. Azure Synapse provides a different implementation of these Spark capabilities that are documented here.

Spark pools

A serverless Apache Spark pool is created in the Azure portal. It's the definition of a Spark pool that, when instantiated, is used to create a Spark instance that processes data. When a Spark pool is created, it exists only as metadata, and no resources are consumed, running, or charged for. A Spark pool has a series of properties that control the characteristics of a Spark instance. These characteristics include but aren't limited to name, size, scaling behavior, time to live.

As there's no dollar or resource cost associated with creating Spark pools, any number can be created with any number of different configurations. Permissions can also be applied to Spark pools allowing users only to have access to some and not others.

A best practice is to create smaller Spark pools that may be used for development and debugging and then larger ones for running production workloads.

You can read how to create a Spark pool and see all their properties here Get started with Spark pools in Azure Synapse Analytics

Spark instances

Spark instances are created when you connect to a Spark pool, create a session, and run a job. As multiple users may have access to a single Spark pool, a new Spark instance is created for each user that connects.

When you submit a second job, if there is capacity in the pool, the existing Spark instance also has capacity. Then, the existing instance will process the job. Otherwise, if capacity is available at the pool level, then a new Spark instance will be created.

Examples

Example 1

- You create a Spark pool called SP1; it has a fixed cluster size of 20 nodes.
- You submit a notebook job, J1 that uses 10 nodes, a Spark instance, SI1 is created to process the job.
- You now submit another job, J2, that uses 10 nodes because there is still capacity in the pool and the instance, the J2, is processed by SI1.
- If J2 had asked for 11 nodes, there would not have been capacity in SP1 or SI1. In this case, if J2 comes from a notebook, then the job will be rejected; if J2 comes from a batch job, then it will be queued.

Example 2

- You create a Spark pool call SP2; it has an autoscale enabled 10 – 20 nodes

- You submit a notebook job, J1 that uses 10 nodes, a Spark instance, SI1, is created to process the job.
- You now submit another job, J2, that uses 10 nodes, because there is still capacity in the pool the instance auto grows to 20 nodes and processes J2.

Example 3

- You create a Spark pool called SP1; it has a fixed cluster size of 20 nodes.
- You submit a notebook job, J1 that uses 10 nodes, a Spark instance, SI1 is created to process the job.
- Another user, U2, submits a Job, J3, that uses 10 nodes, a new Spark instance, SI2, is created to process the job.
- You now submit another job, J2, that uses 10 nodes because there's still capacity in the pool and the instance, J2, is processed by SI1.

Quotas and resource constraints in Apache Spark for Azure Synapse

Workspace level

Every Azure Synapse workspace comes with a default quota of vCores that can be used for Spark. The quota is split between the user quota and the dataflow quota so that neither usage pattern uses up all the vCores in the workspace. The quota is different depending on the type of your subscription but is symmetrical between user and dataflow. However if you request more vCores than are remaining in the workspace, then you will get the following error:

```
Failed to start session: [User] MAXIMUM_WORKSPACE_CAPACITY_EXCEEDED
Your Spark job requested 480 vcores.
However, the workspace only has xxx vcores available out of quota of yyy vcores.
Try reducing the numbers of vcores requested or increasing your vcore quota. Click here for more information
- https://go.microsoft.com/fwlink/?linkid=213499
```

The link in the message points to this article.

The following article describes how to request an increase in workspace vCore quota.

- Select "Azure Synapse Analytics" as the service type.
- In the Quota details window, select Apache Spark (vCore) per workspace

Request a capacity increase via the Azure portal

Spark pool level

When you define a Spark pool you are effectively defining a quota per user for that pool, if you run multiple notebooks or jobs or a mix of the 2 it is possible to exhaust the pool quota. If you do, then an error message like the following will be generated

```
Failed to start session: Your Spark job requested xx vcores.
However, the pool is consuming yy vcores out of available zz vcores.Try ending the running job(s) in the
pool, reducing the numbers of vcores requested, increasing the pool maximum size or using another pool
```

To solve this problem you have to reduce your usage of the pool resources before submitting a new resource request by running a notebook or a job.

Apache Spark pool configurations in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

A Spark pool is a set of metadata that defines the compute resource requirements and associated behavior characteristics when a Spark instance is instantiated. These characteristics include but aren't limited to name, number of nodes, node size, scaling behavior, and time to live. A Spark pool in itself does not consume any resources. There are no costs incurred with creating Spark pools. Charges are only incurred once a Spark job is executed on the target Spark pool and the Spark instance is instantiated on demand.

You can read how to create a Spark pool and see all their properties here Get started with Spark pools in Synapse Analytics

Isolated Compute

The Isolated Compute option provides additional security to Spark compute resources from untrusted services by dedicating the physical compute resource to a single customer. Isolated compute option is best suited for workloads that require a high degree of isolation from other customer's workloads for reasons that include meeting compliance and regulatory requirements.
The Isolate Compute option is only available with the XXXLarge (80 vCPU / 504 GB) node size and only available in the following regions. The isolated compute option can be enabled or disabled after pool creation although the instance may need to be restarted. If you expect to enable this feature in the future, ensure that your Synapse workspace is created in an isolated compute supported region.

- East US
- West US 2
- South Central US
- US Gov Arizona
- US Gov Virginia

Nodes

Apache Spark pool instance consists of one head node and two or more worker nodes with a minimum of three nodes in a Spark instance. The head node runs additional management services such as Livy, Yarn Resource Manager, Zookeeper, and the Spark driver. All nodes run services such as Node Agent and Yarn Node Manager. All worker nodes run the Spark Executor service.

Node Sizes

A Spark pool can be defined with node sizes that range from a Small compute node with 4 vCore and 32 GB of memory up to a XXLarge compute node with 64 vCore and 512 GB of memory per node. Node sizes can be altered after pool creation although the instance may need to be restarted.

SIZE	VCORE	MEMORY
Small	4	32 GB
Medium	8	64 GB

SIZE	VCORE	MEMORY
Large	16	128 GB
XLarge	32	256 GB
XXLarge	64	512 GB
XXX Large (Isolated Compute)	80	504 GB

Autoscale

Apache Spark pools provide the ability to automatically scale up and down compute resources based on the amount of activity. When the autoscale feature is enabled, you can set the minimum and maximum number of nodes to scale. When the autoscale feature is disabled, the number of nodes set will remain fixed. This setting can be altered after pool creation although the instance may need to be restarted.

Elastic pool storage

Apache Spark pools utilize temporary disk storage while the pool is instantiated. For many Spark jobs, it is difficult to estimate cluster storage requirements, which may cause your Spark jobs to fail if the worker nodes exhaust storage. Elastic pool storage allows the Spark engine to monitor worker node temporary cluster storage, and attach additional disks if needed. No action is required by customers. Customers should see fewer job failures as a result of elastic pool storage.

> **NOTE**
> Azure Synapse Elastic pool storage is currently in Public Preview. During Public Preview there is no charge for use of Elastic Pool Storage.

Automatic pause

The automatic pause feature releases resources after a set idle period, reducing the overall cost of an Apache Spark pool. The number of minutes of idle time can be set once this feature is enabled. The automatic pause feature is independent of the autoscale feature. Resources can be paused whether the autoscale is enabled or disabled. This setting can be altered after pool creation although active sessions will need to be restarted.

GPU-accelerated Apache Spark pools in Azure Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics now supports Apache Spark pools accelerated with graphics processing units (GPUs).

By using NVIDIA GPUs, data scientists and engineers can reduce the time necessary to run data integration pipelines, score machine learning models, and more. This article describes how GPU-accelerated pools can be created and used with Azure Synapse Analytics. This article also details the GPU drivers and libraries that are pre-installed as part of the GPU-accelerated runtime.

> **NOTE**
> Azure Synapse GPU-enabled pools are currently in Public Preview.

Create a GPU-accelerated pool

To simplify the process for creating and managing pools, Azure Synapse takes care of pre-installing low-level libraries and setting up all the complex networking requirements between compute nodes. This integration allows users to get started with GPU- accelerated pools within just a few minutes. To learn more about how to create a GPU-accelerated pool, you can visit the quickstart on how to create a GPU-accelerated pool.

> **NOTE**
> - GPU-accelerated pools can be created in workspaces located in East US, Australia East, and North Europe.
> - GPU-accelerated pools are only availble with the Apache Spark 3 runtime.
> - You might need to request a limit increase in order to create GPU-enabled clusters.

GPU-accelerated runtime

NVIDIA GPU driver, CUDA, and cuDNN

Azure Synapse Analytics now offers GPU-accelerated Apache Spark pools, which include various NVIDIA libraries and configurations. By default, Azure Synapse Analytics installs the NVIDIA driver and libraries required to use GPUs on Spark driver and worker instances:

- CUDA 11.2
- libnccl2=2.8.4
- libnccl-dev=2.8.4
- libcudnn8=8.1.1
- libcudnn8-dev=8.1.1

> **NOTE**
> This software contains source code provided by NVIDIA Corporation. Specifically, to support the GPU-accelerated pools, Azure Synapse Apache Spark pools include code from CUDA Samples.

NVIDIA End User License Agreement (EULA)

When you select a GPU-accelerated Hardware option in Synapse Spark, you implicitly agree to the terms and conditions outlined in the NVIDIA EULA with respect to:

- CUDA 11.2: EULA :: CUDA Toolkit Documentation (nvidia.com)
- libnccl2=2.8.4: nccl/LICENSE.txt at master · NVIDIA/nccl (github.com)
- libnccl-dev=2.8.4: nccl/LICENSE.txt at master · NVIDIA/nccl (github.com)
- libcudnn8=8.1.1: Software License Agreement :: NVIDIA Deep Learning cuDNN Documentation
- libcudnn8-dev=8.1.1: Software License Agreement :: NVIDIA Deep Learning cuDNN Documentation
- The CUDA, NCCL, and cuDNN libraries, and the NVIDIA End User License Agreement (with NCCL Supplement) for the NCCL library

Accelerate ETL workloads

With built-in support for NVIDIA's RAPIDS Accelerator for Apache Spark, GPU-accelerated Spark pools in Azure Synapse can provide significant performance improvements compared to standard analytical benchmarks without requiring any code changes. Built on top of NVIDIA CUDA and UCX, NVIDIA RAPIDS enables GPU-accelerated SQL, DataFrame operations, and Spark shuffles. Since there are no code changes required to leverage these accelerations, users can also accelerate their data pipelines that rely on Linux Foundation's Delta Lake or Microsoft's Hyperspace indexing.

To learn more about how you can use the NVIDIA RAPIDS Accelerator with your GPU-accelerated pool in Azure Synapse Analytics, visit this guide on how to improve performance with RAPIDS.

Train deep learning models

Deep learning models are often data and computation intensive. Because of this, organizations often accelerate their training process with GPU-enabled clusters. In Azure Synapse Analytics, organizations can build models using frameworks like Tensorflow and PyTorch. Then, users can scale up their deep learning models with Horovod and Petastorm.

To learn more about how you can train distributed deep learning models, visit the following guides: - Tutorial: Distributed training with Horovod and Tensorflow - Tutorial: Distributed training with Horovod and PyTorch

Improve machine learning scoring workloads

Many organizations rely on large batch scoring jobs to frequently execute during narrow windows of time. To achieve improved batch scoring jobs, you can also use GPU-accelerated Spark pools with Microsoft's Hummingbird library. With Hummingbird, users can take their traditional, tree-based ML models and compile them into tensor computations. Hummingbird allows users to then seamlessly leverage native hardware acceleration and neural network frameworks to accelerate their ML model scoring without needing to rewrite their models.

What is Delta Lake

8/19/2022 • 2 minutes to read • Edit Online

Azure Synapse Analytics is compatible with Linux Foundation Delta Lake. Delta Lake is an open-source storage layer that brings ACID (atomicity, consistency, isolation, and durability) transactions to Apache Spark and big data workloads.

The current version of Delta Lake included with Azure Synapse has language support for Scala, PySpark, and .NET. There are links at the bottom of the page to more detailed examples and documentation.

Key features

FEATURE	DESCRIPTION
ACID Transactions	Data lakes are typically populated via multiple processes and pipelines, some of which are writing data concurrently with reads. Prior to Delta Lake and the addition of transactions, data engineers had to go through a manual error prone process to ensure data integrity. Delta Lake brings familiar ACID transactions to data lakes. It provides serializability, the strongest level of isolation level. Learn more at Diving into Delta Lake: Unpacking the Transaction Log.
Scalable Metadata Handling	In big data, even the metadata itself can be "big data". Delta Lake treats metadata just like data, leveraging Spark's distributed processing power to handle all its metadata. As a result, Delta Lake can handle petabyte-scale tables with billions of partitions and files at ease.
Time Travel (data versioning)	The ability to "undo" a change or go back to a previous version is one of the key features of transactions. Delta Lake provides snapshots of data enabling you to revert to earlier versions of data for audits, rollbacks or to reproduce experiments. Learn more in Introducing Delta Lake Time Travel for Large Scale Data Lakes.
Open Format	Apache Parquet is the baseline format for Delta Lake, enabling you to leverage the efficient compression and encoding schemes that are native to the format.
Unified Batch and Streaming Source and Sink	A table in Delta Lake is both a batch table, as well as a streaming source and sink. Streaming data ingest, batch historic backfill, and interactive queries all just work out of the box.
Schema Enforcement	Schema enforcement helps ensure that the data types are correct and required columns are present, preventing bad data from causing data inconsistency. For more information, see Diving Into Delta Lake: Schema Enforcement & Evolution
Schema Evolution	Delta Lake enables you to make changes to a table schema that can be applied automatically, without having to write migration DDL. For more information, see Diving Into Delta Lake: Schema Enforcement & Evolution

FEATURE	DESCRIPTION
Audit History	Delta Lake transaction log records details about every change made to data providing a full audit trail of the changes.
Updates and Deletes	Delta Lake supports Scala / Java / Python and SQL APIs for a variety of functionality. Support for merge, update, and delete operations helps you to meet compliance requirements. For more information, see Announcing the Delta Lake 0.6.1 Release, Announcing the Delta Lake 0.7 Release and Simple, Reliable Upserts and Deletes on Delta Lake Tables using Python APIs, which includes code snippets for merge, update, and delete DML commands.
100% Compatible with Apache Spark API	Developers can use Delta Lake with their existing data pipelines with minimal change as it is fully compatible with existing Spark implementations.

For full documentation, see the Delta Lake Documentation Page

For more information, see Delta Lake Project.

The need for optimize write on Apache Spark

8/19/2022 • 3 minutes to read • Edit Online

Analytical workloads on Big Data processing engines such as Apache Spark perform most efficiently when using standardized larger file sizes. The relation between the file size, the number of files, the number of Spark workers and its configurations, play a critical role on performance. Ingestion workloads into data lake tables may have the inherited characteristic of constantly writing lots of small files; this scenario is commonly known as the "small file problem".

Optimize Write is a Delta Lake on Synapse feature that reduces the number of files written and aims to increase individual file size of the written data. It dynamically optimizes partitions while generating files with a default 128 MB size. The target file size may be changed per workload requirements using configurations.

This feature achieves the file size by using an extra data shuffle phase over partitions, causing an extra processing cost while writing the data. The small write penalty should be outweighed by read efficiency on the tables.

> **NOTE**
> - Optimize write is available as a Preview feature.
> - It is available on Synapse Pools for Apache Spark versions 3.1 and 3.2.

Benefits of Optimize Writes

- It's available on Delta Lake tables for both Batch and Streaming write patterns.
- There's no need to change the `spark.write` command pattern. The feature is enabled by a configuration setting or a table property.
- It reduces the number of write transactions as compared to the OPTIMIZE command.
- OPTIMIZE operations will be faster as it will operate on fewer files.
- VACUUM command for deletion of old unreferenced files will also operate faster.
- Queries will scan fewer files with more optimal file sizes, improving either read performance or resource usage.

Optimize write usage scenarios

When to use it

- Delta lake partitioned tables subject to write patterns that generate suboptimal (less than 128 MB) or non-standardized files sizes (files with different sizes between itself).
- Repartitioned data frames that will be written to disk with suboptimal files size.
- Delta lake partitioned tables targeted by small batch SQL commands like UPDATE, DELETE, MERGE, CREATE TABLE AS SELECT, INSERT INTO, etc.
- Streaming ingestion scenarios with append data patterns to Delta lake partitioned tables where the extra write latency is tolerable.

When to avoid it

- Non partitioned tables.
- Use cases where extra write latency isn't acceptable.
- Large tables with well defined optimization schedules and read patterns.

How to enable and disable the optimize write feature

The optimize write feature is disabled by default.

Once the configuration is set for the pool or session, all Spark write patterns will use the functionality.

To use the optimize write feature, enable it using the following configuration:

1. Scala and PySpark

```
spark.conf.set("spark.microsoft.delta.optimizeWrite.enabled", "true")
```

2. Spark SQL

```
SET `spark.microsoft.delta.optimizeWrite.enabled` = true
```

To check the current configuration value, use the command as shown below:

1. Scala and PySpark

```
spark.conf.get("spark.microsoft.delta.optimizeWrite.enabled")
```

2. Spark SQL

```
SET `spark.microsoft.delta.optimizeWrite.enabled`
```

To disable the optimize write feature, change the following configuration as shown below:

1. Scala and PySpark

```
spark.conf.set("spark.microsoft.delta.optimizeWrite.enabled", "false")
```

2. Spark SQL

```
SET `spark.microsoft.delta.optimizeWrite.enabled` = false
```

Controlling optimize write using table properties

On new tables

1. SQL

```
CREATE TABLE <table_name> TBLPROPERTIES (delta.autoOptimize.optimizeWrite = true)
```

2. Scala

Using the DeltaTableBuilder API:

```
val table = DeltaTable.create()
  .tableName("<table_name>")
  .addColumnn("<colName>", <dataType>)
  .location("<table_location>")
  .property("delta.autoOptimize.optimizeWrite", "true")
  .execute()
```

On existing tables

1. SQL

```
ALTER TABLE <table_name> SET TBLPROPERTIES (delta.autoOptimize.optimizeWrite = true)
```

2. Scala

Using the DeltaTableBuilder API

```
val table = DeltaTable.replace()
  .tableName("<table_name>")
  .location("<table_location>")
  .property("delta.autoOptimize.optimizeWrite", "true")
  .execute()
```

How to get & change the current max file size configuration for Optimize Write

To get the current config value, use the bellow commands. The default is 128 MB.

1. Scala and PySpark

```
spark.conf.get("spark.microsoft.delta.optimizeWrite.binSize")
```

2. SQL

```
SET `spark.microsoft.delta.optimizeWrite.binSize`
```

- To change the config value

1. Scala and PySpark

```
spark.conf.set("spark.microsoft.delta.optimizeWrite.binSize", "134217728")
```

2. SQL

```
SET `spark.microsoft.delta.optimizeWrite.binSize` = 134217728
```

Next steps

- Use serverless Apache Spark pool in Synapse Studio.
- Run a Spark application in notebook.
- Create Apache Spark job definition in Azure Studio.

Automatically scale Azure Synapse Analytics Apache Spark pools

8/19/2022 • 3 minutes to read • Edit Online

Apache Spark for Azure Synapse Analytics pool's Autoscale feature automatically scales the number of nodes in a cluster instance up and down. During the creation of a new Apache Spark for Azure Synapse Analytics pool, a minimum and maximum number of nodes can be set when Autoscale is selected. Autoscale then monitors the resource requirements of the load and scales the number of nodes up or down. There's no additional charge for this feature.

Metrics monitoring

Autoscale continuously monitors the Spark instance and collects the following metrics:

METRIC	DESCRIPTION
Total Pending CPU	The total number of cores required to start execution of all pending jobs.
Total Pending Memory	The total memory (in MB) required to start execution of all pending jobs.
Total Free CPU	The sum of all unused cores on the active nodes.
Total Free Memory	The sum of unused memory (in MB) on the active nodes.
Used Memory per Node	The load on a node. A node on which 10 GB of memory is used, is considered under more load than a worker with 2 GB of used memory.

The above metrics are checked every 30 seconds. Autoscale makes scale-up and scale-down decisions based on these metrics.

Load-based scale conditions

When the following conditions are detected, Autoscale will issue a scale request:

SCALE-UP	SCALE-DOWN
Total pending CPU is greater than total free CPU for more than 1 minute.	Total pending CPU is less than total free CPU for more than 2 minutes.
Total pending memory is greater than total free memory for more than 1 minute.	Total pending memory is less than total free memory for more than 2 minutes.

For scale-up, the Azure Synapse Autoscale service calculates how many new nodes are needed to meet the current CPU and memory requirements, and then issues a scale-up request to add the required number of nodes.

For scale-down, based on the number of executors, application masters per node, the current CPU and memory

requirements, Autoscale issues a request to remove a certain number of nodes. The service also detects which nodes are candidates for removal based on current job execution. The scale down operation first decommissions the nodes, and then removes them from the cluster.

Get started

Create a serverless Apache Spark pool with Autoscaling

To enable the Autoscale feature, complete the following steps as part of the normal pool creation process:

1. On the **Basics** tab, select the **Enable autoscale** checkbox.
2. Enter the desired values for the following properties:
   - **Min** number of nodes.
   - **Max** number of nodes.

The initial number of nodes will be the minimum. This value defines the initial size of the instance when it's created. The minimum number of nodes can't be fewer than three.

Optionally, you can enable dynamic allocation of executors in scenarios where the executor requirements are vastly different across stages of a Spark Job or the volume of data processed fluctuates with time. By enabling Dynamic Allocation of Executors, we can utilize capacity as required.

On enabling dynamic allocation, it allows the job to scale the number of executors within min and max number of executors specified.

Apache Spark enables configuration of Dynamic Allocation of Executors through code as below:

```
%%configure -f
{
    "conf" : {
        "spark.dynamicAllocation.maxExecutors" : "6",
        "spark.dynamicAllocation.enable": "true",
        "spark.dynamicAllocation.minExecutors": "2"
 }
}
```

The defaults specified through the code override the values set through the user interface.

On enabling Dynamic allocation, Executors scale up or down based on the utilization of the Executors. This ensure that the Executors are provisioned in accordance with the needs of the job being run.

Best practices

Consider the latency of scale up or scale down operations

It can take 1 to 5 minutes for a scaling operation to complete.

Prepare for scaling down

During the instance scaling down process, Autoscale will put the nodes in decommissioning state so that no new executors can launch on that node.

The running jobs will continue to run and finish. The pending jobs will wait to be scheduled as normal with fewer available nodes.

Next steps

Quickstart to set up a new Spark pool Create a Spark pool

Intelligent Cache in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

The Intelligent Cache works seamlessly behind the scenes and caches data to help speed up the execution of Spark as it reads from your ADLS Gen2 data lake. It also automatically detects changes to the underlying files and will automatically refresh the files in the cache, providing you with the most recent data and when the cache size reaches its limit, the cache will automatically release the least read data to make space for more recent data. This feature lowers the total cost of ownership by improving performance up to 65% on subsequent reads of the files that are stored in the available cache for Parquet files and 50% for CSV files.

When querying a file or table from your data lake, the Apache Spark engine in Synapse will make a call to the remote ADLS Gen2 storage to read the underlying files. With every query request to read the same data, the Spark engine must make a call to remote ADLS Gen2 storage. This redundant process adds latency to your total processing time. Spark provides a caching feature that you must manually set the cache and release the cache to minimize the latency and improve overall performance. However, this can cause results to have stale data if the underlying data changes.

The Synapse Intelligent Cache simplifies this process by automatically caching each read within the allocated cache storage space on each Spark node. Each request for a file will check to see if the file exists in the cache and compare the tag from the remote storage to determine if the file is stale. If the file doesn't exist or if the file is stale, then Spark will read the file and store it in the cache. When the cache becomes full, the file with the oldest last access time will be evicted from the cache to allow for more recent files.

The Synapse cache is a single cache per node. If you're using a medium size node and run with two small executors on a single medium size node, these two executors would share the same cache.

Enable or Disable the cache

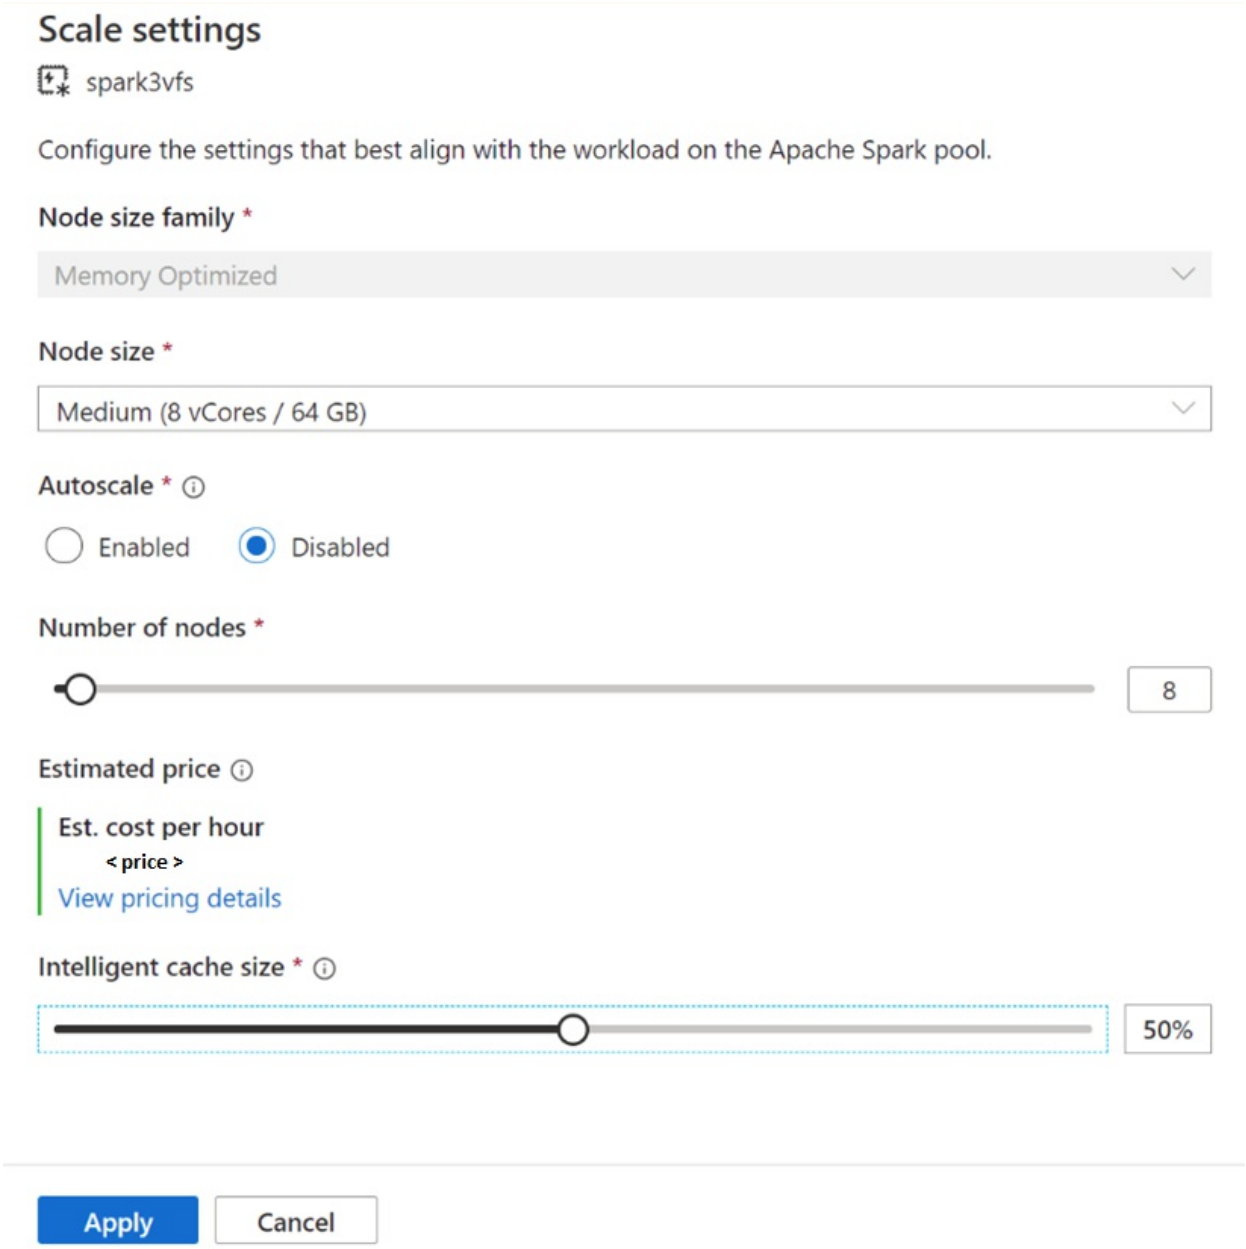
The cache size can be adjusted based on the percent of total disk size available for each Apache Spark pool.By default, the cache is set to disabled but it's as easy as moving the **slider** bar from 0 (disabled) to the desired percentage for your cache size to enable it.We reserve a minimum of 20% of available disk space for data shuffles.For shuffle intensive workloads, you can minimize the cache size or disable the cache. We recommend starting with a 50% cache size and adjust as necessary. It's important to note that if your workload requires a lot of disk space on the local SSD for shuffle or RDD caching, then consider reducing the cache size to reduce the chance of failure due to insufficient storage. The actual size of the available storage and the cache size on each node will depend on the node family and node size.

Enabling cache for new Spark pools

When creating a new Spark pool, browse under the **additional settings** tab to find the **Intelligent Cache slider** you can move to your preferred size to enable the feature.

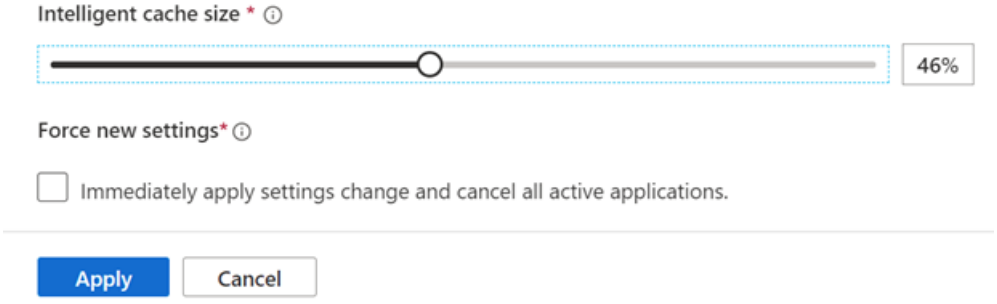
Enabling/Disabling cache for existing Spark pools

For existing Spark pools, browse to the **Scale settings** of your Apache Spark pool of choice to enable, by moving the **slider** to a value more than 0, or disable it, by moving **slider** to 0.



Changing cache size for existing Spark pools

To change the Intelligent Cache size of a pool, you must force a restart if the pool has active sessions. If the Spark pool has an active session, then it will show **Force new settings**. Click on the **check box** and select **Apply** to automatically restart the session.



Enabling and disabling the cache within the session

Easily disable the Intelligent Cache within a session by running the following code in your notebook:

```
%spark

spark.conf.set("spark.synapse.vegas.useCache", "false")
```

```
%pyspark

spark.conf.set('spark.synapse.vegas.useCache', 'false')
```

And enable by running:

```
%spark

spark.conf.set("spark.synapse.vegas.useCache", "true")
```

```
%pyspark

spark.conf.set('spark.synapse.vegas.useCache', 'true')
```

When to use the Intelligent Cache and when not to?

This feature will benefit you if:

- Your workload requires reading the same file multiple times and the file size can fit into the cache.
- Your workload uses Delta tables, parquet file formats and CSV files.
- You're using Apache Spark 3 or higher on Azure Synapse.

You won't see the benefit of this feature if:

- You're reading a file that exceeds the cache size because the beginning of the files could be evicted and subsequent queries will have to refetch the data from the remote storage. In this case, you won't see any benefits from the Intelligent Cache and you may want to increase your cache size and/or node size.
- Your workload requires large amounts of shuffle, then disabling the Intelligent Cache will free up available space to prevent your job from failing due to insufficient storage space.
- You're using a Spark 2.4 pool, you'll need to upgrade your pool to the latest version of Spark.

Learn more

To learn more on Apache Spark, see the following articles:

- What is Apache Spark
- Apache Spark core concepts
- Azure Synapse Runtime for Apache Spark 3.2
- Apache Spark pool sizes and configurations

To learn about configuring Spark session settings

- Configure Spark session settings
- How to set Spark / Pyspark custom configs

Next steps

An Apache Spark pool provides open-source big data compute capabilities where data can be loaded, modeled, processed, and distributed for faster analytic insight. To learn more about how to create one to run your Spark workloads, visit the following tutorials:

- Create a new serverless Apache Spark pool using the Azure portal

- Create a serverless Apache Spark pool using Synapse Studio

Azure Synapse runtimes

8/19/2022 • 2 minutes to read • Edit Online

Apache Spark pools in Azure Synapse use runtimes to tie together essential component versions such as Azure Synapse optimizations, packages, and connectors with a specific Apache Spark version. Each runtime will be upgraded periodically to include new improvements, features, and patches.

When you create a serverless Apache Spark pool, you will have the option to select the corresponding Apache Spark version. Based on this, the pool will come pre-installed with the associated runtime components and packages. The runtimes have the following advantages:

- Faster session startup times
- Tested compatibility with specific Apache Spark versions
- Access to popular, compatible connectors and open-source packages

NOTE

- Maintenance updates will be automatically applied to new sessions for a given serverless Apache Spark pool.
- You should test and validate that your applications run properly when using new runtime versions.

IMPORTANT

Log4j 1.2.x security patches

Open-source Log4j library version 1.2.x has several known CVEs (Common Vulnerabilities and Exposures), as described here.

On all Synapse Spark Pool runtimes, we have patched the Log4j 1.2.17 JARs to mitigate the following CVEs: CVE-2019-1751, CVE-2020-9488, CVE-2021-4104, CVE-2022-23302, CVE-2022-2330, CVE-2022-23307

The applied patch works by removing the following files which are required to invoke the vulnerabilities:

- `org/apache/log4j/net/SocketServer.class`
- `org/apache/log4j/net/SMTPAppender.class`
- `org/apache/log4j/net/JMSAppender.class`
- `org/apache/log4j/net/JMSSink.class`
- `org/apache/log4j/jdbc/JDBCAppender.class`
- `org/apache/log4j/chainsaw/*`

While the above classes were not used in the default Log4j configurations in Synapse, it is possible that some user application could still depend on it. If your application needs to use these classes, use Library Management to add a secure version of Log4j to the Spark Pool. **Do not use Log4j version 1.2.17**, as it would be reintroducing the vulnerabilities.

Supported Azure Synapse runtime releases

The following table lists the runtime name, Apache Spark version, and release date for supported Azure Synapse Runtime releases.

RUNTIME NAME	RELEASE DATE	RELEASE STAGE	END OF LIFE ANNOUNCEMENT DATE	END OF LIFE EFFECTIVE DATE
Azure Synapse Runtime for Apache Spark 3.2	July 8, 2022	GA	July 8, 2023	July 8, 2024
Azure Synapse Runtime for Apache Spark 3.1	May 26, 2021	LTS	January 26, 2023	January 26, 2024
Azure Synapse Runtime for Apache Spark 2.4	December 15, 2020	**End of Life Announced (EOLA)**	**July 29, 2022**	**July 28, 2023**

Runtime release stages

For the complete runtime for Apache Spark lifecycle and support policies, refer to Synapse runtime for Apache Spark lifecycle and supportability.

Runtime patching

Azure Synapse runtime for Apache Spark patches are rolled out monthly containing bug, feature and security fixes to the Apache Spark core engine, language environments, connectors and libraries.

The patch policy differs based on the runtime lifecycle stage:

1. Generally Available (GA) runtime: Receive no upgrades on major versions (i.e. 3.x -> 4.x). And will upgrade a minor version (i.e. 3.x -> 3.y) as long as there are no deprecation or regression impacts.
2. Preview runtime: No major version upgrades unless strictly necessary. Minor versions (3.x -> 3.y) will be upgraded to add latest features to a runtime.
3. Long Term Support (LTS) runtime will be patched with security fixes only.
4. End of life announced (EOLA) runtime will not have bug and feature fixes. Security fixes will be backported based on risk assessment.

Azure Synapse Runtime for Apache Spark 3.2

8/19/2022 • 5 minutes to read • Edit Online

Azure Synapse Analytics supports multiple runtimes for Apache Spark. This document will cover the runtime components and versions for the Azure Synapse Runtime for Apache Spark 3.2.

Component versions

COMPONENT	VERSION
Apache Spark	3.2.1
Operating System	Ubuntu 18.04
Java	1.8.0_282
Scala	2.12.15
Hadoop	3.3.1
.NET Core	3.1
.NET	2.0.0
Delta Lake	1.2
Python	3.8

Azure Synapse Runtime for Apache Spark 3.1

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics supports multiple runtimes for Apache Spark. This document will cover the runtime components and versions for the Azure Synapse Runtime for Apache Spark 3.1.

Component versions

COMPONENT	VERSION
Apache Spark	3.1.2
Operating System	Ubuntu 18.04
Java	1.8.0_282
Scala	2.12.10
Hadoop	3.1.1
.NET Core	3.1
.NET	2.0.0
Delta Lake	1.0
Python	3.8

Azure Synapse Runtime for Apache Spark 2.4

8/19/2022 • 3 minutes to read • Edit Online

Azure Synapse Analytics supports multiple runtimes for Apache Spark. This document will cover the runtime components and versions for the Azure Synapse Runtime for Apache Spark 2.4.

Component versions

COMPONENT	VERSION
Apache Spark	2.4.8
Operating System	Ubuntu 16.04
Java	1.8.0_272
Scala	2.11
.NET Core	3.1
.NET	1.0.0
Delta Lake	0.6
Python	3.6

Synapse runtime for Apache Spark lifecycle and supportability

8/19/2022 • 3 minutes to read • Edit Online

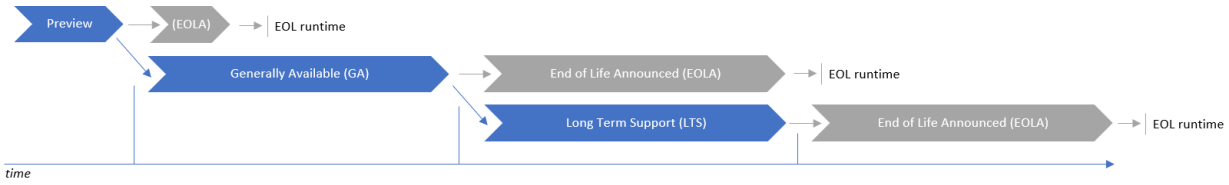
Apache Spark pools in Azure Synapse use runtimes to tie together essential component versions such as Azure Synapse optimizations, packages, and connectors with a specific Apache Spark version. Each runtime will be upgraded periodically to include new improvements, features, and patches.

Release cadence

The Apache Spark project usually releases minor versions about **every 6 months**. Once released, the Azure Synapse team aims to provide a **preview runtime within approximately 90 days**, if possible.

Runtime lifecycle

The following chart captures a typical lifecycle path for a Synapse runtime for Apache Spark.



RUNTIME RELEASE STAGE	TYPICAL LIFECYCLE*	NOTES
Preview	3 months*	Microsoft Azure Preview terms apply. See here for details: Preview Terms Of Use | Microsoft Azure
Generally Available (GA)	12 months*	Generally available (GA) runtimes are open to all eligible customers and are ready for production use. A GA runtime may not be elected to move into an LTS stage at Microsoft discretion.
Long Term Support (LTS)	12 months*	Long term support (LTS) runtimes are open to all eligible customers and are ready for production use, but customers are encouraged to expedite validation and workload migration to latest GA runtimes.
End of Life announced (EOLA)	12 months* for GA or LTS runtimes. 1 month* for Preview runtimes.	Prior to the end of a given runtime's lifecycle, we aim to provide 12 months notice to customers as an exit ramp to migrate workloads to a GA runtime.
End of Life (EOL)	-	At this stage, the runtime is retired and no longer supported.

** Expected duration of a runtime in each stage. These timelines are provided as an example for a given runtime, and may vary depending on various factors. Lifecycle timelines are subject to change at Microsoft discretion.*

*** Your use of runtimes is governed by the terms applicable to your Azure subscription.*

> **IMPORTANT**
>
> - The above timelines are provided as examples based on current Apache Spark releases. If the Apache Spark project changes the lifecycle of a specific version affecting a Synapse runtime, changes to the stage dates will be noted on the release notes.
> - Both GA and LTS runtimes may be moved into EOL stage faster based on outstanding security risks and usage rates criteria at Microsoft discretion.
> - Please refer to Lifecycle FAQ - Microsoft Azure for information about Azure lifecycle policies.

Release stages and support

Preview runtimes

Azure Synapse Analytics provides previews to give you a chance to evaluate and share feedback on features before they become generally available (GA).

At the end of the Preview lifecycle for the runtime, Microsoft will assess if the runtime will move into a Generally Availability (GA) based on customer usage, security and stability criteria.

If not eligible for GA stage, the Preview runtime will move into the retirement cycle.

Generally available runtimes

Once a runtime is Generally Available, only security fixes will be backported. In addition, new components or features will be introduced if they do not change underlying dependencies or component versions.

At the end of the GA lifecycle for the runtime, Microsoft will assess if the runtime will have an extended lifecycle (LTS) based on customer usage, security and stability criteria.

If not eligible for LTS stage, the GA runtime will move into the retirement cycle.

Long term support runtimes

For runtimes that are covered by Long term support (LTS) customers are encouraged to expedite validation and migration of code base and workloads to the latest GA runtimes. We recommend that customers do not onboard new workloads using an LTS runtime. Security fixes and stability improvements may be backported, but no new components or features will be introduced into the runtime at this stage.

End of life announcement

Prior to the end of the runtime lifecycle at any stage, an end of life announcement (EOLA) is performed.

Support SLAs are applicable for EOL announced runtimes, but all customers must migrate to a GA stage runtime no later than the EOL date.

Existing pools will work as expected, but **no new Synapse Spark pools of such a version can be created, as the runtime version will not be listed on Azure Synapse Studio, Synapse API, or Azure Portal.**

If necessary due to outstanding security issues, runtime usage, or other factors, Microsoft may expedite moving a runtime into the final EOL stage at any time, at Microsoft's discretion.

End of life and retirement

As of the applicable EOL date, runtimes are considered retired.

- Existing Spark Pools definitions and metadata will still exist in the workspace for a defined period, yet **all**

pipelines, jobs and notebooks will not be able to execute.

- Spark Pools definitions will be deleted from the Synapse workspace in 90 days after the applicable EOL date.

Machine learning with Apache Spark

8/19/2022 • 3 minutes to read • Edit Online

Apache Spark in Azure Synapse Analytics enables machine learning with big data, providing the ability to obtain valuable insight from large amounts of structured, unstructured, and fast-moving data.

This section includes an overview and tutorials for machine learning workflows, including exploratory data analysis, feature engineering, model training, model scoring, and deployment.

Synapse Runtime

The Synapse Runtime is a curated environment optimized for data science and machine learning. The Synapse Runtime offers a range of popular open-source libraries and builds in the Azure Machine Learning SDK by default. The Synapse Runtime also includes many external libraries, including PyTorch, Scikit-Learn, XGBoost, and more.

Learn more about the available libraries and related versions by viewing the published Azure Synapse Analytics runtime.

Exploratory data analysis

When using Apache Spark in Azure Synapse Analytics, there are various built-in options to help you visualize your data, including Synapse notebook chart options, access to popular open-source libraries like Seaborn and Matplotlib, as well as integration with Synapse SQL and Power BI.

Learn more about the data visualization and data analysis options by viewing the article on how to visualize data using Azure Synapse Notebooks.

Feature engineering

By default, the Synapse Runtime includes a set of libraries that are commonly used for feature engineering. For large datasets, you can use Spark SQL, MLlib, and Koalas for feature engineering. For smaller datasets, third-party libraries like Numpy, Pandas, and Scikit-learn also provide useful methods for these scenarios.

Train models

There are several options when training machine learning models using Azure Spark in Azure Synapse Analytics: Apache Spark MLlib, Azure Machine Learning, and various other open-source libraries.

Learn more about the machine learning capabilities by viewing the article on how to train models in Azure Synapse Analytics.

SparkML and MLlib

Spark's in-memory distributed computation capabilities make it a good choice for the iterative algorithms used in machine learning and graph computations. `spark.ml` provides a uniform set of high-level APIs that help users create and tune machine learning pipelines.To learn more about `spark.ml`, you can visit the Apache Spark ML programming guide.

Azure Machine Learning automated ML

Azure Machine Learning automated ML (automated machine learning) helps automate the process of developing machine learning models. It allows data scientists, analysts, and developers to build ML models with

high scale, efficiency, and productivity all while sustaining model quality. The components to run the Azure Machine Learning automated ML SDK is built directly into the Synapse Runtime.

Open-source libraries

Every Apache Spark pool in Azure Synapse Analytics comes with a set of pre-loaded and popular machine learning libraries. Some of the relevant machine learning libraries that are included by default include:

- Scikit-learn is one of the most popular single-node machine learning libraries for classical ML algorithms. Scikit-learn supports most of the supervised and unsupervised learning algorithms and can also be used for data-mining and data-analysis.
- XGBoost is a popular machine learning library that contains optimized algorithms for training decision trees and random forests.
- PyTorch & TensorFlow are powerful Python deep learning libraries. Within an Apache Spark pool in Azure Synapse Analytics, you can use these libraries to build single-machine models by setting the number of executors on your pool to zero. Even though Apache Spark is not functional under this configuration, it is a simple and cost-effective way to create single-machine models.

Track model development

MLFlow is an open-source library for managing the life cycle of your machine learning experiments. MLFlow Tracking is a component of MLflow that logs and tracks your training run metrics and model artifacts. To learn more about how you can use MLFlow Tracking through Azure Synapse Analytics and Azure Machine Learning, visit this tutorial on how to use MLFlow.

Model scoring

Model scoring, or inferencing, is the phase where a model is used to make predictions. For model scoring with SparkML or MLLib, you can leverage the native Spark methods to perform inferencing directly on a Spark DataFrame. For other open-source libraries and model types, you can also create a Spark UDF to scale out inference on large datasets. For smaller datasets, you can also use the native model inference methods provided by the library.

Register and serve models

Registering a model allows you to store, version, and track metadata about models in your workspace. After you have finished training your model, you can register your model to the Azure Machine Learning model registry. Once registered, ONNX models can also be used to enrich the data stored in dedicated SQL pools.

Next steps

To get started with machine learning in Azure Synapse Analytics, be sure to check out the following tutorials:

- Analyze data with Azure Synapse Notebooks
- Train a machine learning model with automated ML
- Train a machine learning model with Apache Spark MLlib

Azure Synapse Analytics notebooks

8/19/2022 • 2 minutes to read • Edit Online

A Synapse Studio notebook is a web interface for you to create files that contain live code, visualizations, and narrative text. Notebooks are a good place to validate ideas and use quick experiments to get insights from your data.

With an Synapse Studio notebook, you can:

- Get started with zero setup effort.
- Keep data secure with built-in enterprise security features.
- Analyze data across raw formats (CSV, txt, JSON, etc.), processed file formats (parquet, Delta Lake, ORC, etc.), and SQL tabular data files against Spark and SQL.
- Be productive with enhanced authoring capabilities and built-in data visualization.

This section contains articles on mixing languages, creating data visualizations, parameterizing notebooks, building pipelines, and more. It also contains references and tutorials on how you can get started with your notebook development.

Create, manage, and use notebooks

You can manage notebooks using the Synapse Studio UI.

To learn more on how you can create and manage notebooks, see the following articles:

- Manage Notebooks
  - Create notebooks
  - Develop notebooks
  - Bring data to a notebook
  - Use multiple languages using magic commands and temporary tables
  - Use cell magic commands
- Development
  - Configure Spark session settings
  - Use Microsoft Spark utilities
  - Visualize data using notebooks and libraries
  - Integrate a notebook into pipelines

Next steps

Notebooks are also widely used in data preparation, data visualization, machine learning, and other big data scenarios. To learn more about how you can use notebooks for your data analysis and big data scenarios, please visit the following tutorials:

- Create a notebook
- Create visualizations using Synapse Studio notebooks
- Build machine learning models with Apache Spark MLlib
- Build machine learning models with Azure automated ML

Manage libraries for Apache Spark in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Libraries provide reusable code that you might want to include in your programs or projects.

You might need to update your serverless Apache Spark pool environment for various reasons. For example, you might find that:

- One of your core dependencies released a new version.
- You need an extra package for training your machine learning model or preparing your data.
- You have found a better package and no longer need the older package.
- Your team has built a custom package that you need available in your Apache Spark pool.

To make third party or locally built code available to your applications, install a library onto one of your serverless Apache Spark pools or notebook session.

> **IMPORTANT**
>
> - There are three levels of package installing on Synapse Analytics -- default level, Spark pool level and session level.
> - Apache Spark in Azure Synapse Analytics has a full Anaconda install plus extra libraries served as the default level installation which is fully managed by Synapse. The Spark pool level packages can be used by all running Artifacts, e.g., Notebook and Spark job definition attaching the corresponding Spark pool. The session level installation will create an environment for the specific Notebook session, the change of session level libraries will not be persisted between sessions.
> - You can upload custom libraries and a specific version of an open-source library that you would like to use in your Azure Synapse Analytics Workspace. The workspace packages can be installed in your Spark pools.
> - To be noted, the pool level library management can take certain amount of time depending on the size of packages and the complexity of required dependencies. The session level installation is suggested with experimental and quick iterative scenarios.

Default Installation

Default packages include a full Anaconda install plus extra commonly used libraries. The full libraries list can be found at Apache Spark version support.

When a Spark instance starts, these libraries are included automatically. More packages can be added at the Spark pool level or session level.

Workspace packages

When your team develops custom applications or models, you might develop various code artifacts like *.whl* or *.jar* files to package your code.

In Synapse, workspace packages can be custom or private *.whl* or *.jar* files. You can upload these packages to your workspace and later assign them to a specific serverless Apache Spark pool. Once assigned, these workspace packages are installed automatically on all Spark pool sessions.

To learn more about how to manage workspace libraries, see the following article:

- Manage workspace packages

Pool packages

In some cases, you might want to standardize the packages that are used on an Apache Spark pool. This standardization can be useful if the same packages are commonly installed by multiple people on your team.

Using the Azure Synapse Analytics pool management capabilities, you can configure the default set of libraries to install on a given serverless Apache Spark pool. These libraries are installed on top of the base runtime.

Currently, pool management is only supported for Python. For Python, Synapse Spark pools use Conda to install and manage Python package dependencies. When specifying your pool-level libraries, you can now provide a *requirements.txt* or an *environment.yml* file. This environment configuration file is used every time a Spark instance is created from that Spark pool.

To learn more about these capabilities, see Manage Spark pool packages.

> **IMPORTANT**
>
> - If the package you are installing is large or takes a long time to install, this fact affects the Spark instance start up time.
> - Altering the PySpark, Python, Scala/Java, .NET, or Spark version is not supported.
> - Installing packages from PyPI is not supported within DEP-enabled workspaces.

Session-scoped packages

Often, when doing interactive data analysis or machine learning, you might try newer packages or you might need packages that are currently unavailable on your Apache Spark pool. Instead of updating the pool configuration, users can now use session-scoped packages to add, manage, and update session dependencies.

Session-scoped packages allow users to define package dependencies at the start of their session. When you install a session-scoped package, only the current session has access to the specified packages. As a result, these session-scoped packages don't affect other sessions or jobs using the same Apache Spark pool. In addition, these libraries are installed on top of the base runtime and pool level packages.

To learn more about how to manage session-scoped packages, see the following articles:

- Python session packages: At the start of a session, provide a Conda *environment.yml* to install more Python packages from popular repositories.
- Scala/Java session packages: At the start of your session, provide a list of *.jar* files to install using `%%configure`.

Manage your packages outside Synapse Analytics UI

If your team want to manage the libraries without visiting the package management UIs, you have the options to manage the workspace packages and pool level package updates through Azure PowerShell cmdlets or REST APIs for Synapse Analytics.

To learn more about Azure PowerShell cmdlets and package management REST APIs, see the following articles:

- Azure PowerShell cmdlets for Synapse Analytics: Manage your Spark pool libraries through Azure PowerShell cmdlets
- Package management REST APIs: Manage your Spark pool libraries through REST APIs

Monitor your Apache Spark applications in Synapse Studio

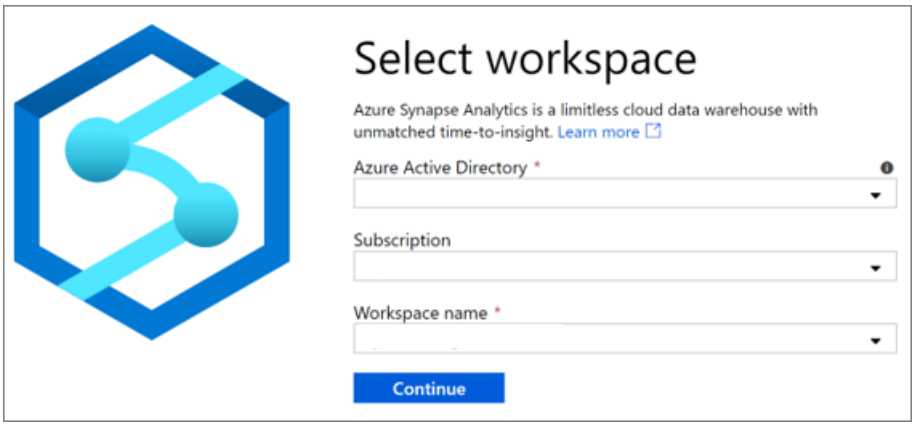
8/19/2022 • 2 minutes to read • Edit Online

With Azure Synapse Analytics, you can use Apache Spark to run notebooks, jobs, and other kinds of applications on your Apache Spark pools in your workspace.

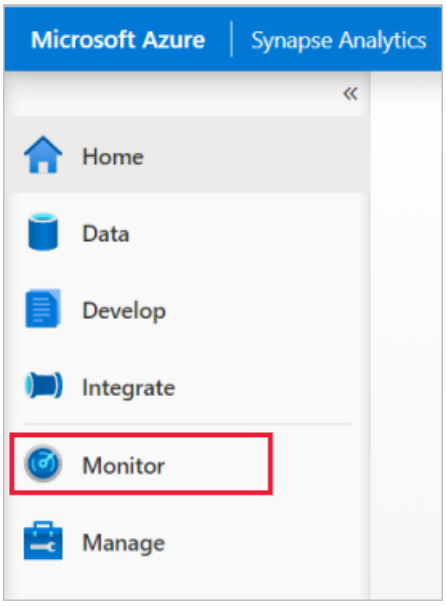
This article explains how to monitor your Apache Spark applications, allowing you to keep an eye on the latest status, issues, and progress.

Access Apache Spark applications list

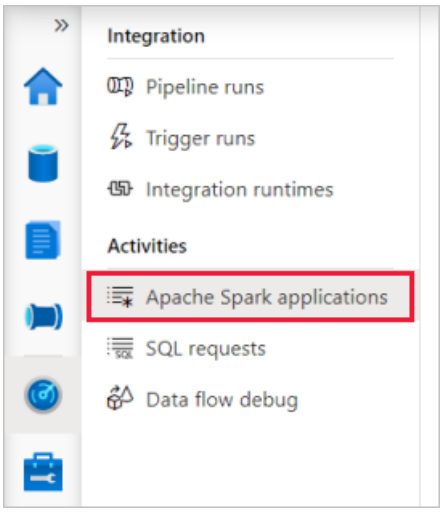
To see the list of Apache Spark applications in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.



Select **Apache Spark applications** to view the list of Apache Spark applications.



Filter your Apache Spark applications

You can filter the list of Apache Spark applications to the ones you're interested in. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the Apache Spark applications that contain the name "sales":

View details about a specific Apache Spark application

To view the details about one of your Apache Spark applications, select the Apache Spark application and view the details. If the Apache Spark application is still running, you can monitor the progress. Read more.

Next steps

For more information on monitoring pipeline runs, see the Monitor pipeline runs Synapse Studio article.

For more information on debugging Apache Spark application, see the Monitor Apache Spark applications on Synapse Studio article.

Linux Foundation Delta Lake overview

8/19/2022 • 10 minutes to read • Edit Online

This article has been adapted for more clarity from its original counterpart here. This article helps you quickly explore the main features of Delta Lake. The article provides code snippets that show how to read from and write to Delta Lake tables from interactive, batch, and streaming queries. The code snippets are also available in a set of notebooks PySpark here, Scala here, and C# here

Here's what we will cover:

- Create a table
- Read data
- Update table data
- Overwrite table data
- Conditional update without overwrite
- Read older versions of data using Time Travel
- Write a stream of data to a table
- Read a stream of changes from a table
- SQL Support

Configuration

Make sure you modify the below as appropriate for your environment.

```
import random

session_id = random.randint(0,1000000)
delta_table_path = "/delta/delta-table-{0}".format(session_id)

delta_table_path
```

```
var sessionId = (new Random()).Next(10000000);
var deltaTablePath = $"/delta/delta-table-{sessionId}";

deltaTablePath
```

```
val sessionId = scala.util.Random.nextInt(1000000)
val deltaTablePath = s"/delta/delta-table-$sessionId";
```

Results in:

'/delta/delta-table-335323'

Create a table

To create a Delta Lake table, write a DataFrame out a DataFrame in the delta format. You can change the format from Parquet, CSV, JSON, and so on, to delta.

The code that follows shows you how to create a new Delta Lake table using the schema inferred from your DataFrame.

```
data = spark.range(0,5)
data.show()
data.write.format("delta").save(delta_table_path)
```

```
var data = spark.Range(0,5);
data.Show();
data.Write().Format("delta").Save(deltaTablePath);
```

```
val data = spark.range(0, 5)
data.show
data.write.format("delta").save(deltaTablePath)
```

Results in:

ID
0
1
2
3
4

Read data

You read data in your Delta Lake table by specifying the path to the files and the delta format.

```
df = spark.read.format("delta").load(delta_table_path)
df.show()
```

```
var df = spark.Read().Format("delta").Load(deltaTablePath);
df.Show()
```

```
val df = spark.read.format("delta").load(deltaTablePath)
df.show()
```

Results in:

ID
1
3
4

ID
0
2

The order of the results is different from above as there was no order explicitly specified before outputting the results.

Update table data

Delta Lake supports several operations to modify tables using standard DataFrame APIs, this is one of the big enhancements that delta format adds. The following example runs a batch job to overwrite the data in the table.

```
data = spark.range(5,10)
data.write.format("delta").mode("overwrite").save(delta_table_path)
df.show()
```

```
var data = spark.Range(5,10);
data.Write().Format("delta").Mode("overwrite").Save(deltaTablePath);
df.Show();
```

```
val data = spark.range(5, 10)
data.write.format("delta").mode("overwrite").save(deltaTablePath)
df.show()
```

Results in:

ID
7
8
5
9
6

Here you can see that all five records have been updated to hold new values.

Save as catalog tables

Delta Lake can write to managed or external catalog tables.

```
data.write.format("delta").saveAsTable("ManagedDeltaTable")
spark.sql("CREATE TABLE ExternalDeltaTable USING DELTA LOCATION '{0}'".format(delta_table_path))
spark.sql("SHOW TABLES").show()
```

```
data.Write().Format("delta").SaveAsTable("ManagedDeltaTable");
spark.Sql($"CREATE TABLE ExternalDeltaTable USING DELTA LOCATION '{deltaTablePath}'");
spark.Sql("SHOW TABLES").Show();
```

```
data.write.format("delta").saveAsTable("ManagedDeltaTable")
spark.sql(s"CREATE TABLE ExternalDeltaTable USING DELTA LOCATION '$deltaTablePath'")
spark.sql("SHOW TABLES").show
```

Results in:

DATABASE	TABLENAME	ISTEMPORARY
default	externaldeltatable	false
default	manageddeltatable	false

With this code, you created a new table in the catalog from an existing dataframe, referred to as a managed table. Then you defined a new external table in the catalog that uses an existing location, referred to as an external table. In the output you can see both tables, no matter how they were created, are listed in the catalog.

Now you can look at the extended properties of both of these tables

```
spark.sql("DESCRIBE EXTENDED ManagedDeltaTable").show(truncate=False)
```

```
spark.Sql("DESCRIBE EXTENDED ManagedDeltaTable").Show(truncate: 0);
```

```
spark.sql("DESCRIBE EXTENDED ManagedDeltaTable").show(truncate=false)
```

Results in:

Conditional update without overwrite

Delta Lake provides programmatic APIs to conditional update, delete, and merge (this is commonly referred to as an upsert) data into tables.

```
from delta.tables import *
from pyspark.sql.functions import *

delta_table = DeltaTable.forPath(spark, delta_table_path)

delta_table.update(
  condition = expr("id % 2 == 0"),
  set = { "id": expr("id + 100") })
delta_table.toDF().show()
```

```
using Microsoft.Spark.Extensions.Delta;
using Microsoft.Spark.Extensions.Delta.Tables;
using Microsoft.Spark.Sql;
using static Microsoft.Spark.Sql.Functions;

var deltaTable = DeltaTable.ForPath(deltaTablePath);

deltaTable.Update(
  condition: Expr("id % 2 == 0"),
  set: new Dictionary<string, Column>(){{ "id", Expr("id + 100") }});
deltaTable.ToDF().Show();
```

```
import io.delta.tables._
import org.apache.spark.sql.functions._

val deltaTable = DeltaTable.forPath(deltaTablePath)

// Update every even value by adding 100 to it
deltaTable.update(
  condition = expr("id % 2 == 0"),
  set = Map("id" -> expr("id + 100")))
deltaTable.toDF.show
```

Results in:

ID
106
108
5
7
9

Here you just added 100 to every even ID.

```
delta_table.delete("id % 2 == 0")
delta_table.toDF().show()
```

```
deltaTable.Delete(condition: Expr("id % 2 == 0"));
deltaTable.ToDF().Show();
```

```
deltaTable.delete(condition = expr("id % 2 == 0"))
deltaTable.toDF.show
```

Results in:

ID
5
7
9

Notice that every even row has been deleted.

```
new_data = spark.range(0,20).alias("newData")

delta_table.alias("oldData")\
    .merge(new_data.alias("newData"), "oldData.id = newData.id")\
    .whenMatchedUpdate(set = { "id": lit("-1")})\
    .whenNotMatchedInsert(values = { "id": col("newData.id") })\
    .execute()

delta_table.toDF().show(100)
```

```
var newData = spark.Range(20).As("newData");

deltaTable
    .As("oldData")
    .Merge(newData, "oldData.id = newData.id")
    .WhenMatched()
        .Update(new Dictionary<string, Column>() {{"id", Lit("-1")}})
    .WhenNotMatched()
        .Insert(new Dictionary<string, Column>() {{"id", Col("newData.id")}})
    .Execute();

deltaTable.ToDF().Show(100);
```

```
val newData = spark.range(0, 20).toDF

deltaTable.as("oldData").
  merge(
    newData.as("newData"),
    "oldData.id = newData.id").
  whenMatched.
  update(Map("id" -> lit(-1))).
  whenNotMatched.
  insert(Map("id" -> col("newData.id"))).
  execute()

deltaTable.toDF.show()
```

Results in:

ID
18
15
19
2
1
6
8
3

ID
-1
10
13
0
16
4
-1
12
11
14
-1
17

Here you have a combination of the existing data. The existing data has been assigned the value -1 in the update(WhenMatched) code path. The new data that was created at the top of the snippet and was added via the insert code path (WhenNotMatched), was also added.

History

Delta Lake's has the ability to allow looking into history of a table. That is, the changes that were made to the underlying Delta Table. The cell below shows how simple it is to inspect the history.

```
delta_table.history().show(20, 1000, False)
```

```
deltaTable.History().Show(20, 1000, false);
```

```
deltaTable.history.show(false)
```

Results in:

VERSION	TIMESTAMP	USERID	USERNAME	OPERATION	OPERATIONPARAMETERS	JOB	NOTEBOOK	CLUSTERID	READVERSION	ISOLATIONLEVEL	ISBLINDAPPEND

VERSION	TIMESTAMP	USERID	USERNAME	OPERATION	OPERATIONPARAMETERS	JOB	NOTEBOOK	CLUSTERID	READVERSION	ISOLATIONLEVEL	ISBLINDAPPEND
4	2020-04-25 00:36:27	null	null	MERGE	[predicate -> (oldData.`ID` = newData.`ID`)]	null	null	null	3	null	false
3	2020-04-25 00:36:08	null	null	DELETE	[predicate -> ["((`ID` % CAST(2 AS BIGINT)) = CAST(0 AS BIGINT))"]]	null	null	null	2	null	false
2	2020-04-25 00:35:51	null	null	UPDATE	[predicate -> ((ID#744L % cast(2 as bigint)) = cast(0 as bigint))]	null	null	null	1	null	false
1	2020-04-25 00:35:05	null	null	WRITE	[mode -> Overwrite, partitionBy -> []]	null	null	null	0	null	false
0	2020-04-25 00:34:34	null	null	WRITE	[mode -> ErrorIfExists, partitionBy -> []]	null	null	null	null	null	true

Here you can see all of the modifications made over the above code snippets.

Read older versions of data using Time Travel

It's possible to query previous snapshots of your Delta Lake table by using a feature called Time Travel. If you want to access the data that you overwrote, you can query a snapshot of the table before you overwrote the first set of data using the versionAsOf option.

Once you run the cell below, you should see the first set of data from before you overwrote it. Time Travel is an extremely powerful feature that takes advantage of the power of the Delta Lake transaction log to access data that is no longer in the table. Removing the version 0 option (or specifying version 1) would let you see the newer data again. For more information, see Query an older snapshot of a table.

```
df = spark.read.format("delta").option("versionAsOf", 0).load(delta_table_path)
df.show()
```

```
var df = spark.Read().Format("delta").Option("versionAsOf", 0).Load(deltaTablePath);
df.Show();
```

```
val df = spark.read.format("delta").option("versionAsOf", 0).load(deltaTablePath)
df.show()
```

Results in:

ID
0
1
4
3
2

Here you can see you have gone back to the earliest version of the data.

Write a stream of data to a table

You can also write to a Delta Lake table using Spark's Structured Streaming. The Delta Lake transaction log guarantees exactly once processing, even when there are other streams or batch queries running concurrently against the table. By default, streams run in append mode, which adds new records to the table.

For more information about Delta Lake integration with Structured Streaming, see Table Streaming Reads and Writes.

In the cells below, here's what we are doing:

- Cell 30 Show the newly appended data
- Cell 31 Inspect history
- Cell 32 Stop the structured streaming job
- Cell 33 Inspect history <--You'll notice appends have stopped

First you are going to set up a simple Spark Streaming job to generate a sequence and make the job write to

your Delta Table.

```
streaming_df = spark.readStream.format("rate").load()
stream = streaming_df\
    .selectExpr("value as id")\
    .writeStream\
    .format("delta")\
    .option("checkpointLocation", "/tmp/checkpoint-{0}".format(session_id))\
    .start(delta_table_path)
```

```
var streamingDf = spark.ReadStream().Format("rate").Load();
var stream = streamingDf.SelectExpr("value as
id").WriteStream().Format("delta").Option("checkpointLocation", $"/tmp/checkpoint-
{sessionId}").Start(deltaTablePath);
```

```
val streamingDf = spark.readStream.format("rate").load()
val stream = streamingDf.select($"value" as "id").writeStream.format("delta").option("checkpointLocation",
s"/tmp/checkpoint-$sessionId").start(deltaTablePath)
```

Read a stream of changes from a table

While the stream is writing to the Delta Lake table, you can also read from that table as a streaming source. For example, you can start another streaming query that prints all the changes made to the Delta Lake table.

```
delta_table.toDF().sort(col("id").desc()).show(100)
```

```
deltaTable.ToDF().Sort(Col("id").Desc()).Show(100);
```

```
deltaTable.toDF.sort($"id".desc).show
```

Results in:

ID

0	2020-04-25 00:34:34	WRITE	[mode -> ErrorIfExists, partitionBy -> []]	null

Here you are dropping some of the less interesting columns to simplify the viewing experience of the history view.

```
stream.stop()
delta_table.history().drop("userId", "userName", "job", "notebook", "clusterId", "isolationLevel",
"isBlindAppend").show(100, 1000, False)
```

```
stream.Stop();
deltaTable.History().Drop("userId", "userName", "job", "notebook", "clusterId", "isolationLevel",
"isBlindAppend").Show(100, 1000, false);
```

```
stream.stop
deltaTable.history.show
```

Results in:

VERSION	TIMESTAMP	OPERATION	OPERATIONPARAMETERS	READVERSION
5	2020-04-25 00:37:09	STREAMING UPDATE	[outputMode -> Append, queryId -> d26b4f8a-7e5a-44f2-a5fb-23a7bd02aef7, epochId -> 0]	4
4	2020-04-25 00:36:27	MERGE	[predicate -> (oldData.`id` = newData.`id`)]	3
3	2020-04-25 00:36:08	DELETE	[predicate -> ["((`id` % CAST(2 AS BIGINT)) = CAST(0 AS BIGINT))"]]	2

VERSION	TIMESTAMP	OPERATION	OPERATIONPARAMETERS	READVERSION
2	2020-04-25 00:35:51	UPDATE	[predicate -> ((id#744L % cast(2 as bigint)) = cast(0 as bigint))]	1
1	2020-04-25 00:35:05	WRITE	[mode -> Overwrite, partitionBy -> []]	0
0	2020-04-25 00:34:34	WRITE	[mode -> ErrorIfExists, partitionBy -> []]	null

Convert Parquet to Delta

You can do an in-place conversion from the Parquet format to Delta.

Here you are going to test if the existing table is in delta format or not.

```
parquet_path = "/parquet/parquet-table-{0}".format(session_id)
data = spark.range(0,5)
data.write.parquet(parquet_path)
DeltaTable.isDeltaTable(spark, parquet_path)
```

```
var parquetPath = $"/parquet/parquet-table-{sessionId}";
var data = spark.Range(0,5);
data.Write().Parquet(parquetPath);
DeltaTable.IsDeltaTable(parquetPath)
```

```
val parquetPath = s"/parquet/parquet-table-$sessionId"
val data = spark.range(0,5)
data.write.parquet(parquetPath)
DeltaTable.isDeltaTable(parquetPath)
```

Results in:

False

Now you are going to convert the data to delta format and verify it worked.

```
DeltaTable.convertToDelta(spark, "parquet.`{0}`".format(parquet_path))
DeltaTable.isDeltaTable(spark, parquet_path)
```

```
DeltaTable.ConvertToDelta(spark, $"parquet.`{parquetPath}`");
DeltaTable.IsDeltaTable(parquetPath)
```

```
DeltaTable.convertToDelta(spark, s"parquet.`$parquetPath`")
DeltaTable.isDeltaTable(parquetPath)
```

Results in:

True

SQL support

Delta supports table utility commands through SQL. You can use SQL to:

- Get a DeltaTable's history
- Vacuum a DeltaTable
- Convert a Parquet file to Delta

```
spark.sql("DESCRIBE HISTORY delta.`{0}`".format(delta_table_path)).show()
```

```
spark.Sql($"DESCRIBE HISTORY delta.`{deltaTablePath}`").Show();
```

```
spark.sql(s"DESCRIBE HISTORY delta.`$deltaTablePath`").show()
```

Results in:

VERSION	TIMESTAMP	USERID	USERNAME	OPERATION	OPERATIONPARAMETERS	JOB	NOTEBOOK	CLUSTERID	READVERSION	ISOLATIONLEVEL	ISBLINDAPPEND
5	2020-04-25 00:37:09	null	null	STREAMING UPDATE	[outputMode -> Ap...	null	null	null	4	null	true

```
spark.sql("VACUUM delta.`{0}`".format(delta_table_path)).show()
```

```
spark.Sql($"VACUUM delta.`{deltaTablePath}`").Show();
```

```
spark.sql(s"VACUUM delta.`$deltaTablePath`").show()
```

Results in:

PATH
abfss://data@arca...

Now you are going to verify that a table is not a delta format table, then convert it to delta format using Spark SQL and confirm it was converted correctly.

```
parquet_id = random.randint(0,1000)
parquet_path = "/parquet/parquet-table-{0}-{1}".format(session_id, parquet_id)
data = spark.range(0,5)
data.write.parquet(parquet_path)
DeltaTable.isDeltaTable(spark, parquet_path)
spark.sql("CONVERT TO DELTA parquet.`{0}`".format(parquet_path))
DeltaTable.isDeltaTable(spark, parquet_path)
```

```
var parquetId =  (new Random()).Next(10000000);
var parquetPath = $"/parquet/parquet-table-{sessionId}-{parquetId}";
var data = spark.Range(0,5);
data.Write().Parquet(parquetPath);
DeltaTable.IsDeltaTable(parquetPath);
spark.Sql($"CONVERT TO DELTA parquet.`{parquetPath}`");
DeltaTable.IsDeltaTable(parquetPath);
```

```
val parquetId = scala.util.Random.nextInt(1000)
val parquetPath = s"/parquet/parquet-table-$sessionId-$parquetId"
val data = spark.range(0,5)
data.write.parquet(parquetPath)
DeltaTable.isDeltaTable(parquetPath)
spark.sql(s"CONVERT TO DELTA parquet.`$parquetPath`")
DeltaTable.isDeltaTable(parquetPath)
```

Results in:

True

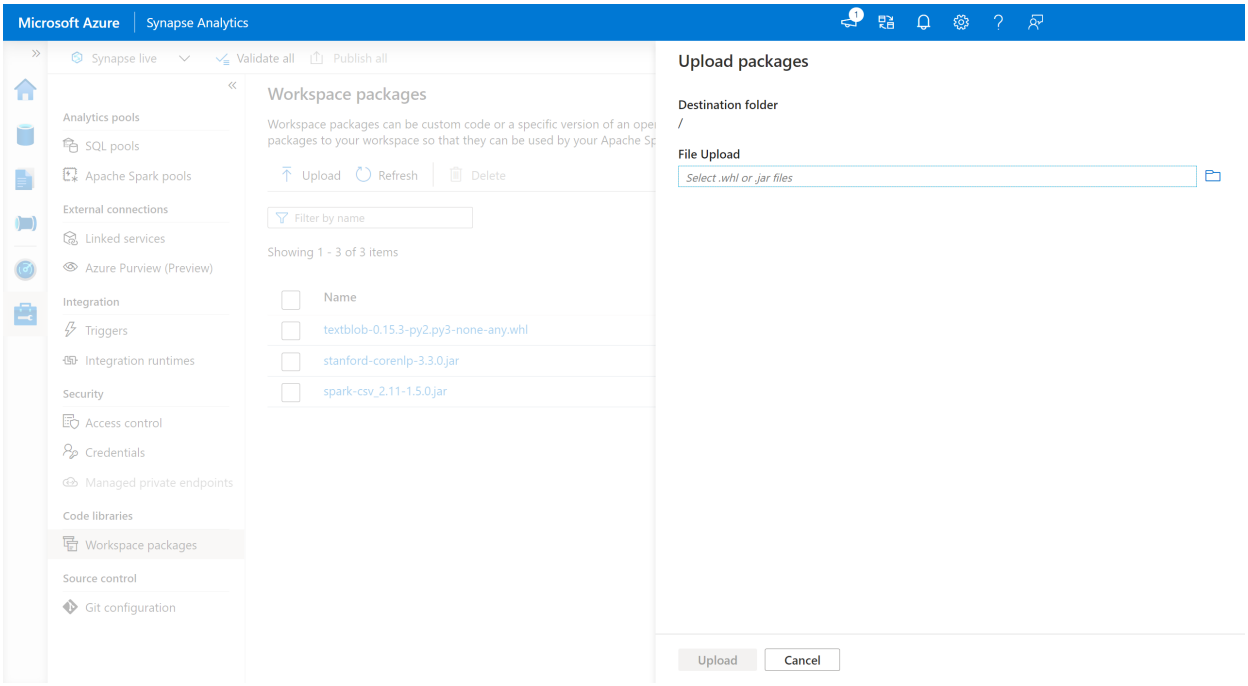
Workspace packages

8/19/2022 • 2 minutes to read • Edit Online

Workspace packages can be custom or private wheel or jar files. You can upload these packages to your workspace and later assign them to a specific Spark pool.

To add workspace packages:

1. Navigate to the **Manage** > **Workspace packages** tab.
2. Upload your wheel files by using the file selector.
3. Once the files have been uploaded to the Azure Synapse workspace, you can add these packages to a given Apache Spark pool.



WARNING

- Within Azure Synapse, an Apache Spark pool can leverage custom libraries that are either uploaded as Workspace Packages or uploaded within a well-known Azure Data Lake Storage path. However, both of these options cannot be used simultaneously within the same Apache Spark pool. If packages are provided using both methods, only the wheel files specified in the Workspace packages list will be installed.
- Once Workspace Packages are used to install packages on a given Apache Spark pool, there is a limitation that you can no longer specify packages using the Storage account path on the same pool.

Storage account

Custom-built wheel packages can be installed on the Apache Spark pool by uploading all the wheel files into the Azure Data Lake Storage (Gen2) account that is linked with the Synapse workspace.

The files should be uploaded to the following path in the storage account's default container:

```
abfss://<file_system>@<account_name>.dfs.core.windows.net/synapse/workspaces/<workspace_name>/sparkpools/<pool_name>/libraries/python/
```
