SecurityLevel	The level of security that the driver uses for the connection to the data store. The driver supports SSL connections with one-way authentication using SSL version 3. Example: `SecurityLevel=preferredSecured`. Supported values are: - **Only unsecured (onlyUnSecured)**: The driver doesn't use SSL. - **Preferred unsecured (preferredUnSecured) (default)**: If the server provides a choice, the driver doesn't use SSL. - **Preferred secured (preferredSecured)**: If the server provides a choice, the driver uses SSL. - **Only secured (onlySecured)**: The driver doesn't connect unless an SSL connection is available.	No
CaCertFile	The full path to the SSL certificate that's used by the server. Example: `CaCertFile=<cert path>;`	Yes, if SSL is enabled

Example

```
{
    "name": "NetezzaLinkedService",
    "properties": {
        "type": "Netezza",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<user name>;PWD=
<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "NetezzaLinkedService",
    "properties": {
        "type": "Netezza",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<user name>;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties that the Netezza dataset supports.

For a full list of sections and properties that are available for defining datasets, see Datasets.

To copy data from Netezza, set the **type** property of the dataset to **NetezzaTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **NetezzaTable**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)

PROPERTY	DESCRIPTION	REQUIRED
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "NetezzaDataset",
    "properties": {
        "type": "NetezzaTable",
        "linkedServiceName": {
            "referenceName": "<Netezza linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {}
    }
}
```

Copy Activity properties

This section provides a list of properties that the Netezza source supports.

For a full list of sections and properties that are available for defining activities, see Pipelines.

Netezza as source

> **TIP**
> To load data from Netezza efficiently by using data partitioning, learn more from Parallel copy from Netezza section.

To copy data from Netezza, set the **source** type in Copy Activity to **NetezzaSource**. The following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity source must be set to **NetezzaSource**.	Yes
query	Use the custom SQL query to read data. Example: `"SELECT * FROM MyTable"`	No (if "tableName" in dataset is specified)
partitionOptions	Specifies the data partitioning options used to load data from Netezza. Allow values are: **None** (default), **DataSlice**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from a Netezza database is controlled by `parallelCopies` setting on the copy activity.	No

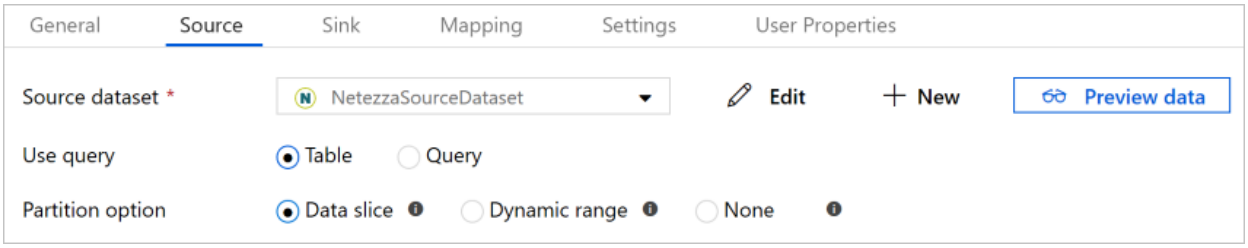
PROPERTY	DESCRIPTION	REQUIRED
partitionSettings	Specify the group of the settings for data partitioning. Apply when partition option isn't `None`.	No
partitionColumnName	Specify the name of the source column **in integer type** that will be used by range partitioning for parallel copy. If not specified, the primary key of the table is autodetected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionColumnName` in WHERE clause. See example in Parallel copy from Netezza section.	No
partitionUpperBound	The maximum value of the partition column to copy data out. Apply when partition option is `DynamicRange`. If you use query to retrieve source data, hook `?AdfRangePartitionUpbound` in the WHERE clause. For an example, see the Parallel copy from Netezza section.	No
partitionLowerBound	The minimum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionLowbound` in the WHERE clause. For an example, see the Parallel copy from Netezza section.	No

Example:

```
"activities":[
    {
        "name": "CopyFromNetezza",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Netezza input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "NetezzaSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Parallel copy from Netezza

The Data Factory Netezza connector provides built-in data partitioning to copy data from Netezza in parallel. You can find data partitioning options on the **Source** table of the copy activity.



When you enable partitioned copy, the service runs parallel queries against your Netezza source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Netezza database.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Netezza database. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommanded to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table.	**Partition option**: Data Slice. During execution, the service automatically partitions the data based on Netezza's built-in data slices, and copies data by partitions.

SCENARIO	SUGGESTED SETTINGS
Load large amount of data by using a custom query.	**Partition option**: Data Slice. **Query**: `SELECT * FROM <TABLENAME> WHERE mod(datasliceid, ?AdfPartitionCount) = ?AdfDataSliceCondition AND <your_additional_where_clause>` . During execution, the service replaces `?AdfPartitionCount` (with parallel copy number set on copy activity) and `?AdfDataSliceCondition` with the data slice partition logic, and sends to Netezza.
Load large amount of data by using a custom query, having an integer column with evenly distributed value for range partitioning.	**Partition options**: Dynamic range partition. **Query**: `SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ? AdfRangePartitionUpbound AND ? AdfRangePartitionColumnName >= ? AdfRangePartitionLowbound AND <your_additional_where_clause>` . **Partition column**: Specify the column used to partition data. You can partition against the column with integer data type. **Partition upper bound** and **partition lower bound**: Specify if you want to filter against the partition column to retrieve data only between the lower and upper range. During execution, the service replaces `?AdfRangePartitionColumnName`, `?AdfRangePartitionUpbound`, and `?AdfRangePartitionLowbound` with the actual column name and value ranges for each partition, and sends to Netezza. For example, if your partition column "ID" set with the lower bound as 1 and the upper bound as 80, with parallel copy set as 4, the service retrieves data by 4 partitions. Their IDs are between [1,20], [21, 40], [41, 60], and [61, 80], respectively.

Example: query with data slice partition

```
"source": {
    "type": "NetezzaSource",
    "query":"SELECT * FROM <TABLENAME> WHERE mod(datasliceid, ?AdfPartitionCount) = ?AdfDataSliceCondition
AND <your_additional_where_clause>",
    "partitionOption": "DataSlice"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "NetezzaSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ?AdfRangePartitionUpbound AND ?
AdfRangePartitionColumnName >= ?AdfRangePartitionLowbound AND <your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<dynamic_range_partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column>",
        "partitionLowerBound": "<lower_value_of_partition_column>"
    }
}
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Copy data from an OData source by using Azure Data Factory or Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from an OData source. The article builds on Copy Activity, which presents a general overview of Copy Activity.

Supported capabilities

This OData connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see Supported data stores.

Specifically, this OData connector supports:

- OData version 3.0 and 4.0.
- Copying data by using one of the following authentications: **Anonymous**, **Basic**, **Windows**, and **Azure Active Directory service principal**.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

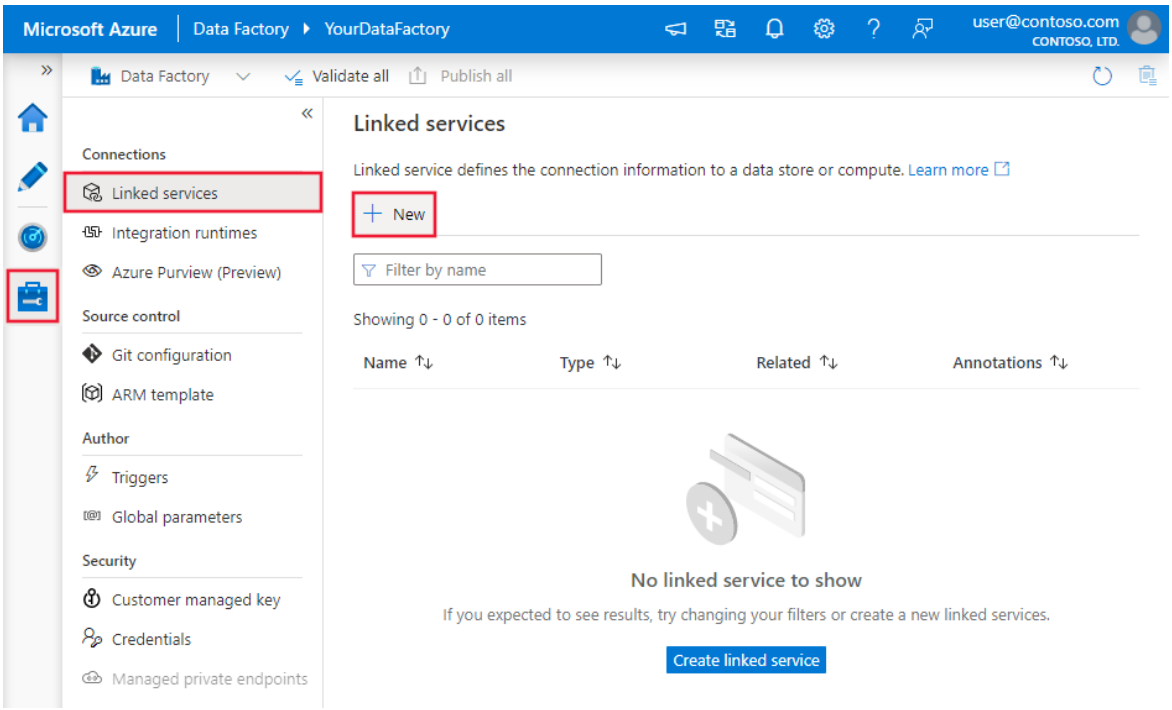
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an OData store using UI

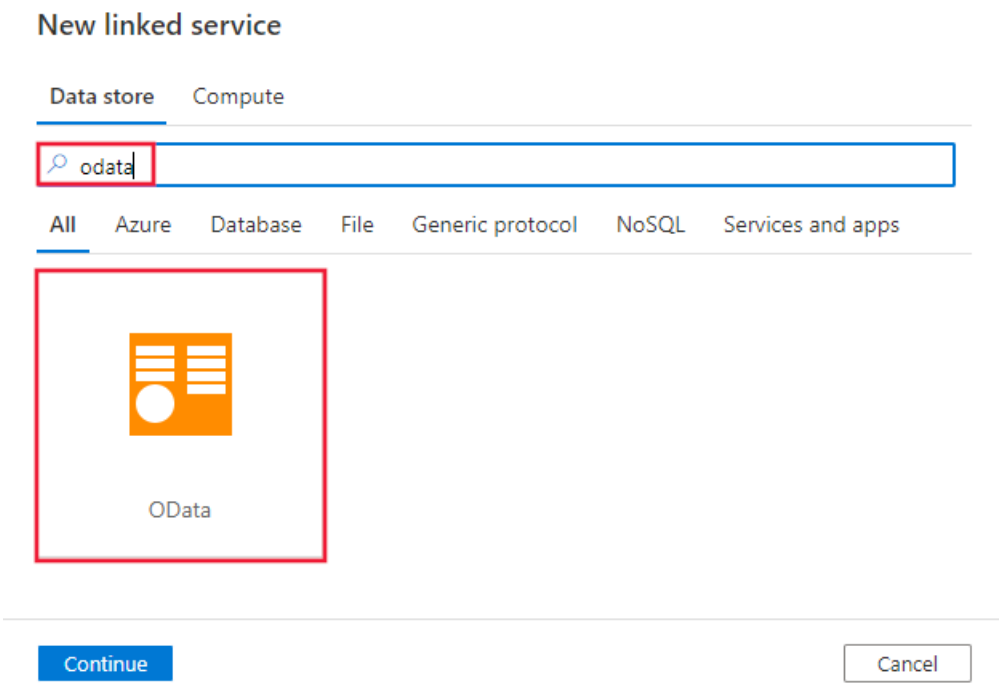
Use the following steps to create a linked service to an OData store in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

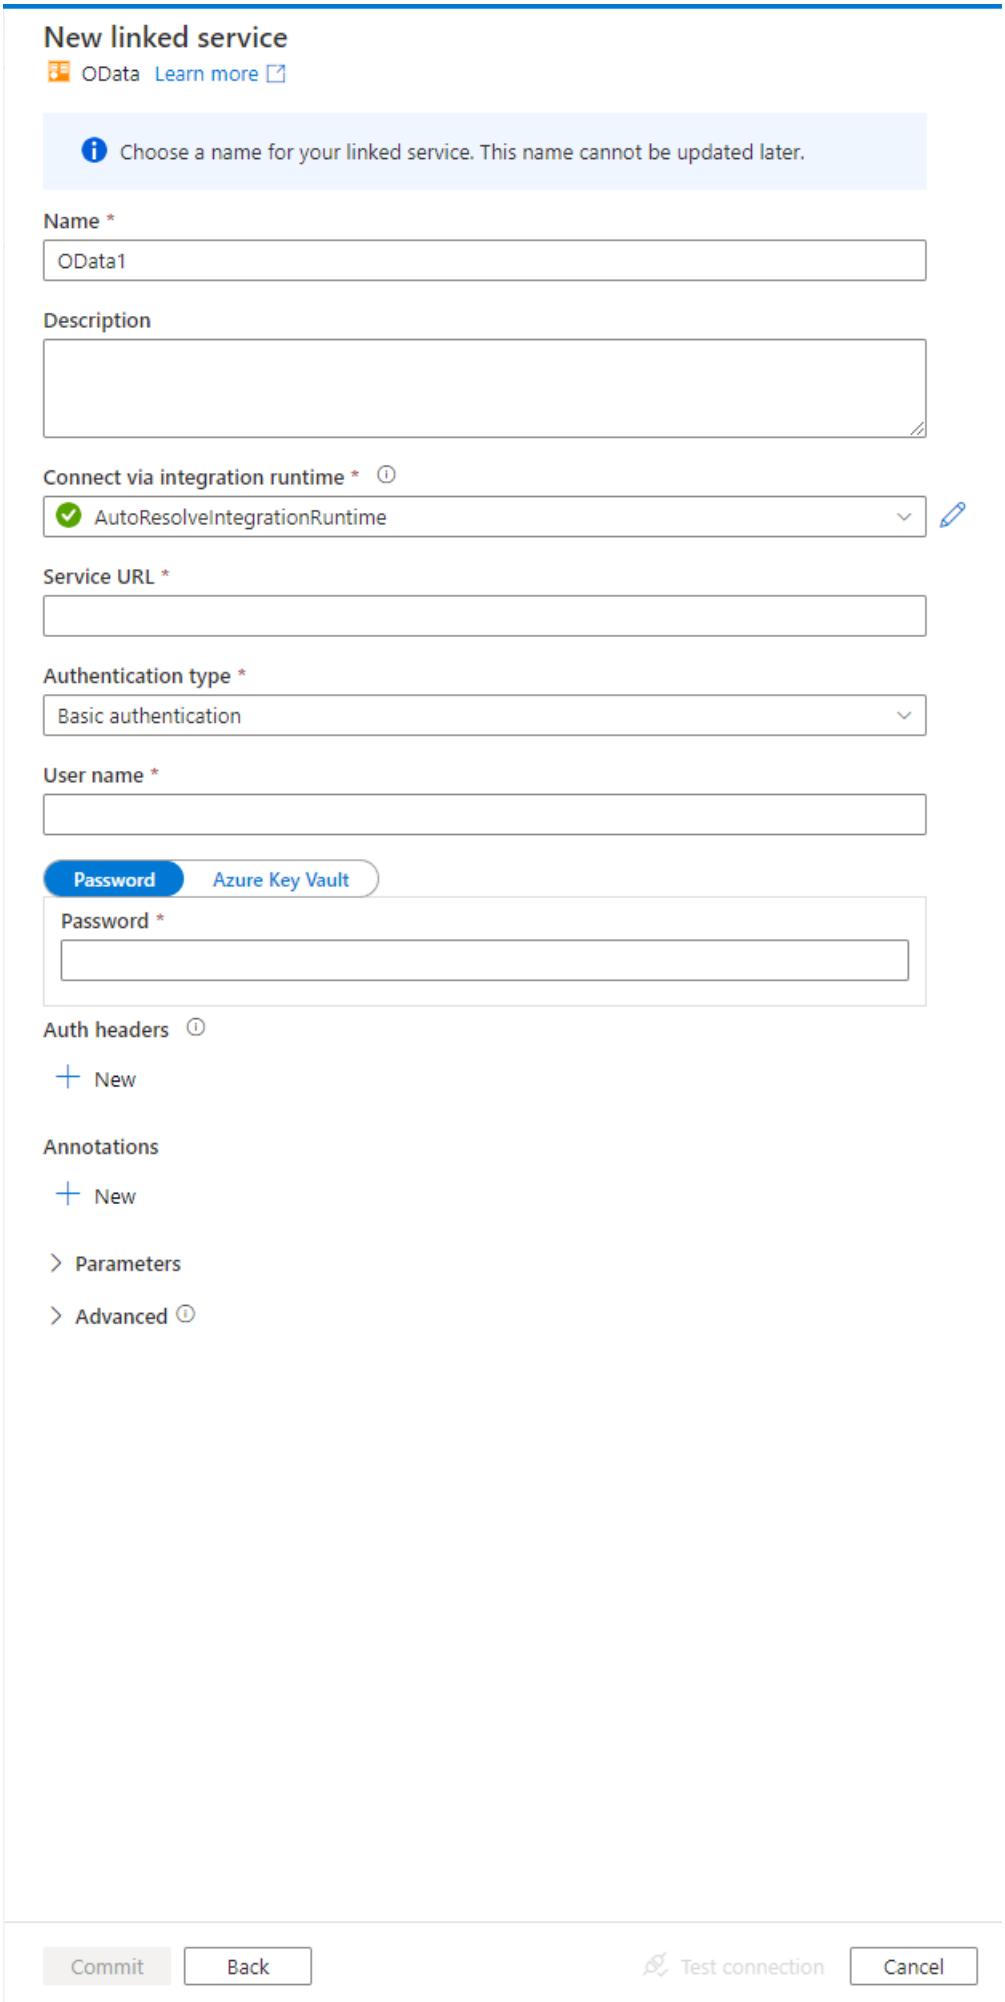
   - Azure Data Factory
   - Azure Synapse



2. Search for OData and select the OData connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define Data Factory entities that are specific to an OData connector.

Linked service properties

The following properties are supported for an OData linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **OData**.	Yes
url	The root URL of the OData service.	Yes
authenticationType	The type of authentication used to connect to the OData source. Allowed values are **Anonymous**, **Basic**, **Windows**, and **AadServicePrincipal**. User-based OAuth isn't supported. You can additionally configure authentication headers in `authHeader` property.	Yes
authHeaders	Additional HTTP request headers for authentication. For example, to use API key authentication, you can select authentication type as "Anonymous" and specify API key in the header.	No
userName	Specify **userName** if you use Basic or Windows authentication.	No
password	Specify **password** for the user account you specified for **userName**. Mark this field as a **SecureString** type to store it securely. You also can reference a secret stored in Azure Key Vault.	No
servicePrincipalId	Specify the Azure Active Directory application's client ID.	No
aadServicePrincipalCredentialType	Specify the credential type to use for service principal authentication. Allowed values are: `ServicePrincipalKey` or `ServicePrincipalCert`.	No
servicePrincipalKey	Specify the Azure Active Directory application's key. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	No

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalEmbeddedCert	Specify the base64 encoded certificate of your application registered in Azure Active Directory, and ensure the certificate content type is **PKCS #12**. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	No
servicePrincipalEmbeddedCertPassword	Specify the password of your certificate if your certificate is secured with a password. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	No
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering the mouse in the top-right corner of the Azure portal.	No
aadResourceId	Specify the Azure AD resource you are requesting for authorization.	No
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your Azure Active Directory application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the service's cloud environment is used.	No
connectVia	The Integration Runtime to use to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure Integration Runtime is used.	No

Example 1: Using Anonymous authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "https://services.odata.org/OData/OData.svc",
            "authenticationType": "Anonymous"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: Using Basic authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "<endpoint of OData source>",
            "authenticationType": "Basic",
            "userName": "<user name>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 3: Using Windows authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "<endpoint of OData source>",
            "authenticationType": "Windows",
            "userName": "<domain>\\<user>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 4: Using service principal key authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "<endpoint of OData source>",
            "authenticationType": "AadServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "aadServicePrincipalCredentialType": "ServicePrincipalKey",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "aadResourceId": "<AAD resource URL>"
        }
    },
    "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
    }
}
```

Example 5: Using service principal cert authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "<endpoint of OData source>",
            "authenticationType": "AadServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "aadServicePrincipalCredentialType": "ServicePrincipalCert",
            "servicePrincipalEmbeddedCert": {
                "type": "SecureString",
                "value": "<base64 encoded string of (.pfx) certificate data>"
            },
            "servicePrincipalEmbeddedCertPassword": {
                "type": "SecureString",
                "value": "<password of your certificate>"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "aadResourceId": "<AAD resource e.g. https://tenant.sharepoint.com>"
        }
    },
    "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
    }
}
```

Example 6: Using API key authentication

```
{
    "name": "ODataLinkedService",
    "properties": {
        "type": "OData",
        "typeProperties": {
            "url": "<endpoint of OData source>",
            "authenticationType": "Anonymous",
            "authHeader": {
                "APIKey": {
                    "type": "SecureString",
                    "value": "<API key>"
                }
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties that the OData dataset supports.

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services.

To copy data from OData, set the **type** property of the dataset to **ODataResource**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **ODataResource**.	Yes
path	The path to the OData resource.	Yes

Example

```
{
    "name": "ODataDataset",
    "properties":
    {
        "type": "ODataResource",
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<OData linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties":
        {
            "path": "Products"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties that the OData source supports.

For a full list of sections and properties that are available for defining activities, see Pipelines.

OData as source

To copy data from OData, the following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity source must be set to **ODataSource**.	Yes
query	OData query options for filtering data. Example: `"$select=Name,Description&$top=5"`. **Note**: The OData connector copies data from the combined URL: `[URL specified in linked service]/[path specified in dataset]?[query specified in copy activity source]`. For more information, see OData URL components.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. If not specified, the default value is **00:30:00** (30 minutes).	No

Example

```
"activities":[
    {
        "name": "CopyFromOData",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<OData input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ODataSource",
                "query": "$select=Name,Description&$top=5"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Data type mapping for OData

When you copy data from OData, the following mappings are used between OData data types and interim data types used within the service internally. To learn how Copy Activity maps the source schema and data type to the sink, see Schema and data type mappings.

ODATA DATA TYPE	INTERIM SERVICE DATA TYPE
Edm.Binary	Byte[]
Edm.Boolean	Bool
Edm.Byte	Byte[]
Edm.DateTime	DateTime
Edm.Decimal	Decimal
Edm.Double	Double
Edm.Single	Single
Edm.Guid	Guid
Edm.Int16	Int16
Edm.Int32	Int32
Edm.Int64	Int64
Edm.SByte	Int16
Edm.String	String
Edm.Time	TimeSpan
Edm.DateTimeOffset	DateTimeOffset

> **NOTE**
> OData complex data types (such as **Object**) aren't supported.

Copy data from Project Online

Project Online requires user-based OAuth, which is not supported by Azure Data Factory. To copy data from Project Online, you can use the OData connector and an access token obtained from tools like Postman.

Caution

The access token expires in 1 hour by default, you need to get a new access token when it expires.

1. Use **Postman** to get the access token:

   a. Navigate to **Authorization** tab on the Postman Website.

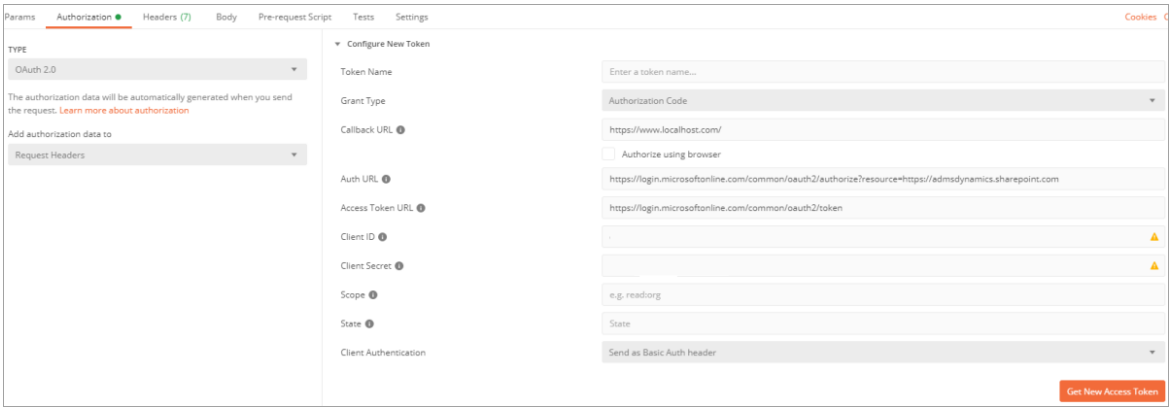
   b. In the **Type** box, select **OAuth 2.0**, and in the **Add authorization data to** box, select **Request Headers**.

   c. Fill the following information in the **Configure New Token** page to get a new access token:

   - **Grant type**: Select **Authorization Code**.
   - **Callback URL**: Enter `https://www.localhost.com/`.
   - **Auth URL**: Enter `https://login.microsoftonline.com/common/oauth2/authorize?resource=https://<your tenant name>.sharepoint.com`. Replace `<your tenant name>` with your own tenant name.
   - **Access Token URL**: Enter `https://login.microsoftonline.com/common/oauth2/token`.
   - **Client ID**: Enter your Azure Active Directory service principal ID.
   - **Client Secret**: Enter your service principal secret.
   - **Client Authentication**: Select **Send as Basic Auth header**.

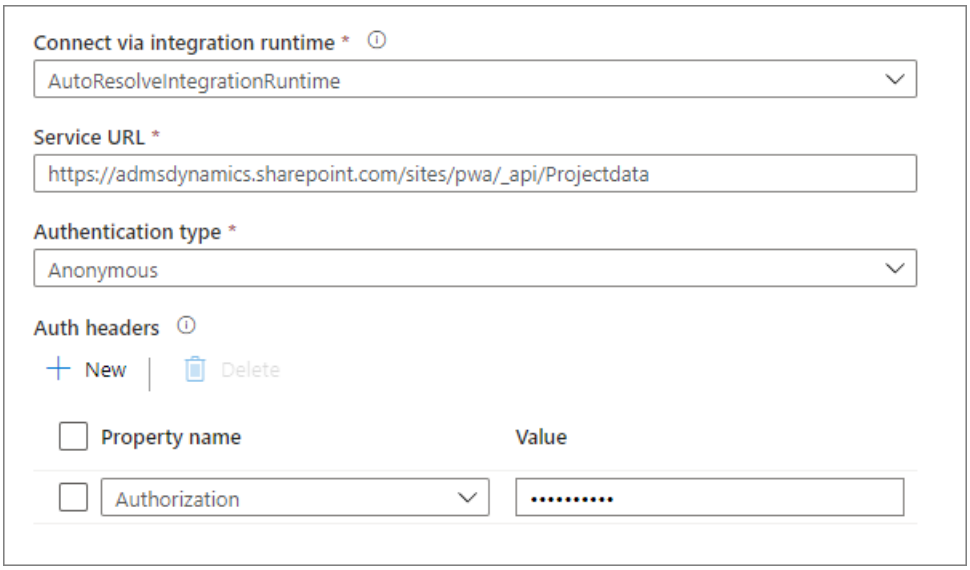
   d. You will be asked to sign in with your username and password.

   e. Once you get your access token, please copy and save it for the next step.



2. Create the OData linked service:

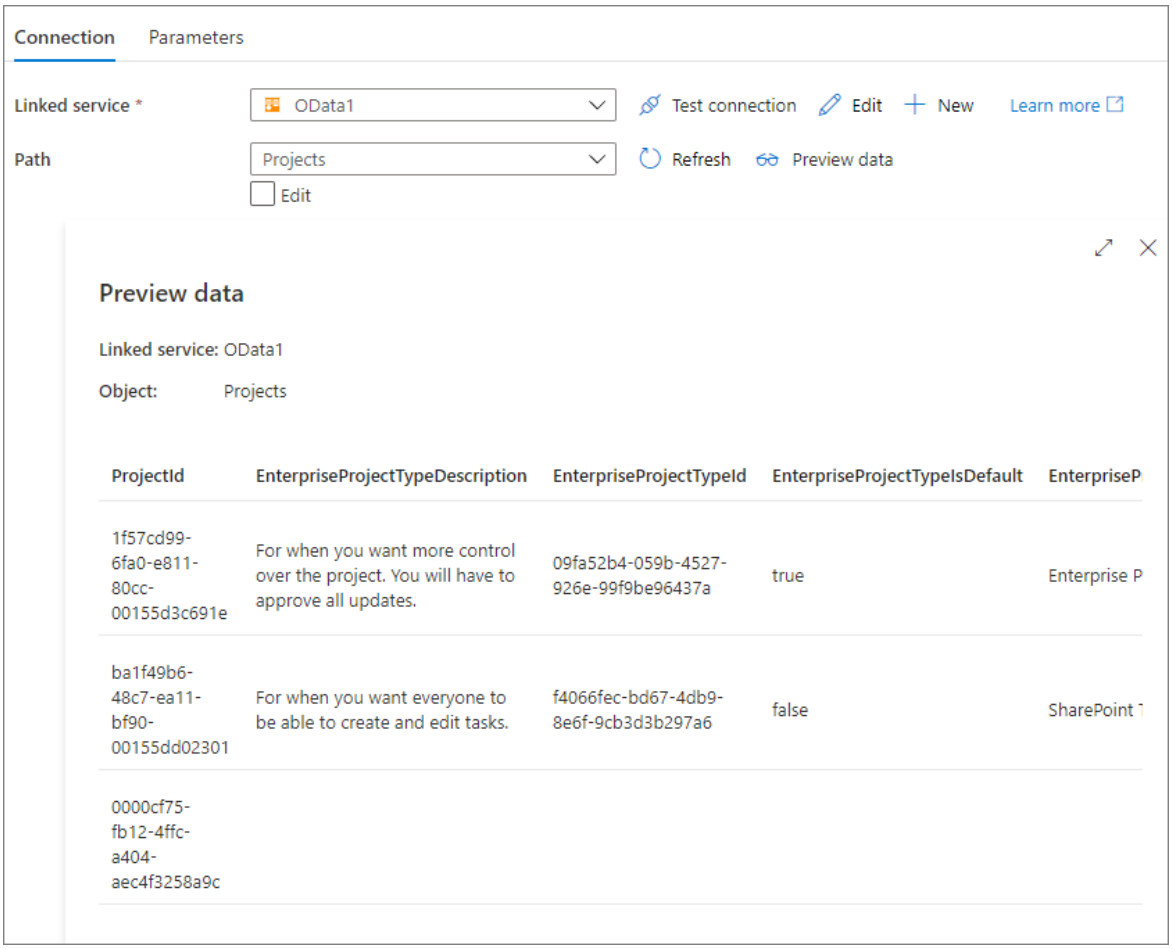
- **Service URL**: Enter `https://<your tenant name>.sharepoint.com/sites/pwa/_api/Projectdata`. Replace `<your tenant name>` with your own tenant name.
- **Authentication type**: Select **Anonymous**.
- **Auth headers**:
  - **Property name**: Choose **Authorization**.
  - **Value**: Enter `Bearer <access token from step 1>`.
- Test the linked service.



3. Create the OData dataset:

   a. Create the dataset with the OData linked service created in step 2.

   b. Preview data.



Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Copy data from and to ODBC data stores using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory to copy data from and to an ODBC data store. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This ODBC connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this ODBC connector supports copying data from/to **any ODBC-compatible data stores** using **Basic** or **Anonymous** authentication. A **64-bit ODBC driver** is required. For ODBC sink, the service support ODBC version 2.0 standard.

Prerequisites

To use this ODBC connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Install the 64-bit ODBC driver for the data store on the Integration Runtime machine.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

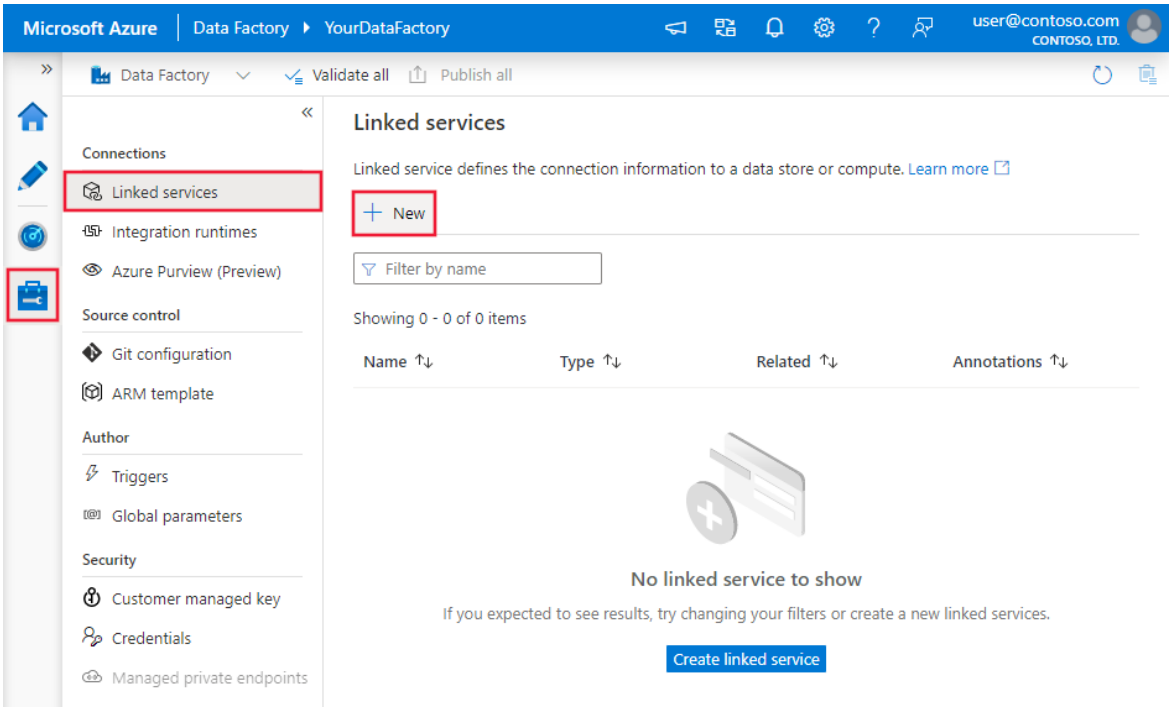
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an ODBC data store using UI

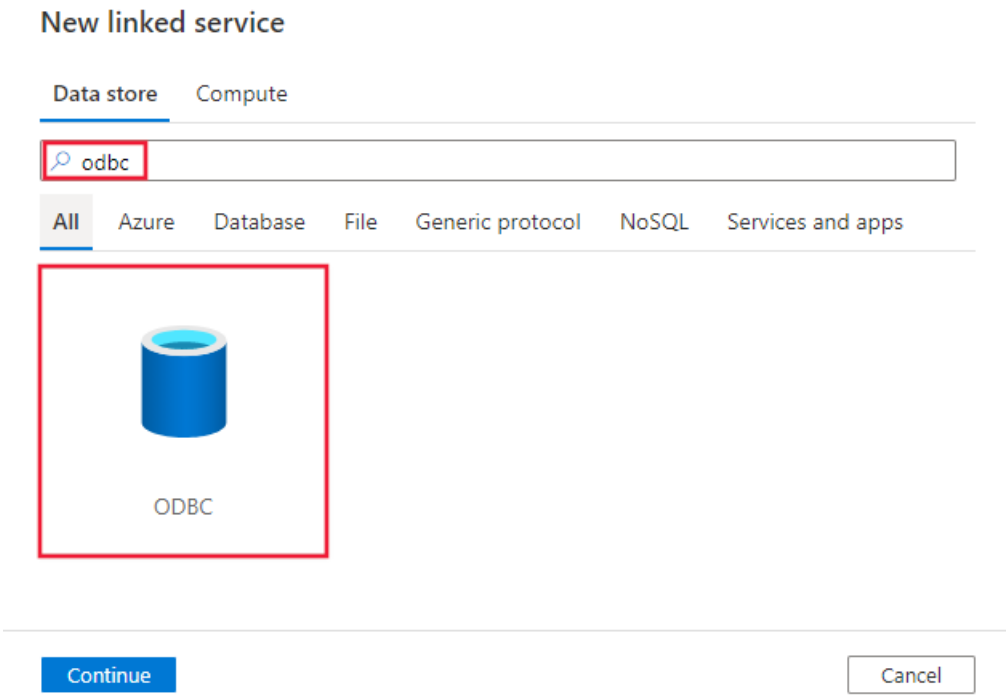
Use the following steps to create a linked service to an ODBC data store in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

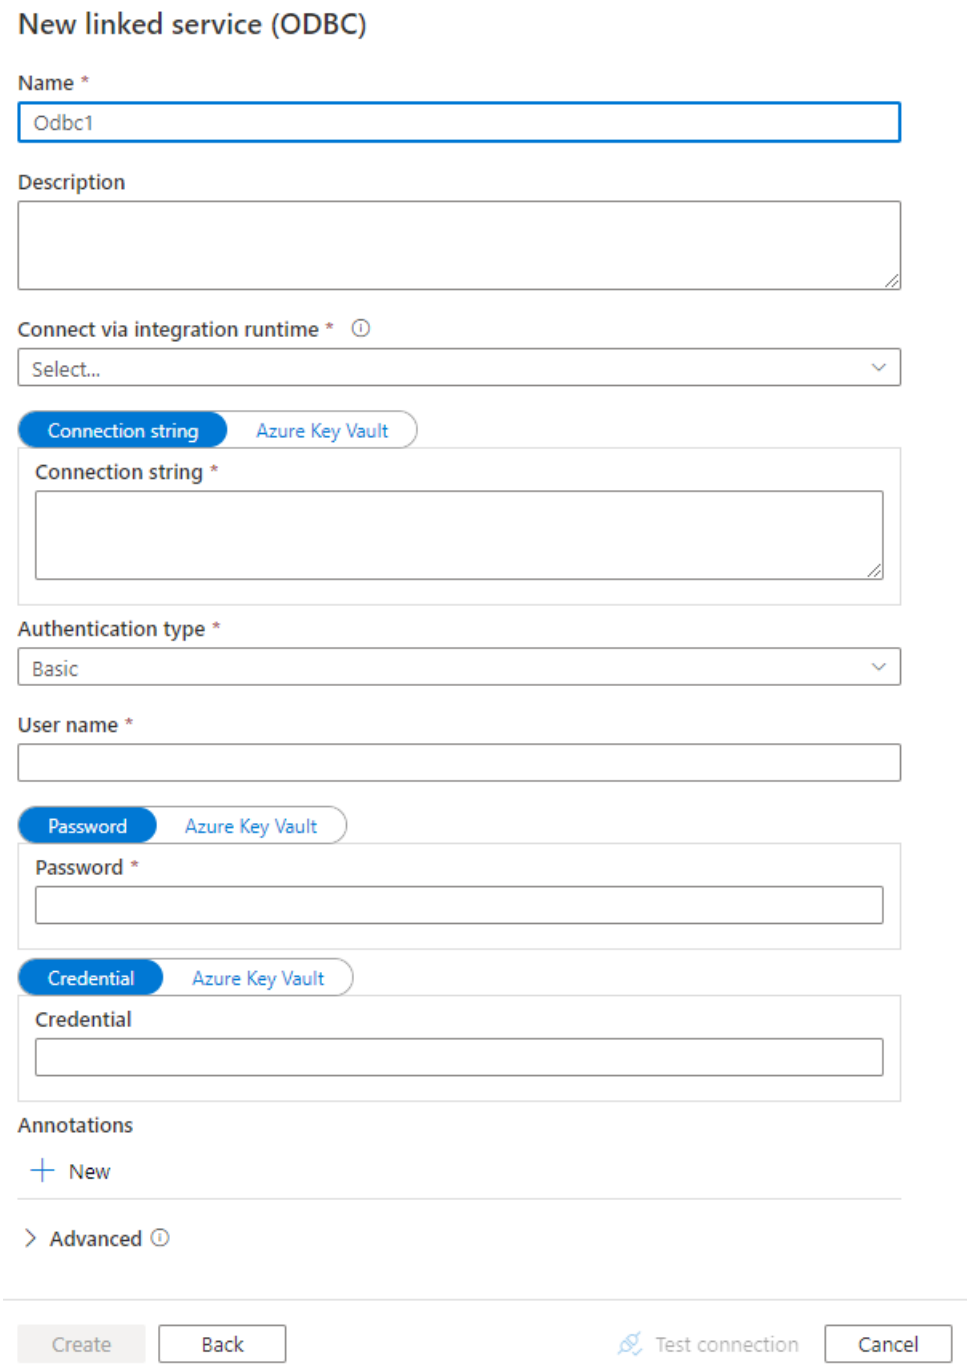
   - Azure Data Factory
   - Azure Synapse



2. Search for ODBC and select the ODBC connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to ODBC connector.

Linked service properties

The following properties are supported for ODBC linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Odbc**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	The connection string excluding the credential portion. You can specify the connection string with pattern like `Driver={SQL Server};Server=Server.database.windows.net; Database=TestDatabase;`, or use the system DSN (Data Source Name) you set up on the Integration Runtime machine with `DSN=<name of the DSN on IR machine>;` (you need still specify the credential portion in linked service accordingly). You can also put a password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to Store credentials in Azure Key Vault with more details.	Yes
authenticationType	Type of authentication used to connect to the ODBC data store. Allowed values are: **Basic** and **Anonymous**.	Yes
userName	Specify user name if you are using Basic authentication.	No
password	Specify password for the user account you specified for the userName. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
credential	The access credential portion of the connection string specified in driver-specific property-value format. Example: `"RefreshToken=<secret refresh token>;"`. Mark this field as a SecureString.	No
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example 1: using Basic authentication

```
{
    "name": "ODBCLinkedService",
    "properties": {
        "type": "Odbc",
        "typeProperties": {
            "connectionString": "<connection string>",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: using Anonymous authentication

```
{
    "name": "ODBCLinkedService",
    "properties": {
        "type": "Odbc",
        "typeProperties": {
            "connectionString": "<connection string>",
            "authenticationType": "Anonymous",
            "credential": {
                "type": "SecureString",
                "value": "RefreshToken=<secret refresh token>;"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by ODBC dataset.

To copy data from/to ODBC-compatible data store, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **OdbcTable**	Yes
tableName	Name of the table in the ODBC data store.	No for source (if "query" in activity source is specified); Yes for sink

Example

```
{
    "name": "ODBCDataset",
    "properties": {
        "type": "OdbcTable",
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<ODBC linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "<table name>"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by ODBC source.

ODBC as source

To copy data from ODBC-compatible data store, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **OdbcSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromODBC",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<ODBC input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "OdbcSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

ODBC as sink

To copy data to ODBC-compatible data store, set the sink type in the copy activity to **OdbcSink**. The following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to: **OdbcSink**	Yes
writeBatchTimeout	Wait time for the batch insert operation to complete before it times out. Allowed values are: timespan. Example: "00:30:00" (30 minutes).	No
writeBatchSize	Inserts data into the SQL table when the buffer size reaches writeBatchSize. Allowed values are: integer (number of rows).	No (default is 0 - auto detected)
preCopyScript	Specify a SQL query for Copy Activity to execute before writing data into data store in each run. You can use this property to clean up the pre-loaded data.	No

> **NOTE**
>
> For "writeBatchSize", if it's not set (auto-detected), copy activity first detects whether the driver supports batch operations, and set it to 10000 if it does, or set it to 1 if it doesn't. If you explicitly set the value other than 0, copy activity honors the value and fails at runtime if the driver doesn't support batch operations.

Example:

```
"activities":[
    {
        "name": "CopyToODBC",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<ODBC output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "OdbcSink",
                "writeBatchSize": 100000
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Troubleshoot connectivity issues

To troubleshoot connection issues, use the **Diagnostics** tab of **Integration Runtime Configuration Manager**.

1. Launch **Integration Runtime Configuration Manager**.
2. Switch to the **Diagnostics** tab.
3. Under the "Test Connection" section, select the **type** of data store (linked service).
4. Specify the **connection string** that is used to connect to the data store, choose the **authentication** and enter **user name**, **password**, and/or **credentials**.
5. Click **Test connection** to test the connection to the data store.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Microsoft 365 (Office 365) into Azure using Azure Data Factory or Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Azure Data Factory and Synapse Analytics pipelines integrate with Microsoft Graph data connect, allowing you to bring the rich organizational data in your Microsoft 365 (Office 365) tenant into Azure in a scalable way and build analytics applications and extract insights based on these valuable data assets. Integration with Privileged Access Management provides secured access control for the valuable curated data in Microsoft 365 (Office 365). Please refer to this link for an overview on Microsoft Graph data connect and refer to this link for licensing information.

This article outlines how to use the Copy Activity to copy data from Microsoft 365 (Office 365). It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Microsoft 365 (Office 365) connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②

① Azure integration runtime ② Self-hosted integration runtime

ADF Microsoft 365 (Office 365) connector and Microsoft Graph data connect enables at scale ingestion of different types of datasets from Exchange Email enabled mailboxes, including address book contacts, calendar events, email messages, user information, mailbox settings, and so on. Refer here to see the complete list of datasets available.

For now, within a single copy activity you can only **copy data from Microsoft 365 (Office 365) into Azure Blob Storage, Azure Data Lake Storage Gen1, and Azure Data Lake Storage Gen2 in JSON format** (type setOfObjects). If you want to load Microsoft 365 (Office 365) into other types of data stores or in other formats, you can chain the first copy activity with a subsequent copy activity to further load data into any of the supported ADF destination stores (refer to "supported as a sink" column in the "Supported data stores and formats" table).

IMPORTANT

- The Azure subscription containing the data factory or Synapse workspace and the sink data store must be under the same Azure Active Directory (Azure AD) tenant as Microsoft 365 (Office 365) tenant.
- Ensure the Azure Integration Runtime region used for copy activity as well as the destination is in the same region where the Microsoft 365 (Office 365) tenant users' mailbox is located. Refer here to understand how the Azure IR location is determined. Refer to table here for the list of supported Office regions and corresponding Azure regions.
- Service Principal authentication is the only authentication mechanism supported for Azure Blob Storage, Azure Data Lake Storage Gen1, and Azure Data Lake Storage Gen2 as destination stores.

> **NOTE**
> Please use Azure integration runtime in both source and sink linked services. The self-hosted integration runtime and the managed virtual network integration runtime are not supported.

Prerequisites

To copy data from Microsoft 365 (Office 365) into Azure, you need to complete the following prerequisite steps:

- Your Microsoft 365 (Office 365) tenant admin must complete on-boarding actions as described here.
- Create and configure an Azure AD web application in Azure Active Directory. For instructions, see Create an Azure AD application.
- Make note of the following values, which you will use to define the linked service for Microsoft 365 (Office 365):
  - Tenant ID. For instructions, see Get tenant ID.
  - Application ID and Application key. For instructions, see Get application ID and authentication key.
- Add the user identity who will be making the data access request as the owner of the Azure AD web application (from the Azure AD web application > Settings > Owners > Add owner).
  - The user identity must be in the Microsoft 365 (Office 365) organization you are getting data from and must not be a Guest user.

Approving new data access requests

If this is the first time you are requesting data for this context (a combination of which data table is being access, which destination account is the data being loaded into, and which user identity is making the data access request), you will see the copy activity status as "In Progress", and only when you click into "Details" link under Actions will you see the status as "RequestingConsent". A member of the data access approver group needs to approve the request in the Privileged Access Management before the data extraction can proceed.

Refer here on how the approver can approve the data access request, and refer here for an explanation on the overall integration with Privileged Access Management, including how to set up the data access approver group.

Getting started

> **TIP**
> For a walkthrough of using Microsoft 365 (Office 365) connector, see Load data from Microsoft 365 (Office 365) article.

You can create a pipeline with the copy activity by using one of the following tools or SDKs. Select a link to go to a tutorial with step-by-step instructions to create a pipeline with a copy activity.

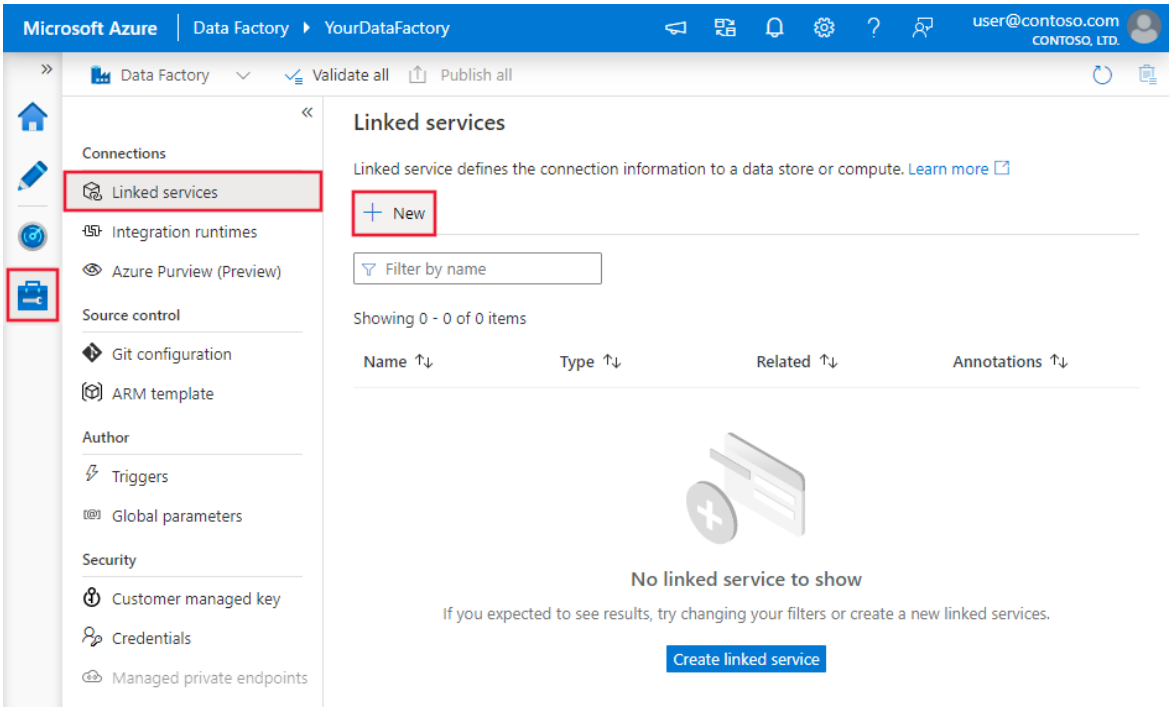
- Azure portal
- .NET SDK
- Python SDK
- Azure PowerShell
- REST API
- Azure Resource Manager template.

Create a linked service to Microsoft 365 (Office 365) using UI

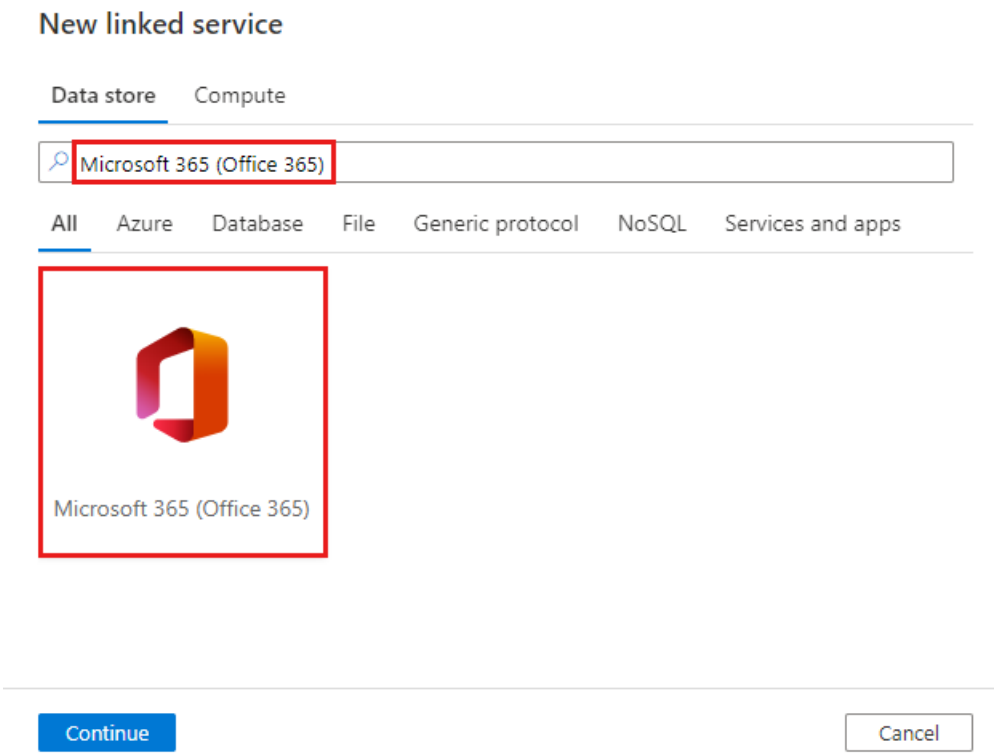
Use the following steps to create a linked service to Microsoft 365 (Office 365) in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

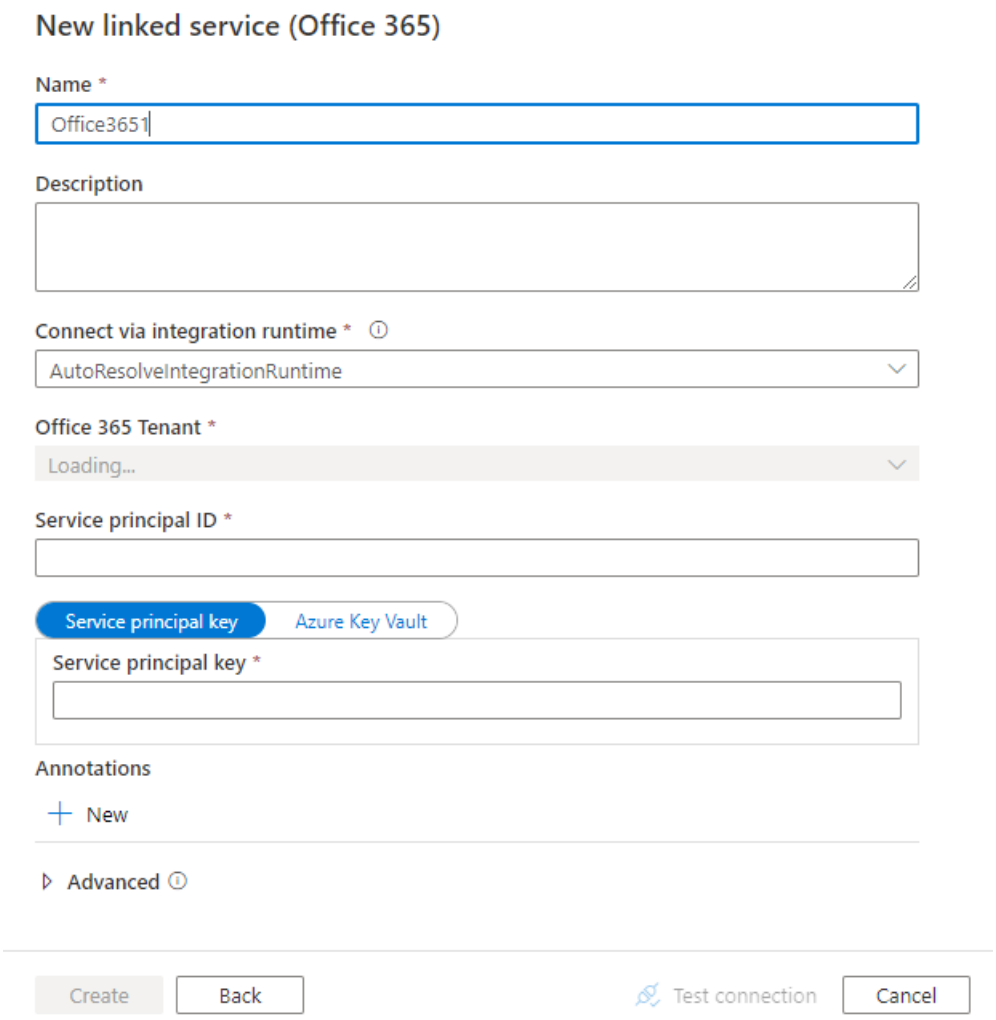
   - Azure Data Factory
   - Azure Synapse



2. Search for Microsoft 365 (Office 365) and select the Microsoft 365 (Office 365) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Microsoft 365 (Office 365) connector.

Linked service properties

The following properties are supported for Microsoft 365 (Office 365) linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Office365**	Yes
office365TenantId	Azure tenant ID to which the Microsoft 365 (Office 365) account belongs.	Yes
servicePrincipalTenantId	Specify the tenant information under which your Azure AD web application resides.	Yes
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key. Mark this field as a SecureString to store it securely.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. If not specified, it uses the default Azure Integration Runtime.	No

NOTE

The difference between **office365TenantId** and **servicePrincipalTenantId** and the corresponding value to provide:

- If you are an enterprise developer developing an application against Microsoft 365 (Office 365) data for your own organization's usage, then you should supply the same tenant ID for both properties, which is your organization's AAD tenant ID.
- If you are an ISV developer developing an application for your customers, then office365TenantId will be your customer's (application installer) AAD tenant ID and servicePrincipalTenantId will be your company's AAD tenant ID.

Example:

```
{
    "name": "Office365LinkedService",
    "properties": {
        "type": "Office365",
        "typeProperties": {
            "office365TenantId": "<Microsoft 365 (Office 365) tenant id>",
            "servicePrincipalTenantId": "<AAD app service principal tenant id>",
            "servicePrincipalId": "<AAD app service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<AAD app service principal key>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Microsoft 365 (Office 365) dataset.

To copy data from Microsoft 365 (Office 365), the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **Office365Table**	Yes
tableName	Name of the dataset to extract from Microsoft 365 (Office 365). Refer here for the list of Microsoft 365 (Office 365) datasets available for extraction.	Yes

If you were setting `dateFilterColumn`, `startTime`, `endTime`, and `userScopeFilterUri` in dataset, it is still supported as-is, while you are suggested to use the new model in activity source going forward.

Example

```
{
    "name": "DS_May2019_O365_Message",
    "properties": {
        "type": "Office365Table",
        "linkedServiceName": {
            "referenceName": "<Microsoft 365 (Office 365) linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [],
        "typeProperties": {
            "tableName": "BasicDataSet_v0.Event_v1"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Microsoft 365 (Office 365) source.

Microsoft 365 (Office 365) as source

To copy data from Microsoft 365 (Office 365), the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **Office365Source**	Yes
allowedGroups	Group selection predicate. Use this property to select up to 10 user groups for whom the data will be retrieved. If no groups are specified, then data will be returned for the entire organization.	No
userScopeFilterUri	When `allowedGroups` property is not specified, you can use a predicate expression that is applied on the entire tenant to filter the specific rows to extract from Microsoft 365 (Office 365). The predicate format should match the query format of Microsoft Graph APIs, e.g. `https://graph.microsoft.com/v1.0/users?$filter=Department eq 'Finance'` .	No
dateFilterColumn	Name of the DateTime filter column. Use this property to limit the time range for which Microsoft 365 (Office 365) data is extracted.	Yes if dataset has one or more DateTime columns. Refer here for list of datasets that require this DateTime filter.
startTime	Start DateTime value to filter on.	Yes if `dateFilterColumn` is specified
endTime	End DateTime value to filter on.	Yes if `dateFilterColumn` is specified

PROPERTY	DESCRIPTION	REQUIRED
outputColumns	Array of the columns to copy to sink.	No

Example:

```
"activities": [
    {
        "name": "CopyFromO365ToBlob",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Microsoft 365 (Office 365) input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "Office365Source",
                "dateFilterColumn": "CreatedDateTime",
                "startTime": "2019-04-28T16:00:00.000Z",
                "endTime": "2019-05-05T16:00:00.000Z",
                "userScopeFilterUri": "https://graph.microsoft.com/v1.0/users?$filter=Department eq
'Finance'",
                "outputColumns": [
                    {
                        "name": "Id"
                    },
                    {
                        "name": "CreatedDateTime"
                    },
                    {
                        "name": "LastModifiedDateTime"
                    },
                    {
                        "name": "ChangeKey"
                    },
                    {
                        "name": "Categories"
                    },
                    {
                        "name": "OriginalStartTimeZone"
                    },
                    {
                        "name": "OriginalEndTimeZone"
                    },
                    {
                        "name": "ResponseStatus"
                    },
                    {
                        "name": "iCalUId"
                    },
                    {
                        "name": "ReminderMinutesBeforeStart"
                    },
                    {
                        "name": "IsReminderOn"
                    },
                    {
                        "name": "HasAttachments"
```

```
                    },
                    {
                        "name": "Subject"
                    },
                    {
                        "name": "Body"
                    },
                    {
                        "name": "Importance"
                    },
                    {
                        "name": "Sensitivity"
                    },
                    {
                        "name": "Start"
                    },
                    {
                        "name": "End"
                    },
                    {
                        "name": "Location"
                    },
                    {
                        "name": "IsAllDay"
                    },
                    {
                        "name": "IsCancelled"
                    },
                    {
                        "name": "IsOrganizer"
                    },
                    {
                        "name": "Recurrence"
                    },
                    {
                        "name": "ResponseRequested"
                    },
                    {
                        "name": "ShowAs"
                    },
                    {
                        "name": "Type"
                    },
                    {
                        "name": "Attendees"
                    },
                    {
                        "name": "Organizer"
                    },
                    {
                        "name": "WebLink"
                    },
                    {
                        "name": "Attachments"
                    },
                    {
                        "name": "BodyPreview"
                    },
                    {
                        "name": "Locations"
                    },
                    {
                        "name": "OnlineMeetingUrl"
                    },
                    {
                        "name": "OriginalStart"
                    },
                    {
                        "name": "SeriesMasterId"
```

```
                    }
                ]
            },
            "sink": {
                "type": "BlobSink"
            }
        }
    }
]
```

Copy data from and to Oracle by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 13 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory to copy data from and to an Oracle database. It builds on the copy activity overview.

Supported capabilities

This Oracle connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Lookup activity	① ②
Script activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this Oracle connector supports:

- The following versions of an Oracle database:
  - Oracle 19c R1 (19.1) and higher
  - Oracle 18c R1 (18.1) and higher
  - Oracle 12c R1 (12.1) and higher
  - Oracle 11g R1 (11.1) and higher
  - Oracle 10g R1 (10.1) and higher
  - Oracle 9i R2 (9.2) and higher
  - Oracle 8i R3 (8.1.7) and higher
  - Oracle Database Cloud Exadata Service
- Parallel copying from an Oracle source. See the Parallel copy from Oracle section for details.

> **NOTE**
> Oracle proxy server isn't supported.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data

access strategies.

The integration runtime provides a built-in Oracle driver. Therefore, you don't need to manually install a driver when you copy data from and to Oracle.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

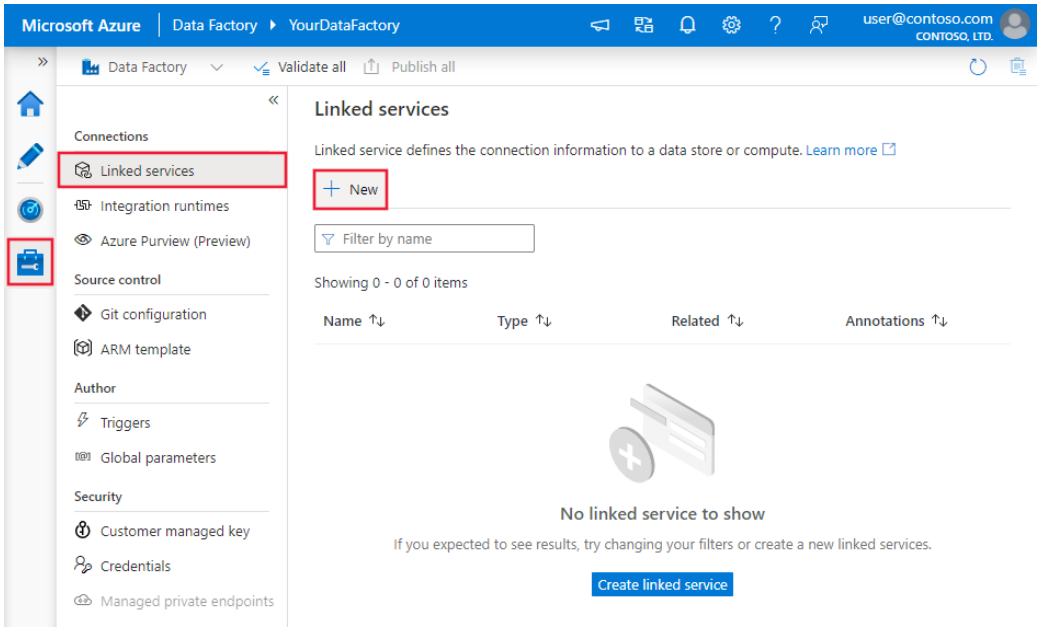
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Oracle using UI

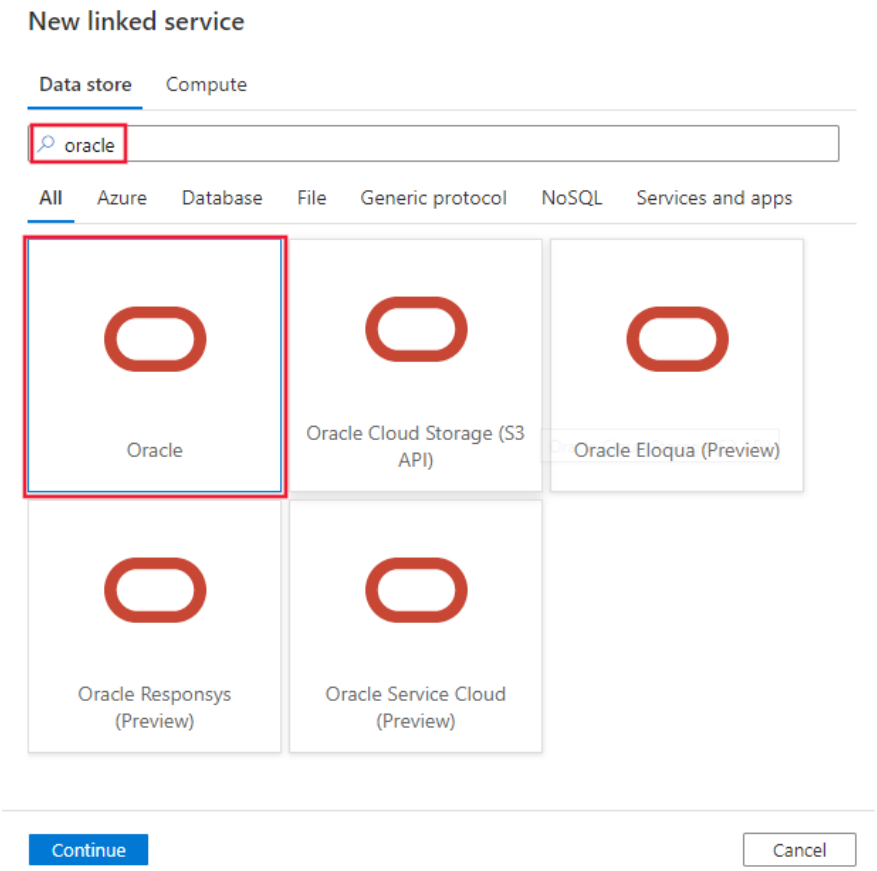
Use the following steps to create a linked service to Oracle in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

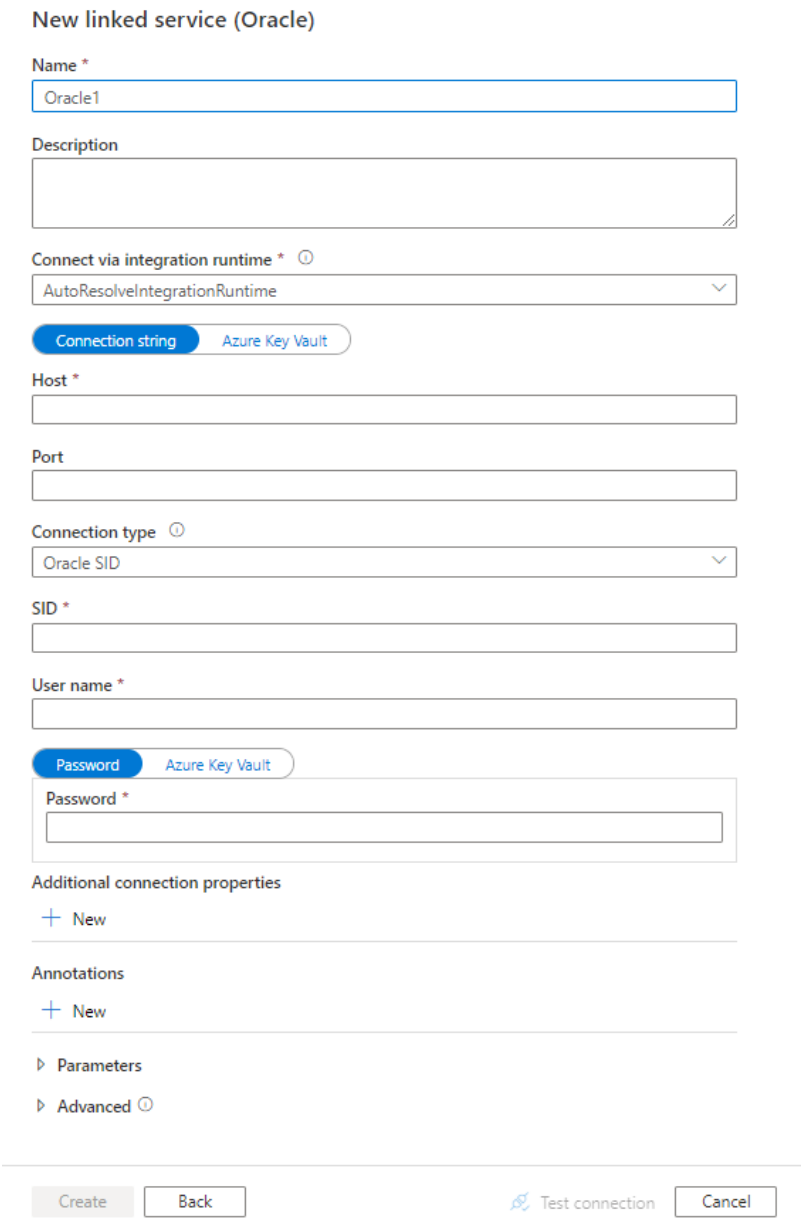
   - Azure Data Factory
   - Azure Synapse



2. Search for Oracle and select the Oracle connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to the Oracle connector.

Linked service properties

The Oracle linked service supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Oracle**.	Yes

PROPERTY	DESCRIPTION	REQUIRED

connectionString	Specifies the information needed to connect to the Oracle Database instance.
	You can also put a password in Azure Key Vault, and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault with more details.
	
	Supported connection type: You can use **Oracle SID** or **Oracle Service Name** to identify your database:
	- If you use SID:
	`Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;`
	- If you use Service Name:
	`Host=<host>;Port=<port>;ServiceName=<servicename>;User Id=<username>;Password=<password>;`
	For advanced Oracle native connection options, you can choose to add an entry in TNSNAMES.ORA file on the Oracle server, and in Oracle linked service, choose to use Oracle Service Name connection type and configure the corresponding service name.
		Yes

connectVia	The integration runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure Integration Runtime is used.	No

TIP

If you get an error, "ORA-01025: UPI parameter out of range", and your Oracle version is 8i, add `WireProtocolMode=1` to your connection string. Then try again.

If you have multiple Oracle instances for failover scenario, you can create Oracle linked service and fill in the primary host, port, user name, password, etc., and add a new "**Additional connection properties**" with property name as `AlternateServers` and value as `(HostName=<secondary host>:PortNumber=<secondary port>:ServiceName=<secondary service name>)` - do not miss the brackets and pay attention to the colons (`:`) as separator. As an example, the following value of alternate servers defines two alternate database servers for connection failover:

```
(HostName=AccountingOracleServer:PortNumber=1521:SID=Accounting,HostName=255.201.11.24:PortNumber=1522:ServiceName=ABackup.NA.MyC
```

.

More connection properties you can set in connection string per your case:

PROPERTY	DESCRIPTION	ALLOWED VALUES
ArraySize	The number of bytes the connector can fetch in a single network round trip. E.g., `ArraySize=10485760`. Larger values increase throughput by reducing the number of times to fetch data across the network. Smaller values increase response time, as there is less of a delay waiting for the server to transmit data.	An integer from 1 to 4294967296 (4 GB). Default value is `60000`. The value 1 does not define the number of bytes, but indicates allocating space for exactly one row of data.

To enable encryption on Oracle connection, you have two options:

- To use **Triple-DES Encryption (3DES) and Advanced Encryption Standard (AES)**, on the Oracle server side, go to Oracle Advanced Security (OAS) and configure the encryption settings. For details, see this Oracle documentation. The Oracle Application Development Framework (ADF) connector automatically negotiates the encryption method to use the one you configure in OAS when establishing a connection to Oracle.
- To use **TLS**:

  1. Get the TLS/SSL certificate info. Get the Distinguished Encoding Rules (DER)-encoded certificate information of your TLS/SSL cert, and save the output (----- Begin Certificate ... End Certificate -----) as a text file.

     ```
     openssl x509 -inform DER -in [Full Path to the DER Certificate including the name of the DER Certificate] -text
     ```

     Example: Extract cert info from DERcert.cer, and then save the output to cert.txt.

     ```
     openssl x509 -inform DER -in DERcert.cer -text
     Output:
     -----BEGIN CERTIFICATE-----
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX
     XXXXXXXXX
     -----END CERTIFICATE-----
     ```

  2. Build the `keystore` or `truststore`. The following command creates the `truststore` file, with or without a password, in PKCS-12 format.

     ```
     openssl pkcs12 -in [Path to the file created in the previous step] -out [Path and name of TrustStore] -passout pass:[Keystore PWD] -nokeys -export
     ```

     Example: Create a PKCS12 `truststore` file, named MyTrustStoreFile, with a password.

     ```
     openssl pkcs12 -in cert.txt -out MyTrustStoreFile -passout pass:ThePWD -nokeys -export
     ```

  3. Place the `truststore` file on the self-hosted IR machine. For example, place the file at C:\MyTrustStoreFile.

  4. In the service, configure the Oracle connection string with `EncryptionMethod=1` and the corresponding `TrustStore` / `TrustStorePassword` value. For example,
     `Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;EncryptionMethod=1;TrustStore=C:\\MyTrustStoreFile;TrustStorePassword=<trust_store_password>`
     .

Example:

```
{
    "name": "OracleLinkedService",
    "properties": {
        "type": "Oracle",
        "typeProperties": {
            "connectionString": "Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;Password=<password>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "OracleLinkedService",
    "properties": {
        "type": "Oracle",
        "typeProperties": {
            "connectionString": "Host=<host>;Port=<port>;Sid=<sid>;User Id=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties supported by the Oracle dataset. For a full list of sections and properties available for defining datasets, see Datasets.

To copy data from and to Oracle, set the type property of the dataset to `OracleTable`. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to `OracleTable`.	Yes
schema	Name of the schema.	No for source, Yes for sink
table	Name of the table/view.	No for source, Yes for sink
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No for source, Yes for sink

Example:

```
{
    "name": "OracleDataset",
    "properties":
    {
        "type": "OracleTable",
        "schema": [],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        },
        "linkedServiceName": {
            "referenceName": "<Oracle linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

This section provides a list of properties supported by the Oracle source and sink. For a full list of sections and properties available for defining activities, see Pipelines.

Oracle as source

> **TIP**
> To load data from Oracle efficiently by using data partitioning, learn more from Parallel copy from Oracle.

To copy data from Oracle, set the source type in the copy activity to `OracleSource`. The following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to `OracleSource`.	Yes
oracleReaderQuery	Use the custom SQL query to read data. An example is `"SELECT * FROM MyTable"`. When you enable partitioned load, you need to hook any corresponding built-in partition parameters in your query. For examples, see the Parallel copy from Oracle section.	No
partitionOptions	Specifies the data partitioning options used to load data from Oracle. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from an Oracle database is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
partitionNames	The list of physical partitions that needs to be copied. Apply when the partition option is `PhysicalPartitionsOfTable`. If you use a query to retrieve the source data, hook `?AdfTabularPartitionName` in the WHERE clause. For an example, see the Parallel copy from Oracle section.	No
partitionColumnName	Specify the name of the source column **in integer type** that will be used by range partitioning for parallel copy. If not specified, the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionColumnName` in the WHERE clause. For an example, see the Parallel copy from Oracle section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionUpbound` in the WHERE clause. For an example, see the Parallel copy from Oracle section.	No
partitionLowerBound	The minimum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionLowbound` in the WHERE clause. For an example, see the Parallel copy from Oracle section.	No

Example: copy data by using a basic query without partition

```
"activities":[
    {
        "name": "CopyFromOracle",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Oracle input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "OracleSource",
                "oracleReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Oracle as sink

To copy data to Oracle, set the sink type in the copy activity to `OracleSink`. The following properties are supported in the copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to `OracleSink`.	Yes
writeBatchSize	Inserts data into the SQL table when the buffer size reaches `writeBatchSize`. Allowed values are Integer (number of rows).	No (default is 10,000)

PROPERTY	DESCRIPTION	REQUIRED
writeBatchTimeout	The wait time for the batch insert operation to complete before it times out. Allowed values are Timespan. An example is 00:30:00 (30 minutes).	No
preCopyScript	Specify a SQL query for the copy activity to run before writing data into Oracle in each run. You can use this property to clean up the preloaded data.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToOracle",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Oracle output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "OracleSink"
            }
        }
    }
]
```

Parallel copy from Oracle

The Oracle connector provides built-in data partitioning to copy data from Oracle in parallel. You can find data partitioning options on the **Source** tab of the copy activity.

When you enable partitioned copy, the service runs parallel queries against your Oracle source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Oracle database.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data

from your Oracle database. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommanded to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions.
Full load from large table, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column**: Specify the column used to partition data. If not specified, the primary key column is used.
Load a large amount of data by using a custom query, with physical partitions.	**Partition option**: Physical partitions of table. **Query**: `SELECT * FROM <TABLENAME> PARTITION("?AdfTabularPartitionName") WHERE <your_additional_where_clause>` . **Partition name**: Specify the partition name(s) to copy data from. If not specified, the service automatically detects the physical partitions on the table you specified in the Oracle dataset. During execution, the service replaces `?AdfTabularPartitionName` with the actual partition name, and sends to Oracle.
Load a large amount of data by using a custom query, without physical partitions, while with an integer column for data partitioning.	**Partition options**: Dynamic range partition. **Query**: `SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ?AdfRangePartitionUpbound AND ?AdfRangePartitionColumnName >= ?AdfRangePartitionLowbound AND <your_additional_where_clause>` . **Partition column**: Specify the column used to partition data. You can partition against the column with integer data type. **Partition upper bound** and **partition lower bound**: Specify if you want to filter against partition column to retrieve data only between the lower and upper range. During execution, the service replaces `?AdfRangePartitionColumnName`, `?AdfRangePartitionUpbound`, and `?AdfRangePartitionLowbound` with the actual column name and value ranges for each partition, and sends to Oracle. For example, if your partition column "ID" is set with the lower bound as 1 and the upper bound as 80, with parallel copy set as 4, the service retrieves data by 4 partitions. Their IDs are between [1,20], [21, 40], [41, 60], and [61, 80], respectively.

TIP

When copying data from a non-partitioned table, you can use "Dynamic range" partition option to partition against an integer column. If your source data doesn't have such type of column, you can leverage ORA_HASH function in source query to generate a column and use it as partition column.

Example: query with physical partition

```
"source": {
    "type": "OracleSource",
    "query":"SELECT * FROM <TABLENAME> PARTITION(\"?AdfTabularPartitionName\") WHERE
<your_additional_where_clause>",
    "partitionOption": "PhysicalPartitionsOfTable",
    "partitionSettings": {
        "partitionNames": [
            "<partitionA_name>",
            "<partitionB_name>"
        ]
    }
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "OracleSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ?AdfRangePartitionUpbound AND ?
AdfRangePartitionColumnName >= ?AdfRangePartitionLowbound AND <your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column>",
        "partitionLowerBound": "<lower_value_of_partition_column>"
    }
}
```

Data type mapping for Oracle

When you copy data from and to Oracle, the following interim data type mappings are used within the service. To learn about how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

ORACLE DATA TYPE	INTERIM DATA TYPE
BFILE	Byte[]
BLOB	Byte[] (only supported on Oracle 10g and higher)
CHAR	String
CLOB	String
DATE	DateTime
FLOAT	Decimal, String (if precision > 28)
INTEGER	Decimal, String (if precision > 28)
LONG	String
LONG RAW	Byte[]
NCHAR	String
NCLOB	String
NUMBER (p,s)	Decimal, String (if p > 28)
NUMBER without precision and scale	Double
NVARCHAR2	String

ORACLE DATA TYPE	INTERIM DATA TYPE
RAW	Byte[]
ROWID	String
TIMESTAMP	DateTime
TIMESTAMP WITH LOCAL TIME ZONE	String
TIMESTAMP WITH TIME ZONE	String
UNSIGNED INTEGER	Number
VARCHAR2	String
XML	String

> **NOTE**
> The data types INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND aren't supported.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Oracle Cloud Storage using Azure Data Factory or Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to copy data from Oracle Cloud Storage. To learn more, read the introductory articles for Azure Data Factory and Synapse Analytics.

Supported capabilities

This Oracle Cloud Storage connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, this Oracle Cloud Storage connector supports copying files as is or parsing files with the supported file formats and compression codecs. It takes advantage of Oracle Cloud Storage's S3-compatible interoperability.

Prerequisites

To copy data from Oracle Cloud Storage, please refer here for the prerequisites and required permission.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

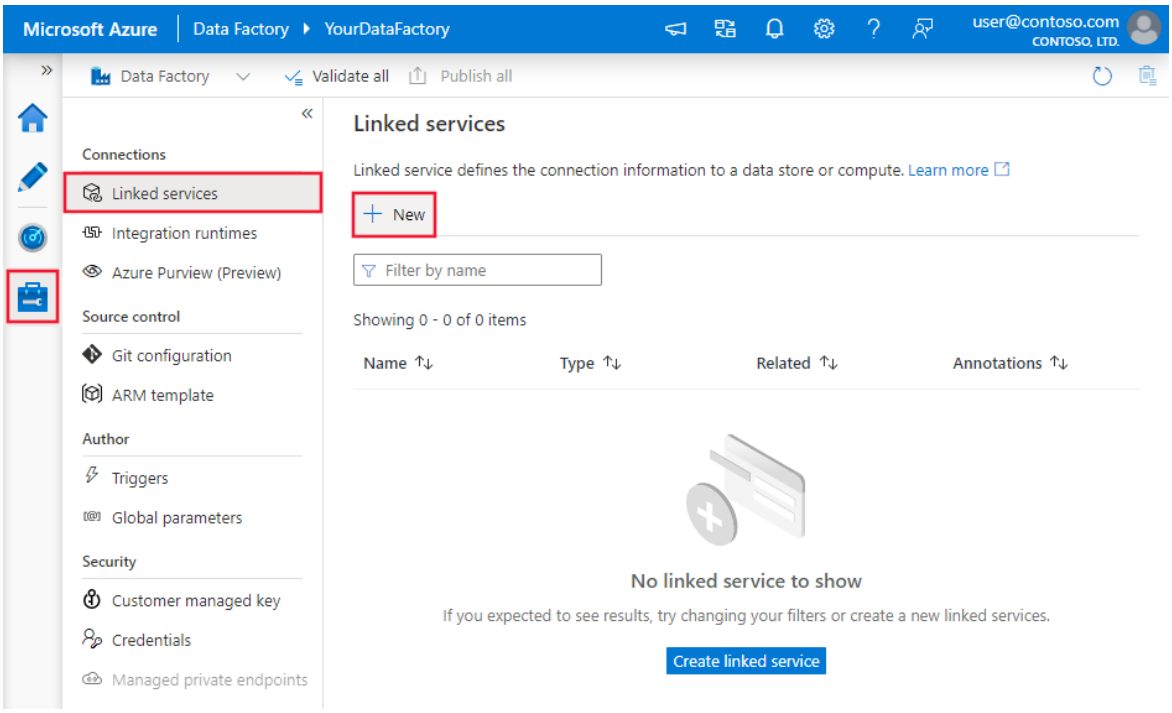
Create a linked service to Oracle Cloud Storage using UI

Use the following steps to create a linked service to Oracle Cloud Storage in the Azure portal UI.

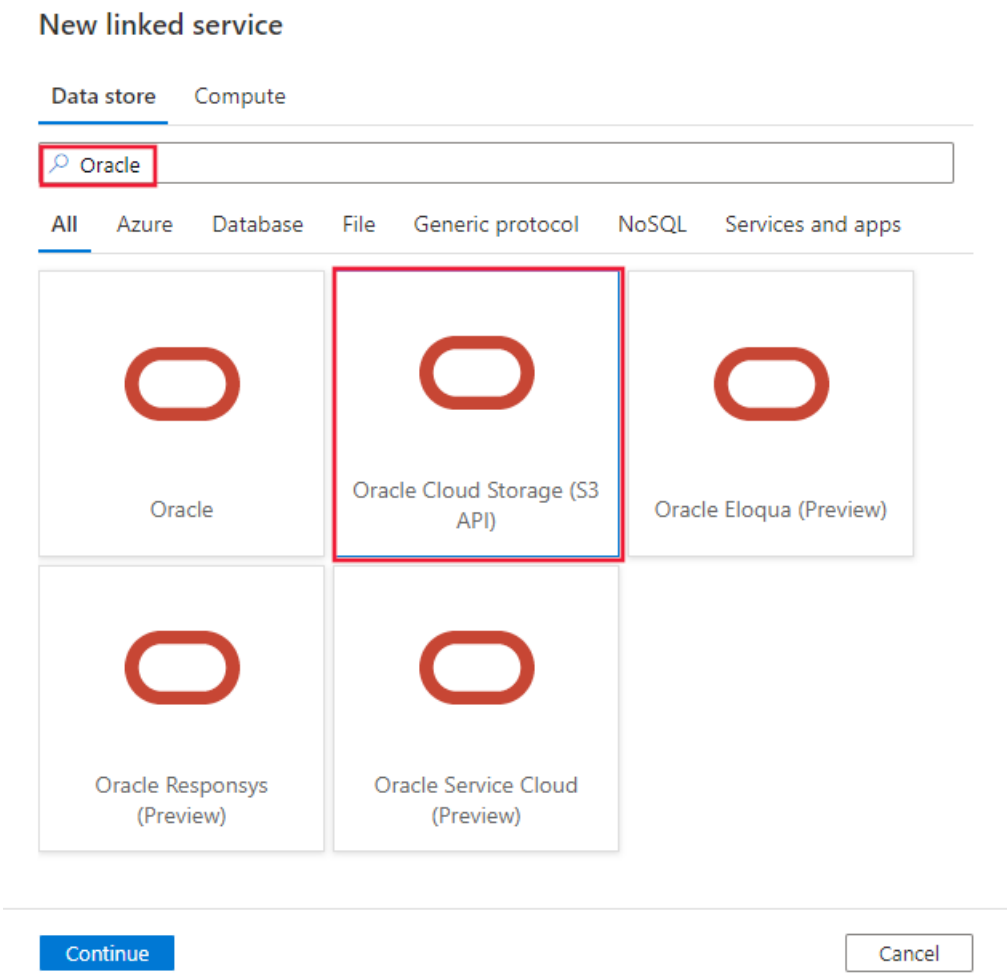
1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services,

then click New:

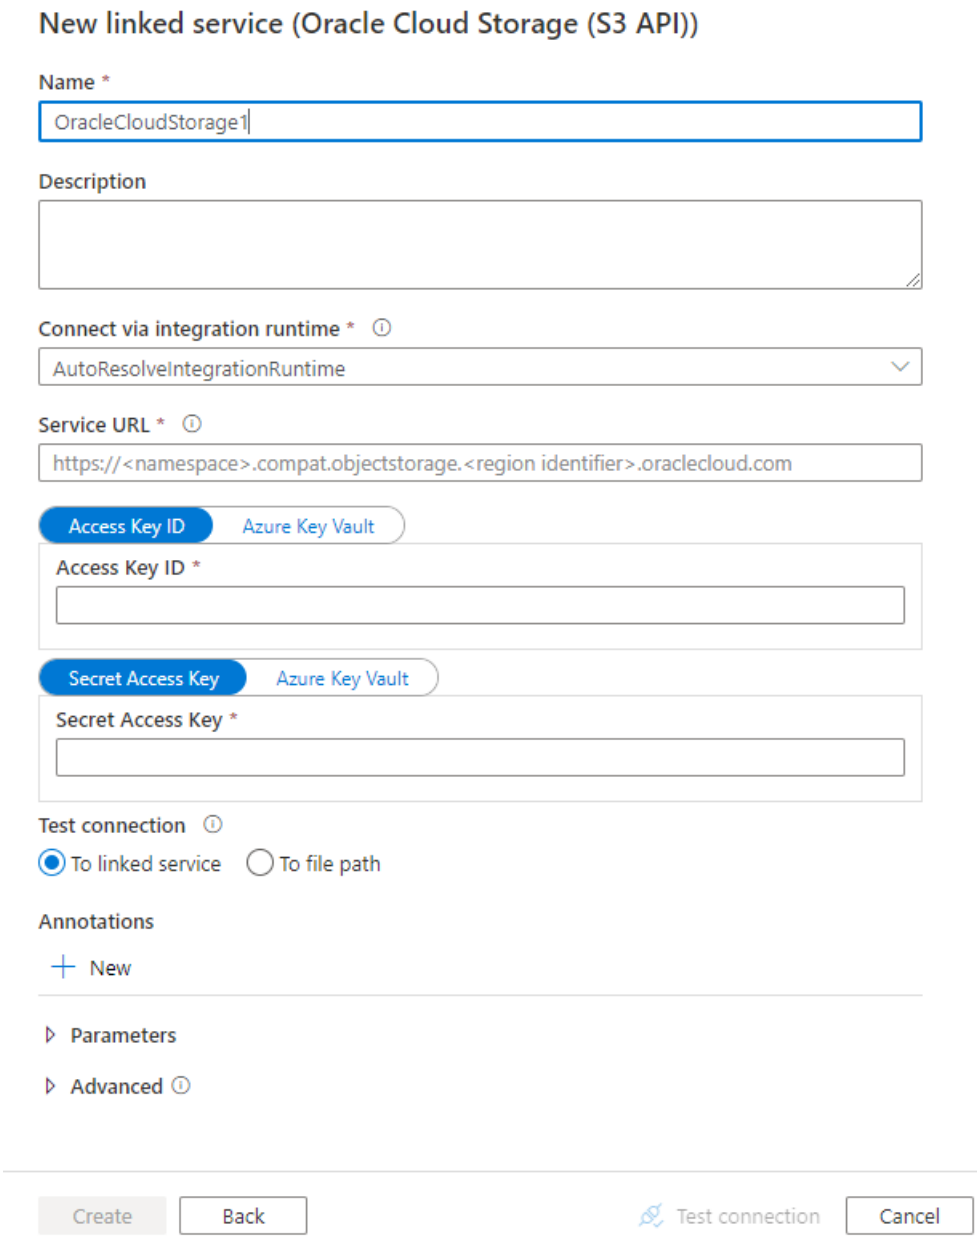
- Azure Data Factory
- Azure Synapse



2. Search for Oracle and select the Oracle Cloud Storage connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to Oracle Cloud Storage.

Linked service properties

The following properties are supported for Oracle Cloud Storage linked services:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **OracleCloudStorage**.	Yes
accessKeyId	ID of the secret access key. To find the access key and secret, see Prerequisites.	Yes

PROPERTY	DESCRIPTION	REQUIRED
secretAccessKey	The secret access key itself. Mark this field as **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes
serviceUrl	Specify the custom endpoint as `https://<namespace>.compat.objectstorage.<region identifier>.oraclecloud.com`. Refer here for more details	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	No

Here's an example:

```
{
    "name": "OracleCloudStorageLinkedService",
    "properties": {
        "type": "OracleCloudStorage",
        "typeProperties": {
            "accessKeyId": "<access key id>",
            "secretAccessKey": {
                "type": "SecureString",
                "value": "<secret access key>"
            },
            "serviceUrl": "https://<namespace>.compat.objectstorage.<region identifier>.oraclecloud.com"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for Oracle Cloud Storage under `location` settings in a format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `location` in the dataset must be set to **OracleCloudStorageLocation**.	Yes
bucketName	The Oracle Cloud Storage bucket name.	Yes
folderPath	The path to folder under the given bucket. If you want to use a wildcard to filter the folder, skip this setting and specify that in activity source settings.	No
fileName	The file name under the given bucket and folder path. If you want to use a wildcard to filter the files, skip this setting and specify that in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<Oracle Cloud Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "OracleCloudStorageLocation",
                "bucketName": "bucketname",
                "folderPath": "folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties that the Oracle Cloud Storage source supports.

Oracle Cloud Storage as a source type

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format

- ORC format
- Parquet format
- XML format

The following properties are supported for Oracle Cloud Storage under `storeSettings` settings in a format-based copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property under `storeSettings` must be set to **OracleCloudStorageReadSettings**.	Yes
Locate the files to copy:		
OPTION 1: static path	Copy from the given bucket or folder/file path specified in the dataset. If you want to copy all files from a bucket or folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: Oracle Cloud Storage prefix - prefix	Prefix for the Oracle Cloud Storage key name under the given bucket configured in the dataset to filter source Oracle Cloud Storage files. Oracle Cloud Storage keys whose names start with `bucket_in_dataset/this_prefix` are selected. It utilizes Oracle Cloud Storage's service-side filter, which provides better performance than a wildcard filter.	No
OPTION 3: wildcard - wildcardFolderPath	The folder path with wildcard characters under the given bucket configured in a dataset to filter source folders. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your folder name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	No
OPTION 3: wildcard - wildcardFileName	The file name with wildcard characters under the given bucket and folder path (or wildcard folder path) to filter source files. Allowed wildcards are: `*` (matches zero or more characters) and `?` (matches zero or single character). Use `^` to escape if your file name has a wildcard or this escape character inside. See more examples in Folder and file filter examples.	Yes

PROPERTY	DESCRIPTION	REQUIRED
OPTION 3: a list of files - fileListPath	Indicates to copy a given file set. Point to a text file that includes a list of files you want to copy, one file per line, which is the relative path to the path configured in the dataset. When you're using this option, do not specify the file name in the dataset. See more examples in File list examples.	No
Additional settings:		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. Note that when **recursive** is set to **true** and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are **true** (default) and **false**. This property doesn't apply when you configure `fileListPath`.	No
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeStart	Files are filtered based on the attribute: last modified. The files will be selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of "2018-12-01T05:00:00Z". The properties can be **NULL**, which means no file attribute filter will be applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is **NULL**, the files whose last modified attribute is greater than or equal to the datetime value will be selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is **NULL**, the files whose last modified attribute is less than the datetime value will be selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No

PROPERTY	DESCRIPTION	REQUIRED
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromOracleCloudStorage",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "OracleCloudStorageReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv"
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Folder and file filter examples

This section describes the resulting behavior of the folder path and file name with wildcard filters.

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)

BUCKET	KEY	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
bucket	`Folder*/*`	false	bucket FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
bucket	`Folder*/*`	true	bucket FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	false	bucket FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
bucket	`Folder*/*.csv`	true	bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This section describes the resulting behavior of using a file list path in the Copy activity source.

Assume that you have the following source folder structure and want to copy the files in bold:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	CONFIGURATION
bucket FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In dataset:** - Bucket: `bucket` - Folder path: `FolderA` **In copy activity source:** - File list path: `bucket/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy, one file per line, with the relative path to the path configured in the dataset.

Next steps

For a list of data stores that the Copy activity supports as sources and sinks, see Supported data stores.

Copy data from Oracle Eloqua using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Oracle Eloqua. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and provide feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Oracle Eloqua connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

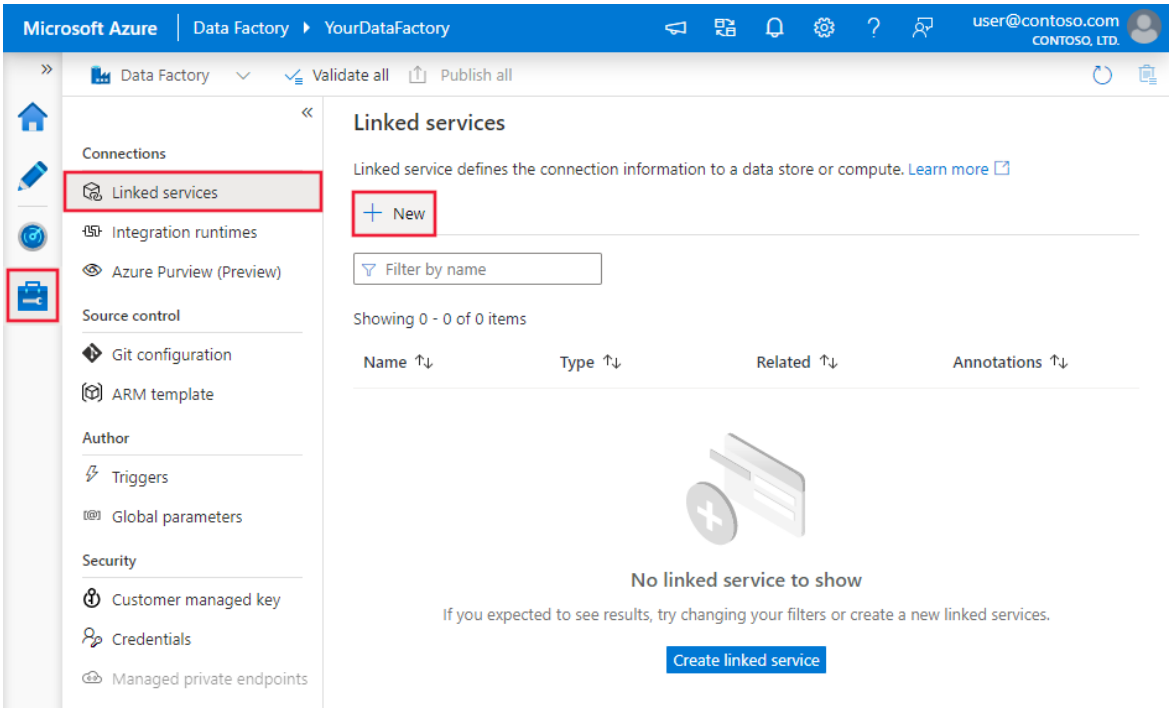
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Oracle Eloqua using UI

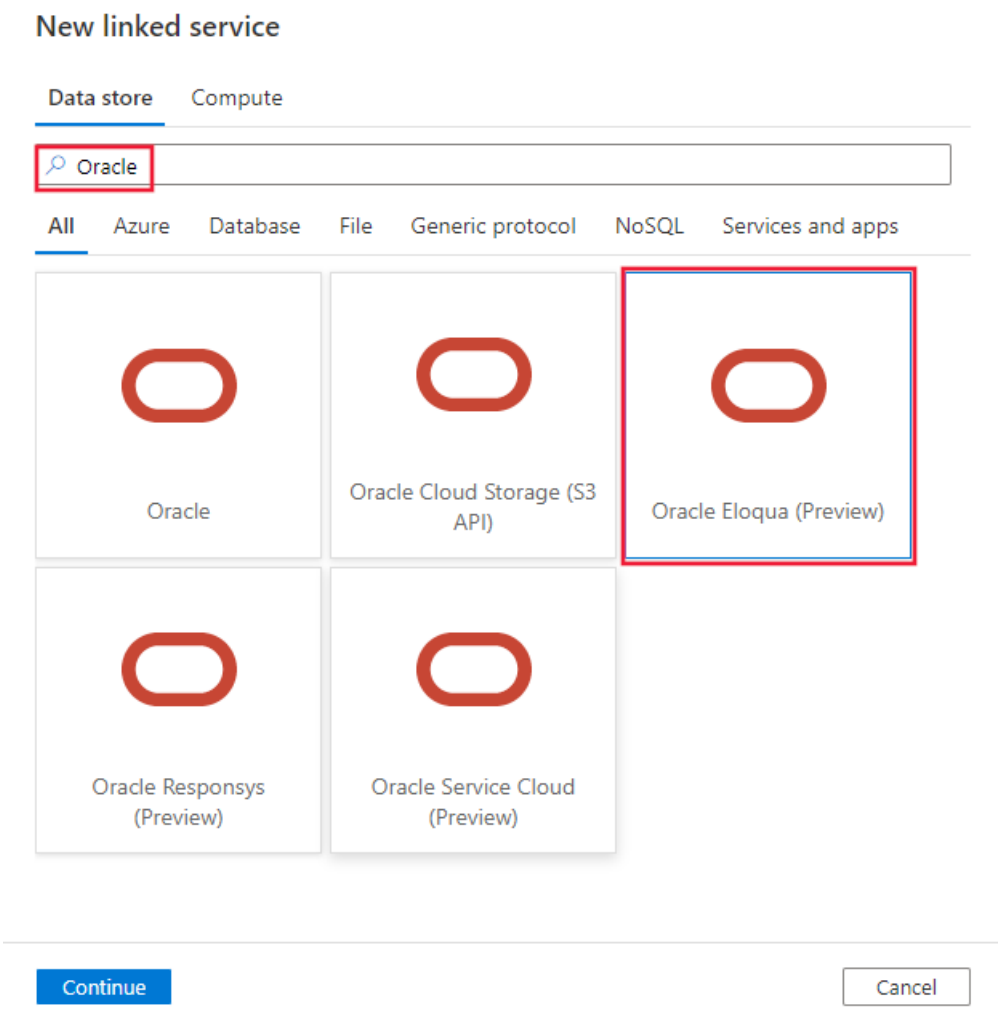
Use the following steps to create a linked service to Oracle Eloqua in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

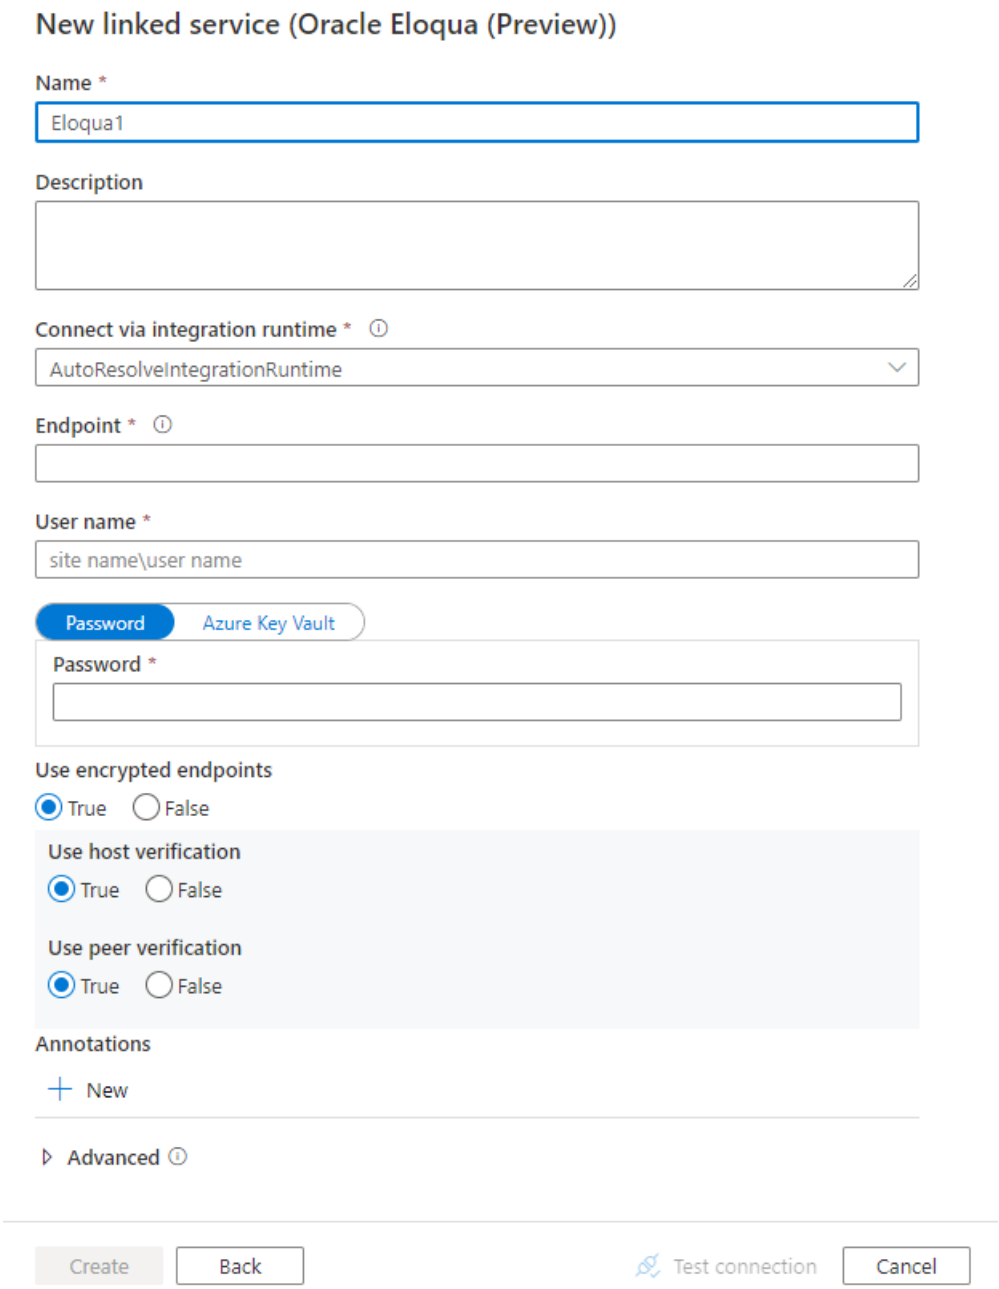
- Azure Data Factory
- Azure Synapse



2. Search for Oracle and select the Oracle Eloqua connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Oracle Eloqua connector.

Linked service properties

The following properties are supported for Oracle Eloqua linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Eloqua**	Yes

PROPERTY	DESCRIPTION	REQUIRED
endpoint	The endpoint of the Eloqua server. Eloqua supports multiple data centers, to determine your endpoint, login to https://login.eloqua.com with your credential, then copy the **base URL** portion from the redirected URL with the pattern of `xxx.xxx.eloqua.com`.	Yes
username	The site name and user name of your Eloqua account in the form: `SiteName\Username` e.g. `Eloqua\Alice`.	Yes
password	The password corresponding to the user name. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "EloquaLinkedService",
    "properties": {
        "type": "Eloqua",
        "typeProperties": {
            "endpoint" : "<base URL e.g. xxx.xxx.eloqua.com>",
            "username" : "<site name>\\<user name e.g. Eloqua\\Alice>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Oracle Eloqua dataset.

To copy data from Oracle Eloqua, set the type property of the dataset to **EloquaObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **EloquaObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "EloquaDataset",
    "properties": {
        "type": "EloquaObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Eloqua linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Oracle Eloqua source.

Eloqua as source

To copy data from Oracle Eloqua, set the source type in the copy activity to **EloquaSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **EloquaSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Accounts"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromEloqua",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Eloqua input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "EloquaSource",
                "query": "SELECT * FROM Accounts"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of supported data stores in the service, see supported data stores.

Copy data from Oracle Responsys using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Oracle Responsys. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Oracle Responsys connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

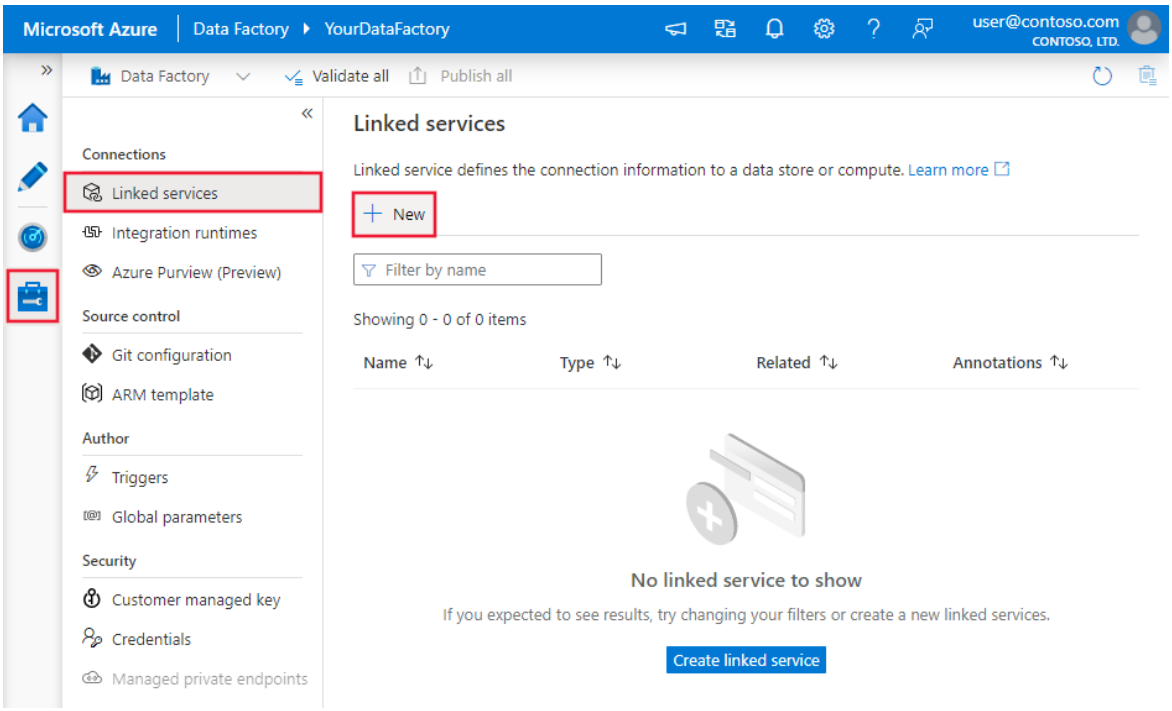
You can create a pipeline with copy activity using .NET SDK, Python SDK, Azure PowerShell, REST API, or Azure Resource Manager template. See Copy activity tutorial for step-by-step instructions to create a pipeline with a copy activity.

Create a linked service to Oracle Responsys using UI

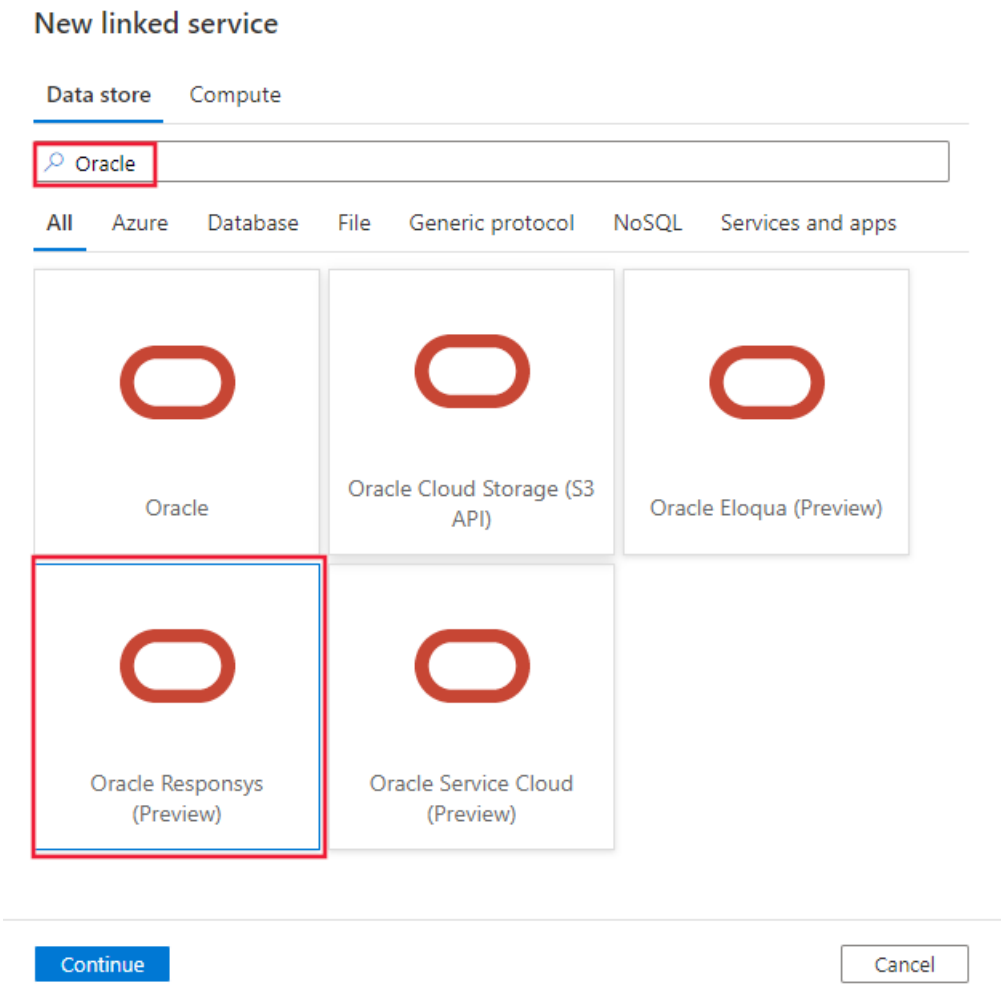
Use the following steps to create a linked service to Oracle Responsys in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

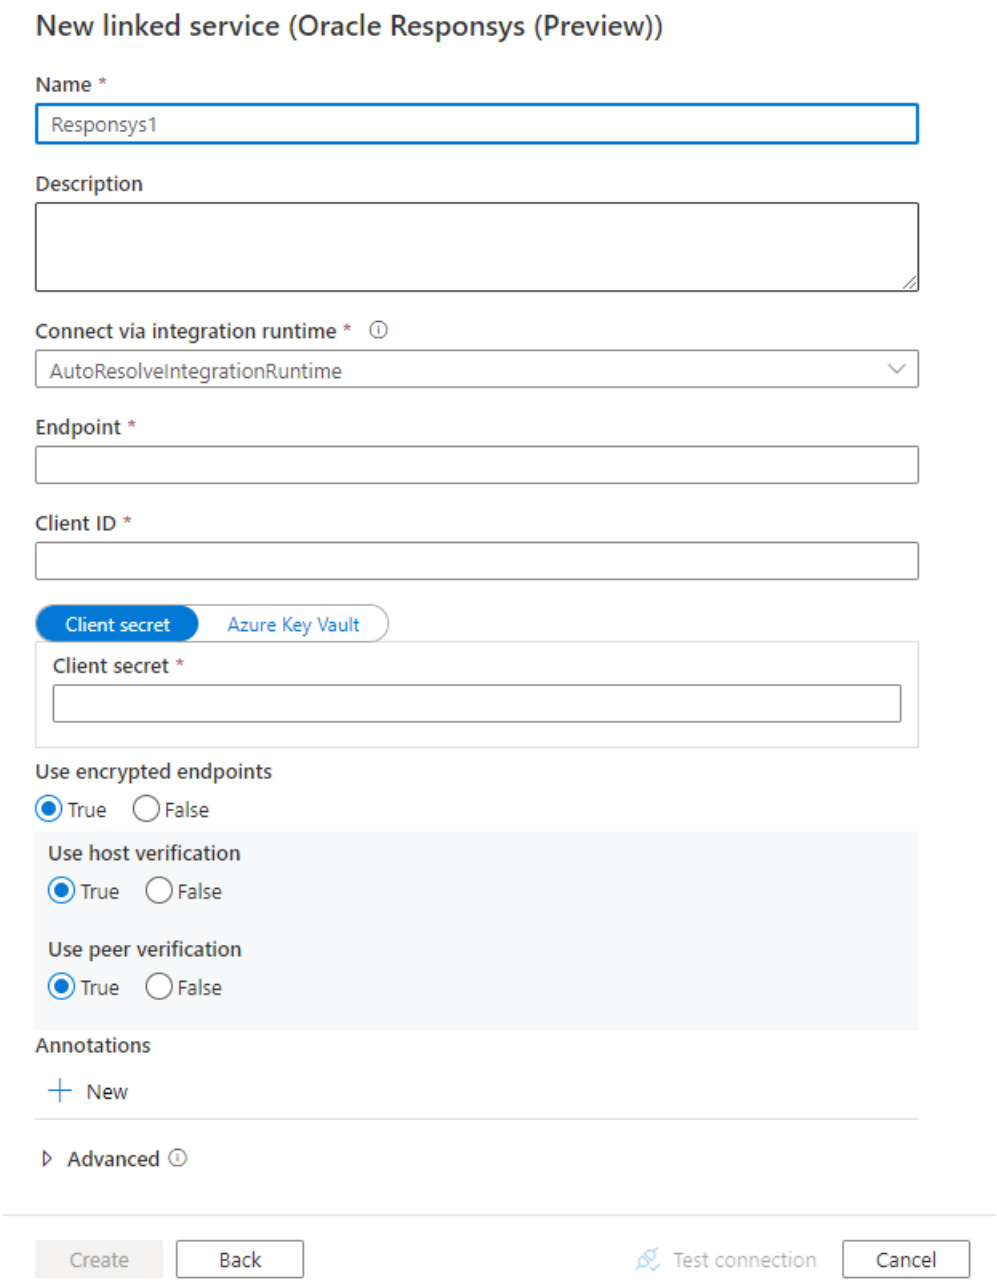
   - Azure Data Factory
   - Azure Synapse



2. Search for Oracle and select the Oracle Responsys connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Oracle Responsys connector.

Linked service properties

The following properties are supported for Oracle Responsys linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Responsys**	Yes
endpoint	The endpoint of the Respopnsys server	Yes
clientId	The client ID associated with the Responsys application.	Yes

PROPERTY	DESCRIPTION	REQUIRED
clientSecret	The client secret associated with the Responsys application. You can choose to mark this field as a SecureString to store it securely in the service, or store password in Azure Key Vault and let the service copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "OracleResponsysLinkedService",
    "properties": {
        "type": "Responsys",
        "typeProperties": {
            "endpoint" : "<endpoint>",
            "clientId" : "<clientId>",
            "clientSecret": {
                 "type": "SecureString",
                 "value": "<clientSecret>"
            },
            "useEncryptedEndpoints" : true,
            "useHostVerification" : true,
            "usePeerVerification" : true
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Oracle Responsys dataset.

To copy data from Oracle Responsys, set the type property of the dataset to **ResponsysObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ResponsysObject**	Yes

PROPERTY	DESCRIPTION	REQUIRED
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "OracleResponsysDataset",
    "properties": {
        "type": "ResponsysObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Oracle Responsys linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Oracle Responsys source.

Oracle Responsys as source

To copy data from Oracle Responsys, set the source type in the copy activity to **ResponsysSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **ResponsysSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromOracleResponsys",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Oracle Responsys input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ResponsysSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Oracle Service Cloud using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Oracle Service Cloud. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and provide feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Oracle Service Cloud connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

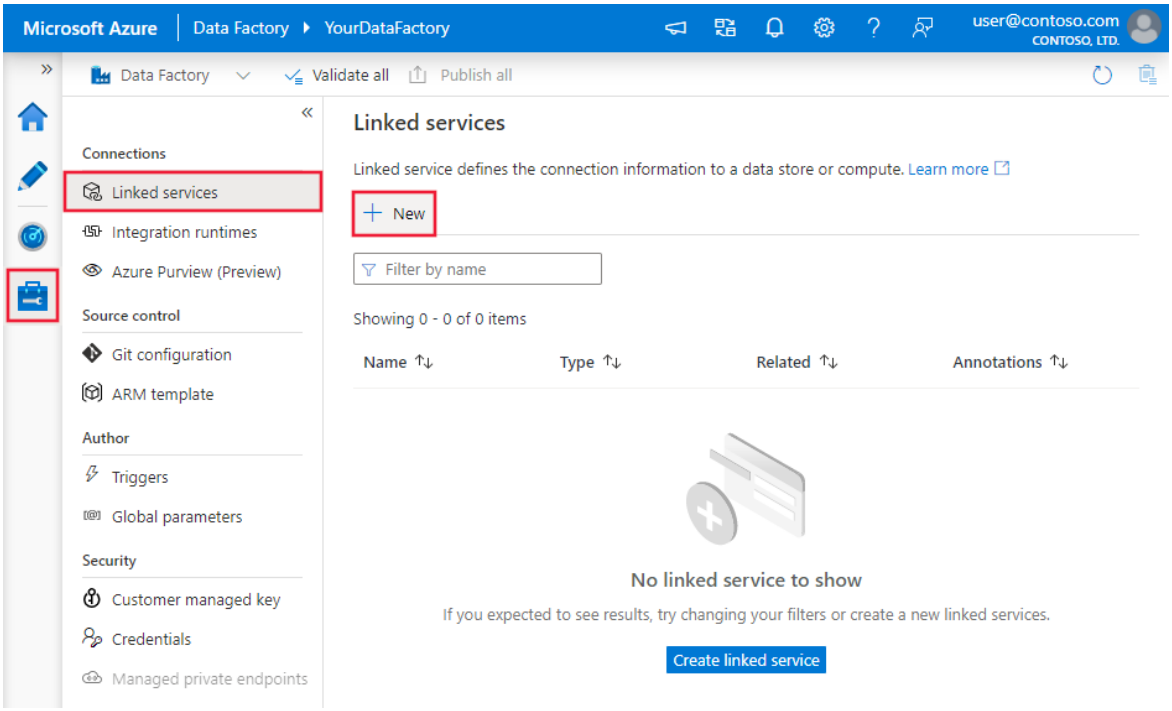
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Oracle Service Cloud using UI

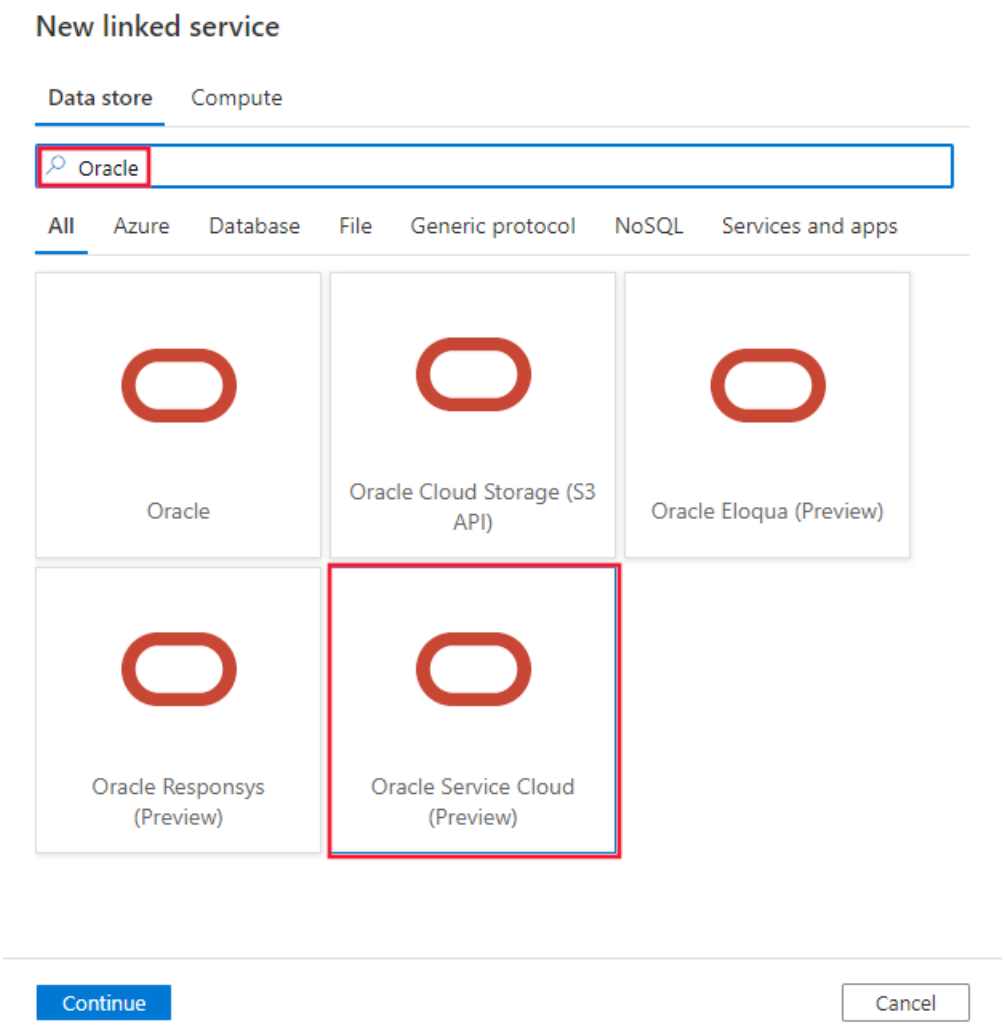
Use the following steps to create a linked service to Oracle Service Cloud in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

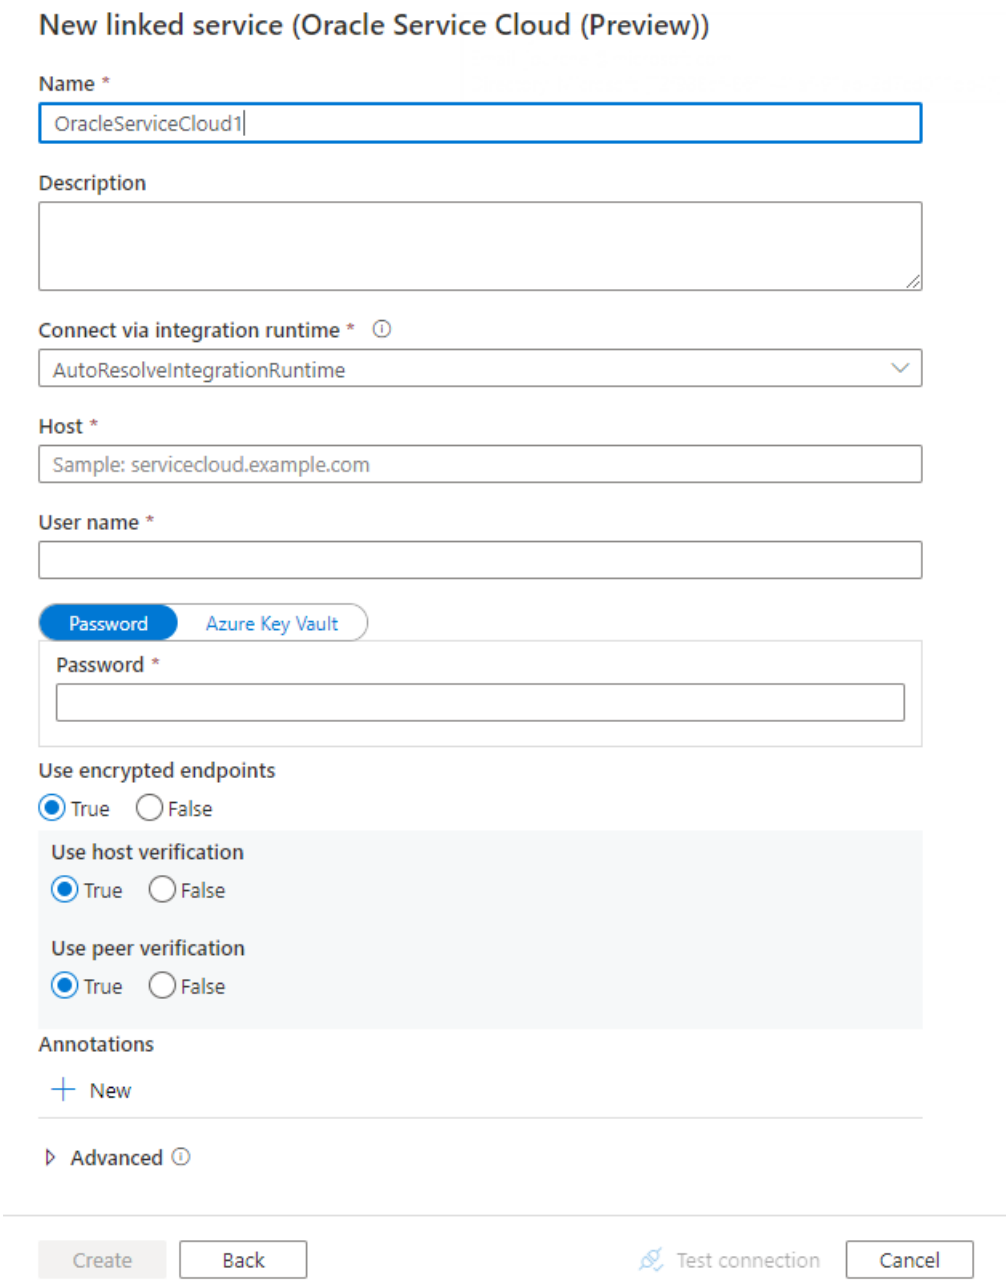
- Azure Data Factory
- Azure Synapse



2. Search for Oracle and select the Oracle Service Cloud connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Oracle Service Cloud connector.

Linked service properties

The following properties are supported for Oracle Service Cloud linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **OracleServiceCloud**	Yes
host	The URL of the Oracle Service Cloud instance.	Yes
username	The user name that you use to access Oracle Service Cloud server.	Yes

PROPERTY	DESCRIPTION	REQUIRED
password	The password corresponding to the user name that you provided in the username key. You can choose to mark this field as a SecureString to store it securely in the service, or store password in Azure Key Vault and let the service copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "OracleServiceCloudLinkedService",
    "properties": {
        "type": "OracleServiceCloud",
        "typeProperties": {
            "host" : "<host>",
            "username" : "<username>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            },
            "useEncryptedEndpoints" : true,
            "useHostVerification" : true,
            "usePeerVerification" : true,
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Oracle Service Cloud dataset.

To copy data from Oracle Service Cloud, set the type property of the dataset to **OracleServiceCloudObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **OracleServiceCloudObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "OracleServiceCloudDataset",
    "properties": {
        "type": "OracleServiceCloudObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<OracleServiceCloud linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Oracle Service Cloud source.

Oracle Service Cloud as source

To copy data from Oracle Service Cloud, set the source type in the copy activity to **OracleServiceCloudSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **OracleServiceCloudSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromOracleServiceCloud",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<OracleServiceCloud input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "OracleServiceCloudSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

ORC format in Azure Data Factory and Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the ORC files or write the data into ORC format**.

ORC format is supported for the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the ORC dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Orc**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section**.	Yes
compressionCodec	The compression codec to use when writing to ORC files. When reading from ORC files, Data Factories automatically determine the compression codec based on the file metadata. Supported types are **none**, **zlib**, **snappy** (default), and **lzo**. Note currently Copy activity doesn't support LZO when read/write ORC files.	No

Below is an example of ORC dataset on Azure Blob Storage:

```
{
    "name": "OrcDataset",
    "properties": {
        "type": "Orc",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            }
        }
    }
}
```

Note the following points:

- Complex data types (e.g. MAP, LIST, STRUCT) are currently supported only in Data Flows, not in Copy Activity. To use complex types in data flows, do not import the file schema in the dataset, leaving schema blank in the dataset. Then, in the Source transformation, import the projection.
- White space in column name is not supported.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the ORC source and sink.

ORC as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **OrcSource**.	Yes
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

ORC as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **OrcSink**.	Yes
formatSettings	A group of properties. Refer to **ORC write settings** table below.	No

PROPERTY	DESCRIPTION	REQUIRED
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **ORC write settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **OrcWriteSettings**.	Yes
maxRowsPerFile	When writing data into a folder, you can choose to write to multiple files and specify the max rows per file.	No
fileNamePrefix	Applicable when `maxRowsPerFile` is configured. Specify the file name prefix when writing data to multiple files, resulted in this pattern: `<fileNamePrefix>_00000.<fileExtension>`. If not specified, file name prefix will be auto generated. This property does not apply when source is file-based store or partition-option-enabled data store.	No

Mapping data flow properties

In mapping data flows, you can read and write to ORC format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and SFTP, and you can read ORC format in Amazon S3.

You can point to ORC files either using ORC dataset or using an inline dataset.

Source properties

The below table lists the properties supported by an ORC source. You can edit these properties in the **Source options** tab.

When using inline dataset, you will see additional file settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `orc`	yes	`orc`	format

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `[<from>, <to>]`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

Source example

The associated data flow script of an ORC source configuration is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    rowUrlColumn: 'fileName',
    format: 'orc') ~> OrcSource
```

Sink properties

The below table lists the properties supported by an ORC sink. You can edit these properties in the **Settings** tab.

When using inline dataset, you will see additional file settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `orc`	yes	`orc`	format
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>`	no	Pattern: String Per partition: String[] As data in column: String Output to single file: `['<fileName>']`	filePattern partitionFileNames rowUrlColumn partitionFileNames

Sink example

The associated data flow script of an ORC sink configuration is:

```
OrcSource sink(
    format: 'orc',
    filePattern:'output[n].orc',
    truncate: true,
    allowSchemaDrift: true,
    validateSchema: false,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> OrcSink
```

Using Self-hosted Integration Runtime

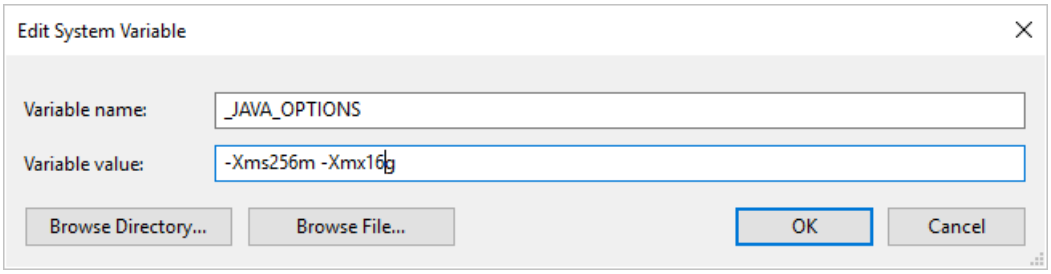
> **IMPORTANT**
> For copy empowered by Self-hosted Integration Runtime e.g. between on-premises and cloud data stores, if you are not copying ORC files **as-is**, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** and **Microsoft Visual C++ 2010 Redistributable Package** on your IR machine. Check the following paragraph with more details.

For copy running on Self-hosted IR with ORC file serialization/deserialization, the service locates the Java runtime by firstly checking the registry `(SOFTWARE\JavaSoft\Java Runtime Environment\{Current Version}\JavaHome)` for JRE, if not found, secondly checking system variable `JAVA_HOME` for OpenJDK.

- **To use JRE**: The 64-bit IR requires 64-bit JRE. You can find it from here.
- **To use OpenJDK**: It's supported since IR version 3.13. Package the jvm.dll with all other required assemblies of OpenJDK into Self-hosted IR machine, and set system environment variable JAVA_HOME accordingly.
- **To install Visual C++ 2010 Redistributable Package**: Visual C++ 2010 Redistributable Package is not installed with self-hosted IR installations. You can find it from here.

TIP

If you copy data to/from ORC format using Self-hosted Integration Runtime and hit error saying "An error occurred when invoking java, message: **java.lang.OutOfMemoryError:Java heap space**", you can add an environment variable `_JAVA_OPTIONS` in the machine that hosts the Self-hosted IR to adjust the min/max heap size for JVM to empower such copy, then rerun the pipeline.



Example: set variable `_JAVA_OPTIONS` with value `-Xms256m -Xmx16g`. The flag `Xms` specifies the initial memory allocation pool for a Java Virtual Machine (JVM), while `Xmx` specifies the maximum memory allocation pool. This means that JVM will be started with `Xms` amount of memory and will be able to use a maximum of `Xmx` amount of memory. By default, the service uses min 64 MB and max 1G.

Parquet format in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the Parquet files or write the data into Parquet format**.

Parquet format is supported for the following connectors:

- Amazon S3
- Amazon S3 Compatible Storage
- Azure Blob
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Files
- File System
- FTP
- Google Cloud Storage
- HDFS
- HTTP
- Oracle Cloud Storage
- SFTP

For a list of supported features for all available connectors, visit the Connectors Overview article.

Using Self-hosted Integration Runtime

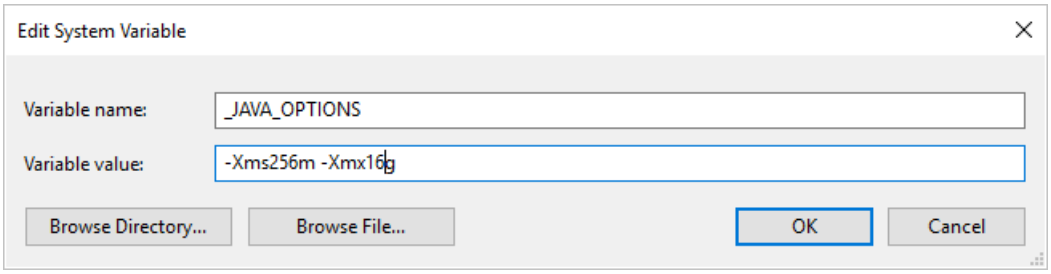
> **IMPORTANT**
> For copy empowered by Self-hosted Integration Runtime e.g. between on-premises and cloud data stores, if you are not copying Parquet files **as-is**, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** on your IR machine. Check the following paragraph with more details.

For copy running on Self-hosted IR with Parquet file serialization/deserialization, the service locates the Java runtime by firstly checking the registry `(SOFTWARE\JavaSoft\Java Runtime Environment\{Current Version}\JavaHome)` for JRE, if not found, secondly checking system variable `JAVA_HOME` for OpenJDK.

- **To use JRE**: The 64-bit IR requires 64-bit JRE. You can find it from here.
- **To use OpenJDK**: It's supported since IR version 3.13. Package the jvm.dll with all other required assemblies of OpenJDK into Self-hosted IR machine, and set system environment variable JAVA_HOME accordingly, and then restart Self-hosted IR for taking effect immediately.

TIP

If you copy data to/from Parquet format using Self-hosted Integration Runtime and hit error saying "An error occurred when invoking java, message: **java.lang.OutOfMemoryError:Java heap space**", you can add an environment variable `_JAVA_OPTIONS` in the machine that hosts the Self-hosted IR to adjust the min/max heap size for JVM to empower such copy, then rerun the pipeline.



Example: set variable `_JAVA_OPTIONS` with value `-Xms256m -Xmx16g`. The flag `Xms` specifies the initial memory allocation pool for a Java Virtual Machine (JVM), while `Xmx` specifies the maximum memory allocation pool. This means that JVM will be started with `Xms` amount of memory and will be able to use a maximum of `Xmx` amount of memory. By default, the service uses min 64 MB and max 1G.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Parquet dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Parquet**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section**.	Yes
compressionCodec	The compression codec to use when writing to Parquet files. When reading from Parquet files, Data Factories automatically determine the compression codec based on the file metadata. Supported types are "**none**", "**gzip**", "**snappy**" (default), and "**lzo**". Note currently Copy activity doesn't support LZO when read/write Parquet files.	No

NOTE

White space in column name is not supported for Parquet files.

Below is an example of Parquet dataset on Azure Blob Storage:

```
{
    "name": "ParquetDataset",
    "properties": {
        "type": "Parquet",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "compressionCodec": "snappy"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Parquet source and sink.

Parquet as source

The following properties are supported in the copy activity ***source*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **ParquetSource**.	Yes
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Parquet as sink

The following properties are supported in the copy activity ***sink*** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **ParquetSink**.	Yes
formatSettings	A group of properties. Refer to **Parquet write settings** table below.	No
storeSettings	A group of properties on how to write data to a data store. Each file-based connector has its own supported write settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **Parquet write settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **ParquetWriteSettings**.	Yes
maxRowsPerFile	When writing data into a folder, you can choose to write to multiple files and specify the max rows per file.	No
fileNamePrefix	Applicable when `maxRowsPerFile` is configured. Specify the file name prefix when writing data to multiple files, resulted in this pattern: `<fileNamePrefix>_00000.<fileExtension>`. If not specified, file name prefix will be auto generated. This property does not apply when source is file-based store or partition-option-enabled data store.	No

Mapping data flow properties

In mapping data flows, you can read and write to parquet format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2 and SFTP, and you can read parquet format in Amazon S3.

Source properties

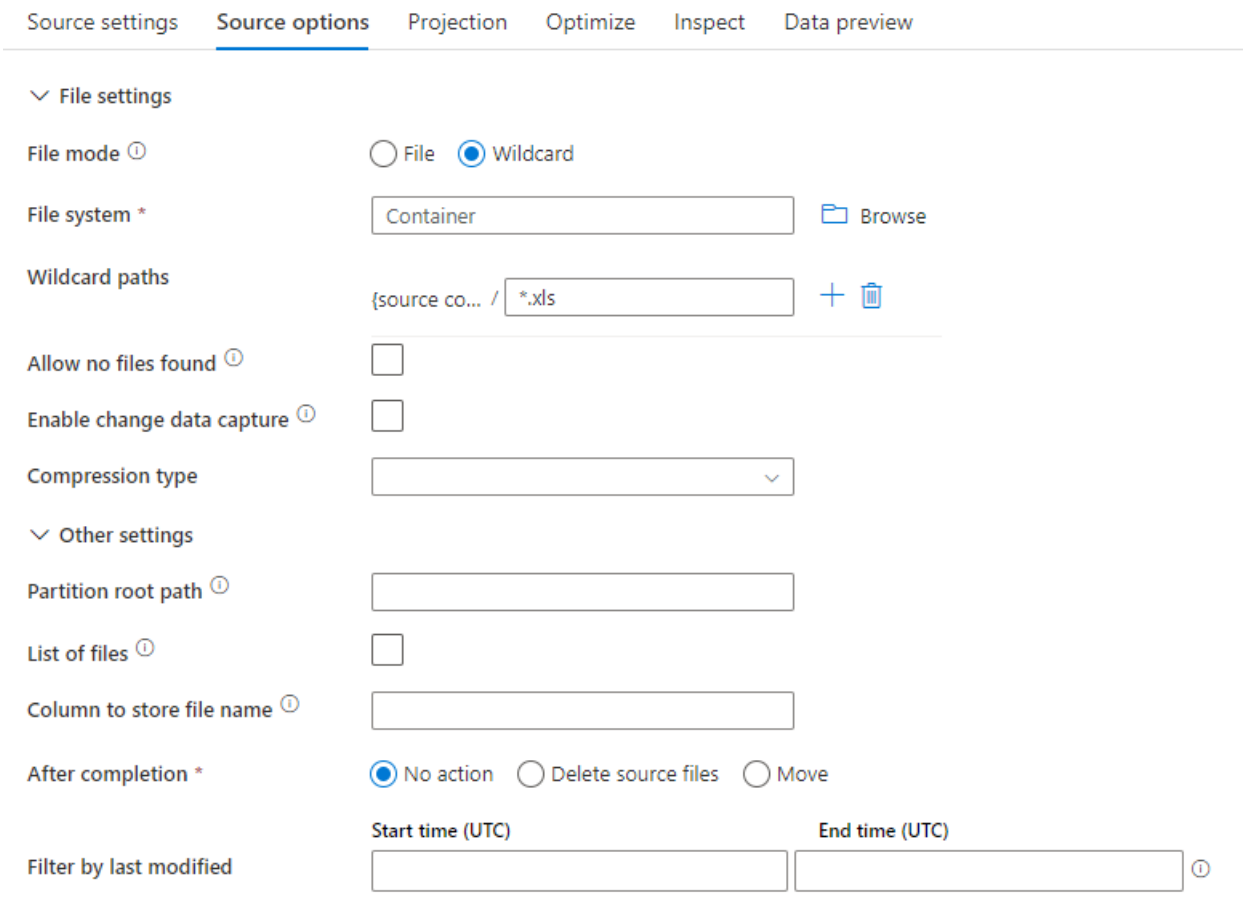
The below table lists the properties supported by a parquet source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `parquet`	yes	`parquet`	format
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	no	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	no	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	no	`true` or `false`	fileList

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Column to store file name	Create a new column with the source file name and path	no	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	no	Delete: `true` or `false` Move: `[<from>, <to>]`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	no	Timestamp	modifiedAfter modifiedBefore
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

Source example

The below image is an example of a parquet source configuration in mapping data flows.



The associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    rowUrlColumn: 'fileName',
    format: 'parquet') ~> ParquetSource
```

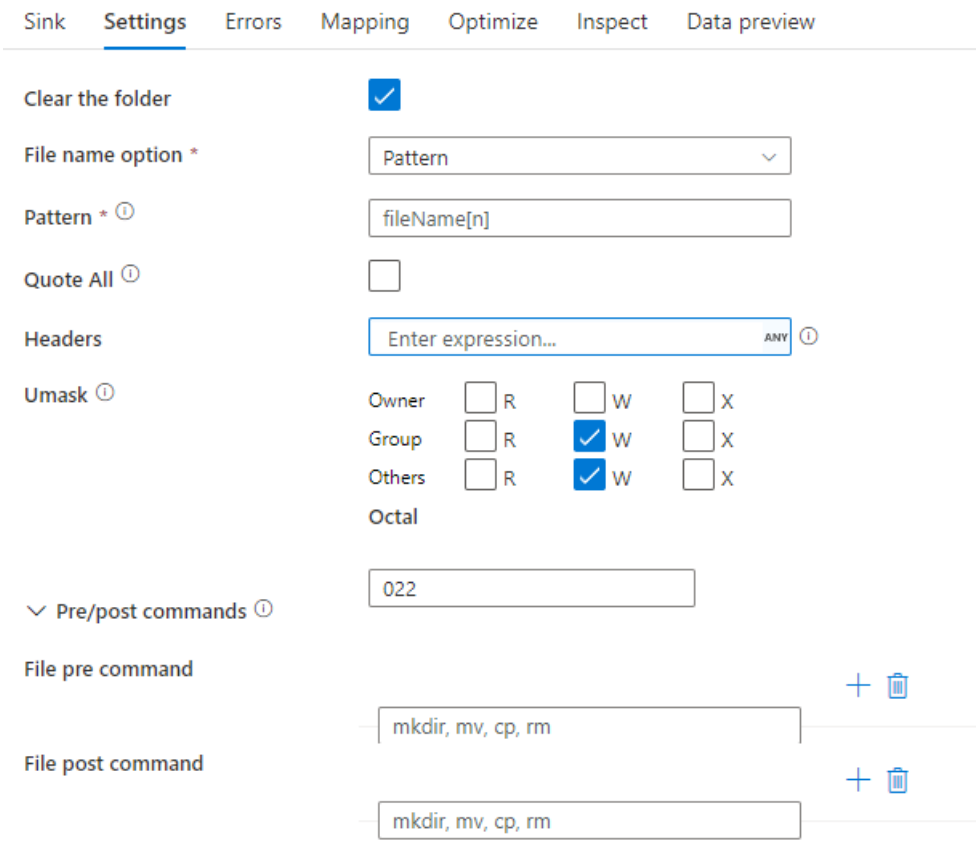
Sink properties

The below table lists the properties supported by a parquet sink. You can edit these properties in the **Settings** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Format	Format must be `parquet`	yes	`parquet`	format
Clear the folder	If the destination folder is cleared prior to write	no	`true` or `false`	truncate
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>`	no	Pattern: String Per partition: String[] As data in column: String Output to single file: `['<fileName>']`	filePattern partitionFileNames rowUrlColumn partitionFileNames

Sink example

The below image is an example of a parquet sink configuration in mapping data flows.



The associated data flow script is:

```
ParquetSource sink(
    format: 'parquet',
    filePattern:'output[n].parquet',
    truncate: true,
    allowSchemaDrift: true,
    validateSchema: false,
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> ParquetSink
```

Data type support

Parquet complex data types (e.g. MAP, LIST, STRUCT) are currently supported only in Data Flows, not in Copy Activity. To use complex types in data flows, do not import the file schema in the dataset, leaving schema blank in the dataset. Then, in the Source transformation, import the projection.

Copy data from PayPal using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from PayPal. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This PayPal connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

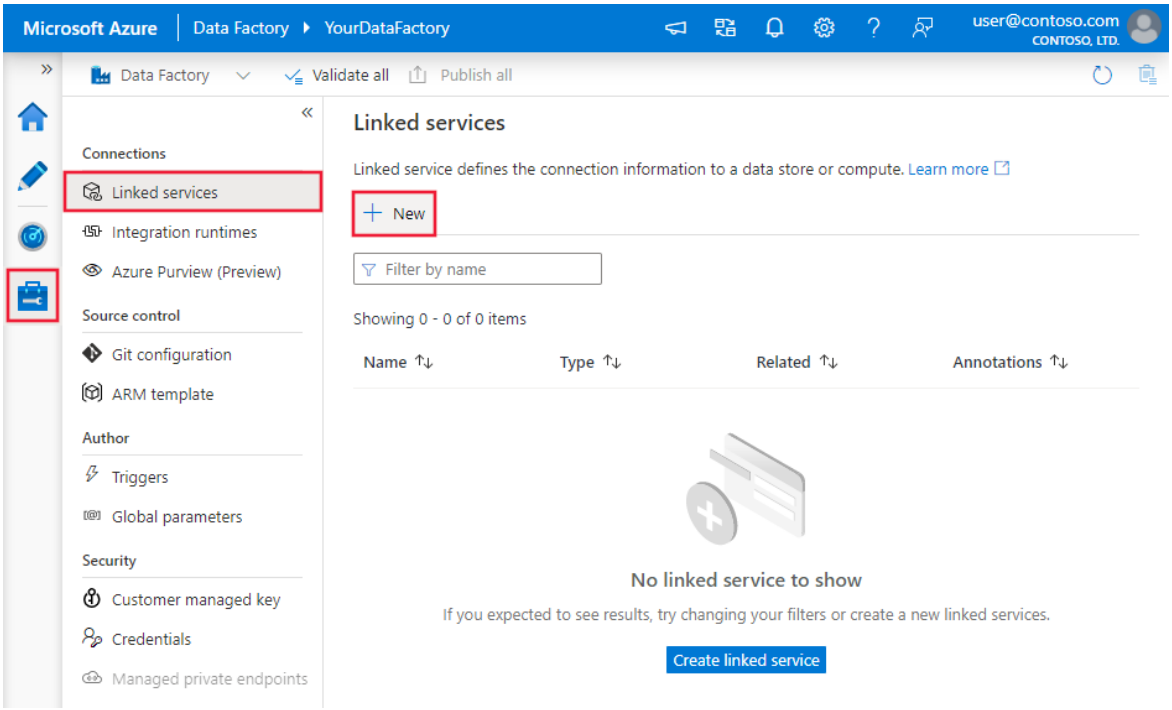
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to PayPal using UI

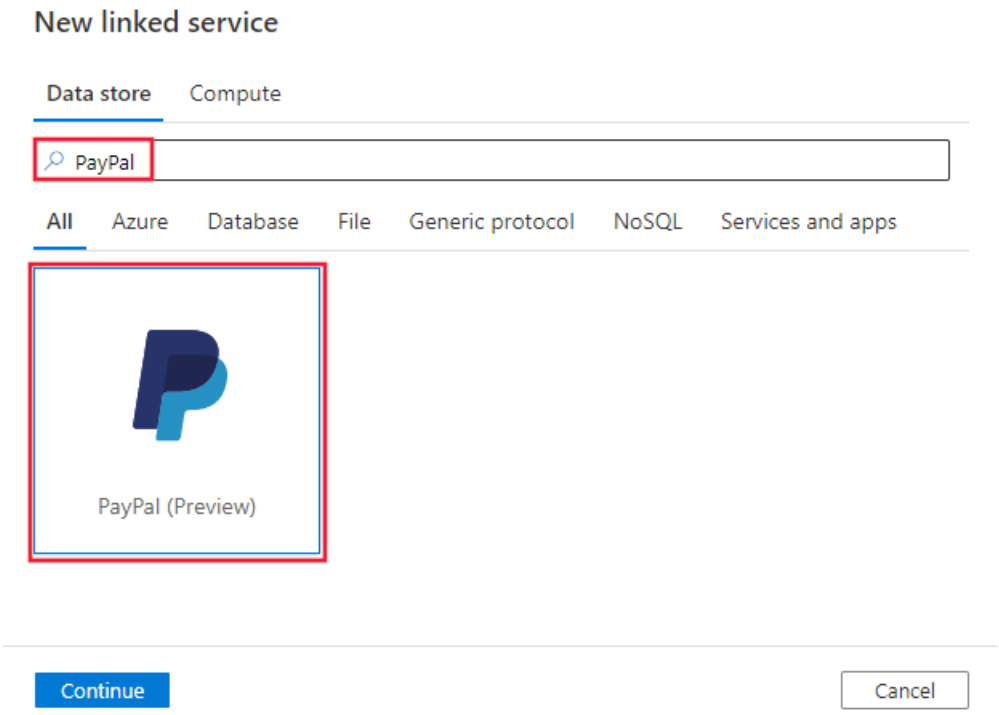
Use the following steps to create a linked service to PayPal in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

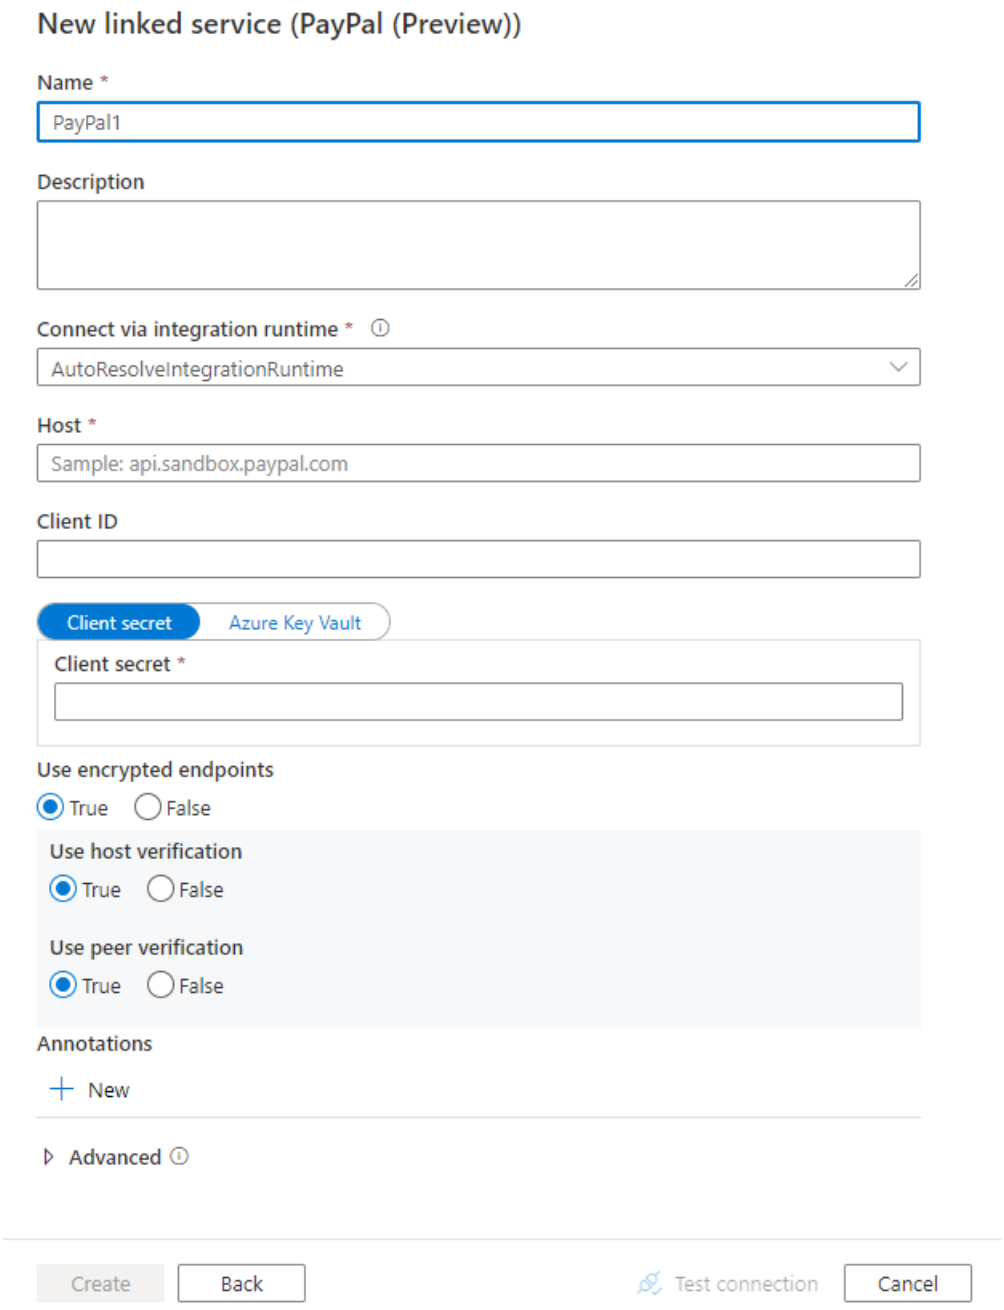
- Azure Data Factory
- Azure Synapse



2. Search for PayPal and select the PayPal connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to PayPal connector.

Linked service properties

The following properties are supported for PayPal linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **PayPal**	Yes
host	The URL of the PayPal instance. (that is, api.sandbox.paypal.com)	Yes

PROPERTY	DESCRIPTION	REQUIRED
clientId	The client ID associated with your PayPal application.	Yes
clientSecret	The client secret associated with your PayPal application. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "PayPalLinkedService",
    "properties": {
        "type": "PayPal",
        "typeProperties": {
            "host" : "api.sandbox.paypal.com",
            "clientId" : "<clientId>",
            "clientSecret": {
                 "type": "SecureString",
                 "value": "<clientSecret>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by PayPal dataset.

To copy data from PayPal, set the type property of the dataset to **PayPalObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **PayPalObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "PayPalDataset",
    "properties": {
        "type": "PayPalObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<PayPal linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by PayPal source.

PayPal as source

To copy data from PayPal, set the source type in the copy activity to **PayPalSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **PayPalSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Payment_Experience"` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromPayPal",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<PayPal input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "PayPalSource",
                "query": "SELECT * FROM Payment_Experience"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Phoenix using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Phoenix. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Phoenix connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK

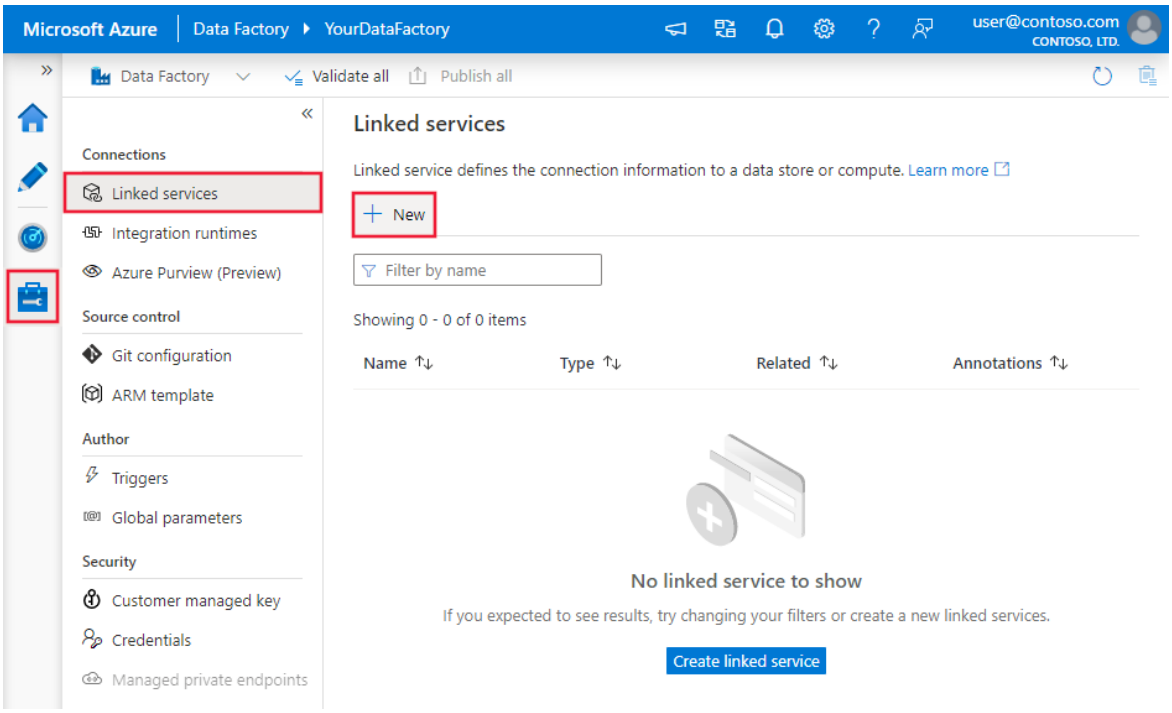
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Phoenix using UI

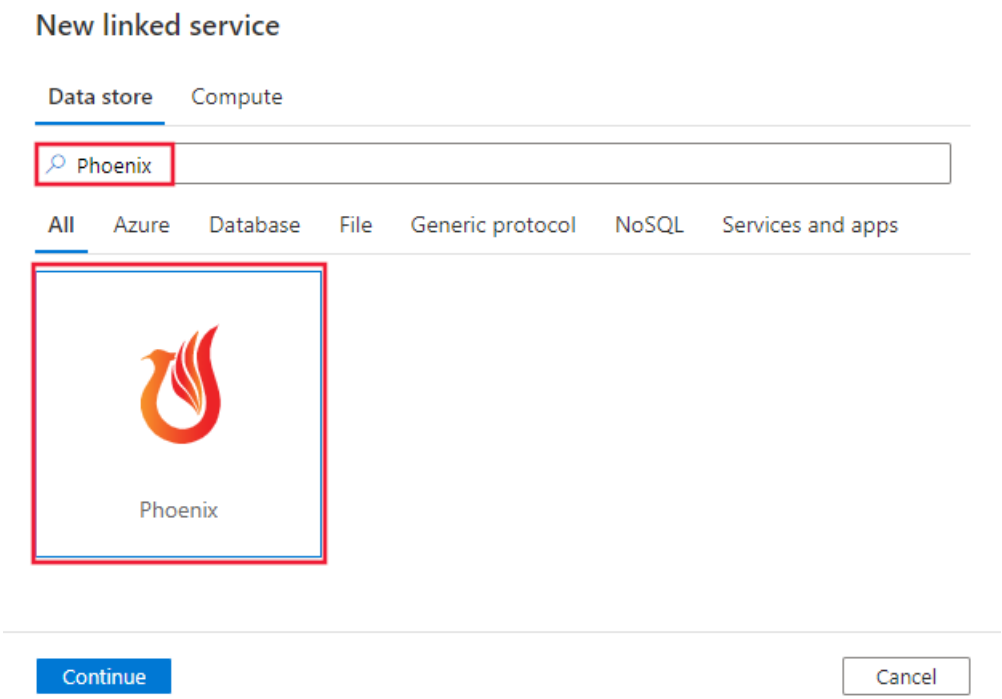
Use the following steps to create a linked service to Phoenix in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

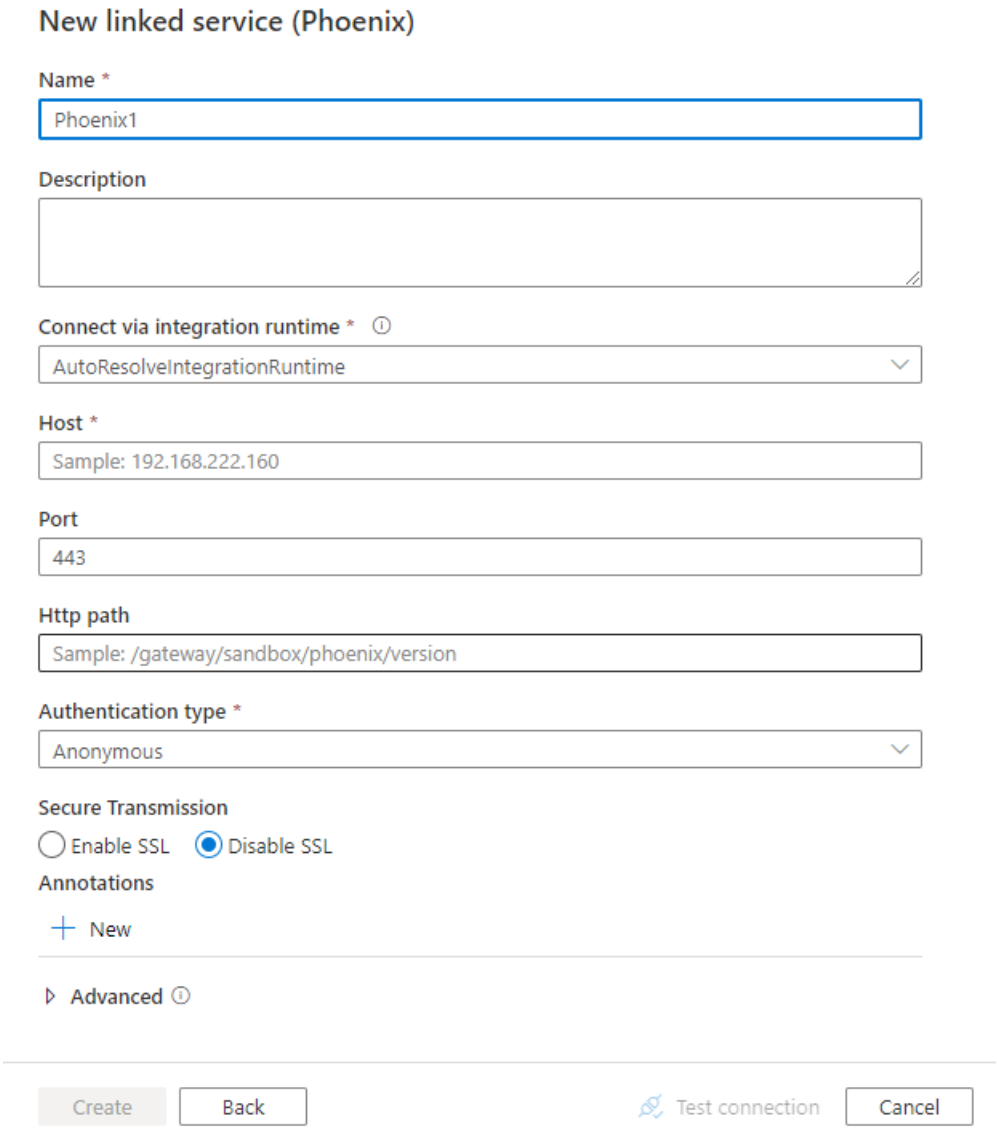
   - Azure Data Factory
   - Azure Synapse



2. Search for Phoenix and select the Phoenix connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Phoenix connector.

Linked service properties

The following properties are supported for Phoenix linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Phoenix**	Yes
host	The IP address or host name of the Phoenix server. (that is, 192.168.222.160)	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	The TCP port that the Phoenix server uses to listen for client connections. The default value is 8765. If you connect to Azure HDInsights, specify port as 443.	No
httpPath	The partial URL corresponding to the Phoenix server. (that is, /gateway/sandbox/phoenix/version). Specify `/hbasephoenix0` if using HDInsights cluster.	No
authenticationType	The authentication mechanism used to connect to the Phoenix server. Allowed values are: **Anonymous**, **UsernameAndPassword**, **WindowsAzureHDInsightService**	Yes
username	The user name used to connect to the Phoenix server.	No
password	The password corresponding to the user name. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is false.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when connecting over TLS. The default value is false.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

> **NOTE**
> If your cluster doesn't support sticky session e.g. HDInsight, explicitly add node index at the end of the http path setting, e.g. specify `/hbasephoenix0` instead of `/hbasephoenix`.

Example:

```
{
    "name": "PhoenixLinkedService",
    "properties": {
        "type": "Phoenix",
        "typeProperties": {
            "host" : "<cluster>.azurehdinsight.net",
            "port" : "443",
            "httpPath" : "/hbasephoenix0",
            "authenticationType" : "WindowsAzureHDInsightService",
            "username" : "<username>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Phoenix dataset.

To copy data from Phoenix, set the type property of the dataset to **PhoenixObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **PhoenixObject**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "PhoenixDataset",
    "properties": {
        "type": "PhoenixObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Phoenix linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Phoenix source.

Phoenix as source

To copy data from Phoenix, set the source type in the copy activity to **PhoenixSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **PhoenixSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromPhoenix",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Phoenix input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "PhoenixSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from PostgreSQL using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from a PostgreSQL database. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This PostgreSQL connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this PostgreSQL connector supports PostgreSQL **version 7.4 and above**.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

The Integration Runtime provides a built-in PostgreSQL driver starting from version 3.7, therefore you don't need to manually install any driver.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK

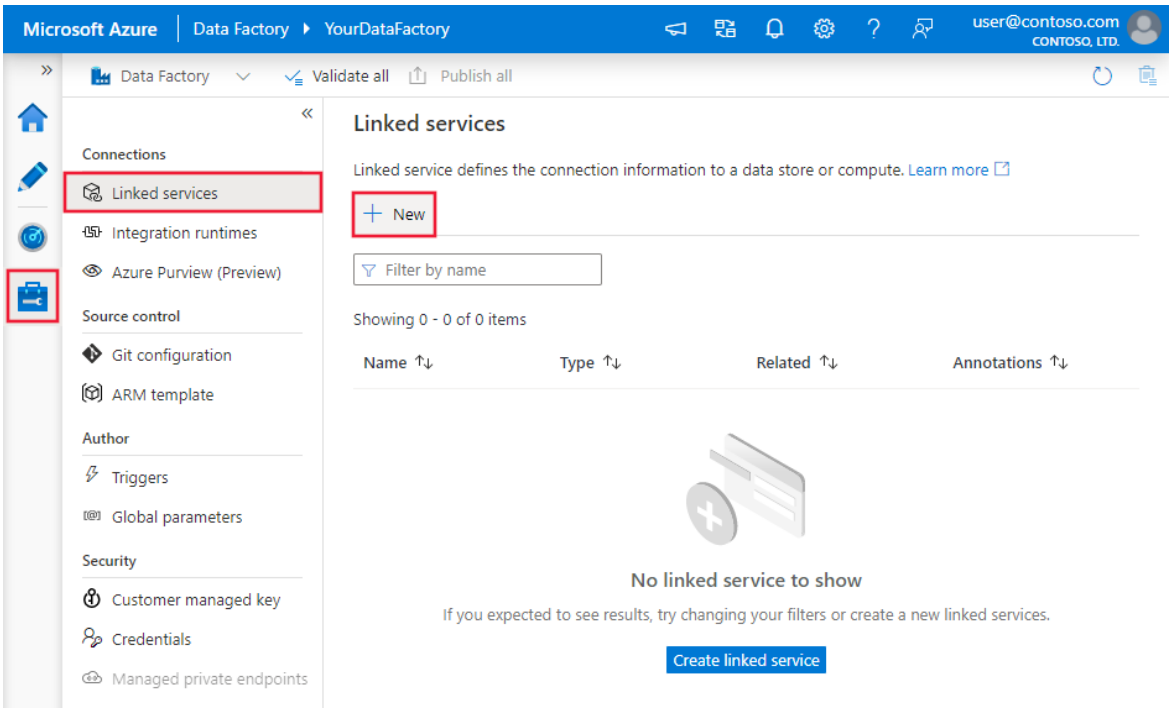
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to PostgreSQL using UI

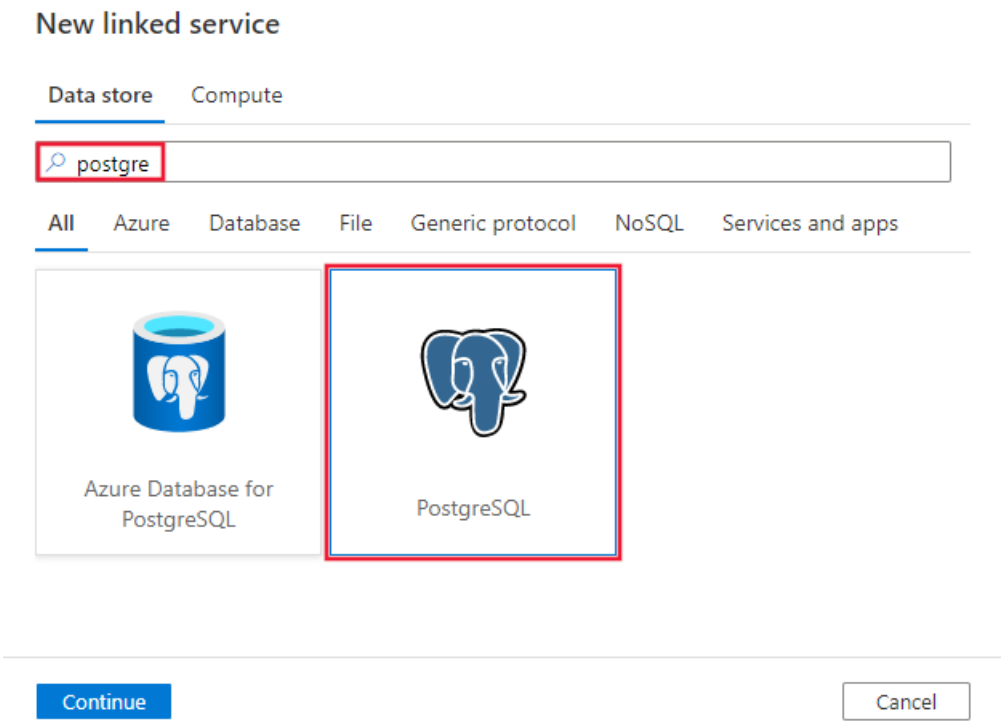
Use the following steps to create a linked service to PostgreSQL in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

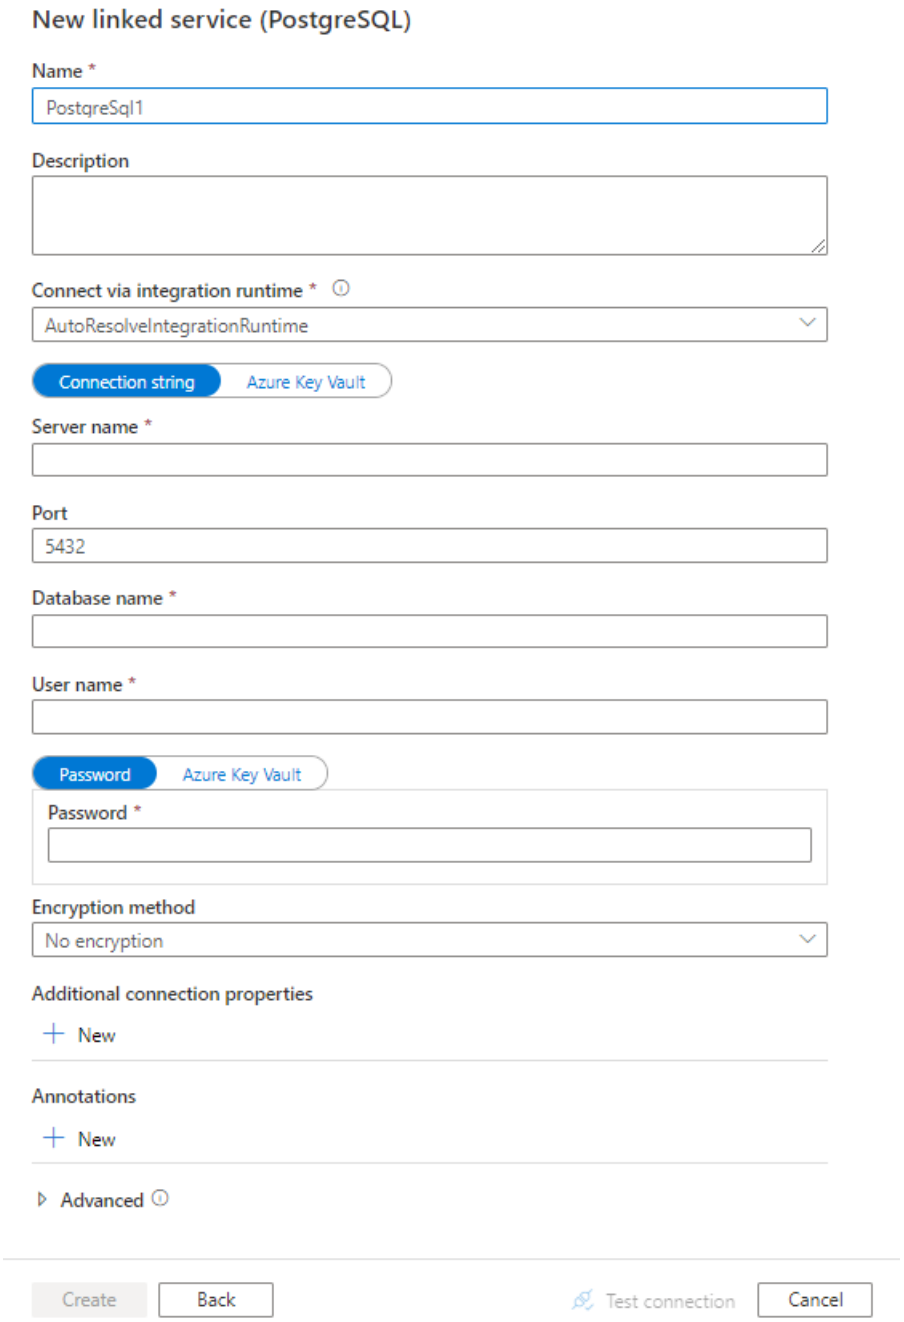
   - Azure Data Factory
   - Azure Synapse



2. Search for Postgre and select the PostgreSQL connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to PostgreSQL connector.

Linked service properties

The following properties are supported for PostgreSQL linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **PostgreSql**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to Azure Database for PostgreSQL. You can also put password in Azure Key Vault and pull the `password` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

A typical connection string is `Server=<server>;Database=<database>;Port=<port>;UID=<username>;Password=<Password>`. More properties you can set per your case:

PROPERTY	DESCRIPTION	OPTIONS	REQUIRED
EncryptionMethod (EM)	The method the driver uses to encrypt data sent between the driver and the database server. E.g., `EncryptionMethod=<0/1/6>;`	0 (No Encryption) **(Default)** / 1 (SSL) / 6 (RequestSSL)	No
ValidateServerCertificate (VSC)	Determines whether the driver validates the certificate that is sent by the database server when SSL encryption is enabled (Encryption Method=1). E.g., `ValidateServerCertificate=<0/1>;`	0 (Disabled) **(Default)** / 1 (Enabled)	No

Example:

```
{
    "name": "PostgreSqlLinkedService",
    "properties": {
        "type": "PostgreSql",
        "typeProperties": {
            "connectionString": "Server=<server>;Database=<database>;Port=<port>;UID=<username>;Password=
<Password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "PostgreSqlLinkedService",
    "properties": {
        "type": "PostgreSql",
        "typeProperties": {
            "connectionString": "Server=<server>;Database=<database>;Port=<port>;UID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

If you were using PostgreSQL linked service with the following payload, it is still supported as-is, while you are suggested to use the new one going forward.

Previous payload:

```
{
    "name": "PostgreSqlLinkedService",
    "properties": {
        "type": "PostgreSql",
        "typeProperties": {
            "server": "<server>",
            "database": "<database>",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by PostgreSQL dataset.

To copy data from PostgreSQL, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **PostgreSqlTable**	Yes

PROPERTY	DESCRIPTION	REQUIRED
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "PostgreSQLDataset",
    "properties":
    {
        "type": "PostgreSqlTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<PostgreSQL linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it's still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by PostgreSQL source.

PostgreSQL as source

To copy data from PostgreSQL, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **PostgreSqlSource**	Yes
query	Use the custom SQL query to read data. For example: `"query": "SELECT * FROM \"MySchema\".\"MyTable\""` .	No (if "tableName" in dataset is specified)

> **NOTE**
> Schema and table names are case-sensitive. Enclose them in `""` (double quotes) in the query.

Example:

```
"activities":[
    {
        "name": "CopyFromPostgreSQL",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<PostgreSQL input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "PostgreSqlSource",
                "query": "SELECT * FROM \"MySchema\".\"MyTable\""
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Presto using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Presto. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Presto connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

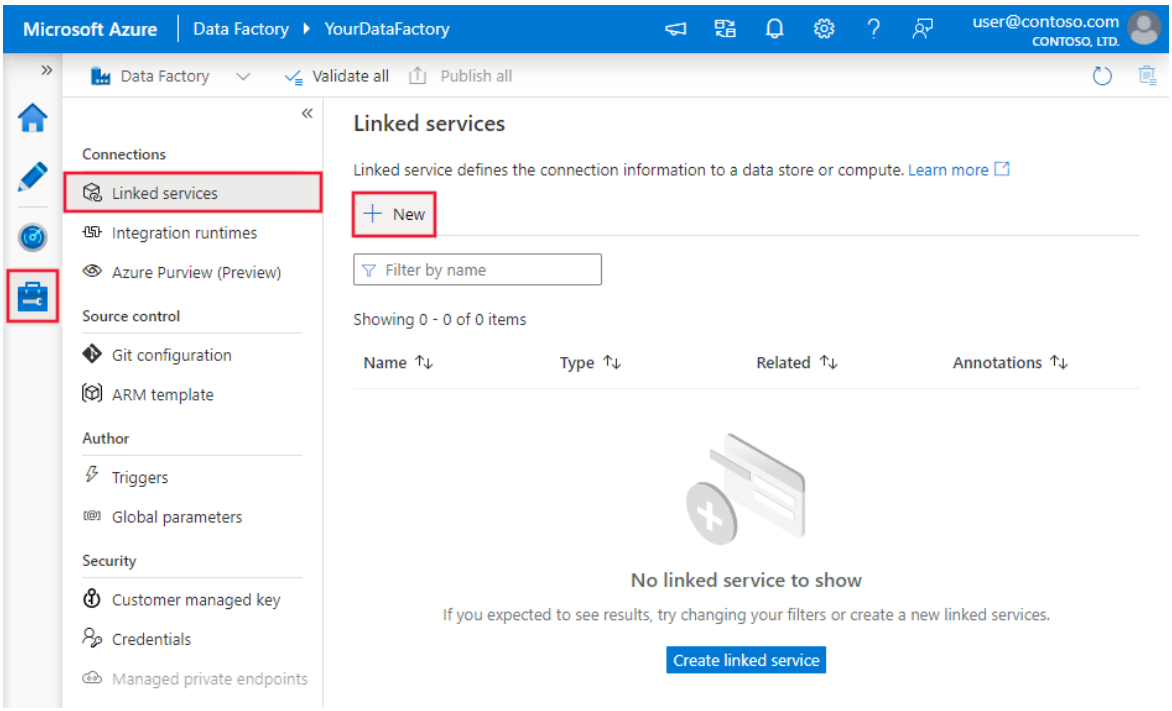
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Presto using UI

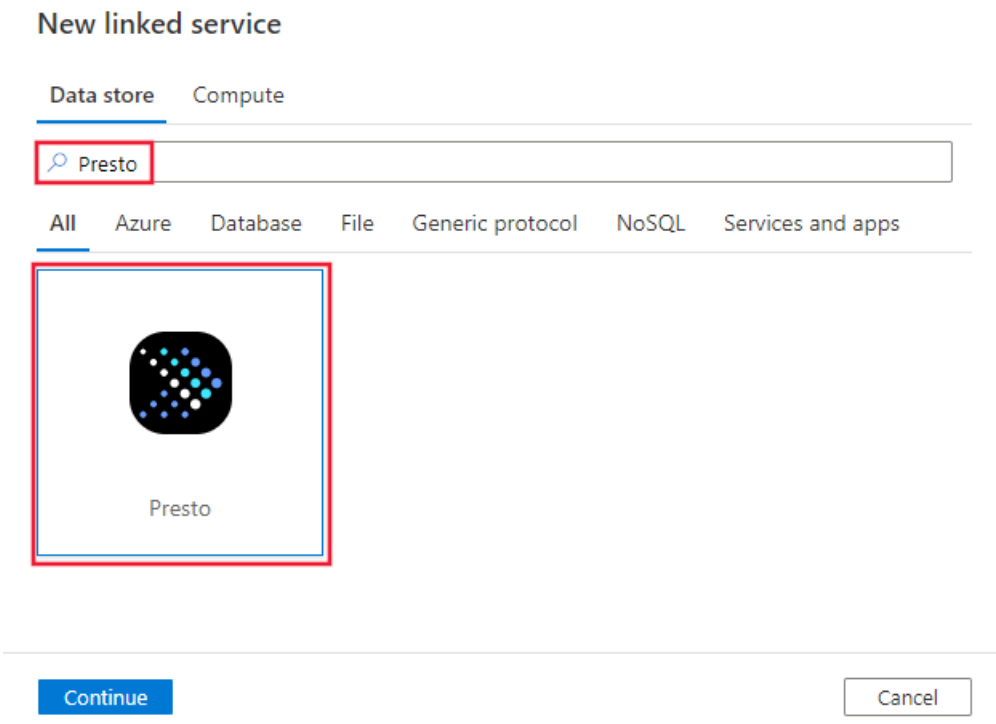
Use the following steps to create a linked service to Presto in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

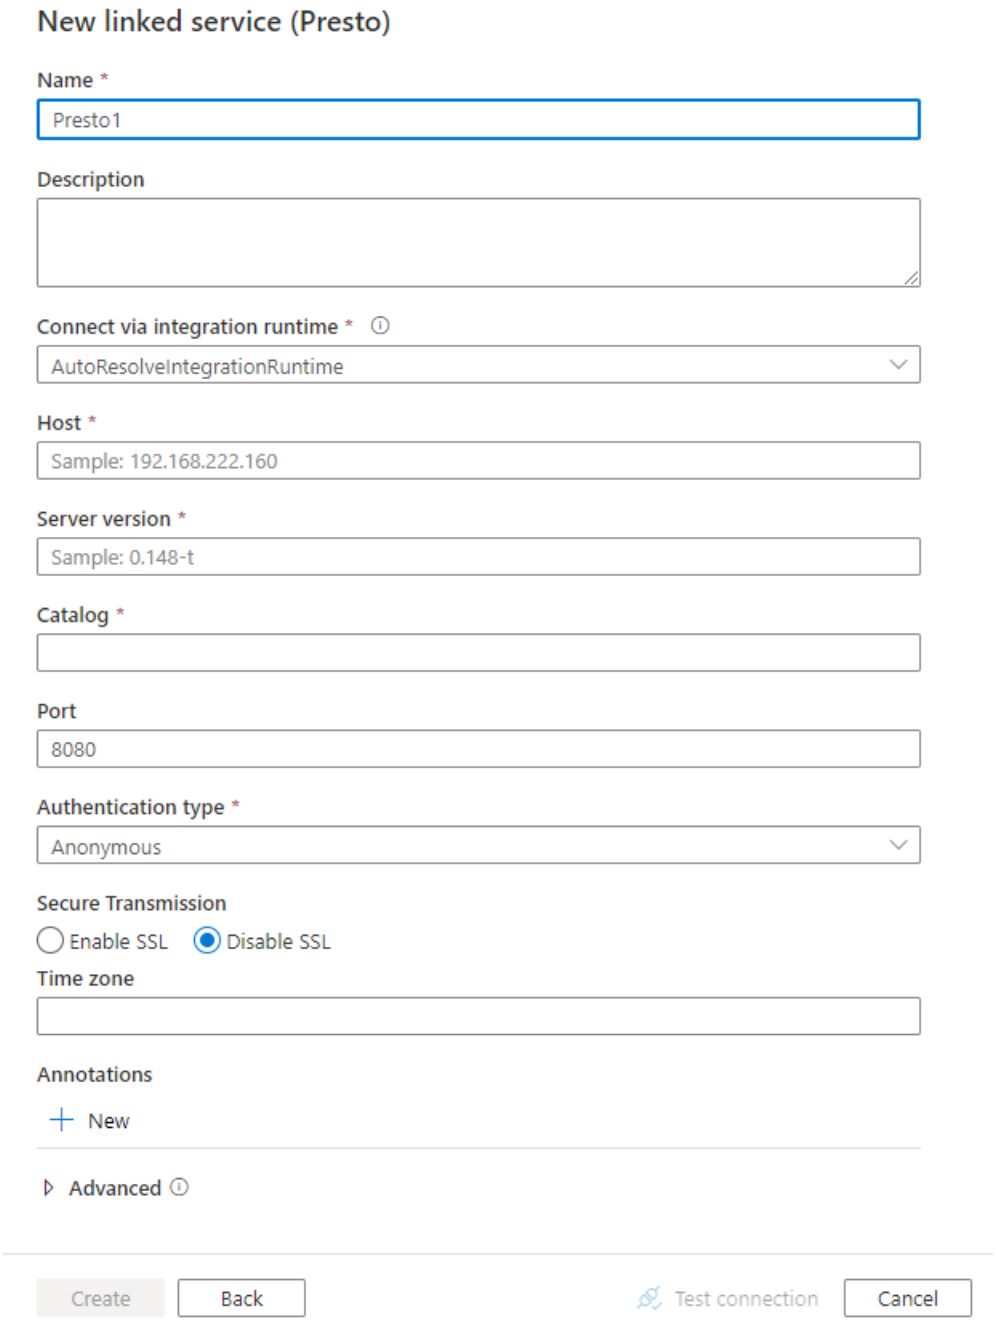
   - Azure Data Factory
   - Azure Synapse



2. Search for Presto and select the Presto connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Presto connector.

Linked service properties

The following properties are supported for Presto linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Presto**	Yes
host	The IP address or host name of the Presto server. (e.g. 192.168.222.160)	Yes

PROPERTY	DESCRIPTION	REQUIRED
serverVersion	The version of the Presto server. (e.g. 0.148-t)	Yes
catalog	The catalog context for all request against the server.	Yes
port	The TCP port that the Presto server uses to listen for client connections. The default value is 8080.	No
authenticationType	The authentication mechanism used to connect to the Presto server. Allowed values are: **Anonymous**, **LDAP**	Yes
username	The user name used to connect to the Presto server.	No
password	The password corresponding to the user name. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is false.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when connecting over TLS. The default value is false.	No
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No
timeZoneID	The local time zone used by the connection. Valid values for this option are specified in the IANA Time Zone Database. The default value is the system time zone.	No

Example:

```
{
    "name": "PrestoLinkedService",
    "properties": {
        "type": "Presto",
        "typeProperties": {
            "host" : "<host>",
            "serverVersion" : "0.148-t",
            "catalog" : "<catalog>",
            "port" : "<port>",
            "authenticationType" : "LDAP",
            "username" : "<username>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            },
            "timeZoneID" : "Europe/Berlin"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Presto dataset.

To copy data from Presto, set the type property of the dataset to **PrestoObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **PrestoObject**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "PrestoDataset",
    "properties": {
        "type": "PrestoObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Presto linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Presto source.

Presto as source

To copy data from Presto, set the source type in the copy activity to **PrestoSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **PrestoSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromPresto",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Presto input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "PrestoSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Transform data in Quickbase (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in Quickbase (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Quickbase connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

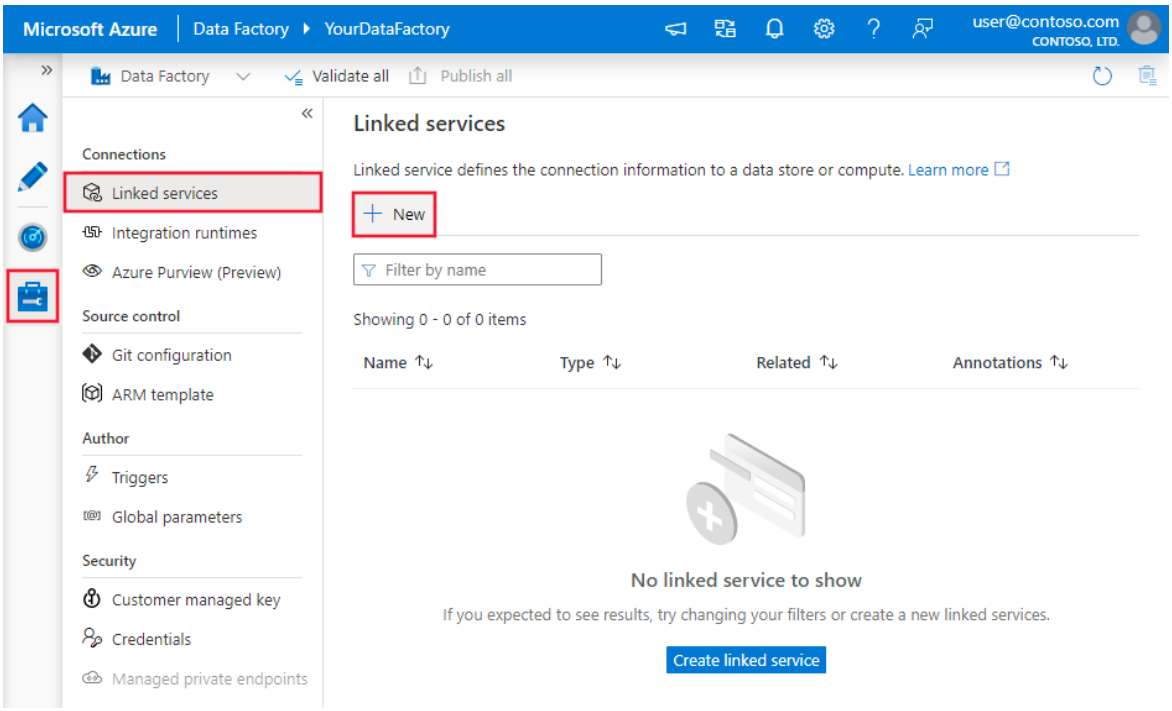
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a Quickbase linked service using UI

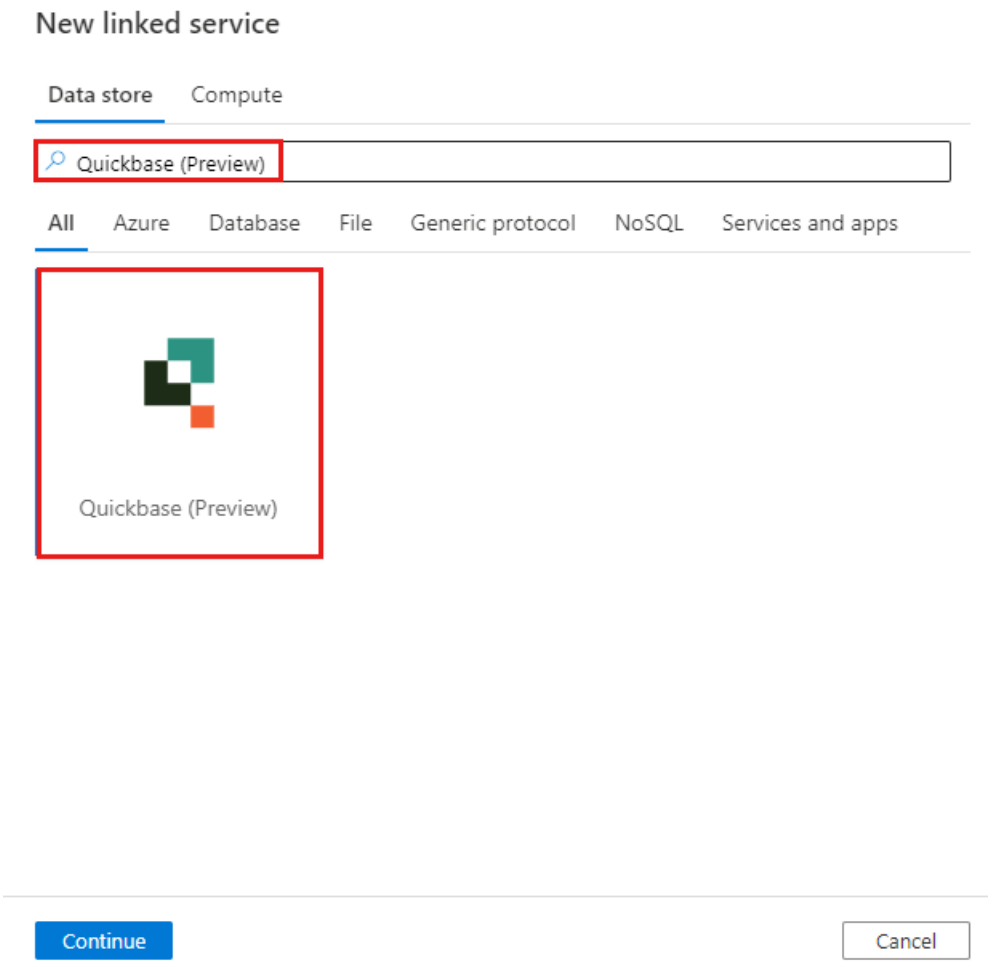
Use the following steps to create a Quickbase linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

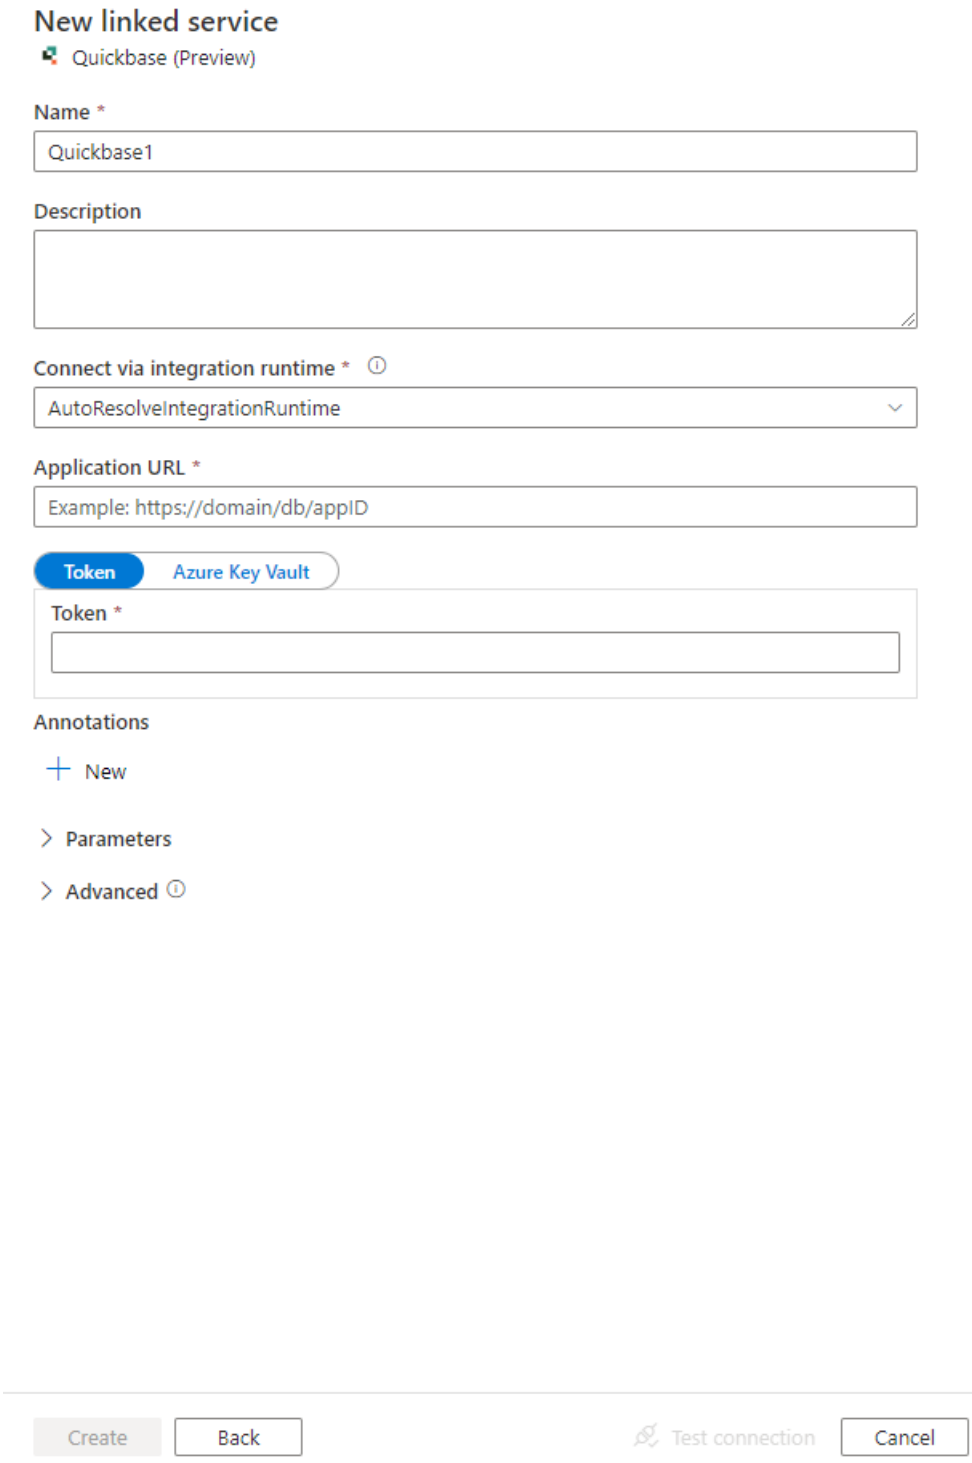
   - Azure Data Factory
   - Azure Synapse



2. Search for Quickbase (Preview) and select the Quickbase (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Quickbase.

Linked service properties

The following properties are supported for the Quickbase linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Quickbase**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
url	The application URL of the Quickbase service.	Yes
userToken	Specify a user token for the Quickbase. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "QuickbaseLinkedService",
    "properties": {
        "type": "Quickbase",
        "typeProperties": {
            "url": "<application url>",
            "userToken": {
                "type": "SecureString",
                "value": "<user token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from Quickbase. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by Quickbase source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	Data flow will fetch all the data from the table specified in the source options.	Yes when use inline mode	-	table
Report	Data flow will fetch the specified report for the table specified in the source options.	No	-	report

Quickbase source script examples

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'quickbase',
 format: 'rest',
 table: 'Table',
 report: 'Report') ~> Quickbasesource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from QuickBooks Online using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from QuickBooks Online. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This QuickBooks connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

This connector supports QuickBooks OAuth 2.0 authentication.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

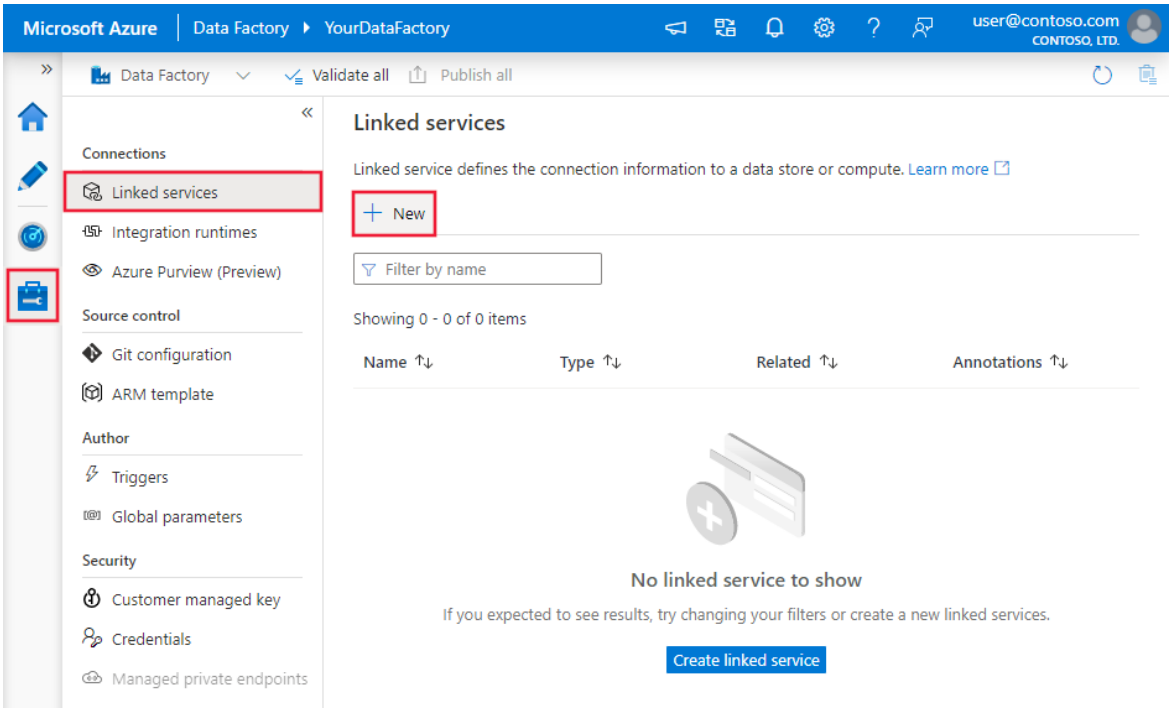
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to QuickBooks using UI

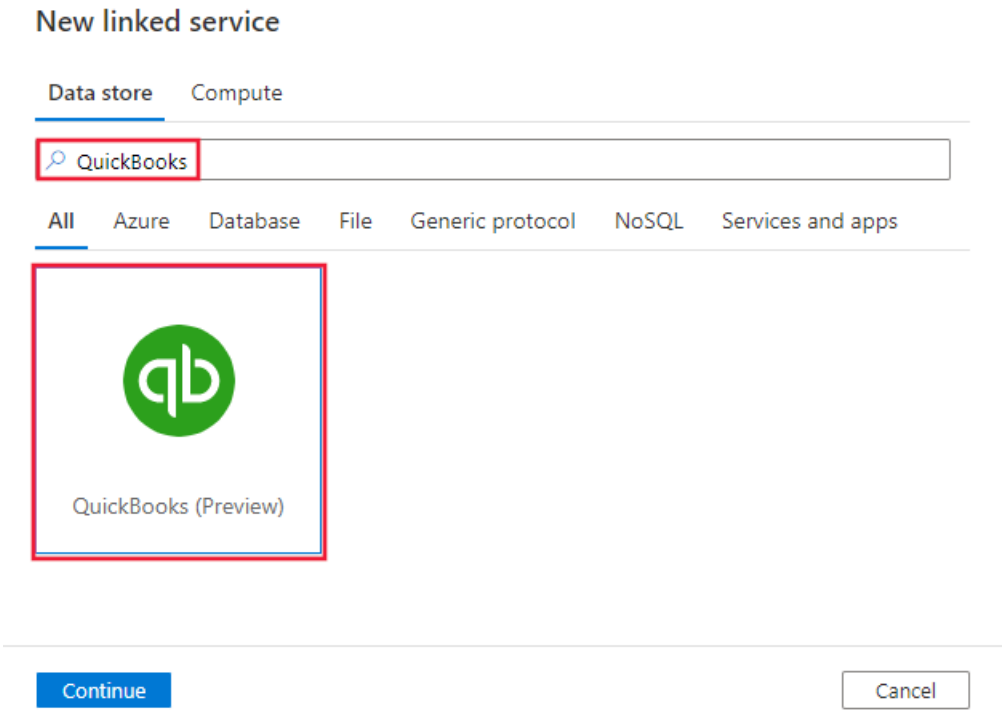
Use the following steps to create a linked service to QuickBooks in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

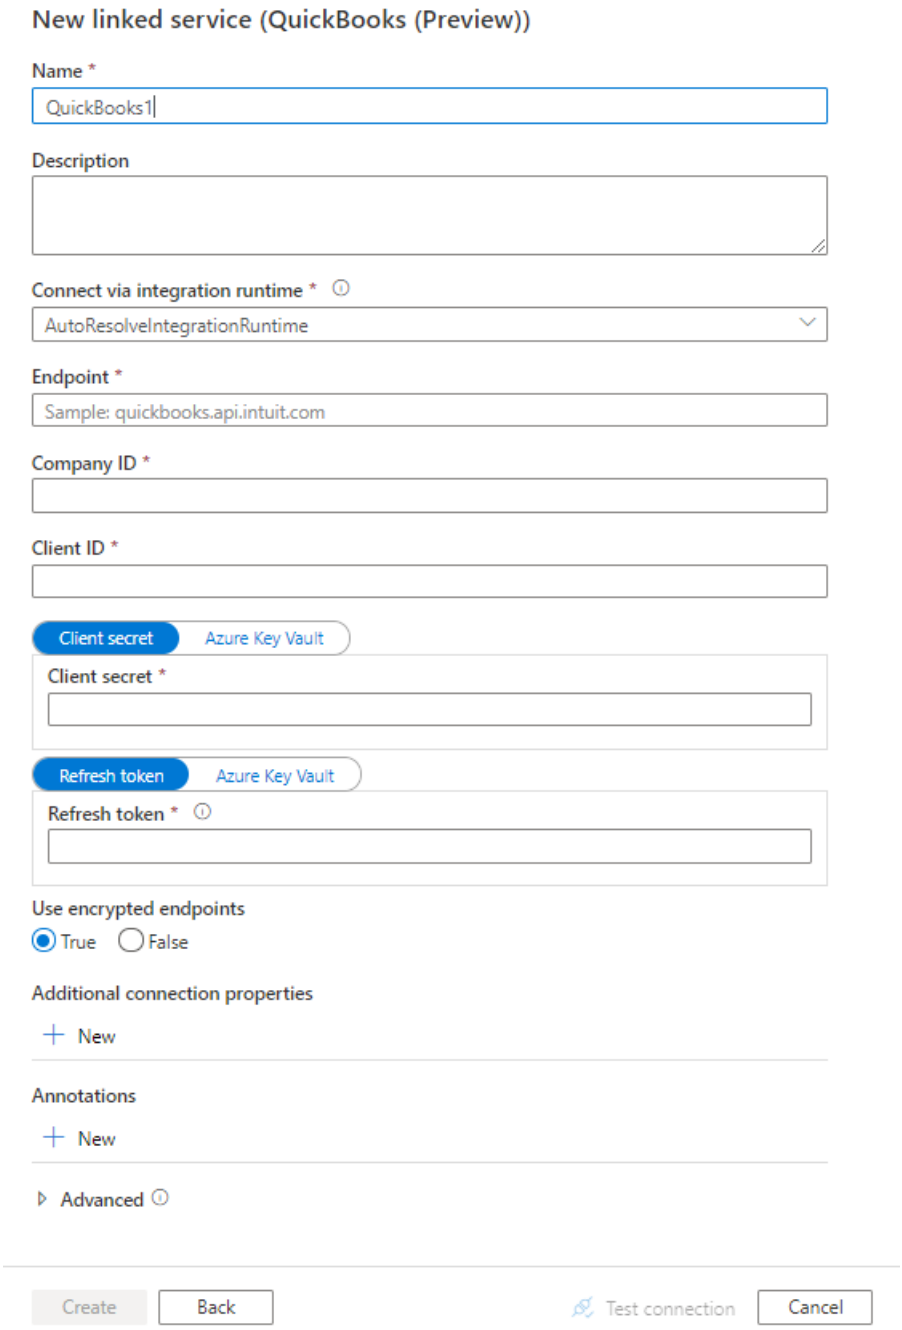
- Azure Data Factory
- Azure Synapse



2. Search for QuickBooks and select the QuickBooks connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to QuickBooks connector.

Linked service properties

The following properties are supported for QuickBooks linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **QuickBooks**	Yes
connectionProperties	A group of properties that defines how to connect to QuickBooks.	Yes
Under `connectionProperties`:		

PROPERTY	DESCRIPTION	REQUIRED
endpoint	The endpoint of the QuickBooks Online server. (that is, quickbooks.api.intuit.com)	Yes
companyId	The company ID of the QuickBooks company to authorize. For info about how to find the company ID, see How do I find my Company ID.	Yes
consumerKey	The client ID of your QuickBooks Online application for OAuth 2.0 authentication. Learn more from here.	Yes
consumerSecret	The client secret of your QuickBooks Online application for OAuth 2.0 authentication. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
refreshToken	The OAuth 2.0 refresh token associated with the QuickBooks application. Learn more from here. Note refresh token will be expired after 180 days. Customer need to regularly update the refresh token. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No

Example:

```
{
    "name": "QuickBooksLinkedService",
    "properties": {
        "type": "QuickBooks",
        "typeProperties": {
            "connectionProperties":{
                "endpoint":"quickbooks.api.intuit.com",
                "companyId":"<company id>",
                "consumerKey":"<consumer key>",
                "consumerSecret":{
                     "type": "SecureString",
                     "value": "<clientSecret>"
             },
                "refreshToken":{
                     "type": "SecureString",
                     "value": "<refresh token>"
             },
                "useEncryptedEndpoints":true
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by QuickBooks dataset.

To copy data from QuickBooks Online, set the type property of the dataset to **QuickBooksObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **QuickBooksObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "QuickBooksDataset",
    "properties": {
        "type": "QuickBooksObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<QuickBooks linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by QuickBooks source.

QuickBooks as source

To copy data from QuickBooks Online, set the source type in the copy activity to **QuickBooksSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **QuickBooksSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM "Bill" WHERE Id = '123'"` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromQuickBooks",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<QuickBooks input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "QuickBooksSource",
                "query": "SELECT * FROM \"Bill\" WHERE Id = '123' "
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Copy data from Quickbooks Desktop

The Copy Activity in the service cannot copy data directly from Quickbooks Desktop. To copy data from Quickbooks Desktop, export your Quickbooks data to a comma-separated-values (CSV) file and then upload the file to Azure Blob Storage. From there, you can use the service to copy the data to the sink of your choice.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data from and to a REST endpoint by using Azure Data Factory

8/19/2022 • 21 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory to copy data from and to a REST endpoint. The article builds on Copy Activity in Azure Data Factory, which presents a general overview of Copy Activity.

The difference among this REST connector, HTTP connector, and the Web table connector are:

- **REST connector** specifically supports copying data from RESTful APIs.
- **HTTP connector** is generic to retrieve data from any HTTP endpoint, for example, to download file. Before this REST connector you may happen to use HTTP connector to copy data from RESTful APIs, which is supported but less functional comparing to REST connector.
- **Web table connector** extracts table content from an HTML webpage.

Supported capabilities

This REST connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see Supported data stores.

Specifically, this generic REST connector supports:

- Copying data from a REST endpoint by using the **GET** or **POST** methods and copying data to a REST endpoint by using the **POST**, **PUT** or **PATCH** methods.
- Copying data by using one of the following authentications: **Anonymous**, **Basic**, **AAD service principal**, and **user-assigned managed identity**.
- **Pagination** in the REST APIs.
- For REST as source, copying the REST JSON response as-is or parse it by using schema mapping. Only response payload in **JSON** is supported.

> **TIP**
> To test a request for data retrieval before you configure the REST connector in Data Factory, learn about the API specification for header and body requirements. You can use tools like Postman or a web browser to validate.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

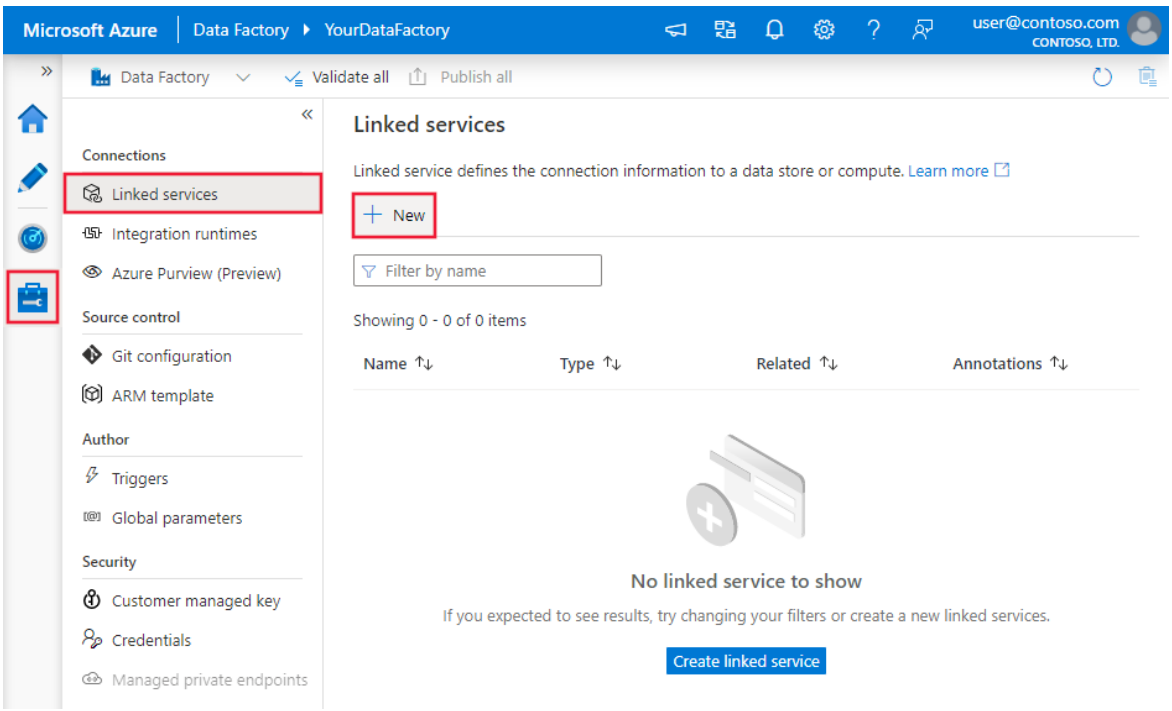
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a REST linked service using UI

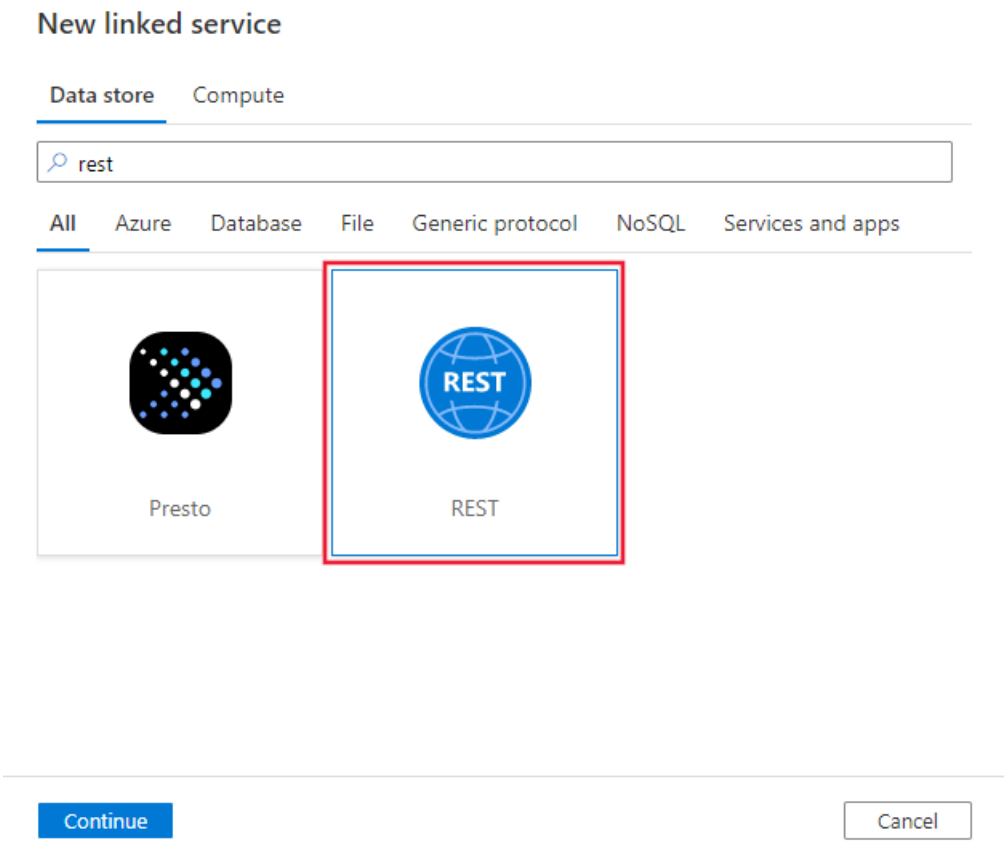
Use the following steps to create a REST linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

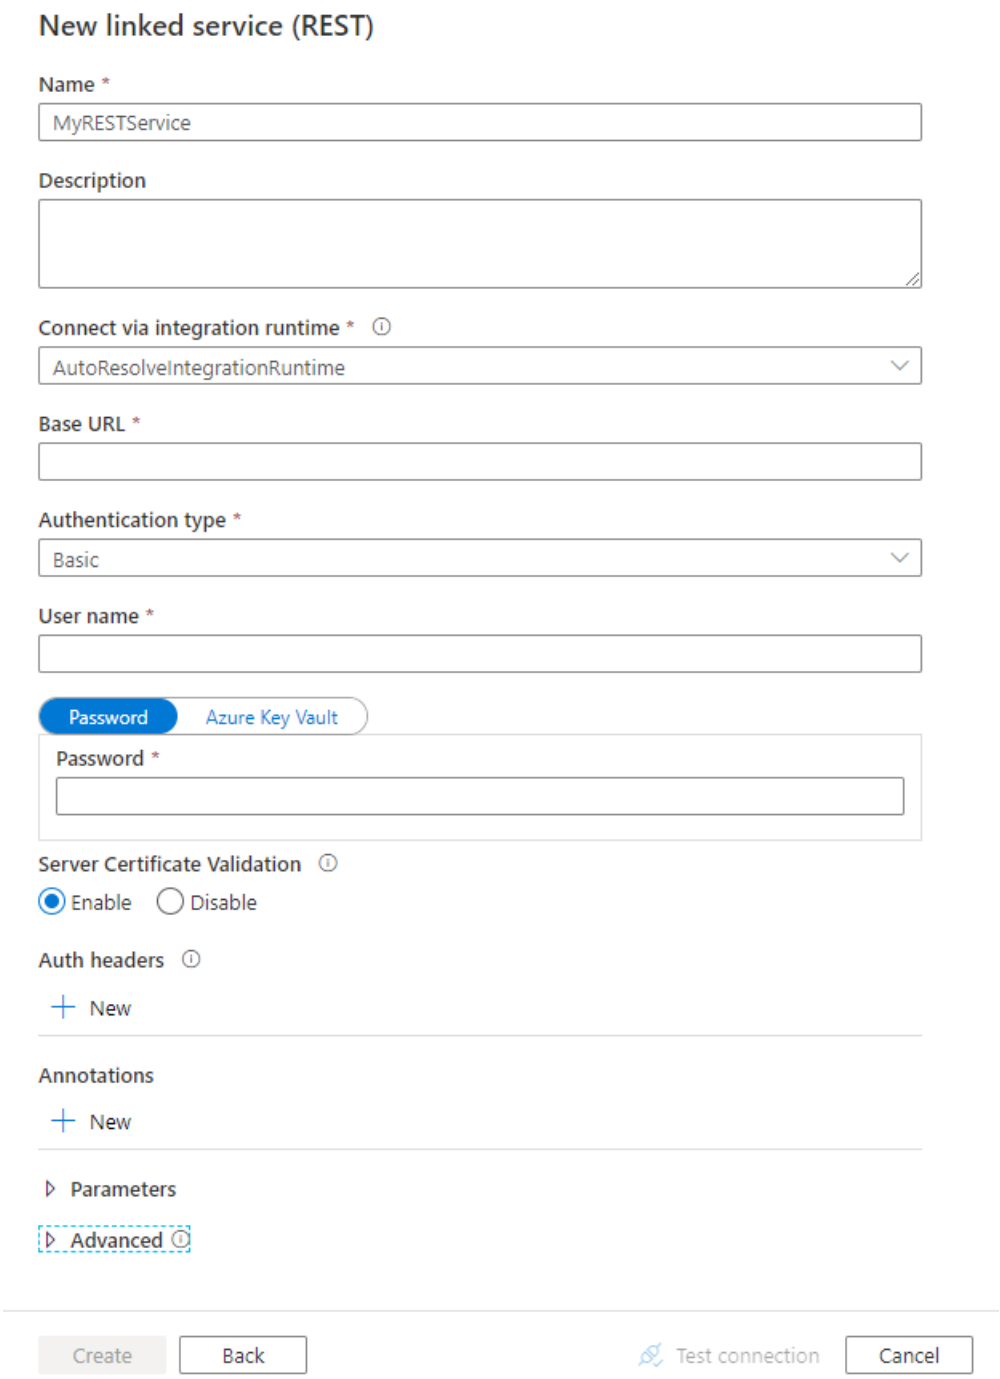
   - Azure Data Factory
   - Azure Synapse



2. Search for REST and select the REST connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define Data Factory entities that are specific to the REST connector.

Linked service properties

The following properties are supported for the REST linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property must be set to **RestService**.	Yes
url	The base URL of the REST service.	Yes

PROPERTY	DESCRIPTION	REQUIRED
enableServerCertificateValidation	Whether to validate server-side TLS/SSL certificate when connecting to the endpoint.	No (the default is **true**)
authenticationType	Type of authentication used to connect to the REST service. Allowed values are **Anonymous**, **Basic**, **AadServicePrincipal**, **OAuth2ClientCredential**, and **ManagedServiceIdentity**. You can additionally configure authentication headers in `authHeader` property. Refer to corresponding sections below on more properties and examples respectively.	Yes
authHeaders	Additional HTTP request headers for authentication. For example, to use API key authentication, you can select authentication type as "Anonymous" and specify API key in the header.	No
connectVia	The Integration Runtime to use to connect to the data store. Learn more from Prerequisites section. If not specified, this property uses the default Azure Integration Runtime.	No

For different authentication types, see the corresponding sections for details.

- Basic authentication
- AAD service principal authentication
- OAuth2 Client Credential authentication
- User-assigned managed identity authentication
- Anonymous authentication

Use basic authentication

Set the **authenticationType** property to **Basic**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user name to use to access the REST endpoint.	Yes
password	The password for the user (the **userName** value). Mark this field as a **SecureString** type to store it securely in Data Factory. You can also reference a secret stored in Azure Key Vault.	Yes

Example

```
{
    "name": "RESTLinkedService",
    "properties": {
        "type": "RestService",
        "typeProperties": {
            "authenticationType": "Basic",
            "url" : "<REST endpoint>",
            "userName": "<user name>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use AAD service principal authentication

Set the **authenticationType** property to **AadServicePrincipal**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the Azure Active Directory application's client ID.	Yes
servicePrincipalKey	Specify the Azure Active Directory application's key. Mark this field as a **SecureString** to store it securely in Data Factory, or reference a secret stored in Azure Key Vault.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. Retrieve it by hovering the mouse in the top-right corner of the Azure portal.	Yes
aadResourceId	Specify the AAD resource you are requesting for authorization, for example, `https://management.core.windows.net`.	Yes
azureCloudType	For service principal authentication, specify the type of Azure cloud environment to which your AAD application is registered. Allowed values are **AzurePublic**, **AzureChina**, **AzureUsGovernment**, and **AzureGermany**. By default, the data factory's cloud environment is used.	No

Example

```
{
    "name": "RESTLinkedService",
    "properties": {
        "type": "RestService",
        "typeProperties": {
            "url": "<REST endpoint e.g. https://www.example.com/>",
            "authenticationType": "AadServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "value": "<service principal key>",
                "type": "SecureString"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "aadResourceId": "<AAD resource URL e.g. https://management.core.windows.net>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use OAuth2 Client Credential authentication

Set the **authenticationType** property to **OAuth2ClientCredential**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
tokenEndpoint	The token endpoint of the authorization server to acquire the access token.	Yes
clientId	The client ID associated with your application.	Yes
clientSecret	The client secret associated with your application. Mark this field as a **SecureString** type to store it securely in Data Factory. You can also reference a secret stored in Azure Key Vault.	Yes
scope	The scope of the access required. It describes what kind of access will be requested.	No
resource	The target service or resource to which the access will be requested.	No

Example

```
{
    "name": "RESTLinkedService",
    "properties": {
        "type": "RestService",
        "typeProperties": {
            "url": "<REST endpoint e.g. https://www.example.com/>",
            "enableServerCertificateValidation": true,
            "authenticationType": "OAuth2ClientCredential",
            "clientId": "<client ID>",
            "clientSecret": {
                "type": "SecureString",
                "value": "<client secret>"
            },
            "tokenEndpoint": "<token endpoint>",
            "scope": "<scope>",
            "resource": "<resource>"
        }
    }
}
```

Use user-assigned managed identity authentication

Set the **authenticationType** property to **ManagedServiceIdentity**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
aadResourceId	Specify the AAD resource you are requesting for authorization, for example, `https://management.core.windows.net`.	Yes
credentials	Specify the user-assigned managed identity as the credential object.	Yes

Example

```
{
    "name": "RESTLinkedService",
    "properties": {
        "type": "RestService",
        "typeProperties": {
            "url": "<REST endpoint e.g. https://www.example.com/>",
            "authenticationType": "ManagedServiceIdentity",
            "aadResourceId": "<AAD resource URL e.g. https://management.core.windows.net>",
            "credential": {
                "referenceName": "credential1",
                "type": "CredentialReference"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Using authentication headers

In addition, you can configure request headers for authentication along with the built-in authentication types.

Example: Using API key authentication

```
{
    "name": "RESTLinkedService",
    "properties": {
        "type": "RestService",
        "typeProperties": {
            "url": "<REST endpoint>",
            "authenticationType": "Anonymous",
            "authHeader": {
                "x-api-key": {
                    "type": "SecureString",
                    "value": "<API key>"
                }
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties that the REST dataset supports.

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services.

To copy data from REST, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **RestResource**.	Yes
relativeUrl	A relative URL to the resource that contains the data. When this property isn't specified, only the URL that's specified in the linked service definition is used. The HTTP connector copies data from the combined URL: `[URL specified in linked service]/[relative URL specified in dataset]` .	No

If you were setting `requestMethod`, `additionalHeaders`, `requestBody` and `paginationRules` in dataset, it is still supported as-is, while you are suggested to use the new model in activity going forward.

Example:

```
{
    "name": "RESTDataset",
    "properties": {
        "type": "RestResource",
        "typeProperties": {
            "relativeUrl": "<relative url>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<REST linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy Activity properties

This section provides a list of properties supported by the REST source and sink.

For a full list of sections and properties that are available for defining activities, see Pipelines.

REST as source

The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **RestSource**.	Yes
requestMethod	The HTTP method. Allowed values are **GET** (default) and **POST**.	No
additionalHeaders	Additional HTTP request headers.	No
requestBody	The body for the HTTP request.	No
paginationRules	The pagination rules to compose next page requests. Refer to pagination support section on details.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. The default value is **00:01:40**.	No
requestInterval	The time to wait before sending the request for next page. The default value is **00:00:01**	No

NOTE

REST connector ignores any "Accept" header specified in `additionalHeaders`. As REST connector only support response in JSON, it will auto generate a header of `Accept: application/json`.

Example 1: Using the Get method with pagination

```
"activities":[
    {
        "name": "CopyFromREST",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<REST input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "RestSource",
                "additionalHeaders": {
                    "x-user-defined": "helloworld"
                },
                "paginationRules": {
                    "AbsoluteUrl": "$.paging.next"
                },
                "httpRequestTimeout": "00:01:00"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Example 2: Using the Post method

```
"activities":[
    {
        "name": "CopyFromREST",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<REST input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "RestSource",
                "requestMethod": "Post",
                "requestBody": "<body for POST REST request>",
                "httpRequestTimeout": "00:01:00"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

REST as sink

The following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity sink must be set to **RestSink**.	Yes
requestMethod	The HTTP method. Allowed values are **POST** (default), **PUT**, and **PATCH**.	No
additionalHeaders	Additional HTTP request headers.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to write the data. The default value is **00:01:40**.	No
requestInterval	The interval time between different requests in millisecond. Request interval value should be a number between [10, 60000].	No
httpCompressionType	HTTP compression type to use while sending data with Optimal Compression Level. Allowed values are **none** and **gzip**.	No

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	Number of records to write to the REST sink per batch. The default value is 10000.	No

REST connector as sink works with the REST APIs that accept JSON. The data will be sent in JSON with the following pattern. As needed, you can use the copy activity schema mapping to reshape the source data to conform to the expected payload by the REST API.

```
[
    { <data object> },
    { <data object> },
    ...
]
```

Example:

```
"activities":[
    {
        "name": "CopyToREST",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<REST output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "RestSink",
                "requestMethod": "POST",
                "httpRequestTimeout": "00:01:40",
                "requestInterval": 10,
                "writeBatchSize": 10000,
                "httpCompressionType": "none",
            },
        }
    }
]
```

Mapping data flow properties

REST is supported in data flows for both integration datasets and inline datasets.

Source transformation

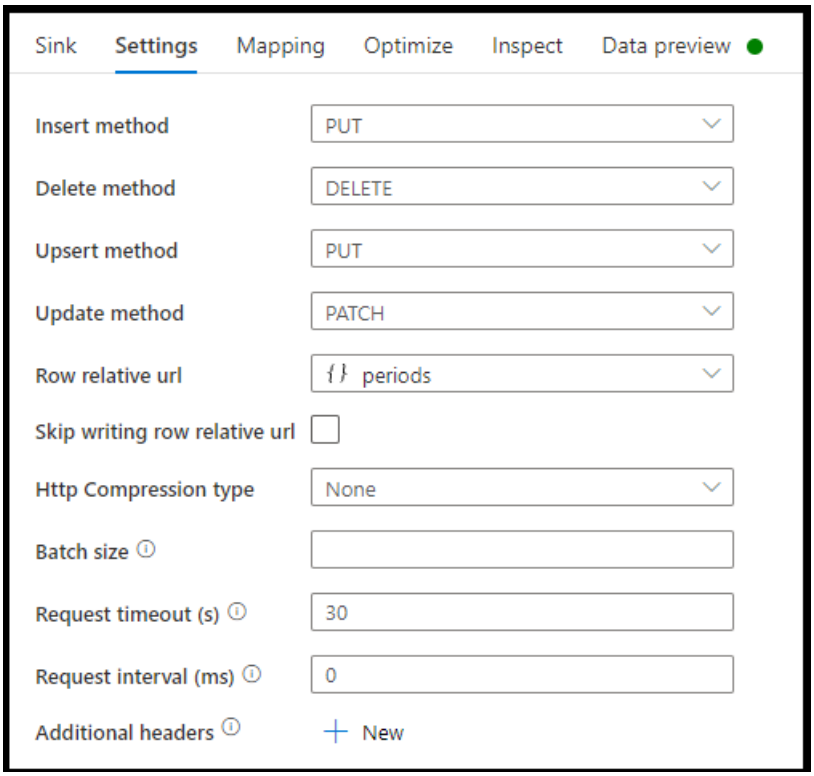
PROPERTY	DESCRIPTION	REQUIRED
requestMethod	The HTTP method. Allowed values are **GET** and **POST**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
relativeUrl	A relative URL to the resource that contains the data. When this property isn't specified, only the URL that's specified in the linked service definition is used. The HTTP connector copies data from the combined URL: `[URL specified in linked service]/[relative URL specified in dataset]` .	No
additionalHeaders	Additional HTTP request headers.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to write the data. The default value is **00:01:40**.	No
requestInterval	The interval time between different requests in millisecond. Request interval value should be a number between [10, 60000].	No
QueryParameters.*request_query_parameter* OR QueryParameters['request_query_parameter']	"request_query_parameter" is user-defined, which references one query parameter name in the next HTTP request URL.	No

Sink transformation

PROPERTY	DESCRIPTION	REQUIRED
additionalHeaders	Additional HTTP request headers.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to write the data. The default value is **00:01:40**.	No
requestInterval	The interval time between different requests in millisecond. Request interval value should be a number between [10, 60000].	No
httpCompressionType	HTTP compression type to use while sending data with Optimal Compression Level. Allowed values are **none** and **gzip**.	No
writeBatchSize	Number of records to write to the REST sink per batch. The default value is 10000.	No

You can set the delete, insert, update, and upsert methods as well as the relative row data to send to the REST sink for CRUD operations.



Sample data flow script

Notice the use of an alter row transformation prior to the sink to instruct ADF what type of action to take with your REST sink. I.e. insert, update, upsert, delete.

```
AlterRow1 sink(allowSchemaDrift: true,
 validateSchema: false,
 deletable:true,
 insertable:true,
 updateable:true,
 upsertable:true,
 rowRelativeUrl: 'periods',
 insertHttpMethod: 'PUT',
 deleteHttpMethod: 'DELETE',
 upsertHttpMethod: 'PUT',
 updateHttpMethod: 'PATCH',
 timeout: 30,
 requestFormat: ['type' -> 'json'],
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true) ~> sink1
```

Pagination support

When copying data from REST APIs, normally, the REST API limits its response payload size of a single request under a reasonable number; while to return large amount of data, it splits the result into multiple pages and requires callers to send consecutive requests to get next page of the result. Usually, the request for one page is dynamic and composed by the information returned from the response of previous page.

This generic REST connector supports the following pagination patterns:

- Next request's absolute or relative URL = property value in current response body
- Next request's absolute or relative URL = header value in current response headers
- Next request's query parameter = property value in current response body
- Next request's query parameter = header value in current response headers
- Next request's header = property value in current response body

- Next request's header = header value in current response headers

Pagination rules are defined as a dictionary in dataset, which contains one or more case-sensitive key-value pairs. The configuration will be used to generate the request starting from the second page. The connector will stop iterating when it gets HTTP status code 204 (No Content), or any of the JSONPath expressions in "paginationRules" returns null.

Supported keys in pagination rules:

KEY	DESCRIPTION
AbsoluteUrl	Indicates the URL to issue the next request. It can be **either absolute URL or relative URL**.
QueryParameters.*request_query_parameter* OR QueryParameters['request_query_parameter']	"request_query_parameter" is user-defined, which references one query parameter name in the next HTTP request URL.
Headers.*request_header* OR Headers['request_header']	"request_header" is user-defined, which references one header name in the next HTTP request.
EndCondition:*end_condition*	"end_condition" is user-defined, which indicates the condition that will end the pagination loop in the next HTTP request.
MaxRequestNumber	Indicates the maximum pagination request number. Leave it as empty means no limit.
SupportRFC5988	By default, this is set to true if no pagination rule is defined. You can disable this rule by setting `supportRFC5988` to false or remove this property from script.

Supported values in pagination rules:

VALUE	DESCRIPTION
Headers.*response_header* OR Headers['response_header']	"response_header" is user-defined, which references one header name in the current HTTP response, the value of which will be used to issue next request.
A JSONPath expression starting with "$" (representing the root of the response body)	The response body should contain only one JSON object. The JSONPath expression should return a single primitive value, which will be used to issue next request.

NOTE

The pagination rules in mapping data flows is different from it in copy activity in the following aspects:

1. Range is not supported in mapping data flows.
2. `['']` is not supported in mapping data flows. Instead, use `{}` to escape special character. For example, `body.{@odata.nextLink}`, whose JSON node `@odata.nextLink` contains special character `.`.
3. The end condition is supported in mapping data flows, but the condition syntax is different from it in copy activity. `body` is used to indicate the response body instead of `$`. `header` is used to indicate the response header instead of `headers`. Here are two examples showing this difference:
   - Example 1:
     Copy activity: **"EndCondition:$.data": "Empty"**
     Mapping data flows: **"EndCondition:body.data": "Empty"**
   - Example 2:
     Copy activity: **"EndCondition:headers.complete": "Exist"**
     Mapping data flows: **"EndCondition:header.complete": "Exist"**

Pagination rules examples

This section provides a list of examples for pagination rules settings.

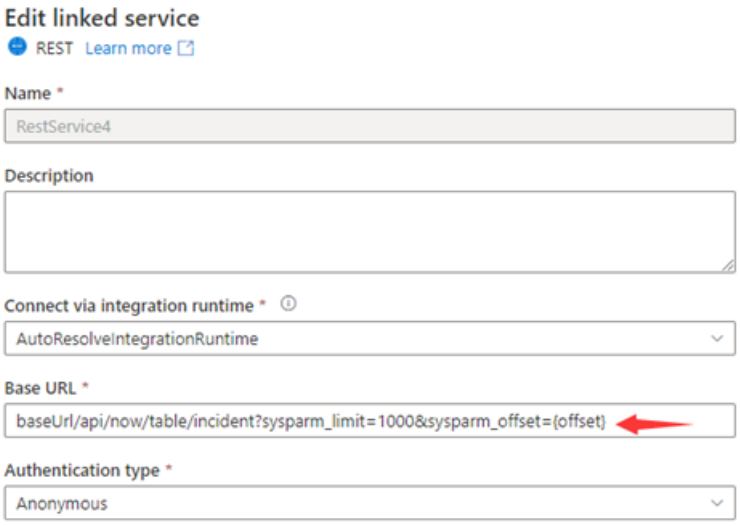
Example 1: Variables in QueryParameters

This example provides the configuration steps to send multiple requests whose variables are in QueryParameters.

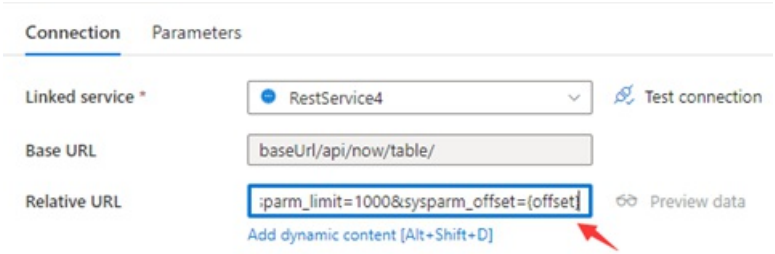
Multiple requests:

```
baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=0,
baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=1000,
......
baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=10000
```

Step 1: Input `sysparm_offset={offset}` either in **Base URL** or **Relative URL** as shown in the following screenshots:



or



Step 2: Set **Pagination rules** as either option 1 or option 2:

- Option1: **"QueryParameters.{offset}" : "RANGE:0:10000:1000"**
- Option2: **"AbsoluteUrl.{offset}" : "RANGE:0:10000:1000"**

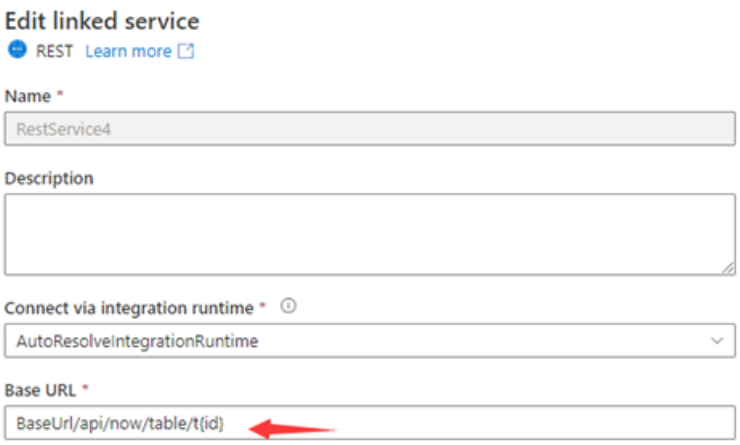
Example 2: Variables in AbsoluteUrl

This example provides the configuration steps to send multiple requests whose variables are in AbsoluteUrl.

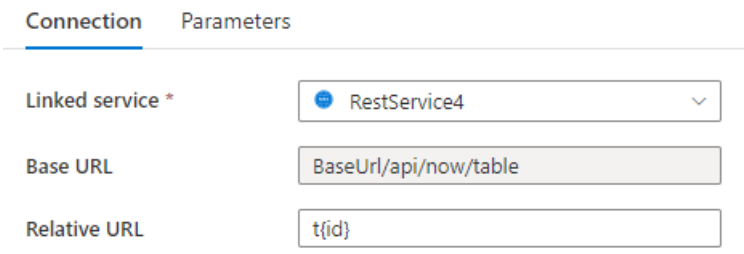
Multiple requests:

```
BaseUrl/api/now/table/t1
BaseUrl/api/now/table/t2
......
BaseUrl/api/now/table/t100
```

Step 1: Input `{id}` either in **Base URL** in the linked service configuration page or **Relative URL** in the dataset connection pane.



or



Step 2: Set **Pagination rules** as **"AbsoluteUrl.{id}" :"RANGE:1:100:1"**.

Example 3: Variables in Headers

This example provides the configuration steps to send multiple requests whose variables are in Headers.

Multiple requests:

RequestUrl: *https://example/table*

Request 1: `Header(id->0)`

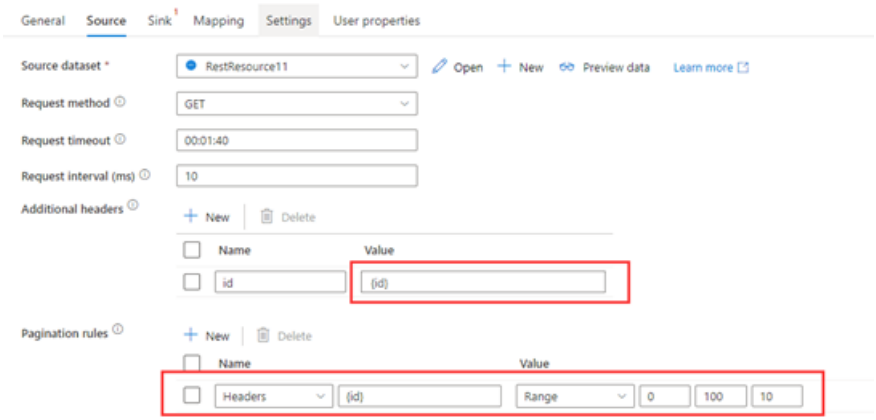
Request 2: `Header(id->10)`

.....

Request 100: `Header(id->100)`

Step 1: Input `{id}` in **Additional headers**.

Step 2: Set **Pagination rules** as **"Headers.{id}" : "RARNGE:0:100:10"**.



Example 4: **Variables are in AbsoluteUrl/QueryParameters/Headers, the end variable is not pre-defined and the end condition is based on the response**

This example provides configuration steps to send multiple requests whose variables are in AbsoluteUrl/QueryParameters/Headers but the end variable is not defined. For different responses, different end condition rule settings are shown in Example 4.1-4.6.

Multiple requests:

```
Request 1: baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=0,
Request 2: baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=1000,
Request 3: baseUrl/api/now/table/incident?sysparm_limit=1000&sysparm_offset=2000,
......
```

Two responses encountered in this example:

Response 1 :

```
{
    Data: [
        {key1: val1, key2: val2
        },
        {key1: val3, key2: val4
        }
    ]
}
```

Response 2 :

```
{
    Data: [
        {key1: val5, key2: val6
        },
        {key1: val7, key2: val8
        }
    ]
}
```

Step 1: Set the range of **Pagination rules** as Example 1 and leave the end of range empty as **"AbsoluteUrl.**

{offset}": "RANGE:0::1000".

Step 2: Set different end condition rules according to different last responses. See below examples:

- **Example 4.1: The pagination ends when the value of the specific node in response is empty**

  The REST API returns the last response in the following structure:

  ```
  {
      Data: []
  }
  ```

  Set the end condition rule as **"EndCondition:$.data": "Empty"** to end the pagination when the value of the specific node in response is empty.

- **Example 4.2: The pagination ends when the value of the specific node in response dose not exist**

  The REST API returns the last response in the following structure:

  ```
  {}
  ```

  Set the end condition rule as **"EndCondition:$.data": "NonExist"** to end the pagination when the value of the specific node in response dose not exist.

  
- **Example 4.3: The pagination ends when the value of the specific node in response exists**

  The REST API returns the last response in the following structure:

  ```
  {
      Data: [
          {key1: val991, key2: val992
          },
          {key1: val993, key2: val994
          }
      ],
              Complete: true
  }
  ```

  Set the end condition rule as **"EndCondition:$.Complete": "Exist"** to end the pagination when the value of the specific node in response exists.

- **Example 4.4: The pagination ends when the value of the specific node in response is a user-defined const value**

  The REST API returns the response in the following structure:

```
{
    Data: [
        {key1: val1, key2: val2
        },
        {key1: val3, key2: val4
        }
    ],
            Complete: false
}
```

.....

And the last response is in the following structure:

```
{
    Data: [
        {key1: val991, key2: val992
        },
        {key1: val993, key2: val994
        }
    ],
            Complete: true
}
```

Set the end condition rule as **"EndCondition:$.Complete": "Const:true"** to end the pagination when the value of the specific node in response is a user-defined const value.

- **Example 4.5: The pagination ends when the value of the header key in response equals to user-defined const value**

  The header keys in REST API responses are shown in the structure below:

  Response header 1: `header(Complete->0)`
  .....
  Last Response header: `header(Complete->1)`

  Set the end condition rule as **"EndCondition:headers.Complete": "Const:1"** to end the pagination when the value of the header key in response is equal to user-defined const value.

- **Example 4.6: The pagination ends when the key exists in the response header**

  The header keys in REST API responses are shown in the structure below:

  Response header 1: `header()`
  .....
  Last Response header: `header(CompleteTime->20220920)`

  Set the end condition rule as **"EndCondition:headers.CompleteTime": "Exist"** to end the pagination when the key exists in the response header.

Example 5: Set end condition to avoid endless requests when range rule is not defined

This example provides the configuration steps to send multiple requests when the range rule is not used. The

end condition can be set refer to Example 4.1-4.6 to avoid endless requests. The REST API returns response in the following structure, in which case next page's URL is represented in ***paging.next***.

```
{
    "data": [
        {
            "created_time": "2017-12-12T14:12:20+0000",
            "name": "album1",
            "id": "1809938745705498_1809939942372045"
        },
        {
            "created_time": "2017-12-12T14:14:03+0000",
            "name": "album2",
            "id": "1809938745705498_1809941802371859"
        },
        {
            "created_time": "2017-12-12T14:14:11+0000",
            "name": "album3",
            "id": "1809938745705498_1809941879038518"
        }
    ],
    "paging": {
        "cursors": {
            "after": "MTAxNTExOTQ1MjAwNzI5NDE=",
            "before": "NDMyNzQyODI3OTQw"
        },
        "previous": "https://graph.facebook.com/me/albums?limit=25&before=NDMyNzQyODI3OTQw",
        "next": "https://graph.facebook.com/me/albums?limit=25&after=MTAxNTExOTQ1MjAwNzI5NDE="
    }
}
...
```

The last response is:

```
{
    "data": [],
    "paging": {
        "cursors": {
            "after": "MTAxNTExOTQ1MjAwNzI5NDE=",
            "before": "NDMyNzQyODI3OTQw"
        },
        "previous": "https://graph.facebook.com/me/albums?limit=25&before=NDMyNzQyODI3OTQw",
        "next": "Same with Last Request URL"
    }
}
```

Step 1: Set **Pagination rules** as **"AbsoluteUrl": "$.paging.next"**.

Step 2: If `next` in the last response is always same with the last request URL and not empty, endless requests will be sent. The end condition can be used to avoid endless requests. Therefore, set the end condition rule refer to Example 4.1-4.6.

Example 6: Set the max request number to avoid endless request

Set **MaxRequestNumber** to avoid endless request as shown in the following screenshot:

Example 7: The RFC 5988 pagination rule is supported by default

The backend will automatically get the next URL based on the RFC 5988 style links in the header.

Sample of the HTTP header returned by a service that complies with RFC 5988¶

```
Link: <https://rest-api.acme.com/api/v1/customer.json?opaqueA>; rel="current",
      <https://rest-api.acme.com/api/v1/customer.json?opaqueB>; rel="next",
      <https://rest-api.acme.com/api/v1/customer.json?opaqueC>; rel="first",
      <https://rest-api.acme.com/api/v1/customer.json?opaqueD>; rel="last"
```

In this example, the data source will send the next request to https://rest-api.acme.com/api/v1/customer.json?opaqueB

If there is no URL marked with `rel="next"`, the data source will consider that there are no more pages.

TIP

If you don't want to enable this default pagination rule, you can set `supportRFC5988` to `false` or just delete it in the script.

```
"paginationRules": {
    "supportRFC5988": "false"
}
```

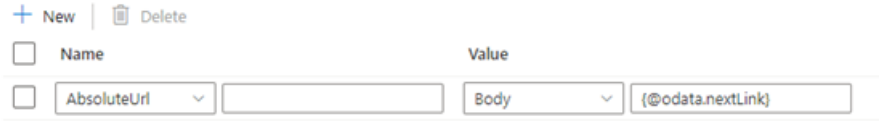
Example 8: The next request URL is from the response body when use pagination in mapping data flows

This example states how to set the pagination rule and the end condition rule in mapping data flows when the next request URL is from the response body.

The response schema is shown below:

Column name	Type
body	{} complex
@odata.context	abc string
@odata.nextLink	abc string
value	[] complex
headers	map

The pagination rules should be set as the following screenshot:



By default, the pagination will stop when body .**{@odata.nextLink}** is null or empty.

But if the value of **@odata.nextLink** in the last response body is equal to the last request URL, then it will lead to the endless loop. To avoid this condition, define end condition rules.

- If **Value** in the last response is **Empty**, then the end condition rule can be set as below:

- If the value of the complete key in the response header equals to true indicates the end of pagination,

then the end condition rule can be set as below:

Example 9: The response format is XML and the next request URL is from the response body when use pagination in mapping data flows

This example states how to set the pagination rule in mapping data flows when the response format is XML and the next request URL is from the response body. As shown in the following screenshot, the first URL is *https://<user>.dfs.core.windows.net/bugfix/test/movie_1.xml*

```
▼<movie>
   <movieId>1</movieId>
   <title>Rambo</title>
   <releaseDate>1945-12-12</releaseDate>
   <rated>true</rated>
   <screenedOn>1946-12-12 12:12:12</screenedOn>
   <ticketPrice>10.345</ticketPrice>
   <next>https:// <user>     .dfs.core.windows.net/bugfix/test/movie_2.xml</next>
 </movie>
```

The response schema is shown below:

Column name	Type
body	complex
movie	complex
movieId	short
next	string
rated	boolean
releaseDate	date
screenedOn	timestamp
ticketPrice	double
title	string
headers	map

The pagination rule syntax is the same as in Example 8 and should be set as below in this example:

Export JSON response as-is

You can use this REST connector to export REST API JSON response as-is to various file-based stores. To achieve

such schema-agnostic copy, skip the "structure" (also called *schema*) section in dataset and schema mapping in copy activity.

Schema mapping

To copy data from REST endpoint to tabular sink, refer to schema mapping.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks in Azure Data Factory, see Supported data stores and formats.

Copy data from and to Salesforce using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Azure Synapse pipelines to copy data from and to Salesforce. It builds on the Copy Activity overview article that presents a general overview of the copy activity.

Supported capabilities

This Salesforce connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks, see the Supported data stores table.

Specifically, this Salesforce connector supports:

- Salesforce Developer, Professional, Enterprise, or Unlimited editions.
- Copying data from and to Salesforce production, sandbox, and custom domain.

> **NOTE**
> This function supports copy of any schema from the above mentioned Salesforce environments, including the Nonprofit Success Pack (NPSP).

The Salesforce connector is built on top of the Salesforce REST/Bulk API. When copying data from Salesforce, the connector automatically chooses between REST and Bulk APIs based on the data size – when the result set is large, Bulk API is used for better performance; You can explicitly set the API version used to read/write data via `apiVersion` property in linked service. When copying data to Salesforce, the connector uses BULK API v1.

> **NOTE**
> The connector no longer sets default version for Salesforce API. For backward compatibility, if a default API version was set before, it keeps working. The default value is 45.0 for source, and 40.0 for sink.

Prerequisites

API permission must be enabled in Salesforce.

Salesforce request limits

Salesforce has limits for both total API requests and concurrent API requests. Note the following points:

- If the number of concurrent requests exceeds the limit, throttling occurs and you see random failures.
- If the total number of requests exceeds the limit, the Salesforce account is blocked for 24 hours.

You might also receive the "REQUEST_LIMIT_EXCEEDED" error message in both scenarios. For more information, see the "API request limits" section in Salesforce developer limits.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

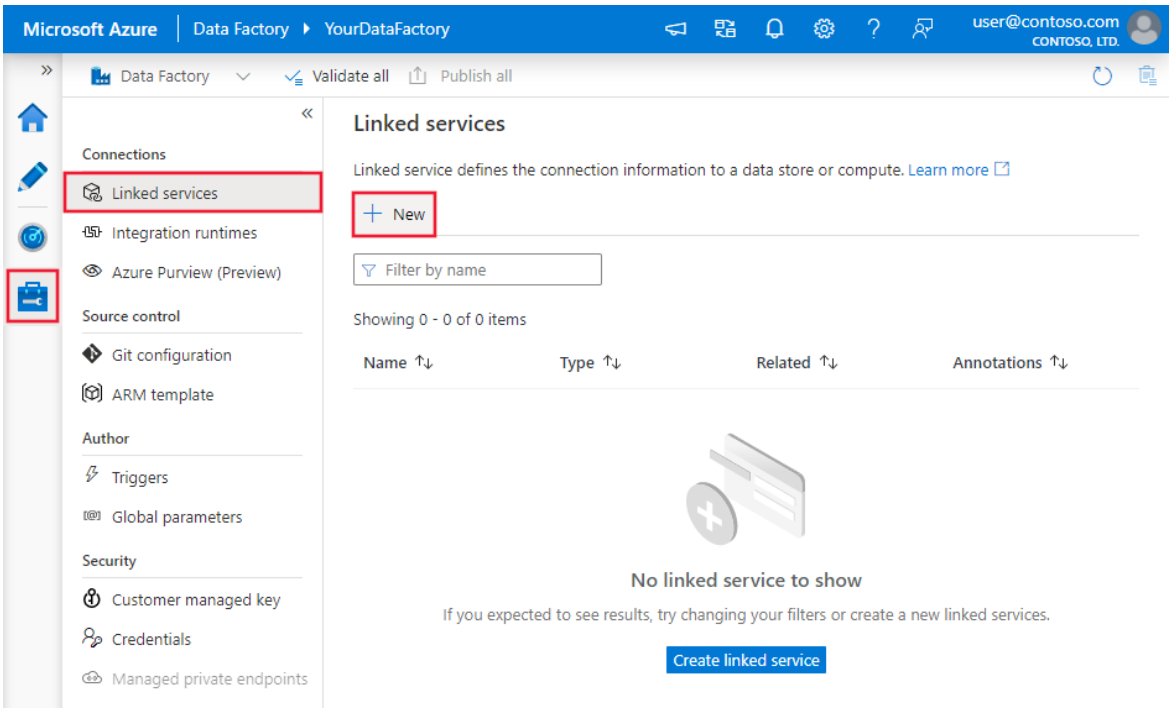
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Salesforce using UI

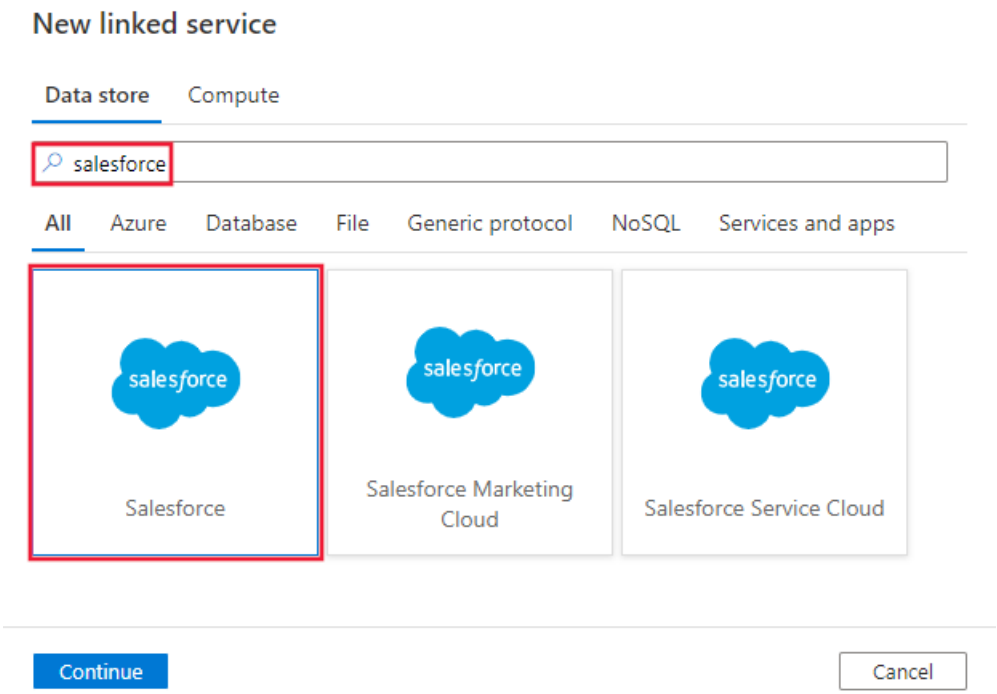
Use the following steps to create a linked service to Salesforce in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

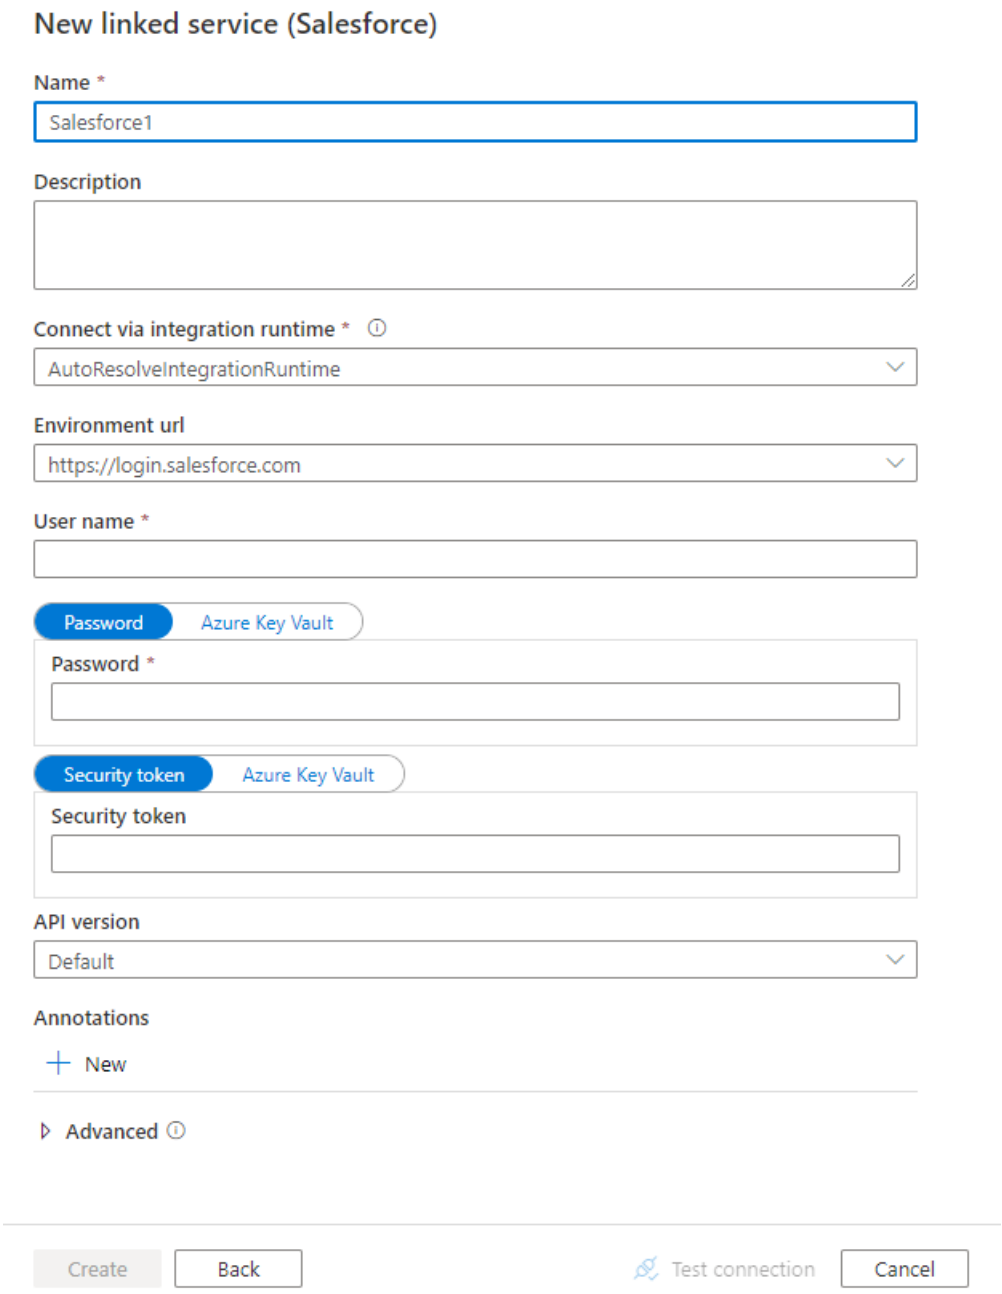
   - Azure Data Factory
   - Azure Synapse



2. Search for Salesforce and select the Salesforce connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to the Salesforce connector.

Linked service properties

The following properties are supported for the Salesforce linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Salesforce**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
environmentUrl	Specify the URL of the Salesforce instance. - Default is `"https://login.salesforce.com"`. - To copy data from sandbox, specify `"https://test.salesforce.com"`. - To copy data from custom domain, specify, for example, `"https://[domain].my.salesforce.com"`.	No
username	Specify a user name for the user account.	Yes
password	Specify a password for the user account. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
securityToken	Specify a security token for the user account. To learn about security tokens in general, see Security and the API. The security token can be skipped only if you add the Integration Runtime's IP to the trusted IP address list on Salesforce. When using Azure IR, refer to Azure Integration Runtime IP addresses. For instructions on how to get and reset a security token, see Get a security token. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
apiVersion	Specify the Salesforce REST/Bulk API version to use, e.g. `52.0`.	No
connectVia	The integration runtime to be used to connect to the data store. If not specified, it uses the default Azure Integration Runtime.	No

Example: Store credentials

```
{
    "name": "SalesforceLinkedService",
    "properties": {
        "type": "Salesforce",
        "typeProperties": {
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            },
            "securityToken": {
                "type": "SecureString",
                "value": "<security token>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Store credentials in Key Vault

```
{
    "name": "SalesforceLinkedService",
    "properties": {
        "type": "Salesforce",
        "typeProperties": {
            "username": "<username>",
            "password": {
                "type": "AzureKeyVaultSecret",
                "secretName": "<secret name of password in AKV>",
                "store":{
                    "referenceName": "<Azure Key Vault linked service>",
                    "type": "LinkedServiceReference"
                }
            },
            "securityToken": {
                "type": "AzureKeyVaultSecret",
                "secretName": "<secret name of security token in AKV>",
                "store":{
                    "referenceName": "<Azure Key Vault linked service>",
                    "type": "LinkedServiceReference"
                }
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Salesforce dataset.

To copy data from and to Salesforce, set the type property of the dataset to **SalesforceObject**. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SalesforceObject**.	Yes
objectApiName	The Salesforce object name to retrieve data from.	No for source, Yes for sink

> **IMPORTANT**
>
> The "__c" part of **API Name** is needed for any custom object.

Example:

```
{
    "name": "SalesforceDataset",
    "properties": {
        "type": "SalesforceObject",
        "typeProperties": {
            "objectApiName": "MyTable__c"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Salesforce linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

> **NOTE**
>
> For backward compatibility: When you copy data from Salesforce, if you use the previous "RelationalTable" type dataset, it keeps working while you see a suggestion to switch to the new "SalesforceObject" type.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **RelationalTable**.	Yes
tableName	Name of the table in Salesforce.	No (if "query" in the activity source is specified)

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Salesforce source and sink.

Salesforce as a source type

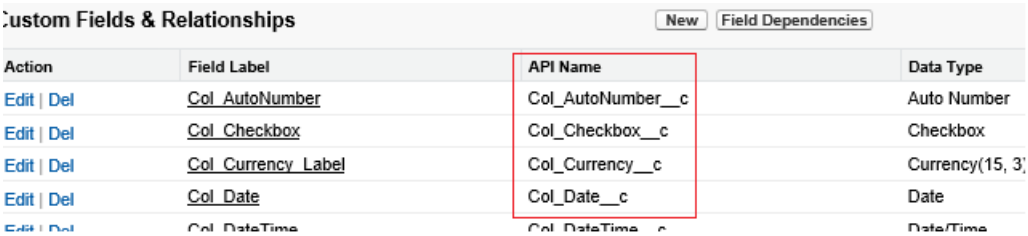
To copy data from Salesforce, set the source type in the copy activity to **SalesforceSource**. The following

properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **SalesforceSource**.	Yes
query	Use the custom query to read data. You can use Salesforce Object Query Language (SOQL) query or SQL-92 query. See more tips in query tips section. If query is not specified, all the data of the Salesforce object specified in "objectApiName" in dataset will be retrieved.	No (if "objectApiName" in the dataset is specified)
readBehavior	Indicates whether to query the existing records, or query all records including the deleted ones. If not specified, the default behavior is the former. Allowed values: **query** (default), **queryAll**.	No

IMPORTANT

The "__c" part of **API Name** is needed for any custom object.



Example:

```
"activities":[
    {
        "name": "CopyFromSalesforce",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Salesforce input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SalesforceSource",
                "query": "SELECT Col_Currency__c, Col_Date__c, Col_Email__c FROM AllDataType__c"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

NOTE

For backward compatibility: When you copy data from Salesforce, if you use the previous "RelationalSource" type copy, the source keeps working while you see a suggestion to switch to the new "SalesforceSource" type.

NOTE

Salesforce source doesn't support proxy settings in the self-hosted integration runtime, but sink does.

Salesforce as a sink type

To copy data to Salesforce, set the sink type in the copy activity to **SalesforceSink**. The following properties are supported in the copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **SalesforceSink**.	Yes
writeBehavior	The write behavior for the operation. Allowed values are **Insert** and **Upsert**.	No (default is Insert)
externalIdFieldName	The name of the external ID field for the upsert operation. The specified field must be defined as "External ID Field" in the Salesforce object. It can't have NULL values in the corresponding input data.	Yes for "Upsert"

PROPERTY	DESCRIPTION	REQUIRED
writeBatchSize	The row count of data written to Salesforce in each batch.	No (default is 5,000)
ignoreNullValues	Indicates whether to ignore NULL values from input data during a write operation. Allowed values are **true** and **false**. - **True**: Leave the data in the destination object unchanged when you do an upsert or update operation. Insert a defined default value when you do an insert operation. - **False**: Update the data in the destination object to NULL when you do an upsert or update operation. Insert a NULL value when you do an insert operation.	No (default is false)
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example: Salesforce sink in a copy activity

```
"activities":[
    {
        "name": "CopyToSalesforce",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Salesforce output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SalesforceSink",
                "writeBehavior": "Upsert",
                "externalIdFieldName": "CustomerId__c",
                "writeBatchSize": 10000,
                "ignoreNullValues": true
            }
        }
    }
]
```

Query tips

Retrieve data from a Salesforce report

You can retrieve data from Salesforce reports by specifying a query as `{call "<report name>"}`. An example is `"query": "{call \"TestReport\"}"`.

Retrieve deleted records from the Salesforce Recycle Bin

To query the soft deleted records from the Salesforce Recycle Bin, you can specify `readBehavior` as `queryAll`.

Difference between SOQL and SQL query syntax

When copying data from Salesforce, you can use either SOQL query or SQL query. Note that these two has different syntax and functionality support, do not mix it. You are suggested to use the SOQL query, which is natively supported by Salesforce. The following table lists the main differences:

SYNTAX	SOQL MODE	SQL MODE
Column selection	Need to enumerate the fields to be copied in the query, e.g. `SELECT field1, filed2 FROM objectname`	`SELECT *` is supported in addition to column selection.
Quotation marks	Filed/object names cannot be quoted.	Field/object names can be quoted, e.g. `SELECT "id" FROM "Account"`
Datetime format	Refer to details here and samples in next section.	Refer to details here and samples in next section.
Boolean values	Represented as `False` and `True`, e.g. `SELECT … WHERE IsDeleted=True`.	Represented as 0 or 1, e.g. `SELECT … WHERE IsDeleted=1`.
Column renaming	Not supported.	Supported, e.g.: `SELECT a AS b FROM …`.
Relationship	Supported, e.g. `Account_vod__r.nvs_Country__c`.	Not supported.

Retrieve data by using a where clause on the DateTime column

When you specify the SOQL or SQL query, pay attention to the DateTime format difference. For example:

- SOQL sample:

```
SELECT Id, Name, BillingCity FROM Account WHERE LastModifiedDate >=
@{formatDateTime(pipeline().parameters.StartTime,'yyyy-MM-ddTHH:mm:ssZ')} AND LastModifiedDate <
@{formatDateTime(pipeline().parameters.EndTime,'yyyy-MM-ddTHH:mm:ssZ')}
```

- SQL sample:

```
SELECT * FROM Account WHERE LastModifiedDate >=
{ts'@{formatDateTime(pipeline().parameters.StartTime,'yyyy-MM-dd HH:mm:ss')}'} AND LastModifiedDate <
{ts'@{formatDateTime(pipeline().parameters.EndTime,'yyyy-MM-dd HH:mm:ss')}'}
```

Error of MALFORMED_QUERY: Truncated

If you hit error of "MALFORMED_QUERY: Truncated", normally it's due to you have JunctionIdList type column in data and Salesforce has limitation on supporting such data with large number of rows. To mitigate, try to exclude JunctionIdList column or limit the number of rows to copy (you can partition to multiple copy activity runs).

Data type mapping for Salesforce

When you copy data from Salesforce, the following mappings are used from Salesforce data types to interim data types within the service internally. To learn about how the copy activity maps the source schema and data

type to the sink, see Schema and data type mappings.

SALESFORCE DATA TYPE	SERVICE INTERIM DATA TYPE
Auto Number	String
Checkbox	Boolean
Currency	Decimal
Date	DateTime
Date/Time	DateTime
Email	String
ID	String
Lookup Relationship	String
Multi-Select Picklist	String
Number	Decimal
Percent	Decimal
Phone	String
Picklist	String
Text	String
Text Area	String
Text Area (Long)	String
Text Area (Rich)	String
Text (Encrypted)	String
URL	String

NOTE

Salesforce Number type is mapping to Decimal type in Azure Data Factory and Azure Synapse pipelines as a service interim data type. Decimal type honors the defined precision and scale.For data whose decimal places exceeds the defined scale, its value will be rounded off in preview data and copy.To avoid getting such precision loss in Azure Data Factory and Azure Synapse pipelines, consider increasing the decimal places to a reasonably large value in **Custom Field Definition Edit** page of Salesforce.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from and to Salesforce Service Cloud using Azure Data Factory or Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from and to Salesforce Service Cloud. It builds on the Copy Activity overview article that presents a general overview of the copy activity.

Supported capabilities

This Salesforce Service Cloud connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks, see the Supported data stores table.

Specifically, this Salesforce Service Cloud connector supports:

- Salesforce Developer, Professional, Enterprise, or Unlimited editions.
- Copying data from and to Salesforce production, sandbox, and custom domain.

The Salesforce connector is built on top of the Salesforce REST/Bulk API. By default, when copying data from Salesforce, the connector uses v45 and automatically chooses between REST and Bulk APIs based on the data size – when the result set is large, Bulk API is used for better performance; when writing data to Salesforce, the connector uses v40 of Bulk API. You can also explicitly set the API version used to read/write data via `apiVersion` property in linked service.

Prerequisites

API permission must be enabled in Salesforce.

Salesforce request limits

Salesforce has limits for both total API requests and concurrent API requests. Note the following points:

- If the number of concurrent requests exceeds the limit, throttling occurs and you see random failures.
- If the total number of requests exceeds the limit, the Salesforce account is blocked for 24 hours.

You might also receive the "REQUEST_LIMIT_EXCEEDED" error message in both scenarios. For more information, see the "API request limits" section in Salesforce developer limits.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

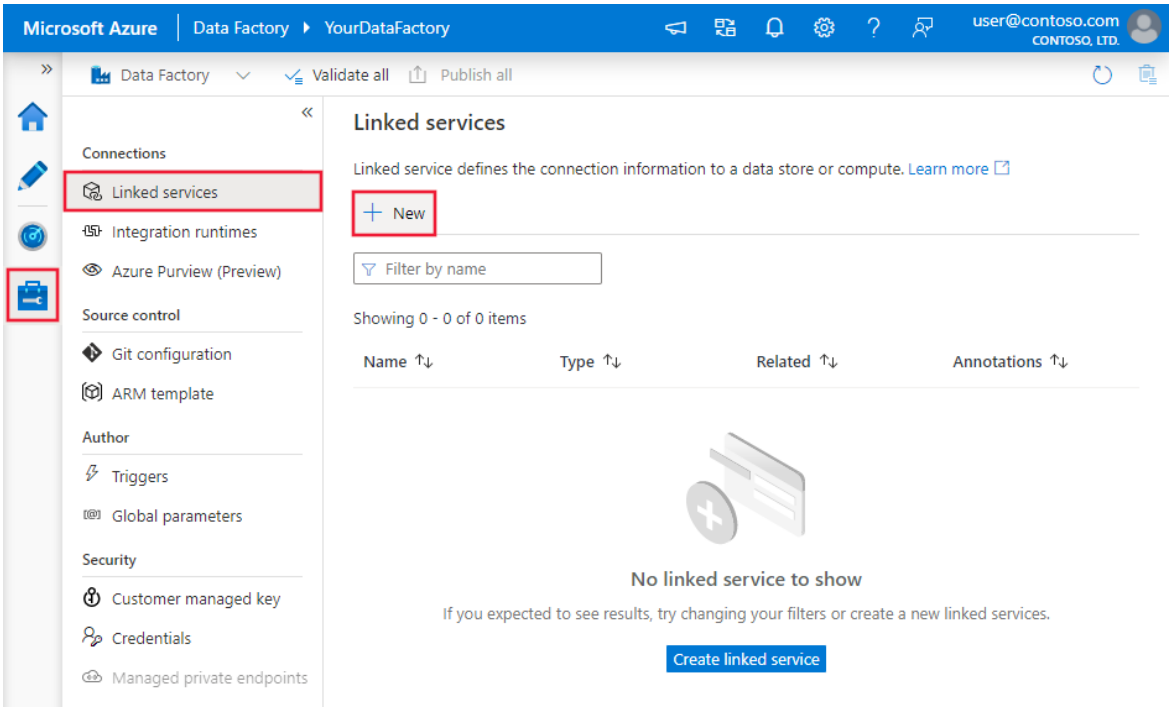
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Salesforce Service Cloud using UI

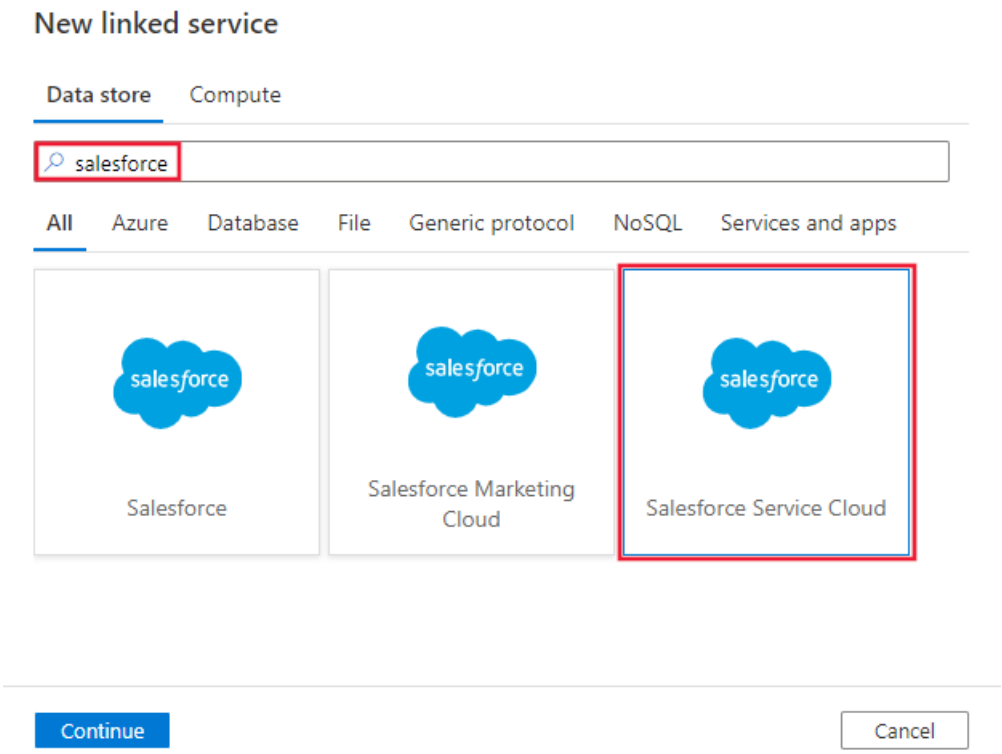
Use the following steps to create a linked service to Salesforce Service Cloud in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

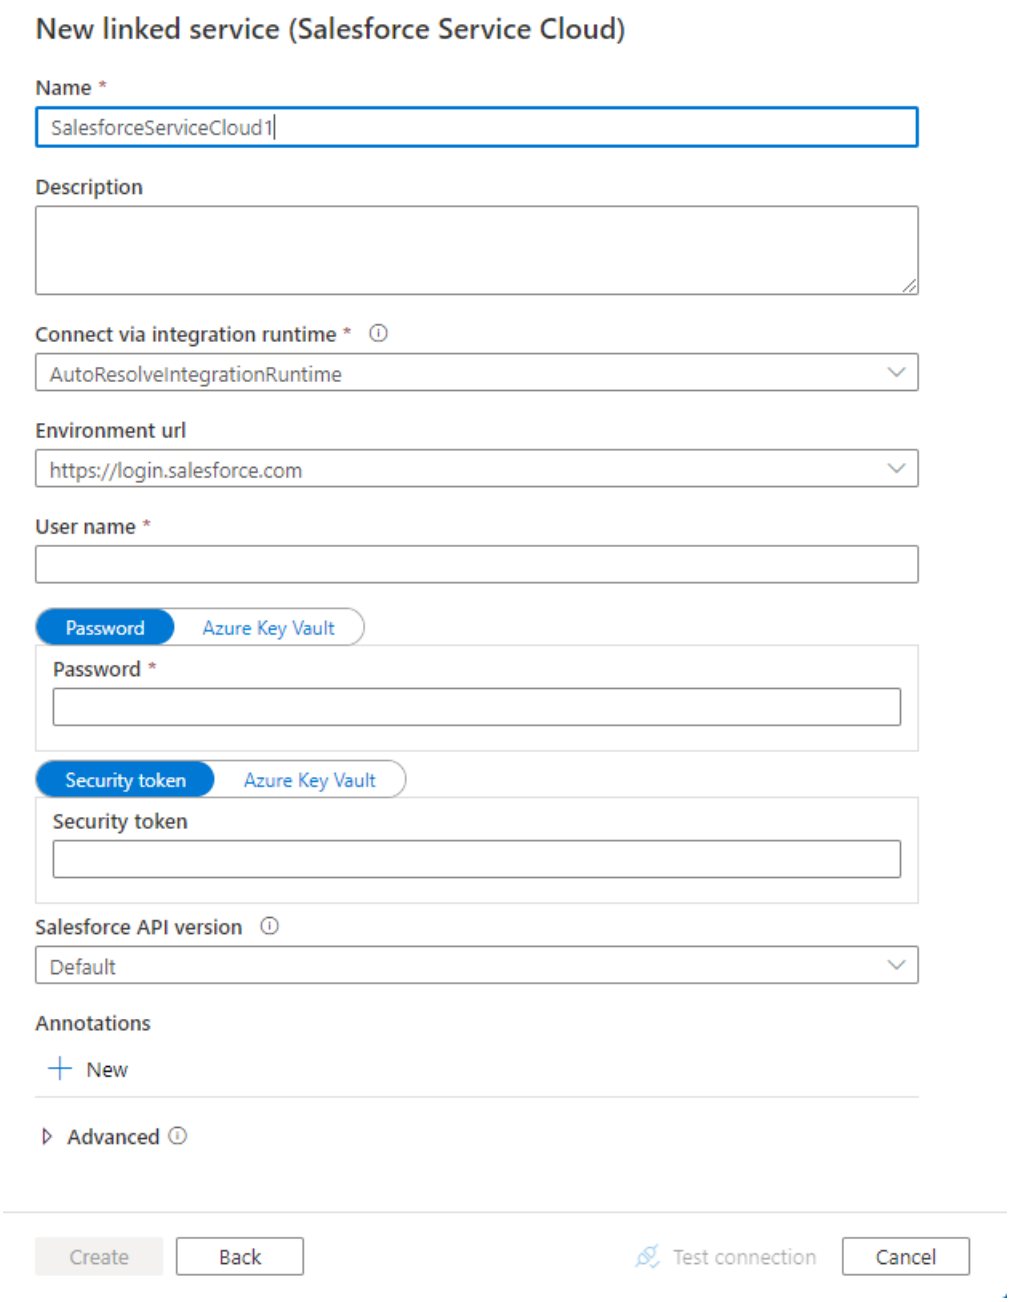
   - Azure Data Factory
   - Azure Synapse



2. Search for Salesforce and select the Salesforce Service Cloud connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to the Salesforce Service Cloud connector.

Linked service properties

The following properties are supported for the Salesforce linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SalesforceServiceCloud**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
environmentUrl	Specify the URL of the Salesforce Service Cloud instance. - Default is `"https://login.salesforce.com"`. - To copy data from sandbox, specify `"https://test.salesforce.com"`. - To copy data from custom domain, specify, for example, `"https://[domain].my.salesforce.com"`.	No
username	Specify a user name for the user account.	Yes
password	Specify a password for the user account. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
securityToken	Specify a security token for the user account. To learn about security tokens in general, see Security and the API. The security token can be skipped only if you add the Integration Runtime's IP to the trusted IP address list on Salesforce. When using Azure IR, refer to Azure Integration Runtime IP addresses. For instructions on how to get and reset a security token, see Get a security token. Mark this field as a SecureString to store it securely in Data Factory, or reference a secret stored in Azure Key Vault.	No
apiVersion	Specify the Salesforce REST/Bulk API version to use, e.g. `48.0`. By default, the connector uses v45 to copy data from Salesforce, and uses v40 to copy data to Salesforce.	No
connectVia	The integration runtime to be used to connect to the data store. If not specified, it uses the default Azure Integration Runtime.	No

Example: Store credentials

```
{
    "name": "SalesforceServiceCloudLinkedService",
    "properties": {
        "type": "SalesforceServiceCloud",
        "typeProperties": {
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            },
            "securityToken": {
                "type": "SecureString",
                "value": "<security token>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Store credentials in Key Vault

```
{
    "name": "SalesforceServiceCloudLinkedService",
    "properties": {
        "type": "SalesforceServiceCloud",
        "typeProperties": {
            "username": "<username>",
            "password": {
                "type": "AzureKeyVaultSecret",
                "secretName": "<secret name of password in AKV>",
                "store":{
                    "referenceName": "<Azure Key Vault linked service>",
                    "type": "LinkedServiceReference"
                }
            },
            "securityToken": {
                "type": "AzureKeyVaultSecret",
                "secretName": "<secret name of security token in AKV>",
                "store":{
                    "referenceName": "<Azure Key Vault linked service>",
                    "type": "LinkedServiceReference"
                }
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the Salesforce Service Cloud dataset.

To copy data from and to Salesforce Service Cloud, the following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SalesforceServiceCloudObject**.	Yes
objectApiName	The Salesforce object name to retrieve data from.	No for source, Yes for sink

> **IMPORTANT**
>
> The "__c" part of **API Name** is needed for any custom object.

Custom Object Definition Detail

Singular Label	AllDataType
Plural Label	AllDataTypes
Object Name	AllDataType
API Name	AllDataType__c

Example:

```
{
    "name": "SalesforceServiceCloudDataset",
    "properties": {
        "type": "SalesforceServiceCloudObject",
        "typeProperties": {
            "objectApiName": "MyTable__c"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Salesforce Service Cloud linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **RelationalTable**.	Yes
tableName	Name of the table in Salesforce Service Cloud.	No (if "query" in the activity source is specified)

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Salesforce Service Cloud source and sink.

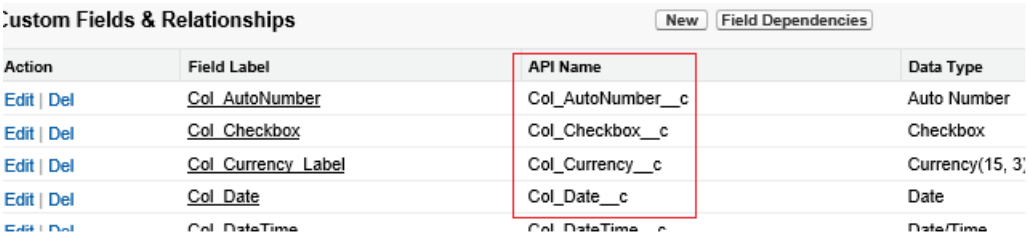
Salesforce Service Cloud as a source type

To copy data from Salesforce Service Cloud, the following properties are supported in the copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **SalesforceServiceCloudSource**.	Yes
query	Use the custom query to read data. You can use Salesforce Object Query Language (SOQL) query or SQL-92 query. See more tips in query tips section. If query is not specified, all the data of the Salesforce Service Cloud object specified in "objectApiName" in dataset will be retrieved.	No (if "objectApiName" in the dataset is specified)
readBehavior	Indicates whether to query the existing records, or query all records including the deleted ones. If not specified, the default behavior is the former. Allowed values: **query** (default), **queryAll**.	No

> **IMPORTANT**
>
> The "__c" part of **API Name** is needed for any custom object.



Example:

```
"activities":[
    {
        "name": "CopyFromSalesforceServiceCloud",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Salesforce Service Cloud input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SalesforceServiceCloudSource",
                "query": "SELECT Col_Currency__c, Col_Date__c, Col_Email__c FROM AllDataType__c"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

NOTE

Salesforce Service Cloud source doesn't support proxy settings in the self-hosted integration runtime, but sink does.

Salesforce Service Cloud as a sink type

To copy data to Salesforce Service Cloud, the following properties are supported in the copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **SalesforceServiceCloudSink**.	Yes
writeBehavior	The write behavior for the operation. Allowed values are **Insert** and **Upsert**.	No (default is Insert)
externalIdFieldName	The name of the external ID field for the upsert operation. The specified field must be defined as "External ID Field" in the Salesforce Service Cloud object. It can't have NULL values in the corresponding input data.	Yes for "Upsert"
writeBatchSize	The row count of data written to Salesforce Service Cloud in each batch.	No (default is 5,000)

PROPERTY	DESCRIPTION	REQUIRED
ignoreNullValues	Indicates whether to ignore NULL values from input data during a write operation. Allowed values are **true** and **false**. - **True**: Leave the data in the destination object unchanged when you do an upsert or update operation. Insert a defined default value when you do an insert operation. - **False**: Update the data in the destination object to NULL when you do an upsert or update operation. Insert a NULL value when you do an insert operation.	No (default is false)
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToSalesforceServiceCloud",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Salesforce Service Cloud output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SalesforceServiceCloudSink",
                "writeBehavior": "Upsert",
                "externalIdFieldName": "CustomerId__c",
                "writeBatchSize": 10000,
                "ignoreNullValues": true
            }
        }
    }
]
```

Query tips

Retrieve data from a Salesforce Service Cloud report

You can retrieve data from Salesforce Service Cloud reports by specifying a query as `{call "<report name>"}`.
An example is `"query": "{call \"TestReport\"}"`.

Retrieve deleted records from the Salesforce Service Cloud Recycle Bin

To query the soft deleted records from the Salesforce Service Cloud Recycle Bin, you can specify `readBehavior` as `queryAll`.

Difference between SOQL and SQL query syntax

When copying data from Salesforce Service Cloud, you can use either SOQL query or SQL query. Note that these two has different syntax and functionality support, do not mix it. You are suggested to use the SOQL query, which is natively supported by Salesforce Service Cloud. The following table lists the main differences:

SYNTAX	SOQL MODE	SQL MODE
Column selection	Need to enumerate the fields to be copied in the query, e.g. `SELECT field1, filed2 FROM objectname`	`SELECT *` is supported in addition to column selection.
Quotation marks	Filed/object names cannot be quoted.	Field/object names can be quoted, e.g. `SELECT "id" FROM "Account"`
Datetime format	Refer to details here and samples in next section.	Refer to details here and samples in next section.
Boolean values	Represented as `False` and `True`, e.g. `SELECT … WHERE IsDeleted=True`.	Represented as 0 or 1, e.g. `SELECT … WHERE IsDeleted=1`.
Column renaming	Not supported.	Supported, e.g.: `SELECT a AS b FROM …`.
Relationship	Supported, e.g. `Account_vod__r.nvs_Country__c`.	Not supported.

Retrieve data by using a where clause on the DateTime column

When you specify the SOQL or SQL query, pay attention to the DateTime format difference. For example:

- SOQL sample:

```
SELECT Id, Name, BillingCity FROM Account WHERE LastModifiedDate >=
@{formatDateTime(pipeline().parameters.StartTime,'yyyy-MM-ddTHH:mm:ssZ')} AND LastModifiedDate <
@{formatDateTime(pipeline().parameters.EndTime,'yyyy-MM-ddTHH:mm:ssZ')}
```

- SQL sample:

```
SELECT * FROM Account WHERE LastModifiedDate >=
{ts'@{formatDateTime(pipeline().parameters.StartTime,'yyyy-MM-dd HH:mm:ss')}'} AND LastModifiedDate <
{ts'@{formatDateTime(pipeline().parameters.EndTime,'yyyy-MM-dd HH:mm:ss')}'}
```

Error of MALFORMED_QUERY: Truncated

If you hit error of "MALFORMED_QUERY: Truncated", normally it's due to you have JunctionIdList type column in data and Salesforce has limitation on supporting such data with large number of rows. To mitigate, try to exclude JunctionIdList column or limit the number of rows to copy (you can partition to multiple copy activity runs).

Data type mapping for Salesforce Service Cloud

When you copy data from Salesforce Service Cloud, the following mappings are used from Salesforce Service Cloud data types to interim data types used internally within the service. To learn about how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

SALESFORCE SERVICE CLOUD DATA TYPE	INTERIM SERVICE DATA TYPE
Auto Number	String
Checkbox	Boolean
Currency	Decimal
Date	DateTime
Date/Time	DateTime
Email	String
ID	String
Lookup Relationship	String
Multi-Select Picklist	String
Number	Decimal
Percent	Decimal
Phone	String
Picklist	String
Text	String
Text Area	String
Text Area (Long)	String
Text Area (Rich)	String
Text (Encrypted)	String
URL	String

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Salesforce Marketing Cloud using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory or Synapse Analytics pipelines to copy data from Salesforce Marketing Cloud. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Salesforce Marketing Cloud connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The Salesforce Marketing Cloud connector supports OAuth 2 authentication, and it supports both legacy and enhanced package types. The connector is built on top of the Salesforce Marketing Cloud REST API.

> **NOTE**
> This connector doesn't support retrieving custom objects or custom data extensions.

Getting started

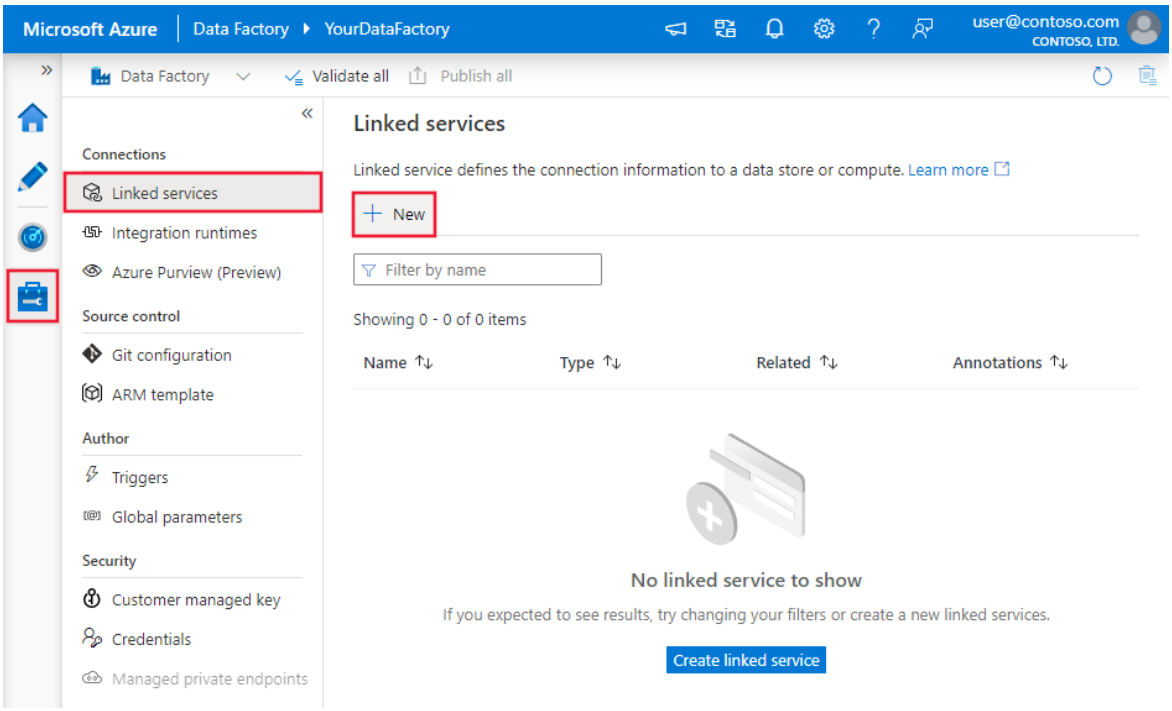
You can create a pipeline with copy activity using .NET SDK, Python SDK, Azure PowerShell, REST API, or Azure Resource Manager template. See Copy activity tutorial for step-by-step instructions to create a pipeline with a copy activity.

Create a linked service to Salesforce Marketing Cloud using UI

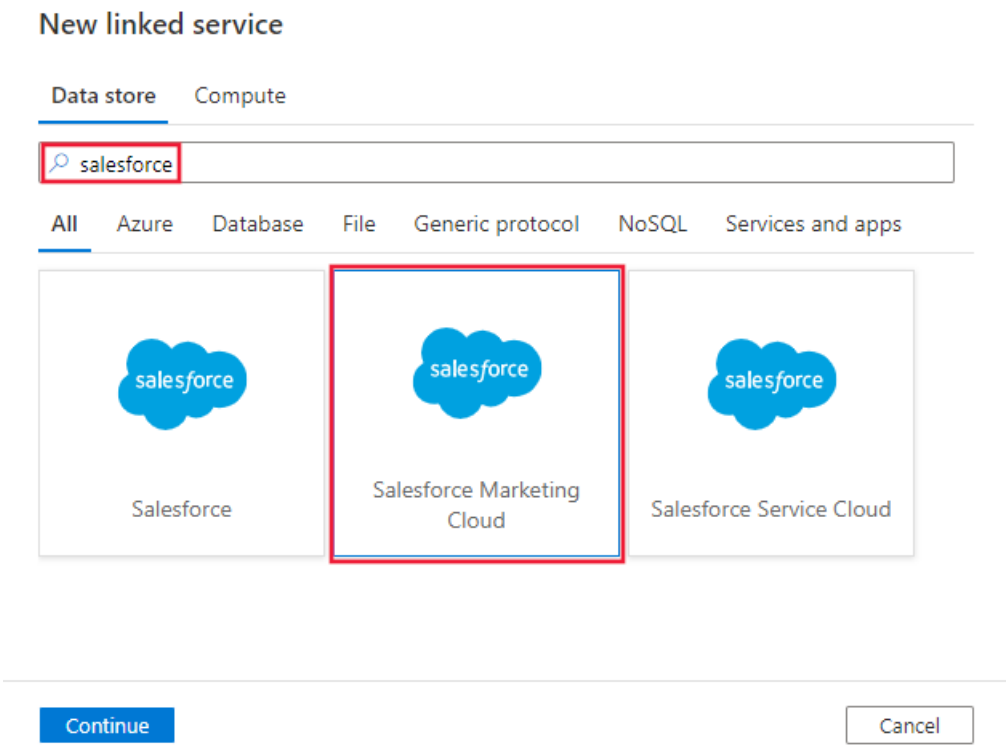
Use the following steps to create a linked service to Salesforce Marketing Cloud in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

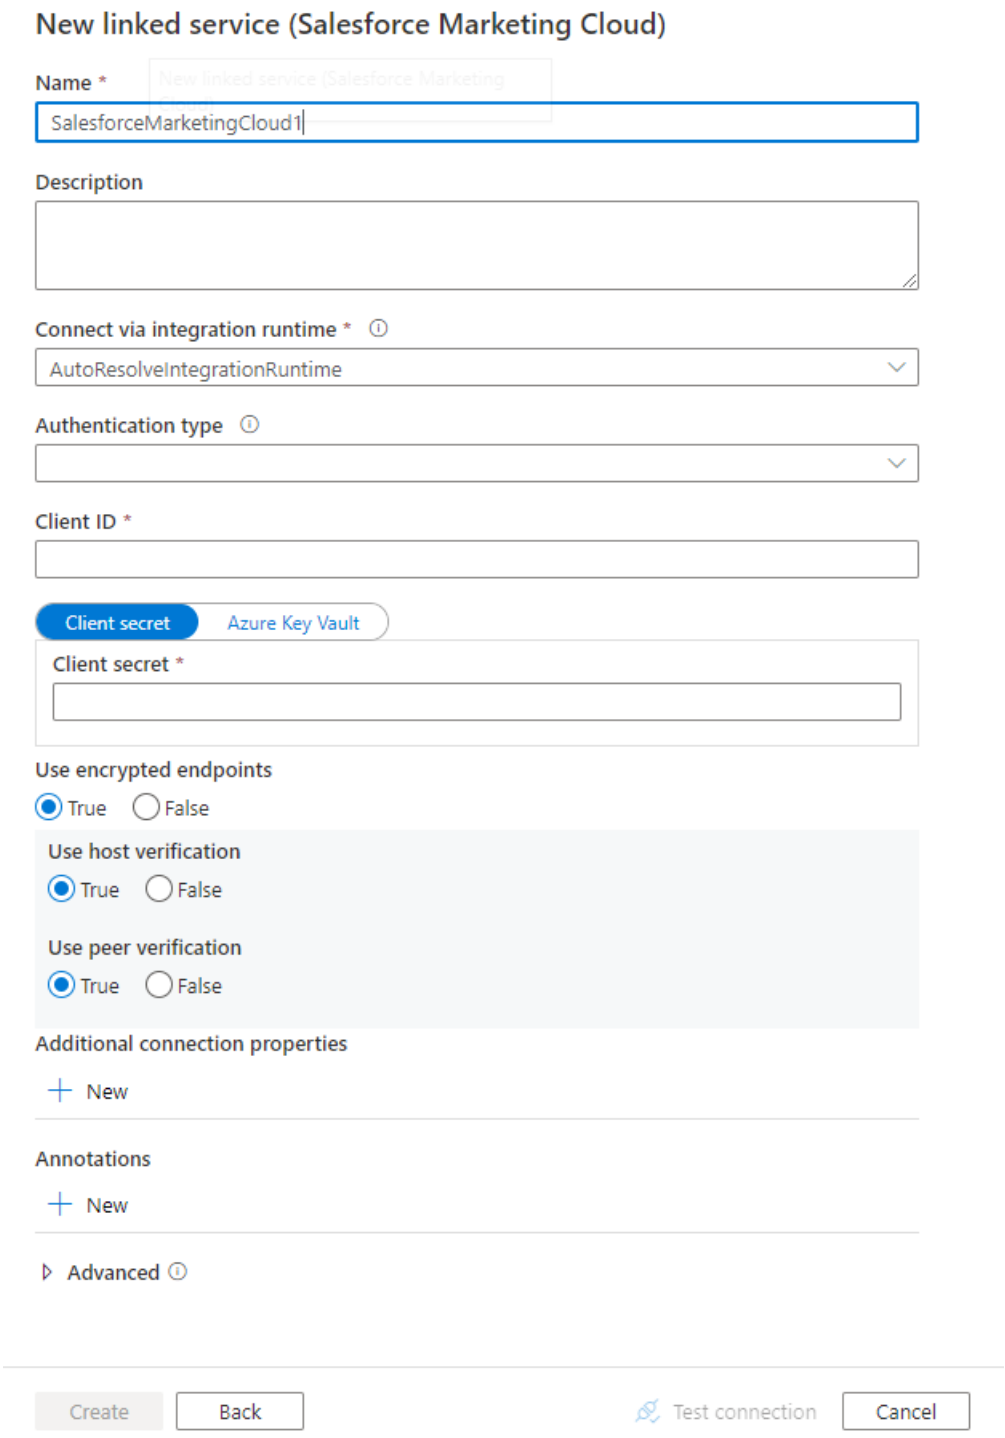
   - Azure Data Factory
   - Azure Synapse



2. Search for Salesforce and select the Salesforce Marketing Cloud connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Salesforce Marketing Cloud connector.

Linked service properties

The following properties are supported for Salesforce Marketing Cloud linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SalesforceMarketingCloud**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionProperties	A group of properties that defines how to connect to Salesforce Marketing Cloud.	Yes
Under `connectionProperties`*:*		
authenticationType	Specifies the authentication method to use. Allowed values are `Enhanced sts OAuth 2.0` or `OAuth_2.0`. Salesforce Marketing Cloud legacy package only supports `OAuth_2.0`, while enhanced package needs `Enhanced sts OAuth 2.0`. Since August 1, 2019, Salesforce Marketing Cloud has removed the ability to create legacy packages. All new packages are enhanced packages.	Yes
host	For enhanced package, the host should be your subdomain which is represented by a 28-character string starting with the letters "mc", e.g. `mc563885gzs27c5t9-63k636ttgm`. For legacy package, specify `www.exacttargetapis.com`.	Yes
clientId	The client ID associated with the Salesforce Marketing Cloud application.	Yes
clientSecret	The client secret associated with the Salesforce Marketing Cloud application. You can choose to mark this field as a SecureString to store it securely in the service, or store the secret in Azure Key Vault and let the service copy activity pull from there when performing data copy - learn more from Store credentials in Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example: using enhanced STS OAuth 2 authentication for enhanced package

```
{
    "name": "SalesforceMarketingCloudLinkedService",
    "properties": {
        "type": "SalesforceMarketingCloud",
        "typeProperties": {
            "connectionProperties": {
                "host": "<subdomain e.g. mc563885gzs27c5t9-63k636ttgm>",
                "authenticationType": "Enhanced sts OAuth 2.0",
                "clientId": "<clientId>",
                "clientSecret": {
                     "type": "SecureString",
                     "value": "<clientSecret>"
             },
                "useEncryptedEndpoints": true,
                "useHostVerification": true,
                "usePeerVerification": true
            }
        }
    }
}
```

Example: using OAuth 2 authentication for legacy package

```
{
    "name": "SalesforceMarketingCloudLinkedService",
    "properties": {
        "type": "SalesforceMarketingCloud",
        "typeProperties": {
            "connectionProperties": {
                "host": "www.exacttargetapis.com",
                "authenticationType": "OAuth_2.0",
                "clientId": "<clientId>",
                "clientSecret": {
                     "type": "SecureString",
                     "value": "<clientSecret>"
             },
                "useEncryptedEndpoints": true,
                "useHostVerification": true,
                "usePeerVerification": true
            }
        }
    }
}
```

If you were using Salesforce Marketing Cloud linked service with the following payload, it is still supported as-is, while you are suggested to use the new one going forward which adds enhanced package support.

```
{
    "name": "SalesforceMarketingCloudLinkedService",
    "properties": {
        "type": "SalesforceMarketingCloud",
        "typeProperties": {
            "clientId": "<clientId>",
            "clientSecret": {
                 "type": "SecureString",
                 "value": "<clientSecret>"
            },
            "useEncryptedEndpoints": true,
            "useHostVerification": true,
            "usePeerVerification": true
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Salesforce Marketing Cloud dataset.

To copy data from Salesforce Marketing Cloud, set the type property of the dataset to **SalesforceMarketingCloudObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SalesforceMarketingCloudObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "SalesforceMarketingCloudDataset",
    "properties": {
        "type": "SalesforceMarketingCloudObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SalesforceMarketingCloud linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Salesforce Marketing Cloud source.

Salesforce Marketing Cloud as source

To copy data from Salesforce Marketing Cloud, set the source type in the copy activity to **SalesforceMarketingCloudSource**. The following properties are supported in the copy activity **source**

section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SalesforceMarketingCloudSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromSalesforceMarketingCloud",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SalesforceMarketingCloud input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SalesforceMarketingCloudSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

NOTE

Contacts table is not supported.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from SAP Business Warehouse via Open Hub using Azure Data Factory or Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from an SAP Business Warehouse (BW) via Open Hub. It builds on the copy activity overview article that presents a general overview of copy activity.

> **TIP**
> To learn about overall support for the SAP data integration scenario, see SAP data integration whitepaper with detailed introduction on each SAP connector, comparison and guidance.

Supported capabilities

This SAP Business Warehouse Open Hub connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this SAP Business Warehouse Open Hub connector supports:

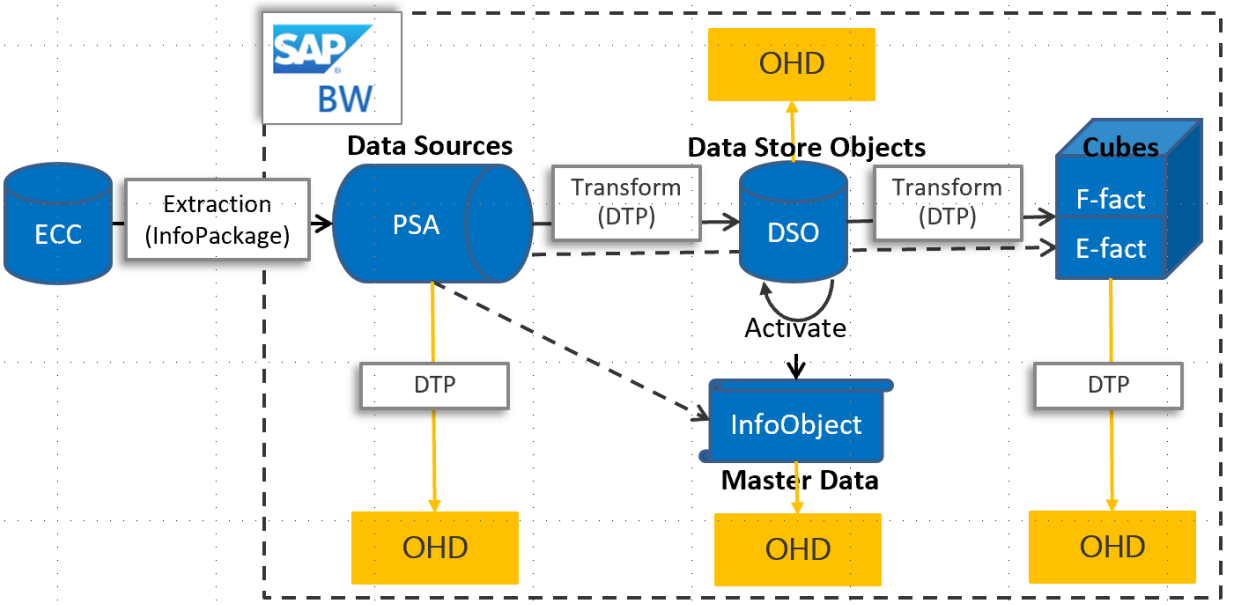
- SAP Business Warehouse **version 7.01 or higher (in a recent SAP Support Package Stack released after the year 2015)**. SAP BW/4HANA is not supported by this connector.
- Copying data via Open Hub Destination local table, which underneath can be DSO, InfoCube, MultiProvider, DataSource, etc.
- Copying data using basic authentication.
- Connecting to an SAP application server or SAP message server.
- Retrieving data via RFC.

SAP BW Open Hub Integration

SAP BW Open Hub Service is an efficient way to extract data from SAP BW. The following diagram shows one of the typical flows customers have in their SAP system, in which case data flows from SAP ECC -> PSA -> DSO -> Cube.

SAP BW Open Hub Destination (OHD) defines the target to which the SAP data is relayed. Any objects supported by SAP Data Transfer Process (DTP) can be used as open hub data sources, for example, DSO, InfoCube, DataSource, etc. Open Hub Destination type - where the relayed data is stored - can be database tables (local or remote) and flat files. This SAP BW Open Hub connector support copying data from OHD local table in BW. In

case you are using other types, you can directly connect to the database or file system using other connectors.



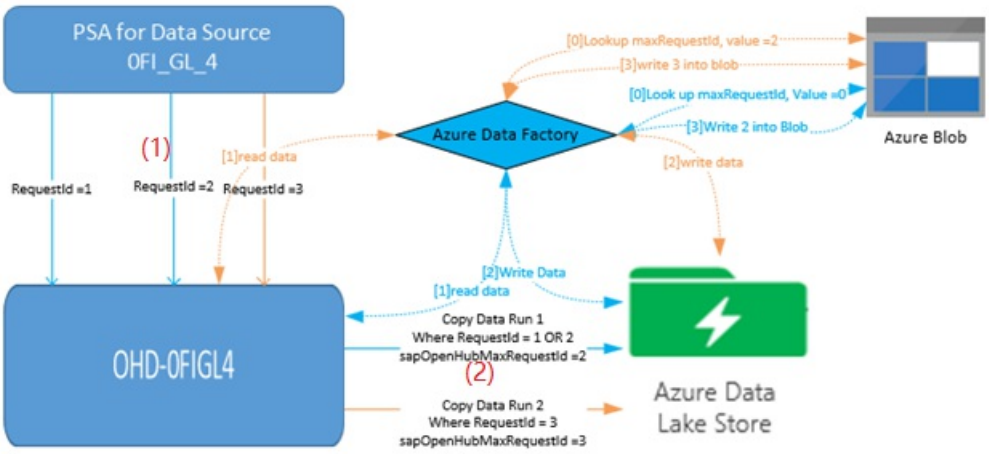
Delta extraction flow

The SAP BW Open Hub Connector offers two optional properties: `excludeLastRequest` and `baseRequestId` which can be used to handle delta load from Open Hub.

- **excludeLastRequestId**: Whether to exclude the records of the last request. Default value is true.
- **baseRequestId**: The ID of request for delta loading. Once it is set, only data with requestId larger than the value of this property will be retrieved.

Overall, the extraction from SAP InfoProviders consists of two steps:

1. **SAP BW Data Transfer Process (DTP)** This step copies the data from an SAP BW InfoProvider to an SAP BW Open Hub table
2. **Data copy** In this step, the Open Hub table is read by the connector



In the first step, a DTP is executed. Each execution creates a new SAP request ID. The request ID is stored in the Open Hub table and is then used by the connector to identify the delta. The two steps run asynchronously: the DTP is triggered by SAP, and the data copy is triggered through the service.

By default, the service is not reading the latest delta from the Open Hub table (option "exclude last request" is true). Hereby, the data in the service is not 100% up to date with the data in the Open Hub table (the last delta is missing). In return, this procedure ensures that no rows get lost caused by the asynchronous extraction. It works fine even when the service is reading the Open Hub table while the DTP is still writing into the same table.

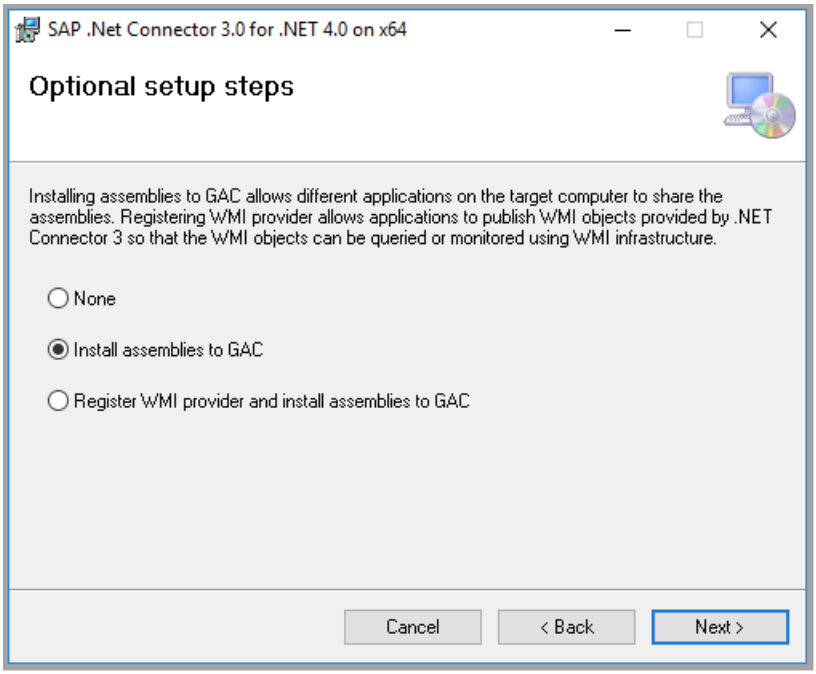
You typically store the max copied request ID in the last run by the service in a staging data store (such as Azure Blob in above diagram). Therefore, the same request is not read a second time by the service in the subsequent run. Meanwhile, note the data is not automatically deleted from the Open Hub table.

For proper delta handling, it is not allowed to have request IDs from different DTPs in the same Open Hub table. Therefore, you must not create more than one DTP for each Open Hub Destination (OHD). When needing Full and Delta extraction from the same InfoProvider, you should create two OHDs for the same InfoProvider.

Prerequisites

To use this SAP Business Warehouse Open Hub connector, you need to:

- Set up a Self-hosted Integration Runtime with version 3.13 or above. See Self-hosted Integration Runtime article for details.
- Download the **64-bit SAP .NET Connector 3.0** from SAP's website, and install it on the Self-hosted IR machine. When installing, in the optional setup steps window, make sure you select the **Install Assemblies to GAC** option as shown in the following image.



- SAP user being used in the BW connector needs to have following permissions:
  - Authorization for RFC and SAP BW.
  - Permissions to the "Execute" Activity of Authorization Object "S_SDSAUTH".
- Create SAP Open Hub Destination type as **Database Table** with "Technical Key" option checked. It is also recommended to leave the Deleting Data from Table as unchecked although it is not required. Use the DTP (directly execute or integrate into existing process chain) to land data from source object (such as cube) you have chosen to the open hub destination table.

Getting started

> **TIP**
> For a walkthrough of using SAP BW Open Hub connector, see Load data from SAP Business Warehouse (BW).

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool

- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

The following sections provide details about properties that are used to define entities specific to SAP Business Warehouse Open Hub connector.

Linked service properties

The following properties are supported for SAP Business Warehouse Open Hub linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapOpenHub**	Yes
server	Name of the server on which the SAP BW instance resides.	Yes
systemNumber	System number of the SAP BW system. Allowed value: two-digit decimal number represented as a string.	Yes
messageServer	The host name of the SAP message server. Use to connect to an SAP message server.	No
messageServerService	The service name or port number of the message server. Use to connect to an SAP message server.	No
systemId	The ID of the SAP system where the table is located. Use to connect to an SAP message server.	No
logonGroup	The logon group for the SAP system. Use to connect to an SAP message server.	No
clientId	Client ID of the client in the SAP W system. Allowed value: three-digit decimal number represented as a string.	Yes
language	Language that the SAP system uses.	No (default value is **EN**)
userName	Name of the user who has access to the SAP server.	Yes

PROPERTY	DESCRIPTION	REQUIRED
password	Password for the user. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "SapBwOpenHubLinkedService",
    "properties": {
        "type": "SapOpenHub",
        "typeProperties": {
            "server": "<server name>",
            "systemNumber": "<system number>",
            "clientId": "<client id>",
            "userName": "<SAP user>",
            "password": {
                "type": "SecureString",
                "value": "<Password for SAP user>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the SAP BW Open Hub dataset.

To copy data from and to SAP BW Open Hub, set the type property of the dataset to **SapOpenHubTable**. The following properties are supported.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SapOpenHubTable**.	Yes
openHubDestinationName	The name of the Open Hub Destination to copy data from.	Yes

If you were setting `excludeLastRequest` and `baseRequestId` in dataset, it is still supported as-is, while you are suggested to use the new model in activity source going forward.

Example:

```
{
    "name": "SAPBWOpenHubDataset",
    "properties": {
        "type": "SapOpenHubTable",
        "typeProperties": {
            "openHubDestinationName": "<open hub destination name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP BW Open Hub linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by SAP BW Open Hub source.

SAP BW Open Hub as source

To copy data from SAP BW Open Hub, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the copy activity source must be set to **SapOpenHubSource**.	Yes
excludeLastRequest	Whether to exclude the records of the last request.	No (default is **true**)
baseRequestId	The ID of request for delta loading. Once it is set, only data with requestId **larger than** the value of this property will be retrieved.	No
customRfcReadTableFunctionModule	A custom RFC function module that can be used to read data from an SAP table. You can use a custom RFC function module to define how the data is retrieved from your SAP system and returned to the service. The custom function module must have an interface implemented (import, export, tables) that's similar to `/SAPDS/RFC_READ_TABLE2`, which is the default interface used by the service.	No
sapDataColumnDelimiter	The single character that is used as delimiter passed to SAP RFC to split the output data.	No

TIP

If your Open Hub table only contains the data generated by single request ID, for example, you always do full load and overwrite the existing data in the table, or you only run the DTP once for test, remember to uncheck the "excludeLastRequest" option in order to copy the data out.

To speed up the data loading, you can set `parallelCopies` on the copy activity to load data from SAP BW Open Hub in parallel. For example, if you set `parallelCopies` to four, the service concurrently executes four RFC calls, and each RFC call retrieves a portion of data from your SAP BW Open Hub table partitioned by the DTP request ID and package ID. This applies when the number of unique DTP request ID + package ID is bigger than the value of `parallelCopies`. When copying data into file-based data store, it's also recommanded to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

Example:

```
"activities":[
    {
        "name": "CopyFromSAPBWOpenHub",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP BW Open Hub input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapOpenHubSource",
                "excludeLastRequest": true
            },
            "sink": {
                "type": "<sink type>"
            },
            "parallelCopies": 4
        }
    }
]
```

Data type mapping for SAP BW Open Hub

When copying data from SAP BW Open Hub, the following mappings are used from SAP BW data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

SAP ABAP TYPE	INTERIM SERVICE DATA TYPE
C (String)	String
I (integer)	Int32

SAP ABAP TYPE	INTERIM SERVICE DATA TYPE
F (Float)	Double
D (Date)	String
T (Time)	String
P (BCD Packed, Currency, Decimal, Qty)	Decimal
N (Numc)	String
X (Binary and Raw)	String

Lookup activity properties

To learn details about the properties, check Lookup activity.

Troubleshooting tips

Symptoms: If you are running SAP BW on HANA and observe only subset of data is copied over using copy activity (1 million rows), the possible cause is that you enable "SAP HANA Execution" option in your DTP, in which case the service can only retrieve the first batch of data.

Resolution: Disable "SAP HANA Execution" option in DTP, reprocess the data, then try executing the copy activity again.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from SAP Business Warehouse with Azure Data Factory or Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

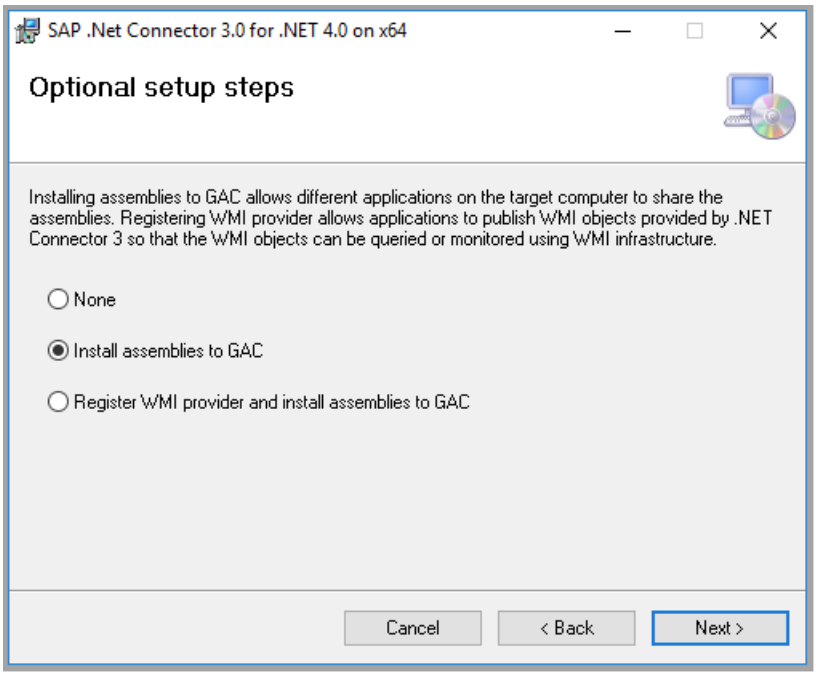
APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article shows how to use Azure Data Factory or Synapse Analytics pipelines to copy data from SAP Business Warehouse (BW) via Open Hub to Azure Data Lake Storage Gen2. You can use a similar process to copy data to other supported sink data stores.

> **TIP**
> For general information about copying data from SAP BW, including SAP BW Open Hub integration and delta extraction flow, see Copy data from SAP Business Warehouse via Open Hub by using Azure Data Factory.

Prerequisites

- **Azure Data Factory or Synapse workspace**: If you don't have one, follow the steps to create a data factory or create a Synapse workspace.
- **SAP BW Open Hub Destination (OHD) with destination type "Database Table"**: To create an OHD or to check that your OHD is configured correctly for integration with the service, see the SAP BW Open Hub Destination configurations section of this article.
- **The SAP BW user needs the following permissions**:
  - Authorization for Remote Function Calls (RFC) and SAP BW.
  - Permissions to the "Execute" activity of the **S_SDSAUTH** authorization object.
- **A self-hosted integration runtime (IR) with SAP .NET connector 3.0**. Follow these setup steps:
  1. Install and register the self-hosted integration runtime, version 3.13 or later. (This process is described later in this article.)
  2. Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website, and install it on the same computer as the self-hosted IR. During installation, make sure that you select **Install Assemblies to GAC** in the **Optional setup steps** dialog box, as the following image shows:



Do a full copy from SAP BW Open Hub

In the Azure portal, go to your service. Select **Open** on the **Open Azure Data Factory Studio** or **Open Synapse Studio** tile to open the service UI in a separate tab.

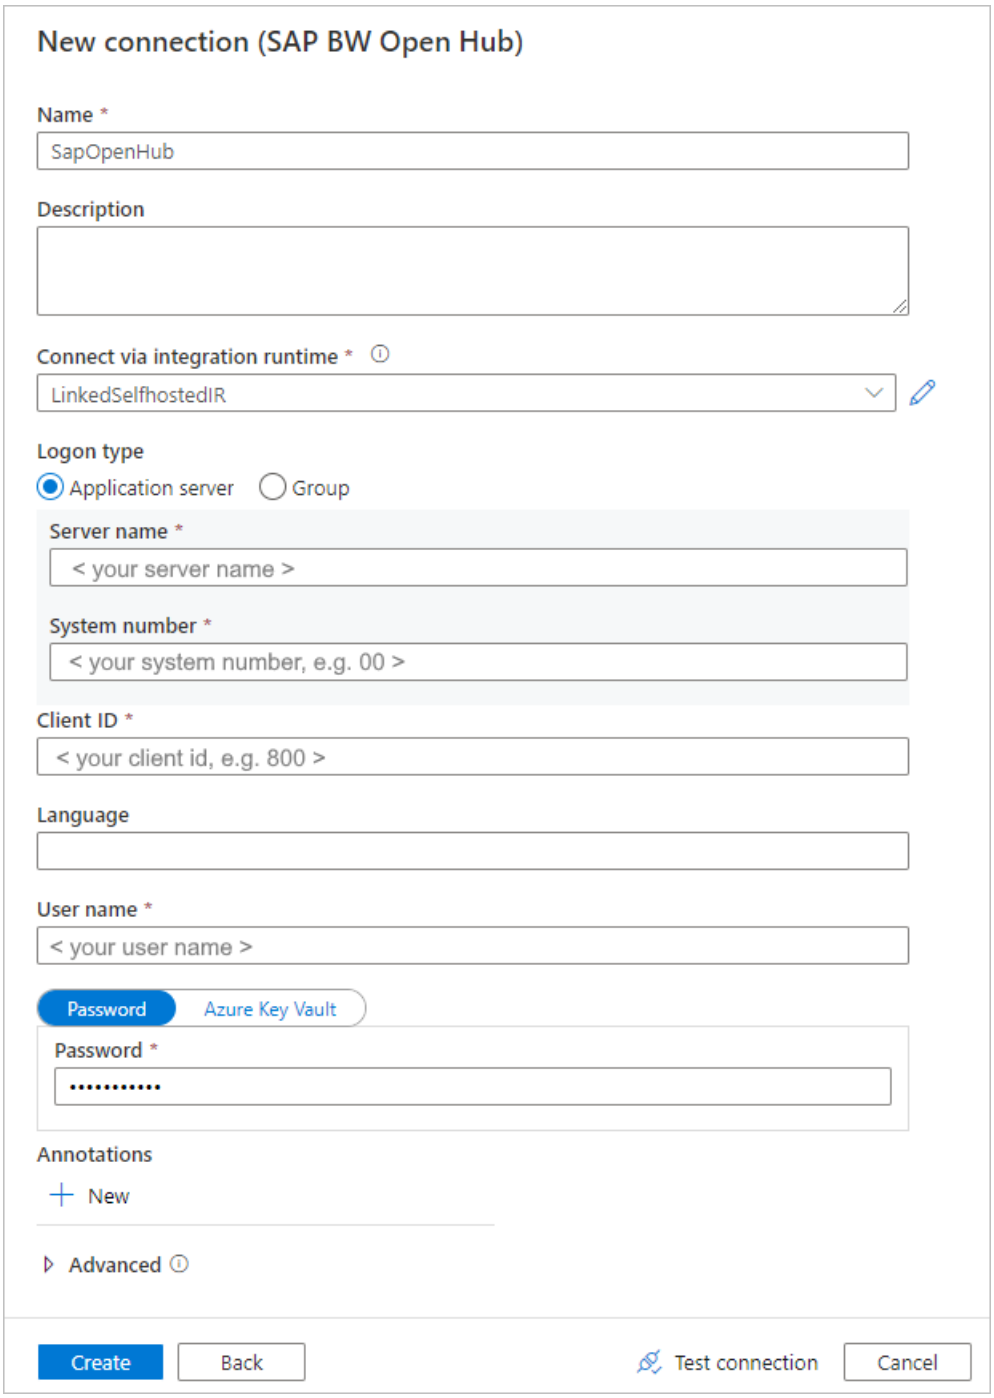
1. On the home page, select **Ingest** to open the Copy Data tool.
2. On the **Properties** page, choose **Built-in copy task** under **Task type**, and choose **Run once now** under **Task cadence or task schedule**, and then select **Next**.
3. On the **Source data store** page, select **+ New connection**. Select **SAP BW Open Hub** from the connector gallery, and then select **Continue**. To filter the connectors, you can type **SAP** in the search box.
4. On the **New connection (SAP BW Open Hub)** page, follow these steps to create a new connection.
   a. From the **Connect via integration runtime** list, select an existing self-hosted IR. Or, choose to create one if you don't have one yet.

      To create a new self-hosted IR, select **+New**, and then select **Self-hosted**. Enter a **Name**, and then select **Next**. Select **Express setup** to install on the current computer, or follow the **Manual setup** steps that are provided.

      As mentioned in Prerequisites, make sure that you have SAP Connector for Microsoft .NET 3.0 installed on the same computer where the self-hosted IR is running.

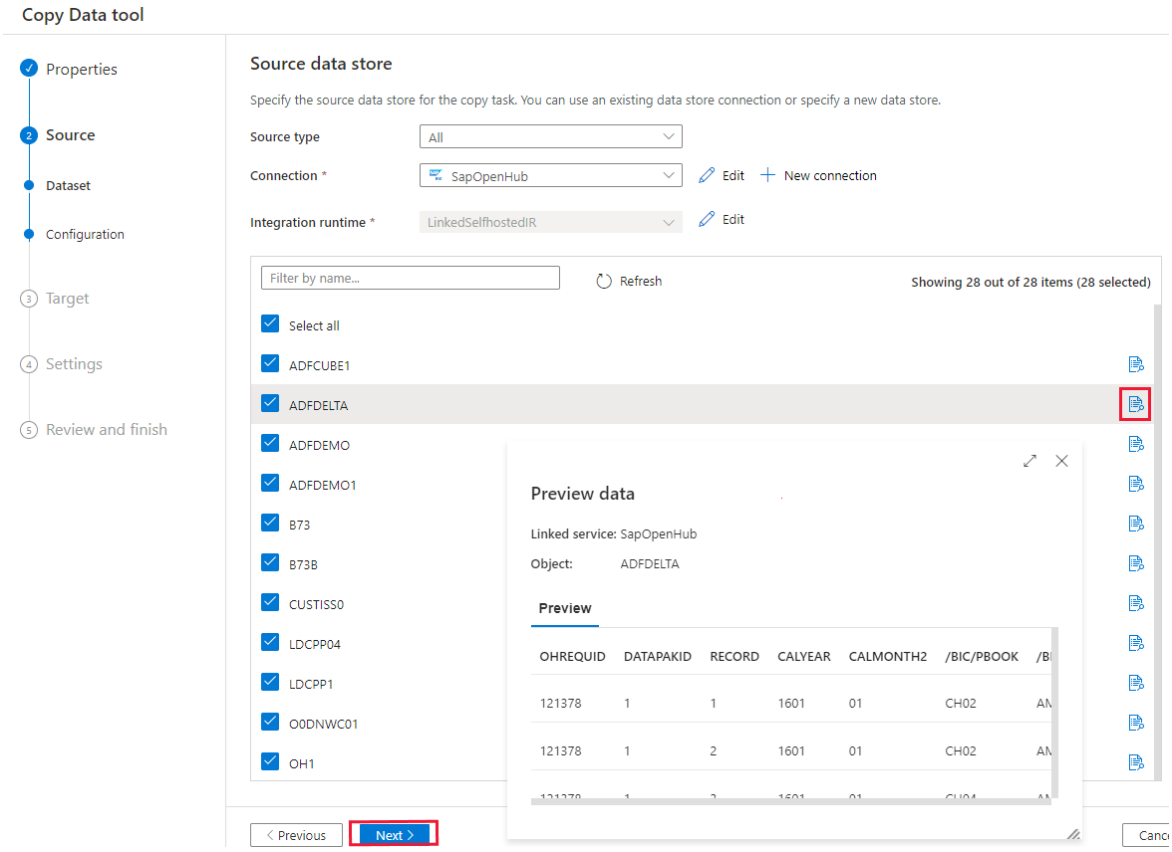
   b. Fill in the SAP BW **Server name**, **System number**, **Client ID**, **Language** (if other than **EN**), **User name**, and **Password**.

   c. Select **Test connection** to validate the settings, and then select **Create**.



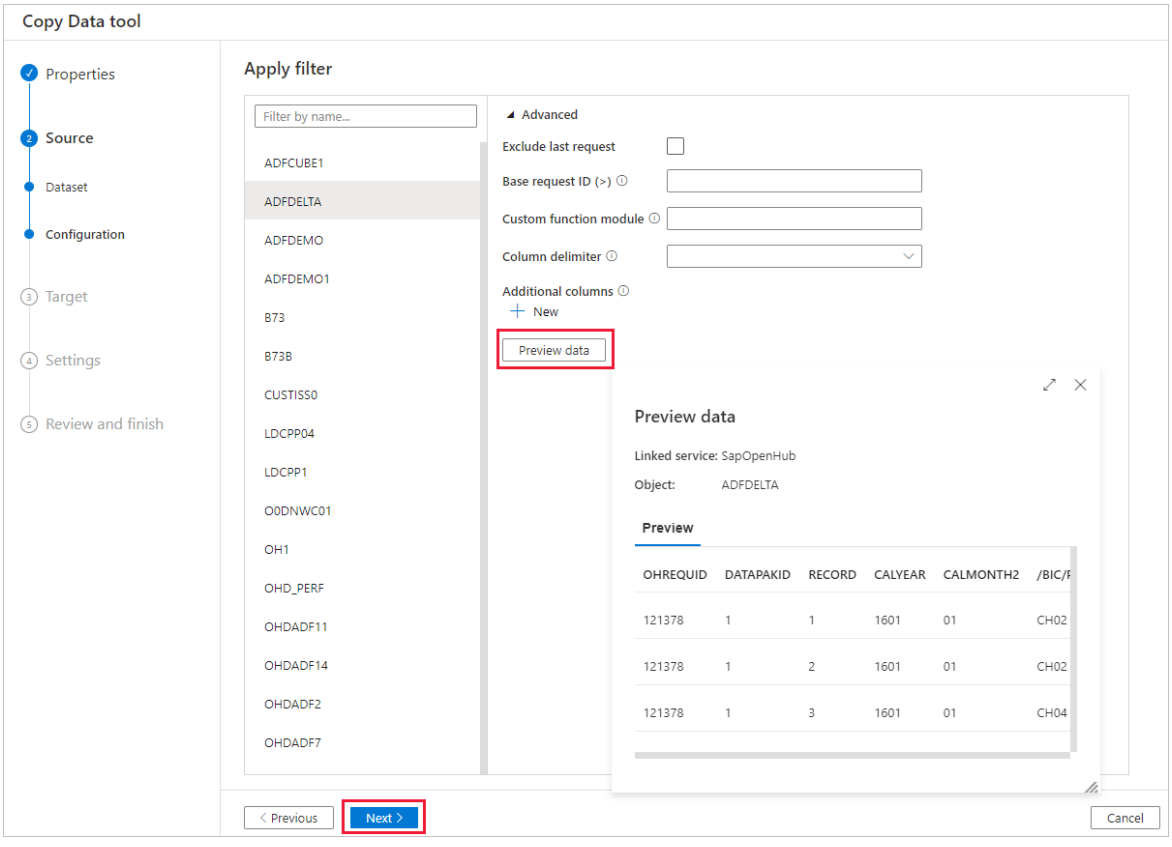
d. On the **Source data store** page, select the newly created connection in the **Connection** block.

e. In the section of selecting Open Hub destinations, browse the Open Hub Destinations that are available in your SAP BW. You can preview the data in each destination by selecting the preview button at the end of each row. Select the OHD to copy data from, and then select **Next**.



5. Specify a filter, if you need one. If your OHD only contains data from a single data-transfer process (DTP) execution with a single request ID, or you're sure that your DTP is finished and you want to copy the data, clear the **Exclude Last Request** check box in **Advanced** section. You can preview the data by selecting **Preview data** button.

   Learn more about these settings in the SAP BW Open Hub Destination configurations section of this article. Then select **Next**.



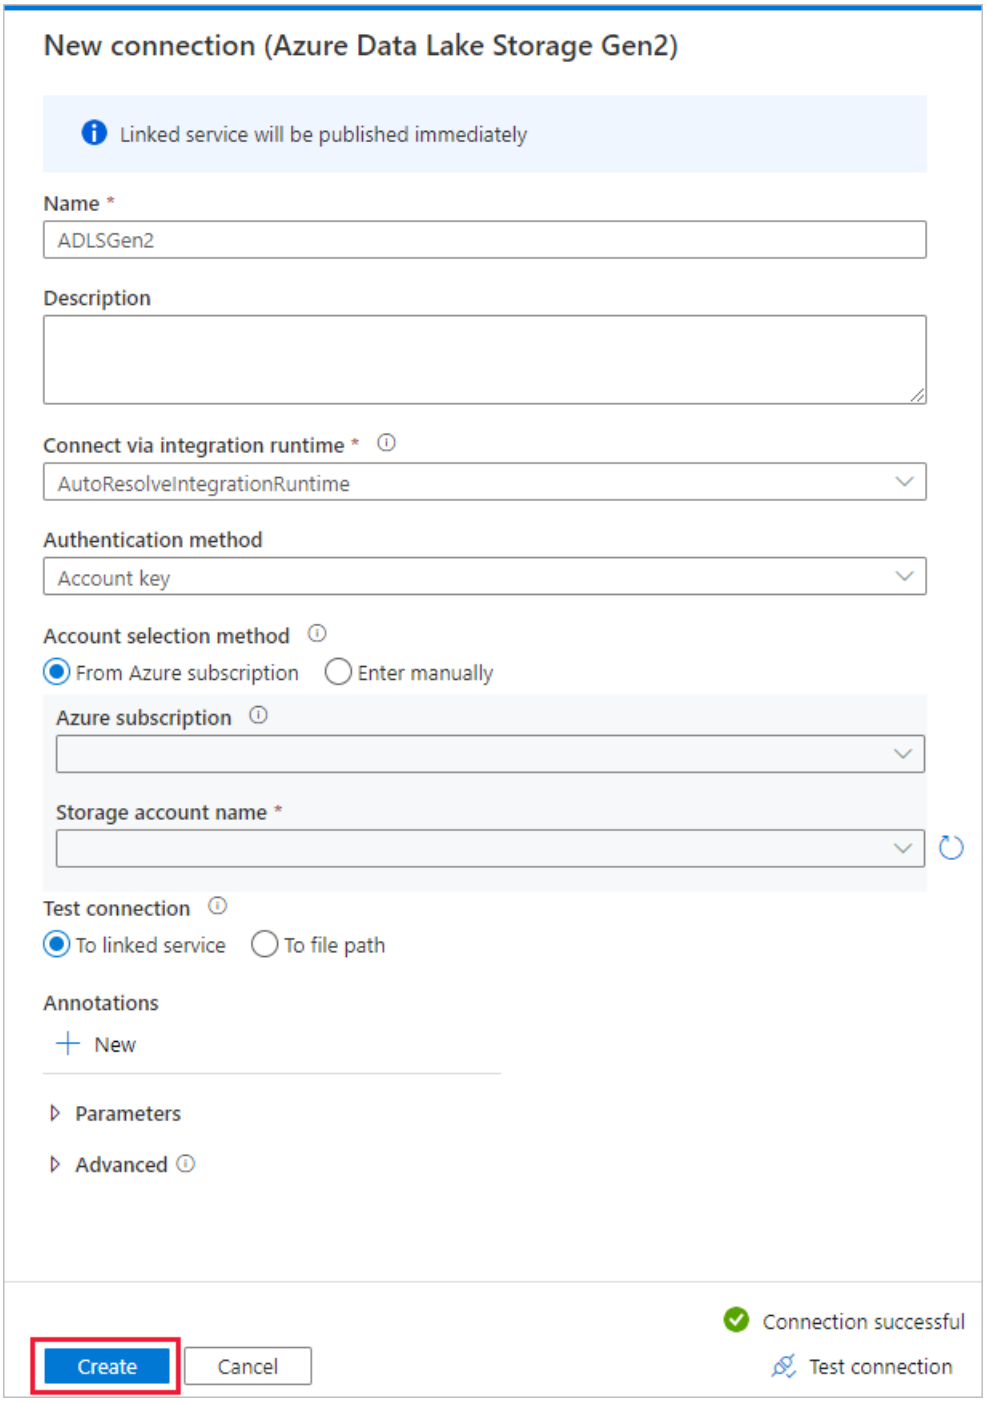
6. On the **Destination data store** page, select **+ New connection** > **Azure Data Lake Storage Gen2** >

Continue.

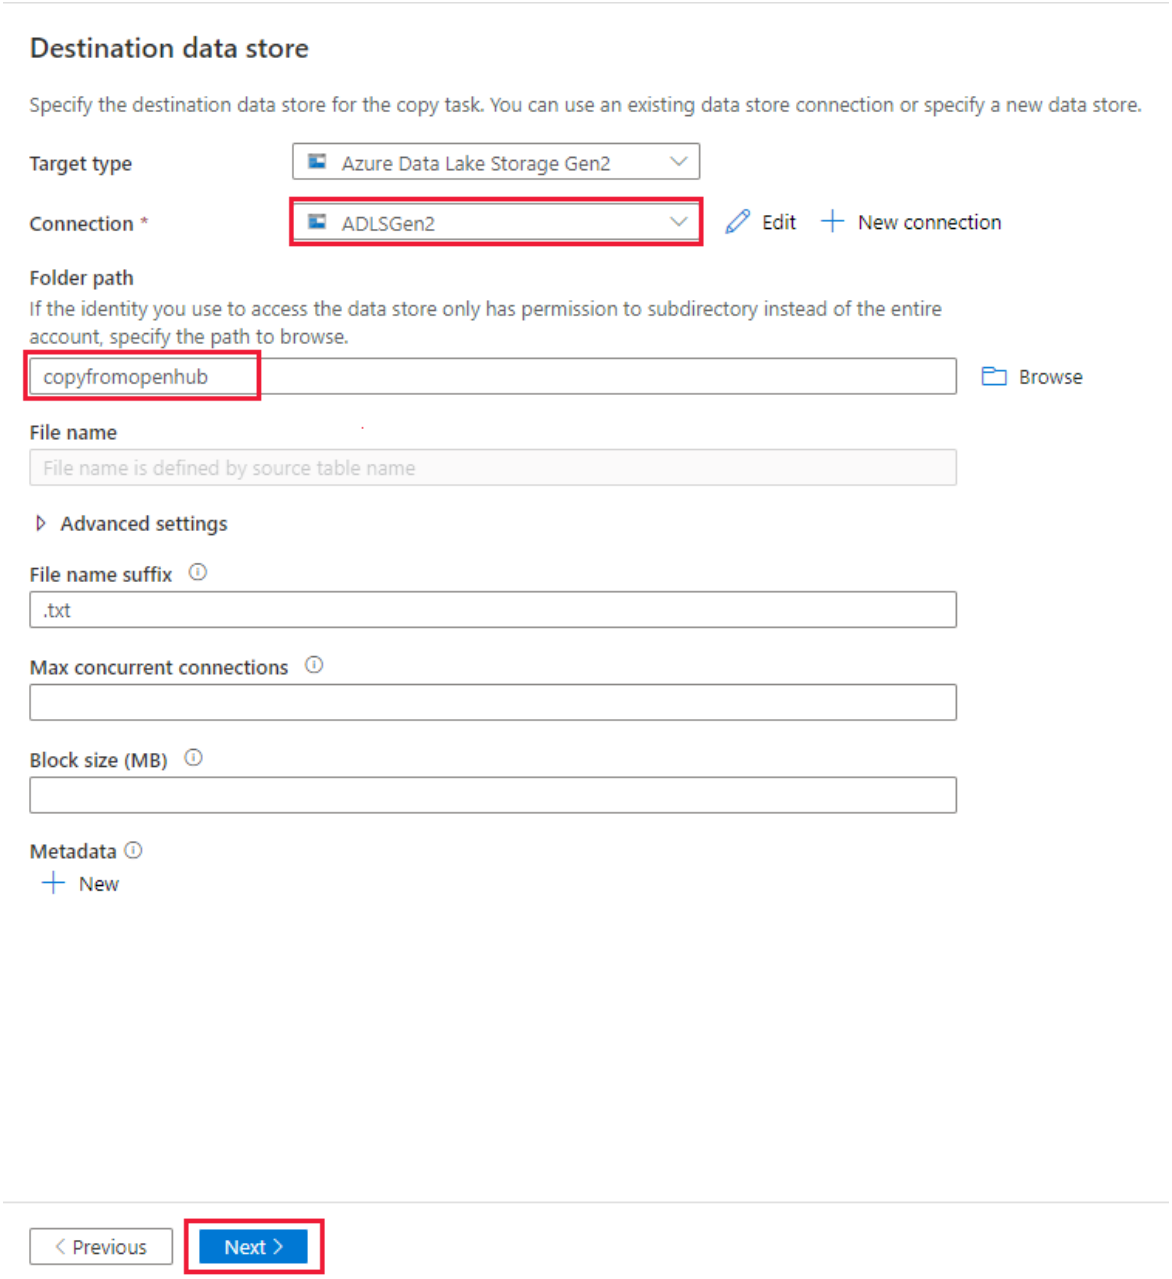
7. On the **New connection (Azure Data Lake Storage Gen2)** page, follow these steps to create a connection.

   a. Select your Data Lake Storage Gen2-capable account from the **Name** drop-down list.

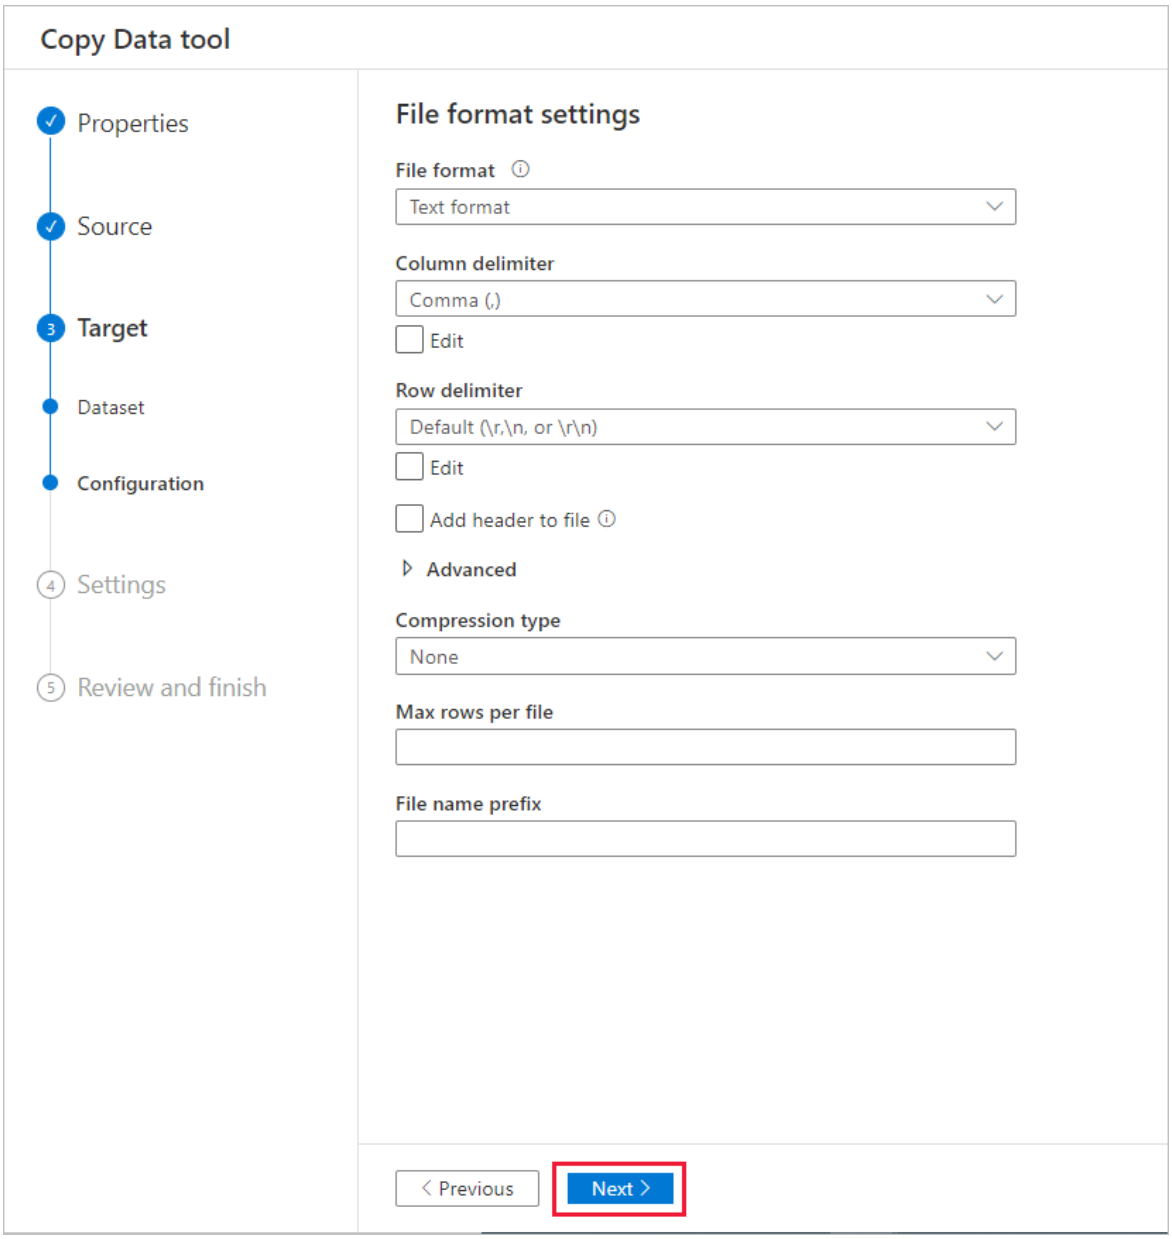
   b. Select **Create** to create the connection.



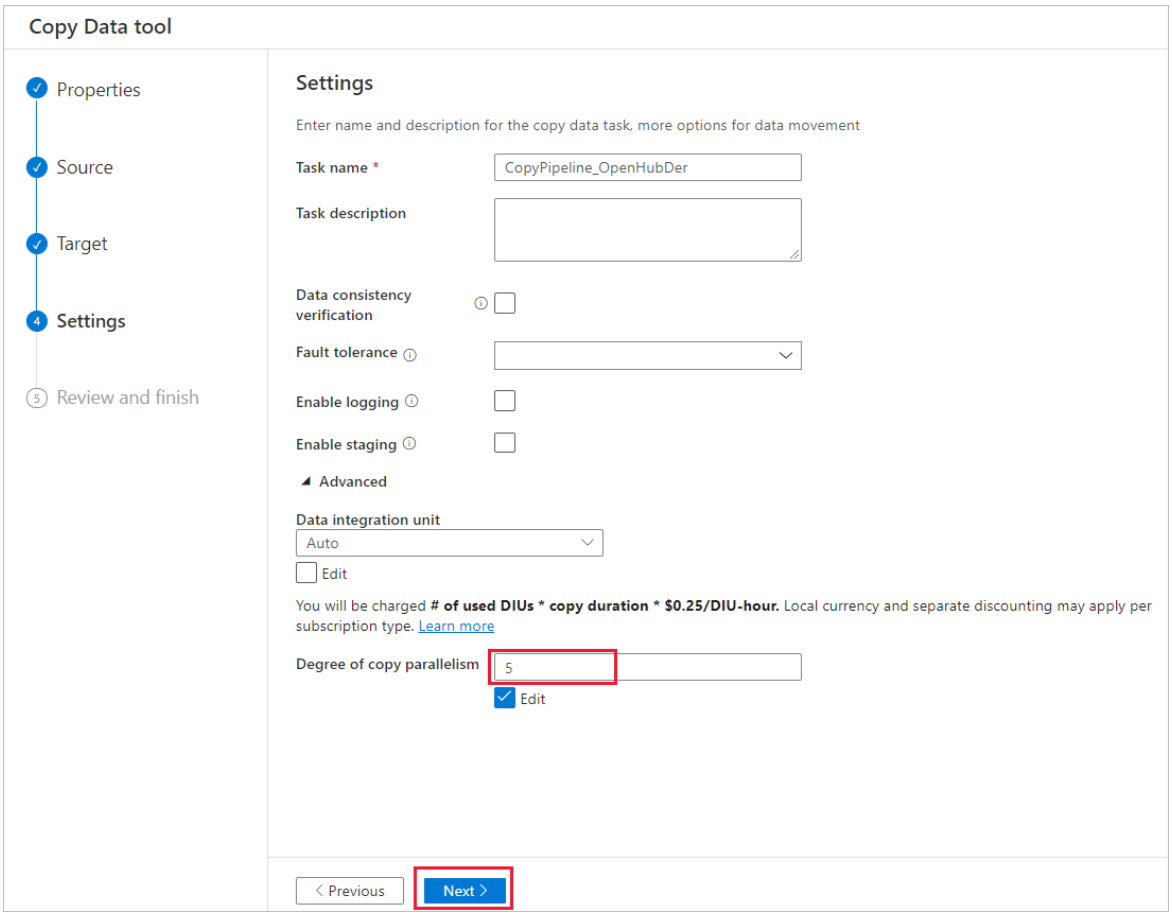
8. On the **Destination data store** page, select the newly created connection in the **Connection** section, and enter **copyfromopenhub** as the output folder name. Then select **Next**.



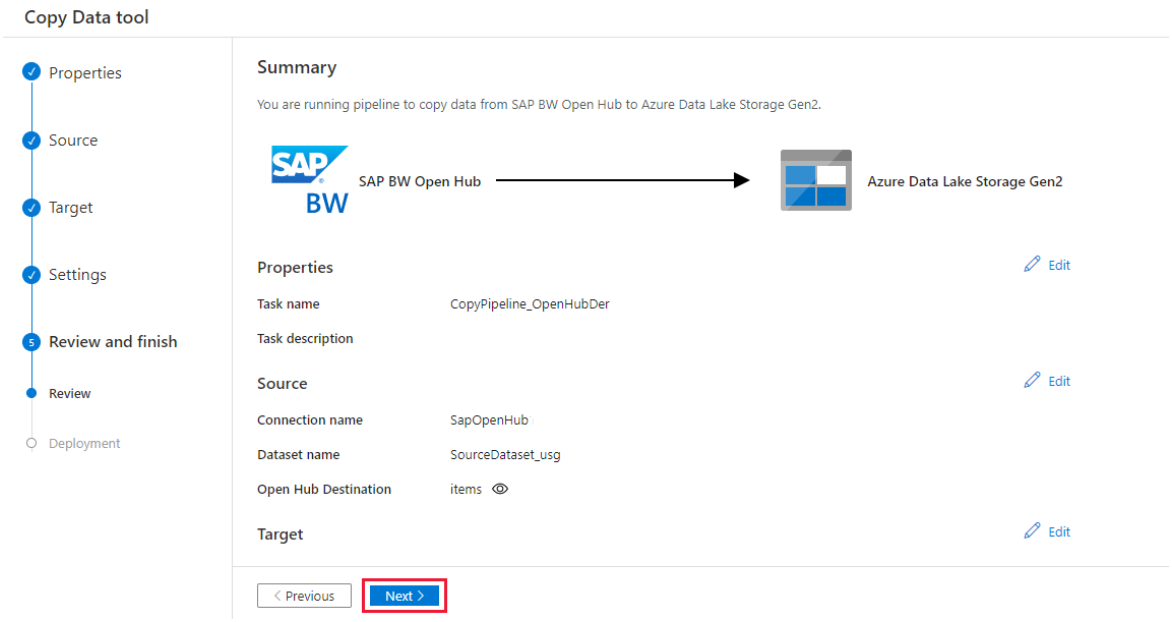
9. On the **File format setting** page, select **Next** to use the default settings.



10. On the **Settings** page, specify a **Task name**, and expand **Advanced**. Enter a value for **Degree of copy parallelism** such as 5 to load from SAP BW in parallel. Then select **Next**.



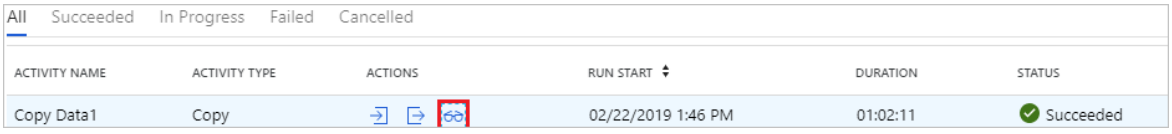
11. On the **Summary** page, review the settings. Then select **Next**.



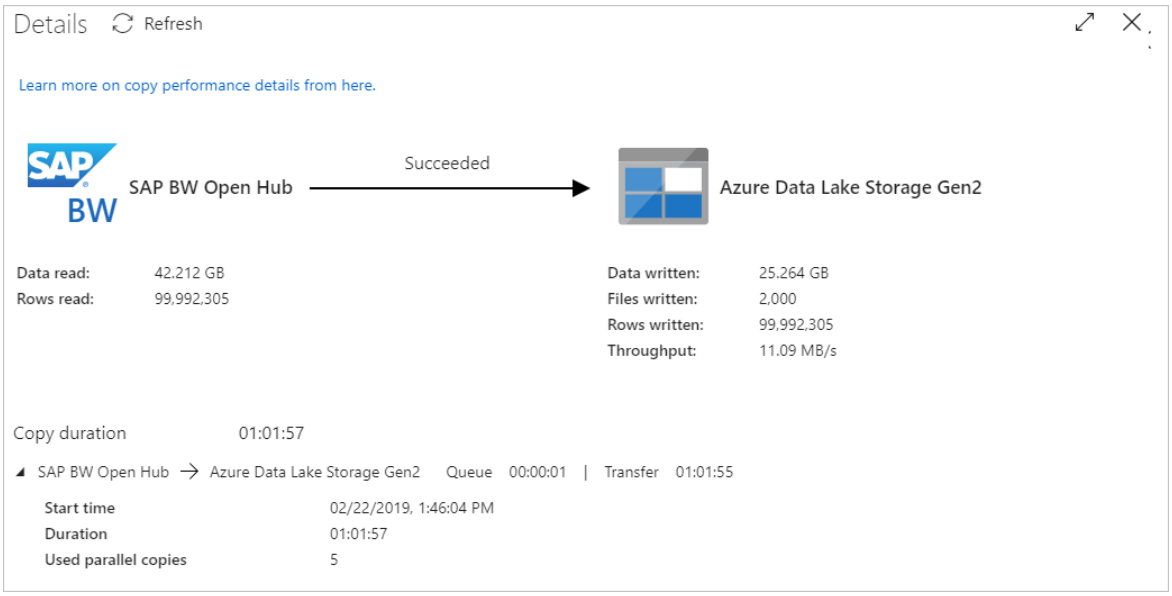
12. On the **Deployment** page, select **Monitor** to monitor the pipeline.

13. Notice that the **Monitor** tab on the left side of the page is automatically selected. You can use links under the **Pipeline name** column in the **Pipeline runs** page to view activity details and to rerun the pipeline.

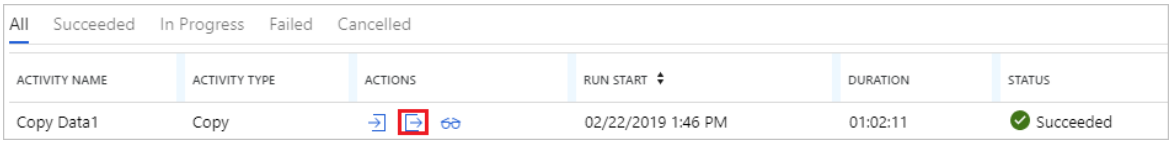
14. To view activity runs that are associated with the pipeline run, select links under the **Pipeline name** column. There's only one activity (copy activity) in the pipeline, so you see only one entry. To switch back to the pipeline-runs view, select the **All pipeline runs** link at the top. Select **Refresh** to refresh the list.

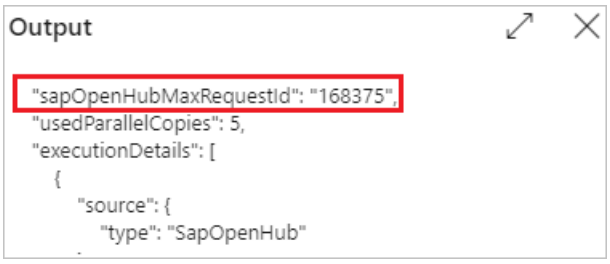


15. To monitor the execution details for each copy activity, select the **Details** link, which is an eyeglasses icon in the same row of each copy activity in the activity-monitoring view. Available details include the data volume copied from the source to the sink, data throughput, execution steps and duration, and configurations used.



16. To view the **maximum Request ID** of each copy activity, go back to the activity-monitoring view and select **Output** in the same row of each copy activity.



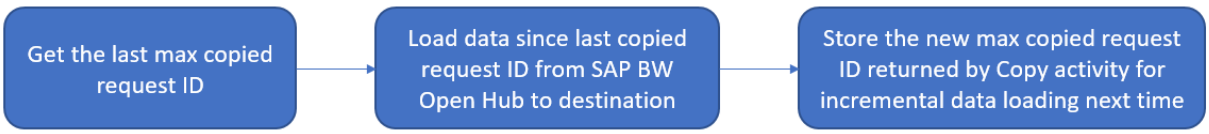


Incremental copy from SAP BW Open Hub

> **TIP**
> See SAP BW Open Hub connector delta extraction flow to learn how the SAP BW Open Hub connector copies incremental data from SAP BW. This article can also help you understand basic connector configuration.

Now, let's continue to configure incremental copy from SAP BW Open Hub.

Incremental copy uses a "high-watermark" mechanism that's based on the **request ID**. That ID is automatically generated in SAP BW Open Hub Destination by the DTP. The following diagram shows this workflow:

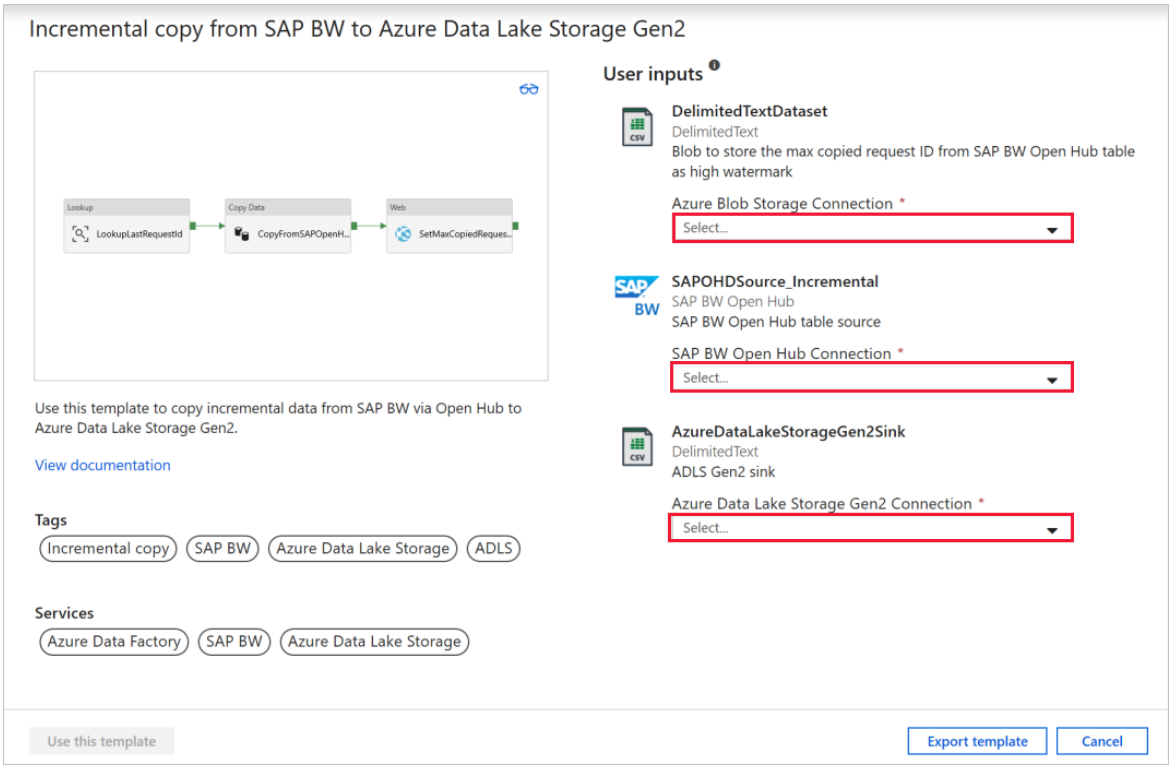


On the home page, select **Pipeline templates** in the **Discover more** section to use the built-in template.

1. Search for **SAP BW** to find and select the **Incremental copy from SAP BW to Azure Data Lake Storage Gen2** template. This template copies data into Azure Data Lake Storage Gen2. You can use a similar workflow to copy to other sink types.

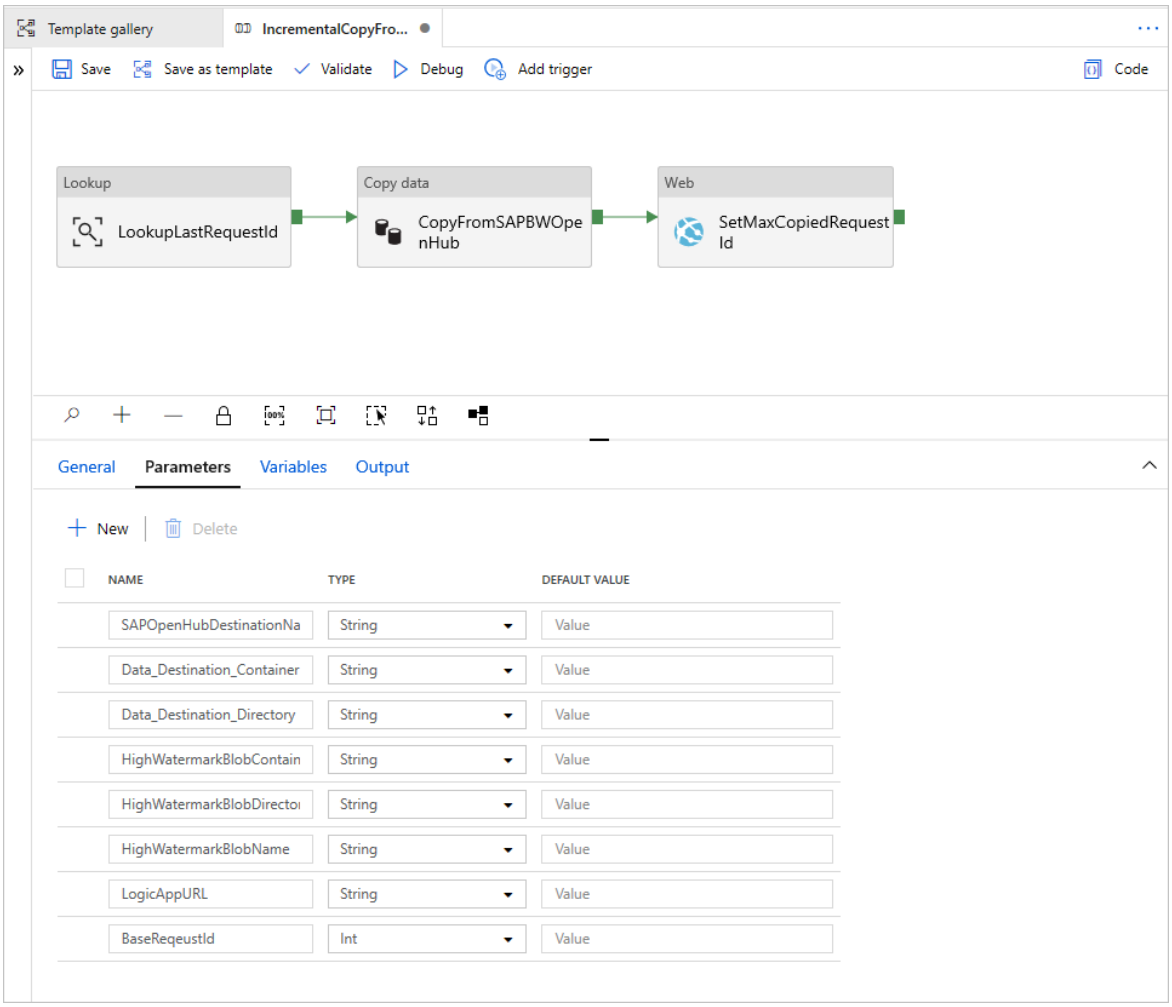
2. On the template's main page, select or create the following three connections, and then select **Use this template** in the lower-right corner of the window.

   - **Azure Blob storage**: In this walkthrough, we use Azure Blob storage to store the high watermark, which is the *max copied request ID*.
   - **SAP BW Open Hub**: This is the source to copy data from. Refer to the previous full-copy walkthrough for detailed configuration.
   - **Azure Data Lake Storage Gen2**: This is the sink to copy data to. Refer to the previous full-copy walkthrough for detailed configuration.



3. This template generates a pipeline with the following three activities and makes them chained on-success: *Lookup*, *Copy Data*, and *Web*.

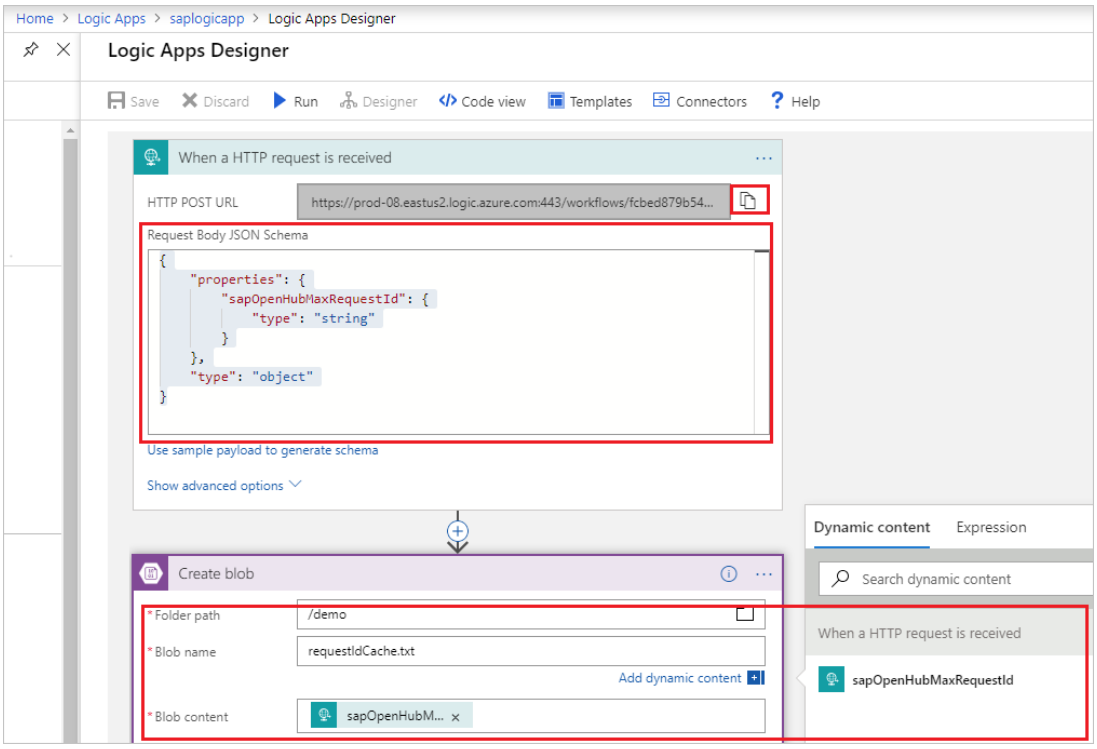
   Go to the pipeline **Parameters** tab. You see all the configurations that you need to provide.



- **SAPOpenHubDestinationName**: Specify the Open Hub table name to copy data from.
- **Data_Destination_Container**: Specify the destination Azure Data Lake Storage Gen2 container to copy data to. If the container doesn't exist, the copy activity creates one during execution.
- **Data_Destination_Directory**: Specify the folder path under the Azure Data Lake Storage Gen2 container to copy data to. If the path doesn't exist, the copy activity creates a path during execution.
- **HighWatermarkBlobContainer**: Specify the container to store the high-watermark value.
- **HighWatermarkBlobDirectory**: Specify the folder path under the container to store the high-watermark value.
- **HighWatermarkBlobName**: Specify the blob name to store the high watermark value, such as `requestIdCache.txt`. In Blob storage, go to the corresponding path of HighWatermarkBlobContainer+HighWatermarkBlobDirectory+HighWatermarkBlobName, such as *container/path/requestIdCache.txt*. Create a blob with content 0.

- **LogicAppURL**: In this template, we use WebActivity to call Azure Logic Apps to set the high-watermark value in Blob storage. Or, you can use Azure SQL Database to store it. Use a stored procedure activity to update the value.

  You must first create a logic app, as the following image shows. Then, paste in the **HTTP POST URL**.



a. Go to the Azure portal. Select a new **Logic Apps** service. Select **+Blank Logic App** to go to **Logic Apps Designer**.

b. Create a trigger of **When an HTTP request is received**. Specify the HTTP request body as follows:

```
{
   "properties": {
      "sapOpenHubMaxRequestId": {
         "type": "string"
      }
   },
   "type": "object"
}
```

c. Add a **Create blob** action. For **Folder path** and **Blob name**, use the same values that you configured previously in *HighWatermarkBlobContainer+HighWatermarkBlobDirectory* and *HighWatermarkBlobName*.

d. Select **Save**. Then, copy the value of **HTTP POST URL** to use in the pipeline.

4. After you provide the pipeline parameters, select **Debug** > **Finish** to invoke a run to validate the configuration. Or, select **Publish** to publish all the changes, and then select **Add trigger** to execute a run.

SAP BW Open Hub Destination configurations

This section introduces configuration of the SAP BW side to use the SAP BW Open Hub connector to copy data.

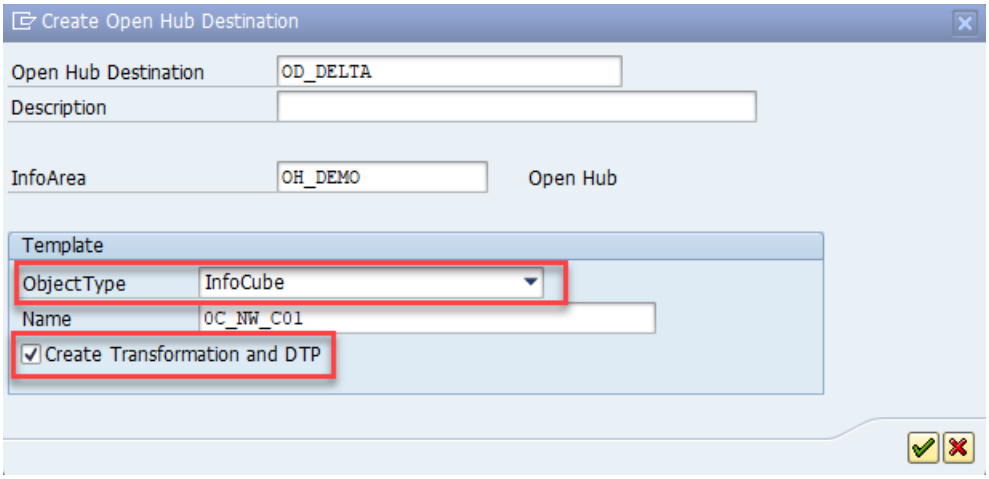
Configure delta extraction in SAP BW

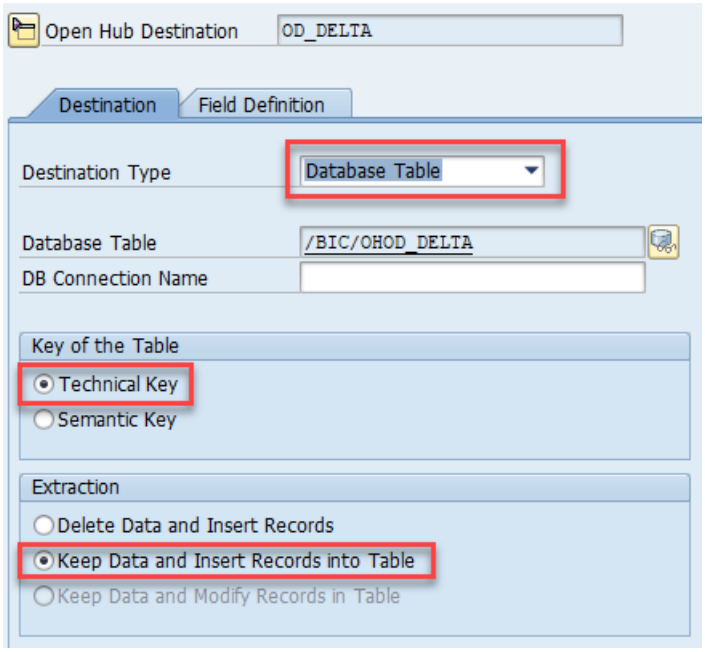
If you need both historical copy and incremental copy or only incremental copy, configure delta extraction in SAP BW.

1. Create the Open Hub Destination. You can create the OHD in SAP Transaction RSA1, which automatically creates the required transformation and data-transfer process. Use the following settings:

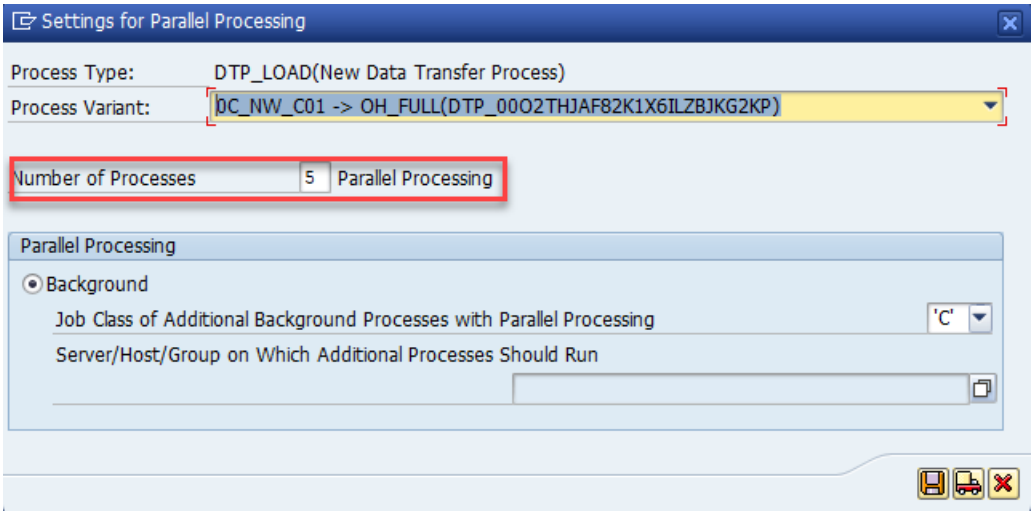
   - **ObjectType**: You can use any object type. Here, we use **InfoCube** as an example.

- **Destination Type**: Select **Database Table**.
- **Key of the Table**: Select **Technical Key**.
- **Extraction**: Select **Keep Data and Insert Records into Table**.





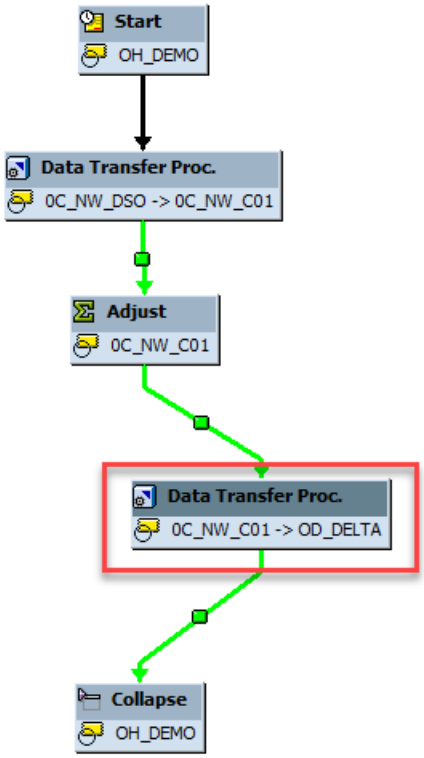
You might increase the number of parallel running SAP work processes for the DTP:



2. Schedule the DTP in process chains.

   A delta DTP for a cube only works if the necessary rows haven't been compressed. Make sure that BW cube compression isn't running before the DTP to the Open Hub table. The easiest way to do this is to integrate the DTP into your existing process chains. In the following example, the DTP (to the OHD) is

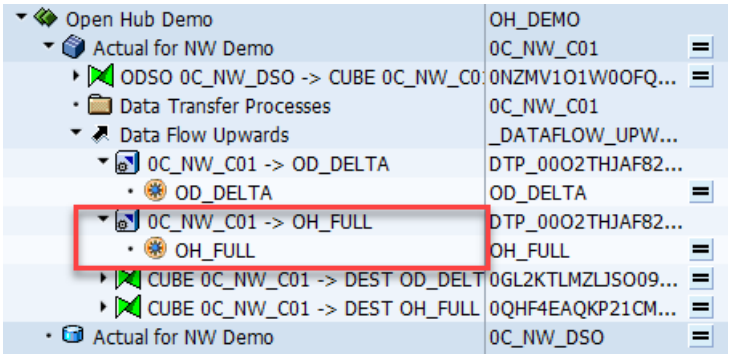
inserted into the process chain between the *Adjust* (aggregate rollup) and *Collapse* (cube compression) steps.



Configure full extraction in SAP BW

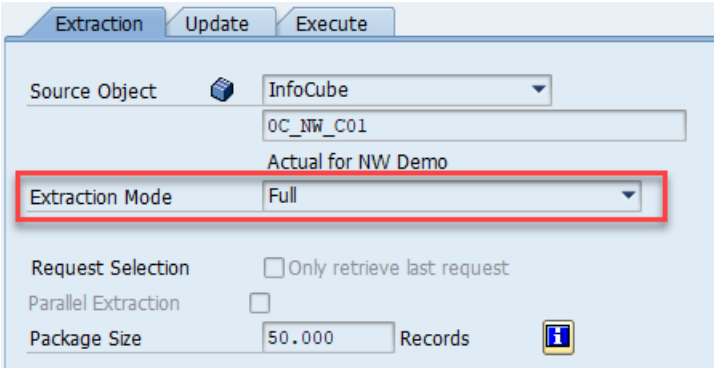
In addition to delta extraction, you might want a full extraction of the same SAP BW InfoProvider. This usually applies if you want to do full copy but not incremental, or you want to resync delta extraction.

You can't have more than one DTP for the same OHD. So, you must create an additional OHD before delta extraction.



For a full load OHD, choose different options than for delta extraction:

- In OHD: Set the **Extraction** option to **Delete Data and Insert Records**. Otherwise, data will be extracted many times when you repeat the DTP in a BW process chain.
- In the DTP: Set **Extraction Mode** to **Full**. You must change the automatically created DTP from **Delta** to **Full** immediately after the OHD is created, as this image shows:



- In the BW Open Hub connector: Turn off **Exclude last request**. Otherwise, nothing will be extracted.

You typically run the full DTP manually. Or, you can create a process chain for the full DTP. It's typically a separate chain that's independent of your existing process chains. In either case, *make sure that the DTP is finished before you start the extraction by using copy*. Otherwise, only partial data will be copied.

Run delta extraction the first time

The first delta extraction is technically a *full extraction*. By default, the SAP BW Open Hub connector excludes the last request when it copies data. For the first delta extraction, no data is extracted by the copy activity until a subsequent DTP generates delta data in the table with a separate request ID. There are two ways to avoid this scenario:

- Turn off the **Exclude last request** option for the first delta extraction. Make sure that the first delta DTP is finished before you start the delta extraction the first time.
- Use the procedure for resyncing the delta extraction, as described in the next section.

Resync delta extraction

The following scenarios change the data in SAP BW cubes but are not considered by the delta DTP:

- SAP BW selective deletion (of rows by using any filter condition)
- SAP BW request deletion (of faulty requests)

An SAP Open Hub Destination isn't a data-mart-controlled data target (in all SAP BW support packages since 2015). So, you can delete data from a cube without changing the data in the OHD. You must then resync the data of the cube with the service:

1. Run a full extraction in the service (by using a full DTP in SAP).
2. Delete all rows in the Open Hub table for the delta DTP.
3. Set the status of the delta DTP to **Fetched**.

After this, all subsequent delta DTPs and delta extractions work as expected.

To set the status of the delta DTP to **Fetched**, you can use the following option to run the delta DTP manually:

No Data Transfer; Delta Status in Source: Fetched

SAP Business Warehouse Open Hub connector

Copy data from SAP Business Warehouse using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from an SAP Business Warehouse (BW). It builds on the copy activity overview article that presents a general overview of copy activity.

> **TIP**
> To learn the service's overall support on SAP data integration scenario, see SAP data integration using Azure Data Factory whitepaper with detailed introduction on each SAP connector, comparison and guidance.

Supported capabilities

This SAP Business Warehouse connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this SAP Business Warehouse connector supports:

- SAP Business Warehouse **version 7.x**.
- Copying data from **InfoCubes and QueryCubes** (including BEx queries) using MDX queries.
- Copying data using basic authentication.

> **NOTE**
> The SAP Business Warehouse connector does not currently support parameters with MDX. If filtering with MDX parameters is required you can consider using the alternative SAP Open Hub connector instead.

Prerequisites

To use this SAP Business Warehouse connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Install the **SAP NetWeaver library** on the Integration Runtime machine. You can get the SAP Netweaver library from your SAP administrator, or directly from the SAP Software Download Center. Search for the **SAP Note #1025361** to get the download location for the most recent version. Make sure that you pick the **64-**

bit SAP NetWeaver library which matches your Integration Runtime installation. Then install all files included in the SAP NetWeaver RFC SDK according to the SAP Note. The SAP NetWeaver library is also included in the SAP Client Tools installation.

> **TIP**
>
> To troubleshoot connectivity issue to SAP BW, make sure:
>
> - All dependency libraries extracted from the NetWeaver RFC SDK are in place in the %windir%\system32 folder. Usually it has icudt34.dll, icuin34.dll, icuuc34.dll, libicudecnumber.dll, librfc32.dll, libsapucum.dll, sapcrypto.dll, sapcryto_old.dll, sapnwrfc.dll.
> - The needed ports used to connect to SAP Server are enabled on the Self-hosted IR machine, which usually are port 3300 and 3201.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

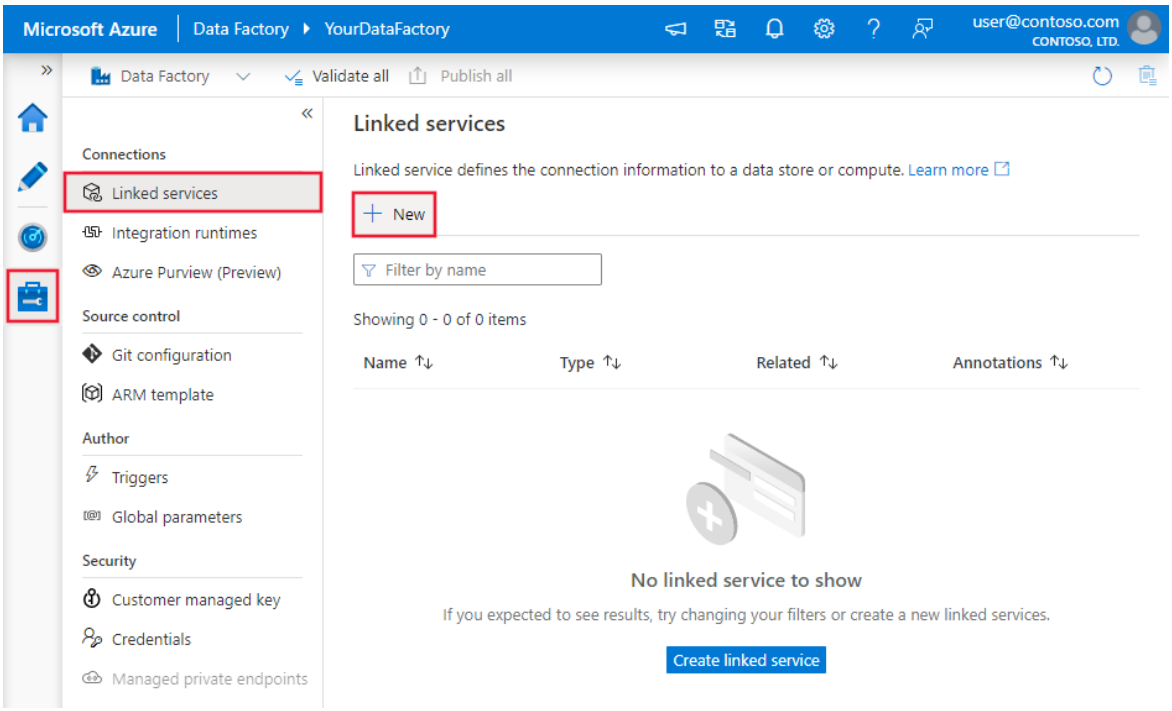
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to SAP BW using UI

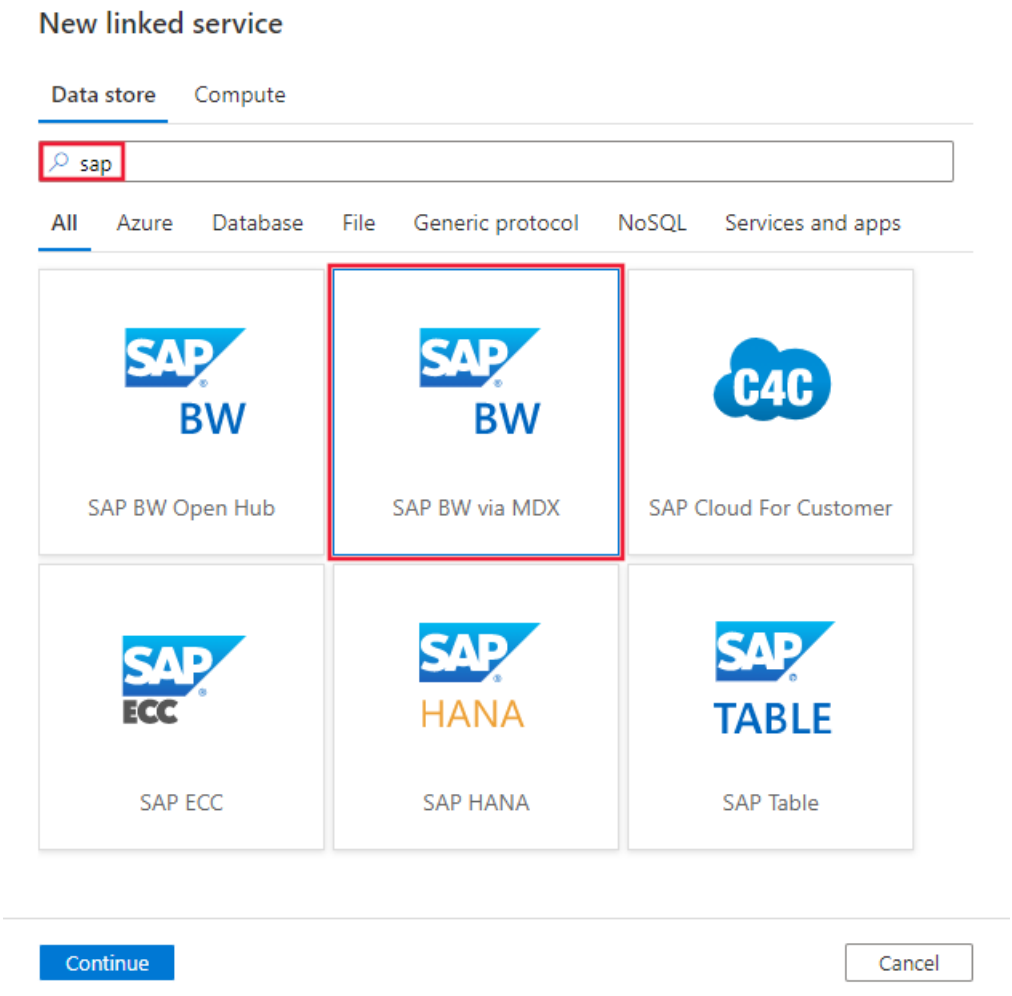
Use the following steps to create a linked service to SAP BW in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

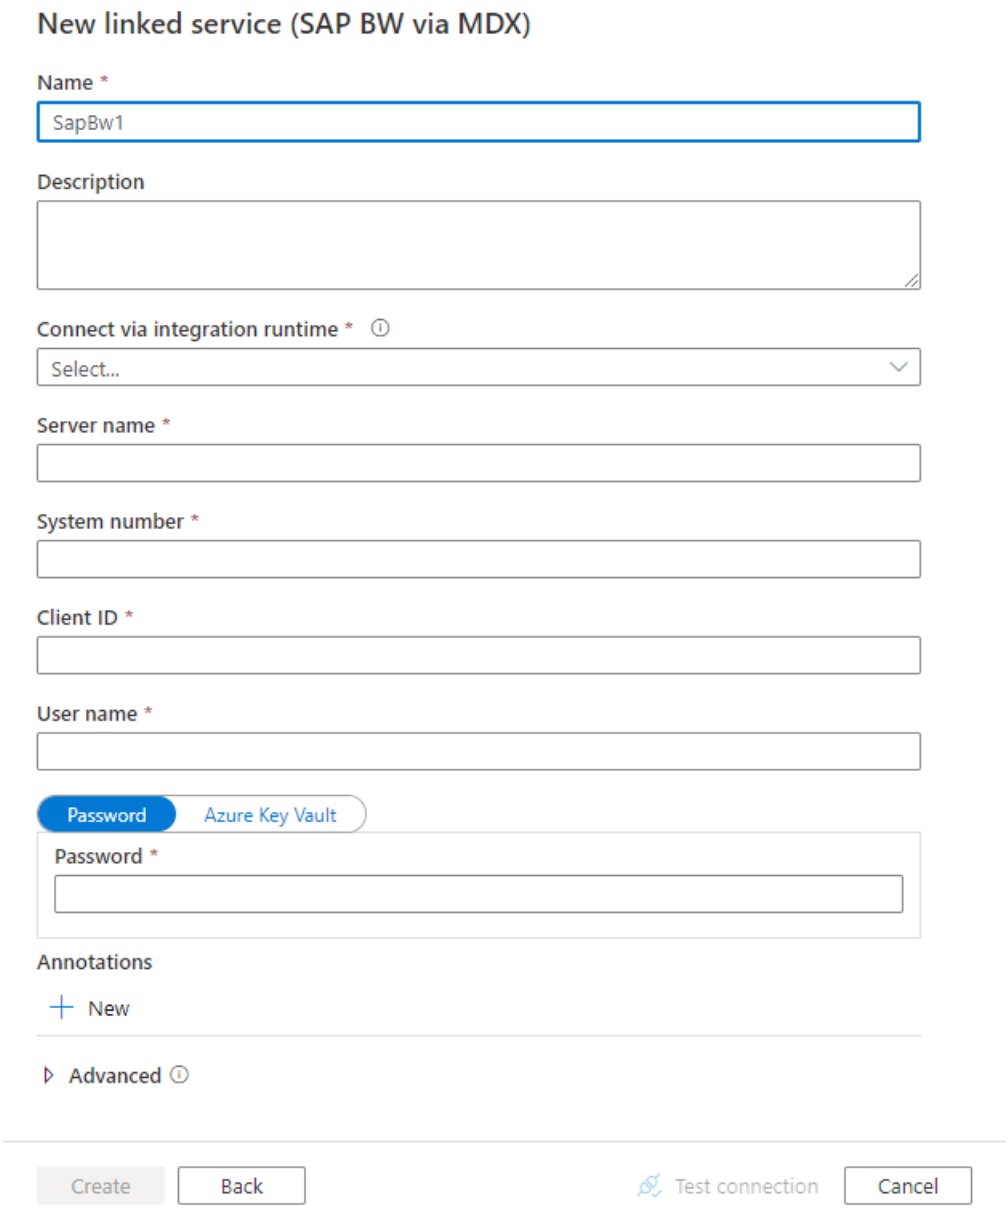
   - Azure Data Factory
   - Azure Synapse



2. Search for SAP and select the SAP BW via MDX connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to SAP Business Warehouse connector.

Linked service properties

The following properties are supported for SAP Business Warehouse (BW) linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapBw**	Yes
server	Name of the server on which the SAP BW instance resides.	Yes
systemNumber	System number of the SAP BW system. Allowed value: two-digit decimal number represented as a string.	Yes

PROPERTY	DESCRIPTION	REQUIRED
clientId	Client ID of the client in the SAP W system. Allowed value: three-digit decimal number represented as a string.	Yes
userName	Name of the user who has access to the SAP server.	Yes
password	Password for the user. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "SapBwLinkedService",
    "properties": {
        "type": "SapBw",
        "typeProperties": {
            "server": "<server name>",
            "systemNumber": "<system number>",
            "clientId": "<client id>",
            "userName": "<SAP user>",
            "password": {
                "type": "SecureString",
                "value": "<Password for SAP user>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by SAP BW dataset.

To copy data from SAP BW, set the type property of the dataset to **SapBwCube**. While there are no type-specific properties supported for the SAP BW dataset of type RelationalTable.

Example:

```
{
    "name": "SAPBWDataset",
    "properties": {
        "type": "SapBwCube",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP BW linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by SAP BW source.

SAP BW as source

To copy data from SAP BW, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SapBwSource**	Yes
query	Specifies the MDX query to read data from the SAP BW instance.	Yes

Example:

```
"activities":[
    {
        "name": "CopyFromSAPBW",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP BW input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapBwSource",
                "query": "<MDX query for SAP BW>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Data type mapping for SAP BW

When copying data from SAP BW, the following mappings are used from SAP BW data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

SAP BW DATA TYPE	INTERIM SERVICE DATA TYPE
ACCP	Int
CHAR	String
CLNT	String
CURR	Decimal
CUKY	String
DEC	Decimal
FLTP	Double
INT1	Byte
INT2	Int16

SAP BW DATA TYPE	INTERIM SERVICE DATA TYPE
INT4	Int
LANG	String
LCHR	String
LRAW	Byte[]
PREC	Int16
QUAN	Decimal
RAW	Byte[]
RAWSTRING	Byte[]
STRING	String
UNIT	String
DATS	String
NUMC	String
TIMS	String

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from or to SAP Cloud for Customer (C4C) using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from/to SAP Cloud for Customer (C4C). It builds on the copy activity overview article that presents a general overview of copy activity.

> **TIP**
> To learn the service's overall support on SAP data integration scenario, see SAP data integration using Azure Data Factory whitepaper with detailed introduction on each SAP connector, comparison and guidance.

Supported capabilities

This SAP Cloud for Customer connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this connector enables the service to copy data from/to SAP Cloud for Customer including the SAP Cloud for Sales, SAP Cloud for Service, and SAP Cloud for Social Engagement solutions.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

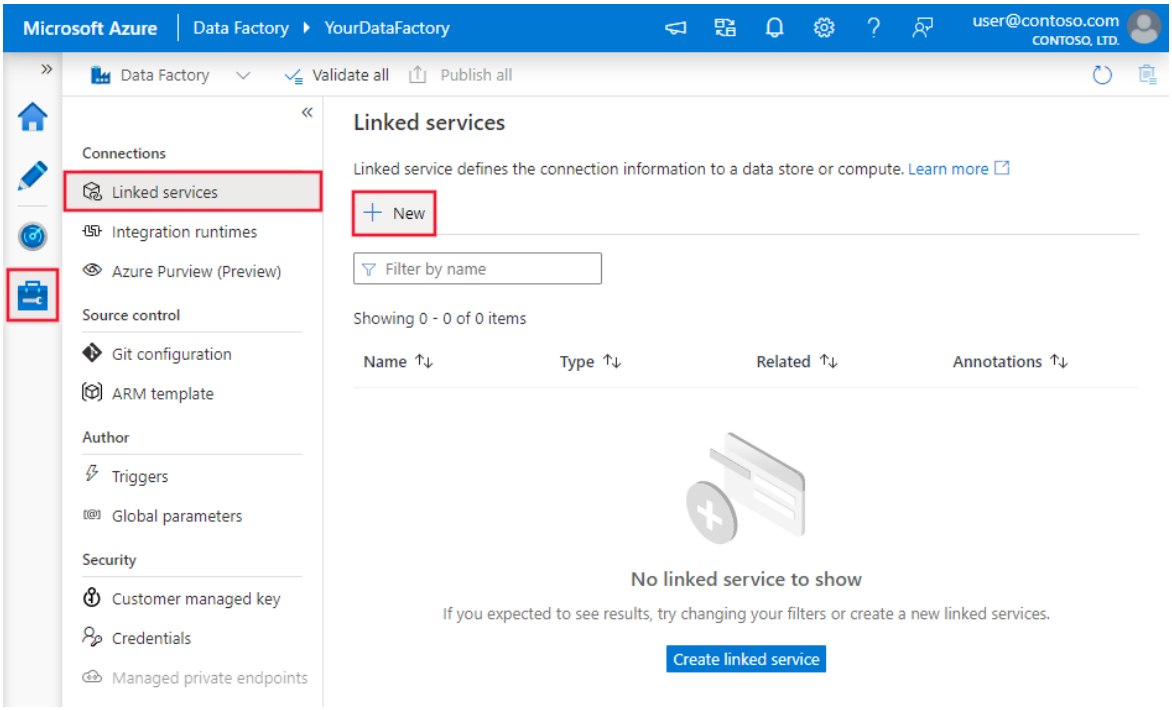
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to SAP Cloud for Customer using UI

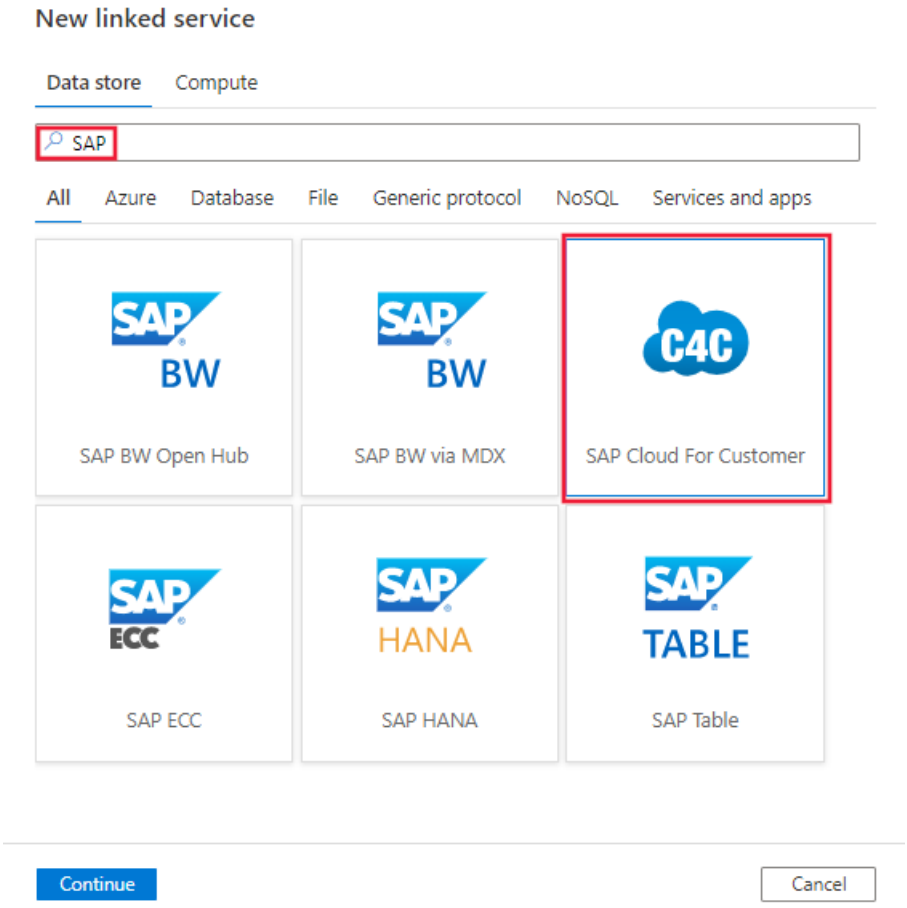
Use the following steps to create a linked service to SAP Cloud for Customer in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

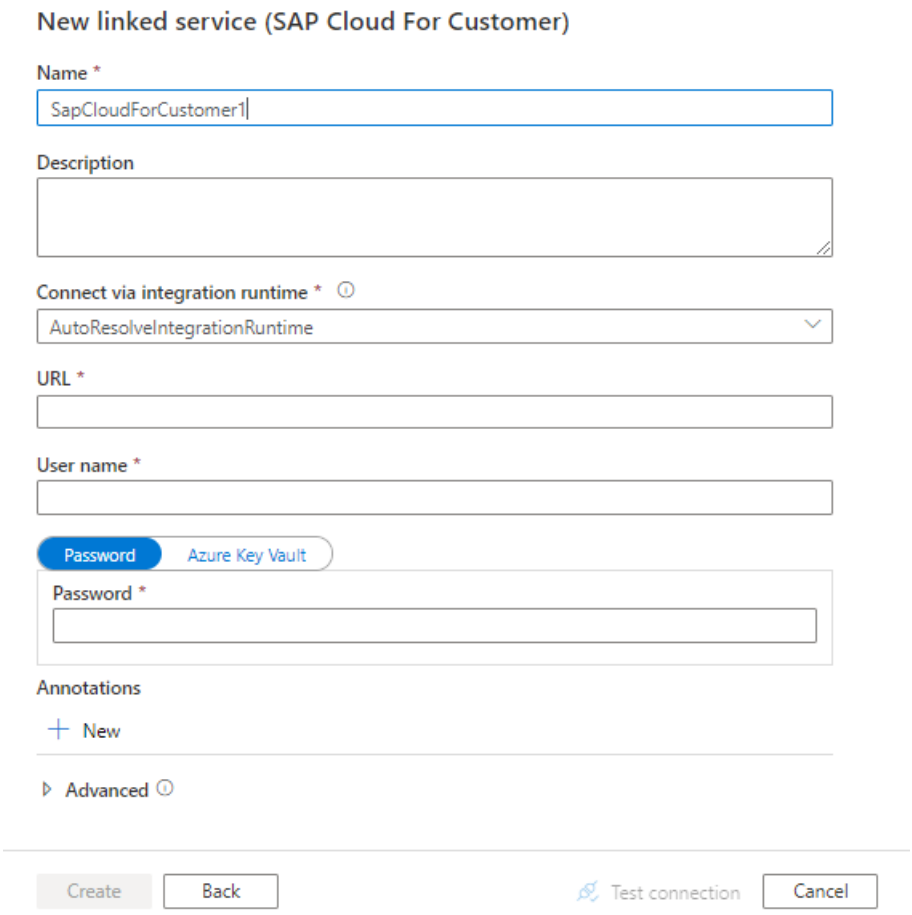
   - Azure Data Factory
   - Azure Synapse



2. Search for SAP and select the SAP Cloud for Customer connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to SAP Cloud for Customer connector.

Linked service properties

The following properties are supported for SAP Cloud for Customer linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapCloudForCustomer**.	Yes
url	The URL of the SAP C4C OData service.	Yes
username	Specify the user name to connect to the SAP C4C.	Yes
password	Specify the password for the user account you specified for the username. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to connect to the data store. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "SAPC4CLinkedService",
    "properties": {
        "type": "SapCloudForCustomer",
        "typeProperties": {
            "url": "https://<tenantname>.crm.ondemand.com/sap/c4c/odata/v1/c4codata/" ,
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by SAP Cloud for Customer dataset.

To copy data from SAP Cloud for Customer, set the type property of the dataset to **SapCloudForCustomerResource**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SapCloudForCustomerResource**	Yes
path	Specify path of the SAP C4C OData entity.	Yes

Example:

```
{
    "name": "SAPC4CDataset",
    "properties": {
        "type": "SapCloudForCustomerResource",
        "typeProperties": {
            "path": "<path e.g. LeadCollection>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP C4C linked service>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by SAP Cloud for Customer source.

SAP C4C as source

To copy data from SAP Cloud for Customer, set the source type in the copy activity to **SapCloudForCustomerSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapCloudForCustomerSource**	Yes
query	Specify the custom OData query to read data.	No
httpRequestTimeout	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. If not specified, the default value is **00:30:00** (30 minutes).	No

Sample query to get data for a specific day:

```
"query": "$filter=CreatedOn ge datetimeoffset'2017-07-31T10:02:06.4202620Z' and CreatedOn le
datetimeoffset'2017-08-01T10:02:06.4202620Z'"
```

Example:

```
"activities":[
    {
        "name": "CopyFromSAPC4C",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP C4C input dataset>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapCloudForCustomerSource",
                "query": "<custom query e.g. $top=10>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

SAP C4C as sink

To copy data to SAP Cloud for Customer, set the sink type in the copy activity to **SapCloudForCustomerSink**. The following properties are supported in the copy activity **sink** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapCloudForCustomerSink**	Yes
writeBehavior	The write behavior of the operation. Could be “Insert”, “Update”.	No. Default “Insert”.
writeBatchSize	The batch size of write operation. The batch size to get best performance may be different for different table or server.	No. Default 10.
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyToSapC4c",
        "type": "Copy",
        "inputs": [{
            "type": "DatasetReference",
            "referenceName": "<dataset type>"
        }],
        "outputs": [{
            "type": "DatasetReference",
            "referenceName": "SapC4cDataset"
        }],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SapCloudForCustomerSink",
                "writeBehavior": "Insert",
                "writeBatchSize": 30
            },
            "parallelCopies": 10,
            "dataIntegrationUnits": 4,
            "enableSkipIncompatibleRow": true,
            "redirectIncompatibleRowSettings": {
                "linkedServiceName": {
                    "referenceName": "ErrorLogBlobLinkedService",
                    "type": "LinkedServiceReference"
                },
                "path": "incompatiblerows"
            }
        }
    }
]
```

Data type mapping for SAP Cloud for Customer

When copying data from SAP Cloud for Customer, the following mappings are used from SAP Cloud for Customer data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

SAP C4C ODATA DATA TYPE	INTERIM SERVICE DATA TYPE
Edm.Binary	Byte[]
Edm.Boolean	Bool
Edm.Byte	Byte[]
Edm.DateTime	DateTime
Edm.Decimal	Decimal
Edm.Double	Double
Edm.Single	Single
Edm.Guid	Guid

SAP C4C ODATA DATA TYPE	INTERIM SERVICE DATA TYPE
Edm.Int16	Int16
Edm.Int32	Int32
Edm.Int64	Int64
Edm.SByte	Int16
Edm.String	String
Edm.Time	TimeSpan
Edm.DateTimeOffset	DateTimeOffset

Lookup activity properties

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from SAP ECC using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory to copy data from SAP Enterprise Central Component (ECC). For more information, see Copy activity overview.

> **TIP**
> To learn the overall support on SAP data integration scenario, see SAP data integration using Azure Data Factory whitepaper with detailed introduction on each SAP connector, comparison and guidance.

Supported capabilities

This SAP ECC connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

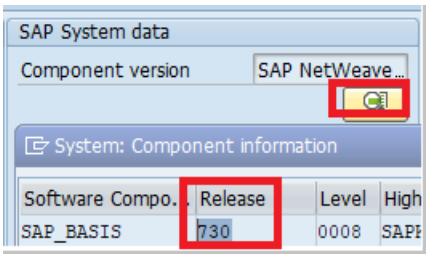
For a list of data stores that are supported as sources or sinks, see the Supported data stores table.

Specifically, this SAP ECC connector supports:

- Copying data from SAP ECC on SAP NetWeaver version 7.0 and later.
- Copying data from any objects exposed by SAP ECC OData services, such as:
  - SAP tables or views.
  - Business Application Programming Interface [BAPI] objects.
  - Data extractors.
  - Data or intermediate documents (IDOCs) sent to SAP Process Integration (PI) that can be received as OData via relative adapters.
- Copying data by using basic authentication.

The version 7.0 or later refers to SAP NetWeaver version instead of SAP ECC version. For example,SAP ECC 6.0 EHP 7 in general has NetWeaver version >=7.4. In case you are unsure about your environment, here are the steps to confirm the version from your SAP system:

1. Use SAP GUI to connect to the SAP System.
2. Go to **System** -> **Status**.
3. Check the release of the SAP_BASIS, ensure it is equal to or larger than 701.



> **TIP**
> To copy data from SAP ECC via an SAP table or view, use the SAP table connector, which is faster and more scalable.

Prerequisites

To use this SAP ECC connector, you need to expose the SAP ECC entities via OData services through SAP Gateway. More specifically:

- **Set up SAP Gateway**. For servers with SAP NetWeaver versions later than 7.4, SAP Gateway is already installed. For earlier versions, you must install the embedded SAP Gateway or the SAP Gateway hub system before exposing SAP ECC data through OData services. To set up SAP Gateway, see the installation guide.
- **Activate and configure the SAP OData service**. You can activate the OData service through TCODE SICF in seconds. You can also configure which objects need to be exposed. For more information, see the step-by-step guidance.

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

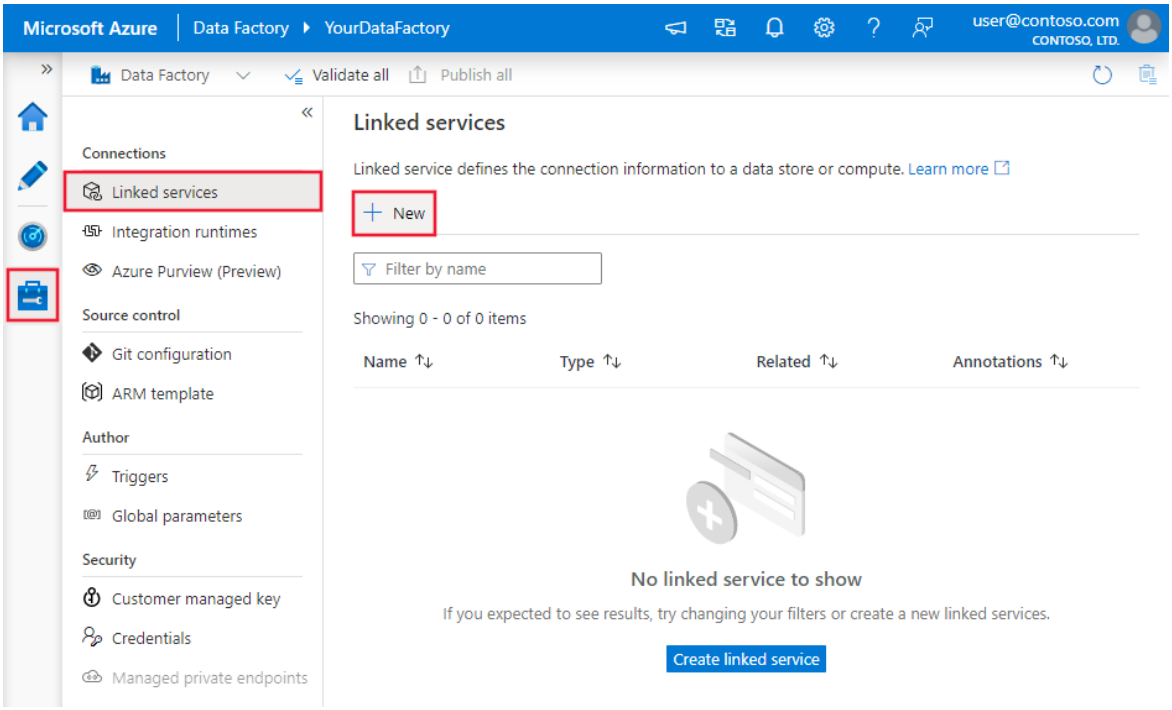
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to SAP ECC using UI

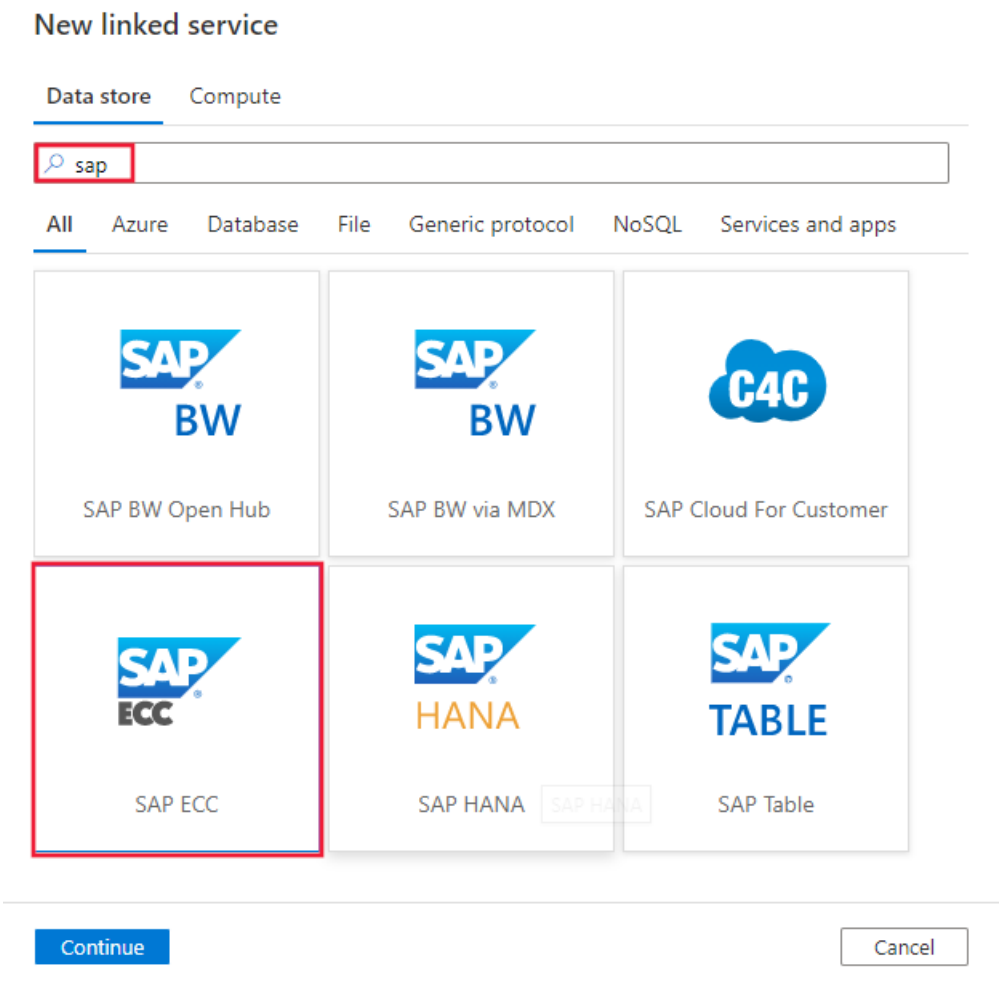
Use the following steps to create a linked service to SAP ECC in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

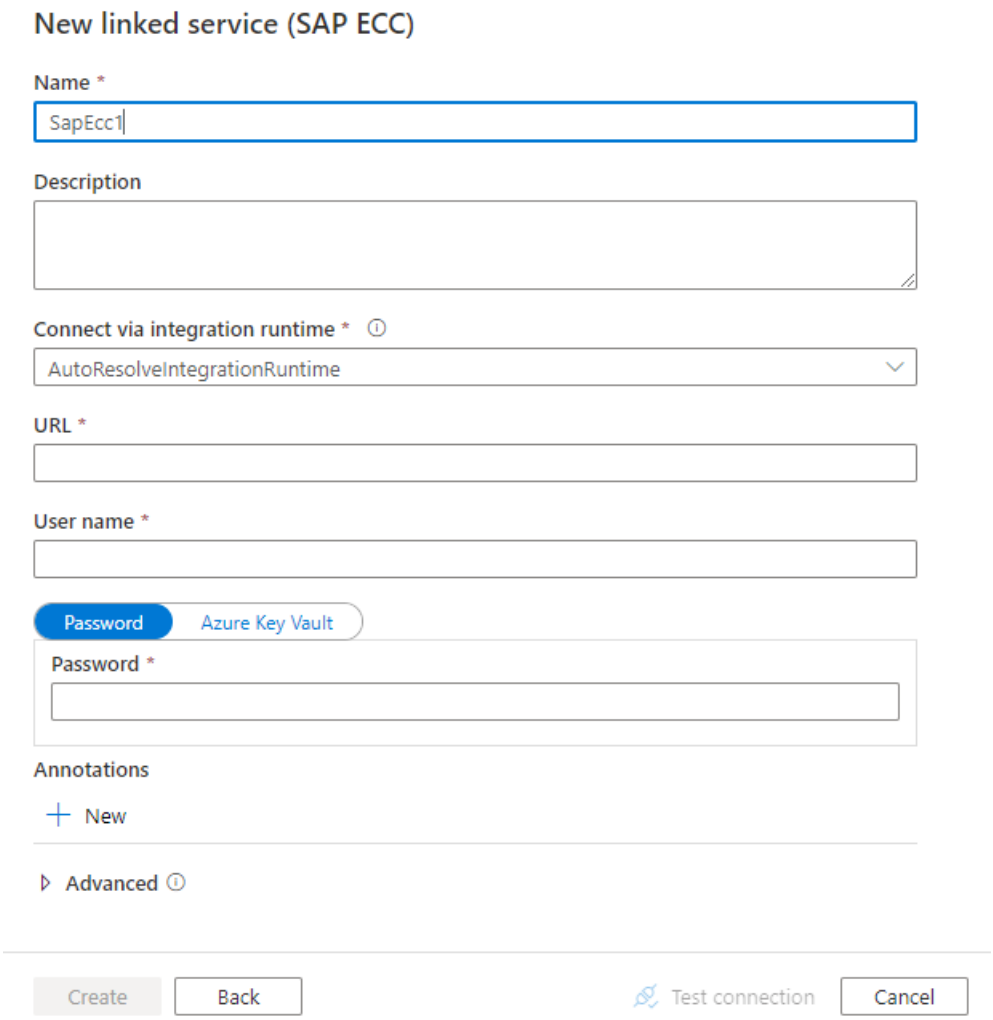
   - Azure Data Factory
   - Azure Synapse



2. Search for SAP and select the SAP ECC connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define the entities specific to the SAP ECC connector.

Linked service properties

The following properties are supported for the SAP ECC linked service:

PROPERTY	DESCRIPTION	REQUIRED
`type`	The `type` property must be set to `SapEcc`.	Yes
`url`	The URL of the SAP ECC OData service.	Yes
`username`	The username used to connect to SAP ECC.	No
`password`	The plaintext password used to connect to SAP ECC.	No

PROPERTY	DESCRIPTION	REQUIRED
`connectVia`	The integration runtime to be used to connect to the data store. Learn more from Prerequisites section. If you don't specify a runtime, the default Azure integration runtime is used.	No

Example

```
{
    "name": "SapECCLinkedService",
    "properties": {
        "type": "SapEcc",
        "typeProperties": {
            "url": "<SAP ECC OData URL, e.g.,
http://eccsvrname:8000/sap/opu/odata/sap/zgw100_dd02l_so_srv/>",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    },
    "connectVia": {
        "referenceName": "<name of integration runtime>",
        "type": "IntegrationRuntimeReference"
    }
}
```

Dataset properties

For a full list of the sections and properties available for defining datasets, see Datasets. The following section provides a list of the properties supported by the SAP ECC dataset.

To copy data from SAP ECC, set the `type` property of the dataset to `SapEccResource`.

The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
`path`	Path of the SAP ECC OData entity.	Yes

Example

```
{
    "name": "SapEccDataset",
    "properties": {
        "type": "SapEccResource",
        "typeProperties": {
            "path": "<entity path, e.g., dd04tentitySet>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP ECC linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of the sections and properties available for defining activities, see Pipelines. The following section provides a list of the properties supported by the SAP ECC source.

SAP ECC as a source

To copy data from SAP ECC, set the `type` property in the `source` section of the copy activity to `SapEccSource`.

The following properties are supported in the copy activity's `source` section:

PROPERTY	DESCRIPTION	REQUIRED
`type`	The `type` property of the copy activity's `source` section must be set to `SapEccSource`.	Yes

`query`	The OData query options to filter the data. For example:
	`"$select=Name,Description&$top=10"`
	The SAP ECC connector copies data from the combined URL:
	`<URL specified in the linked service>/<path specified in the dataset>?<query specified in the copy activity's source section>`
	For more information, see OData URL components.
		No

`sapDataColumnDelimiter`	The single character that is used as delimiter passed to SAP RFC to split the output data.	No
`httpRequestTimeout`	The timeout (the **TimeSpan** value) for the HTTP request to get a response. This value is the timeout to get a response, not the timeout to read response data. If not specified, the default value is **00:30:00** (30 minutes).	No

Example

```
"activities":[
    {
        "name": "CopyFromSAPECC",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP ECC input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapEccSource",
                "query": "$top=10"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Data type mappings for SAP ECC

When you're copying data from SAP ECC, the following mappings are used from OData data types for SAP ECC data to interim data types the service uses internally. To learn how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

ODATA DATA TYPE	INTERIM SERVICE DATA TYPE
`Edm.Binary`	`String`
`Edm.Boolean`	`Bool`
`Edm.Byte`	`String`
`Edm.DateTime`	`DateTime`
`Edm.Decimal`	`Decimal`
`Edm.Double`	`Double`
`Edm.Single`	`Single`
`Edm.Guid`	`String`
`Edm.Int16`	`Int16`
`Edm.Int32`	`Int32`

ODATA DATA TYPE	INTERIM SERVICE DATA TYPE
`Edm.Int64`	`Int64`
`Edm.SByte`	`Int16`
`Edm.String`	`String`
`Edm.Time`	`TimeSpan`
`Edm.DateTimeOffset`	`DateTimeOffset`

> **NOTE**
> Complex data types aren't currently supported.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of the data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from SAP HANA using Azure Data Factory or Synapse Analytics

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from an SAP HANA database. It builds on the copy activity overview article that presents a general overview of copy activity.

> **TIP**
> To learn about overall support for the SAP data integration scenario, see SAP data integration whitepaper with detailed introduction on each SAP connector, comparison and guidance.

Supported capabilities

This SAP HANA connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this SAP HANA connector supports:

- Copying data from any version of SAP HANA database.
- Copying data from **HANA information models** (such as Analytic and Calculation views) and **Row/Column tables**.
- Copying data using **Basic** or **Windows** authentication.
- Parallel copying from a SAP HANA source. See the Parallel copy from SAP HANA section for details.

> **TIP**
> To copy data **into** SAP HANA data store, use generic ODBC connector. See SAP HANA sink section with details. Note the linked services for SAP HANA connector and ODBC connector are with different type thus cannot be reused.

Prerequisites

To use this SAP HANA connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Install the SAP HANA ODBC driver on the Integration Runtime machine. You can download the SAP HANA ODBC driver from the SAP Software Download Center. Search with the keyword **SAP HANA CLIENT for**

Windows.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

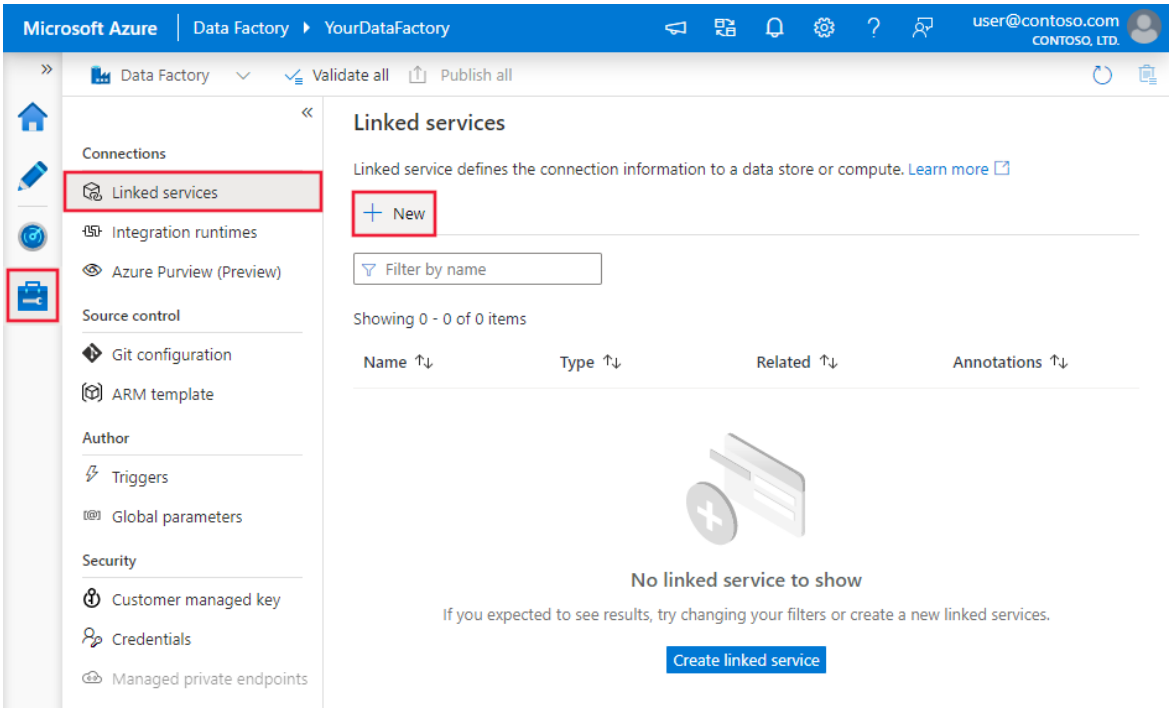
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to SAP HANA using UI

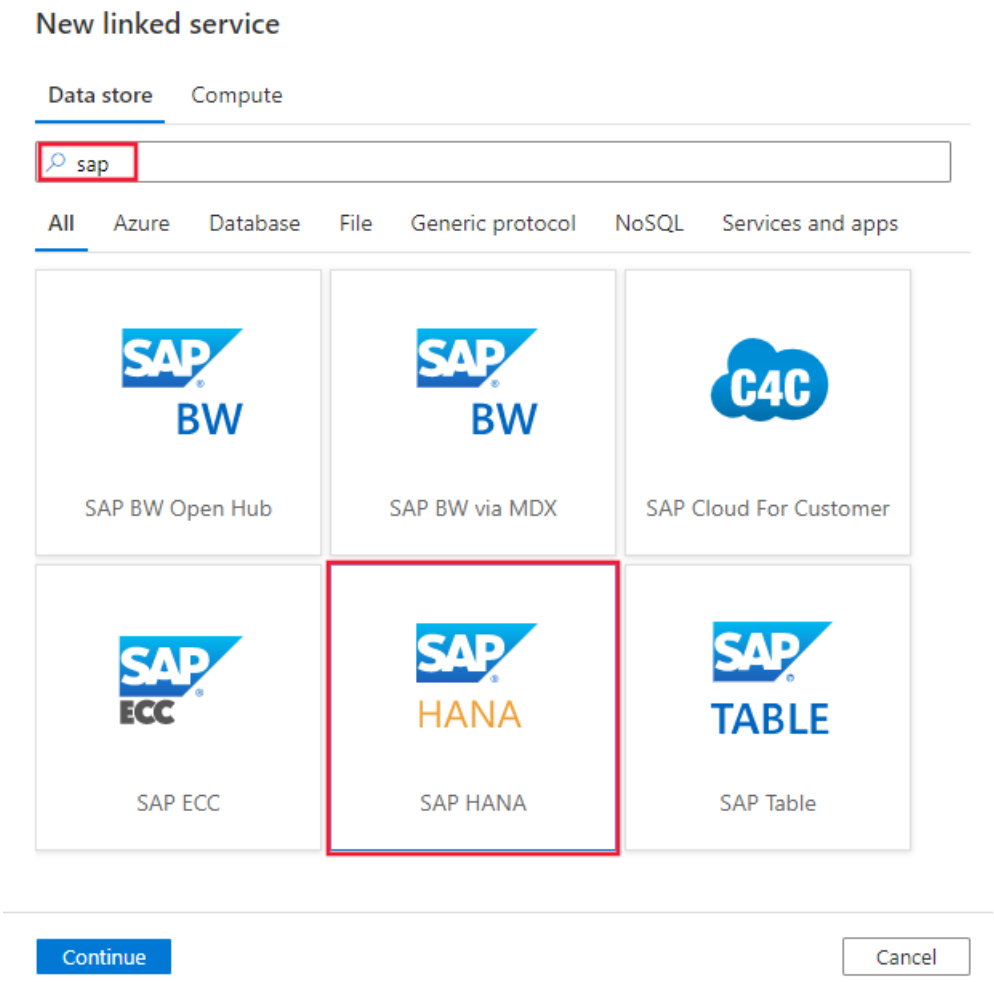
Use the following steps to create a linked service to SAP HANA in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

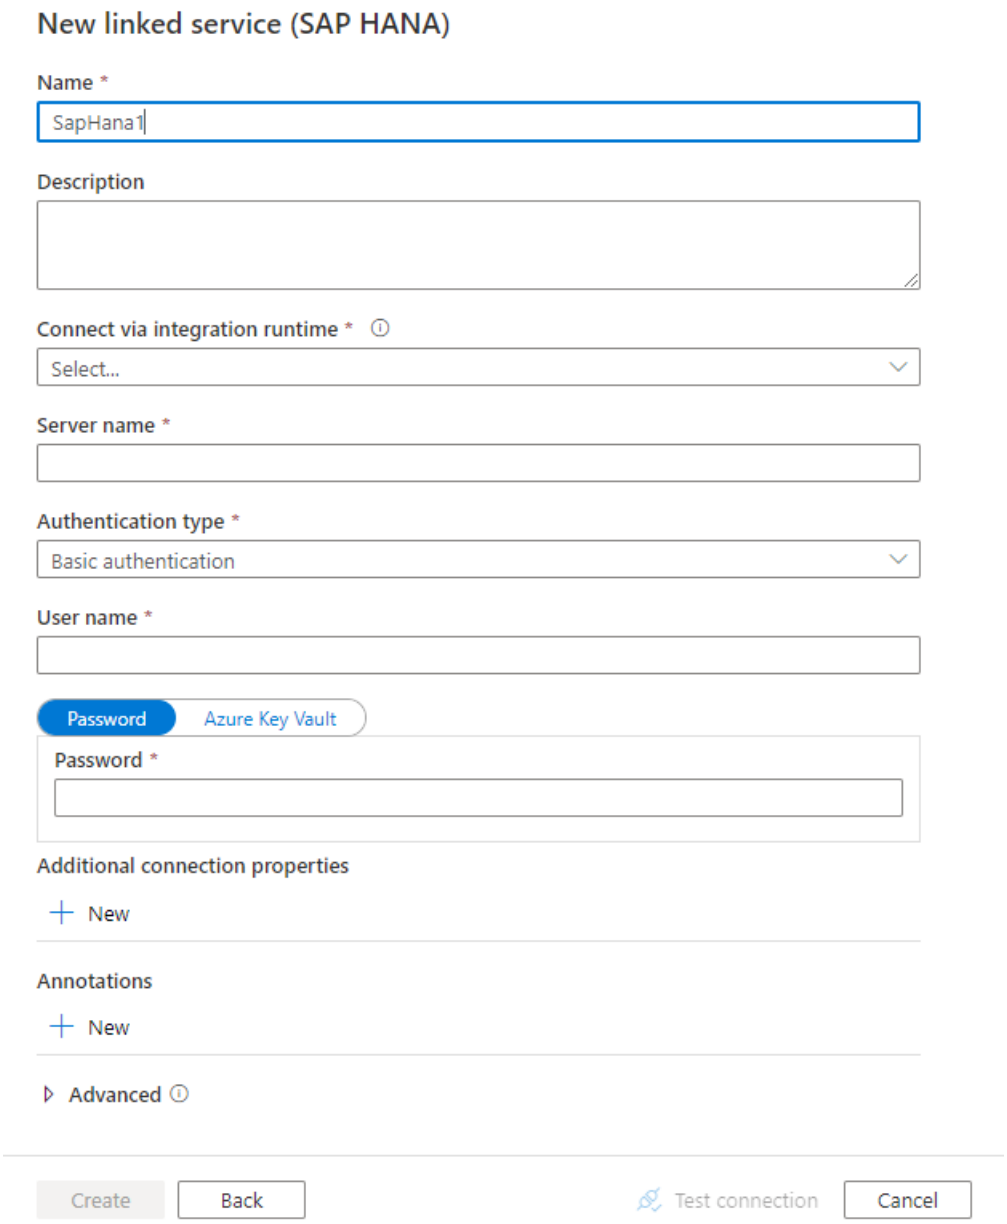
   - Azure Data Factory
   - Azure Synapse



2. Search for SAP and select the SAP HANA connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to SAP HANA connector.

Linked service properties

The following properties are supported for SAP HANA linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **SapHana**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specify information that's needed to connect to the SAP HANA by using either **basic authentication** or **Windows authentication**. Refer to the following samples. In connection string, server/port is mandatory (default port is 30015), and username and password is mandatory when using basic authentication. For additional advanced settings, refer to SAP HANA ODBC Connection Properties You can also put password in Azure Key Vault and pull the password configuration out of the connection string. Refer to Store credentials in Azure Key Vault article with more details.	Yes
userName	Specify user name when using Windows authentication. Example: `user@domain.com`	No
password	Specify password for the user account. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example: use basic authentication

```
{
    "name": "SapHanaLinkedService",
    "properties": {
        "type": "SapHana",
        "typeProperties": {
            "connectionString": "SERVERNODE=<server>:<port (optional)>;UID=<userName>;PWD=<Password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: use Windows authentication

```
{
    "name": "SapHanaLinkedService",
    "properties": {
        "type": "SapHana",
        "typeProperties": {
            "connectionString": "SERVERNODE=<server>:<port (optional)>;",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

If you were using SAP HANA linked service with the following payload, it is still supported as-is, while you are suggested to use the new one going forward.

Example:

```
{
    "name": "SapHanaLinkedService",
    "properties": {
        "type": "SapHana",
        "typeProperties": {
            "server": "<server>:<port (optional)>",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by SAP HANA dataset.

To copy data from SAP HANA, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SapHanaTable**	Yes
schema	Name of the schema in the SAP HANA database.	No (if "query" in activity source is specified)

PROPERTY	DESCRIPTION	REQUIRED
table	Name of the table in the SAP HANA database.	No (if "query" in activity source is specified)

Example:

```
{
    "name": "SAPHANADataset",
    "properties": {
        "type": "SapHanaTable",
        "typeProperties": {
            "schema": "<schema name>",
            "table": "<table name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP HANA linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by SAP HANA source.

SAP HANA as source

> **TIP**
> To ingest data from SAP HANA efficiently by using data partitioning, learn more from Parallel copy from SAP HANA section.

To copy data from SAP HANA, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SapHanaSource**	Yes
query	Specifies the SQL query to read data from the SAP HANA instance.	Yes

PROPERTY	DESCRIPTION	REQUIRED
partitionOptions	Specifies the data partitioning options used to ingest data from SAP HANA. Learn more from Parallel copy from SAP HANA section. Allow values are:**None**(default),**PhysicalPartitionsOfTable**, **SapHanaDynamicRange**. Learn more from Parallel copy from SAP HANA section. `PhysicalPartitionsOfTable` can only be used when copying data from a table but not query. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from SAP HANA is controlled by the `parallelCopies` setting on the copy activity.	False
partitionSettings	Specify the group of the settings for data partitioning. Apply when partition option is `SapHanaDynamicRange`.	False
partitionColumnName	Specify the name of the source column that will be used by partition for parallel copy. If not specified, the index or the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `SapHanaDynamicRange`. If you use a query to retrieve the source data, hook `?AdfHanaDynamicRangePartitionCondition` in WHERE clause. See example in Parallel copy from SAP HANA section.	Yes when using `SapHanaDynamicRange` partition.
packetSize	Specifies the network packet size (in Kilobytes) to split data to multiple blocks. If you have large amount of data to copy, increasing packet size can increase reading speed from SAP HANA in most cases. Performance testing is recommended when adjusting the packet size.	No. Default value is 2048 (2MB).

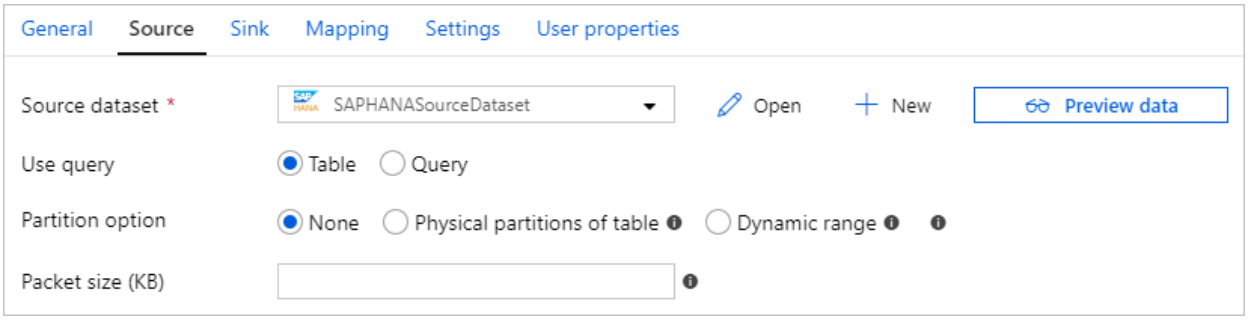
Example:

```
"activities":[
    {
        "name": "CopyFromSAPHANA",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP HANA input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapHanaSource",
                "query": "<SQL query for SAP HANA>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed copy source, it is still supported as-is, while you are suggested to use the new one going forward.

Parallel copy from SAP HANA

The SAP HANA connector provides built-in data partitioning to copy data from SAP HANA in parallel. You can find data partitioning options on the **Source** table of the copy activity.



When you enable partitioned copy, the service runs parallel queries against your SAP HANA source to retrieve data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your SAP HANA.

You are suggested to enable parallel copy with data partitioning especially when you ingest large amount of data from your SAP HANA. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS

SCENARIO	SUGGESTED SETTINGS
Full load from large table.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partition type of the specified SAP HANA table, and choose the corresponding partition strategy: - **Range Partitioning**: Get the partition column and partition ranges defined for the table, then copy the data by range. - **Hash Partitioning**: Use hash partition key as partition column, then partition and copy the data based on ranges calculated by the service. - **Round-Robin Partitioning** or **No Partition**: Use primary key as partition column, then partition and copy the data based on ranges calculated by the service.

Load large amount of data by using a custom query.	**Partition option**: Dynamic range partition.
	Query:
	`SELECT * FROM <TABLENAME> WHERE ? AdfHanaDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to apply dynamic range partition.
	
	During execution, the service first calculates the value ranges of the specified partition column, by evenly distributes the rows in a number of buckets according to the number of distinct partition column values the parallel copy setting, then replaces `?AdfHanaDynamicRangePartitionCondition` with filtering the partition column value range for each partition, and sends to SAP HANA.
	
	If you want to use multiple columns as partition column, you can concatenate the values of each column as one column in the query and specify it as the partition column, like
	`SELECT * FROM (SELECT *, CONCAT(<KeyColumn1>, <KeyColumn2>) AS PARTITIONCOLUMN FROM <TABLENAME>) WHERE ?AdfHanaDynamicRangePartitionCondition`
	.

Example: query with physical partitions of a table

```
"source": {
    "type": "SapHanaSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "SapHanaSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfHanaDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "SapHanaDynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<Partition_column_name>"
    }
}
```

Data type mapping for SAP HANA

When copying data from SAP HANA, the following mappings are used from SAP HANA data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

SAP HANA DATA TYPE	INTERIM SERVICE DATA TYPE
ALPHANUM	String
BIGINT	Int64
BINARY	Byte[]
BINTEXT	String
BLOB	Byte[]
BOOL	Byte
CLOB	String
DATE	DateTime
DECIMAL	Decimal
DOUBLE	Double
FLOAT	Double
INTEGER	Int32
NCLOB	String
NVARCHAR	String
REAL	Single
SECONDDATE	DateTime
SHORTTEXT	String
SMALLDECIMAL	Decimal
SMALLINT	Int16
STGEOMETRYTYPE	Byte[]
STPOINTTYPE	Byte[]
TEXT	String
TIME	TimeSpan

SAP HANA DATA TYPE	INTERIM SERVICE DATA TYPE
TINYINT	Byte
VARCHAR	String
TIMESTAMP	DateTime
VARBINARY	Byte[]

SAP HANA sink

Currently, the SAP HANA connector is not supported as sink, while you can use generic ODBC connector with SAP HANA driver to write data into SAP HANA.

Follow the Prerequisites to set up Self-hosted Integration Runtime and install SAP HANA ODBC driver first. Create an ODBC linked service to connect to your SAP HANA data store as shown in the following example, then create dataset and copy activity sink with ODBC type accordingly. Learn more from ODBC connector article.

```
{
    "name": "SAPHANAViaODBCLinkedService",
    "properties": {
        "type": "Odbc",
        "typeProperties": {
            "connectionString": "Driver={HDBODBC};servernode=<HANA server>.clouddatahub-int.net:30015",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from an SAP table using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory and Azure Synapse Analytics pipelines to copy data from an SAP table. For more information, see Copy activity overview.

> **TIP**
> To learn the overall support on SAP data integration scenario, see SAP data integration using Azure Data Factory whitepaper with detailed introduction on each SAP connector, comparsion and guidance.

Supported capabilities

This SAP table connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of the data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

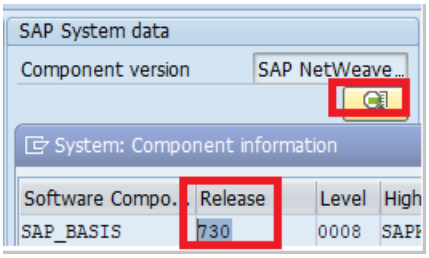
Specifically, this SAP table connector supports:

- Copying data from an SAP table in:
  - SAP ERP Central Component (SAP ECC) version 7.01 or later (in a recent SAP Support Package Stack released after 2015).
  - SAP Business Warehouse (SAP BW) version 7.01 or later (in a recent SAP Support Package Stack released after 2015).
  - SAP S/4HANA.
  - Other products in SAP Business Suite version 7.01 or later (in a recent SAP Support Package Stack released after 2015).
- Copying data from both an SAP transparent table, a pooled table, a clustered table, and a view.
- Copying data by using basic authentication or Secure Network Communications (SNC), if SNC is configured.
- Connecting to an SAP application server or SAP message server.
- Retrieving data via default or custom RFC.

The version 7.01 or later refers to SAP NetWeaver version instead of SAP ECC version. For example,SAP ECC 6.0 EHP 7 in general has NetWeaver version >=7.4. In case you are unsure about your environment, here are the

steps to confirm the version from your SAP system:

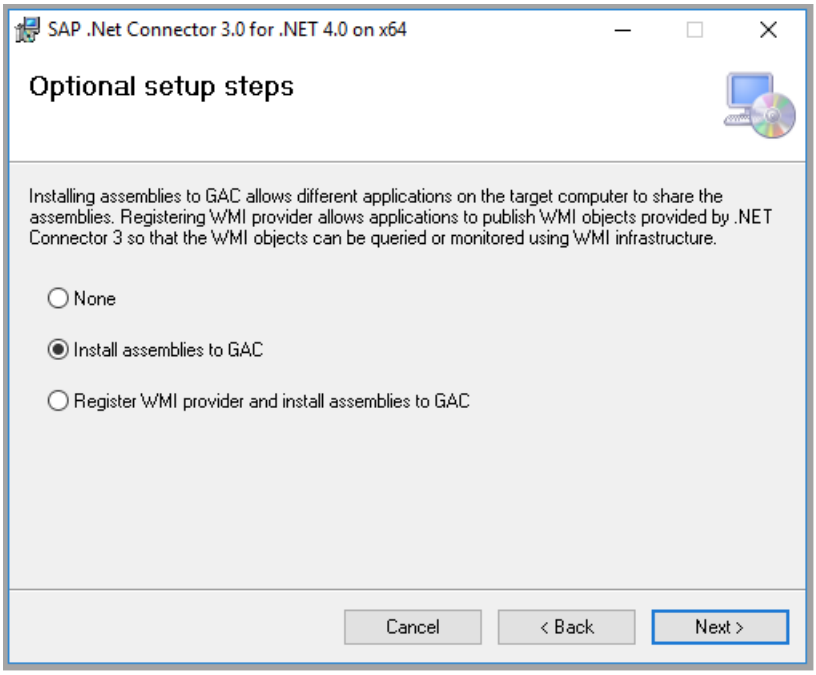
1. Use SAP GUI to connect to the SAP System.
2. Go to **System** -> **Status**.
3. Check the release of the SAP_BASIS, ensure it is equal to or larger than 701.



Prerequisites

To use this SAP table connector, you need to:

- Set up a self-hosted integration runtime (version 3.17 or later). For more information, see Create and configure a self-hosted integration runtime.
- Download the 64-bit SAP Connector for Microsoft .NET 3.0 from SAP's website, and install it on the self-hosted integration runtime machine. During installation, make sure you select the **Install Assemblies to GAC** option in the **Optional setup steps** window.



- The SAP user who's being used in the SAP table connector must have the following permissions:
  - Authorization for using Remote Function Call (RFC) destinations.
  - Permissions to the Execute activity of the S_SDSAUTH authorization object. You can refer to SAP Note 460089 on the majority authorization objects. Certain RFCs are required by the underlying NCo connector, for example RFC_FUNCTION_SEARCH.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal

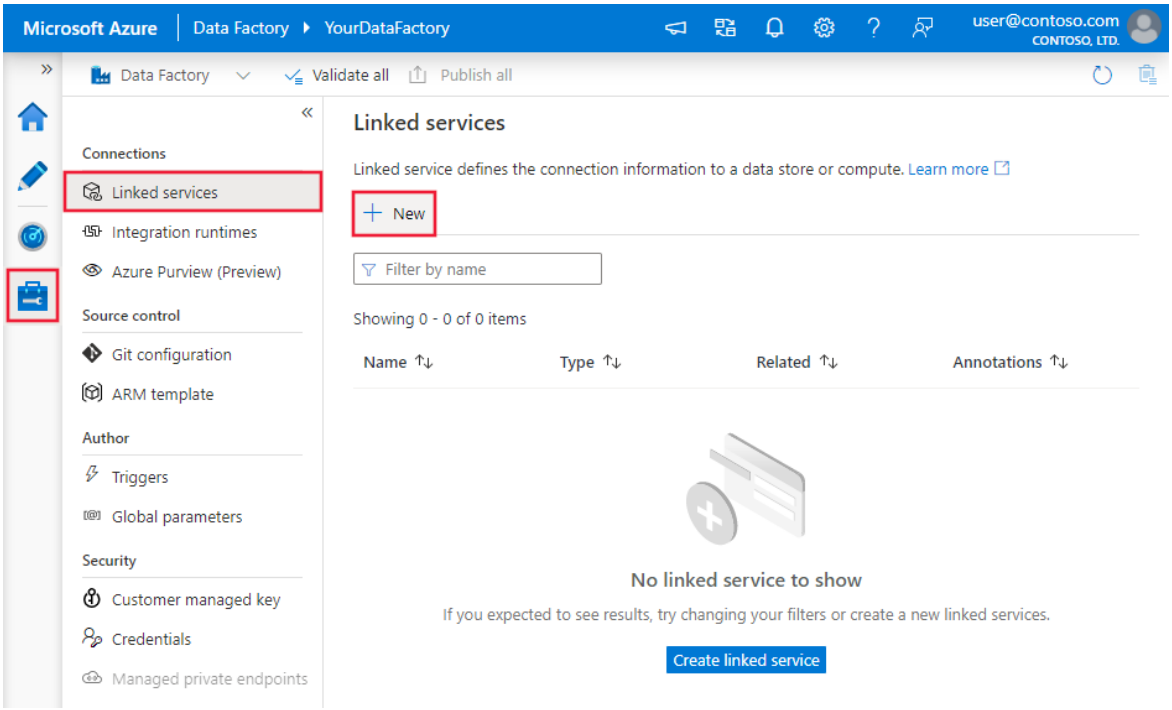
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to an SAP table using UI

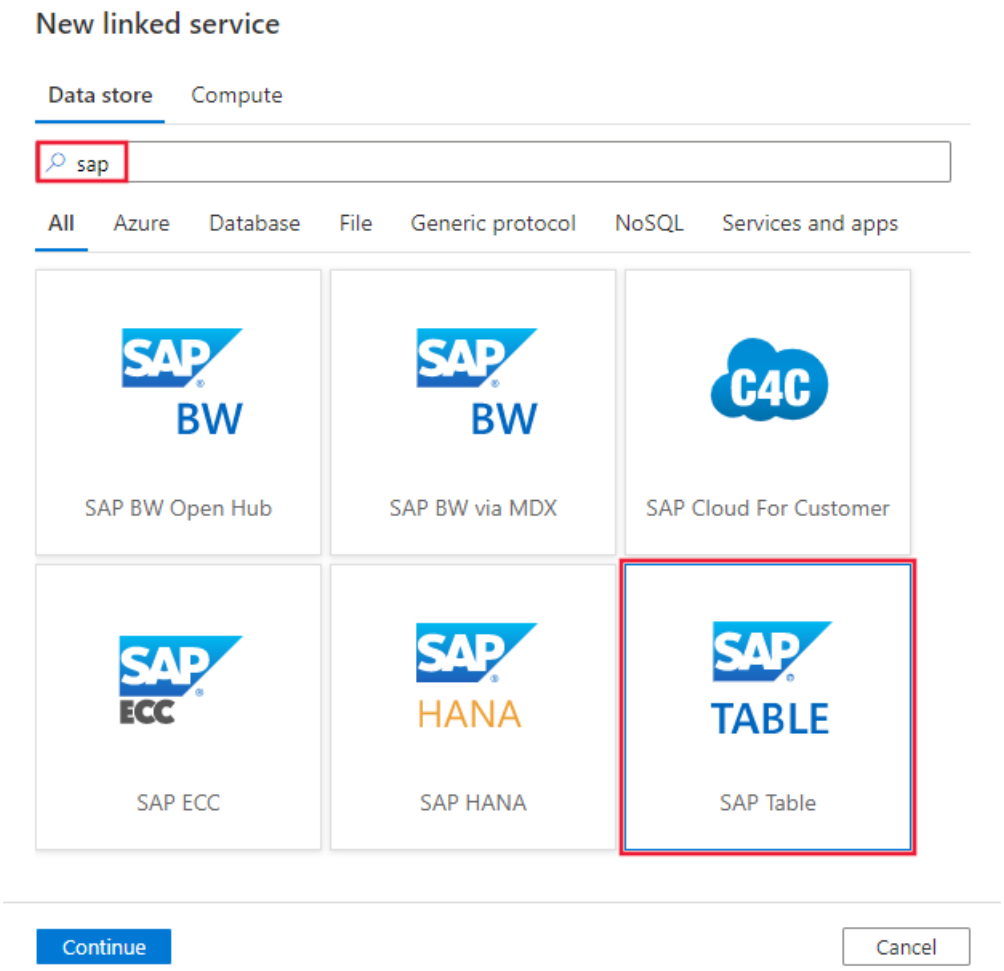
Use the following steps to create a linked service to an SAP table in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

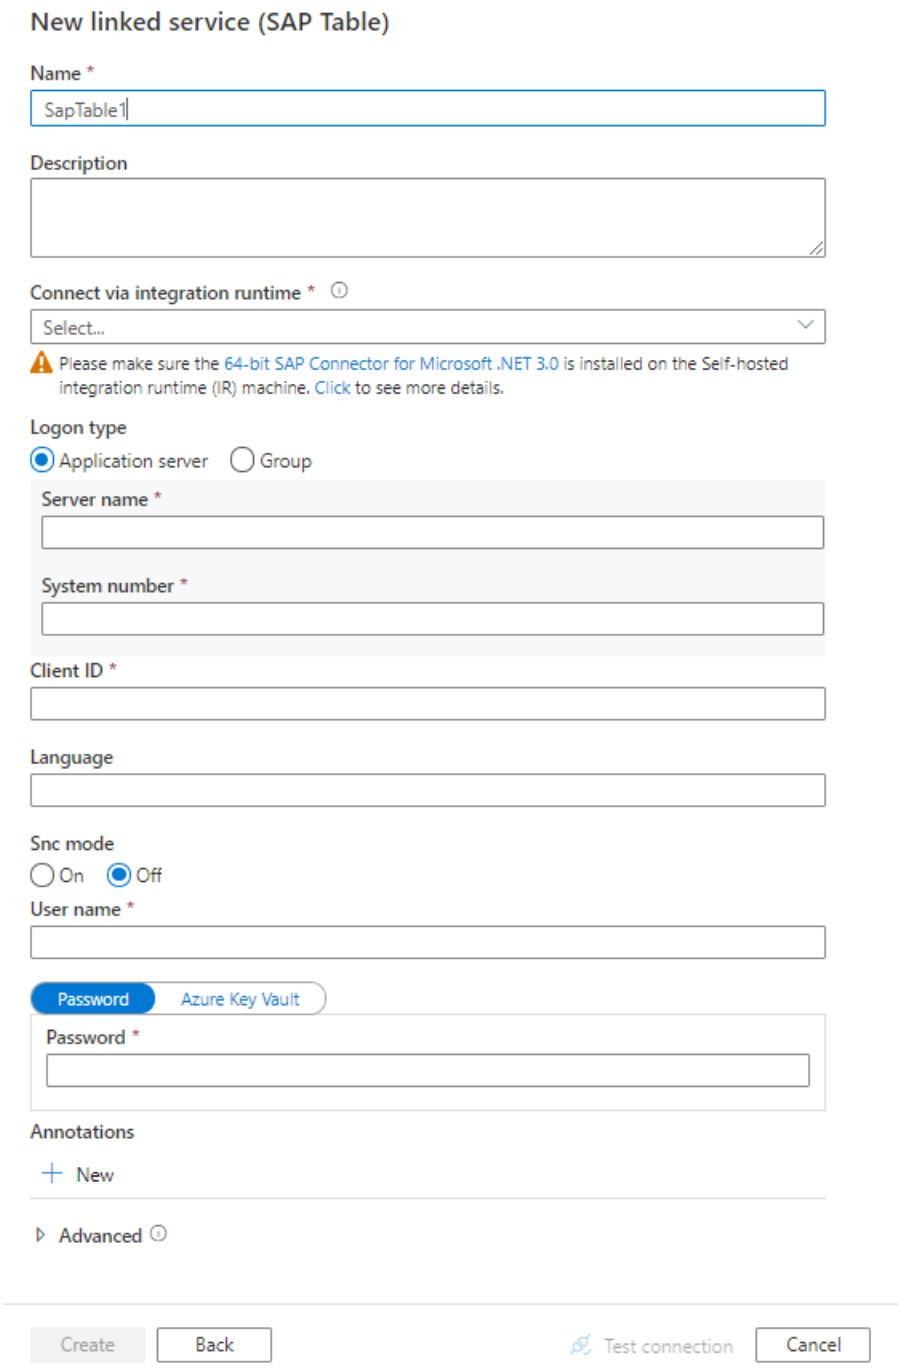
   - Azure Data Factory
   - Azure Synapse



2. Search for SAP and select the SAP table connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define the entities specific to the SAP table connector.

Linked service properties

The following properties are supported for the SAP BW Open Hub linked service:

PROPERTY	DESCRIPTION	REQUIRED
`type`	The `type` property must be set to `SapTable`.	Yes

PROPERTY	DESCRIPTION	REQUIRED
`server`	The name of the server on which the SAP instance is located. Use to connect to an SAP application server.	No
`systemNumber`	The system number of the SAP system. Use to connect to an SAP application server. Allowed value: A two-digit decimal number represented as a string.	No
`messageServer`	The host name of the SAP message server. Use to connect to an SAP message server.	No
`messageServerService`	The service name or port number of the message server. Use to connect to an SAP message server.	No
`systemId`	The ID of the SAP system where the table is located. Use to connect to an SAP message server.	No
`logonGroup`	The logon group for the SAP system. Use to connect to an SAP message server.	No
`clientId`	The ID of the client in the SAP system. Allowed value: A three-digit decimal number represented as a string.	Yes
`language`	The language that the SAP system uses. Default value is `EN`.	No
`userName`	The name of the user who has access to the SAP server.	Yes
`password`	The password for the user. Mark this field with the `SecureString` type to store it securely, or reference a secret stored in Azure Key Vault.	Yes
`sncMode`	The SNC activation indicator to access the SAP server where the table is located. Use if you want to use SNC to connect to the SAP server. Allowed values are `0` (off, the default) or `1` (on).	No

PROPERTY	DESCRIPTION	REQUIRED
`sncMyName`	The initiator's SNC name to access the SAP server where the table is located. Applies when `sncMode` is on.	No
`sncPartnerName`	The communication partner's SNC name to access the SAP server where the table is located. Applies when `sncMode` is on.	No
`sncLibraryPath`	The external security product's library to access the SAP server where the table is located. Applies when `sncMode` is on.	No
`sncQop`	The SNC Quality of Protection level to apply. Applies when `sncMode` is On. Allowed values are `1` (Authentication), `2` (Integrity), `3` (Privacy), `8` (Default), `9` (Maximum).	No
`connectVia`	The integration runtime to be used to connect to the data store. A self-hosted integration runtime is required, as mentioned earlier in Prerequisites.	Yes

Example 1: Connect to an SAP application server

```
{
    "name": "SapTableLinkedService",
    "properties": {
        "type": "SapTable",
        "typeProperties": {
            "server": "<server name>",
            "systemNumber": "<system number>",
            "clientId": "<client ID>",
            "userName": "<SAP user>",
            "password": {
                "type": "SecureString",
                "value": "<Password for SAP user>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: Connect to an SAP message server

```
{
    "name": "SapTableLinkedService",
    "properties": {
        "type": "SapTable",
        "typeProperties": {
            "messageServer": "<message server name>",
            "messageServerService": "<service name or port>",
            "systemId": "<system ID>",
            "logonGroup": "<logon group>",
            "clientId": "<client ID>",
            "userName": "<SAP user>",
            "password": {
                "type": "SecureString",
                "value": "<Password for SAP user>"
            }
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 3: Connect by using SNC

```
{
    "name": "SapTableLinkedService",
    "properties": {
        "type": "SapTable",
        "typeProperties": {
            "server": "<server name>",
            "systemNumber": "<system number>",
            "clientId": "<client ID>",
            "userName": "<SAP user>",
            "password": {
                "type": "SecureString",
                "value": "<Password for SAP user>"
            },
            "sncMode": 1,
            "sncMyName": "<SNC myname>",
            "sncPartnerName": "<SNC partner name>",
            "sncLibraryPath": "<SNC library path>",
            "sncQop": "8"
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of the sections and properties for defining datasets, see Datasets. The following section provides a list of the properties supported by the SAP table dataset.

To copy data from and to the SAP BW Open Hub linked service, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
`type`	The `type` property must be set to `SapTableResource`.	Yes
`tableName`	The name of the SAP table to copy data from.	Yes

Example

```
{
    "name": "SAPTableDataset",
    "properties": {
        "type": "SapTableResource",
        "typeProperties": {
            "tableName": "<SAP table name>"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<SAP table linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of the sections and properties for defining activities, see Pipelines. The following section provides a list of the properties supported by the SAP table source.

SAP table as source

To copy data from an SAP table, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
`type`	The `type` property must be set to `SapTableSource`.	Yes
`rowCount`	The number of rows to be retrieved.	No
`rfcTableFields`	The fields (columns) to copy from the SAP table. For example, `column0, column1`.	No
`rfcTableOptions`	The options to filter the rows in an SAP table. For example, `COLUMN0 EQ 'SOMEVALUE'`. See also the SAP query operator table later in this article.	No

PROPERTY	DESCRIPTION	REQUIRED
`customRfcReadTableFunctionModule`	A custom RFC function module that can be used to read data from an SAP table. You can use a custom RFC function module to define how the data is retrieved from your SAP system and returned to the service. The custom function module must have an interface implemented (import, export, tables) that's similar to `/SAPDS/RFC_READ_TABLE2`, which is the default interface used by the service.	No
`partitionOption`	The partition mechanism to read from an SAP table. The supported options include: • `None` • `PartitionOnInt` (normal integer or integer values with zero padding on the left, such as `0000012345`) • `PartitionOnCalendarYear` (4 digits in the format "YYYY") • `PartitionOnCalendarMonth` (6 digits in the format "YYYYMM") • `PartitionOnCalendarDate` (8 digits in the format "YYYYMMDD") • `PartitionOntime` (6 digits in the format "HHMMSS", such as `235959`)	No
`partitionColumnName`	The name of the column used to partition the data.	No
`partitionUpperBound`	The maximum value of the column specified in `partitionColumnName` that will be used to continue with partitioning.	No
`partitionLowerBound`	The minimum value of the column specified in `partitionColumnName` that will be used to continue with partitioning. (Note: `partitionLowerBound` cannot be "0" when partition option is `PartitionOnInt`)	No
`maxPartitionsNumber`	The maximum number of partitions to split the data into. The default value is 1.	No

PROPERTY	DESCRIPTION	REQUIRED
`sapDataColumnDelimiter`	The single character that is used as delimiter passed to SAP RFC to split the output data.	No

TIP

If your SAP table has a large volume of data, such as several billion rows, use `partitionOption` and `partitionSetting` to split the data into smaller partitions. In this case, the data is read per partition, and each data partition is retrieved from your SAP server via a single RFC call.

Taking `partitionOption` as `partitionOnInt` as an example, the number of rows in each partition is calculated with this formula: (total rows falling between `partitionUpperBound` and `partitionLowerBound`)/ `maxPartitionsNumber` .

To load data partitions in parallel to speed up copy, the parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your SAP table. We strongly recommend making `maxPartitionsNumber` a multiple of the value of the `parallelCopies` property. When copying data into file-based data store, it's also recommanded to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

TIP

The `BASXML` is enabled by default for this SAP Table connector within the service.

In `rfcTableOptions` , you can use the following common SAP query operators to filter the rows:

OPERATOR	DESCRIPTION
`EQ`	Equal to
`NE`	Not equal to
`LT`	Less than
`LE`	Less than or equal to
`GT`	Greater than
`GE`	Greater than or equal to
`IN`	As in `TABCLASS IN ('TRANSP', 'INTTAB')`
`LIKE`	As in `LIKE 'Emma%'`

Example

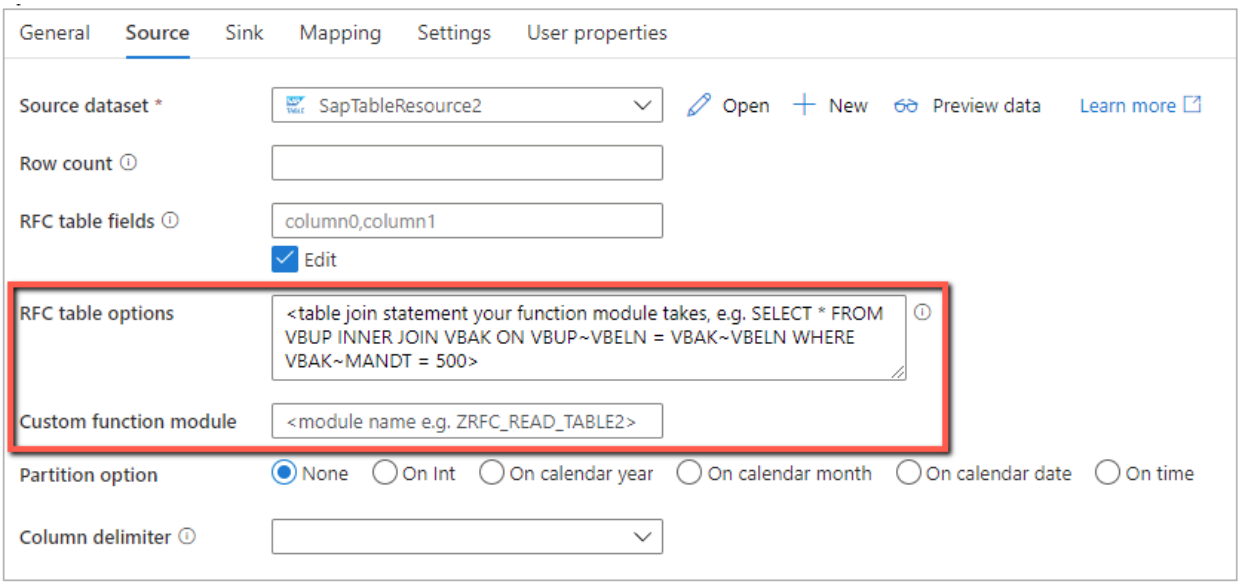
```
"activities":[
    {
        "name": "CopyFromSAPTable",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SAP table input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SapTableSource",
                "partitionOption": "PartitionOnInt",
                "partitionSettings": {
                     "partitionColumnName": "<partition column name>",
                     "partitionUpperBound": "2000",
                     "partitionLowerBound": "1",
                     "maxPartitionsNumber": 500
                 }
            },
            "sink": {
                "type": "<sink type>"
            },
            "parallelCopies": 4
        }
    }
]
```

Join SAP tables

Currently SAP Table connector only supports one single table with the default function module. To get the joined data of multiple tables, you can leverage the customRfcReadTableFunctionModule property in the SAP Table connector following steps below:

- Write a custom function module, which can take a query as OPTIONS and apply your own logic to retrieve the data.
- For the "Custom function module", enter the name of your custom function module.
- For the "RFC table options", specify the table join statement to feed into your function module as OPTIONS, such as "`<TABLE1>` INNER JOIN `<TABLE2>` ON COLUMN0".

Below is an example:



TIP

You can also consider having the joined data aggregated in the VIEW, which is supported by SAP Table connector. You can also try to extract related tables to get onboard onto Azure (e.g. Azure Storage, Azure SQL Database), then use Data Flow to proceed with further join or filter.

Create custom function module

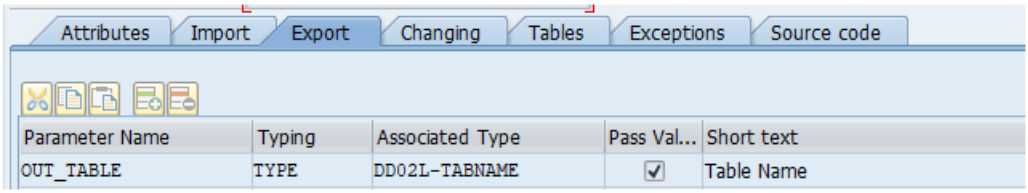
For SAP table, currently we support customRfcReadTableFunctionModule property in the copy source, which allows you to leverage your own logic and process data.

As a quick guidance, here are some requirements to get started with the "Custom function module":

- Definition:

```
*"----------------------------------------------------------------------
*"*"Local Interface:
*"  IMPORTING
*"     VALUE(QUERY_TABLE) TYPE  DD02L-TABNAME
*"     VALUE(DELIMITER) TYPE  SONV-FLAG OPTIONAL
*"     VALUE(NO_DATA) TYPE  SONV-FLAG OPTIONAL
*"     VALUE(ROWSKIPS) TYPE  SOID-ACCNT OPTIONAL
*"     VALUE(ROWCOUNT) TYPE  SOID-ACCNT OPTIONAL
*"  EXPORTING
*"     VALUE(OUT_TABLE) TYPE  DD02L-TABNAME
*"  TABLES
*"      OPTIONS STRUCTURE  /SAPDS/RFC_DB_OPT
*"      FIELDS STRUCTURE  RFC_DB_FLD
*"      TBLOUT128 STRUCTURE  /SAPDS/TAB128
*"      TBLOUT512 STRUCTURE  /SAPDS/TAB512
*"      TBLOUT2048 STRUCTURE  /SAPDS/TAB2048
*"      TBLOUT8192 STRUCTURE  /SAPDS/TAB8192
*"      TBLOUT30000 STRUCTURE  /SAPDS/TAB30K
*"  EXCEPTIONS
*"      TABLE_NOT_AVAILABLE
*"      TABLE_WITHOUT_DATA
*"      OPTION_NOT_VALID
*"      FIELD_NOT_VALID
*"      NOT_AUTHORIZED
*"      DATA_BUFFER_EXCEEDED
*"----------------------------------------------------------------------
```

- Export data into one of the tables below:



Parameter Name	Typing	Associated Type	Optional	Short text
OPTIONS	LIKE	/SAPDS/RFC_DB_OPT	☐	RFC Table Read: Select Options / WH...
FIELDS	LIKE	RFC_DB_FLD	☐	RFC Table Read: Description of Fields ...
TBLOUT128	LIKE	/SAPDS/TAB128	☐	DataServices: Table with 128 char field
TBLOUT512	LIKE	/SAPDS/TAB512	☐	DataServices: Table with 512 chars
TBLOUT2048	LIKE	/SAPDS/TAB2048	☐	DataServices: Table with 2048 chars
TBLOUT8192	LIKE	/SAPDS/TAB8192	☐	DataServices: Table with 8192 chars
TBLOUT30000	LIKE	/SAPDS/TAB30K	☐	DataServices: Table with 30000 chars

Below are illustrations of how SAP table connector works with custom function module:

1. Build connection with SAP server via SAP NCO.
2. Invoke "Custom function module" with the parameters set as below:
   - QUERY_TABLE: the table name you set in the SAP Table dataset;
   - Delimiter: the delimiter you set in the SAP Table Source;
   - ROWCOUNT/Option/Fields: the Rowcount/Aggregated Option/Fields you set in the Table source.
3. Get the result and parse the data in below ways:
   a. Parse the value in the Fields table to get the schemas.

   b. Get the values of the output table to see which table contains these values.

   c. Get the values in the OUT_TABLE, parse the data and then write it into the sink.

Data type mappings for an SAP table

When you're copying data from an SAP table, the following mappings are used from the SAP table data types to interim data types used within the service. To learn how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

SAP ABAP TYPE	SERVICE INTERIM DATA TYPE
`C` (String)	`String`
`I` (Integer)	`Int32`
`F` (Float)	`Double`
`D` (Date)	`String`

SAP ABAP TYPE	SERVICE INTERIM DATA TYPE
`T` (Time)	`String`
`P` (BCD Packed, Currency, Decimal, Qty)	`Decimal`
`N` (Numeric)	`String`
`X` (Binary and Raw)	`String`

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of the data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from ServiceNow using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in Azure Data Factory and Synapse Analytics pipelines to copy data from ServiceNow. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This ServiceNow connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity. Therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

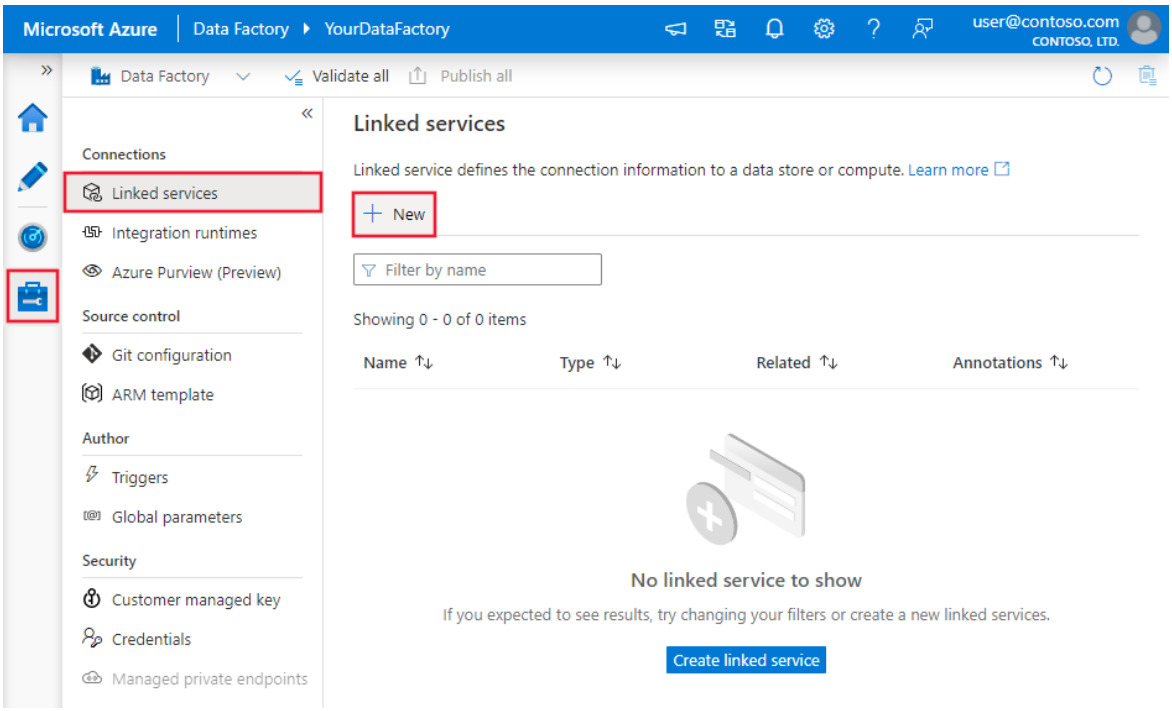
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to ServiceNow using UI

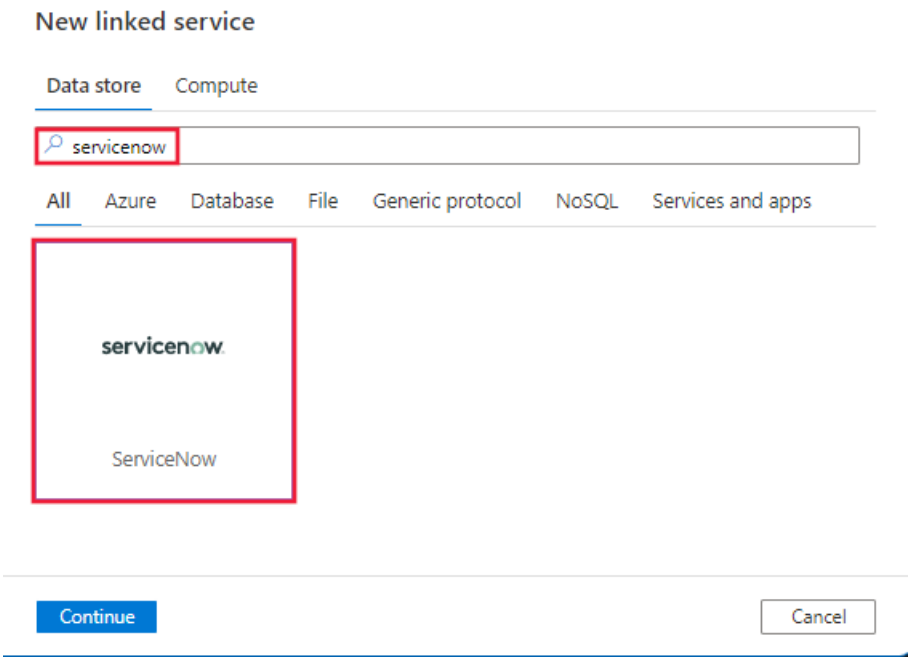
Use the following steps to create a linked service to ServiceNow in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

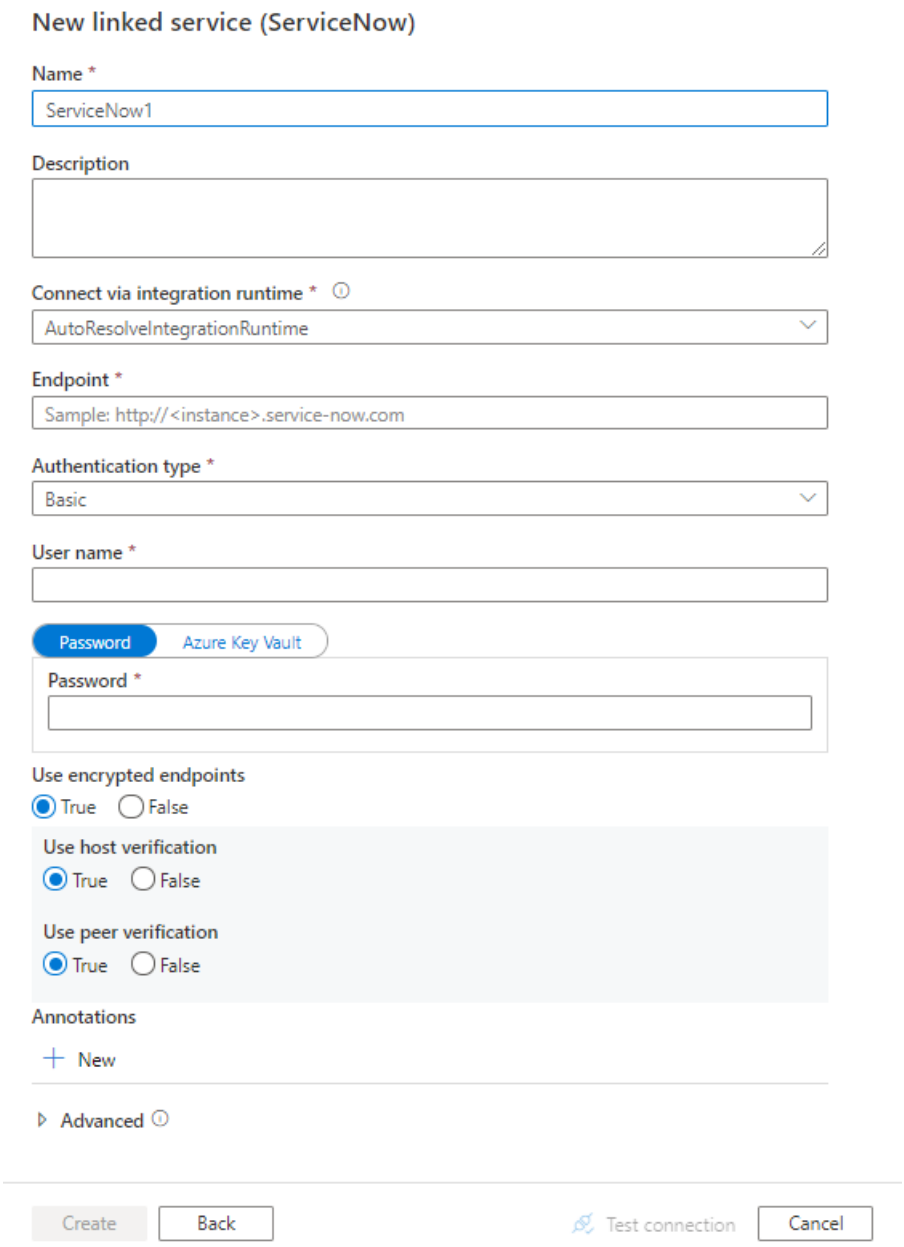
   - Azure Data Factory
   - Azure Synapse



2. Search for ServiceNow and select the ServiceNow connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to ServiceNow connector.

Linked service properties

The following properties are supported for ServiceNow linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **ServiceNow**	Yes
endpoint	The endpoint of the ServiceNow server (`http://<instance>.service-now.com`).	Yes

PROPERTY	DESCRIPTION	REQUIRED
authenticationType	The authentication type to use. Allowed values are: **Basic**, **OAuth2**	Yes
username	The user name used to connect to the ServiceNow server for Basic and OAuth2 authentication.	Yes
password	The password corresponding to the user name for Basic and OAuth2 authentication. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
clientId	The client ID for OAuth2 authentication.	No
clientSecret	The client secret for OAuth2 authentication. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "ServiceNowLinkedService",
    "properties": {
        "type": "ServiceNow",
        "typeProperties": {
            "endpoint" : "http://<instance>.service-now.com",
            "authenticationType" : "Basic",
            "username" : "<username>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by ServiceNow dataset.

To copy data from ServiceNow, set the type property of the dataset to **ServiceNowObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ServiceNowObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "ServiceNowDataset",
    "properties": {
        "type": "ServiceNowObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<ServiceNow linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by ServiceNow source.

ServiceNow as source

To copy data from ServiceNow, set the source type in the copy activity to **ServiceNowSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **ServiceNowSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Actual.alm_asset"`.	No (if "tableName" in dataset is specified)

Note the following when specifying the schema and column for ServiceNow in query, and **refer to Performance tips on copy performance implication**.

- **Schema:** specify the schema as `Actual` or `Display` in the ServiceNow query, which you can look at it as the parameter of `sysparm_display_value` as true or false when calling ServiceNow REST APIs.
- **Column:** the column name for actual value under `Actual` schema is `[column name]_value`, while for display value under `Display` schema is `[column name]_display_value`. Note the column name need map to the schema being used in the query.

Sample query: `SELECT col_value FROM Actual.alm_asset` OR `SELECT col_display_value FROM Display.alm_asset`

Example:

```
"activities":[
    {
        "name": "CopyFromServiceNow",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<ServiceNow input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ServiceNowSource",
                "query": "SELECT * FROM Actual.alm_asset"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Performance tips

Schema to use

ServiceNow has 2 different schemas, one is **"Actual"** which returns actual data, the other is **"Display"** which returns the display values of data.

If you have a filter in your query, use "Actual" schema which has better copy performance. When querying against "Actual" schema, ServiceNow natively support filter when fetching the data to only return the filtered resultset, whereas when querying "Display" schema, ADF retrieve all the data and apply filter internally.

Index

ServiceNow table index can help improve query performance, refer to Create a table index.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data in SFTP server using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 21 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity to copy data from and to the secure FTP (SFTP) server, and use Data Flow to transform data in SFTP server. To learn more read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This SFTP connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②
GetMetadata activity	① ②
Delete activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

Specifically, the SFTP connector supports:

- Copying files from and to the SFTP server by using **Basic**, **SSH public key** or **multi-factor** authentication.
- Copying files as is or by parsing or generating files with the supported file formats and compression codecs.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

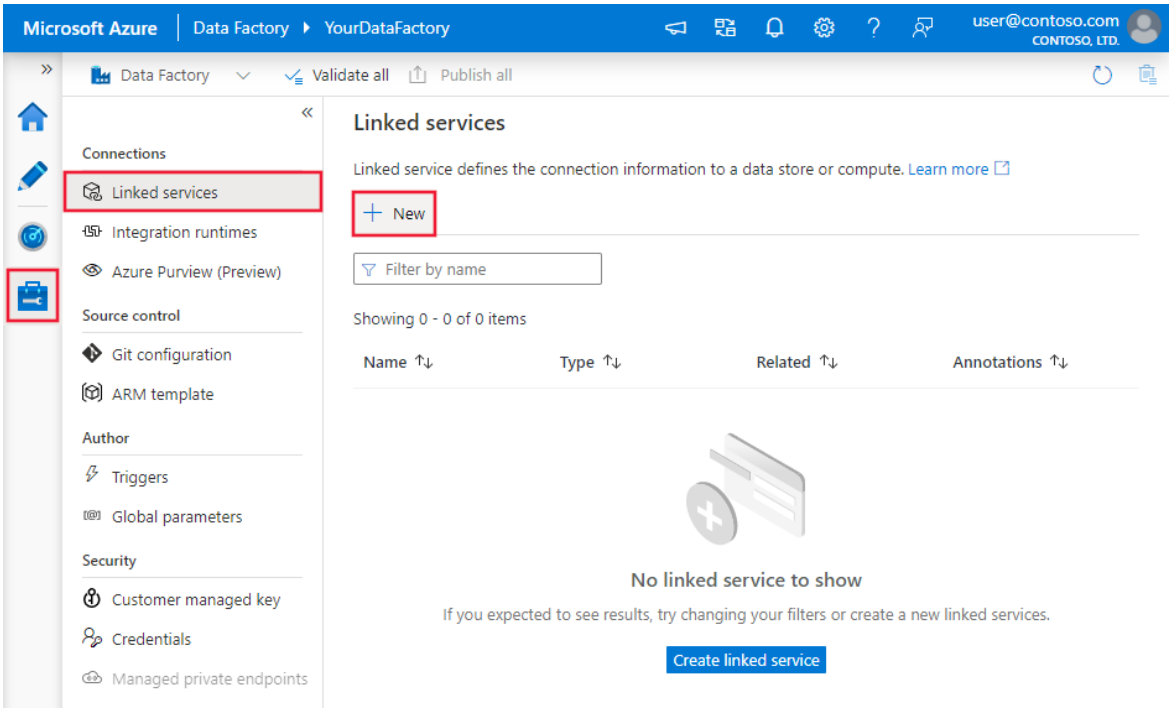
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create an SFTP linked service using UI

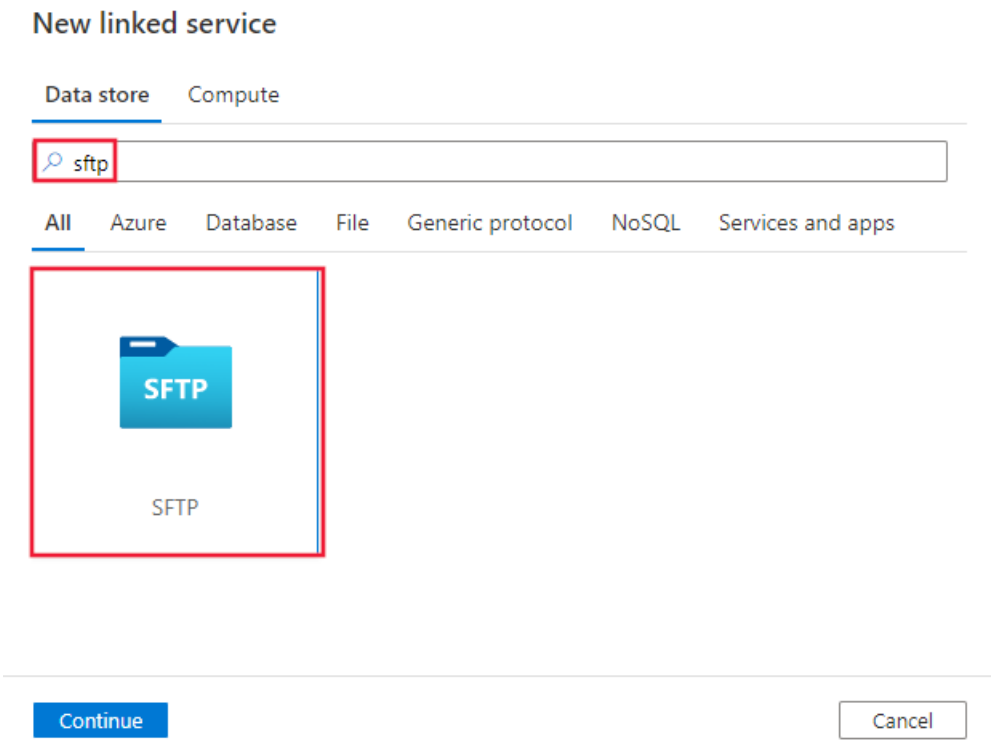
Use the following steps to create an SFTP linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

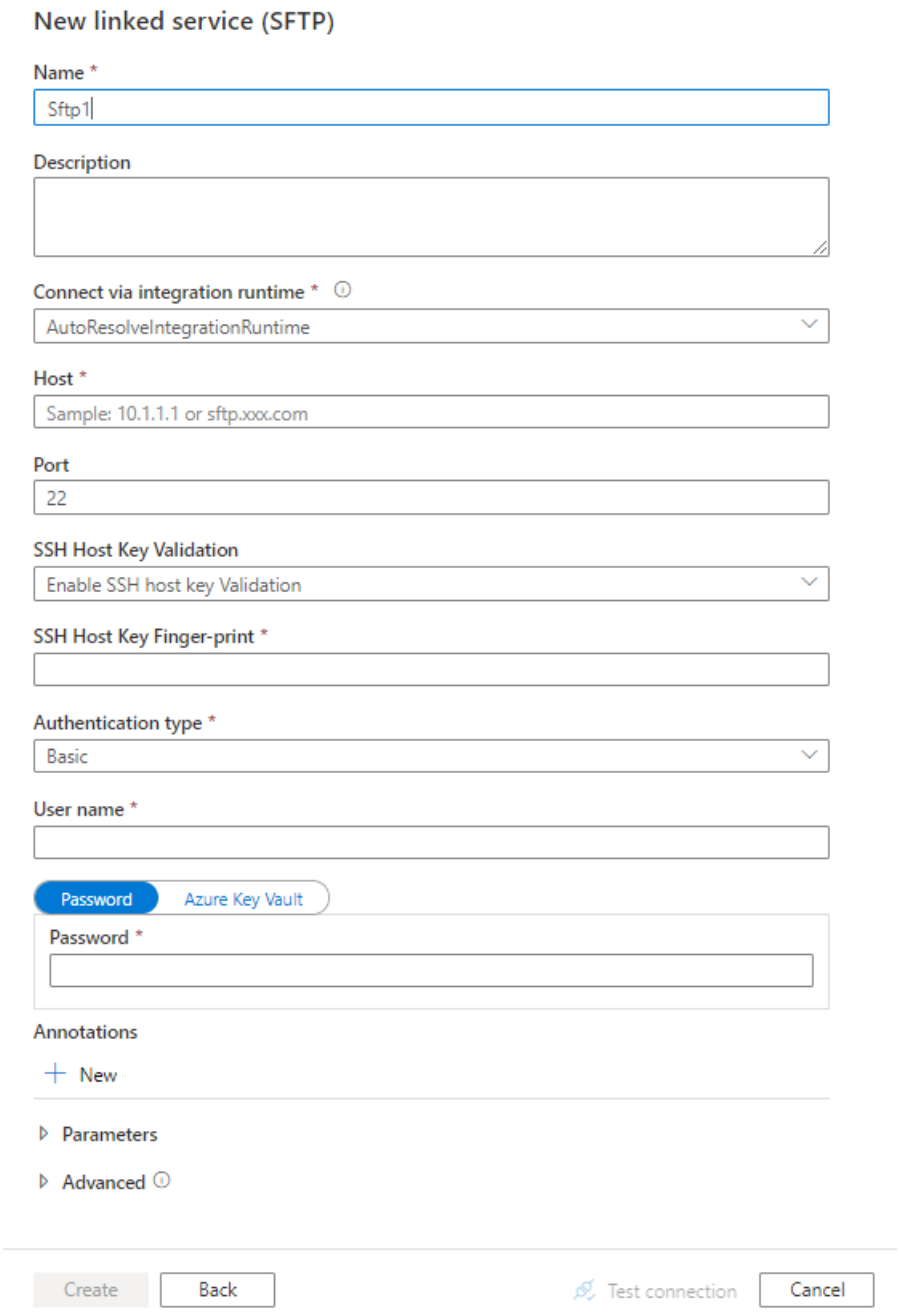
   - Azure Data Factory
   - Azure Synapse



2. Search for SFTP and select the SFTP connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define entities specific to SFTP.

Linked service properties

The following properties are supported for the SFTP linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to *Sftp*.	Yes
host	The name or IP address of the SFTP server.	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	The port on which the SFTP server is listening. The allowed value is an integer, and the default value is *22*.	No
skipHostKeyValidation	Specify whether to skip host key validation. Allowed values are *true* and *false* (default).	No
hostKeyFingerprint	Specify the fingerprint of the host key.	Yes, if the "skipHostKeyValidation" is set to false.
authenticationType	Specify the authentication type. Allowed values are *Basic*, *SshPublicKey* and *MultiFactor*. For more properties, see the Use basic authentication section. For JSON examples, see the Use SSH public key authentication section.	Yes
connectVia	The integration runtime to be used to connect to the data store. To learn more, see the Prerequisites section. If the integration runtime isn't specified, the service uses the default Azure Integration Runtime.	No

Use basic authentication

To use basic authentication, set the *authenticationType* property to *Basic*, and specify the following properties in addition to the SFTP connector generic properties that were introduced in the preceding section:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user who has access to the SFTP server.	Yes
password	The password for the user (userName). Mark this field as a SecureString to store it securely, or reference a secret stored in an Azure key vault.	Yes

Example:

```
{
    "name": "SftpLinkedService",
    "properties": {
        "type": "Sftp",
        "typeProperties": {
            "host": "<sftp server>",
            "port": 22,
            "skipHostKeyValidation": false,
            "hostKeyFingerPrint": "ssh-rsa 2048 xx:00:00:00:xx:00:x0:0x:0x:0x:0x:00:00:x0:x0:00",
            "authenticationType": "Basic",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use SSH public key authentication

To use SSH public key authentication, set "authenticationType" property as **SshPublicKey**, and specify the following properties besides the SFTP connector generic ones introduced in the last section:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user who has access to the SFTP server.	Yes
privateKeyPath	Specify the absolute path to the private key file that the integration runtime can access. This applies only when the self-hosted type of integration runtime is specified in "connectVia."	Specify either `privateKeyPath` or `privateKeyContent`.
privateKeyContent	Base64 encoded SSH private key content. SSH private key should be OpenSSH format. Mark this field as a SecureString to store it securely, or reference a secret stored in an Azure key vault.	Specify either `privateKeyPath` or `privateKeyContent`.
passPhrase	Specify the pass phrase or password to decrypt the private key if the key file or the key content is protected by a pass phrase. Mark this field as a SecureString to store it securely, or reference a secret stored in an Azure key vault.	Yes, if the private key file or the key content is protected by a pass phrase.

NOTE

The SFTP connector supports an RSA/DSA OpenSSH key. Make sure that your key file content starts with "-----BEGIN [RSA/DSA] PRIVATE KEY-----". If the private key file is a PPK-format file, use the PuTTY tool to convert from PPK to OpenSSH format.

Example 1: SshPublicKey authentication using private key filePath

```
{
    "name": "SftpLinkedService",
    "properties": {
        "type": "Sftp",
        "typeProperties": {
            "host": "<sftp server>",
            "port": 22,
            "skipHostKeyValidation": true,
            "authenticationType": "SshPublicKey",
            "userName": "xxx",
            "privateKeyPath": "D:\\privatekey_openssh",
            "passPhrase": {
                "type": "SecureString",
                "value": "<pass phrase>"
            }
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example 2: SshPublicKey authentication using private key content

```
{
    "name": "SftpLinkedService",
    "type": "Linkedservices",
    "properties": {
        "type": "Sftp",
        "typeProperties": {
            "host": "<sftp server>",
            "port": 22,
            "skipHostKeyValidation": true,
            "authenticationType": "SshPublicKey",
            "userName": "<username>",
            "privateKeyContent": {
                "type": "SecureString",
                "value": "<base64 string of the private key content>"
            },
            "passPhrase": {
                "type": "SecureString",
                "value": "<pass phrase>"
            }
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Use multi-factor authentication

To use multi-factor authentication which is a combination of basic and SSH public key authentications, specify the user name, password and the private key info described in above sections.

Example: multi-factor authentication

```
{
    "name": "SftpLinkedService",
    "properties": {
        "type": "Sftp",
        "typeProperties": {
            "host": "<host>",
            "port": 22,
            "authenticationType": "MultiFactor",
            "userName": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            },
            "privateKeyContent": {
                "type": "SecureString",
                "value": "<base64 encoded private key content>"
            },
            "passPhrase": {
                "type": "SecureString",
                "value": "<passphrase for private key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of integration runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see the Datasets article.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for SFTP under `location` settings in the format-based dataset:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property under `location` in dataset must be set to *SftpLocation*.	Yes
folderPath	The path to the folder. If you want to use a wildcard to filter the folder, skip this setting and specify the path in activity source settings.	No

PROPERTY	DESCRIPTION	REQUIRED
fileName	The file name under the specified folderPath. If you want to use a wildcard to filter files, skip this setting and specify the file name in activity source settings.	No

Example:

```
{
    "name": "DelimitedTextDataset",
    "properties": {
        "type": "DelimitedText",
        "linkedServiceName": {
            "referenceName": "<SFTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, auto retrieved during authoring > ],
        "typeProperties": {
            "location": {
                "type": "SftpLocation",
                "folderPath": "root/folder/subfolder"
            },
            "columnDelimiter": ",",
            "quoteChar": "\"",
            "firstRowAsHeader": true,
            "compressionCodec": "gzip"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties that are available for defining activities, see the Pipelines article. This section provides a list of properties that are supported by the SFTP source.

SFTP as source

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

The following properties are supported for SFTP under the `storeSettings` settings in the format-based Copy source:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property under `storeSettings` must be set to *SftpReadSettings*.	Yes

PROPERTY	DESCRIPTION	REQUIRED
Locate the files to copy		
OPTION 1: static path	Copy from the folder/file path that's specified in the dataset. If you want to copy all files from a folder, additionally specify `wildcardFileName` as `*`.	
OPTION 2: wildcard - wildcardFolderPath	The folder path with wildcard characters to filter source folders. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character); use `^` to escape if your actual folder name has a wildcard or this escape char inside. For more examples, see Folder and file filter examples.	No
OPTION 2: wildcard - wildcardFileName	The file name with wildcard characters under the specified folderPath/wildcardFolderPath to filter source files. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character); use `^` to escape if your actual file name has wildcard or this escape char inside. For more examples, see Folder and file filter examples.	Yes
OPTION 3: a list of files - fileListPath	Indicates to copy a specified file set. Point to a text file that includes a list of files you want to copy (one file per line, with the relative path to the path configured in the dataset). When you use this option, don't specify the file name in the dataset. For more examples, see File list examples.	No
Additional settings		
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When recursive is set to true and the sink is a file-based store, an empty folder or subfolder isn't copied or created at the sink. Allowed values are *true* (default) and *false*. This property doesn't apply when you configure `fileListPath`.	No

PROPERTY	DESCRIPTION	REQUIRED
deleteFilesAfterCompletion	Indicates whether the binary files will be deleted from source store after successfully moving to the destination store. The file deletion is per file, so when copy activity fails, you will see some files have already been copied to the destination and deleted from source, while others are still remaining on source store. This property is only valid in binary files copy scenario. The default value: false.	No
modifiedDatetimeStart	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to the UTC time zone in the format of *2018-12-01T05:00:00Z*. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected. This property doesn't apply when you configure `fileListPath`.	No
modifiedDatetimeEnd	Same as above.	No
enablePartitionDiscovery	For files that are partitioned, specify whether to parse the partitions from the file path and add them as additional source columns. Allowed values are **false** (default) and **true**.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionRootPath	When partition discovery is enabled, specify the absolute root path in order to read partitioned folders as data columns. If it is not specified, by default, - When you use file path in dataset or list of files on source, partition root path is the path configured in dataset. - When you use wildcard folder filter, partition root path is the sub-path before the first wildcard. For example, assuming you configure the path in dataset as "root/folder/year=2020/month=08/day=27": - If you specify partition root path as "root/folder/year=2020", copy activity will generate two more columns `month` and `day` with value "08" and "27" respectively, in addition to the columns inside the files. - If partition root path is not specified, no extra column will be generated.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No
disableChunking	When copying data from SFTP, the service tries to get the file length first, then divide the file into multiple parts and read them in parallel. Specify whether your SFTP server supports getting file length or seeking to read from a certain offset. Allowed values are **false** (default), **true**.	No

Example:

```
"activities":[
    {
        "name": "CopyFromSFTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Delimited text input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "DelimitedTextSource",
                "formatSettings":{
                    "type": "DelimitedTextReadSettings",
                    "skipLineCount": 10
                },
                "storeSettings":{
                    "type": "SftpReadSettings",
                    "recursive": true,
                    "wildcardFolderPath": "myfolder*A",
                    "wildcardFileName": "*.csv",
                    "disableChunking": false
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

SFTP as a sink

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The following properties are supported for SFTP under `storeSettings` settings in a format-based Copy sink:

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property under `storeSettings` must be set to *SftpWriteSettings*.	Yes

PROPERTY	DESCRIPTION	REQUIRED
copyBehavior	Defines the copy behavior when the source is files from a file-based data store. Allowed values are: - **PreserveHierarchy (default)**: Preserves the file hierarchy in the target folder. The relative path of the source file to the source folder is identical to the relative path of the target file to the target folder. - **FlattenHierarchy**: All files from the source folder are in the first level of the target folder. The target files have autogenerated names. - **MergeFiles**: Merges all files from the source folder to one file. If the file name is specified, the merged file name is the specified name. Otherwise, it's an autogenerated file name.	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No
useTempFileRename	Indicate whether to upload to temporary files and rename them, or directly write to the target folder or file location. By default, the service first writes to temporary files and then renames them when the upload is finished. This sequence helps to (1) avoid conflicts that might result in a corrupted file if you have other processes writing to the same file, and (2) ensure that the original version of the file exists during the transfer. If your SFTP server doesn't support a rename operation, disable this option and make sure that you don't have a concurrent write to the target file. For more information, see the troubleshooting tip at the end of this table.	No. Default value is *true*.
operationTimeout	The wait time before each write request to SFTP server times out. Default value is 60 min (01:00:00).	No

TIP

If you receive the error "UserErrorSftpPathNotFound," "UserErrorSftpPermissionDenied," or "SftpOperationFail" when you're writing data into SFTP, and the SFTP user you use *does* have the proper permissions, check to see whether your SFTP server support file rename operation is working. If it isn't, disable the **Upload with temp file** (`useTempFileRename`) option and try again. To learn more about this property, see the preceding table. If you use a self-hosted integration runtime for the Copy activity, be sure to use version 4.6 or later.

Example:

```
"activities":[
    {
        "name": "CopyToSFTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "BinarySink",
                "storeSettings":{
                    "type": "SftpWriteSettings",
                    "copyBehavior": "PreserveHierarchy"
                }
            }
        }
    }
]
```

Folder and file filter examples

This section describes the behavior that results from using wildcard filters with folder paths and file names.

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	(empty, use default)	false	FolderA **File1.csv** **File2.json** Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	(empty, use default)	true	FolderA **File1.csv** **File2.json** Subfolder1 **File3.csv** **File4.json** **File5.csv** AnotherFolderB File6.csv

FOLDERPATH	FILENAME	RECURSIVE	SOURCE FOLDER STRUCTURE AND FILTER RESULT (FILES IN BOLD ARE RETRIEVED)
`Folder*`	`*.csv`	false	FolderA **File1.csv** File2.json Subfolder1 File3.csv File4.json File5.csv AnotherFolderB File6.csv
`Folder*`	`*.csv`	true	FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** AnotherFolderB File6.csv

File list examples

This table describes the behavior that results from using a file list path in the Copy activity source. It assumes that you have the following source folder structure and want to copy the files that are in bold type:

SAMPLE SOURCE STRUCTURE	CONTENT IN FILELISTTOCOPY.TXT	AZURE DATA FACTORY CONFIGURATION
root FolderA **File1.csv** File2.json Subfolder1 **File3.csv** File4.json **File5.csv** Metadata FileListToCopy.txt	File1.csv Subfolder1/File3.csv Subfolder1/File5.csv	**In the dataset:** - Folder path: `root/FolderA` **In the Copy activity source:** - File list path: `root/Metadata/FileListToCopy.txt` The file list path points to a text file in the same data store that includes a list of files you want to copy (one file per line, with the relative path to the path configured in the dataset).

Mapping data flow properties

When you're transforming data in mapping data flows, you can read and write files from SFTP in the following formats:

- Avro
- Delimited text
- Excel
- JSON
- ORC
- Parquet
- XML

Format specific settings are located in the documentation for that format. For more information, see Source transformation in mapping data flow and Sink transformation in mapping data flow.

> **NOTE**
> SSH host key validation is not supported in mapping data flow now.

> **NOTE**
> To access on premise SFTP sever, you need to use Azure Data Factory or Synapse workspace Managed Virtual Network using a private endpoint. Refer to this tutorial for detailed steps.

Source transformation

The below table lists the properties supported by SFTP source. You can edit these properties in the **Source options** tab. When using inline dataset, you will see additional settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wildcard path	Using a wildcard pattern will instruct ADF to loop through each matching folder and file in a single source transformation. This is an effective way to process multiple files within a single flow.	No	String[]	wildcardPaths
Partition Root Path	If you have partitioned folders in your file source with a `key=value` format (for example, `year=2019`), then you can assign the top level of that partition folder tree to a column name in your data flow data stream.	No	String	partitionRootPath
Allow no files found	If true, an error is not thrown if no files are found.	No	`true` or `false`	ignoreNoFilesFound
List of files	This is a file set. Create a text file that includes a list of relative path files to process. Point to this text file.	No	`true` or `false`	fileList

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Column to store file name	Store the name of the source file in a column in your data. Enter a new column name here to store the file name string.	No	String	rowUrlColumn
After completion	Choose to do nothing with the source file after the data flow runs, delete the source file, or move the source file. The paths for the move are relative.	No	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	You can filter which files you process by specifying a date range of when they were last modified. All date-times are in UTC.	No	Timestamp	modifiedAfter modifiedBefore

SFTP source script example

When you use SFTP dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 ignoreNoFilesFound: true,
 purgeFiles: true,
 fileList: true,
 modifiedAfter: (toTimestamp(1647388800000L)),
 modifiedBefore: (toTimestamp(1647561600000L)),
 partitionRootPath: 'partdata',
 wildcardPaths:['partdata/**/*.csv']) ~> SFTPSource
```

Sink transformation

The below table lists the properties supported by SFTP sink. You can edit these properties in the **Settings** tab. When using inline dataset, you will see additional settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Clear the folder	Determines whether or not the destination folder gets cleared before the data is written.	No	`true` or `false`	truncate

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
File name option	The naming format of the data written. By default, one file per partition in format `part-#####-tid-<guid>` .	No	Pattern: String Per partition: String[] Name file as column data: String Name folder as column data: String Output to single file: `['<fileName>']`	filePattern partitionFileNames rowUrlColumn rowFolderUrlColumn partitionFileNames
Quote all	Determines whether to enclose all values in quotes.	No	`true` or `false`	quoteAll

SFTP sink script example

When you use SFTP dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
 validateSchema: false,
 filePattern:'loans[n].csv',
 truncate: true,
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true) ~> SFTPSink
```

Lookup activity properties

For information about Lookup activity properties, see Lookup activity.

GetMetadata activity properties

For information about GetMetadata activity properties, see GetMetadata activity.

Delete activity properties

For information about Delete activity properties, see Delete activity.

Legacy models

> **NOTE**
> The following models are still supported as is for backward compatibility. We recommend that you use the previously discussed new model, because the authoring UI has switched to generating the new model.

Legacy dataset model

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property of the dataset must be set to *FileShare*.	Yes

PROPERTY	DESCRIPTION	REQUIRED
folderPath	The path to the folder. A wildcard filter is supported. Allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character); use `^` to escape if your actual file name has a wildcard or this escape char inside. Examples: rootfolder/subfolder/, see more examples in Folder and file filter examples.	Yes
fileName	**Name or wildcard filter** for the files under the specified "folderPath". If you don't specify a value for this property, the dataset points to all files in the folder. For filter, the allowed wildcards are `*` (matches zero or more characters) and `?` (matches zero or a single character). - Example 1: `"fileName": "*.csv"` - Example 2: `"fileName": "???20180427.txt"` Use `^` to escape if your actual folder name has wildcard or this escape char inside.	No
modifiedDatetimeStart	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of *2018-12-01T05:00:00Z*. The overall performance of data movement will be affected by enabling this setting when you want to do file filter from large numbers of files. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected.	No

PROPERTY	DESCRIPTION	REQUIRED
modifiedDatetimeEnd	Files are filtered based on the attribute *Last Modified*. The files are selected if their last modified time is greater than or equal to `modifiedDatetimeStart` and less than `modifiedDatetimeEnd`. The time is applied to UTC time zone in the format of *2018-12-01T05:00:00Z*. The overall performance of data movement will be affected by enabling this setting when you want to do file filter from large numbers of files. The properties can be NULL, which means that no file attribute filter is applied to the dataset. When `modifiedDatetimeStart` has a datetime value but `modifiedDatetimeEnd` is NULL, it means that the files whose last modified attribute is greater than or equal to the datetime value are selected. When `modifiedDatetimeEnd` has a datetime value but `modifiedDatetimeStart` is NULL, it means that the files whose last modified attribute is less than the datetime value are selected.	No
format	If you want to copy files as is between file-based stores (binary copy), skip the format section in both input and output dataset definitions. If you want to parse files with a specific format, the following file format types are supported: *TextFormat*, *JsonFormat*, *AvroFormat*, *OrcFormat*, and *ParquetFormat*. Set the *type* property under format to one of these values. For more information, see Text format, Json format, Avro format, Orc format, and Parquet format sections.	No (only for binary copy scenario)
compression	Specify the type and level of compression for the data. For more information, see Supported file formats and compression codecs. Supported types are *GZip*, *Deflate*, *BZip2*, and *ZipDeflate*. Supported levels are *Optimal* and *Fastest*.	No

TIP

To copy all files under a folder, specify *folderPath* only.
To copy a single file with a specified name, specify *folderPath* with the folder part and *fileName* with the file name.
To copy a subset of files under a folder, specify *folderPath* with the folder part and *fileName* with the wildcard filter.

> **NOTE**
>
> If you were using *fileFilter* property for the file filter, it is still supported as is, but we recommend that you use the new filter capability added to *fileName* from now on.

Example:

```
{
    "name": "SFTPDataset",
    "type": "Datasets",
    "properties": {
        "type": "FileShare",
        "linkedServiceName":{
            "referenceName": "<SFTP linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "folderPath": "folder/subfolder/",
            "fileName": "*",
            "modifiedDatetimeStart": "2018-12-01T05:00:00Z",
            "modifiedDatetimeEnd": "2018-12-01T06:00:00Z",
            "format": {
                "type": "TextFormat",
                "columnDelimiter": ",",
                "rowDelimiter": "\n"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

Legacy Copy activity source model

PROPERTY	DESCRIPTION	REQUIRED
type	The *type* property of the Copy activity source must be set to *FileSystemSource*	Yes
recursive	Indicates whether the data is read recursively from the subfolders or only from the specified folder. When recursive is set to *true* and the sink is a file-based store, empty folders and subfolders won't be copied or created at the sink. Allowed values are *true* (default) and *false*	No
maxConcurrentConnections	The upper limit of concurrent connections established to the data store during the activity run. Specify a value only when you want to limit concurrent connections.	No

Example:

```
"activities":[
    {
        "name": "CopyFromSFTP",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SFTP input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "FileSystemSource",
                "recursive": true
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Next steps

For a list of data stores that are supported as sources and sinks by the Copy activity, see supported data stores.

Copy data from SharePoint Online List by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Copy Activity in Azure Data Factory and Azure Synapse pipelines to copy data from SharePoint Online List. The article builds on Copy Activity, which presents a general overview of Copy Activity.

Supported capabilities

This SharePoint Online List connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks, see the Supported data stores table.

Specifically, this SharePoint List Online connector uses service principal authentication and retrieves data via OData protocol.

> **TIP**
> This connector supports copying data from SharePoint Online **List** but not file. Learn how to copy file from Copy file from SharePoint Online section.

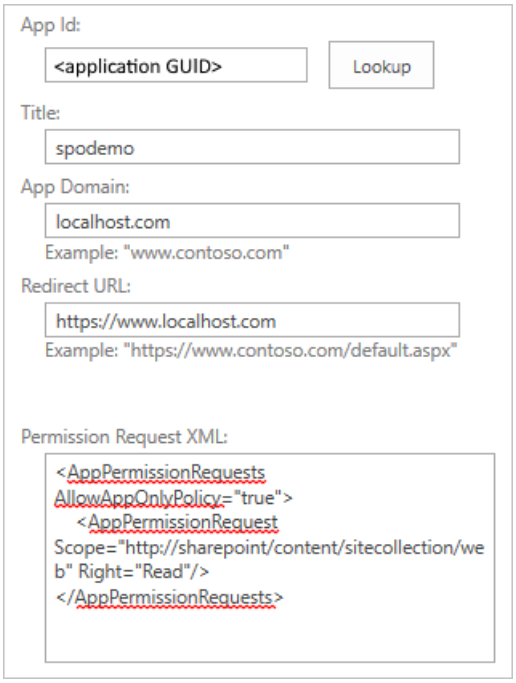
Prerequisites

The SharePoint List Online connector uses service principal authentication to connect to SharePoint. Follow these steps to set it up:

1. Register an application entity in Azure Active Directory (Azure AD) by following Register your application with an Azure AD tenant. Make note of the following values, which you use to define the linked service:
   - Application ID
   - Application key
   - Tenant ID
2. Grant SharePoint Online site permission to your registered application by following the steps below. To do this, you need a site admin role.
   a. Open SharePoint Online site link e.g. `https://[your_site_url]/_layouts/15/appinv.aspx` (replace the site URL).
   b. Search the application ID you registered, fill the empty fields, and click "Create".

- App Domain: `localhost.com`
- Redirect URL: `https://www.localhost.com`
- Permission Request XML:

```
<AppPermissionRequests AllowAppOnlyPolicy="true">
    <AppPermissionRequest Scope="http://sharepoint/content/sitecollection/web"
Right="Read"/>
</AppPermissionRequests>
```



c. Click "Trust It" for this app.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

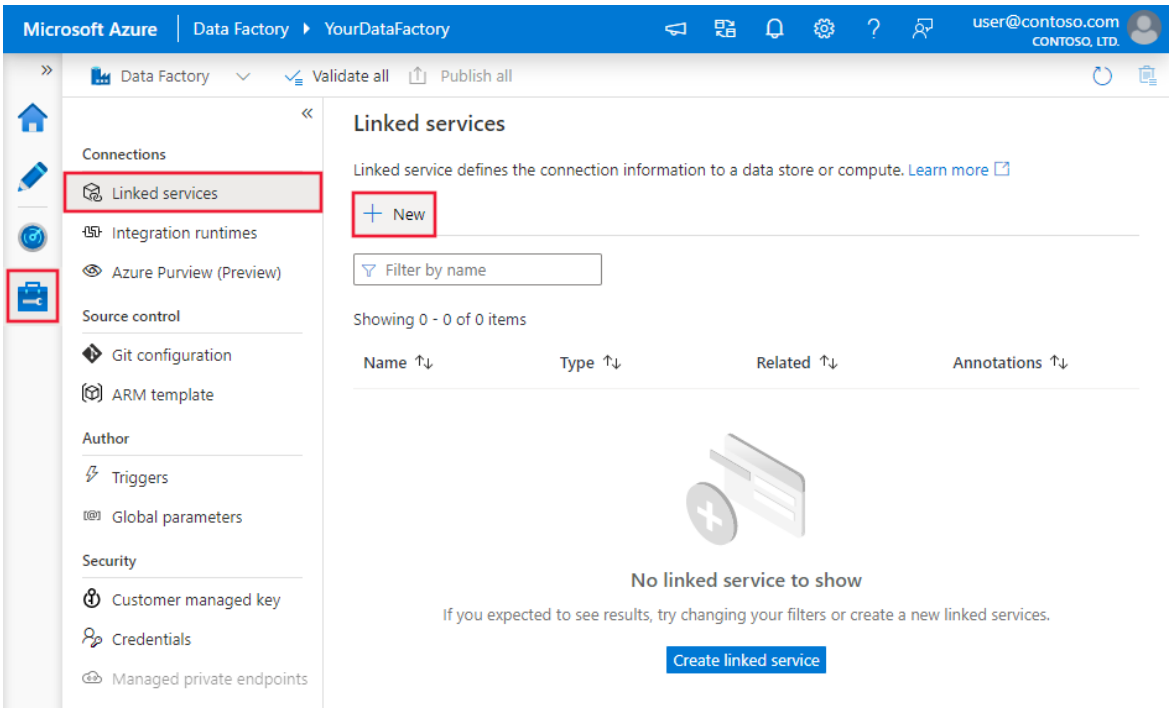
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to a SharePoint Online List using UI

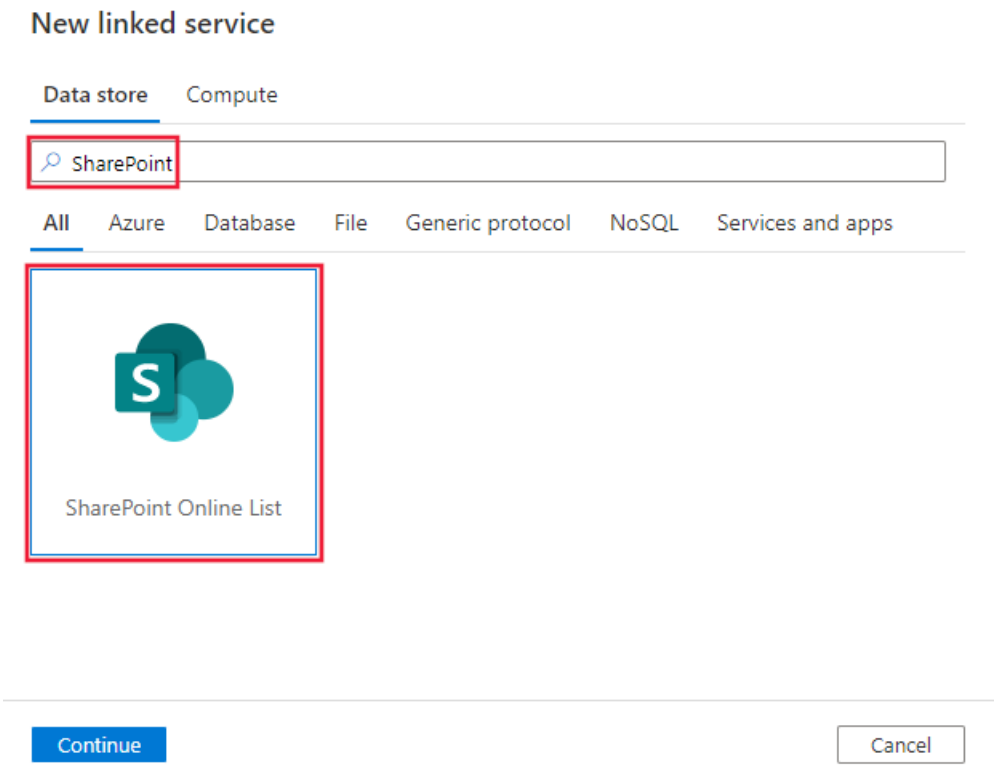
Use the following steps to create a linked service to a SharePoint Online List in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

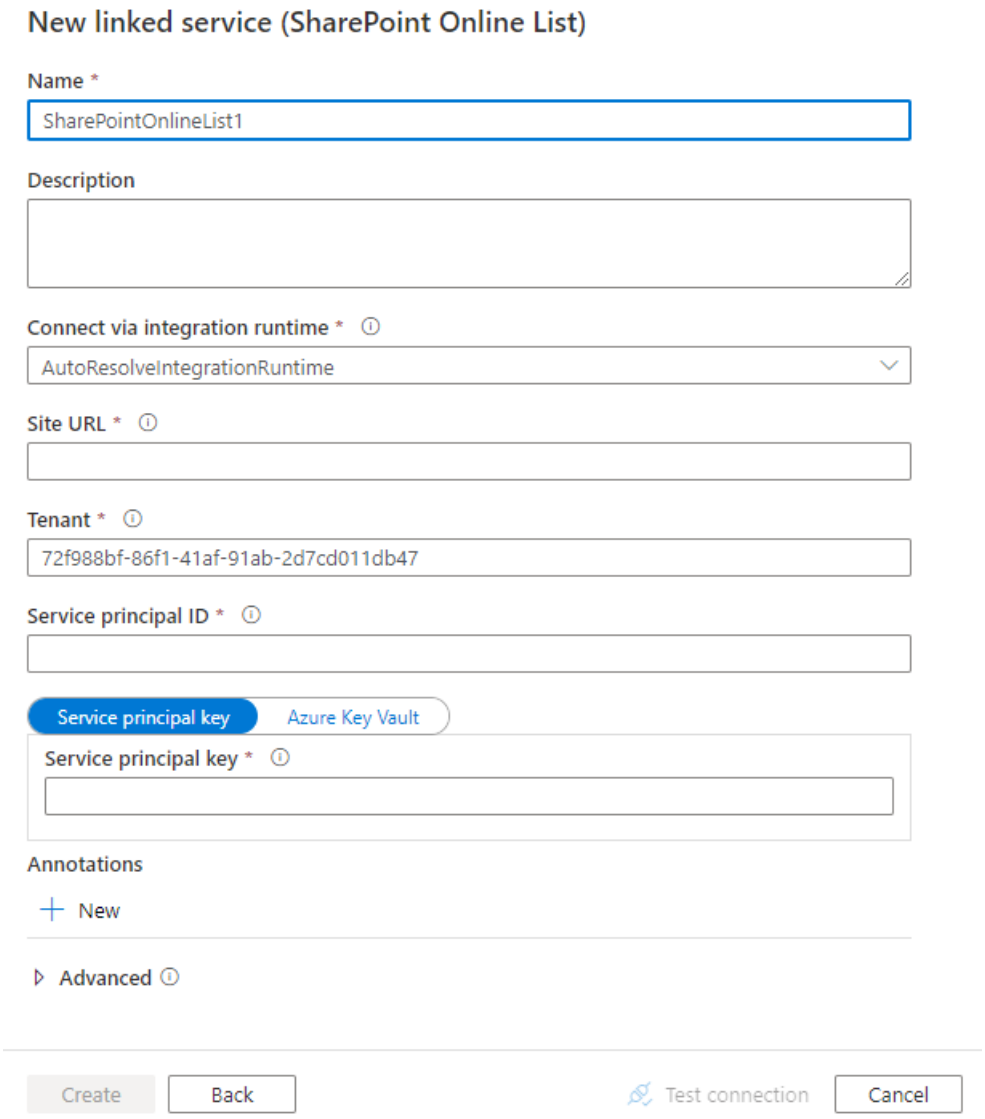
   - Azure Data Factory
   - Azure Synapse



2. Search for SharePoint and select the SharePoint Online List connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties you can use to define entities that are specific to SharePoint Online List connector.

Linked service properties

The following properties are supported for a SharePoint Online List linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to:**SharePointOnlineList**.	Yes
siteUrl	The SharePoint Online site url, e.g. `https://contoso.sharepoint.com/sites/siteName` .	Yes
servicePrincipalId	The Application (client) ID of the application registered in Azure Active Directory.	Yes

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalKey	The application's key. Mark this field as a **SecureString** to store it securely, or reference a secret stored in Azure Key Vault.	Yes
tenantId	The tenant ID under which your application resides.	Yes
connectVia	The Integration Runtime to use to connect to the data store. Learn more from Prerequisites, earlier in this article. If not specified, the default Azure Integration Runtime is used.	No

Example:

```
{
    "name": "SharePointOnlineList",
    "properties": {
        "type": "SharePointOnlineList",
        "typeProperties": {
            "siteUrl": "<site URL>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            },
            "tenantId": "<tenant ID>"
        }
    }
}
```

Dataset properties

For a full list of sections and properties that are available for defining datasets, see Datasets and linked services. The following section provides a list of the properties supported by the SAP table dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the dataset must be set to **SharePointOnlineLResource**.	Yes
listName	The name of the SharePoint Online List.	Yes

Example

```
{
    "name": "SharePointOnlineListDataset",
    "properties":
    {
        "type": "SharePointOnlineListResource",
        "linkedServiceName": {
            "referenceName": "<SharePoint Online List linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties":
        {
            "listName":"<name of the list>"
        }
    }
}
```

Copy Activity properties

For a full list of sections and properties that are available for defining activities, see Pipelines. The following section provides a list of the properties supported by the SharePoint Online List source.

SharePoint Online List as source

To copy data from SharePoint Online List, the following properties are supported in the Copy Activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The **type** property of the Copy Activity source must be set to **SharePointOnlineListSource**.	Yes
query	Custom OData query options for filtering data. Example: `"$top=10&$select=Title,Number"`.	No
httpRequestTimeout	The timeout (in second) for the HTTP request to get a response. Default is 300 (5 minutes).	No

Example

```
"activities":[
    {
        "name": "CopyFromSharePointOnlineList",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SharePoint Online List input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source":{
                "type":"SharePointOnlineListSource",
                "query":"<ODataquerye.g.$top=10&$select=Title,Number>"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

NOTE

It isn't possible to select more than one *choice* data type for a SharePoint Online List source.

Data type mapping for SharePoint Online List

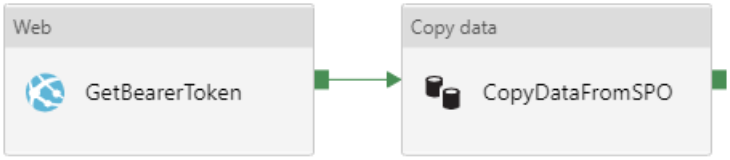
When you copy data from SharePoint Online List, the following mappings are used between SharePoint Online List data types and interim data types used by the service internally.

SHAREPOINT ONLINE DATA TYPE	ODATA DATA TYPE	INTERIM DATA TYPE
Single line of text	Edm.String	String
Multiple lines of text	Edm.String	String
Choice (menu to choose from)	Edm.String	String
Number (1, 1.0, 100)	Edm.Double	Double
Currency ($, ¥, €)	Edm.Double	Double
Date and Time	Edm.DateTime	DateTime
Lookup (information already on this site)	Edm.Int32	Int32
Yes/No (check box)	Edm.Boolean	Boolean
Person or Group	Edm.Int32	Int32

SHAREPOINT ONLINE DATA TYPE	ODATA DATA TYPE	INTERIM DATA TYPE
Hyperlink or Picture	Edm.String	String
Calculated (calculation based on other columns)	Edm.String / Edm.Double / Edm.DateTime / Edm.Boolean	String / Double / DateTime / Boolean
Attachment	Not supported	
Task Outcome	Not supported	
External Data	Not supported	
Managed Metadata	Not supported	

Copy file from SharePoint Online

You can copy file from SharePoint Online by using **Web activity** to authenticate and grab access token from SPO, then passing to subsequent **Copy activity** to copy data with **HTTP connector as source**.



1. Follow the Prerequisites section to create AAD application and grant permission to SharePoint Online.
2. Create a **Web Activity** to get the access token from SharePoint Online:
   - **URL**: `https://accounts.accesscontrol.windows.net/[Tenant-ID]/tokens/OAuth/2`. Replace the tenant ID.
   - **Method**: POST
   - **Headers**:
     - Content-Type: application/x-www-form-urlencoded
   - **Body**:
     `grant_type=client_credentials&client_id=[Client-ID]@[Tenant-ID]&client_secret=[Client-Secret]&resource=00000003-0000-0ff1-ce00-000000000000/[Tenant-Name].sharepoint.com@[Tenant-ID]`
     . Replace the client ID (application ID), client secret (application key), tenant ID, and tenant name (of the SharePoint tenant).

   Caution

   Set the Secure Output option to true in Web activity to prevent the token value from being logged in plain text. Any further activities that consume this value should have their Secure Input option set to true.
3. Chain with a **Copy activity** with HTTP connector as source to copy SharePoint Online file content:
   - HTTP linked service:
     - **Base URL**:
       `https://[site-url]/_api/web/GetFileByServerRelativeUrl('[relative-path-to-file]')/$value`.
       Replace the site URL and relative path to file. Make sure to include the SharePoint site URL along with the Domain name, such as
       `https://[sharepoint-domain-name].sharepoint.com/sites/[sharepoint-site]/_api/web/GetFileByServerRelativeUrl('/sites/[sharepoint-site]/[relative-path-to-file]')/$value`
       .
     - **Authentication type:** Anonymous *(to use the Bearer token configured in copy activity source*

later)

- Dataset: choose the format you want. To copy file as-is, select "Binary" type.
- Copy activity source:
  - **Request method**: GET
  - **Additional header**: use the following expression `@{concat('Authorization: Bearer ', activity('<Web-activity-name>').output.access_token)}`, which uses the Bearer token generated by the upstream Web activity as authorization header. Replace the Web activity name.
- Configure the copy activity sink as usual.

> **NOTE**
>
> Even if an Azure AD application has `FullControl` permissions on SharePoint Online, you can't copy files from document libraries with IRM enabled.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores that Copy Activity supports as sources and sinks, see Supported data stores and formats.

Copy data from Shopify using Azure Data Factoryor Synapse Analytics (Preview)

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Shopify. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Shopify connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

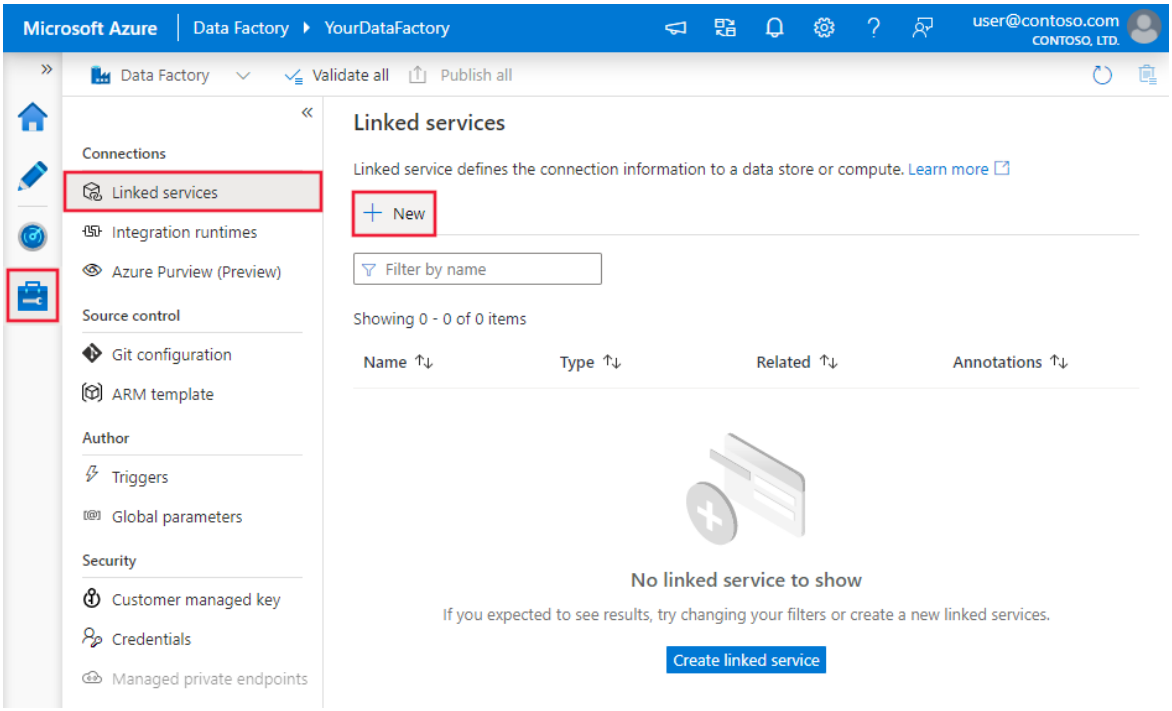
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Shopify using UI

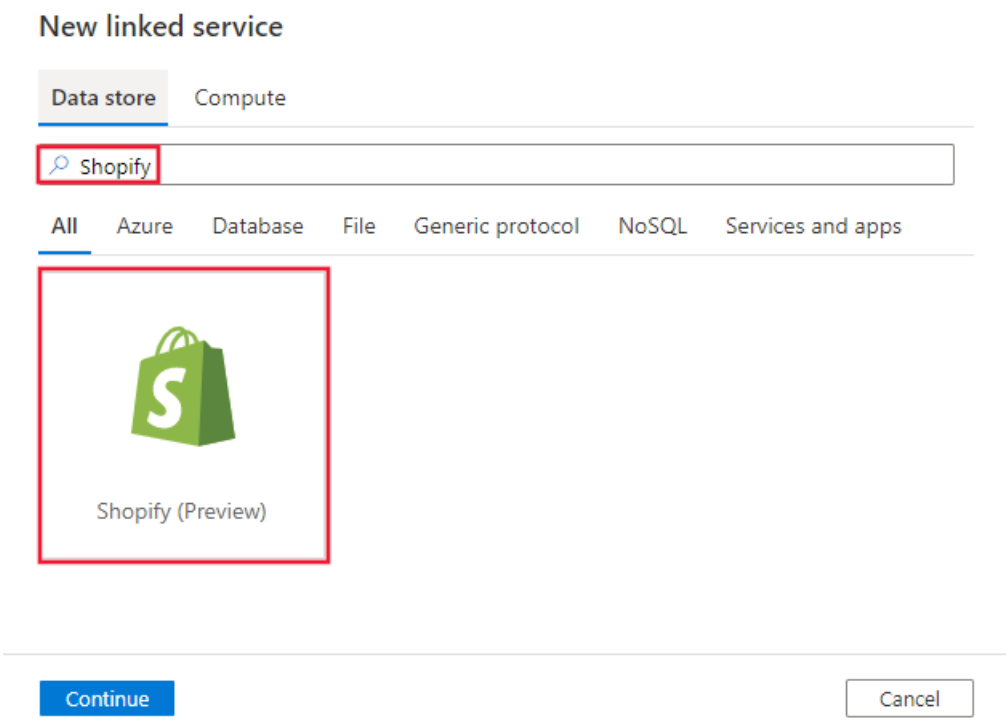
Use the following steps to create a linked service to Shopify in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

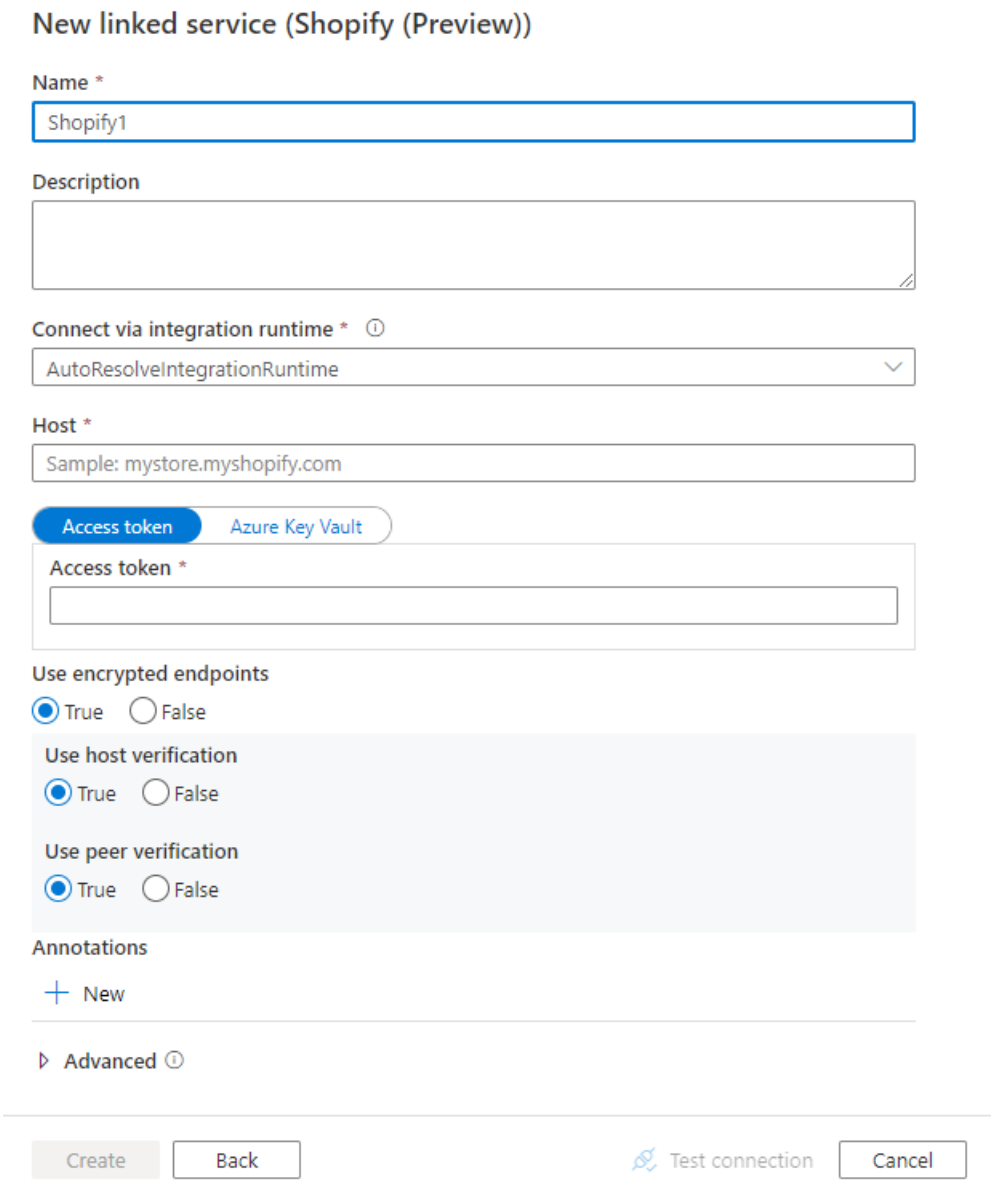
- Azure Data Factory
- Azure Synapse



2. Search for Shopify and select the Shopify connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Shopify connector.

Linked service properties

The following properties are supported for Shopify linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Shopify**	Yes
host	The endpoint of the Shopify server. (that is, mystore.myshopify.com)	Yes

PROPERTY	DESCRIPTION	REQUIRED
accessToken	The API access token that can be used to access Shopify's data. The token does not expire if it is offline mode. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example:

```
{
    "name": "ShopifyLinkedService",
    "properties": {
        "type": "Shopify",
        "typeProperties": {
            "host" : "mystore.myshopify.com",
            "accessToken": {
                 "type": "SecureString",
                 "value": "<accessToken>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Shopify dataset.

To copy data from Shopify, set the type property of the dataset to **ShopifyObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ShopifyObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "ShopifyDataset",
    "properties": {
        "type": "ShopifyObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Shopify linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Shopify source.

Shopify as source

To copy data from Shopify, set the source type in the copy activity to **ShopifySource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **ShopifySource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM "Products" WHERE Product_Id = '123'"` .	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromShopify",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Shopify input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ShopifySource",
                "query": "SELECT * FROM \"Products\" WHERE Product_Id = '123'"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Transform data in Smartsheet (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in Smartsheet (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Smartsheet connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

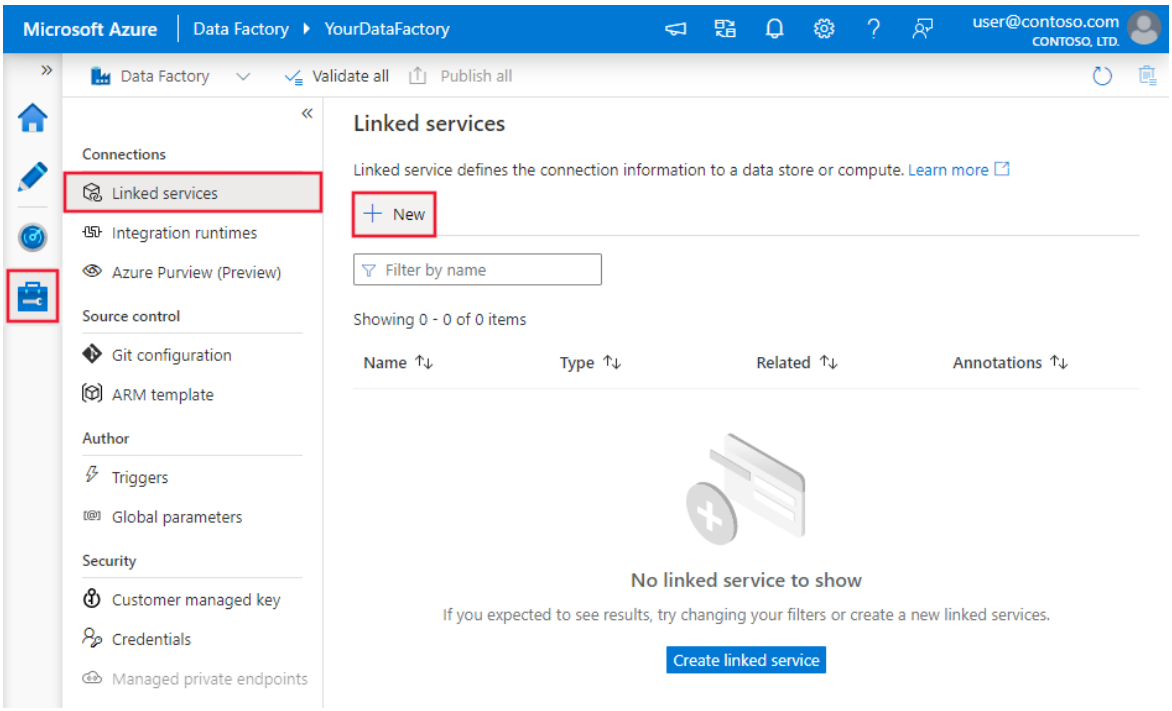
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a Smartsheet linked service using UI

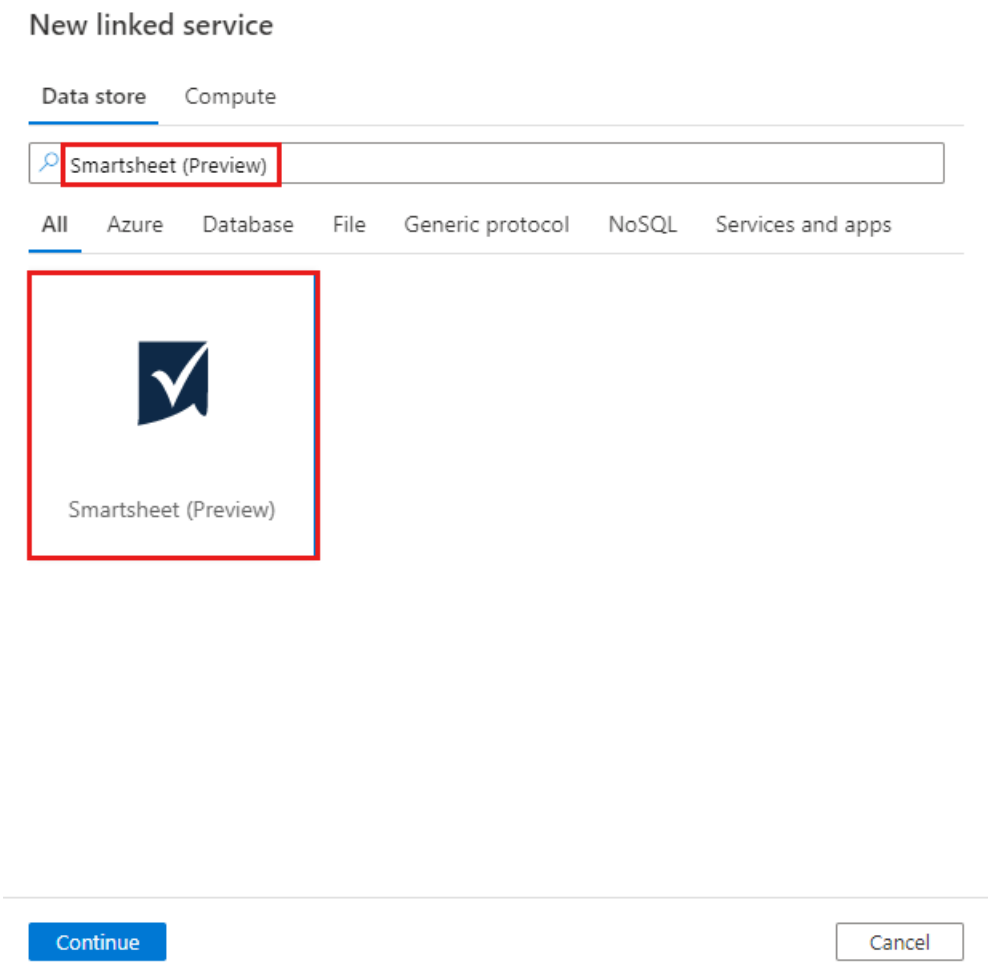
Use the following steps to create a Smartsheet linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

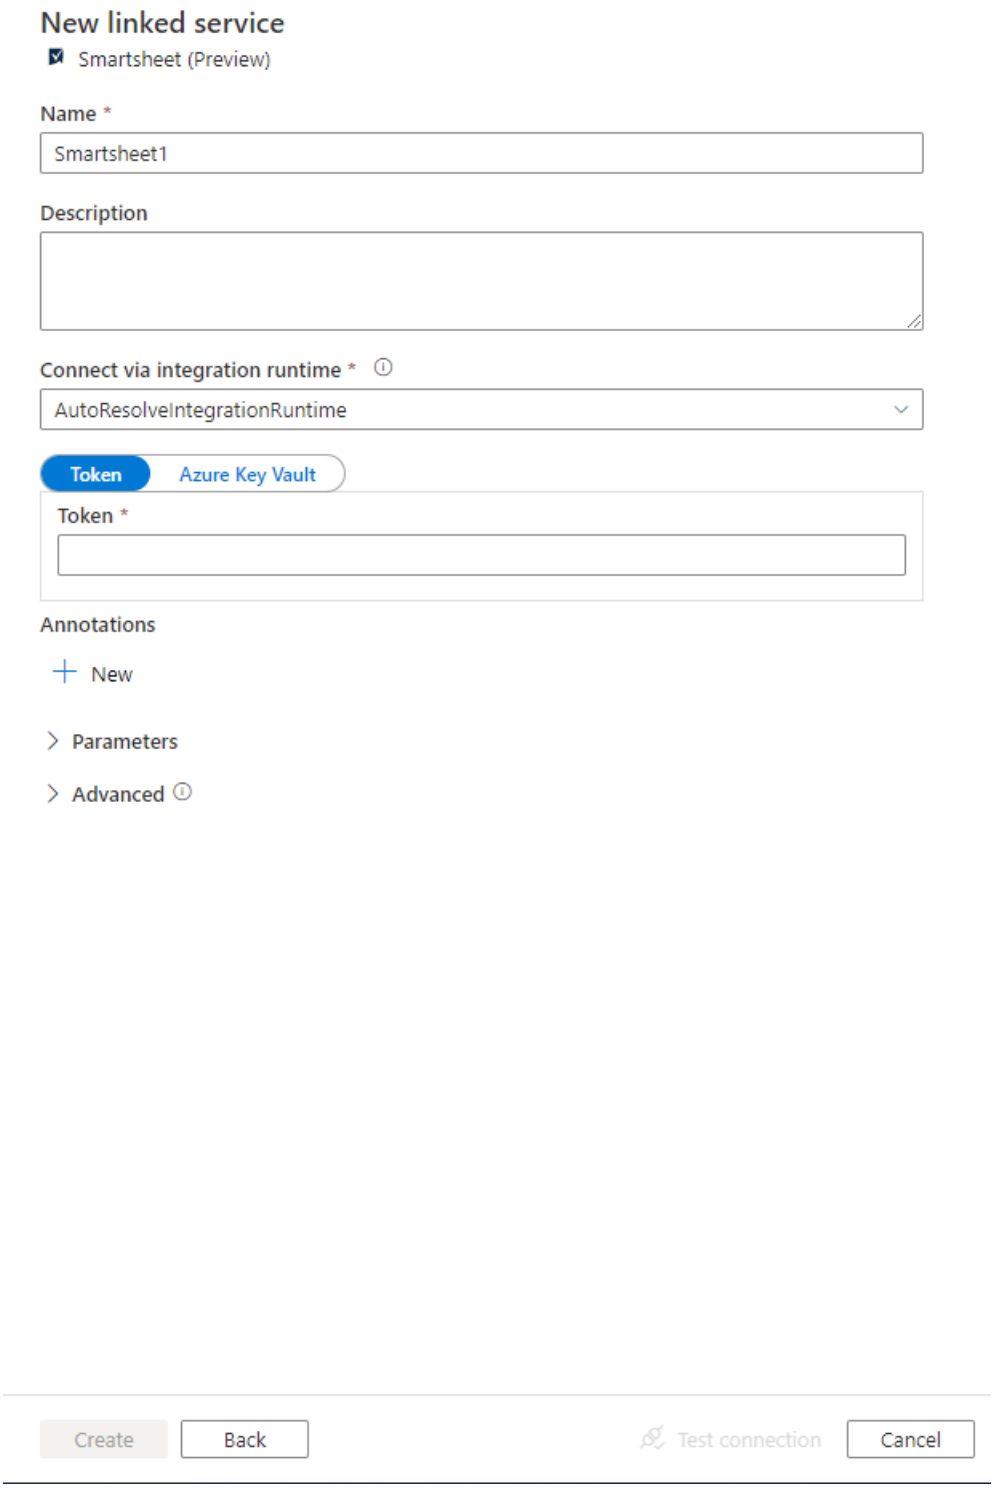
   - Azure Data Factory
   - Azure Synapse



2. Search for Smartsheet (Preview) and select the Smartsheet (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Smartsheet.

Linked service properties

The following properties are supported for the Smartsheet linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Smartsheet**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
apiToken	Specify an API token for the Smartsheet. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "SmartsheetLinkedService",
    "properties": {
        "type": "Smartsheet",
        "typeProperties": {
            "apiToken": {
                "type": "SecureString",
                "value": "<API token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from Smartsheet. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by Smartsheet source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Entity type	The type of the data asset in Smartsheet.	Yes when use inline mode	`sheets` `reports`	entityType
Entity name	The name of a sheet or a report in Smartsheet.	Yes when use inline mode	String	entityId

Smartsheet source script examples

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'smartsheet',
 format: 'rest',
 entityId: 'Sheet1',
 entityType: 'sheets') ~> SmartsheetSource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy and transform data in Snowflake using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 15 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy activity in Azure Data Factory and Azure Synapse pipelines to copy data from and to Snowflake, and use Data Flow to transform data in Snowflake. For more information, see the introductory article for Data Factory or Azure Synapse Analytics.

Supported capabilities

This Snowflake connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②
Script activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For the Copy activity, this Snowflake connector supports the following functions:

- Copy data from Snowflake that utilizes Snowflake's COPY into [location] command to achieve the best performance.
- Copy data to Snowflake that takes advantage of Snowflake's COPY into [table] command to achieve the best performance. It supports Snowflake on Azure.
- If a proxy is required to connect to Snowflake from a self-hosted Integration Runtime, you must configure the environment variables for HTTP_PROXY and HTTPS_PROXY on the Integration Runtime host.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it. Make sure to add the IP addresses that the self-hosted integration runtime uses to the allowed list.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allowed list.

The Snowflake account that is used for Source or Sink should have the necessary `USAGE` access on the Database and Read / Write access on Schema and the Tables/Views under it. In addition, it should also have `CREATE STAGE` on the schema to be able to create the External stage with SAS URI.

The following Account properties values must be set

PROPERTY	DESCRIPTION	REQUIRED	DEFAULT
REQUIRE_STORAGE_INTEGRATION_FOR_STAGE_CREATION	Specifies whether to require a storage integration object as cloud credentials when creating a named external stage (using CREATE STAGE) to access a private cloud storage location.	FALSE	FALSE
REQUIRE_STORAGE_INTEGRATION_FOR_STAGE_OPERATION	Specifies whether to require using a named external stage that references a storage integration object as cloud credentials when loading data from or unloading data to a private cloud storage location.	FALSE	FALSE

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

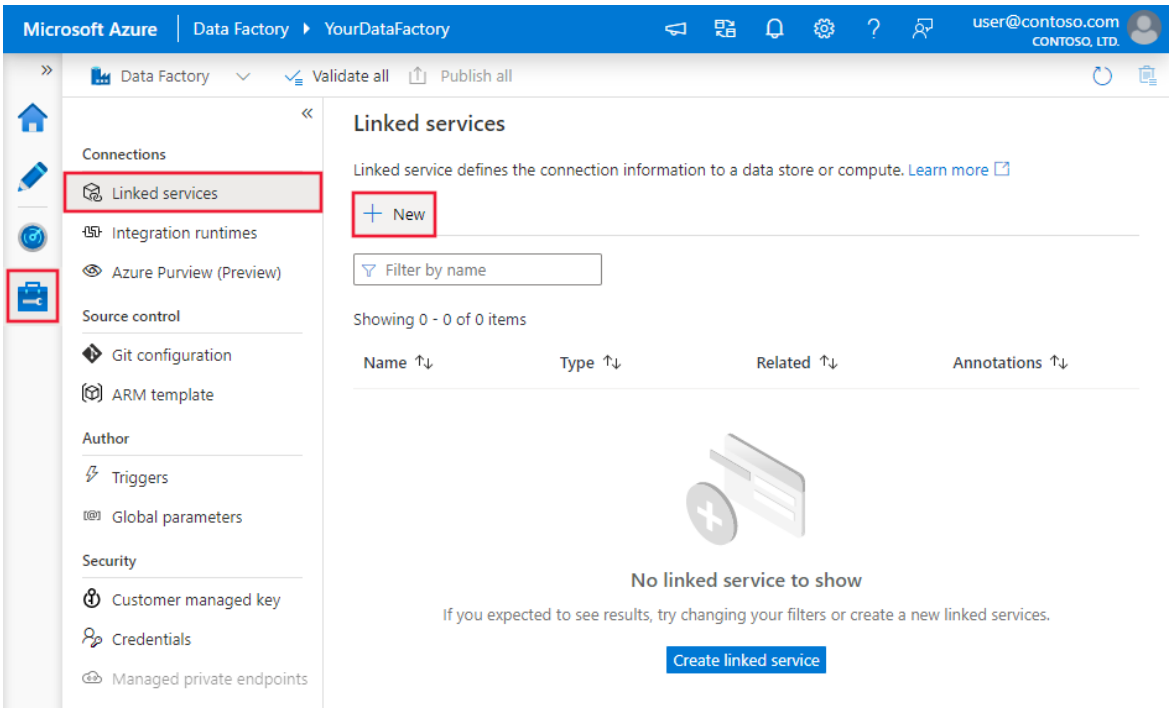
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Snowflake using UI

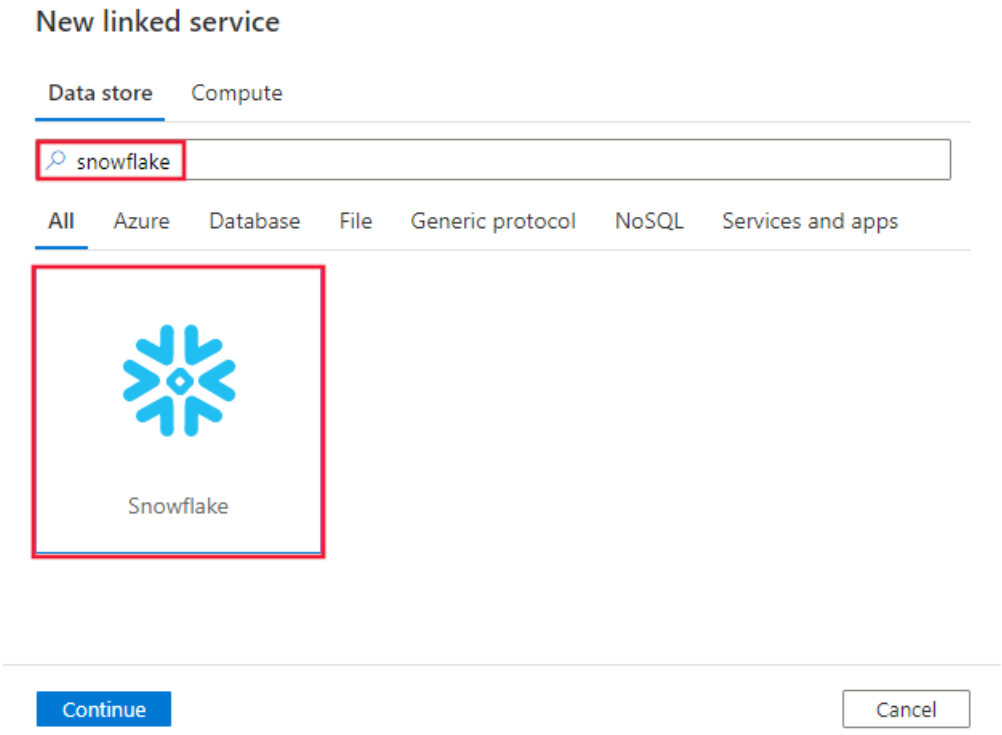
Use the following steps to create a linked service to Snowflake in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

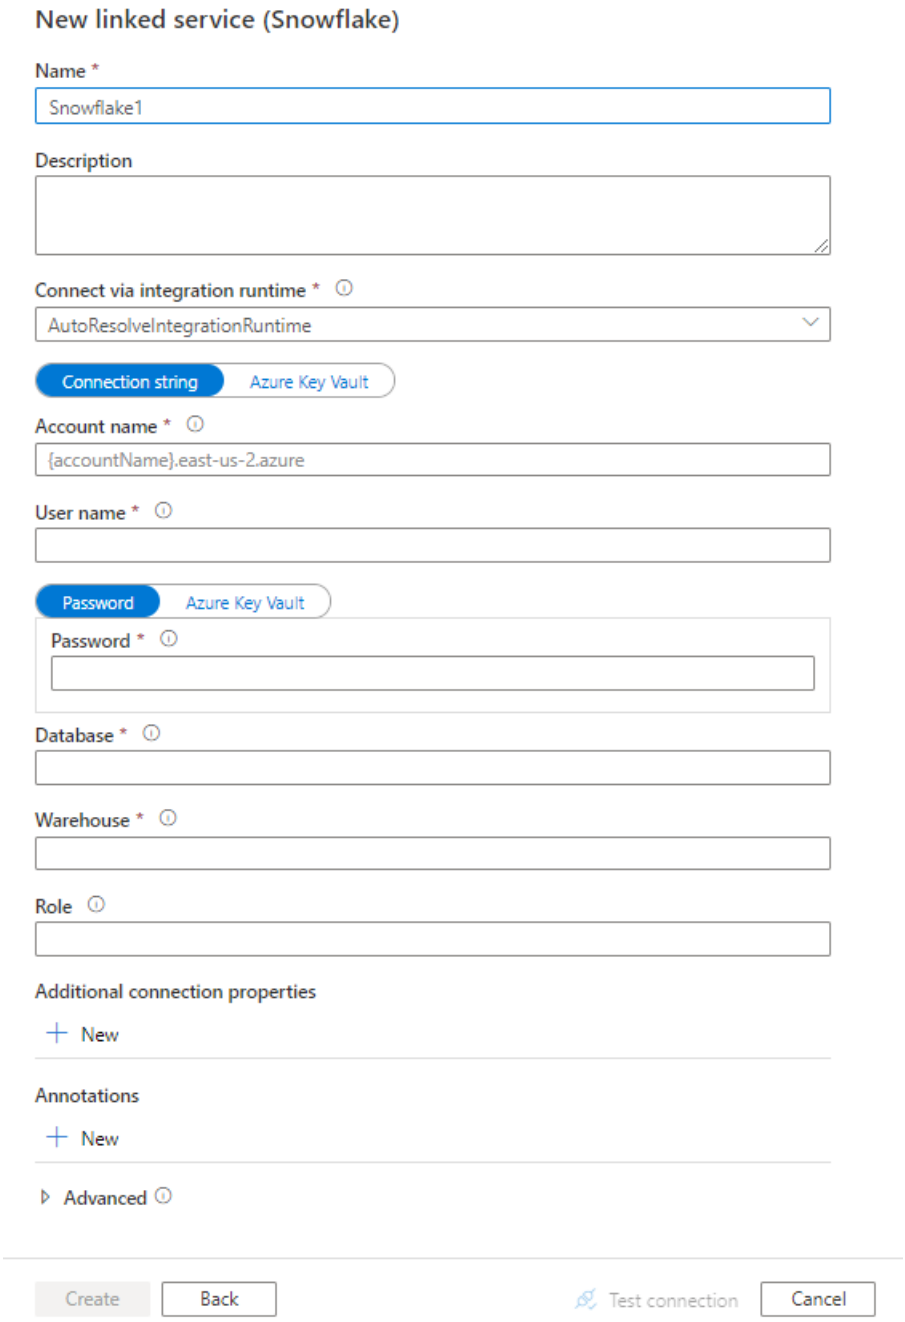
   - Azure Data Factory
   - Azure Synapse



2. Search for Snowflake and select the Snowflake connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that define entities specific to a Snowflake connector.

Linked service properties

The following properties are supported for a Snowflake-linked service.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Snowflake**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specifies the information needed to connect to the Snowflake instance. You can choose to put password or entire connection string in Azure Key Vault. Refer to the examples below the table, as well as the Store credentials in Azure Key Vault article, for more details. Some typical settings: - **Account name:** The full account name of your Snowflake account (including additional segments that identify the region and cloud platform), e.g. xy12345.east-us-2.azure. - **User name:** The login name of the user for the connection. - **Password:** The password for the user. - **Database:** The default database to use once connected. It should be an existing database for which the specified role has privileges. - **Warehouse:** The virtual warehouse to use once connected. It should be an existing warehouse for which the specified role has privileges. - **Role:** The default access control role to use in the Snowflake session. The specified role should be an existing role that has already been assigned to the specified user. The default role is PUBLIC.	Yes
connectVia	The integration runtime that is used to connect to the data store. You can use the Azure integration runtime or a self-hosted integration runtime (if your data store is located in a private network). If not specified, it uses the default Azure integration runtime.	No

Example:

```
{
    "name": "SnowflakeLinkedService",
    "properties": {
        "type": "Snowflake",
        "typeProperties": {
            "connectionString": "jdbc:snowflake://<accountname>.snowflakecomputing.com/?user=
<username>&password=<password>&db=<database>&warehouse=<warehouse>&role=<myRole>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Password in Azure Key Vault:

```
{
    "name": "SnowflakeLinkedService",
    "properties": {
        "type": "Snowflake",
        "typeProperties": {
            "connectionString": "jdbc:snowflake://<accountname>.snowflakecomputing.com/?user=<username>&db=
<database>&warehouse=<warehouse>&role=<myRole>",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article.

The following properties are supported for the Snowflake dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **SnowflakeTable**.	Yes
schema	Name of the schema. Note the schema name is case-sensitive.	No for source, yes for sink
table	Name of the table/view. Note the table name is case-sensitive.	No for source, yes for sink

Example:

```
{
    "name": "SnowflakeDataset",
    "properties": {
        "type": "SnowflakeTable",
        "typeProperties": {
            "schema": "<Schema name for your Snowflake database>",
            "table": "<Table name for your Snowflake database>"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "linkedServiceName": {
            "referenceName": "<name of linked service>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the Snowflake source and sink.

Snowflake as the source

Snowflake connector utilizes Snowflake's COPY into [location] command to achieve the best performance.

If sink data store and format are natively supported by the Snowflake COPY command, you can use the Copy activity to directly copy from Snowflake to sink. For details, see Direct copy from Snowflake. Otherwise, use built-in Staged copy from Snowflake.

To copy data from Snowflake, the following properties are supported in the Copy activity **source** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the Copy activity source must be set to **SnowflakeSource**.	Yes
query	Specifies the SQL query to read data from Snowflake. If the names of the schema, table and columns contain lower case, quote the object identifier in query e.g. `select * from "schema"."myTable"`. Executing stored procedure is not supported.	No
exportSettings	Advanced settings used to retrieve data from Snowflake. You can configure the ones supported by the COPY into command that the service will pass through when you invoke the statement.	No
Under `exportSettings`*:*		
type	The type of export command, set to **SnowflakeExportCopyCommand**.	Yes
additionalCopyOptions	Additional copy options, provided as a dictionary of key-value pairs. Examples: MAX_FILE_SIZE, OVERWRITE. For more information, see Snowflake Copy Options.	No
additionalFormatOptions	Additional file format options that are provided to COPY command as a dictionary of key-value pairs. Examples: DATE_FORMAT, TIME_FORMAT, TIMESTAMP_FORMAT. For more information, see Snowflake Format Type Options.	No

> **NOTE**
>
> Make sure you have permission to execute the following command and access the schema *INFORMATION_SCHEMA* and the table *COLUMNS*.
>
> - `COPY INTO <location>`

Direct copy from Snowflake

If your sink data store and format meet the criteria described in this section, you can use the Copy activity to directly copy from Snowflake to sink. The service checks the settings and fails the Copy activity run if the following criteria is not met:

- The **sink linked service** is **Azure Blob storage** with **shared access signature** authentication. If you want to directly copy data to Azure Data Lake Storage Gen2 in the following supported format, you can create an Azure Blob linked service with SAS authentication against your ADLS Gen2 account, to avoid using staged copy from Snowflake.
- The **sink data format** is of **Parquet**, **delimited text**, or **JSON** with the following configurations:
  - For **Parquet** format, the compression codec is **None**, **Snappy**, or **Lzo**.
  - For **delimited text** format:
    - `rowDelimiter` is **\r\n**, or any single character.
    - `compression` can be **no compression**, **gzip**, **bzip2**, or **deflate**.
    - `encodingName` is left as default or set to **utf-8**.
    - `quoteChar` is **double quote**, **single quote**, or **empty string** (no quote char).
  - For **JSON** format, direct copy only supports the case that source Snowflake table or query result only has single column and the data type of this column is **VARIANT**, **OBJECT**, or **ARRAY**.
    - `compression` can be **no compression**, **gzip**, **bzip2**, or **deflate**.
    - `encodingName` is left as default or set to **utf-8**.
    - `filePattern` in copy activity sink is left as default or set to **setOfObjects**.
- In copy activity source, `additionalColumns` is not specified.
- Column mapping is not specified.

Example:

```
"activities":[
    {
        "name": "CopyFromSnowflake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Snowflake input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SnowflakeSource",
                "sqlReaderQuery": "SELECT * FROM MYTABLE",
                "exportSettings": {
                    "type": "SnowflakeExportCopyCommand",
                    "additionalCopyOptions": {
                        "MAX_FILE_SIZE": "64000000",
                        "OVERWRITE": true
                    },
                    "additionalFormatOptions": {
                        "DATE_FORMAT": "'MM/DD/YYYY'"
                    }
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Staged copy from Snowflake

When your sink data store or format is not natively compatible with the Snowflake COPY command, as mentioned in the last section, enable the built-in staged copy using an interim Azure Blob storage instance. The staged copy feature also provides you better throughput. The service exports data from Snowflake into staging storage, then copies the data to sink, and finally cleans up your temporary data from the staging storage. See Staged copy for details about copying data by using staging.

To use this feature, create an Azure Blob storage linked service that refers to the Azure storage account as the interim staging. Then specify the `enableStaging` and `stagingSettings` properties in the Copy activity.

> **NOTE**
>
> The staging Azure Blob storage linked service must use shared access signature authentication, as required by the Snowflake COPY command. Make sure you grant proper access permission to Snowflake in the staging Azure Blob storage. To learn more about this, see this article.

Example:

```
"activities":[
    {
        "name": "CopyFromSnowflake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Snowflake input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SnowflakeSource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingBlob",
                    "type": "LinkedServiceReference"
                },
                "path": "mystagingpath"
            }
        }
    }
]
```

Snowflake as sink

Snowflake connector utilizes Snowflake's COPY into [table] command to achieve the best performance. It supports writing data to Snowflake on Azure.

If source data store and format are natively supported by Snowflake COPY command, you can use the Copy activity to directly copy from source to Snowflake. For details, see Direct copy to Snowflake. Otherwise, use built-in Staged copy to Snowflake.

To copy data to Snowflake, the following properties are supported in the Copy activity **sink** section.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the Copy activity sink, set to **SnowflakeSink**.	Yes
preCopyScript	Specify a SQL query for the Copy activity to run before writing data into Snowflake in each run. Use this property to clean up the preloaded data.	No

PROPERTY	DESCRIPTION	REQUIRED
importSettings	Advanced settings used to write data into Snowflake. You can configure the ones supported by the COPY into command that the service will pass through when you invoke the statement.	No
Under `importSettings`*:*		
type	The type of import command, set to **SnowflakeImportCopyCommand**.	Yes
additionalCopyOptions	Additional copy options, provided as a dictionary of key-value pairs. Examples: ON_ERROR, FORCE, LOAD_UNCERTAIN_FILES. For more information, see Snowflake Copy Options.	No
additionalFormatOptions	Additional file format options provided to the COPY command, provided as a dictionary of key-value pairs. Examples: DATE_FORMAT, TIME_FORMAT, TIMESTAMP_FORMAT. For more information, see Snowflake Format Type Options.	No

NOTE

Make sure you have permission to execute the following command and access the schema *INFORMATION_SCHEMA* and the table *COLUMNS*.

- `SELECT CURRENT_REGION()`
- `COPY INTO <table>`
- `SHOW REGIONS`
- `CREATE OR REPLACE STAGE`
- `DROP STAGE`

Direct copy to Snowflake

If your source data store and format meet the criteria described in this section, you can use the Copy activity to directly copy from source to Snowflake. The service checks the settings and fails the Copy activity run if the following criteria is not met:

- The **source linked service** is **Azure Blob storage** with **shared access signature** authentication. If you want to directly copy data from Azure Data Lake Storage Gen2 in the following supported format, you can create an Azure Blob linked service with SAS authentication against your ADLS Gen2 account, to avoid using staged copy to Snowflake..
- The **source data format** is **Parquet**, **Delimited text**, or **JSON** with the following configurations:
  - For **Parquet** format, the compression codec is **None**, or **Snappy**.
  - For **delimited text** format:
    - `rowDelimiter` is **\r\n**, or any single character. If row delimiter is not "\r\n", `firstRowAsHeader`

need to be **false**, and `skipLineCount` is not specified.

- `compression` can be **no compression**, **gzip**, **bzip2**, or **deflate**.
- `encodingName` is left as default or set to "UTF-8", "UTF-16", "UTF-16BE", "UTF-32", "UTF-32BE", "BIG5", "EUC-JP", "EUC-KR", "GB18030", "ISO-2022-JP", "ISO-2022-KR", "ISO-8859-1", "ISO-8859-2", "ISO-8859-5", "ISO-8859-6", "ISO-8859-7", "ISO-8859-8", "ISO-8859-9", "WINDOWS-1250", "WINDOWS-1251", "WINDOWS-1252", "WINDOWS-1253", "WINDOWS-1254", "WINDOWS-1255".
- `quoteChar` is **double quote**, **single quote**, or **empty string** (no quote char).

- For **JSON** format, direct copy only supports the case that sink Snowflake table only has single column and the data type of this column is **VARIANT**, **OBJECT**, or **ARRAY**.
  - `compression` can be **no compression**, **gzip**, **bzip2**, or **deflate**.
  - `encodingName` is left as default or set to **utf-8**.
  - Column mapping is not specified.

- In the Copy activity source:
  - `additionalColumns` is not specified.
  - If your source is a folder, `recursive` is set to true.
  - `prefix`, `modifiedDateTimeStart`, `modifiedDateTimeEnd`, and `enablePartitionDiscovery` are not specified.

Example:

```
"activities":[
    {
        "name": "CopyToSnowflake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Snowflake output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SnowflakeSink",
                "importSettings": {
                    "type": "SnowflakeImportCopyCommand",
                    "copyOptions": {
                        "FORCE": "TRUE",
                        "ON_ERROR": "SKIP_FILE",
                    },
                    "fileFormatOptions": {
                        "DATE_FORMAT": "YYYY-MM-DD",
                    }
                }
            }
        }
    }
]
```

Staged copy to Snowflake

When your source data store or format is not natively compatible with the Snowflake COPY command, as mentioned in the last section, enable the built-in staged copy using an interim Azure Blob storage instance. The staged copy feature also provides you better throughput. The service automatically converts the data to meet the data format requirements of Snowflake. It then invokes the COPY command to load data into Snowflake. Finally, it cleans up your temporary data from the blob storage. See Staged copy for details about copying data using staging.

To use this feature, create an Azure Blob storage linked service that refers to the Azure storage account as the interim staging. Then specify the `enableStaging` and `stagingSettings` properties in the Copy activity.

> **NOTE**
>
> The staging Azure Blob storage linked service need to use shared access signature authentication as required by the Snowflake COPY command.

Example:

```
"activities":[
    {
        "name": "CopyToSnowflake",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Snowflake output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SnowflakeSink"
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingBlob",
                    "type": "LinkedServiceReference"
                },
                "path": "mystagingpath"
            }
        }
    }
]
```

Mapping data flow properties

When transforming data in mapping data flow, you can read from and write to tables in Snowflake. For more information, see the source transformation and sink transformation in mapping data flows. You can choose to use a Snowflake dataset or an inline dataset as source and sink type.

Source transformation

The below table lists the properties supported by Snowflake source. You can edit these properties in the **Source options** tab. The connector utilizes Snowflake internal data transfer.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow will fetch all the data from the table specified in the Snowflake dataset or in the source options when using inline dataset.	No	String	*(for inline dataset only)* tableName schemaName
Query	If you select Query as input, enter a query to fetch data from Snowflake. This setting overrides any table that you've chosen in dataset. If the names of the schema, table and columns contain lower case, quote the object identifier in query e.g. `select * from "schema"."myTable"`.	No	String	query

Snowflake source script examples

When you use Snowflake dataset as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 query: 'select * from MYTABLE',
 format: 'query') ~> SnowflakeSource
```

If you use inline dataset, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 format: 'query',
 query: 'select * from MYTABLE',
 store: 'snowflake') ~> SnowflakeSource
```

Sink transformation

The below table lists the properties supported by Snowflake sink. You can edit these properties in the **Settings** tab. When using inline dataset, you will see additional settings, which are the same as the properties described in dataset properties section. The connector utilizes Snowflake internal data transfer.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your Snowflake destination. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	deletable insertable updateable upsertable
Key columns	For updates, upserts and deletes, a key column or columns must be set to determine which row to alter.	No	Array	keys
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate

Snowflake sink script examples

When you use Snowflake dataset as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
 validateSchema: false,
 deletable:true,
 insertable:true,
 updateable:true,
 upsertable:false,
 keys:['movieId'],
 format: 'table',
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true) ~> SnowflakeSink
```

If you use inline dataset, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
 validateSchema: false,
 format: 'table',
 tableName: 'table',
 schemaName: 'schema',
 deletable: true,
 insertable: true,
 updateable: true,
 upsertable: false,
 store: 'snowflake',
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true) ~> SnowflakeSink
```

Lookup activity properties

For more information about the properties, see Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by Copy activity, see supported data stores and formats.

Copy data from Spark using Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Spark. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Spark connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell

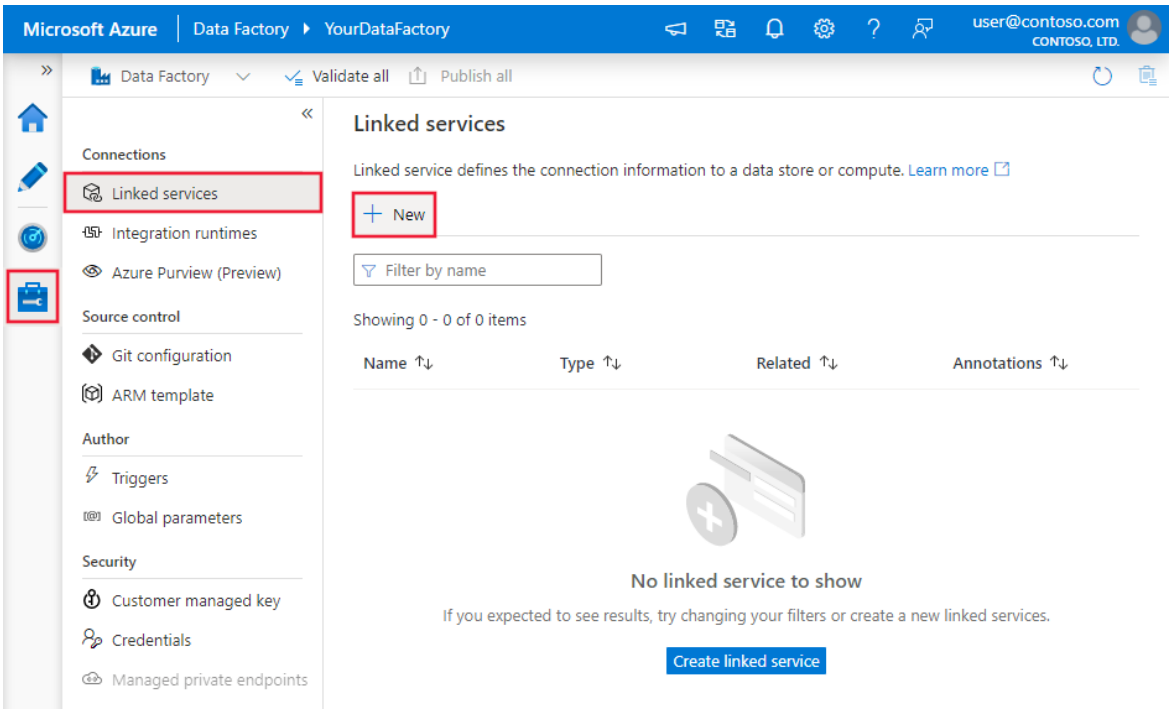
- The REST API
- The Azure Resource Manager template

Create a linked service to Spark using UI

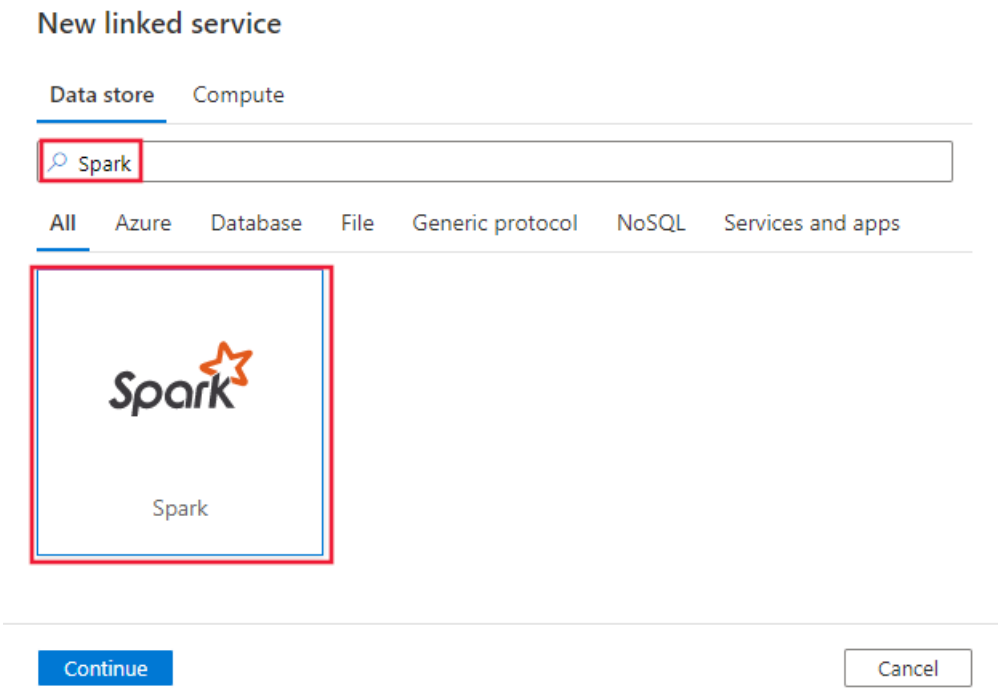
Use the following steps to create a linked service to Spark in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

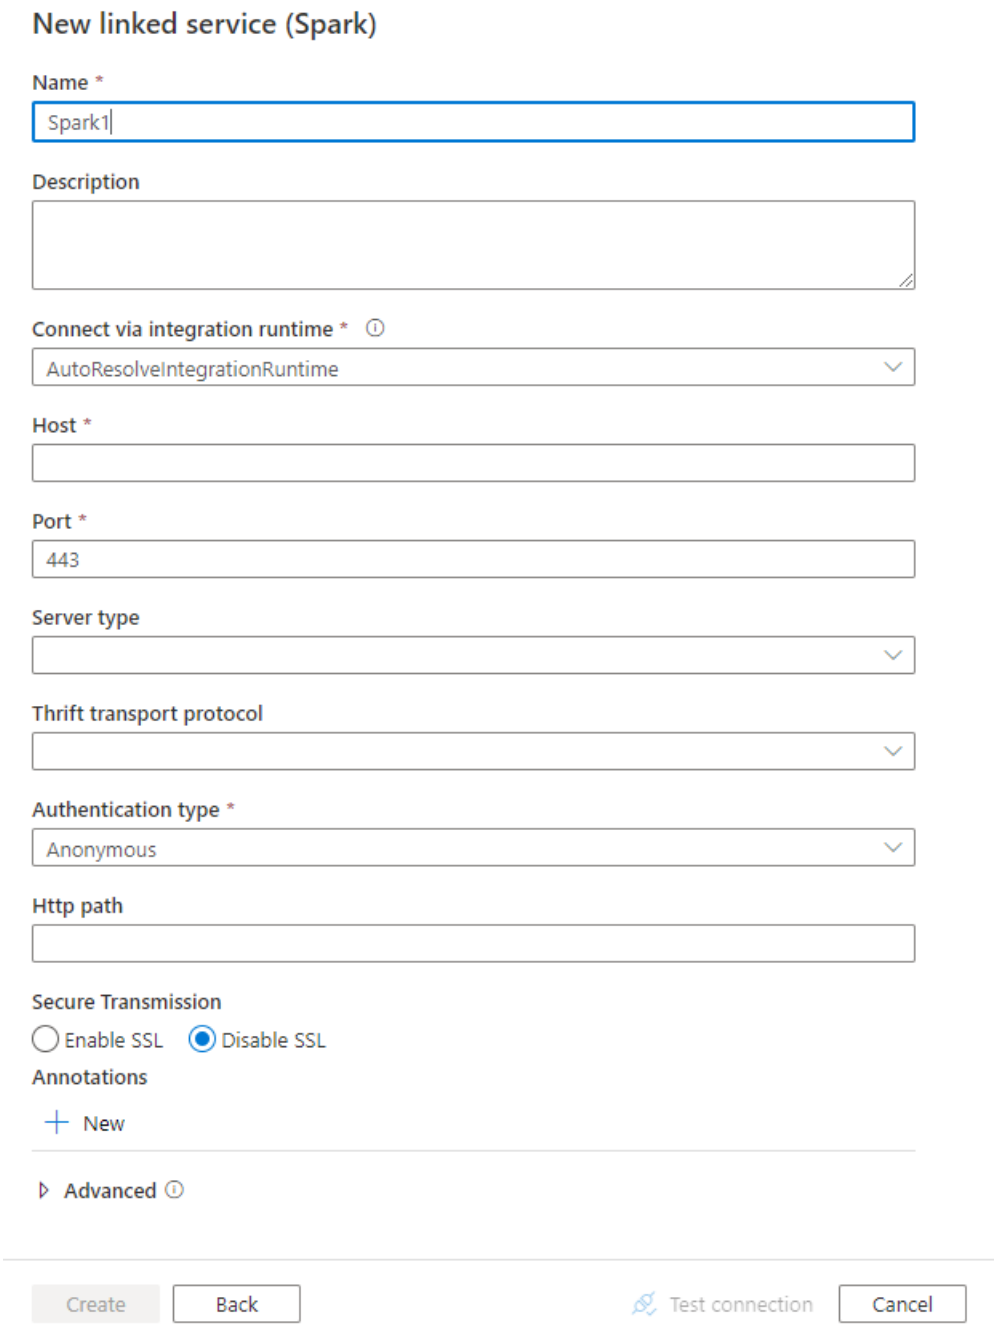
   - Azure Data Factory
   - Azure Synapse



2. Search for Spark and select the Spark connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Spark connector.

Linked service properties

The following properties are supported for Spark linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Spark**	Yes
host	IP address or host name of the Spark server	Yes

PROPERTY	DESCRIPTION	REQUIRED
port	The TCP port that the Spark server uses to listen for client connections. If you connect to Azure HDInsights, specify port as 443.	Yes
serverType	The type of Spark server. Allowed values are: **SharkServer**, **SharkServer2**, **SparkThriftServer**	No
thriftTransportProtocol	The transport protocol to use in the Thrift layer. Allowed values are: **Binary**, **SASL**, **HTTP**	No
authenticationType	The authentication method used to access the Spark server. Allowed values are: **Anonymous**, **Username**, **UsernameAndPassword**, **WindowsAzureHDInsightService**	Yes
username	The user name that you use to access Spark Server.	No
password	The password corresponding to the user. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	No
httpPath	The partial URL corresponding to the Spark server.	No
enableSsl	Specifies whether the connections to the server are encrypted using TLS. The default value is false.	No
trustedCertPath	The full path of the .pem file containing trusted CA certificates for verifying the server when connecting over TLS. This property can only be set when using TLS on self-hosted IR. The default value is the cacerts.pem file installed with the IR.	No
useSystemTrustStore	Specifies whether to use a CA certificate from the system trust store or from a specified PEM file. The default value is false.	No
allowHostNameCNMismatch	Specifies whether to require a CA-issued TLS/SSL certificate name to match the host name of the server when connecting over TLS. The default value is false.	No

PROPERTY	DESCRIPTION	REQUIRED
allowSelfSignedServerCert	Specifies whether to allow self-signed certificates from the server. The default value is false.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "SparkLinkedService",
    "properties": {
        "type": "Spark",
        "typeProperties": {
            "host" : "<cluster>.azurehdinsight.net",
            "port" : "<port>",
            "authenticationType" : "WindowsAzureHDInsightService",
            "username" : "<username>",
            "password": {
                 "type": "SecureString",
                 "value": "<password>"
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Spark dataset.

To copy data from Spark, set the type property of the dataset to **SparkObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SparkObject**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "SparkDataset",
    "properties": {
        "type": "SparkObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Spark linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Spark source.

Spark as source

To copy data from Spark, set the source type in the copy activity to **SparkSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SparkSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromSpark",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Spark input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SparkSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy and transform data to and from SQL Server by using Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 28 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory and Azure Synapse pipelines to copy data from and to SQL Server database and use Data Flow to transform data in SQL Server database. To learn more read the introductory article for Azure Data Factory or Azure Synapse Analytics.

Supported capabilities

This SQL Server connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/sink)	① ②
Mapping data flow (source/sink)	①
Lookup activity	① ②
GetMetadata activity	① ②
Script activity	① ②
Stored procedure activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources or sinks by the copy activity, see the Supported data stores table.

Specifically, this SQL Server connector supports:

- SQL Server version 2005 and above.
- Copying data by using SQL or Windows authentication.
- As a source, retrieving data by using a SQL query or a stored procedure. You can also choose to parallel copy from SQL Server source, see the Parallel copy from SQL database section for details.
- As a sink, automatically creating destination table if not exists based on the source schema; appending data to a table or invoking a stored procedure with custom logic during copy.

SQL Server Express LocalDB is not supported.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Get started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

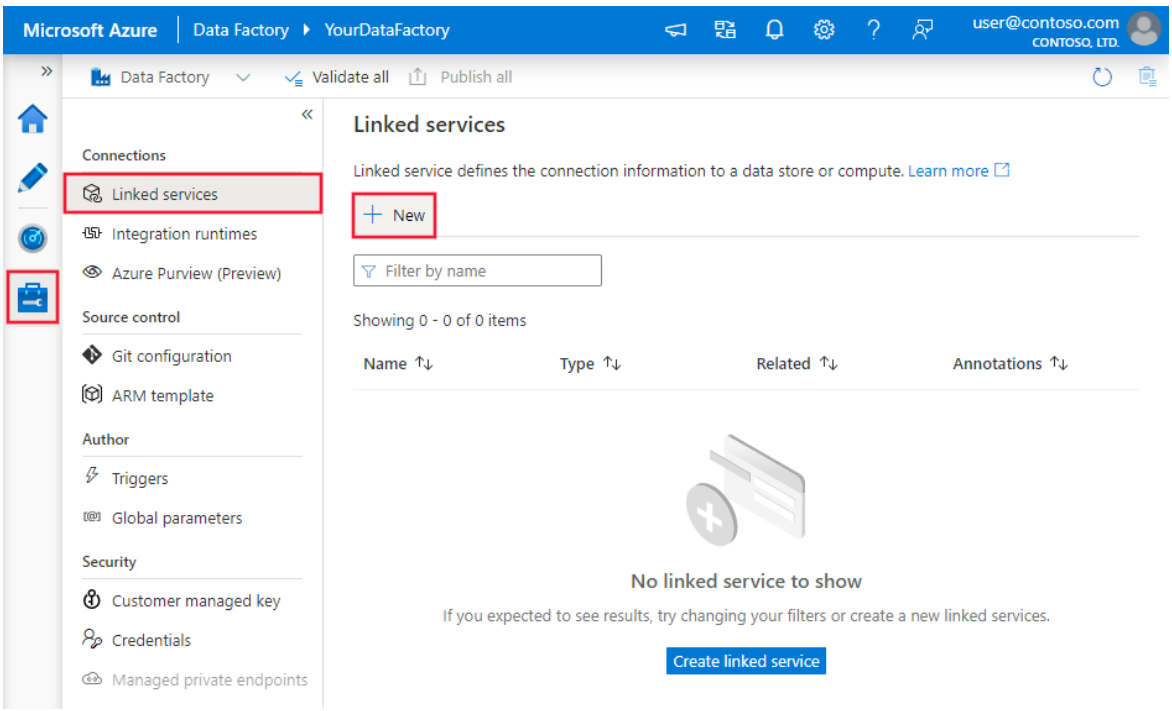
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a SQL Server linked service using UI

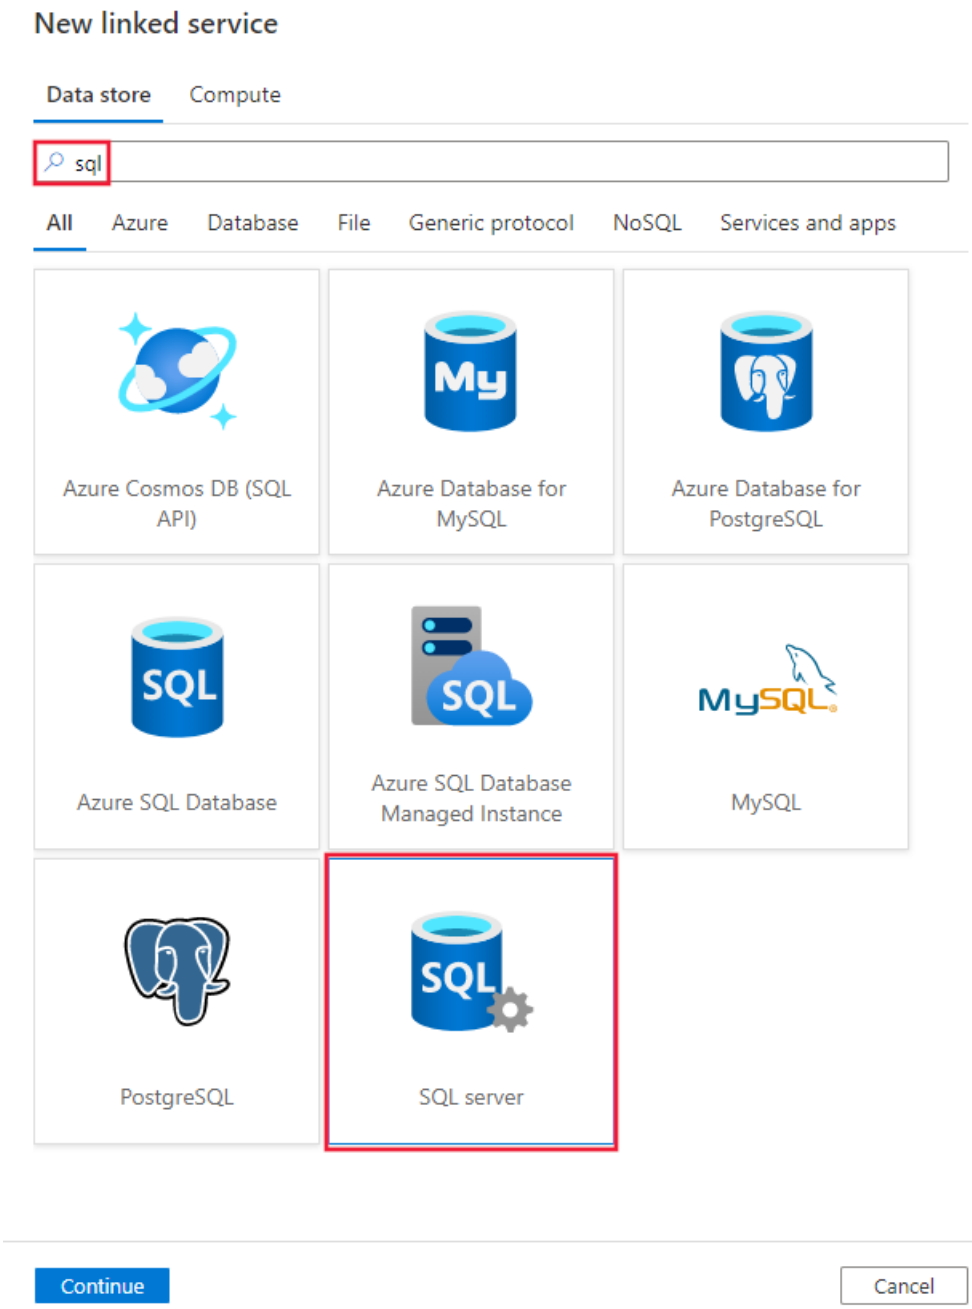
Use the following steps to create a SQL Server linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

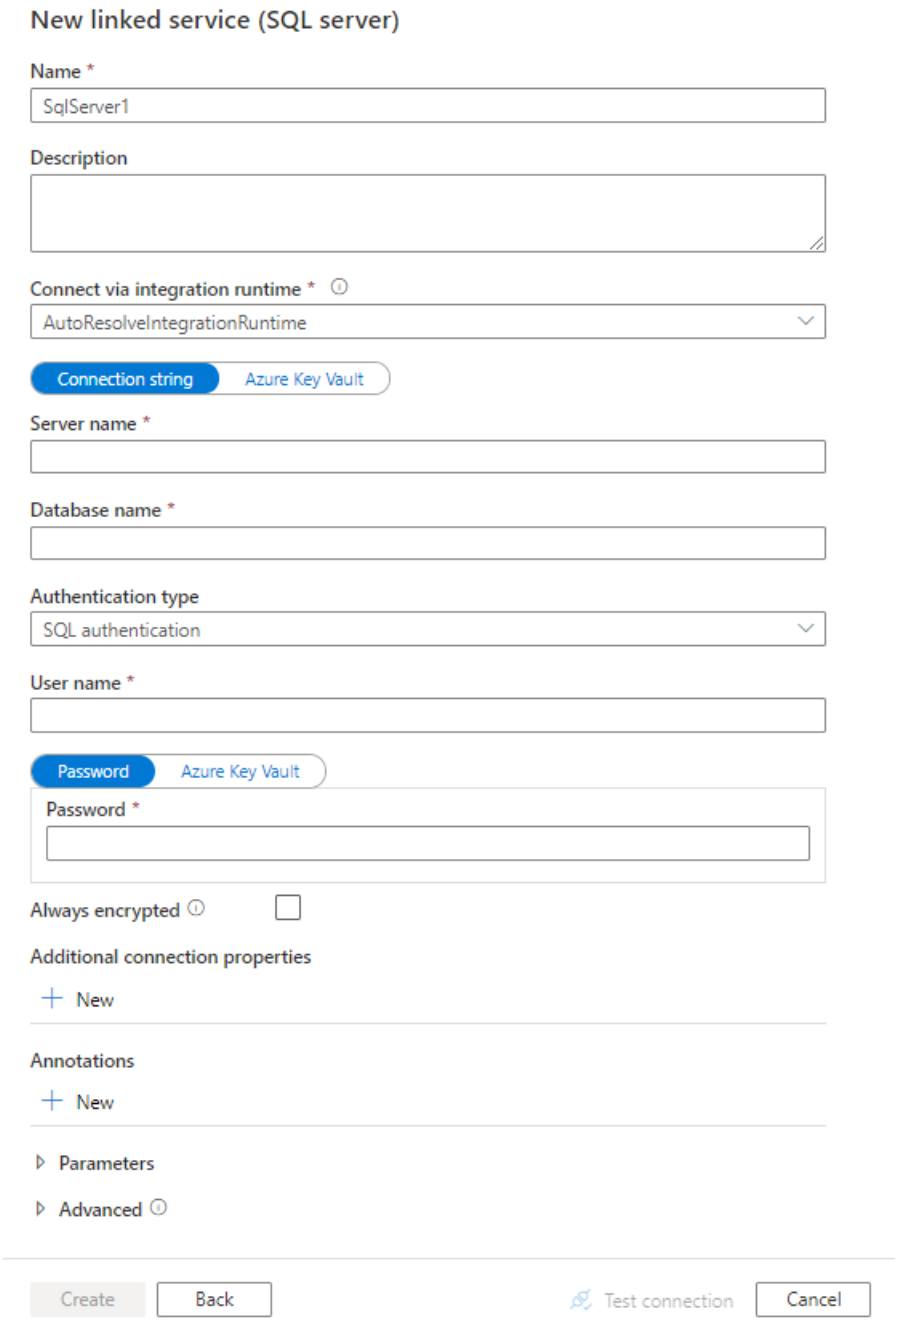
   - Azure Data Factory
   - Azure Synapse



2. Search for SQL and select the SQL Server connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory and Synapse pipeline entities specific to the SQL Server database connector.

Linked service properties

This SQL server connector supports the following authentication types. See the corresponding sections for details.

- SQL authentication
- Windows authentication

> **TIP**
>
> If you hit an error with the error code "UserErrorFailedToConnectToSqlServer" and a message like "The session limit for the database is XXX and has been reached," add `Pooling=false` to your connection string and try again.

SQL authentication

To use SQL authentication, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SqlServer**.	Yes
connectionString	Specify **connectionString** information that's needed to connect to the SQL Server database. Specify a login name as your user name, and ensure the database that you want to connect is mapped to this login. Refer to the following samples.	Yes
password	If you want to put a password in Azure Key Vault, pull the `password` configuration out of the connection string. For more information, see the JSON example following the table and Store credentials in Azure Key Vault.	No
alwaysEncryptedSettings	Specify **alwaysencryptedsettings** information that's needed to enable Always Encrypted to protect sensitive data stored in SQL server by using either managed identity or service principal. For more information, see the JSON example following the table and Using Always Encrypted section. If not specified, the default always encrypted setting is disabled.	No
connectVia	This integration runtime is used to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure integration runtime is used.	No

Example: Use SQL authentication

```
{
    "name": "SqlServerLinkedService",
    "properties": {
        "type": "SqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;Password=<password>;"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Use SQL authentication with a password in Azure Key Vault

```
{
    "name": "SqlServerLinkedService",
    "properties": {
        "type": "SqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Use Always Encrypted

```
{
    "name": "SqlServerLinkedService",
    "properties": {
        "type": "SqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=False;User ID=<username>;Password=<password>;"
        },
        "alwaysEncryptedSettings": {
            "alwaysEncryptedAkvAuthType": "ServicePrincipal",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "<service principal key>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Windows authentication

To use Windows authentication, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **SqlServer**.	Yes
connectionString	Specify **connectionString** information that's needed to connect to the SQL Server database. Refer to the following samples.	

PROPERTY	DESCRIPTION	REQUIRED
userName	Specify a user name. An example is **domainname\username**.	Yes
password	Specify a password for the user account you specified for the user name. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes
alwaysEncryptedSettings	Specify **alwaysencryptedsettings** information that's needed to enable Always Encrypted to protect sensitive data stored in SQL server by using either managed identity or service principal. For more information, see Using Always Encrypted section. If not specified, the default always encrypted setting is disabled.	No
connectVia	This integration runtime is used to connect to the data store. Learn more from Prerequisites section. If not specified, the default Azure integration runtime is used.	No

> **NOTE**
> Windows authentication is not supported in data flow.

Example: Use Windows authentication

```
{
    "name": "SqlServerLinkedService",
    "properties": {
        "type": "SqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=True;",
            "userName": "<domain\\username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: Use Windows authentication with a password in Azure Key Vault

```
{
    "name": "SqlServerLinkedService",
    "properties": {
        "annotations": [],
        "type": "SqlServer",
        "typeProperties": {
            "connectionString": "Data Source=<servername>\\<instance name if using named instance>;Initial
Catalog=<databasename>;Integrated Security=True;",
            "userName": "<domain\\username>",
            "password": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by the SQL Server dataset.

To copy data from and to a SQL Server database, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **SqlServerTable**.	Yes
schema	Name of the schema.	No for source, Yes for sink
table	Name of the table/view.	No for source, Yes for sink
tableName	Name of the table/view with schema. This property is supported for backward compatibility. For new workload, use `schema` and `table`.	No for source, Yes for sink

Example

```
{
    "name": "SQLServerDataset",
    "properties":
    {
        "type": "SqlServerTable",
        "linkedServiceName": {
            "referenceName": "<SQL Server linked service name>",
            "type": "LinkedServiceReference"
        },
        "schema": [ < physical schema, optional, retrievable during authoring > ],
        "typeProperties": {
            "schema": "<schema_name>",
            "table": "<table_name>"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for use to define activities, see the Pipelines article. This section provides a list of properties supported by the SQL Server source and sink.

SQL Server as a source

> **TIP**
> To load data from SQL Server efficiently by using data partitioning, learn more from Parallel copy from SQL database.

To copy data from SQL Server, set the source type in the copy activity to **SqlSource**. The following properties are supported in the copy activity source section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **SqlSource**.	Yes
sqlReaderQuery	Use the custom SQL query to read data. An example is `select * from MyTable`.	No
sqlReaderStoredProcedureName	This property is the name of the stored procedure that reads data from the source table. The last SQL statement must be a SELECT statement in the stored procedure.	No
storedProcedureParameters	These parameters are for the stored procedure. Allowed values are name or value pairs. The names and casing of parameters must match the names and casing of the stored procedure parameters.	No

PROPERTY	DESCRIPTION	REQUIRED
isolationLevel	Specifies the transaction locking behavior for the SQL source. The allowed values are: **ReadCommitted**, **ReadUncommitted**, **RepeatableRead**, **Serializable**, **Snapshot**. If not specified, the database's default isolation level is used. Refer to this doc for more details.	No
partitionOptions	Specifies the data partitioning options used to load data from SQL Server. Allowed values are: **None** (default), **PhysicalPartitionsOfTable**, and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from SQL Server is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when the partition option isn't `None`.	No
Under `partitionSettings`***:***		
partitionColumnName	Specify the name of the source column **in integer or date/datetime type** (`int`, `smallint`, `bigint`, `date`, `smalldatetime`, `datetime`, `datetime2`, or `datetimeoffset`) that will be used by range partitioning for parallel copy. If not specified, the index or the primary key of the table is auto-detected and used as the partition column. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfDynamicRangePartitionCondition` in the WHERE clause. For an example, see the Parallel copy from SQL database section.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionUpperBound	The maximum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No
partitionLowerBound	The minimum value of the partition column for partition range splitting. This value is used to decide the partition stride, not for filtering the rows in table. All rows in the table or query result will be partitioned and copied. If not specified, copy activity auto detect the value. Apply when the partition option is `DynamicRange`. For an example, see the Parallel copy from SQL database section.	No

Note the following points:

- If **sqlReaderQuery** is specified for **SqlSource**, the copy activity runs this query against the SQL Server source to get the data. You also can specify a stored procedure by specifying **sqlReaderStoredProcedureName** and **storedProcedureParameters** if the stored procedure takes parameters.
- When using stored procedure in source to retrieve data, note if your stored procedure is designed as returning different schema when different parameter value is passed in, you may encounter failure or see unexpected result when importing schema from UI or when copying data to SQL database with auto table creation.

Example: Use SQL query

```
"activities":[
    {
        "name": "CopyFromSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SQL Server input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlSource",
                "sqlReaderQuery": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Example: Use a stored procedure

```
"activities":[
    {
        "name": "CopyFromSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<SQL Server input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SqlSource",
                "sqlReaderStoredProcedureName": "CopyTestSrcStoredProcedureWithParameters",
                "storedProcedureParameters": {
                    "stringData": { "value": "str3" },
                    "identifier": { "value": "$$Text.Format('{0:yyyy}', <datetime parameter>)", "type":
"Int"}
                }
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

The stored procedure definition

```
CREATE PROCEDURE CopyTestSrcStoredProcedureWithParameters
(
    @stringData varchar(20),
    @identifier int
)
AS
SET NOCOUNT ON;
BEGIN
    select *
    from dbo.UnitTestSrcTable
    where dbo.UnitTestSrcTable.stringData != stringData
    and dbo.UnitTestSrcTable.identifier != identifier
END
GO
```

SQL Server as a sink

> **TIP**
> Learn more about the supported write behaviors, configurations, and best practices from Best practice for loading data into SQL Server.

To copy data to SQL Server, set the sink type in the copy activity to **SqlSink**. The following properties are supported in the copy activity sink section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity sink must be set to **SqlSink**.	Yes
preCopyScript	This property specifies a SQL query for the copy activity to run before writing data into SQL Server. It's invoked only once per copy run. You can use this property to clean up the preloaded data.	No
tableOption	Specifies whether to automatically create the sink table if not exists based on the source schema. Auto table creation is not supported when sink specifies stored procedure. Allowed values are: `none` (default), `autoCreate`.	No
sqlWriterStoredProcedureName	The name of the stored procedure that defines how to apply source data into a target table. This stored procedure is *invoked per batch*. For operations that run only once and have nothing to do with source data, for example, delete or truncate, use the `preCopyScript` property. See example from Invoke a stored procedure from a SQL sink.	No
storedProcedureTableTypeParameterName	The parameter name of the table type specified in the stored procedure.	No

PROPERTY	DESCRIPTION	REQUIRED
sqlWriterTableType	The table type name to be used in the stored procedure. The copy activity makes the data being moved available in a temp table with this table type. Stored procedure code can then merge the data that's being copied with existing data.	No
storedProcedureParameters	Parameters for the stored procedure. Allowed values are name and value pairs. Names and casing of parameters must match the names and casing of the stored procedure parameters.	No
writeBatchSize	Number of rows to insert into the SQL table *per batch*. Allowed values are integers for the number of rows. By default, the service dynamically determines the appropriate batch size based on the row size.	No
writeBatchTimeout	This property specifies the wait time for the batch insert operation to complete before it times out. Allowed values are for the timespan. An example is "00:30:00" for 30 minutes. If no value is specified, the timeout defaults to "02:00:00".	No
maxConcurrentConnections	The upper limit of concurrent connecti ons established to the data store durin g the activity run. Specify a value only when you want to limit concurrent con nections.	No
WriteBehavior	Specify the write behavior for copy activity to load data into SQL Server Database. The allowed value is **Insert** and **Upsert**. By default, the service uses insert to load data.	No
upsertSettings	Specify the group of the settings for write behavior. Apply when the WriteBehavior option is `Upert`.	No
Under `upsertSettings`***:***		
useTempDB	Specify whether to use the a global temporary table or physical table as the interim table for upsert. By default, the service uses global temporary table as the interim table. value is `true`.	No

PROPERTY	DESCRIPTION	REQUIRED
interimSchemaName	Specify the interim schema for creating interim table if physical table is used. Note: user need to have the permission for creating and deleting table. By default, interim table will share the same schema as sink table. Apply when the useTempDB option is `False`.	No
keys	Specify the column names for unique row identification. Either a single key or a series of keys can be used. If not specified, the primary key is used.	No

Example 1: Append data

```
"activities":[
    {
        "name": "CopyToSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<SQL Server output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SqlSink",
                "tableOption": "autoCreate",
                "writeBatchSize": 100000
            }
        }
    }
]
```

Example 2: Invoke a stored procedure during copy

Learn more details from Invoke a stored procedure from a SQL sink.

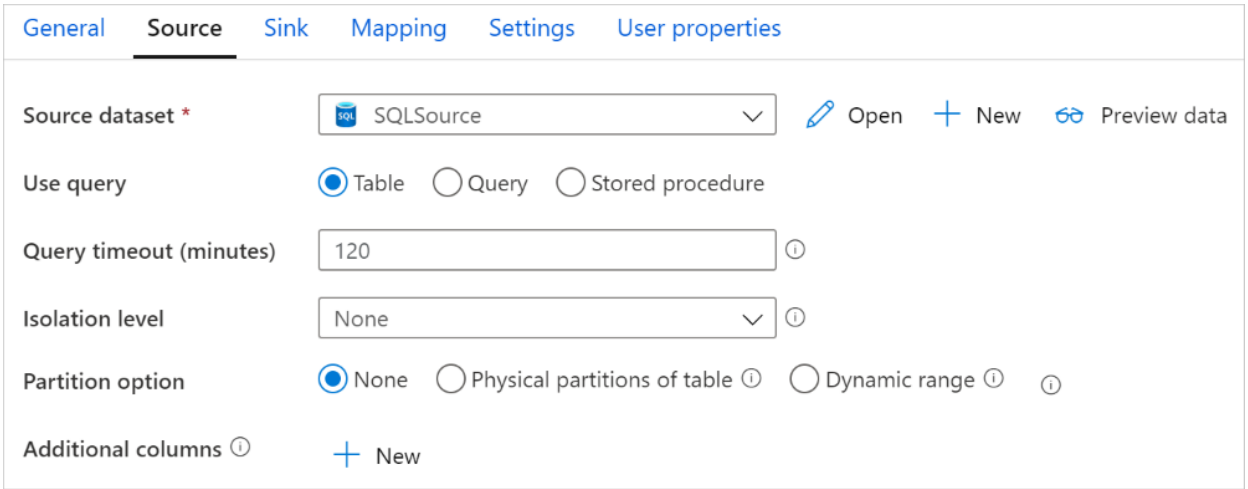
```
"activities":[
    {
        "name": "CopyToSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<SQL Server output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SqlSink",
                "sqlWriterStoredProcedureName": "CopyTestStoredProcedureWithParameters",
                "storedProcedureTableTypeParameterName": "MyTable",
                "sqlWriterTableType": "MyTableType",
                "storedProcedureParameters": {
                    "identifier": { "value": "1", "type": "Int" },
                    "stringData": { "value": "str1" }
                }
            }
        }
    }
]
```

Example 3: Upsert data

```
"activities":[
    {
        "name": "CopyToSQLServer",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<SQL Server output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>"
            },
            "sink": {
                "type": "SqlSink",
                "tableOption": "autoCreate",
                "writeBehavior": "upsert",
                "upsertSettings": {
                    "useTempDB": true,
                    "keys": [
                        "<column name>"
                    ]
                },
            }
        }
    }
]
```

Parallel copy from SQL database

The SQL Server connector in copy activity provides built-in data partitioning to copy data in parallel. You can find data partitioning options on the **Source** tab of the copy activity.



When you enable partitioned copy, copy activity runs parallel queries against your SQL Server source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your SQL Server.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your SQL Server. The following are suggested configurations for different scenarios. When copying data

into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table, with physical partitions.	**Partition option**: Physical partitions of table. During execution, the service automatically detects the physical partitions, and copies data by partitions. To check if your table has physical partition or not, you can refer to this query.
Full load from large table, without physical partitions, while with an integer or datetime column for data partitioning.	**Partition options**: Dynamic range partition. **Partition column** (optional): Specify the column used to partition data. If not specified, the primary key column is used. **Partition upper bound** and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the table will be partitioned and copied. If not specified, copy activity auto detects the values and it can take long time depending on MIN and MAX values. It is recommended to provide upper bound and lower bound. For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions - IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.

SCENARIO	SUGGESTED SETTINGS

Load a large amount of data by using a custom query, without physical partitions, while with an integer or date/datetime column for data partitioning.	**Partition options**: Dynamic range partition.
	Query:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	.
	Partition column: Specify the column used to partition data.
	Partition upper bound and **partition lower bound** (optional): Specify if you want to determine the partition stride. This is not for filtering the rows in table, all rows in the query result will be partitioned and copied. If not specified, copy activity auto detect the value.
	
	During execution, the service replaces `?AdfRangePartitionColumnName` with the actual column name and value ranges for each partition, and sends to SQL Server.
	For example, if your partition column "ID" has values range from 1 to 100, and you set the lower bound as 20 and the upper bound as 80, with parallel copy as 4, the service retrieves data by 4 partitions- IDs in range <=20, [21, 50], [51, 80], and >=81, respectively.
	
	Here are more sample queries for different scenarios:
	1. Query the whole table:
	`SELECT * FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition`
	2. Query from a table with column selection and additional where-clause filters:
	`SELECT <column_list> FROM <TableName> WHERE ? AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	3. Query with subqueries:
	`SELECT <column_list> FROM (<your_sub_query>) AS T WHERE ?AdfDynamicRangePartitionCondition AND <your_additional_where_clause>`
	4. Query with partition in subquery:
	`SELECT <column_list> FROM (SELECT <your_sub_query_column_list> FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition) AS T`

Best practices to load data with partition option:

1. Choose distinctive column as partition column (like primary key or unique key) to avoid data skew.
2. If the table has built-in partition, use partition option "Physical partitions of table" to get better performance.
3. If you use Azure Integration Runtime to copy data, you can set larger "Data Integration Units (DIU)" (>4) to utilize more computing resource. Check the applicable scenarios there.
4. "Degree of copy parallelism" control the partition numbers, setting this number too large sometime hurts the performance, recommend setting this number as (DIU or number of Self-hosted IR nodes) * (2 to 4).

Example: full load from large table with physical partitions

```
"source": {
    "type": "SqlSource",
    "partitionOption": "PhysicalPartitionsOfTable"
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "SqlSource",
    "query":"SELECT * FROM <TableName> WHERE ?AdfDynamicRangePartitionCondition AND
<your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column (optional) to decide the partition stride,
not as data filter>",
        "partitionLowerBound": "<lower_value_of_partition_column (optional) to decide the partition stride,
not as data filter>"
    }
}
```

Sample query to check physical partition

```
SELECT DISTINCT s.name AS SchemaName, t.name AS TableName, pf.name AS PartitionFunctionName, c.name AS
ColumnName, iif(pf.name is null, 'no', 'yes') AS HasPartition
FROM sys.tables AS t
LEFT JOIN sys.objects AS o ON t.object_id = o.object_id
LEFT JOIN sys.schemas AS s ON o.schema_id = s.schema_id
LEFT JOIN sys.indexes AS i ON t.object_id = i.object_id
LEFT JOIN sys.index_columns AS ic ON ic.partition_ordinal > 0 AND ic.index_id = i.index_id AND ic.object_id
= t.object_id
LEFT JOIN sys.columns AS c ON c.object_id = ic.object_id AND c.column_id = ic.column_id
LEFT JOIN sys.partition_schemes ps ON i.data_space_id = ps.data_space_id
LEFT JOIN sys.partition_functions pf ON pf.function_id = ps.function_id
WHERE s.name='[your schema]' AND t.name = '[your table name]'
```

If the table has physical partition, you would see "HasPartition" as "yes" like the following.

SchemaName	TableName	PartitionFunctionName	ColumnName	HasPartition
dbo	PerfWithPartition	RangePF1	Id	yes

Best practice for loading data into SQL Server

When you copy data into SQL Server, you might require different write behavior:

- Append: My source data has only new records.
- Upsert: My source data has both inserts and updates.
- Overwrite: I want to reload the entire dimension table each time.
- Write with custom logic: I need extra processing before the final insertion into the destination table.

See the respective sections for how to configure and best practices.

Append data

Appending data is the default behavior of this SQL Server sink connector. the service does a bulk insert to write to your table efficiently. You can configure the source and sink accordingly in the copy activity.

Upsert data

Copy activity now supports natively loading data into a database temporary table and then update the data in sink table if key exists and otherwise insert new data. To learn more about upsert settings in copy activities, see SQL Server as a sink.

Overwrite the entire table

You can configure the **preCopyScript** property in a copy activity sink. In this case, for each copy activity that runs, the service runs the script first. Then it runs the copy to insert the data. For example, to overwrite the entire table with the latest data, specify a script to first delete all the records before you bulk load the new data from

the source.

Write data with custom logic

The steps to write data with custom logic are similar to those described in the Upsert data section. When you need to apply extra processing before the final insertion of source data into the destination table, you can load to a staging table then invoke stored procedure activity, or invoke a stored procedure in copy activity sink to apply data.

Invoke a stored procedure from a SQL sink

When you copy data into SQL Server database, you also can configure and invoke a user-specified stored procedure with additional parameters on each batch of the source table. The stored procedure feature takes advantage of table-valued parameters. Note that the service automatically wraps the stored procedure in its own transaction, so any transaction created inside the stored procedure will become a nested transaction, and could have implications for exception handling.

You can use a stored procedure when built-in copy mechanisms don't serve the purpose. An example is when you want to apply extra processing before the final insertion of source data into the destination table. Some extra processing examples are when you want to merge columns, look up additional values, and insert into more than one table.

The following sample shows how to use a stored procedure to do an upsert into a table in the SQL Server database. Assume that the input data and the sink **Marketing** table each have three columns: **ProfileID**, **State**, and **Category**. Do the upsert based on the **ProfileID** column, and only apply it for a specific category called "ProductA".

1. In your database, define the table type with the same name as **sqlWriterTableType**. The schema of the table type is the same as the schema returned by your input data.

   ```
   CREATE TYPE [dbo].[MarketingType] AS TABLE(
       [ProfileID] [varchar](256) NOT NULL,
       [State] [varchar](256) NOT NULL,
       [Category] [varchar](256) NOT NULL
   )
   ```

2. In your database, define the stored procedure with the same name as **sqlWriterStoredProcedureName**. It handles input data from your specified source and merges into the output table. The parameter name of the table type in the stored procedure is the same as **tableName** defined in the dataset.

   ```
   CREATE PROCEDURE spOverwriteMarketing @Marketing [dbo].[MarketingType] READONLY, @category
   varchar(256)
   AS
   BEGIN
   MERGE [dbo].[Marketing] AS target
   USING @Marketing AS source
   ON (target.ProfileID = source.ProfileID and target.Category = @category)
   WHEN MATCHED THEN
       UPDATE SET State = source.State
   WHEN NOT MATCHED THEN
       INSERT (ProfileID, State, Category)
       VALUES (source.ProfileID, source.State, source.Category);
   END
   ```

3. Define the **SQL sink** section in the copy activity as follows:

```
"sink": {
    "type": "SqlSink",
    "sqlWriterStoredProcedureName": "spOverwriteMarketing",
    "storedProcedureTableTypeParameterName": "Marketing",
    "sqlWriterTableType": "MarketingType",
    "storedProcedureParameters": {
        "category": {
            "value": "ProductA"
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read and write to tables from SQL Server Database. For more information, see the source transformation and sink transformation in mapping data flows.

> **NOTE**
>
> To access on premise SQL Server, you need to use Azure Data Factory or Synapse workspace Managed Virtual Network using a private endpoint. Refer to this tutorial for detailed steps.

Source transformation

The below table lists the properties supported by SQL Server source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	If you select Table as input, data flow fetches all the data from the table specified in the dataset.	No	-	-

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Query	If you select Query as input, specify a SQL query to fetch data from source, which overrides any table you specify in dataset. Using queries is a great way to reduce rows for testing or lookups. **Order By** clause is not supported, but you can set a full SELECT FROM statement. You can also use user-defined table functions. **select * from udfGetData()** is a UDF in SQL that returns a table that you can use in data flow. Query example: `Select * from MyTable where customerId > 1000 and customerId < 2000`	No	String	query
Batch size	Specify a batch size to chunk large data into reads.	No	Integer	batchSize
Isolation Level	Choose one of the following isolation levels: - Read Committed - Read Uncommitted (default) - Repeatable Read - Serializable - None (ignore isolation level)	No	READ_COMMITTED READ_UNCOMMITTED REPEATABLE_READ SERIALIZABLE NONE	isolationLevel

TIP

The common table expression (CTE) in SQL is not supported in the mapping data flow **Query** mode, because the prerequisite of using this mode is that queries can be used in the SQL query FROM clause but CTEs cannot do this. To use CTEs, you need to create a stored procedure using the following query:

```
CREATE PROC CTESP @query nvarchar(max)
AS
BEGIN
EXECUTE sp_executesql @query;
END
```

Then use the **Stored procedure** mode in the source transformation of the mapping data flow and set the `@query` like example `with CTE as (select 'test' as a) select * from CTE`. Then you can use CTEs as expected.

SQL Server source script example

When you use SQL Server as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
    validateSchema: false,
    isolationLevel: 'READ_UNCOMMITTED',
    query: 'select * from MYTABLE',
    format: 'query') ~> SQLSource
```

Sink transformation

The below table lists the properties supported by SQL Server sink. You can edit these properties in the **Sink options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Update method	Specify what operations are allowed on your database destination. The default is to only allow inserts. To update, upsert, or delete rows, an Alter row transformation is required to tag rows for those actions.	Yes	`true` or `false`	deletable insertable updateable upsertable
Key columns	For updates, upserts and deletes, key column(s) must be set to determine which row to alter. The column name that you pick as the key will be used as part of the subsequent update, upsert, delete. Therefore, you must pick a column that exists in the Sink mapping.	No	Array	keys

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Skip writing key columns	If you wish to not write the value to the key column, select "Skip writing key columns".	No	`true` or `false`	skipKeyWrites
Table action	Determines whether to recreate or remove all rows from the destination table prior to writing. - **None**: No action will be done to the table. - **Recreate**: The table will get dropped and recreated. Required if creating a new table dynamically. - **Truncate**: All rows from the target table will get removed.	No	`true` or `false`	recreate truncate
Batch size	Specify how many rows are being written in each batch. Larger batch sizes improve compression and memory optimization, but risk out of memory exceptions when caching data.	No	Integer	batchSize
Pre and Post SQL scripts	Specify multi-line SQL scripts that will execute before (pre-processing) and after (post-processing) data is written to your Sink database.	No	String	preSQLs postSQLs

TIP

1. It's recommended to break single batch scripts with multiple commands into multiple batches.
2. Only Data Definition Language (DDL) and Data Manipulation Language (DML) statements that return a simple update count can be run as part of a batch. Learn more from Performing batch operations

SQL Server sink script example

When you use SQL Server as sink type, the associated data flow script is:

```
IncomingStream sink(allowSchemaDrift: true,
    validateSchema: false,
    deletable:false,
    insertable:true,
    updateable:true,
    upsertable:true,
    keys:['keyColumn'],
    format: 'table',
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> SQLSink
```

Data type mapping for SQL Server

When you copy data from and to SQL Server, the following mappings are used from SQL Server data types to Azure Data Factory interim data types. Synapse pipelines, which implement Data Factory, use the same mappings. To learn how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

SQL SERVER DATA TYPE	DATA FACTORY INTERIM DATA TYPE
bigint	Int64
binary	Byte[]
bit	Boolean
char	String, Char[]
date	DateTime
Datetime	DateTime
datetime2	DateTime
Datetimeoffset	DateTimeOffset
Decimal	Decimal
FILESTREAM attribute (varbinary(max))	Byte[]
Float	Double
image	Byte[]
int	Int32
money	Decimal
nchar	String, Char[]
ntext	String, Char[]
numeric	Decimal

SQL SERVER DATA TYPE	DATA FACTORY INTERIM DATA TYPE
nvarchar	String, Char[]
real	Single
rowversion	Byte[]
smalldatetime	DateTime
smallint	Int16
smallmoney	Decimal
sql_variant	Object
text	String, Char[]
time	TimeSpan
timestamp	Byte[]
tinyint	Int16
uniqueidentifier	Guid
varbinary	Byte[]
varchar	String, Char[]
xml	String

> **NOTE**
>
> For data types that map to the Decimal interim type, currently Copy activity supports precision up to 28. If you have data that requires precision larger than 28, consider converting to a string in a SQL query.
>
> When copying data from SQL Server using Azure Data Factory, the bit data type is mapped to the Boolean interim data type. If you have data that need to be kept as the bit data type, use queries with T-SQL CAST or CONVERT.

Lookup activity properties

To learn details about the properties, check Lookup activity.

GetMetadata activity properties

To learn details about the properties, check GetMetadata activity

Using Always Encrypted

When you copy data from/to SQL Server with Always Encrypted, follow below steps:

1. Store the Column Master Key (CMK) in an Azure Key Vault. Learn more on how to configure Always

Encrypted by using Azure Key Vault

2. Make sure to grant access to the key vault where the Column Master Key (CMK) is stored. Refer to this article for required permissions.

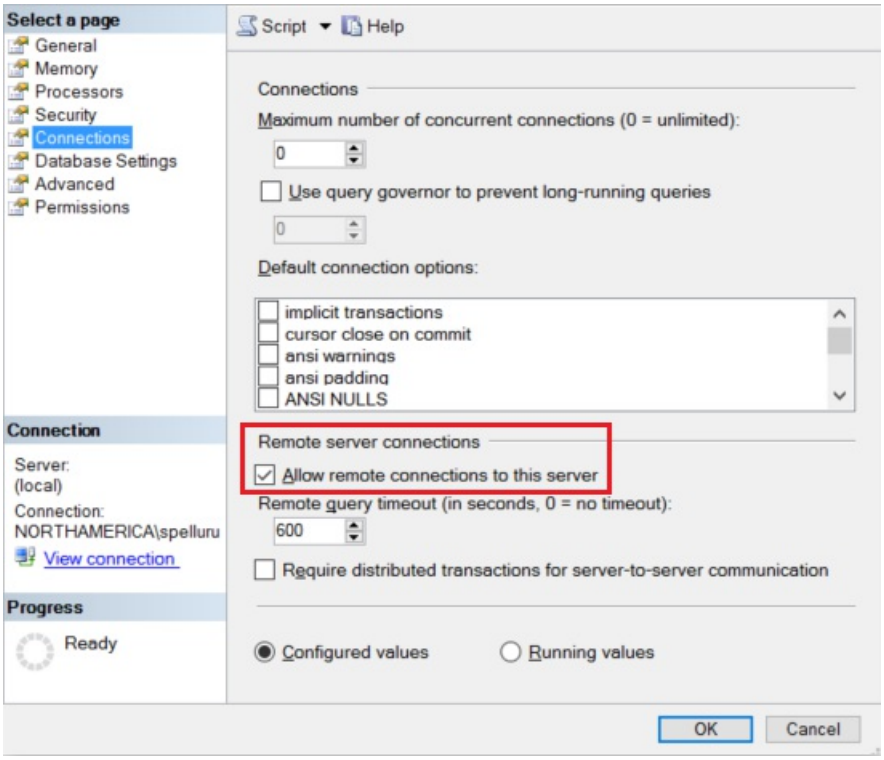
3. Create linked service to connect to your SQL database and enable 'Always Encrypted' function by using either managed identity or service principal.

> **NOTE**
>
> SQL Server Always Encrypted supports below scenarios:
>
> 1. Either source or sink data stores is using managed identity or service principal as key provider authentication type.
> 2. Both source and sink data stores are using managed identity as key provider authentication type.
> 3. Both source and sink data stores are using the same service principal as key provider authentication type.

> **NOTE**
>
> Currently, SQL Server **Always Encrypted** is only supported for source transformation in mapping data flows.

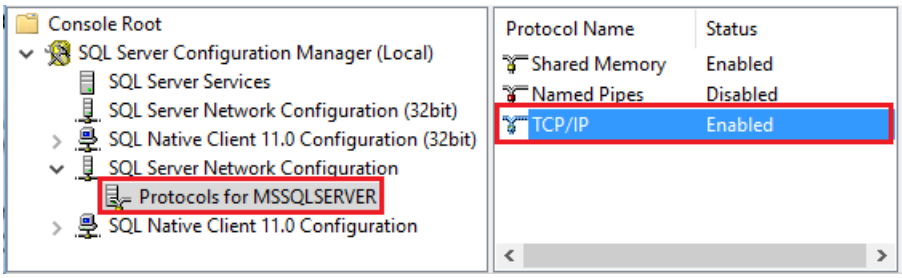
Troubleshoot connection issues

1. Configure your SQL Server instance to accept remote connections. Start **SQL Server Management Studio**, right-click **server**, and select **Properties**. Select **Connections** from the list, and select the **Allow remote connections to this server** check box.



For detailed steps, see Configure the remote access server configuration option.

2. Start **SQL Server Configuration Manager**. Expand **SQL Server Network Configuration** for the instance you want, and select **Protocols for MSSQLSERVER**. Protocols appear in the right pane. Enable TCP/IP by right-clicking **TCP/IP** and selecting **Enable**.



For more information and alternate ways of enabling TCP/IP protocol, see Enable or disable a server network protocol.

3. In the same window, double-click **TCP/IP** to launch the **TCP/IP Properties** window.
4. Switch to the **IP Addresses** tab. Scroll down to see the **IPAll** section. Write down the **TCP Port**. The default is **1433**.
5. Create a **rule for the Windows Firewall** on the machine to allow incoming traffic through this port.
6. **Verify connection**: To connect to SQL Server by using a fully qualified name, use SQL Server Management Studio from a different machine. An example is `"<machine>.<domain>.corp.<company>.com,1433"`.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Square using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Square. It builds on the copy activity overview article that presents a general overview of copy activity.

IMPORTANT

This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

NOTE

Currently, this connector doesn't support sandbox accounts.

Supported capabilities

This Square connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

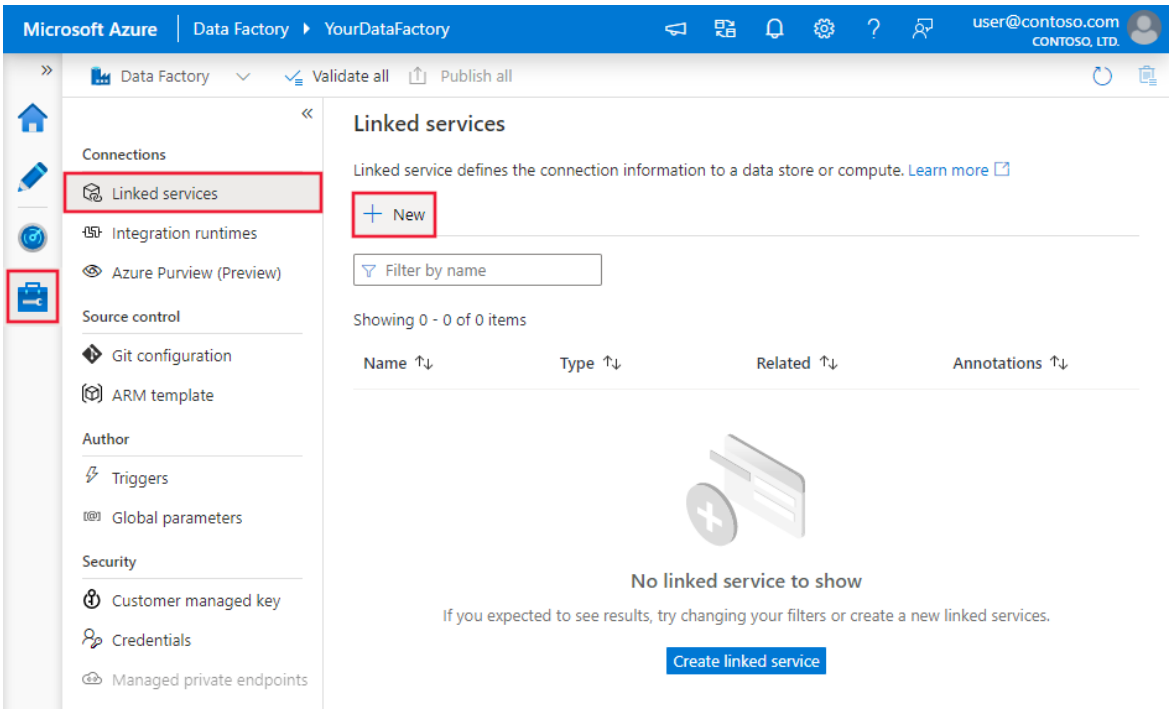
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Square using UI

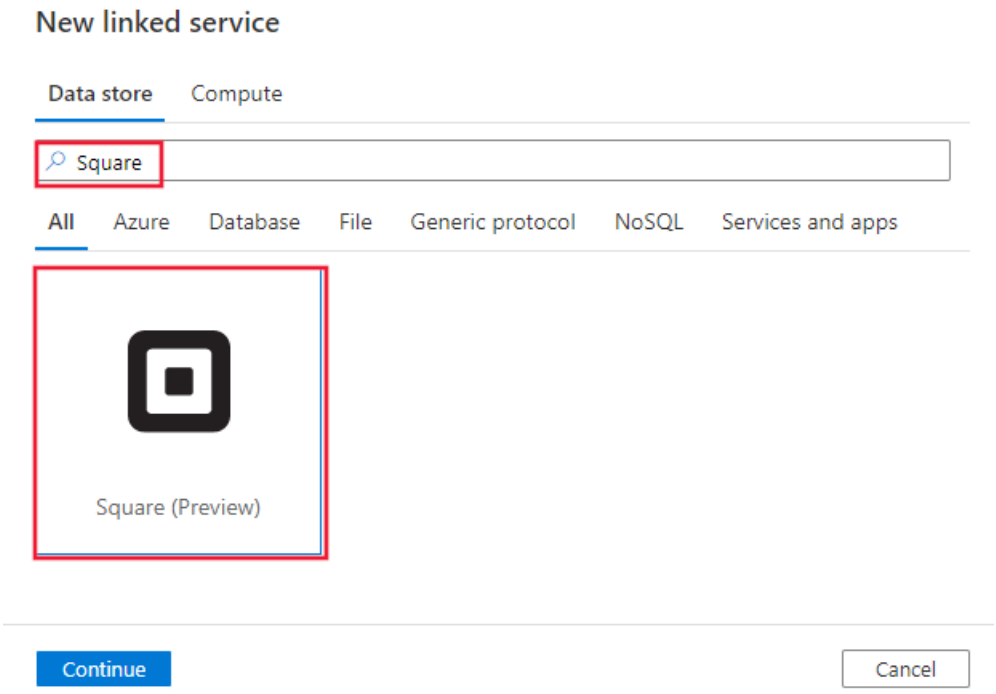
Use the following steps to create a linked service to Square in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

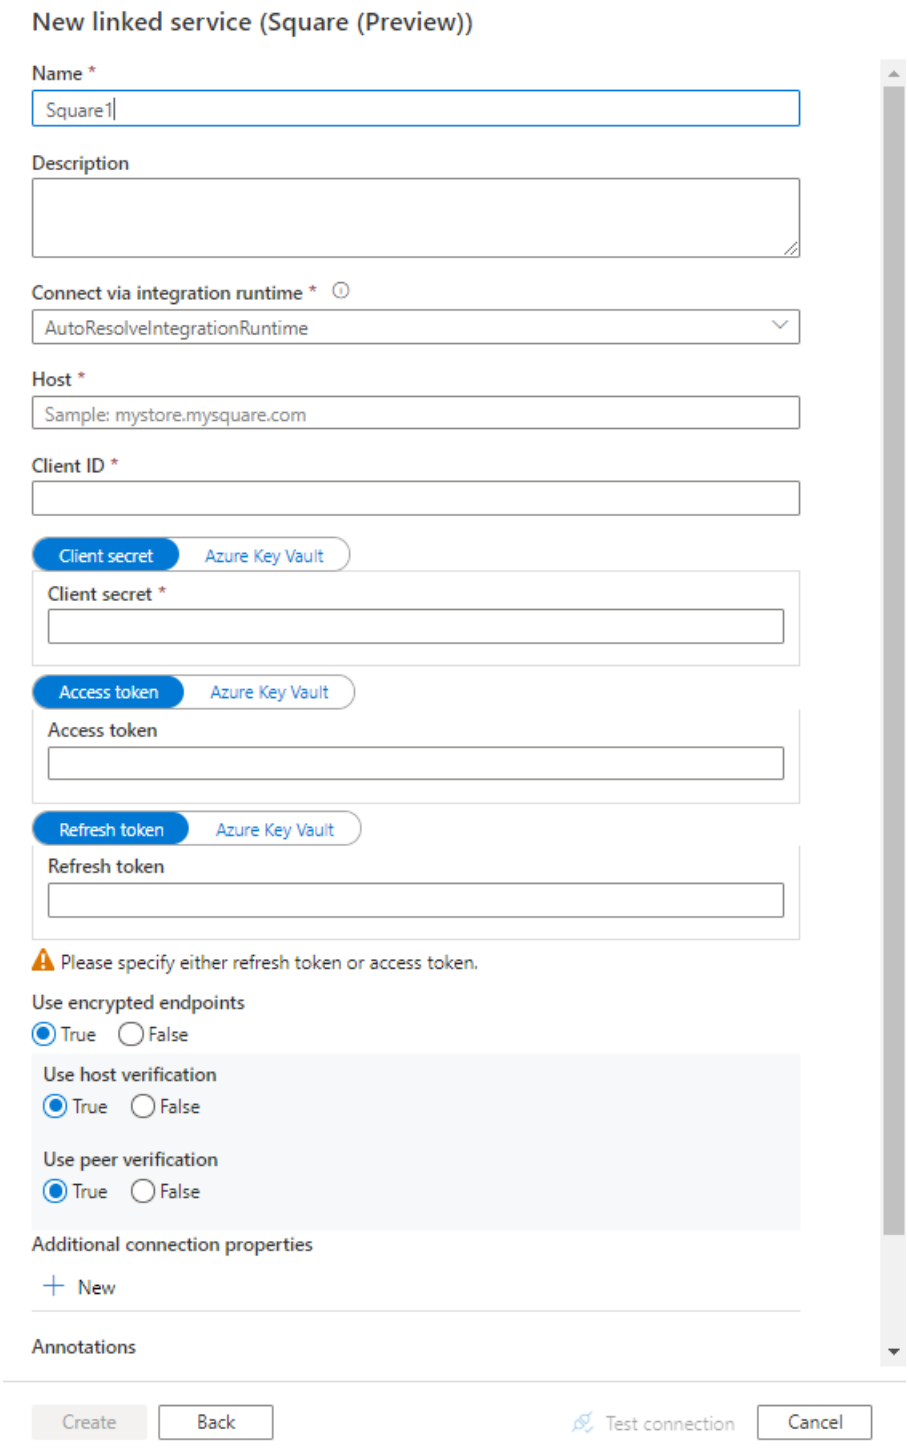
   - Azure Data Factory
   - Azure Synapse



2. Search for Square and select the Square connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Square connector.

Linked service properties

The following properties are supported for Square linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Square**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionProperties	A group of properties that defines how to connect to Square.	Yes
Under `connectionProperties`*:*		
host	The URL of the Square instance. (i.e. mystore.mysquare.com)	Yes
clientId	The client ID associated with your Square application.	Yes
clientSecret	The client secret associated with your Square application. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
accessToken	The access token obtained from Square. Grants limited access to a Square account by asking an authenticated user for explicit permissions. OAuth access tokens expires 30 days after issued, but refresh tokens do not expire. Access tokens can be refreshed by refresh token. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
refreshToken	The refresh token obtained from Square. Used to obtain new access tokens when the current one expires. Mark this field as a SecureString to store it securelyFactory, or reference a secret stored in Azure Key Vault.	No
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Square support two types of access token: **personal** and **OAuth**.

- Personal access tokens are used to get unlimited Connect API access to resources in your own Square account.
- OAuth access tokens are used to get authenticated and scoped Connect API access to any Square account.

Use them when your app accesses resources in other Square accounts on behalf of account owners. OAuth access tokens can also be used to access resources in your own Square account.

> **IMPORTANT**
> To perform **Test connection** in the linked service, `MERCHANT_PROFILE_READ` is required to get a scoped OAuth access token. For permissions to access other tables, see Square OAuth Permissions Reference.

Authentication via personal access token only needs `accessToken`, while authentication via OAuth requires `accessToken` and `refreshToken`. Learn how to retrieve access token from here.

Example:

```
{
    "name": "SquareLinkedService",
    "properties": {
        "type": "Square",
        "typeProperties": {
            "connectionProperties":{
                "host":"<e.g. mystore.mysquare.com>",
                "clientId":"<client ID>",
                "clientSecrect":{
                    "type": "SecureString",
                    "value": "<clientSecret>"
                },
                "accessToken":{
                    "type": "SecureString",
                    "value": "<access token>"
                },
                "refreshToken":{
                    "type": "SecureString",
                    "value": "<refresh token>"
                },
                "useEncryptedEndpoints":true,
                "useHostVerification":true,
                "usePeerVerification":true
            }
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Square dataset.

To copy data from Square, set the type property of the dataset to **SquareObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SquareObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "SquareDataset",
    "properties": {
        "type": "SquareObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Square linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Square source.

Square as source

To copy data from Square, set the source type in the copy activity to **SquareSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SquareSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Business"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromSquare",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Square input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SquareSource",
                "query": "SELECT * FROM Business"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Sybase using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from a Sybase database. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Sybase connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this Sybase connector supports:

- SAP Sybase SQL Anywhere (ASA) **version 16 and above**.
- Copying data using **Basic** or **Windows** authentication.

Sybase IQ and ASE are not supported. You can use generic ODBC connector with Sybase driver instead.

Prerequisites

To use this Sybase connector, you need to:

- Set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.
- Install the data provider for Sybase iAnywhere.Data.SQLAnywhere 16 or above on the Integration Runtime machine.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API

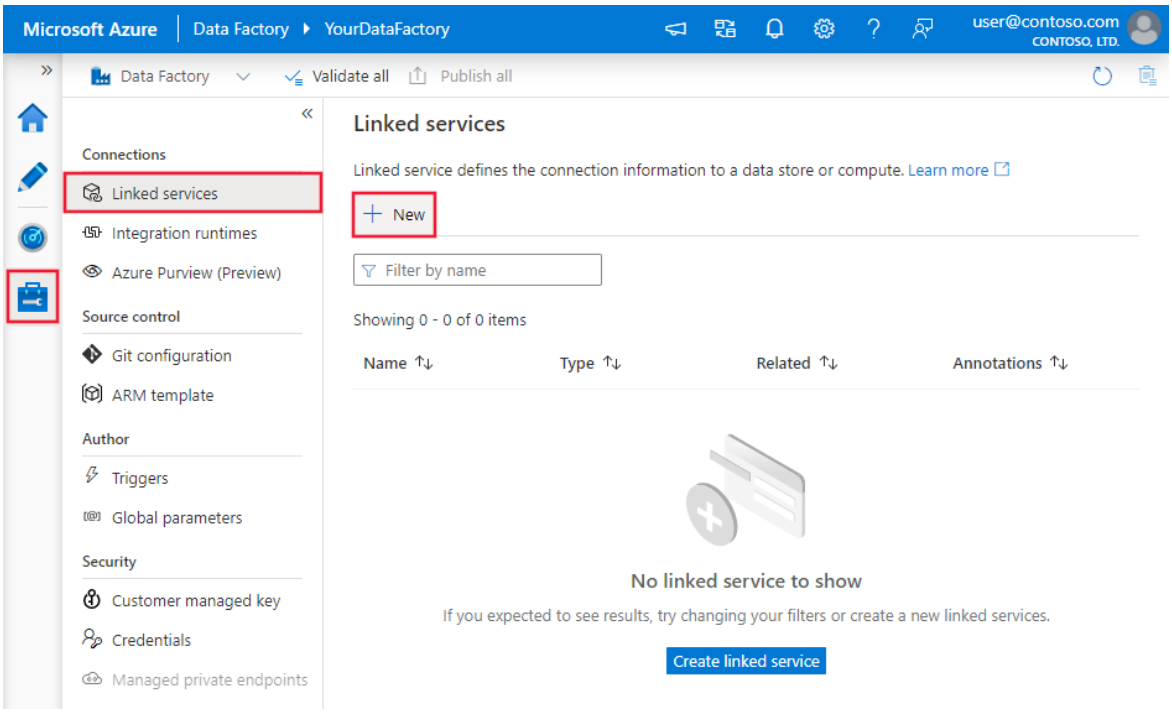
- The Azure Resource Manager template

Create a linked service to Sybase using UI

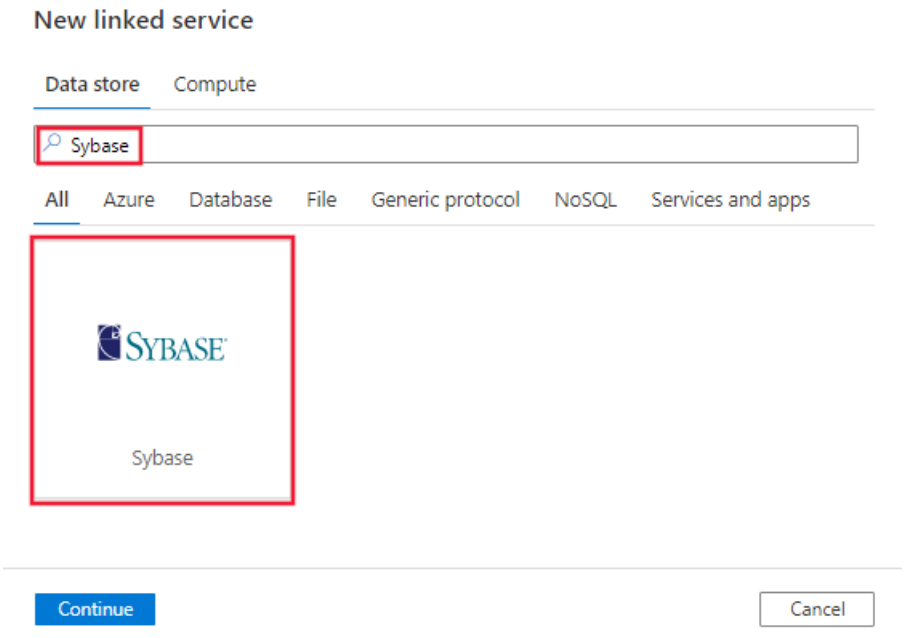
Use the following steps to create a linked service to Sybase in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

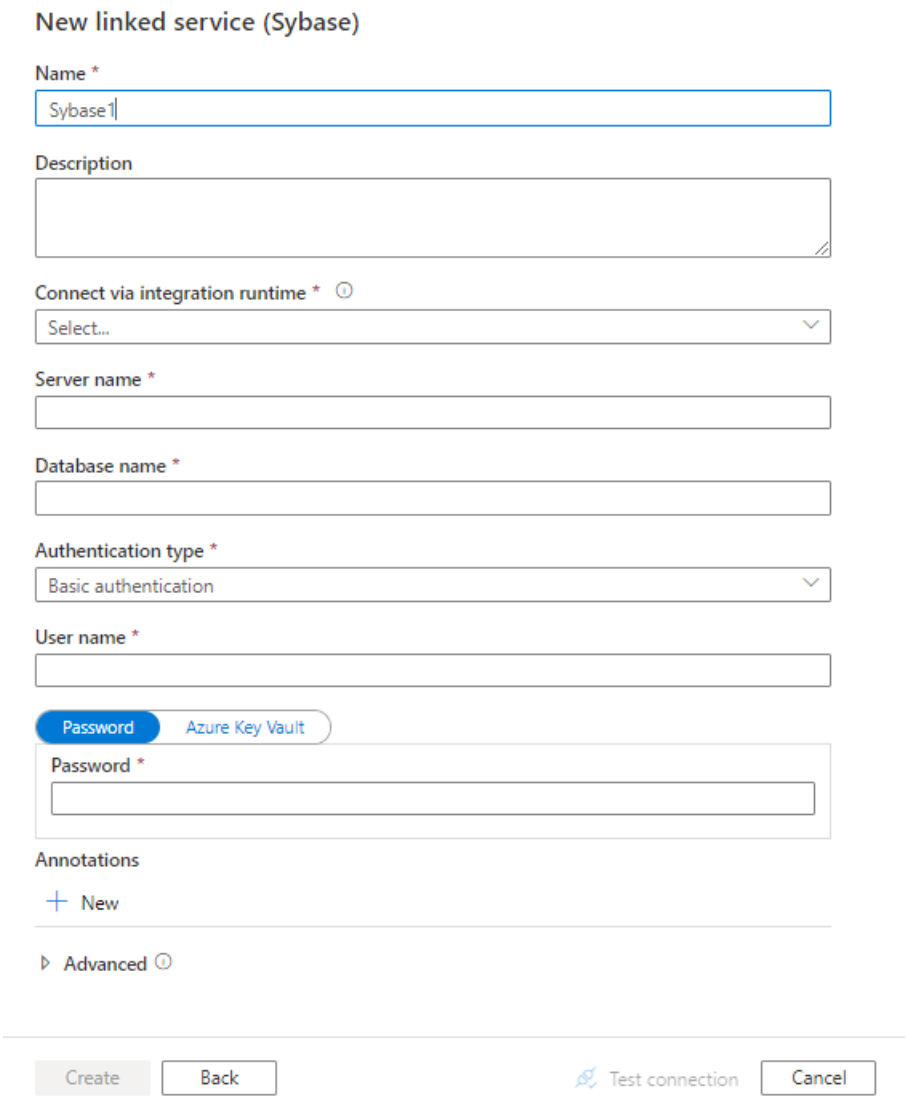
   - Azure Data Factory
   - Azure Synapse



2. Search for Sybase and select the Sybase connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Sybase connector.

Linked service properties

The following properties are supported for Sybase linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Sybase**	Yes
server	Name of the Sybase server.	Yes
database	Name of the Sybase database.	Yes
authenticationType	Type of authentication used to connect to the Sybase database. Allowed values are: **Basic**, and **Windows**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
username	Specify user name to connect to the Sybase database.	Yes
password	Specify password for the user account you specified for the username. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "SybaseLinkedService",
    "properties": {
        "type": "Sybase",
        "typeProperties": {
            "server": "<server>",
            "database": "<database>",
            "authenticationType": "Basic",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Sybase dataset.

To copy data from Sybase, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **SybaseTable**	Yes
tableName	Name of the table in the Sybase database.	No (if "query" in activity source is specified)

Example

```
{
    "name": "SybaseDataset",
    "properties": {
        "type": "SybaseTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Sybase linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

If you were using `RelationalTable` typed dataset, it is still supported as-is, while you are suggested to use the new one going forward.

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Sybase source.

Sybase as source

To copy data from Sybase, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **SybaseSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromSybase",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Sybase input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "SybaseSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

If you were using `RelationalSource` typed source, it is still supported as-is, while you are suggested to use the new one going forward.

Data type mapping for Sybase

When copying data from Sybase, the following mappings are used from Sybase data types to interim data types used internally within the service. See Schema and data type mappings to learn about how copy activity maps the source schema and data type to the sink.

Sybase supports T-SQL types. For a mapping table from SQL types to interim service data types, see Azure SQL Database Connector - data type mapping section.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Transform data in TeamDesk (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in TeamDesk (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This TeamDesk connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

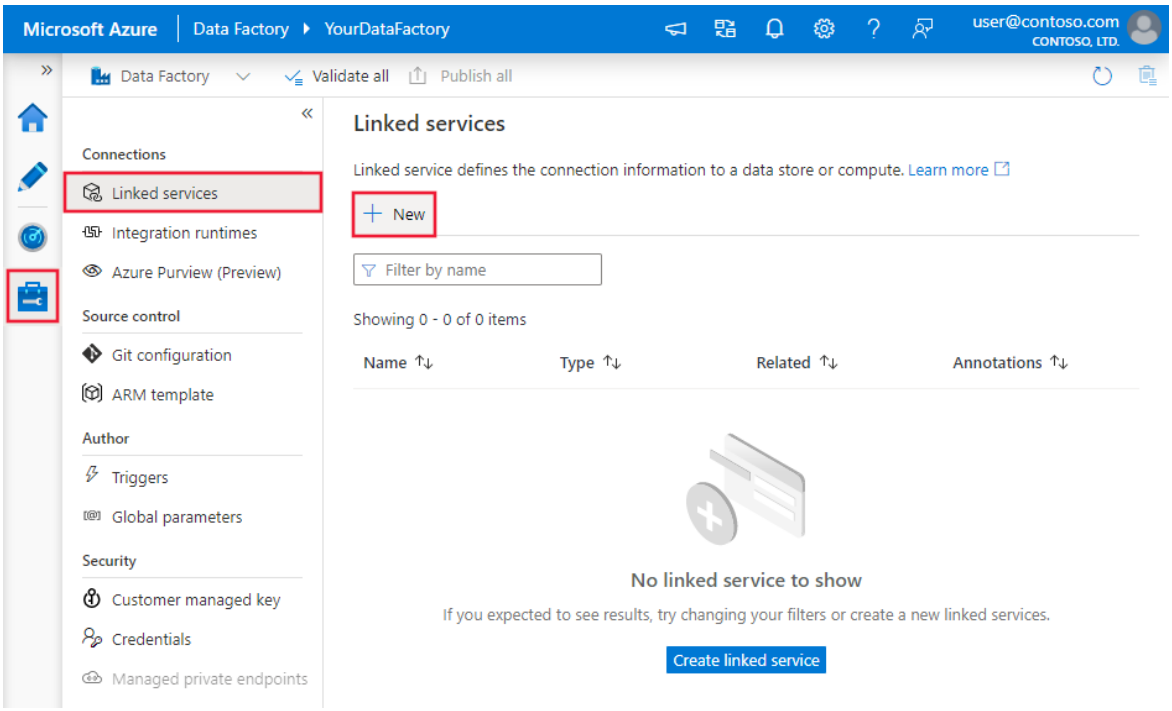
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a TeamDesk linked service using UI

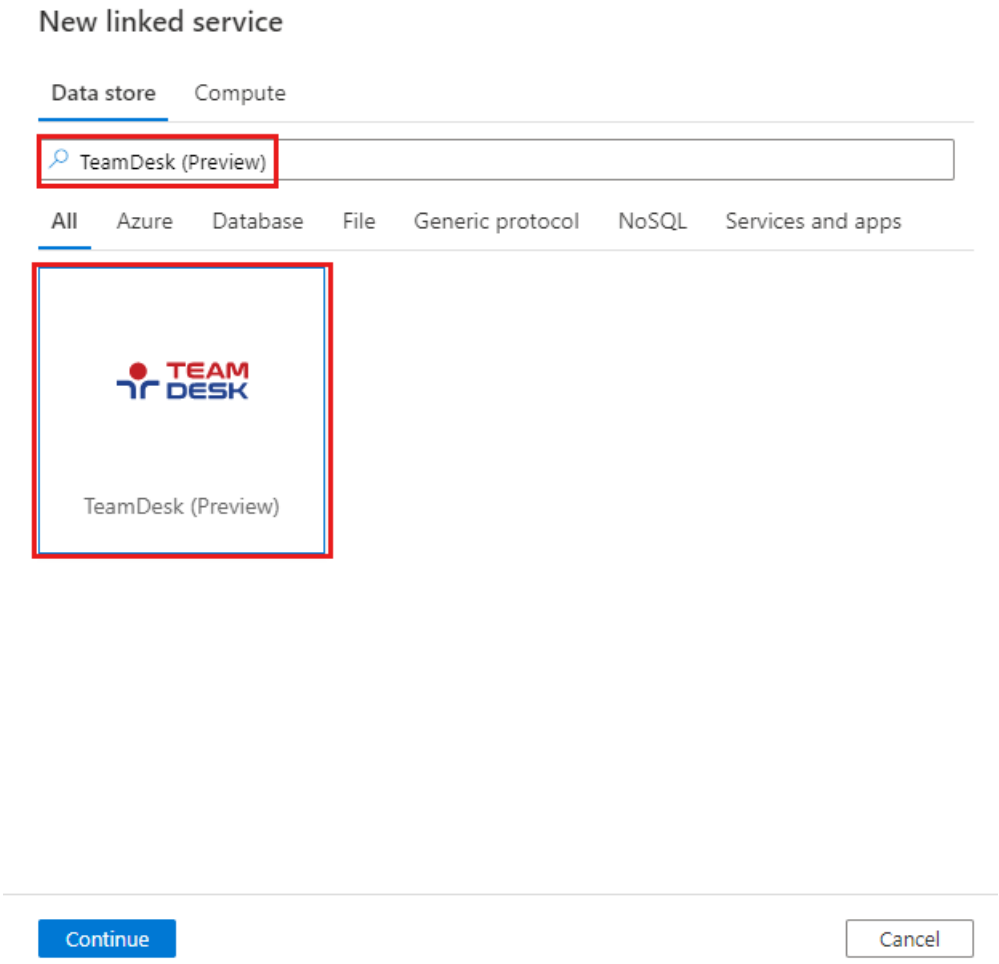
Use the following steps to create a TeamDesk linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

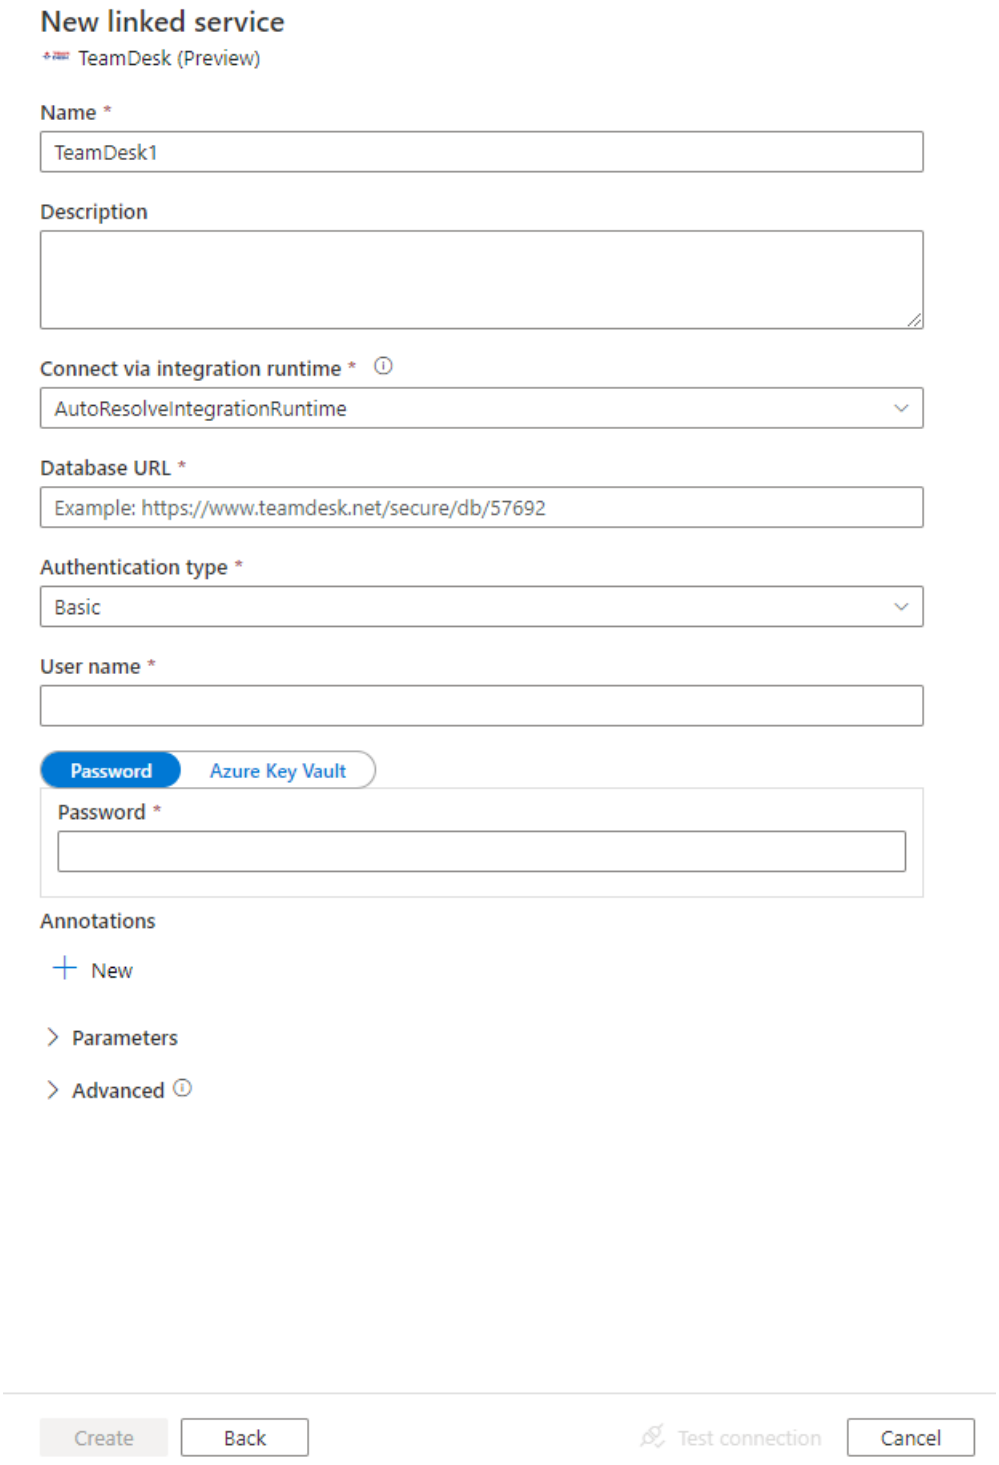
   - Azure Data Factory
   - Azure Synapse



2. Search for TeamDesk (Preview) and select the TeamDesk (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to TeamDesk.

Linked service properties

The following properties are supported for the TeamDesk linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **TeamDesk**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
url	The URL of your TeamDesk database. An example is `https://www.teamdesk.net/secure/db/xxxxx`.	Yes
authenticationType	Type of authentication used to connect to the TeamDesk service. Allowed values are **basic** and **token**. Refer to corresponding sections below on more properties and examples respectively.	Yes

Basic authentication

Set the **authenticationType** property to **basic**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user name used to log in to TeamDesk.	Yes
password	Specify a password for the user account you specified for the user name. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "TeamDeskLinkedService",
    "properties": {
        "type": "TeamDesk",
        "typeProperties": {
            "url": "https://www.teamdesk.net/secure/db/xxxxx",
            "authenticationType": "basic",
            "userName": "<user name>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    }
}
```

Token authentication

Set the **authenticationType** property to **token**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
apiToken	Specify an API token for the TeamDesk. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "TeamDeskLinkedService",
    "properties": {
        "type": "TeamDesk",
        "typeProperties": {
            "url": "https://www.teamdesk.net/secure/db/xxxxx",
            "authenticationType": "token",
            "apiToken": {
                "type": "SecureString",
                "value": "<API token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from TeamDesk. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by TeamDesk source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Table	Data flow will fetch all the data from the table specified in the source options.	Yes when use inline mode	-	table
View	Data flow will fetch the specified view in the table specified in the source options.	No	-	view

TeamDesk source script examples

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'teamdesk',
 format: 'rest',
 table: 'Table',
 view: 'View') ~> TeamDesksource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Teradata Vantage using Azure Data Factory and Synapse Analytics

8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the copy activity in Azure Data Factory and Synapse Analytics pipelines to copy data from Teradata Vantage. It builds on the copy activity overview.

Supported capabilities

This Teradata connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

Specifically, this Teradata connector supports:

- Teradata **version 14.10, 15.0, 15.10, 16.0, 16.10, and 16.20**.
- Copying data by using **Basic**, **Windows**, or **LDAP** authentication.
- Parallel copying from a Teradata source. See the Parallel copy from Teradata section for details.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

If you use Self-hosted Integration Runtime, note it provides a built-in Teradata driver starting from version 3.18. You don't need to manually install any driver. The driver requires "Visual C++ Redistributable 2012 Update 4" on the self-hosted integration runtime machine. If you don't yet have it installed, download it from here.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

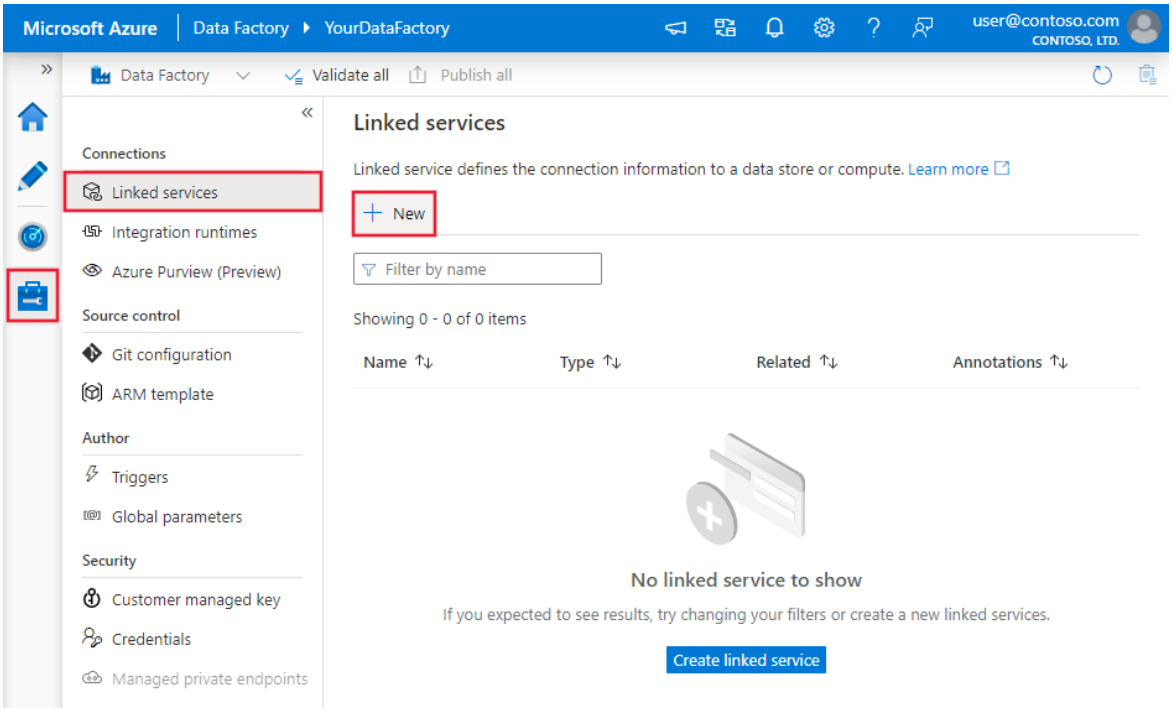
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Teradata using UI

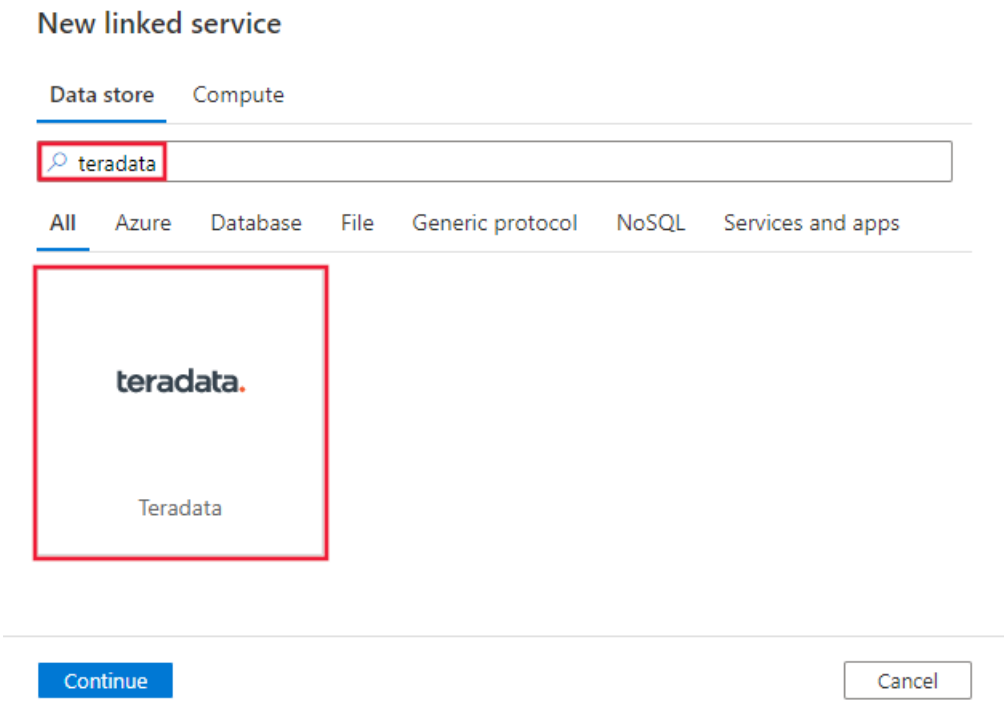
Use the following steps to create a linked service to Teradata in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

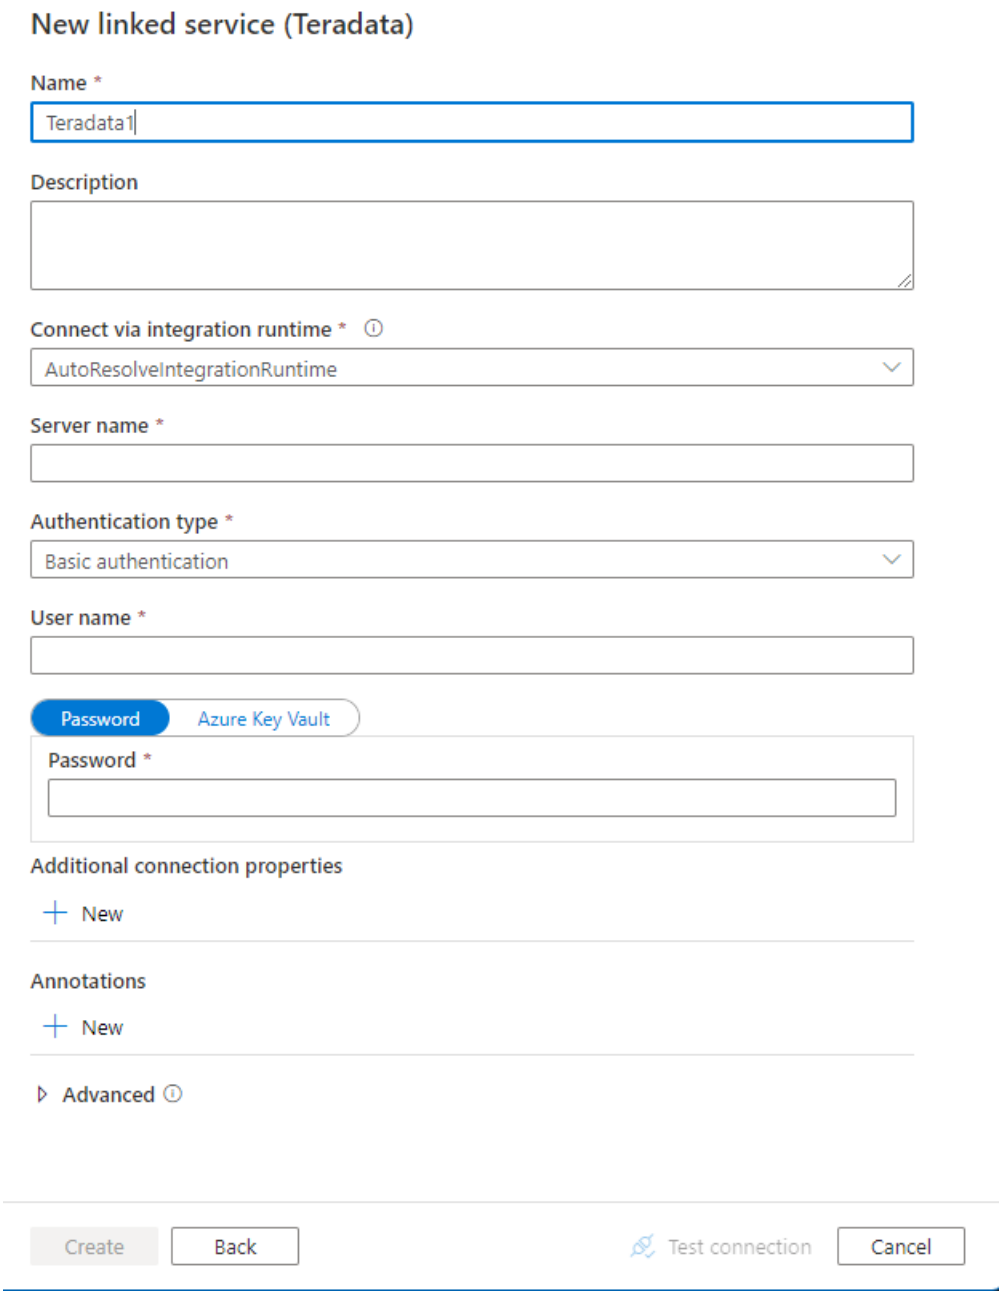
   - Azure Data Factory
   - Azure Synapse



2. Search for Teradata and select the Teradata connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to the Teradata connector.

Linked service properties

The Teradata linked service supports the following properties:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Teradata**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	Specifies the information needed to connect to the Teradata instance. Refer to the following samples. You can also put a password in Azure Key Vault, and pull the `password` configuration out of the connection string. Refer to Store credentials in Azure Key Vault with more details.	Yes
username	Specify a user name to connect to Teradata. Applies when you are using Windows authentication.	No
password	Specify a password for the user account you specified for the user name. You can also choose to reference a secret stored in Azure Key Vault. Applies when you are using Windows authentication, or referencing a password in Key Vault for basic authentication.	No
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

More connection properties you can set in connection string per your case:

PROPERTY	DESCRIPTION	DEFAULT VALUE
TdmstPortNumber	The number of the port used to access Teradata database. Do not change this value unless instructed to do so by Technical Support.	1025
UseDataEncryption	Specifies whether to encrypt all communication with the Teradata database. Allowed values are 0 or 1. - **0 (disabled, default)**: Encrypts authentication information only. - **1 (enabled)**: Encrypts all data that is passed between the driver and the database.	`0`

PROPERTY	DESCRIPTION	DEFAULT VALUE
CharacterSet	The character set to use for the session. E.g., `CharacterSet=UTF16`. This value can be a user-defined character set, or one of the following pre-defined character sets: - ASCII - UTF8 - UTF16 - LATIN1252_0A - LATIN9_0A - LATIN1_0A - Shift-JIS (Windows, DOS compatible, KANJISJIS_0S) - EUC (Unix compatible, KANJIEC_0U) - IBM Mainframe (KANJIEBCDIC5035_0I) - KANJI932_1S0 - BIG5 (TCHBIG5_1R0) - GB (SCHGB2312_1T0) - SCHINESE936_6R0 - TCHINESE950_8R0 - NetworkKorean (HANGULKSC5601_2R4) - HANGUL949_7R0 - ARABIC1256_6A0 - CYRILLIC1251_2A0 - HEBREW1255_5A0 - LATIN1250_1A0 - LATIN1254_7A0 - LATIN1258_8A0 - THAI874_4A0	`ASCII`
MaxRespSize	The maximum size of the response buffer for SQL requests, in kilobytes (KBs). E.g., `MaxRespSize=10485760`. For Teradata Database version 16.00 or later, the maximum value is 7361536. For connections that use earlier versions, the maximum value is 1048576.	`65536`
MechanismName	To use the LDAP protocol to authenticate the connection, specify `MechanismName=LDAP`.	N/A

Example using basic authentication

```
{
    "name": "TeradataLinkedService",
    "properties": {
        "type": "Teradata",
        "typeProperties": {
            "connectionString": "DBCName=<server>;Uid=<username>;Pwd=<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example using Windows authentication

```
{
    "name": "TeradataLinkedService",
    "properties": {
        "type": "Teradata",
        "typeProperties": {
            "connectionString": "DBCName=<server>",
            "username": "<username>",
            "password": "<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example using LDAP authentication

```
{
    "name": "TeradataLinkedService",
    "properties": {
        "type": "Teradata",
        "typeProperties": {
            "connectionString": "DBCName=<server>;MechanismName=LDAP;Uid=<username>;Pwd=<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

> **NOTE**
>
> The following payload is still supported. Going forward, however, you should use the new one.

Previous payload:

```
{
    "name": "TeradataLinkedService",
    "properties": {
        "type": "Teradata",
        "typeProperties": {
            "server": "<server>",
            "authenticationType": "<Basic/Windows>",
            "username": "<username>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

This section provides a list of properties supported by the Teradata dataset. For a full list of sections and properties available for defining datasets, see Datasets.

To copy data from Teradata, the following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to `TeradataTable`.	Yes
database	The name of the Teradata instance.	No (if "query" in activity source is specified)
table	The name of the table in the Teradata instance.	No (if "query" in activity source is specified)

Example:

```
{
    "name": "TeradataDataset",
    "properties": {
        "type": "TeradataTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Teradata linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

NOTE

`RelationalTable` type dataset is still supported. However, we recommend that you use the new dataset.

Previous payload:

```
{
    "name": "TeradataDataset",
    "properties": {
        "type": "RelationalTable",
        "linkedServiceName": {
            "referenceName": "<Teradata linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {}
    }
}
```

Copy activity properties

This section provides a list of properties supported by Teradata source. For a full list of sections and properties available for defining activities, see Pipelines.

Teradata as source

> **TIP**
> To load data from Teradata efficiently by using data partitioning, learn more from Parallel copy from Teradata section.

To copy data from Teradata, the following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to `TeradataSource`.	Yes
query	Use the custom SQL query to read data. An example is `"SELECT * FROM MyTable"`. When you enable partitioned load, you need to hook any corresponding built-in partition parameters in your query. For examples, see the Parallel copy from Teradata section.	No (if table in dataset is specified)
partitionOptions	Specifies the data partitioning options used to load data from Teradata. Allow values are: **None** (default), **Hash** and **DynamicRange**. When a partition option is enabled (that is, not `None`), the degree of parallelism to concurrently load data from Teradata is controlled by the `parallelCopies` setting on the copy activity.	No
partitionSettings	Specify the group of the settings for data partitioning. Apply when partition option isn't `None`.	No

PROPERTY	DESCRIPTION	REQUIRED
partitionColumnName	Specify the name of the source column that will be used by range partition or Hash partition for parallel copy. If not specified, the primary index of the table is autodetected and used as the partition column. Apply when the partition option is `Hash` or `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfHashPartitionCondition` or `?AdfRangePartitionColumnName` in WHERE clause. See example in Parallel copy from Teradata section.	No
partitionUpperBound	The maximum value of the partition column to copy data out. Apply when partition option is `DynamicRange`. If you use query to retrieve source data, hook `?AdfRangePartitionUpbound` in the WHERE clause. For an example, see the Parallel copy from Teradata section.	No
partitionLowerBound	The minimum value of the partition column to copy data out. Apply when the partition option is `DynamicRange`. If you use a query to retrieve the source data, hook `?AdfRangePartitionLowbound` in the WHERE clause. For an example, see the Parallel copy from Teradata section.	No

NOTE

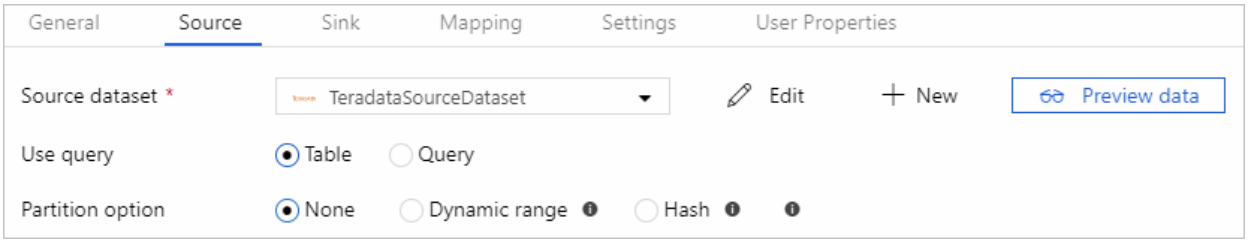
`RelationalSource` type copy source is still supported, but it doesn't support the new built-in parallel load from Teradata (partition options). However, we recommend that you use the new dataset.

Example: copy data by using a basic query without partition

```
"activities":[
    {
        "name": "CopyFromTeradata",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Teradata input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "TeradataSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Parallel copy from Teradata

The Teradata connector provides built-in data partitioning to copy data from Teradata in parallel. You can find data partitioning options on the **Source** table of the copy activity.



When you enable partitioned copy, the service runs parallel queries against your Teradata source to load data by partitions. The parallel degree is controlled by the `parallelCopies` setting on the copy activity. For example, if you set `parallelCopies` to four, the service concurrently generates and runs four queries based on your specified partition option and settings, and each query retrieves a portion of data from your Teradata.

You are suggested to enable parallel copy with data partitioning especially when you load large amount of data from your Teradata. The following are suggested configurations for different scenarios. When copying data into file-based data store, it's recommended to write to a folder as multiple files (only specify folder name), in which case the performance is better than writing to a single file.

SCENARIO	SUGGESTED SETTINGS
Full load from large table.	**Partition option**: Hash. During execution, the service automatically detects the primary index column, applies a hash against it, and copies data by partitions.

SCENARIO	SUGGESTED SETTINGS
Load large amount of data by using a custom query.	**Partition option**: Hash. **Query**: `SELECT * FROM <TABLENAME> WHERE ? AdfHashPartitionCondition AND <your_additional_where_clause>` . **Partition column**: Specify the column used for apply hash partition. If not specified, the service automatically detects the PK column of the table you specified in the Teradata dataset. During execution, the service replaces `?AdfHashPartitionCondition` with the hash partition logic, and sends to Teradata.
Load large amount of data by using a custom query, having an integer column with evenly distributed value for range partitioning.	**Partition options**: Dynamic range partition. **Query**: `SELECT * FROM <TABLENAME> WHERE ? AdfRangePartitionColumnName <= ? AdfRangePartitionUpbound AND ? AdfRangePartitionColumnName >= ? AdfRangePartitionLowbound AND <your_additional_where_clause>` . **Partition column**: Specify the column used to partition data. You can partition against the column with integer data type. **Partition upper bound** and **partition lower bound**: Specify if you want to filter against the partition column to retrieve data only between the lower and upper range. During execution, the service replaces `?AdfRangePartitionColumnName`, `?AdfRangePartitionUpbound`, and `?AdfRangePartitionLowbound` with the actual column name and value ranges for each partition, and sends to Teradata. For example, if your partition column "ID" set with the lower bound as 1 and the upper bound as 80, with parallel copy set as 4, the service retrieves data by 4 partitions. Their IDs are between [1,20], [21, 40], [41, 60], and [61, 80], respectively.

Example: query with hash partition

```
"source": {
    "type": "TeradataSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfHashPartitionCondition AND <your_additional_where_clause>",
    "partitionOption": "Hash",
    "partitionSettings": {
        "partitionColumnName": "<hash_partition_column_name>"
    }
}
```

Example: query with dynamic range partition

```
"source": {
    "type": "TeradataSource",
    "query":"SELECT * FROM <TABLENAME> WHERE ?AdfRangePartitionColumnName <= ?AdfRangePartitionUpbound AND ?
AdfRangePartitionColumnName >= ?AdfRangePartitionLowbound AND <your_additional_where_clause>",
    "partitionOption": "DynamicRange",
    "partitionSettings": {
        "partitionColumnName": "<dynamic_range_partition_column_name>",
        "partitionUpperBound": "<upper_value_of_partition_column>",
        "partitionLowerBound": "<lower_value_of_partition_column>"
    }
}
```

Data type mapping for Teradata

When you copy data from Teradata, the following mappings apply from Teradata's data types to the internal data types used by the service. To learn about how the copy activity maps the source schema and data type to the sink, see Schema and data type mappings.

TERADATA DATA TYPE	INTERIM SERVICE DATA TYPE
BigInt	Int64
Blob	Byte[]
Byte	Byte[]
ByteInt	Int16
Char	String
Clob	String
Date	DateTime
Decimal	Decimal
Double	Double
Graphic	Not supported. Apply explicit cast in source query.
Integer	Int32
Interval Day	Not supported. Apply explicit cast in source query.
Interval Day To Hour	Not supported. Apply explicit cast in source query.
Interval Day To Minute	Not supported. Apply explicit cast in source query.
Interval Day To Second	Not supported. Apply explicit cast in source query.
Interval Hour	Not supported. Apply explicit cast in source query.
Interval Hour To Minute	Not supported. Apply explicit cast in source query.

TERADATA DATA TYPE	INTERIM SERVICE DATA TYPE
Interval Hour To Second	Not supported. Apply explicit cast in source query.
Interval Minute	Not supported. Apply explicit cast in source query.
Interval Minute To Second	Not supported. Apply explicit cast in source query.
Interval Month	Not supported. Apply explicit cast in source query.
Interval Second	Not supported. Apply explicit cast in source query.
Interval Year	Not supported. Apply explicit cast in source query.
Interval Year To Month	Not supported. Apply explicit cast in source query.
Number	Double
Period (Date)	Not supported. Apply explicit cast in source query.
Period (Time)	Not supported. Apply explicit cast in source query.
Period (Time With Time Zone)	Not supported. Apply explicit cast in source query.
Period (Timestamp)	Not supported. Apply explicit cast in source query.
Period (Timestamp With Time Zone)	Not supported. Apply explicit cast in source query.
SmallInt	Int16
Time	TimeSpan
Time With Time Zone	TimeSpan
Timestamp	DateTime
Timestamp With Time Zone	DateTime
VarByte	Byte[]
VarChar	String
VarGraphic	Not supported. Apply explicit cast in source query.
Xml	Not supported. Apply explicit cast in source query.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Transform data in Twilio (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in Twilio (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Twilio connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

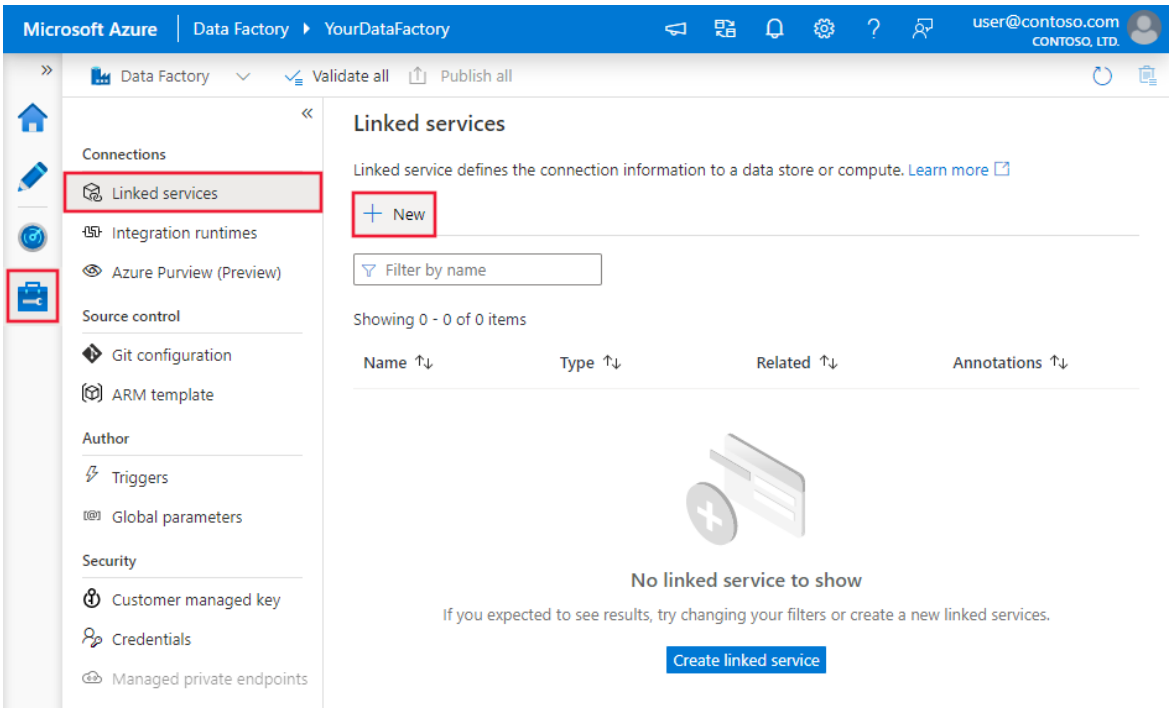
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a Twilio linked service using UI

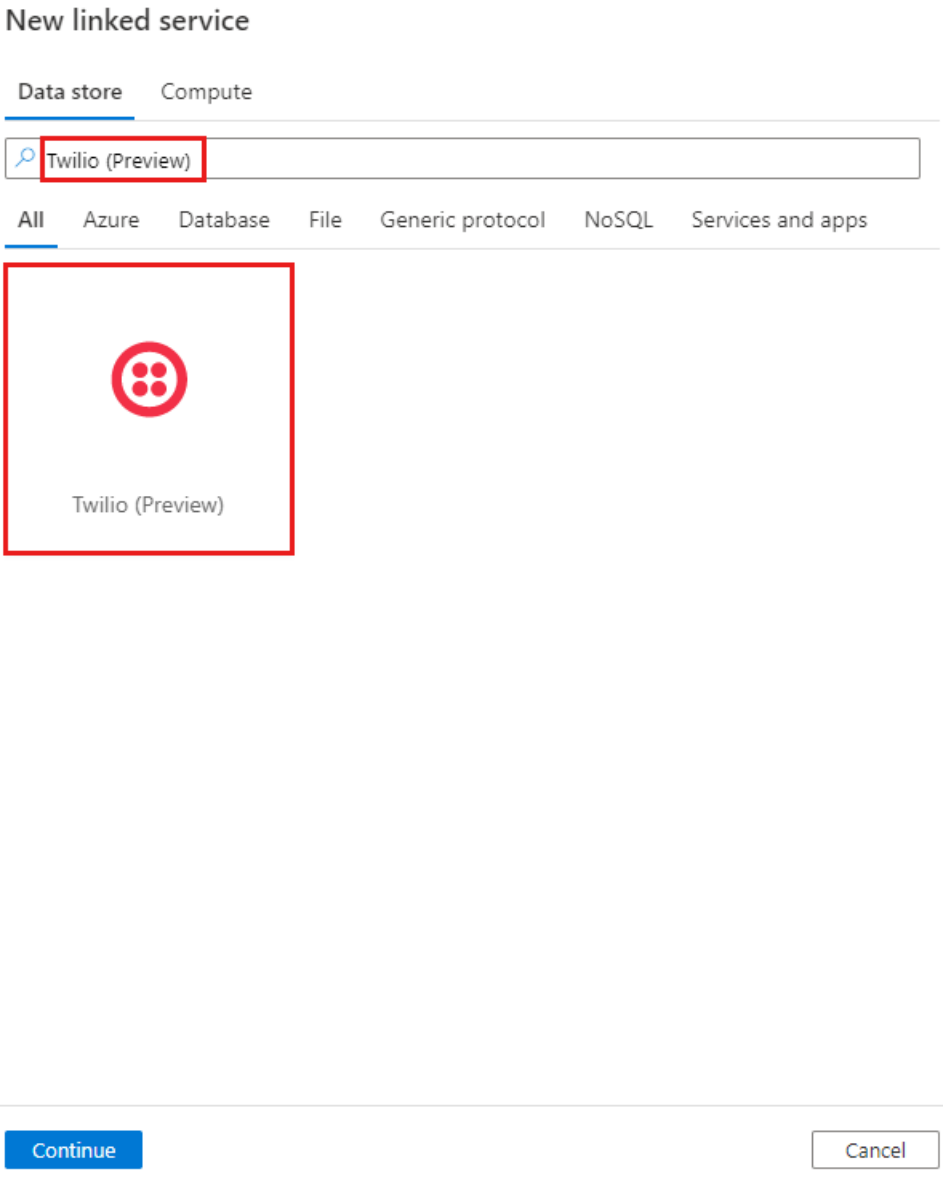
Use the following steps to create a Twilio linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

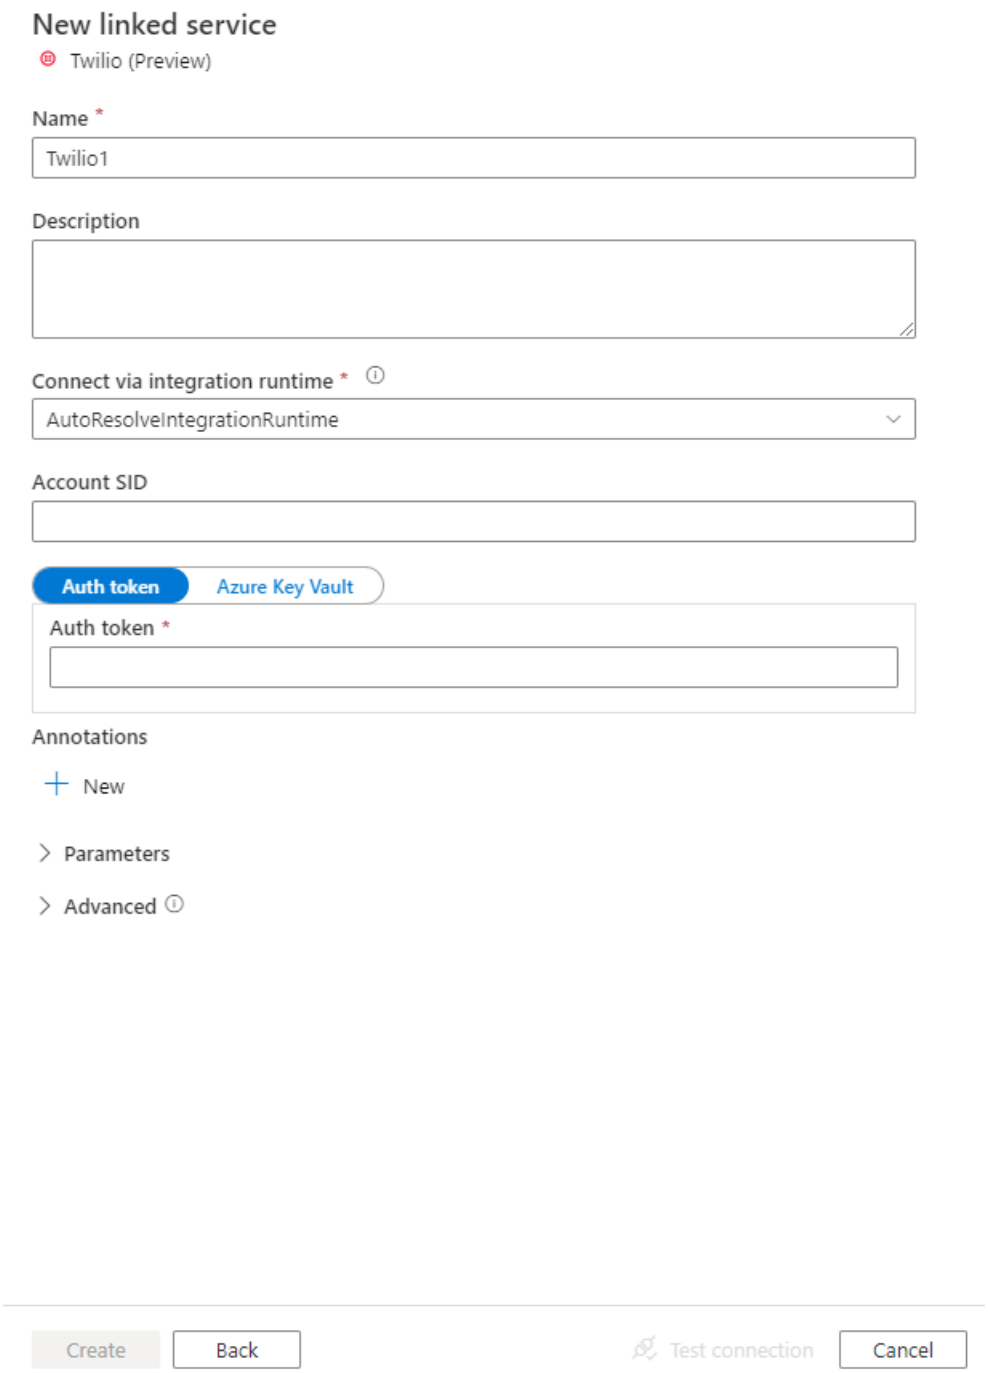
   - Azure Data Factory
   - Azure Synapse



2. Search for Twilio (Preview) and select the Twilio (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Twilio.

Linked service properties

The following properties are supported for the Twilio linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Twilio**.	Yes
userName	The account SID of your Twilio account.	No

PROPERTY	DESCRIPTION	REQUIRED
password	The auth token of your Twilio account. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "TwilioLinkedService",
    "properties": {
        "type": "Twilio",
        "typeProperties": {
            "userName": "<account SID>",
            "password": {
                "type": "SecureString",
                "value": "<auth token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read resources from Twilio. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by Twilio source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Resource	The type of resources that data flow fetch from Twilio.	Yes	`Messages` `Calls`	resource
From	The phone number with country code, for example `+17755425856`.	No	String	from
To	The phone number with country code, for example `+17755425856`.	No	String	to

Twilio source script example

When you use Twilio as source type, the associated data flow script is:

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'twilio',
 format: 'rest',
 resource: 'Messages',
 from: '+17755425856') ~> TwilioSource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Vertica using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Vertica. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Vertica connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks by the copy activity, see the Supported data stores table.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Prerequisites

If your data store is located inside an on-premises network, an Azure virtual network, or Amazon Virtual Private Cloud, you need to configure a self-hosted integration runtime to connect to it.

If your data store is a managed cloud data service, you can use the Azure Integration Runtime. If the access is restricted to IPs that are approved in the firewall rules, you can add Azure Integration Runtime IPs to the allow list.

You can also use the managed virtual network integration runtime feature in Azure Data Factory to access the on-premises network without installing and configuring a self-hosted integration runtime.

For more information about the network security mechanisms and options supported by Data Factory, see Data access strategies.

Getting started

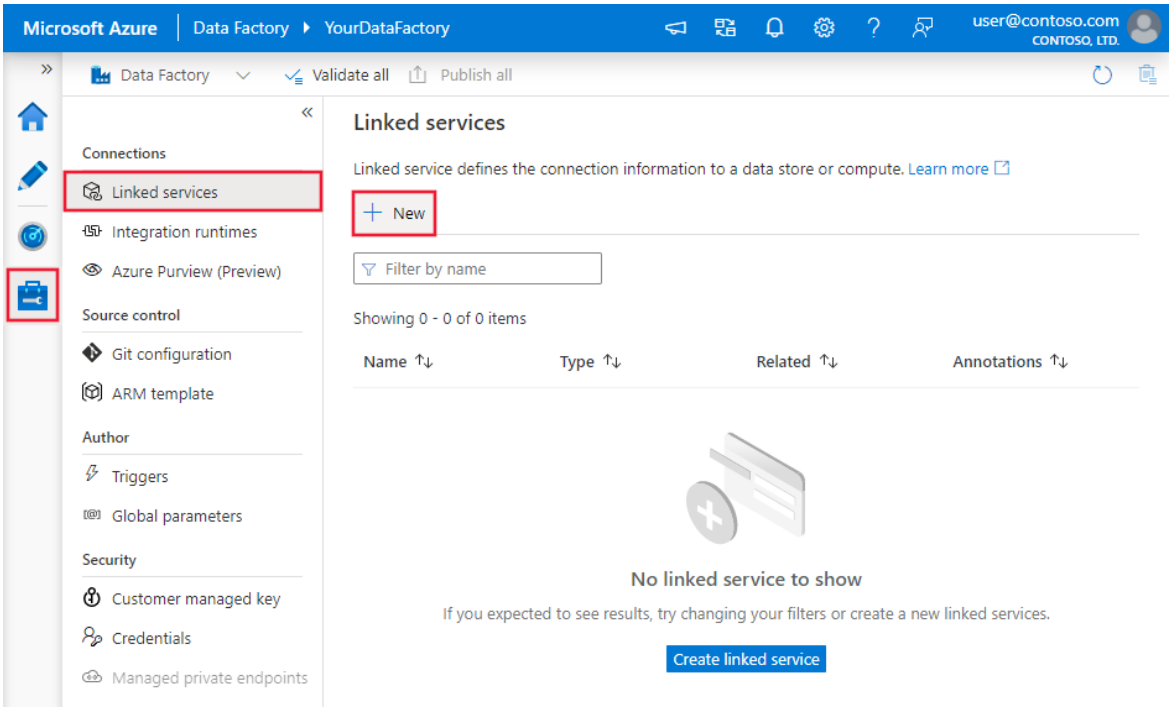
You can create a pipeline with copy activity using .NET SDK, Python SDK, Azure PowerShell, REST API, or Azure Resource Manager template. See Copy activity tutorial for step-by-step instructions to create a pipeline with a copy activity.

Create a linked service to Vertica using UI

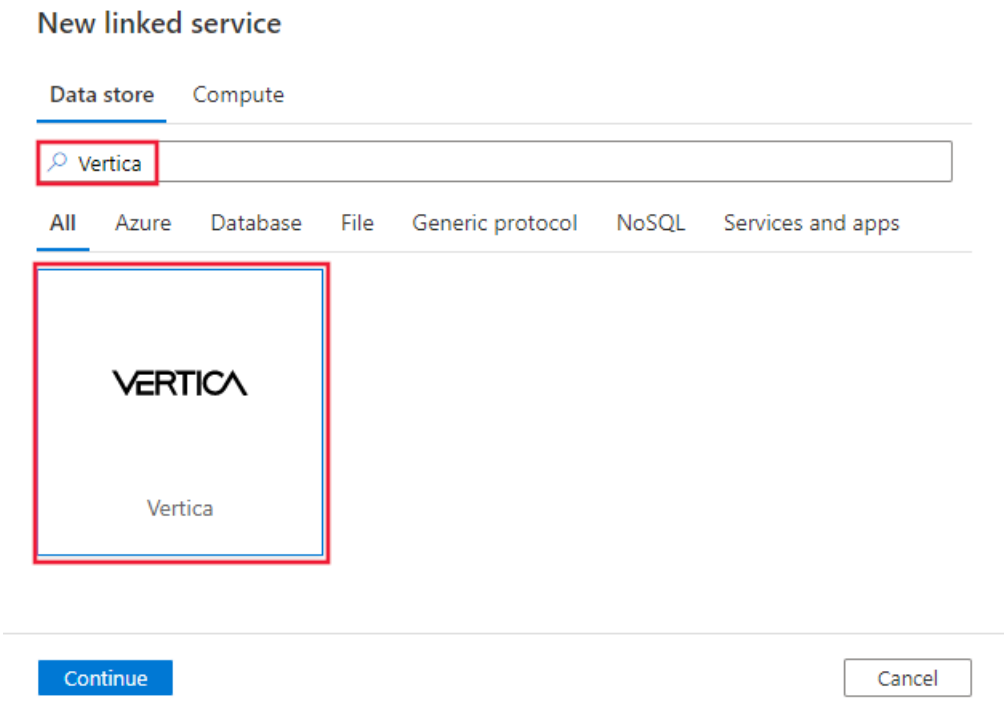
Use the following steps to create a linked service to Vertica in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

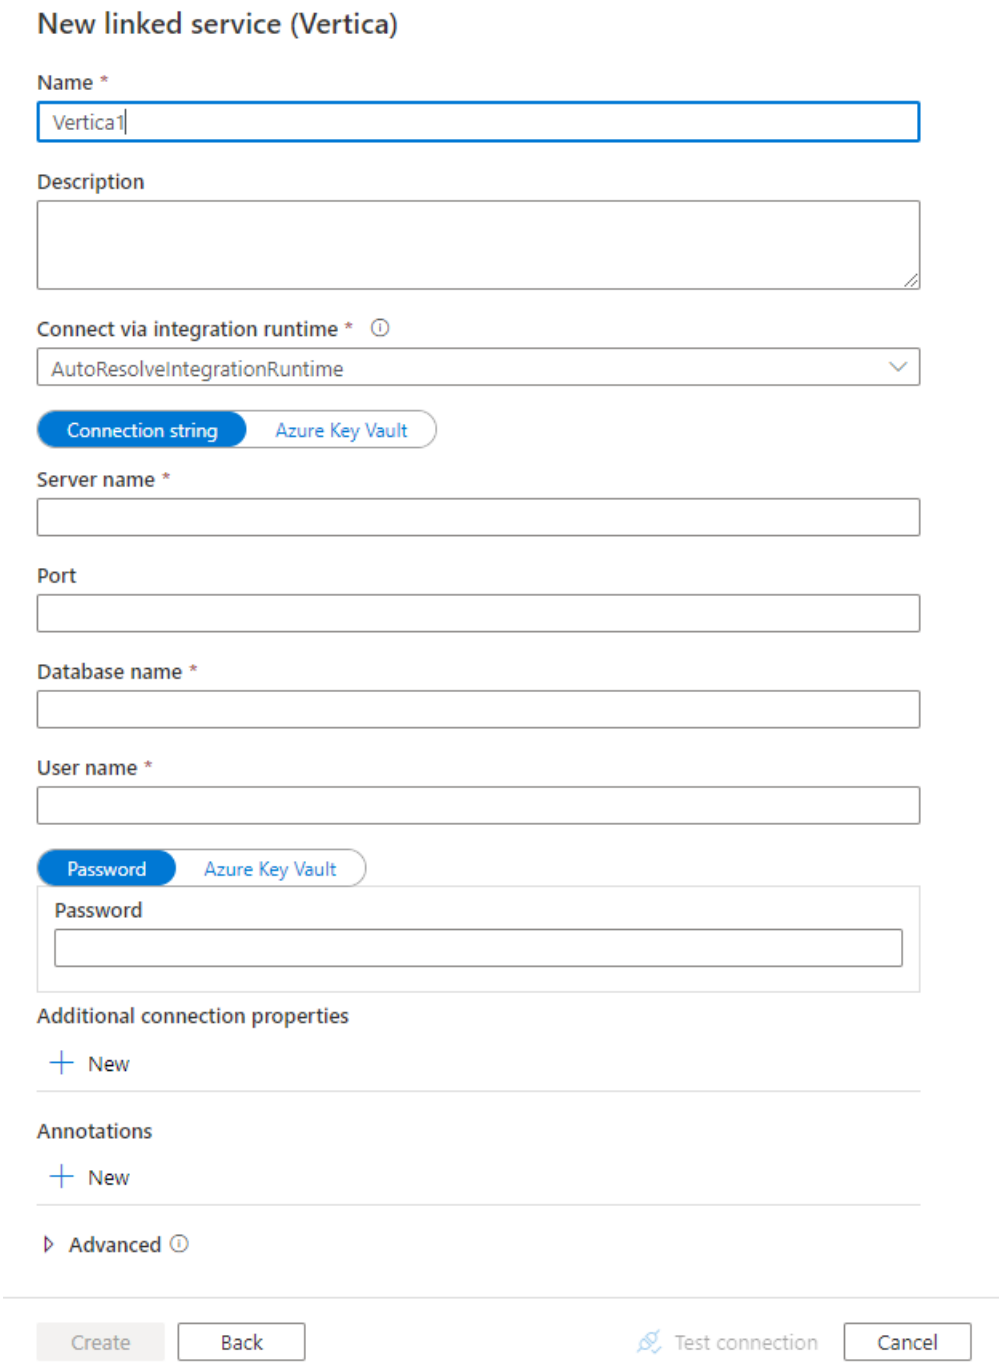
   - Azure Data Factory
   - Azure Synapse



2. Search for Vertica and select the Vertica connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Vertica connector.

Linked service properties

The following properties are supported for Vertica linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Vertica**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionString	An ODBC connection string to connect to Vertica. You can also put password in Azure Key Vault and pull the `pwd` configuration out of the connection string. Refer to the following samples and Store credentials in Azure Key Vault article with more details.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. Learn more from Prerequisites section. If not specified, it uses the default Azure Integration Runtime.	No

Example:

```
{
    "name": "VerticaLinkedService",
    "properties": {
        "type": "Vertica",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<user name>;PWD=
<password>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Example: store password in Azure Key Vault

```
{
    "name": "VerticaLinkedService",
    "properties": {
        "type": "Vertica",
        "typeProperties": {
            "connectionString": "Server=<server>;Port=<port>;Database=<database>;UID=<user name>;",
            "pwd": {
                "type": "AzureKeyVaultSecret",
                "store": {
                    "referenceName": "<Azure Key Vault linked service name>",
                    "type": "LinkedServiceReference"
                },
                "secretName": "<secretName>"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section

provides a list of properties supported by Vertica dataset.

To copy data from Vertica, set the type property of the dataset to **VerticaTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **VerticaTable**	Yes
schema	Name of the schema.	No (if "query" in activity source is specified)
table	Name of the table.	No (if "query" in activity source is specified)
tableName	Name of the table with schema. This property is supported for backward compatibility. Use `schema` and `table` for new workload.	No (if "query" in activity source is specified)

Example

```
{
    "name": "VerticaDataset",
    "properties": {
        "type": "VerticaTable",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Vertica linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Vertica source.

Vertica as source

To copy data from Vertica, set the source type in the copy activity to **VerticaSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **VerticaSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM MyTable"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromVertica",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Vertica input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "VerticaSource",
                "query": "SELECT * FROM MyTable"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Web table by using Azure Data Factory or Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from a Web table database. It builds on the copy activity overview article that presents a general overview of copy activity.

The difference among this Web table connector, the REST connector and the HTTP connector are:

- **Web table connector** extracts table content from an HTML webpage.
- **REST connector** specifically support copying data from RESTful APIs.
- **HTTP connector** is generic to retrieve data from any HTTP endpoint, e.g. to download file.

Supported capabilities

This Web table connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	②
Lookup activity	②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this Web table connector supports **extracting table content from an HTML page**.

Prerequisites

To use this Web table connector, you need to set up a Self-hosted Integration Runtime. See Self-hosted Integration Runtime article for details.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

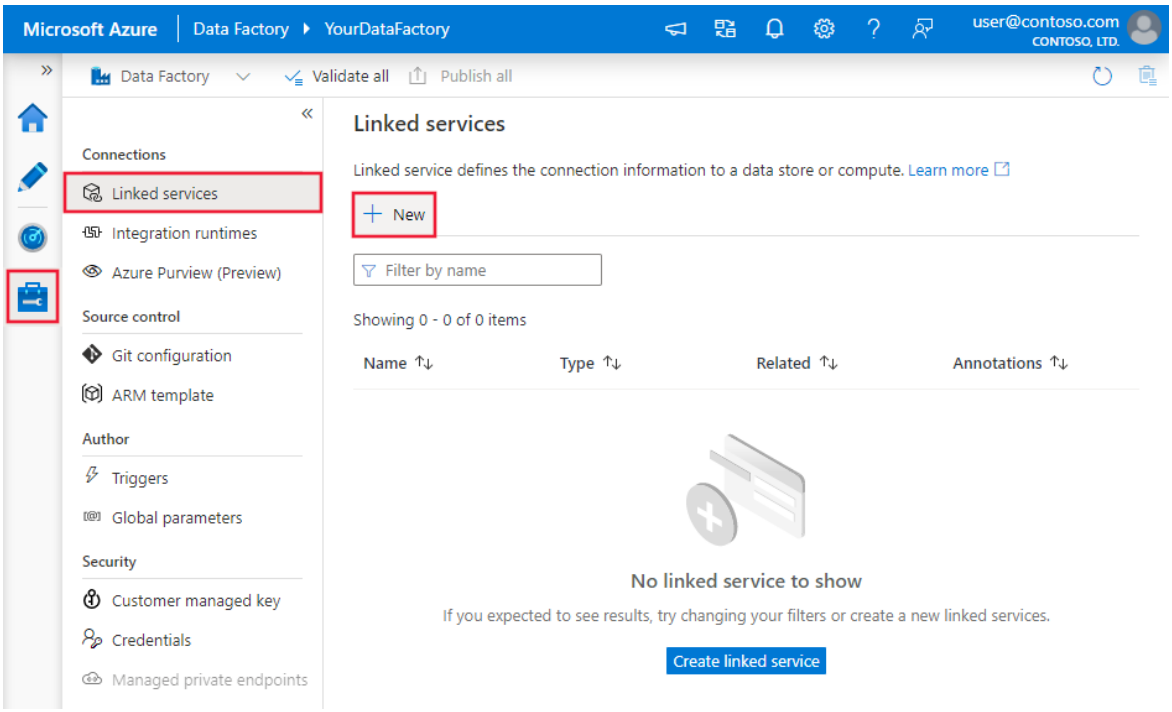
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Web Table using UI

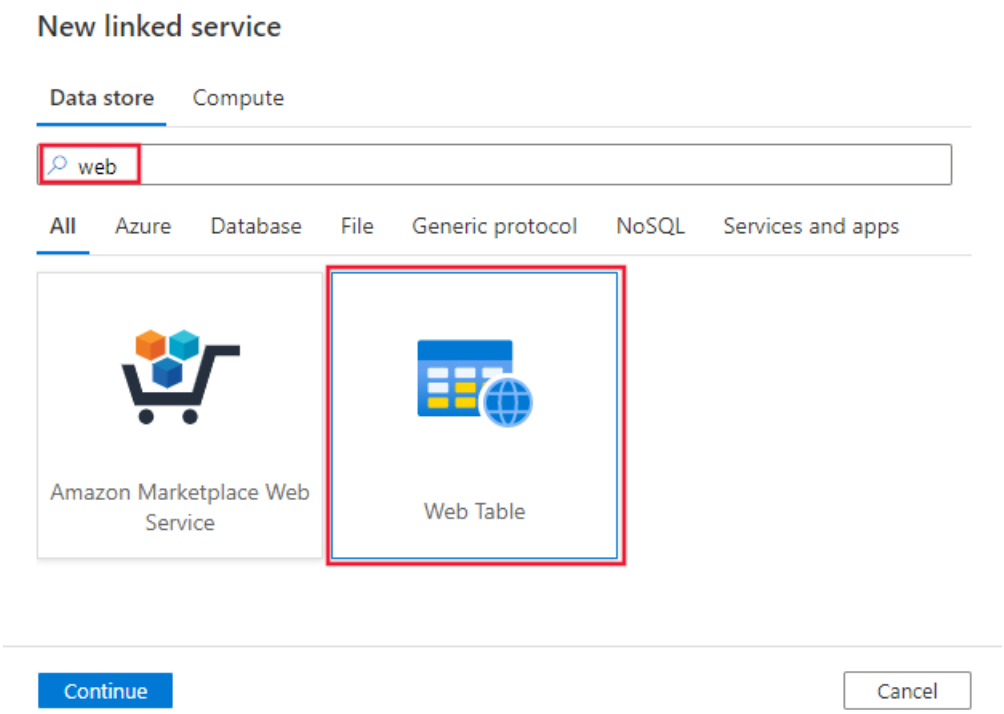
Use the following steps to create a linked service to Web Table in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

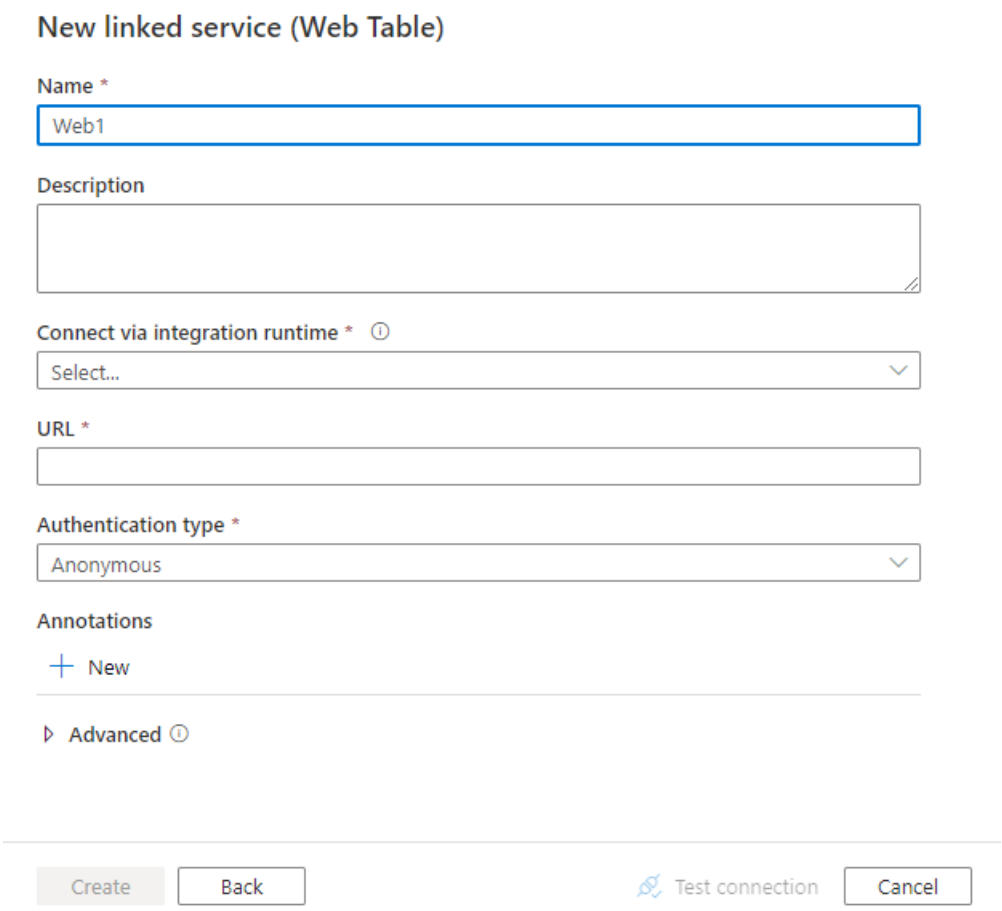
   - Azure Data Factory
   - Azure Synapse



2. Search for Web and select the Web Table connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Web table connector.

Linked service properties

The following properties are supported for Web table linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Web**	Yes
url	URL to the Web source	Yes
authenticationType	Allowed value is: **Anonymous**.	Yes
connectVia	The Integration Runtime to be used to connect to the data store. A Self-hosted Integration Runtime is required as mentioned in Prerequisites.	Yes

Example:

```
{
    "name": "WebLinkedService",
    "properties": {
        "type": "Web",
        "typeProperties": {
            "url" : "https://en.wikipedia.org/wiki/",
            "authenticationType": "Anonymous"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Web table dataset.

To copy data from Web table, set the type property of the dataset to **WebTable**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **WebTable**	Yes
path	A relative URL to the resource that contains the table.	No. When path is not specified, only the URL specified in the linked service definition is used.
index	The index of the table in the resource. See Get index of a table in an HTML page section for steps to getting index of a table in an HTML page.	Yes

Example:

```
{
    "name": "WebTableInput",
    "properties": {
        "type": "WebTable",
        "typeProperties": {
            "index": 1,
            "path": "AFI's_100_Years...100_Movies"
        },
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Web linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section

provides a list of properties supported by Web table source.

Web table as source

To copy data from Web table, set the source type in the copy activity to **WebSource**, no additional properties are supported.

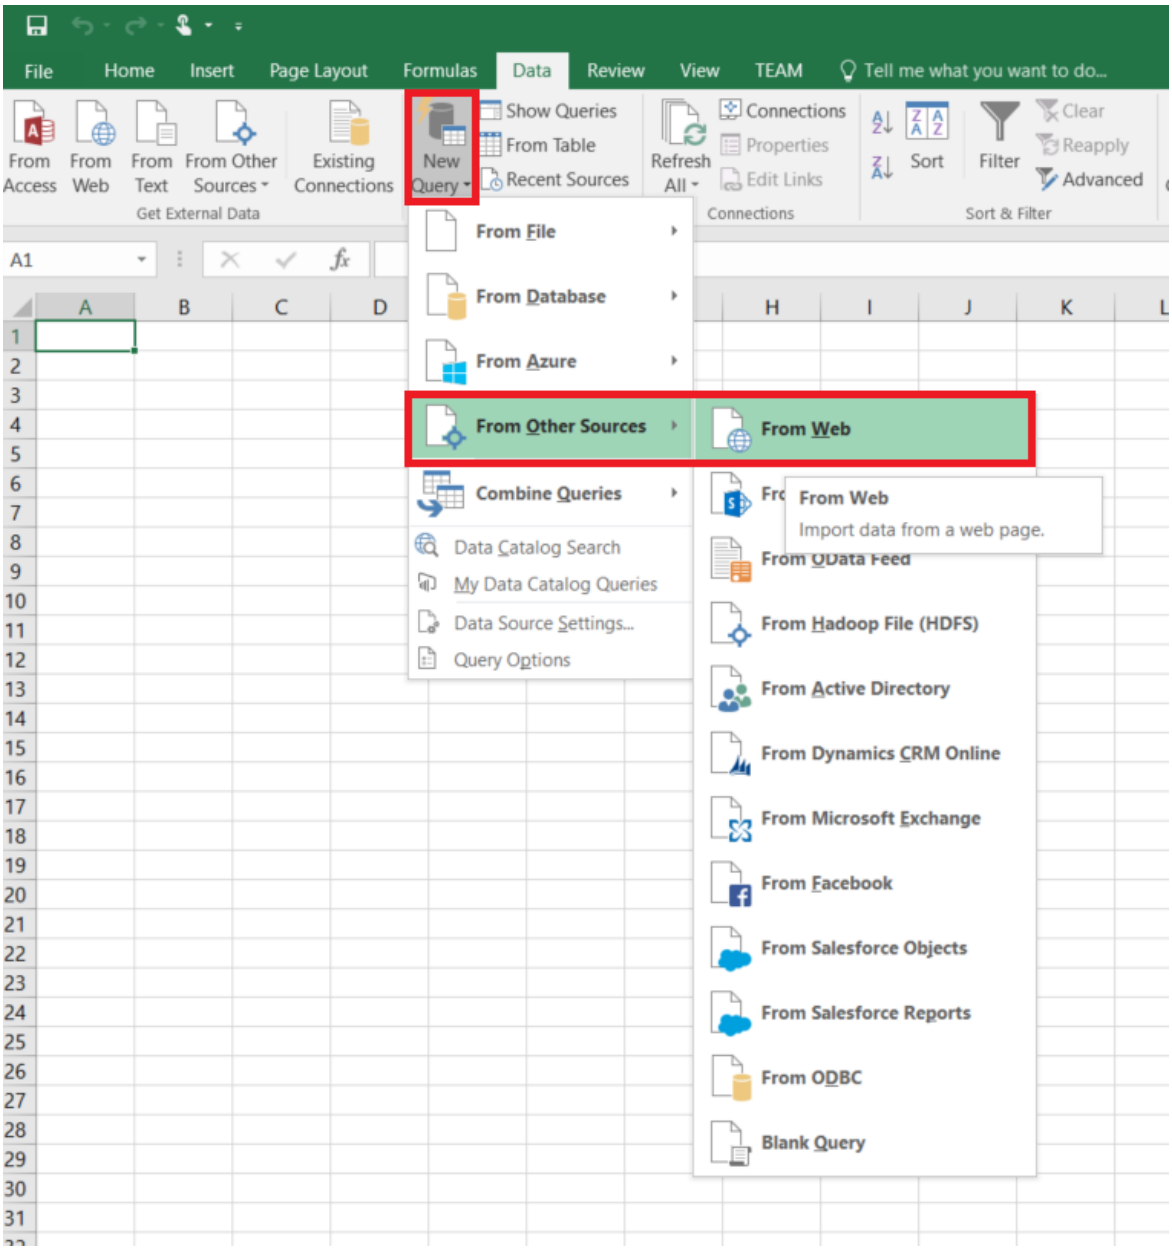
Example:

```
"activities":[
    {
        "name": "CopyFromWebTable",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Web table input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "WebSource"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

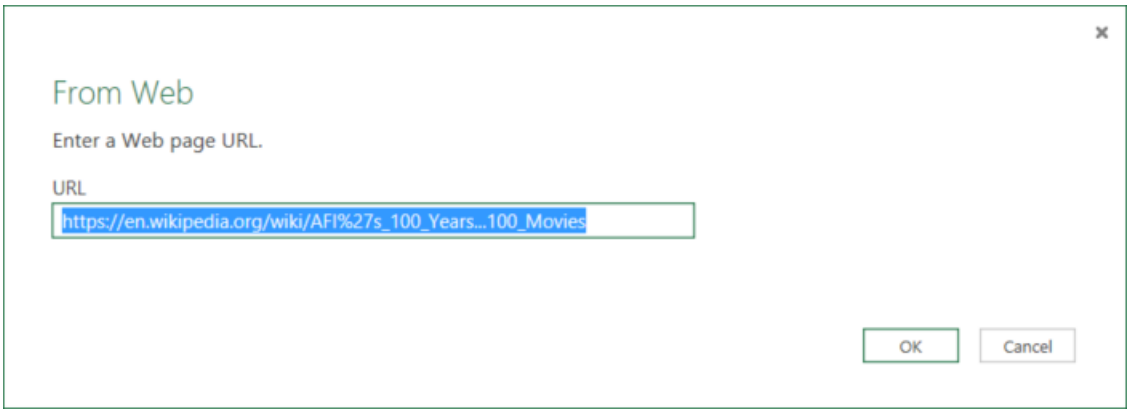
Get index of a table in an HTML page

To get the index of a table which you need to configure in dataset properties, you can use e.g. Excel 2016 as the tool as follows:

1. Launch **Excel 2016** and switch to the **Data** tab.
2. Click **New Query** on the toolbar, point to **From Other Sources** and click **From Web**.

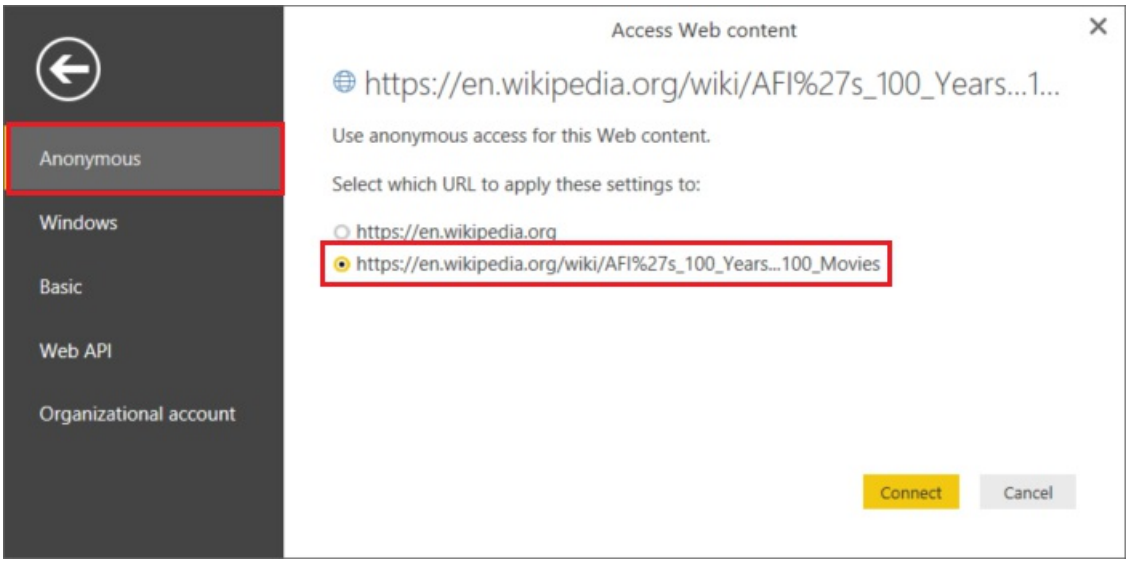


3. In the **From Web** dialog box, enter **URL** that you would use in linked service JSON (for example: https://en.wikipedia.org/wiki/) along with path you would specify for the dataset (for example: AFI%27s_100_Years...100_Movies), and click **OK**.

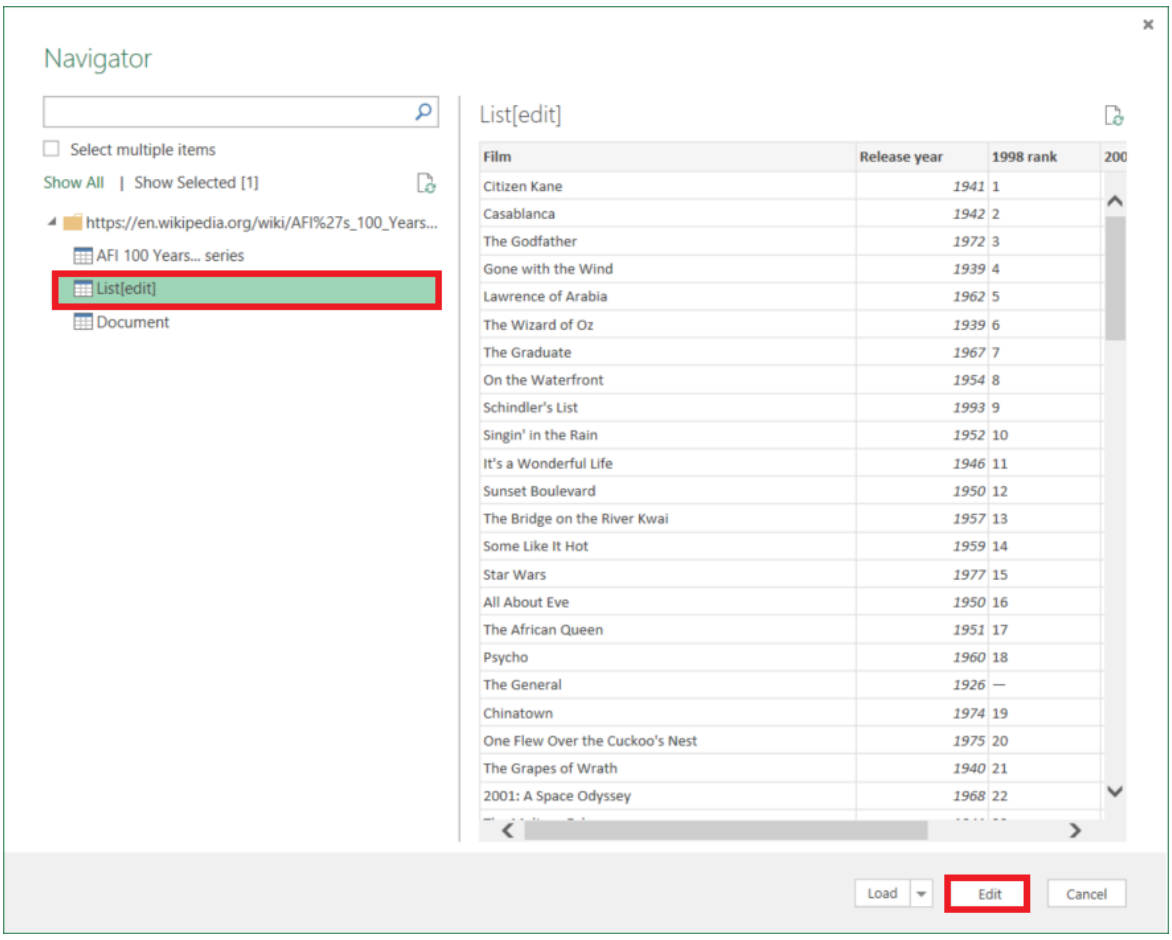


URL used in this example: https://en.wikipedia.org/wiki/AFI%27s_100_Years...100_Movies

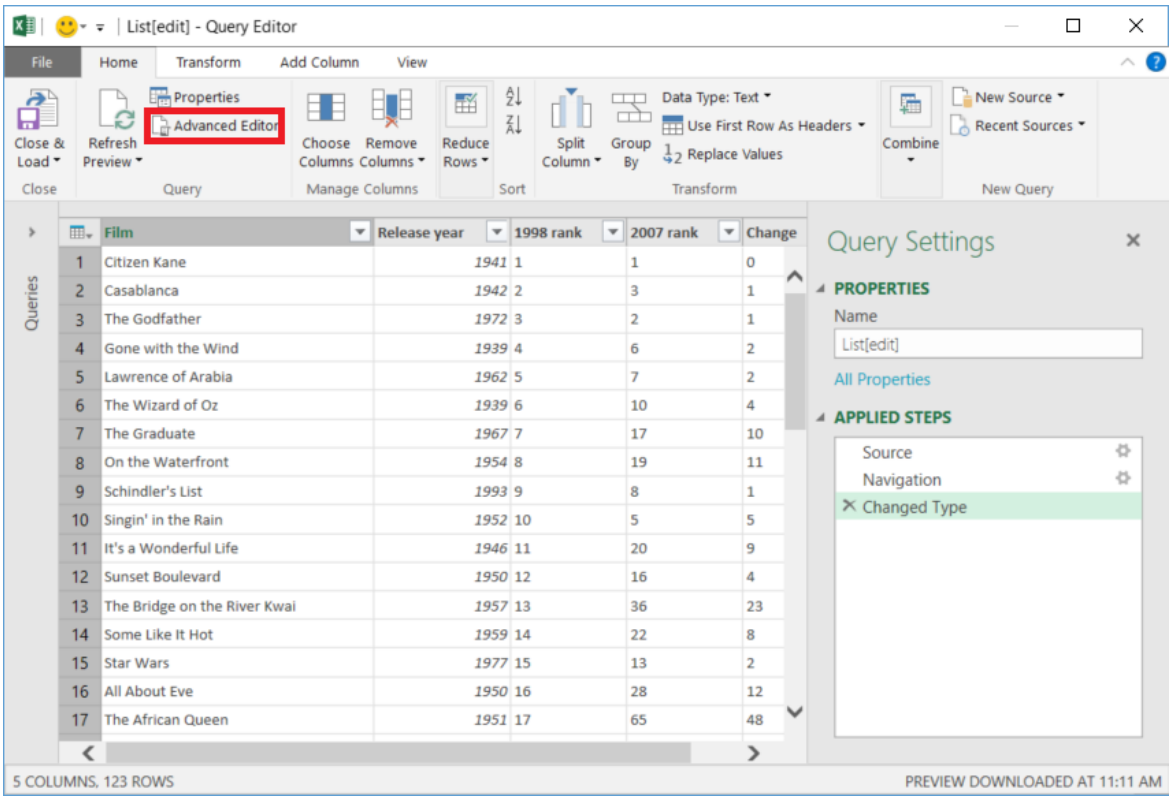
4. If you see **Access Web content** dialog box, select the right **URL**, **authentication**, and click **Connect**.



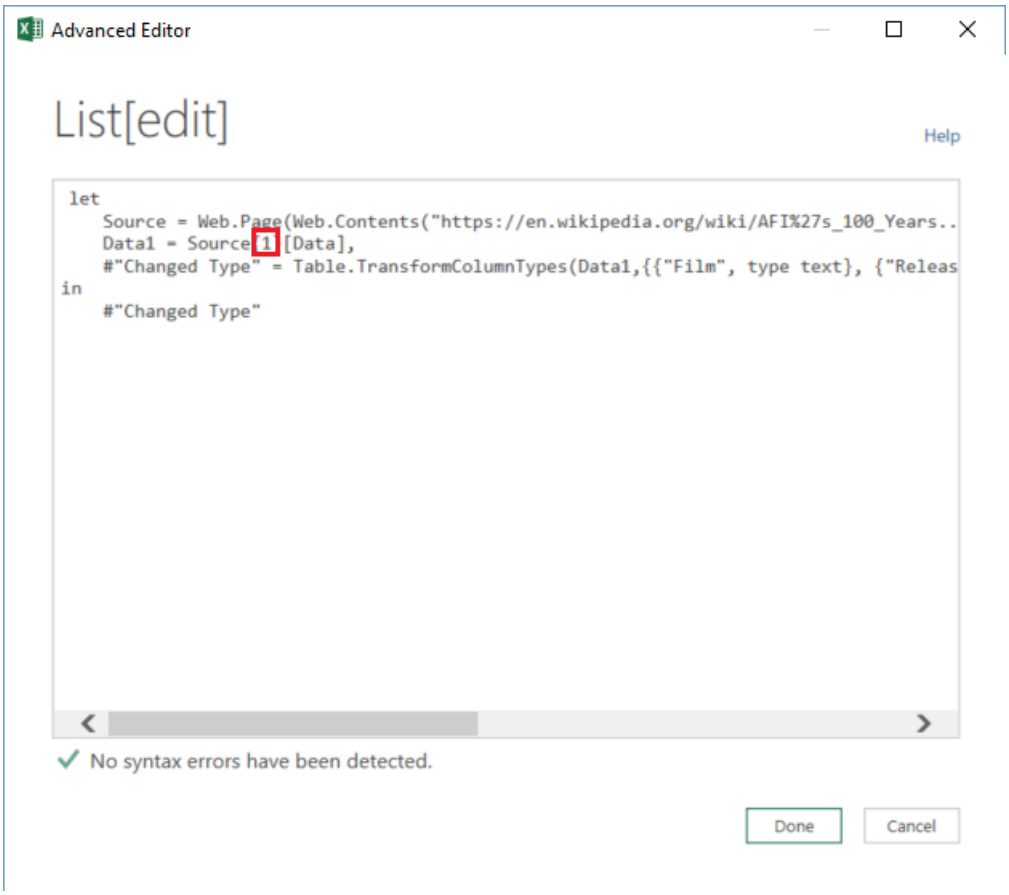
5. Click a **table** item in the tree view to see content from the table and then click **Edit** button at the bottom.



6. In the **Query Editor** window, click **Advanced Editor** button on the toolbar.



7. In the Advanced Editor dialog box, the number next to "Source" is the index.



If you are using Excel 2013, use Microsoft Power Query for Excel to get the index. See Connect to a web page article for details. The steps are similar if you are using Microsoft Power BI for Desktop.

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy data from Xero using Azure Data Factory or Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Xero. It builds on the copy activity overview article that presents a general overview of copy activity.

Supported capabilities

This Xero connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Specifically, this Xero connector supports:

- OAuth 2.0 and OAuth 1.0 authentication. For OAuth 1.0, the connector supports Xero private application but not public application.
- All Xero tables (API endpoints) except "Reports".

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

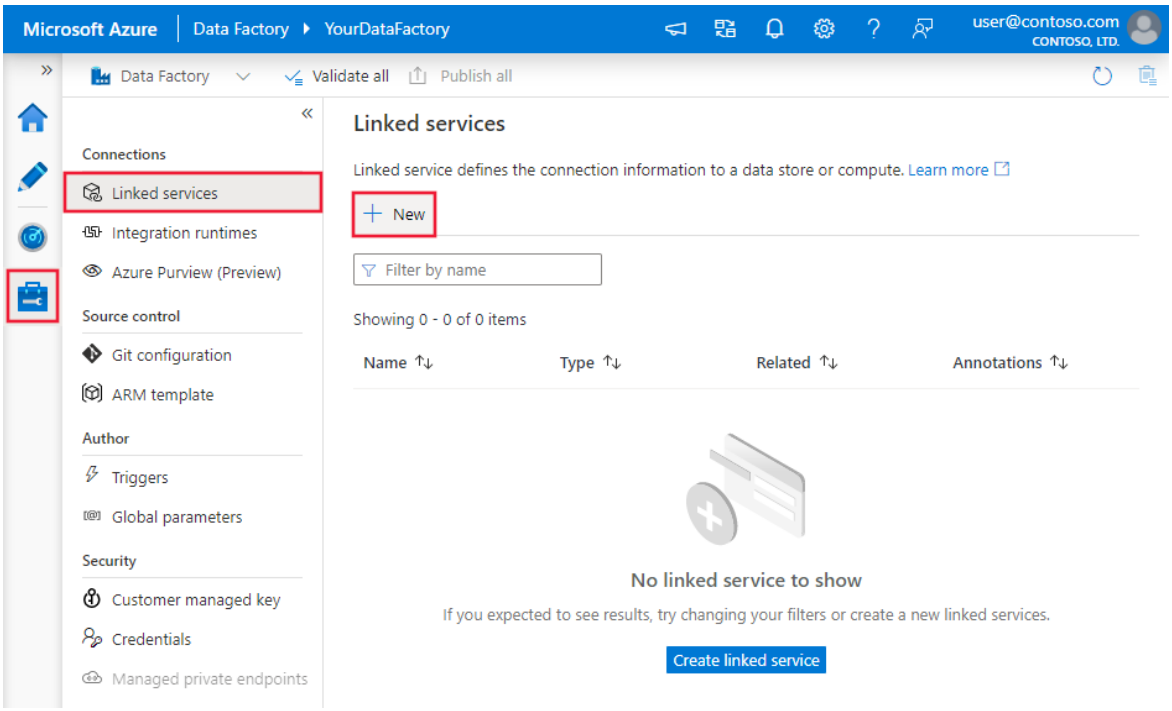
- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

Create a linked service to Xero using UI

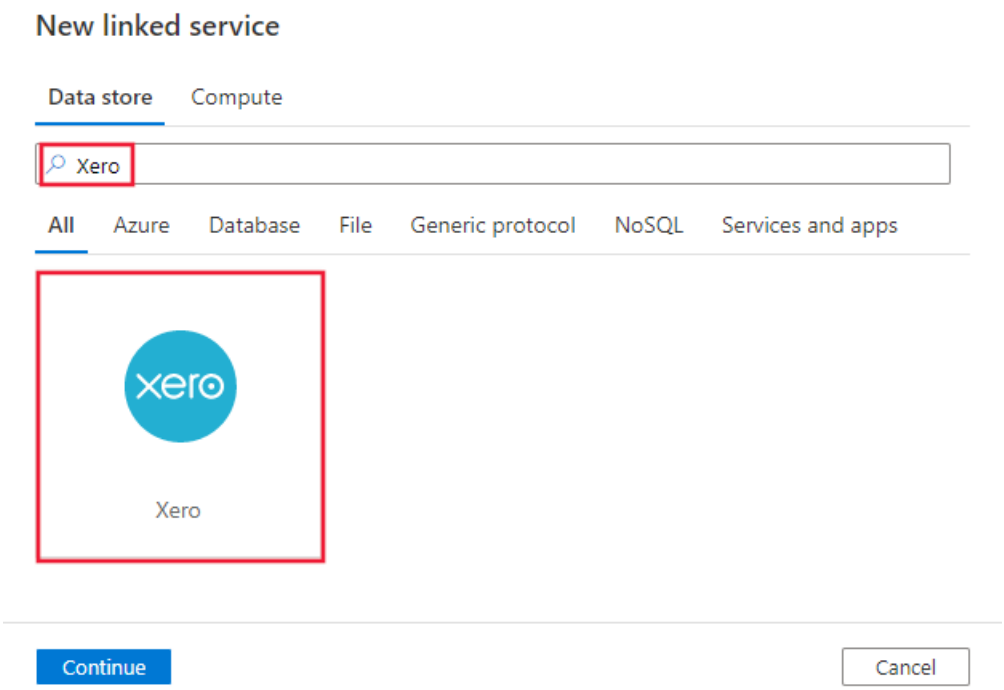
Use the following steps to create a linked service to Xero in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then click New:

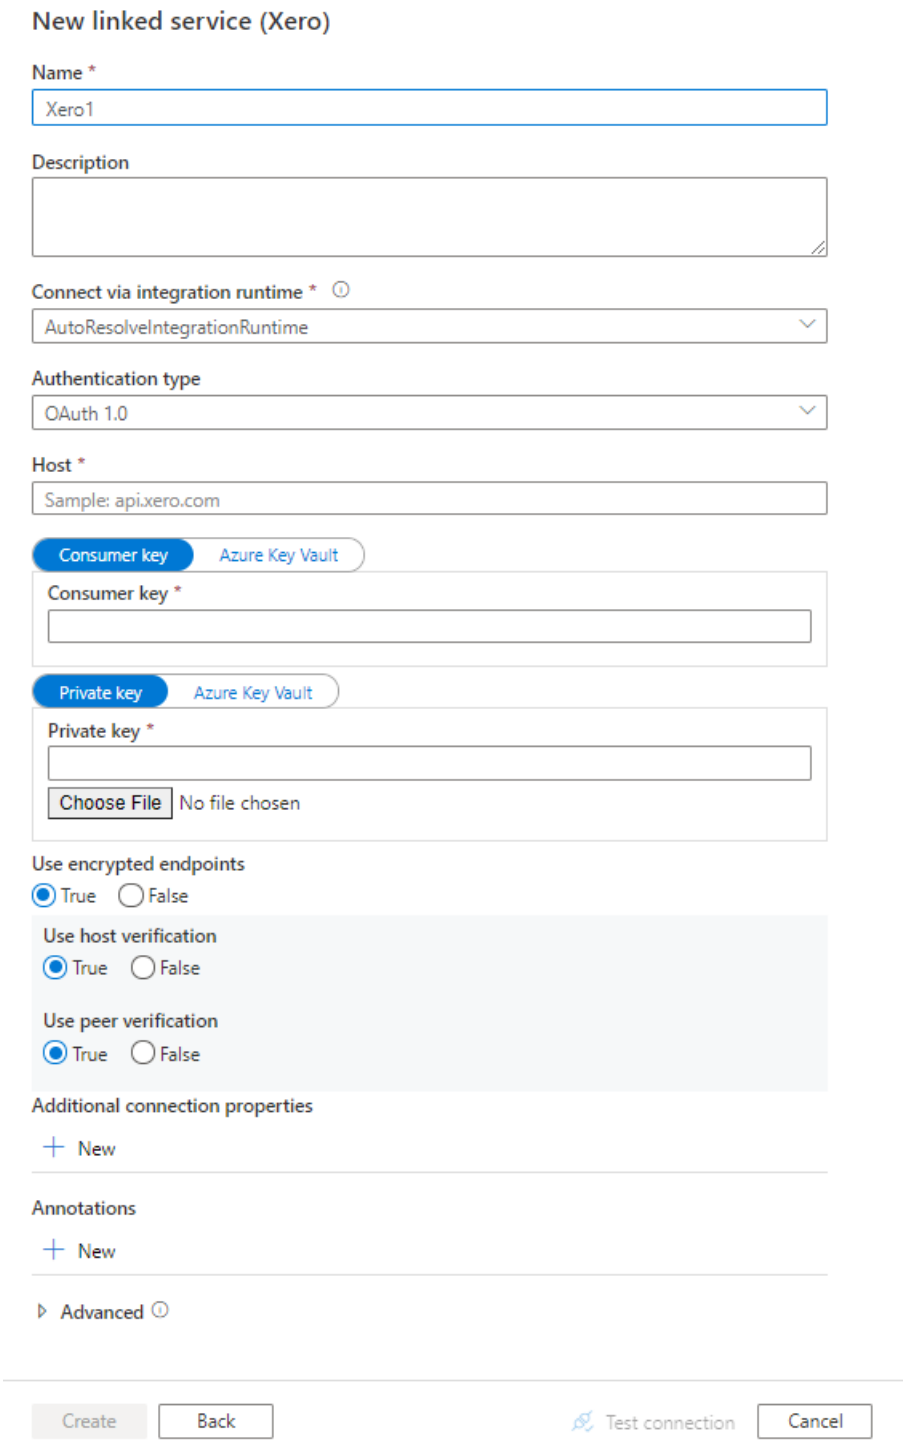
   - Azure Data Factory
   - Azure Synapse



2. Search for Xero and select the Xero connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Xero connector.

Linked service properties

The following properties are supported for Xero linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Xero**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionProperties	A group of properties that defines how to connect to Xero.	Yes
Under `connectionProperties`*:*		
host	The endpoint of the Xero server (`api.xero.com`).	Yes
authenticationType	Allowed values are `OAuth_2.0` and `OAuth_1.0` .	Yes
consumerKey	For OAuth 2.0, specify the **client ID** for your Xero application. For OAuth 1.0, specify the consumer key associated with the Xero application. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
privateKey	For OAuth 2.0, specify the **client secret** for your Xero application. For OAuth 1.0, specify the private key from the .pem file that was generated for your Xero private application. Note to **generate the privatekey.pem with numbits of 512** using `openssl genrsa -out privatekey.pem 512` , 1024 is not supported. Include all the text from the .pem file including the Unix line endings(\n), see sample below. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
tenantId	The tenant ID associated with your Xero application. Applicable for OAuth 2.0 authentication. Learn how to get the tenant ID from Check the tenants you're authorized to access section.	Yes for OAuth 2.0 authentication

PROPERTY	DESCRIPTION	REQUIRED
refreshToken	Applicable for OAuth 2.0 authentication. TheOAuth 2.0 refreshtoken is associated withtheXero application and used to refresh the accesstoken; the access token expires after 30 minutes. Learn about how the Xero authorization flow works and how to get the refresh token from this article. To get a refresh token, you must request the offline_access scope. **Know limitation**: Note Xero resets the refresh token after it's used for access token refresh. For operationalized workload, before each copy activity run, you need to set a valid refresh token for the service to use. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes for OAuth 2.0 authentication
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether the host name is required in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example: OAuth 2.0 authentication

```
{
    "name": "XeroLinkedService",
    "properties": {
        "type": "Xero",
        "typeProperties": {
            "connectionProperties": {
                "host":"api.xero.com",
                "authenticationType":"OAuth_2.0",
                "consumerKey": {
                    "type": "SecureString",
                    "value": "<client ID>"
                },
                "privateKey": {
                    "type": "SecureString",
                    "value": "<client secret>"
                },
                "tenantId":"<tenant ID>",
                "refreshToken":{
                    "type": "SecureString",
                    "value": "<refresh token>"
                },
                "useEncryptedEndpoints":true,
                "useHostVerification":true,
                "usePeerVerification":true
            }
        }
    }
}
```

Example: OAuth 1.0 authentication

```
{
    "name": "XeroLinkedService",
    "properties": {
        "type": "Xero",
        "typeProperties": {
            "connectionProperties": {
                "host":"api.xero.com",
                "authenticationType":"OAuth_1.0",
                "consumerKey": {
                    "type": "SecureString",
                    "value": "<consumer key>"
                },
                "privateKey": {
                    "type": "SecureString",
                    "value": "<private key>"
                },
                "useEncryptedEndpoints":true,
                "useHostVerification":true,
                "usePeerVerification":true
}
        }
    }
}
```

Sample private key value:

Include all the text from the .pem file including the Unix line endings(\n).

```
"-----BEGIN RSA PRIVATE KEY-----
\nMII***********************************************P\nbu***********************************************
*****s\nU/***********************************************B\nA***********************************************
**********W\njH***********************************************e\nsx***********************************
*****************l\nq***********************************************X\nh***************************
************************i\nd***********************************************s\nA**********************
*****************************dsfb\nN***********************************************M\np*************
************************************Ly\nK***********************************************Y=\n-----
END RSA PRIVATE KEY-----"
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Xero dataset.

To copy data from Xero, set the type property of the dataset to **XeroObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **XeroObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "XeroDataset",
    "properties": {
        "type": "XeroObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Xero linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Xero source.

Xero as source

To copy data from Xero, set the source type in the copy activity to **XeroSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **XeroSource**	Yes

PROPERTY	DESCRIPTION	REQUIRED
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Contacts"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromXero",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Xero input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "XeroSource",
                "query": "SELECT * FROM Contacts"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Note the following when specifying the Xero query:

- Tables with complex items will be split to multiple tables. For example, Bank transactions has a complex data structure "LineItems", so data of bank transaction is mapped to table `Bank_Transaction` and `Bank_Transaction_Line_Items`, with `Bank_Transaction_ID` as foreign key to link them together.
- Xero data is available through two schemas: `Minimal` (default) and `Complete`. The Complete schema contains prerequisite call tables which require additional data (e.g. ID column) before making the desired query.

The following tables have the same information in the Minimal and Complete schema. To reduce the number of API calls, use Minimal schema (default).

- Bank_Transactions
- Contact_Groups
- Contacts
- Contacts_Sales_Tracking_Categories
- Contacts_Phones
- Contacts_Addresses
- Contacts_Purchases_Tracking_Categories
- Credit_Notes
- Credit_Notes_Allocations

- Expense_Claims
- Expense_Claim_Validation_Errors
- Invoices
- Invoices_Credit_Notes
- Invoices_ Prepayments
- Invoices_Overpayments
- Manual_Journals
- Overpayments
- Overpayments_Allocations
- Prepayments
- Prepayments_Allocations
- Receipts
- Receipt_Validation_Errors
- Tracking_Categories

The following tables can only be queried with complete schema:

- Complete.Bank_Transaction_Line_Items
- Complete.Bank_Transaction_Line_Item_Tracking
- Complete.Contact_Group_Contacts
- Complete.Contacts_Contact_ Persons
- Complete.Credit_Note_Line_Items
- Complete.Credit_Notes_Line_Items_Tracking
- Complete.Expense_Claim_ Payments
- Complete.Expense_Claim_Receipts
- Complete.Invoice_Line_Items
- Complete.Invoices_Line_Items_Tracking
- Complete.Manual_Journal_Lines
- Complete.Manual_Journal_Line_Tracking
- Complete.Overpayment_Line_Items
- Complete.Overpayment_Line_Items_Tracking
- Complete.Prepayment_Line_Items
- Complete.Prepayment_Line_Item_Tracking
- Complete.Receipt_Line_Items
- Complete.Receipt_Line_Item_Tracking
- Complete.Tracking_Category_Options

For a list of supported data stores by the copy activity, see supported data stores.

XML format in Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Follow this article when you want to **parse the XML files**.

XML format is supported for the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP. It is supported as source but not sink.

Dataset properties

For a full list of sections and properties available for defining datasets, see the Datasets article. This section provides a list of properties supported by the XML dataset.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to **Xml**.	Yes
location	Location settings of the file(s). Each file-based connector has its own location type and supported properties under `location`. **See details in connector article -> Dataset properties section**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
encodingName	The encoding type used to read/write test files. Allowed values are as follows: "UTF-8", "UTF-16", "UTF-16BE", "UTF-32", "UTF-32BE", "US-ASCII", "UTF-7", "BIG5", "EUC-JP", "EUC-KR", "GB2312", "GB18030", "JOHAB", "SHIFT-JIS", "CP875", "CP866", "IBM00858", "IBM037", "IBM273", "IBM437", "IBM500", "IBM737", "IBM775", "IBM850", "IBM852", "IBM855", "IBM857", "IBM860", "IBM861", "IBM863", "IBM864", "IBM865", "IBM869", "IBM870", "IBM01140", "IBM01141", "IBM01142", "IBM01143", "IBM01144", "IBM01145", "IBM01146", "IBM01147", "IBM01148", "IBM01149", "ISO-2022-JP", "ISO-2022-KR", "ISO-8859-1", "ISO-8859-2", "ISO-8859-3", "ISO-8859-4", "ISO-8859-5", "ISO-8859-6", "ISO-8859-7", "ISO-8859-8", "ISO-8859-9", "ISO-8859-13", "ISO-8859-15", "WINDOWS-874", "WINDOWS-1250", "WINDOWS-1251", "WINDOWS-1252", "WINDOWS-1253", "WINDOWS-1254", "WINDOWS-1255", "WINDOWS-1256", "WINDOWS-1257", "WINDOWS-1258".	No
nullValue	Specifies the string representation of null value. The default value is **empty string**.	No
compression	Group of properties to configure file compression. Configure this section when you want to do compression/decompression during activity execution.	No

PROPERTY	DESCRIPTION	REQUIRED
type (*under* `compression`)	The compression codec used to read/write XML files. Allowed values are **bzip2**, **gzip**, **deflate**, **ZipDeflate**, **TarGzip**, **Tar**, **snappy**, or **lz4**. Default is not compressed. **Note** currently Copy activity doesn't support "snappy" & "lz4", and mapping data flow doesn't support "ZipDeflate", "TarGzip" and "Tar". **Note** when using copy activity to decompress **ZipDeflate**/**TarGzip**/**Tar** file(s) and write to file-based sink data store, by default files are extracted to the folder: `<path specified in dataset>/<folder named as source compressed file>/`, use `preserveZipFileNameAsFolder` / `preserveCompressionFileNameAsFolder` on copy activity source to control whether to preserve the name of the compressed file(s) as folder structure.	No.
level (*under* `compression`)	The compression ratio. Allowed values are **Optimal** or **Fastest**. - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed. - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete. For more information, see Compression Level topic.	No

Below is an example of XML dataset on Azure Blob Storage:

```
{
    "name": "XMLDataset",
    "properties": {
        "type": "Xml",
        "linkedServiceName": {
            "referenceName": "<Azure Blob Storage linked service name>",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "container": "containername",
                "folderPath": "folder/subfolder",
            },
            "compression": {
                "type": "ZipDeflate"
            }
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by the XML source.

Learn about how to map XML data and sink data store/format from schema mapping. When previewing XML files, data is shown with JSON hierarchy, and you use JSON path to point to the fields.

XML as source

The following properties are supported in the copy activity ***source*** section. Learn more from XML connector behavior.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to **XmlSource**.	Yes
formatSettings	A group of properties. Refer to **XML read settings** table below.	No
storeSettings	A group of properties on how to read data from a data store. Each file-based connector has its own supported read settings under `storeSettings`. **See details in connector article -> Copy activity properties section**.	No

Supported **XML read settings** under `formatSettings`:

PROPERTY	DESCRIPTION	REQUIRED
type	The type of formatSettings must be set to **XmlReadSettings**.	Yes
validationMode	Specifies whether to validate the XML schema. Allowed values are **none** (default, no validation), **xsd** (validate using XSD), **dtd** (validate using DTD).	No
namespaces	Whether to enable namespace when parsing the XML files. Allowed values are: **true** (default), **false**.	No
namespacePrefixes	Namespace URI to prefix mapping, which is used to name fields when parsing the xml file. If an XML file has namespace and namespace is enabled, by default, the field name is the same as it is in the XML document. If there is an item defined for the namespace URI in this map, the field name is `prefix:fieldName`.	No
detectDataType	Whether to detect integer, double, and Boolean data types. Allowed values are: **true** (default), **false**.	No

PROPERTY	DESCRIPTION	REQUIRED
compressionProperties	A group of properties on how to decompress data for a given compression codec.	No
preserveZipFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `ZipDeflateReadSettings`)	Applies when input dataset is configured with **ZipDeflate** compression. Indicates whether to preserve the source zip file name as folder structure during copy. - When set to **true (default)**, the service writes unzipped files to `<path specified in dataset>/<folder named as source zip file>/`. - When set to **false**, the service writes unzipped files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source zip files to avoid racing or unexpected behavior.	No
preserveCompressionFileNameAsFolder (*under* `compressionProperties` -> `type` *as* `TarGZipReadSettings` *or* `TarReadSettings`)	Applies when input dataset is configured with **TarGzip/Tar** compression. Indicates whether to preserve the source compressed file name as folder structure during copy. - When set to **true (default)**, the service writes decompressed files to `<path specified in dataset>/<folder named as source compressed file>/`. - When set to **false**, the service writes decompressed files directly to `<path specified in dataset>`. Make sure you don't have duplicated file names in different source files to avoid racing or unexpected behavior.	No

Mapping data flow properties

In mapping data flows, you can read XML format in the following data stores: Azure Blob Storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Amazon S3 and SFTP. You can point to XML files either using XML dataset or using an inline dataset.

Source properties

The below table lists the properties supported by an XML source. You can edit these properties in the **Source options** tab. Learn more from XML connector behavior. When using inline dataset, you will see additional file settings, which are the same as the properties described in dataset properties section.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Wild card paths	All files matching the wildcard path will be processed. Overrides the folder and file path set in the dataset.	No	String[]	wildcardPaths
Partition root path	For file data that is partitioned, you can enter a partition root path in order to read partitioned folders as columns	No	String	partitionRootPath
List of files	Whether your source is pointing to a text file that lists files to process	No	`true` or `false`	fileList
Column to store file name	Create a new column with the source file name and path	No	String	rowUrlColumn
After completion	Delete or move the files after processing. File path starts from the container root	No	Delete: `true` or `false` Move: `['<from>', '<to>']`	purgeFiles moveFiles
Filter by last modified	Choose to filter files based upon when they were last altered	No	Timestamp	modifiedAfter modifiedBefore
Validation mode	Specifies whether to validate the XML schema.	No	`None` (default, no validation) `xsd` (validate using XSD) `dtd` (validate using DTD).	validationMode
Namespaces	Whether to enable namespace when parsing the XML files.	No	`true` (default) or `false`	namespaces

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY
Namespace prefix pairs	Namespace URI to prefix mapping, which is used to name fields when parsing the xml file. If an XML file has namespace and namespace is enabled, by default, the field name is the same as it is in the XML document. If there is an item defined for the namespace URI in this map, the field name is `prefix:fieldName`.	No	Array with pattern `['URI1'->'prefix1','URI2'->'prefix2']`	namespacePrefixes
Allow no files found	If true, an error is not thrown if no files are found	no	`true` or `false`	ignoreNoFilesFound

XML source script example

The below script is an example of an XML source configuration in mapping data flows using dataset mode.

```
source(allowSchemaDrift: true,
    validateSchema: false,
    validationMode: 'xsd',
    namespaces: true) ~> XMLSource
```

The below script is an example of an XML source configuration using inline dataset mode.

```
source(allowSchemaDrift: true,
    validateSchema: false,
    format: 'xml',
    fileSystem: 'filesystem',
    folderPath: 'folder',
    validationMode: 'xsd',
    namespaces: true) ~> XMLSource
```

XML connector behavior

Note the following when using XML as source.

- XML attributes:
  - Attributes of an element are parsed as the subfields of the element in the hierarchy.
  - The name of the attribute field follows the pattern `@attributeName`.
- XML schema validation:
  - You can choose to not validate schema, or validate schema using XSD or DTD.
  - When using XSD or DTD to validate XML files, the XSD/DTD must be referred inside the XML files through relative path.

- Namespace handling:
  - Namespace can be disabled when using data flow, in which case the attributes that defines the namespace will be parsed as normal attributes.
  - When namespace is enabled, the names of the element and attributes follow the pattern `namespaceUri,elementName` and `namespaceUri,@attributeName` by default. You can define namespace prefix for each namespace URI in source, in which case the names of the element and attributes follow the pattern `definedPrefix:elementName` or `definedPrefix:@attributeName` instead.
- Value column:
  - If an XML element has both simple text value and attributes/child elements, the simple text value is parsed as the value of a "value column" with built-in field name `_value_`. And it inherits the namespace of the element as well if applies.

Transform data in Zendesk (Preview) using Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use Data Flow to transform data in Zendesk (Preview). To learn more, read the introductory article for Azure Data Factory or Azure Synapse Analytics.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Zendesk connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Mapping data flow (source/-)	①

① Azure integration runtime ② Self-hosted integration runtime

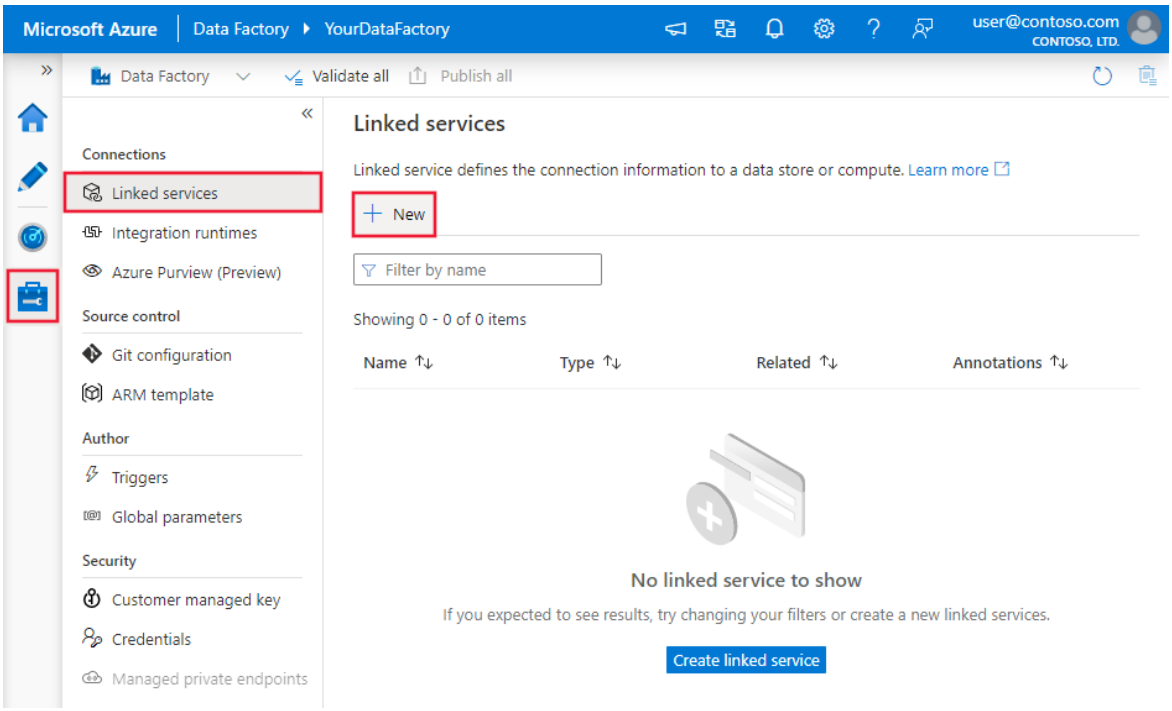
For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

Create a Zendesk linked service using UI

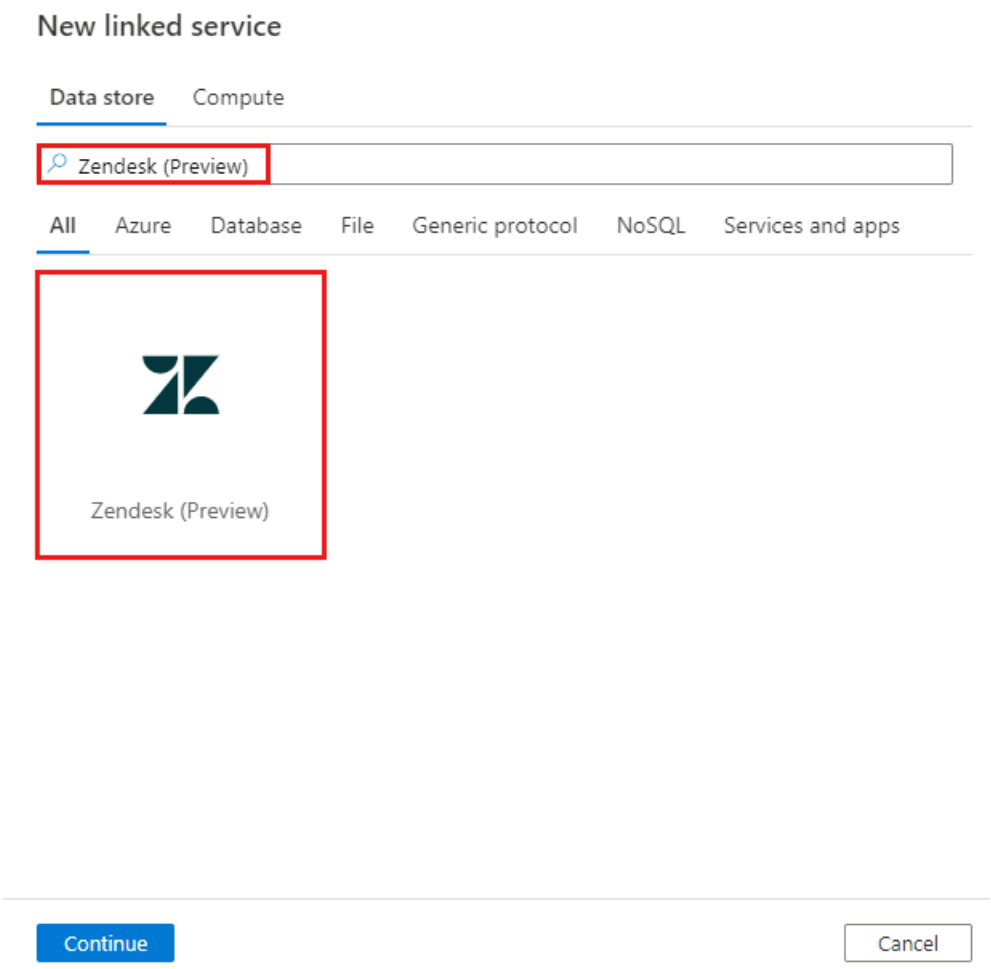
Use the following steps to create a Zendesk linked service in the Azure portal UI.

1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services, then select New:

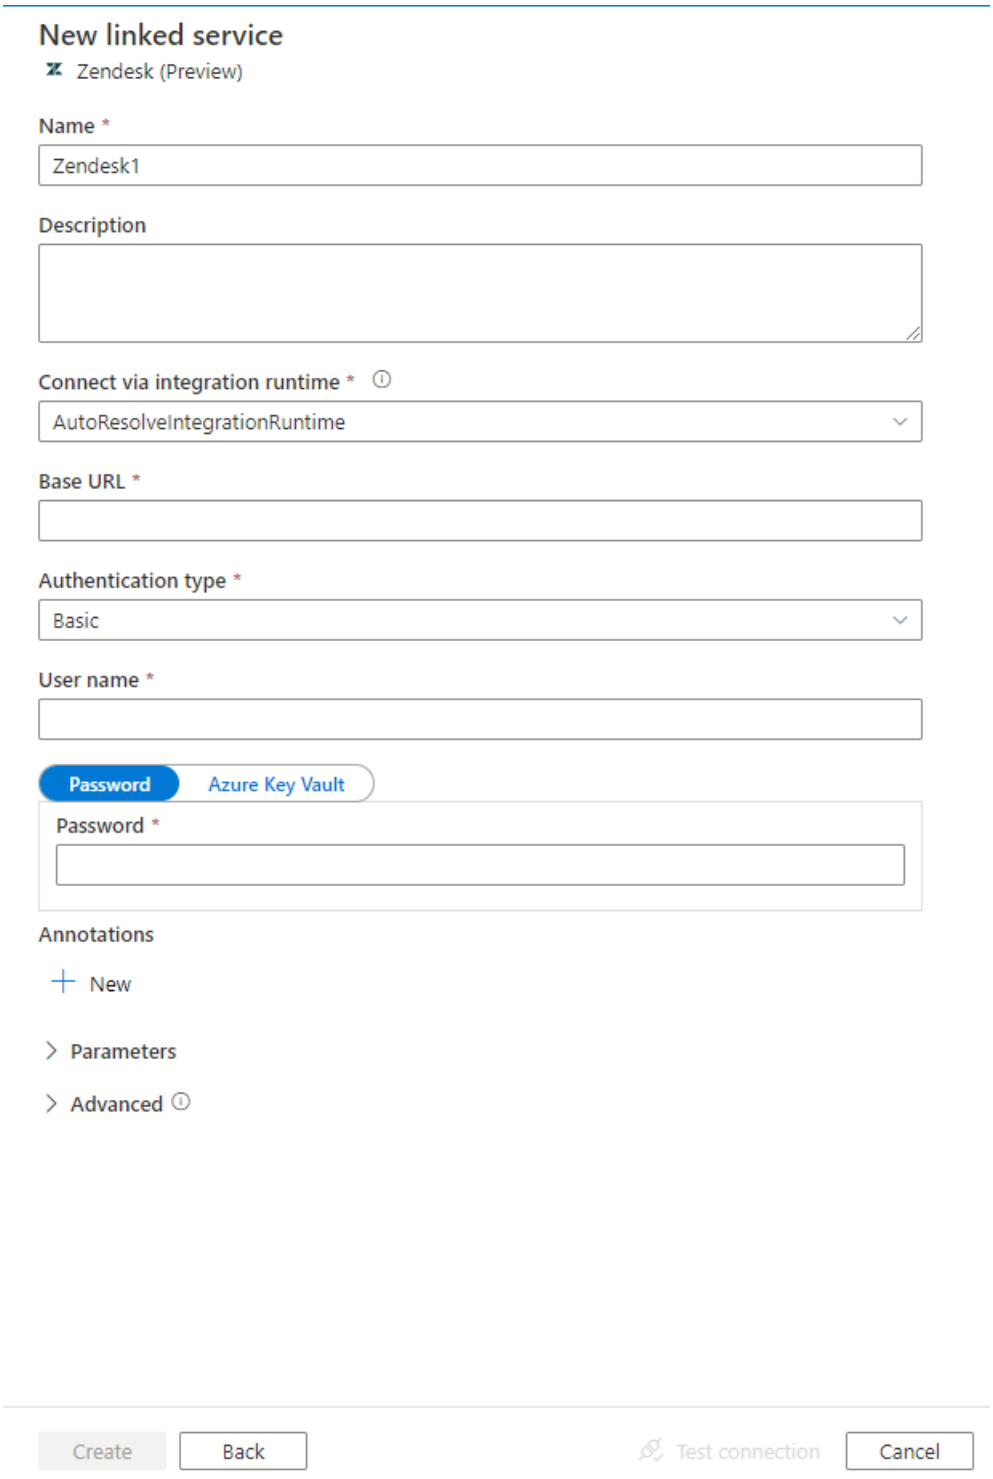
   - Azure Data Factory
   - Azure Synapse



2. Search for Zendesk (Preview) and select the Zendesk (Preview) connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide information about properties that are used to define Data Factory and Synapse pipeline entities specific to Zendesk.

Linked service properties

The following properties are supported for the Zendesk linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to **Zendesk**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
url	The base URL of your Zendesk service.	Yes
authenticationType	Type of authentication used to connect to the Zendesk service. Allowed values are **basic** and **token**. Refer to corresponding sections below on more properties and examples respectively.	Yes

Basic authentication

Set the **authenticationType** property to **basic**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
userName	The user name used to log in to Zendesk.	Yes
password	Specify a password for the user account you specified for the user name. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "ZendeskLinkedService",
    "properties": {
        "type": "Zendesk",
        "typeProperties": {
            "url": "<base url>",
            "authenticationType": "basic",
            "userName": "<user name>",
            "password": {
                "type": "SecureString",
                "value": "<password>"
            }
        }
    }
}
```

Token authentication

Set the **authenticationType** property to **token**. In addition to the generic properties that are described in the preceding section, specify the following properties:

PROPERTY	DESCRIPTION	REQUIRED
apiToken	Specify an API token for the Zendesk. Mark this field as **SecureString** to store it securely. Or, you can reference a secret stored in Azure Key Vault.	Yes

Example:

```
{
    "name": "ZendeskLinkedService",
    "properties": {
        "type": "Zendesk",
        "typeProperties": {
            "url": "<base url>",
            "authenticationType": "token",
            "apiToken": {
                "type": "SecureString",
                "value": "<API token>"
            }
        }
    }
}
```

Mapping data flow properties

When transforming data in mapping data flow, you can read tables from Zendesk. For more information, see the source transformation in mapping data flows. You can only use an inline dataset as source type.

Source transformation

The below table lists the properties supported by Zendesk source. You can edit these properties in the **Source options** tab.

NAME	DESCRIPTION	REQUIRED	ALLOWED VALUES	DATA FLOW SCRIPT PROPERTY

Entity	The logical name of the entity in Zendesk.	Yes when use inline mode	`activities`
			`group_memberships`
			`groups`
			`organizations`
			`requests`
			`satisfaction_ratings`
			`sessions`
			`tags`
			`targets`
			`ticket_audits`
			`ticket_fields`
			`ticket_metrics`
			`tickets`
			`triggers`
			`users`
			`views`
				entity

Zendesk source script examples

```
source(allowSchemaDrift: true,
 validateSchema: false,
 store: 'zendesk',
 format: 'rest',
 entity: 'tickets') ~> ZendeskSource
```

Next steps

For a list of data stores supported as sources and sinks by the copy activity, see Supported data stores.

Copy data from Zoho using Azure Data Factory or Synapse Analytics (Preview)

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to use the Copy Activity in an Azure Data Factory or Synapse Analytics pipeline to copy data from Zoho. It builds on the copy activity overview article that presents a general overview of copy activity.

> **IMPORTANT**
> This connector is currently in preview. You can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, please contact Azure support.

Supported capabilities

This Zoho connector is supported for the following capabilities:

SUPPORTED CAPABILITIES	IR
Copy activity (source/-)	① ②
Lookup activity	① ②

① Azure integration runtime ② Self-hosted integration runtime

For a list of data stores that are supported as sources/sinks, see the Supported data stores table.

This connector supports Xero access token authentication and OAuth 2.0 authentication.

The service provides a built-in driver to enable connectivity, therefore you don't need to manually install any driver using this connector.

Getting started

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

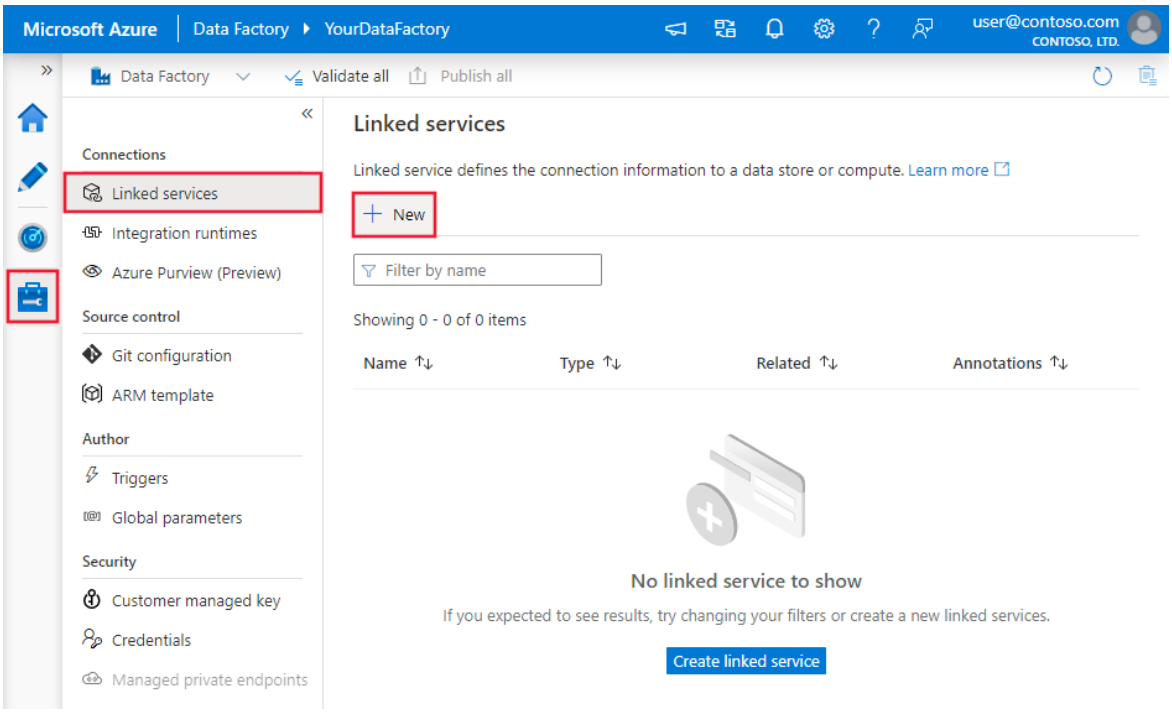
Create a linked service to Zoho using UI

Use the following steps to create a linked service to Zoho in the Azure portal UI.

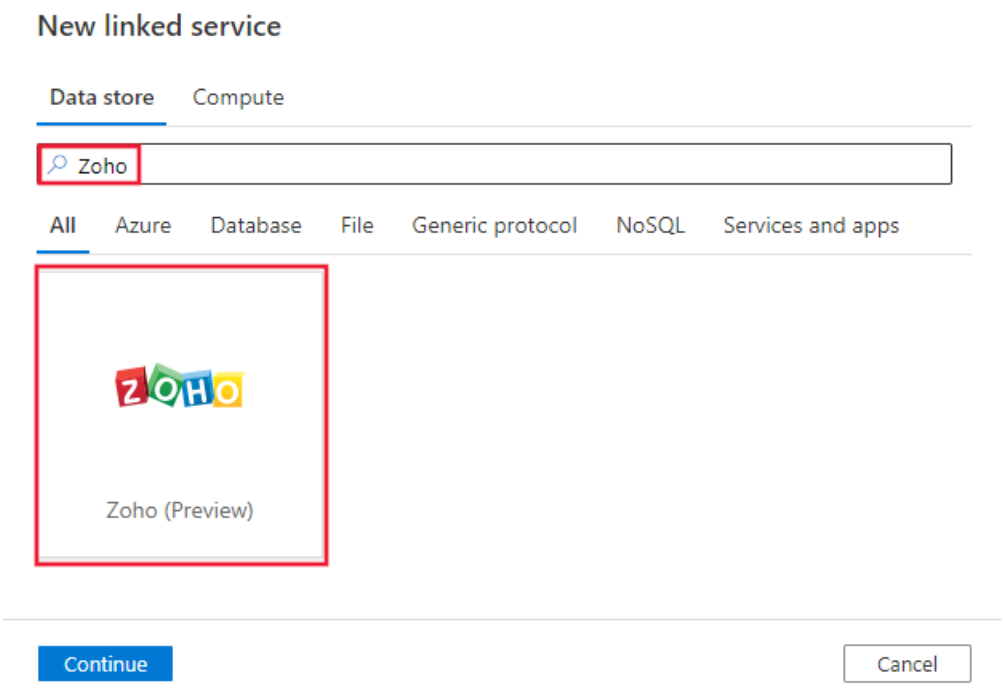
1. Browse to the Manage tab in your Azure Data Factory or Synapse workspace and select Linked Services,

then click New:

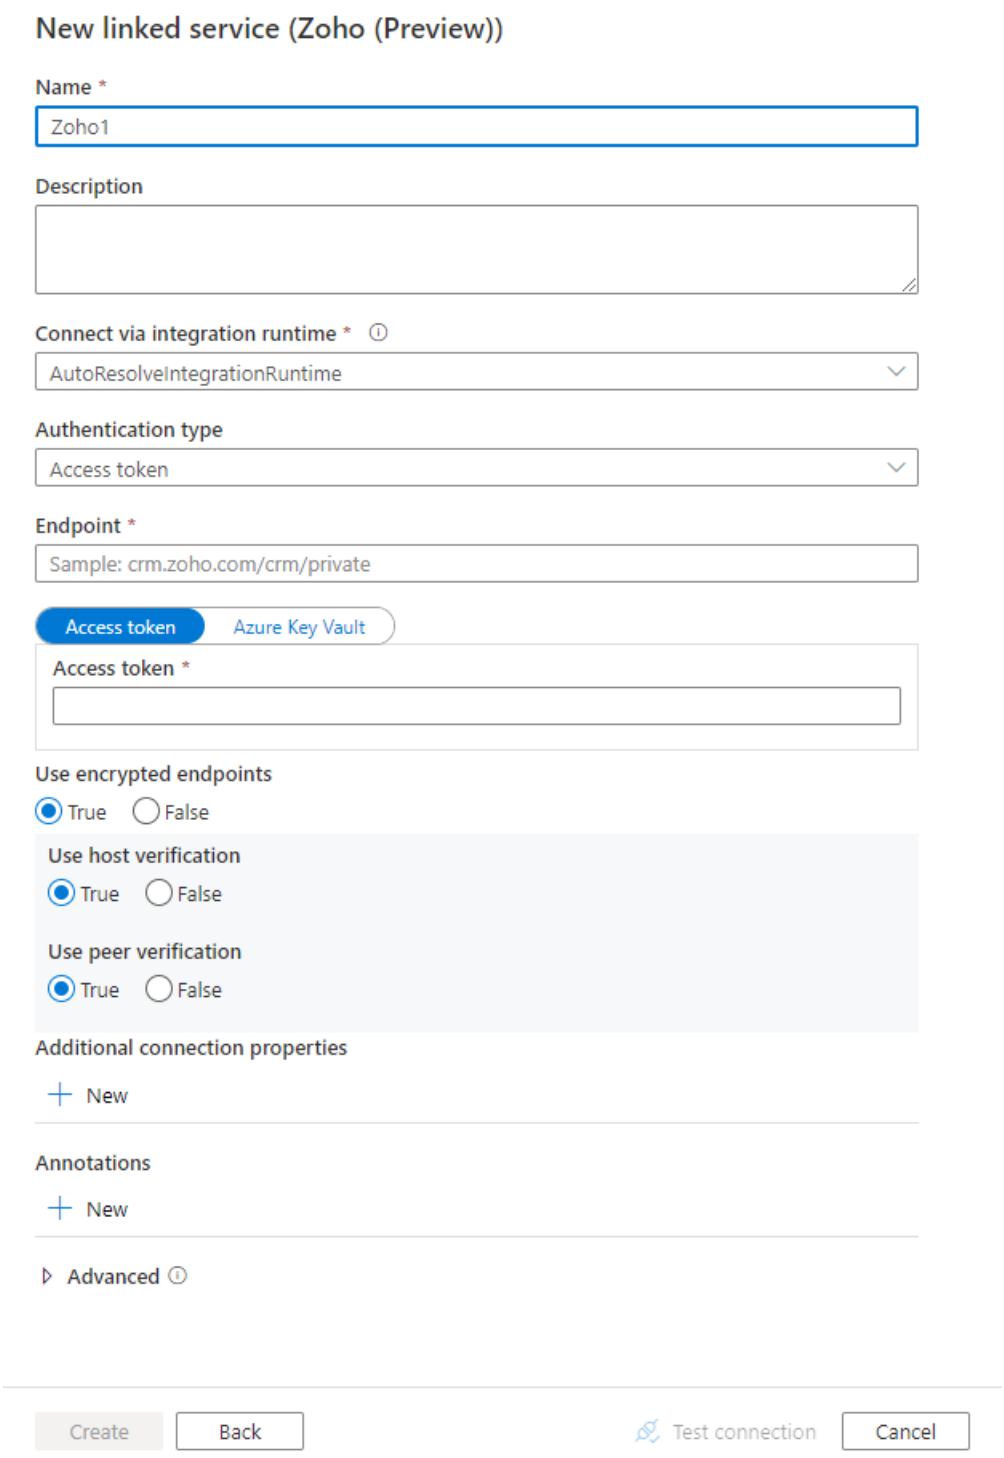
- Azure Data Factory
- Azure Synapse



2. Search for Zoho and select the Zoho connector.



3. Configure the service details, test the connection, and create the new linked service.



Connector configuration details

The following sections provide details about properties that are used to define Data Factory entities specific to Zoho connector.

Linked service properties

The following properties are supported for Zoho linked service:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **Zoho**	Yes

PROPERTY	DESCRIPTION	REQUIRED
connectionProperties	A group of properties that defines how to connect to Zoho.	Yes
Under `connectionProperties`*:*		
endpoint	The endpoint of the Zoho server (`crm.zoho.com/crm/private`).	Yes
authenticationType	Allowed values are `OAuth_2.0` and `Access Token` .	Yes
clientId	The client ID associated with your Zoho application.	Yes for OAuth 2.0 authentication
clientSecrect	The clientsecret associated with your Zoho application. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes for OAuth 2.0 authentication
refreshToken	The OAuth 2.0 refresh token associated with your Zoho application, used to refresh the access token when it expires. Refresh token will never expire. To get a refresh token, you must request the `offline` access_type, learn more from this article. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes for OAuth 2.0 authentication
accessToken	The access token for Zoho authentication. Mark this field as a SecureString to store it securely, or reference a secret stored in Azure Key Vault.	Yes
useEncryptedEndpoints	Specifies whether the data source endpoints are encrypted using HTTPS. The default value is true.	No
useHostVerification	Specifies whether to require the host name in the server's certificate to match the host name of the server when connecting over TLS. The default value is true.	No
usePeerVerification	Specifies whether to verify the identity of the server when connecting over TLS. The default value is true.	No

Example: OAuth 2.0 authentication

```
{
    "name": "ZohoLinkedService",
    "properties": {
        "type": "Zoho",
        "typeProperties": {
            "connectionProperties": {
                "authenticationType":"OAuth_2.0",
                "endpoint":"crm.zoho.com/crm/private",
                "clientId":"<client ID>",
                "clientSecrect":{
                    "type": "SecureString",
                    "value": "<client secret>"
                },
                "accessToken":{
                    "type": "SecureString",
                    "value": "<access token>"
                },
                "refreshToken":{
                    "type": "SecureString",
                    "value": "<refresh token>"
                },
                "useEncryptedEndpoints":true,
                "useHostVerification":true,
                "usePeerVerification":true
}
        }
    }
}
```

Example: access token authentication

```
{
    "name": "ZohoLinkedService",
    "properties": {
        "type": "Zoho",
        "typeProperties": {
            "connectionProperties": {
                "authenticationType":"Access Token",
                "endpoint":"crm.zoho.com/crm/private",
                "accessToken":{
                    "type": "SecureString",
                    "value": "<access token>"
                },
                "useEncryptedEndpoints":true,
                "useHostVerification":true,
                "usePeerVerification":true
}
        }
    }
}
```

Dataset properties

For a full list of sections and properties available for defining datasets, see the datasets article. This section provides a list of properties supported by Zoho dataset.

To copy data from Zoho, set the type property of the dataset to **ZohoObject**. The following properties are supported:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the dataset must be set to: **ZohoObject**	Yes
tableName	Name of the table.	No (if "query" in activity source is specified)

Example

```
{
    "name": "ZohoDataset",
    "properties": {
        "type": "ZohoObject",
        "typeProperties": {},
        "schema": [],
        "linkedServiceName": {
            "referenceName": "<Zoho linked service name>",
            "type": "LinkedServiceReference"
        }
    }
}
```

Copy activity properties

For a full list of sections and properties available for defining activities, see the Pipelines article. This section provides a list of properties supported by Zoho source.

Zoho as source

To copy data from Zoho, set the source type in the copy activity to **ZohoSource**. The following properties are supported in the copy activity **source** section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity source must be set to: **ZohoSource**	Yes
query	Use the custom SQL query to read data. For example: `"SELECT * FROM Accounts"`.	No (if "tableName" in dataset is specified)

Example:

```
"activities":[
    {
        "name": "CopyFromZoho",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<Zoho input dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<output dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "ZohoSource",
                "query": "SELECT * FROM Accounts"
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Lookup activity properties

To learn details about the properties, check Lookup activity.

Next steps

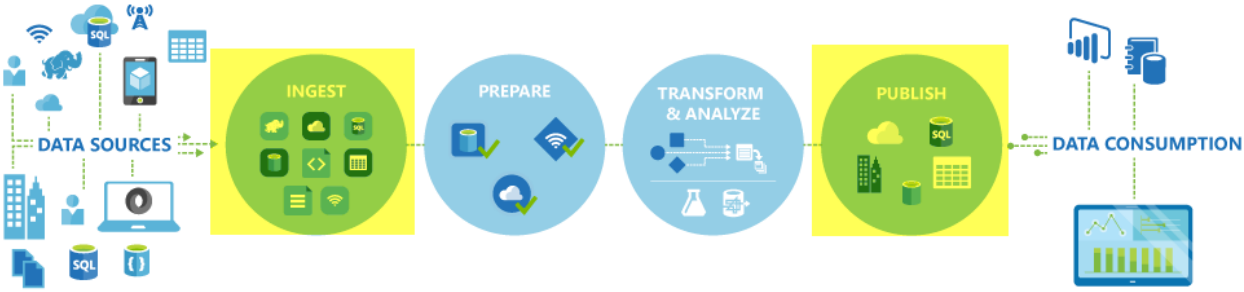
For a list of data stores supported as sources and sinks by the copy activity, see supported data stores.

Copy activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 14 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

In Azure Data Factory and Synapse pipelines, you can use the Copy activity to copy data among data stores located on-premises and in the cloud. After you copy the data, you can use other activities to further transform and analyze it. You can also use the Copy activity to publish transformation and analysis results for business intelligence (BI) and application consumption.



The Copy activity is executed on an integration runtime. You can use different types of integration runtimes for different data copy scenarios:

- When you're copying data between two data stores that are publicly accessible through the internet from any IP, you can use the Azure integration runtime for the copy activity. This integration runtime is secure, reliable, scalable, and globally available.
- When you're copying data to and from data stores that are located on-premises or in a network with access control (for example, an Azure virtual network), you need to set up a self-hosted integration runtime.

An integration runtime needs to be associated with each source and sink data store. For information about how the Copy activity determines which integration runtime to use, see Determining which IR to use.

To copy data from a source to a sink, the service that runs the Copy activity performs these steps:

1. Reads data from a source data store.
2. Performs serialization/deserialization, compression/decompression, column mapping, and so on. It performs these operations based on the configuration of the input dataset, output dataset, and Copy activity.
3. Writes data to the sink/destination data store.

If a connector is marked *Preview*, you can try it out and give us feedback. If you want to take a dependency on preview connectors in your solution, contact Azure support.

Supported file formats

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

You can use the Copy activity to copy files as-is between two file-based data stores, in which case the data is copied efficiently without any serialization or deserialization. In addition, you can also parse or generate files of a given format, for example, you can perform the following:

- Copy data from a SQL Server database and write to Azure Data Lake Storage Gen2 in Parquet format.
- Copy files in text (CSV) format from an on-premises file system and write to Azure Blob storage in Avro format.
- Copy zipped files from an on-premises file system, decompress them on-the-fly, and write extracted files to Azure Data Lake Storage Gen2.
- Copy data in Gzip compressed-text (CSV) format from Azure Blob storage and write it to Azure SQL Database.
- Many more activities that require serialization/deserialization or compression/decompression.

Supported regions

The service that enables the Copy activity is available globally in the regions and geographies listed in Azure

integration runtime locations. The globally available topology ensures efficient data movement that usually avoids cross-region hops. See Products by region to check the availability of Data Factory, Synapse Workspaces and data movement in a specific region.

Configuration

To perform the Copy activity with a pipeline, you can use one of the following tools or SDKs:

- The Copy Data tool
- The Azure portal
- The .NET SDK
- The Python SDK
- Azure PowerShell
- The REST API
- The Azure Resource Manager template

In general, to use the Copy activity in Azure Data Factory or Synapse pipelines, you need to:

1. **Create linked services for the source data store and the sink data store.** You can find the list of supported connectors in the Supported data stores and formats section of this article. Refer to the connector article's "Linked service properties" section for configuration information and supported properties.
2. **Create datasets for the source and sink.** Refer to the "Dataset properties" sections of the source and sink connector articles for configuration information and supported properties.
3. **Create a pipeline with the Copy activity.** The next section provides an example.

Syntax

The following template of a Copy activity contains a complete list of supported properties. Specify the ones that fit your scenario.

```
"activities":[
    {
        "name": "CopyActivityTemplate",
        "type": "Copy",
        "inputs": [
            {
                "referenceName": "<source dataset name>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<sink dataset name>",
                "type": "DatasetReference"
            }
        ],
        "typeProperties": {
            "source": {
                "type": "<source type>",
                <properties>
            },
            "sink": {
                "type": "<sink type>"
                <properties>
            },
            "translator":
            {
                "type": "TabularTranslator",
                "columnMappings": "<column mapping>"
            },
            "dataIntegrationUnits": <number>,
            "parallelCopies": <number>,
            "enableStaging": true/false,
            "stagingSettings": {
                <properties>
            },
            "enableSkipIncompatibleRow": true/false,
            "redirectIncompatibleRowSettings": {
                <properties>
            }
        }
    }
]
```

Syntax details

PROPERTY	DESCRIPTION	REQUIRED?
type	For a Copy activity, set to `Copy`	Yes
inputs	Specify the dataset that you created that points to the source data. The Copy activity supports only a single input.	Yes
outputs	Specify the dataset that you created that points to the sink data. The Copy activity supports only a single output.	Yes
typeProperties	Specify properties to configure the Copy activity.	Yes

PROPERTY	DESCRIPTION	REQUIRED?
source	Specify the copy source type and the corresponding properties for retrieving data. For more information, see the "Copy activity properties" section in the connector article listed in Supported data stores and formats.	Yes
sink	Specify the copy sink type and the corresponding properties for writing data. For more information, see the "Copy activity properties" section in the connector article listed in Supported data stores and formats.	Yes
translator	Specify explicit column mappings from source to sink. This property applies when the default copy behavior doesn't meet your needs. For more information, see Schema mapping in copy activity.	No
dataIntegrationUnits	Specify a measure that represents the amount of power that the Azure integration runtime uses for data copy. These units were formerly known as cloud Data Movement Units (DMU). For more information, see Data Integration Units.	No
parallelCopies	Specify the parallelism that you want the Copy activity to use when reading data from the source and writing data to the sink. For more information, see Parallel copy.	No
preserve	Specify whether to preserve metadata/ACLs during data copy. For more information, see Preserve metadata.	No
enableStaging stagingSettings	Specify whether to stage the interim data in Blob storage instead of directly copying data from source to sink. For information about useful scenarios and configuration details, see Staged copy.	No
enableSkipIncompatibleRow redirectIncompatibleRowSettings	Choose how to handle incompatible rows when you copy data from source to sink. For more information, see Fault tolerance.	No

Monitoring

You can monitor the Copy activity run in the Azure Data Factory and Synapse pipelines both visually and programmatically. For details, see Monitor copy activity.

Incremental copy

Data Factory and Synapse pipelines enable you to incrementally copy delta data from a source data store to a sink data store. For details, see Tutorial: Incrementally copy data.

Performance and tuning

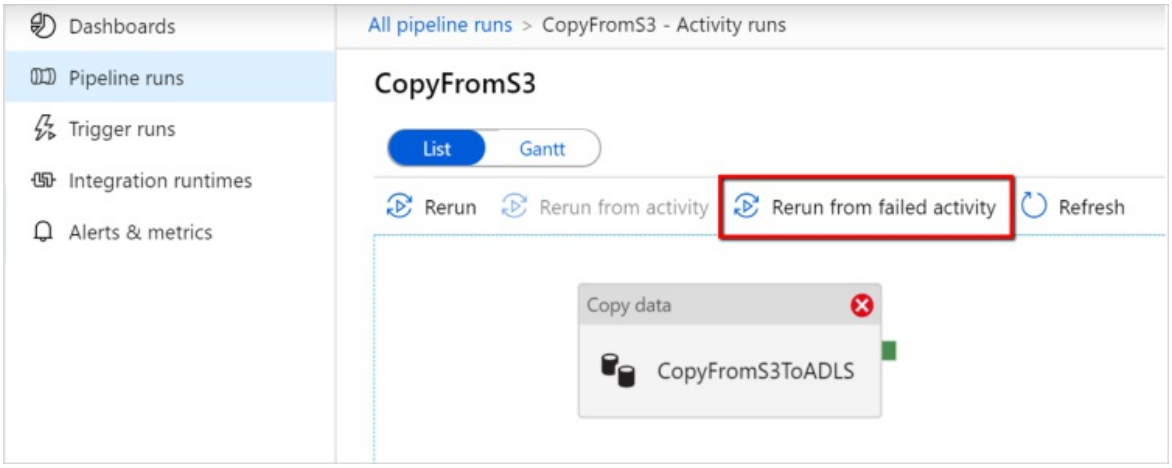
The copy activity monitoring experience shows you the copy performance statistics for each of your activity run. The Copy activity performance and scalability guide describes key factors that affect the performance of data movement via the Copy activity. It also lists the performance values observed during testing and discusses how to optimize the performance of the Copy activity.

Resume from last failed run

Copy activity supports resume from last failed run when you copy large size of files as-is with binary format between file-based stores and choose to preserve the folder/file hierarchy from source to sink, e.g. to migrate data from Amazon S3 to Azure Data Lake Storage Gen2. It applies to the following file-based connectors: Amazon S3, Amazon S3 Compatible Storage Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, Oracle Cloud Storage and SFTP.

You can leverage the copy activity resume in the following two ways:

- **Activity level retry:** You can set retry count on copy activity. During the pipeline execution, if this copy activity run fails, the next automatic retry will start from last trial's failure point.
- **Rerun from failed activity:** After pipeline execution completion, you can also trigger a rerun from the failed activity in the ADF UI monitoring view or programmatically. If the failed activity is a copy activity, the pipeline will not only rerun from this activity, but also resume from the previous run's failure point.



Few points to note:

- Resume happens at file level. If copy activity fails when copying a file, in next run, this specific file will be re-copied.
- For resume to work properly, do not change the copy activity settings between the reruns.
- When you copy data from Amazon S3, Azure Blob, Azure Data Lake Storage Gen2 and Google Cloud Storage, copy activity can resume from arbitrary number of copied files. While for the rest of file-based connectors as source, currently copy activity supports resume from a limited number of files, usually at the range of tens of thousands and varies depending on the length of the file paths; files beyond this number will be re-copied during reruns.

For other scenarios than binary file copy, copy activity rerun starts from the beginning.

Preserve metadata along with data

While copying data from source to sink, in scenarios like data lake migration, you can also choose to preserve the metadata and ACLs along with data using copy activity. See Preserve metadata for details.

Schema and data type mapping

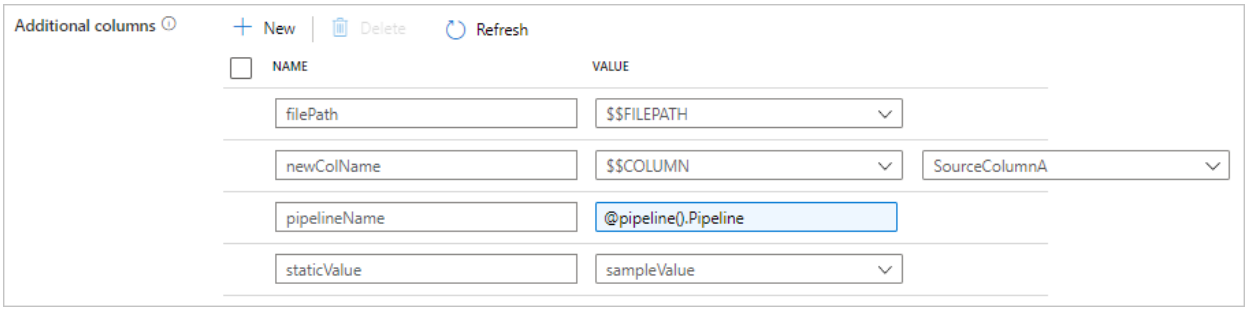
See Schema and data type mapping for information about how the Copy activity maps your source data to your sink.

Add additional columns during copy

In addition to copying data from source data store to sink, you can also configure to add additional data columns to copy along to sink. For example:

- When copy from file-based source, store the relative file path as an additional column to trace from which file the data comes from.
- Duplicate the specified source column as another column.
- Add a column with ADF expression, to attach ADF system variables like pipeline name/pipeline ID, or store other dynamic value from upstream activity's output.
- Add a column with static value to meet your downstream consumption need.

You can find the following configuration on copy activity source tab. You can also map those additional columns in copy activity schema mapping as usual by using your defined column names.



> **TIP**
> This feature works with the latest dataset model. If you don't see this option from the UI, try creating a new dataset.

To configure it programmatically, add the `additionalColumns` property in your copy activity source:

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
additionalColumns	Add additional data columns to copy to sink. Each object under the `additionalColumns` array represents an extra column. The `name` defines the column name, and the `value` indicates the data value of that column. Allowed data values are: - `$$FILEPATH` - a reserved variable indicates to store the source files' relative path to the folder path specified in dataset. Apply to file-based source. - `$$COLUMN:<source_column_name>` - a reserved variable pattern indicates to duplicate the specified source column as another column - **Expression** - **Static value**	No

Example:

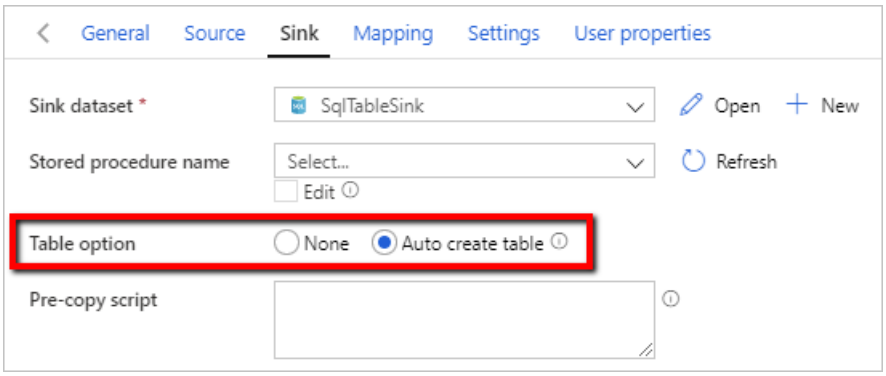
```
"activities":[
    {
        "name": "CopyWithAdditionalColumns",
        "type": "Copy",
        "inputs": [...],
        "outputs": [...],
        "typeProperties": {
            "source": {
                "type": "<source type>",
                "additionalColumns": [
                    {
                        "name": "filePath",
                        "value": "$$FILEPATH"
                    },
                    {
                        "name": "newColName",
                        "value": "$$COLUMN:SourceColumnA"
                    },
                    {
                        "name": "pipelineName",
                        "value": {
                            "value": "@pipeline().Pipeline",
                            "type": "Expression"
                        }
                    },
                    {
                        "name": "staticValue",
                        "value": "sampleValue"
                    }
                ],
                ...
            },
            "sink": {
                "type": "<sink type>"
            }
        }
    }
]
```

Auto create sink tables

When copying data into SQL database/Azure Synapse Analytics, if the destination table does not exist, copy activity supports automatically creating it based on the source data. It aims to help you quickly get started to load the data and evaluate SQL database/Azure Synapse Analytics. After the data ingestion, you can review and adjust the sink table schema according to your needs.

This feature is supported when copying data from any source into the following sink data stores. You can find the option on *ADF authoring UI –> Copy activity sink –> Table option –> Auto create table*, or via `tableOption` property in copy activity sink payload.

- Azure SQL Database
- Azure SQL Database Managed Instance
- Azure Synapse Analytics
- SQL Server



Fault tolerance

By default, the Copy activity stops copying data and returns a failure when source data rows are incompatible with sink data rows. To make the copy succeed, you can configure the Copy activity to skip and log the incompatible rows and copy only the compatible data. See Copy activity fault tolerance for details.

Data consistency verification

When you move data from source to destination store, copy activity provides an option for you to do additional data consistency verification to ensure the data is not only successfully copied from source to destination store, but also verified to be consistent between source and destination store. Once inconsistent files have been found during the data movement, you can either abort the copy activity or continue to copy the rest by enabling fault tolerance setting to skip inconsistent files. You can get the skipped file names by enabling session log setting in copy activity. See Data consistency verification in copy activity for details.

Session log

You can log your copied file names, which can help you to further ensure the data is not only successfully copied from source to destination store, but also consistent between source and destination store by reviewing the copy activity session logs. See Session log in copy activity for details.

Next steps

See the following quickstarts, tutorials, and samples:

- Copy data from one location to another location in the same Azure Blob storage account
- Copy data from Azure Blob storage to Azure SQL Database
- Copy data from a SQL Server database to Azure

Monitor copy activity

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

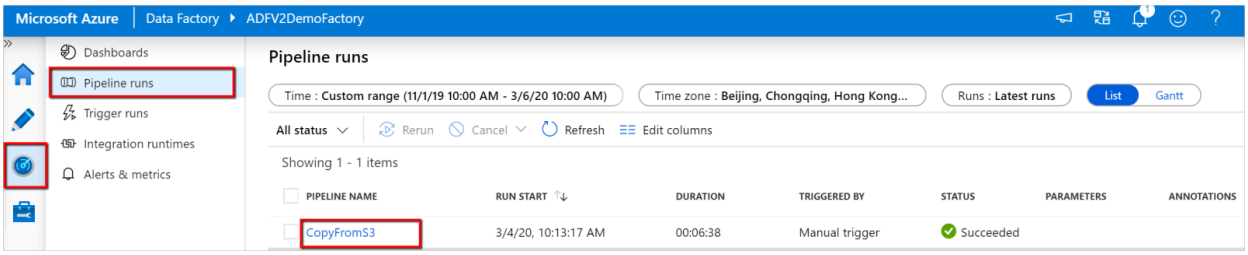
This article outlines how to monitor the copy activity execution in Azure Data Factory and Synapse pipelines. It builds on the copy activity overview article that presents a general overview of copy activity. You can also monitor copy activities generated with the Copy Data Tool as well as Delete activities using the same approach.

Monitor visually

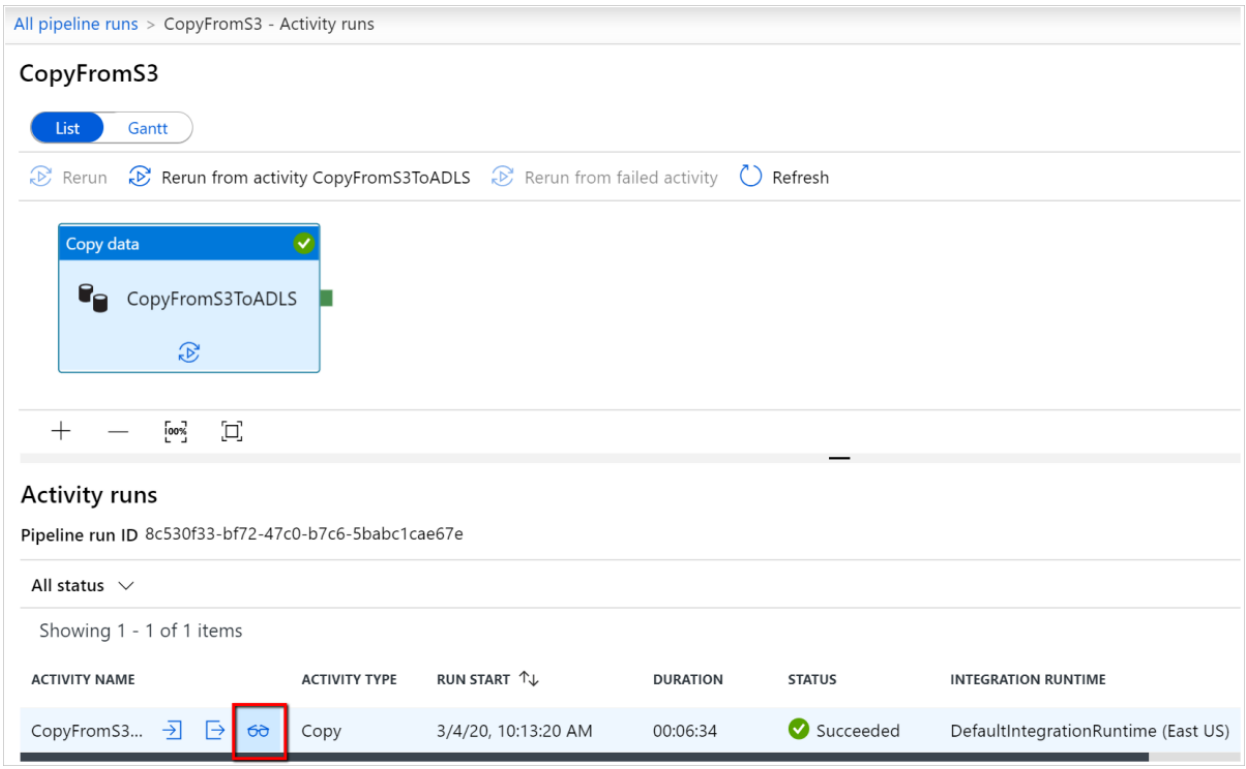
Once you've created and published a pipeline, you can associate it with a trigger or manually kick off an ad hoc run. You can monitor all of your pipeline runs natively in the user experience. Learn about monitoring in general from Visually monitor Azure Data Factory and Synapse pipelines.

To monitor the Copy activity run, go to the **Data Factory Studio** or **Azure Synapse Studio** UI for your service instance. On the **Monitor** tab, you see a list of pipeline runs, click the **pipeline name** link to access the list of activity runs in the pipeline run.

- Azure Data Factory
- Azure Synapse



At this level, you can see links to copy activity input, output, and errors (if the Copy activity run fails), as well as statistics like duration/status. Clicking the **Details** button (eyeglasses) next to the copy activity name will give you deep details on your copy activity execution.

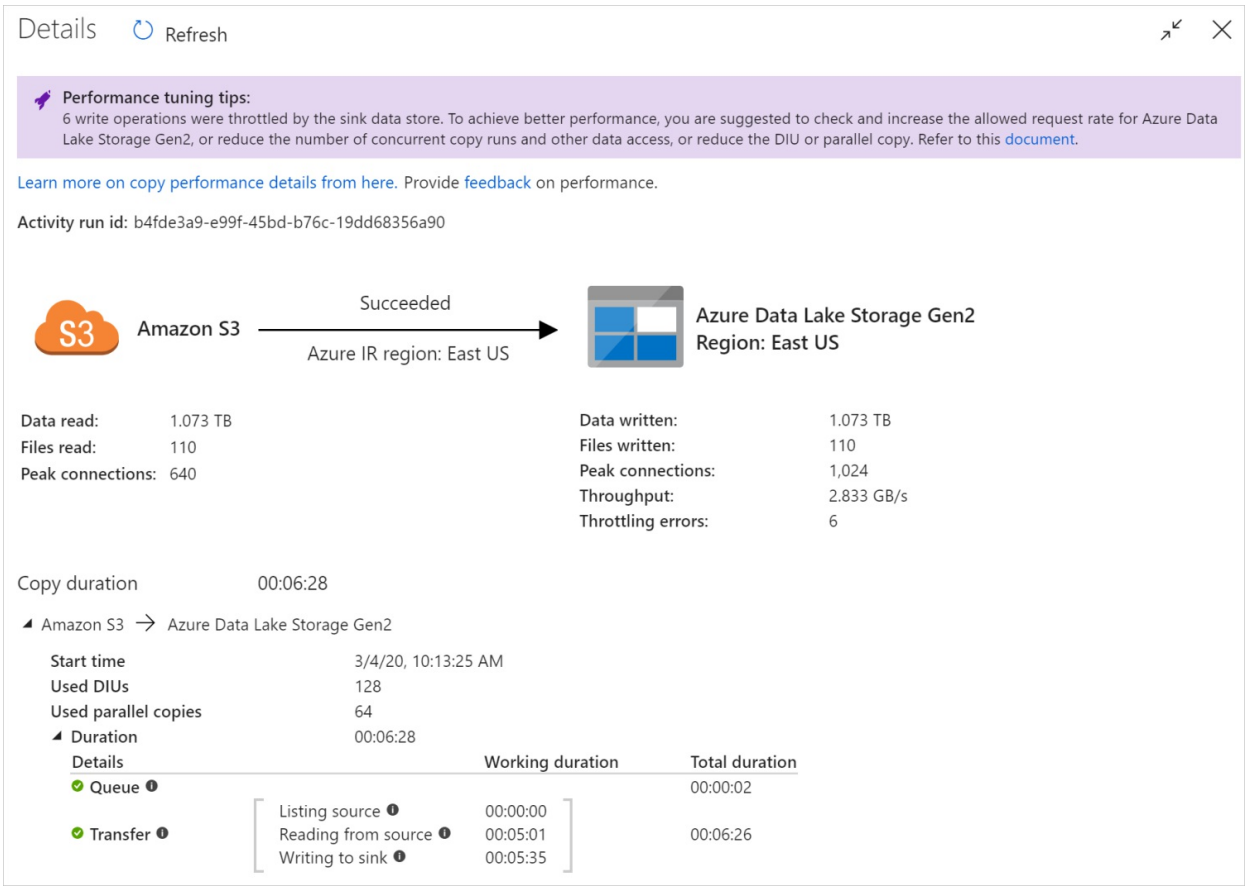


In this graphical monitoring view, the service presents you the copy activity execution information, including data read/written volume, number of files/rows of data copied from source to sink, throughput, the configurations applied for your copy scenario, steps the copy activity goes through with corresponding durations and details, and more. Refer to this table on each possible metric and its detailed description.

In some scenarios, when you run a Copy activity, you'll see **"Performance tuning tips"** at the top of the copy activity monitoring view as shown in the example. The tips tell you the bottleneck identified by the service for the specific copy run, along with suggestion on what to change to boost copy throughput. Learn more about auto performance tuning tips.

The bottom **execution details and durations** describes the key steps your copy activity goes through, which is especially useful for troubleshooting the copy performance. The bottleneck of your copy run is the one with the longest duration. Refer to Troubleshoot copy activity performance on for what each stage represents and the detailed troubleshooting guidance.

Example: Copy from Amazon S3 to Azure Data Lake Storage Gen2



Monitor programmatically

Copy activity execution details and performance characteristics are also returned in the **Copy Activity run result** > **Output** section, which is used to render the UI monitoring view. Following is a complete list of properties that might be returned. You'll see only the properties that are applicable to your copy scenario. For information about how to monitor activity runs programmatically in general, see Programmatically monitor an Azure Data Factory or Synapse pipeline.

PROPERTY NAME	DESCRIPTION	UNIT IN OUTPUT
dataRead	The actual amount of data read from the source.	Int64 value, in bytes
dataWritten	The actual mount of data written/committed to the sink. The size may be different from `dataRead` size, as it relates how each data store stores the data.	Int64 value, in bytes
filesRead	The number of files read from the file-based source.	Int64 value (no unit)
filesWritten	The number of files written/committed to the file-based sink.	Int64 value (no unit)
filesSkipped	The number of files skipped from the file-based source.	Int64 value (no unit)

PROPERTY NAME	DESCRIPTION	UNIT IN OUTPUT
dataConsistencyVerification	Details of data consistency verification where you can see if your copied data has been verified to be consistent between source and destination store. Learn more from this article.	Array
sourcePeakConnections	Peak number of concurrent connections established to the source data store during the Copy activity run.	Int64 value (no unit)
sinkPeakConnections	Peak number of concurrent connections established to the sink data store during the Copy activity run.	Int64 value (no unit)
rowsRead	Number of rows read from the source. This metric does not apply when copying files as-is without parsing them, for example, when source and sink datasets are binary format type, or other format type with identical settings.	Int64 value (no unit)
rowsCopied	Number of rows copied to sink. This metric does not apply when copying files as-is without parsing them, for example, when source and sink datasets are binary format type, or other format type with identical settings.	Int64 value (no unit)
rowsSkipped	Number of incompatible rows that were skipped. You can enable incompatible rows to be skipped by setting `enableSkipIncompatibleRow` to true.	Int64 value (no unit)
copyDuration	Duration of the copy run.	Int32 value, in seconds
throughput	Rate of data transfer, calculated by `dataRead` divided by `copyDuration`.	Floating point number, in KBps
sourcePeakConnections	Peak number of concurrent connections established to the source data store during the Copy activity run.	Int32 value (no unit)
sinkPeakConnections	Peak number of concurrent connections established to the sink data store during the Copy activity run.	Int32 value (no unit)
sqlDwPolyBase	Whether PolyBase is used when data is copied into Azure Synapse Analytics.	Boolean

PROPERTY NAME	DESCRIPTION	UNIT IN OUTPUT
redshiftUnload	Whether UNLOAD is used when data is copied from Redshift.	Boolean
hdfsDistcp	Whether DistCp is used when data is copied from HDFS.	Boolean
effectiveIntegrationRuntime	The integration runtime (IR) or runtimes used to power the activity run, in the format `<IR name> (<region if it's Azure IR>)`.	Text (string)
usedDataIntegrationUnits	The effective Data Integration Units during copy.	Int32 value
usedParallelCopies	The effective parallelCopies during copy.	Int32 value
logPath	Path to the session log of skipped data in the blob storage. See Fault tolerance.	Text (string)
executionDetails	More details on the stages the Copy activity goes through and the corresponding steps, durations, configurations, and so on. We don't recommend that you parse this section because it might change. To better understand how it helps you understand and troubleshoot copy performance, refer to Monitor visually section.	Array
perfRecommendation	Copy performance tuning tips. See Performance tuning tips for details.	Array
billingReference	The billing consumption for the given run. Learn more from Monitor consumption at activity-run level.	Object
durationInQueue	Queueing duration in second before the copy activity starts to execute.	Object

Example:

```

Delete Activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

You can use the Delete Activity in Azure Data Factory to delete files or folders from on-premises storage stores or cloud storage stores. Use this activity to clean up or archive files when they are no longer needed.

> **WARNING**
> Deleted files or folders cannot be restored (unless the storage has soft-delete enabled). Be cautious when using the Delete activity to delete files or folders.

Best practices

Here are some recommendations for using the Delete activity:

- Back up your files before deleting them with the Delete activity in case you need to restore them in the future.
- Make sure that the service has write permissions to delete folders or files from the storage store.
- Make sure you are not deleting files that are being written at the same time.
- If you want to delete files or folder from an on-premises system, make sure you are using a self-hosted integration runtime with a version greater than 3.14.

Supported data stores

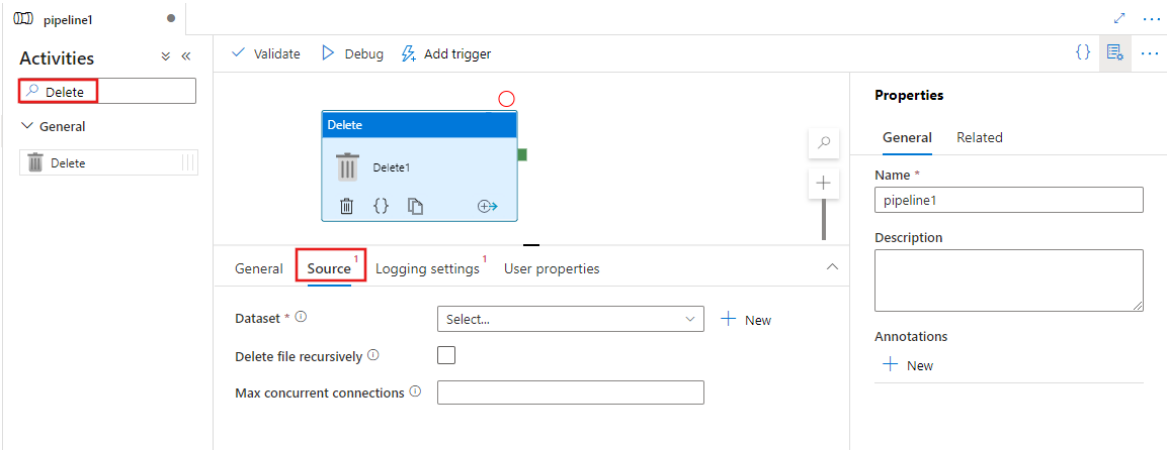
- Azure Blob storage
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Files
- File System
- FTP
- SFTP
- Amazon S3
- Amazon S3 Compatible Storage
- Google Cloud Storage
- Oracle Cloud Storage
- HDFS

Create a Delete activity with UI

To use a Delete activity in a pipeline, complete the following steps:

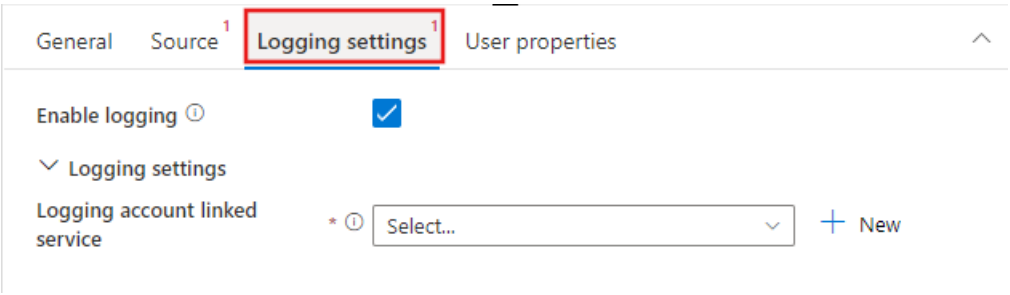
1. Search for *Delete* in the pipeline Activities pane, and drag a Delete activity to the pipeline canvas.
2. Select the new Delete activity on the canvas if it is not already selected, and its **Source** tab, to edit its

details.



3. Select an existing or create a new Dataset specifying the files to be deleted. If multiple files are selected, optionally enable recursive deletion, which deletes data in any child folders as well. You can also specify a maximum number of concurrent connections for the operation.

4. Optionally configure logging by selecting the **Logging settings** tab and selecting an existing or creating a new logging account linked service location to log results of the delete operations performed.



Syntax

```
{
    "name": "DeleteActivity",
    "type": "Delete",
    "typeProperties": {
        "dataset": {
            "referenceName": "<dataset name>",
            "type": "DatasetReference"
        },
        "storeSettings": {
            "type": "<source type>",
            "recursive": true/false,
            "maxConcurrentConnections": <number>
        },
        "enableLogging": true/false,
        "logStorageSettings": {
            "linkedServiceName": {
                "referenceName": "<name of linked service>",
                "type": "LinkedServiceReference"
            },
            "path": "<path to save log file>"
        }
    }
}
```

Type properties

PROPERTY	DESCRIPTION	REQUIRED
dataset	Provides the dataset reference to determine which files or folder to be deleted	Yes
recursive	Indicates whether the files are deleted recursively from the subfolders or only from the specified folder.	No. The default is `false`.
maxConcurrentConnections	The number of the connections to connect to storage store concurrently for deleting folder or files.	No. The default is `1`.
enablelogging	Indicates whether you need to record the folder or file names that have been deleted. If true, you need to further provide a storage account to save the log file, so that you can track the behaviors of the Delete activity by reading the log file.	No
logStorageSettings	Only applicable when enablelogging = true. A group of storage properties that can be specified where you want to save the log file containing the folder or file names that have been deleted by the Delete activity.	No
linkedServiceName	Only applicable when enablelogging = true. The linked service of Azure Storage, Azure Data Lake Storage Gen1, or Azure Data Lake Storage Gen2 to store the log file that contains the folder or file names that have been deleted by the Delete activity. Be aware it must be configured with the same type of Integration Runtime from the one used by delete activity to delete files.	No
path	Only applicable when enablelogging = true. The path to save the log file in your storage account. If you do not provide a path, the service creates a container for you.	No

Monitoring

There are two places where you can see and monitor the results of the Delete activity:

- From the output of the Delete activity.
- From the log file.

Sample output of the Delete activity

```
{
  "datasetName": "AmazonS3",
  "type": "AmazonS3Object",
  "prefix": "test",
  "bucketName": "adf",
  "recursive": true,
  "isWildcardUsed": false,
  "maxConcurrentConnections": 2,
  "filesDeleted": 4,
  "logPath": "https://sample.blob.core.windows.net/mycontainer/5c698705-a6e2-40bf-911e-e0a927de3f07",
  "effectiveIntegrationRuntime": "MyAzureIR (West Central US)",
  "executionDuration": 650
}
```

Sample log file of the Delete activity

NAME	CATEGORY	STATUS	ERROR
test1/yyy.json	File	Deleted	
test2/hello789.txt	File	Deleted	
test2/test3/hello000.txt	File	Deleted	
test2/test3/zzz.json	File	Deleted	

Examples of using the Delete activity

Delete specific folders or files

The store has the following folder structure:

Root/
  Folder_A_1/
    1.txt
    2.txt
    3.csv
  Folder_A_2/
    4.txt
    5.csv
    Folder_B_1/
      6.txt
      7.csv
    Folder_B_2/
      8.txt

Now you are using the Delete activity to delete folder or files by the combination of different property value from the dataset and the Delete activity:

FOLDERPATH	FILENAME	RECURSIVE	OUTPUT

FOLDERPATH	FILENAME	RECURSIVE	OUTPUT
Root/ Folder_A_2	NULL	False	Root/ Folder_A_1/ 1.txt 2.txt 3.csv Folder_A_2/ ~~4.txt~~ ~~5.csv~~ Folder_B_1/ 6.txt 7.csv Folder_B_2/ 8.txt
Root/ Folder_A_2	NULL	True	Root/ Folder_A_1/ 1.txt 2.txt 3.csv ~~Folder_A_2/~~ ~~4.txt~~ ~~5.csv~~ ~~Folder_B_1/~~ ~~6.txt~~ ~~7.csv~~ ~~Folder_B_2/~~ ~~8.txt~~
Root/ Folder_A_2	*.txt	False	Root/ Folder_A_1/ 1.txt 2.txt 3.csv Folder_A_2/ ~~4.txt~~ 5.csv Folder_B_1/ 6.txt 7.csv Folder_B_2/ 8.txt
Root/ Folder_A_2	*.txt	True	Root/ Folder_A_1/ 1.txt 2.txt 3.csv Folder_A_2/ ~~4.txt~~ 5.csv Folder_B_1/ ~~6.txt~~ 7.csv Folder_B_2/ ~~8.txt~~

Periodically clean up the time-partitioned folder or files

You can create a pipeline to periodically clean up the time partitioned folder or files. For example, the folder structure is similar as: `/mycontainer/2018/12/14/*.csv`. You can leverage the service system variable from

schedule trigger to identify which folder or files should be deleted in each pipeline run.

Sample pipeline

```
{
    "name":"cleanup_time_partitioned_folder",
    "properties":{
        "activities":[
            {
                "name":"DeleteOneFolder",
                "type":"Delete",
                "dependsOn":[

                ],
                "policy":{
                    "timeout":"7.00:00:00",
                    "retry":0,
                    "retryIntervalInSeconds":30,
                    "secureOutput":false,
                    "secureInput":false
                },
                "userProperties":[

                ],
                "typeProperties":{
                    "dataset":{
                        "referenceName":"PartitionedFolder",
                        "type":"DatasetReference",
                        "parameters":{
                            "TriggerTime":{
                                "value":"@formatDateTime(pipeline().parameters.TriggerTime, 'yyyy/MM/dd')",
                                "type":"Expression"
                            }
                        }
                    },
                    "logStorageSettings":{
                        "linkedServiceName":{
                            "referenceName":"BloblinkedService",
                            "type":"LinkedServiceReference"
                        },
                        "path":"mycontainer/log"
                    },
                    "enableLogging":true,
                    "storeSettings":{
                        "type":"AzureBlobStorageReadSettings",
                        "recursive":true
                    }
                }
            }
        ],
        "parameters":{
            "TriggerTime":{
                "type":"string"
            }
        },
        "annotations":[

        ]
    }
}
```

Sample dataset

```
{
    "name":"PartitionedFolder",
    "properties":{
        "linkedServiceName":{
            "referenceName":"BloblinkedService",
            "type":"LinkedServiceReference"
        },
        "parameters":{
            "TriggerTime":{
                "type":"string"
            }
        },
        "annotations":[

        ],
        "type":"Binary",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "folderPath":{
                    "value":"@dataset().TriggerTime",
                    "type":"Expression"
                },
                "container":{
                    "value":"mycontainer",
                    "type":"Expression"
                }
            }
        }
    }
}
```

Sample trigger

```
{
    "name": "DailyTrigger",
    "properties": {
        "runtimeState": "Started",
        "pipelines": [
            {
                "pipelineReference": {
                    "referenceName": "cleanup_time_partitioned_folder",
                    "type": "PipelineReference"
                },
                "parameters": {
                    "TriggerTime": "@trigger().scheduledTime"
                }
            }
        ],
        "type": "ScheduleTrigger",
        "typeProperties": {
            "recurrence": {
                "frequency": "Day",
                "interval": 1,
                "startTime": "2018-12-13T00:00:00.000Z",
                "timeZone": "UTC",
                "schedule": {
                    "minutes": [
                        59
                    ],
                    "hours": [
                        23
                    ]
                }
            }
        }
    }
}
```

Clean up the expired files that were last modified before 2018.1.1

You can create a pipeline to clean up the old or expired files by leveraging file attribute filter: "LastModified" in dataset.

Sample pipeline

```
{
    "name":"CleanupExpiredFiles",
    "properties":{
        "activities":[
            {
                "name":"DeleteFilebyLastModified",
                "type":"Delete",
                "dependsOn":[

                ],
                "policy":{
                    "timeout":"7.00:00:00",
                    "retry":0,
                    "retryIntervalInSeconds":30,
                    "secureOutput":false,
                    "secureInput":false
                },
                "userProperties":[

                ],
                "typeProperties":{
                    "dataset":{
                        "referenceName":"BlobFilesLastModifiedBefore201811",
                        "type":"DatasetReference"
                    },
                    "logStorageSettings":{
                        "linkedServiceName":{
                            "referenceName":"BloblinkedService",
                            "type":"LinkedServiceReference"
                        },
                        "path":"mycontainer/log"
                    },
                    "enableLogging":true,
                    "storeSettings":{
                        "type":"AzureBlobStorageReadSettings",
                        "recursive":true,
                        "modifiedDatetimeEnd":"2018-01-01T00:00:00.000Z"
                    }
                }
            }
        ],
        "annotations":[

        ]
    }
}
```

Sample dataset

```
{
    "name":"BlobFilesLastModifiedBefore201811",
    "properties":{
        "linkedServiceName":{
            "referenceName":"BloblinkedService",
            "type":"LinkedServiceReference"
        },
        "annotations":[

        ],
        "type":"Binary",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "fileName":"*",
                "folderPath":"mydirectory",
                "container":"mycontainer"
            }
        }
    }
}
```

Move files by chaining the Copy activity and the Delete activity

You can move a file by using a Copy activity to copy a file and then a Delete activity to delete a file in a pipeline. When you want to move multiple files, you can use the GetMetadata activity + Filter activity + Foreach activity + Copy activity + Delete activity as in the following sample.

> **NOTE**
>
> If you want to move the entire folder by defining a dataset containing a folder path only, and then using a Copy activity and a Delete activity to reference to the same dataset representing a folder, you need to be very careful. You must ensure that there **will not** be any new files arriving into the folder between the copy operation and the delete operation. If new files arrive in the folder at the moment when your copy activity just completed the copy job but the Delete activity has not been started, then the Delete activity might delete the newly arriving file which has NOT been copied to the destination yet by deleting the entire folder.

Sample pipeline

```
{
    "name":"MoveFiles",
    "properties":{
        "activities":[
            {
                "name":"GetFileList",
                "type":"GetMetadata",
                "dependsOn":[

                ],
                "policy":{
                    "timeout":"7.00:00:00",
                    "retry":0,
                    "retryIntervalInSeconds":30,
                    "secureOutput":false,
                    "secureInput":false
                },
                "userProperties":[

                ],
                "typeProperties":{
                    "dataset":{
                        "referenceName":"OneSourceFolder",
                        "type":"DatasetReference",
```

```
                    "parameters":{
                        "Container":{
                            "value":"@pipeline().parameters.SourceStore_Location",
                            "type":"Expression"
                        },
                        "Directory":{
                            "value":"@pipeline().parameters.SourceStore_Directory",
                            "type":"Expression"
                        }
                    }
                },
                "fieldList":[
                    "childItems"
                ],
                "storeSettings":{
                    "type":"AzureBlobStorageReadSettings",
                    "recursive":true
                },
                "formatSettings":{
                    "type":"BinaryReadSettings"
                }
            }
        },
        {
            "name":"FilterFiles",
            "type":"Filter",
            "dependsOn":[
                {
                    "activity":"GetFileList",
                    "dependencyConditions":[
                        "Succeeded"
                    ]
                }
            ],
            "userProperties":[

            ],
            "typeProperties":{
                "items":{
                    "value":"@activity('GetFileList').output.childItems",

```

Sample datasets

Dataset used by GetMetadata activity to enumerate the file list.

```
{
    "name":"OneSourceFolder",
    "properties":{
        "linkedServiceName":{
            "referenceName":"AzureStorageLinkedService",
            "type":"LinkedServiceReference"
        },
        "parameters":{
            "Container":{
                "type":"String"
            },
            "Directory":{
                "type":"String"
            }
        },
        "annotations":[

        ],
        "type":"Binary",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "folderPath":{
                    "value":"@{dataset().Directory}",
                    "type":"Expression"
                },
                "container":{
                    "value":"@{dataset().Container}",
                    "type":"Expression"
                }
            }
        }
    }
}
```

Dataset for data source used by copy activity and the Delete activity.

```
{
    "name":"OneSourceFile",
    "properties":{
        "linkedServiceName":{
            "referenceName":"AzureStorageLinkedService",
            "type":"LinkedServiceReference"
        },
        "parameters":{
            "Container":{
                "type":"String"
            },
            "Directory":{
                "type":"String"
            },
            "filename":{
                "type":"string"
            }
        },
        "annotations":[

        ],
        "type":"Binary",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "fileName":{
                    "value":"@dataset().filename",
                    "type":"Expression"
                },
                "folderPath":{
                    "value":"@{dataset().Directory}",
                    "type":"Expression"
                },
                "container":{
                    "value":"@{dataset().Container}",
                    "type":"Expression"
                }
            }
        }
    }
}
```

Dataset for data destination used by copy activity.

```
{
    "name":"OneDestinationFile",
    "properties":{
        "linkedServiceName":{
            "referenceName":"AzureStorageLinkedService",
            "type":"LinkedServiceReference"
        },
        "parameters":{
            "Container":{
                "type":"String"
            },
            "Directory":{
                "type":"String"
            },
            "filename":{
                "type":"string"
            }
        },
        "annotations":[

        ],
        "type":"Binary",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "fileName":{
                    "value":"@dataset().filename",
                    "type":"Expression"
                },
                "folderPath":{
                    "value":"@{dataset().Directory}",
                    "type":"Expression"
                },
                "container":{
                    "value":"@{dataset().Container}",
                    "type":"Expression"
                }
            }
        }
    }
}
```

You can also get the template to move files from here.

Known limitation

- Delete activity does not support deleting list of folders described by wildcard.
- When using file attribute filter in delete activity: modifiedDatetimeStart and modifiedDatetimeEnd to select files to be deleted, make sure to set "wildcardFileName": "*" in delete activity as well.

Next steps

Learn more about moving files in Azure Data Factory and Synapse pipelines.

- Copy Data tool

Copy Data tool in Azure Data Factory and Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Copy Data tool eases and optimizes the process of ingesting data into a data lake, which is usually a first step in an end-to-end data integration scenario. It saves time, especially when you use the service to ingest data from a data source for the first time. Some of the benefits of using this tool are:

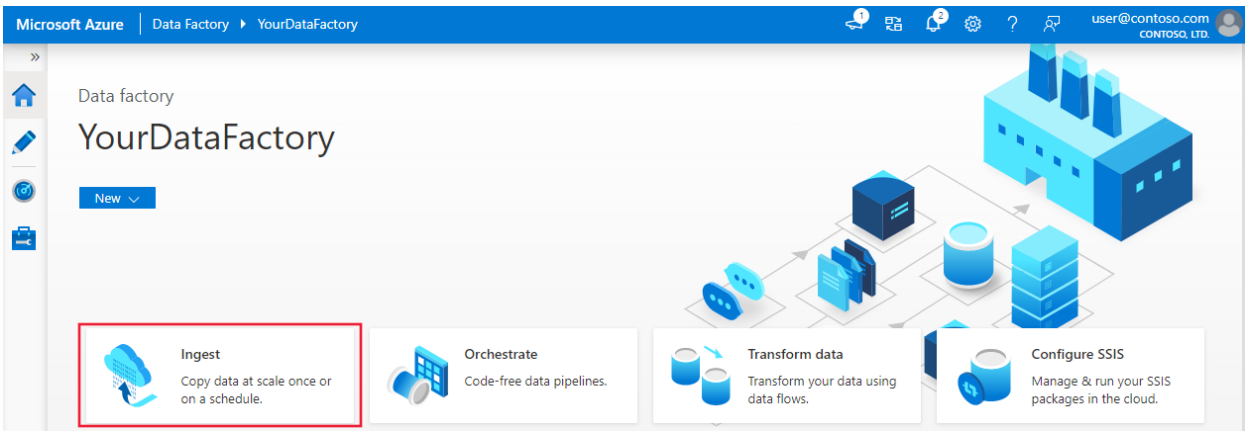
- When using the Copy Data tool, you do not need understand service definitions for linked services, datasets, pipelines, activities, and triggers.
- The flow of Copy Data tool is intuitive for loading data into a data lake. The tool automatically creates all the necessary resources to copy data from the selected source data store to the selected destination/sink data store.
- The Copy Data tool helps you validate the data that is being ingested at the time of authoring, which helps you avoid any potential errors at the beginning itself.
- If you need to implement complex business logic to load data into a data lake, you can still edit the resources created by the Copy Data tool by using the per-activity authoring in the UI.

The following table provides guidance on when to use the Copy Data tool vs. per-activity authoring in the UI:

COPY DATA TOOL	PER ACTIVITY (COPY ACTIVITY) AUTHORING
You want to easily build a data loading task without learning about entities (linked services, datasets, pipelines, etc.)	You want to implement complex and flexible logic for loading data into lake.
You want to quickly load a large number of data artifacts into a data lake.	You want to chain Copy activity with subsequent activities for cleansing or processing data.

To start the Copy Data tool, click the **Ingest** tile on the home page of your the Data Factory or Synapse Studio UI.

- Azure Data Factory
- Synapse Analytics



After you launch copy data tool, you will see two types of the tasks: one is **built-in copy task** and another is **metadata driven copy task**. The built-in copy task leads you to create a pipeline within five minutes to

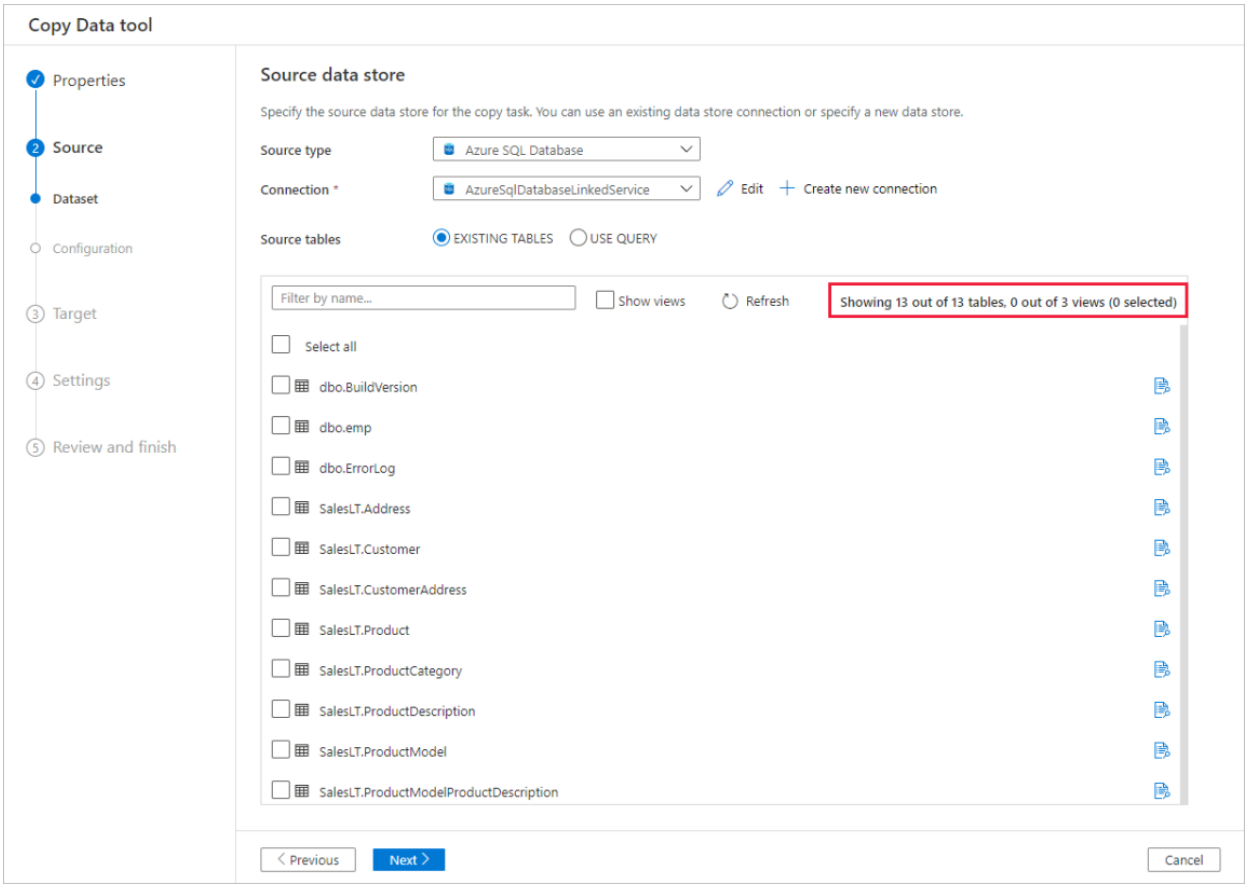
replicate data without learning about entities. The metadata driven copy task to ease your journey of creating parameterized pipelines and external control table in order to manage to copy large amounts of objects (for example, thousands of tables) at scale. You can see more details in metadata driven copy data.

Intuitive flow for loading data into a data lake

This tool allows you to easily move data from a wide variety of sources to destinations in minutes with an intuitive flow:

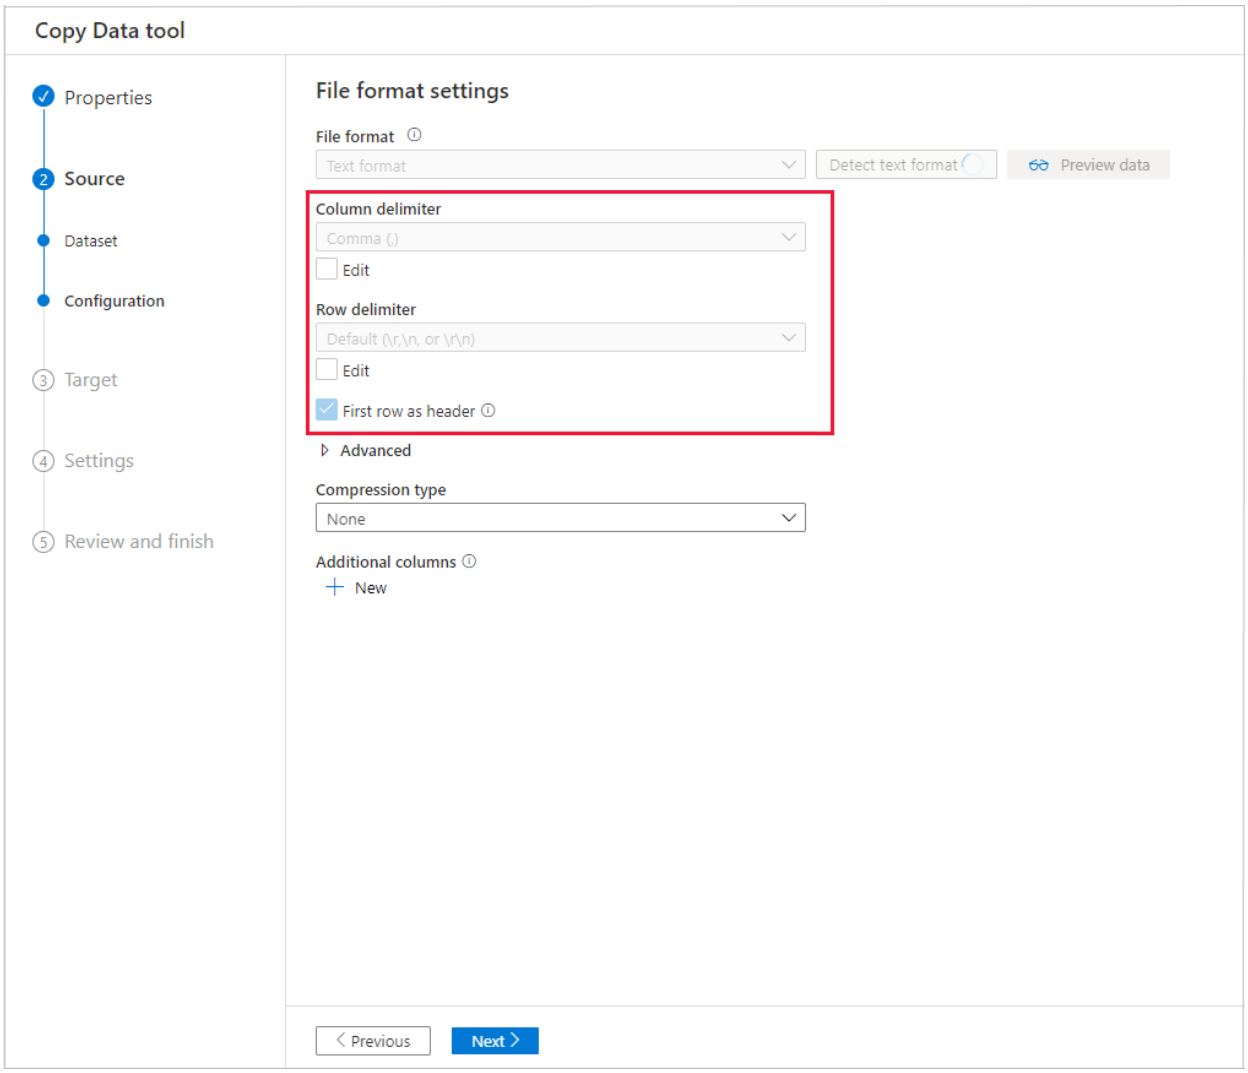
1. Configure settings for the **source**.
2. Configure settings for the **destination**.
3. Configure **advanced settings** for the copy operation such as column mapping, performance settings, and fault tolerance settings.
4. Specify a **schedule** for the data loading task.
5. Review **summary** of entities to be created.
6. **Edit** the pipeline to update settings for the copy activity as needed.

   The tool is designed with big data in mind from the start, with support for diverse data and object types. You can use it to move hundreds of folders, files, or tables. The tool supports automatic data preview, schema capture and automatic mapping, and data filtering as well.

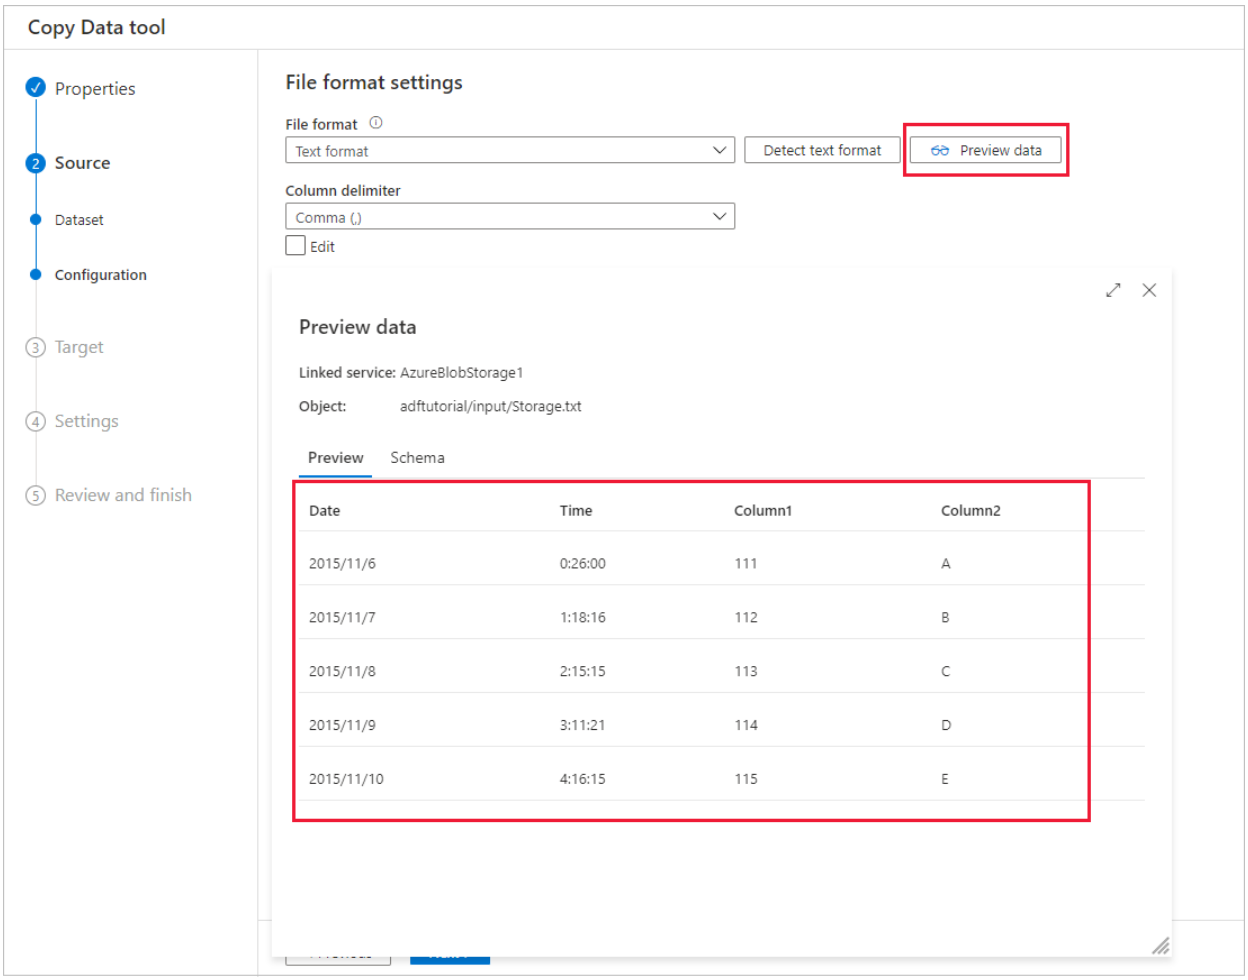


Automatic data preview

You can preview part of the data from the selected source data store, which allows you to validate the data that is being copied. In addition, if the source data is in a text file, the Copy Data tool parses the text file to automatically detect the row and column delimiters, and schema.



After the detection, select **Preview data**:



Schema capture and automatic mapping

The schema of data source may not be same as the schema of data destination in many cases. In this scenario, you need to map columns from the source schema to columns from the destination schema.

The Copy Data tool monitors and learns your behavior when you are mapping columns between source and destination stores. After you pick one or a few columns from source data store, and map them to the destination schema, the Copy Data tool starts to analyze the pattern for column pairs you picked from both sides. Then, it applies the same pattern to the rest of the columns. Therefore, you see all the columns have been mapped to the destination in a way you want just after several clicks. If you are not satisfied with the choice of column mapping provided by Copy Data tool, you can ignore it and continue with manually mapping the columns. Meanwhile, the Copy Data tool constantly learns and updates the pattern, and ultimately reaches the right pattern for the column mapping you want to achieve.

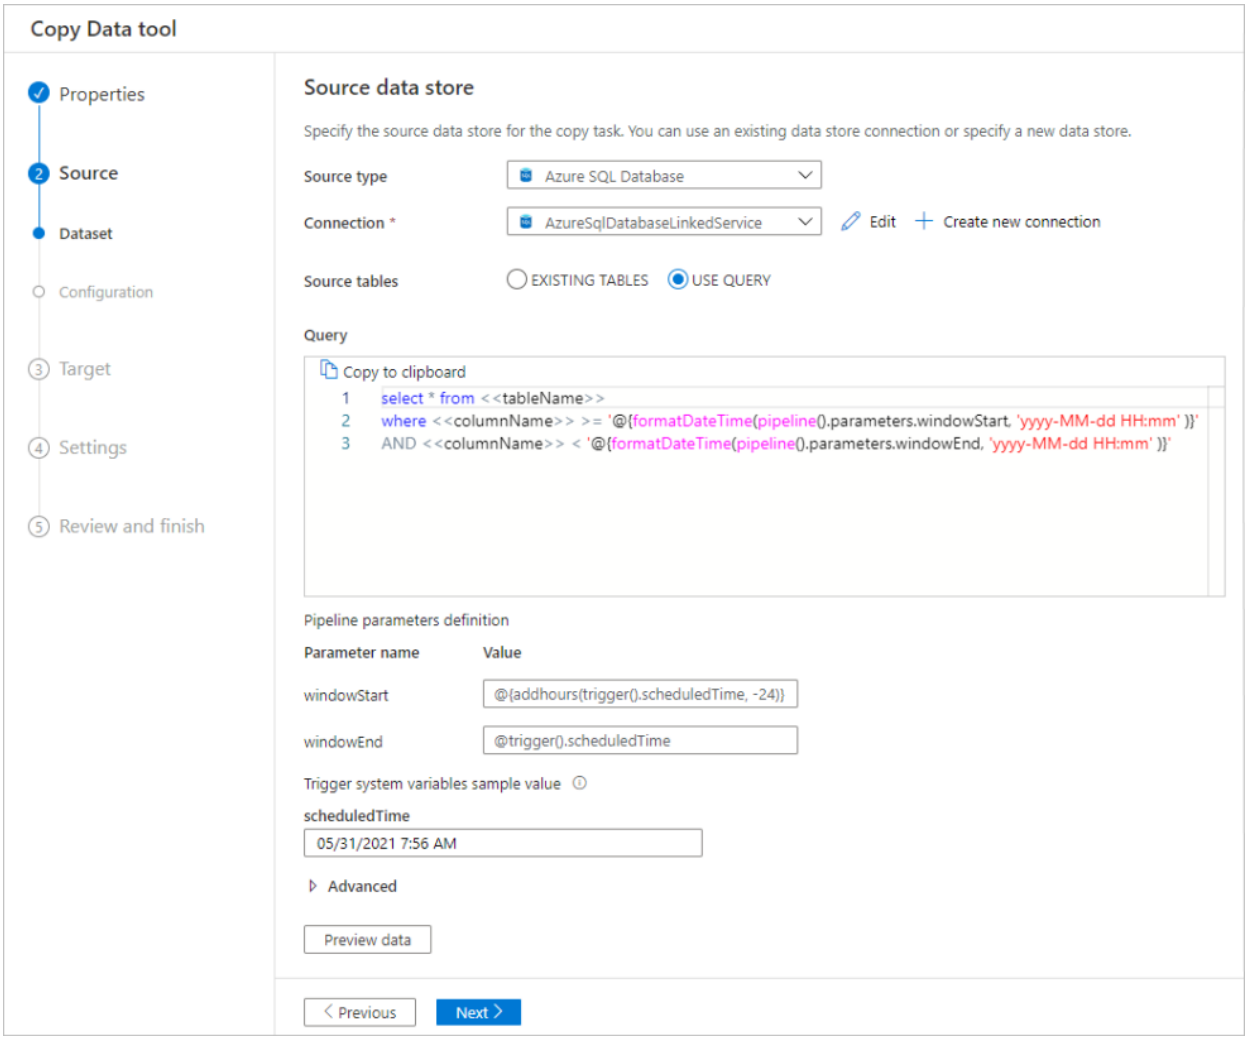
> **NOTE**
> When copying data from SQL Server or Azure SQL Database into Azure Synapse Analytics, if the table does not exist in the destination store, Copy Data tool supports creation of the table automatically by using the source schema.

Filter data

You can filter source data to select only the data that needs to be copied to the sink data store. Filtering reduces the volume of the data to be copied to the sink data store and therefore enhances the throughput of the copy operation. Copy Data tool provides a flexible way to filter data in a relational database by using the SQL query language, or files in an Azure blob folder.

Filter data in a database

The following screenshot shows a SQL query to filter the data.



Filter data in an Azure blob folder

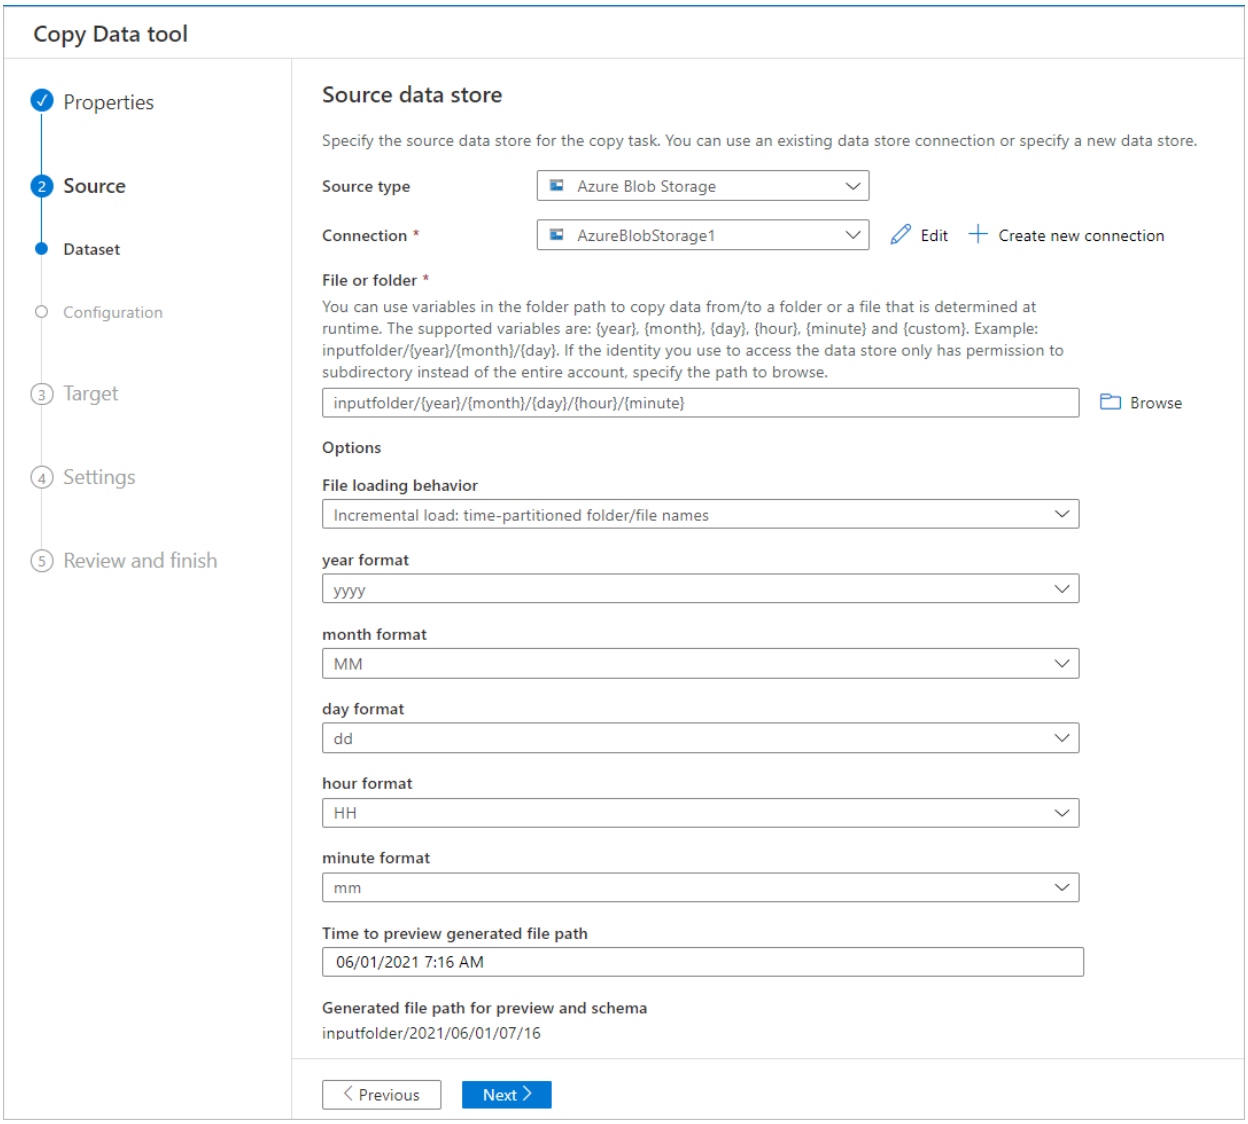
You can use variables in the folder path to copy data from a folder. The supported variables are: **{year}**, **{month}**, **{day}**, **{hour}**, and **{minute}**. For example: inputfolder/{year}/{month}/{day}.

Suppose that you have input folders in the following format:

```
2016/03/01/01
2016/03/01/02
2016/03/01/03
...
```

Click the **Browse** button for **File or folder**, browse to one of these folders (for example, 2016->03->01->02), and click **Choose**. You should see 2016/03/01/02 in the text box.

Then, replace **2016** with **{year}**, **03** with **{month}**, **01** with **{day}**, and **02** with **{hour}**, and press the **Tab** key. When you select **Incremental load: time-partitioned folder/file names** in the **File loading behavior** section and you select **Schedule** or **Tumbling window** on the **Properties** page, you should see drop-down lists to select the format for these four variables:



The Copy Data tool generates parameters with expressions, functions, and system variables that can be used to represent {year}, {month}, {day}, {hour}, and {minute} when creating pipeline.

Scheduling options

You can run the copy operation once or on a schedule (hourly, daily, and so on). These options can be used for the connectors across different environments, including on-premises, cloud, and local desktop.

A one-time copy operation enables data movement from a source to a destination only once. It applies to data of any size and any supported format. The scheduled copy allows you to copy data on a recurrence that you specify. You can use rich settings (like retry, timeout, and alerts) to configure the scheduled copy.

Supported file formats and compression codecs by copy activity in Azure Data Factory and Azure Synapse pipelines

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article applies to the following connectors: Amazon S3, Amazon S3 Compatible Storage, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, Oracle Cloud Storage and SFTP.

Azure Data Factory supports the following file formats. Refer to each article for format-based settings.

- Avro format
- Binary format
- Delimited text format
- Excel format
- JSON format
- ORC format
- Parquet format
- XML format

You can use the Copy activity to copy files as-is between two file-based data stores, in which case the data is copied efficiently without any serialization or deserialization.

In addition, you can also parse or generate files of a given format. For example, you can perform the following:

- Copy data from a SQL Server database and write to Azure Data Lake Storage Gen2 in Parquet format.
- Copy files in text (CSV) format from an on-premises file system and write to Azure Blob storage in Avro format.
- Copy zipped files from an on-premises file system, decompress them on-the-fly, and write extracted files to Azure Data Lake Storage Gen2.
- Copy data in Gzip compressed-text (CSV) format from Azure Blob storage and write it to Azure SQL Database.
- Many more activities that require serialization/deserialization or compression/decompression.

Copy activity performance and scalability guide

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Sometimes you want to perform a large-scale data migration from data lake or enterprise data warehouse (EDW), to Azure. Other times you want to ingest large amounts of data, from different sources into Azure, for big data analytics. In each case, it is critical to achieve optimal performance and scalability.

Azure Data Factory and Azure Synapse Analytics pipelines provide a mechanism to ingest data, with the following advantages:

- Handles large amounts of data
- Is highly performant
- Is cost-effective

These advantages are an excellent fit for data engineers who want to build scalable data ingestion pipelines that are highly performant.

After reading this article, you will be able to answer the following questions:

- What level of performance and scalability can I achieve using copy activity for data migration and data ingestion scenarios?
- What steps should I take to tune the performance of the copy activity?
- What performance optimizations can I utilize for a single copy activity run?
- What other external factors to consider when optimizing copy performance?

> **NOTE**
> If you aren't familiar with the copy activity in general, see the copy activity overview before you read this article.

Copy performance and scalability achievable using Azure Data Factory and Synapse pipelines

Azure Data Factory and Synapse pipelines offer a serverless architecture that allows parallelism at different levels.

This architecture allows you to develop pipelines that maximize data movement throughput for your environment. These pipelines fully utilize the following resources:

- Network bandwidth between the source and destination data stores
- Source or destination data store input/output operations per second (IOPS) and bandwidth

This full utilization means you can estimate the overall throughput by measuring the minimum throughput available with the following resources:

- Source data store
- Destination data store
- Network bandwidth in between the source and destination data stores

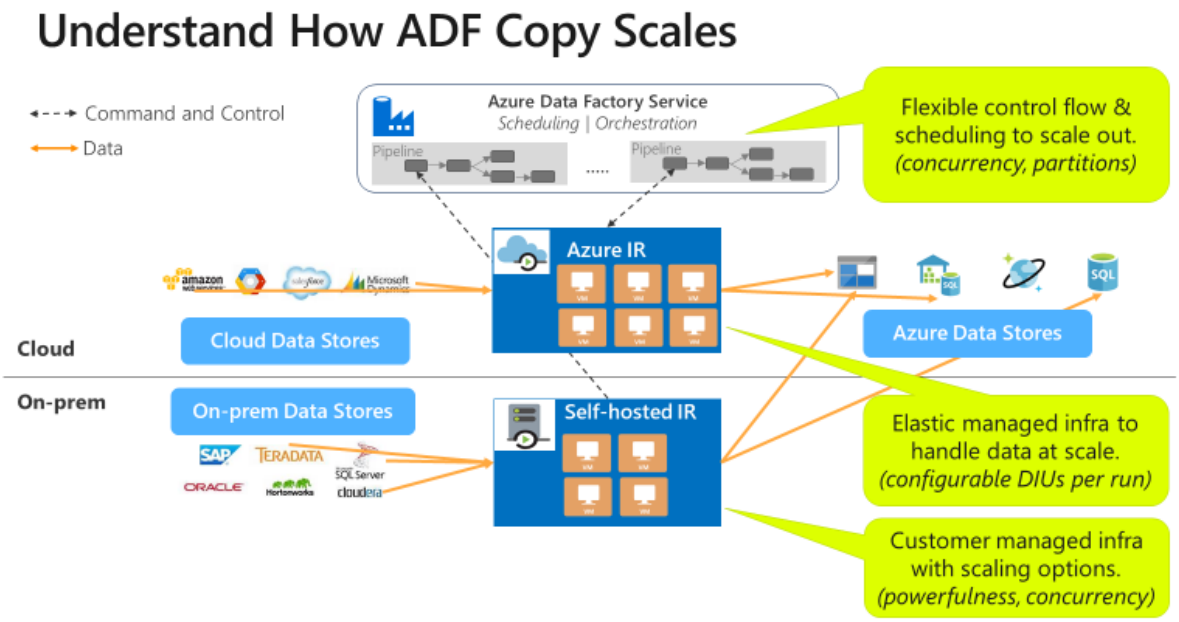
The table below shows the calculation of data movement duration. The duration in each cell is calculated based

on a given network and data store bandwidth and a given data payload size.

> **NOTE**
>
> The duration provided below are meant to represent achievable performance in an end-to-end data integration solution by using one or more performance optimization techniques described in Copy performance optimization features, including using ForEach to partition and spawn off multiple concurrent copy activities. We recommend you to follow steps laid out in Performance tuning steps to optimize copy performance for your specific dataset and system configuration. You should use the numbers obtained in your performance tuning tests for production deployment planning, capacity planning, and billing projection.

DATA SIZE / BANDWIDTH	50 MBPS	100 MBPS	500 MBPS	1 GBPS	5 GBPS	10 GBPS	50 GBPS
1 GB	2.7 min	1.4 min	0.3 min	0.1 min	0.03 min	0.01 min	0.0 min
10 GB	27.3 min	13.7 min	2.7 min	1.3 min	0.3 min	0.1 min	0.03 min
100 GB	4.6 hrs	2.3 hrs	0.5 hrs	0.2 hrs	0.05 hrs	0.02 hrs	0.0 hrs
1 TB	46.6 hrs	23.3 hrs	4.7 hrs	2.3 hrs	0.5 hrs	0.2 hrs	0.05 hrs
10 TB	19.4 days	9.7 days	1.9 days	0.9 days	0.2 days	0.1 days	0.02 days
100 TB	194.2 days	97.1 days	19.4 days	9.7 days	1.9 days	1 day	0.2 days
1 PB	64.7 mo	32.4 mo	6.5 mo	3.2 mo	0.6 mo	0.3 mo	0.06 mo
10 PB	647.3 mo	323.6 mo	64.7 mo	31.6 mo	6.5 mo	3.2 mo	0.6 mo

Copy is scalable at different levels:



- Control flow can start multiple copy activities in parallel, for example using For Each loop.
- A single copy activity can take advantage of scalable compute resources.
  - When using Azure integration runtime (IR), you can specify up to 256 data integration units (DIUs) for each copy activity, in a serverless manner.
  - When using self-hosted IR, you can take either of the following approaches:
    - Manually scale up the machine.
    - Scale out to multiple machines (up to 4 nodes), and a single copy activity will partition its file set across all nodes.
- A single copy activity reads from and writes to the data store using multiple threads in parallel.

Performance tuning steps

Take the following steps to tune the performance of your service with the copy activity:

1. **Pick up a test dataset and establish a baseline.**

   During development, test your pipeline by using the copy activity against a representative data sample. The dataset you choose should represent your typical data patterns along the following attributes:

   - Folder structure
   - File pattern
   - Data schema

   And your dataset should be big enough to evaluate copy performance. A good size takes at least 10 minutes for copy activity to complete. Collect execution details and performance characteristics following copy activity monitoring.

2. **How to maximize performance of a single copy activity**:

   We recommend you to first maximize performance using a single copy activity.

   - **If the copy activity is being executed on an *Azure* integration runtime:**

     Start with default values for Data Integration Units (DIU) and parallel copy settings.

   - **If the copy activity is being executed on a *self-hosted* integration runtime:**

We recommend that you use a dedicated machine to host IR. The machine should be separate from the server hosting the data store. Start with default values for parallel copy setting and using a single node for the self-hosted IR.

Conduct a performance test run. Take a note of the performance achieved. Include the actual values used, such as DIUs and parallel copies. Refer to copy activity monitoring on how to collect run results and performance settings used. Learn how to troubleshoot copy activity performance to identify and resolve the bottleneck.

Iterate to conduct additional performance test runs following the troubleshooting and tuning guidance. Once single copy activity runs cannot achieve better throughput, consider whether to maximize aggregate throughput by running multiple copies concurrently. This option is discussed in the next numbered bullet.

3. **How to maximize aggregate throughput by running multiple copies concurrently:**

   By now you have maximized the performance of a single copy activity. If you have not yet achieved the throughput upper limits of your environment, you can run multiple copy activities in parallel. You can run in parallel by using control flow constructs. One such construct is the For Each loop. For more information, see the following articles about solution templates:

   - Copy files from multiple containers
   - Migrate data from Amazon S3 to ADLS Gen2
   - Bulk copy with a control table

4. **Expand the configuration to your entire dataset.**

   When you're satisfied with the execution results and performance, you can expand the definition and pipeline to cover your entire dataset.

Troubleshoot copy activity performance

Follow the Performance tuning steps to plan and conduct performance test for your scenario. And learn how to troubleshoot each copy activity run's performance issue from Troubleshoot copy activity performance.

Copy performance optimization features

The service provides the following performance optimization features:

- Data Integration Units
- Self-hosted integration runtime scalability
- Parallel copy
- Staged copy

Data Integration Units

A Data Integration Unit (DIU) is a measure that represents the power of a single unit in Azure Data Factory and Synapse pipelines. Power is a combination of CPU, memory, and network resource allocation. DIU only applies to Azure integration runtime. DIU does not apply to self-hosted integration runtime. Learn more here.

Self-hosted integration runtime scalability

You might want to host an increasing concurrent workload. Or you might want to achieve higher performance in your present workload level. You can enhance the scale of processing by the following approaches:

- You can scale *up* the self-hosted IR, by increasing the number of concurrent jobs that can run on a node. Scale up works only if the processor and memory of the node are being less than fully utilized.
- You can scale *out* the self-hosted IR, by adding more nodes (machines).

For more information, see:

- Copy activity performance optimization features: Self-hosted integration runtime scalability
- Create and configure a self-hosted integration runtime: Scale considerations

Parallel copy

You can set the `parallelCopies` property to indicate the parallelism you want the copy activity to use. Think of this property as the maximum number of threads within the copy activity. The threads operate in parallel. The threads either read from your source, or write to your sink data stores. Learn more.

Staged copy

A data copy operation can send the data *directly* to the sink data store. Alternatively, you can choose to use Blob storage as an *interim staging* store. Learn more.

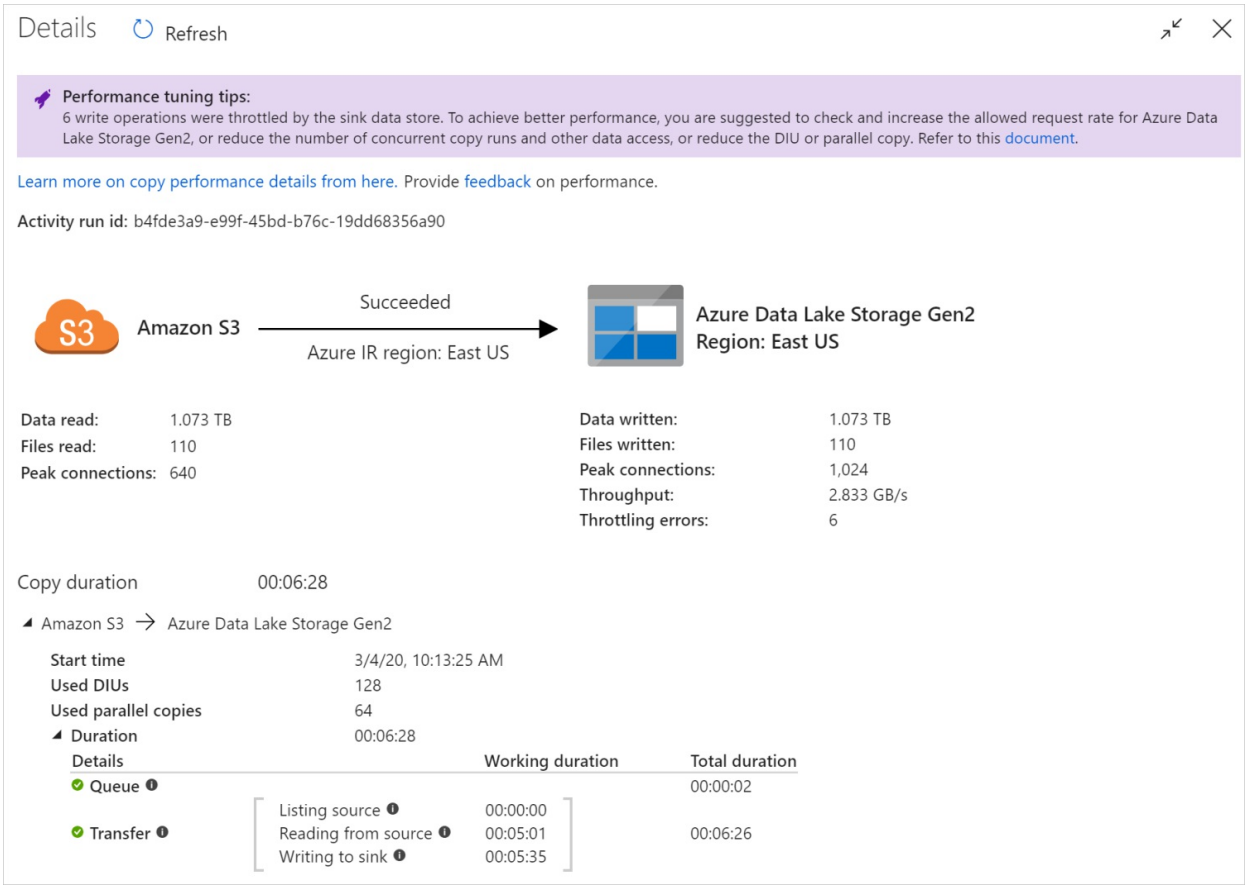
Troubleshoot copy activity performance

8/19/2022 • 15 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines how to troubleshoot copy activity performance issue in Azure Data Factory.

After you run a copy activity, you can collect the run result and performance statistics in copy activity monitoring view. The following is an example.



Performance tuning tips

In some scenarios, when you run a copy activity, you'll see **"Performance tuning tips"** at the top as shown in the above example. The tips tell you the bottleneck identified by the service for this particular copy run, along with suggestion on how to boost copy throughput. Try making the recommended change, then run the copy again.

As a reference, currently the performance tuning tips provide suggestions for the following cases:

CATEGORY	PERFORMANCE TUNING TIPS
Data store specific	Loading data into **Azure Synapse Analytics**: suggest using PolyBase or COPY statement if it's not used.
	Copying data from/to **Azure SQL Database**: when DTU is under high utilization, suggest upgrading to higher tier.

CATEGORY	PERFORMANCE TUNING TIPS
	Copying data from/to **Azure Cosmos DB**: when RU is under high utilization, suggest upgrading to larger RU.
	Copying data from **SAP Table**: when copying large amount of data, suggest leveraging SAP connector's partition option to enable parallel load and increase the max partition number.
	Ingesting data from **Amazon Redshift**: suggest using UNLOAD if it's not used.
Data store throttling	If a number of read/write operations are throttled by the data store during copy, suggest checking and increase the allowed request rate for the data store, or reduce the concurrent workload.
Integration runtime	If you use a **Self-hosted Integration Runtime (IR)** and copy activity waits long in the queue until the IR has available resource to execute, suggest scaling out/up your IR.
	If you use an **Azure Integration Runtime** that is in a not optimal region resulting in slow read/write, suggest configuring to use an IR in another region.
Fault tolerance	If you configure fault tolerance and skipping incompatible rows results in slow performance, suggest ensuring source and sink data are compatible.
Staged copy	If staged copy is configured but not helpful for your source-sink pair, suggest removing it.
Resume	When copy activity is resumed from last failure point but you happen to change the DIU setting after the original run, note the new DIU setting doesn't take effect.

Understand copy activity execution details

The execution details and durations at the bottom of the copy activity monitoring view describes the key stages your copy activity goes through (see example at the beginning of this article), which is especially useful for troubleshooting the copy performance. The bottleneck of your copy run is the one with the longest duration. Refer to the following table on each stage's definition, and learn how to Troubleshoot copy activity on Azure IR and Troubleshoot copy activity on Self-hosted IR with such info.

STAGE	DESCRIPTION
Queue	The elapsed time until the copy activity actually starts on the integration runtime.
Pre-copy script	The elapsed time between copy activity starting on IR and copy activity finishing executing the pre-copy script in sink data store. Apply when you configure the pre-copy script for database sinks, e.g. when writing data into Azure SQL Database do clean up before copy new data.

STAGE	DESCRIPTION
Transfer	The elapsed time between the end of the previous step and the IR transferring all the data from source to sink. Note the sub-steps under transfer run in parallel, and some operations are not shown now e.g. parsing/generating file format. - **Time to first byte:** The time elapsed between the end of the previous step and the time when the IR receives the first byte from the source data store. Applies to non-file-based sources. - **Listing source:** The amount of time spent on enumerating source files or data partitions. The latter applies when you configure partition options for database sources, e.g. when copy data from databases like Oracle/SAP HANA/Teradata/Netezza/etc. -**Reading from source:** The amount of time spent on retrieving data from source data store. - **Writing to sink:** The amount of time spent on writing data to sink data store. Note some connectors do not have this metric at the moment, including Azure Cognitive Search, Azure Data Explorer, Azure Table storage, Oracle, SQL Server, Common Data Service, Dynamics 365, Dynamics CRM, Salesforce/Salesforce Service Cloud.

Troubleshoot copy activity on Azure IR

Follow the Performance tuning steps to plan and conduct performance test for your scenario.

When the copy activity performance doesn't meet your expectation, to troubleshoot single copy activity running on Azure Integration Runtime, if you see performance tuning tips shown up in the copy monitoring view, apply the suggestion and try again. Otherwise, understand copy activity execution details, check which stage has the **longest** duration, and apply the guidance below to boost copy performance:

- **"Pre-copy script" experienced long duration:** it means the pre-copy script running on sink database takes long to finish. Tune the specified pre-copy script logic to enhance the performance. If you need further help on improving the script, contact your database team.
- **"Transfer - Time to first byte" experienced long working duration**: it means your source query takes long to return any data. Check and optimize the query or server. If you need further help, contact your data store team.
- **"Transfer - Listing source" experienced long working duration**: it means enumerating source files or source database data partitions is slow.
  - When copying data from file-based source, if you use **wildcard filter** on folder path or file name (`wildcardFolderPath` or `wildcardFileName`), or use **file last modified time filter** (`modifiedDatetimeStart` or `modifiedDatetimeEnd`), note such filter would result in copy activity listing all the files under the specified folder to client side then apply the filter. Such file enumeration could become the bottleneck especially when only small set of files met the filter rule.
    - Check whether you can copy files based on datetime partitioned file path or name. Such way doesn't bring burden on listing source side.
    - Check if you can use data store's native filter instead, specifically "**prefix**" for Amazon S3/Azure Blob storage/Azure Files and "**listAfter/listBefore**" for ADLS Gen1. Those filters are data store server-side filter and would have much better performance.

    - Consider to split single large data set into several smaller data sets, and let those copy jobs run concurrently each tackles portion of data. You can do this with Lookup/GetMetadata + ForEach + Copy. Refer to Copy files from multiple containers or Migrate data from Amazon S3 to ADLS Gen2 solution templates as general example.
  - Check if the service reports any throttling error on source or if your data store is under high utilization state. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
  - Use Azure IR in the same or close to your source data store region.
- **"Transfer - reading from source" experienced long working duration**:
  - Adopt connector-specific data loading best practice if applies. For example, when copying data from Amazon Redshift, configure to use Redshift UNLOAD.
  - Check if the service reports any throttling error on source or if your data store is under high utilization. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
  - Check your copy source and sink pattern:
    - If your copy pattern supports larger than 4 Data Integration Units (DIUs) - refer to this section on details, generally you can try increasing DIUs to get better performance.
    - Otherwise, consider to split single large data set into several smaller data sets, and let those copy jobs run concurrently each tackles portion of data. You can do this with Lookup/GetMetadata + ForEach + Copy. Refer to Copy files from multiple containers, Migrate data from Amazon S3 to ADLS Gen2, or Bulk copy with a control table solution templates as general example.
  - Use Azure IR in the same or close to your source data store region.
- **"Transfer - writing to sink" experienced long working duration**:
  - Adopt connector-specific data loading best practice if applies. For example, when copying data into Azure Synapse Analytics, use PolyBase or COPY statement.
  - Check if the service reports any throttling error on sink or if your data store is under high utilization. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
  - Check your copy source and sink pattern:
    - If your copy pattern supports larger than 4 Data Integration Units (DIUs) - refer to this section on details, generally you can try increasing DIUs to get better performance.
    - Otherwise, gradually tune the parallel copies, note that too many parallel copies may even hurt the performance.
  - Use Azure IR in the same or close to your sink data store region.

Troubleshoot copy activity on Self-hosted IR

Follow the Performance tuning steps to plan and conduct performance test for your scenario.

When the copy performance doesn't meet your expectation, to troubleshoot single copy activity running on Azure Integration Runtime, if you see performance tuning tips shown up in the copy monitoring view, apply the suggestion and try again. Otherwise, understand copy activity execution details, check which stage has the **longest** duration, and apply the guidance below to boost copy performance:

- **"Queue" experienced long duration:** it means the copy activity waits long in the queue until your Self-hosted IR has resource to execute. Check the IR capacity and usage, and scale up or out according to your workload.
- **"Transfer - Time to first byte" experienced long working duration**: it means your source query takes long to return any data. Check and optimize the query or server. If you need further help, contact your data store team.
- **"Transfer - Listing source" experienced long working duration**: it means enumerating source files or source database data partitions is slow.
    - Check if the Self-hosted IR machine has low latency connecting to source data store. If your source is in Azure, you can use this tool to check the latency from the Self-hosted IR machine to the Azure region, the less the better.
    - When copying data from file-based source, if you use **wildcard filter** on folder path or file name (`wildcardFolderPath` or `wildcardFileName`), or use **file last modified time filter** (`modifiedDatetimeStart` or `modifiedDatetimeEnd`), note such filter would result in copy activity listing all the files under the specified folder to client side then apply the filter. Such file enumeration could become the bottleneck especially when only small set of files met the filter rule.
        - Check whether you can copy files based on datetime partitioned file path or name. Such way doesn't bring burden on listing source side.
        - Check if you can use data store's native filter instead, specifically "**prefix**" for Amazon S3/Azure Blob storage/Azure Files and "**listAfter/listBefore**" for ADLS Gen1. Those filters are data store server-side filter and would have much better performance.
        - Consider to split single large data set into several smaller data sets, and let those copy jobs run concurrently each tackles portion of data. You can do this with Lookup/GetMetadata + ForEach + Copy. Refer to Copy files from multiple containers or Migrate data from Amazon S3 to ADLS Gen2 solution templates as general example.
    - Check if the service reports any throttling error on source or if your data store is under high utilization state. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
- **"Transfer - reading from source" experienced long working duration**:
    - Check if the Self-hosted IR machine has low latency connecting to source data store. If your source is in Azure, you can use this tool to check the latency from the Self-hosted IR machine to the Azure regions, the less the better.
    - Check if the Self-hosted IR machine has enough inbound bandwidth to read and transfer the data efficiently. If your source data store is in Azure, you can use this tool to check the download speed.
    - Check the Self-hosted IR's CPU and memory usage trend in Azure portal -> your data factory or Synapse workspace -> overview page. Consider to scale up/out IR if the CPU usage is high or available memory is low.
    - Adopt connector-specific data loading best practice if applies. For example:
        - When copying data from Oracle, Netezza, Teradata, SAP HANA, SAP Table, and SAP Open Hub), enable data partition options to copy data in parallel.
        - When copying data from HDFS, configure to use DistCp.
        - When copying data from Amazon Redshift, configure to use Redshift UNLOAD.

- Check if the service reports any throttling error on source or if your data store is under high utilization. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
- Check your copy source and sink pattern:
  - If you copy data from partition-option-enabled data stores, consider to gradually tune the parallel copies, note that too many parallel copies may even hurt the performance.
  - Otherwise, consider to split single large data set into several smaller data sets, and let those copy jobs run concurrently each tackles portion of data. You can do this with Lookup/GetMetadata + ForEach + Copy. Refer to Copy files from multiple containers, Migrate data from Amazon S3 to ADLS Gen2, or Bulk copy with a control table solution templates as general example.

- **"Transfer - writing to sink" experienced long working duration**:
  - Adopt connector-specific data loading best practice if applies. For example, when copying data into Azure Synapse Analytics, use PolyBase or COPY statement.
  - Check if the Self-hosted IR machine has low latency connecting to sink data store. If your sink is in Azure, you can use this tool to check the latency from the Self-hosted IR machine to the Azure region, the less the better.
  - Check if the Self-hosted IR machine has enough outbound bandwidth to transfer and write the data efficiently. If your sink data store is in Azure, you can use this tool to check the upload speed.
  - Check if the Self-hosted IR's CPU and memory usage trend in Azure portal -> your data factory or Synapse workspace -> overview page. Consider to scale up/out IR if the CPU usage is high or available memory is low.
  - Check if the service reports any throttling error on sink or if your data store is under high utilization. If so, either reduce your workloads on the data store, or try contacting your data store administrator to increase the throttling limit or available resource.
  - Consider to gradually tune the parallel copies, note that too many parallel copies may even hurt the performance.

Connector and IR performance

This section explores some performance troubleshooting guides for particular connector type or integration runtime.

Activity execution time varies using Azure IR vs Azure VNet IR

Activity execution time varies when the dataset is based on different Integration Runtime.

- **Symptoms**: Simply toggling the Linked Service dropdown in the dataset performs the same pipeline activities, but has drastically different run-times. When the dataset is based on the Managed Virtual Network Integration Runtime, it takes more time on average than the run when based on the Default Integration Runtime.
- **Cause**: Checking the details of pipeline runs, you can see that the slow pipeline is running on Managed VNet (Virtual Network) IR while the normal one is running on Azure IR. By design, Managed VNet IR takes longer queue time than Azure IR as we are not reserving one compute node per service instance, so there is a warm up for each copy activity to start, and it occurs primarily on VNet join rather than Azure IR.

Low performance when loading data into Azure SQL Database

- **Symptoms**: Copying data in to Azure SQL Database turns to be slow.
- **Cause**: The root cause of the issue is mostly triggered by the bottleneck of Azure SQL Database side. Following are some possible causes:
  - Azure SQL Database tier is not high enough.
  - Azure SQL Database DTU usage is close to 100%. You can monitor the performance and consider to upgrade the Azure SQL Database tier.
  - Indexes are not set properly. Remove all the indexes before data load and recreate them after load complete.
  - WriteBatchSize is not large enough to fit schema row size. Try to enlarge the property for the issue.
  - Instead of bulk insert, stored procedure is being used, which is expected to have worse performance.

Timeout or slow performance when parsing large Excel file

- **Symptoms**:
  - When you create Excel dataset and import schema from connection/store, preview data, list, or refresh worksheets, you may hit timeout error if the excel file is large in size.
  - When you use copy activity to copy data from large Excel file (>= 100 MB) into other data store, you may experience slow performance or OOM issue.
- **Cause**:
  - For operations like importing schema, previewing data, and listing worksheets on excel dataset, the timeout is 100 s and static. For large Excel file, these operations may not finish within the timeout value.
  - The copy activity reads the whole Excel file into memory then locate the specified worksheet and cells to read data. This behavior is due to the underlying SDK the service uses.
- **Resolution**:
  - For importing schema, you can generate a smaller sample file, which is a subset of original file, and choose "import schema from sample file" instead of "import schema from connection/store".
  - For listing worksheet, in the worksheet dropdown, you can click "Edit" and input the sheet name/index instead.
  - To copy large excel file (>100 MB) into other store, you can use Data Flow Excel source which sport streaming read and perform better.

Copy activity performance optimization features

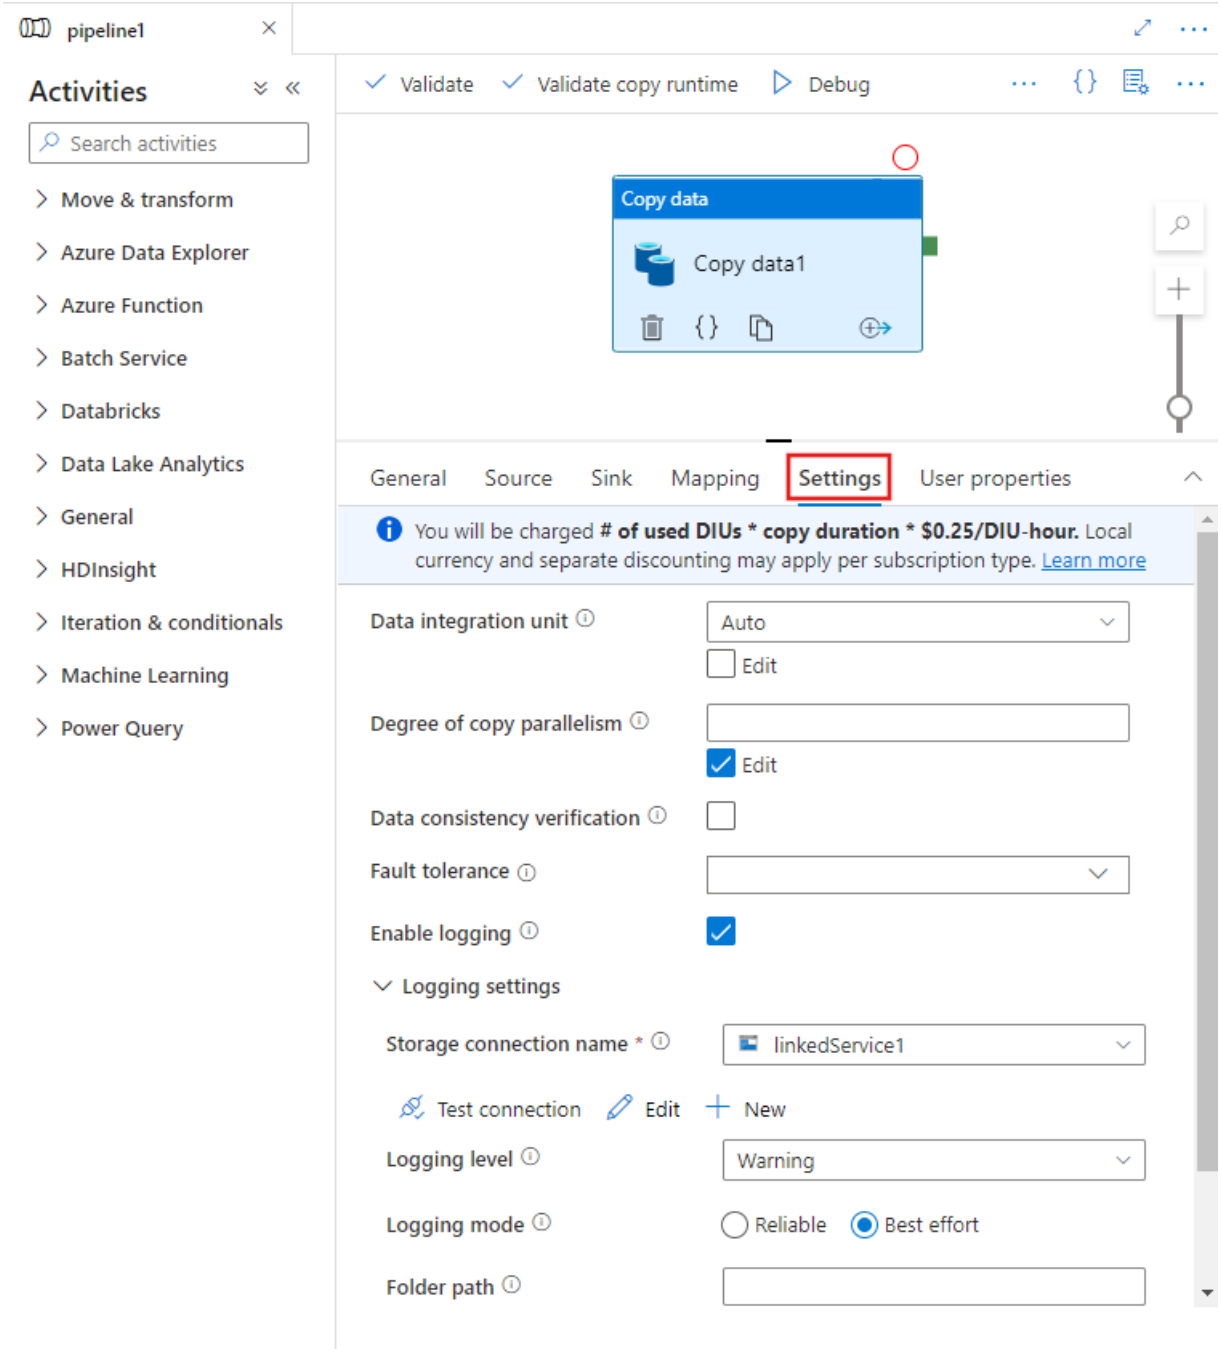
8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article outlines the copy activity performance optimization features that you can leverage in Azure Data Factory and Synapse pipelines.

Configuring performance features with UI

When you select a Copy activity on the pipeline editor canvas and choose the Settings tab in the activity configuration area below the canvas, you will see options to configure all of the performance features detailed below.



Data Integration Units

A Data Integration Unit is a measure that represents the power (a combination of CPU, memory, and network resource allocation) of a single unit within the service. Data Integration Unit only applies to Azure integration runtime, but not self-hosted integration runtime.

The allowed DIUs to empower a copy activity run is **between 2 and 256**. If not specified or you choose "Auto" on the UI, the service dynamically applies the optimal DIU setting based on your source-sink pair and data pattern. The following table lists the supported DIU ranges and default behavior in different copy scenarios:

COPY SCENARIO	SUPPORTED DIU RANGE	DEFAULT DIUS DETERMINED BY SERVICE
Between file stores	- **Copy from or to single file**: 2-4 - **Copy from and to multiple files**: 2-256 depending on the number and size of the files For example, if you copy data from a folder with 4 large files and choose to preserve hierarchy, the max effective DIU is 16; when you choose to merge file, the max effective DIU is 4.	Between 4 and 32 depending on the number and size of the files
From file store to non-file store	- **Copy from single file**: 2-4 - **Copy from multiple files**: 2-256 depending on the number and size of the files For example, if you copy data from a folder with 4 large files, the max effective DIU is 16.	- **Copy into Azure SQL Database or Azure Cosmos DB**: between 4 and 16 depending on the sink tier (DTUs/RUs) and source file pattern - **Copy into Azure Synapse Analytics** using PolyBase or COPY statement: 2 - Other scenario: 4
From non-file store to file store	- **Copy from partition-option-enabled data stores** (including Azure Database for PostgreSQL, Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, Oracle, Netezza, SQL Server, and Teradata): 2-256 when writing to a folder, and 2-4 when writing to one single file. Note per source data partition can use up to 4 DIUs. - **Other scenarios**: 2-4	- **Copy from REST or HTTP**: 1 - **Copy from Amazon Redshift** using UNLOAD: 2 - **Other scenario**: 4
Between non-file stores	- **Copy from partition-option-enabled data stores** (including Azure Database for PostgreSQL, Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, Oracle, Netezza, SQL Server, and Teradata): 2-256 when writing to a folder, and 2-4 when writing to one single file. Note per source data partition can use up to 4 DIUs. - **Other scenarios**: 2-4	- **Copy from REST or HTTP**: 1 - **Other scenario**: 4

You can see the DIUs used for each copy run in the copy activity monitoring view or activity output. For more information, see Copy activity monitoring. To override this default, specify a value for the `dataIntegrationUnits` property as follows. The *actual number of DIUs* that the copy operation uses at run time is equal to or less than

the configured value, depending on your data pattern.

You will be charged **# of used DIUs * copy duration * unit price/DIU-hour**. See the current prices here. Local currency and separate discounting may apply per subscription type.

Example:

```
"activities":[
    {
        "name": "Sample copy activity",
        "type": "Copy",
        "inputs": [...],
        "outputs": [...],
        "typeProperties": {
            "source": {
                "type": "BlobSource",
            },
            "sink": {
                "type": "AzureDataLakeStoreSink"
            },
            "dataIntegrationUnits": 128
        }
    }
]
```

Self-hosted integration runtime scalability

If you would like to achieve higher throughput, you can either scale up or scale out the Self-hosted IR:

- If the CPU and available memory on the Self-hosted IR node are not fully utilized, but the execution of concurrent jobs is reaching the limit, you should scale up by increasing the number of concurrent jobs that can run on a node. See here for instructions.
- If on the other hand, the CPU is high on the Self-hosted IR node or available memory is low, you can add a new node to help scale out the load across the multiple nodes. See here for instructions.

Note in the following scenarios, single copy activity execution can leverage multiple Self-hosted IR nodes:

- Copy data from file-based stores, depending on the number and size of the files.
- Copy data from partition-option-enabled data store (including Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, Oracle, Netezza, SAP HANA, SAP Open Hub, SAP Table, SQL Server, and Teradata), depending on the number of data partitions.

Parallel copy

You can set parallel copy (`parallelCopies` property) on copy activity to indicate the parallelism that you want the copy activity to use. You can think of this property as the maximum number of threads within the copy activity that read from your source or write to your sink data stores in parallel.

The parallel copy is orthogonal to Data Integration Units or Self-hosted IR nodes. It is counted across all the DIUs or Self-hosted IR nodes.

For each copy activity run, by default the service dynamically applies the optimal parallel copy setting based on your source-sink pair and data pattern.

TIP

The default behavior of parallel copy usually gives you the best throughput, which is auto-determined by the service based on your source-sink pair, data pattern and number of DIUs or the Self-hosted IR's CPU/memory/node count. Refer to Troubleshoot copy activity performance on when to tune parallel copy.

The following table lists the parallel copy behavior:

COPY SCENARIO	PARALLEL COPY BEHAVIOR
Between file stores	`parallelCopies` determines the parallelism **at the file level**. The chunking within each file happens underneath automatically and transparently. It's designed to use the best suitable chunk size for a given data store type to load data in parallel. The actual number of parallel copies copy activity uses at run time is no more than the number of files you have. If the copy behavior is **mergeFile** into file sink, the copy activity can't take advantage of file-level parallelism.
From file store to non-file store	- When copying data into Azure SQL Database or Azure Cosmos DB, default parallel copy also depend on the sink tier (number of DTUs/RUs). - When copying data into Azure Table, default parallel copy is 4.
From non-file store to file store	- When copying data from partition-option-enabled data store (including Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, Oracle, Amazon RDS for Oracle, Netezza, SAP HANA, SAP Open Hub, SAP Table, SQL Server, Amazon RDS for SQL Server and Teradata), default parallel copy is 4. The actual number of parallel copies copy activity uses at run time is no more than the number of data partitions you have. When use Self-hosted Integration Runtime and copy to Azure Blob/ADLS Gen2, note the max effective parallel copy is 4 or 5 per IR node. - For other scenarios, parallel copy doesn't take effect. Even if parallelism is specified, it's not applied.
Between non-file stores	- When copying data into Azure SQL Database or Azure Cosmos DB, default parallel copy also depend on the sink tier (number of DTUs/RUs). - When copying data from partition-option-enabled data store (including Azure SQL Database, Azure SQL Managed Instance, Azure Synapse Analytics, Oracle, Amazon RDS for Oracle, Netezza, SAP HANA, SAP Open Hub, SAP Table, SQL Server, Amazon RDS for SQL Server and Teradata), default parallel copy is 4. - When copying data into Azure Table, default parallel copy is 4.

To control the load on machines that host your data stores, or to tune copy performance, you can override the default value and specify a value for the `parallelCopies` property. The value must be an integer greater than or equal to 1. At run time, for the best performance, the copy activity uses a value that is less than or equal to the value that you set.

When you specify a value for the `parallelCopies` property, take the load increase on your source and sink data stores into account. Also consider the load increase to the self-hosted integration runtime if the copy activity is

empowered by it. This load increase happens especially when you have multiple activities or concurrent runs of the same activities that run against the same data store. If you notice that either the data store or the self-hosted integration runtime is overwhelmed with the load, decrease the `parallelCopies` value to relieve the load.

Example:

```
"activities":[
    {
        "name": "Sample copy activity",
        "type": "Copy",
        "inputs": [...],
        "outputs": [...],
        "typeProperties": {
            "source": {
                "type": "BlobSource",
            },
            "sink": {
                "type": "AzureDataLakeStoreSink"
            },
            "parallelCopies": 32
        }
    }
]
```

Staged copy

When you copy data from a source data store to a sink data store, you might choose to use Azure Blob storage or Azure Data Lake Storage Gen2 as an interim staging store. Staging is especially useful in the following cases:

- **You want to ingest data from various data stores into Azure Synapse Analytics via PolyBase, copy data from/to Snowflake, or ingest data from Amazon Redshift/HDFS performantly.** Learn more details from:
  - Use PolyBase to load data into Azure Synapse Analytics.
  - Snowflake connector
  - Amazon Redshift connector
  - HDFS connector
- **You don't want to open ports other than port 80 and port 443 in your firewall because of corporate IT policies.** For example, when you copy data from an on-premises data store to an Azure SQL Database or an Azure Synapse Analytics, you need to activate outbound TCP communication on port 1433 for both the Windows firewall and your corporate firewall. In this scenario, staged copy can take advantage of the self-hosted integration runtime to first copy data to a staging storage over HTTP or HTTPS on port 443, then load the data from staging into SQL Database or Azure Synapse Analytics. In this flow, you don't need to enable port 1433.
- **Sometimes it takes a while to perform a hybrid data movement (that is, to copy from an on-premises data store to a cloud data store) over a slow network connection.** To improve performance, you can use staged copy to compress the data on-premises so that it takes less time to move data to the staging data store in the cloud. Then you can decompress the data in the staging store before you load into the destination data store.

How staged copy works

When you activate the staging feature, first the data is copied from the source data store to the staging storage (bring your own Azure Blob or Azure Data Lake Storage Gen2). Next, the data is copied from the staging to the sink data store. The copy activity automatically manages the two-stage flow for you, and also cleans up temporary data from the staging storage after the data movement is complete.

When you activate data movement by using a staging store, you can specify whether you want the data to be compressed before you move data from the source data store to the staging store and then decompressed before you move data from an interim or staging data store to the sink data store.

Currently, you can't copy data between two data stores that are connected via different Self-hosted IRs, neither with nor without staged copy. For such scenario, you can configure two explicitly chained copy activities to copy from source to staging then from staging to sink.

Configuration

Configure the **enableStaging** setting in the copy activity to specify whether you want the data to be staged in storage before you load it into a destination data store. When you set **enableStaging** to `TRUE`, specify the additional properties listed in the following table.

PROPERTY	DESCRIPTION	DEFAULT VALUE	REQUIRED
enableStaging	Specify whether you want to copy data via an interim staging store.	False	No
linkedServiceName	Specify the name of an Azure Blob storage or Azure Data Lake Storage Gen2 linked service, which refers to the instance of Storage that you use as an interim staging store.	N/A	Yes, when **enableStaging** is set to TRUE
path	Specify the path that you want to contain the staged data. If you don't provide a path, the service creates a container to store temporary data.	N/A	No
enableCompression	Specifies whether data should be compressed before it's copied to the destination. This setting reduces the volume of data being transferred.	False	No

> **NOTE**
> If you use staged copy with compression enabled, the service principal or MSI authentication for staging blob linked service isn't supported.

Here's a sample definition of a copy activity with the properties that are described in the preceding table:

```
"activities":[
    {
        "name": "CopyActivityWithStaging",
        "type": "Copy",
        "inputs": [...],
        "outputs": [...],
        "typeProperties": {
            "source": {
                "type": "OracleSource",
            },
            "sink": {
                "type": "SqlDWSink"
            },
            "enableStaging": true,
            "stagingSettings": {
                "linkedServiceName": {
                    "referenceName": "MyStagingStorage",
                    "type": "LinkedServiceReference"
                },
                "path": "stagingcontainer/path"
            }
        }
    }
]
```

Staged copy billing impact

You're charged based on two steps: copy duration and copy type.

- When you use staging during a cloud copy, which is copying data from a cloud data store to another cloud data store, both stages empowered by Azure integration runtime, you're charged the [sum of copy duration for step 1 and step 2] x [cloud copy unit price].
- When you use staging during a hybrid copy, which is copying data from an on-premises data store to a cloud data store, one stage empowered by a self-hosted integration runtime, you're charged for [hybrid copy duration] x [hybrid copy unit price] + [cloud copy duration] x [cloud copy unit price].

Next steps

Preserve metadata and ACLs using copy activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

When you use Azure Data Factory or Synapse Analytics pipelines copy activity to copy data from source to sink, in the following scenarios, you can also preserve the metadata and ACLs along.

Preserve metadata for lake migration

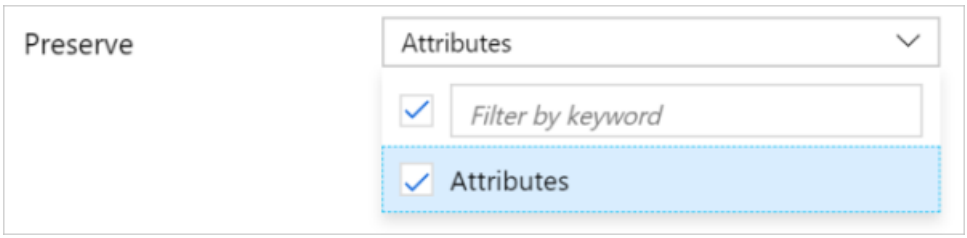
When you migrate data from one data lake to another including Amazon S3, Azure Blob, Azure Data Lake Storage Gen2, and Azure Files, you can choose to preserve the file metadata along with data.

Copy activity supports preserving the following attributes during data copy:

- **All the customer specified metadata**
- And the following **five data store built-in system properties**: `contentType`, `contentLanguage` (except for Amazon S3), `contentEncoding`, `contentDisposition`, `cacheControl`.

Handle differences in metadata: Amazon S3 and Azure Storage allow different sets of characters in the keys of customer specified metadata. When you choose to preserve metadata using copy activity, the service automatically replaces the invalid characters with '_'.

When you copy files as-is from Amazon S3/Azure Data Lake Storage Gen2/Azure Blob storage/Azure Files to Azure Data Lake Storage Gen2/Azure Blob storage/Azure Files with binary format, you can find the **Preserve** option on the **Copy Activity** > **Settings** tab for activity authoring or the **Settings** page in Copy Data Tool.



Here's an example of copy activity JSON configuration (see `preserve`):

```
"activities":[
    {
        "name": "CopyAndPreserveMetadata",
        "type": "Copy",
        "typeProperties": {
            "source": {
                "type": "BinarySource",
                "storeSettings": {
                    "type": "AmazonS3ReadSettings",
                    "recursive": true
                }
            },
            "sink": {
                "type": "BinarySink",
                "storeSettings": {
                    "type": "AzureBlobFSWriteSettings"
                }
            },
            "preserve": [
                "Attributes"
            ]
        },
        "inputs": [
            {
                "referenceName": "<Binary dataset Amazon S3/Azure Blob/ADLS Gen2 source>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Binary dataset for Azure Blob/ADLS Gen2 sink>",
                "type": "DatasetReference"
            }
        ]
    }
]
```

Preserve ACLs from Data Lake Storage Gen1/Gen2 to Gen2

When you upgrade from Azure Data Lake Storage Gen1 to Gen2 or copy data between ADLS Gen2, you can choose to preserve the POSIX access control lists (ACLs) along with data files. For more information on access control, see Access control in Azure Data Lake Storage Gen1 and Access control in Azure Data Lake Storage Gen2.

Copy activity supports preserving the following types of ACLs during data copy. You can select one or more types:

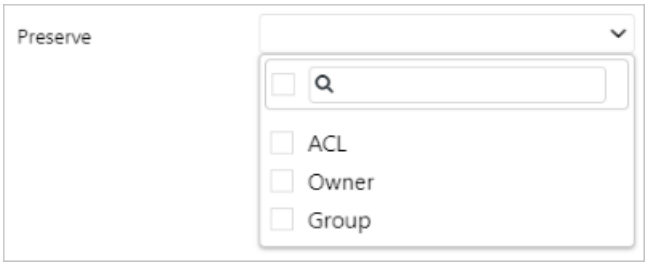
- **ACL**: Copy and preserve POSIX access control lists on files and directories. It copies the full existing ACLs from source to sink.
- **Owner**: Copy and preserve the owning user of files and directories. Super-user access to sink Data Lake Storage Gen2 is required.
- **Group**: Copy and preserve the owning group of files and directories. Super-user access to sink Data Lake Storage Gen2 or the owning user (if the owning user is also a member of the target group) is required.

If you specify to copy from a folder, the service replicates the ACLs for that given folder and the files and directories under it, if `recursive` is set to true. If you specify to copy from a single file, the ACLs on that file are copied.

> **NOTE**
>
> When you use the copy activity to preserve ACLs from Data Lake Storage Gen1/Gen2 to Gen2, the existing ACLs on sink Gen2's corresponding folder/files will be overwritten.

> **IMPORTANT**
>
> When you choose to preserve ACLs, make sure you grant high enough permissions for the service to operate against your sink Data Lake Storage Gen2 account. For example, use account key authentication or assign the Storage Blob Data Owner role to the service principal or managed identity.

When you configure source as Data Lake Storage Gen1/Gen2 with binary format or the binary copy option, and sink as Data Lake Storage Gen2 with binary format or the binary copy option, you can find the **Preserve** option on the **Settings** page in Copy Data Tool or on the **Copy Activity** > **Settings** tab for activity authoring.



Here's an example of copy activity JSON configuration (see `preserve`):

```
"activities":[
    {
        "name": "CopyAndPreserveACLs",
        "type": "Copy",
        "typeProperties": {
            "source": {
                "type": "BinarySource",
                "storeSettings": {
                    "type": "AzureDataLakeStoreReadSettings",
                    "recursive": true
                }
            },
            "sink": {
                "type": "BinarySink",
                "storeSettings": {
                    "type": "AzureBlobFSWriteSettings"
                }
            },
            "preserve": [
                "ACL",
                "Owner",
                "Group"
            ]
        },
        "inputs": [
            {
                "referenceName": "<Binary dataset name for Azure Data Lake Storage Gen1/Gen2 source>",
                "type": "DatasetReference"
            }
        ],
        "outputs": [
            {
                "referenceName": "<Binary dataset name for Azure Data Lake Storage Gen2 sink>",
                "type": "DatasetReference"
            }
        ]
    }
]
```

Schema and data type mapping in copy activity

8/19/2022 • 13 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes how the Azure Data Factory copy activity perform schema mapping and data type mapping from source data to sink data.

Schema mapping

Default mapping

By default, copy activity maps source data to sink **by column names** in case-sensitive manner. If sink doesn't exist, for example, writing to file(s), the source field names will be persisted as sink names. If the sink already exists, it must contain all columns being copied from the source. Such default mapping supports flexible schemas and schema drift from source to sink from execution to execution - all the data returned by source data store can be copied to sink.

If your source is text file without header line, explicit mapping is required as the source doesn't contain column names.

Explicit mapping

You can also specify explicit mapping to customize the column/field mapping from source to sink based on your need. With explicit mapping, you can copy only partial source data to sink, or map source data to sink with different names, or reshape tabular/hierarchical data. Copy activity:

1. Reads the data from source and determine the source schema.
2. Applies your defined mapping.
3. Writes the data to sink.

Learn more about:

- Tabular source to tabular sink
- Hierarchical source to tabular sink
- Tabular/Hierarchical source to hierarchical sink

You can configure the mapping on the Authoring UI -> copy activity -> mapping tab, or programmatically specify the mapping in copy activity -> `translator` property. The following properties are supported in `translator` -> `mappings` array -> objects -> `source` and `sink`, which points to the specific column/field to map data.

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the source or sink column/field. Apply for tabular source and sink.	Yes
ordinal	Column index. Start from 1. Apply and required when using delimited text without header line.	No

PROPERTY	DESCRIPTION	REQUIRED
path	JSON path expression for each field to extract or map. Apply for hierarchical source and sink, for example, Cosmos DB, MongoDB, or REST connectors. For fields under the root object, the JSON path starts with root `$`; for fields inside the array chosen by `collectionReference` property, JSON path starts from the array element without `$`.	No
type	Interim data type of the source or sink column. In general, you don't need to specify or change this property. Learn more about data type mapping.	No
culture	Culture of the source or sink column. Apply when type is `Datetime` or `Datetimeoffset`. The default is `en-us`. In general, you don't need to specify or change this property. Learn more about data type mapping.	No
format	Format string to be used when type is `Datetime` or `Datetimeoffset`. Refer to Custom Date and Time Format Strings on how to format datetime. In general, you don't need to specify or change this property. Learn more about data type mapping.	No

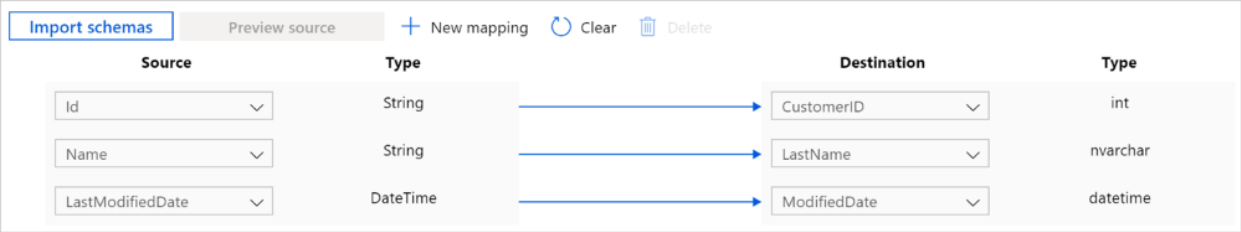
The following properties are supported under `translator` in addition to `mappings`:

PROPERTY	DESCRIPTION	REQUIRED
collectionReference	Apply when copying data from hierarchical source, for example, Cosmos DB, MongoDB, or REST connectors. If you want to iterate and extract data from the objects **inside an array field** with the same pattern and convert to per row per object, specify the JSON path of that array to do cross-apply.	No

Tabular source to tabular sink

For example, to copy data from Salesforce to Azure SQL Database and explicitly map three columns:

1. On copy activity -> mapping tab, click **Import schemas** button to import both source and sink schemas.
2. Map the needed fields and exclude/delete the rest.



The same mapping can be configured as the following in copy activity payload (see `translator`):

```
{
    "name": "CopyActivityTabularToTabular",
    "type": "Copy",
    "typeProperties": {
        "source": { "type": "SalesforceSource" },
        "sink": { "type": "SqlSink" },
        "translator": {
            "type": "TabularTranslator",
            "mappings": [
                {
                    "source": { "name": "Id" },
                    "sink": { "name": "CustomerID" }
                },
                {
                    "source": { "name": "Name" },
                    "sink": { "name": "LastName" }
                },
                {
                    "source": { "name": "LastModifiedDate" },
                    "sink": { "name": "ModifiedDate" }
                }
            ]
        }
    },
    ...
}
```

To copy data from delimited text file(s) without header line, the columns are represented by ordinal instead of names.

```
{
    "name": "CopyActivityTabularToTabular",
    "type": "Copy",
    "typeProperties": {
        "source": { "type": "DelimitedTextSource" },
        "sink": { "type": "SqlSink" },
        "translator": {
            "type": "TabularTranslator",
            "mappings": [
                {
                    "source": { "ordinal": "1" },
                    "sink": { "name": "CustomerID" }
                },
                {
                    "source": { "ordinal": "2" },
                    "sink": { "name": "LastName" }
                },
                {
                    "source": { "ordinal": "3" },
                    "sink": { "name": "ModifiedDate" }
                }
            ]
        }
    },
    ...
}
```

Hierarchical source to tabular sink

When copying data from hierarchical source to tabular sink, copy activity supports the following capabilities:

- Extract data from objects and arrays.
- Cross apply multiple objects with the same pattern from an array, in which case to convert one JSON object into multiple records in tabular result.

For more advanced hierarchical-to-tabular transformation, you can use Data Flow.

For example, if you have source MongoDB document with the following content:

```
{
    "id": {
        "$oid": "592e07800000000000000000"
    },
    "number": "01",
    "date": "20170122",
    "orders": [
        {
            "prod": "p1",
            "price": 23
        },
        {
            "prod": "p2",
            "price": 13
        },
        {
            "prod": "p3",
            "price": 231
        }
    ],
    "city": [ { "name": "Seattle" } ]
}
```

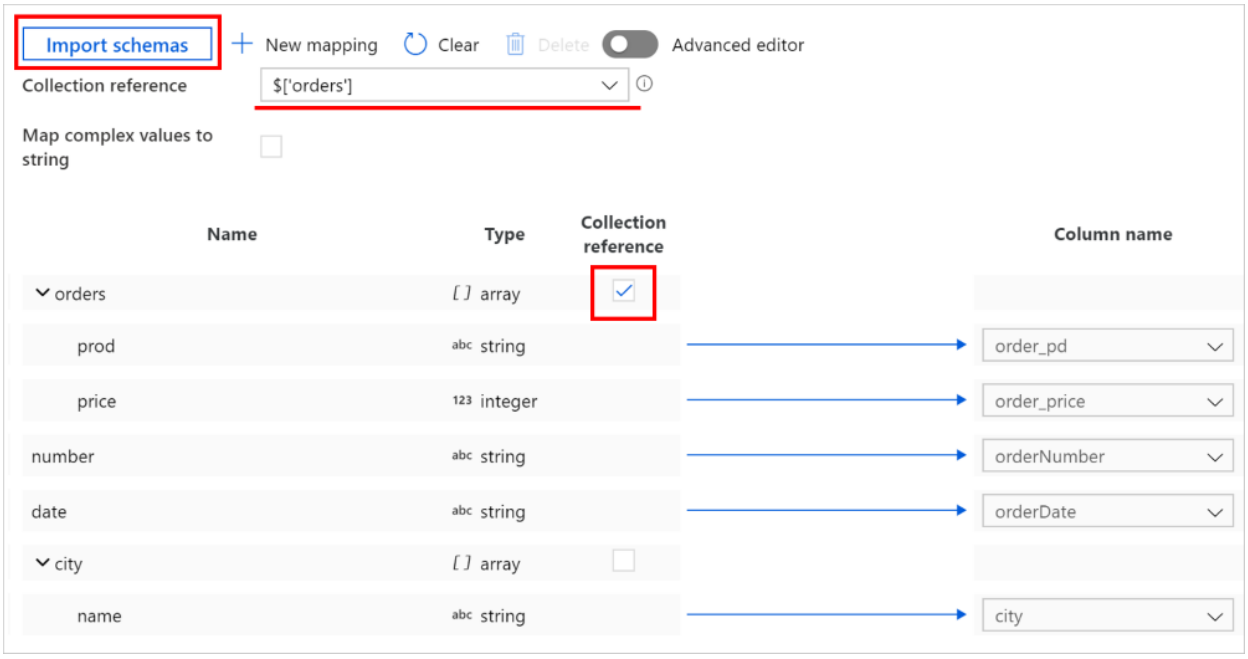
And you want to copy it into a text file in the following format with header line, by flattening the data inside the array *(order_pd and order_price)* and cross join with the common root info *(number, date, and city)*:

ORDERNUMBER	ORDERDATE	ORDER_PD	ORDER_PRICE	CITY
01	20170122	P1	23	Seattle
01	20170122	P2	13	Seattle
01	20170122	P3	231	Seattle

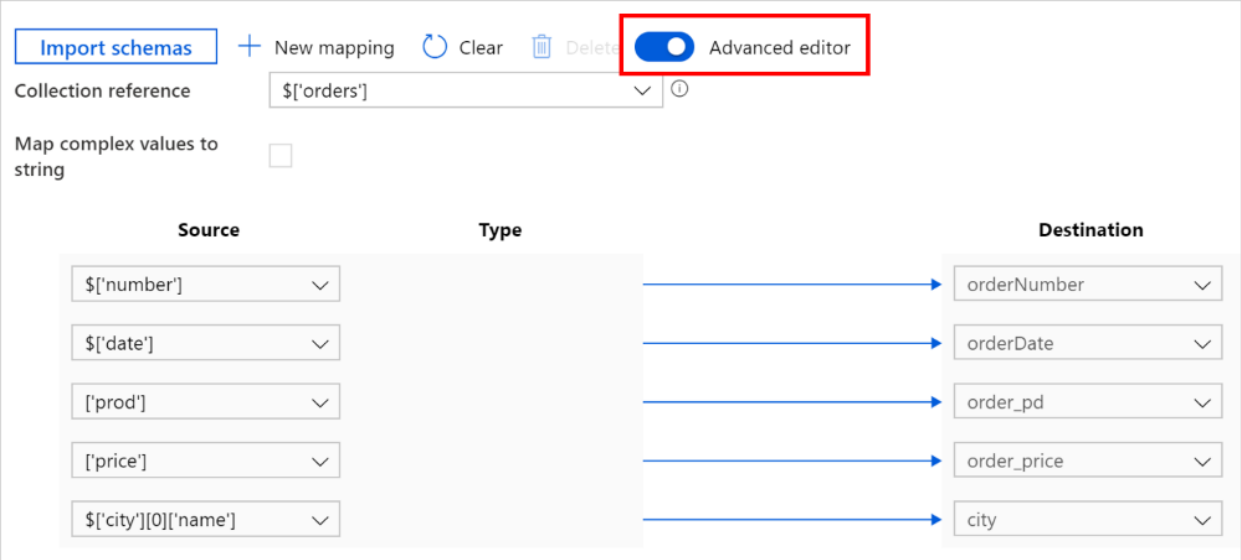
You can define such mapping on Data Factory authoring UI:

1. On copy activity -> mapping tab, click **Import schemas** button to import both source and sink schemas. As the service samples the top few objects when importing schema, if any field doesn't show up, you can add it to the correct layer in the hierarchy - hover on an existing field name and choose to add a node, an object, or an array.
2. Select the array from which you want to iterate and extract data. It will be auto populated as **Collection reference**. Note only single array is supported for such operation.
3. Map the needed fields to sink. The service automatically determines the corresponding JSON paths for the hierarchical side.

> **NOTE**
> For records where the array marked as collection reference is empty and the check box is selected, the entire record is skipped.



You can also switch to **Advanced editor**, in which case you can directly see and edit the fields' JSON paths. If you choose to add new mapping in this view, specify the JSON path.



The same mapping can be configured as the following in copy activity payload (see `translator`):

```
{
    "name": "CopyActivityHierarchicalToTabular",
    "type": "Copy",
    "typeProperties": {
        "source": { "type": "MongoDbV2Source" },
        "sink": { "type": "DelimitedTextSink" },
        "translator": {
            "type": "TabularTranslator",
            "mappings": [
                {
                    "source": { "path": "$['number']" },
                    "sink": { "name": "orderNumber" }
                },
                {
                    "source": { "path": "$['date']" },
                    "sink": { "name": "orderDate" }
                },
                {
                    "source": { "path": "['prod']" },
                    "sink": { "name": "order_pd" }
                },
                {
                    "source": { "path": "['price']" },
                    "sink": { "name": "order_price" }
                },
                {
                    "source": { "path": "$['city'][0]['name']" },
                    "sink": { "name": "city" }
                }
            ],
            "collectionReference": "$['orders']"
        }
    },
    ...
}
```

Tabular/Hierarchical source to hierarchical sink

The user experience flow is similar to Hierarchical source to tabular sink.

When copying data from tabular source to hierarchical sink, writing to array inside object is not supported.

When copying data from hierarchical source to hierarchical sink, you can additionally preserve entire layer's hierarchy, by selecting the object/array and map to sink without touching the inner fields.

For more advanced data reshape transformation, you can use Data Flow.

Parameterize mapping

If you want to create a templatized pipeline to copy large number of objects dynamically, determine whether you can leverage the default mapping or you need to define explicit mapping for respective objects.

If explicit mapping is needed, you can:

1. Define a parameter with object type at the pipeline level, for example, `mapping`.
2. Parameterize the mapping: on copy activity -> mapping tab, choose to add dynamic content and select the above parameter. The activity payload would be as the following:

```
{
    "name": "CopyActivityHierarchicalToTabular",
    "type": "Copy",
    "typeProperties": {
        "source": {...},
        "sink": {...},
        "translator": {
            "value": "@pipeline().parameters.mapping",
            "type": "Expression"
        },
        ...
    }
}
```

3. Construct the value to pass into the mapping parameter. It should be the entire object of `translator` definition, refer to the samples in explicit mapping section. For example, for tabular source to tabular sink copy, the value should be

```
{"type":"TabularTranslator","mappings":[{"source":{"name":"Id"},"sink":{"name":"CustomerID"}},
{"source":{"name":"Name"},"sink":{"name":"LastName"}},{"source":{"name":"LastModifiedDate"},"sink":
{"name":"ModifiedDate"}}]}
```

.

Data type mapping

Copy activity performs source types to sink types mapping with the following flow:

1. Convert from source native data types to interim data types used by Azure Data Factory and Synapse pipelines.
2. Automatically convert interim data type as needed to match corresponding sink types, applicable for both default mapping and explicit mapping.
3. Convert from interim data types to sink native data types.

Copy activity currently supports the following interim data types: Boolean, Byte, Byte array, Datetime, DatetimeOffset, Decimal, Double, GUID, Int16, Int32, Int64, SByte, Single, String, Timespan, UInt16, UInt32, and UInt64.

The following data type conversions are supported between the interim types from source to sink.

SOURCE \SINK	BOOLEAN	BYTE ARRAY	DECIMAL	DATE/TIME (1)	FLOAT-POINT (2)	GUID	INTEGER (3)	STRING	TIMESPAN
Boolean	✓		✓		✓		✓	✓	

SOURCE \SINK	BOOLEAN	BYTE ARRAY	DECIMAL	DATE/TIME (1)	FLOAT-POINT (2)	GUID	INTEGER (3)	STRING	TIMESPAN
Byte array		✓						✓	
Date/Time				✓				✓	
Decimal	✓		✓		✓		✓	✓	
Float-point	✓		✓		✓		✓	✓	
GUID						✓		✓	
Integer	✓		✓		✓		✓	✓	
String	✓	✓	✓	✓	✓	✓	✓	✓	✓
TimeSpan								✓	✓

(1) Date/Time includes DateTime and DateTimeOffset.

(2) Float-point includes Single and Double.

(3) Integer includes SByte, Byte, Int16, UInt16, Int32, UInt32, Int64, and UInt64.

> **NOTE**
>
> - Currently such data type conversion is supported when copying between tabular data. Hierarchical sources/sinks are not supported, which means there is no system-defined data type conversion between source and sink interim types.
> - This feature works with the latest dataset model. If you don't see this option from the UI, try creating a new dataset.

The following properties are supported in copy activity for data type conversion (under `translator` section for programmatical authoring):

PROPERTY	DESCRIPTION	REQUIRED

PROPERTY	DESCRIPTION	REQUIRED
typeConversion	Enable the new data type conversion experience. Default value is false due to backward compatibility. For new copy activities created via Data Factory authoring UI since late June 2020, this data type conversion is enabled by default for the best experience, and you can see the following type conversion settings on copy activity -> mapping tab for applicable scenarios. To create pipeline programmatically, you need to explicitly set `typeConversion` property to true to enable it. For existing copy activities created before this feature is released, you won't see type conversion options on the authoring UI for backward compatibility.	No
typeConversionSettings	A group of type conversion settings. Apply when `typeConversion` is set to `true`. The following properties are all under this group.	No
Under `typeConversionSettings`		
allowDataTruncation	Allow data truncation when converting source data to sink with different type during copy, for example, from decimal to integer, from DatetimeOffset to Datetime. Default value is true.	No
treatBooleanAsNumber	Treat booleans as numbers, for example, true as 1. Default value is false.	No
dateTimeFormat	Format string when converting between dates without time zone offset and strings, for example, `yyyy-MM-dd HH:mm:ss.fff`. Refer to Custom Date and Time Format Strings for detailed information.	No
dateTimeOffsetFormat	Format string when converting between dates with time zone offset and strings, for example, `yyyy-MM-dd HH:mm:ss.fff zzz`. Refer to Custom Date and Time Format Strings for detailed information.	No

PROPERTY	DESCRIPTION	REQUIRED
timeSpanFormat	Format string when converting between time periods and strings, for example, `dd\.hh\:mm`. Refer to Custom TimeSpan Format Strings for detailed information.	No
culture	Culture information to be used when convert types, for example, `en-us` or `fr-fr`.	No

Example:

```
{
    "name": "CopyActivity",
    "type": "Copy",
    "typeProperties": {
        "source": {
         "type": "ParquetSource"
        },
        "sink": {
            "type": "SqlSink"
        },
        "translator": {
            "type": "TabularTranslator",
            "typeConversion": true,
            "typeConversionSettings": {
                "allowDataTruncation": true,
                "treatBooleanAsNumber": true,
                "dateTimeFormat": "yyyy-MM-dd HH:mm:ss.fff",
                "dateTimeOffsetFormat": "yyyy-MM-dd HH:mm:ss.fff zzz",
                "timeSpanFormat": "dd\.hh\:mm",
                "culture": "en-gb"
            }
        }
 },
    ...
}
```

Legacy models

> **NOTE**
> The following models to map source columns/fields to sink are still supported as is for backward compatibility. We suggest that you use the new model mentioned in schema mapping. The authoring UI has switched to generating the new model.

Alternative column-mapping (legacy model)

You can specify copy activity -> `translator` -> `columnMappings` to map between tabular-shaped data. In this case, the "structure" section is required for both input and output datasets. Column mapping supports **mapping all or subset of columns in the source dataset "structure" to all columns in the sink dataset "structure"**. The following are error conditions that result in an exception:

- Source data store query result does not have a column name that is specified in the input dataset "structure" section.
- Sink data store (if with pre-defined schema) does not have a column name that is specified in the output dataset "structure" section.

- Either fewer columns or more columns in the "structure" of sink dataset than specified in the mapping.
- Duplicate mapping.

In the following example, the input dataset has a structure, and it points to a table in an on-premises Oracle database.

```
{
    "name": "OracleDataset",
    "properties": {
        "structure":
         [
            { "name": "UserId"},
            { "name": "Name"},
            { "name": "Group"}
         ],
        "type": "OracleTable",
        "linkedServiceName": {
            "referenceName": "OracleLinkedService",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "SourceTable"
        }
    }
}
```

In this sample, the output dataset has a structure and it points to a table in Salesfoce.

```
{
    "name": "SalesforceDataset",
    "properties": {
        "structure":
        [
            { "name": "MyUserId"},
            { "name": "MyName" },
            { "name": "MyGroup"}
        ],
        "type": "SalesforceObject",
        "linkedServiceName": {
            "referenceName": "SalesforceLinkedService",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "tableName": "SinkTable"
        }
    }
}
```

The following JSON defines a copy activity in a pipeline. The columns from source mapped to columns in sink by using the **translator** -> **columnMappings** property.

```
{
    "name": "CopyActivity",
    "type": "Copy",
    "inputs": [
        {
            "referenceName": "OracleDataset",
            "type": "DatasetReference"
        }
    ],
    "outputs": [
        {
            "referenceName": "SalesforceDataset",
            "type": "DatasetReference"
        }
    ],
    "typeProperties":    {
        "source": { "type": "OracleSource" },
        "sink": { "type": "SalesforceSink" },
        "translator":
        {
            "type": "TabularTranslator",
            "columnMappings":
            {
                "UserId": "MyUserId",
                "Group": "MyGroup",
                "Name": "MyName"
            }
        }
    }
}
```

If you are using the syntax of `"columnMappings": "UserId: MyUserId, Group: MyGroup, Name: MyName"` to specify column mapping, it is still supported as-is.

Alternative schema-mapping (legacy model)

You can specify copy activity -> `translator` -> `schemaMapping` to map between hierarchical-shaped data and tabular-shaped data, for example, copy from MongoDB/REST to text file and copy from Oracle to Azure Cosmos DB's API for MongoDB. The following properties are supported in copy activity `translator` section:

PROPERTY	DESCRIPTION	REQUIRED
type	The type property of the copy activity translator must be set to: **TabularTranslator**	Yes

PROPERTY	DESCRIPTION	REQUIRED
schemaMapping	A collection of key-value pairs, which represents the mapping relation **from source side to sink side**. - **Key:** represents source. For **tabular source**, specify the column name as defined in dataset structure; for **hierarchical source**, specify the JSON path expression for each field to extract and map. - **Value:** represents sink. For **tabular sink**, specify the column name as defined in dataset structure; for **hierarchical sink**, specify the JSON path expression for each field to extract and map. In the case of hierarchical data, for fields under root object, JSON path starts with root $; for fields inside the array chosen by `collectionReference` property, JSON path starts from the array element.	Yes
collectionReference	If you want to iterate and extract data from the objects **inside an array field** with the same pattern and convert to per row per object, specify the JSON path of that array to do cross-apply. This property is supported only when hierarchical data is source.	No

Example: copy from MongoDB to Oracle:

For example, if you have MongoDB document with the following content:

```
{
    "id": {
        "$oid": "592e07800000000000000000"
    },
    "number": "01",
    "date": "20170122",
    "orders": [
        {
            "prod": "p1",
            "price": 23
        },
        {
            "prod": "p2",
            "price": 13
        },
        {
            "prod": "p3",
            "price": 231
        }
    ],
    "city": [ { "name": "Seattle" } ]
}
```

and you want to copy it into an Azure SQL table in the following format, by flattening the data inside the array *(order_pd and order_price)* and cross join with the common root info *(number, date, and city)*:

ORDERNUMBER	ORDERDATE	ORDER_PD	ORDER_PRICE	CITY
01	20170122	P1	23	Seattle
01	20170122	P2	13	Seattle
01	20170122	P3	231	Seattle

Configure the schema-mapping rule as the following copy activity JSON sample:

```
{
    "name": "CopyFromMongoDBToOracle",
    "type": "Copy",
    "typeProperties": {
        "source": {
            "type": "MongoDbV2Source"
        },
        "sink": {
            "type": "OracleSink"
        },
        "translator": {
            "type": "TabularTranslator",
            "schemaMapping": {
                "$.number": "orderNumber",
                "$.date": "orderDate",
                "prod": "order_pd",
                "price": "order_price",
                "$.city[0].name": "city"
            },
            "collectionReference":  "$.orders"
        }
    }
}
```

- Copy activity overview

Fault tolerance of copy activity in Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 12 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

When you copy data from source to destination store, the copy activity provides certain level of fault tolerances to prevent interruption from failures in the middle of data movement. For example, you are copying millions of rows from source to destination store, where a primary key has been created in the destination database, but source database does not have any primary keys defined. When you happen to copy duplicated rows from source to the destination, you will hit the PK violation failure on the destination database. At this moment, copy activity offers you two ways to handle such errors:

- You can abort the copy activity once any failure is encountered.
- You can continue to copy the rest by enabling fault tolerance to skip the incompatible data. For example, skip the duplicated row in this case. In addition, you can log the skipped data by enabling session log within copy activity. You can refer to session log in copy activity for more details.

Copying binary files

The service supports the following fault tolerance scenarios when copying binary files. You can choose to abort the copy activity or continue to copy the rest in the following scenarios:

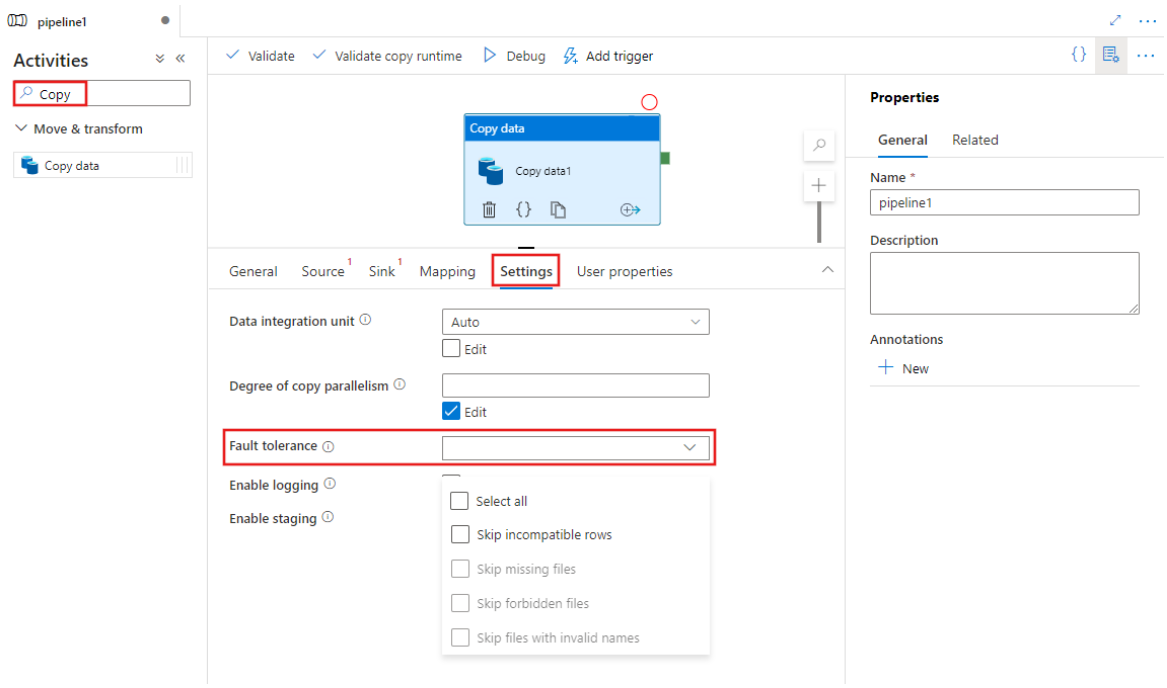
1. The files to be copied by the service are being deleted by other applications at the same time.
2. Some particular folders or files do not allow the service access because ACLs of those files or folders require higher permission level than the configured connection information.
3. One or more files are not verified to be consistent between source and destination store if you enable data consistency verification setting.

Enable fault tolerance with UI

To configure fault tolerance in a Copy activity in a pipeline with UI, complete the following steps:

1. If you did not create a Copy activity for your pipeline already, search for *Copy* in the pipeline Activities pane, and drag a Copy Data activity to the pipeline canvas.

2. Select the new Copy Data activity on the canvas if it is not already selected, and its **Settings** tab, to configure fault tolerance.



Configuration

When you copy binary files between storage stores, you can enable fault tolerance as followings:

```
"typeProperties": {
    "source": {
        "type": "BinarySource",
        "storeSettings": {
            "type": "AzureDataLakeStoreReadSettings",
            "recursive": true
            }
    },
    "sink": {
        "type": "BinarySink",
        "storeSettings": {
            "type": "AzureDataLakeStoreWriteSettings"
        }
    },
    "skipErrorFile": {
        "fileMissing": true,
        "fileForbidden": true,
        "dataInconsistency": true,
        "invalidFileName": true
    },
    "validateDataConsistency": true,
    "logSettings": {
        "enableCopyActivityLog": true,
        "copyActivityLogSettings": {
            "logLevel": "Warning",
            "enableReliableLogging": false
        },
        "logLocationSettings": {
            "linkedServiceName": {
               "referenceName": "ADLSGen2",
               "type": "LinkedServiceReference"
            },
            "path": "sessionlog/"
        }
    }
}
```

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
skipErrorFile	A group of properties to specify the types of failures you want to skip during the data movement.		No
fileMissing	One of the key-value pairs within skipErrorFile property bag to determine if you want to skip files that are being deleted by other applications at the time the service is performing the copy operation. -True: you want to copy the rest by skipping the files being deleted by other applications. - False: you want to abort the copy activity once any files are being deleted from source store in the middle of data movement. Be aware this property is set to true as default.	True(default) False	No
fileForbidden	One of the key-value pairs within skipErrorFile property bag to determine if you want to skip the particular files, when the ACLs of those files or folders require higher permission level than the configured connection. -True: you want to copy the rest by skipping the files. - False: you want to abort the copy activity once getting the permission issue on folders or files.	True False(default)	No
dataInconsistency	One of the key-value pairs within skipErrorFile property bag to determine if you want to skip the inconsistent data between source and destination store. -True: you want to copy the rest by skipping inconsistent data. - False: you want to abort the copy activity once inconsistent data found. Be aware this property is only valid when you set validateDataConsistency as True.	True False(default)	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
invalidFileName	One of the key-value pairs within skipErrorFile property bag to determine if you want to skip the particular files, when the file names are invalid for the destination store. -True: you want to copy the rest by skipping the files having invalid file names. - False: you want to abort the copy activity once any files have invalid file names. Be aware this property works when copying binary files from any storage store to ADLS Gen2 or copying binary files from AWS S3 to any storage store only.	True False(default)	No
logSettings	A group of properties that can be specified when you want to log the skipped object names.		No
linkedServiceName	The linked service of Azure Blob Storage or Azure Data Lake Storage Gen2 to store the session log files.	The names of an `AzureBlobStorage` or `AzureBlobFS` type linked service, which refers to the instance that you use to store the log file.	No
path	The path of the log files.	Specify the path that you use to store the log files. If you do not provide a path, the service creates a container for you.	No

NOTE

The followings are the prerequisites of enabling fault tolerance in copy activity when copying binary files. For skipping particular files when they are being deleted from source store:

- The source dataset and sink dataset have to be binary format, and the compression type cannot be specified.
- The supported data store types are Azure Blob storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, SFTP, Amazon S3, Google Cloud Storage and HDFS.
- Only if when you specify multiple files in source dataset, which can be a folder, wildcard or a list of files, copy activity can skip the particular error files. If a single file is specified in source dataset to be copied to the destination, copy activity will fail if any error occurred.

For skipping particular files when their access are forbidden from source store:

- The source dataset and sink dataset have to be binary format, and the compression type cannot be specified.
- The supported data store types are Azure Blob storage, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, SFTP, Amazon S3 and HDFS.
- Only if when you specify multiple files in source dataset, which can be a folder, wildcard or a list of files, copy activity can skip the particular error files. If a single file is specified in source dataset to be copied to the destination, copy activity will fail if any error occurred.

For skipping particular files when they are verified to be inconsistent between source and destination store:

- You can get more details from data consistency doc here.

Monitoring

Output from copy activity

You can get the number of files being read, written, and skipped via the output of each copy activity run.

```
"output": {
            "dataRead": 695,
            "dataWritten": 186,
            "filesRead": 3,
            "filesWritten": 1,
            "filesSkipped": 2,
            "throughput": 297,
            "logFilePath": "myfolder/a84bf8d4-233f-4216-8cb5-45962831cd1b/",
            "dataConsistencyVerification":
           {
                "VerificationResult": "Verified",
                "InconsistentData": "Skipped"
           }
       }
```

Session log from copy activity

If you configure to log the skipped file names, you can find the log file from this path:

```
https://[your-blob-account].blob.core.windows.net/[path-if-configured]/copyactivity-logs/[copy-activity-name]/[copy-activity-run-id]/[auto-generated-GUID].csv
```

.

The log files have to be the csv files. The schema of the log file is as following:

COLUMN	DESCRIPTION
Timestamp	The timestamp when the file was skipped.

COLUMN	DESCRIPTION
Level	The log level of this item. It will be in 'Warning' level for the item showing file skipping.
OperationName	Copy activity operational behavior on each file. It will be 'FileSkip' to specify the file to be skipped.
OperationItem	The file names to be skipped.
Message	More information to illustrate why the file being skipped.

The example of a log file is as following:

```
Timestamp,Level,OperationName,OperationItem,Message
2020-03-24 05:35:41.0209942,Warning,FileSkip,"bigfile.csv","File is skipped after read 322961408 bytes:
ErrorCode=UserErrorSourceBlobNotExist,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Mes
sage=The required Blob is missing. ContainerName:
https://transferserviceonebox.blob.core.windows.net/skipfaultyfile, path:
bigfile.csv.,Source=Microsoft.DataTransfer.ClientLibrary,'."
2020-03-24 05:38:41.2595989,Warning,FileSkip,"3_nopermission.txt","File is skipped after read 0 bytes:
ErrorCode=AdlsGen2OperationFailed,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Message
=ADLS Gen2 operation failed for: Operation returned an invalid status code 'Forbidden'. Account:
'adlsgen2perfsource'. FileSystem: 'skipfaultyfilesforbidden'. Path: '3_nopermission.txt'. ErrorCode:
'AuthorizationPermissionMismatch'. Message: 'This request is not authorized to perform this operation using
this permission.'. RequestId: '35089f5d-101f-008c-489e-
01cce4000000'..,Source=Microsoft.DataTransfer.ClientLibrary,''Type=Microsoft.DataTransfer.Common.Shared.Hybr
idDeliveryException,Message=Operation returned an invalid status code
'Forbidden',Source=,''Type=Microsoft.Azure.Storage.Data.Models.ErrorSchemaException,Message='Type=Microsoft.
Azure.Storage.Data.Models.ErrorSchemaException,Message=Operation returned an invalid status code
'Forbidden',Source=Microsoft.DataTransfer.ClientLibrary,',Source=Microsoft.DataTransfer.ClientLibrary,'."
```

From the log above, you can see bigfile.csv has been skipped due to another application deleted this file when the service was copying it. And 3_nopermission.txt has been skipped because the service is not allowed to access it due to permission issue.

Copying tabular data

Supported scenarios

Copy activity supports three scenarios for detecting, skipping, and logging incompatible tabular data:

- **Incompatibility between the source data type and the sink native type**.

  For example: Copy data from a CSV file in Blob storage to a SQL database with a schema definition that contains three INT type columns. The CSV file rows that contain numeric data, such as 123,456,789 are copied successfully to the sink store. However, the rows that contain non-numeric values, such as 123,456, abc are detected as incompatible and are skipped.

- **Mismatch in the number of columns between the source and the sink**.

  For example: Copy data from a CSV file in Blob storage to a SQL database with a schema definition that contains six columns. The CSV file rows that contain six columns are copied successfully to the sink store. The CSV file rows that contain more than six columns are detected as incompatible and are skipped.

- **Primary key violation when writing to SQL Server/Azure SQL Database/Azure Cosmos DB**.

  For example: Copy data from a SQL server to a SQL database. A primary key is defined in the sink SQL database, but no such primary key is defined in the source SQL server. The duplicated rows that exist in

the source cannot be copied to the sink. Copy activity copies only the first row of the source data into the sink. The subsequent source rows that contain the duplicated primary key value are detected as incompatible and are skipped.

NOTE

- To load data into Azure Synapse Analytics using PolyBase, configure PolyBase's native fault tolerance settings by specifying reject policies via "polyBaseSettings" in copy activity. You can still enable redirecting PolyBase incompatible rows to Blob or ADLS as normal as shown below.
- This feature doesn't apply when copy activity is configured to invoke Amazon Redshift Unload.
- This feature doesn't apply when copy activity is configured to invoke a stored procedure from a SQL sink.

Configuration

The following example provides a JSON definition to configure skipping the incompatible rows in copy activity:

```
"typeProperties": {
    "source": {
        "type": "AzureSqlSource"
    },
    "sink": {
        "type": "AzureSqlSink"
    },
    "enableSkipIncompatibleRow": true,
    "logSettings": {
        "enableCopyActivityLog": true,
        "copyActivityLogSettings": {
            "logLevel": "Warning",
            "enableReliableLogging": false
        },
        "logLocationSettings": {
            "linkedServiceName": {
               "referenceName": "ADLSGen2",
               "type": "LinkedServiceReference"
            },
            "path": "sessionlog/"
        }
    }
},
```

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
enableSkipIncompatibleRow	Specifies whether to skip incompatible rows during copy or not.	True False (default)	No
logSettings	A group of properties that can be specified when you want to log the incompatible rows.		No
linkedServiceName	The linked service of Azure Blob Storage or Azure Data Lake Storage Gen2 to store the log that contains the skipped rows.	The names of an `AzureBlobStorage` or `AzureBlobFS` type linked service, which refers to the instance that you use to store the log file.	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
path	The path of the log files that contains the skipped rows.	Specify the path that you want to use to log the incompatible data. If you do not provide a path, the service creates a container for you.	No

Monitor skipped rows

After the copy activity run completes, you can see the number of skipped rows in the output of the copy activity:

```
"output": {
            "dataRead": 95,
            "dataWritten": 186,
            "rowsCopied": 9,
            "rowsSkipped": 2,
            "copyDuration": 16,
            "throughput": 0.01,
            "logFilePath": "myfolder/a84bf8d4-233f-4216-8cb5-45962831cd1b/",
            "errors": []
        },
```

If you configure to log the incompatible rows, you can find the log file from this path:

```
https://[your-blob-account].blob.core.windows.net/[path-if-configured]/copyactivity-logs/[copy-activity-name]/[copy-activity-run-id]/[auto-generated-GUID].csv
```

.

The log files will be the csv files. The schema of the log file is as following:

COLUMN	DESCRIPTION
Timestamp	The timestamp when the incompatible rows were skipped
Level	The log level of this item. It will be in 'Warning' level if this item shows the skipped rows
OperationName	Copy activity operational behavior on each row. It will be 'TabularRowSkip' to specify that the particular incompatible row has been skipped
OperationItem	The skipped rows from the source data store.
Message	More information to illustrate why the incompatibility of this particular row.

An example of the log file content is as follows:

```
Timestamp, Level, OperationName, OperationItem, Message
2020-02-26 06:22:32.2586581, Warning, TabularRowSkip, """data1"", ""data2"", ""data3"","" "Column 'Prop_2' contains an invalid value 'data3'. Cannot convert 'data3' to type 'DateTime'."
2020-02-26 06:22:33.2586351, Warning, TabularRowSkip, """data4"", ""data5"", ""data6"","", "Violation of PRIMARY KEY constraint 'PK_tblintstrdatetimewithpk'. Cannot insert duplicate key in object 'dbo.tblintstrdatetimewithpk'. The duplicate key value is (data4)."
```

From the sample log file above, you can see one row "data1, data2, data3" has been skipped due to type

conversion issue from source to destination store. Another row "data4, data5, data6" has been skipped due to PK violation issue from source to destination store.

Copying tabular data (legacy):

The following approach is the legacy way to enable fault tolerance for copying tabular data only. If you are creating new pipeline or activity, you are encouraged to start from here instead.

Configuration

The following example provides a JSON definition to configure skipping the incompatible rows in copy activity:

```
"typeProperties": {
    "source": {
        "type": "BlobSource"
    },
    "sink": {
        "type": "SqlSink",
    },
    "enableSkipIncompatibleRow": true,
    "redirectIncompatibleRowSettings": {
         "linkedServiceName": {
              "referenceName": "<Azure Storage or Data Lake Store linked service>",
              "type": "LinkedServiceReference"
            },
            "path": "redirectcontainer/erroroutput"
     }
}
```

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
enableSkipIncompatibleRow	Specifies whether to skip incompatible rows during copy or not.	True False (default)	No
redirectIncompatibleRowSettings	A group of properties that can be specified when you want to log the incompatible rows.		No
linkedServiceName	The linked service of Azure Storage or Azure Data Lake Store to store the log that contains the skipped rows.	The names of an `AzureStorage` or `AzureDataLakeStore` type linked service, which refers to the instance that you want to use to store the log file.	No
path	The path of the log file that contains the skipped rows.	Specify the path that you want to use to log the incompatible data. If you do not provide a path, the service creates a container for you.	No

Monitor skipped rows

After the copy activity run completes, you can see the number of skipped rows in the output of the copy activity:

```
"output": {
            "dataRead": 95,
            "dataWritten": 186,
            "rowsCopied": 9,
            "rowsSkipped": 2,
            "copyDuration": 16,
            "throughput": 0.01,
            "redirectRowPath": "https://myblobstorage.blob.core.windows.net//myfolder/a84bf8d4-233f-4216-
8cb5-45962831cd1b/",
            "errors": []
        },
```

If you configure to log the incompatible rows, you can find the log file at this path:

```
https://[your-blob-account].blob.core.windows.net/[path-if-configured]/[copy-activity-run-id]/[auto-
generated-GUID].csv
```

.

The log files can only be the csv files. The original data being skipped will be logged with comma as column delimiter if needed. We add two more columns "ErrorCode" and "ErrorMessage" in additional to the original source data in log file, where you can see the root cause of the incompatibility. The ErrorCode and ErrorMessage will be quoted by double quotes.

An example of the log file content is as follows:

```
data1, data2, data3, "UserErrorInvalidDataValue", "Column 'Prop_2' contains an invalid value 'data3'. Cannot
convert 'data3' to type 'DateTime'."
data4, data5, data6, "2627", "Violation of PRIMARY KEY constraint 'PK_tblintstrdatetimewithpk'. Cannot
insert duplicate key in object 'dbo.tblintstrdatetimewithpk'. The duplicate key value is (data4)."
```

- Copy activity performance

Data consistency verification in copy activity

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

When you move data from source to destination store, the copy activity provides an option for you to do additional data consistency verification to ensure the data is not only successfully copied from source to destination store, but also verified to be consistent between source and destination store. Once inconsistent files have been found during the data movement, you can either abort the copy activity or continue to copy the rest by enabling fault tolerance setting to skip inconsistent files. You can get the skipped file names by enabling session log setting in copy activity. You can refer to session log in copy activity for more details.

Supported data stores and scenarios

- Data consistency verification is supported by all the connectors except FTP, SFTP, HTTP, Snowflake, Office 365 and Azure Databricks Delta Lake.
- Data consistency verification is not supported in staging copy scenario.
- When copying binary files, data consistency verification is only available when 'PreserveHierarchy' behavior is set in copy activity.
- When copying multiple binary files in single copy activity with data consistency verification enabled, you have an option to either abort the copy activity or continue to copy the rest by enabling fault tolerance setting to skip inconsistent files.
- When copying a table in single copy activity with data consistency verification enabled, copy activity fails if the number of rows read from the source is different from the number of rows copied to the destination plus the number of incompatible rows that were skipped.

Configuration

The following example provides a JSON definition to enable data consistency verification in Copy Activity:

```
"typeProperties": {
"source": {
        "type": "BinarySource",
        "storeSettings": {
            "type": "AzureDataLakeStoreReadSettings",
            "recursive": true
        }
    },
    "sink": {
        "type": "BinarySink",
        "storeSettings": {
            "type": "AzureDataLakeStoreWriteSettings"
        }
},
    "validateDataConsistency": true,
    "skipErrorFile": {
        "dataInconsistency": true
    },
    "logSettings": {
        "enableCopyActivityLog": true,
        "copyActivityLogSettings": {
            "logLevel": "Warning",
            "enableReliableLogging": false
        },
        "logLocationSettings": {
            "linkedServiceName": {
               "referenceName": "ADLSGen2",
               "type": "LinkedServiceReference"
            },
            "path": "sessionlog/"
        }
    }
}
```

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
validateDataConsistency	If you set true for this property, when copying binary files, copy activity will check file size, lastModifiedDate, and MD5 checksum for each binary file copied from source to destination store to ensure the data consistency between source and destination store. When copying tabular data, copy activity will check the total row count after job completes to ensure the total number of rows read from the source is same as the number of rows copied to the destination plus the number of incompatible rows that were skipped. Be aware the copy performance will be affected by enabling this option.	True False (default)	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
dataInconsistency	One of the key-value pairs within skipErrorFile property bag to determine if you want to skip the inconsistent files. -True: you want to copy the rest by skipping inconsistent files. - False: you want to abort the copy activity once inconsistent file found. Be aware this property is only valid when you are copying binary files and set validateDataConsistency as True.	True False (default)	No
logSettings	A group of properties that can be specified to enable session log to log skipped files.		No
linkedServiceName	The linked service of Azure Blob Storage or Azure Data Lake Storage Gen2 to store the session log files.	The names of an `AzureBlobStorage` or `AzureBlobFS` types linked service, which refers to the instance that you use to store the log files.	No
path	The path of the log files.	Specify the path that you want to store the log files. If you do not provide a path, the service creates a container for you.	No

NOTE

- When copying binary files from, or to Azure Blob or Azure Data Lake Storage Gen2, the service does block level MD5 checksum verification leveraging Azure Blob API and Azure Data Lake Storage Gen2 API. If ContentMD5 on files exist on Azure Blob or Azure Data Lake Storage Gen2 as data sources, the service does file level MD5 checksum verification after reading the files as well. After copying files to Azure Blob or Azure Data Lake Storage Gen2 as data destination, the service writes ContentMD5 to Azure Blob or Azure Data Lake Storage Gen2 which can be further consumed by downstream applications for data consistency verification.
- The service does file size verification when copying binary files between any storage stores.

Monitoring

Output from copy activity

After the copy activity runs completely, you can see the result of data consistency verification from the output of each copy activity run:

```
"output": {
            "dataRead": 695,
            "dataWritten": 186,
            "filesRead": 3,
            "filesWritten": 1,
            "filesSkipped": 2,
            "throughput": 297,
            "logFilePath": "myfolder/a84bf8d4-233f-4216-8cb5-45962831cd1b/",
            "dataConsistencyVerification":
           {
                "VerificationResult": "Verified",
                "InconsistentData": "Skipped"
           }
        }
```

You can see the details of data consistency verification from "dataConsistencyVerification property".

Value of **VerificationResult**:

- **Verified**: Your copied data has been verified to be consistent between source and destination store.
- **NotVerified**: Your copied data has not been verified to be consistent because you have not enabled the validateDataConsistency in copy activity.
- **Unsupported**: Your copied data has not been verified to be consistent because data consistency verification is not supported for this particular copy pair.

Value of **InconsistentData**:

- **Found**: The copy activity has found inconsistent data.
- **Skipped**: The copy activity has found and skipped inconsistent data.
- **None**: The copy activity has not found any inconsistent data. It can be either because your data has been verified to be consistent between source and destination store or because you disabled validateDataConsistency in copy activity.

Session log from copy activity

If you configure to log the inconsistent file, you can find the log file from this path: `https://[your-blob-account].blob.core.windows.net/[path-if-configured]/copyactivity-logs/[copy-activity-name]/[copy-activity-run-id]/[auto-generated-GUID].csv`. The log files will be the csv files.

The schema of a log file is as following:

COLUMN	DESCRIPTION
Timestamp	The timestamp when the service skips the inconsistent files.
Level	The log level of this item. It will be in 'Warning' level for the item showing file skipping.
OperationName	The copy activity operational behavior on each file. It will be 'FileSkip' to specify the file to be skipped.
OperationItem	The file name to be skipped.
Message	More information to illustrate why files being skipped.

The example of a log file is as following:

```
Timestamp, Level, OperationName, OperationItem, Message
2020-02-26 06:22:56.3190846, Warning, FileSkip, "sample1.csv", "File is skipped after read 548000000 bytes:
ErrorCode=DataConsistencySourceDataChanged,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryExceptio
n,Message=Source file 'sample1.csv' is changed by other clients during the copy activity run.,Source=,'."
```

From the log file above, you can see sample1.csv has been skipped because it failed to be verified to be consistent between source and destination store. You can get more details about why sample1.csv becomes inconsistent is because it was being changed by other applications when the copy activity is copying at the same time.

- Copy activity fault tolerance

Supported file formats and compression codecs in Azure Data Factory and Synapse Analytics (legacy)

8/19/2022 • 18 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article applies to the following connectors: Amazon S3, Azure Blob, Azure Data Lake Storage Gen1, Azure Data Lake Storage Gen2, Azure Files, File System, FTP, Google Cloud Storage, HDFS, HTTP, and SFTP.

IMPORTANT

The service introduced new format-based dataset model, see corresponding format article with details:

- Avro format
- Binary format
- Delimited text format
- JSON format
- ORC format
- Parquet format

The rest configurations mentioned in this article are still supported as-is for backward compabitility. You are suggested to use the new model going forward.

Text format (legacy)

NOTE

Learn the new model from Delimited text format article. The following configurations on file-based data store dataset is still supported as-is for backward compabitility. You are suggested to use the new model going forward.

If you want to read from a text file or write to a text file, set the `type` property in the `format` section of the dataset to **TextFormat**. You can also specify the following **optional** properties in the `format` section. See TextFormat example section on how to configure.

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
columnDelimiter	The character used to separate columns in a file. You can consider to use a rare unprintable character that may not exist in your data. For example, specify "\u0001", which represents Start of Heading (SOH).	Only one character is allowed. The **default** value is **comma (',')**. To use a Unicode character, refer to Unicode Characters to get the corresponding code for it.	No
rowDelimiter	The character used to separate rows in a file.	Only one character is allowed. The **default** value is any of the following values on read: **["\r\n", "\r", "\n"]** and **"\r\n"** on write.	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
escapeChar	The special character used to escape a column delimiter in the content of input file. You cannot specify both escapeChar and quoteChar for a table.	Only one character is allowed. No default value. Example: if you have comma (',') as the column delimiter but you want to have the comma character in the text (example: "Hello, world"), you can define '$' as the escape character and use string "Hello$, world" in the source.	No
quoteChar	The character used to quote a string value. The column and row delimiters inside the quote characters would be treated as part of the string value. This property is applicable to both input and output datasets. You cannot specify both escapeChar and quoteChar for a table.	Only one character is allowed. No default value. For example, if you have comma (',') as the column delimiter but you want to have comma character in the text (example: <Hello, world>), you can define " (double quote) as the quote character and use the string "Hello, world" in the source.	No
nullValue	One or more characters used to represent a null value.	One or more characters. The **default** values are **"\N" and "NULL"** on read and **"\N"** on write.	No
encodingName	Specify the encoding name.	A valid encoding name. see Encoding.EncodingName Property. Example: windows-1250 or shift_jis. The **default** value is **UTF-8**.	No
firstRowAsHeader	Specifies whether to consider the first row as a header. For an input dataset, the service reads first row as a header. For an output dataset, the service writes first row as a header. See Scenarios for using `firstRowAsHeader` and `skipLineCount` for sample scenarios.	True **False (default)**	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
skipLineCount	Indicates the number of **non-empty** rows to skip when reading data from input files. If both skipLineCount and firstRowAsHeader are specified, the lines are skipped first and then the header information is read from the input file. See Scenarios for using `firstRowAsHeader` and `skipLineCount` for sample scenarios.	Integer	No
treatEmptyAsNull	Specifies whether to treat null or empty string as a null value when reading data from an input file.	**True (default)** False	No

TextFormat example

In the following JSON definition for a dataset, some of the optional properties are specified.

```
"typeProperties":
{
    "folderPath": "mycontainer/myfolder",
    "fileName": "myblobname",
    "format":
    {
        "type": "TextFormat",
        "columnDelimiter": ",",
        "rowDelimiter": ";",
        "quoteChar": "\"",
        "NullValue": "NaN",
        "firstRowAsHeader": true,
        "skipLineCount": 0,
        "treatEmptyAsNull": true
    }
},
```

To use an `escapeChar` instead of `quoteChar`, replace the line with `quoteChar` with the following escapeChar:

```
"escapeChar": "$",
```

Scenarios for using firstRowAsHeader and skipLineCount

- You are copying from a non-file source to a text file and would like to add a header line containing the schema metadata (for example: SQL schema). Specify `firstRowAsHeader` as true in the output dataset for this scenario.
- You are copying from a text file containing a header line to a non-file sink and would like to drop that line. Specify `firstRowAsHeader` as true in the input dataset.
- You are copying from a text file and want to skip a few lines at the beginning that contain no data or header information. Specify `skipLineCount` to indicate the number of lines to be skipped. If the rest of the file contains a header line, you can also specify `firstRowAsHeader`. If both `skipLineCount` and `firstRowAsHeader` are specified, the lines are skipped first and then the header information is read from the input file

JSON format (legacy)

> **NOTE**
>
> Learn the new model from JSON format article. The following configurations on file-based data store dataset is still supported as-is for backward compatibility. You are suggested to use the new model going forward.

To **import/export a JSON file as-is into/from Azure Cosmos DB**, see Import/export JSON documents section in Move data to/from Azure Cosmos DB article.

If you want to parse the JSON files or write the data in JSON format, set the `type` property in the `format` section to **JsonFormat**. You can also specify the following **optional** properties in the `format` section. See JsonFormat example section on how to configure.

PROPERTY	DESCRIPTION	REQUIRED
filePattern	Indicate the pattern of data stored in each JSON file. Allowed values are: **setOfObjects** and **arrayOfObjects**. The **default** value is **setOfObjects**. See JSON file patterns section for details about these patterns.	No
jsonNodeReference	If you want to iterate and extract data from the objects inside an array field with the same pattern, specify the JSON path of that array. This property is supported only when copying data **from** JSON files.	No
jsonPathDefinition	Specify the JSON path expression for each column mapping with a customized column name (start with lowercase). This property is supported only when copying data **from** JSON files, and you can extract data from object or array. For fields under root object, start with root $; for fields inside the array chosen by `jsonNodeReference` property, start from the array element. See JsonFormat example section on how to configure.	No
encodingName	Specify the encoding name. For the list of valid encoding names, see: Encoding.EncodingName Property. For example: windows-1250 or shift_jis. The **default** value is: **UTF-8**.	No
nestingSeparator	Character that is used to separate nesting levels. The default value is '.' (dot).	No

> **NOTE**
>
> For the case of cross-apply data in array into multiple rows (case 1 -> sample 2 in JsonFormat examples), you can only choose to expand single array using property `jsonNodeReference`.

JSON file patterns

Copy activity can parse the following patterns of JSON files:

- Type I: setOfObjects

  Each file contains single object, or line-delimited/concatenated multiple objects. When this option is chosen in an output dataset, copy activity produces a single JSON file with each object per line (line-delimited).

  - single object JSON example

    ```
    {
        "time": "2015-04-29T07:12:20.9100000Z",
        "callingimsi": "466920403025604",
        "callingnum1": "678948008",
        "callingnum2": "567834760",

```

JsonFormat example

Case 1: Copying data from JSON files

Sample 1: extract data from object and array

In this sample, you expect one root JSON object maps to single record in tabular result. If you have a JSON file with the following content:

```
{
    "id": "ed0e4960-d9c5-11e6-85dc-d7996816aad3",
    "context": {
        "device": {
            "type": "PC"
        },
        "custom": {
            "dimensions": [
                {
                    "TargetResourceType": "Microsoft.Compute/virtualMachines"
                },
                {
                    "ResourceManagementProcessRunId": "827f8aaa-ab72-437c-ba48-d8917a7336a3"
                },
                {
                    "OccurrenceTime": "1/13/2017 11:24:37 AM"
                }
            ]
        }
    }
}
```

and you want to copy it into an Azure SQL table in the following format, by extracting data from both objects and array:

ID	DEVICETYPE	TARGETRESOURCETYPE	RESOURCEMANAGEMENTPROCESSRUNID	OCCURRENCETIME
ed0e4960-d9c5-11e6-85dc-d7996816aad3	PC	Microsoft.Compute/virtualMachines	827f8aaa-ab72-437c-ba48-d8917a7336a3	1/13/2017 11:24:37 AM

The input dataset with **JsonFormat** type is defined as follows: (partial definition with only the relevant parts). More specifically:

- `structure` section defines the customized column names and the corresponding data type while converting to tabular data. This section is **optional** unless you need to do column mapping. For more information, see Map source dataset columns to destination dataset columns.
- `jsonPathDefinition` specifies the JSON path for each column indicating where to extract the data from. To copy data from array, you can use `array[x].property` to extract value of the given property from the `xth` object, or you can use `array[*].property` to find the value from any object containing such property.

```
"properties": {
    "structure": [
        {
            "name": "id",
            "type": "String"
        },
        {
            "name": "deviceType",
            "type": "String"
        },
        {
            "name": "targetResourceType",
            "type": "String"
        },
        {
            "name": "resourceManagementProcessRunId",
            "type": "String"
        },
        {
            "name": "occurrenceTime",
            "type": "DateTime"
        }
    ],
    "typeProperties": {
        "folderPath": "mycontainer/myfolder",
        "format": {
            "type": "JsonFormat",
            "filePattern": "setOfObjects",
            "jsonPathDefinition": {"id": "$.id", "deviceType": "$.context.device.type",
"targetResourceType": "$.context.custom.dimensions[0].TargetResourceType", "resourceManagementProcessRunId":
"$.context.custom.dimensions[1].ResourceManagementProcessRunId", "occurrenceTime": "
$.context.custom.dimensions[2].OccurrenceTime"}
        }
    }
}
```

Sample 2: cross apply multiple objects with the same pattern from array

In this sample, you expect to transform one root JSON object into multiple records in tabular result. If you have a JSON file with the following content:

```
{
    "ordernumber": "01",
    "orderdate": "20170122",
    "orderlines": [
        {
            "prod": "p1",
            "price": 23
        },
        {
            "prod": "p2",
            "price": 13
        },
        {
            "prod": "p3",
            "price": 231
        }
    ],
    "city": [ { "sanmateo": "No 1" } ]
}
```

and you want to copy it into an Azure SQL table in the following format, by flattening the data inside the array and cross join with the common root info:

ORDERNUMBER	ORDERDATE	ORDER_PD	ORDER_PRICE	CITY
01	20170122	P1	23	`[{"sanmateo":"No 1"}]`
01	20170122	P2	13	`[{"sanmateo":"No 1"}]`
01	20170122	P3	231	`[{"sanmateo":"No 1"}]`

The input dataset with **JsonFormat** type is defined as follows: (partial definition with only the relevant parts). More specifically:

- `structure` section defines the customized column names and the corresponding data type while converting to tabular data. This section is **optional** unless you need to do column mapping. For more information, see Map source dataset columns to destination dataset columns.
- `jsonNodeReference` indicates to iterate and extract data from the objects with the same pattern under **array** `orderlines`.
- `jsonPathDefinition` specifies the JSON path for each column indicating where to extract the data from. In this example, `ordernumber`, `orderdate`, and `city` are under root object with JSON path starting with `$.`, while `order_pd` and `order_price` are defined with path derived from the array element without `$.`.

```
"properties": {
    "structure": [
        {
            "name": "ordernumber",
            "type": "String"
        },
        {
            "name": "orderdate",
            "type": "String"
        },
        {
            "name": "order_pd",
            "type": "String"
        },
        {
            "name": "order_price",
            "type": "Int64"
        },
        {
            "name": "city",
            "type": "String"
        }
    ],
    "typeProperties": {
        "folderPath": "mycontainer/myfolder",
        "format": {
            "type": "JsonFormat",
            "filePattern": "setOfObjects",
            "jsonNodeReference": "$.orderlines",
            "jsonPathDefinition": {"ordernumber": "$.ordernumber", "orderdate": "$.orderdate", "order_pd":
"prod", "order_price": "price", "city": " $.city"}
        }
    }
}
```

Note the following points:

- If the `structure` and `jsonPathDefinition` are not defined in the dataset, the Copy Activity detects the schema from the first object and flatten the whole object.
- If the JSON input has an array, by default the Copy Activity converts the entire array value into a string. You can choose to extract data from it using `jsonNodeReference` and/or `jsonPathDefinition`, or skip it by not specifying it in `jsonPathDefinition`.
- If there are duplicate names at the same level, the Copy Activity picks the last one.
- Property names are case-sensitive. Two properties with same name but different casings are treated as two separate properties.

Case 2: Writing data to JSON file

If you have the following table in SQL Database:

ID	ORDER_DATE	ORDER_PRICE	ORDER_BY
1	20170119	2000	David
2	20170120	3500	Patrick
3	20170121	4000	Jason

and for each record, you expect to write to a JSON object in the following format:

```
{
    "id": "1",
    "order": {
        "date": "20170119",
        "price": 2000,
        "customer": "David"
    }
}
```

The output dataset with **JsonFormat** type is defined as follows: (partial definition with only the relevant parts). More specifically, `structure` section defines the customized property names in destination file, `nestingSeparator` (default is ".") are used to identify the nest layer from the name. This section is **optional** unless you want to change the property name comparing with source column name, or nest some of the properties.

```
"properties": {
    "structure": [
        {
            "name": "id",
            "type": "String"
        },
        {
            "name": "order.date",
            "type": "String"
        },
        {
            "name": "order.price",
            "type": "Int64"
        },
        {
            "name": "order.customer",
            "type": "String"
        }
    ],
    "typeProperties": {
        "folderPath": "mycontainer/myfolder",
        "format": {
            "type": "JsonFormat"
        }
    }
}
```

Parquet format (legacy)

> **NOTE**
>
> Learn the new model from Parquet format article. The following configurations on file-based data store dataset is still supported as-is for backward compabitility. You are suggested to use the new model going forward.

If you want to parse the Parquet files or write the data in Parquet format, set the `format` `type` property to **ParquetFormat**. You do not need to specify any properties in the Format section within the typeProperties section. Example:

```
"format":
{
    "type": "ParquetFormat"
}
```

Note the following points:

- Complex data types are not supported (MAP, LIST).
- White space in column name is not supported.
- Parquet file has the following compression-related options: NONE, SNAPPY, GZIP, and LZO. The service supports reading data from Parquet file in any of these compressed formats except LZO - it uses the compression codec in the metadata to read the data. However, when writing to a Parquet file, the service chooses SNAPPY, which is the default for Parquet format. Currently, there is no option to override this behavior.

IMPORTANT

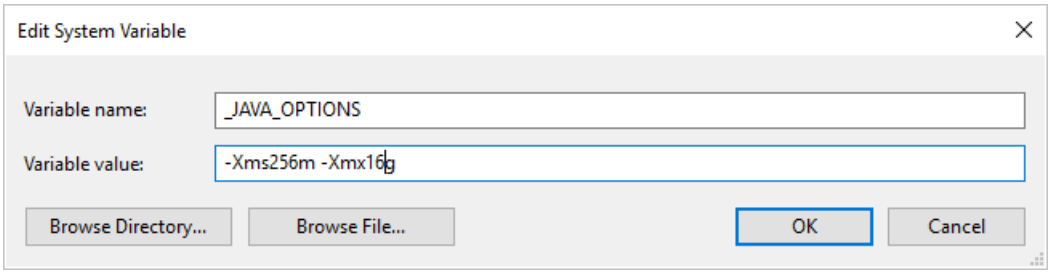
For copy empowered by Self-hosted Integration Runtime e.g. between on-premises and cloud data stores, if you are not copying Parquet files **as-is**, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** on your IR machine. See the following paragraph with more details.

For copy running on Self-hosted IR with Parquet file serialization/deserialization, the service locates the Java runtime by firstly checking the registry `(SOFTWARE\JavaSoft\Java Runtime Environment\{Current Version}\JavaHome)` for JRE, if not found, secondly checking system variable `JAVA_HOME` for OpenJDK.

- **To use JRE**: The 64-bit IR requires 64-bit JRE. You can find it from here.
- **To use OpenJDK**: it's supported since IR version 3.13. Package the jvm.dll with all other required assemblies of OpenJDK into Self-hosted IR machine, and set system environment variable JAVA_HOME accordingly.

TIP

If you copy data to/from Parquet format using Self-hosted Integration Runtime and hit error saying "An error occurred when invoking java, message: **java.lang.OutOfMemoryError:Java heap space**", you can add an environment variable `_JAVA_OPTIONS` in the machine that hosts the Self-hosted IR to adjust the min/max heap size for JVM to empower such copy, then rerun the pipeline.



Example: set variable `_JAVA_OPTIONS` with value `-Xms256m -Xmx16g`. The flag `Xms` specifies the initial memory allocation pool for a Java Virtual Machine (JVM), while `Xmx` specifies the maximum memory allocation pool. This means that JVM will be started with `Xms` amount of memory and will be able to use a maximum of `Xmx` amount of memory. By default, the service uses min 64MB and max 1G.

Data type mapping for Parquet files

INTERIM SERVICE DATA TYPE	PARQUET PRIMITIVE TYPE	PARQUET ORIGINAL TYPE (DESERIALIZE)	PARQUET ORIGINAL TYPE (SERIALIZE)
Boolean	Boolean	N/A	N/A
SByte	Int32	Int8	Int8
Byte	Int32	UInt8	Int16
Int16	Int32	Int16	Int16
UInt16	Int32	UInt16	Int32
Int32	Int32	Int32	Int32
UInt32	Int64	UInt32	Int64

INTERIM SERVICE DATA TYPE	PARQUET PRIMITIVE TYPE	PARQUET ORIGINAL TYPE (DESERIALIZE)	PARQUET ORIGINAL TYPE (SERIALIZE)
Int64	Int64	Int64	Int64
UInt64	Int64/Binary	UInt64	Decimal
Single	Float	N/A	N/A
Double	Double	N/A	N/A
Decimal	Binary	Decimal	Decimal
String	Binary	Utf8	Utf8
DateTime	Int96	N/A	N/A
TimeSpan	Int96	N/A	N/A
DateTimeOffset	Int96	N/A	N/A
ByteArray	Binary	N/A	N/A
Guid	Binary	Utf8	Utf8
Char	Binary	Utf8	Utf8
CharArray	Not supported	N/A	N/A

ORC format (legacy)

> **NOTE**
> Learn the new model from ORC format article. The following configurations on file-based data store dataset is still supported as-is for backward compatibility. You are suggested to use the new model going forward.

If you want to parse the ORC files or write the data in ORC format, set the `format` `type` property to **OrcFormat**. You do not need to specify any properties in the Format section within the typeProperties section. Example:

```
"format":
{
    "type": "OrcFormat"
}
```

Note the following points:

- Complex data types are not supported (STRUCT, MAP, LIST, UNION).
- White space in column name is not supported.
- ORC file has three compression-related options: NONE, ZLIB, SNAPPY. The service supports reading data from ORC file in any of these compressed formats. It uses the compression codec is in the metadata to read the data. However, when writing to an ORC file, the service chooses ZLIB, which is the default for ORC.

Currently, there is no option to override this behavior.

> **IMPORTANT**
> For copy empowered by Self-hosted Integration Runtime e.g. between on-premises and cloud data stores, if you are not copying ORC files **as-is**, you need to install the **64-bit JRE 8 (Java Runtime Environment) or OpenJDK** on your IR machine. See the following paragraph with more details.

For copy running on Self-hosted IR with ORC file serialization/deserialization, the service locates the Java runtime by firstly checking the registry `(SOFTWARE\JavaSoft\Java Runtime Environment\{Current Version}\JavaHome)` for JRE, if not found, secondly checking system variable `JAVA_HOME` for OpenJDK.

- **To use JRE**: The 64-bit IR requires 64-bit JRE. You can find it from here.
- **To use OpenJDK**: it's supported since IR version 3.13. Package the jvm.dll with all other required assemblies of OpenJDK into Self-hosted IR machine, and set system environment variable JAVA_HOME accordingly.

Data type mapping for ORC files

INTERIM SERVICE DATA TYPE	ORC TYPES
Boolean	Boolean
SByte	Byte
Byte	Short
Int16	Short
UInt16	Int
Int32	Int
UInt32	Long
Int64	Long
UInt64	String
Single	Float
Double	Double
Decimal	Decimal
String	String
DateTime	Timestamp
DateTimeOffset	Timestamp
TimeSpan	Timestamp

INTERIM SERVICE DATA TYPE	ORC TYPES
ByteArray	Binary
Guid	String
Char	Char(1)

AVRO format (legacy)

> **NOTE**
> Learn the new model from Avro format article. The following configurations on file-based data store dataset is still supported as-is for backward compatibility. You are suggested to use the new model going forward.

If you want to parse the Avro files or write the data in Avro format, set the `format` `type` property to **AvroFormat**. You do not need to specify any properties in the Format section within the typeProperties section. Example:

```
"format":
{
    "type": "AvroFormat",
}
```

To use Avro format in a Hive table, you can refer to Apache Hive's tutorial.

Note the following points:

- Complex data types are not supported (records, enums, arrays, maps, unions, and fixed).

Compression support (legacy)

The service supports compress/decompress data during copy. When you specify `compression` property in an input dataset, the copy activity read the compressed data from the source and decompress it; and when you specify the property in an output dataset, the copy activity compress then write data to the sink. Here are a few sample scenarios:

- Read GZIP compressed data from an Azure blob, decompress it, and write result data to Azure SQL Database. You define the input Azure Blob dataset with the `compression` `type` property as GZIP.
- Read data from a plain-text file from on-premises File System, compress it using GZip format, and write the compressed data to an Azure blob. You define an output Azure Blob dataset with the `compression` `type` property as GZip.
- Read .zip file from FTP server, decompress it to get the files inside, and land those files in Azure Data Lake Store. You define an input FTP dataset with the `compression` `type` property as ZipDeflate.
- Read a GZIP-compressed data from an Azure blob, decompress it, compress it using BZIP2, and write result data to an Azure blob. You define the input Azure Blob dataset with `compression` `type` set to GZIP and the output dataset with `compression` `type` set to BZIP2.

To specify compression for a dataset, use the **compression** property in the dataset JSON as in the following example:

```
{
    "name": "AzureBlobDataSet",
    "properties": {
        "type": "AzureBlob",
        "linkedServiceName": {
            "referenceName": "StorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "fileName": "pagecounts.csv.gz",
            "folderPath": "compression/file/",
            "format": {
                "type": "TextFormat"
            },
            "compression": {
                "type": "GZip",
                "level": "Optimal"
            }
        }
    }
}
```

The **compression** section has two properties:

- **Type:** the compression codec, which can be **GZIP**, **Deflate**, **BZIP2**, or **ZipDeflate**. Note when using copy activity to decompress ZipDeflate file(s) and write to file-based sink data store, files will be extracted to the folder: `<path specified in dataset>/<folder named as source zip file>/`.
- **Level:** the compression ratio, which can be **Optimal** or **Fastest**.
  - **Fastest:** The compression operation should complete as quickly as possible, even if the resulting file is not optimally compressed.
  - **Optimal**: The compression operation should be optimally compressed, even if the operation takes a longer time to complete.

    For more information, see Compression Level topic.

> **NOTE**
>
> Compression settings are not supported for data in the **AvroFormat**, **OrcFormat**, or **ParquetFormat**. When reading files in these formats, the service detects and uses the compression codec in the metadata. When writing to files in these formats, the service chooses the default compression codec for that format. For example, ZLIB for OrcFormat and SNAPPY for ParquetFormat.

Unsupported file types and compression formats

You can use the extensibility features to transform files that aren't supported. Two options include Azure Functions and custom tasks by using Azure Batch.

You can see a sample that uses an Azure function to extract the contents of a tar file. For more information, see Azure Functions activity.

You can also build this functionality using a custom dotnet activity. Further information is available here

Next steps

Transform data in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

Overview

This article explains data transformation activities in Azure Data Factory and Synapse pipelines that you can use to transform and process your raw data into predictions and insights at scale. A transformation activity executes in a computing environment such as Azure Databricks or Azure HDInsight. It provides links to articles with detailed information on each transformation activity.

The service supports the following data transformation activities that can be added to pipelines either individually or chained with another activity.

Transform natively in Azure Data Factory and Azure Synapse Analytics with data flows

Mapping data flows

Mapping data flows are visually designed data transformations in Azure Data Factory and Azure Synapse. Data flows allow data engineers to develop graphical data transformation logic without writing code. The resulting data flows are executed as activities within pipelines that use scaled-out Spark clusters. Data flow activities can be operationalized via existing scheduling, control, flow, and monitoring capabilities within the service. For more information, see mapping data flows.

Data wrangling

Power Query in Azure Data Factory enables cloud-scale data wrangling, which allows you to do code-free data preparation at cloud scale iteratively. Data wrangling integrates with Power Query Online and makes Power Query M functions available for data wrangling at cloud scale via spark execution. For more information, see data wrangling in Azure Data Factory.

> **NOTE**
>
> Power Query is currently only supported in Azure Data Factory, and not in Azure Synapse. For a list of specific features supported in each service, see Available features in Azure Data Factory & Azure Synapse Analytics pipelines.

External transformations

Optionally, you can hand-code transformations and manage the external compute environment yourself.

HDInsight Hive activity

The HDInsight Hive activity in a pipeline executes Hive queries on your own or on-demand Windows/Linux-based HDInsight cluster. See Hive activity article for details about this activity.

HDInsight Pig activity

The HDInsight Pig activity in a pipeline executes Pig queries on your own or on-demand Windows/Linux-based HDInsight cluster. See Pig activity article for details about this activity.

HDInsight MapReduce activity

The HDInsight MapReduce activity in a pipeline executes MapReduce programs on your own or on-demand Windows/Linux-based HDInsight cluster. See MapReduce activity article for details about this activity.

HDInsight Streaming activity

The HDInsight Streaming activity in a pipeline executes Hadoop Streaming programs on your own or on-demand Windows/Linux-based HDInsight cluster. See HDInsight Streaming activity for details about this activity.

HDInsight Spark activity

The HDInsight Spark activity in a pipeline executes Spark programs on your own HDInsight cluster. For details, see Invoke Spark programs with Azure Data Factory or Azure Synapse Analytics.

ML Studio (classic) activities

> **IMPORTANT**
>
> Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.
>
> Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.
>
> - See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
> - Learn more about Azure Machine Learning
>
> ML Studio (classic) documentation is being retired and may not be updated in the future.

The service enables you to easily create pipelines that use a published ML Studio (classic) web service for predictive analytics. Using the Batch Execution activity in a pipeline, you can invoke a Studio (classic) web service to make predictions on the data in batch.

Over time, the predictive models in the Studio (classic) scoring experiments need to be retrained using new input datasets. After you are done with retraining, you want to update the scoring web service with the retrained machine learning model. You can use the Update Resource activity to update the web service with the newly trained model.

See Use ML Studio (classic) activities for details about these Studio (classic) activities.

Stored procedure activity

You can use the SQL Server Stored Procedure activity in a Data Factory pipeline to invoke a stored procedure in one of the following data stores: Azure SQL Database, Azure Synapse Analytics, SQL Server Database in your enterprise or an Azure VM. See Stored Procedure activity article for details.

Data Lake Analytics U-SQL activity

Data Lake Analytics U-SQL activity runs a U-SQL script on an Azure Data Lake Analytics cluster. See Data Analytics U-SQL activity article for details.

Azure Synapse Notebook activity

The Azure Synapse Notebook Activity in a Synapse pipeline runs a Synapse notebook in your Azure Synapse workspace. See Transform data by running an Azure Synapse notebook.

Databricks Notebook activity

The Azure Databricks Notebook Activity in a pipeline runs a Databricks notebook in your Azure Databricks workspace. Azure Databricks is a managed platform for running Apache Spark. See Transform data by running a Databricks notebook.

Databricks Jar activity

The Azure Databricks Jar Activity in a pipeline runs a Spark Jar in your Azure Databricks cluster. Azure Databricks is a managed platform for running Apache Spark. See Transform data by running a Jar activity in Azure Databricks.

Databricks Python activity

The Azure Databricks Python Activity in a pipeline runs a Python file in your Azure Databricks cluster. Azure Databricks is a managed platform for running Apache Spark. See Transform data by running a Python activity in Azure Databricks.

Custom activity

If you need to transform data in a way that is not supported by Data Factory, you can create a custom activity with your own data processing logic and use the activity in the pipeline. You can configure the custom .NET activity to run using either an Azure Batch service or an Azure HDInsight cluster. See Use custom activities article for details.

You can create a custom activity to run R scripts on your HDInsight cluster with R installed. See Run R Script using Azure Data Factory and Synapse pipelines.

Compute environments

You create a linked service for the compute environment and then use the linked service when defining a transformation activity. There are two supported types of compute environments.

- **On-Demand**: In this case, the computing environment is fully managed by the service. It is automatically created by the service before a job is submitted to process data and removed when the job is completed. You can configure and control granular settings of the on-demand compute environment for job execution, cluster management, and bootstrapping actions.
- **Bring Your Own**: In this case, you can register your own computing environment (for example HDInsight cluster) as a linked service. The computing environment is managed by you and the service uses it to execute the activities.

See Compute Linked Services article to learn about supported compute services.

Next steps

See the following tutorial for an example of using a transformation activity: Tutorial: transform data using Spark

Data Flow activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

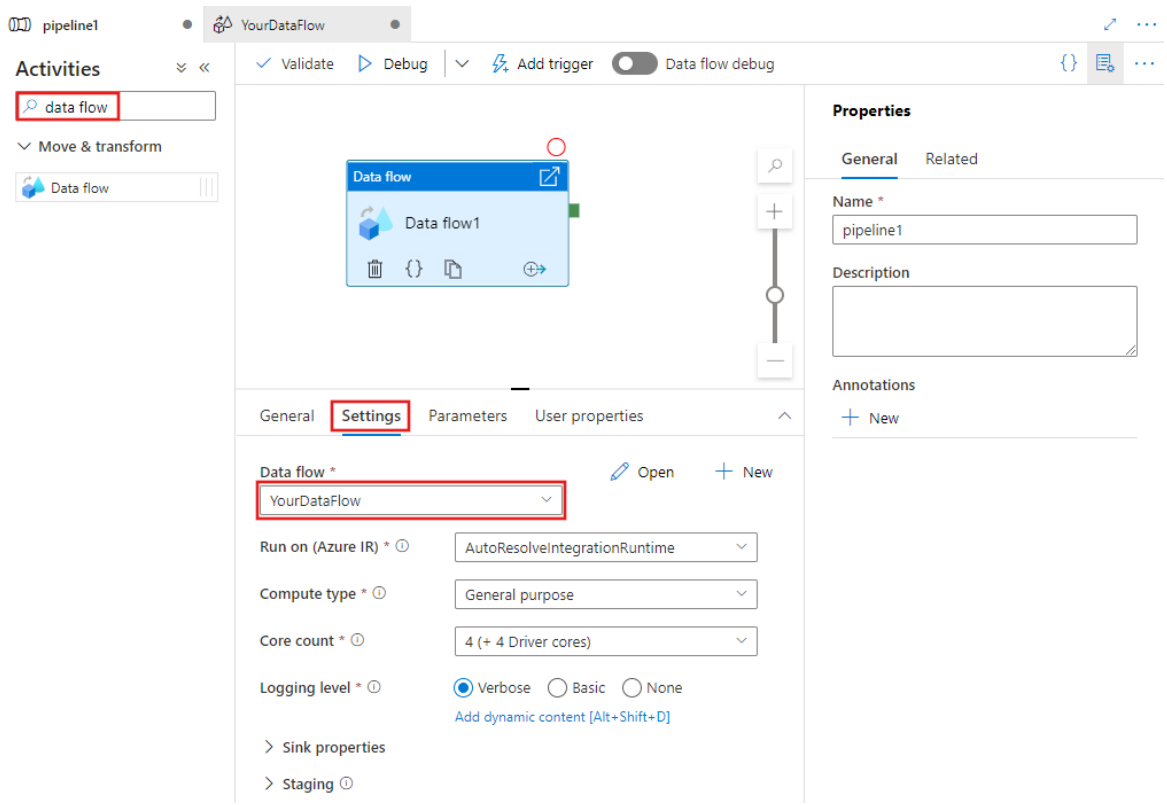
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Use the Data Flow activity to transform and move data via mapping data flows. If you're new to data flows, see Mapping Data Flow overview

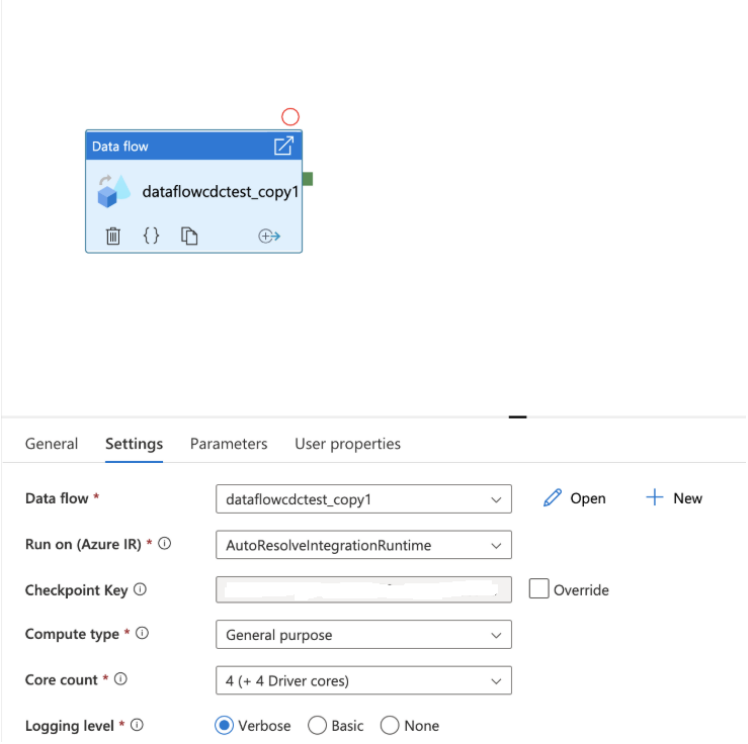
Create a Data Flow activity with UI

To use a Data Flow activity in a pipeline, complete the following steps:

1. Search for *Data Flow* in the pipeline Activities pane, and drag a Data Flow activity to the pipeline canvas.
2. Select the new Data Flow activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Checkpoint key is used to set the checkpoint when data flow is used for changed data capture. You can overwrite it. Data flow activities use a guid value as checkpoint key instead of "pipelinename + activityname" so that it can always keep tracking customer's change data capture state even there's any renaming actions. All existing data flow activity will use the old pattern key for backward compatibility. Checkpoint key option after publishing a new data flow activity with change data capture enabled data flow resource is shown as below.



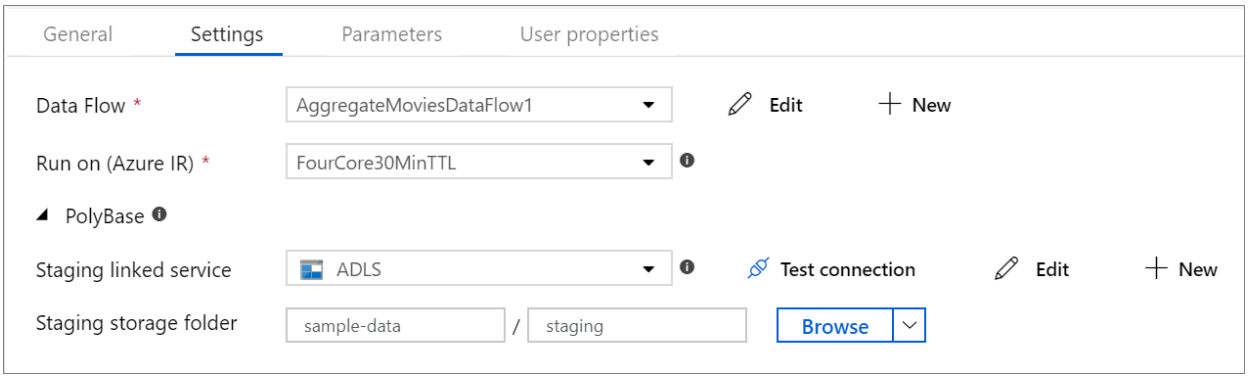
4. Select an existing data flow or create a new one using the New button. Select other options as required to complete your configuration.

Syntax

```
{
    "name": "MyDataFlowActivity",
    "type": "ExecuteDataFlow",
    "typeProperties": {
      "dataflow": {
         "referenceName": "MyDataFlow",
         "type": "DataFlowReference"
      },
      "compute": {
         "coreCount": 8,
         "computeType": "General"
      },
      "traceLevel": "Fine",
      "runConcurrently": true,
      "continueOnError": true,
      "staging": {
          "linkedService": {
              "referenceName": "MyStagingLinkedService",
              "type": "LinkedServiceReference"
          },
          "folderPath": "my-container/my-folder"
      },
      "integrationRuntime": {
          "referenceName": "MyDataFlowIntegrationRuntime",
          "type": "IntegrationRuntimeReference"
      }
}
```

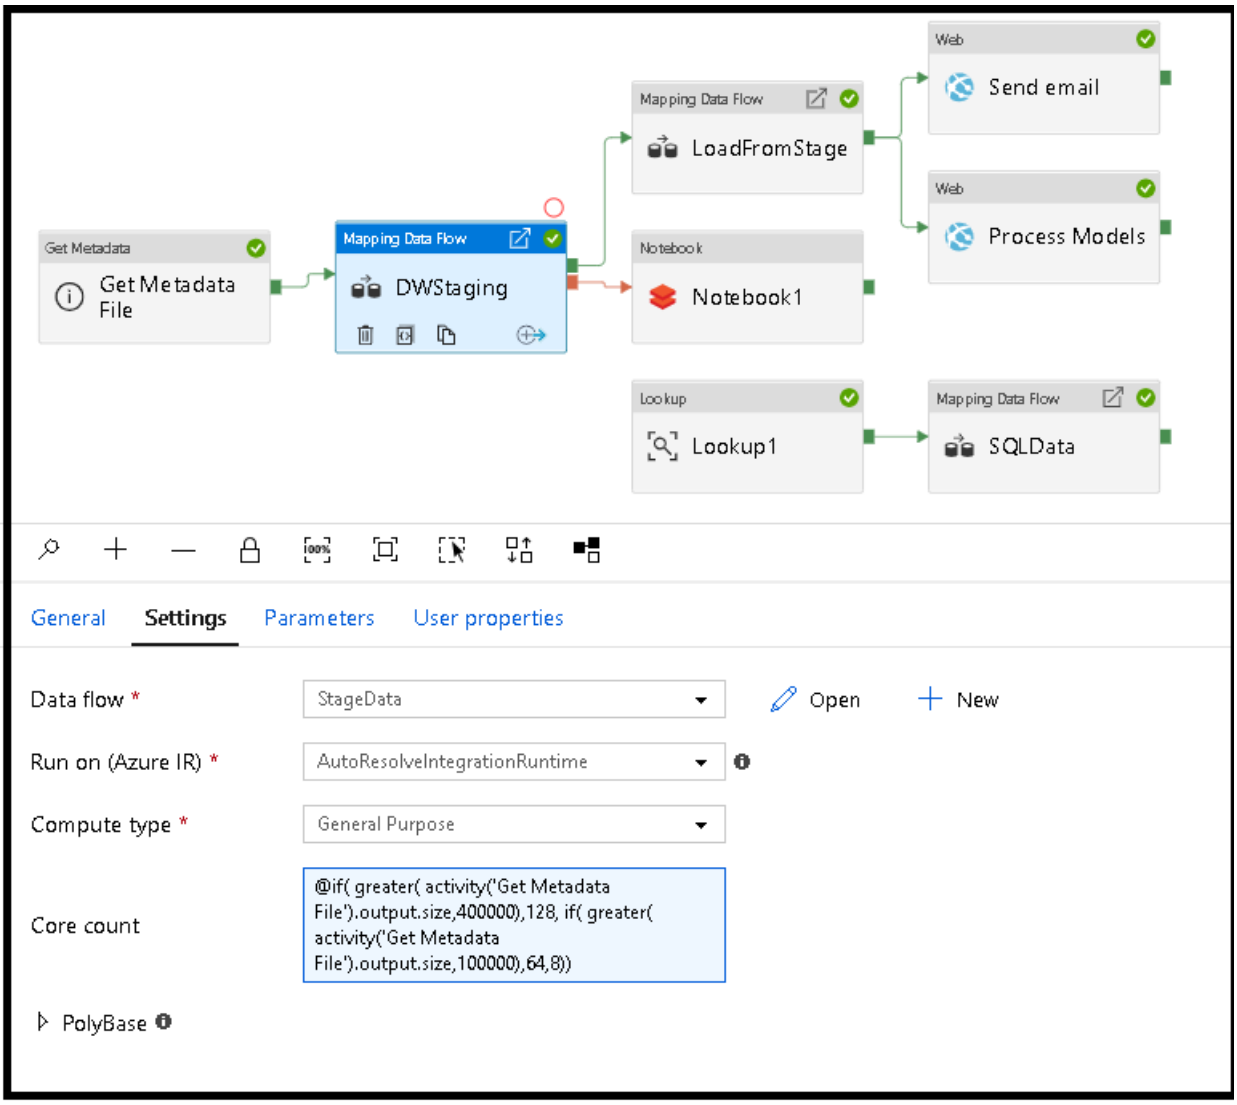
Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
dataflow	The reference to the Data Flow being executed	DataFlowReference	Yes
integrationRuntime	The compute environment the data flow runs on. If not specified, the auto-resolve Azure integration runtime will be used.	IntegrationRuntimeReference	No
compute.coreCount	The number of cores used in the spark cluster. Can only be specified if the auto-resolve Azure Integration runtime is used	8, 16, 32, 48, 80, 144, 272	No
compute.computeType	The type of compute used in the spark cluster. Can only be specified if the auto-resolve Azure Integration runtime is used	"General", "MemoryOptimized"	No
staging.linkedService	If you're using an Azure Synapse Analytics source or sink, specify the storage account used for PolyBase staging. If your Azure Storage is configured with VNet service endpoint, you must use managed identity authentication with "allow trusted Microsoft service" enabled on storage account, refer to Impact of using VNet Service Endpoints with Azure storage. Also learn the needed configurations for Azure Blob and Azure Data Lake Storage Gen2 respectively.	LinkedServiceReference	Only if the data flow reads or writes to an Azure Synapse Analytics
staging.folderPath	If you're using an Azure Synapse Analytics source or sink, the folder path in blob storage account used for PolyBase staging	String	Only if the data flow reads or writes to Azure Synapse Analytics
traceLevel	Set logging level of your data flow activity execution	Fine, Coarse, None	No



Dynamically size data flow compute at runtime

The Core Count and Compute Type properties can be set dynamically to adjust to the size of your incoming source data at runtime. Use pipeline activities like Lookup or Get Metadata in order to find the size of the source dataset data. Then, use Add Dynamic Content in the Data Flow activity properties. You can choose small, medium, or large compute sizes. Optionally, pick "Custom" and configure the compute types and number of cores manually.



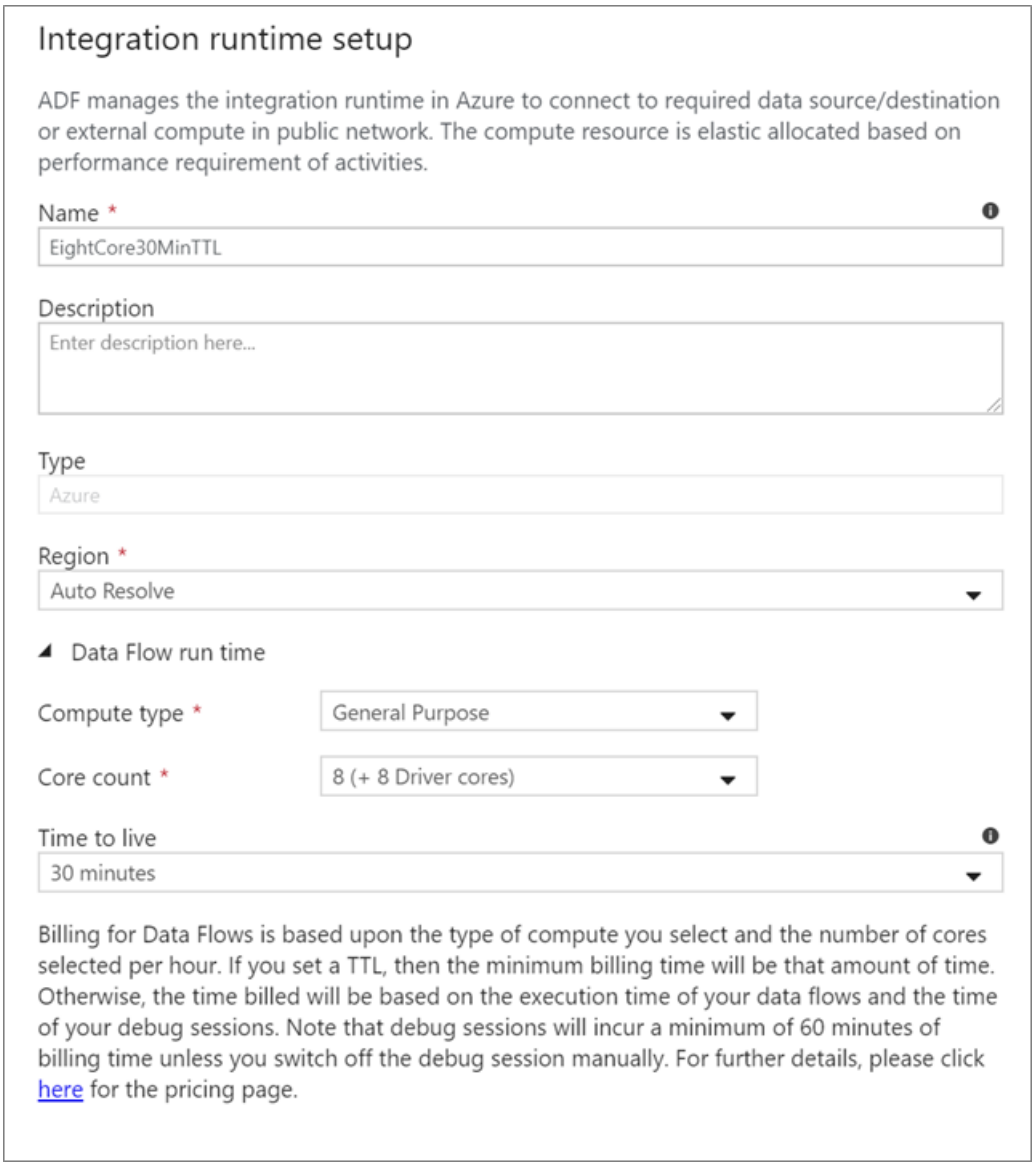
Here is a brief video tutorial explaining this technique

Data Flow integration runtime

Choose which Integration Runtime to use for your Data Flow activity execution. By default, the service will use the auto-resolve Azure Integration runtime with four worker cores. This IR has a general purpose compute type and runs in the same region as your service instance. For operationalized pipelines, it is highly recommended that you create your own Azure Integration Runtimes that define specific regions, compute type, core counts,

and TTL for your data flow activity execution.

A minimum compute type of General Purpose with an 8+8 (16 total v-cores) configuration and a 10-minute Time to live (TTL) is the minimum recommendation for most production workloads. By setting a small TTL, the Azure IR can maintain a warm cluster that will not incur the several minutes of start time for a cold cluster. For more information, see Azure integration runtime.



IMPORTANT

The Integration Runtime selection in the Data Flow activity only applies to *triggered executions* of your pipeline. Debugging your pipeline with data flows runs on the cluster specified in the debug session.

PolyBase

If you're using an Azure Synapse Analytics as a sink or source, you must choose a staging location for your PolyBase batch load. PolyBase allows for batch loading in bulk instead of loading the data row-by-row. PolyBase drastically reduces the load time into Azure Synapse Analytics.

Checkpoint key

When using the change capture option for data flow sources, ADF will maintain and manage the checkpoint for you automatically. The default checkpoint key is a hash of the data flow name and the pipeline name. If you are using a dynamic pattern for your source tables or folders, you may wish to override this hash and set your own checkpoint key value here.

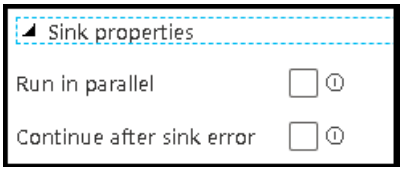
Logging level

If you do not require every pipeline execution of your data flow activities to fully log all verbose telemetry logs, you can optionally set your logging level to "Basic" or "None". When executing your data flows in "Verbose" mode (default), you are requesting the service to fully log activity at each individual partition level during your data transformation. This can be an expensive operation, so only enabling verbose when troubleshooting can improve your overall data flow and pipeline performance. "Basic" mode will only log transformation durations while "None" will only provide a summary of durations.

Sink properties

The grouping feature in data flows allow you to both set the order of execution of your sinks as well as to group sinks together using the same group number. To help manage groups, you can ask the service to run sinks, in the same group, in parallel. You can also set the sink group to continue even after one of the sinks encounters an error.

The default behavior of data flow sinks is to execute each sink sequentially, in a serial manner, and to fail the data flow when an error is encountered in the sink. Additionally, all sinks are defaulted to the same group unless you go into the data flow properties and set different priorities for the sinks.



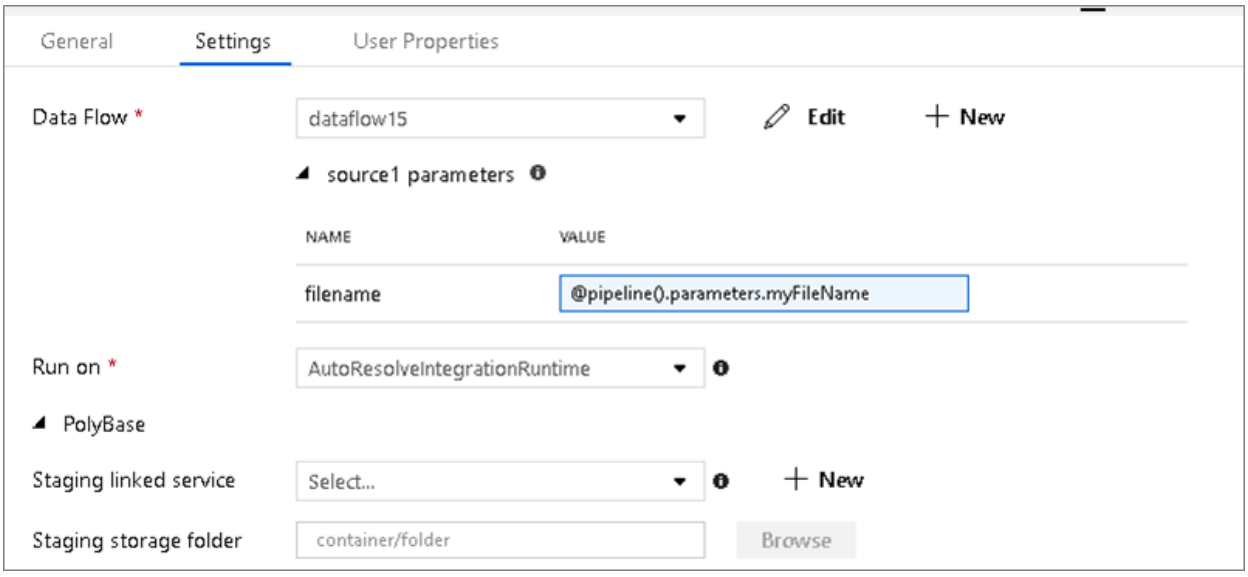
First row only

This option is only available for data flows that have cache sinks enabled for "Output to activity". The output from the data flow that is injected directly into your pipeline is limited to 2MB. Setting "first row only" helps you to limit the data output from data flow when injecting the data flow activity output directly to your pipeline.

Parameterizing Data Flows

Parameterized datasets

If your data flow uses parameterized datasets, set the parameter values in the **Settings** tab.

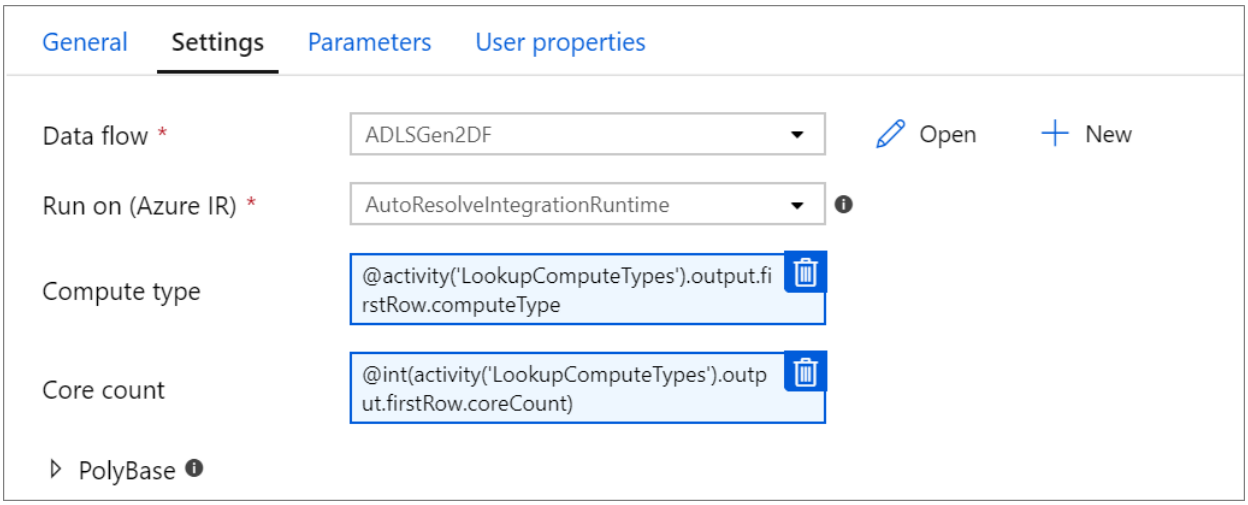


Parameterized data flows

If your data flow is parameterized, set the dynamic values of the data flow parameters in the **Parameters** tab. You can use either the pipeline expression language or the data flow expression language to assign dynamic or literal parameter values. For more information, see Data Flow Parameters.

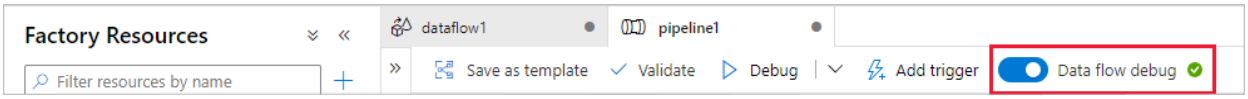
Parameterized compute properties.

You can parameterize the core count or compute type if you use the auto-resolve Azure Integration runtime and specify values for compute.coreCount and compute.computeType.



Pipeline debug of Data Flow activity

To execute a debug pipeline run with a Data Flow activity, you must switch on data flow debug mode via the **Data Flow Debug** slider on the top bar. Debug mode lets you run the data flow against an active Spark cluster. For more information, see Debug Mode.



The debug pipeline runs against the active debug cluster, not the integration runtime environment specified in the Data Flow activity settings. You can choose the debug compute environment when starting up debug mode.

Monitoring the Data Flow activity

The Data Flow activity has a special monitoring experience where you can view partitioning, stage time, and data lineage information. Open the monitoring pane via the eyeglasses icon under **Actions**. For more information, see Monitoring Data Flows.

Use Data Flow activity results in a subsequent activity

The data flow activity outputs metrics regarding the number of rows written to each sink and rows read from each source. These results are returned in the `output` section of the activity run result. The metrics returned are in the format of the below json.

```
{
    "runStatus": {
        "metrics": {
            "<your sink name1>": {
                "rowsWritten": <number of rows written>,
                "sinkProcessingTime": <sink processing time in ms>,
                "sources": {
                    "<your source name1>": {
                        "rowsRead": <number of rows read>
                    },
                    "<your source name2>": {
                        "rowsRead": <number of rows read>
                    },
                    ...
                }
            },
            "<your sink name2>": {
                ...
            },
            ...
        }
    }
}
```

For example, to get to number of rows written to a sink named 'sink1' in an activity named 'dataflowActivity', use `@activity('dataflowActivity').output.runStatus.metrics.sink1.rowsWritten`.

To get the number of rows read from a source named 'source1' that was used in that sink, use `@activity('dataflowActivity').output.runStatus.metrics.sink1.sources.source1.rowsRead`.

> **NOTE**
> If a sink has zero rows written, it will not show up in metrics. Existence can be verified using the `contains` function. For example, `contains(activity('dataflowActivity').output.runStatus.metrics, 'sink1')` will check whether any rows were written to sink1.

Transform data by running a Synapse notebook

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Azure Synapse notebook activity in a Synapse pipeline runs a Synapse notebook in your Azure Synapse workspace. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities.

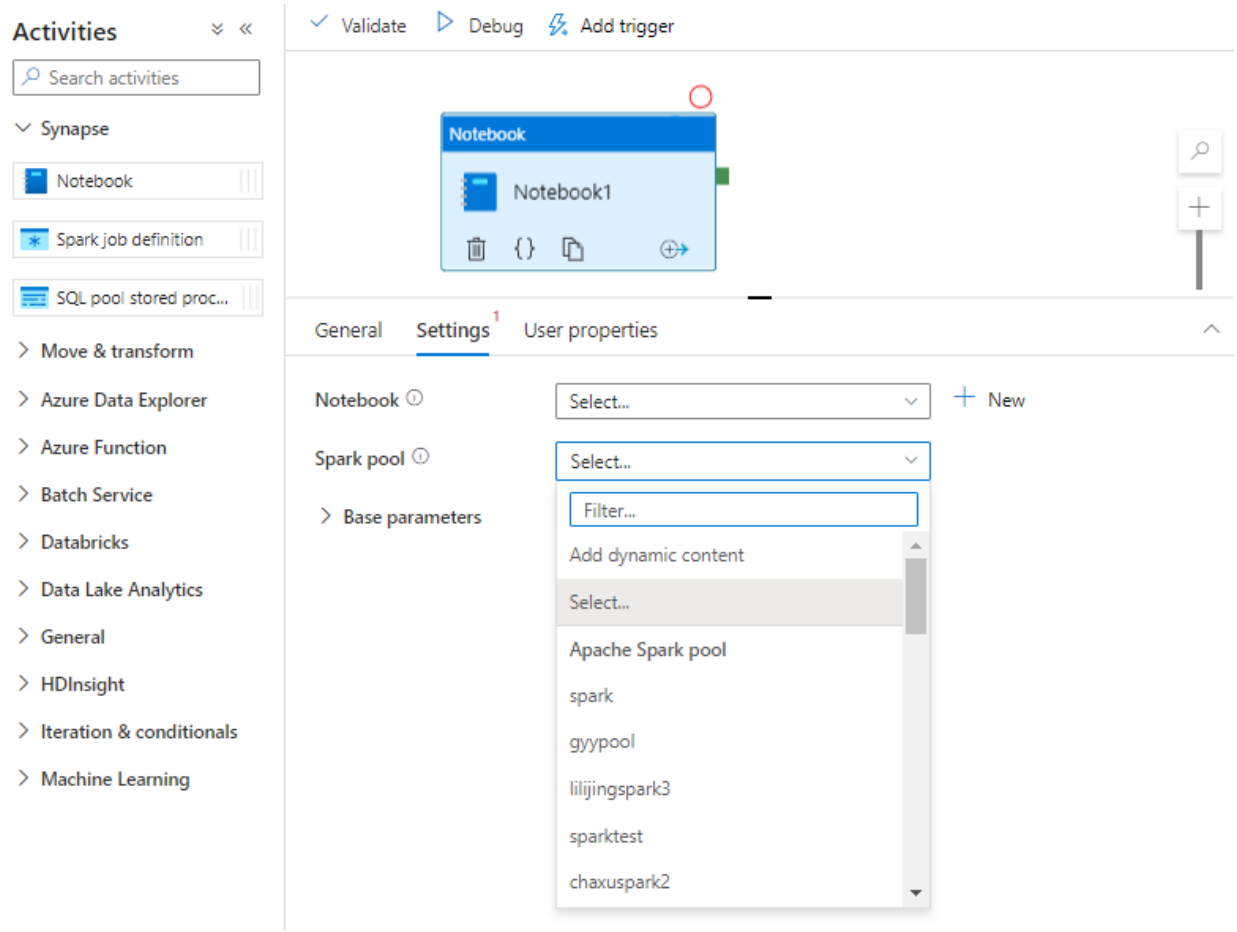
Create a Synapse notebook activity

You can create a Synapse notebook activity directly from the Synapse pipeline canvas or from the notebook editor. The Synapse notebook activity runs on the Spark pool that gets chosen in the Synapse notebook.

Add a Synapse notebook activity from pipeline canvas

Drag and drop **Synapse notebook** under **Activities** onto the Synapse pipeline canvas. Select on the Synapse notebook activity box and config the notebook content for current activity in the **settings**. You can select an existing notebook from the current workspace or add a new one.

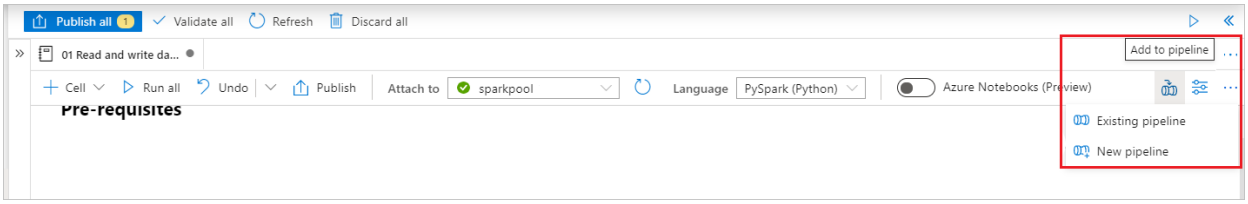
You can also select an Apache Spark pool in the settings. It should be noted that the Apache spark pool set here will replace the Apache spark pool used in the notebook. If Apache spark pool is not selected in the settings of notebook content for current activity, the Apache spark pool selected in that notebook will be used to run.



> **NOTE**
>
> The execution of parallel Spark Notebooks in Azure Synapse pipelines be queued and executed in a FIFO manner, jobs order in the queue is according to the time sequence, the expire time of a job in the queue is 3 days, please notice that queue for notebook only work in synapse pipeline.

Add a notebook to Synapse pipeline

Select the **Add to pipeline** button on the upper right corner to add a notebook to an existing pipeline or create a new pipeline.

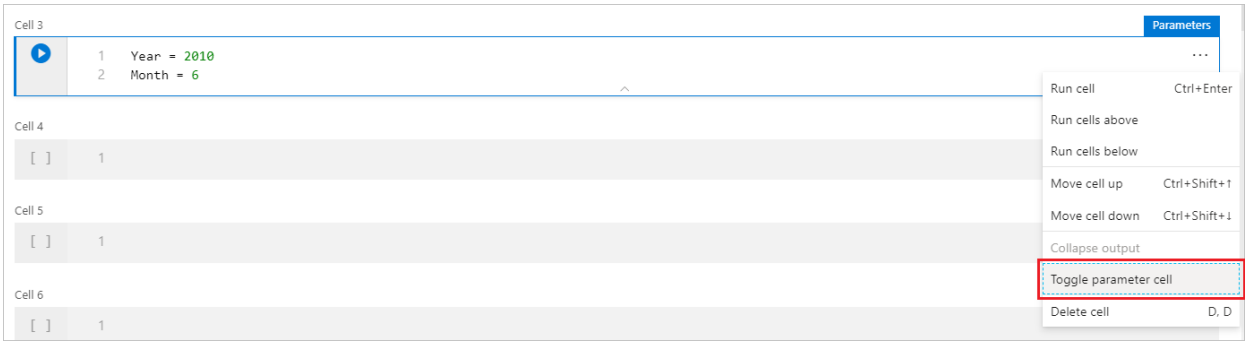


Passing parameters

Designate a parameters cell

- Classic notebook
- Preview notebook

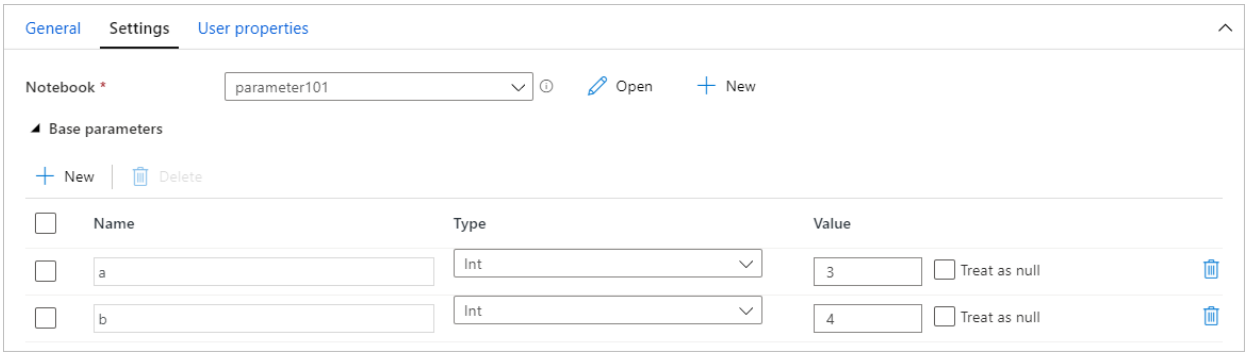
To parameterize your notebook, select the ellipses (...) to access the other cell actions menu at the far right. Then select **Toggle parameter cell** to designate the cell as the parameters cell.



Azure Data Factory looks for the parameters cell and uses the values as defaults for the parameters passed in at execution time. The execution engine will add a new cell beneath the parameters cell with input parameters to overwrite the default values.

Assign parameters values from a pipeline

Once you've created a notebook with parameters, you can execute it from a pipeline with the Synapse notebook activity. After you add the activity to your pipeline canvas, you'll be able to set the parameters values under **Base parameters** section on the **Settings** tab.



When assigning parameter values, you can use the pipeline expression language or system variables.

Read Synapse notebook cell output value

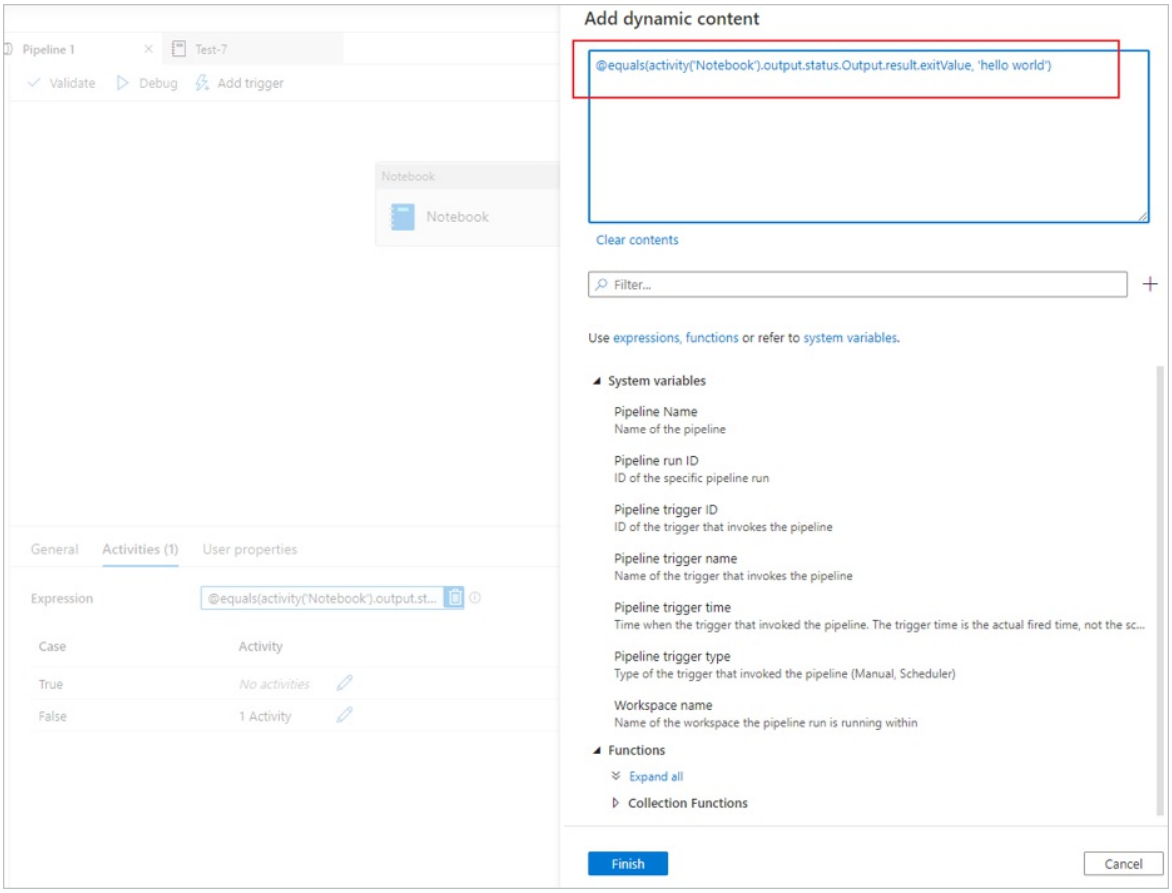
You can read the notebook cell output value in the next activities by following the steps below:

1. Call mssparkutils.notebook.exit API in your Synapse notebook activity to return the value that you want to show in activity output, for example:

   ```
   mssparkutils.notebook.exit("hello world")
   ```

   Saving the notebook content and retrigger the pipeline, the notebook activity output will contain the exitValue that can be consumed for the following activities in step 2.

2. Read exitValue property from notebook activity output. Here is a sample expression that is used to check whether the exitValue fetched from the notebook activity output equals "hello world":



Run another Synapse notebook

You can reference other notebooks in a Synapse notebook activity via calling %run magic or mssparkutils notebook utilities. Both support nesting function calls. The key differences of these two methods that you should consider based on your scenario are:

- %run magic copies all cells from the referenced notebook to the %run cell and shares the variable context. When notebook1 references notebook2 via `%run notebook2` and notebook2 calls a mssparkutils.notebook.exit function, the cell execution in notebook1 will be stopped. We recommend you use %run magic when you want to "include" a notebook file.
- mssparkutils notebook utilities calls the referenced notebook as a method or a function. The variable context isn't shared. When notebook1 references notebook2 via `mssparkutils.notebook.run("notebook2")` and notebook2 calls a mssparkutils.notebook.exit function, the cell execution in notebook1 will continue. We

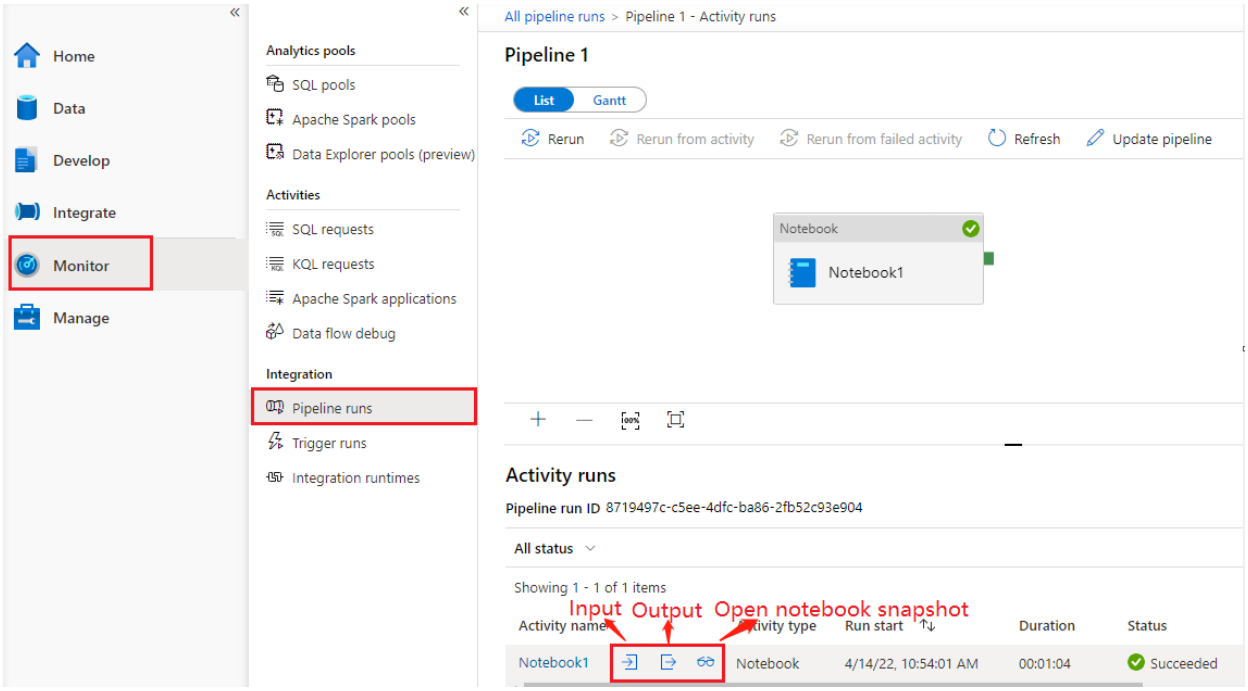
recommend you use mssparkutils notebook utilities when you want to "import" a notebook.

> **NOTE**
> Run another Synapse notebook from a Synapse pipeline will only work for a notebook with Preview enabled.

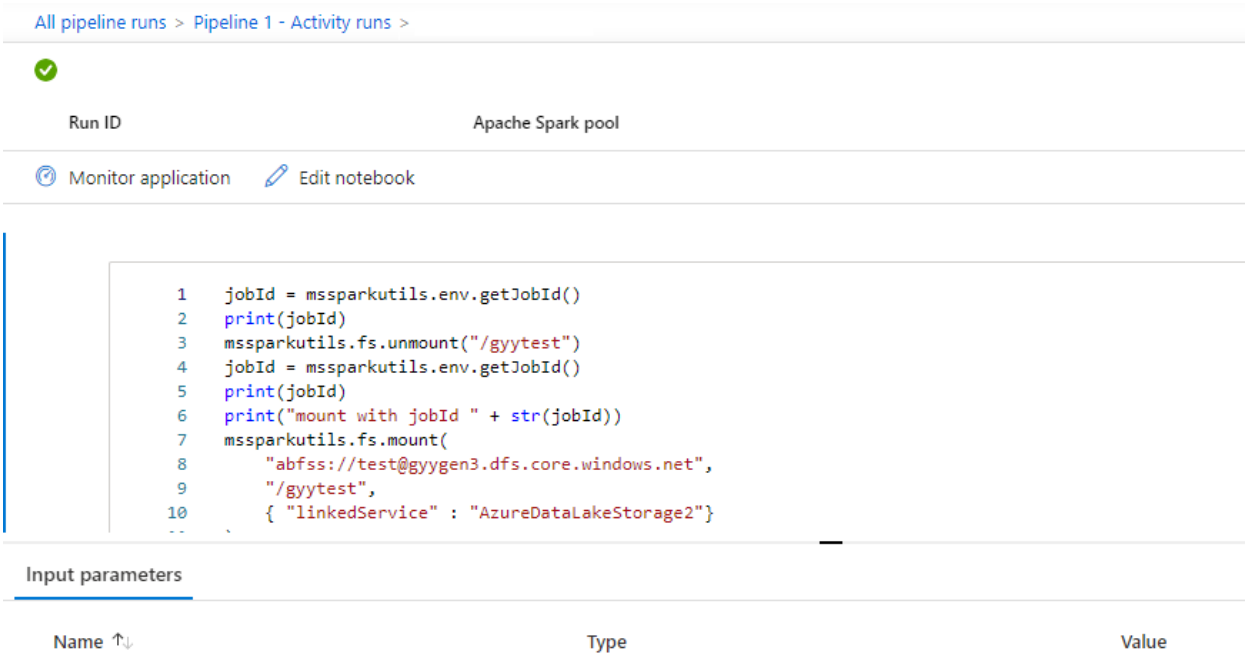
See notebook activity run history

Go to **Pipeline runs** under the **Monitor** tab, you'll see the pipeline you have triggered. Open the pipeline that contains notebook activity to see the run history.

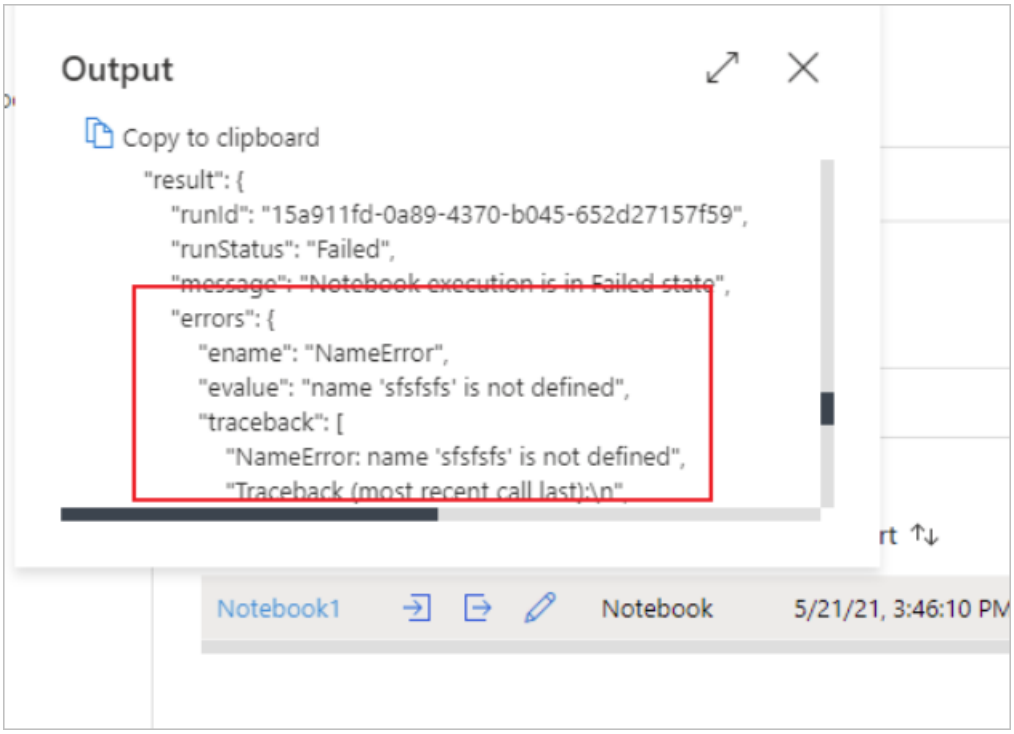
You can see the latest notebook run snapshot including both cells input and output by selecting the **open notebook** button.



Open notebook snapshot:



You can see the notebook activity input or output by selecting the **input** or **Output** button. If your pipeline failed with a user error, select the **output** to check the **result** field to see the detailed user error traceback.



Synapse notebook activity definition

Here's the sample JSON definition of a Synapse notebook activity:

```
{
    "name": "parameter_test",
    "type": "SynapseNotebook",
    "dependsOn": [],
    "policy": {
        "timeout": "7.00:00:00",
        "retry": 0,
        "retryIntervalInSeconds": 30,
        "secureOutput": false,
        "secureInput": false
    },
    "userProperties": [],
    "typeProperties": {
        "notebook": {
            "referenceName": "parameter_test",
            "type": "NotebookReference"
        },
        "parameters": {
            "input": {
                "value": {
                    "value": "@pipeline().parameters.input",
                    "type": "Expression"
                }
            }
        }
    }
}
```

Synapse notebook activity output

Here's the sample JSON of a Synapse notebook activity output:

```
{
    "status": {
        "Status": 1,
        "Output": {
            "status": <livySessionInfo>
            },
            "result": {
                "runId": "<GUID>",
                "runStatus": "Succeed",
                "message": "Notebook execution is in Succeeded state",
                "lastCheckedOn": "2021-03-23T00:40:10.6033333Z",
                "errors": {
                    "ename": "",
                    "evalue": ""
                },
                "sessionId": 4,
                "sparkpool": "sparkpool",
                "snapshotUrl": "https://myworkspace.dev.azuresynapse.net/notebooksnapshot/{guid}",
                "exitCode": "abc" // return value from user notebook via mssparkutils.notebook.exit("abc")
            }
        },
        "Error": null,
        "ExecutionDetails": {}
    },

    "effectiveIntegrationRuntime": "DefaultIntegrationRuntime (West US 2)",
    "executionDuration": 234,
    "durationInQueue": {
        "integrationRuntimeQueue": 0
    },
    "billingReference": {
        "activityType": "ExternalActivity",
        "billableDuration": [
            {
                "meterType": "AzureIR",
                "duration": 0.06666666666666667,
                "unit": "Hours"
            }
        ]
    }
}
```

Transform data by using SQL pool stored procedure activity in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

You use data transformation activities in a pipeline to transform and process raw data into predictions and insights. This article builds on the transform data article, which presents a general overview of data transformation and the supported transformation activities.

In Azure Synapse Analytics, you can use the SQL pool Stored Procedure Activity to invoke a stored procedure in a dedicated SQL pool.

Syntax details

The following settings are supported in SQL pool stored procedure activity:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For SQL pool stored procedure activity, the activity type is **SqlPoolStoredProcedure**	Yes
sqlPool	Reference to a dedicated SQL pool in the current Azure Synapse workspace.	Yes
storedProcedureName	Specify the name of the stored procedure to invoke.	Yes
storedProcedureParameters	Specify the values for stored procedure parameters. Use `"param1": { "value": "param1Value","type":"param1Type" }` to pass parameter values and their type supported by the data source. If you need to pass null for a parameter, use `"param1": { "value": null }` (all lower case).	No

Example:

```
{
    "name": "SQLPoolStoredProcedureActivity",
    "description":"Description",
    "type": "SqlPoolStoredProcedure",
    "sqlPool": {
        "referenceName": "DedicatedSQLPool",
        "type": "SqlPoolReference"
    },
    "typeProperties": {
        "storedProcedureName": "usp_sample",
        "storedProcedureParameters": {
            "identifier": { "value": "1", "type": "Int" },
            "stringData": { "value": "str1" }

        }
    }
}
```

Azure Function activity in Azure Data Factory

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

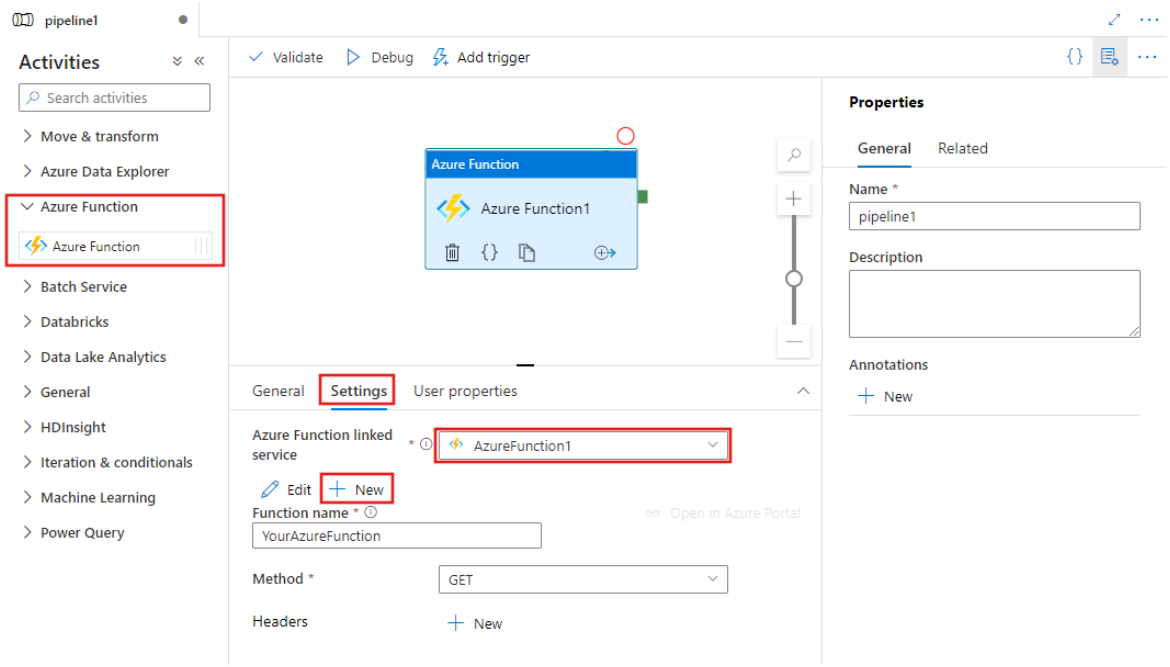
The Azure Function activity allows you to run Azure Functions in an Azure Data Factory or Synapse pipeline. To run an Azure Function, you must create a linked service connection. Then you can use the linked service with an activity that specifies the Azure Function that you plan to execute.

Create an Azure Function activity with UI

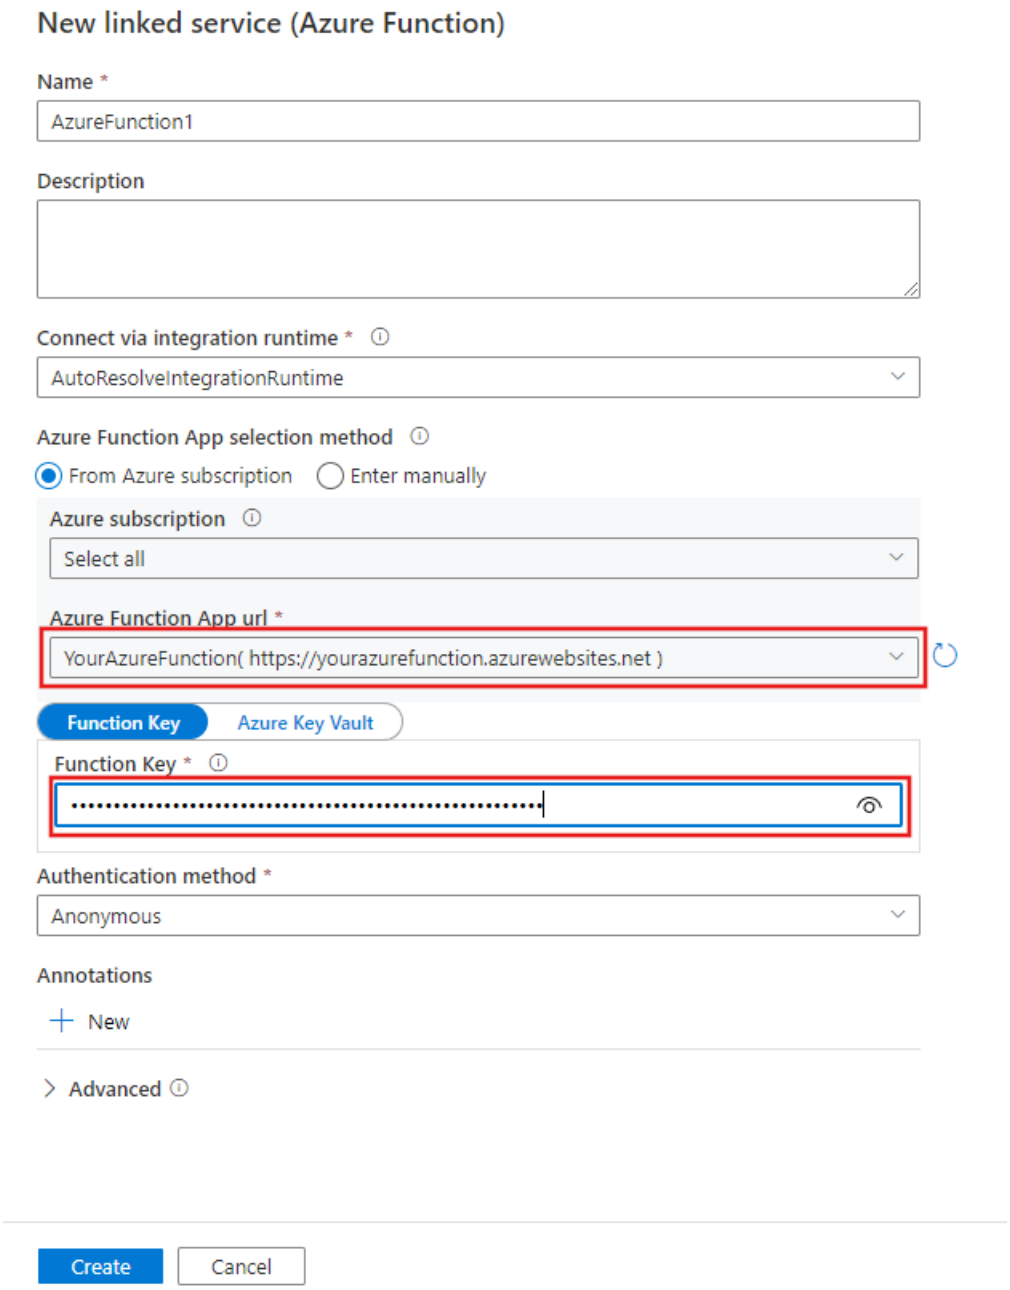
To use an Azure Function activity in a pipeline, complete the following steps:

1. Expand the Azure Function section of the pipeline Activities pane, and drag an Azure Function activity to the pipeline canvas.

2. Select the new Azure Function activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. If you do not already have an Azure Function linked service defined, select New to create a new one. In the new Azure Function linked service pane, choose your existing Azure Function App url and provide a Function Key.



4. After selecting the Azure Function linked service, provide the function name and other details to complete the configuration.

Azure Function linked service

The return type of the Azure function has to be a valid `JObject`. (Keep in mind that JArray is *not* a `JObject`.) Any return type other than `JObject` fails and raises the user error *Response Content is not a valid JObject*.

Function Key provides secure access to function name with each one having separate unique keys or master key within a function app. Managed identity provides secure access to the entire function app. User needs to provide key to access function name. For more information, see the function documentation for more details about Function access key

PROPERTY	DESCRIPTION	REQUIRED
Type	The type property must be set to: **AzureFunction**	Yes

PROPERTY	DESCRIPTION	REQUIRED
Function app url	URL for the Azure Function App. Format is `https://<accountname>.azurewebsites.net`. This URL is the value under **URL** section when viewing your Function App in the Azure portal	Yes
Function key	Access key for the Azure Function. Click on the **Manage** section for the respective function, and copy either the **Function Key** or the **Host key**. Find out more here: Azure Functions HTTP triggers and bindings	Yes

Azure Function activity

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
Name	Name of the activity in the pipeline	String	Yes
Type	Type of activity is 'AzureFunctionActivity'	String	Yes
Linked service	The Azure Function linked service for the corresponding Azure Function App	Linked service reference	Yes
Function name	Name of the function in the Azure Function App that this activity calls	String	Yes
Method	REST API method for the function call	String Supported Types: "GET", "POST", "PUT"	Yes
Header	Headers that are sent to the request. For example, to set the language and type on a request: "headers": { "Accept-Language": "en-us", "Content-Type": "application/json" }	String (or expression with resultType of string)	No
Body	Body that is sent along with the request to the function api method	String (or expression with resultType of string) or object.	Required for PUT/POST methods

See the schema of the request payload in Request payload schema section.

Routing and queries

The Azure Function Activity supports **routing**. For example, if your Azure Function has the endpoint `https://functionAPP.azurewebsites.net/api/<functionName>/<value>?code=<secret>`, then the `functionName` to use in the Azure Function Activity is `<functionName>/<value>`. You can parameterize this function to provide the desired `functionName` at runtime.

> **NOTE**
> The `functionName` for Durable Functions should be taken from the **route** property of the function's binding in its JSON definition, to include its routing information. Simply using the `functionName` without the route detail included will result in a failure because the Function App cannot be found.

The Azure Function Activity also supports **queries**. A query must be included as part of the `functionName`. For example, when the function name is `HttpTriggerCSharp` and the query that you want to include is `name=hello`, then you can construct the `functionName` in the Azure Function Activity as `HttpTriggerCSharp?name=hello`. This function can be parameterized so the value can be determined at runtime.

Timeout and long running functions

Azure Functions times out after 230 seconds regardless of the `functionTimeout` setting you've configured in the settings. For more information, see this article. To work around this behavior, follow an async pattern or use Durable Functions. The benefit of Durable Functions is that they offer their own state-tracking mechanism, so you don't need to implement your own state-tracking.

Learn more about Durable Functions in this article. You can set up an Azure Function Activity to call the Durable Function, which will return a response with a different URI, such as this example. Because `statusQueryGetUri` returns HTTP Status 202 while the function is running, you can poll the status of the function by using a Web Activity. Set up a Web Activity with the `url` field set to `@activity('<AzureFunctionActivityName>').output.statusQueryGetUri`. When the Durable Function completes, the output of the function will be the output of the Web Activity.

Sample

You can find a sample that uses an Azure Function to extract the content of a tar file here.

Transform data by running a Jar activity in Azure Databricks

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

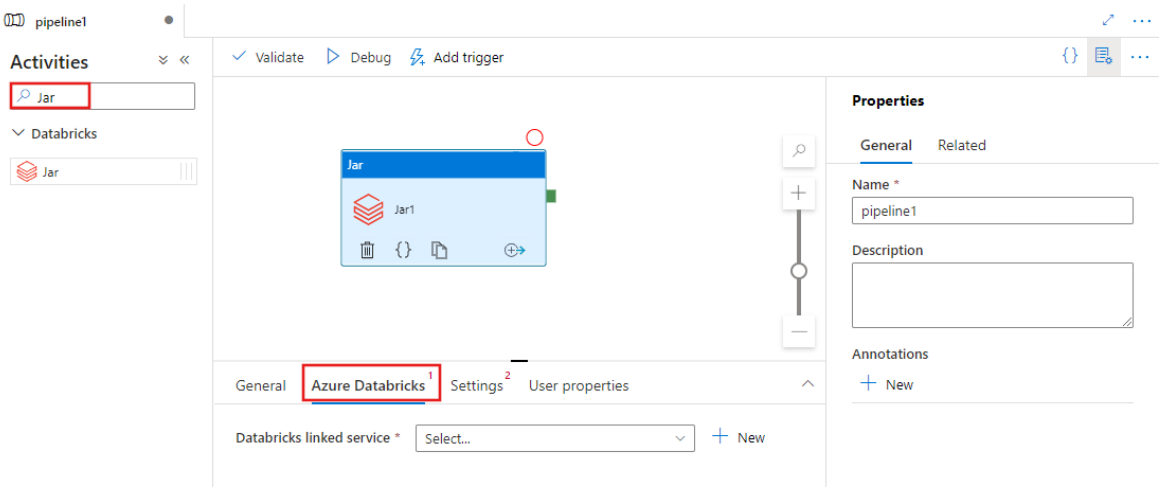
The Azure Databricks Jar Activity in a pipeline runs a Spark Jar in your Azure Databricks cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities. Azure Databricks is a managed platform for running Apache Spark.

For an eleven-minute introduction and demonstration of this feature, watch the following video:

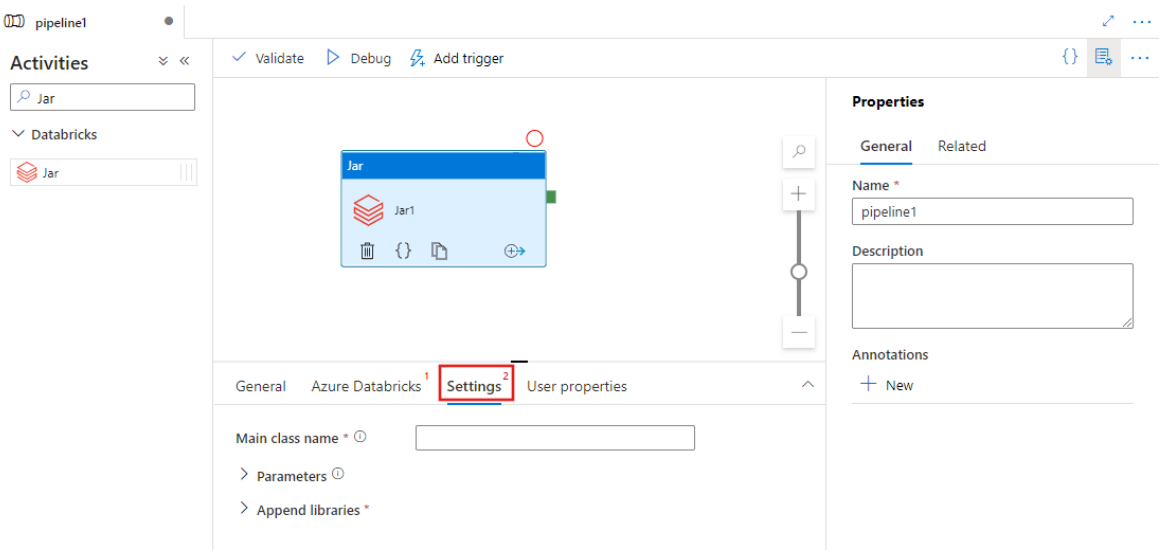
Add a Jar activity for Azure Databricks to a pipeline with UI

To use a Jar activity for Azure Databricks in a pipeline, complete the following steps:

1. Search for *Jar* in the pipeline Activities pane, and drag a Jar activity to the pipeline canvas.
2. Select the new Jar activity on the canvas if it is not already selected.
3. Select the **Azure Databricks** tab to select or create a new Azure Databricks linked service that will execute the Jar activity.



4. Select the **Settings** tab and specify a class name to be executed on Azure Databricks, optional parameters to be passed to the Jar, and libraries to be installed on the cluster to execute the job.



Databricks Jar activity definition

Here's the sample JSON definition of a Databricks Jar Activity:

```
{
    "name": "SparkJarActivity",
    "type": "DatabricksSparkJar",
    "linkedServiceName": {
        "referenceName": "AzureDatabricks",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "mainClassName": "org.apache.spark.examples.SparkPi",
        "parameters": [ "10" ],
        "libraries": [
            {
                "jar": "dbfs:/docs/sparkpi.jar"
            }
        ]
    }
}
```

Databricks Jar activity properties

The following table describes the JSON properties used in the JSON definition:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline.	Yes
description	Text describing what the activity does.	No
type	For Databricks Jar Activity, the activity type is DatabricksSparkJar.	Yes
linkedServiceName	Name of the Databricks Linked Service on which the Jar activity runs. To learn about this linked service, see Compute linked services article.	Yes

PROPERTY	DESCRIPTION	REQUIRED
mainClassName	The full name of the class containing the main method to be executed. This class must be contained in a JAR provided as a library. A JAR file can contain multiple classes. Each of the classes can contain a main method.	Yes
parameters	Parameters that will be passed to the main method. This property is an array of strings.	No
libraries	A list of libraries to be installed on the cluster that will execute the job. It can be an array of <string, object>	Yes (at least one containing the mainClassName method)

NOTE

Known Issue - When using the same Interactive cluster for running concurrent Databricks Jar activities (without cluster restart), there is a known issue in Databricks where in parameters of the 1st activity will be used by following activities as well. Hence resulting to incorrect parameters being passed to the subsequent jobs. To mitigate this use a Job cluster instead.

Supported libraries for databricks activities

In the previous Databricks activity definition, you specified these library types: `jar`, `egg`, `maven`, `pypi`, `cran`.

```
{
    "libraries": [
        {
            "jar": "dbfs:/mnt/libraries/library.jar"
        },
        {
            "egg": "dbfs:/mnt/libraries/library.egg"
        },
        {
            "maven": {
                "coordinates": "org.jsoup:jsoup:1.7.2",
                "exclusions": [ "slf4j:slf4j" ]
            }
        },
        {
            "pypi": {
                "package": "simplejson",
                "repo": "http://my-pypi-mirror.com"
            }
        },
        {
            "cran": {
                "package": "ada",
                "repo": "https://cran.us.r-project.org"
            }
        }
    ]
}
```

For more information, see the Databricks documentation for library types.

How to upload a library in Databricks

You can use the Workspace UI:

1. Use the Databricks workspace UI
2. To obtain the dbfs path of the library added using UI, you can use Databricks CLI.

   Typically the Jar libraries are stored under dbfs:/FileStore/jars while using the UI. You can list all through the CLI: *databricks fs ls dbfs:/FileStore/job-jars*

Or you can use the Databricks CLI:

1. Follow Copy the library using Databricks CLI
2. Use Databricks CLI (installation steps)

   As an example, to copy a JAR to dbfs: `dbfs cp SparkPi-assembly-0.1.jar dbfs:/docs/sparkpi.jar`

Next steps

For an eleven-minute introduction and demonstration of this feature, watch the video.

Transform data by running a Databricks notebook

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

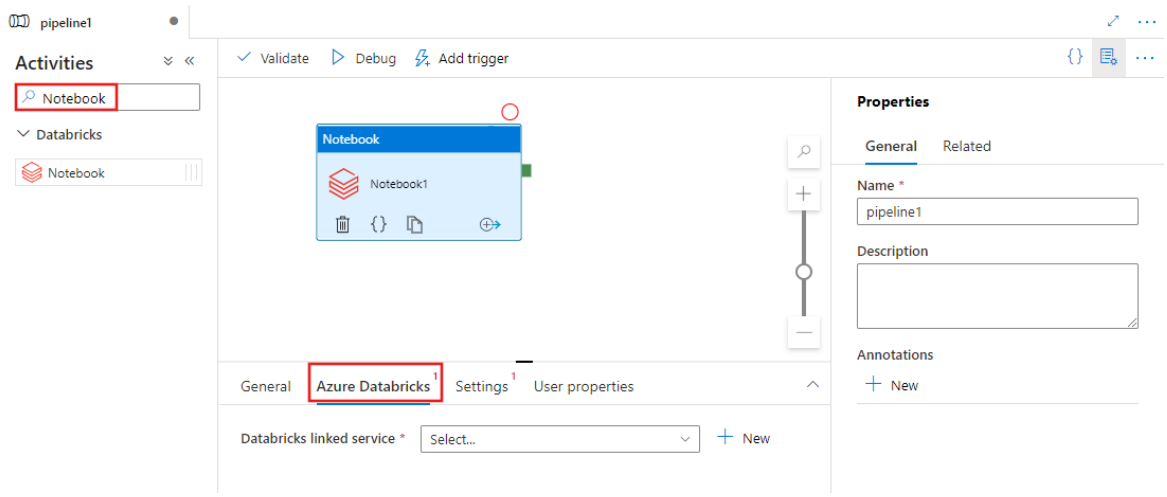
The Azure Databricks Notebook Activity in a pipeline runs a Databricks notebook in your Azure Databricks workspace. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities. Azure Databricks is a managed platform for running Apache Spark.

You can create a Databricks notebook with an ARM template using JSON, or directly through the Azure Data Factory Studio user interface. For a step-by-step walkthrough of how to create a Databricks notebook activity using the user interface, reference the tutorial Run a Databricks notebook with the Databricks Notebook Activity in Azure Data Factory.

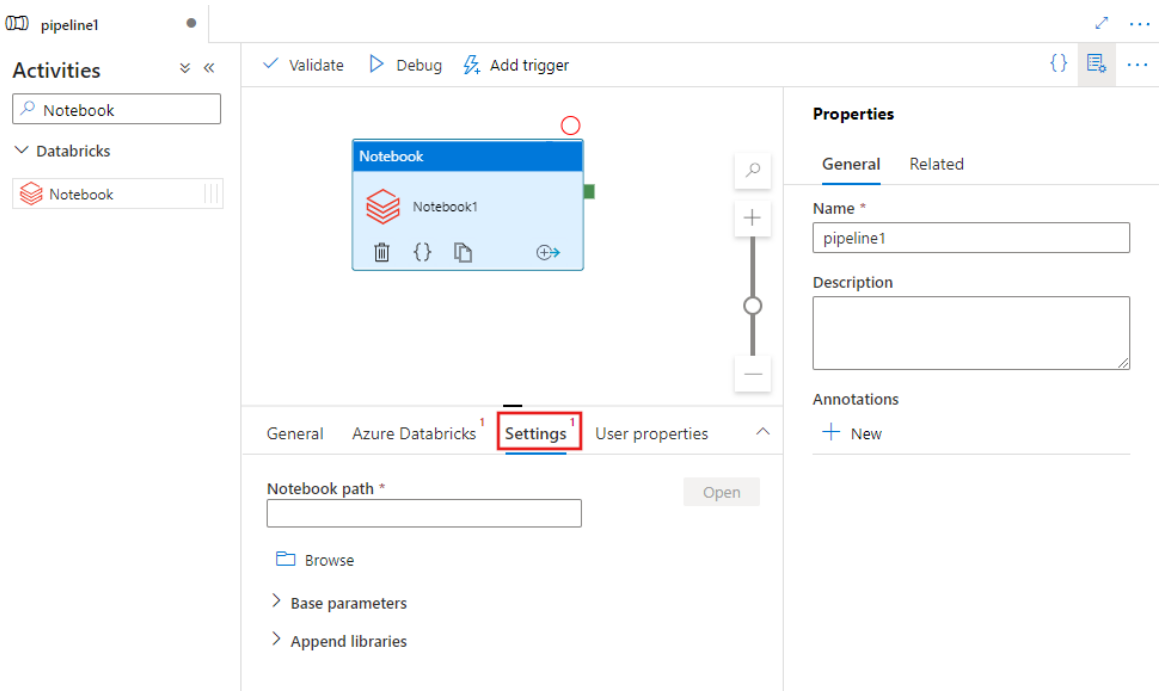
Add a Notebook activity for Azure Databricks to a pipeline with UI

To use a Notebook activity for Azure Databricks in a pipeline, complete the following steps:

1. Search for *Notebook* in the pipeline Activities pane, and drag a Notebook activity to the pipeline canvas.
2. Select the new Notebook activity on the canvas if it is not already selected.
3. Select the **Azure Databricks** tab to select or create a new Azure Databricks linked service that will execute the Notebook activity.



4. Select the **Settings** tab and specify the notebook path to be executed on Azure Databricks, optional base parameters to be passed to the notebook, and any additional libraries to be installed on the cluster to execute the job.



Databricks Notebook activity definition

Here is the sample JSON definition of a Databricks Notebook Activity:

```
{
    "activity": {
        "name": "MyActivity",
        "description": "MyActivity description",
        "type": "DatabricksNotebook",
        "linkedServiceName": {
            "referenceName": "MyDatabricksLinkedservice",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "notebookPath": "/Users/user@example.com/ScalaExampleNotebook",
            "baseParameters": {
                "inputpath": "input/folder1/",
                "outputpath": "output/"
            },
            "libraries": [
                {
                "jar": "dbfs:/docs/library.jar"
                }
            ]
        }
    }
}
```

Databricks Notebook activity properties

The following table describes the JSON properties used in the JSON definition:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline.	Yes
description	Text describing what the activity does.	No

PROPERTY	DESCRIPTION	REQUIRED
type	For Databricks Notebook Activity, the activity type is DatabricksNotebook.	Yes
linkedServiceName	Name of the Databricks Linked Service on which the Databricks notebook runs. To learn about this linked service, see Compute linked services article.	Yes
notebookPath	The absolute path of the notebook to be run in the Databricks Workspace. This path must begin with a slash.	Yes
baseParameters	An array of Key-Value pairs. Base parameters can be used for each activity run. If the notebook takes a parameter that is not specified, the default value from the notebook will be used. Find more on parameters in Databricks Notebooks.	No
libraries	A list of libraries to be installed on the cluster that will execute the job. It can be an array of <string, object>.	No

Supported libraries for Databricks activities

In the above Databricks activity definition, you specify these library types: *jar*, *egg*, *whl*, *maven*, *pypi*, *cran*.

```
{
    "libraries": [
        {
            "jar": "dbfs:/mnt/libraries/library.jar"
        },
        {
            "egg": "dbfs:/mnt/libraries/library.egg"
        },
        {
            "whl": "dbfs:/mnt/libraries/mlflow-0.0.1.dev0-py2-none-any.whl"
        },
        {
            "whl": "dbfs:/mnt/libraries/wheel-libraries.wheelhouse.zip"
        },
        {
            "maven": {
                "coordinates": "org.jsoup:jsoup:1.7.2",
                "exclusions": [ "slf4j:slf4j" ]
            }
        },
        {
            "pypi": {
                "package": "simplejson",
                "repo": "http://my-pypi-mirror.com"
            }
        },
        {
            "cran": {
                "package": "ada",
                "repo": "https://cran.us.r-project.org"
            }
        }
    ]
}
```

For more information, see the Databricks documentation for library types.

Passing parameters between notebooks and pipelines

You can pass parameters to notebooks using *baseParameters* property in databricks activity.

In certain cases, you might require to pass back certain values from notebook back to the service, which can be used for control flow (conditional checks) in the service or be consumed by downstream activities (size limit is 2 MB).

1. In your notebook, you may call dbutils.notebook.exit("returnValue") and corresponding "returnValue" will be returned to the service.

2. You can consume the output in the service by using expression such as `@{activity('databricks notebook activity name').output.runOutput}`.

> **IMPORTANT**
>
> If you are passing JSON object you can retrieve values by appending property names. Example:
> `@{activity('databricks notebook activity name').output.runOutput.PropertyName}`

How to upload a library in Databricks

You can use the Workspace UI:

1. Use the Databricks workspace UI
2. To obtain the dbfs path of the library added using UI, you can use Databricks CLI.

   Typically the Jar libraries are stored under dbfs:/FileStore/jars while using the UI. You can list all through the CLI: *databricks fs ls dbfs:/FileStore/job-jars*

Or you can use the Databricks CLI:

1. Follow Copy the library using Databricks CLI
2. Use Databricks CLI (installation steps)

   As an example, to copy a JAR to dbfs: `dbfs cp SparkPi-assembly-0.1.jar dbfs:/docs/sparkpi.jar`

Transform data by running a Python activity in Azure Databricks

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

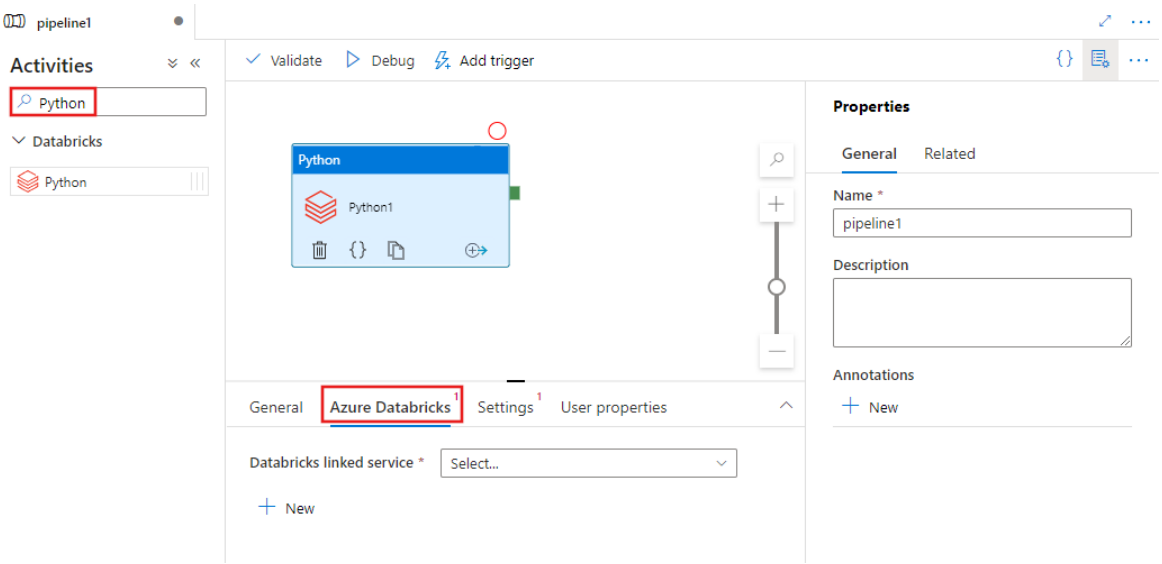
The Azure Databricks Python Activity in a pipeline runs a Python file in your Azure Databricks cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities. Azure Databricks is a managed platform for running Apache Spark.

For an eleven-minute introduction and demonstration of this feature, watch the following video:

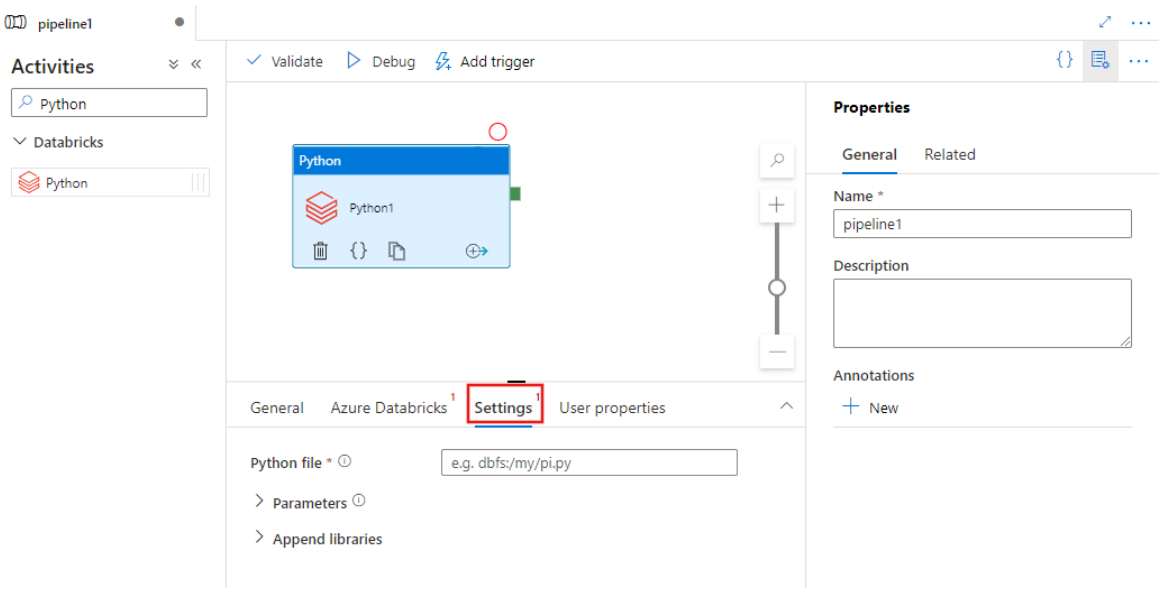
Add a Python activity for Azure Databricks to a pipeline with UI

To use a Python activity for Azure Databricks in a pipeline, complete the following steps:

1. Search for *Python* in the pipeline Activities pane, and drag a Python activity to the pipeline canvas.
2. Select the new Python activity on the canvas if it is not already selected.
3. Select the **Azure Databricks** tab to select or create a new Azure Databricks linked service that will execute the Python activity.



4. Select the **Settings** tab and specify the path within Azure Databricks to a Python file to be executed, optional parameters to be passed, and any additional libraries to be installed on the cluster to execute the job.



Databricks Python activity definition

Here is the sample JSON definition of a Databricks Python Activity:

```
{
    "activity": {
        "name": "MyActivity",
        "description": "MyActivity description",
        "type": "DatabricksSparkPython",
        "linkedServiceName": {
            "referenceName": "MyDatabricksLinkedService",
            "type": "LinkedServiceReference"
        },
        "typeProperties": {
            "pythonFile": "dbfs:/docs/pi.py",
            "parameters": [
                "10"
            ],
            "libraries": [
                {
                    "pypi": {
                        "package": "tensorflow"
                    }
                }
            ]
        }
    }
}
```

Databricks Python activity properties

The following table describes the JSON properties used in the JSON definition:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline.	Yes
description	Text describing what the activity does.	No
type	For Databricks Python Activity, the activity type is DatabricksSparkPython.	Yes

PROPERTY	DESCRIPTION	REQUIRED
linkedServiceName	Name of the Databricks Linked Service on which the Python activity runs. To learn about this linked service, see Compute linked services article.	Yes
pythonFile	The URI of the Python file to be executed. Only DBFS paths are supported.	Yes
parameters	Command line parameters that will be passed to the Python file. This is an array of strings.	No
libraries	A list of libraries to be installed on the cluster that will execute the job. It can be an array of <string, object>	No

Supported libraries for databricks activities

In the above Databricks activity definition you specify these library types: *jar*, *egg*, *maven*, *pypi*, *cran*.

```
{
    "libraries": [
        {
            "jar": "dbfs:/mnt/libraries/library.jar"
        },
        {
            "egg": "dbfs:/mnt/libraries/library.egg"
        },
        {
            "maven": {
                "coordinates": "org.jsoup:jsoup:1.7.2",
                "exclusions": [ "slf4j:slf4j" ]
            }
        },
        {
            "pypi": {
                "package": "simplejson",
                "repo": "http://my-pypi-mirror.com"
            }
        },
        {
            "cran": {
                "package": "ada",
                "repo": "https://cran.us.r-project.org"
            }
        }
    ]
}
```

For more details refer Databricks documentation for library types.

How to upload a library in Databricks

You can use the Workspace UI:

1. Use the Databricks workspace UI

2. To obtain the dbfs path of the library added using UI, you can use Databricks CLI.

   Typically the Jar libraries are stored under dbfs:/FileStore/jars while using the UI. You can list all through the CLI: *databricks fs ls dbfs:/FileStore/job-jars*

Or you can use the Databricks CLI:

1. Follow Copy the library using Databricks CLI
2. Use Databricks CLI (installation steps)

   As an example, to copy a JAR to dbfs: `dbfs cp SparkPi-assembly-0.1.jar dbfs:/docs/sparkpi.jar`

Process data by running U-SQL scripts on Azure Data Lake Analytics with Azure Data Factory and Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

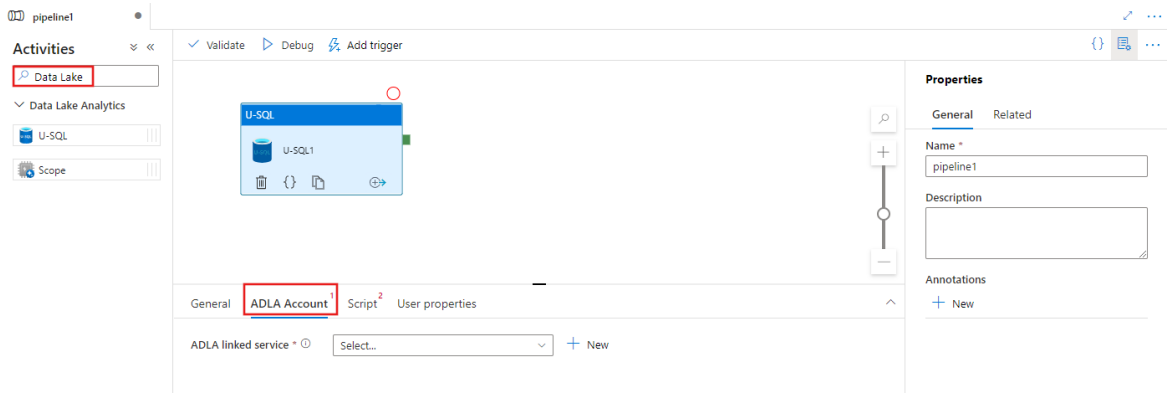
A pipeline in an Azure Data Factory or Synapse Analytics workspace processes data in linked storage services by using linked compute services. It contains a sequence of activities where each activity performs a specific processing operation. This article describes the **Data Lake Analytics U-SQL Activity** that runs a **U-SQL** script on an **Azure Data Lake Analytics** compute linked service.

Create an Azure Data Lake Analytics account before creating a pipeline with a Data Lake Analytics U-SQL Activity. To learn about Azure Data Lake Analytics, see Get started with Azure Data Lake Analytics.

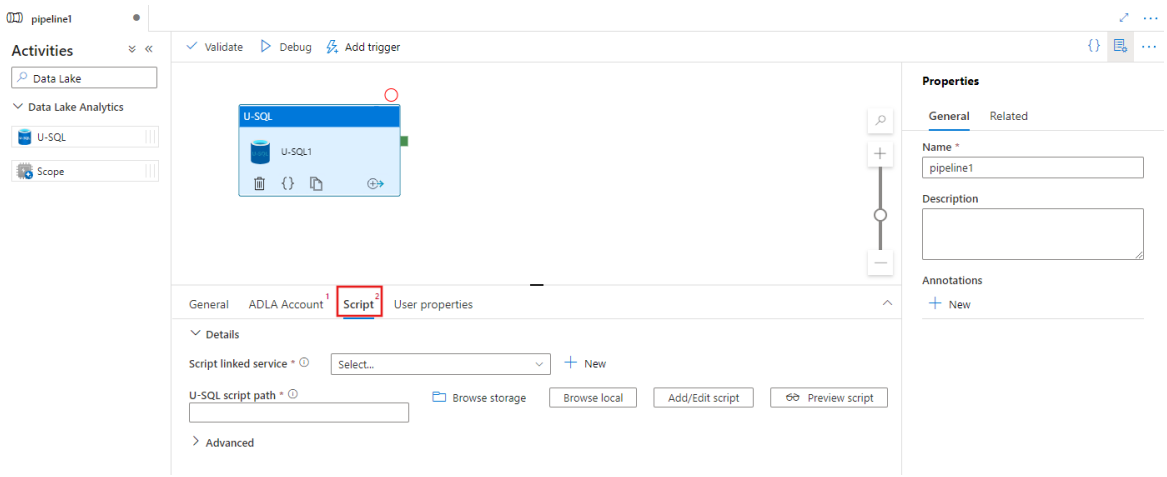
Add a U-SQL activity for Azure Data Lake Analytics to a pipeline with UI

To use a U-SQL activity for Azure Data Lake Analytics in a pipeline, complete the following steps:

1. Search for *Data Lake* in the pipeline Activities pane, and drag a U-SQL activity to the pipeline canvas.
2. Select the new U-SQL activity on the canvas if it is not already selected.
3. Select the **ADLA Account** tab to select or create a new Azure Data Lake Analytics linked service that will be used to execute the U-SQL activity.



4. Select the **Script** tab to select or create a new storage linked service, and a path within the storage location, which will host the script.



Azure Data Lake Analytics linked service

You create an **Azure Data Lake Analytics** linked service to link an Azure Data Lake Analytics compute service to an Azure Data Factory or Synapse Analytics workspace. The Data Lake Analytics U-SQL activity in the pipeline refers to this linked service.

The following table provides descriptions for the generic properties used in the JSON definition.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property should be set to: **AzureDataLakeAnalytics**.	Yes
accountName	Azure Data Lake Analytics Account Name.	Yes
dataLakeAnalyticsUri	Azure Data Lake Analytics URI.	No
subscriptionId	Azure subscription ID	No
resourceGroupName	Azure resource group name	No

Service principal authentication

The Azure Data Lake Analytics linked service requires a service principal authentication to connect to the Azure Data Lake Analytics service. To use service principal authentication, register an application entity in Azure Active Directory (Azure AD) and grant it the access to both the Data Lake Analytics and the Data Lake Store it uses. For detailed steps, see Service-to-service authentication. Make note of the following values, which you use to define the linked service:

- Application ID
- Application key
- Tenant ID

Grant service principal permission to your Azure Data Lake Analytics using the Add User Wizard.

Use service principal authentication by specifying the following properties:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalKey	Specify the application's key.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes

Example: Service principal authentication

```
{
    "name": "AzureDataLakeAnalyticsLinkedService",
    "properties": {
        "type": "AzureDataLakeAnalytics",
        "typeProperties": {
            "accountName": "<account name>",
            "dataLakeAnalyticsUri": "<azure data lake analytics URI>",
            "servicePrincipalId": "<service principal id>",
            "servicePrincipalKey": {
                "value": "<service principal key>",
                "type": "SecureString"
            },
            "tenant": "<tenant info, e.g. microsoft.onmicrosoft.com>",
            "subscriptionId": "<optional, subscription id of ADLA>",
            "resourceGroupName": "<optional, resource group name of ADLA>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

To learn more about the linked service, see Compute linked services.

Data Lake Analytics U-SQL Activity

The following JSON snippet defines a pipeline with a Data Lake Analytics U-SQL Activity. The activity definition has a reference to the Azure Data Lake Analytics linked service you created earlier. To execute a Data Lake Analytics U-SQL script, the service submits the script you specified to the Data Lake Analytics, and the required inputs and outputs is defined in the script for Data Lake Analytics to fetch and output.

```
{
    "name": "ADLA U-SQL Activity",
    "description": "description",
    "type": "DataLakeAnalyticsU-SQL",
    "linkedServiceName": {
        "referenceName": "<linked service name of Azure Data Lake Analytics>",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "scriptLinkedService": {
            "referenceName": "<linked service name of Azure Data Lake Store or Azure Storage which contains
the U-SQL script>",
            "type": "LinkedServiceReference"
        },
        "scriptPath": "scripts\\kona\\SearchLogProcessing.txt",
        "degreeOfParallelism": 3,
        "priority": 100,
        "parameters": {
            "in": "/datalake/input/SearchLog.tsv",
            "out": "/datalake/output/Result.tsv"
        }
    }
}
```

The following table describes names and descriptions of properties that are specific to this activity.

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline	Yes
description	Text describing what the activity does.	No
type	For Data Lake Analytics U-SQL activity, the activity type is **DataLakeAnalyticsU-SQL**.	Yes
linkedServiceName	Linked Service to Azure Data Lake Analytics. To learn about this linked service, see Compute linked services article.	Yes
scriptPath	Path to folder that contains the U-SQL script. Name of the file is case-sensitive.	Yes
scriptLinkedService	Linked service that links the **Azure Data Lake Store** or **Azure Storage** that contains the script	Yes
degreeOfParallelism	The maximum number of nodes simultaneously used to run the job.	No
priority	Determines which jobs out of all that are queued should be selected to run first. The lower the number, the higher the priority.	No
parameters	Parameters to pass into the U-SQL script.	No

PROPERTY	DESCRIPTION	REQUIRED
runtimeVersion	Runtime version of the U-SQL engine to use.	No
compilationMode	Compilation mode of U-SQL. Must be one of these values: **Semantic**: Only perform semantic checks and necessary sanity checks, **Full**: Perform the full compilation, including syntax check, optimization, code generation, etc., **SingleBox**: Perform the full compilation, with TargetType setting to SingleBox. If you don't specify a value for this property, the server determines the optimal compilation mode.	No

See SearchLogProcessing.txt for the script definition.

Sample U-SQL script

```
@searchlog =
    EXTRACT UserId          int,
            Start           DateTime,
            Region          string,
            Query           string,
            Duration        int,
            Urls            string,
            ClickedUrls     string
    FROM @in
    USING Extractors.Tsv(nullEscape:"#NULL#");

@rs1 =
    SELECT Start, Region, Duration
    FROM @searchlog
WHERE Region == "en-gb";

@rs1 =
    SELECT Start, Region, Duration
    FROM @rs1
    WHERE Start <= DateTime.Parse("2012/02/19");

OUTPUT @rs1
    TO @out
      USING Outputters.Tsv(quoting:false, dateTimeFormat:null);
```

In above script example, the input and output to the script is defined in **@in** and **@out** parameters. The values for **@in** and **@out** parameters in the U-SQL script are passed dynamically by the service using the 'parameters' section.

You can specify other properties such as degreeOfParallelism and priority as well in your pipeline definition for the jobs that run on the Azure Data Lake Analytics service.

Dynamic parameters

In the sample pipeline definition, in and out parameters are assigned with hard-coded values.

```
"parameters": {
    "in": "/datalake/input/SearchLog.tsv",
    "out": "/datalake/output/Result.tsv"
}
```

It is possible to use dynamic parameters instead. For example:

```
"parameters": {
    "in": "/datalake/input/@{formatDateTime(pipeline().parameters.WindowStart,'yyyy/MM/dd')}/data.tsv",
    "out": "/datalake/output/@{formatDateTime(pipeline().parameters.WindowStart,'yyyy/MM/dd')}/result.tsv"
}
```

In this case, input files are still picked up from the /datalake/input folder and output files are generated in the /datalake/output folder. The file names are dynamic based on the window start time being passed in when pipeline gets triggered.

Transform data using Hadoop Hive activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

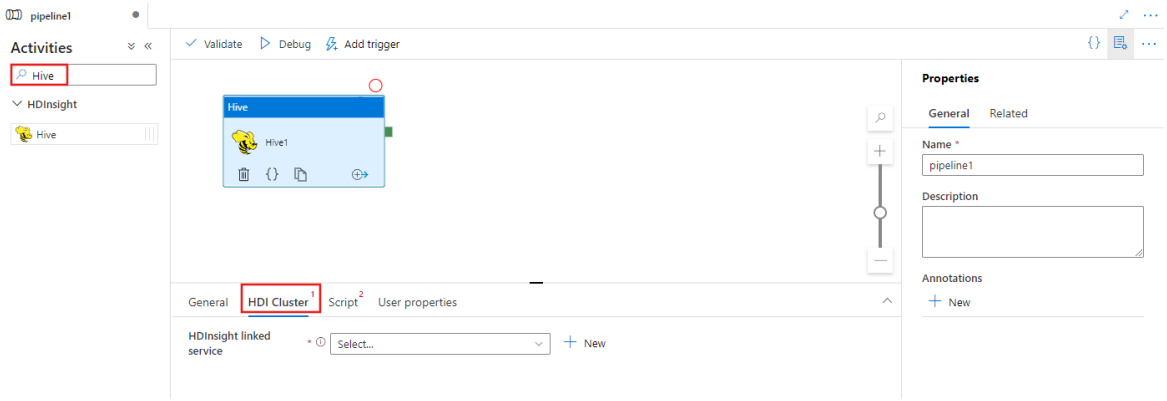
The HDInsight Hive activity in an Azure Data Factory or Synapse Analytics pipeline executes Hive queries on your own or on-demand HDInsight cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities.

If you are new to Azure Data Factory and Synapse Analytics, read through the introduction articles for Azure Data Factory or Synapse Analytics, and do the Tutorial: transform data before reading this article.

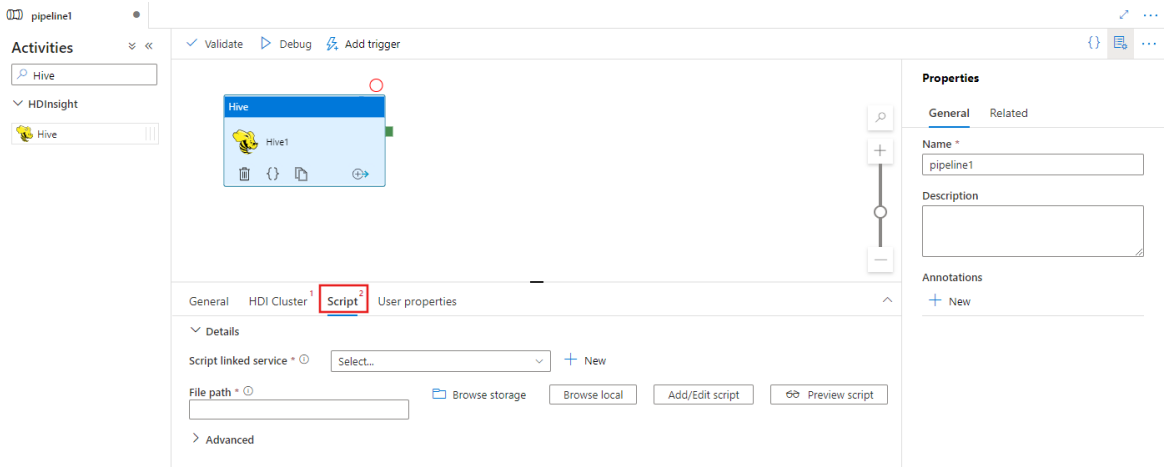
Add an HDInsight Hive activity to a pipeline with UI

To use an HDInsight Hive activity for Azure Data Lake Analytics in a pipeline, complete the following steps:

1. Search for *Hive* in the pipeline Activities pane, and drag a Hive activity to the pipeline canvas.
2. Select the new Hive activity on the canvas if it is not already selected.
3. Select the **HDI Cluster** tab to select or create a new linked service to an HDInsight cluster that will be used to execute the Hive activity.



4. Select the **Script** tab to select or create a new storage linked service, and a path within the storage location, which will host the script.



Syntax

```
{
    "name": "Hive Activity",
    "description": "description",
    "type": "HDInsightHive",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "scriptLinkedService": {
            "referenceName": "MyAzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "scriptPath": "MyAzureStorage\\HiveScripts\\MyHiveSript.hql",
        "getDebugInfo": "Failure",
        "arguments": [
            "SampleHadoopJobArgument1"
        ],
        "defines": {
            "param1": "param1Value"
        }
    }
}
```

Syntax details

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For Hive Activity, the activity type is HDInsightHive	Yes
linkedServiceName	Reference to the HDInsight cluster registered as a linked service. To learn about this linked service, see Compute linked services article.	Yes
scriptLinkedService	Reference to an Azure Storage Linked Service used to store the Hive script to be executed. Only **Azure Blob Storage** and **ADLS Gen2** linked services are supported here. If you don't specify this Linked Service, the Azure Storage Linked Service defined in the HDInsight Linked Service is used.	No
scriptPath	Provide the path to the script file stored in the Azure Storage referred by scriptLinkedService. The file name is case-sensitive.	Yes

PROPERTY	DESCRIPTION	REQUIRED
getDebugInfo	Specifies when the log files are copied to the Azure Storage used by HDInsight cluster (or) specified by scriptLinkedService. Allowed values: None, Always, or Failure. Default value: None.	No
arguments	Specifies an array of arguments for a Hadoop job. The arguments are passed as command-line arguments to each task.	No
defines	Specify parameters as key/value pairs for referencing within the Hive script.	No
queryTimeout	Query timeout value (in minutes). Applicable when the HDInsight cluster is with Enterprise Security Package enabled.	No

> **NOTE**
> The default value for queryTimeout is 120 minutes.

Transform data using Hadoop MapReduce activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The HDInsight MapReduce activity in an Azure Data Factory or Synapse Analytics pipeline invokes MapReduce program on your own or on-demand HDInsight cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities.

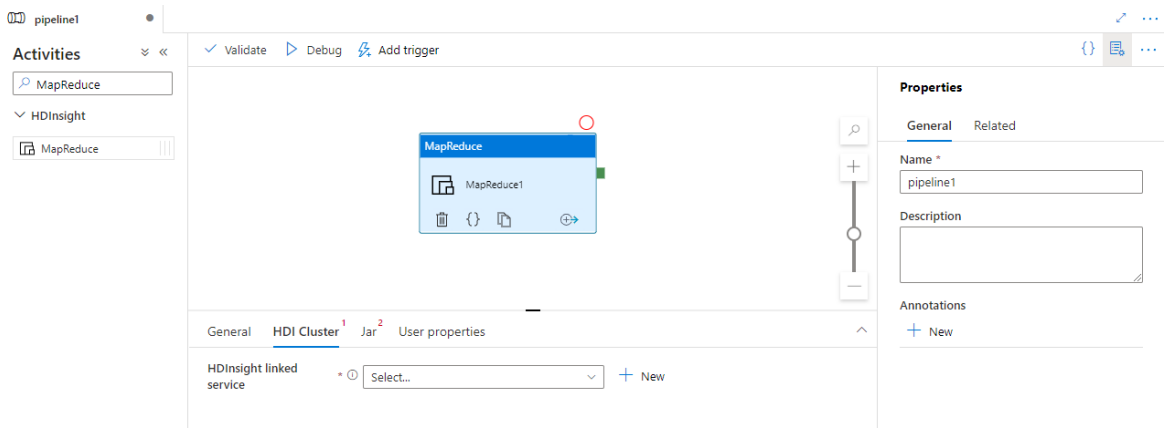
To learn more, read through the introduction articles for Azure Data Factory and Synapse Analytics, and do the tutorial: Tutorial: transform data before reading this article.

See Pig and Hive for details about running Pig/Hive scripts on a HDInsight cluster from a pipeline by using HDInsight Pig and Hive activities.

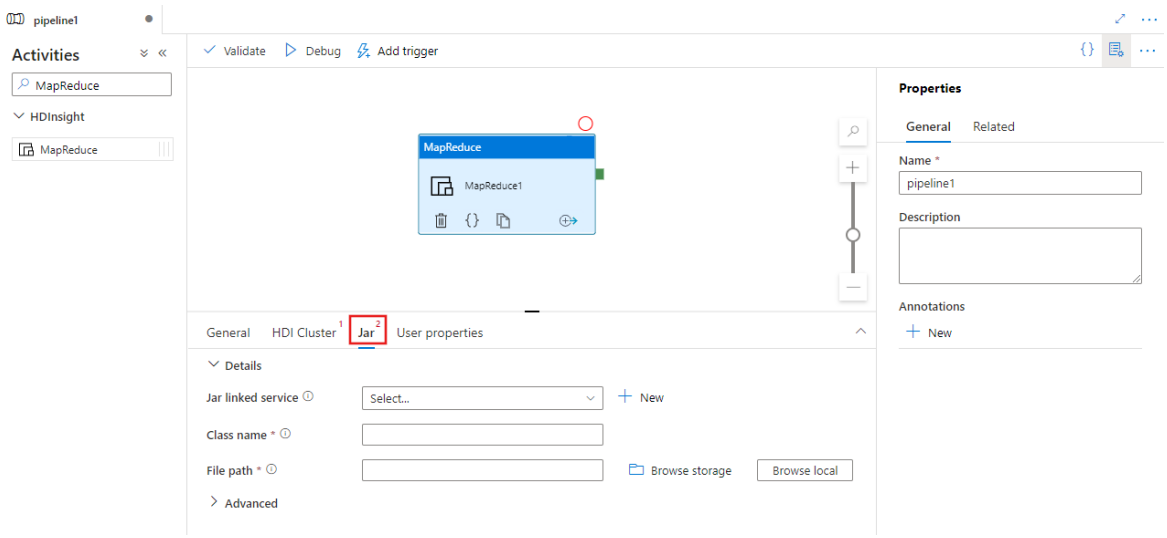
Add an HDInsight MapReduce activity to a pipeline with UI

To use an HDInsight MapReduce activity to a pipeline, complete the following steps:

1. Search for *MapReduce* in the pipeline Activities pane, and drag a MapReduce activity to the pipeline canvas.
2. Select the new MapReduce activity on the canvas if it is not already selected.
3. Select the **HDI Cluster** tab to select or create a new linked service to an HDInsight cluster that will be used to execute the MapReduce activity.



4. Select the **Jar** tab to select or create a new Jar linked service to an Azure Storage account that will host your script. Specify a class name to be executed there, and a file path within the storage location. You can also configure advanced details including a Jar libs location, debugging configuration, and arguments and parameters to be passed to the script.



Syntax

```
{
    "name": "Map Reduce Activity",
    "description": "Description",
    "type": "HDInsightMapReduce",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "className": "org.myorg.SampleClass",
        "jarLinkedService": {
            "referenceName": "MyAzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "jarFilePath": "MyAzureStorage/jars/sample.jar",
        "getDebugInfo": "Failure",
        "arguments": [
            "-SampleHadoopJobArgument1"
        ],
        "defines": {
            "param1": "param1Value"
        }
    }
}
```

Syntax details

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For MapReduce Activity, the activity type is HDinsightMapReduce	Yes

PROPERTY	DESCRIPTION	REQUIRED
linkedServiceName	Reference to the HDInsight cluster registered as a linked service. To learn about this linked service, see Compute linked services article.	Yes
className	Name of the Class to be executed	Yes
jarLinkedService	Reference to an Azure Storage Linked Service used to store the Jar files. Only **Azure Blob Storage** and **ADLS Gen2** linked services are supported here. If you don't specify this Linked Service, the Azure Storage Linked Service defined in the HDInsight Linked Service is used.	No
jarFilePath	Provide the path to the Jar files stored in the Azure Storage referred by jarLinkedService. The file name is case-sensitive.	Yes
jarlibs	String array of the path to the Jar library files referenced by the job stored in the Azure Storage defined in jarLinkedService. The file name is case-sensitive.	No
getDebugInfo	Specifies when the log files are copied to the Azure Storage used by HDInsight cluster (or) specified by jarLinkedService. Allowed values: None, Always, or Failure. Default value: None.	No
arguments	Specifies an array of arguments for a Hadoop job. The arguments are passed as command-line arguments to each task.	No
defines	Specify parameters as key/value pairs for referencing within the Hive script.	No

Example

You can use the HDInsight MapReduce Activity to run any MapReduce jar file on an HDInsight cluster. In the following sample JSON definition of a pipeline, the HDInsight Activity is configured to run a Mahout JAR file.

```
{
    "name": "MapReduce Activity for Mahout",
    "description": "Custom MapReduce to generate Mahout result",
    "type": "HDInsightMapReduce",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "className": "org.apache.mahout.cf.taste.hadoop.similarity.item.ItemSimilarityJob",
        "jarLinkedService": {
            "referenceName": "MyStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "jarFilePath": "adfsamples/Mahout/jars/mahout-examples-0.9.0.2.2.7.1-34.jar",
        "arguments": [
            "-s",
            "SIMILARITY_LOGLIKELIHOOD",
            "--input",
            "wasb://adfsamples@spestore.blob.core.windows.net/Mahout/input",
            "--output",
            "wasb://adfsamples@spestore.blob.core.windows.net/Mahout/output/",
            "--maxSimilaritiesPerItem",
            "500",
            "--tempDir",
            "wasb://adfsamples@spestore.blob.core.windows.net/Mahout/temp/mahout"
        ]
    }
}
```

You can specify any arguments for the MapReduce program in the **arguments** section. At runtime, you see a few extra arguments (for example: mapreduce.job.tags) from the MapReduce framework. To differentiate your arguments with the MapReduce arguments, consider using both option and value as arguments as shown in the following example (-s,--input,--output etc., are options immediately followed by their values).

Transform data using Hadoop Pig activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

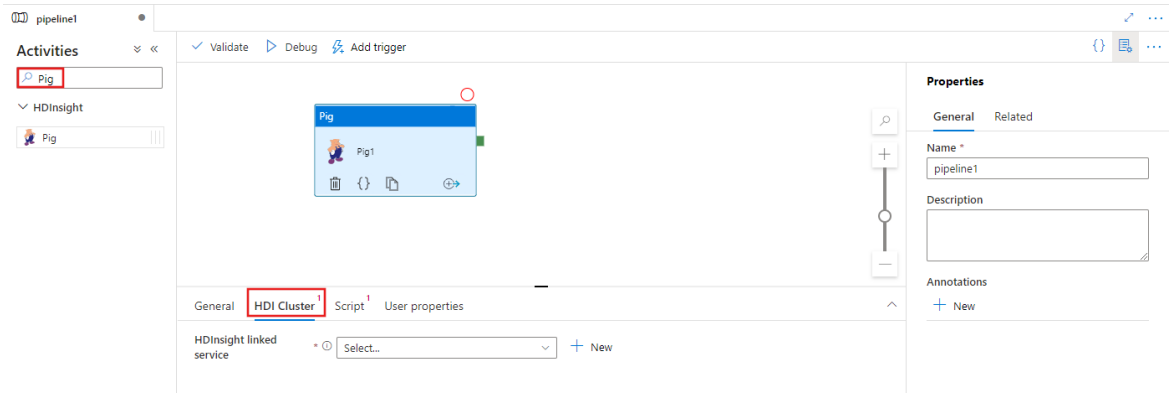
The HDInsight Pig activity in a Data Factory pipeline executes Pig queries on your own or on-demand HDInsight cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities.

To learn more, read through the introduction to Azure Data Factory or Synapse Analytics and do the Tutorial: transform data before reading this article.

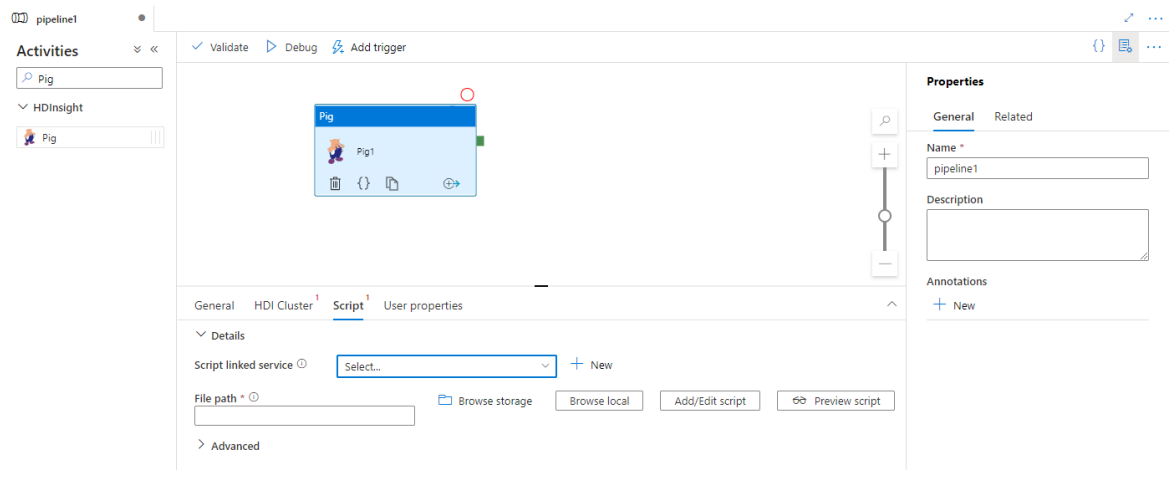
Add an HDInsight Pig activity to a pipeline with UI

To use an HDInsight Pig activity to a pipeline, complete the following steps:

1. Search for *Pig* in the pipeline Activities pane, and drag a Pig activity to the pipeline canvas.
2. Select the new Pig activity on the canvas if it is not already selected.
3. Select the **HDI Cluster** tab to select or create a new linked service to an HDInsight cluster that will be used to execute the MapReduce activity.



4. Select the **Script** tab to select or create a new script linked service to an Azure Storage location where your script will be hosted. Specify a class name to be executed there, and a file path within the storage location. You can also configure advanced details including debugging configuration, and arguments and parameters to be passed to the script.



Syntax

```
{
    "name": "Pig Activity",
    "description": "description",
    "type": "HDInsightPig",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "scriptLinkedService": {
            "referenceName": "MyAzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "scriptPath": "MyAzureStorage\\PigScripts\\MyPigSript.pig",
        "getDebugInfo": "Failure",
        "arguments": [
            "SampleHadoopJobArgument1"
        ],
        "defines": {
            "param1": "param1Value"
        }
    }
}
```

Syntax details

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For Hive Activity, the activity type is HDInsightPig	Yes
linkedServiceName	Reference to the HDInsight cluster registered as a linked service. To learn about this linked service, see Compute linked services article.	Yes
scriptLinkedService	Reference to an Azure Storage Linked Service used to store the Pig script to be executed. Only **Azure Blob Storage** and **ADLS Gen2** linked services are supported here. If you don't specify this Linked Service, the Azure Storage Linked Service defined in the HDInsight Linked Service is used.	No
scriptPath	Provide the path to the script file stored in the Azure Storage referred by scriptLinkedService. The file name is case-sensitive.	No

PROPERTY	DESCRIPTION	REQUIRED
getDebugInfo	Specifies when the log files are copied to the Azure Storage used by HDInsight cluster (or) specified by scriptLinkedService. Allowed values: None, Always, or Failure. Default value: None.	No
arguments	Specifies an array of arguments for a Hadoop job. The arguments are passed as command-line arguments to each task.	No
defines	Specify parameters as key/value pairs for referencing within the Pig script.	No

Transform data using Spark activity in Azure Data Factory and Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

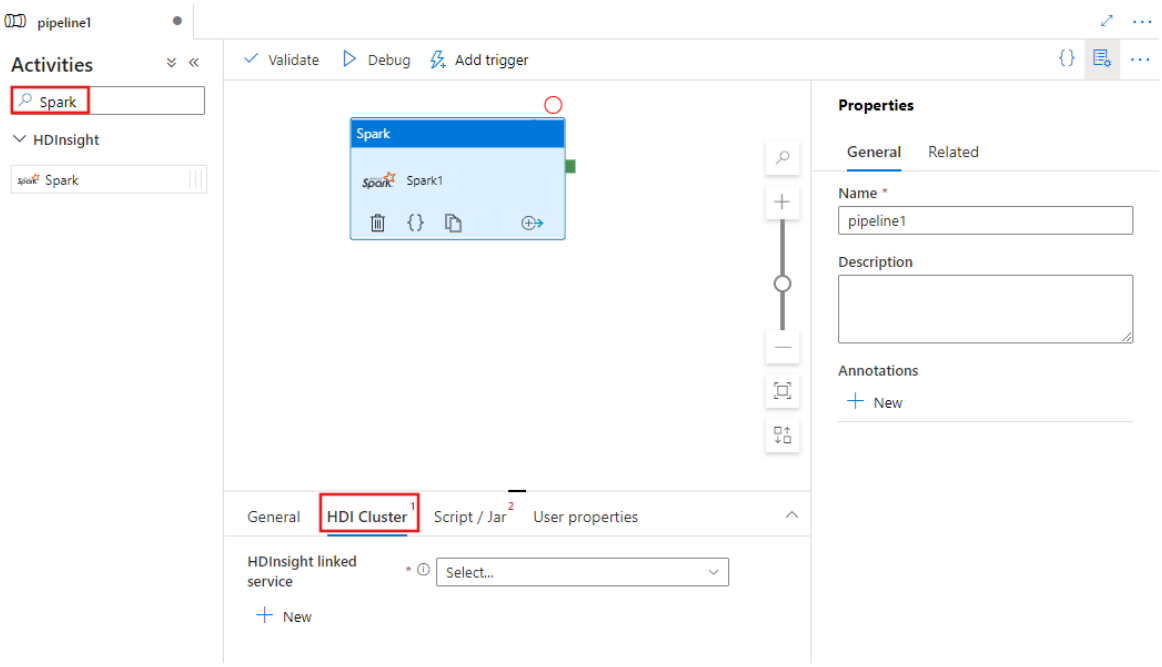
APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Spark activity in a data factory and Synapse pipelines executes a Spark program on your own or on-demand HDInsight cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities. When you use an on-demand Spark linked service, the service automatically creates a Spark cluster for you just-in-time to process the data and then deletes the cluster once the processing is complete.

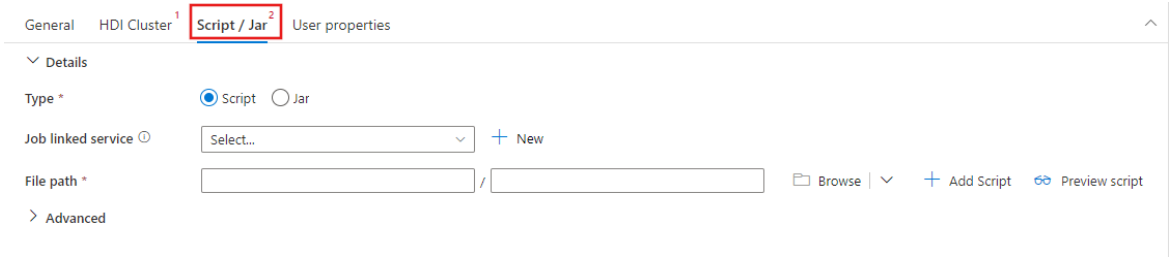
Add a Spark activity to a pipeline with UI

To use a Spark activity to a pipeline, complete the following steps:

1. Search for *Spark* in the pipeline Activities pane, and drag a Spark activity to the pipeline canvas.
2. Select the new Spark activity on the canvas if it is not already selected.
3. Select the **HDI Cluster** tab to select or create a new linked service to an HDInsight cluster that will be used to execute the Spark activity.



4. Select the **Script / Jar** tab to select or create a new job linked service to an Azure Storage account that will host your script. Specify a path to the file to be executed there. You can also configure advanced details including a proxy user, debugging configuration, and arguments and Spark configuration parameters to be passed to the script.



Spark activity properties

Here is the sample JSON definition of a Spark Activity:

```
{
    "name": "Spark Activity",
    "description": "Description",
    "type": "HDInsightSpark",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "sparkJobLinkedService": {
            "referenceName": "MyAzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "rootPath": "adfspark",
        "entryFilePath": "test.py",
        "sparkConfig": {
            "ConfigItem1": "Value"
        },
        "getDebugInfo": "Failure",
        "arguments": [
            "SampleHadoopJobArgument1"
        ]
    }
}
```

The following table describes the JSON properties used in the JSON definition:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline.	Yes
description	Text describing what the activity does.	No
type	For Spark Activity, the activity type is HDInsightSpark.	Yes
linkedServiceName	Name of the HDInsight Spark Linked Service on which the Spark program runs. To learn about this linked service, see Compute linked services article.	Yes

PROPERTY	DESCRIPTION	REQUIRED
SparkJobLinkedService	The Azure Storage linked service that holds the Spark job file, dependencies, and logs. Only **Azure Blob Storage** and **ADLS Gen2** linked services are supported here. If you do not specify a value for this property, the storage associated with HDInsight cluster is used. The value of this property can only be an Azure Storage linked service.	No
rootPath	The Azure Blob container and folder that contains the Spark file. The file name is case-sensitive. Refer to folder structure section (next section) for details about the structure of this folder.	Yes
entryFilePath	Relative path to the root folder of the Spark code/package. The entry file must be either a Python file or a .jar file.	Yes
className	Application's Java/Spark main class	No
arguments	A list of command-line arguments to the Spark program.	No
proxyUser	The user account to impersonate to execute the Spark program	No
sparkConfig	Specify values for Spark configuration properties listed in the topic: Spark Configuration - Application properties.	No
getDebugInfo	Specifies when the Spark log files are copied to the Azure storage used by HDInsight cluster (or) specified by sparkJobLinkedService. Allowed values: None, Always, or Failure. Default value: None.	No

Folder structure

Spark jobs are more extensible than Pig/Hive jobs. For Spark jobs, you can provide multiple dependencies such as jar packages (placed in the Java CLASSPATH), Python files (placed on the PYTHONPATH), and any other files.

Create the following folder structure in the Azure Blob storage referenced by the HDInsight linked service. Then, upload dependent files to the appropriate sub folders in the root folder represented by **entryFilePath**. For example, upload Python files to the pyFiles subfolder and jar files to the jars subfolder of the root folder. At runtime, the service expects the following folder structure in the Azure Blob storage:

PATH	DESCRIPTION	REQUIRED	TYPE

PATH	DESCRIPTION	REQUIRED	TYPE
`.` (root)	The root path of the Spark job in the storage linked service	Yes	Folder
<user defined >	The path pointing to the entry file of the Spark job	Yes	File
./jars	All files under this folder are uploaded and placed on the Java classpath of the cluster	No	Folder
./pyFiles	All files under this folder are uploaded and placed on the PYTHONPATH of the cluster	No	Folder
./files	All files under this folder are uploaded and placed on executor working directory	No	Folder
./archives	All files under this folder are uncompressed	No	Folder
./logs	The folder that contains logs from the Spark cluster.	No	Folder

Here is an example for a storage containing two Spark job files in the Azure Blob Storage referenced by the HDInsight linked service.

```
SparkJob1
 main.jar
 files
  input1.txt
  input2.txt
 jars
  package1.jar
  package2.jar
 logs

 archives

 pyFiles

SparkJob2
 main.py
 pyFiles
  scrip1.py
  script2.py
 logs

 archives

 jars

 files
```

Transform data using Hadoop Streaming activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

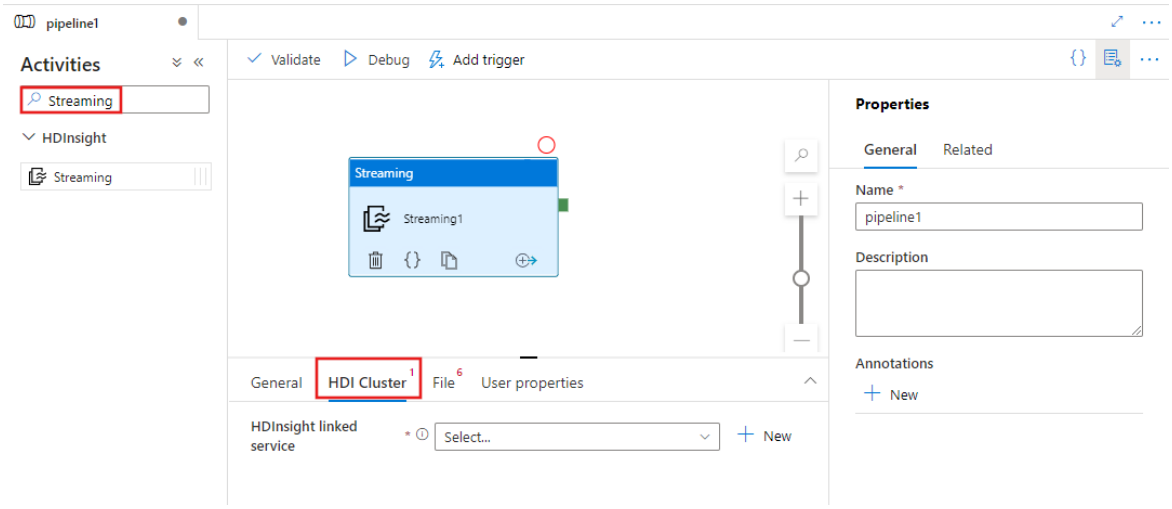
The HDInsight Streaming Activity in an Azure Data Factory or Synapse Analytics pipeline executes Hadoop Streaming programs on your own or on-demand HDInsight cluster. This article builds on the data transformation activities article, which presents a general overview of data transformation and the supported transformation activities.

To learn more, read through the introduction articles to Azure Data Factory and Synapse Analytics and do the Tutorial: transform data before reading this article.

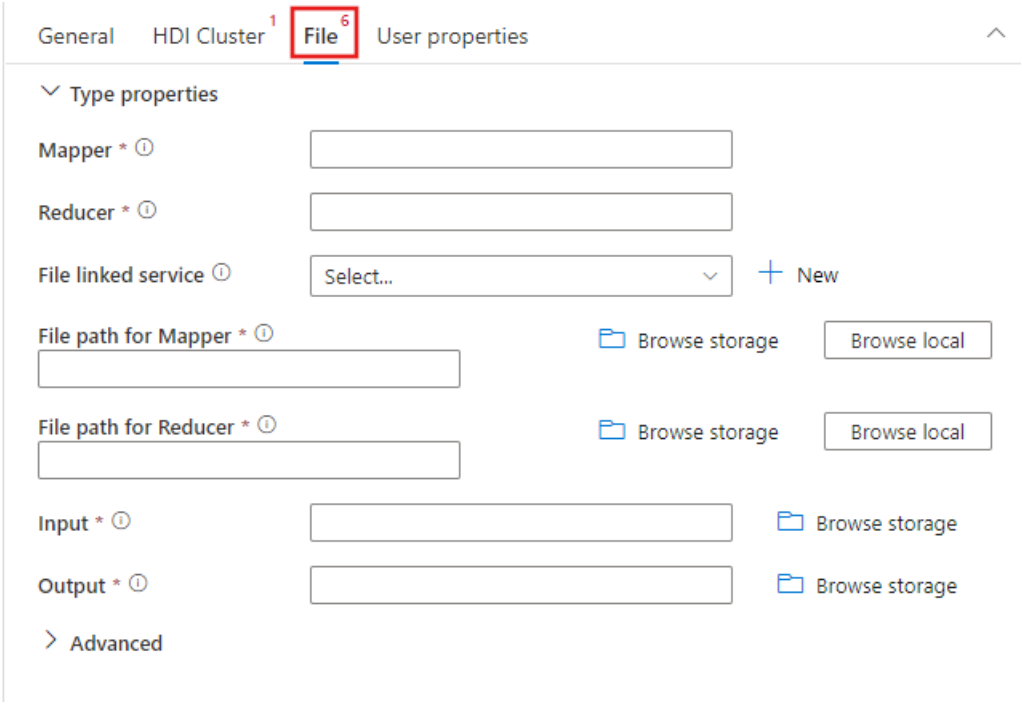
Add an HDInsight Streaming activity to a pipeline with UI

To use an HDInsight Streaming activity to a pipeline, complete the following steps:

1. Search for *Streaming* in the pipeline Activities pane, and drag a Streaming activity to the pipeline canvas.
2. Select the new Streaming activity on the canvas if it is not already selected.
3. Select the **HDI Cluster** tab to select or create a new linked service to an HDInsight cluster that will be used to execute the Streaming activity.



4. Select the **File** tab to specify the mapper and reducer names for your streaming job, and select or create a new linked service to an Azure Storage account that will the mapper, reducer, input, and output files for the job. You can also configure advanced details including debugging configuration, arguments, and parameters to be passed to the job.



JSON sample

```
{
    "name": "Streaming Activity",
    "description": "Description",
    "type": "HDInsightStreaming",
    "linkedServiceName": {
        "referenceName": "MyHDInsightLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "mapper": "MyMapper.exe",
        "reducer": "MyReducer.exe",
        "combiner": "MyCombiner.exe",
        "fileLinkedService": {
            "referenceName": "MyAzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "filePaths": [
            "<containername>/example/apps/MyMapper.exe",
            "<containername>/example/apps/MyReducer.exe",
            "<containername>/example/apps/MyCombiner.exe"
        ],
        "input": "wasb://<containername>@<accountname>.blob.core.windows.net/example/input/MapperInput.txt",
        "output":
"wasb://<containername>@<accountname>.blob.core.windows.net/example/output/ReducerOutput.txt",
        "commandEnvironment": [
            "CmdEnvVarName=CmdEnvVarValue"
        ],
        "getDebugInfo": "Failure",
        "arguments": [
            "SampleHadoopJobArgument1"
        ],
        "defines": {
            "param1": "param1Value"
        }
    }
}
```

Syntax details

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For Hadoop Streaming Activity, the activity type is HDInsightStreaming	Yes
linkedServiceName	Reference to the HDInsight cluster registered as a linked service. To learn about this linked service, see Compute linked services article.	Yes
mapper	Specifies the name of the mapper executable	Yes
reducer	Specifies the name of the reducer executable	Yes
combiner	Specifies the name of the combiner executable	No
fileLinkedService	Reference to an Azure Storage Linked Service used to store the Mapper, Combiner, and Reducer programs to be executed. Only **Azure Blob Storage** and **ADLS Gen2** linked services are supported here. If you don't specify this Linked Service, the Azure Storage Linked Service defined in the HDInsight Linked Service is used.	No
filePath	Provide an array of path to the Mapper, Combiner, and Reducer programs stored in the Azure Storage referred by fileLinkedService. The path is case-sensitive.	Yes
input	Specifies the WASB path to the input file for the Mapper.	Yes
output	Specifies the WASB path to the output file for the Reducer.	Yes
getDebugInfo	Specifies when the log files are copied to the Azure Storage used by HDInsight cluster (or) specified by scriptLinkedService. Allowed values: None, Always, or Failure. Default value: None.	No
arguments	Specifies an array of arguments for a Hadoop job. The arguments are passed as command-line arguments to each task.	No

PROPERTY	DESCRIPTION	REQUIRED
defines	Specify parameters as key/value pairs for referencing within the Hive script.	No

Execute Azure Machine Learning pipelines in Azure Data Factory and Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Run your Azure Machine Learning pipelines as a step in your Azure Data Factory and Synapse Analytics pipelines. The Machine Learning Execute Pipeline activity enables batch prediction scenarios such as identifying possible loan defaults, determining sentiment, and analyzing customer behavior patterns.

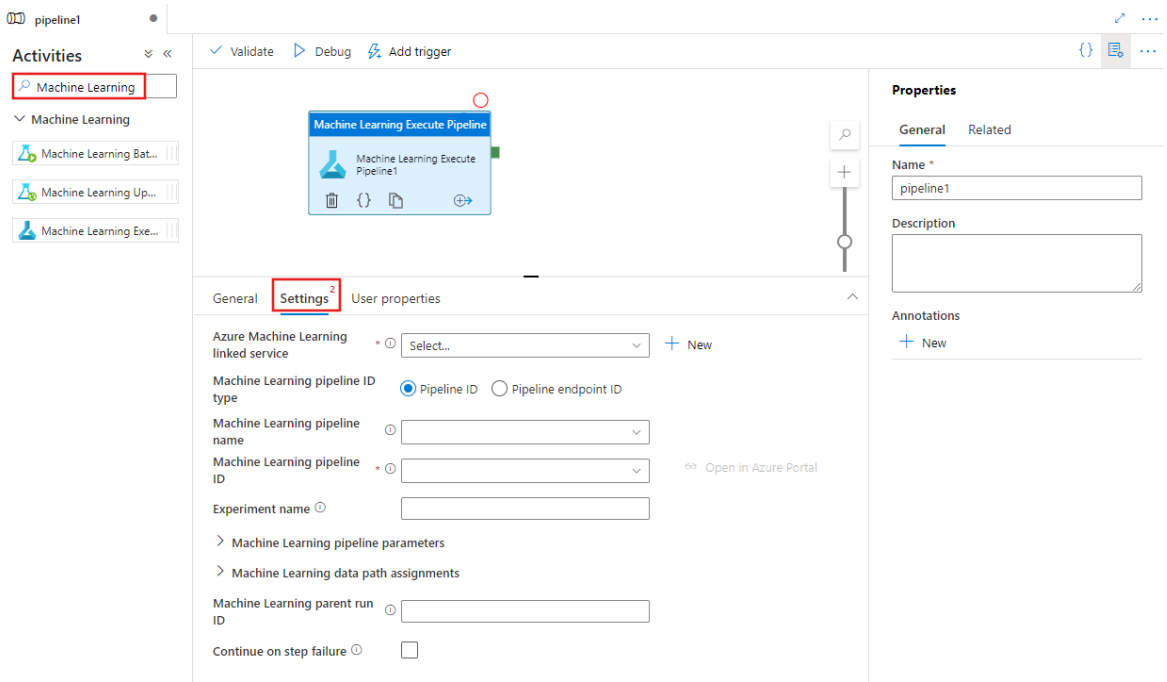
The below video features a six-minute introduction and demonstration of this feature.

Create a Machine Learning Execute Pipeline activity with UI

To use a Machine Learning Execute Pipeline activity in a pipeline, complete the following steps:

1. Search for *Machine Learning* in the pipeline Activities pane, and drag a Machine Learning Execute Pipeline activity to the pipeline canvas.

2. Select the new Machine Learning Execute Pipeline activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Select an existing or create a new Azure Machine Learning linked service, and provide details of the pipeline and experiment, and any pipeline parameters or data path assignments required for the pipeline.

Syntax

```
{
    "name": "Machine Learning Execute Pipeline",
    "type": "AzureMLExecutePipeline",
    "linkedServiceName": {
        "referenceName": "AzureMLService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "mlPipelineId": "machine learning pipeline ID",
        "experimentName": "experimentName",
        "mlPipelineParameters": {
            "mlParameterName": "mlParameterValue"
        }
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the activity in the pipeline	String	Yes
type	Type of activity is 'AzureMLExecutePipeline'	String	Yes
linkedServiceName	Linked Service to Azure Machine Learning	Linked service reference	Yes
mlPipelineId	ID of the published Azure Machine Learning pipeline	String (or expression with resultType of string)	Yes
experimentName	Run history experiment name of the Machine Learning pipeline run	String (or expression with resultType of string)	No
mlPipelineParameters	Key, Value pairs to be passed to the published Azure Machine Learning pipeline endpoint. Keys must match the names of pipeline parameters defined in the published Machine Learning pipeline	Object with key value pairs (or Expression with resultType object)	No
mlParentRunId	The parent Azure Machine Learning pipeline run ID	String (or expression with resultType of string)	No
dataPathAssignments	Dictionary used for changing datapaths in Azure Machine learning. Enables the switching of datapaths	Object with key value pairs	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
continueOnStepFailure	Whether to continue execution of other steps in the Machine Learning pipeline run if a step fails	boolean	No

> **NOTE**
> To populate the dropdown items in Machine Learning pipeline name and ID, the user needs to have permission to list ML pipelines. The UI calls AzureMLService APIs directly using the logged in user's credentials.

Create a predictive pipeline using Machine Learning Studio (classic) with Azure Data Factory or Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

NOTE

Since Machine Learning Studio (classic) resources can no longer be created after 1 Dec, 2021, users are encouraged to use Azure Machine Learning with the Machine Learning Execute Pipeline activity rather than using the Batch Execution activity to execute Machine Learning Studio (classic) batches.

ML Studio (classic) enables you to build, test, and deploy predictive analytics solutions. From a high-level point of view, it is done in three steps:

1. **Create a training experiment**. You do this step by using the ML Studio (classic). ML Studio (classic) is a collaborative visual development environment that you use to train and test a predictive analytics model using training data.
2. **Convert it to a predictive experiment**. Once your model has been trained with existing data and you are ready to use it to score new data, you prepare and streamline your experiment for scoring.
3. **Deploy it as a web service**. You can publish your scoring experiment as an Azure web service. You can send data to your model via this web service end point and receive result predictions from the model.

Using Machine Learning Studio (classic) with Azure Data Factory or Synapse Analytics

Azure Data Factory and Synapse Analytics enable you to easily create pipelines that use a published Machine Learning Studio (classic) web service for predictive analytics. Using the **Batch Execution Activity** in a pipeline, you can invoke Machine Learning Studio (classic) web service to make predictions on the data in batch.

Over time, the predictive models in the Machine Learning Studio (classic) scoring experiments need to be retrained using new input datasets. You can retrain a model from a pipeline by doing the following steps:

1. Publish the training experiment (not predictive experiment) as a web service. You do this step in the ML Studio (classic) as you did to expose predictive experiment as a web service in the previous scenario.
2. Use the ML Studio (classic) Batch Execution Activity to invoke the web service for the training experiment.

Basically, you can use the ML Studio (classic) Batch Execution activity to invoke both training web service and scoring web service.

After you are done with retraining, update the scoring web service (predictive experiment exposed as a web service) with the newly trained model by using the **ML Studio (classic) Update Resource Activity**. See Updating models using Update Resource Activity article for details.

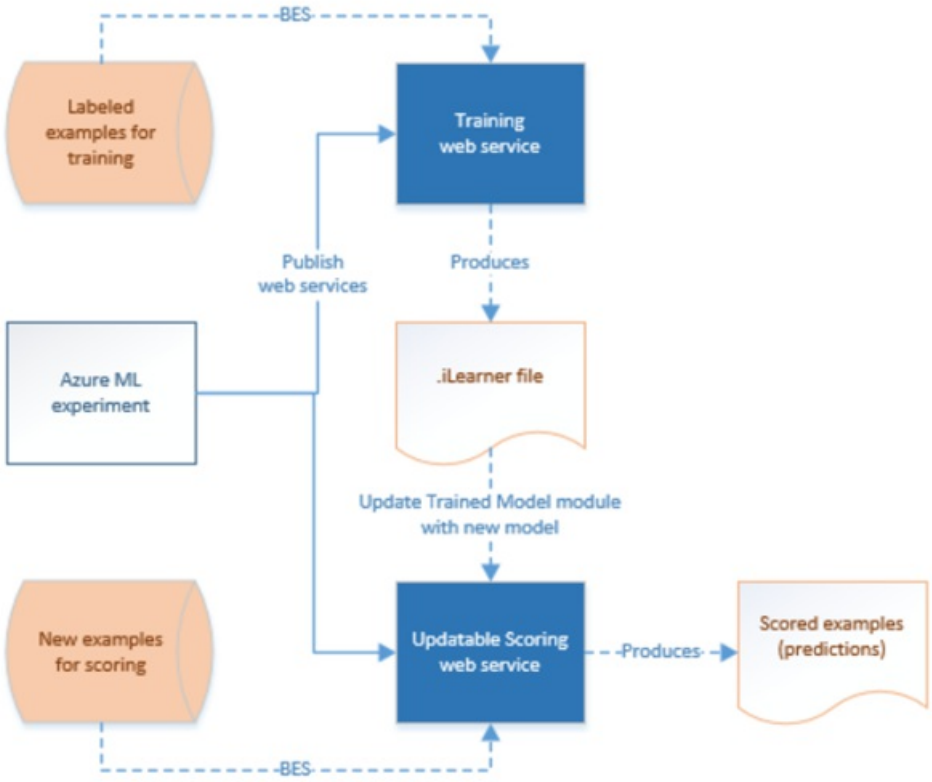
ML Studio (classic) linked service

You create an **Machine Learning Studio (classic)** linked service to link a Machine Learning Studio (classic) Web Service. The Linked Service is used by Machine Learning Studio (classic) Batch Execution Activity and Update Resource Activity.

```
{
    "type" : "linkedServices",
    "name": "AzureMLLinkedService",
    "properties": {
        "type": "AzureML",
        "typeProperties": {
            "mlEndpoint": "URL to Azure ML Predictive Web Service",
            "apiKey": {
                "type": "SecureString",
                "value": "api key"
            }
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

See Compute linked services article for descriptions about properties in the JSON definition.

Machine Learning Studio (classic) supports both Classic Web Services and New Web Services for your predictive experiment. You can choose the right one to use from your Data Factory or Synapse workspace. To get the information required to create the Machine Learning Studio (classic) Linked Service, go to https://services.azureml.net, where all your (new) Web Services and Classic Web Services are listed. Click the Web Service you would like to access, and click **Consume** page. Copy **Primary Key** for **apiKey** property, and **Batch Requests** for **mlEndpoint** property.



ML Studio (classic) Batch Execution activity

The following JSON snippet defines an ML Studio (classic) Batch Execution activity. The activity definition has a reference to the ML Studio (classic) linked service you created earlier.

```
{
    "name": "AzureMLExecutionActivityTemplate",
    "description": "description",
    "type": "AzureMLBatchExecution",
    "linkedServiceName": {
        "referenceName": "AzureMLLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "webServiceInputs": {
            "<web service input name 1>": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService1",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"path1"
            },
            "<web service input name 2>": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService1",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"path2"
            }
        },
        "webServiceOutputs": {
            "<web service output name 1>": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService2",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"path3"
            },
            "<web service output name 2>": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService2",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"path4"
            }
        },
        "globalParameters": {
            "<Parameter 1 Name>": "<parameter value>",
            "<parameter 2 name>": "<parameter 2 value>"
        }
    }
}
```

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline	Yes
description	Text describing what the activity does.	No
type	For Data Lake Analytics U-SQL activity, the activity type is **AzureMLBatchExecution**.	Yes
linkedServiceName	Linked Services to the ML Studio (classic) Linked Service. To learn about this linked service, see Compute linked services article.	Yes

PROPERTY	DESCRIPTION	REQUIRED
webServiceInputs	Key, Value pairs, mapping the names of ML Studio (classic) Web Service Inputs. Key must match the input parameters defined in the published ML Studio (classic) Web Service. Value is an Azure Storage Linked Services and FilePath properties pair specifying the input Blob locations.	No
webServiceOutputs	Key, Value pairs, mapping the names of ML Studio (classic) Web Service Outputs. Key must match the output parameters defined in the published ML Studio (classic) Web Service. Value is an Azure Storage Linked Services and FilePath properties pair specifying the output Blob locations.	No
globalParameters	Key, Value pairs to be passed to the ML Studio (classic) Batch Execution Service endpoint. Keys must match the names of web service parameters defined in the published ML Studio (classic) web service. Values are passed in the GlobalParameters property of the ML Studio (classic) batch execution request	No

Scenario 1: Experiments using Web service inputs/outputs that refer to data in Azure Blob Storage

In this scenario, the Machine Learning Studio (classic) Web service makes predictions using data from a file in an Azure blob storage and stores the prediction results in the blob storage. The following JSON defines a pipeline with an AzureMLBatchExecution activity. The input and output data in Azure Blog Storage is referenced using a LinkedName and FilePath pair. In the sample Linked Service of inputs and outputs are different, you can use different Linked Services for each of your inputs/outputs for the service to be able to pick up the right files and send to Machine Learning Studio (classic) Web Service.

> **IMPORTANT**
> In your ML Studio (classic) experiment, web service input and output ports, and global parameters have default names ("input1", "input2") that you can customize. The names you use for webServiceInputs, webServiceOutputs, and globalParameters settings must exactly match the names in the experiments. You can view the sample request payload on the Batch Execution Help page for your ML Studio (classic) endpoint to verify the expected mapping.

```
{
    "name": "AzureMLExecutionActivityTemplate",
    "description": "description",
    "type": "AzureMLBatchExecution",
    "linkedServiceName": {
        "referenceName": "AzureMLLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "webServiceInputs": {
            "input1": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService1",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"amltest/input/in1.csv"
            },
            "input2": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService1",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"amltest/input/in2.csv"
            }
        },
        "webServiceOutputs": {
            "outputName1": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService2",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"amltest2/output/out1.csv"
            },
            "outputName2": {
                "LinkedServiceName":{
                    "referenceName": "AzureStorageLinkedService2",
                    "type": "LinkedServiceReference"
                },
                "FilePath":"amltest2/output/out2.csv"
            }
        }
    }
}
```

Scenario 2: Experiments using Reader/Writer Modules to refer to data in various storages

Another common scenario when creating ML Studio (classic) experiments is to use Import Data and Output Data modules. The Import Data module is used to load data into an experiment and the Output Data module is to save data from your experiments. For details about Import Data and Output Data modules, see Import Data and Output Data topics on MSDN Library.

When using the Import Data and Output Data modules, it is good practice to use a Web service parameter for each property of these modules. These web parameters enable you to configure the values during runtime. For example, you could create an experiment with an Import Data module that uses an Azure SQL Database: XXX.database.windows.net. After the web service has been deployed, you want to enable the consumers of the web service to specify another logical SQL server called `YYY.database.windows.net`. You can use a Web service parameter to allow this value to be configured.

> **NOTE**
> Web service input and output are different from Web service parameters. In the first scenario, you have seen how an input and output can be specified for an ML Studio (classic) Web service. In this scenario, you pass parameters for a Web service that correspond to properties of Import Data/Output Data modules.

Let's look at a scenario for using Web service parameters. You have a deployed ML Studio (classic) web service that uses a reader module to read data from one of the data sources supported by ML Studio (classic) (for example: Azure SQL Database). After the batch execution is performed, the results are written using a Writer module (Azure SQL Database). No web service inputs and outputs are defined in the experiments. In this case, we recommend that you configure relevant web service parameters for the reader and writer modules. This configuration allows the reader/writer modules to be configured when using the AzureMLBatchExecution activity. You specify Web service parameters in the **globalParameters** section in the activity JSON as follows.

```
"typeProperties": {
    "globalParameters": {
        "Database server name": "<myserver>.database.windows.net",
        "Database name": "<database>",
        "Server user account name": "<user name>",
        "Server user account password": "<password>"
    }
}
```

> **NOTE**
> The Web service parameters are case-sensitive, so ensure that the names you specify in the activity JSON match the ones exposed by the Web service.

After you are done with retraining, update the scoring web service (predictive experiment exposed as a web service) with the newly trained model by using the **ML Studio (classic) Update Resource Activity**. See Updating models using Update Resource Activity article for details.

Update Machine Learning Studio (classic) models by using Update Resource activity

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

NOTE

Since Machine Learning Studio (classic) resources can no longer be created after 1 Dec, 2021, users are encouraged to use Azure Machine Learning with the Machine Learning Execute Pipeline activity rather than using the Update Resource activity to update Machine Learning Studio (classic) models.

This article complements the main Machine Learning Studio (classic) integration article: Create predictive pipelines using Machine Learning Studio (classic). If you haven't already done so, review the main article before reading through this article.

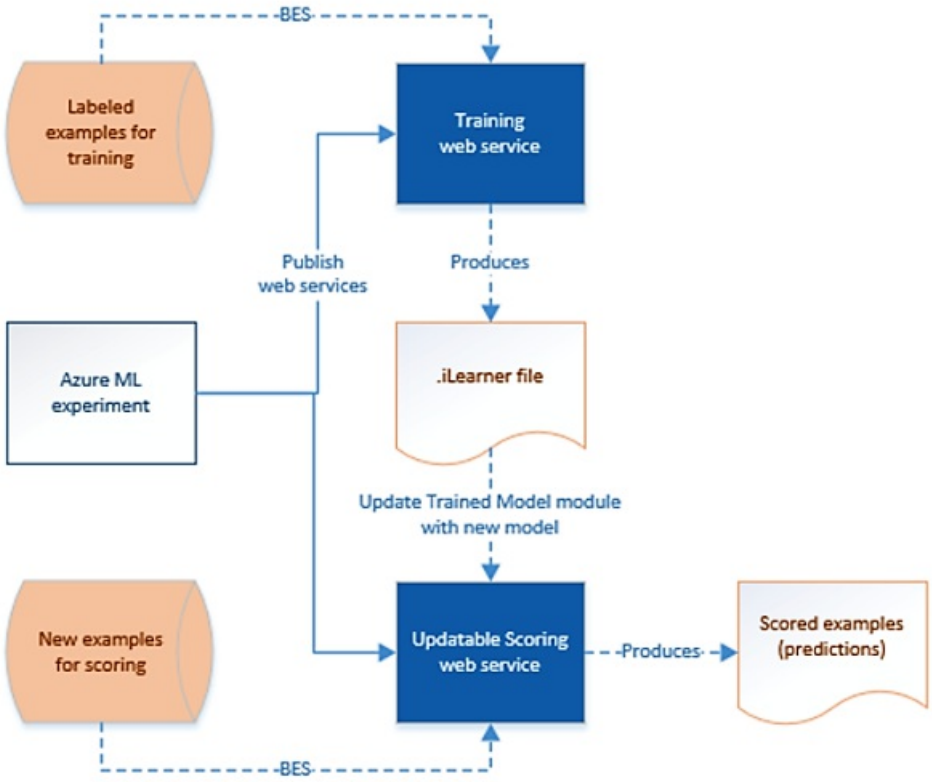
Overview

As part of the process of operationalizing Machine Learning Studio (classic) models, your model is trained and saved. You then use it to create a predictive Web service. The Web service can then be consumed in web sites, dashboards, and mobile apps.

Models you create using Machine Learning Studio (classic) are typically not static. As new data becomes available or when the consumer of the API has their own data the model needs to be retrained.

Retraining may occur frequently. With Batch Execution activity and Update Resource activity, you can operationalize the Machine Learning Studio (classic) model retraining and updating the predictive Web Service.

The following picture depicts the relationship between training and predictive Web Services.



Machine Learning Studio (classic) update resource activity

The following JSON snippet defines an Machine Learning Studio (classic) Batch Execution activity.

```
{
    "name": "amlUpdateResource",
    "type": "AzureMLUpdateResource",
    "description": "description",
    "linkedServiceName": {
        "type": "LinkedServiceReference",
        "referenceName": "updatableScoringEndpoint2"
    },
    "typeProperties": {
        "trainedModelName": "ModelName",
        "trainedModelLinkedServiceName": {
                    "type": "LinkedServiceReference",
                    "referenceName": "StorageLinkedService"
                },
        "trainedModelFilePath": "ilearner file path"
    }
}
```

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in the pipeline	Yes
description	Text describing what the activity does.	No
type	For Machine Learning Studio (classic) Update Resource activity, the activity type is **AzureMLUpdateResource**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
linkedServiceName	Machine Learning Studio (classic) linked service that contains updateResourceEndpoint property.	Yes
trainedModelName	Name of the Trained Model module in the Web Service experiment to be updated	Yes
trainedModelLinkedServiceName	Name of Azure Storage linked service holding the ilearner file that is uploaded by the update operation	Yes
trainedModelFilePath	The relative file path in trainedModelLinkedService to represent the ilearner file that is uploaded by the update operation	Yes

End-to-end workflow

The entire process of operationalizing retraining a model and update the predictive Web Services involves the following steps:

- Invoke the **training Web Service** by using the **Batch Execution activity**. Invoking a training Web Service is the same as invoking a predictive Web Service described in Create predictive pipelines using Machine Learning Studio (classic) and the Batch Execution activity. The output of the training Web Service is an iLearner file that you can use to update the predictive Web Service.
- Invoke the **update resource endpoint** of the **predictive Web Service** by using the **Update Resource activity** to update the Web Service with the newly trained model.

Machine Learning Studio (classic) linked service

For the above mentioned end-to-end workflow to work, you need to create two Machine Learning Studio (classic) linked services:

1. An Machine Learning Studio (classic) linked service to the training web service, this linked service is used by Batch Execution activity in the same way as what's mentioned in Create predictive pipelines using Machine Learning Studio (classic) and the Batch Execution activity. Difference is the output of the training web service is an iLearner file, which is then used by Update Resource activity to update the predictive web service.
2. An Machine Learning Studio (classic) linked service to the update resource endpoint of the predictive web service. This linked service is used by Update Resource activity to update the predictive web service using the iLearner file returned from above step.

For the second Machine Learning Studio (classic) linked service, the configuration is different when your Machine Learning Studio (classic) Web Service is a classic Web Service or a new Web Service. The differences are discussed separately in the following sections.

Web service is new Azure Resource Manager web service

If the web service is the new type of web service that exposes an Azure Resource Manager endpoint, you do not need to add the second **non-default** endpoint. The **updateResourceEndpoint** in the linked service is of the format:

```
https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resource-group-name}/providers/Microsoft.MachineLearning/webServices/{web-service-name}?api-version=2016-05-01-preview
```

You can get values for place holders in the URL when querying the web service on the Machine Learning Studio (classic) Web Services Portal.

The new type of update resource endpoint requires service principal authentication. To use service principal authentication, register an application entity in Azure Active Directory (Azure AD) and grant it the **Contributor** or **Owner** role of the subscription or the resource group where the web service belongs to. The See how to create service principal and assign permissions to manage Azure resource. Make note of the following values, which you use to define the linked service:

- Application ID
- Application key
- Tenant ID

Here is a sample linked service definition:

```
{
    "name": "AzureMLLinkedService",
    "properties": {
        "type": "AzureML",
        "description": "The linked service for AML web service.",
        "typeProperties": {
            "mlEndpoint": "https://ussouthcentral.services.azureml.net/workspaces/0000000000000000000000000000000000000000000000000000/services/00000000000000000000000000000000/jobs?api-version=2.0",
            "apiKey": {
                "type": "SecureString",
                "value": "APIKeyOfEndpoint1"
            },
            "updateResourceEndpoint": "https://management.azure.com/subscriptions/{subscriptionId}/resourceGroups/{resource-group-name}/providers/Microsoft.MachineLearning/webServices/{web-service-name}?api-version=2016-05-01-preview",
            "servicePrincipalId": "000000000-0000-0000-0000-0000000000000",
            "servicePrincipalKey": {
                "type": "SecureString",
                "value": "servicePrincipalKey"
            },
            "tenant": "mycompany.com"
        }
    }
}
```

The following scenario provides more details. It has an example for retraining and updating Machine Learning Studio (classic) models from a pipeline.

Sample: Retraining and updating an Machine Learning Studio (classic) model

This section provides a sample pipeline that uses the **Azure Machine Learning Studio (classic) Batch Execution activity** to retrain a model. The pipeline also uses the **Azure Machine Learning Studio (classic) Update Resource activity** to update the model in the scoring web service. The section also provides JSON snippets for all the linked services, datasets, and pipeline in the example.

Azure Blob storage linked service:

The Azure Storage holds the following data:

- training data. The input data for the Machine Learning Studio (classic) training web service.

- iLearner file. The output from the Machine Learning Studio (classic) training web service. This file is also the input to the Update Resource activity.

Here is the sample JSON definition of the linked service:

```
{
    "name": "StorageLinkedService",
    "properties": {
        "type": "AzureStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=name;AccountKey=key"
        }
    }
}
```

Linked service for Machine Learning Studio (classic) training endpoint

The following JSON snippet defines an Machine Learning Studio (classic) linked service that points to the default endpoint of the training web service.

```
{
    "name": "trainingEndpoint",
    "properties": {
        "type": "AzureML",
        "typeProperties": {
            "mlEndpoint": "https://ussouthcentral.services.azureml.net/workspaces/xxx/services/--training
experiment--/jobs",
            "apiKey": "myKey"
        }
    }
}
```

In **Azure Machine Learning Studio (classic)**, do the following to get values for **mlEndpoint** and **apiKey**:

1. Click **WEB SERVICES** on the left menu.
2. Click the **training web service** in the list of web services.
3. Click copy next to **API key** text box. Paste the key in the clipboard into the Data Factory JSON editor.
4. In the **Azure Machine Learning Studio (classic)**, click **BATCH EXECUTION** link.
5. Copy the **Request URI** from the **Request** section and paste it into the JSON editor.

Linked service for Azure Machine Learning Studio (classic) updatable scoring endpoint:

The following JSON snippet defines an Azure Machine Learning Studio (classic) linked service that points to updatable endpoint of the scoring web service.

```
{
    "name": "updatableScoringEndpoint2",
    "properties": {
        "type": "AzureML",
        "typeProperties": {
            "mlEndpoint":
"https://ussouthcentral.services.azureml.net/workspaces/00000000eb0abe4d6bbb1d7886062747d7/services/00000000
026734a5889e02fbb1f65cefd/jobs?api-version=2.0",
            "apiKey":
"soooooooooh3WvG1hBfKS2BNNcfwSO7hhY6dY98noLfOdqQydYDIXyf2KoIaN3JpALu/AKtflHWMOCuicm/Q==",
            "updateResourceEndpoint": "https://management.azure.com/subscriptions/00000000-0000-0000-0000-
000000000000/resourceGroups/Default-MachineLearning-
SouthCentralUS/providers/Microsoft.MachineLearning/webServices/myWebService?api-version=2016-05-01-preview",
            "servicePrincipalId": "fe200044-c008-4008-a005-94000000731",
            "servicePrincipalKey": "zWa0000000000Tp6FjtZOspK/WMA2tQ08c8U+gZRBlw=",
            "tenant": "mycompany.com"
        }
    }
}
```

Pipeline

The pipeline has two activities: **AzureMLBatchExecution** and **AzureMLUpdateResource**. The Batch Execution activity takes the training data as input and produces an iLearner file as an output. The Update Resource activity then takes this iLearner file and use it to update the predictive web service.

```
{
    "name": "LookupPipelineDemo",
    "properties": {
        "activities": [
            {
                "name": "amlBEGetilearner",
                "description": "Use AML BES to get the ileaner file from training web service",
                "type": "AzureMLBatchExecution",
                "linkedServiceName": {
                    "referenceName": "trainingEndpoint",
                    "type": "LinkedServiceReference"
                },
                "typeProperties": {
                    "webServiceInputs": {
                        "input1": {
                            "LinkedServiceName":{
                                "referenceName": "StorageLinkedService",
                                "type": "LinkedServiceReference"
                            },
                            "FilePath":"azuremltesting/input"
                        },
                        "input2": {
                            "LinkedServiceName":{
                                "referenceName": "StorageLinkedService",
                                "type": "LinkedServiceReference"
                            },
                            "FilePath":"azuremltesting/input"
                        }
                    },
                    "webServiceOutputs": {
                        "output1": {
                            "LinkedServiceName":{
                                "referenceName": "StorageLinkedService",
                                "type": "LinkedServiceReference"
                            },
                            "FilePath":"azuremltesting/output"
                        }
                    }
                }
            },
            {
                "name": "amlUpdateResource",
                "type": "AzureMLUpdateResource",
                "description": "Use AML Update Resource to update the predict web service",
                "linkedServiceName": {
                    "type": "LinkedServiceReference",
                    "referenceName": "updatableScoringEndpoint2"
                },
                "typeProperties": {
                    "trainedModelName": "ADFV2Sample Model [trained model]",

Transform data by using the SQL Server Stored Procedure activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

You use data transformation activities in a Data Factory or Synapse pipeline to transform and process raw data into predictions and insights. The Stored Procedure Activity is one of the transformation activities that pipelines support. This article builds on the transform data article, which presents a general overview of data transformation and the supported transformation activities.

> **NOTE**
> If you are new to Azure Data Factory, read through Introduction to Azure Data Factory and do the tutorial: Tutorial: transform data before reading this article. To learn more about Synapse Analytics, read What is Azure Synapse Analytics.

You can use the Stored Procedure Activity to invoke a stored procedure in one of the following data stores in your enterprise or on an Azure virtual machine (VM):

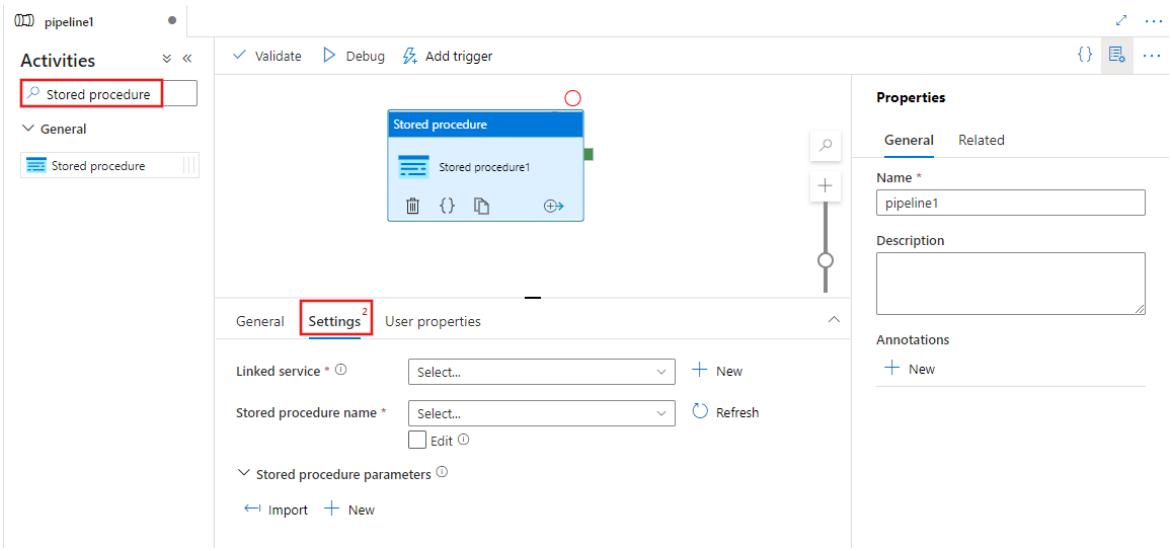
- Azure SQL Database
- Azure Synapse Analytics
- SQL Server Database. If you are using SQL Server, install Self-hosted integration runtime on the same machine that hosts the database or on a separate machine that has access to the database. Self-Hosted integration runtime is a component that connects data sources on-premises/on Azure VM with cloud services in a secure and managed way. See Self-hosted integration runtime article for details.

> **IMPORTANT**
> When copying data into Azure SQL Database or SQL Server, you can configure the **SqlSink** in copy activity to invoke a stored procedure by using the **sqlWriterStoredProcedureName** property. For details about the property, see following connector articles: Azure SQL Database, SQL Server. Invoking a stored procedure while copying data into an Azure Synapse Analytics by using a copy activity is not supported. But, you can use the stored procedure activity to invoke a stored procedure in Azure Synapse Analytics.
>
> When copying data from Azure SQL Database or SQL Server or Azure Synapse Analytics, you can configure **SqlSource** in copy activity to invoke a stored procedure to read data from the source database by using the **sqlReaderStoredProcedureName** property. For more information, see the following connector articles: Azure SQL Database, SQL Server, Azure Synapse Analytics

Create a Stored Procedure activity with UI

To use a Stored Procedure activity in a pipeline, complete the following steps:

1. Search for *Stored Procedure* in the pipeline Activities pane, and drag a Stored Procedure activity to the pipeline canvas.
2. Select the new Stored Procedure activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Select an existing or create a new linked service to an Azure SQL Database, Azure Synapse Analytics, or SQL Server.

4. Choose a stored procedure, and provide any parameters for its execution.

Syntax details

Here is the JSON format for defining a Stored Procedure Activity:

```
{
    "name": "Stored Procedure Activity",
    "description":"Description",
    "type": "SqlServerStoredProcedure",
    "linkedServiceName": {
        "referenceName": "AzureSqlLinkedService",
        "type": "LinkedServiceReference"
    },
    "typeProperties": {
        "storedProcedureName": "usp_sample",
        "storedProcedureParameters": {
            "identifier": { "value": "1", "type": "Int" },
            "stringData": { "value": "str1" }

        }
    }
}
```

The following table describes these JSON properties:

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity	Yes
description	Text describing what the activity is used for	No
type	For Stored Procedure Activity, the activity type is **SqlServerStoredProcedure**	Yes

PROPERTY	DESCRIPTION	REQUIRED
linkedServiceName	Reference to the **Azure SQL Database** or **Azure Synapse Analytics** or **SQL Server** registered as a linked service in Data Factory. To learn about this linked service, see Compute linked services article.	Yes
storedProcedureName	Specify the name of the stored procedure to invoke.	Yes
storedProcedureParameters	Specify the values for stored procedure parameters. Use `"param1": { "value": "param1Value","type":"param1Type" }` to pass parameter values and their type supported by the data source. If you need to pass null for a parameter, use `"param1": { "value": null }` (all lower case).	No

Parameter data type mapping

The data type you specify for the parameter is the internal service type that maps to the data type in the data source you are using. You can find the data type mappings for your data source described in the connectors documentation. For example:

- Azure Synapse Analytics
- Azure SQL Database data type mapping
- Oracle data type mapping
- SQL Server data type mapping

Transform data by using the Script activity in Azure Data Factory or Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

You use data transformation activities in a Data Factory or Synapsepipelineto transform and process raw data into predictions and insights. The Script activity is one of the transformation activities that pipelines support. This article builds on thetransform dataarticle, which presents a general overview of data transformation and the supported transformation activities.

Using the script activity, you can execute common operations with Data Manipulation Language (DML), and Data Definition Language (DDL). DML statements like INSERT, UPDATE, DELETE and SELECT let users insert, modify, delete and retrieve data in the database. DDL statements like CREATE, ALTER and DROPallow a database manager to create, modify, and remove database objects such as tables, indexes, and users.

You can use the Script activity to invoke a SQL script in one of the following data stores in your enterprise or on an Azure virtual machine (VM):

- Azure SQL Database
- Azure Synapse Analytics
- SQL Server Database. If you are using SQL Server, install Self-hosted integration runtime on the same machine that hosts the database or on a separate machine that has access to the database. Self-Hosted integration runtime is a component that connects data sources on-premises/on Azure VM with cloud services in a secure and managed way. Seethe Self-hosted integration runtimearticle for details.
- Oracle
- Snowflake

The script may contain either a single SQL statement or multiple SQL statements that run sequentially.You can use the Execute SQL task for the following purposes:

- Truncate a table in preparation for inserting data.
- Create, alter, and drop database objects such as tables and views.
- Re-create fact and dimension tables before loading data into them.
- Run stored procedures. If the SQL statement invokes a stored procedure that returns results from a temporary table, use the WITH RESULT SETS option to define metadata for the result set.
- Save the rowset returned from a query as activity output for downstream consumption.

Syntax details

Here is the JSON format for defining a Script activity:

```
{
   "name": "<activity name>",
   "type": "Script",
   "linkedServiceName": {
      "referenceName": "<name>",
      "type": "LinkedServiceReference"
    },
   "typeProperties": {
      "scripts" : [
         {
            "text": "<Script Block>",
            "type": "<Query> or <NonQuery>",
            "parameters":[
               {
                  "name": "<name>",
                  "value": "<value>",
                  "type": "<type>",
                  "direction": "<Input> or <Output> or <InputOutput>",
                  "size": 256
               },
               ...
            ]
         },
         ...
      ],
         ...
         ]
      },
      "logSettings": {
         "logDestination": "<ActivityOutput> or <ExternalStore>",
         "logLocationSettings":{
            "linkedServiceName":{
               "referenceName": "<name>",
               "type": "<LinkedServiceReference>"
            },
            "path": "<folder path>"
         }
      }
    }
}
```

The following table describes these JSON properties:

PROPERTY NAME	DESCRIPTION	REQUIRED
name	The name of the activity.	Yes
type	The type of the activity, set to "Script".	Yes
typeProperties	Specify properties to configure the Script Activity.	Yes
linkedServiceName	The target database the script runs on. It should be a reference to a linked service.	Yes
scripts	An array of objects to represent the script.	No
scripts.text	The plain text of a block of queries.	No

PROPERTY NAME	DESCRIPTION	REQUIRED
scripts.type	The type of the block of queries. It can be Query or NonQuery. Default: Query.	No
scripts.parameter	The array of parameters of the script.	No
scripts.parameter.name	The name of the parameter.	No
scripts.parameter.value	The value of the parameter.	No
scripts.parameter.type	The data type of the parameter. The type is logical type and follows type mapping of each connector.	No
scripts.parameter.direction	The direction of the parameter. It can be Input, Output, InputOutput. The value is ignored if the direction is Output. ReturnValue type is not supported. Set the return value of SP to an output parameter to retrieve it.	No
scripts.parameter.size	The max size of the parameter. Only applies to Output/InputOutput direction parameter of type string/byte[].	No
logSettings	The settings to store the output logs. If not specified, script log is disabled.	No
logSettings.logDestination	The destination of log output. It can be ActivityOutput or ExternalStore. Default: ActivityOutput.	No
logSettings.logLocationSettings	The settings of the target location if logDestination is ExternalStore.	No
logSettiongs.logLocationSettings.linkedServiceName	The linked service of the target location. Only blob storage is supported.	No
logSettings.logLocationSettings.path	The folder path under which logs will be stored.	No

Activity output

Sample output:

```
{
  "resultSetCount": 2,
  "resultSets": [
    {
      "rowCount": 10,
      "rows":[
        {
          "<columnName1>": "<value1>",
          "<columnName2>": "<value2>",
          ...
        }
      ]
    },
    ...
  ],
  "recordsAffected": 123,
  "outputParameters":{
    "<parameterName1>": "<value1>",
    "<parameterName2>": "<value2>"
  },
  "outputLogs": "<logs>",
  "outputLogsLocation": "<folder path>",
  "outputTruncated": true,
    ...
}
```

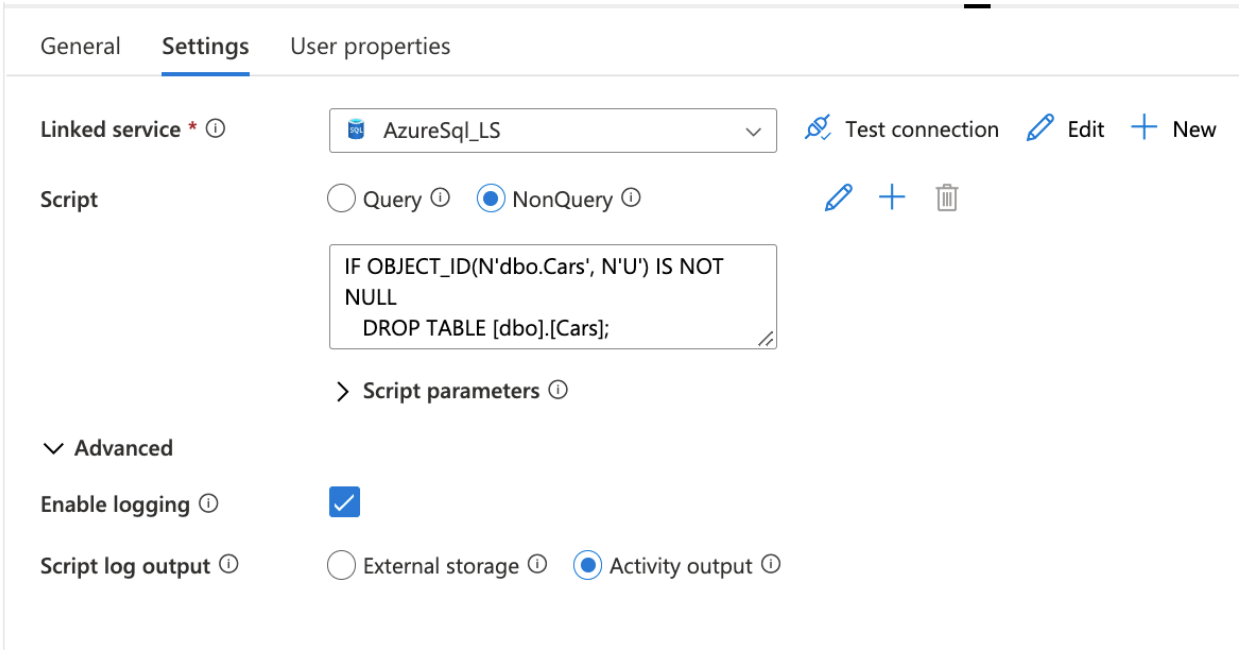
PROPERTY NAME	DESCRIPTION	CONDITION
resultSetCount	The count of result sets returned by the script.	Always
resultSets	The array which contains all the result sets.	Always
resultSets.rowCount	Total rows in the result set.	Always
resultSets.rows	The array of rows in the result set.	Always
recordsAffected	The row count of affected rows by the script.	If scriptType is NonQuery.
outputParameters	The output parameters of the script.	If parameter type is Output or InputOutput.
outputLogs	The logs written by the script, for example, print statement.	If connector supports log statement and enableScriptLogs is true and logLocationSettings is not provided.
outputLogsPath	The full path of the log file.	If enableScriptLogs is true and logLocationSettings is provided.
outputTruncated	Indicator of whether the output exceeds the limits and get truncated.	If output exceeds the limits.

NOTE

- The output is collected every time a script block is executed. The final output is the merged result of all script block outputs. The output parameter with same name in different script block will get overwritten.
- Since the output has size / rows limitation, the output will be truncated in following order: logs -> parameters -> rows. Note, this applies to a single script block, which means the output rows of next script block won't evict previous logs.
- Any error caused by log won't fail the activity.
- For consuming activity output resultSets in down stream activity please refer to the Lookup activity result documentation.
- Use outputLogs when you are using 'PRINT' statements for logging purpose. If query returns resultSets, it will be available in the activity output and will be limited to 5000 rows/ 2MB size limit.

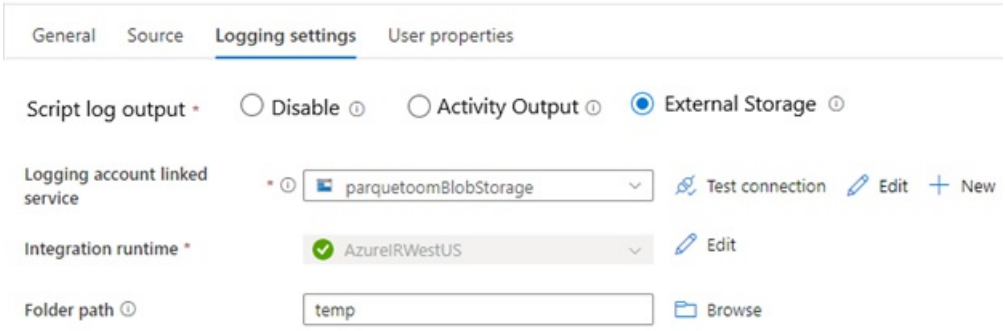
Configure the Script activity using UI

Inline script



Inline scripts integrate well with Pipeline CI/CD since the script is stored as part of the pipeline metadata.

Logging



Logging options:

- *Disable* - No execution output is logged.
- *Activity output* – The script execution output is appended to the activity output. It can be consumed by

downstream activities. The output size is limited to 2MB.

- *External storage* – Persists output to storage. Use this option if the output size is greater than 2MB or you would like to explicitly persist the output on your storage account.

> **NOTE**
>
> **Billing** - The Script activity will be billed as **Pipeline activities**.

Compute environments supported by Azure Data Factory and Synapse pipelines

8/19/2022 • 23 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

This article explains different compute environments that you can use to process or transform data. It also provides details about different configurations (on-demand vs. bring your own) supported when configuring linked services linking these compute environments.

The following table provides a list of supported compute environments and the activities that can run on them.

COMPUTE ENVIRONMENT	ACTIVITIES
On-demand HDInsight cluster or your own HDInsight cluster	Hive, Pig, Spark, MapReduce, Hadoop Streaming
Azure Batch	Custom
ML Studio (classic)	ML Studio (classic) activities: Batch Execution and Update Resource
Azure Machine Learning	Azure Machine Learning Execute Pipeline
Azure Data Lake Analytics	Data Lake Analytics U-SQL
Azure SQL, Azure Synapse Analytics, SQL Server	Stored Procedure
Azure Databricks	Notebook, Jar, Python
Azure Function	Azure Function activity

HDInsight compute environment

Refer to below table for details about the supported storage linked service types for configuration in On-demand and BYOC (Bring your own compute) environment.

IN COMPUTE LINKED SERVICE	PROPERTY NAME	DESCRIPTION	BLOB	ADLS GEN2	AZURE SQL DB	ADLS GEN 1
On-demand	linkedService Name	Azure Storage linked service to be used by the on-demand cluster for storing and processing data.	Yes	Yes	No	No
	additionalLinkedServiceNames	Specifies additional storage accounts for the HDInsight linked service so that the service can register them on your behalf.	Yes	No	No	No
	hcatalogLinkedServiceName	The name of Azure SQL linked service that point to the HCatalog database. The on-demand HDInsight cluster is created by using the Azure SQL database as the metastore.	No	No	Yes	No
BYOC	linkedService Name	The Azure Storage linked service reference.	Yes	Yes	No	No
	additionalLinkedServiceNames	Specifies additional storage accounts for the HDInsight linked service so that the service can register them on your behalf.	No	No	No	No

IN COMPUTE LINKED SERVICE	PROPERTY NAME	DESCRIPTION	BLOB	ADLS GEN2	AZURE SQL DB	ADLS GEN 1
	hcatalogLinkedServiceName	A reference to the Azure SQL linked service that points to the HCatalog database.	No	No	No	No

Azure HDInsight on-demand linked service

In this type of configuration, the computing environment is fully managed by the service. It is automatically created by the service before a job is submitted to process data and removed when the job is completed. You can create a linked service for the on-demand compute environment, configure it, and control granular settings for job execution, cluster management, and bootstrapping actions.

> **NOTE**
> The on-demand configuration is currently supported only for Azure HDInsight clusters. Azure Databricks also supports on-demand jobs using job clusters. For more information, see Azure databricks linked service.

The service can automatically create an on-demand HDInsight cluster to process data. The cluster is created in the same region as the storage account (linkedServiceName property in the JSON) associated with the cluster. The storage account `must` be a general-purpose standard Azure Storage account.

Note the following **important** points about on-demand HDInsight linked service:

- The on-demand HDInsight cluster is created under your Azure subscription. You are able to see the cluster in your Azure portal when the cluster is up and running.
- The logs for jobs that are run on an on-demand HDInsight cluster are copied to the storage account associated with the HDInsight cluster. The clusterUserName, clusterPassword, clusterSshUserName, clusterSshPassword defined in your linked service definition are used to log in to the cluster for in-depth troubleshooting during the lifecycle of the cluster.
- You are charged only for the time when the HDInsight cluster is up and running jobs.
- You can use a **Script Action** with the Azure HDInsight on-demand linked service.

> **IMPORTANT**
> It typically takes **20 minutes** or more to provision an Azure HDInsight cluster on demand.

Example

The following JSON defines a Linux-based on-demand HDInsight linked service. The service automatically creates a **Linux-based** HDInsight cluster to process the required activity.

```
{
  "name": "HDInsightOnDemandLinkedService",
  "properties": {
    "type": "HDInsightOnDemand",
    "typeProperties": {
      "clusterType": "hadoop",
      "clusterSize": 1,
      "timeToLive": "00:15:00",
      "hostSubscriptionId": "<subscription ID>",
      "servicePrincipalId": "<service principal ID>",
      "servicePrincipalKey": {
        "value": "<service principal key>",
        "type": "SecureString"
      },
      "tenant": "<tenent id>",
      "clusterResourceGroup": "<resource group name>",
      "version": "3.6",
      "osType": "Linux",
      "linkedServiceName": {
        "referenceName": "AzureStorageLinkedService",
        "type": "LinkedServiceReference"
      }
    },
    "connectVia": {
      "referenceName": "<name of Integration Runtime>",
      "type": "IntegrationRuntimeReference"
    }
  }
}
```

IMPORTANT

The HDInsight cluster creates a **default container** in the blob storage you specified in the JSON (**linkedServiceName**). HDInsight does not delete this container when the cluster is deleted. This behavior is by design. With on-demand HDInsight linked service, a HDInsight cluster is created every time a slice needs to be processed unless there is an existing live cluster (**timeToLive**) and is deleted when the processing is done.

As more activity runs, you see many containers in your Azure blob storage. If you do not need them for troubleshooting of the jobs, you may want to delete them to reduce the storage cost. The names of these containers follow a pattern: `adf**yourfactoryorworkspacename**-**linkedservicename**-datetimestamp`. Use tools such as Microsoft Azure Storage Explorer to delete containers in your Azure blob storage.

Properties

PROPERTY	DESCRIPTION	REQUIRED
type	The type property should be set to **HDInsightOnDemand**.	Yes
clusterSize	Number of worker/data nodes in the cluster. The HDInsight cluster is created with 2 head nodes along with the number of worker nodes you specify for this property. The nodes are of size Standard_D3 that has 4 cores, so a 4 worker node cluster takes 24 cores (4*4 = 16 cores for worker nodes, plus 2*4 = 8 cores for head nodes). See Set up clusters in HDInsight with Hadoop, Spark, Kafka, and more for details.	Yes

PROPERTY	DESCRIPTION	REQUIRED
linkedServiceName	Azure Storage linked service to be used by the on-demand cluster for storing and processing data. The HDInsight cluster is created in the same region as this Azure Storage account. Azure HDInsight has limitation on the total number of cores you can use in each Azure region it supports. Make sure you have enough core quotas in that Azure region to meet the required clusterSize. For details, refer to Set up clusters in HDInsight with Hadoop, Spark, Kafka, and more Currently, you cannot create an on-demand HDInsight cluster that uses an Azure Data Lake Storage (Gen 2) as the storage. If you want to store the result data from HDInsight processing in an Azure Data Lake Storage (Gen 2), use a Copy Activity to copy the data from the Azure Blob Storage to the Azure Data Lake Storage (Gen 2).	Yes
clusterResourceGroup	The HDInsight cluster is created in this resource group.	Yes

PROPERTY	DESCRIPTION	REQUIRED
timetolive	The allowed idle time for the on-demand HDInsight cluster. Specifies how long the on-demand HDInsight cluster stays alive after completion of an activity run if there are no other active jobs in the cluster. The minimal allowed value is 5 minutes (00:05:00). For example, if an activity run takes 6 minutes and timetolive is set to 5 minutes, the cluster stays alive for 5 minutes after the 6 minutes of processing the activity run. If another activity run is executed with the 6-minutes window, it is processed by the same cluster. Creating an on-demand HDInsight cluster is an expensive operation (could take a while), so use this setting as needed to improve performance of the service by reusing an on-demand HDInsight cluster. If you set timetolive value to 0, the cluster is deleted as soon as the activity run completes. Whereas, if you set a high value, the cluster may stay idle for you to log on for some troubleshooting purpose but it could result in high costs. Therefore, it is important that you set the appropriate value based on your needs. If the timetolive property value is appropriately set, multiple pipelines can share the instance of the on-demand HDInsight cluster.	Yes
clusterType	The type of the HDInsight cluster to be created. Allowed values are "hadoop" and "spark". If not specified, default value is hadoop. Enterprise Security Package enabled cluster cannot be created on-demand, instead use an existing cluster/ bring your own compute.	No
version	Version of the HDInsight cluster. If not specified, it's using the current HDInsight defined default version.	No
hostSubscriptionId	The Azure subscription ID used to create HDInsight cluster. If not specified, it uses the Subscription ID of your Azure login context.	No

PROPERTY	DESCRIPTION	REQUIRED
clusterNamePrefix	The prefix of HDI cluster name, a timestamp automatically appends at the end of the cluster name	No
sparkVersion	The version of spark if the cluster type is "Spark"	No
additionalLinkedServiceNames	Specifies additional storage accounts for the HDInsight linked service so that the service can register them on your behalf. These storage accounts must be in the same region as the HDInsight cluster, which is created in the same region as the storage account specified by linkedServiceName.	No
osType	Type of operating system. Allowed values are: Linux and Windows (for HDInsight 3.3 only). Default is Linux.	No
hcatalogLinkedServiceName	The name of Azure SQL linked service that point to the HCatalog database. The on-demand HDInsight cluster is created by using the Azure SQL Database as the metastore.	No
connectVia	The Integration Runtime to be used to dispatch the activities to this HDInsight linked service. For on-demand HDInsight linked service, it only supports Azure Integration Runtime. If not specified, it uses the default Azure Integration Runtime.	No
clusterUserName	The username to access the cluster.	No
clusterPassword	The password in type of secure string to access the cluster.	No
clusterSshUserName	The username to SSH remotely connects to cluster's node (for Linux).	No
clusterSshPassword	The password in type of secure string to SSH remotely connect cluster's node (for Linux).	No
scriptActions	Specify script for HDInsight cluster customizations during on-demand cluster creation. Currently, the UI authoring tool supports specifying only 1 script action, but you can get through this limitation in the JSON (specify multiple script actions in the JSON).	No

IMPORTANT

HDInsight supports multiple Hadoop cluster versions that can be deployed. Each version choice creates a specific version of the Hortonworks Data Platform (HDP) distribution and a set of components that are contained within that distribution. The list of supported HDInsight versions keeps being updated to provide latest Hadoop ecosystem components and fixes. Make sure you always refer to latest information of Supported HDInsight version and OS Type to ensure you are using supported version of HDInsight.

IMPORTANT

Currently, HDInsight linked services does not support HBase, Interactive Query (Hive LLAP), Storm.

- additionalLinkedServiceNames JSON example

```
"additionalLinkedServiceNames": [{
    "referenceName": "MyStorageLinkedService2",
    "type": "LinkedServiceReference"
}]
```

Service principal authentication

The On-Demand HDInsight linked service requires a service principal authentication to create HDInsight clusters on your behalf. To use service principal authentication, register an application entity in Azure Active Directory (Azure AD) and grant it the **Contributor** role of the subscription or the resource group in which the HDInsight cluster is created. For detailed steps, see Use portal to create an Azure Active Directory application and service principal that can access resources. Make note of the following values, which you use to define the linked service:

- Application ID
- Application key
- Tenant ID

Use service principal authentication by specifying the following properties:

PROPERTY	DESCRIPTION	REQUIRED
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes

Advanced Properties

You can also specify the following properties for the granular configuration of the on-demand HDInsight cluster.

PROPERTY	DESCRIPTION	REQUIRED
coreConfiguration	Specifies the core configuration parameters (as in core-site.xml) for the HDInsight cluster to be created.	No

PROPERTY	DESCRIPTION	REQUIRED
hBaseConfiguration	Specifies the HBase configuration parameters (hbase-site.xml) for the HDInsight cluster.	No
hdfsConfiguration	Specifies the HDFS configuration parameters (hdfs-site.xml) for the HDInsight cluster.	No
hiveConfiguration	Specifies the hive configuration parameters (hive-site.xml) for the HDInsight cluster.	No
mapReduceConfiguration	Specifies the MapReduce configuration parameters (mapred-site.xml) for the HDInsight cluster.	No
oozieConfiguration	Specifies the Oozie configuration parameters (oozie-site.xml) for the HDInsight cluster.	No
stormConfiguration	Specifies the Storm configuration parameters (storm-site.xml) for the HDInsight cluster.	No
yarnConfiguration	Specifies the Yarn configuration parameters (yarn-site.xml) for the HDInsight cluster.	No

- Example – On-demand HDInsight cluster configuration with advanced properties

```
{
    "name": " HDInsightOnDemandLinkedService",
    "properties": {
      "type": "HDInsightOnDemand",
      "typeProperties": {
          "clusterSize": 16,
          "timeToLive": "01:30:00",
          "hostSubscriptionId": "<subscription ID>",
          "servicePrincipalId": "<service principal ID>",
          "servicePrincipalKey": {
            "value": "<service principal key>",
            "type": "SecureString"
          },
          "tenant": "<tenent id>",
          "clusterResourceGroup": "<resource group name>",
          "version": "3.6",
          "osType": "Linux",
          "linkedServiceName": {
              "referenceName": "AzureStorageLinkedService",
              "type": "LinkedServiceReference"
            },
            "coreConfiguration": {
                "templeton.mapper.memory.mb": "5000"
            },
            "hiveConfiguration": {
                "templeton.mapper.memory.mb": "5000"
            },
            "mapReduceConfiguration": {
                "mapreduce.reduce.java.opts": "-Xmx4000m",
                "mapreduce.map.java.opts": "-Xmx4000m",
                "mapreduce.map.memory.mb": "5000",
                "mapreduce.reduce.memory.mb": "5000",
                "mapreduce.job.reduce.slowstart.completedmaps": "0.8"
            },
            "yarnConfiguration": {
                "yarn.app.mapreduce.am.resource.mb": "5000",
                "mapreduce.map.memory.mb": "5000"
            },
            "additionalLinkedServiceNames": [{
                "referenceName": "MyStorageLinkedService2",
                "type": "LinkedServiceReference"
            }]
        }
    },
      "connectVia": {
      "referenceName": "<name of Integration Runtime>",
      "type": "IntegrationRuntimeReference"
    }
}
```

Node sizes

You can specify the sizes of head, data, and zookeeper nodes using the following properties:

PROPERTY	DESCRIPTION	REQUIRED
headNodeSize	Specifies the size of the head node. The default value is: Standard_D3. See the **Specifying node sizes** section for details.	No
dataNodeSize	Specifies the size of the data node. The default value is: Standard_D3.	No

PROPERTY	DESCRIPTION	REQUIRED
zookeeperNodeSize	Specifies the size of the Zoo Keeper node. The default value is: Standard_D3.	No

- Specifying node sizes See the Sizes of Virtual Machines article for string values you need to specify for the properties mentioned in the previous section. The values need to conform to the **CMDLETs & APIS** referenced in the article. As you can see in the article, the data node of Large (default) size has 7-GB memory, which may not be good enough for your scenario.

If you want to create D4 sized head nodes and worker nodes, specify **Standard_D4** as the value for headNodeSize and dataNodeSize properties.

```
"headNodeSize": "Standard_D4",
"dataNodeSize": "Standard_D4",
```

If you specify a wrong value for these properties, you may receive the following **error:** Failed to create cluster. Exception: Unable to complete the cluster create operation. Operation failed with code '400'. Cluster left behind state: 'Error'. Message: 'PreClusterCreationValidationFailure'. When you receive this error, ensure that you are using the **CMDLET & APIS** name from the table in the Sizes of Virtual Machines article.

Bring your own compute environment

In this type of configuration, users can register an already existing computing environment as a linked service. The computing environment is managed by the user and the service uses it to execute the activities.

This type of configuration is supported for the following compute environments:

- Azure HDInsight
- Azure Batch
- Azure Machine Learning
- Azure Data Lake Analytics
- Azure SQL DB, Azure Synapse Analytics, SQL Server

Azure HDInsight linked service

You can create an Azure HDInsight linked service to register your own HDInsight cluster with a data factory or Synapse workspace.

Example

```
{
    "name": "HDInsightLinkedService",
    "properties": {
      "type": "HDInsight",
      "typeProperties": {
        "clusterUri": " https://<hdinsightclustername>.azurehdinsight.net/",
        "userName": "username",
        "password": {
            "value": "passwordvalue",
            "type": "SecureString"
          },
        "linkedServiceName": {
              "referenceName": "AzureStorageLinkedService",
              "type": "LinkedServiceReference"
        }
      },
      "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
      }
    }
  }
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
type	The type property should be set to **HDInsight**.	Yes
clusterUri	The URI of the HDInsight cluster.	Yes
username	Specify the name of the user to be used to connect to an existing HDInsight cluster.	Yes
password	Specify password for the user account.	Yes
linkedServiceName	Name of the Azure Storage linked service that refers to the Azure blob storage used by the HDInsight cluster. Currently, you cannot specify an Azure Data Lake Storage (Gen 2) linked service for this property. If the HDInsight cluster has access to the Data Lake Store, you may access data in the Azure Data Lake Storage (Gen 2) from Hive/Pig scripts.	Yes
isEspEnabled	Specify '*true*' if the HDInsight cluster is Enterprise Security Package enabled. Default is '*false*'.	No

PROPERTY	DESCRIPTION	REQUIRED
connectVia	The Integration Runtime to be used to dispatch the activities to this linked service. You can use Azure Integration Runtime or Self-hosted Integration Runtime. If not specified, it uses the default Azure Integration Runtime. For Enterprise Security Package (ESP) enabled HDInsight cluster use a self-hosted integration runtime, which has a line of sight to the cluster or it should be deployed inside the same Virtual Network as the ESP HDInsight cluster.	No

IMPORTANT

HDInsight supports multiple Hadoop cluster versions that can be deployed. Each version choice creates a specific version of the Hortonworks Data Platform (HDP) distribution and a set of components that are contained within that distribution. The list of supported HDInsight versions keeps being updated to provide latest Hadoop ecosystem components and fixes. Make sure you always refer to latest information of Supported HDInsight version and OS Type to ensure you are using supported version of HDInsight.

IMPORTANT

Currently, HDInsight linked services does not support HBase, Interactive Query (Hive LLAP), Storm.

Azure Batch linked service

NOTE

This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

You can create an Azure Batch linked service to register a Batch pool of virtual machines (VMs) to a data or Synapse workspace. You can run Custom activity using Azure Batch.

See following articles if you are new to Azure Batch service:

- Azure Batch basics for an overview of the Azure Batch service.
- New-AzBatchAccount cmdlet to create an Azure Batch account (or) Azure portal to create the Azure Batch account using Azure portal. See Using PowerShell to manage Azure Batch Account article for detailed instructions on using the cmdlet.
- New-AzBatchPool cmdlet to create an Azure Batch pool.

IMPORTANT

When creating a new Azure Batch pool, 'VirtualMachineConfiguration' must be used and NOT 'CloudServiceConfiguration'. For more details refer Azure Batch Pool migration guidance.

Example

```
{
    "name": "AzureBatchLinkedService",
    "properties": {
      "type": "AzureBatch",
      "typeProperties": {
        "accountName": "batchaccount",
        "accessKey": {
          "type": "SecureString",
          "value": "access key"
        },
        "batchUri": "https://batchaccount.region.batch.azure.com",
        "poolName": "poolname",
        "linkedServiceName": {
          "referenceName": "StorageLinkedService",
          "type": "LinkedServiceReference"
        }
      },
      "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
      }
    }
  }
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
type	The type property should be set to **AzureBatch**.	Yes
accountName	Name of the Azure Batch account.	Yes
accessKey	Access key for the Azure Batch account.	Yes
batchUri	URL to your Azure Batch account, in format of https://*batchaccountname.region*.batch.azure.com.	Yes
poolName	Name of the pool of virtual machines.	Yes
linkedServiceName	Name of the Azure Storage linked service associated with this Azure Batch linked service. This linked service is used for staging files required to run the activity.	Yes
connectVia	The Integration Runtime to be used to dispatch the activities to this linked service. You can use Azure Integration Runtime or Self-hosted Integration Runtime. If not specified, it uses the default Azure Integration Runtime.	No

Machine Learning Studio (classic) linked service

IMPORTANT

Support for Machine Learning Studio (classic) will end on 31 August 2024. We recommend you transition to Azure Machine Learning by that date.

Beginning 1 December 2021, you will not be able to create new Machine Learning Studio (classic) resources (workspace and web service plan). Through 31 August 2024, you can continue to use the existing Machine Learning Studio (classic) experiments and web services.

- See information on moving machine learning projects from ML Studio (classic) to Azure Machine Learning.
- Learn more about Azure Machine Learning

ML Studio (classic) documentation is being retired and may not be updated in the future.

You create an Machine Learning Studio (classic) linked service to register a Machine Learning Studio (classic) batch scoring endpoint to a data factory or Synapse workspace.

Example

```
{
    "name": "AzureMLLinkedService",
    "properties": {
      "type": "AzureML",
      "typeProperties": {
        "mlEndpoint": "https://[batch scoring endpoint]/jobs",
        "apiKey": {
            "type": "SecureString",
            "value": "access key"
        }
     },
     "connectVia": {
        "referenceName": "<name of Integration Runtime>",
        "type": "IntegrationRuntimeReference"
      }
    }
}
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
Type	The type property should be set to: **AzureML**.	Yes
mlEndpoint	The batch scoring URL.	Yes
apiKey	The published workspace model's API.	Yes
updateResourceEndpoint	The Update Resource URL for an ML Studio (classic) Web Service endpoint used to update the predictive Web Service with trained model file	No
servicePrincipalId	Specify the application's client ID.	Required if updateResourceEndpoint is specified
servicePrincipalKey	Specify the application's key.	Required if updateResourceEndpoint is specified

PROPERTY	DESCRIPTION	REQUIRED
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Required if updateResourceEndpoint is specified
connectVia	The Integration Runtime to be used to dispatch the activities to this linked service. You can use Azure Integration Runtime or Self-hosted Integration Runtime. If not specified, it uses the default Azure Integration Runtime.	No

Azure Machine Learning linked service

You create an Azure Machine Learning linked service to connect an Azure Machine Learning workspace to a data factory or Synapse workspace.

> **NOTE**
> Currently only service principal authentication is supported for the Azure Machine Learning linked service.

Example

```
{
    "name": "AzureMLServiceLinkedService",
    "properties": {
        "type": "AzureMLService",
        "typeProperties": {
            "subscriptionId": "subscriptionId",
            "resourceGroupName": "resourceGroupName",
            "mlWorkspaceName": "mlWorkspaceName",
            "servicePrincipalId": "service principal id",
            "servicePrincipalKey": {
                "value": "service principal key",
                "type": "SecureString"
            },
            "tenant": "tenant ID"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime?",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
Type	The type property should be set to: **AzureMLService**.	Yes
subscriptionId	Azure subscription ID	Yes
resourceGroupName	name	Yes

PROPERTY	DESCRIPTION	REQUIRED
mlWorkspaceName	Azure Machine Learning workspace name	Yes
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Required if updateResourceEndpoint is specified
connectVia	The Integration Runtime to be used to dispatch the activities to this linked service. You can use Azure Integration Runtime or Self-hosted Integration Runtime. If not specified, it uses the default Azure Integration Runtime.	No

Azure Data Lake Analytics linked service

You create an **Azure Data Lake Analytics** linked service to link an Azure Data Lake Analytics compute service to a data factory or Synapse workspace. The Data Lake Analytics U-SQL activity in the pipeline refers to this linked service.

Example

```
{
    "name": "AzureDataLakeAnalyticsLinkedService",
    "properties": {
        "type": "AzureDataLakeAnalytics",
        "typeProperties": {
            "accountName": "adftestaccount",
            "dataLakeAnalyticsUri": "azuredatalakeanalytics URI",
            "servicePrincipalId": "service principal id",
            "servicePrincipalKey": {
                "value": "service principal key",
                "type": "SecureString"
            },
            "tenant": "tenant ID",
            "subscriptionId": "<optional, subscription ID of ADLA>",
            "resourceGroupName": "<optional, resource group name of ADLA>"
        },
        "connectVia": {
            "referenceName": "<name of Integration Runtime>",
            "type": "IntegrationRuntimeReference"
        }
    }
}
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
type	The type property should be set to: **AzureDataLakeAnalytics**.	Yes

PROPERTY	DESCRIPTION	REQUIRED
accountName	Azure Data Lake Analytics Account Name.	Yes
dataLakeAnalyticsUri	Azure Data Lake Analytics URI.	No
subscriptionId	Azure subscription ID	No
resourceGroupName	Azure resource group name	No
servicePrincipalId	Specify the application's client ID.	Yes
servicePrincipalKey	Specify the application's key.	Yes
tenant	Specify the tenant information (domain name or tenant ID) under which your application resides. You can retrieve it by hovering the mouse in the upper-right corner of the Azure portal.	Yes
connectVia	The Integration Runtime to be used to dispatch the activities to this linked service. You can use Azure Integration Runtime or Self-hosted Integration Runtime. If not specified, it uses the default Azure Integration Runtime.	No

Azure Databricks linked service

You can create **Azure Databricks linked service** to register Databricks workspace that you use to run the Databricks workloads(notebook, jar, python).

> **IMPORTANT**
> Databricks linked services supports Instance pools & System-assigned managed identity authentication.

Example - Using new job cluster in Databricks

```
{
    "name": "AzureDatabricks_LS",
    "properties": {
        "type": "AzureDatabricks",
        "typeProperties": {
            "domain": "https://eastus.azuredatabricks.net",
            "newClusterNodeType": "Standard_D3_v2",
            "newClusterNumOfWorker": "1:10",
            "newClusterVersion": "4.0.x-scala2.11",
            "accessToken": {
                "type": "SecureString",
                "value": "dapif33c9c721144c3a790b35000b57f7124f"
            }
        }
    }
}
```

Example - Using existing Interactive cluster in Databricks

```
{
    "name": " AzureDataBricksLinedService",
    "properties": {
      "type": " AzureDatabricks",
      "typeProperties": {
        "domain": "https://westeurope.azuredatabricks.net",
        "accessToken": {
            "type": "SecureString",
            "value": "dapif33c9c72344c3a790b35000b57f7124f"
          },
        "existingClusterId": "{clusterId}"
        }
}
```

Properties

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the Linked Service	Yes
type	The type property should be set to: **Azure Databricks**.	Yes
domain	Specify the Azure Region accordingly based on the region of the Databricks workspace. Example: https://eastus.azuredatabricks.net	Yes
accessToken	Access token is required for the service to authenticate to Azure Databricks. Access token needs to be generated from the databricks workspace. More detailed steps to find the access token can be found here	No
MSI	Use the service's managed identity (system-assigned) to authenticate to Azure Databricks. You do not need Access Token when using 'MSI' authentication. More details about Managed Identity authentication can be found here	No
existingClusterId	Cluster ID of an existing cluster to run all jobs on this. This should be an already created Interactive Cluster. You may need to manually restart the cluster if it stops responding. Databricks suggest running jobs on new clusters for greater reliability. You can find the Cluster ID of an Interactive Cluster on Databricks workspace -> Clusters -> Interactive Cluster Name -> Configuration -> Tags. More details	No

PROPERTY	DESCRIPTION	REQUIRED
instancePoolId	Instance Pool ID of an existing pool in databricks workspace.	No
newClusterVersion	The Spark version of the cluster. It creates a job cluster in databricks.	No
newClusterNumOfWorker	Number of worker nodes that this cluster should have. A cluster has one Spark Driver and num_workers Executors for a total of num_workers + 1 Spark nodes. A string formatted Int32, like "1" means numOfWorker is 1 or "1:10" means autoscale from 1 as min and 10 as max.	No
newClusterNodeType	This field encodes, through a single value, the resources available to each of the Spark nodes in this cluster. For example, the Spark nodes can be provisioned and optimized for memory or compute intensive workloads. This field is required for new cluster	No
newClusterSparkConf	a set of optional, user-specified Spark configuration key-value pairs. Users can also pass in a string of extra JVM options to the driver and the executors via spark.driver.extraJavaOptions and spark.executor.extraJavaOptions respectively.	No
newClusterInitScripts	a set of optional, user-defined initialization scripts for the new cluster. Specifying the DBFS path to the init scripts.	No

Azure SQL Database linked service

You create an Azure SQL linked service and use it with the Stored Procedure Activity to invoke a stored procedure from a pipeline. See Azure SQL Connector article for details about this linked service.

Azure Synapse Analytics linked service

You create an Azure Synapse Analytics linked service and use it with the Stored Procedure Activity to invoke a stored procedure from a pipeline. See Azure Synapse Analytics Connector article for details about this linked service.

SQL Server linked service

You create a SQL Server linked service and use it with the Stored Procedure Activity to invoke a stored procedure from a pipeline. See SQL Server connector article for details about this linked service.

Azure Function linked service

You create an Azure Function linked service and use it with the Azure Function activity to run Azure Functions in

a pipeline. The return type of the Azure function has to be a valid `JObject`. (Keep in mind that JArray is *not* a `JObject`.) Any return type other than `JObject` fails and raises the user error *Response Content is not a valid JObject*.

PROPERTY	DESCRIPTION	REQUIRED
type	The type property must be set to: **AzureFunction**	yes
function app url	URL for the Azure Function App. Format is `https://<accountname>.azurewebsites.net`. This URL is the value under **URL** section when viewing your Function App in the Azure portal	yes
function key	Access key for the Azure Function. Click on the **Manage** section for the respective function, and copy either the **Function Key** or the **Host key**. Find out more here: Azure Functions HTTP triggers and bindings	yes

Next steps

For a list of the supported transformation activities, see Transform data.

Append Variable activity in Azure Data Factory and Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

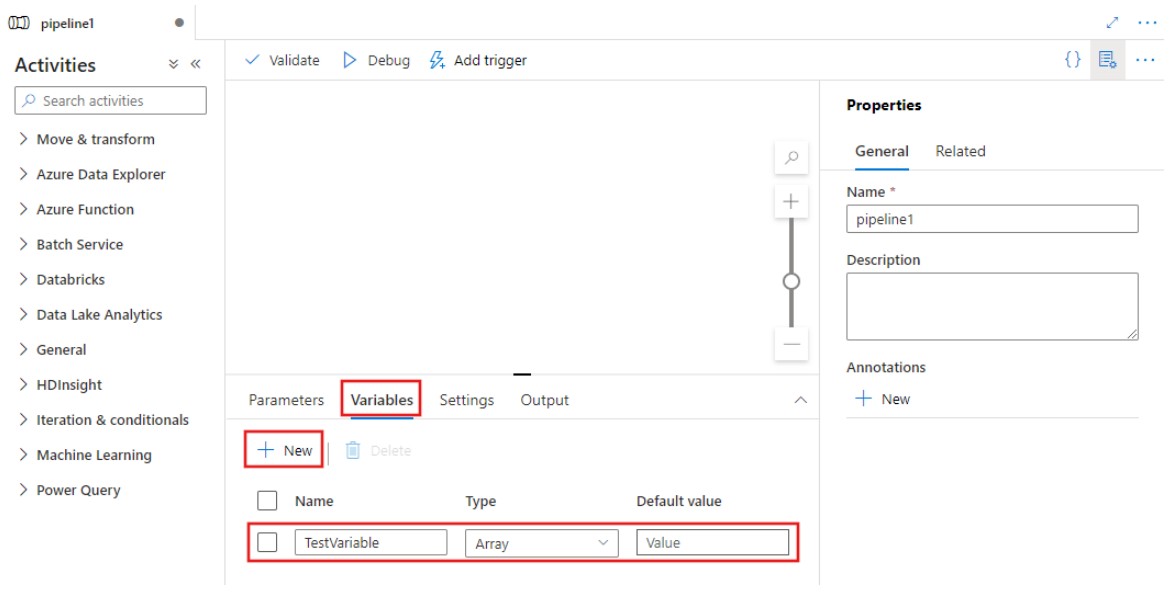
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Use the Append Variable activity to add a value to an existing array variable defined in a Data Factory or Synapse Analytics pipeline.

Create an Append Variable activity with UI

To use a Append Variable activity in a pipeline, complete the following steps:

1. Select the background of the pipeline canvas and use the Variables tab to add an array type variable:

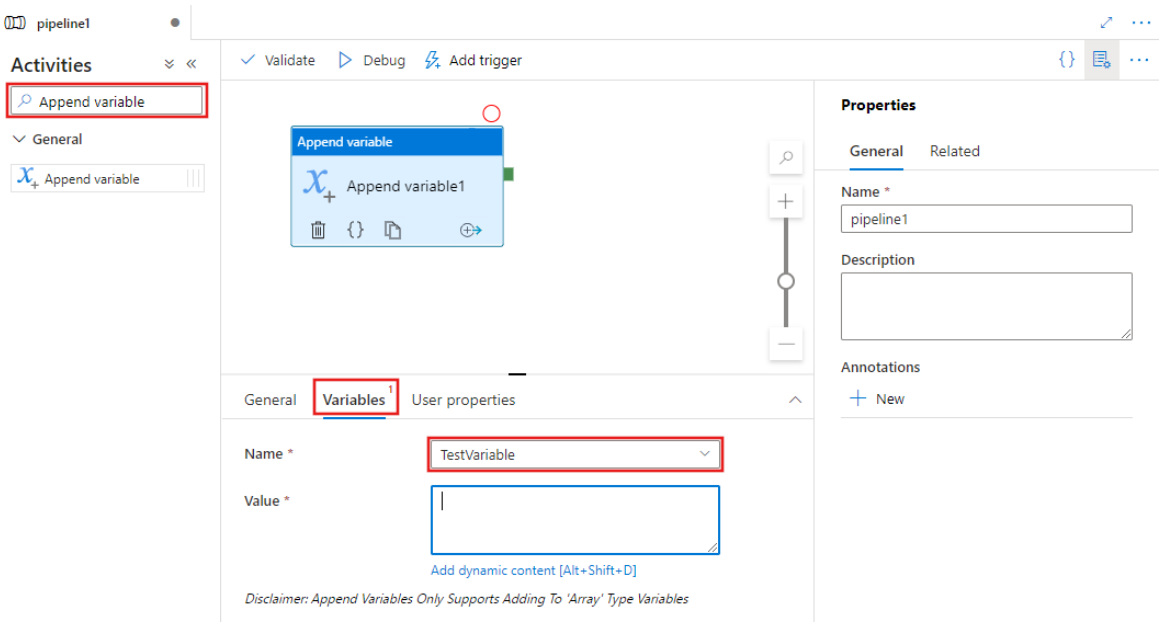


2. Search for *Append Variable* in the pipeline Activities pane, and drag an Append Variable activity to the pipeline canvas.

3. Select the Append Variable activity on the canvas if it is not already selected, and its **Variables** tab, to edit its details.

4. Select the variable for the Name property.

5. Enter an expression for the value, which will be appended to the array in the variable. This can be a literal string expression, or any combination of dynamic expressions, functions, system variables, or outputs from other activities.



Type properties

PROPERTY	DESCRIPTION	REQUIRED
Name	Name of the activity in pipeline	Yes
Description	Text describing what the activity does	No
Type	Activity Type is AppendVariable	Yes
Value	String literal or expression object value used to append into specified variable	Yes
VariableName	Name of the variable that will be modified by activity, the variable must be of type 'Array'	Yes

- Set Variable Activity

Execute Pipeline activity in Azure Data Factory and Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

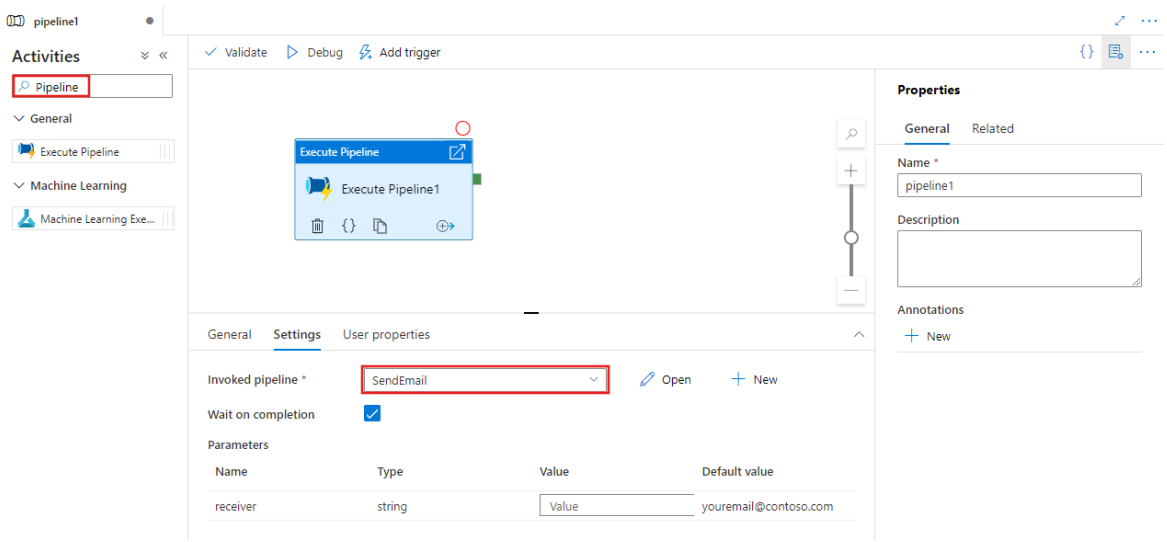
The Execute Pipeline activity allows a Data Factory or Synapse pipeline to invoke another pipeline.

Create an Execute Pipeline activity with UI

To use an Execute Pipeline activity in a pipeline, complete the following steps:

1. Search for *pipeline* in the pipeline Activities pane, and drag an Execute Pipeline activity to the pipeline canvas.

2. Select the new Execute Pipeline activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Select an existing pipeline or create a new one using the New button. Select other options and configure any parameters for the pipeline as required to complete your configuration.

Syntax

```
{
    "name": "MyPipeline",
    "properties": {
        "activities": [
            {
                "name": "ExecutePipelineActivity",
                "type": "ExecutePipeline",
                "typeProperties": {
                    "parameters": {
                        "mySourceDatasetFolderPath": {
                            "value": "@pipeline().parameters.mySourceDatasetFolderPath",
                            "type": "Expression"
                        }
                    },
                    "pipeline": {
                        "referenceName": "<InvokedPipelineName>",
                        "type": "PipelineReference"
                    },
                    "waitOnCompletion": true
                }
            }
        ],
        "parameters": [
            {
                "mySourceDatasetFolderPath": {
                    "type": "String"
                }
            }
        ]
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the execute pipeline activity.	String	Yes
type	Must be set to: **ExecutePipeline**.	String	Yes
pipeline	Pipeline reference to the dependent pipeline that this pipeline invokes. A pipeline reference object has two properties: **referenceName** and **type**. The referenceName property specifies the name of the reference pipeline. The type property must be set to PipelineReference.	PipelineReference	Yes
parameters	Parameters to be passed to the invoked pipeline	A JSON object that maps parameter names to argument values	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
waitOnCompletion	Defines whether activity execution waits for the dependent pipeline execution to finish. Default is true.	Boolean	No

Sample

This scenario has two pipelines:

- **Master pipeline** - This pipeline has one Execute Pipeline activity that calls the invoked pipeline. The master pipeline takes two parameters: `masterSourceBlobContainer`, `masterSinkBlobContainer`.
- **Invoked pipeline** - This pipeline has one Copy activity that copies data from an Azure Blob source to Azure Blob sink. The invoked pipeline takes two parameters: `sourceBlobContainer`, `sinkBlobContainer`.

Master pipeline definition

```
{
  "name": "masterPipeline",
  "properties": {
    "activities": [
      {
        "type": "ExecutePipeline",
        "typeProperties": {
          "pipeline": {
            "referenceName": "invokedPipeline",
            "type": "PipelineReference"
          },
          "parameters": {
            "sourceBlobContainer": {
              "value": "@pipeline().parameters.masterSourceBlobContainer",
              "type": "Expression"
            },
            "sinkBlobContainer": {
              "value": "@pipeline().parameters.masterSinkBlobContainer",
              "type": "Expression"
            }
          },
          "waitOnCompletion": true
        },
        "name": "MyExecutePipelineActivity"
      }
    ],
    "parameters": {
      "masterSourceBlobContainer": {
        "type": "String"
      },
      "masterSinkBlobContainer": {
        "type": "String"
      }
    }
  }
}
```

Invoked pipeline definition

```
{
  "name": "invokedPipeline",
  "properties": {
    "activities": [
      {
        "type": "Copy",
        "typeProperties": {
          "source": {
            "type": "BlobSource"
          },
          "sink": {
            "type": "BlobSink"
          }
        },
        "name": "CopyBlobtoBlob",
        "inputs": [
          {
            "referenceName": "SourceBlobDataset",
            "type": "DatasetReference"
          }
        ],
        "outputs": [
          {
            "referenceName": "sinkBlobDataset",
            "type": "DatasetReference"
          }
        ]
      }
    ],
    "parameters": {
      "sourceBlobContainer": {
        "type": "String"
      },
      "sinkBlobContainer": {
        "type": "String"
      }
    }
  }
}
```

Linked service

```
{
    "name": "BlobStorageLinkedService",
    "properties": {
    "type": "AzureStorage",
    "typeProperties": {
      "connectionString": "DefaultEndpointsProtocol=https;AccountName=*****;AccountKey=*****"
    }
  }
}
```

Source dataset

```
{
    "name": "SourceBlobDataset",
    "properties": {
    "type": "AzureBlob",
    "typeProperties": {
      "folderPath": {
        "value": "@pipeline().parameters.sourceBlobContainer",
        "type": "Expression"
      },
      "fileName": "salesforce.txt"
    },
    "linkedServiceName": {
      "referenceName": "BlobStorageLinkedService",
      "type": "LinkedServiceReference"
    }
  }
}
```

Sink dataset

```
{
    "name": "sinkBlobDataset",
    "properties": {
    "type": "AzureBlob",
    "typeProperties": {
      "folderPath": {
        "value": "@pipeline().parameters.sinkBlobContainer",
        "type": "Expression"
      }
    },
    "linkedServiceName": {
      "referenceName": "BlobStorageLinkedService",
      "type": "LinkedServiceReference"
    }
  }
}
```

Running the pipeline

To run the master pipeline in this example, the following values are passed for the masterSourceBlobContainer and masterSinkBlobContainer parameters:

```
{
  "masterSourceBlobContainer": "executetest",
  "masterSinkBlobContainer": "executesink"
}
```

The master pipeline forwards these values to the invoked pipeline as shown in the following example:

```
{
    "type": "ExecutePipeline",
    "typeProperties": {
      "pipeline": {
        "referenceName": "invokedPipeline",
        "type": "PipelineReference"
      },
      "parameters": {
        "sourceBlobContainer": {
          "value": "@pipeline().parameters.masterSourceBlobContainer",
          "type": "Expression"
        },
        "sinkBlobContainer": {
          "value": "@pipeline().parameters.masterSinkBlobContainer",
          "type": "Expression"
        }
      },

      ....
}
```

Filter activity in Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 2 minutes to read • Edit Online

You can use a Filter activity in a pipeline to apply a filter expression to an input array.

APPLIES TO: Azure Data Factory Azure Synapse Analytics

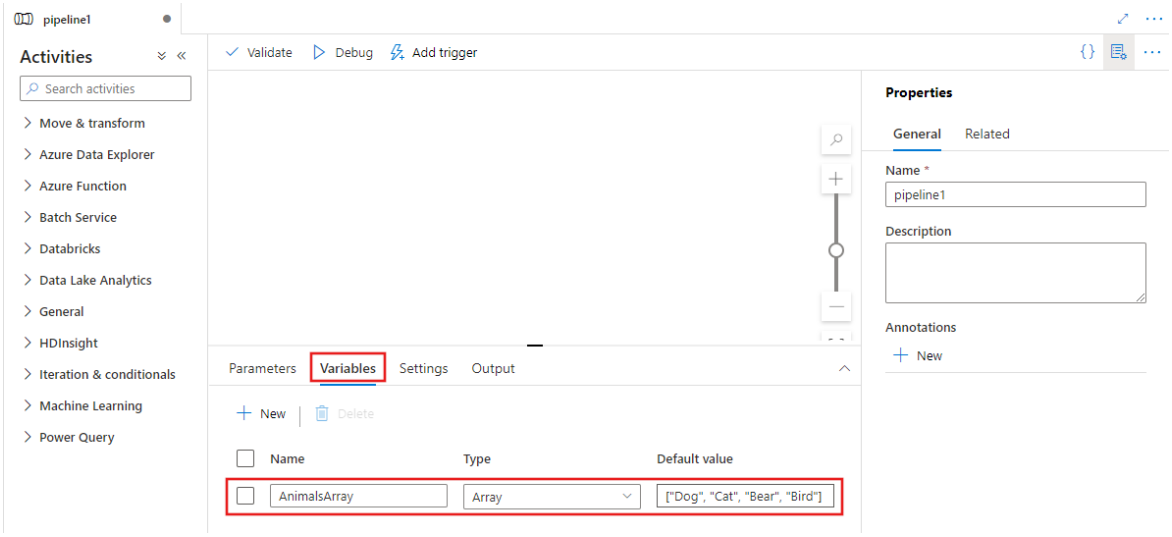
Syntax

```
{
    "name": "MyFilterActivity",
    "type": "filter",
    "typeProperties": {
        "condition": "<condition>",
        "items": "<input array>"
    }
}
```

Create a Filter activity with UI

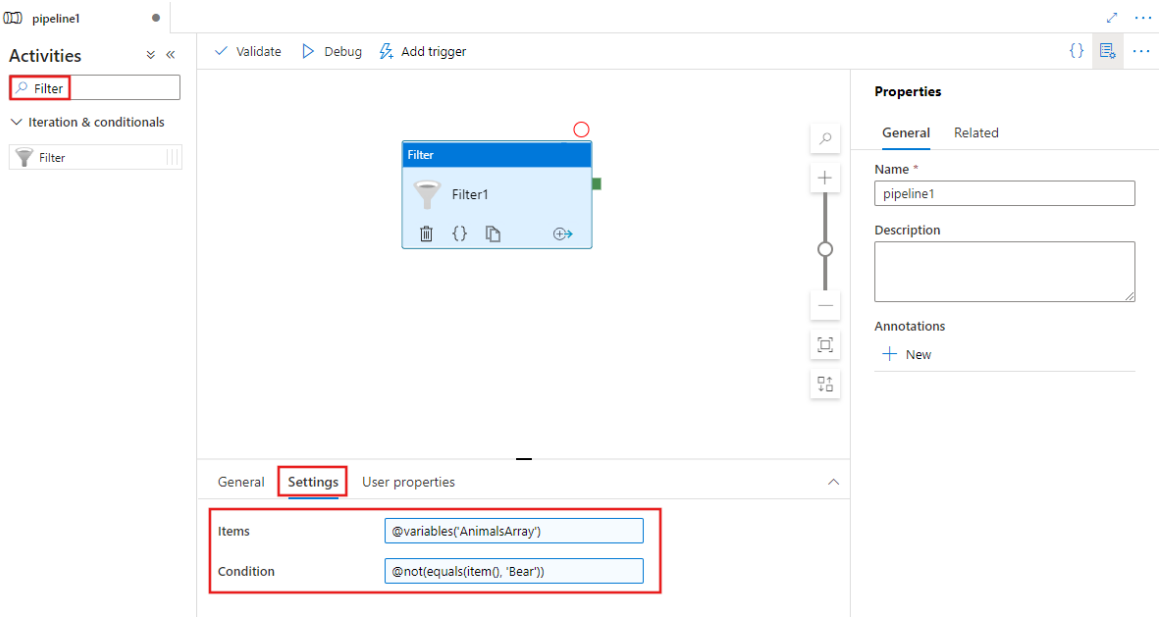
To use a Filter activity in a pipeline, complete the following steps:

1. You can use any array type variable or outputs from other activities as the input for your filter condition. To create an array variable, select the background of the pipeline canvas and then select the **Variables** tab to add an array type variable as shown below.

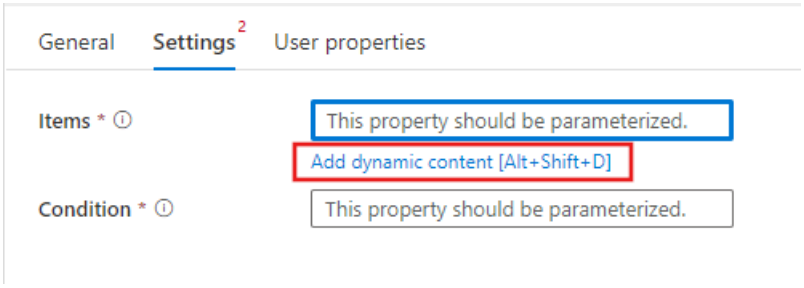


2. Search for *Filter* in the pipeline Activities pane, and drag a Filter activity to the pipeline canvas.

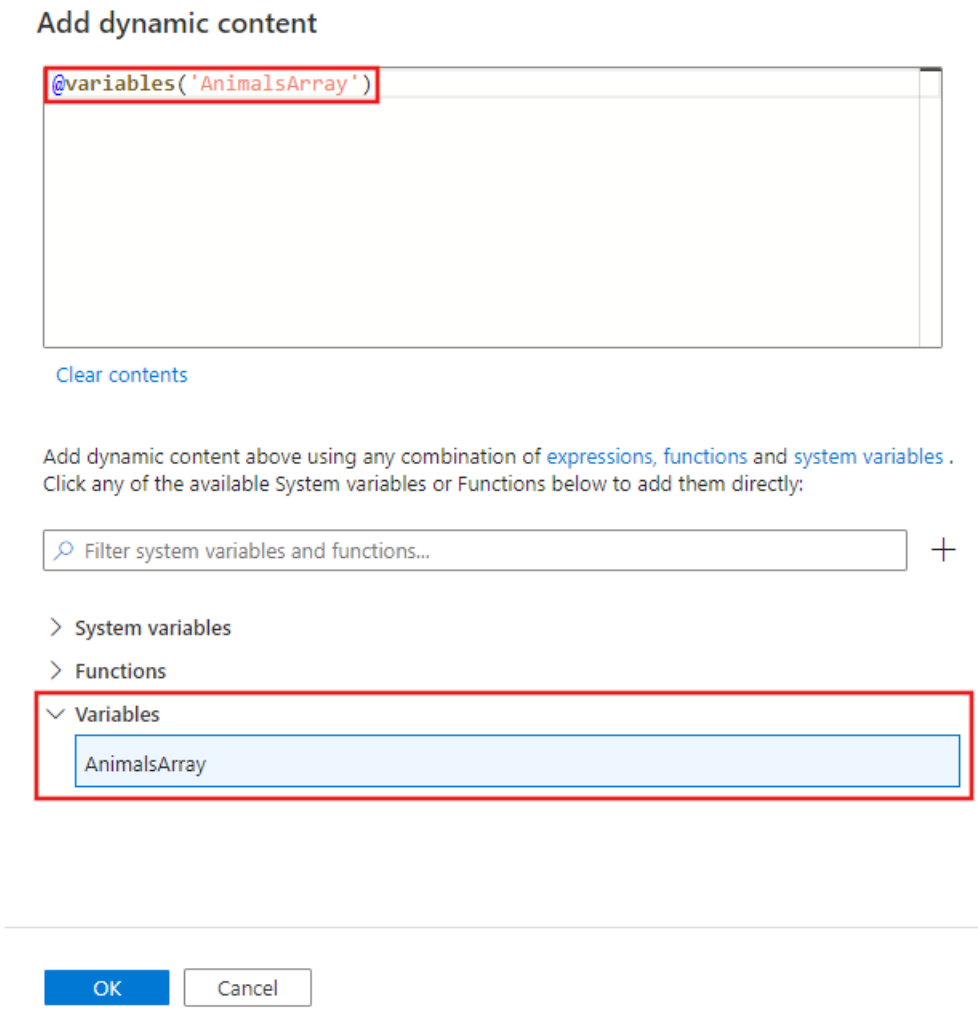
3. Select the new Filter activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



4. Select the **Items** field and then select the **Add dynamic content** link to open the dynamic content editor pane.



5. Select your input array to be filtered in the dynamic content editor. In this example, we select the variable created in the first step.



6. Use the dynamic content editor again to specify a filter condition for the Condition property, as shown above.

7. You can use the output from the Filter activity as an input to other activities like the ForEach activity.

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the `Filter` activity.	String	Yes
type	Must be set to **filter**.	String	Yes
condition	Condition to be used for filtering the input.	Expression	Yes
items	Input array on which filter should be applied.	Expression	Yes

Example

In this example, the pipeline has two activities: **Filter** and **ForEach**. The Filter activity is configured to filter the input array for items with a value greater than 3. The ForEach activity then iterates over the filtered values and sets the variable **test** to the current value.

```
{
    "name": "PipelineName",
    "properties": {
        "activities": [{
                "name": "MyFilterActivity",
                "type": "filter",
                "typeProperties": {
                    "condition": "@greater(item(),3)",
                    "items": "@pipeline().parameters.inputs"
                }
            },
            {
            "name": "MyForEach",
            "type": "ForEach",
            "dependsOn": [
                {
                    "activity": "MyFilterActivity",
                    "dependencyConditions": [
                        "Succeeded"
                    ]
                }
            ],
            "userProperties": [],
            "typeProperties": {
                "items": {
                    "value": "@activity('MyFilterActivity').output.value",
                    "type": "Expression"
                },
                "isSequential": "false",
                "batchCount": 1,
                "activities": [
                    {
                        "name": "Set Variable1",
                        "type": "SetVariable",
                        "dependsOn": [],
                        "userProperties": [],
                        "typeProperties": {
                            "variableName": "test",
                            "value": {
                                "value": "@string(item())",
                                "type": "Expression"
                            }
                        }
                    }
                ]
            }
        }],
        "parameters": {
            "inputs": {
                "type": "Array",
                "defaultValue": [1, 2, 3, 4, 5, 6]
            }
        },
        "variables": {
            "test": {
                "type": "String"
            }
        },
        "annotations": []
    }
}
```

ForEach activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

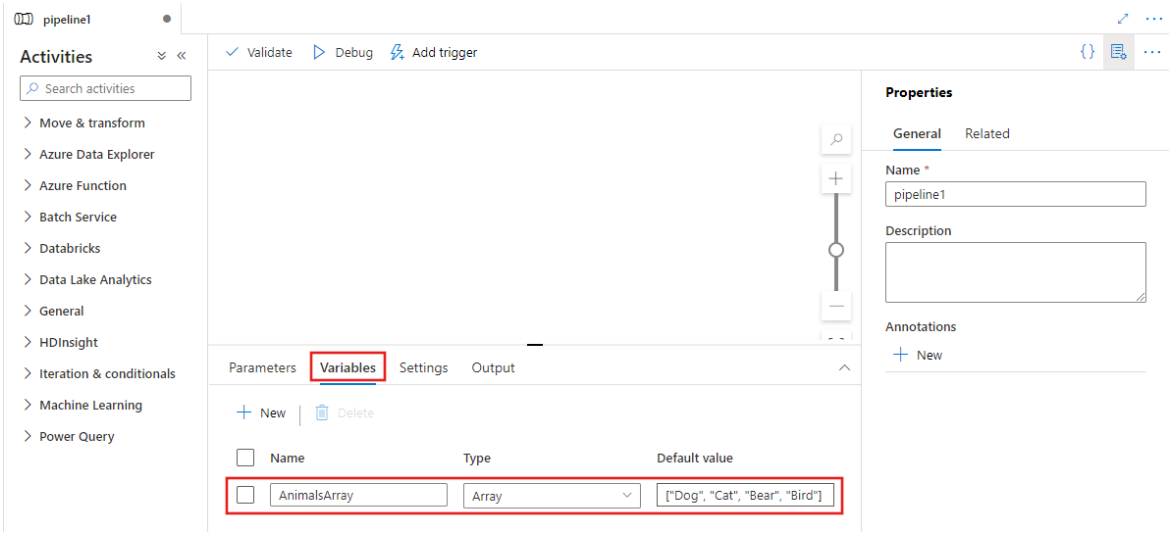
APPLIES TO: Azure Data Factory Azure Synapse Analytics

The ForEach Activity defines a repeating control flow in an Azure Data Factory or Synapse pipeline. This activity is used to iterate over a collection and executes specified activities in a loop. The loop implementation of this activity is similar to Foreach looping structure in programming languages.

Create a ForEach activity with UI

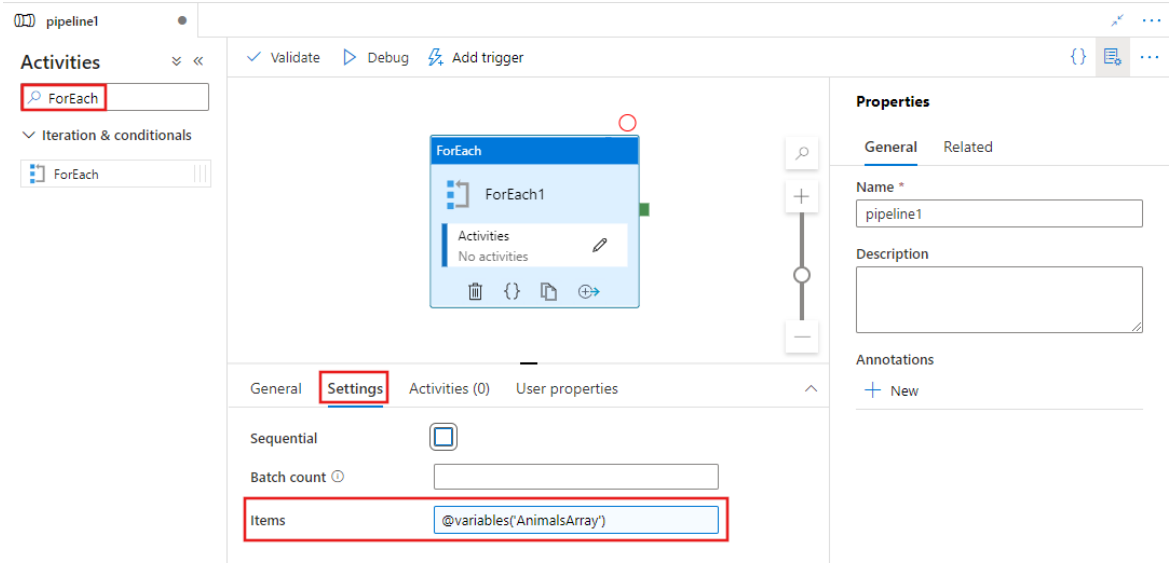
To use a ForEach activity in a pipeline, complete the following steps:

1. You can use any array type variable or outputs from other activities as the input for your ForEach activity. To create an array variable, select the background of the pipeline canvas and then select the **Variables** tab to add an array type variable as shown below.

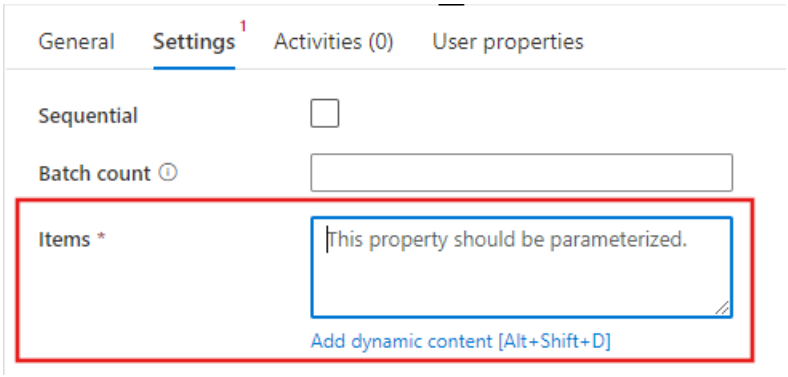


2. Search for *ForEach* in the pipeline Activities pane, and drag a ForEach activity to the pipeline canvas.

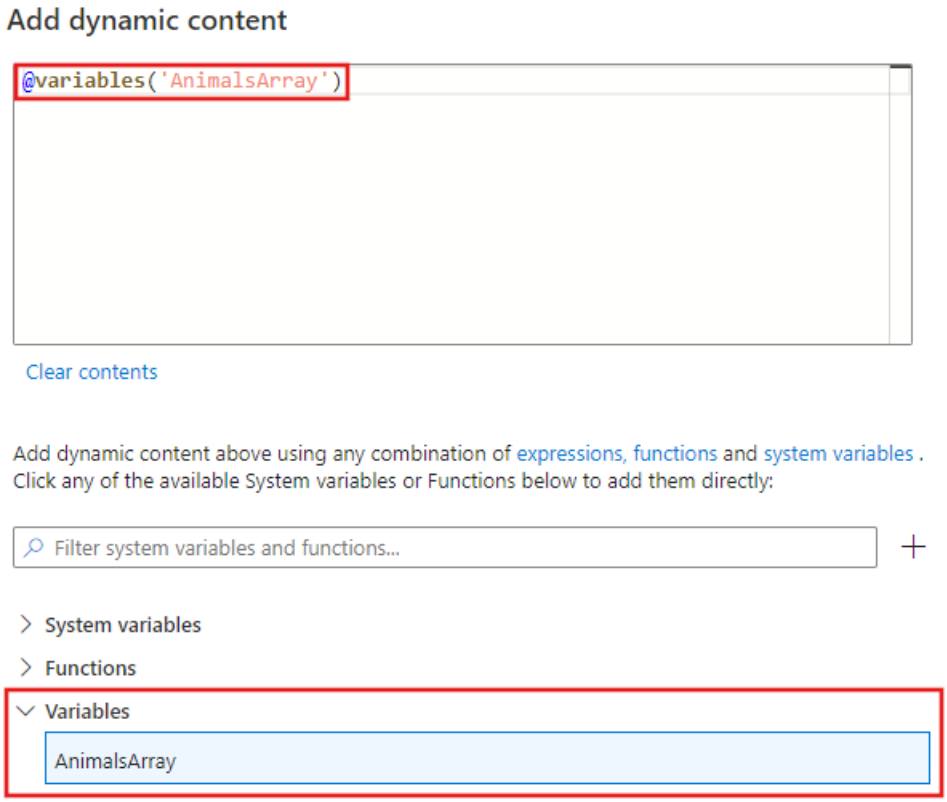
3. Select the new ForEach activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



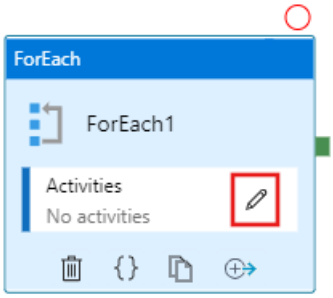
4. Select the **Items** field and then select the **Add dynamic content** link to open the dynamic content editor pane.



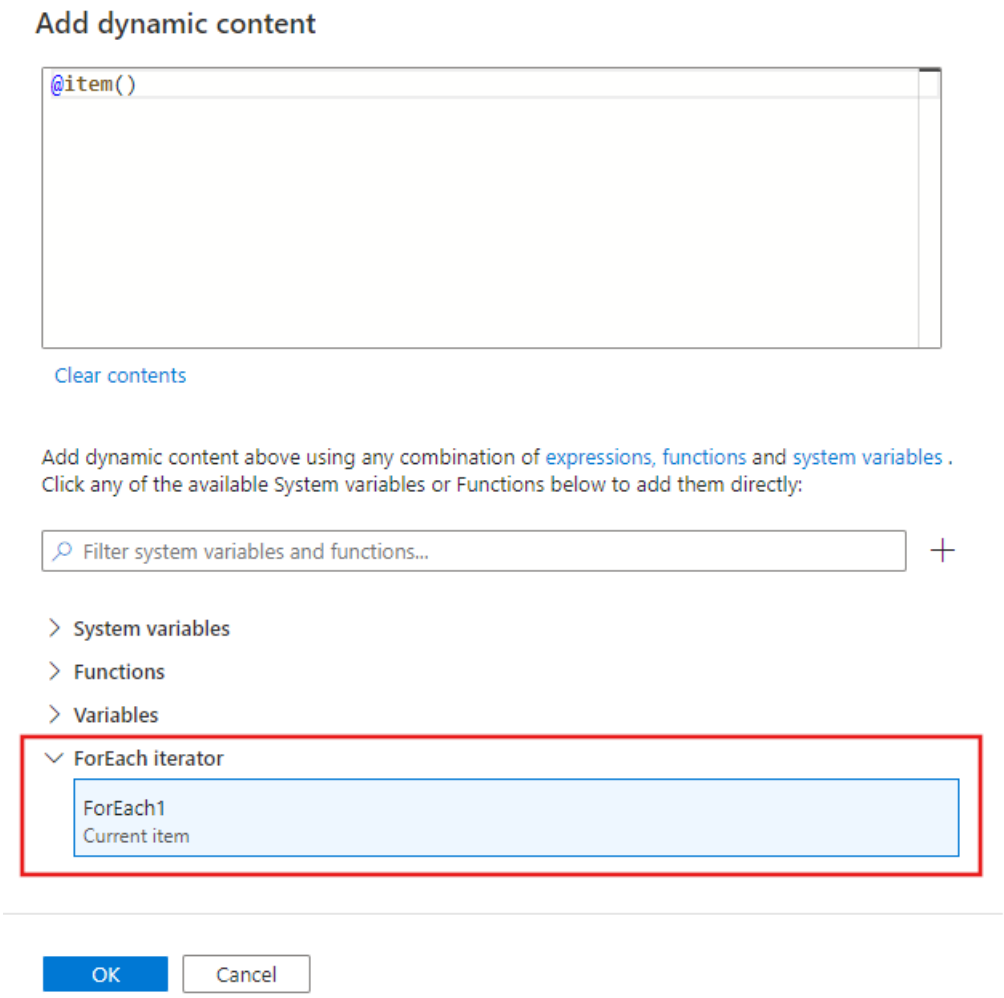
5. Select your input array to be filtered in the dynamic content editor. In this example, we select the variable created in the first step.



6. Select the Activities editor on the ForEach activity to add one or more activities to be executed for each item in the input **Items** array.



7. In any activities you create within the ForEach activity, you can reference the current item the ForEach activity is iterating through from the **Items** list. You can reference the current item anywhere you can use a dynamic expression to specify a property value. In the dynamic content editor, select the ForEach iterator to return the current item.



Syntax

The properties are described later in this article. The items property is the collection and each item in the collection is referred to by using the `@item()` as shown in the following syntax:

```
{
   "name":"MyForEachActivityName",
   "type":"ForEach",
   "typeProperties":{
      "isSequential":"true",
        "items": {
            "value": "@pipeline().parameters.mySinkDatasetFolderPathCollection",
            "type": "Expression"
        },
      "activities":[
         {
            "name":"MyCopyActivity",
            "type":"Copy",
            "typeProperties":{
               ...
            },
            "inputs":[
               {
                  "referenceName":"MyDataset",
                  "type":"DatasetReference",
                  "parameters":{
                     "MyFolderPath":"@pipeline().parameters.mySourceDatasetFolderPath"
                  }
               }
            ],
            "outputs":[
               {
                  "referenceName":"MyDataset",
                  "type":"DatasetReference",
                  "parameters":{
                     "MyFolderPath":"@item()"
                  }
               }
            ]
         }
      ]
   }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the for-each activity.	String	Yes
type	Must be set to **ForEach**	String	Yes

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
isSequential	Specifies whether the loop should be executed sequentially or in parallel. Maximum of 50 loop iterations can be executed at once in parallel). For example, if you have a ForEach activity iterating over a copy activity with 10 different source and sink datasets with **isSequential** set to False, all copies are executed at once. Default is False. If "isSequential" is set to False, ensure that there is a correct configuration to run multiple executables. Otherwise, this property should be used with caution to avoid incurring write conflicts. For more information, see Parallel execution section.	Boolean	No. Default is False.
batchCount	Batch count to be used for controlling the number of parallel execution (when isSequential is set to false). This is the upper concurrency limit, but the for-each activity will not always execute at this number	Integer (maximum 50)	No. Default is 20.
Items	An expression that returns a JSON Array to be iterated over.	Expression (which returns a JSON Array)	Yes
Activities	The activities to be executed.	List of Activities	Yes

Parallel execution

If **isSequential** is set to false, the activity iterates in parallel with a maximum of 50 concurrent iterations. This setting should be used with caution. If the concurrent iterations are writing to the same folder but to different files, this approach is fine. If the concurrent iterations are writing concurrently to the exact same file, this approach most likely causes an error.

Iteration expression language

In the ForEach activity, provide an array to be iterated over for the property **items**." Use `@item()` to iterate over a single enumeration in ForEach activity. For example, if **items** is an array: [1, 2, 3], `@item()` returns 1 in the first iteration, 2 in the second iteration, and 3 in the third iteration. You can also use `@range(0,10)` like expression to iterate ten times starting with 0 ending with 9.

Iterating over a single activity

Scenario: Copy from the same source file in Azure Blob to multiple destination files in Azure Blob.

Pipeline definition

```
{
    "name": "<MyForEachPipeline>",
    "properties": {
        "activities": [
            {
                "name": "<MyForEachActivity>",
                "type": "ForEach",
                "typeProperties": {
                    "isSequential": "true",
                    "items": {
                        "value": "@pipeline().parameters.mySinkDatasetFolderPath",
                        "type": "Expression"
                    },
                    "activities": [
                        {
                            "name": "MyCopyActivity",
                            "type": "Copy",
                            "typeProperties": {
                                "source": {
                                    "type": "BlobSource",
                                    "recursive": "false"
                                },
                                "sink": {
                                    "type": "BlobSink",
                                    "copyBehavior": "PreserveHierarchy"
                                }
                            },
                            "inputs": [
                                {
                                    "referenceName": "<MyDataset>",
                                    "type": "DatasetReference",
                                    "parameters": {
                                        "MyFolderPath": "@pipeline().parameters.mySourceDatasetFolderPath"
                                    }
                                }
                            ],
                            "outputs": [
                                {
                                    "referenceName": "MyDataset",
                                    "type": "DatasetReference",
                                    "parameters": {
                                        "MyFolderPath": "@item()"
                                    }
                                }
                            ]
                        }
                    ]
                }
            }
        ],
        "parameters": {
            "mySourceDatasetFolderPath": {
                "type": "String"
            },
            "mySinkDatasetFolderPath": {
                "type": "String"
            }
        }
    }
}
```

Blob dataset definition

```
{
   "name":"<MyDataset>",
   "properties":{
      "type":"AzureBlob",
      "typeProperties":{
         "folderPath":{
            "value":"@dataset().MyFolderPath",
            "type":"Expression"
         }
      },
      "linkedServiceName":{
         "referenceName":"StorageLinkedService",
         "type":"LinkedServiceReference"
      },
      "parameters":{
         "MyFolderPath":{
            "type":"String"
         }
      }
   }
}
```

Run parameter values

```
{
    "mySourceDatasetFolderPath": "input/",
    "mySinkDatasetFolderPath": [ "outputs/file1", "outputs/file2" ]
}
```

Iterate over multiple activities

It's possible to iterate over multiple activities (for example: copy and web activities) in a ForEach activity. In this scenario, we recommend that you abstract out multiple activities into a separate pipeline. Then, you can use the ExecutePipeline activity in the pipeline with ForEach activity to invoke the separate pipeline with multiple activities.

Syntax

```
{
  "name": "masterPipeline",
  "properties": {
    "activities": [
      {
        "type": "ForEach",
        "name": "<MyForEachMultipleActivities>"
        "typeProperties": {
          "isSequential": true,
          "items": {
            ...
          },
          "activities": [
            {
              "type": "ExecutePipeline",
              "name": "<MyInnerPipeline>"
              "typeProperties": {
                "pipeline": {
                  "referenceName": "<copyHttpPipeline>",
                  "type": "PipelineReference"
                },
                "parameters": {
                  ...
                },
                "waitOnCompletion": true
              }
            }
          ]
        }
      }
    ],
    "parameters": {
      ...
    }
  }
}
```

Example

Scenario: Iterate over an InnerPipeline within a ForEach activity with Execute Pipeline activity. The inner pipeline copies with schema definitions parameterized.

Master Pipeline definition

```
{
  "name": "masterPipeline",
  "properties": {
    "activities": [
      {
        "type": "ForEach",
        "name": "MyForEachActivity",
        "typeProperties": {
          "isSequential": true,
          "items": {
            "value": "@pipeline().parameters.inputtables",
            "type": "Expression"
          },
          "activities": [
            {
              "type": "ExecutePipeline",
              "typeProperties": {
                "pipeline": {
                  "referenceName": "InnerCopyPipeline",
                  "type": "PipelineReference"
                },
                "parameters": {
                  "sourceTableName": {
                    "value": "@item().SourceTable",
                    "type": "Expression"
                  },
                  "sourceTableStructure": {
                    "value": "@item().SourceTableStructure",
                    "type": "Expression"
                  },
                  "sinkTableName": {
                    "value": "@item().DestTable",
                    "type": "Expression"
                  },
                  "sinkTableStructure": {
                    "value": "@item().DestTableStructure",
                    "type": "Expression"
                  }
                },
                "waitOnCompletion": true
              },

                "type": "string"
              }
            ]
        }
    ]

}
```

Aggregating outputs

To aggregate outputs of **foreach** activity, please utilize *Variables* and *Append Variable* activity.

First, declare an `array` *variable* in the pipeline. Then, invoke *Append Variable* activity inside each **foreach** loop. Subsequently, you can retrieve the aggregation from your array.

Limitations and workarounds

Here are some limitations of the ForEach activity and suggested workarounds.

LIMITATION	WORKAROUND
You can't nest a ForEach loop inside another ForEach loop (or an Until loop).	Design a two-level pipeline where the outer pipeline with the outer ForEach loop iterates over an inner pipeline with the nested loop.
The ForEach activity has a maximum `batchCount` of 50 for parallel processing, and a maximum of 100,000 items.	Design a two-level pipeline where the outer pipeline with the ForEach activity iterates over an inner pipeline.
SetVariable can't be used inside a ForEach activity that runs in parallel as the variables are global to the whole pipeline, they are not scoped to a ForEach or any other activity.	Consider using sequential ForEach or use Execute Pipeline inside ForEach (Variable/Parameter handled in child Pipeline).

Get Metadata activity in Azure Data Factory or Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

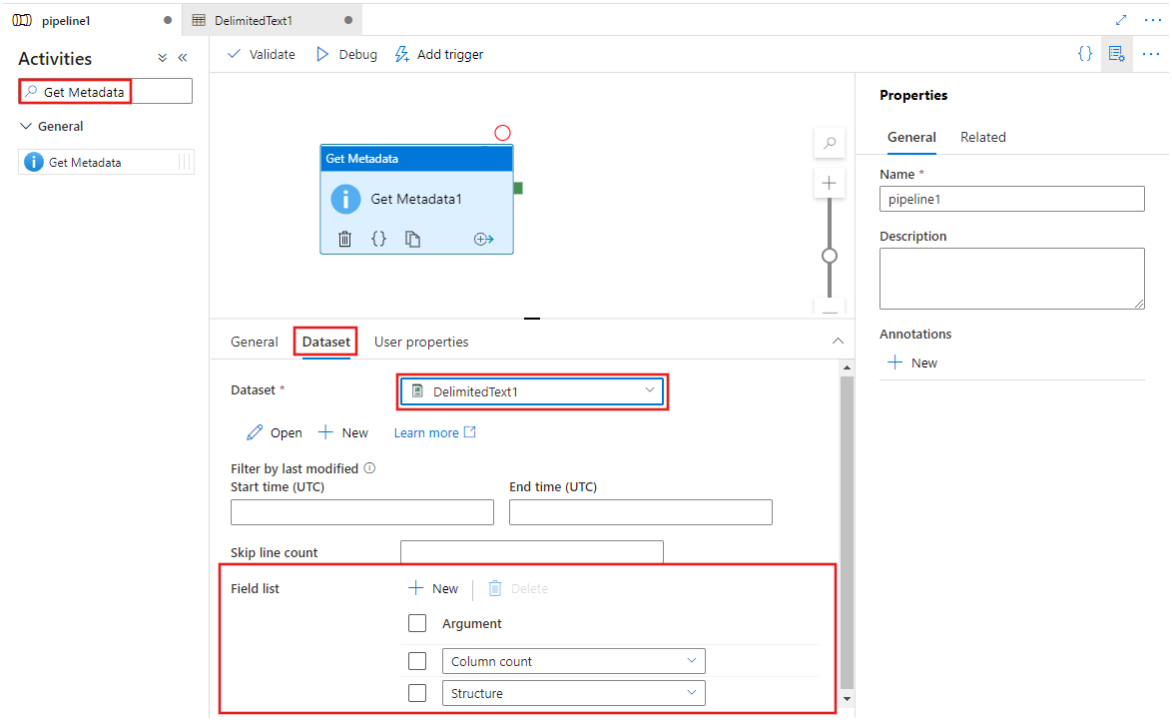
APPLIES TO: Azure Data Factory Azure Synapse Analytics

You can use the Get Metadata activity to retrieve the metadata of any data in Azure Data Factory or a Synapse pipeline. You can use the output from the Get Metadata activity in conditional expressions to perform validation, or consume the metadata in subsequent activities.

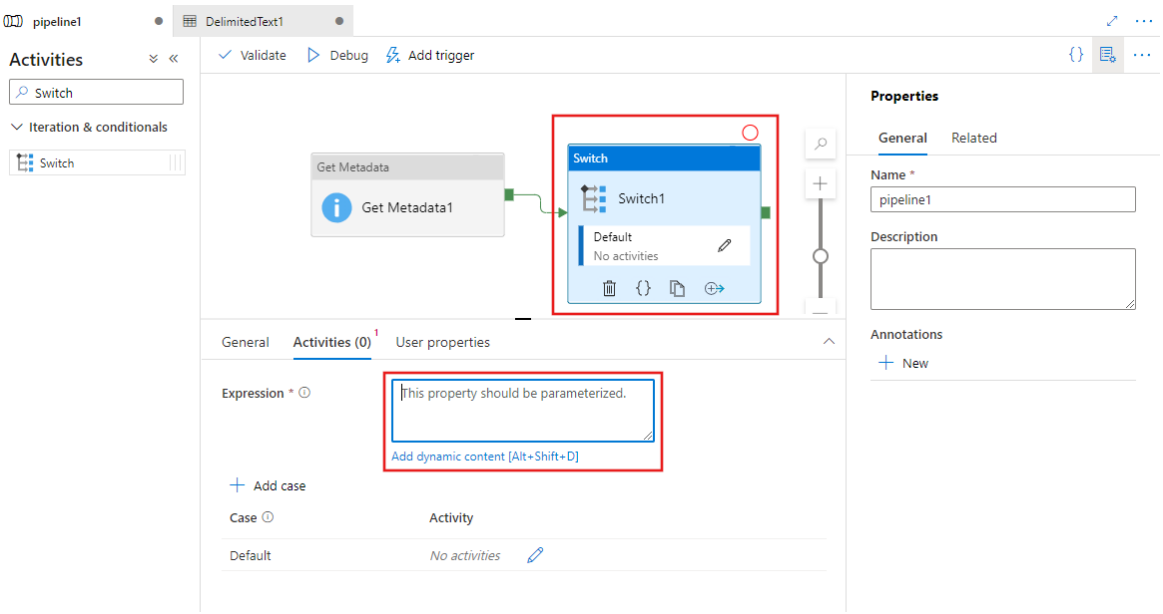
Create a Get Metadata activity with UI

To use a Get Metadata activity in a pipeline, complete the following steps:

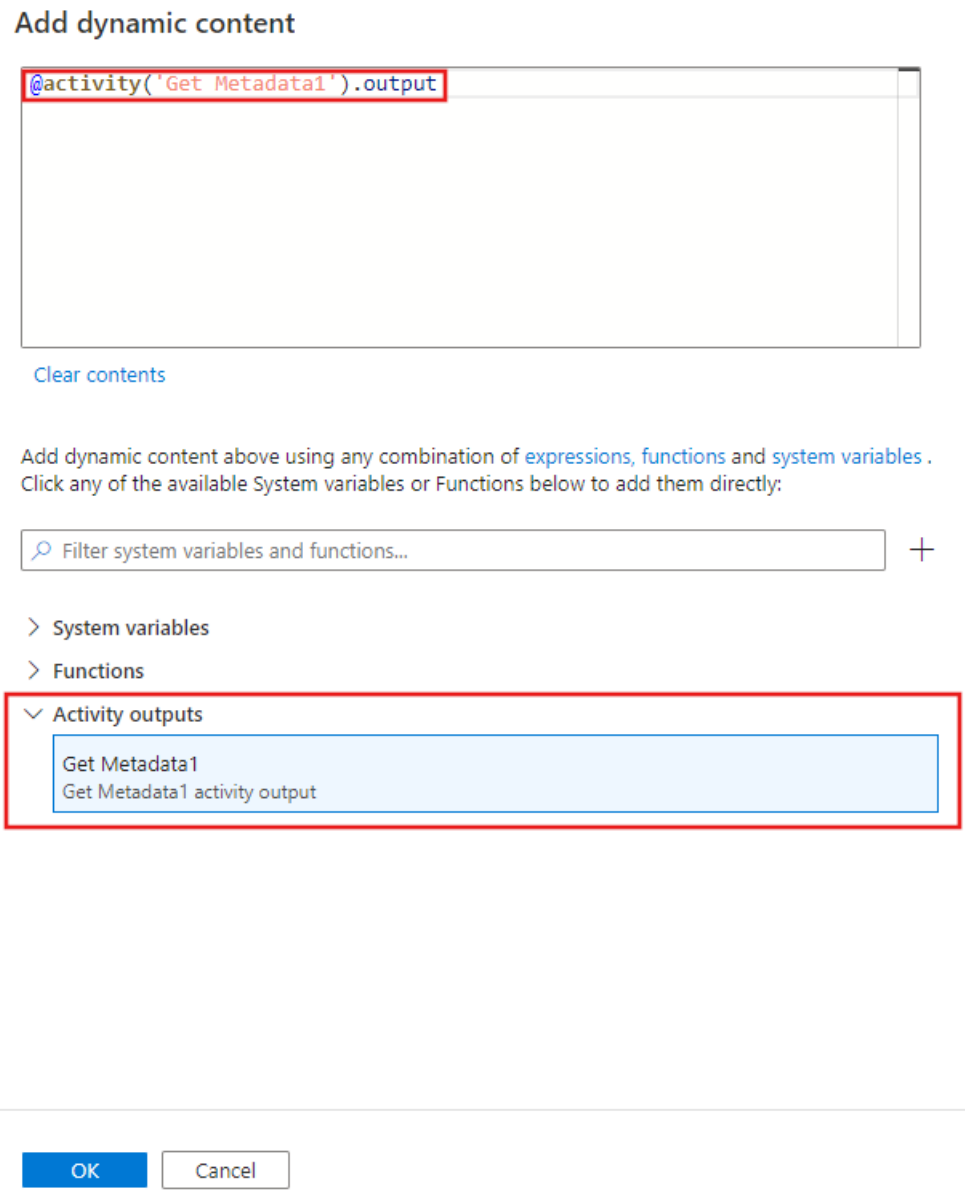
1. Search for *Get Metadata* in the pipeline Activities pane, and drag a Fail activity to the pipeline canvas.
2. Select the new Get Metadata activity on the canvas if it is not already selected, and its **Dataset** tab, to edit its details.
3. Choose a dataset, or create a new one with the New button. Then you can specify filter options and add columns from the available metadata for the dataset.



4. Use the output of the activity as an input to another activity, like a Switch activity in this example. You can reference the output of the Metadata Activity anywhere dynamic content is supported in the other activity.



5. In the dynamic content editor, select the Get Metadata activity output to reference it in the other activity.



Supported capabilities

The Get Metadata activity takes a dataset as an input and returns metadata information as output. Currently, the

following connectors and the corresponding retrievable metadata are supported. The maximum size of returned metadata is **4 MB**.

Supported connectors

File storage

CONNECTOR/METADATA	ITEMNAME (FILE/FOLDER)	ITEMTYPE (FILE/FOLDER)	SIZE (FILE)	CREATED (FILE/FOLDER)	LASTMODIFIED[1] (FILE/FOLDER)	CHILDITEMS (FOLDER)	CONTENTMD5 (FILE)	STRUCTURE[2] (FILE)	COLUMNCOUNT[2] (FILE)	EXISTS[3] (FILE/FOLDER)
Amazon S3	Ã/Ã	Ã/Ã	Ã	x/x	Ã/Ã	Ã	x	Ã	Ã	Ã/Ã
Amazon S3 Compatible Storage	Ã/Ã	Ã/Ã	Ã	x/x	Ã/Ã	Ã	x	Ã	Ã	Ã/Ã

FTP	Ã/Ã	Ã/Ã	Ã	x/x	x/x	Ã	x	Ã	Ã	Ã/Ã

[1] Metadata `lastModified`:

- For Amazon S3, Amazon S3 Compatible Storage, Google Cloud Storage and Oracle Cloud Storage, `lastModified` applies to the bucket and the key but not to the virtual folder, and `exists` applies to the bucket and the key but not to the prefix or virtual folder.
- For Azure Blob storage, `lastModified` applies to the container and the blob but not to the virtual folder.

[2] Metadata `structure` and `columnCount` are not supported when getting metadata from Binary, JSON, or XML files.

[3] Metadata `exists`: For Amazon S3, Amazon S3 Compatible Storage, Google Cloud Storage and Oracle Cloud Storage, `exists` applies to the bucket and the key but not to the prefix or virtual folder.

Note the following:

- When using Get Metadata activity against a folder, make sure you have LIST/EXECUTE permission to the given folder.
- Wildcard filter on folders/files is not supported for Get Metadata activity.
- `modifiedDatetimeStart` and `modifiedDatetimeEnd` filter set on connector:
  - These two properties are used to filter the child items when getting metadata from a folder. It does not apply when getting metadata from a file.
  - When such filter is used, the `childItems` in output includes only the files that are modified within the specified range but not folders.
  - To apply such filter, GetMetadata activity will enumerate all the files in the specified folder and check the modified time. Avoid pointing to a folder with a large number of files even if the expected qualified file count is small.

Relational database

CONNECTOR/METADATA	STRUCTURE	COLUMNCOUNT	EXISTS
Amazon RDS for SQL Server	Ã	Ã	Ã
Azure SQL Database	Ã	Ã	Ã
Azure SQL Managed Instance	Ã	Ã	Ã
Azure Synapse Analytics	Ã	Ã	Ã
SQL Server	Ã	Ã	Ã

Metadata options

You can specify the following metadata types in the Get Metadata activity field list to retrieve the corresponding information:

METADATA TYPE	DESCRIPTION
itemName	Name of the file or folder.
itemType	Type of the file or folder. Returned value is `File` or `Folder`.

METADATA TYPE	DESCRIPTION
size	Size of the file, in bytes. Applicable only to files.
created	Created datetime of the file or folder.
lastModified	Last modified datetime of the file or folder.
childItems	List of subfolders and files in the given folder. Applicable only to folders. Returned value is a list of the name and type of each child item.
contentMD5	MD5 of the file. Applicable only to files.
structure	Data structure of the file or relational database table. Returned value is a list of column names and column types.
columnCount	Number of columns in the file or relational table.
exists	Whether a file, folder, or table exists. If `exists` is specified in the Get Metadata field list, the activity won't fail even if the file, folder, or table doesn't exist. Instead, `exists: false` is returned in the output.

TIP

When you want to validate that a file, folder, or table exists, specify `exists` in the Get Metadata activity field list. You can then check the `exists: true/false` result in the activity output. If `exists` isn't specified in the field list, the Get Metadata activity will fail if the object isn't found.

NOTE

When you get metadata from file stores and configure `modifiedDatetimeStart` or `modifiedDatetimeEnd`, the `childItems` in the output includes only files in the specified path that have a last modified time within the specified range. Items in subfolders are not included.

NOTE

For the **Structure** field list to provide the actual data structure for delimited text and Excel format datasets, you must enable the `First Row as Header` property, which is supported only for these data sources.

Syntax

Get Metadata activity

```
{
    "name":"MyActivity",
    "type":"GetMetadata",
    "dependsOn":[

    ],
    "policy":{
        "timeout":"7.00:00:00",
        "retry":0,
        "retryIntervalInSeconds":30,
        "secureOutput":false,
        "secureInput":false
    },
    "userProperties":[

    ],
    "typeProperties":{
        "dataset":{
            "referenceName":"MyDataset",
            "type":"DatasetReference"
        },
        "fieldList":[
            "size",
            "lastModified",
            "structure"
        ],
        "storeSettings":{
            "type":"AzureBlobStorageReadSettings"
        },
        "formatSettings":{
            "type":"JsonReadSettings"
        }
    }
}
```

Dataset

```
{
    "name":"MyDataset",
    "properties":{
        "linkedServiceName":{
            "referenceName":"AzureStorageLinkedService",
            "type":"LinkedServiceReference"
        },
        "annotations":[

        ],
        "type":"Json",
        "typeProperties":{
            "location":{
                "type":"AzureBlobStorageLocation",
                "fileName":"file.json",
                "folderPath":"folder",
                "container":"container"
            }
        }
    }
}
```

Type properties

Currently, the Get Metadata activity can return the following types of metadata information:

PROPERTY	DESCRIPTION	REQUIRED
fieldList	The types of metadata information required. For details on supported metadata, see the Metadata options section of this article.	Yes
dataset	The reference dataset whose metadata is to be retrieved by the Get Metadata activity. See the Capabilities section for information on supported connectors. Refer to the specific connector topics for dataset syntax details.	Yes
formatSettings	Apply when using format type dataset.	No
storeSettings	Apply when using format type dataset.	No

Sample output

The Get Metadata results are shown in the activity output. Following are two samples showing extensive metadata options. To use the results in a subsequent activity, use this pattern: `@{activity('MyGetMetadataActivity').output.itemName}`.

Get a file's metadata

```
{
  "exists": true,
  "itemName": "test.csv",
  "itemType": "File",
  "size": 104857600,
  "lastModified": "2017-02-23T06:17:09Z",
  "created": "2017-02-23T06:17:09Z",
  "contentMD5": "cMauY+Kz5zDm3eWa9VpoyQ==",
  "structure": [
    {
        "name": "id",
        "type": "Int64"
    },
    {
        "name": "name",
        "type": "String"
    }
  ],
  "columnCount": 2
}
```

Get a folder's metadata

```
{
  "exists": true,
  "itemName": "testFolder",
  "itemType": "Folder",
  "lastModified": "2017-02-23T06:17:09Z",
  "created": "2017-02-23T06:17:09Z",
  "childItems": [
    {
      "name": "test.avro",
      "type": "File"
    },
    {
      "name": "folder hello",
      "type": "Folder"
    }
  ]
}
```

If Condition activity in Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 4 minutes to read • Edit Online

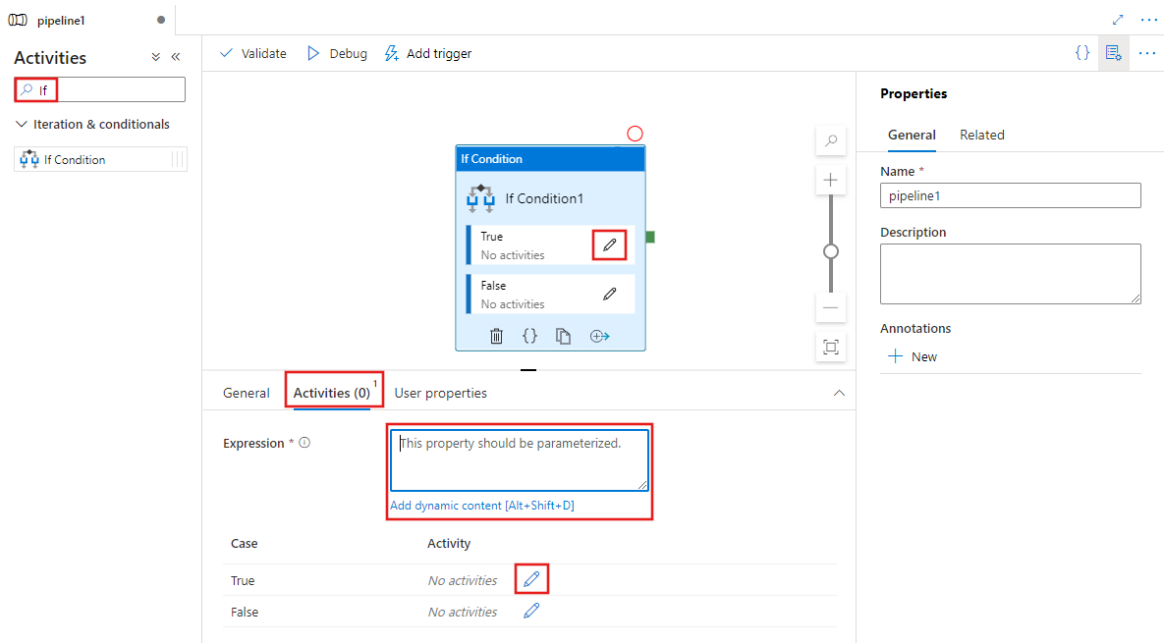
APPLIES TO: Azure Data Factory Azure Synapse Analytics

The If Condition activity provides the same functionality that an if statement provides in programming languages. It executes a set of activities when the condition evaluates to `true` and another set of activities when the condition evaluates to `false`.

Create an If Condition activity with UI

To use an If Condition activity in a pipeline, complete the following steps:

1. Search for *If* in the pipeline Activities pane, and drag an If Condition activity to the pipeline canvas.
2. Select the new If Condition activity on the canvas if it is not already selected, and its **Activities** tab, to edit its details.



3. Enter an expression that returns a boolean true or false value. This can be any combination of dynamic expressions, functions, system variables, or outputs from other activities.
4. Select the Edit Activities buttons on the Activities tab for the If Condition, or directly from the If Condition on the pipeline canvas, to add activities that will be executed when the expression evaluates to `true` or `false`.

Syntax

```
{
    "name": "<Name of the activity>",
    "type": "IfCondition",
    "typeProperties": {
      "expression": {
            "value": "<expression that evaluates to true or false>",
            "type": "Expression"
      },

      "ifTrueActivities": [
            {
                "<Activity 1 definition>"
            },
            {
                "<Activity 2 definition>"
            },
            {
                "<Activity N definition>"
            }
        ],

        "ifFalseActivities": [
            {
                "<Activity 1 definition>"
            },
            {
                "<Activity 2 definition>"
            },
            {
                "<Activity N definition>"
            }
      ]
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the if-condition activity.	String	Yes
type	Must be set to **IfCondition**	String	Yes
expression	Expression that must evaluate to true or false	Expression with result type boolean	Yes
ifTrueActivities	Set of activities that are executed when the expression evaluates to `true`.	Array	Yes
ifFalseActivities	Set of activities that are executed when the expression evaluates to `false`.	Array	Yes

Example

The pipeline in this example copies data from an input folder to an output folder. The output folder is determined by the value of pipeline parameter: routeSelection. If the value of routeSelection is true, the data is copied to outputPath1. And, if the value of routeSelection is false, the data is copied to outputPath2.

> **NOTE**
>
> This section provides JSON definitions and sample PowerShell commands to run the pipeline. For a walkthrough with step-by-step instructions to create a pipeline by using Azure PowerShell and JSON definitions, see tutorial: create a data factory by using Azure PowerShell.

Pipeline with IF-Condition activity (Adfv2QuickStartPipeline.json)

```
{
    "name": "Adfv2QuickStartPipeline",
    "properties": {
        "activities": [
            {
                "name": "MyIfCondition",
                "type": "IfCondition",
                "typeProperties": {
                    "expression":  {
                        "value":  "@bool(pipeline().parameters.routeSelection)",
                        "type": "Expression"
                     },

                    "ifTrueActivities": [
                        {
                            "name": "CopyFromBlobToBlob1",
                            "type": "Copy",
                            "inputs": [
                                {
                                    "referenceName": "BlobDataset",
                                    "parameters": {
                                        "path": "@pipeline().parameters.inputPath"
                                    },
                                    "type": "DatasetReference"
                                }
                            ],
                            "outputs": [
                                {
                                    "referenceName": "BlobDataset",
                                    "parameters": {
                                        "path": "@pipeline().parameters.outputPath1"
                                    },
                                    "type": "DatasetReference"
                                }
                            ],
                            "typeProperties": {
                                "source": {

                                },
                                "sink": {
                                    "type": "BlobSink"
                                }
                            }
                        }
                    ],
                    "ifFalseActivities": [
                        {
                            "name": "CopyFromBlobToBlob2",
                            "type": "Copy",
                            "inputs": [
                                {
                                    "referenceName": "BlobDataset",
                                    "parameters": {
```

```
                                    "path": "@pipeline().parameters.inputPath"
                                },
                                "type": "DatasetReference"
                            }
                        ],
                        "outputs": [
                            {
                                "referenceName": "BlobDataset",
                                "parameters": {
                                    "path": "@pipeline().parameters.outputPath2"
                                },
                                "type": "DatasetReference"
                            }
                        ],
                        "typeProperties": {
                            "source": {
                                "type": "BlobSource"
                            },
                            "sink": {
                                "type": "BlobSink"
                            }
                        }
                    }
                ]
            }
        }
    ],
    "parameters": {
        "inputPath": {
            "type": "String"
        },
        "outputPath1": {
            "type": "String"
        },
        "outputPath2": {
            "type": "String"
        },
        "routeSelection": {
            "type": "String"
        }
    }
}
```

Another example for expression is:

```
"expression":  {
    "value":  "@equals(pipeline().parameters.routeSelection,1)",
    "type": "Expression"
}
```

Azure Storage linked service (AzureStorageLinkedService.json)

```
{
    "name": "AzureStorageLinkedService",
    "properties": {
        "type": "AzureStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<Azure Storage account
name>;AccountKey=<Azure Storage account key>"
        }
    }
}
```

Parameterized Azure Blob dataset (BlobDataset.json)

The pipeline sets the **folderPath** to the value of either **outputPath1** or **outputPath2** parameter of the pipeline.

```
{
    "name": "BlobDataset",
    "properties": {
        "type": "AzureBlob",
        "typeProperties": {
            "folderPath": {
                "value": "@{dataset().path}",
                "type": "Expression"
            }
        },
        "linkedServiceName": {
            "referenceName": "AzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "parameters": {
            "path": {
                "type": "String"
            }
        }
    }
}
```

Pipeline parameter JSON (PipelineParameters.json)

```
{
    "inputPath": "adftutorial/input",
    "outputPath1": "adftutorial/outputIf",
    "outputPath2": "adftutorial/outputElse",
    "routeSelection": "false"
}
```

PowerShell commands

> **NOTE**
>
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

These commands assume that you have saved the JSON files into the folder: C:\ADF.

```
Connect-AzAccount

Lookup activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

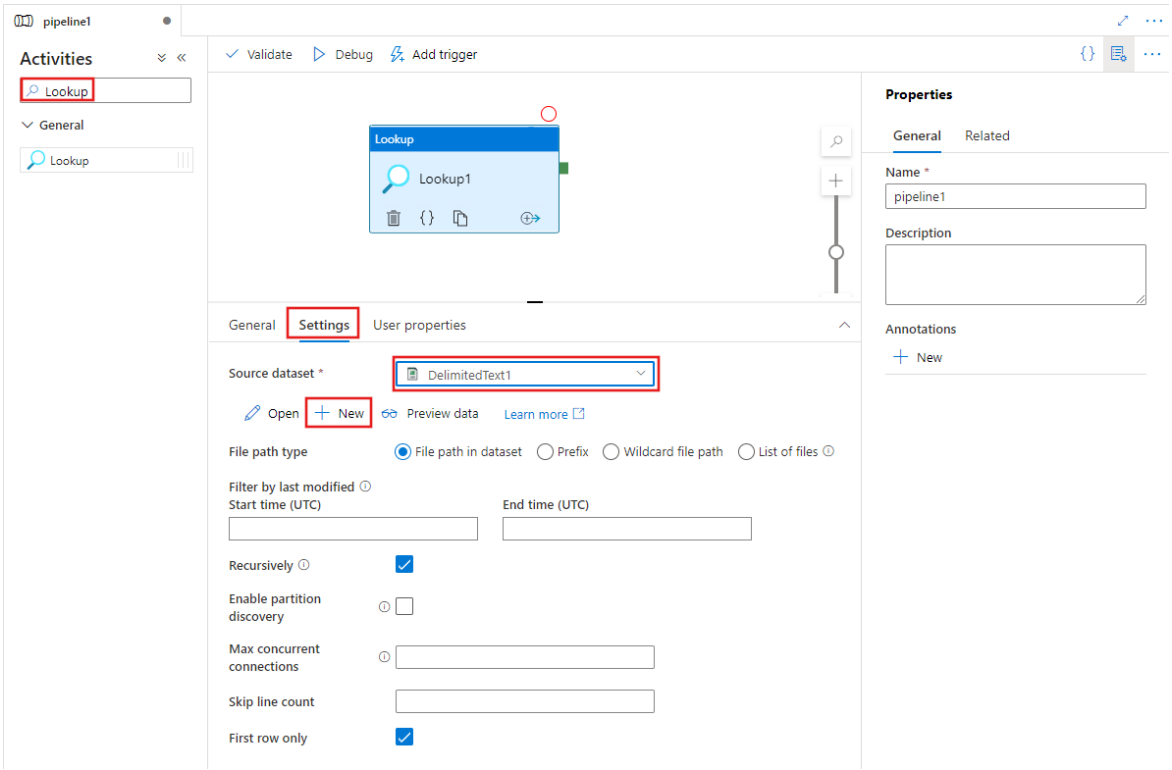
Lookup activity can retrieve a dataset from any of the data sources supported by data factory and Synapse pipelines. You can use it to dynamically determine which objects to operate on in a subsequent activity, instead of hard coding the object name. Some object examples are files and tables.

Lookup activity reads and returns the content of a configuration file or table. It also returns the result of executing a query or stored procedure. The output can be a singleton value or an array of attributes, which can be consumed in a subsequent copy, transformation, or control flow activities like ForEach activity.

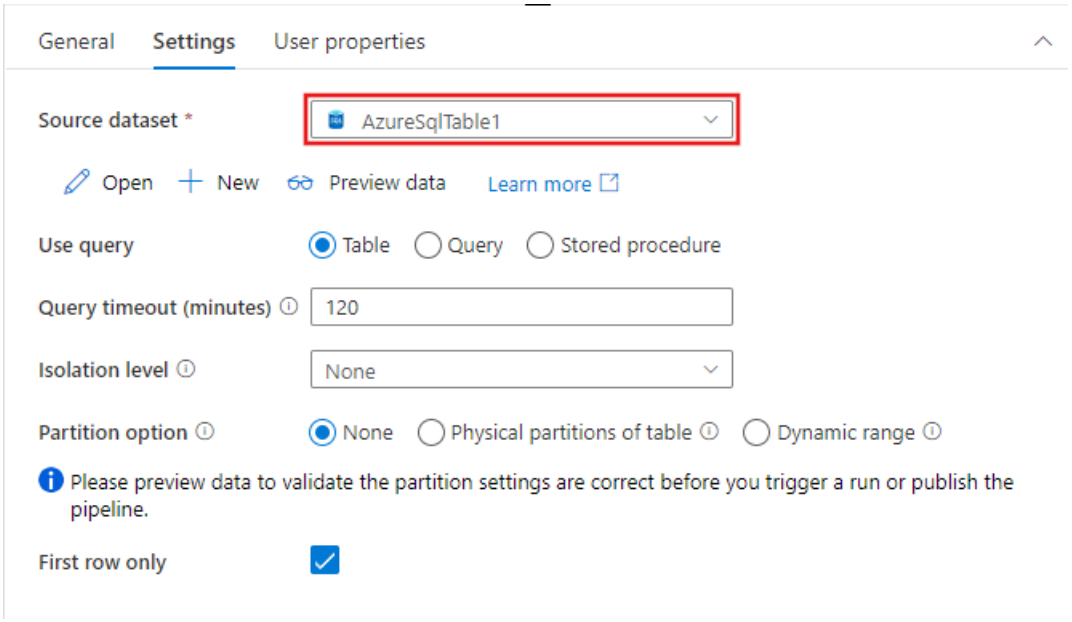
Create a Lookup activity with UI

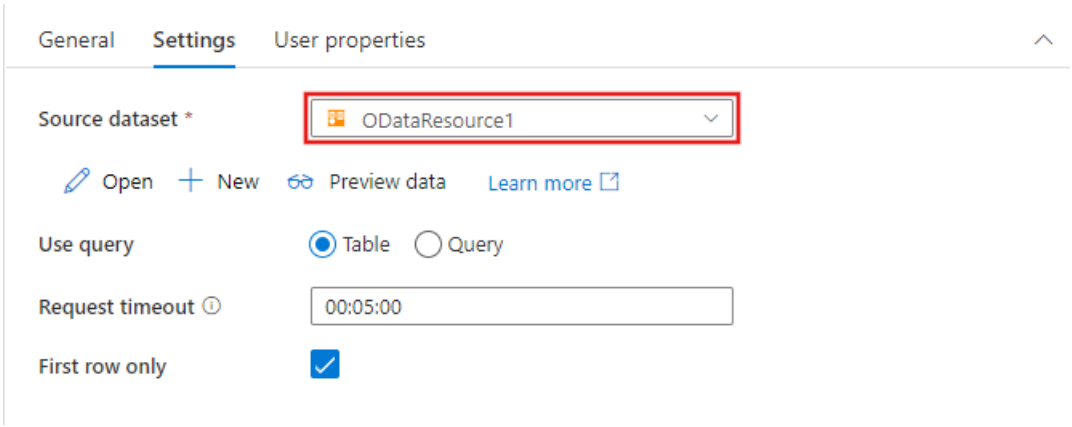
To use a Lookup activity in a pipeline, complete the following steps:

1. Search for *Lookup* in the pipeline Activities pane, and drag a Lookup activity to the pipeline canvas.
2. Select the new Lookup activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Choose an existing source dataset or select the **New** button to create a new one.
4. The options for identifying rows to include from the source dataset will vary based on the dataset type. The example above shows the configuration options for a delimited text dataset. Below are examples of configuration options for an Azure SQL table dataset and an OData dataset.





Supported capabilities

Note the following:

- The Lookup activity can return up to **5000 rows**; if the result set contains more records, the first 5000 rows will be returned.
- The Lookup activity output supports up to **4 MB** in size, activity will fail if the size exceeds the limit.
- The longest duration for Lookup activity before timeout is **24 hours**.

> **NOTE**
> When you use query or stored procedure to lookup data, make sure to return one and exact one result set. Otherwise, Lookup activity fails.

The following data sources are supported for Lookup activity.

Syntax

```
{
    "name":"LookupActivity",
    "type":"Lookup",
    "typeProperties":{
        "source":{
            "type":"<source type>"
        },
        "dataset":{
            "referenceName":"<source dataset name>",
            "type":"DatasetReference"
        },
        "firstRowOnly":<true or false>
    }
}
```

Type properties

NAME	DESCRIPTION	TYPE	REQUIRED?
dataset	Provides the dataset reference for the lookup. Get details from the **Dataset properties** section in each corresponding connector article.	Key/value pair	Yes

NAME	DESCRIPTION	TYPE	REQUIRED?
source	Contains dataset-specific source properties, the same as the Copy Activity source. Get details from the **Copy Activity properties** section in each corresponding connector article.	Key/value pair	Yes
firstRowOnly	Indicates whether to return only the first row or all rows.	Boolean	No. The default is `true`.

NOTE

- Source columns with **ByteArray** type aren't supported.
- **Structure** isn't supported in dataset definitions. For text-format files, use the header row to provide the column name.
- If your lookup source is a JSON file, the `jsonPathDefinition` setting for reshaping the JSON object isn't supported. The entire objects will be retrieved.

Use the Lookup activity result

The lookup result is returned in the `output` section of the activity run result.

- **When `firstRowOnly` is set to `true` (default)**, the output format is as shown in the following code. The lookup result is under a fixed `firstRow` key. To use the result in subsequent activity, use the pattern of `@{activity('LookupActivity').output.firstRow.table}`.

```
{
    "firstRow":
    {
        "Id": "1",
        "schema":"dbo",
        "table":"Table1"
    }
}
```

- **When `firstRowOnly` is set to `false`**, the output format is as shown in the following code. A `count` field indicates how many records are returned. Detailed values are displayed under a fixed `value` array. In such a case, the Lookup activity is followed by a Foreach activity. You pass the `value` array to the ForEach activity `items` field by using the pattern of `@activity('MyLookupActivity').output.value`. To access elements in the `value` array, use the following syntax: `@{activity('lookupActivity').output.value[zero based index].propertyname}`. An example is `@{activity('lookupActivity').output.value[0].schema}`.

```
{
    "count": "2",
    "value": [
        {
            "Id": "1",
            "schema":"dbo",
            "table":"Table1"
        },
        {
            "Id": "2",
            "schema":"dbo",
            "table":"Table2"
        }
    ]
}
```

Example

In this example, the pipeline contains two activities: **Lookup** and **Copy**. The Copy Activity copies data from a SQL table in your Azure SQL Database instance to Azure Blob storage. The name of the SQL table is stored in a JSON file in Blob storage. The Lookup activity looks up the table name at runtime. JSON is modified dynamically by using this approach. You don't need to redeploy pipelines or datasets.

This example demonstrates lookup for the first row only. For lookup for all rows and to chain the results with ForEach activity, see the samples in Copy multiple tables in bulk.

Pipeline

- The Lookup activity is configured to use **LookupDataset**, which refers to a location in Azure Blob storage. The Lookup activity reads the name of the SQL table from a JSON file in this location.
- The Copy Activity uses the output of the Lookup activity, which is the name of the SQL table. The **tableName** property in the **SourceDataset** is configured to use the output from the Lookup activity. Copy Activity copies data from the SQL table to a location in Azure Blob storage. The location is specified by the **SinkDataset** property.

```

Lookup dataset

The **lookup** dataset is the **sourcetable.json** file in the Azure Storage lookup folder specified by the **AzureBlobStorageLinkedService** type.

```
{
    "name": "LookupDataset",
    "properties": {
        "linkedServiceName": {
            "referenceName": "AzureBlobStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "annotations": [],
        "type": "Json",
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "fileName": "sourcetable.json",
                "container": "lookup"
            }
        }
    }
}
```

Source dataset for Copy Activity

The **source** dataset uses the output of the Lookup activity, which is the name of the SQL table. Copy Activity copies data from this SQL table to a location in Azure Blob storage. The location is specified by the **sink** dataset.

```
{
    "name": "SourceDataset",
    "properties": {
        "linkedServiceName": {
            "referenceName": "AzureSqlDatabase",
            "type": "LinkedServiceReference"
        },
        "parameters": {
            "schemaName": {
                "type": "string"
            },
            "tableName": {
                "type": "string"
            }
        },
        "annotations": [],
        "type": "AzureSqlTable",
        "schema": [],
        "typeProperties": {
            "schema": {
                "value": "@dataset().schemaName",
                "type": "Expression"
            },
            "table": {
                "value": "@dataset().tableName",
                "type": "Expression"
            }
        }
    }
}
```

Sink dataset for Copy Activity

Copy Activity copies data from the SQL table to the **filebylookup.csv** file in the **csv** folder in Azure Storage. The file is specified by the **AzureBlobStorageLinkedService** property.

```
{
    "name": "SinkDataset",
    "properties": {
        "linkedServiceName": {
            "referenceName": "AzureBlobStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "parameters": {
            "schema": {
                "type": "string"
            },
            "table": {
                "type": "string"
            }
        },
        "annotations": [],
        "type": "DelimitedText",
        "typeProperties": {
            "location": {
                "type": "AzureBlobStorageLocation",
                "fileName": {
                    "value": "@{dataset().schema}_@{dataset().table}.csv",
                    "type": "Expression"
                },
                "container": "csv"
            },
            "columnDelimiter": ",",
            "escapeChar": "\\",
            "quoteChar": "\""
        },
        "schema": []
    }
}
```

sourcetable.json

You can use following two kinds of formats for **sourcetable.json** file.

Set of objects

```
{
   "Id":"1",
   "schema":"dbo",
   "table":"Table1"
}
{
   "Id":"2",
   "schema":"dbo",
   "table":"Table2"
}
```

Array of objects

```
[
    {
        "Id": "1",
        "schema":"dbo",
        "table":"Table1"
    },
    {
        "Id": "2",
        "schema":"dbo",
        "table":"Table2"
    }
]
```

Limitations and workarounds

Here are some limitations of the Lookup activity and suggested workarounds.

LIMITATION	WORKAROUND
The Lookup activity has a maximum of 5,000 rows, and a maximum size of 4 MB.	Design a two-level pipeline where the outer pipeline iterates over an inner pipeline, which retrieves data that doesn't exceed the maximum rows or size.

Next steps

Set Variable Activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

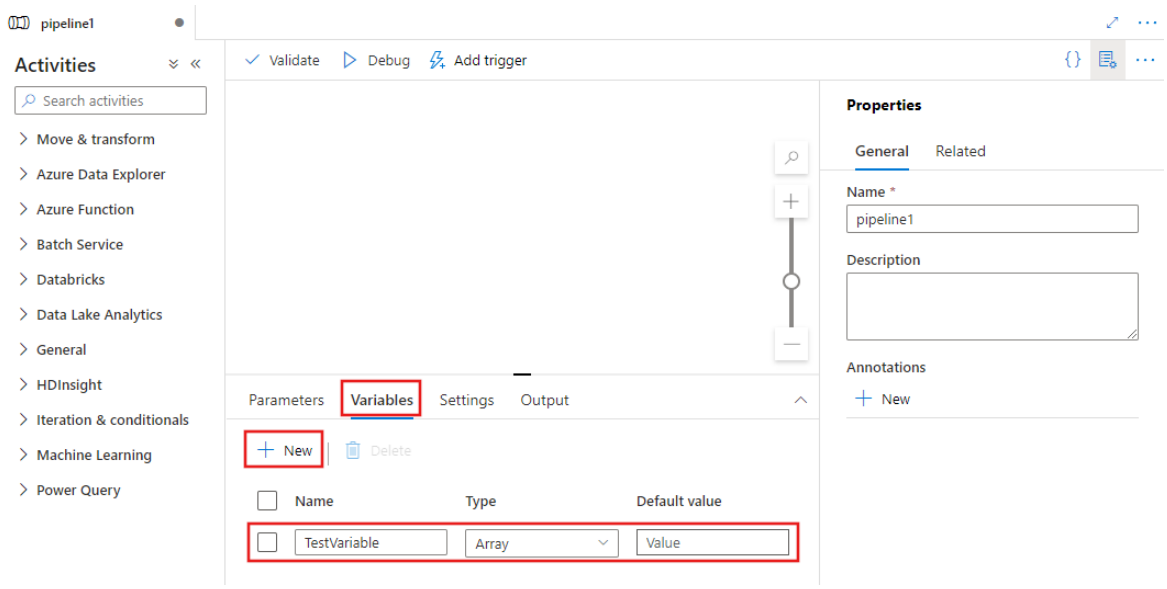
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Use the Set Variable activity to set the value of an existing variable of type String, Bool, or Array defined in a Data Factory or Synapse pipeline.

Create an Append Variable activity with UI

To use a Set Variable activity in a pipeline, complete the following steps:

1. Select the background of the pipeline canvas and use the Variables tab to add a variable:

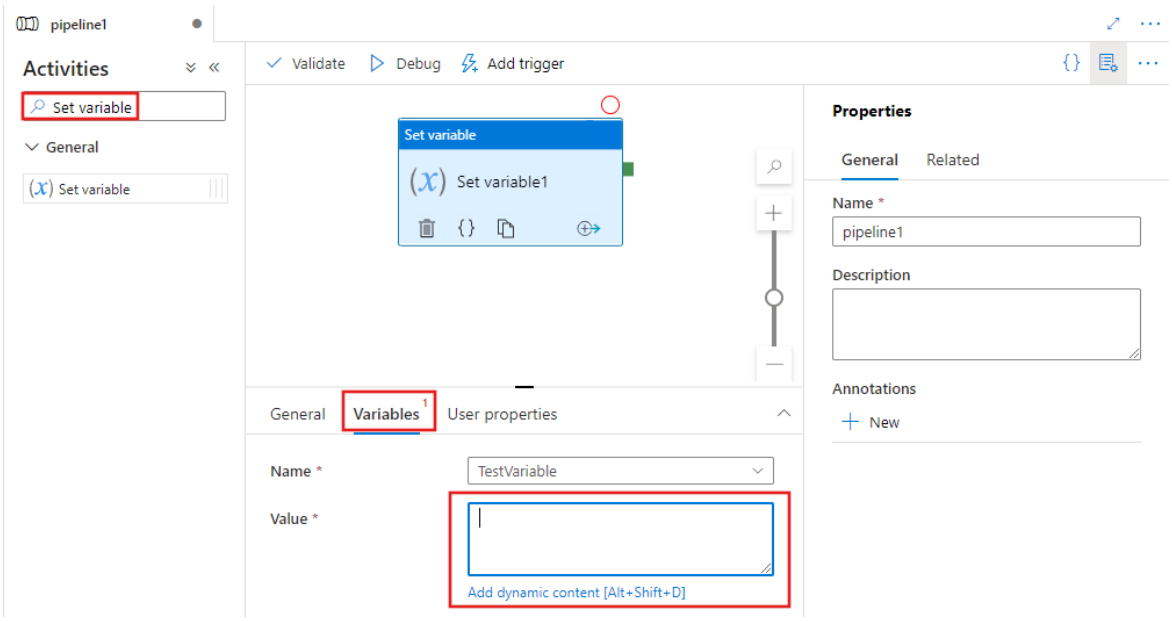


2. Search for *Set Variable* in the pipeline Activities pane, and drag a Set Variable activity to the pipeline canvas.

3. Select the Set Variable activity on the canvas if it is not already selected, and its **Variables** tab, to edit its details.

4. Select the variable for the Name property.

5. Enter an expression to set the value. This can be a literal string expression, or any combination of dynamic expressions, functions, system variables, or outputs from other activities.



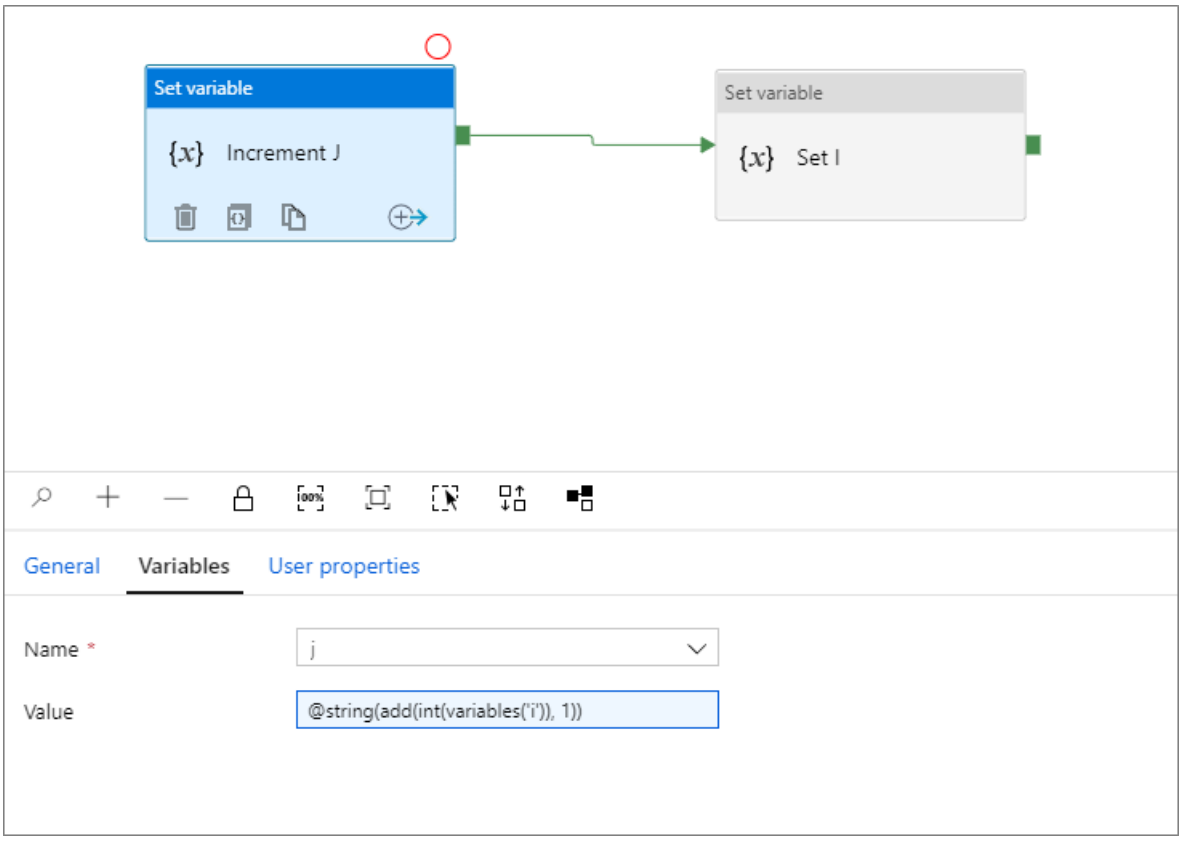
Type properties

PROPERTY	DESCRIPTION	REQUIRED
name	Name of the activity in pipeline	yes
description	Text describing what the activity does	no
type	Must be set to **SetVariable**	yes
value	String literal or expression object value that the variable is assigned to	yes
variableName	Name of the variable that is set by this activity	yes

Incrementing a variable

A common scenario involving variables is using a variable as an iterator within an until or foreach activity. In a set variable activity you cannot reference the variable being set in the `value` field. To workaround this limitation, set a temporary variable and then create a second set variable activity. The second set variable activity sets the value of the iterator to the temporary variable.

Below is an example of this pattern:



Set variable
{x} Increment J
Set variable
{x} Set I
General
Variables
User properties
Name *
j
Value
@string(add(int(variables('i')), 1))

```
{
    "name": "pipeline3",
    "properties": {
        "activities": [
            {
                "name": "Set I",
                "type": "SetVariable",
                "dependsOn": [
                    {
                        "activity": "Increment J",
                        "dependencyConditions": [
                            "Succeeded"
                        ]
                    }
                ],
                "userProperties": [],
                "typeProperties": {
                    "variableName": "i",
                    "value": {
                        "value": "@variables('j')",
                        "type": "Expression"
                    }
                }
            },
            {
                "name": "Increment J",
                "type": "SetVariable",
                "dependsOn": [],
                "userProperties": [],
                "typeProperties": {
                    "variableName": "j",
                    "value": {
                        "value": "@string(add(int(variables('i')), 1))",
                        "type": "Expression"
                    }
                }
            }
        ],
        "variables": {
            "i": {
                "type": "String",
                "defaultValue": "0"
            },
            "j": {
                "type": "String",
                "defaultValue": "0"
            }
        },
        "annotations": []
    }
}
```

Variables are currently scoped at the pipeline level. This means that they are not thread safe and can cause unexpected and undesired behavior if they are accessed from within a parallel iteration activity such as a foreach loop, especially when the value is also being modified within that foreach activity.

Until activity in Azure Data Factory and Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

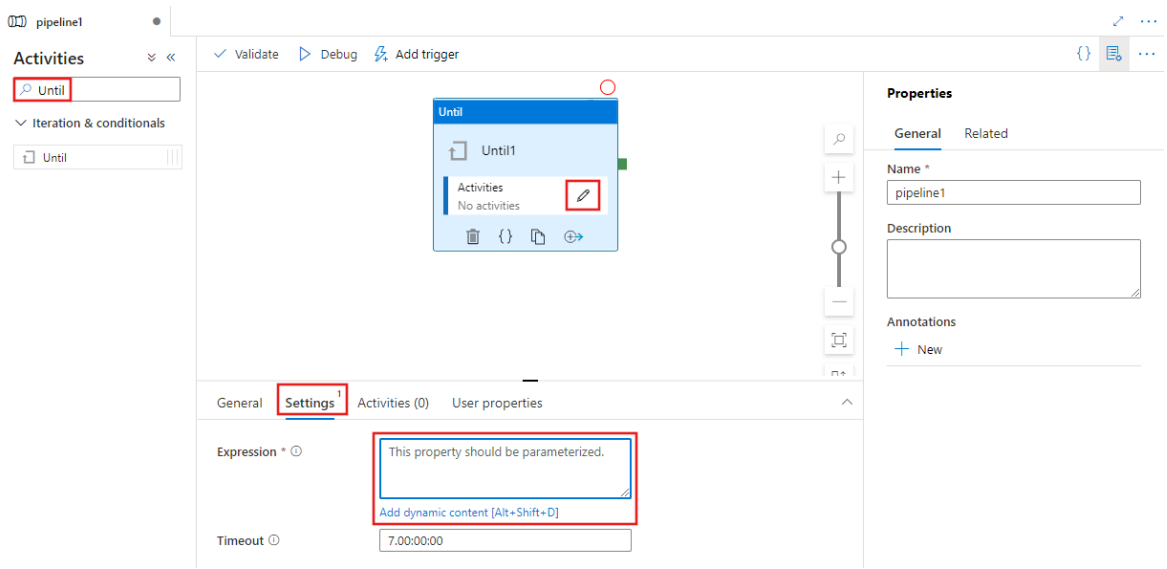
APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Until activity provides the same functionality that a do-until looping structure provides in programming languages. It executes a set of activities in a loop until the condition associated with the activity evaluates to true. You can specify a timeout value for the until activity.

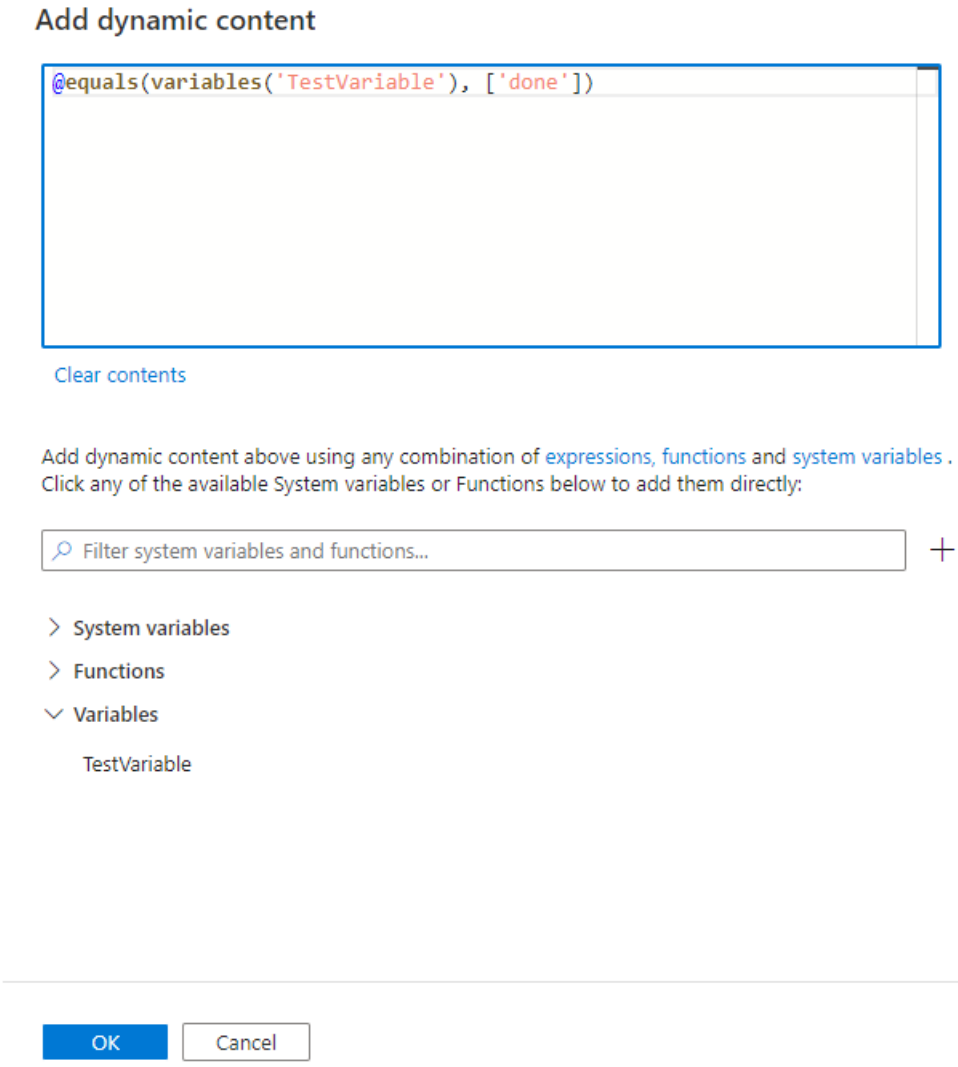
Create an Until activity with UI

To use an Until activity in a pipeline, complete the following steps:

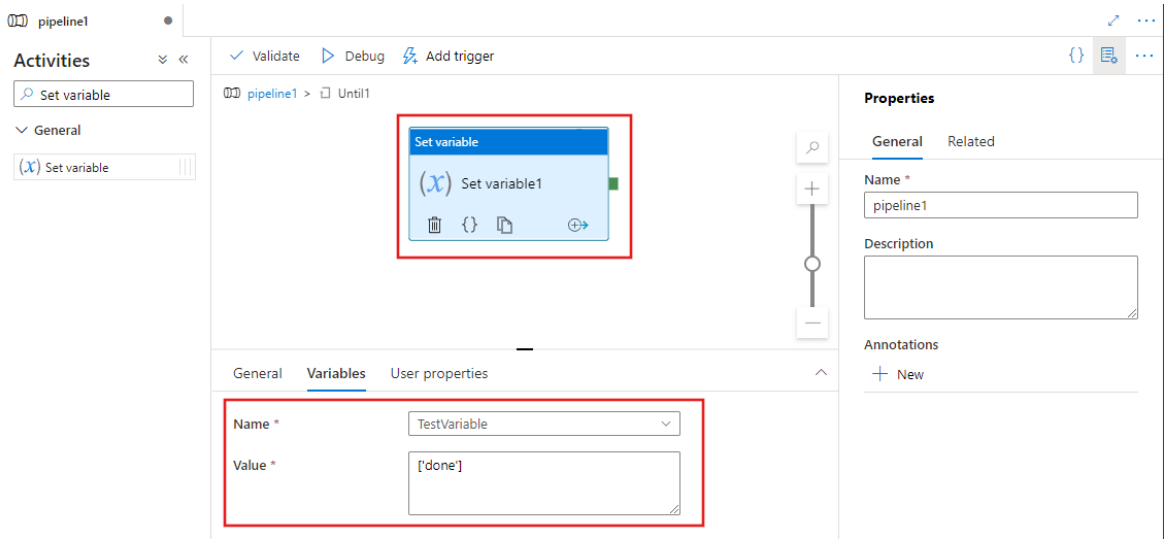
1. Search for *Until* in the pipeline Activities pane, and drag a Set Variable activity to the pipeline canvas.
2. Select the Until activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Enter an expression that will be evaluated after all child activities defined in the Until activity are executed. If the expression evaluates to false, the Until activity will execute all its child activities again. When it evaluates to true, the Until activity will complete. The expression can be a literal string expression, or any combination of dynamic expressions, functions, system variables, or outputs from other activities. The example below checks the value of a previously defined pipeline array variable called TestVariable to see if it evaluates to ['done'].



4. Define activities that the Until activity will execute by selecting the Edit Activities button on the Until activity directly, or by selecting the Activities tab to select it there. A new activities editor pane will be displayed where you can add any activities for the Until activity to execute. In this example, a Set Variable activity simply sets the value of the variable referenced in the expression above to ['done'], so the Until activity's expression will be true the first time it is executed, and the Until activity will stop. In your real-world use, you can check any conditions required and the Until activity will continue to execute its child activities each time the expression is evaluated, until the conditions are met.



Syntax

```
{
    "type": "Until",
    "typeProperties": {
        "expression":  {
            "value":  "<expression that evaluates to true or false>",
            "type": "Expression"
        },
        "timeout": "<time out for the loop. for example: 00:01:00 (1 minute)>",
        "activities": [
            {
                "<Activity 1 definition>"
            },
            {
                "<Activity 2 definition>"
            },
            {
                "<Activity N definition>"
            }
        ]
    },
    "name": "MyUntilActivity"
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the `Until` activity.	String	Yes
type	Must be set to **Until**.	String	Yes
expression	Expression that must evaluate to true or false	Expression.	Yes
timeout	The do-until loop times out after the specified time here.	String. `d.hh:mm:ss` (or) `hh:mm:ss`. The default value is 7 days. Maximum value is: 90 days.	No
Activities	Set of activities that are executed until expression evaluates to `true`.	Array of activities.	Yes

Example 1

> **NOTE**
> This section provides JSON definitions and sample PowerShell commands to run the pipeline. For a walkthrough with step-by-step instructions to create a pipeline by using Azure PowerShell and JSON definitions, see tutorial: create a data factory by using Azure PowerShell.

Pipeline with Until activity

In this example, the pipeline has two activities: **Until** and **Wait**. The Wait activity waits for the specified period of time before running the Web activity in the loop. To learn about expressions and functions, see Expression

language and functions.

```
{
    "name": "DoUntilPipeline",
    "properties": {
        "activities": [
            {
                "type": "Until",
                "typeProperties": {
                    "expression": {
                        "value": "@equals('Failed', coalesce(body('MyUnauthenticatedActivity')?.status,
actions('MyUnauthenticatedActivity')?.status, 'null'))",
                        "type": "Expression"
                    },
                    "timeout": "00:00:01",
                    "activities": [
                        {
                            "name": "MyUnauthenticatedActivity",
                            "type": "WebActivity",
                            "typeProperties": {
                                "method": "get",
                                "url": "https://www.fake.com/",
                                "headers": {
                                    "Content-Type": "application/json"
                                }
                            },
                            "dependsOn": [
                                {
                                    "activity": "MyWaitActivity",
                                    "dependencyConditions": [ "Succeeded" ]
                                }
                            ]
                        },
                        {
                            "type": "Wait",
                            "typeProperties": {
                                "waitTimeInSeconds": 1
                            },
                            "name": "MyWaitActivity"
                        }
                    ]
                },
                "name": "MyUntilActivity"
            }
        ]
    }
}
```

Example 2

The pipeline in this sample copies data from an input folder to an output folder in a loop. The loop terminates when the value for the repeat parameter is set to false or it times out after one minute.

Pipeline with Until activity (Adfv2QuickStartPipeline.json)

```
{
    "name": "Adfv2QuickStartPipeline",
    "properties": {
        "activities": [
            {
                "type": "Until",
                "typeProperties": {
                    "expression":  {
                        "value":  "@equals('false', pipeline().parameters.repeat)",
```

```
                        "type": "Expression"
                    },
                    "timeout": "00:01:00",
                    "activities": [
                        {
                            "name": "CopyFromBlobToBlob",
                            "type": "Copy",
                            "inputs": [
                                {
                                    "referenceName": "BlobDataset",
                                    "parameters": {
                                        "path": "@pipeline().parameters.inputPath"
                                    },
                                    "type": "DatasetReference"
                                }
                            ],
                            "outputs": [
                                {
                                    "referenceName": "BlobDataset",
                                    "parameters": {
                                        "path": "@pipeline().parameters.outputPath"
                                    },
                                    "type": "DatasetReference"
                                }
                            ],
                            "typeProperties": {
                                "source": {
                                    "type": "BlobSource"
                                },
                                "sink": {
                                    "type": "BlobSink"
                                }
                            },
                            "policy": {
                                "retry": 1,
                                "timeout": "00:10:00",
                                "retryIntervalInSeconds": 60
                            }
                        }
                    ]
                },
                "name": "MyUntilActivity"
            }
        ],
        "parameters": {
            "inputPath": {
                "type": "String"
            },
            "outputPath": {
                "type": "String"
            },
            "repeat": {
                "type": "String"
            }
        }
    }
}
```

Azure Storage linked service (AzureStorageLinkedService.json)

```
{
    "name": "AzureStorageLinkedService",
    "properties": {
        "type": "AzureStorage",
        "typeProperties": {
            "connectionString": "DefaultEndpointsProtocol=https;AccountName=<Azure Storage account
name>;AccountKey=<Azure Storage account key>"
        }
    }
}
```

Parameterized Azure Blob dataset (BlobDataset.json)

The pipeline sets the **folderPath** to the value of either **outputPath1** or **outputPath2** parameter of the pipeline.

```
{
    "name": "BlobDataset",
    "properties": {
        "type": "AzureBlob",
        "typeProperties": {
            "folderPath": {
                "value": "@{dataset().path}",
                "type": "Expression"
            }
        },
        "linkedServiceName": {
            "referenceName": "AzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "parameters": {
            "path": {
                "type": "String"
            }
        }
    }
}
```

Pipeline parameter JSON (PipelineParameters.json)

```
{
    "inputPath": "adftutorial/input",
    "outputPath": "adftutorial/outputUntil",
    "repeat": "true"
}
```

Validation activity in Azure Data Factory and Synapse Analytics pipelines

8/19/2022 • 2 minutes to read • Edit Online

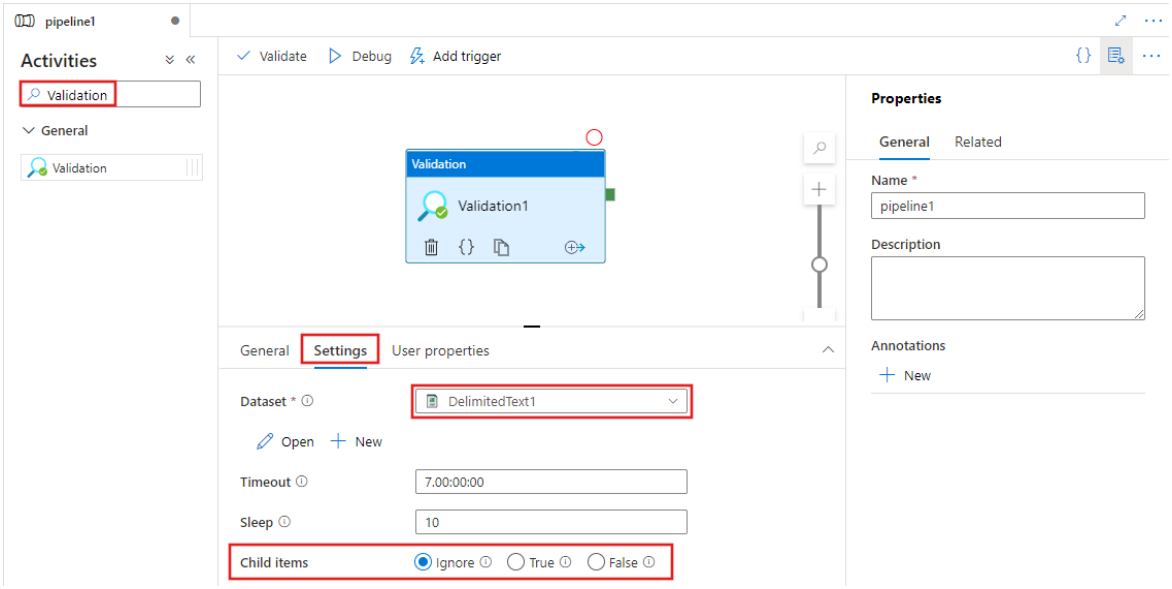
APPLIES TO: Azure Data Factory Azure Synapse Analytics

You can use a Validation in a pipeline to ensure the pipeline only continues execution once it has validated the attached dataset reference exists, that it meets the specified criteria, or timeout has been reached.

Create a Validation activity with UI

To use a Validation activity in a pipeline, complete the following steps:

1. Search for *Validation* in the pipeline Activities pane, and drag a Validation activity to the pipeline canvas.
2. Select the new Validation activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Select a dataset, or define a new one by selecting the New button. For file based datasets like the delimited text example above, you can select either a specific file, or a folder. When a folder is selected, the Validation activity allows you to ignore validation of the existence of child items in the folder, or require whether child items exist or not.
4. The output of the Validation activity can be used as an input to any other activities, and referenced within those activities for any of their properties using dynamic expressions.

Syntax

```
{
    "name": "Validation_Activity",
    "type": "Validation",
    "typeProperties": {
        "dataset": {
            "referenceName": "Storage_File",
            "type": "DatasetReference"
        },
        "timeout": "7.00:00:00",
        "sleep": 10,
        "minimumSize": 20
    }
},
{
    "name": "Validation_Activity_Folder",
    "type": "Validation",
    "typeProperties": {
        "dataset": {
            "referenceName": "Storage_Folder",
            "type": "DatasetReference"
        },
        "timeout": "7.00:00:00",
        "sleep": 10,
        "childItems": true
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the 'Validation' activity	String	Yes
type	Must be set to **Validation**.	String	Yes
dataset	Activity will block execution until it has validated this dataset reference exists and that it meets the specified criteria, or timeout has been reached. Dataset provided should support "MinimumSize" or "ChildItems" property.	Dataset reference	Yes
timeout	Specifies the timeout for the activity to run. If no value is specified, default value is 7 days ("7.00:00:00"). Format is d.hh:mm:ss	String	No
sleep	A delay in seconds between validation attempts. If no value is specified, default value is 10 seconds.	Integer	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
childItems	Checks if the folder has child items. Can be set to-true : Validate that the folder exists and that it has items. Blocks until at least one item is present in the folder or timeout value is reached.-false: Validate that the folder exists and that it is empty. Blocks until folder is empty or until timeout value is reached. If no value is specified, activity will block until the folder exists or until timeout is reached.	Boolean	No
minimumSize	Minimum size of a file in bytes. If no value is specified, default value is 0 bytes	Integer	No

Execute Wait activity in Azure Data Factory and Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

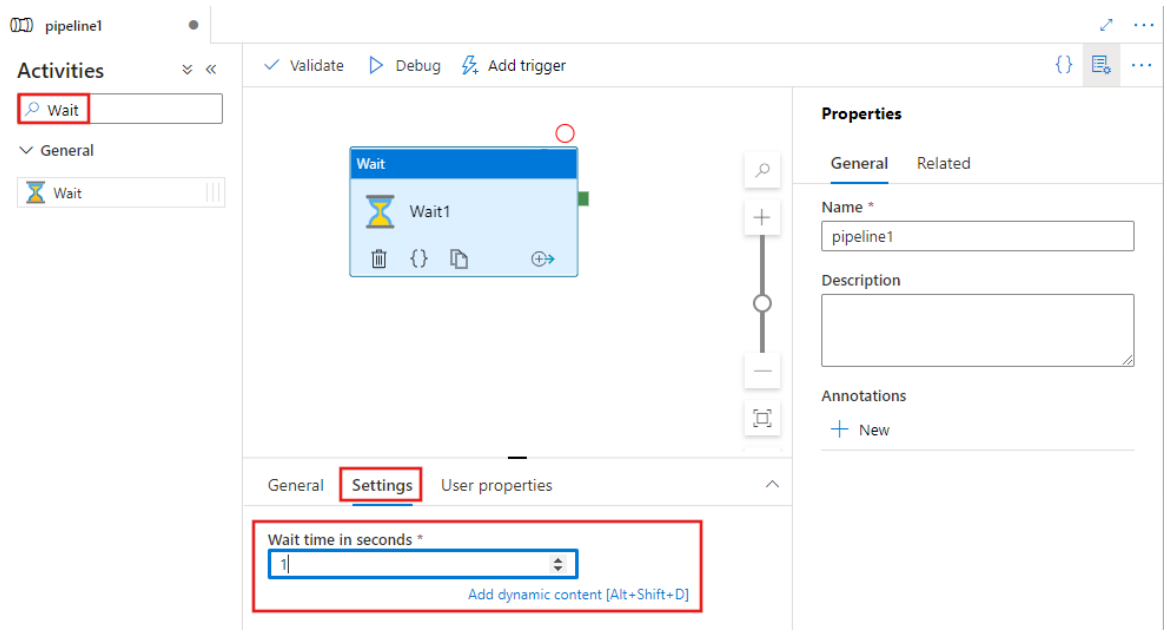
When you use a Wait activity in a pipeline, the pipeline waits for the specified period of time before continuing with execution of subsequent activities.

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Create a Wait activity with UI

To use a Wait activity in a pipeline, complete the following steps:

1. Search for *Wait* in the pipeline Activities pane, and drag a Wait activity to the pipeline canvas.
2. Select the new Wait activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Enter a number of seconds for the activity to wait. This can be a literal number, or any combination of dynamic expressions, functions, system variables, or outputs from other activities.

Syntax

```
{
    "name": "MyWaitActivity",
    "type": "Wait",
    "typeProperties": {
        "waitTimeInSeconds": 1
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the `Wait` activity.	String	Yes
type	Must be set to **Wait**.	String	Yes
waitTimeInSeconds	The number of seconds that the pipeline waits before continuing with the processing.	Integer	Yes

Example

> **NOTE**
> This section provides JSON definitions and sample PowerShell commands to run the pipeline. For a walkthrough with step-by-step instructions to create a pipeline by using Azure PowerShell and JSON definitions, see tutorial: create a data factory by using Azure PowerShell.

Pipeline with Wait activity

In this example, the pipeline has two activities: **Until** and **Wait**. The Wait activity is configured to wait for one second. The pipeline runs the Web activity in a loop with one second waiting time between each run.

```
{
    "name": "DoUntilPipeline",
    "properties": {
        "activities": [
            {
                "type": "Until",
                "typeProperties": {
                    "expression": {
                        "value": "@equals('Failed', coalesce(body('MyUnauthenticatedActivity')?.status,
actions('MyUnauthenticatedActivity')?.status, 'null'))",
                        "type": "Expression"
                    },
                    "timeout": "00:00:01",
                    "activities": [
                        {
                            "name": "MyUnauthenticatedActivity",
                            "type": "WebActivity",
                            "typeProperties": {
                                "method": "get",
                                "url": "https://www.fake.com/",
                                "headers": {
                                    "Content-Type": "application/json"
                                }
                            },
                            "dependsOn": [
                                {
                                    "activity": "MyWaitActivity",
                                    "dependencyConditions": [ "Succeeded" ]
                                }
                            ]
                        },
                        {
                            "type": "Wait",
                            "typeProperties": {
                                "waitTimeInSeconds": 1
                            },
                            "name": "MyWaitActivity"
                        }
                    ]
                },
                "name": "MyUntilActivity"
            }
        ]
    }
}
```

Web activity in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Web Activity can be used to call a custom REST endpoint from an Azure Data Factory or Synapse pipeline. You can pass datasets and linked services to be consumed and accessed by the activity.

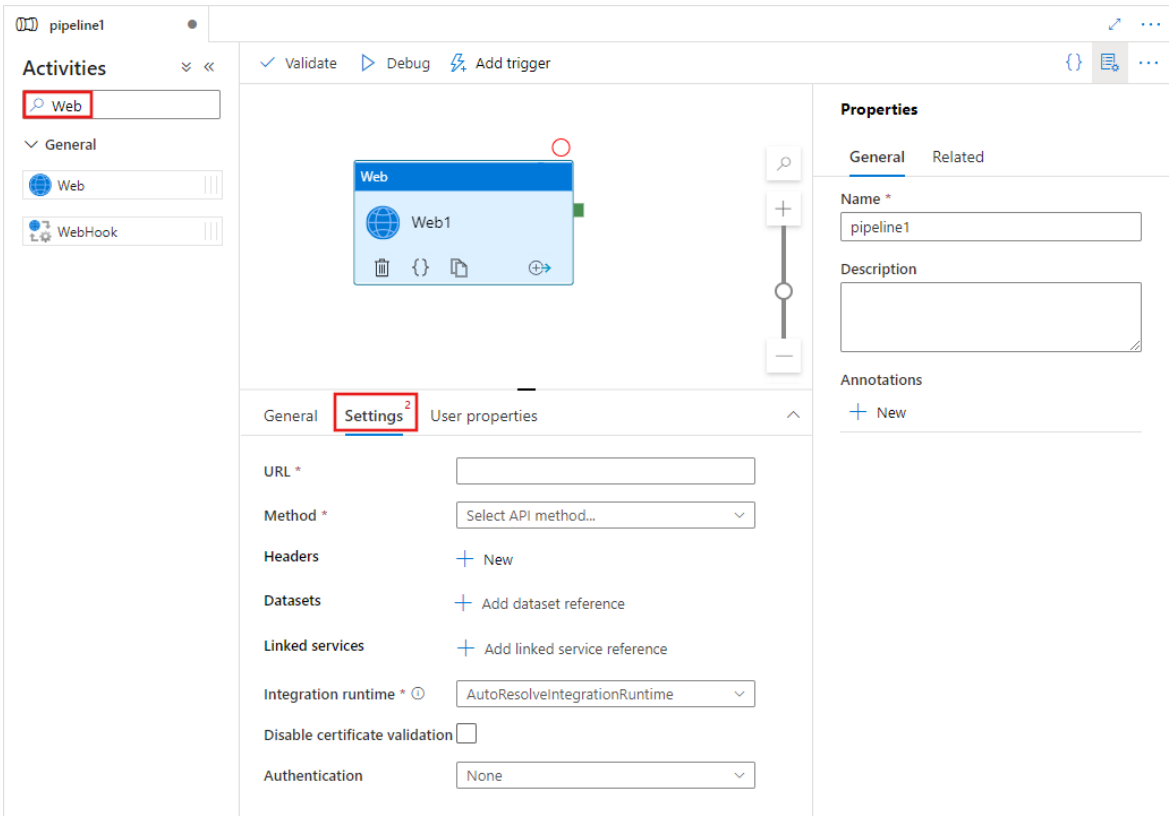
> **NOTE**
> Web Activity is supported for invoking URLs that are hosted in a private virtual network as well by leveraging self-hosted integration runtime. The integration runtime should have a line of sight to the URL endpoint.

> **NOTE**
> The maximum supported output response payload size is 4 MB.

Create a Web activity with UI

To use a Web activity in a pipeline, complete the following steps:

1. Search for *Web* in the pipeline Activities pane, and drag a Web activity to the pipeline canvas.
2. Select the new Web activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Specify a URL, which can be a literal URL string, or any combination of dynamic expressions, functions, system variables, or outputs from other activities. Provide other details to be submitted with the request.

4. Use the output from the activity as the input to any other activity, and reference the output anywhere dynamic content is supported in the destination activity.

Syntax

```
{
   "name":"MyWebActivity",
   "type":"WebActivity",
   "typeProperties":{
      "method":"Post",
      "url":"<URLEndpoint>",
      "httpRequestTimeout": "00:01:00"
      "connectVia": {
          "referenceName": "<integrationRuntimeName>",
          "type": "IntegrationRuntimeReference"
      }
      "headers":{
         "Content-Type":"application/json"
      },
      "authentication":{
         "type":"ClientCertificate",
         "pfx":"****",
         "password":"****"
      },
      "datasets":[
         {
            "referenceName":"<ConsumedDatasetName>",
            "type":"DatasetReference",
            "parameters":{
               ...
            }
         }
      ],
      "linkedServices":[
         {
            "referenceName":"<ConsumedLinkedServiceName>",
            "type":"LinkedServiceReference"
         }
      ]
   }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	Name of the web activity	String	Yes
type	Must be set to **WebActivity**.	String	Yes
method	REST API method for the target endpoint.	String. Supported Types: "GET", "POST", "PUT", "PATCH", "DELETE"	Yes

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
url	Target endpoint and path	String (or expression with resultType of string). The activity will timeout at 1 minute with an error if it does not receive a response from the endpoint. You can increase this response timeout up to 10 mins by updating the httpRequestTimeout property	Yes
httpRequestTimeout	Response timeout duration	hh:mm:ss with the max value as 00:10:00. If not explicitly specified defaults to 00:01:00	No
headers	Headers that are sent to the request. For example, to set the language and type on a request: `"headers" : { "Accept-Language": "en-us", "Content-Type": "application/json" }` .	String (or expression with resultType of string)	No
body	Represents the payload that is sent to the endpoint.	String (or expression with resultType of string). See the schema of the request payload in Request payload schema section.	Required for POST/PUT/PATCH methods.
authentication	Authentication method used for calling the endpoint. Supported Types are "Basic, Client Certificate, System-assigned Managed Identity, User-assigned Managed Identity, Service Principal." For more information, see Authentication section. If authentication is not required, exclude this property.	String (or expression with resultType of string)	No
turnOffAsync	Option to disable invoking HTTP GET on location field in the response header of a HTTP 202 Response. If set true, it stops invoking HTTP GET on http location given in response header. If set false then it continues to invoke HTTP GET call on location given in http response headers.	Allowed values are false (default) and true.	No

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
disableCertValidation	Removes server side certificate validation (not recommended unless you are connecting to a trusted server that does not use a standard CA cert).	Allowed values are false (default) and true.	No
datasets	List of datasets passed to the endpoint.	Array of dataset references. Can be an empty array.	Yes
linkedServices	List of linked services passed to endpoint.	Array of linked service references. Can be an empty array.	Yes
connectVia	The integration runtime to be used to connect to the data store. You can use the Azure integration runtime or the self-hosted integration runtime (if your data store is in a private network). If this property isn't specified, the service uses the default Azure integration runtime.	The integration runtime reference.	No

NOTE

REST endpoints that the web activity invokes must return a response of type JSON. The activity will timeout at 1 minute with an error if it does not receive a response from the endpoint. For endpoints that support Asynchronous Request-Reply pattern, the web activity will continue to wait without timeing out (upto 7 day) or till the endpoints signals completion of the job.

The following table shows the requirements for JSON content:

VALUE TYPE	REQUEST BODY	RESPONSE BODY
JSON object	Supported	Supported
JSON array	Supported (At present, JSON arrays don't work as a result of a bug. A fix is in progress.)	Unsupported
JSON value	Supported	Unsupported
Non-JSON type	Unsupported	Unsupported

Authentication

Below are the supported authentication types in the web activity.

None

If authentication is not required, do not include the "authentication" property.

Basic

Specify user name and password to use with the basic authentication.

```
"authentication":{
   "type":"Basic",
   "username":"****",
   "password":"****"
}
```

Client certificate

Specify base64-encoded contents of a PFX file and the password.

```
"authentication":{
   "type":"ClientCertificate",
   "pfx":"****",
   "password":"****"
}
```

Certificate needs to be an x509 certificate. For conversion to PFX file, you can use your favorite utility. For base-64 encoding, you may use following PowerShell snippet.

```
$fileContentBytes = get-content 'enr.dev.webactivity.pfx' -AsByteStream

[System.Convert]::ToBase64String($fileContentBytes) | Out-File ‘pfx-encoded-bytes.txt’
```

Managed Identity

Specify the resource uri for which the access token will be requested using the managed identity for the data factory or Synapse workspace instance. To call the Azure Resource Management API, use `https://management.azure.com/`. For more information about how managed identities works see the managed identities for Azure resources overview page.

```
"authentication": {
 "type": "MSI",
 "resource": "https://management.azure.com/"
}
```

> **NOTE**
> If your data factory or Synapse workspace is configured with a git repository, you must store your credentials in Azure Key Vault to use basic or client certificate authentication. The service does not store passwords in git.

Request payload schema

When you use the POST/PUT method, the body property represents the payload that is sent to the endpoint. You can pass linked services and datasets as part of the payload. Here is the schema for the payload:

```
{
    "body": {
        "myMessage": "Sample",
        "datasets": [{
            "name": "MyDataset1",
            "properties": {
                ...
            }
        }],
        "linkedServices": [{
            "name": "MyStorageLinkedService1",
            "properties": {
                ...
            }
        }]
    }
}
```

Example

In this example, the web activity in the pipeline calls a REST end point. It passes an Azure SQL linked service and an Azure SQL dataset to the endpoint. The REST end point uses the Azure SQL connection string to connect to the logical SQL server and returns the name of the instance of SQL server.

Pipeline definition

```
{
    "name": "<MyWebActivityPipeline>",
    "properties": {
        "activities": [
            {
                "name": "<MyWebActivity>",
                "type": "WebActivity",
                "typeProperties": {
                    "method": "Post",
                    "url": "@pipeline().parameters.url",
                    "headers": {
                        "Content-Type": "application/json"
                    },
                    "authentication": {
                        "type": "ClientCertificate",
                        "pfx": "*****",
                        "password": "*****"
                    },
                    "datasets": [
                        {
                            "referenceName": "MySQLDataset",
                            "type": "DatasetReference",
                            "parameters": {
                                "SqlTableName": "@pipeline().parameters.sqlTableName"
                            }
                        }
                    ],
                    "linkedServices": [
                        {
                            "referenceName": "SqlLinkedService",
                            "type": "LinkedServiceReference"
                        }
                    ]
                }
            }
        ],
        "parameters": {
            "sqlTableName": {
                "type": "String"
            },
            "url": {
                "type": "String"
            }
        }
    }
}
```

Pipeline parameter values

```
{
    "sqlTableName": "department",
    "url": "https://adftes.azurewebsites.net/api/execute/running"
}
```

Web service endpoint code

```
[HttpPost]
public HttpResponseMessage Execute(JObject payload)
{
    Trace.TraceInformation("Start Execute");

    JObject result = new JObject();
    result.Add("status", "complete");

    JArray datasets = payload.GetValue("datasets") as JArray;
    result.Add("sinktable", datasets[0]["properties"]["typeProperties"]["tableName"].ToString());

    JArray linkedServices = payload.GetValue("linkedServices") as JArray;
    string connString = linkedServices[0]["properties"]["typeProperties"]["connectionString"].ToString();

    System.Data.SqlClient.SqlConnection sqlConn = new System.Data.SqlClient.SqlConnection(connString);

    result.Add("sinkServer", sqlConn.DataSource);

    Trace.TraceInformation("Stop Execute");

    return this.Request.CreateResponse(HttpStatusCode.OK, result);
}
```

Webhook activity in Azure Data Factory

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

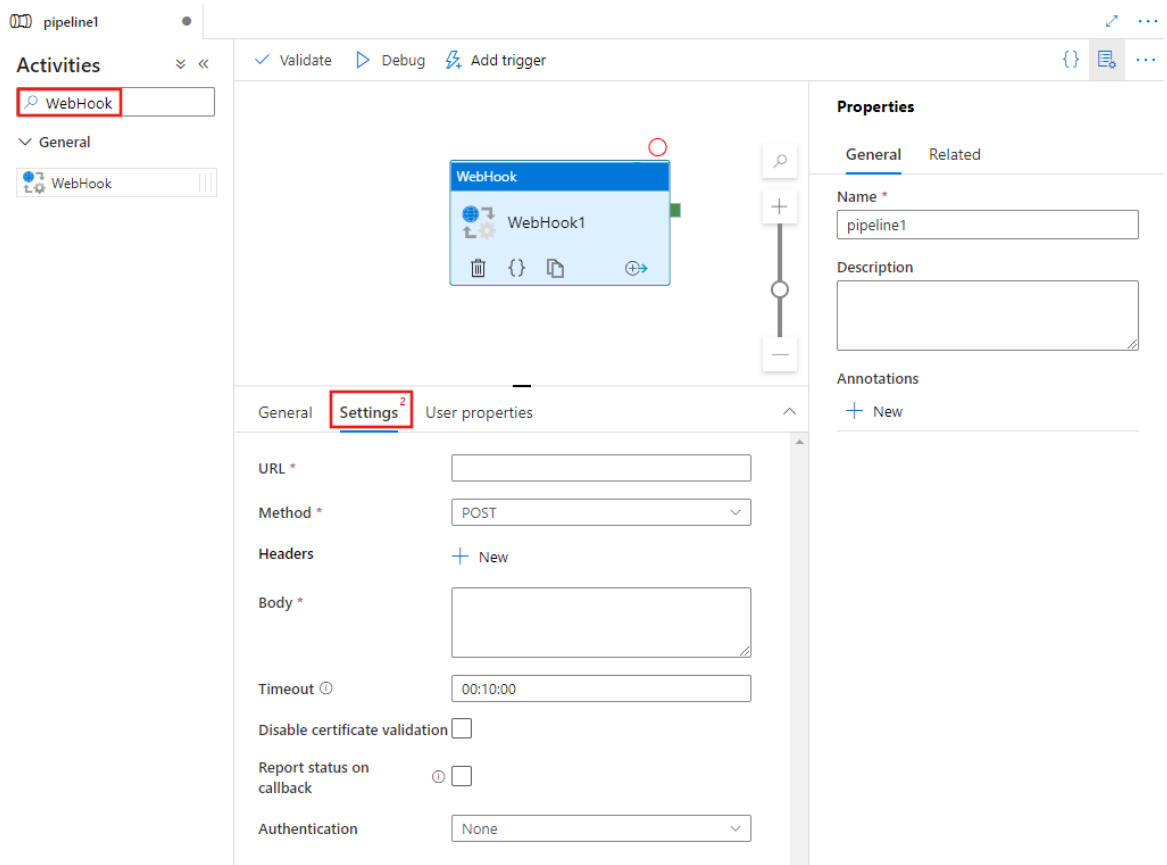
A webhook activity can control the execution of pipelines through custom code. With the webhook activity, code can call an endpoint and pass it a callback URL. The pipeline run waits for the callback invocation before it proceeds to the next activity.

> **IMPORTANT**
> WebHook activity now allows you to surface error status and custom messages back to activity and pipeline. Set *reportStatusOnCallBack* to true, and include *StatusCode* and *Error* in callback payload. For more information, see Additional Notes section.

Create a Webhook activity with UI

To use a Webhook activity in a pipeline, complete the following steps:

1. Search for *Webhook* in the pipeline Activities pane, and drag a Webhook activity to the pipeline canvas.
2. Select the new Fail activity on the canvas if it is not already selected, and its **Settings** tab, to edit its details.



3. Specify a URL for the webhook, which can be a literal URL string, or any combination of dynamic expressions, functions, system variables, or outputs from other activities. Provide other details to be submitted with the request.

4. Use the output from the activity as the input to any other activity, and reference the output anywhere dynamic content is supported in the destination activity.

Syntax

```
{
    "name": "MyWebHookActivity",
    "type": "WebHook",
    "typeProperties": {
        "method": "POST",
        "url": "<URLEndpoint>",
        "headers": {
            "Content-Type": "application/json"
        },
        "body": {
            "key": "value"
        },
        "timeout": "00:03:00",
        "reportStatusOnCallBack": false,
        "authentication": {
            "type": "ClientCertificate",
            "pfx": "****",
            "password": "****"
        }
    }
}
```

Type properties

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
name	The name of the webhook activity.	String	Yes
type	Must be set to "WebHook".	String	Yes
method	The REST API method for the target endpoint.	String. The supported type is "POST".	Yes
url	The target endpoint and path.	A string or an expression with the **resultType** value of a string.	Yes
headers	Headers that are sent to the request. Here's an example that sets the language and type on a request: `"headers" : { "Accept-Language": "en-us", "Content-Type": "application/json" }` .	A string or an expression with the **resultType** value of a string.	Yes. A `Content-Type` header like `"headers":{ "Content-Type":"application/json"}` is required.

PROPERTY	DESCRIPTION	ALLOWED VALUES	REQUIRED
body	Represents the payload that is sent to the endpoint.	Valid JSON or an expression with the **resultType** value of JSON. See Request payload schema for the schema of the request payload.	Yes
authentication	The authentication method used to call the endpoint. Supported types are "Basic" and "ClientCertificate". For more information, see Authentication. If authentication isn't required, exclude this property.	A string or an expression with the **resultType** value of a string.	No
timeout	How long the activity waits for the callback specified by **callBackUri** to be invoked. The default value is 10 minutes ("00:10:00"). Values have the TimeSpan format *d.hh:mm:ss*.	String	No
Report status on callback	Lets a user report the failed status of a webhook activity.	Boolean	No

Authentication

A webhook activity supports the following authentication types.

None

If authentication isn't required, don't include the **authentication** property.

Basic

Specify the username and password to use with basic authentication.

```
"authentication":{
   "type":"Basic",
   "username":"****",
   "password":"****"
}
```

Client certificate

Specify the Base64-encoded contents of a PFX file and a password.

```
"authentication":{
   "type":"ClientCertificate",
   "pfx":"****",
   "password":"****"
}
```

Managed identity

Use the managed identity for your data factory or Synapse workspace to specify the resource URI for which the access token is requested. To call the Azure Resource Management API, use `https://management.azure.com/`. For more information about how managed identities work, see the managed identities for Azure resources overview.

```
"authentication": {
    "type": "MSI",
    "resource": "https://management.azure.com/"
}
```

> **NOTE**
> If the service is configured with a Git repository, you must store your credentials in Azure Key Vault to use basic or client-certificate authentication. The service doesn't store passwords in Git.

Additional notes

The service passes the additional property **callBackUri** in the body sent to the URL endpoint. The service expects this URI to be invoked before the specified timeout value. If the URI isn't invoked, the activity fails with the status "TimedOut".

The webhook activity fails when the call to the custom endpoint fails. Any error message can be added to the callback body and used in a later activity.

For every REST API call, the client times out if the endpoint doesn't respond within one minute. This behavior is standard HTTP best practice. To fix this problem, implement a 202 pattern. In the current case, the endpoint returns 202 (Accepted) and the client polls.

The one-minute timeout on the request has nothing to do with the activity timeout. The latter is used to wait for the callback specified by **callbackUri**.

The body passed back to the callback URI must be valid JSON. Set the `Content-Type` header to `application/json`.

When you use the **Report status on callback** property, you must add the following code to the body when you make the callback:

```
{
    "Output": {
        // output object is used in activity output
        "testProp": "testPropValue"
    },
    "Error": {
        // Optional, set it when you want to fail the activity
        "ErrorCode": "testErrorCode",
        "Message": "error message to show in activity error"
    },
    "StatusCode": "403" // when status code is >=400, activity is marked as failed
}
```

Mapping data flow transformation overview

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Below is a list of the transformations currently supported in mapping data flow. Click on each transformations to learn its configuration details.

NAME	CATEGORY	DESCRIPTION
Aggregate	Schema modifier	Define different types of aggregations such as SUM, MIN, MAX, and COUNT grouped by existing or computed columns.
Alter row	Row modifier	Set insert, delete, update, and upsert policies on rows.
Assert	Row modifier	Set assert rules for each row.
Cast	Schema modifier	Change column data types with type checking.
Conditional split	Multiple inputs/outputs	Route rows of data to different streams based on matching conditions.
Derived column	Schema modifier	Generate new columns or modify existing fields using the data flow expression language.
External call	Schema modifier	Call external endpoints inline row-by-row.
Exists	Multiple inputs/outputs	Check whether your data exists in another source or stream.
Filter	Row modifier	Filter a row based upon a condition.
Flatten	Formatters	Take array values inside hierarchical structures such as JSON and unroll them into individual rows.
Flowlet	Flowlets	Build and include custom re-usable transformation logic.
Join	Multiple inputs/outputs	Combine data from two sources or streams.

NAME	CATEGORY	DESCRIPTION
Lookup	Multiple inputs/outputs	Reference data from another source.
New branch	Multiple inputs/outputs	Apply multiple sets of operations and transformations against the same data stream.
Parse	Formatters	Parse text columns in your data stream that are strings of JSON, delimited text, or XML formatted text.
Pivot	Schema modifier	An aggregation where one or more grouping columns has its distinct row values transformed into individual columns.
Rank	Schema modifier	Generate an ordered ranking based upon sort conditions
Select	Schema modifier	Alias columns and stream names, and drop or reorder columns
Sink	-	A final destination for your data
Sort	Row modifier	Sort incoming rows on the current data stream
Source	-	A data source for the data flow
Stringify	Formatters	Turn complex types into plain strings
Surrogate key	Schema modifier	Add an incrementing non-business arbitrary key value
Union	Multiple inputs/outputs	Combine multiple data streams vertically
Unpivot	Schema modifier	Pivot columns into row values
Window	Schema modifier	Define window-based aggregations of columns in your data streams.

Aggregate transformation in mapping data flow

8/19/2022 • 3 minutes to read • Edit Online

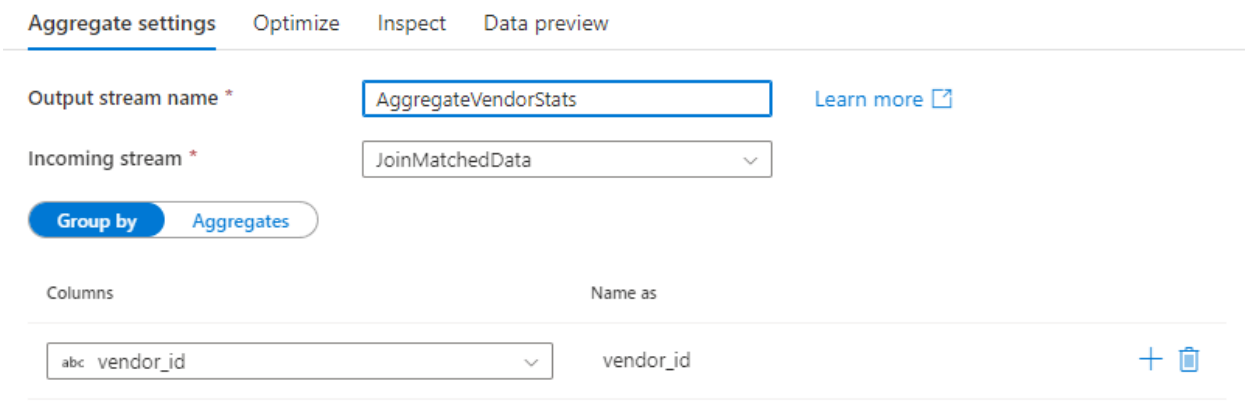
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The Aggregate transformation defines aggregations of columns in your data streams. Using the Expression Builder, you can define different types of aggregations such as SUM, MIN, MAX, and COUNT grouped by existing or computed columns.

Group by

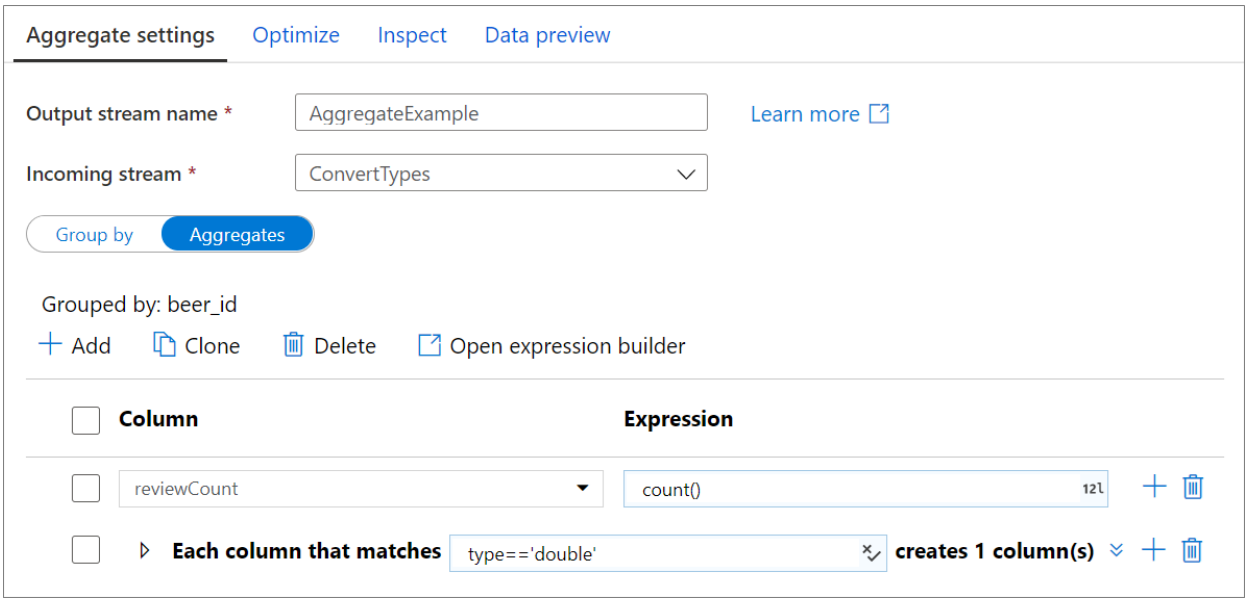
Select an existing column or create a new computed column to use as a group by clause for your aggregation. To use an existing column, select it from the dropdown. To create a new computed column, hover over the clause and click **Computed column**. This opens the data flow expression builder. Once you create your computed column, enter the output column name under the **Name as** field. If you wish to add an additional group by clause, hover over an existing clause and click the plus icon.



A group by clause is optional in an Aggregate transformation.

Aggregate columns

Go to the **Aggregates** tab to build aggregation expressions. You can either overwrite an existing column with an aggregation, or create a new field with a new name. The aggregation expression is entered in the right-hand box next to the column name selector. To edit the expression, click on the text box and open the expression builder. To add more aggregate columns, click on **Add** above the column list or the plus icon next to an existing aggregate column. Choose either **Add column** or **Add column pattern**. Each aggregation expression must contain at least one aggregate function.



NOTE

In Debug mode, the expression builder cannot produce data previews with aggregate functions. To view data previews for aggregate transformations, close the expression builder and view the data via the 'Data Preview' tab.

Column patterns

Use column patterns to apply the same aggregation to a set of columns. This is useful if you wish to persist many columns from the input schema as they are dropped by default. Use a heuristic such as `first()` to persist input columns through the aggregation.

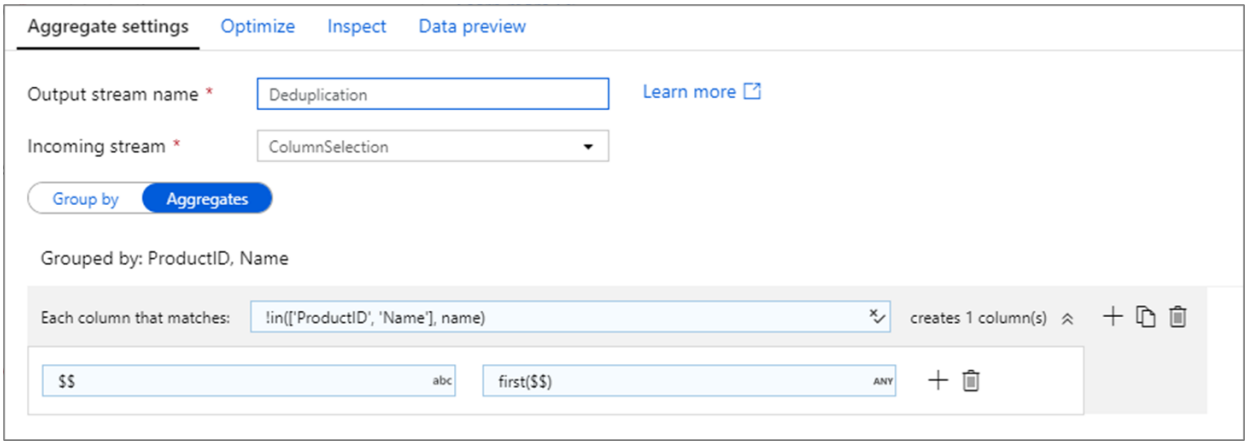
Reconnect rows and columns

Aggregate transformations are similar to SQL aggregate select queries. Columns that aren't included in your group by clause or aggregate functions won't flow through to the output of your aggregate transformation. If you wish to include other columns in your aggregated output, do one of the following methods:

- Use an aggregate function such as `last()` or `first()` to include that additional column.
- Rejoin the columns to your output stream using the self join pattern.

Removing duplicate rows

A common use of the aggregate transformation is removing or identifying duplicate entries in source data. This process is known as deduplication. Based upon a set of group by keys, use a heuristic of your choosing to determine which duplicate row to keep. Common heuristics are `first()`, `last()`, `max()`, and `min()`. Use column patterns to apply the rule to every column except for the group by columns.



In the above example, columns `ProductID` and `Name` are being use for grouping. If two rows have the same values for those two columns, they're considered duplicates. In this aggregate transformation, the values of the first row matched will be kept and all others will be dropped. Using column pattern syntax, all columns whose names aren't `ProductID` and `Name` are mapped to their existing column name and given the value of the first matched rows. The output schema is the same as the input schema.

For data validation scenarios, the `count()` function can be used to count how many duplicates there are.

Data flow script

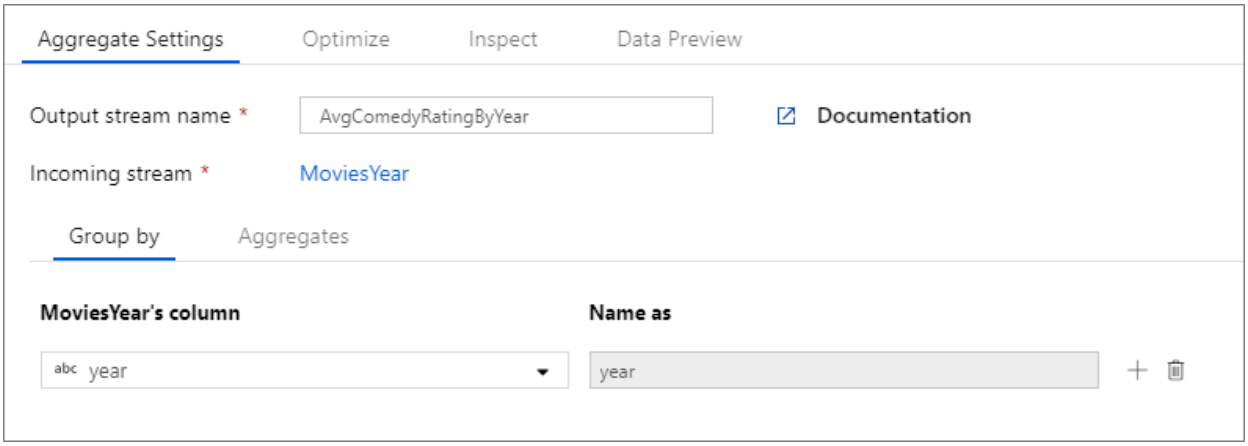
Syntax

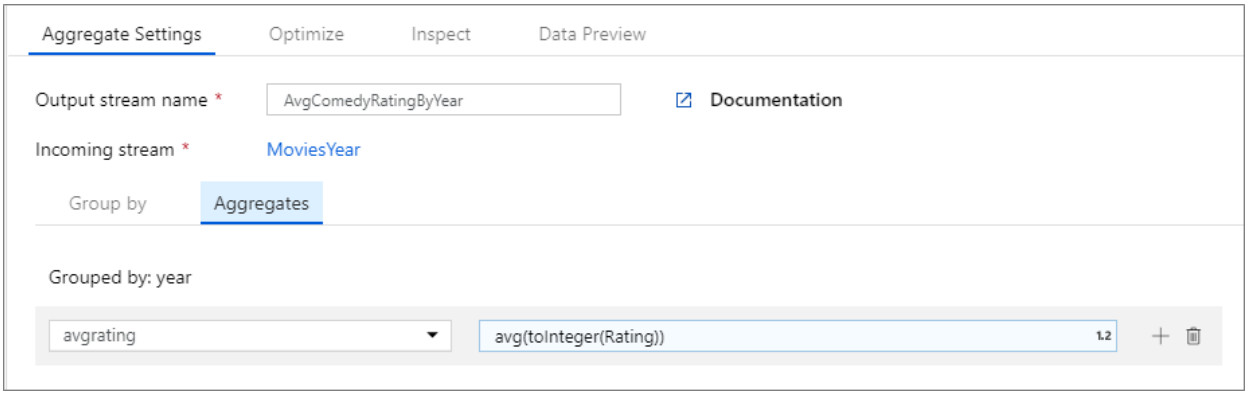
```
<incomingStream>
    aggregate(
           groupBy(
                <groupByColumnName> = <groupByExpression1>,
                <groupByExpression2>
               ),
           <aggregateColumn1> = <aggregateExpression1>,
           <aggregateColumn2> = <aggregateExpression2>,
           each(
                match(matchExpression),
                <metadataColumn1> = <metadataExpression1>,
                <metadataColumn2> = <metadataExpression2>
               )
          ) ~> <aggregateTransformationName>
```

Example

The below example takes an incoming stream `MoviesYear` and groups rows by column `year`. The transformation creates an aggregate column `avgrating` that evaluates to the average of column `Rating`. This aggregate transformation is named `AvgComedyRatingsByYear`.

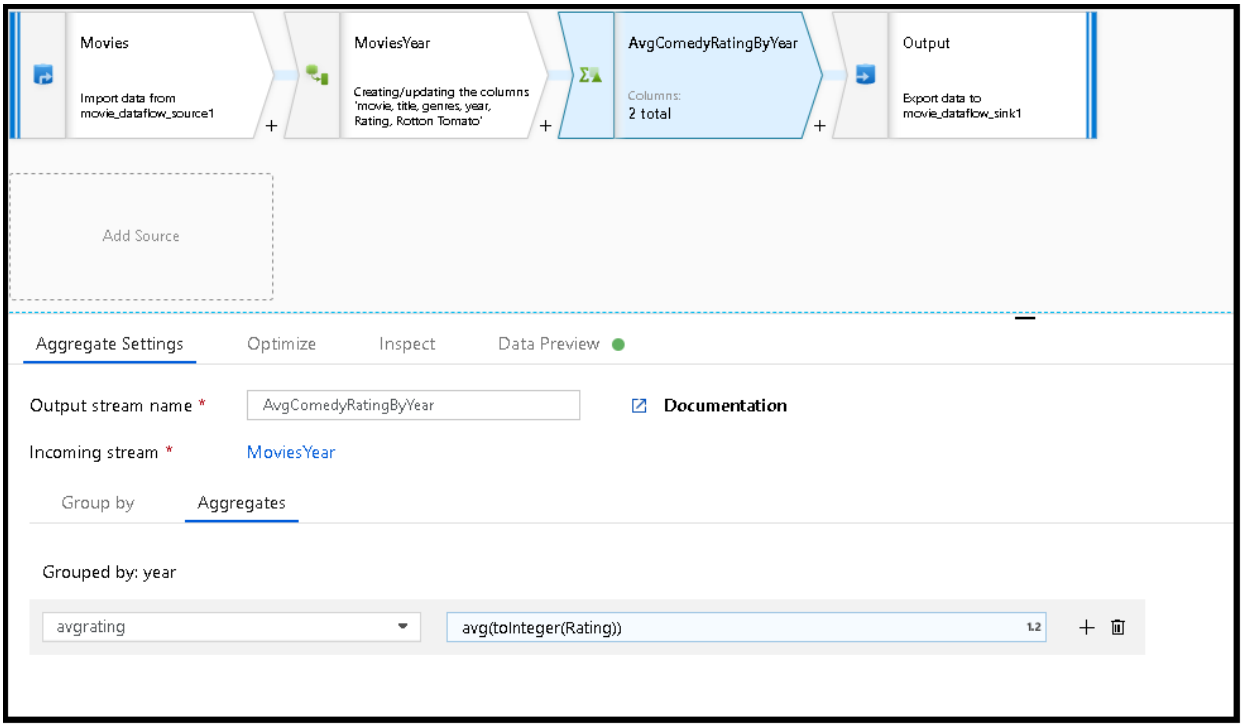
In the UI, this transformation looks like the below image:





The data flow script for this transformation is in the snippet below.

```
MoviesYear aggregate(
                groupBy(year),
                avgrating = avg(toInteger(Rating))
            ) ~> AvgComedyRatingByYear
```



`MoviesYear`: Derived Column defining year and title columns `AvgComedyRatingByYear`: Aggregate transformation for average rating of comedies grouped by year `avgrating`: Name of new column being created to hold the aggregated value

```
MoviesYear aggregate(groupBy(year),
 avgrating = avg(toInteger(Rating))) ~> AvgComedyRatingByYear
```

Next steps

- Define window-based aggregation using the Window transformation

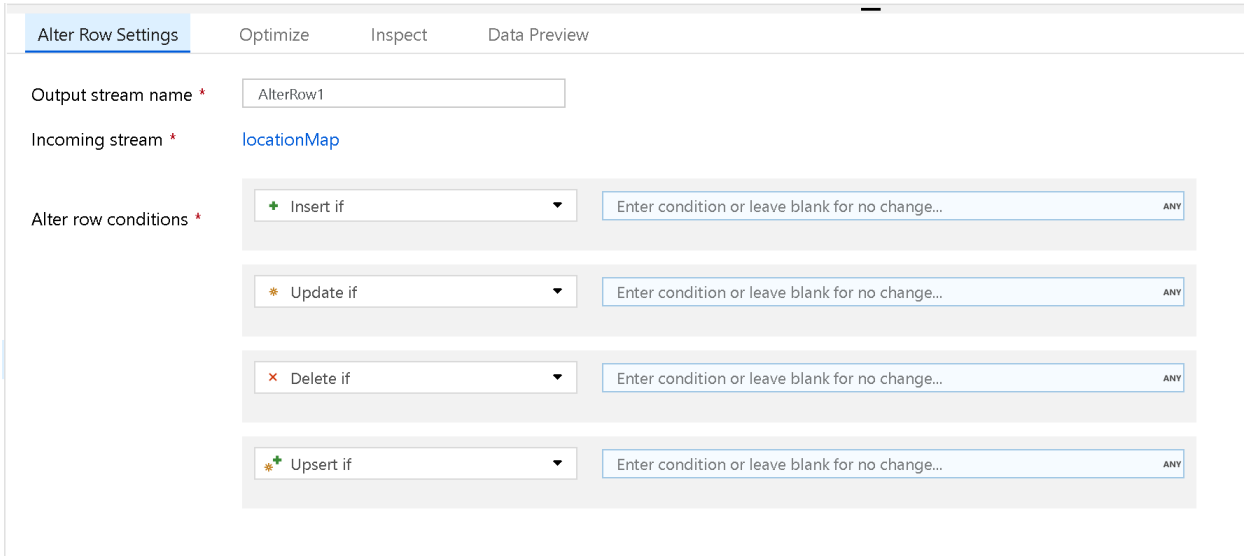
Alter row transformation in mapping data flow

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

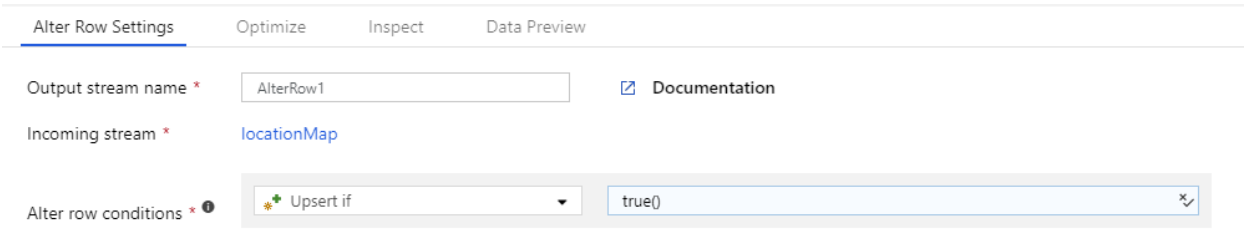
Use the Alter Row transformation to set insert, delete, update, and upsert policies on rows. You can add one-to-many conditions as expressions. These conditions should be specified in order of priority, as each row will be marked with the policy corresponding to the first-matching expression. Each of those conditions can result in a row (or rows) being inserted, updated, deleted, or upserted. Alter Row can produce both DDL & DML actions against your database.



Alter Row transformations will only operate on database, REST, or CosmosDB sinks in your data flow. The actions that you assign to rows (insert, update, delete, upsert) won't occur during debug sessions. Run an Execute Data Flow activity in a pipeline to enact the alter row policies on your database tables.

Specify a default row policy

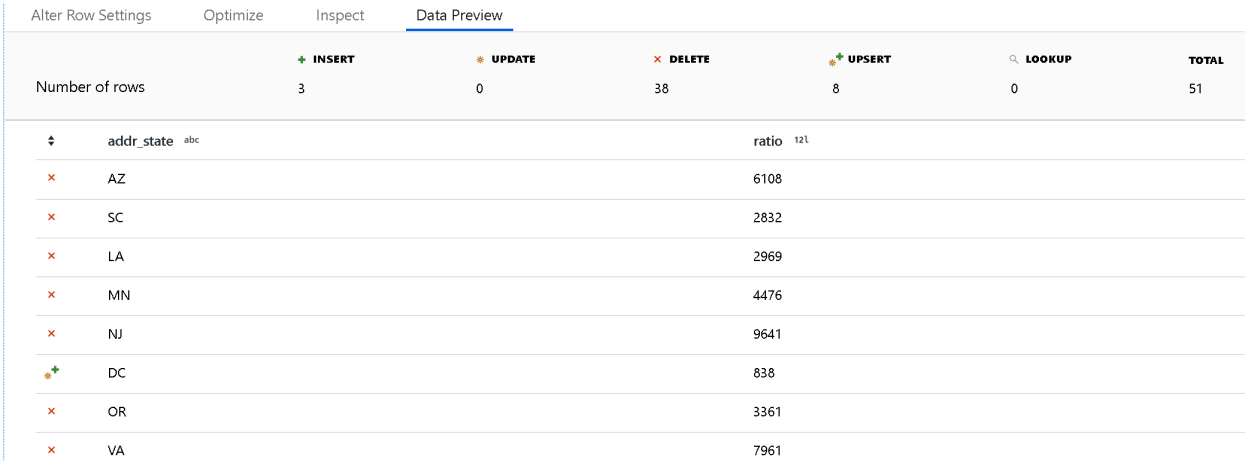
Create an Alter Row transformation and specify a row policy with a condition of `true()`. Each row that doesn't match any of the previously defined expressions will be marked for the specified row policy. By default, each row that doesn't match any conditional expression will be marked for `Insert`.



> **NOTE**
>
> To mark all rows with one policy, you can create a condition for that policy and specify the condition as `true()`.

View policies in data preview

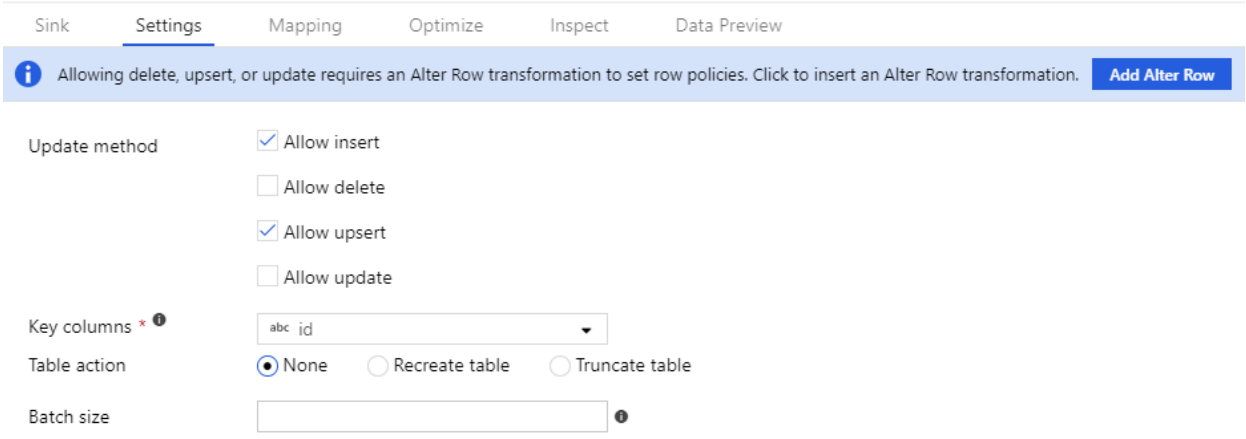
Use debug mode to view the results of your alter row policies in the data preview pane. A data preview of an alter row transformation won't produce DDL or DML actions against your target.



Each alter row policy is represented by an icon that indicates whether an insert, update, upsert, or deleted action will occur. The top header shows how many rows are affected by each policy in the preview.

Allow alter row policies in sink

For the alter row policies to work, the data stream must write to a database or Cosmos sink. In the **Settings** tab in your sink, enable which alter row policies are allowed for that sink.



The default behavior is to only allow inserts. To allow updates, upserts, or deletes, check the box in the sink corresponding to that condition. If updates, upserts, or, deletes are enabled, you must specify which key columns in the sink to match on.

> **NOTE**
>
> If your inserts, updates, or upserts modify the schema of the target table in the sink, the data flow will fail. To modify the target schema in your database, choose **Recreate table** as the table action. This will drop and recreate your table with the new schema definition.

The sink transformation requires either a single key or a series of keys for unique row identification in your

target database. For SQL sinks, set the keys in the sink settings tab. For CosmosDB, set the partition key in the settings and also set the CosmosDB system field "id" in your sink mapping. For CosmosDB, it is mandatory to include the system column "id" for updates, upserts, and deletes.

Merges and upserts with Azure SQL Database and Azure Synapse

Data Flows support merges against Azure SQL Database and Azure Synapse database pool (data warehouse) with the upsert option.

However, you may run into scenarios where your target database schema utilized the identity property of key columns. The service requires you to identify the keys that you will use to match the row values for updates and upserts. But if the target column has the identity property set and you are using the upsert policy, the target database will not allow you to write to the column. You may also run into errors when you try to upsert against a distributed table's distribution column.

Here are ways to fix that:

1. Go to the Sink transformation Settings and set "Skip writing key columns". This will tell the service to not write the column that you have selected as the key value for your mapping.
2. If that key column is not the column that is causing the issue for identity columns, then you can use the Sink transformation pre-processing SQL option: `SET IDENTITY_INSERT tbl_content ON`. Then, turn it off with the post-processing SQL property: `SET IDENTITY_INSERT tbl_content OFF`.
3. For both the identity case and the distribution column case, you can switch your logic from Upsert to using a separate update condition and a separate insert condition using a Conditional Split transformation. This way, you can set the mapping on the update path to ignore the key column mapping.

Data flow script

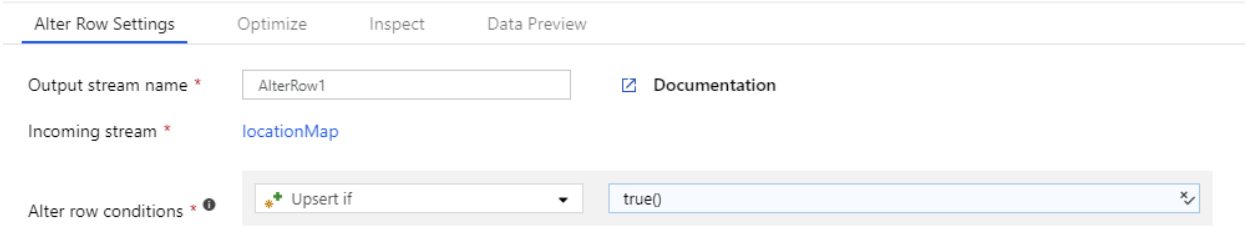
Syntax

```
<incomingStream>
    alterRow(
           insertIf(<condition>?),
           updateIf(<condition>?),
           deleteIf(<condition>?),
           upsertIf(<condition>?),
        ) ~> <alterRowTransformationName>
```

Example

The below example is an alter row transformation named `CleanData` that takes an incoming stream `SpecifyUpsertConditions` and creates three alter row conditions. In the previous transformation, a column named `alterRowCondition` is calculated that determines whether or not a row is inserted, updated, or deleted in the database. If the value of the column has a string value that matches the alter row rule, it is assigned that policy.

In the UI, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
SpecifyUpsertConditions alterRow(insertIf(alterRowCondition == 'insert'),
 updateIf(alterRowCondition == 'update'),
 deleteIf(alterRowCondition == 'delete')) ~> AlterRow
```

Next steps

After the Alter Row transformation, you may want to sink your data into a destination data store.

Conditional split transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

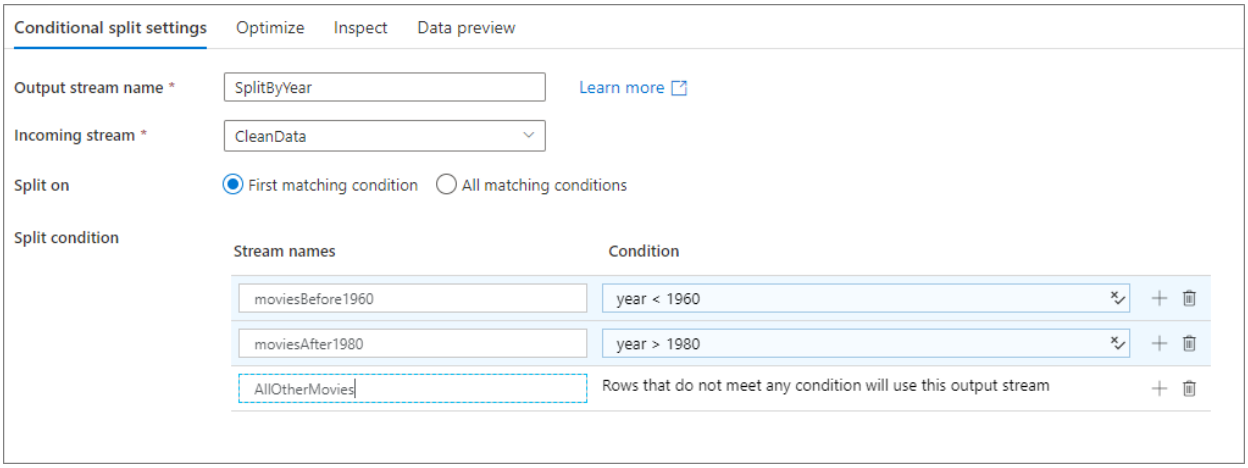
Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The conditional split transformation routes data rows to different streams based on matching conditions. The conditional split transformation is similar to a CASE decision structure in a programming language. The transformation evaluates expressions, and based on the results, directs the data row to the specified stream.

Configuration

The **Split on** setting determines whether the row of data flows to the first matching stream or every stream it matches to.

Use the data flow expression builder to enter an expression for the split condition. To add a new condition, click on the plus icon in an existing row. A default stream can be added as well for rows that don't match any condition.



Data flow script

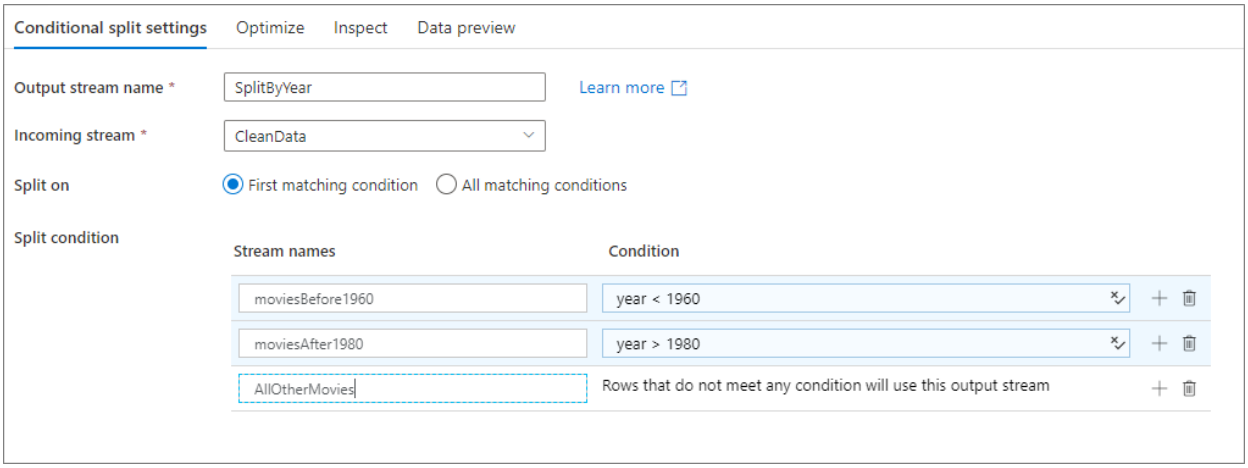
Syntax

```
<incomingStream>
    split(
        <conditionalExpression1>
        <conditionalExpression2>
        ...
        disjoint: {true | false}
    ) ~> <splitTx>@(stream1, stream2, ..., <defaultStream>)
```

Example

The below example is a conditional split transformation named `SplitByYear` that takes in incoming stream `CleanData`. This transformation has two split conditions `year < 1960` and `year > 1980`. `disjoint` is false because the data goes to the first matching condition rather than all matching conditions. Every row matching the first condition goes to output stream `moviesBefore1960`. All remaining rows matching the second condition go to output stream `moviesAFter1980`. All other rows flow through the default stream `AllOtherMovies`.

In the service UI, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
CleanData
    split(
        year < 1960,
     year > 1980,
     disjoint: false
    ) ~> SplitByYear@(moviesBefore1960, moviesAfter1980, AllOtherMovies)
```

Next steps

Common data flow transformations used with conditional split are the join transformation, lookup transformation, and the select transformation

Derived column transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

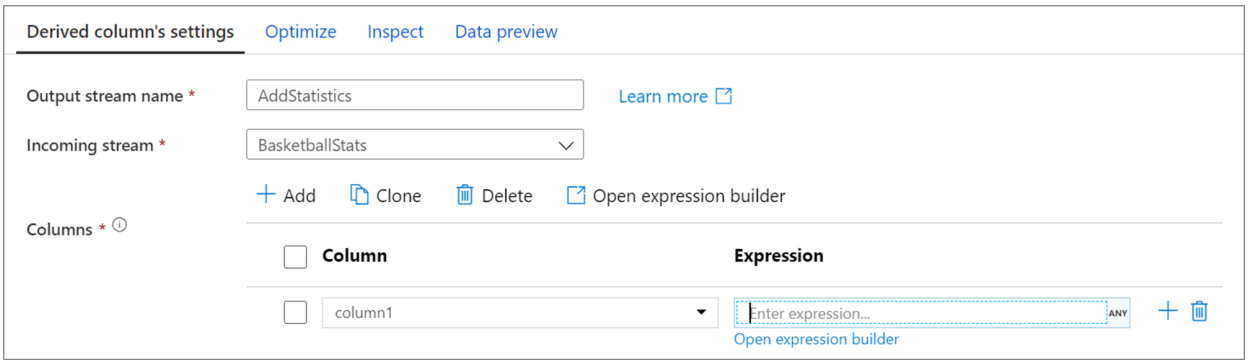
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

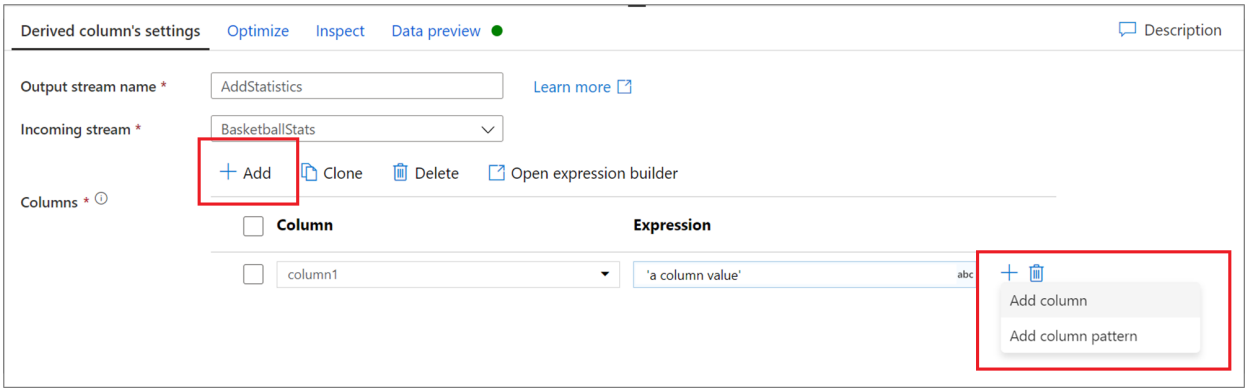
Use the derived column transformation to generate new columns in your data flow or to modify existing fields.

Create and update columns

When creating a derived column, you can either generate a new column or update an existing one. In the **Column** textbox, enter in the column you are creating. To override an existing column in your schema, you can use the column dropdown. To build the derived column's expression, click on the **Enter expression** textbox. You can either start typing your expression or open up the expression builder to construct your logic.

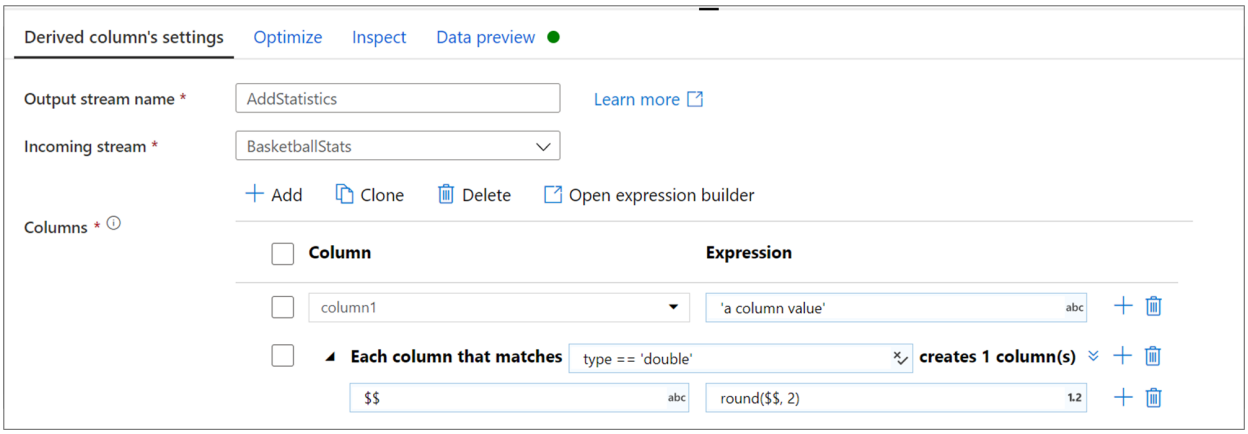


To add more derived columns, click on **Add** above the column list or the plus icon next to an existing derived column. Choose either **Add column** or **Add column pattern**.



Column patterns

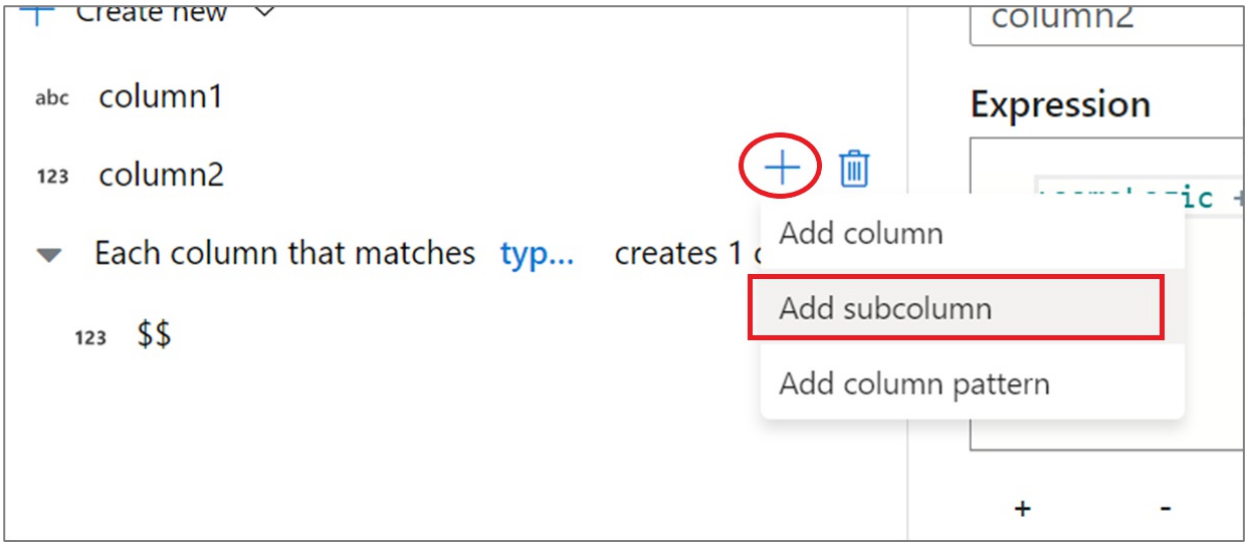
In cases where your schema is not explicitly defined or if you want to update a set of columns in bulk, you will want to create column patterns. Column patterns allow for you to match columns using rules based upon the column metadata and create derived columns for each matched column. For more information, learn how to build column patterns in the derived column transformation.



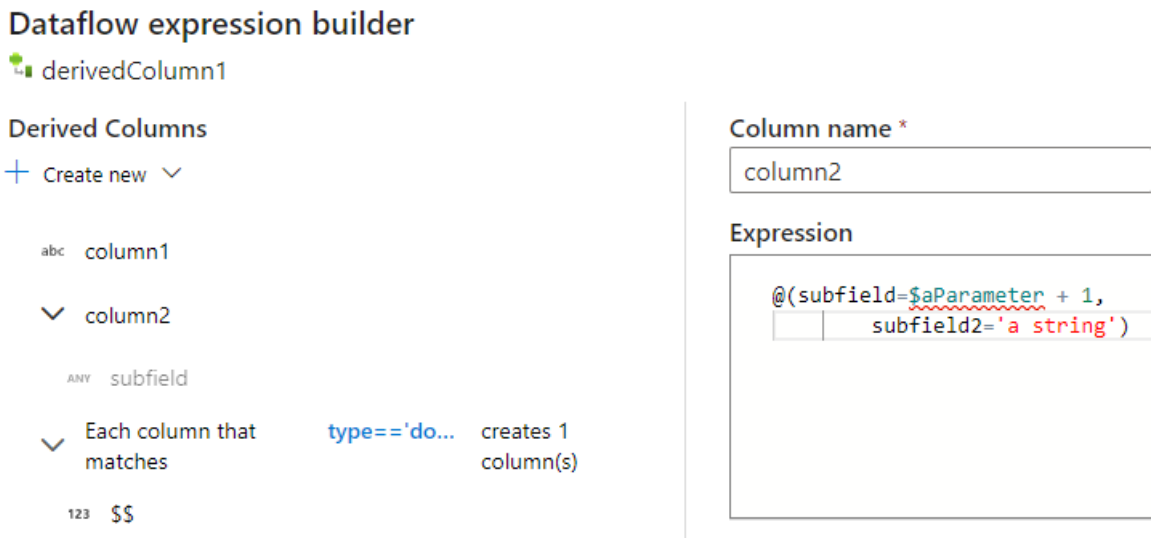
Building schemas using the expression builder

When using the mapping data flow expression builder, you can create, edit, and manage your derived columns in the **Derived Columns** section. All columns that are created or changed in the transformation are listed. Interactively choose which column or pattern you are editing by clicking on the column name. To add an additional column select **Create new** and choose whether you wish to add a single column or a pattern.

When working with complex columns, you can create subcolumns. To do this, click on the plus icon next to any column and select **Add subcolumn**. For more information on handling complex types in data flow, see JSON handling in mapping data flow.



For more information on handling complex types in data flow, see JSON handling in mapping data flow.



Data flow script

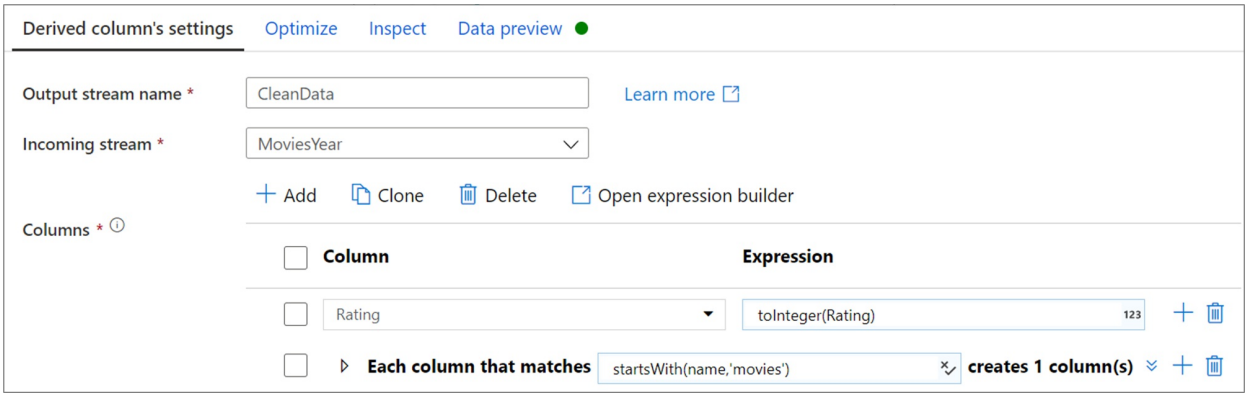
Syntax

```
<incomingStream>
    derive(
           <columnName1> = <expression1>,
           <columnName2> = <expression2>,
           each(
                match(matchExpression),
                <metadataColumn1> = <metadataExpression1>,
                <metadataColumn2> = <metadataExpression2>
               )
          ) ~> <deriveTransformationName>
```

Example

The below example is a derived column named `CleanData` that takes an incoming stream `MoviesYear` and creates two derived columns. The first derived column replaces column `Rating` with Rating's value as an integer type. The second derived column is a pattern that matches each column whose name starts with 'movies'. For each matched column, it creates a column `movie` that is equal to the value of the matched column prefixed with 'movie_'.

In the UI, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
MoviesYear derive(
                Rating = toInteger(Rating),
          each(
                    match(startsWith(name,'movies')),
                    'movie' = 'movie_' + toString($$)
                )
            ) ~> CleanData
```

Next steps

- Learn more about the Mapping Data Flow expression language.

Exists transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

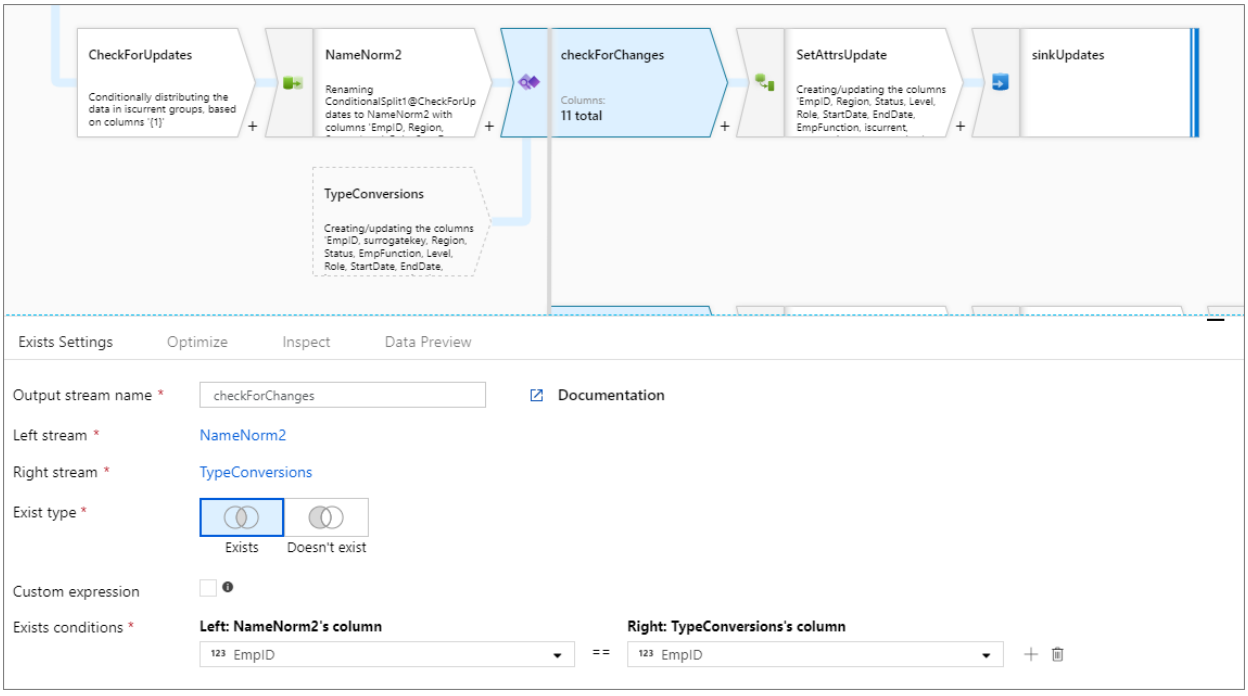
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The exists transformation is a row filtering transformation that checks whether your data exists in another source or stream. The output stream includes all rows in the left stream that either exist or don't exist in the right stream. The exists transformation is similar to `SQL WHERE EXISTS` and `SQL WHERE NOT EXISTS`.

Configuration

1. Choose which data stream you're checking for existence in the **Right stream** dropdown.
2. Specify whether you're looking for the data to exist or not exist in the **Exist type** setting.
3. Select whether or not your want a **Custom expression**.
4. Choose which key columns you want to compare as your exists conditions. By default, data flow looks for equality between one column in each stream. To compare via a computed value, hover over the column dropdown and select **Computed column**.



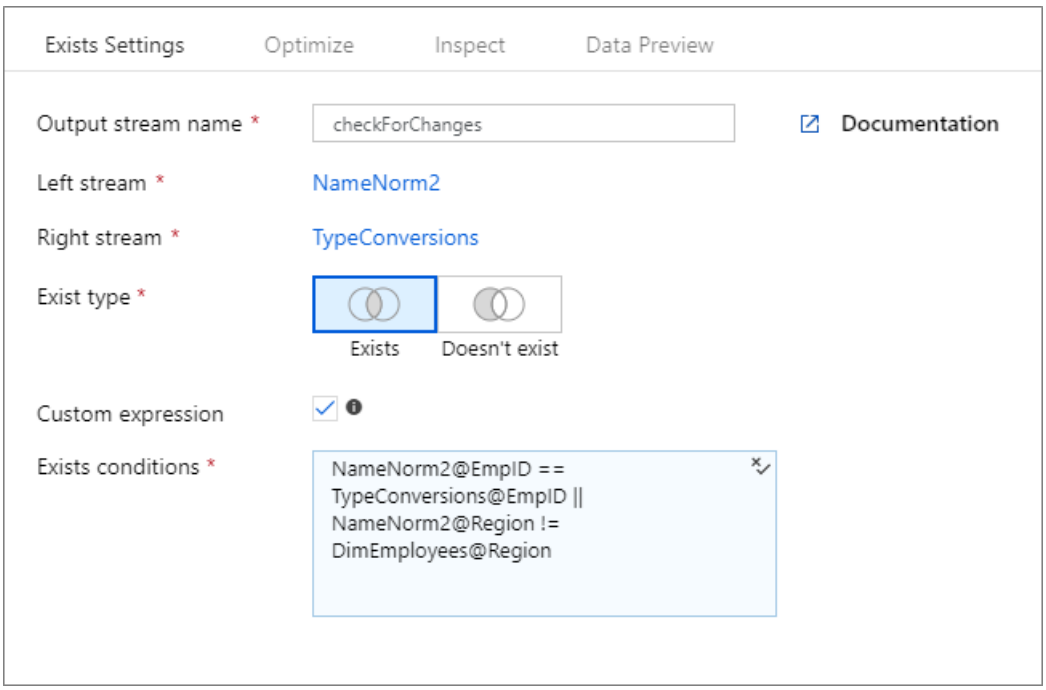
Multiple exists conditions

To compare multiple columns from each stream, add a new exists condition by clicking the plus icon next to an existing row. Each additional condition is joined by an "and" statement. Comparing two columns is the same as the following expression:

```
source1@column1 == source2@column1 && source1@column2 == source2@column2
```

Custom expression

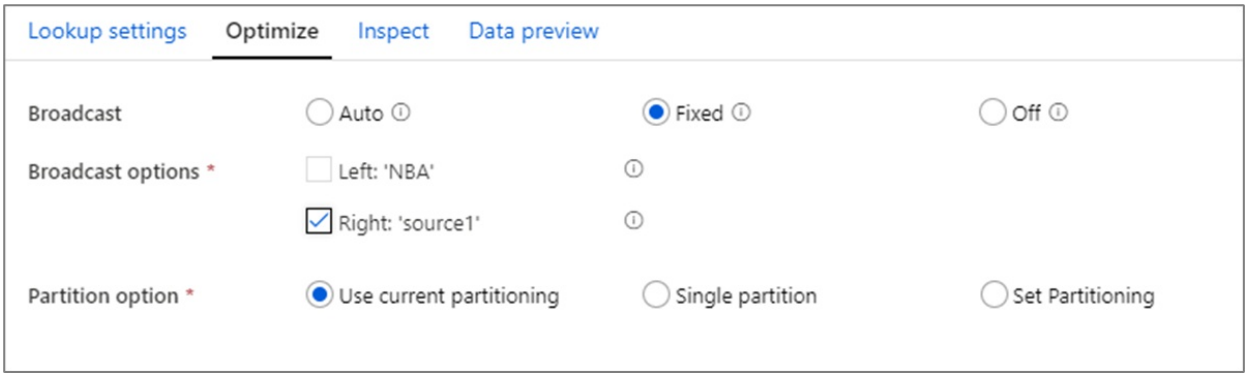
To create a free-form expression that contains operators other than "and" and "equals to", select the **Custom expression** field. Enter a custom expression via the data flow expression builder by clicking on the blue box.



If you are building dynamic patterns in your data flows by using "late binding" of columns via schema drift, you can use the `byName()` expression function to use the exists transformation without hardcoding (i.e. early binding) the column names. Example:

```
toString(byName('ProductNumber','source1')) == toString(byName('ProductNumber','source2'))
```

Broadcast optimization



In joins, lookups and exists transformation, if one or both data streams fit into worker node memory, you can optimize performance by enabling **Broadcasting**. By default, the spark engine will automatically decide whether or not to broadcast one side. To manually choose which side to broadcast, select **Fixed**.

It's not recommended to disable broadcasting via the **Off** option unless your joins are running into timeout errors.

Data flow script

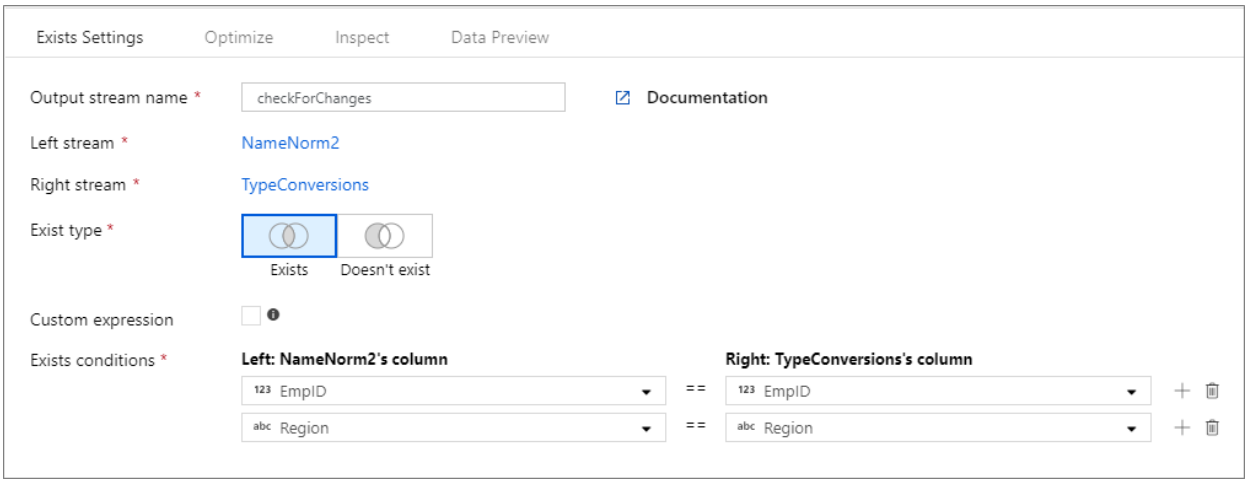
Syntax

```
<leftStream>, <rightStream>
    exists(
        <conditionalExpression>,
        negate: { true | false },
        broadcast: { 'auto' | 'left' | 'right' | 'both' | 'off' }
    ) ~> <existsTransformationName>
```

Example

The below example is an exists transformation named `checkForChanges` that takes left stream `NameNorm2` and right stream `TypeConversions`. The exists condition is the expression `NameNorm2@EmpID == TypeConversions@EmpID && NameNorm2@Region == DimEmployees@Region` that returns true if both the `EMPID` and `Region` columns in each stream matches. As we're checking for existence, `negate` is false. We aren't enabling any broadcasting in the optimize tab so `broadcast` has value `'none'`.

In the UI experience, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
NameNorm2, TypeConversions
    exists(
        NameNorm2@EmpID == TypeConversions@EmpID && NameNorm2@Region == DimEmployees@Region,
     negate:false,
     broadcast: 'auto'
    ) ~> checkForChanges
```

Next steps

Similar transformations are Lookup and Join.

Filter transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

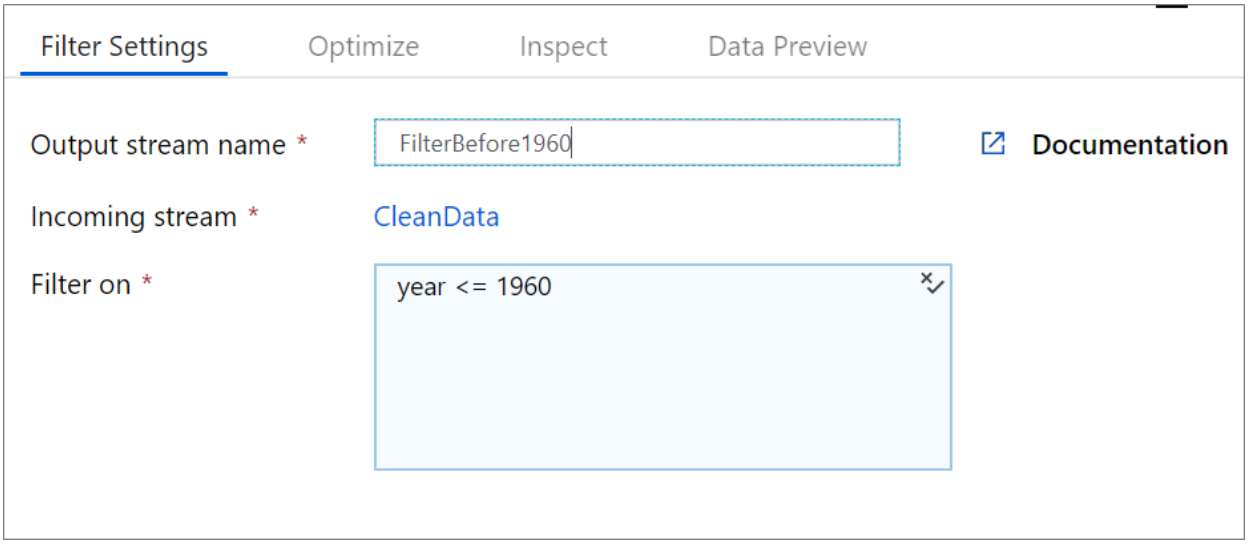
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The Filter transforms allows row filtering based upon a condition. The output stream includes all rows that matching the filtering condition. The filter transformation is similar to a WHERE clause in SQL.

Configuration

Use the data flow expression builder to enter an expression for the filter condition. To open the expression builder, click on the blue box. The filter condition must be of type boolean. For more information on how to create an expression, see the expression builder documentation.



Data flow script

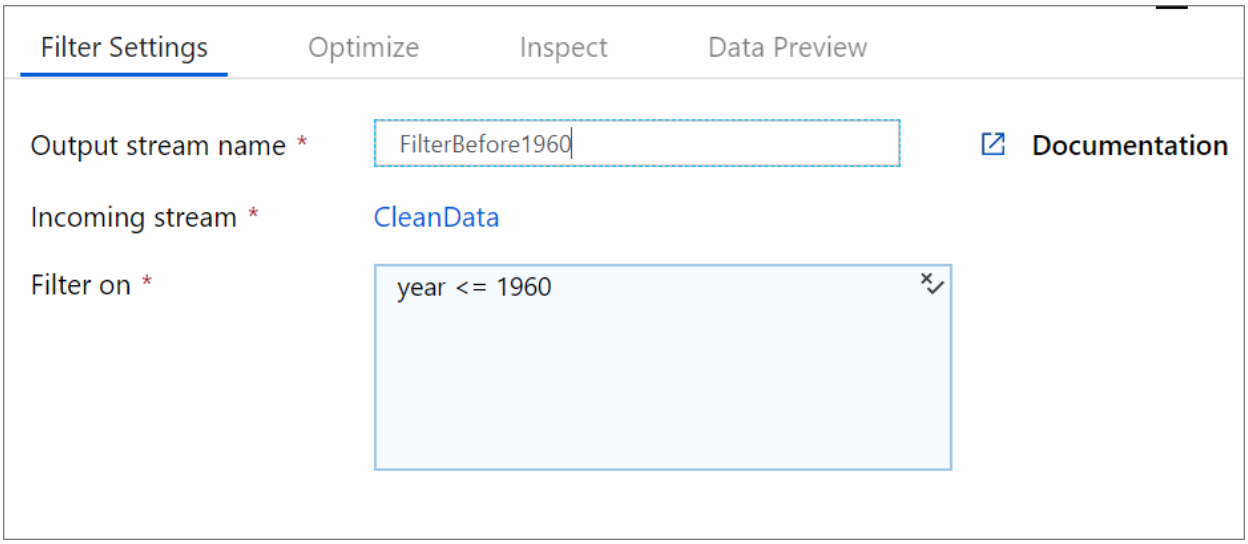
Syntax

```
<incomingStream>
    filter(
        <conditionalExpression>
    ) ~> <filterTransformationName>
```

Example

The below example is a filter transformation named `FilterBefore1960` that takes in incoming stream `CleanData`. The filter condition is the expression `year <= 1960`.

In the UI, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
CleanData
    filter(
        year <= 1960
    ) ~> FilterBefore1960
```

Next steps

Filter out columns with the select transformation

Flatten transformation in mapping data flow

8/19/2022 • 3 minutes to read • Edit Online

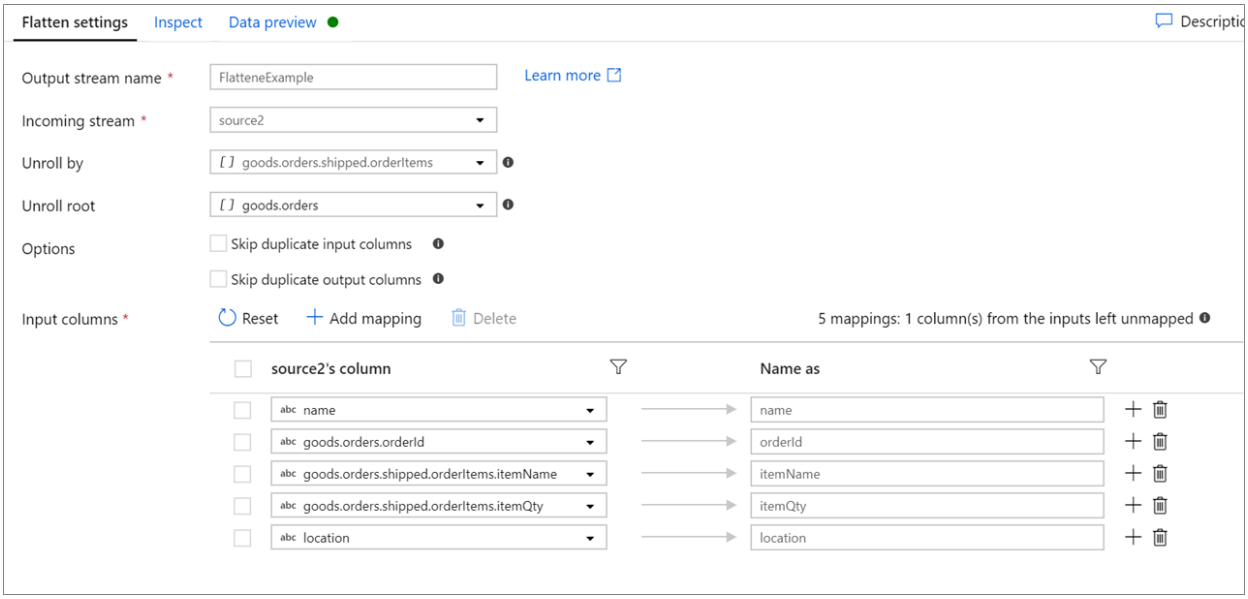
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the flatten transformation to take array values inside hierarchical structures such as JSON and unroll them into individual rows. This process is known as denormalization.

Configuration

The flatten transformation contains the following configuration settings



Unroll by

Select an array to unroll. The output data will have one row per item in each array. If the unroll by array in the input row is null or empty, there will be one output row with unrolled values as null.

Unroll root

By default, the flatten transformation unrolls an array to the top of the hierarchy it exists in. You can optionally select an array as your unroll root. The unroll root must be an array of complex objects that either is or contains the unroll by array. If an unroll root is selected, the output data will contain at least one row per items in the unroll root. If the input row doesn't have any items in the unroll root, it will be dropped from the output data. Choosing an unroll root will always output a less than or equal number of rows than the default behavior.

Flatten mapping

Similar to the select transformation, choose the projection of the new structure from incoming fields and the denormalized array. If a denormalized array is mapped, the output column will be the same data type as the array. If the unroll by array is an array of complex objects that contains subarrays, mapping an item of that subarry will output an array.

Refer to the inspect tab and data preview to verify your mapping output.

Rule-based mapping

The flatten transformation supports rule-based mapping allowing you to create dynamic and flexible transformations that will flatten arrays based on rules and flatten structures based on hierarchy levels.

Matching condition

Enter a pattern matching condition for the column or columns that you wish to flatten using either exact matching or patterns. Example: `like(name,'cust%')`

Deep column traversal

Optional setting that tells the service to handle all subcolumns of a complex object individually instead of handling the complex object as a whole column.

Hierarchy level

Choose the level of the hierarchy that you would like expand.

Name matches (regex)

Optionally choose to express your name matching as a regular expression in this box, instead of using the matching condition above.

Examples

Refer to the following JSON object for the below examples of the flatten transformation

```
{
  "name":"MSFT","location":"Redmond", "satellites": ["Bay Area", "Shanghai"],
  "goods": {
    "trade":true, "customers":["government", "distributer", "retail"],
    "orders":[
        {"orderId":1,"orderTotal":123.34,"shipped":{"orderItems":[{"itemName":"Laptop","itemQty":20},
{"itemName":"Charger","itemQty":2}]}},
        {"orderId":2,"orderTotal":323.34,"shipped":{"orderItems":[{"itemName":"Mice","itemQty":2},
{"itemName":"Keyboard","itemQty":1}]}}
    ]}}
{"name":"Company1","location":"Seattle", "satellites": ["New York"],
  "goods":{"trade":false, "customers":["store1", "store2"],
  "orders":[
      {"orderId":4,"orderTotal":123.34,"shipped":{"orderItems":[{"itemName":"Laptop","itemQty":20},
{"itemName":"Charger","itemQty":3}]}},
      {"orderId":5,"orderTotal":343.24,"shipped":{"orderItems":[{"itemName":"Chair","itemQty":4},
{"itemName":"Lamp","itemQty":2}]}}
    ]}}
{"name": "Company2", "location": "Bellevue",
  "goods": {"trade": true, "customers":["Bank"], "orders": [{"orderId": 4, "orderTotal": 123.34}]}}
{"name": "Company3", "location": "Kirkland"}
```

No unroll root with string array

UNROLL BY	UNROLL ROOT	PROJECTION
goods.customers	None	name customer = goods.customer

Output

```
{ 'MSFT', 'government'}
{ 'MSFT', 'distributer'}
{ 'MSFT', 'retail'}
{ 'Company1', 'store'}
{ 'Company1', 'store2'}
{ 'Company2', 'Bank'}
{ 'Company3', null}
```

No unroll root with complex array

UNROLL BY	UNROLL ROOT	PROJECTION
goods.orders.shipped.orderItems	None	name orderId = goods.orders.orderId itemName = goods.orders.shipped.orderItems.itemName itemQty = goods.orders.shipped.orderItems.itemQty location = location

Output

```
{ 'MSFT', 1, 'Laptop', 20, 'Redmond'}
{ 'MSFT', 1, 'Charger', 2, 'Redmond'}
{ 'MSFT', 2, 'Mice', 2, 'Redmond'}
{ 'MSFT', 2, 'Keyboard', 1, 'Redmond'}
{ 'Company1', 4, 'Laptop', 20, 'Seattle'}
{ 'Company1', 4, 'Charger', 3, 'Seattle'}
{ 'Company1', 5, 'Chair', 4, 'Seattle'}
{ 'Company1', 5, 'Lamp', 2, 'Seattle'}
{ 'Company2', 4, null, null, 'Bellevue'}
{ 'Company3', null, null, null, 'Kirkland'}
```

Same root as unroll array

UNROLL BY	UNROLL ROOT	PROJECTION
goods.orders	goods.orders	name goods.orders.shipped.orderItems.itemName goods.customers location

Output

```
{ 'MSFT', ['Laptop','Charger'], ['government','distributer','retail'], 'Redmond'}
{ 'MSFT', ['Mice', 'Keyboard'], ['government','distributer','retail'], 'Redmond'}
{ 'Company1', ['Laptop','Charger'], ['store', 'store2'], 'Seattle'}
{ 'Company1', ['Chair', 'Lamp'], ['store', 'store2'], 'Seattle'}
{ 'Company2', null, ['Bank'], 'Bellevue'}
```

Unroll root with complex array

UNROLL BY	UNROLL ROOT	PROJECTION
goods.orders.shipped.orderItem	goods.orders	name orderId = goods.orders.orderId itemName = goods.orders.shipped.orderItems.itemName itemQty = goods.orders.shipped.orderItems.itemQty location = location

Output

```
{ 'MSFT', 1, 'Laptop', 20, 'Redmond'}
{ 'MSFT', 1, 'Charger', 2, 'Redmond'}
{ 'MSFT', 2, 'Mice', 2, 'Redmond'}
{ 'MSFT', 2, 'Keyboard', 1, 'Redmond'}
{ 'Company1', 4, 'Laptop', 20, 'Seattle'}
{ 'Company1', 4, 'Charger', 3, 'Seattle'}
{ 'Company1', 5, 'Chair', 4, 'Seattle'}
{ 'Company1', 5, 'Lamp', 2, 'Seattle'}
{ 'Company2', 4, null, null, 'Bellevue'}
```

Data flow script

Syntax

```
<incomingStream>
foldDown(unroll(<unroll cols>),
    mapColumn(
        name,
        each(<array>(type == '<arrayDataType>')),
        each(<array>, match(true())),
        location
    )) ~> <transformationName>
```

Example

```
source foldDown(unroll(goods.orders.shipped.orderItems, goods.orders),
    mapColumn(
        name,
        orderId = goods.orders.orderId,
        itemName = goods.orders.shipped.orderItems.itemName,
        itemQty = goods.orders.shipped.orderItems.itemQty,
        location = location
    ),
    skipDuplicateMapInputs: false,
    skipDuplicateMapOutputs: false)
```

Next steps

- Use the Pivot transformation to pivot rows to columns.
- Use the Unpivot transformation to pivot columns to rows.

Join transformation in mapping data flow

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the join transformation to combine data from two sources or streams in a mapping data flow. The output stream will include all columns from both sources matched based on a join condition.

Join types

Mapping data flows currently supports five different join types.

Inner Join

Inner join only outputs rows that have matching values in both tables.

Left Outer

Left outer join returns all rows from the left stream and matched records from the right stream. If a row from the left stream has no match, the output columns from the right stream are set to NULL. The output will be the rows returned by an inner join plus the unmatched rows from the left stream.

> **NOTE**
> The Spark engine used by data flows will occasionally fail due to possible cartesian products in your join conditions. If this occurs, you can switch to a custom cross join and manually enter your join condition. This may result in slower performance in your data flows as the execution engine may need to calculate all rows from both sides of the relationship and then filter rows.

Right Outer

Right outer join returns all rows from the right stream and matched records from the left stream. If a row from the right stream has no match, the output columns from the left stream are set to NULL. The output will be the rows returned by an inner join plus the unmatched rows from the right stream.

Full Outer

Full outer join outputs all columns and rows from both sides with NULL values for columns that aren't matched.

Custom cross join

Cross join outputs the cross product of the two streams based upon a condition. If you're using a condition that isn't equality, specify a custom expression as your cross join condition. The output stream will be all rows that meet the join condition.

You can use this join type for non-equi joins and `OR` conditions.

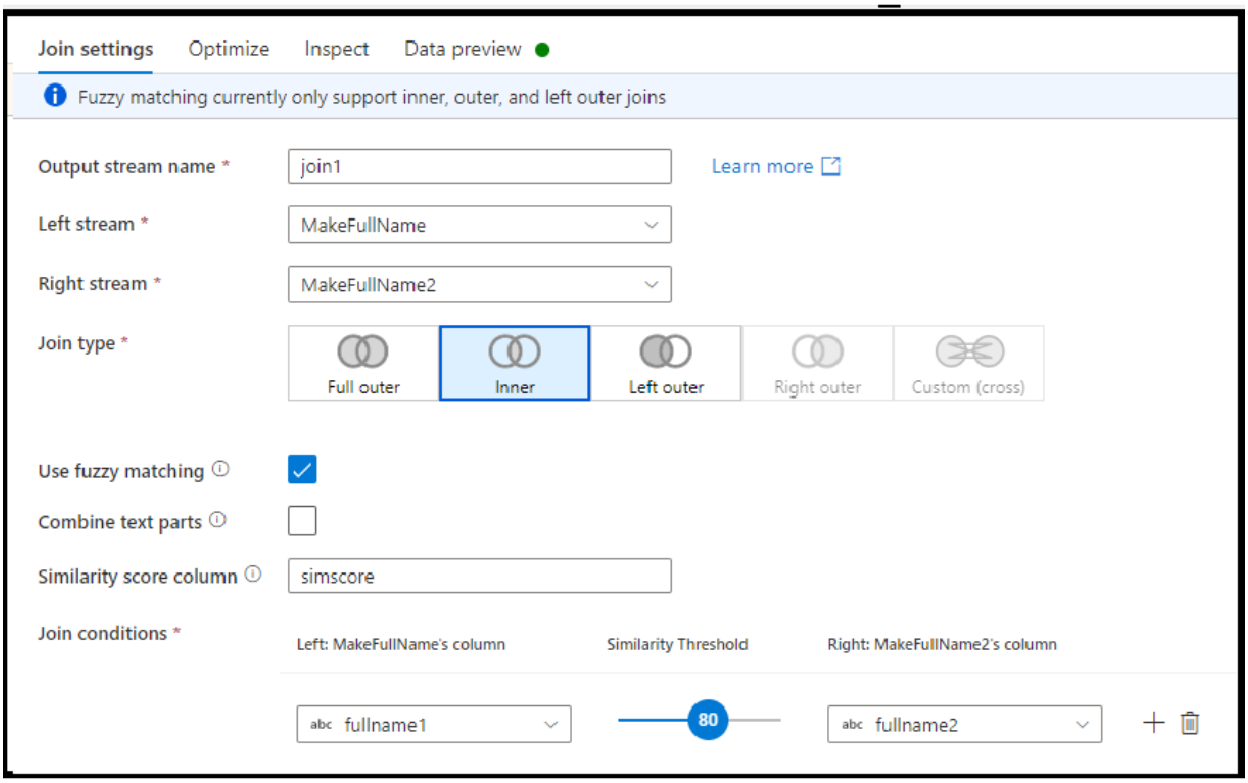
If you would like to explicitly produce a full cartesian product, use the Derived Column transformation in each of the two independent streams before the join to create a synthetic key to match on. For example, create a new column in Derived Column in each stream called `SyntheticKey` and set it equal to `1`. Then use `a.SyntheticKey == b.SyntheticKey` as your custom join expression.

> **NOTE**
> Make sure to include at least one column from each side of your left and right relationship in a custom cross join. Executing cross joins with static values instead of columns from each side results in full scans of the entire dataset, causing your data flow to perform poorly.

Fuzzy join

You can choose to join based on fuzzy join logic instead of exact column value matching by turning on the "Use fuzzy matching" checkbox option.

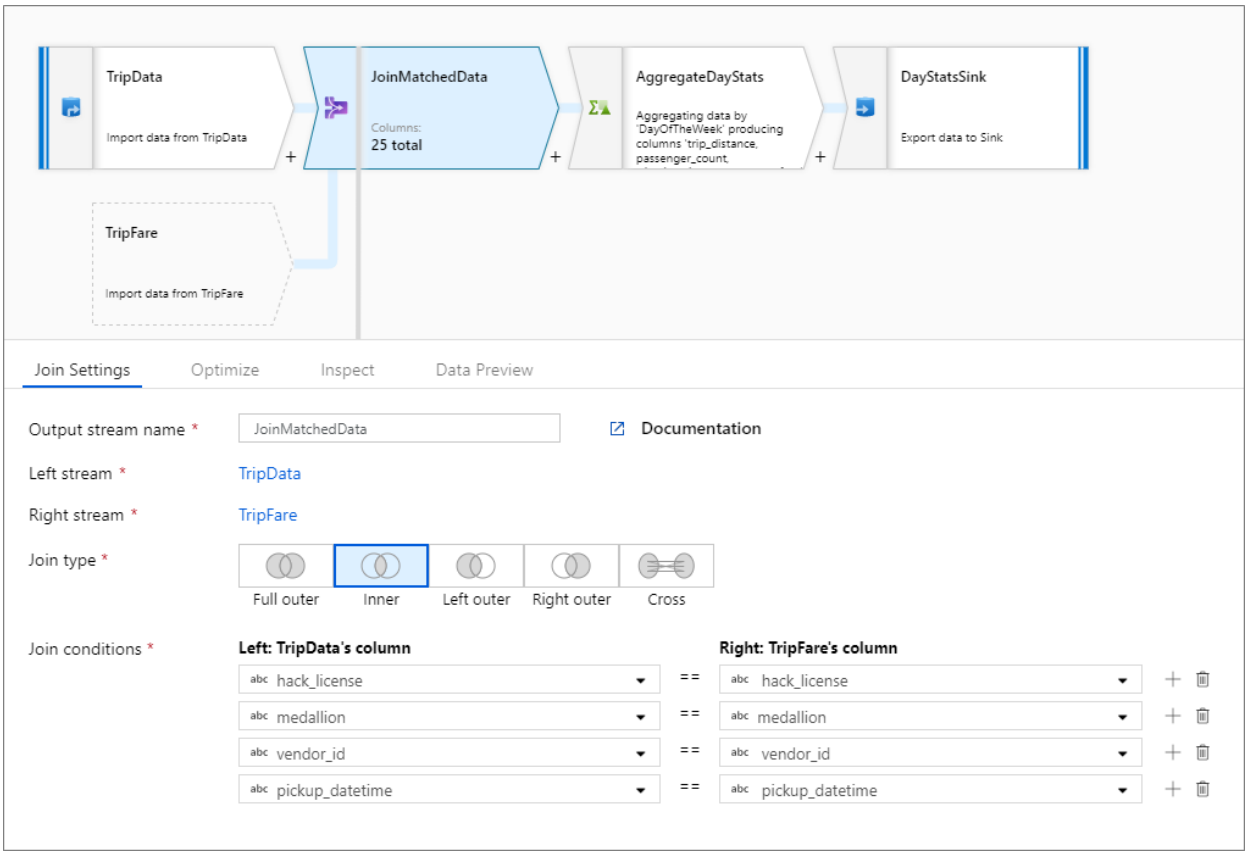
- Combine text parts: Use this option to find matches by remove space between words. For example, Data Factory is matched with DataFactory if this option is enabled.
- Similarity score column: You can optionally choose to store the matching score for each row in a column by entering a new column name here to store that value.
- Similarity threshold: Choose a value between 60 and 100 as a percentage match between values in the columns you've selected.



> **NOTE**
> Fuzzy matching currently works only with string column types and with inner, left outer, and full outer join types. You must turn off the broadcast optimization when using fuzzing matching joins.

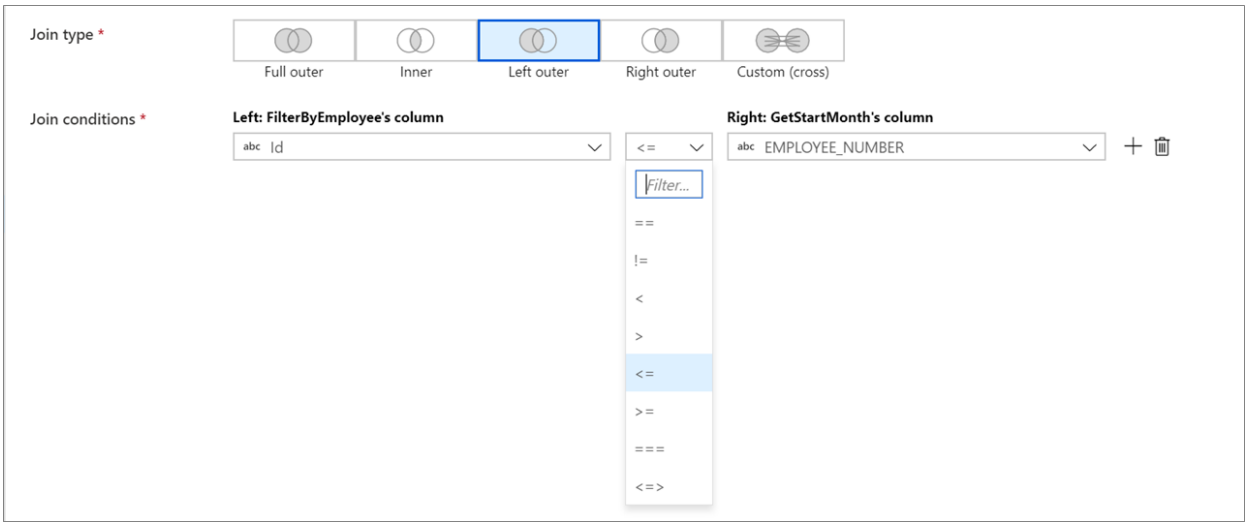
Configuration

1. Choose which data stream you're joining with in the **Right stream** dropdown.
2. Select your **Join type**
3. Choose which key columns you want to match on for your join condition. By default, data flow looks for equality between one column in each stream. To compare via a computed value, hover over the column dropdown and select **Computed column**.



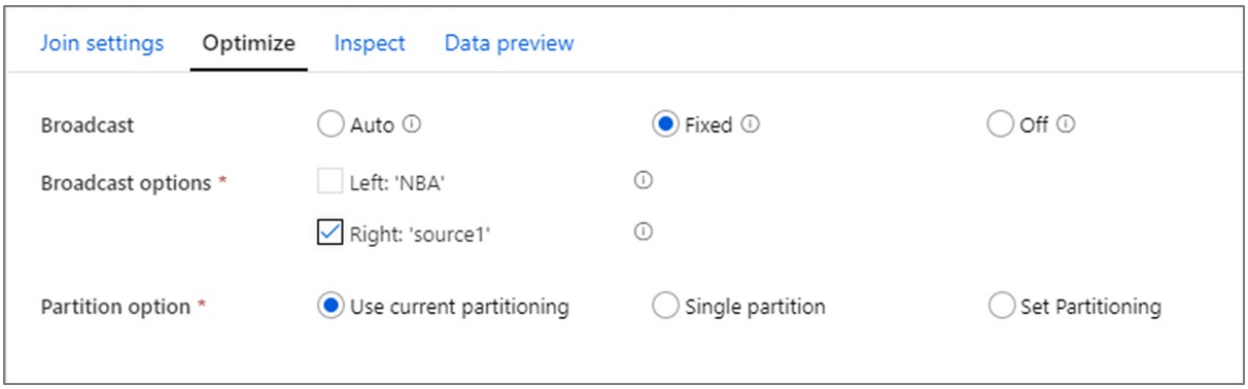
Non-equi joins

To use a conditional operator such as not equals (!=) or greater than (>) in your join conditions, change the operator dropdown between the two columns. Non-equi joins require at least one of the two streams to be broadcasted using **Fixed** broadcasting in the **Optimize** tab.



Optimizing join performance

Unlike merge join in tools like SSIS, the join transformation isn't a mandatory merge join operation. The join keys don't require sorting. The join operation occurs based on the optimal join operation in Spark, either broadcast or map-side join.

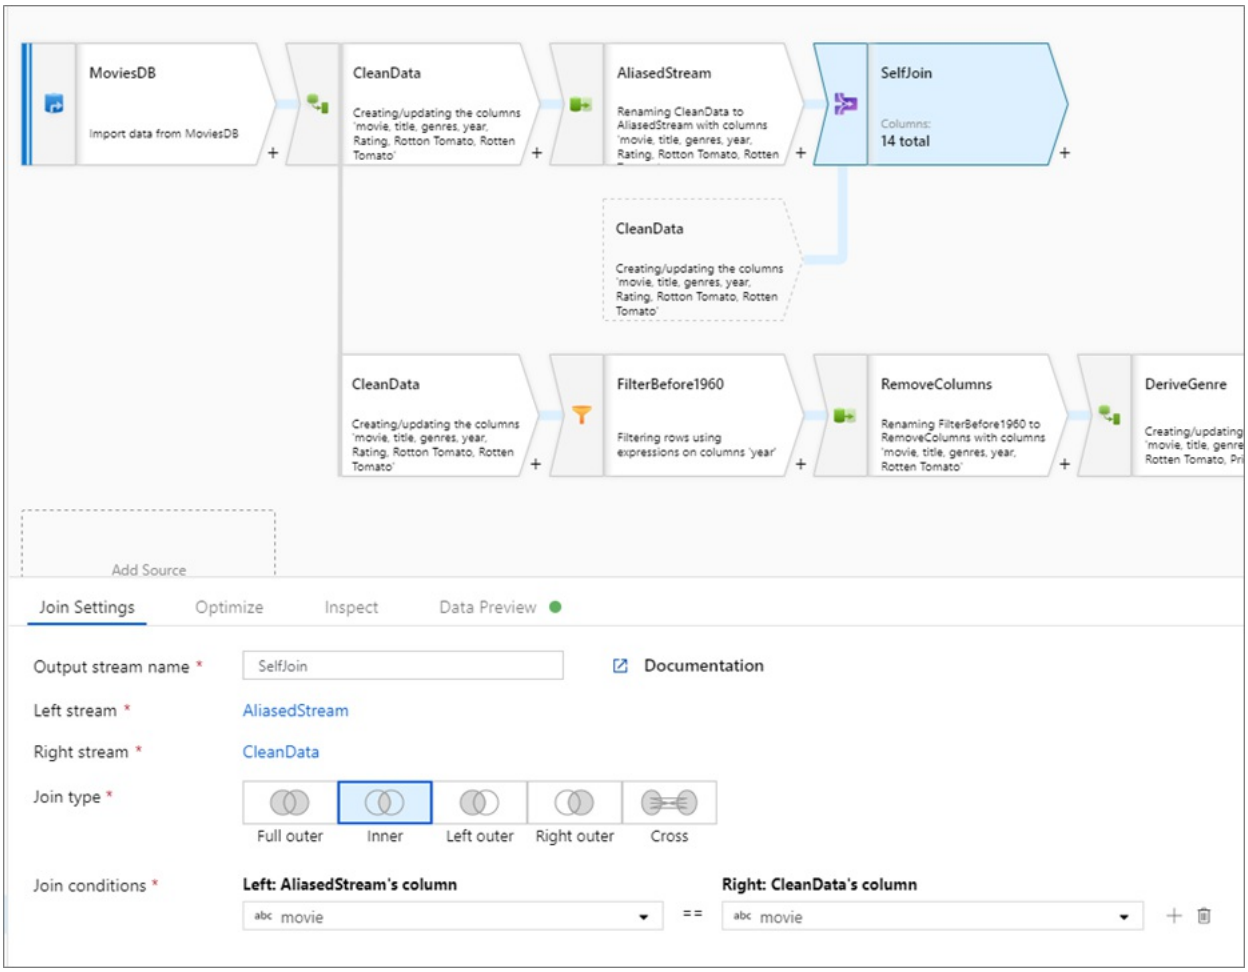


In joins, lookups and exists transformation, if one or both data streams fit into worker node memory, you can optimize performance by enabling **Broadcasting**. By default, the spark engine will automatically decide whether or not to broadcast one side. To manually choose which side to broadcast, select **Fixed**.

It's not recommended to disable broadcasting via the **Off** option unless your joins are running into timeout errors.

Self-Join

To self-join a data stream with itself, alias an existing stream with a select transformation. Create a new branch by clicking on the plus icon next to a transformation and selecting **New branch**. Add a select transformation to alias the original stream. Add a join transformation and choose the original stream as the **Left stream** and the select transformation as the **Right stream**.



Testing join conditions

When testing the join transformations with data preview in debug mode, use a small set of known data. When sampling rows from a large dataset, you can't predict which rows and keys will be read for testing. The result is

non-deterministic, meaning that your join conditions may not return any matches.

Data flow script

Syntax

```
<leftStream>, <rightStream>
    join(
        <conditionalExpression>,
        joinType: { 'inner'> | 'outer' | 'left_outer' | 'right_outer' | 'cross' }
        broadcast: { 'auto' | 'left' | 'right' | 'both' | 'off' }
    ) ~> <joinTransformationName>
```

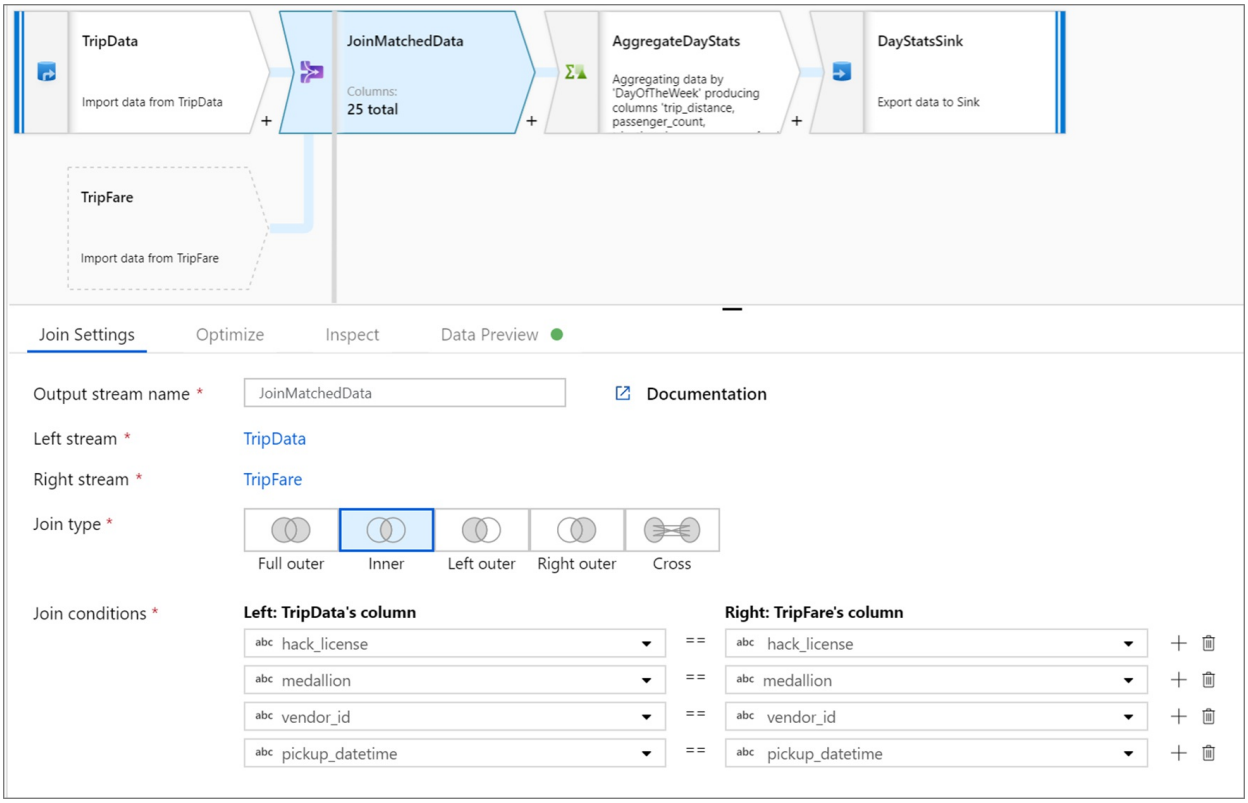
Inner join example

The below example is a join transformation named `JoinMatchedData` that takes left stream `TripData` and right stream `TripFare`. The join condition is the expression

```
hack_license == { hack_license} && TripData@medallion == TripFare@medallion && vendor_id == { vendor_id} &&
pickup_datetime == { pickup_datetime}
```

that returns true if the `hack_license`, `medallion`, `vendor_id`, and `pickup_datetime` columns in each stream match. The `joinType` is `'inner'`. We're enabling broadcasting in only the left stream so `broadcast` has value `'left'`.

In the UI, this transformation looks like the below image:



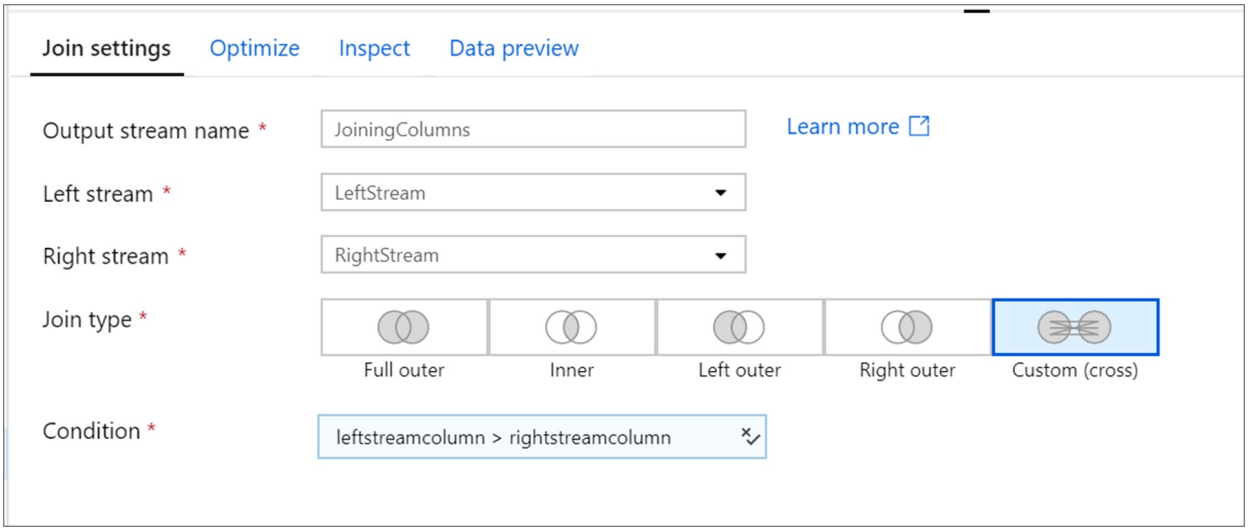
The data flow script for this transformation is in the snippet below:

```
TripData, TripFare
    join(
        hack_license == { hack_license}
        && TripData@medallion == TripFare@medallion
        && vendor_id == { vendor_id}
        && pickup_datetime == { pickup_datetime},
        joinType:'inner',
        broadcast: 'left'
    )~> JoinMatchedData
```

Custom cross join example

The below example is a join transformation named `JoiningColumns` that takes left stream `LeftStream` and right stream `RightStream`. This transformation takes in two streams and joins together all rows where column `leftstreamcolumn` is greater than column `rightstreamcolumn`. The `joinType` is `cross`. Broadcasting is not enabled `broadcast` has value `'none'`.

In the UI, this transformation looks like the below image:



The data flow script for this transformation is in the snippet below:

```
LeftStream, RightStream
    join(
        leftstreamcolumn > rightstreamcolumn,
        joinType:'cross',
        broadcast: 'none'
    )~> JoiningColumns
```

Next steps

After joining data, create a derived column and sink your data to a destination data store.

Lookup transformations in mapping data flow

8/19/2022 • 3 minutes to read • Edit Online

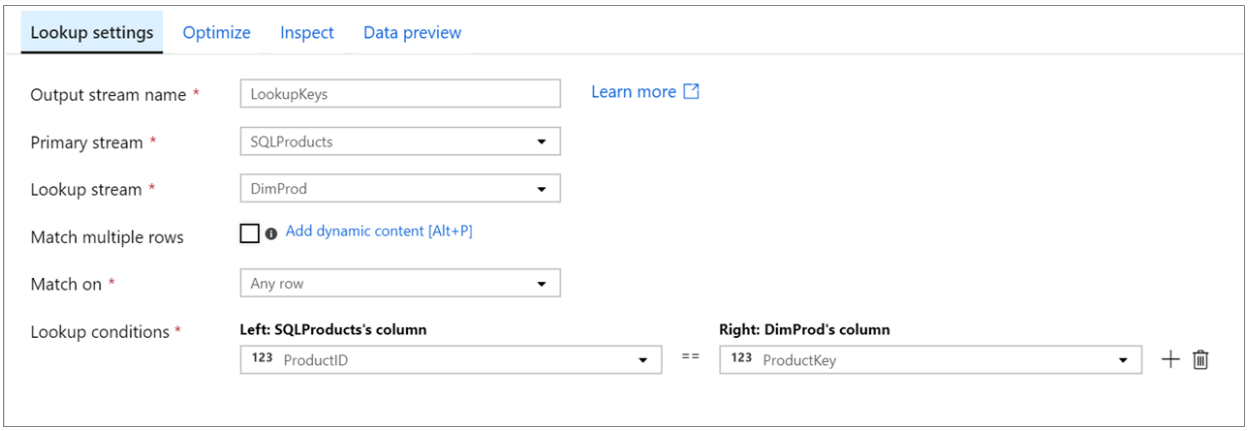
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the lookup transformation to reference data from another source in a data flow stream. The lookup transformation appends columns from matched data to your source data.

A lookup transformation is similar to a left outer join. All rows from the primary stream will exist in the output stream with additional columns from the lookup stream.

Configuration



Primary stream: The incoming stream of data. This stream is equivalent to the left side of a join.

Lookup stream: The data that is appended to the primary stream. Which data is added is determined by the lookup conditions. This stream is equivalent to the right side of a join.

Match multiple rows: If enabled, a row with multiple matches in the primary stream will return multiple rows. Otherwise, only a single row will be returned based upon the 'Match on' condition.

Match on: Only visible if 'Match multiple rows' isn't selected. Choose whether to match on any row, the first match, or the last match. Any row is recommended as it executes the fastest. If first row or last row is selected, you'll be required to specify sort conditions.

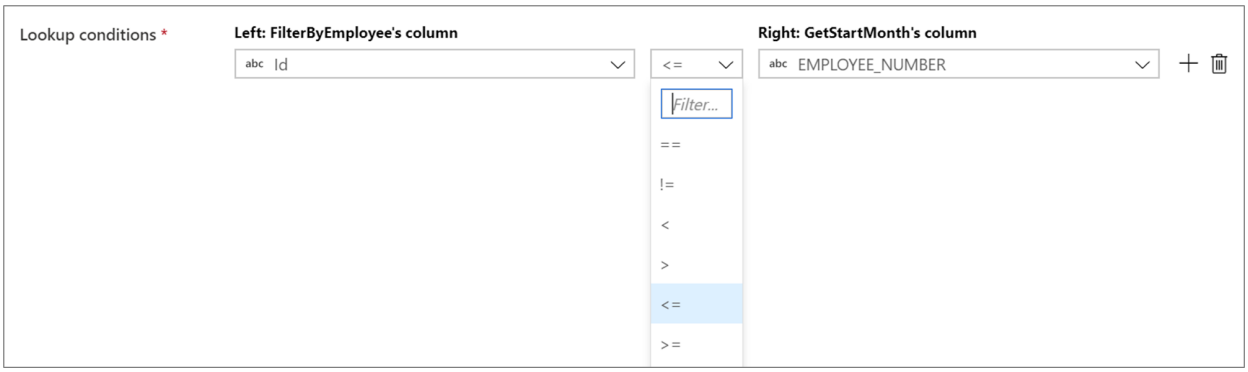
Lookup conditions: Choose which columns to match on. If the equality condition is met, then the rows will be considered a match. Hover and select 'Computed column' to extract a value using the data flow expression language.

All columns from both streams are included in the output data. To drop duplicate or unwanted columns, add a select transformation after your lookup transformation. Columns can also be dropped or renamed in a sink transformation.

Non-equi joins

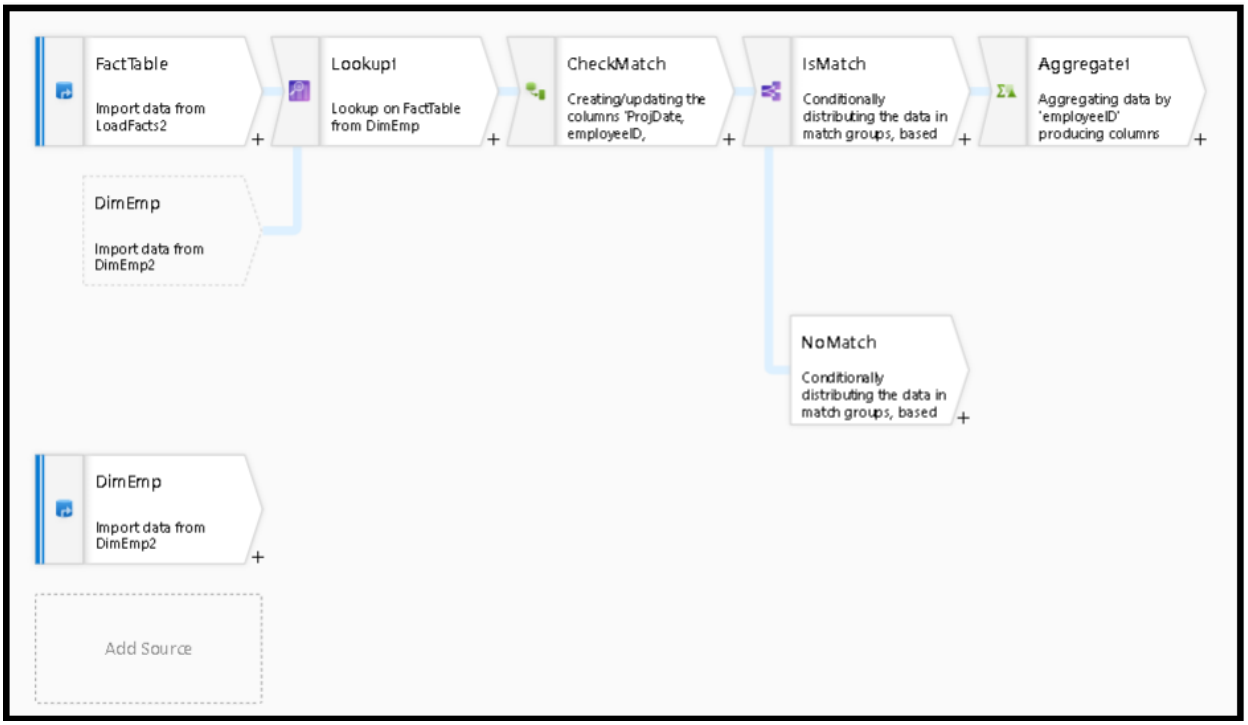
To use a conditional operator such as not equals (!=) or greater than (>) in your lookup conditions, change the

operator dropdown between the two columns. Non-equi joins require at least one of the two streams to be broadcasted using **Fixed** broadcasting in the **Optimize** tab.



Analyzing matched rows

After your lookup transformation, the function `isMatch()` can be used to see if the lookup matched for individual rows.

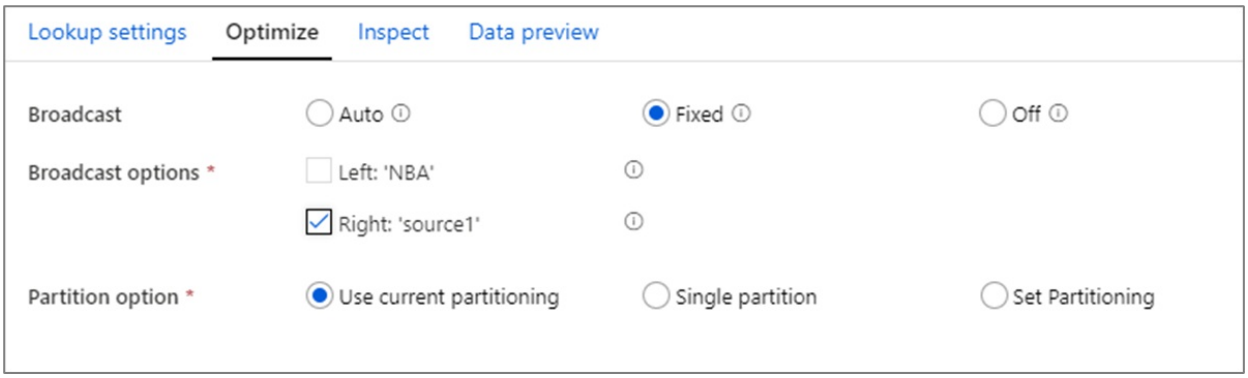


An example of this pattern is using the conditional split transformation to split on the `isMatch()` function. In the example above, matching rows go through the top stream and non-matching rows flow through the `NoMatch` stream.

Testing lookup conditions

When testing the lookup transformation with data preview in debug mode, use a small set of known data. When sampling rows from a large dataset, you can't predict which rows and keys will be read for testing. The result is non-deterministic, meaning that your join conditions may not return any matches.

Broadcast optimization



In joins, lookups and exists transformation, if one or both data streams fit into worker node memory, you can optimize performance by enabling **Broadcasting**. By default, the spark engine will automatically decide whether or not to broadcast one side. To manually choose which side to broadcast, select **Fixed**.

It's not recommended to disable broadcasting via the **Off** option unless your joins are running into timeout errors.

Cached lookup

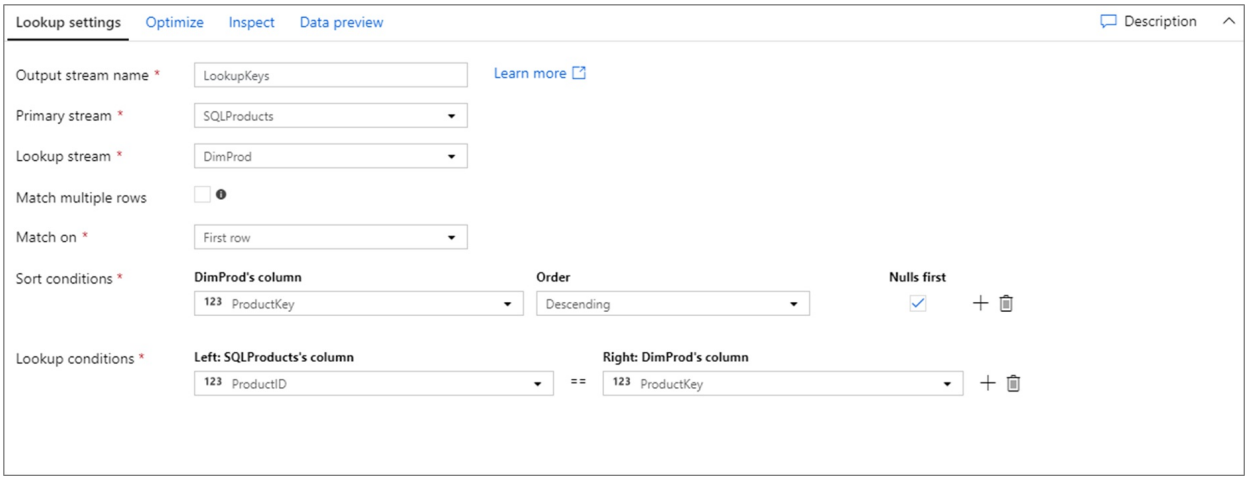
If you're doing multiple smaller lookups on the same source, a cached sink and lookup maybe a better use case than the lookup transformation. Common examples where a cache sink may be better are looking up a max value on a data store and matching error codes to an error message database. For more information, learn about cache sinks and cached lookups.

Data flow script

Syntax

```
<leftStream>, <rightStream>
    lookup(
        <lookupConditionExpression>,
        multiple: { true | false },
        pickup: { 'first' | 'last' | 'any' },  ## Only required if false is selected for multiple
        { desc | asc }( <sortColumn>, { true | false }), ## Only required if 'first' or 'last' is selected.
true/false determines whether to put nulls first
        broadcast: { 'auto' | 'left' | 'right' | 'both' | 'off' }
    ) ~> <lookupTransformationName>
```

Example



The data flow script for the above lookup configuration is in the code snippet below.

```
SQLProducts, DimProd lookup(ProductID == ProductKey,
    multiple: false,
    pickup: 'first',
    asc(ProductKey, true),
    broadcast: 'auto')~> LookupKeys
```

Next steps

- The join and exists transformations both take in multiple stream inputs
- Use a conditional split transformation with `isMatch()` to split rows on matching and non-matching values

Creating a new branch in mapping data flow

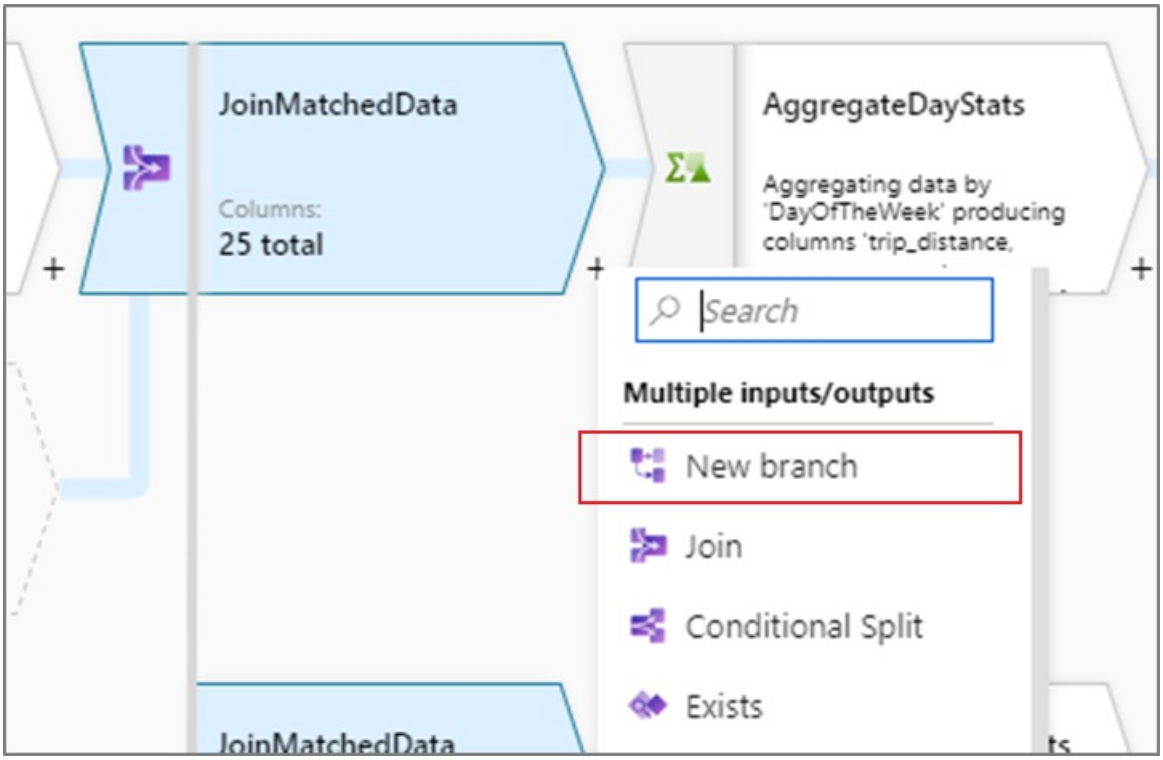
8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

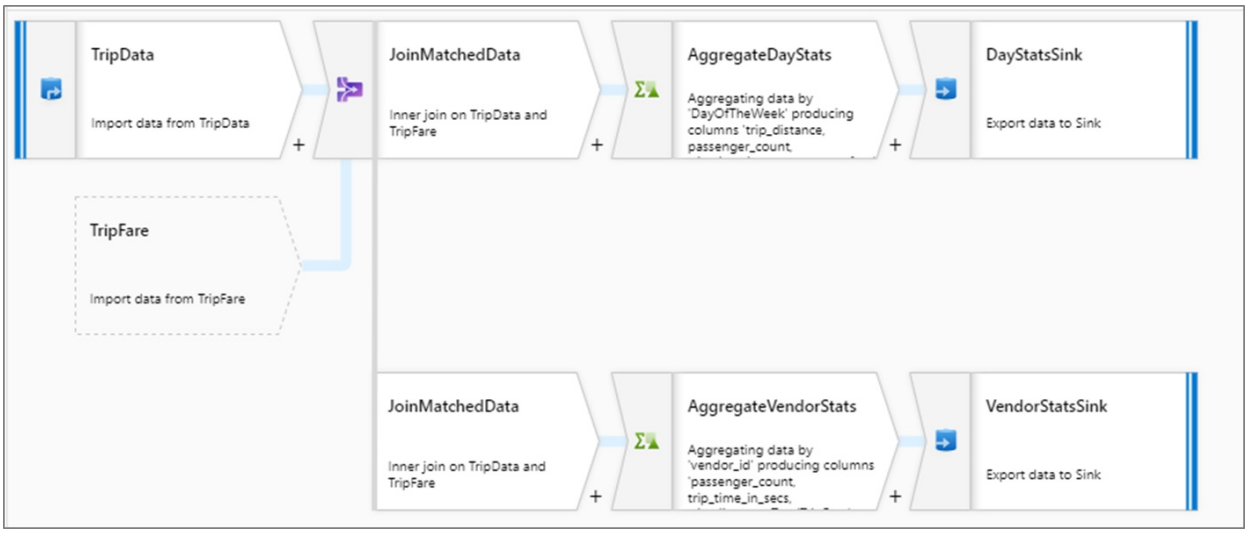
Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Add a new branch to do multiple sets of operations and transformations against the same data stream. Adding a new branch is useful when you want to use the same source to for multiple sinks or for self-joining data together.

A new branch can be added from the transformation list similar to other transformations. **New Branch** will only be available as an action when there's an existing transformation following the transformation you're attempting to branch.



In the below example, the data flow is reading taxi trip data. Output aggregated by both day and vendor is required. Instead of creating two separate data flows that read from the same source, a new branch can be added. This way both aggregations can be executed as part of the same data flow.



NOTE

When clicking the plus (+) to add transformations to your graph, you will only see the New Branch option when there are subsequent transformation blocks. This is because New Branch creates a reference to the existing stream and requires further upstream processing to operate on. If you do not see the New Branch option, add a Derived Column or other transformation first, then return to the previous block and you will see New Branch as an option.

Next steps

After branching, you may want to use the data flow transformations

Pivot transformation in mapping data flow

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

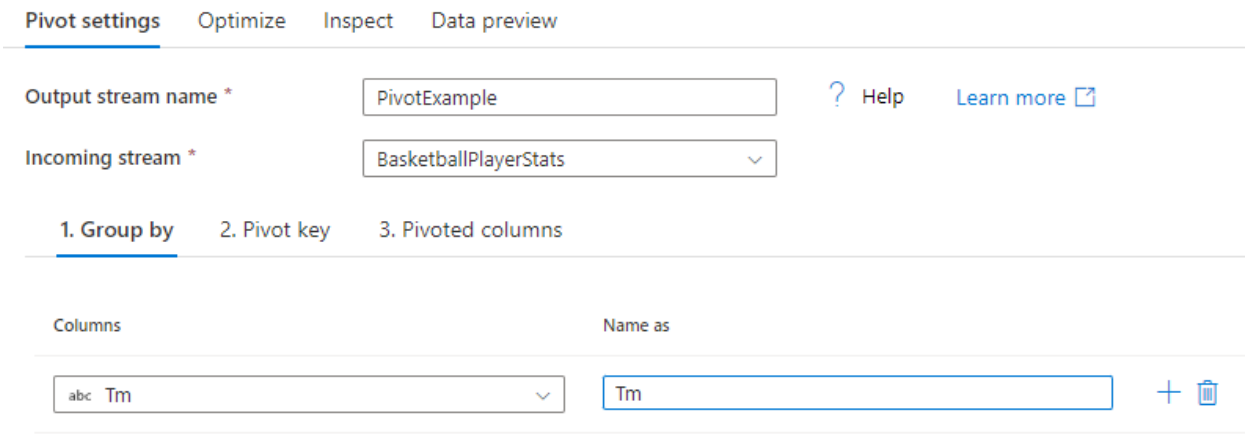
Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the pivot transformation to create multiple columns from the unique row values of a single column. Pivot is an aggregation transformation where you select group by columns and generate pivot columns using aggregate functions.

Configuration

The pivot transformation requires three different inputs: group by columns, the pivot key, and how to generate the pivoted columns

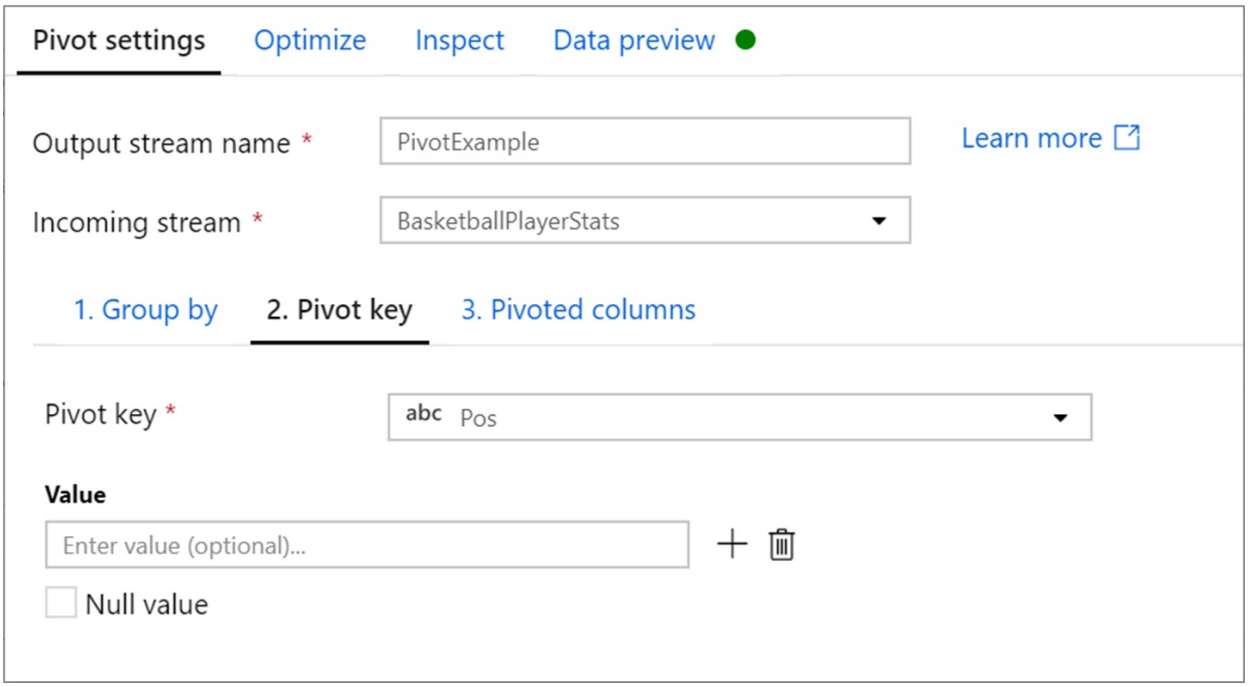
Group by



Select which columns to aggregate the pivoted columns over. The output data will group all rows with the same group by values into one row. The aggregation done in the pivoted column will occur over each group.

This section is optional. If no group by columns are selected, the entire data stream will be aggregated and only one row will be outputted.

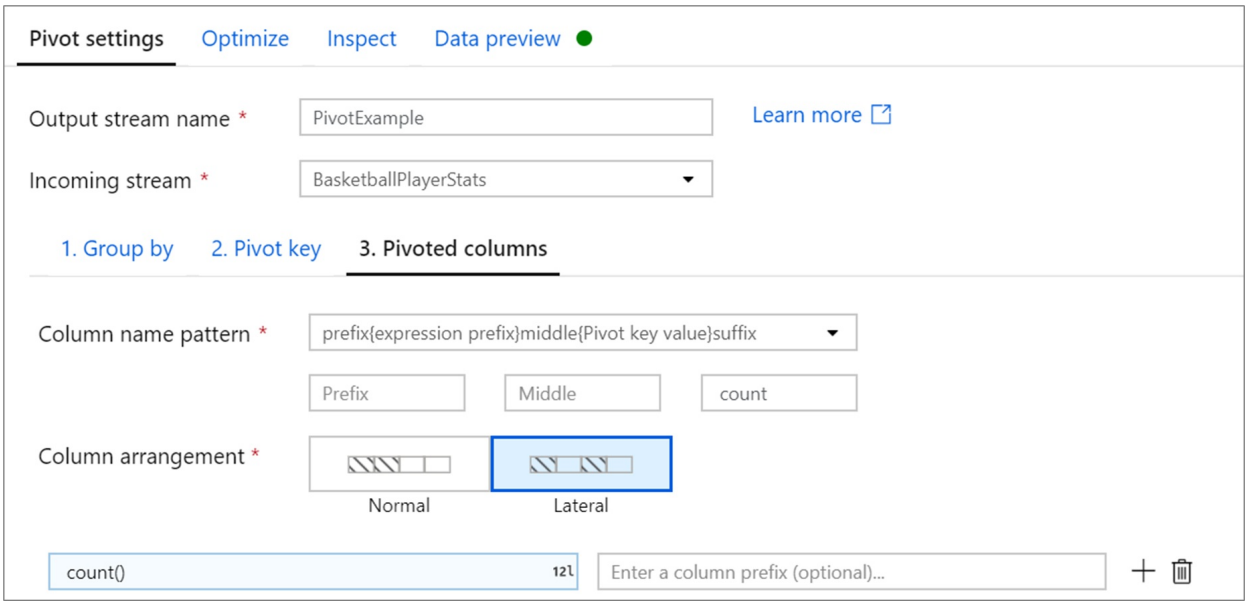
Pivot key



The pivot key is the column whose row values get pivoted into new columns. By default, the pivot transformation will create a new column for each unique row value.

In the section labeled **Value**, you can enter specific row values to be pivoted. Only the row values entered in this section will be pivoted. Enabling **Null value** will create a pivoted column for the null values in the column.

Pivoted columns



For each unique pivot key value that becomes a column, generate an aggregated row value for each group. You can create multiple columns per pivot key. Each pivot column must contain at least one aggregate function.

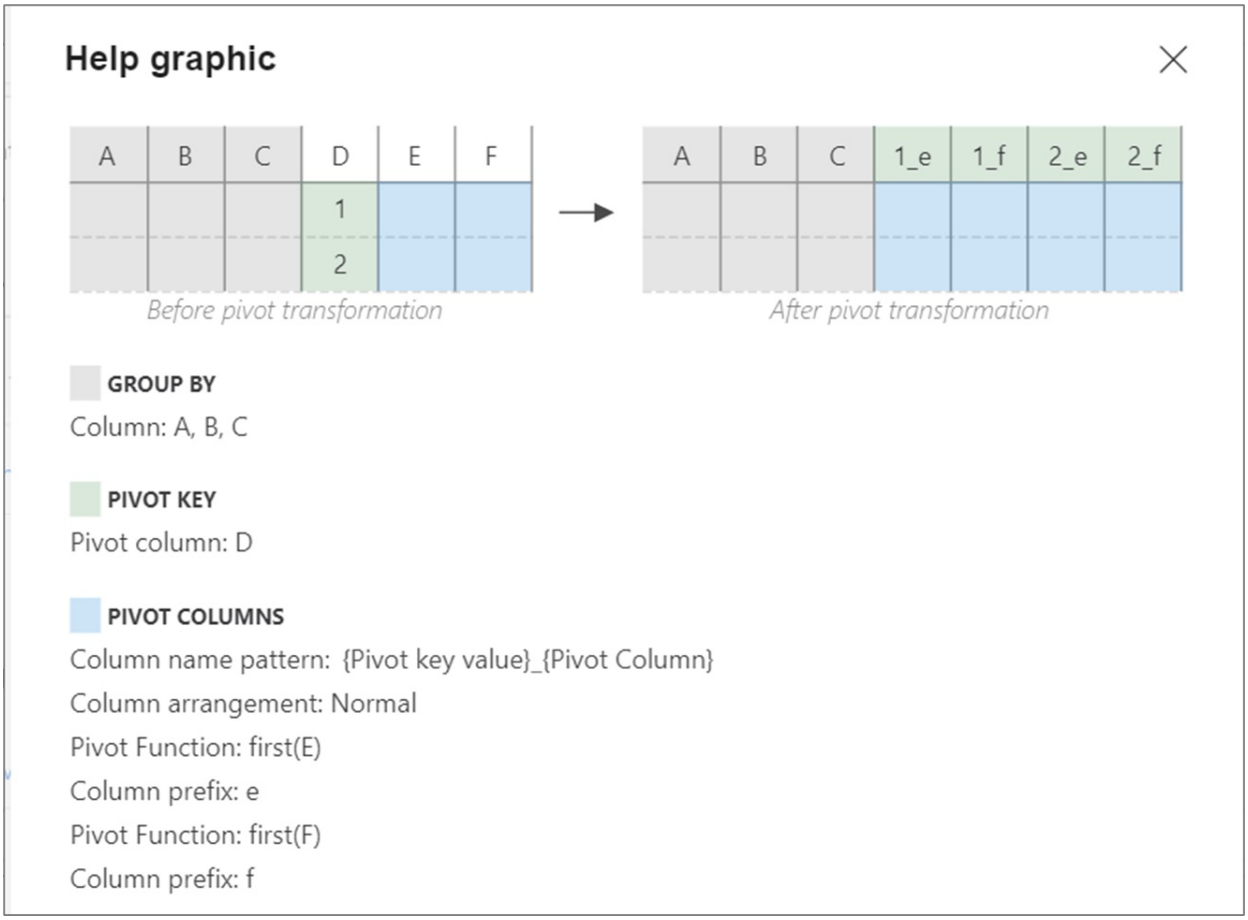
Column name pattern: Select how to format the column name of each pivot column. The outputted column name will be a combination of the pivot key value, column prefix and optional prefix, suffice, middle characters.

Column arrangement: If you generate more than one pivot column per pivot key, choose how you want the columns to be ordered.

Column prefix: If you generate more than one pivot column per pivot key, enter a column prefix for each column. This setting is optional if you only have one pivoted column.

Help graphic

The below help graphic shows how the different pivot components interact with one another



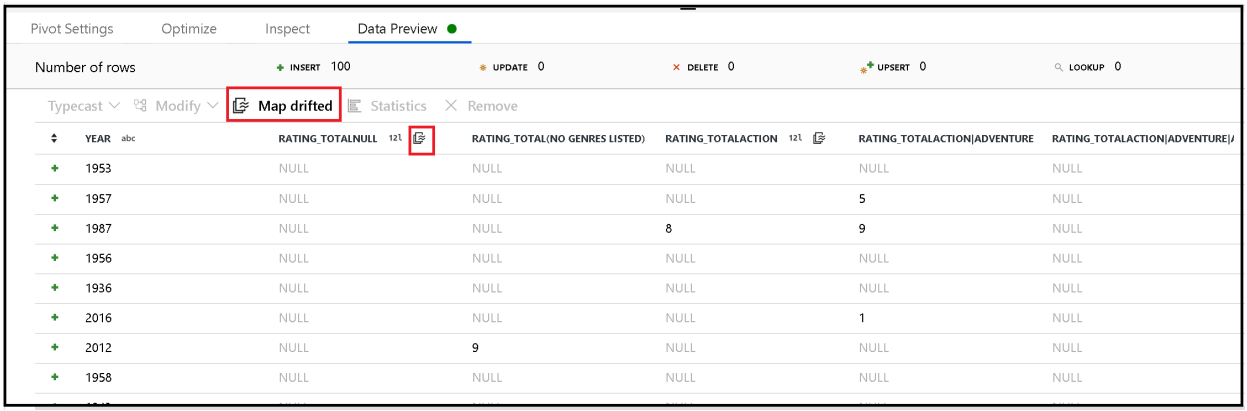
Pivot metadata

If no values are specified in the pivot key configuration, the pivoted columns will be dynamically generated at run time. The number of pivoted columns will equal the number of unique pivot key values multiplied by the number of pivot columns. As this can be a changing number, the UX will not display the column metadata in the **Inspect** tab and there will be no column propagation. To transformation these columns, use the column pattern capabilities of mapping data flow.

If specific pivot key values are set, the pivoted columns will appear in the metadata. The column names will be available to you in the Inspect and Sink mapping.

Generate metadata from drifted columns

Pivot generates new column names dynamically based on row values. You can add these new columns into the metadata that can be referenced later in your data flow. To do this, use the map drifted quick action in data preview.



Sinking pivoted columns

Although pivoted columns are dynamic, they can still be written into your destination data store. Enable **Allow schema drift** in your sink settings. This will allow you to write columns that are not included in metadata. You will not see the new dynamic names in your column metadata, but the schema drift option will allow you to land the data.

Rejoin original fields

The pivot transformation will only project the group by and pivoted columns. If you want your output data to include other input columns, use a self join pattern.

Data flow script

Syntax

```
<incomingStreamName>
    pivot(groupBy(Tm),
        pivotBy(<pivotKeyColumn, [<specifiedColumnName1>,...,<specifiedColumnNameN>]),
        <pivotColumnPrefix> = <pivotedColumnValue>,
        columnNaming: '< prefix >< $N | $V ><middle >< $N | $V >< suffix >',
        lateral: { 'true' | 'false'}
    ) ~> <pivotTransformationName
```

Example

The screens shown in the configuration section, have the following data flow script:

```
BasketballPlayerStats pivot(groupBy(Tm),
    pivotBy(Pos),
    {} = count(),
    columnNaming: '$V$N count',
    lateral: true) ~> PivotExample
```

Next steps

Try the unpivot transformation to turn column values into row values.

Rank transformation in mapping data flow

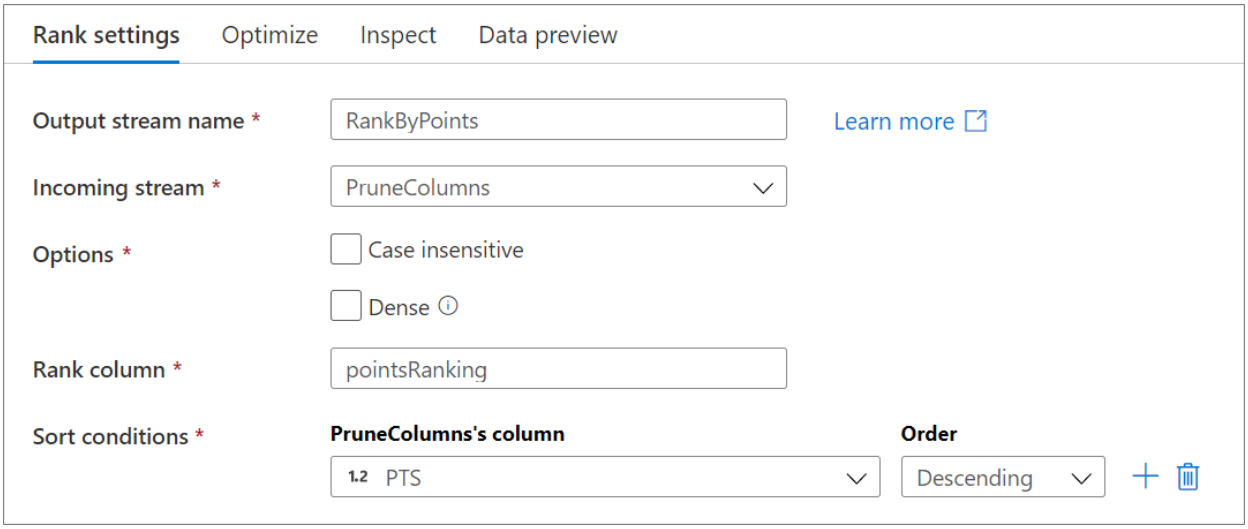
8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the rank transformation to generate an ordered ranking based upon sort conditions specified by the user.

Configuration



Case insensitive: If a sort column is of type string, case will be factored into the ranking.

Dense: If enabled, the rank column will be dense ranked. Each rank count will be a consecutive number and rank values won't be skipped after a tie.

Rank column: The name of the rank column generated. This column will be of type long.

Sort conditions: Choose which columns you're sorting by and in which order the sort happens. The order determines sorting priority.

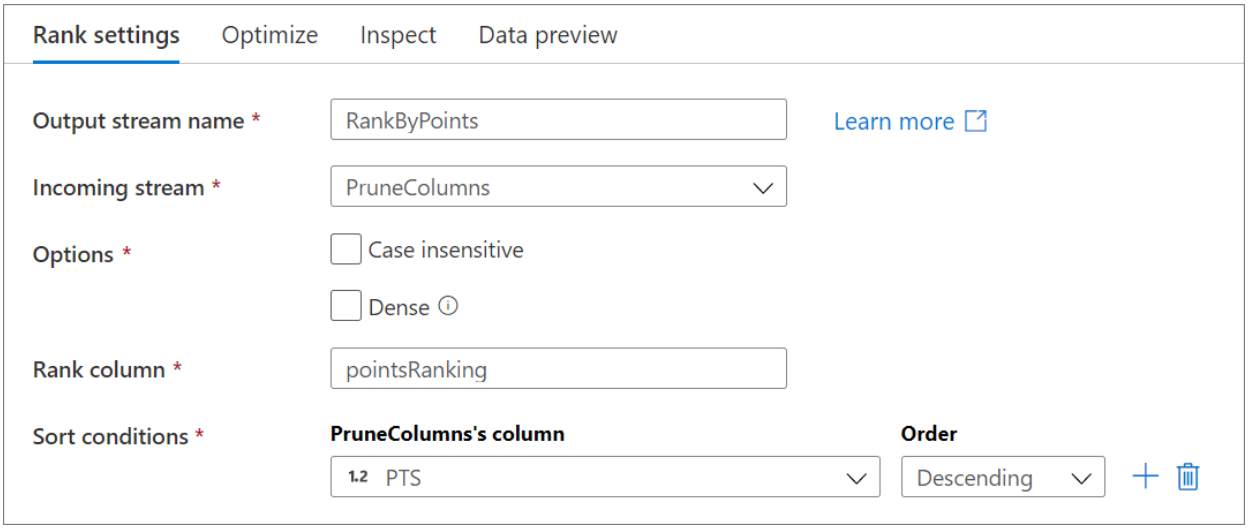
The above configuration takes incoming basketball data and creates a rank column called 'pointsRanking'. The row with the highest value of the column *PTS* will have a *pointsRanking* value of 1.

Data flow script

Syntax

```
<incomingStream>
    rank(
        desc(<sortColumn1>),
        asc(<sortColumn2>),
        ...,
        caseInsensitive: { true | false }
        dense: { true | false }
        output(<rankColumn> as long)
    ) ~> <sortTransformationName<>
```

Example



The data flow script for the above rank configuration is in the following code snippet.

```
PruneColumns
    rank(
        desc(PTS, true),
        caseInsensitive: false,
        output(pointsRanking as long),
        dense: false
    ) ~> RankByPoints
```

Next steps

Filter rows based upon the rank values using the filter transformation.

Select transformation in mapping data flow

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

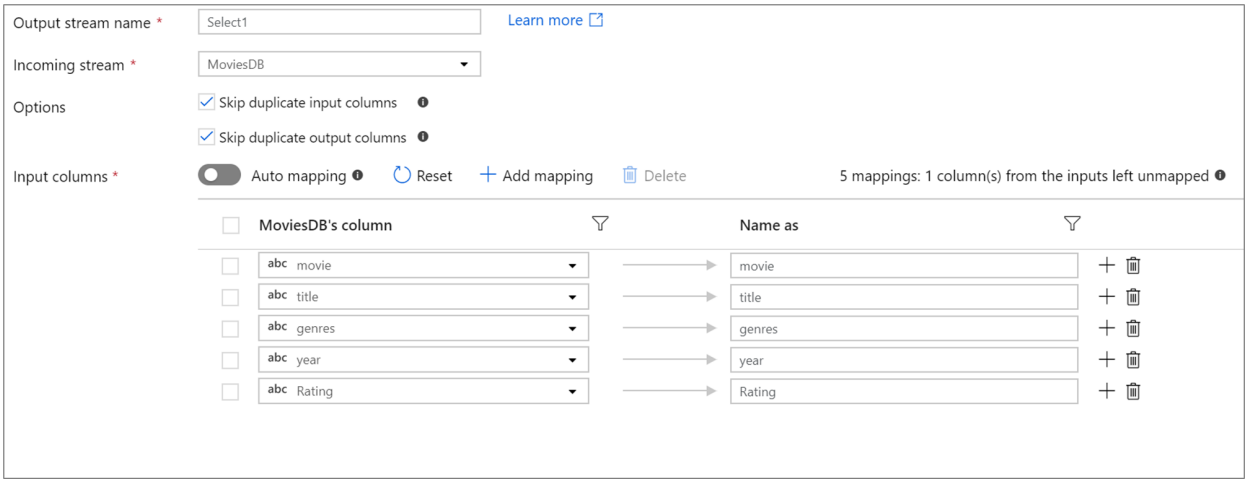
Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the select transformation to rename, drop, or reorder columns. This transformation doesn't alter row data, but chooses which columns are propagated downstream.

In a select transformation, users can specify fixed mappings, use patterns to do rule-based mapping, or enable auto mapping. Fixed and rule-based mappings can both be used within the same select transformation. If a column doesn't match one of the defined mappings, it will be dropped.

Fixed mapping

If there are fewer than 50 columns defined in your projection, all defined columns will have a fixed mapping by default. A fixed mapping takes a defined, incoming column and maps it an exact name.

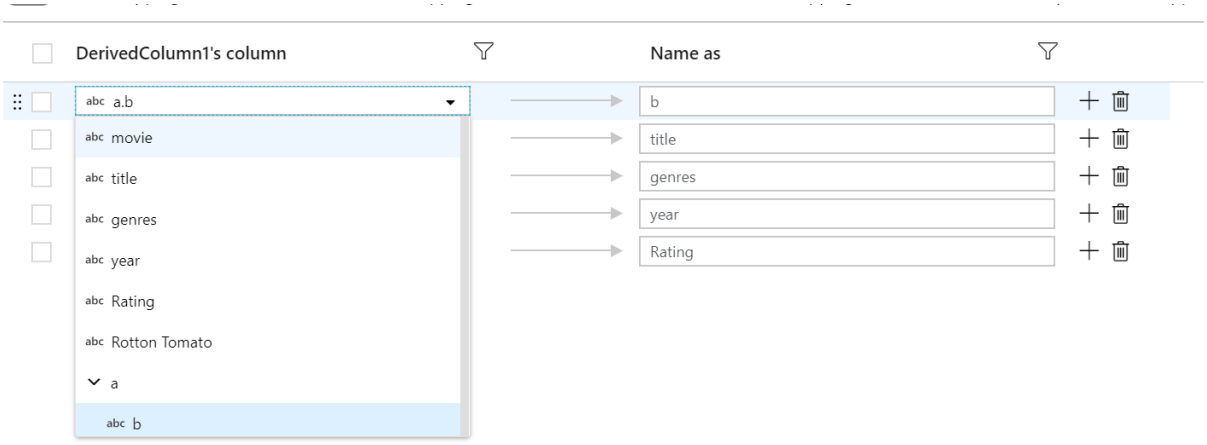


NOTE

You can't map or rename a drifted column using a fixed mapping

Mapping hierarchical columns

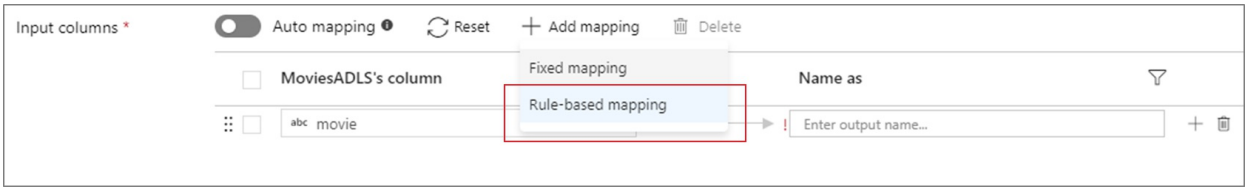
Fixed mappings can be used to map a subcolumn of a hierarchical column to a top-level column. If you have a defined hierarchy, use the column dropdown to select a subcolumn. The select transformation will create a new column with the value and data type of the subcolumn.



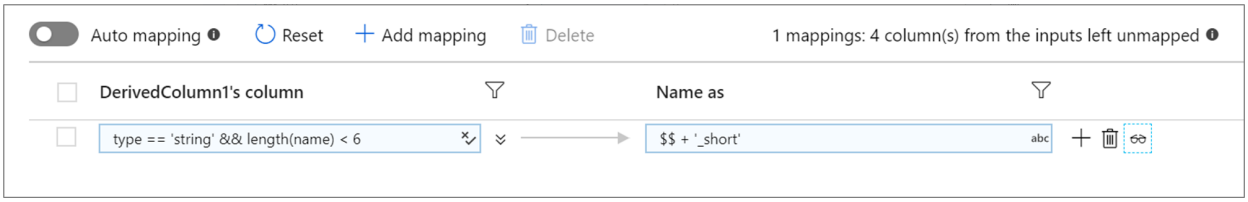
Rule-based mapping

If you wish to map many columns at once or pass drifted columns downstream, use rule-based mapping to define your mappings using column patterns. Match based on the `name`, `type`, `stream`, and `position` of columns. You can have any combination of fixed and rule-based mappings. By default, all projections with greater than 50 columns will default to a rule-based mapping that matches on every column and outputs the inputted name.

To add a rule-based mapping, click **Add mapping** and select **Rule-based mapping**.



Each rule-based mapping requires two inputs: the condition on which to match by and what to name each mapped column. Both values are inputted via the expression builder. In the left expression box, enter your boolean match condition. In the right expression box, specify what the matched column will be mapped to.

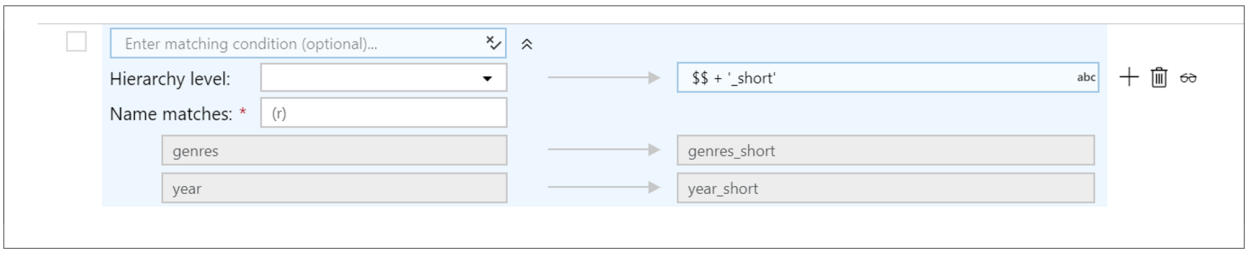


Use `$$` syntax to reference the input name of a matched column. Using the above image as an example, say a user wants to match on all string columns whose names are shorter than six characters. If one incoming column was named `test`, the expression `$$ + '_short'` will rename the column `test_short`. If that's the only mapping that exists, all columns that don't meet the condition will be dropped from the outputted data.

Patterns match both drifted and defined columns. To see which defined columns are mapped by a rule, click the eyeglasses icon next to the rule. Verify your output using data preview.

Regex mapping

If you click the downward chevron icon, you can specify a regex-mapping condition. A regex-mapping condition matches all column names that match the specified regex condition. This can be used in combination with standard rule-based mappings.

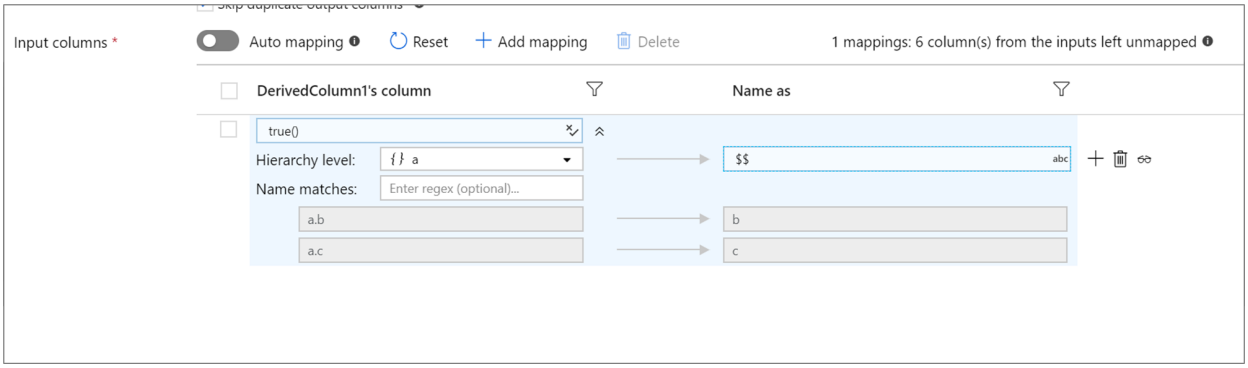


The above example matches on regex pattern `(r)` or any column name that contains a lower case r. Similar to standard rule-based mapping, all matched columns are altered by the condition on the right using `$$` syntax.

If you have multiple regex matches in your column name, you can refer to specific matches using `$n` where 'n' refers to which match. For example, '$2' refers to the second match within a column name.

Rule-based hierarchies

If your defined projection has a hierarchy, you can use rule-based mapping to map the hierarchies subcolumns. Specify a matching condition and the complex column whose subcolumns you wish to map. Every matched subcolumn will be outputted using the 'Name as' rule specified on the right.



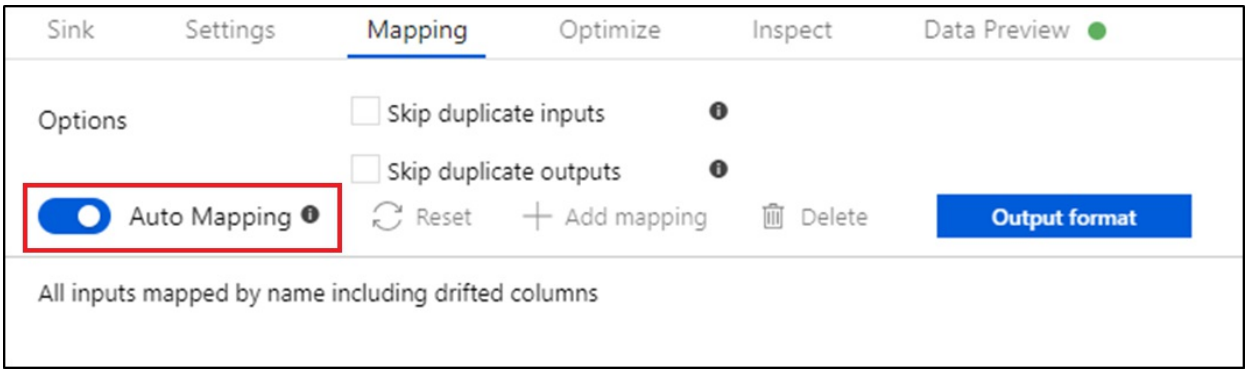
The above example matches on all subcolumns of complex column `a`. `a` contains two subcolumns `b` and `c`. The output schema will include two columns `b` and `c` as the 'Name as' condition is `$$`.

Parameterization

You can parameterize column names using rule-based mapping. Use the keyword `name` to match incoming column names against a parameter. For example, if you have a data flow parameter `mycolumn`, you can create a rule that matches any column name that is equal to `mycolumn`. You can rename the matched column to a hard-coded string such as 'business key' and reference it explicitly. In this example, the matching condition is `name == $mycolumn` and the name condition is 'business key'.

Auto mapping

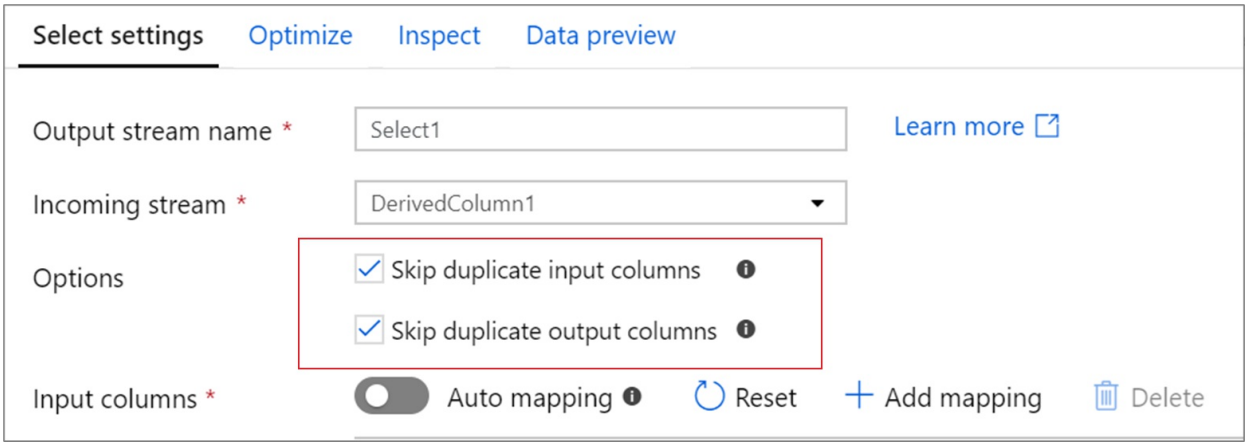
When adding a select transformation, **Auto mapping** can be enabled by switching the Auto mapping slider. With auto mapping, the select transformation maps all incoming columns, excluding duplicates, with the same name as their input. This will include drifted columns, which means the output data may contain columns not defined in your schema. For more information on drifted columns, see schema drift.



With auto mapping on, the select transformation will honor the skip duplicate settings and provide a new alias for the existing columns. Aliasing is useful when doing multiple joins or lookups on the same stream and in self-join scenarios.

Duplicate columns

By default, the select transformation drops duplicate columns in both the input and output projection. Duplicate input columns often come from join and lookup transformations where column names are duplicated on each side of the join. Duplicate output columns can occur if you map two different input columns to the same name. Choose whether to drop or pass on duplicate columns by toggling the checkbox.



Ordering of columns

The order of mappings determines the order of the output columns. If an input column is mapped multiple times, only the first mapping will be honored. For any duplicate column dropping, the first match will be kept.

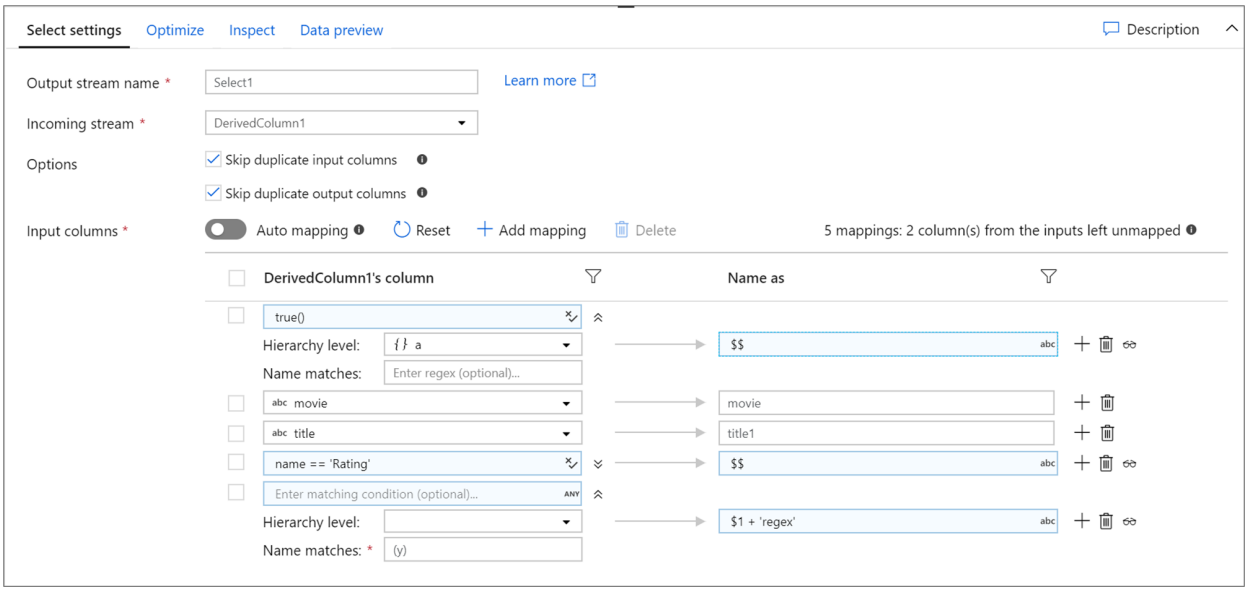
Data flow script

Syntax

```
<incomingStream>
    select(mapColumn(
        each(<hierarchicalColumn>, match(<matchCondition>), <nameCondition> = $$), ## hierarchical rule-
based matching
        <fixedColumn>, ## fixed mapping, no rename
        <renamedFixedColumn> = <fixedColumn>, ## fixed mapping, rename
        each(match(<matchCondition>), <nameCondition> = $$), ## rule-based mapping
        each(patternMatch(<regexMatching>), <nameCondition> = $$) ## regex mapping
    ),
    skipDuplicateMapInputs: { true | false },
    skipDuplicateMapOutputs: { true | false }) ~> <selectTransformationName>
```

Example

Below is an example of a select mapping and its data flow script:



```
DerivedColumn1 select(mapColumn(
        each(a, match(true())),
        movie,
        title1 = title,
        each(match(name == 'Rating')),
        each(patternMatch(`(y)`),
            $1 + 'regex' = $$)
    ),
    skipDuplicateMapInputs: true,
    skipDuplicateMapOutputs: true) ~> Select1
```

Next steps

- After using Select to rename, reorder, and alias columns, use the Sink transformation to land your data into a data store.

Sink transformation in mapping data flow

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

After you finish transforming your data, write it into a destination store by using the sink transformation. Every data flow requires at least one sink transformation, but you can write to as many sinks as necessary to complete your transformation flow. To write to additional sinks, create new streams via new branches and conditional splits.

Each sink transformation is associated with exactly one dataset object or linked service. The sink transformation determines the shape and location of the data you want to write to.

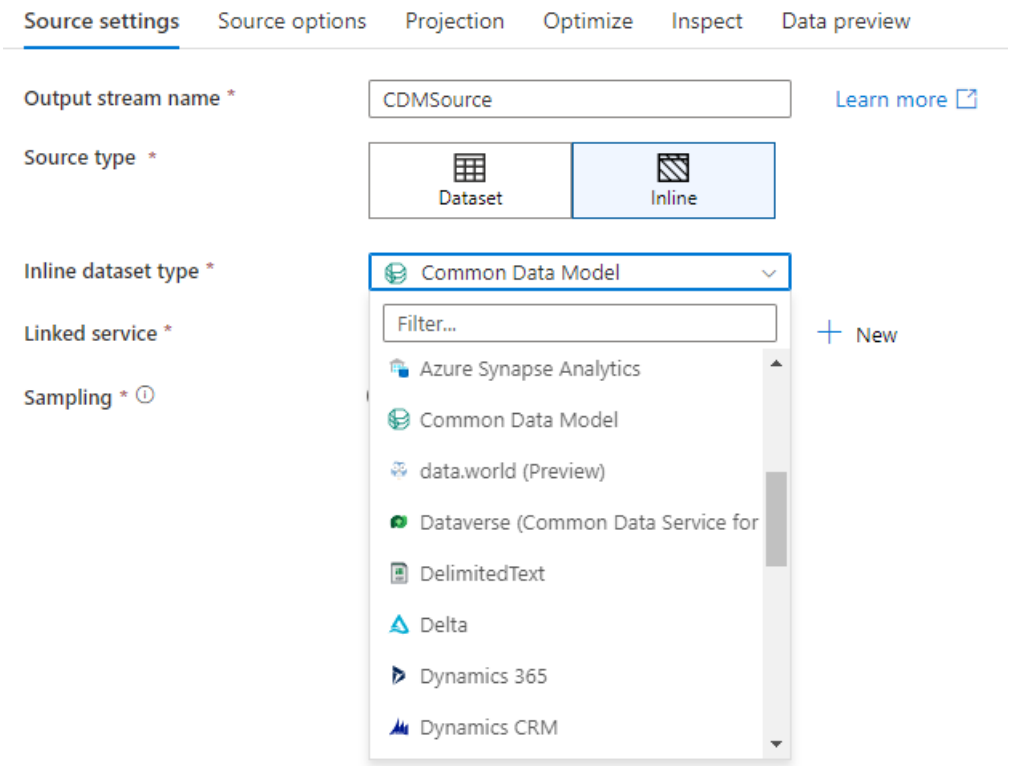
Inline datasets

When you create a sink transformation, choose whether your sink information is defined inside a dataset object or within the sink transformation. Most formats are available in only one or the other. To learn how to use a specific connector, see the appropriate connector document.

When a format is supported for both inline and in a dataset object, there are benefits to both. Dataset objects are reusable entities that can be used in other data flows and activities such as Copy. These reusable entities are especially useful when you use a hardened schema. Datasets aren't based in Spark. Occasionally, you might need to override certain settings or schema projection in the sink transformation.

Inline datasets are recommended when you use flexible schemas, one-off sink instances, or parameterized sinks. If your sink is heavily parameterized, inline datasets allow you to not create a "dummy" object. Inline datasets are based in Spark, and their properties are native to data flow.

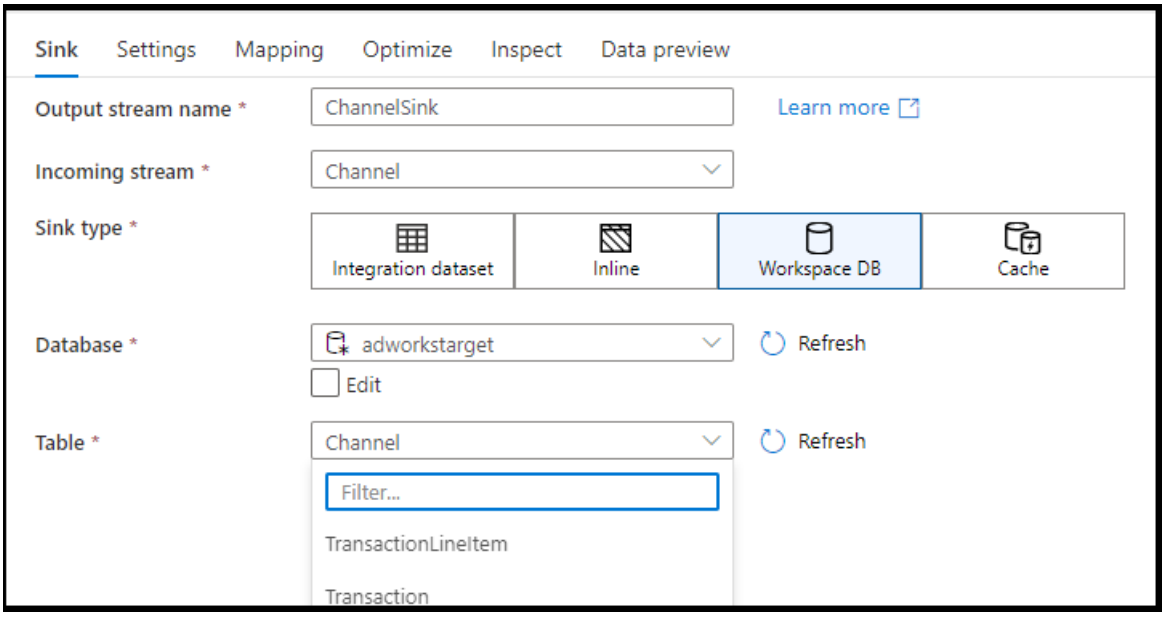
To use an inline dataset, select the format you want in the **Sink type** selector. Instead of selecting a sink dataset, you select the linked service you want to connect to.



Workspace DB (Synapse workspaces only)

When using data flows in Azure Synapse workspaces, you will have an additional option to sink your data directly into a database type that is inside your Synapse workspace. This will alleviate the need to add linked services or datasets for those databases.

> **NOTE**
> The Azure Synapse Workspace DB connector is currently in public preview and can only work with Spark Lake databases at this time



Supported sink types

Mapping data flow follows an extract, load, and transform (ELT) approach and works with *staging* datasets that are all in Azure. Currently, the following datasets can be used in a source transformation.

CONNECTOR	FORMAT	DATASET/INLINE
Azure Blob Storage	Avro Delimited text Delta JSON ORC Parquet	✓/- ✓/- -/✓ ✓/- ✓/✓ ✓/-
Azure Cosmos DB (SQL API)		✓/-
Azure Data Lake Storage Gen1	Avro Delimited text JSON ORC Parquet	✓/- ✓/- ✓/- ✓/✓ ✓/-

Azure Database for MySQL		✓/✓
Azure Database for PostgreSQL		✓/✓
Azure Data Explorer		✓/✓
Azure SQL Database		✓/✓
Azure SQL Managed Instance		✓/-
Azure Synapse Analytics		✓/-
Dataverse		✓/✓
Dynamics 365		✓/✓
Dynamics CRM		✓/✓
SFTP	Avro Delimited text JSON ORC Parquet	✓/✓ ✓/✓ ✓/✓ ✓/✓ ✓/✓
Snowflake		✓/✓
SQL Server		✓/✓

Settings specific to these connectors are located on the **Settings** tab. Information and data flow script examples on these settings are located in the connector documentation.

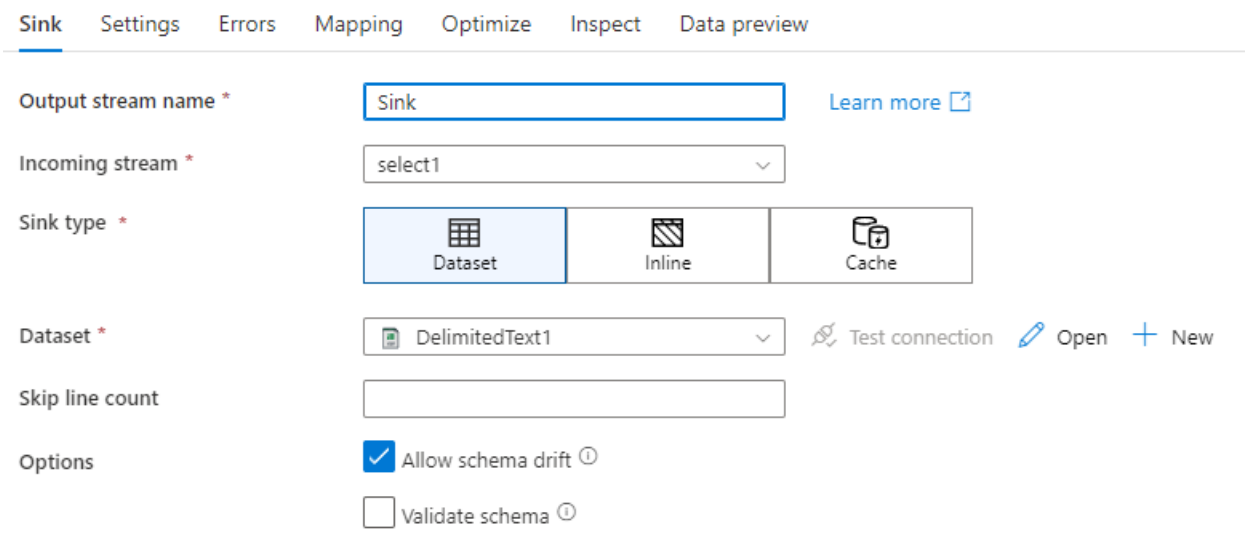
The service has access to more than 90 native connectors. To write data to those other sources from your data

flow, use the Copy Activity to load that data from a supported sink.

Sink settings

After you've added a sink, configure via the **Sink** tab. Here you can pick or create the dataset your sink writes to. Development values for dataset parameters can be configured in Debug settings. (Debug mode must be turned on.)

The following video explains a number of different sink options for text-delimited file types.



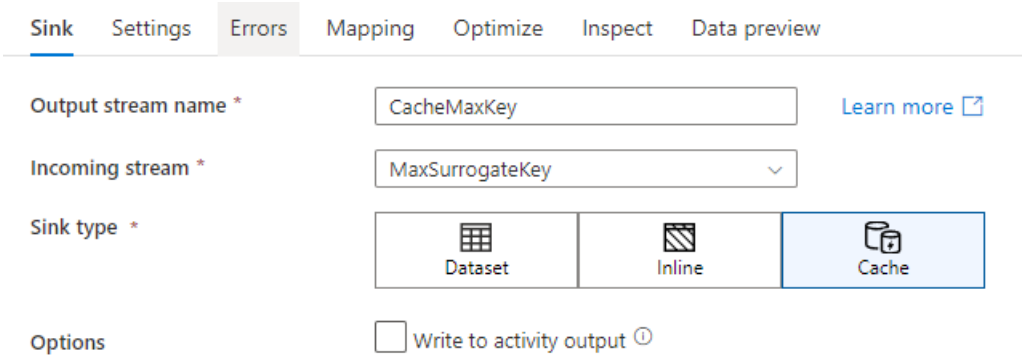
Schema drift: Schema drift is the ability of the service to natively handle flexible schemas in your data flows without needing to explicitly define column changes. Enable **Allow schema drift** to write additional columns on top of what's defined in the sink data schema.

Validate schema: If validate schema is selected, the data flow will fail if any column in sink projection isn't found in the sink store, or if the data types don't match. Use this setting to enforce that the sink schema meets the contract of your defined projection. It's useful in database sink scenarios to signal that column names or types have changed.

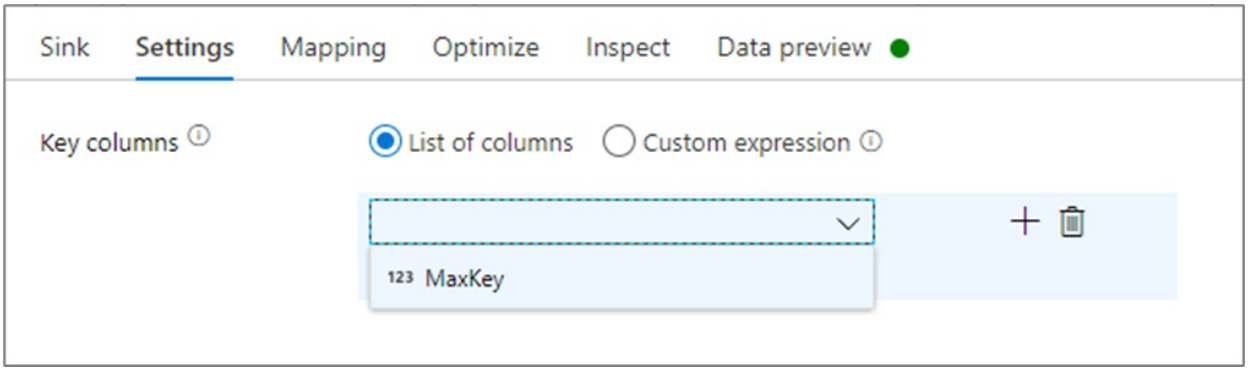
Cache sink

A *cache sink* is when a data flow writes data into the Spark cache instead of a data store. In mapping data flows, you can reference this data within the same flow many times using a *cache lookup*. This is useful when you want to reference data as part of an expression but don't want to explicitly join the columns to it. Common examples where a cache sink can help are looking up a max value on a data store and matching error codes to an error message database.

To write to a cache sink, add a sink transformation and select **Cache** as the sink type. Unlike other sink types, you don't need to select a dataset or linked service because you aren't writing to an external store.



In the sink settings, you can optionally specify the key columns of the cache sink. These are used as matching conditions when using the `lookup()` function in a cache lookup. If you specify key columns, you can't use the `outputs()` function in a cache lookup. To learn more about the cache lookup syntax, see cached lookups.



For example, if I specify a single key column of `column1` in a cache sink called `cacheExample`, calling `cacheExample#lookup()` would have one parameter specifies which row in the cache sink to match on. The function outputs a single complex column with subcolumns for each column mapped.

> **NOTE**
> A cache sink must be in a completely independent data stream from any transformation referencing it via a cache lookup. A cache sink also must be the first sink written.

Write to activity output The cached sink can optionally write your output data to the input of the next pipeline activity. This will allow you to quickly and easily pass data out of your data flow activity without needing to persist the data in a data store.

Field mapping

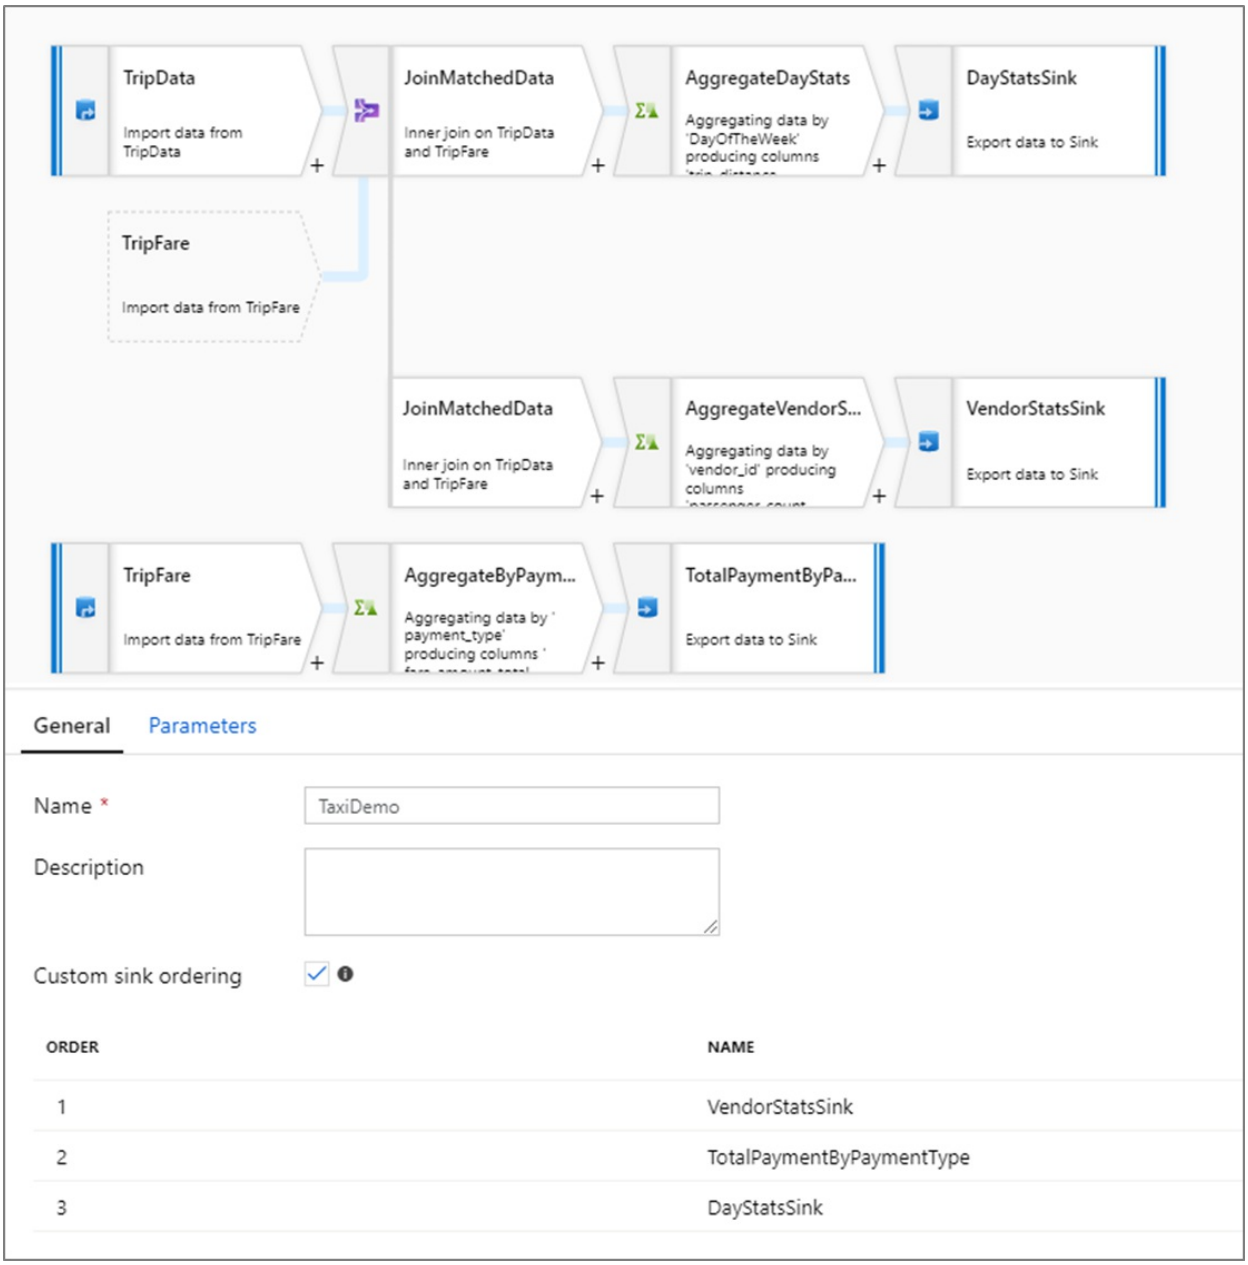
Similar to a select transformation, on the **Mapping** tab of the sink, you can decide which incoming columns will get written. By default, all input columns, including drifted columns, are mapped. This behavior is known as *automapping*.

When you turn off automapping, you can add either fixed column-based mappings or rule-based mappings. With rule-based mappings, you can write expressions with pattern matching. Fixed mapping maps logical and physical column names. For more information on rule-based mapping, see Column patterns in mapping data flow.

Custom sink ordering

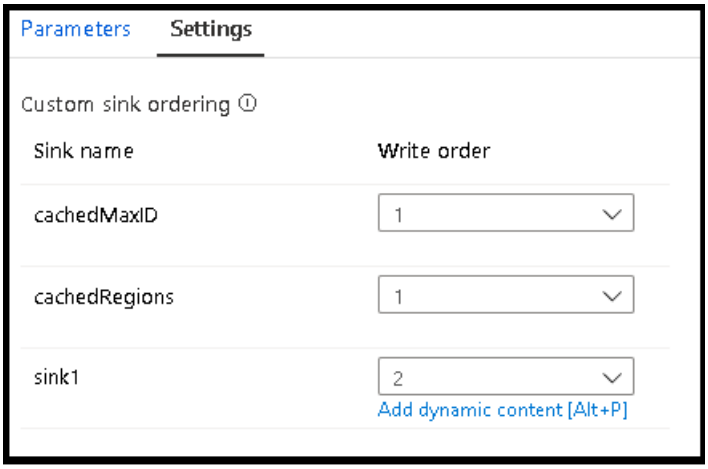
By default, data is written to multiple sinks in a nondeterministic order. The execution engine writes data in parallel as the transformation logic is completed, and the sink ordering might vary each run. To specify an exact sink ordering, enable **Custom sink ordering** on the **General** tab of the data flow. When enabled, sinks are

written sequentially in increasing order.



NOTE

When utilizing cached lookups, make sure that your sink ordering has the cached sinks set to 1, the lowest (or first) in ordering.



Sink groups

You can group sinks together by applying the same order number for a series of sinks. The service will treat those sinks as groups that can execute in parallel. Options for parallel execution will surface in the pipeline data flow activity.

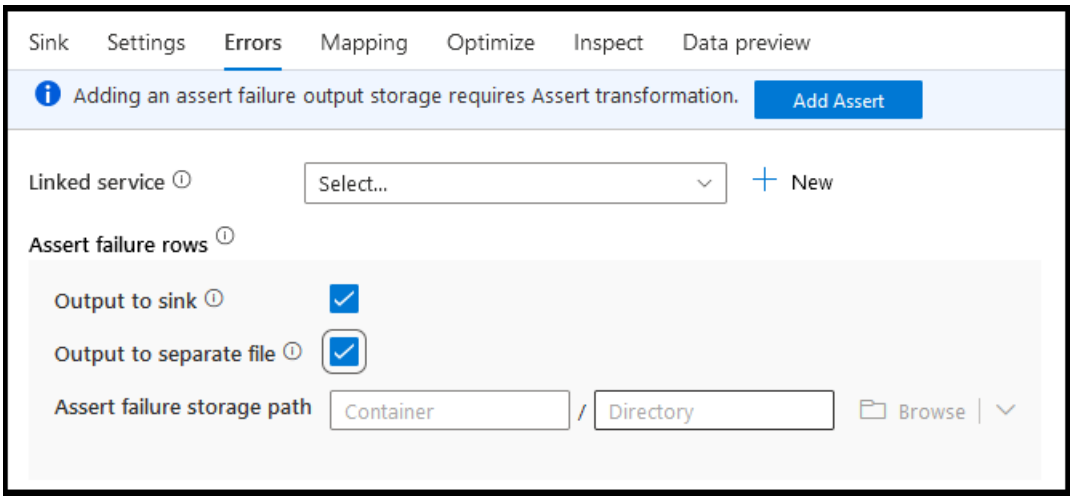
Errors

On the sink errors tab you can configure error row handling to capture and redirect output for database driver errors and failed assertions.

When writing to databases, certain rows of data may fail due to constraints set by the destination. By default, a data flow run will fail on the first error it gets. In certain connectors, you can choose to **Continue on error** that allows your data flow to complete even if individual rows have errors. Currently, this capability is only available in Azure SQL Database and Azure Synapse. For more information, see error row handling in Azure SQL DB.

Below is a video tutorial on how to use database error row handling automatically in your sink transformation.

For assert failure rows, you can use the Assert transformation upstream in your data flow and then redirect failed assertions to an output file here in the sink errors tab. You also have an option here to ignore rows with assertion failures and not output those rows at all to the sink destination data store.



Data preview in sink

When fetching a data preview in debug mode, no data will be written to your sink. A snapshot of what the data looks like will be returned, but nothing will be written to your destination. To test writing data into your sink, run a pipeline debug from the pipeline canvas.

Data flow script

Example

Below is an example of a sink transformation and its data flow script:

```
sink(input(
  movie as integer,
  title as string,
  genres as string,
  year as integer,
  Rating as integer
 ),
 allowSchemaDrift: true,
 validateSchema: false,
 deletable:false,
 insertable:false,
 updateable:true,
 upsertable:false,
 keys:['movie'],
 format: 'table',
 skipDuplicateMapInputs: true,
 skipDuplicateMapOutputs: true,
 saveOrder: 1,
 errorHandlingOption: 'stopOnFirstError') ~> sink1
```

Next steps

Now that you've created your data flow, add a data flow activity to your pipeline.

Sort transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

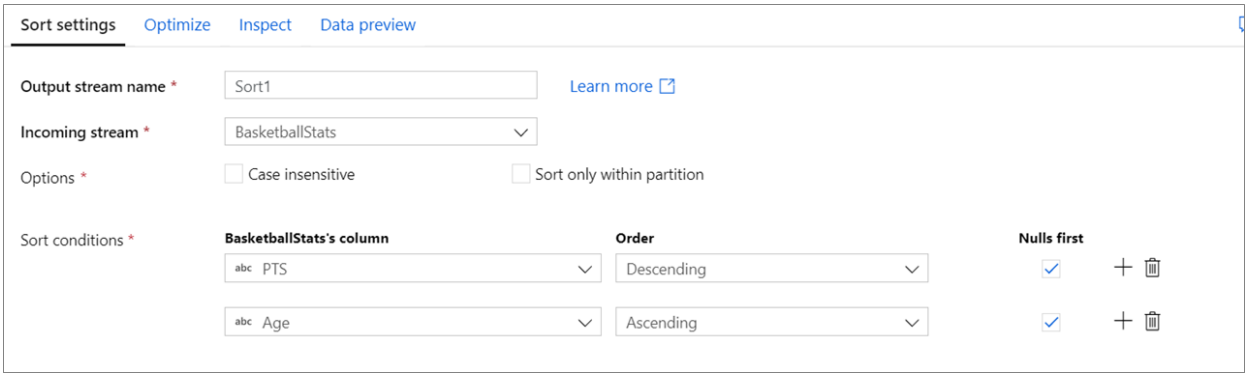
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The sort transformation allows you to sort the incoming rows on the current data stream. You can choose individual columns and sort them in ascending or descending order.

> **NOTE**
> Mapping data flows are executed on spark clusters which distribute data across multiple nodes and partitions. If you choose to repartition your data in a subsequent transformation, you may lose your sorting due to reshuffling of data. The best way to maintain sort order in your data flow is to set single partition in the Optimize tab on the transformation and keep the Sort transformation as close to the Sink as possible.

Configuration



Case insensitive: Whether or not you wish to ignore case when sorting string or text fields

Sort Only Within Partitions: As data flows are run on spark, each data stream is divided into partitions. This setting sorts data only within the incoming partitions rather than sorting the entire data stream.

Sort conditions: Choose which columns you are sorting by and in which order the sort happens. The order determines sorting priority. Choose whether or not nulls will appear at the beginning or end of the data stream.

Computed columns

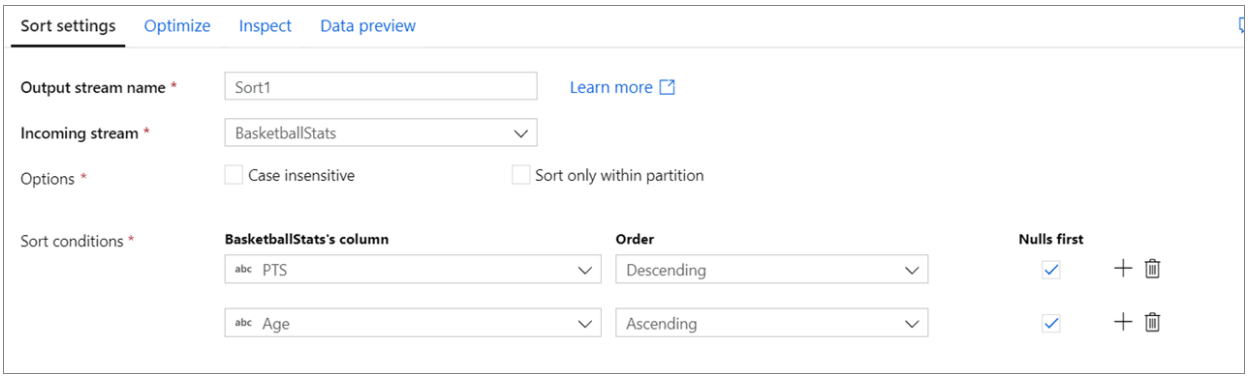
To modify or extract a column value before applying the sort, hover over the column and select "computed column". This will open the expression builder to create an expression for the sort operation instead of using a column value.

Data flow script

Syntax

```
<incomingStream>
    sort(
        desc(<sortColumn1>, { true | false }),
        asc(<sortColumn2>, { true | false }),
        ...
    ) ~> <sortTransformationName<>
```

Example



The data flow script for the above sort configuration is in the code snippet below.

```
BasketballStats sort(desc(PTS, true),
    asc(Age, true)) ~> Sort1
```

Next steps

After sorting, you may want to use the Aggregate Transformation

Source transformation in mapping data flow

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

A source transformation configures your data source for the data flow. When you design data flows, your first step is always configuring a source transformation. To add a source, select the **Add Source** box in the data flow canvas.

Every data flow requires at least one source transformation, but you can add as many sources as necessary to complete your data transformations. You can join those sources together with a join, lookup, or a union transformation.

Each source transformation is associated with exactly one dataset or linked service. The dataset defines the shape and location of the data you want to write to or read from. If you use a file-based dataset, you can use wildcards and file lists in your source to work with more than one file at a time.

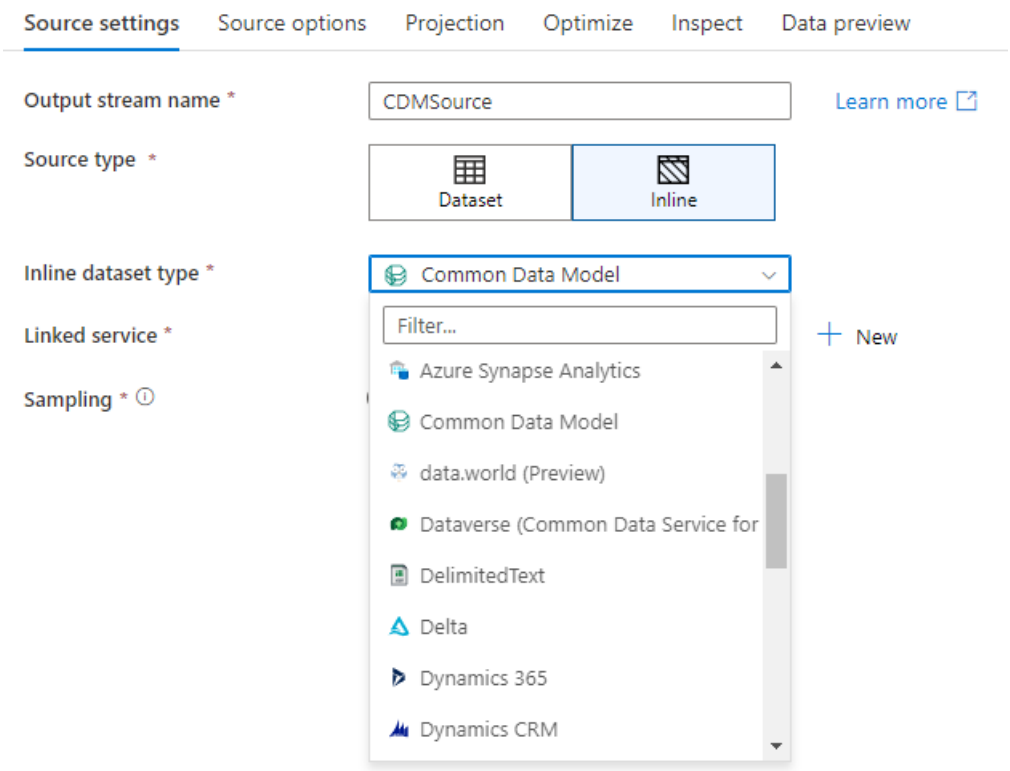
Inline datasets

The first decision you make when you create a source transformation is whether your source information is defined inside a dataset object or within the source transformation. Most formats are available in only one or the other. To learn how to use a specific connector, see the appropriate connector document.

When a format is supported for both inline and in a dataset object, there are benefits to both. Dataset objects are reusable entities that can be used in other data flows and activities such as Copy. These reusable entities are especially useful when you use a hardened schema. Datasets aren't based in Spark. Occasionally, you might need to override certain settings or schema projection in the source transformation.

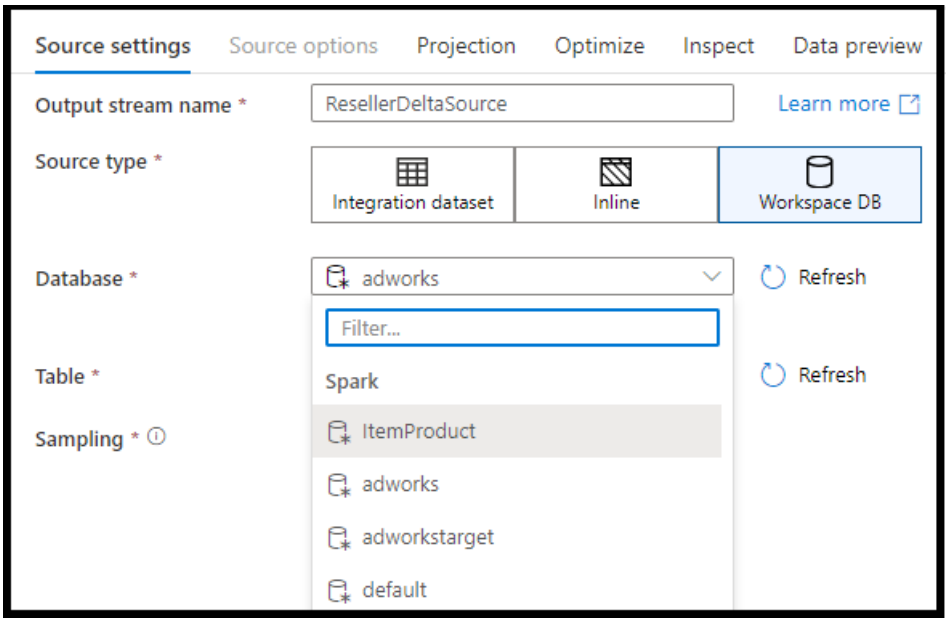
Inline datasets are recommended when you use flexible schemas, one-off source instances, or parameterized sources. If your source is heavily parameterized, inline datasets allow you to not create a "dummy" object. Inline datasets are based in Spark, and their properties are native to data flow.

To use an inline dataset, select the format you want in the **Source type** selector. Instead of selecting a source dataset, you select the linked service you want to connect to.



Workspace DB (Synapse workspaces only)

In Azure Synapse workspaces, an additional option is present in data flow source transformations called `Workspace DB`. This will allow you to directly pick a workspace database of any available type as your source data without requiring additional linked services or datasets.



Supported source types

Mapping data flow follows an extract, load, and transform (ELT) approach and works with *staging* datasets that are all in Azure. Currently, the following datasets can be used in a source transformation.

CONNECTOR	FORMAT	DATASET/INLINE

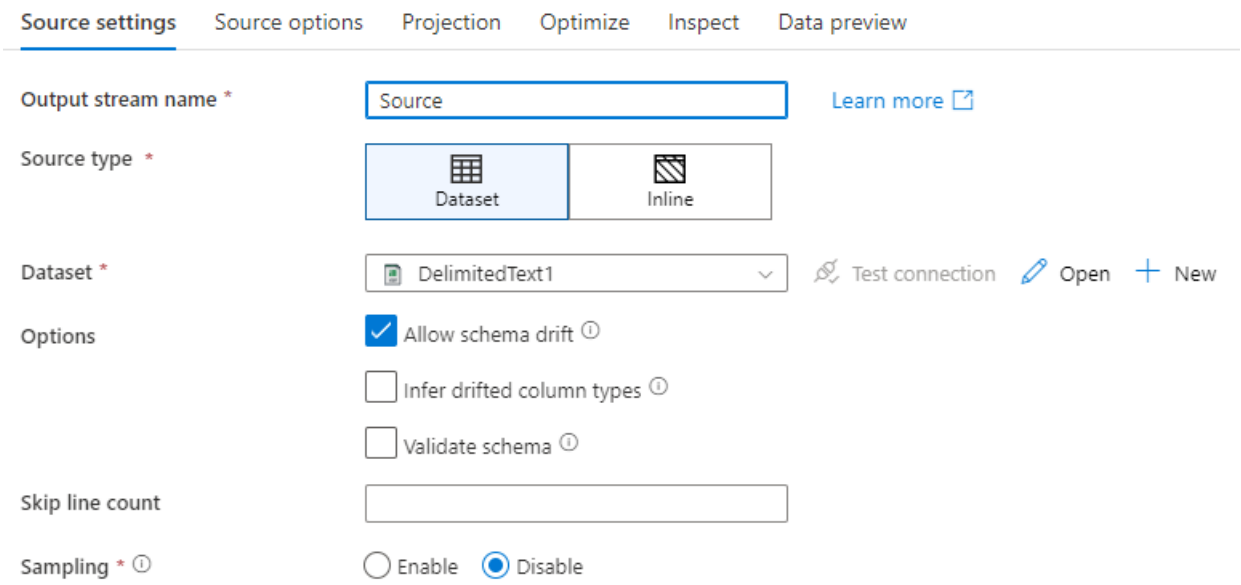
Settings specific to these connectors are located on the **Source options** tab. Information and data flow script examples on these settings are located in the connector documentation.

Azure Data Factory and Synapse pipelines have access to more than 90 native connectors. To include data from those other sources in your data flow, use the Copy Activity to load that data into one of the supported staging areas.

Source settings

After you've added a source, configure via the **Source settings** tab. Here you can pick or create the dataset your source points at. You can also select schema and sampling options for your data.

Development values for dataset parameters can be configured in debug settings. (Debug mode must be turned on.)



Output stream name: The name of the source transformation.

Source type: Choose whether you want to use an inline dataset or an existing dataset object.

Test connection: Test whether or not the data flow's Spark service can successfully connect to the linked service used in your source dataset. Debug mode must be on for this feature to be enabled.

Schema drift: Schema drift is the ability of the service to natively handle flexible schemas in your data flows without needing to explicitly define column changes.

- Select the **Allow schema drift** check box if the source columns will change often. This setting allows all incoming source fields to flow through the transformations to the sink.
- Selecting **Infer drifted column types** instructs the service to detect and define data types for each new column discovered. With this feature turned off, all drifted columns will be of type string.

Validate schema: If **Validate schema** is selected, the data flow will fail to run if the incoming source data doesn't match the defined schema of the dataset.

Skip line count: The **Skip line count** field specifies how many lines to ignore at the beginning of the dataset.

Sampling: Enable **Sampling** to limit the number of rows from your source. Use this setting when you test or sample data from your source for debugging purposes. This is very useful when executing data flows in debug mode from a pipeline.

To validate your source is configured correctly, turn on debug mode and fetch a data preview. For more information, see Debug mode.

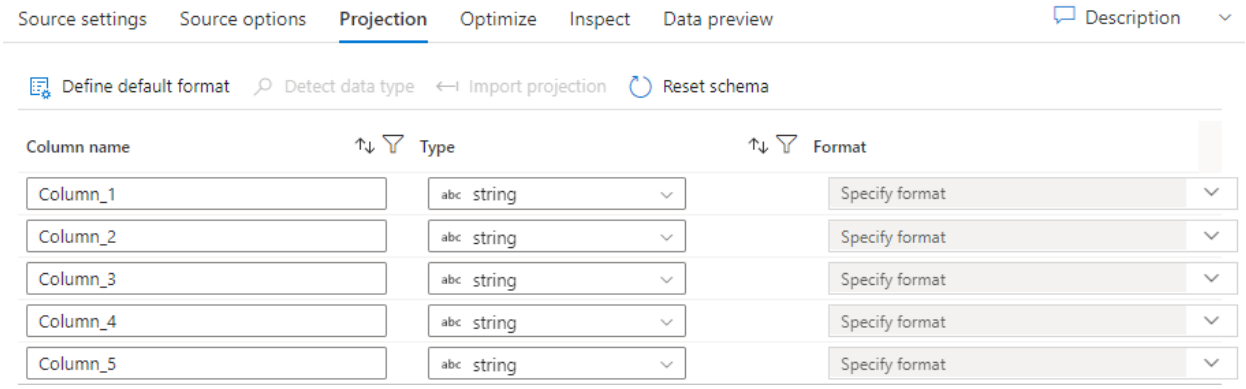
> **NOTE**
> When debug mode is turned on, the row limit configuration in debug settings will overwrite the sampling setting in the source during data preview.

Source options

The **Source options** tab contains settings specific to the connector and format chosen. For more information and examples, see the relevant connector documentation.

Projection

Like schemas in datasets, the projection in a source defines the data columns, types, and formats from the source data. For most dataset types, such as SQL and Parquet, the projection in a source is fixed to reflect the schema defined in a dataset. When your source files aren't strongly typed (for example, flat .csv files rather than Parquet files), you can define the data types for each field in the source transformation.



If your text file has no defined schema, select **Detect data type** so that the service will sample and infer the data types. Select **Define default format** to autodetect the default data formats.

Reset schema resets the projection to what is defined in the referenced dataset.

Overwrite schema allows you to modify the projected data types here the source, overwriting the schema-defined data types. You can alternatively modify the column data types in a downstream derived-column transformation. Use a select transformation to modify the column names.

Import schema

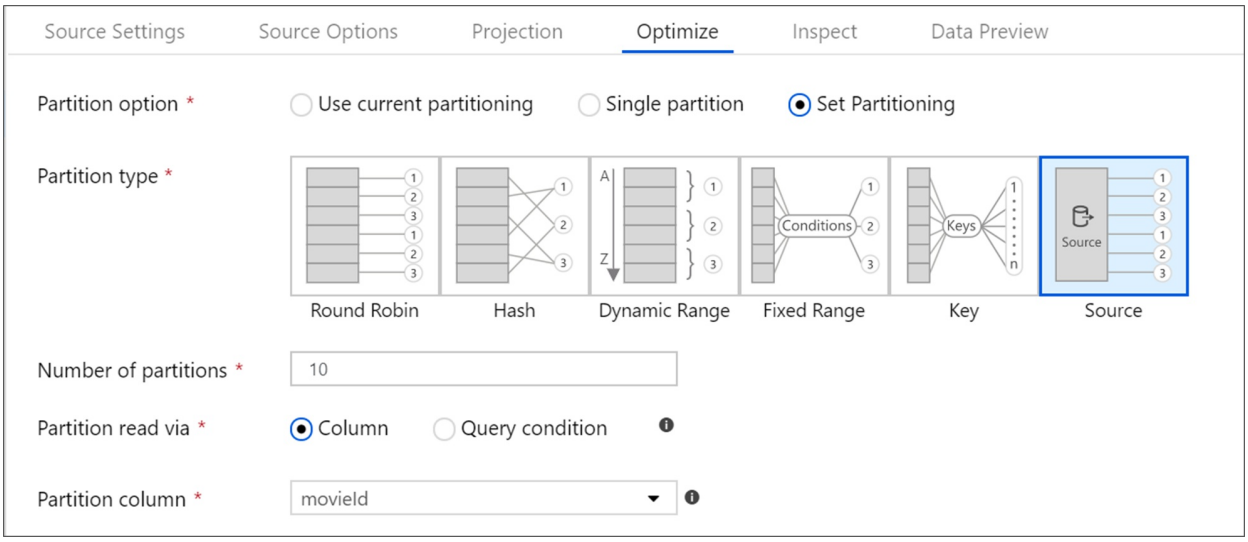
Select the **Import schema** button on the **Projection** tab to use an active debug cluster to create a schema projection. It's available in every source type. Importing the schema here will override the projection defined in the dataset. The dataset object won't be changed.

Importing schema is useful in datasets like Avro and Azure Cosmos DB that support complex data structures that don't require schema definitions to exist in the dataset. For inline datasets, importing schema is the only way to reference column metadata without schema drift.

Optimize the source transformation

The **Optimize** tab allows for editing of partition information at each transformation step. In most cases, **Use current partitioning** will optimize for the ideal partitioning structure for a source.

If you're reading from an Azure SQL Database source, custom **Source** partitioning will likely read data the fastest. The service will read large queries by making connections to your database in parallel. This source partitioning can be done on a column or by using a query.



For more information on optimization within mapping data flow, see the Optimize tab.

Next steps

Begin building your data flow with a derived-column transformation and a select transformation.

Surrogate key transformation in mapping data flow

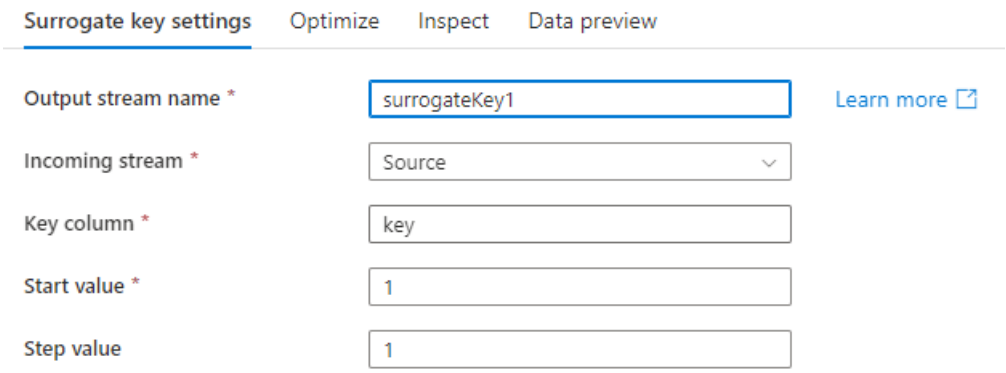
8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use the surrogate key transformation to add an incrementing key value to each row of data. This is useful when designing dimension tables in a star schema analytical data model. In a star schema, each member in your dimension tables requires a unique key that is a non-business key.

Configuration

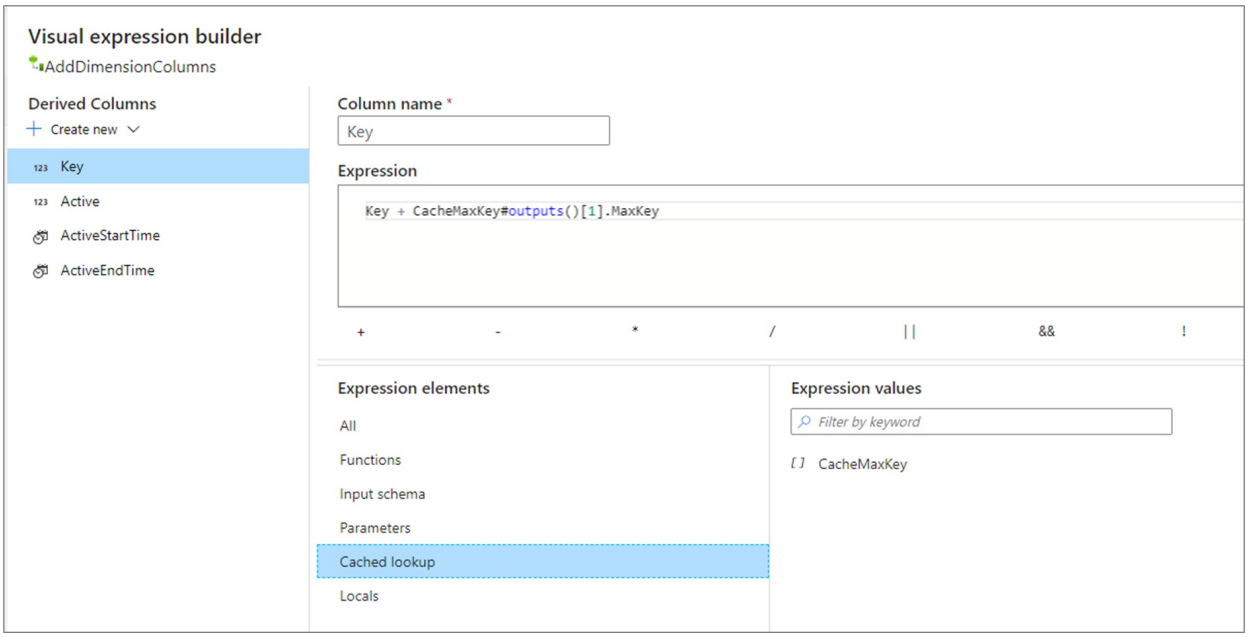


Key column: The name of the generated surrogate key column.

Start value: The lowest key value that will be generated.

Increment keys from existing sources

To start your sequence from a value that exists in a source, we recommend to use a cache sink to save that value and use a derived column transformation to add the two values together. Use a cached lookup to get the output and append it to the generated key. For more information, learn about cache sinks and cached lookups.

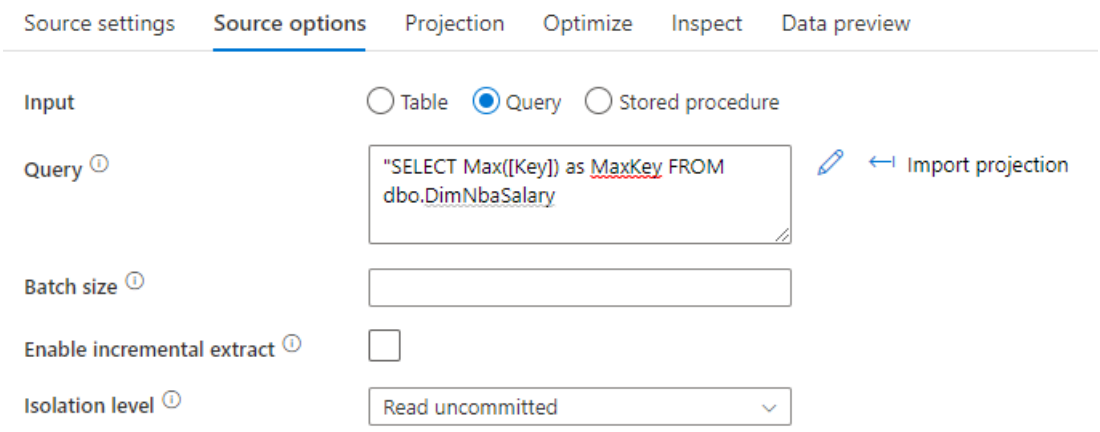


Increment from existing maximum value

To seed the key value with the previous max, there are two techniques that you can use based on where your source data is.

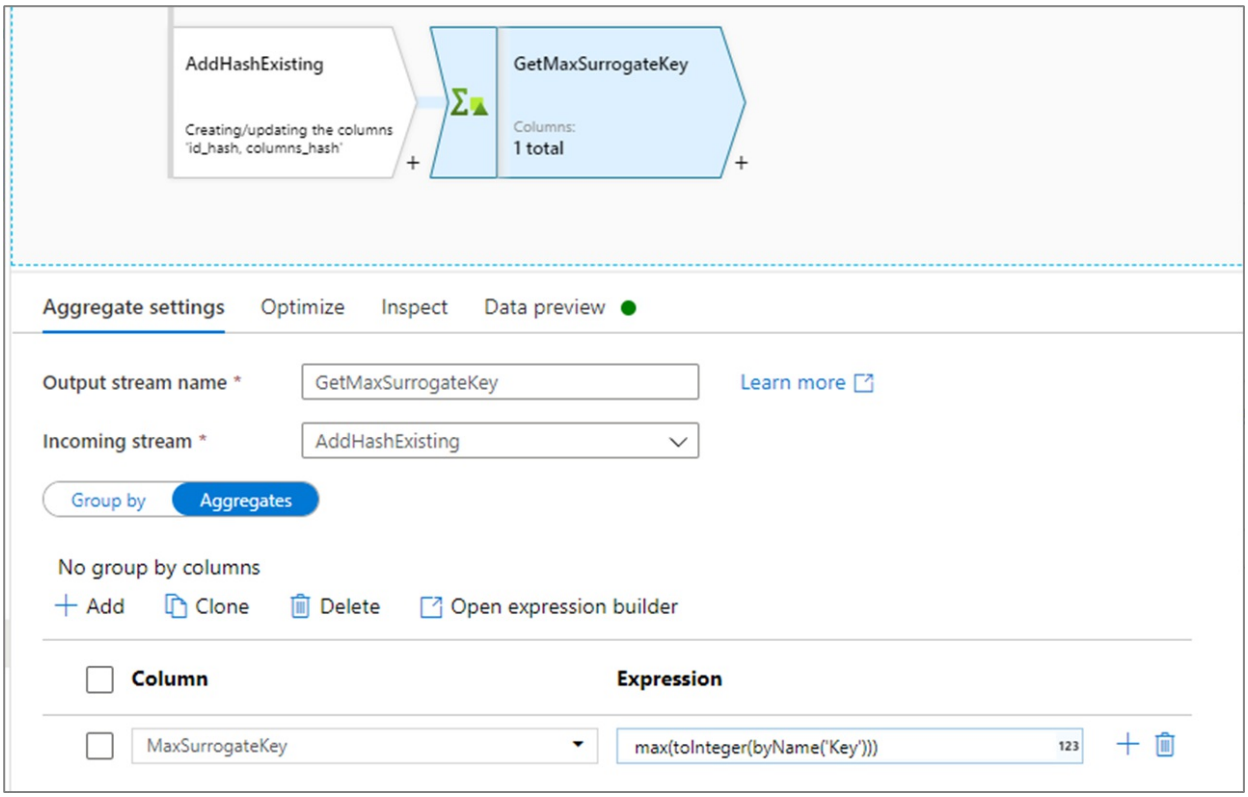
Database sources

Use a SQL query option to select MAX() from your source. For example, `Select MAX(<surrogateKeyName>) as maxval from <sourceTable>`.



File sources

If your previous max value is in a file, use the `max()` function in the aggregate transformation to get the previous max value:



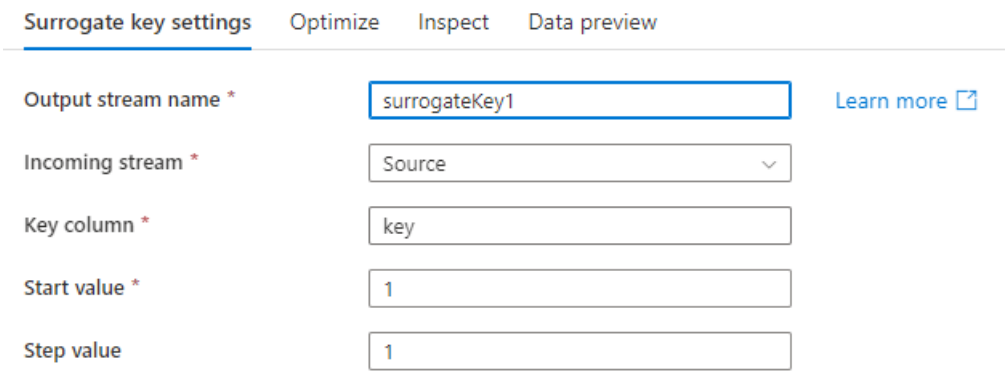
In both cases, you will need to write to a cache sink and lookup the value.

Data flow script

Syntax

```
<incomingStream>
    keyGenerate(
        output(<surrogateColumnName> as long),
        startAt: <number>L
    ) ~> <surrogateKeyTransformationName>
```

Example



The data flow script for the above surrogate key configuration is in the code snippet below.

```
AggregateDayStats
    keyGenerate(
        output(key as long),
        startAt: 1L
    ) ~> SurrogateKey1
```

Next steps

These examples use the Join and Derived Column transformations.

Union transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

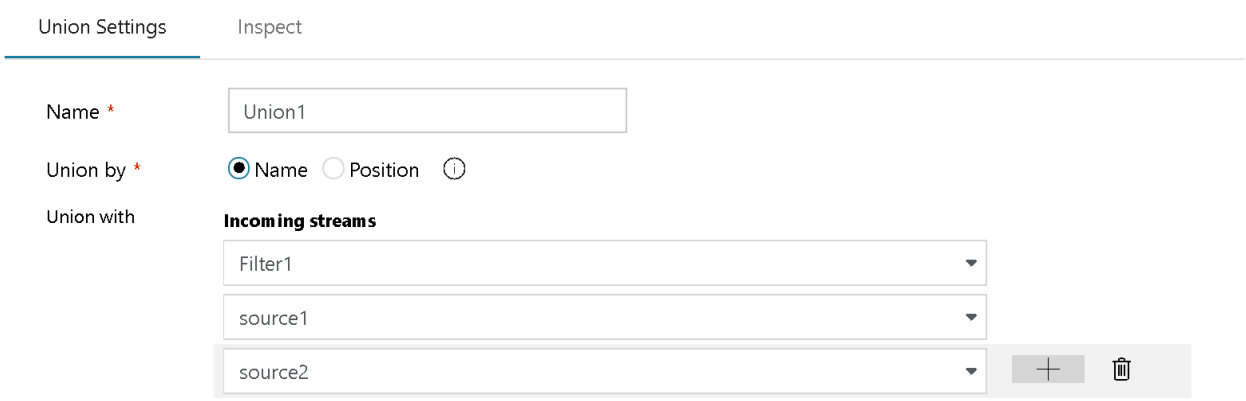
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

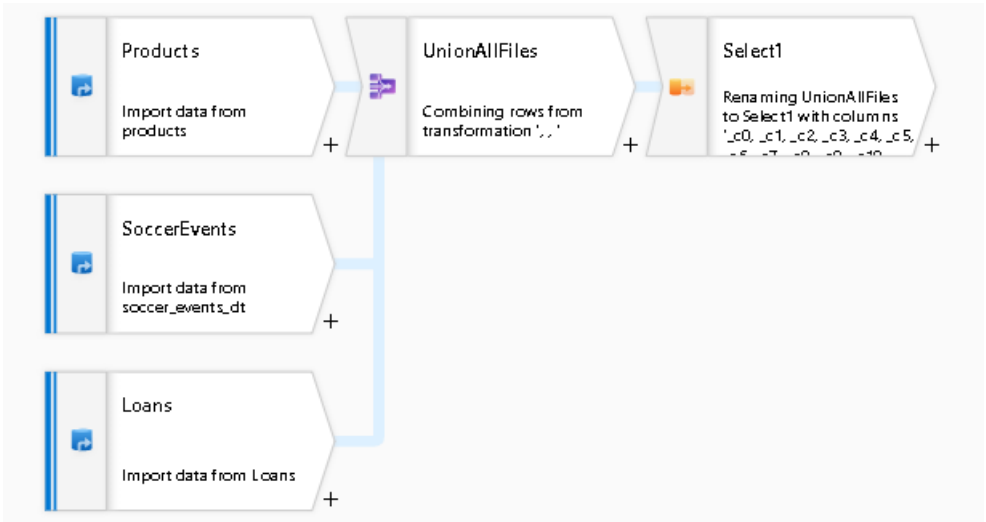
Union will combine multiple data streams into one, with the SQL Union of those streams as the new output from the Union transformation. All of the schema from each input stream will be combined inside of your data flow, without needing to have a join key.

You can combine n-number of streams in the settings table by selecting the "+" icon next to each configured row, including both source data as well as streams from existing transformations in your data flow.

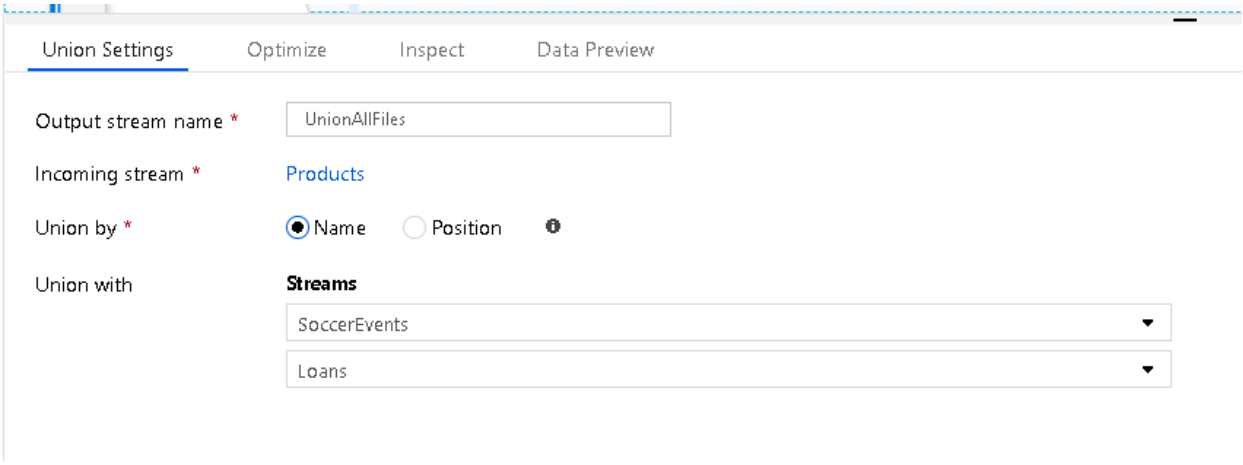
Here is a short video walk-through of the union transformation in the mapping data flow:



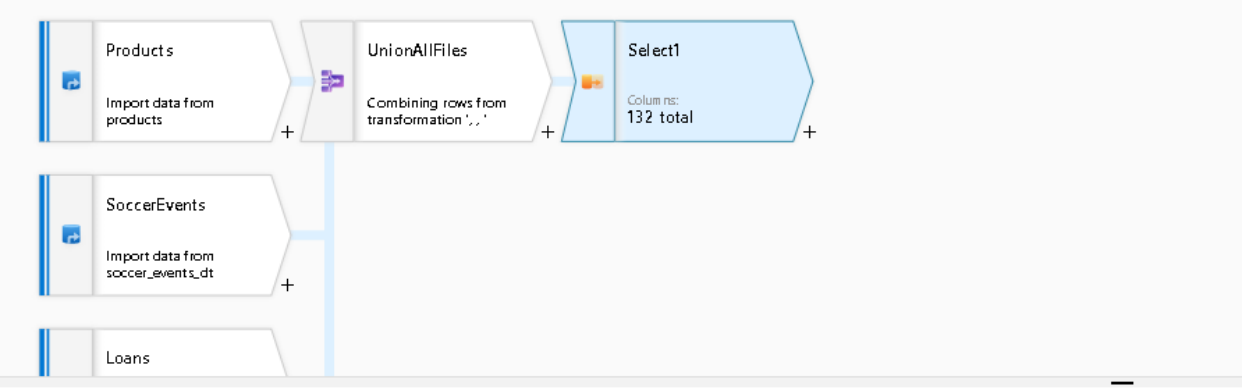
In this case, you can combine disparate metadata from multiple sources (in this example, three different source files) and combine them into a single stream:

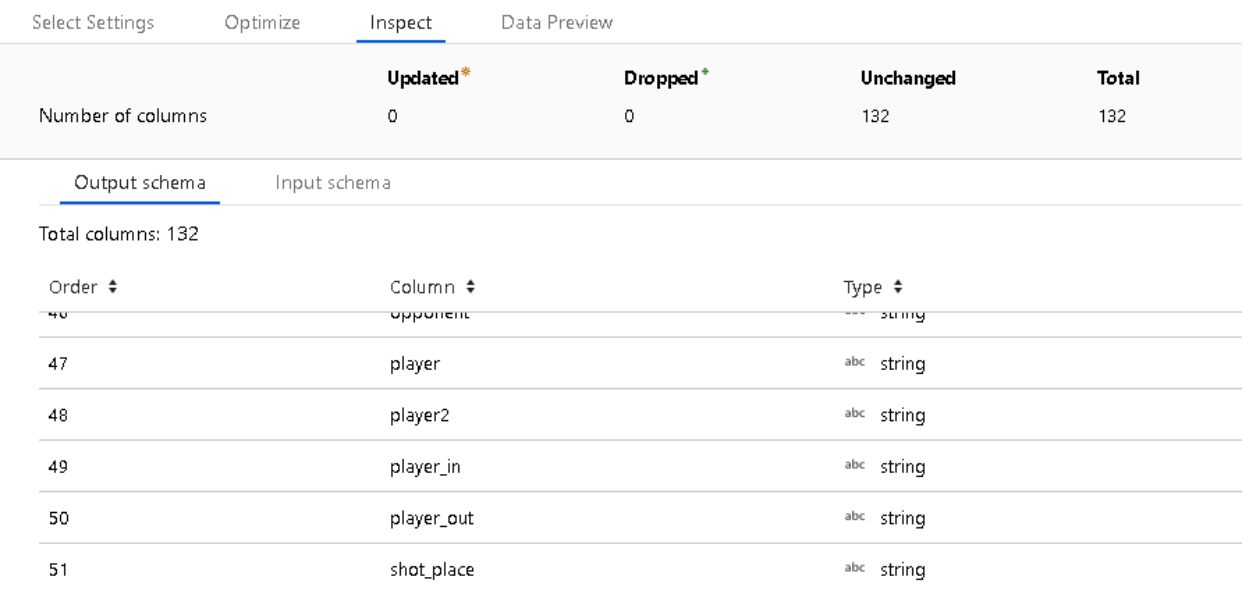


To achieve this, add additional rows in the Union Settings by including all source you wish to add. There is no need for a common lookup or join key:



If you set a Select transformation after your Union, you will be able to rename overlapping fields or fields that were not named from headerless sources. Click on "Inspect" to see the combine metadata with 132 total columns in this example from three different sources:





Name and position

When you choose "union by name", each column value will drop into the corresponding column from each source, with a new concatenated metadata schema.

If you choose "union by position", each column value will drop into the original position from each corresponding source, resulting in a new combined stream of data where the data from each source is added to the same stream:

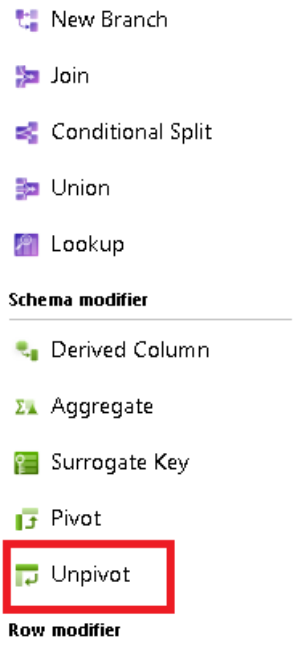
Unpivot transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

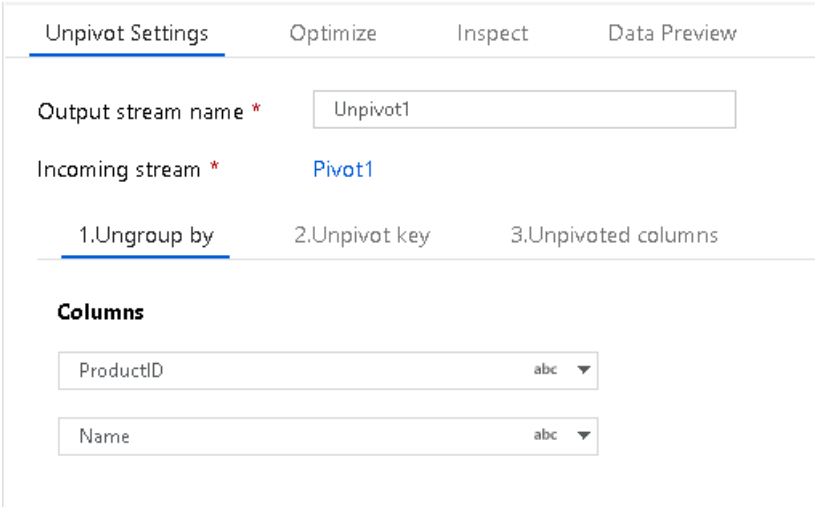
APPLIES TO: Azure Data Factory Azure Synapse Analytics

Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

Use Unpivot in a mapping data flow as a way to turn an unnormalized dataset into a more normalized version by expanding values from multiple columns in a single record into multiple records with the same values in a single column.

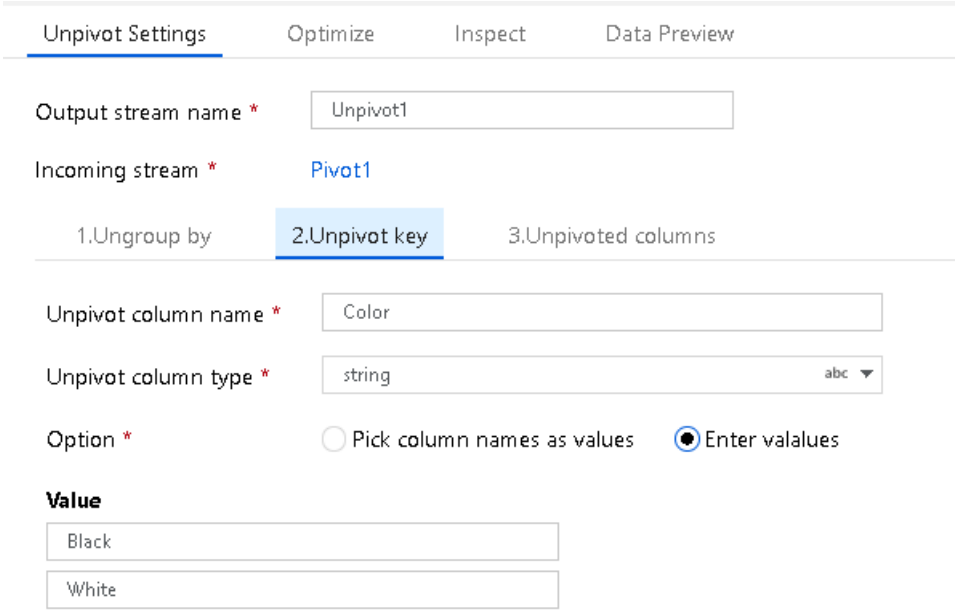


Ungroup By



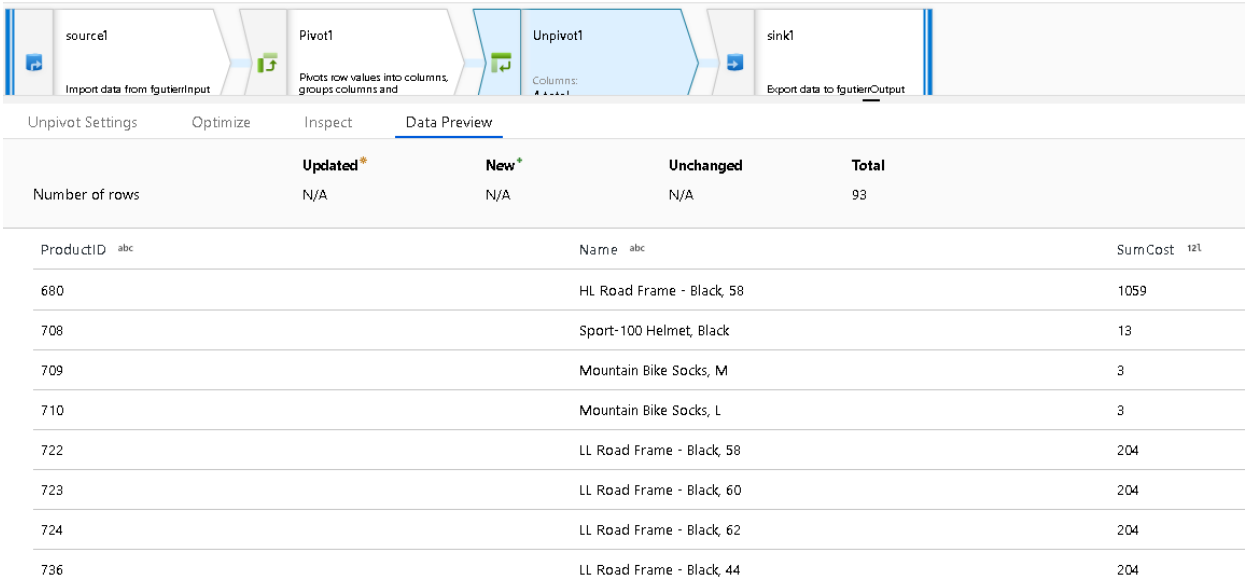
First, set the columns that you wish to ungroup by for your unpivot aggregation. Set one or more columns for ungrouping with the + sign next to the column list.

Unpivot Key



The Unpivot Key is the column that the service will pivot from column to row. By default, each unique value in the dataset for this field will pivot to a row. However, you can optionally enter the values from the dataset that you wish to pivot to row values.

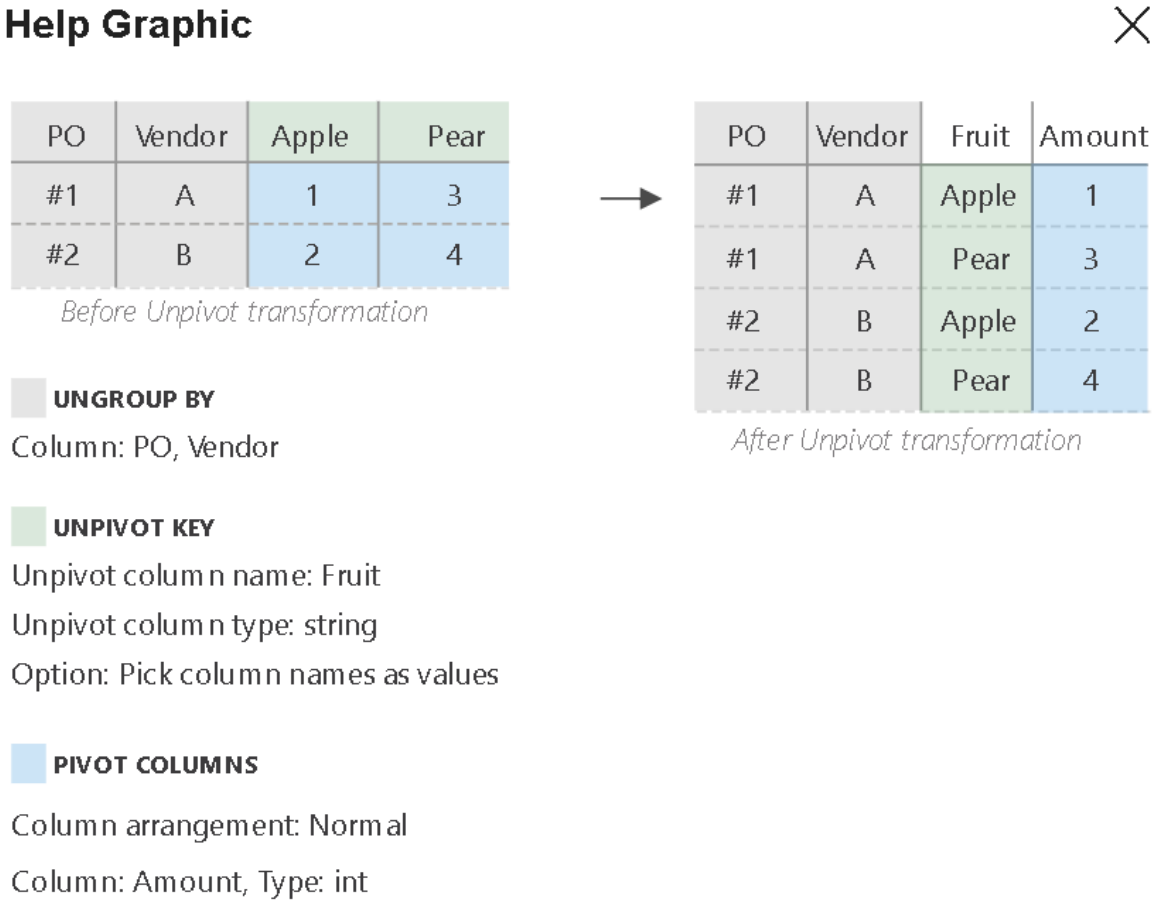
Unpivoted Columns



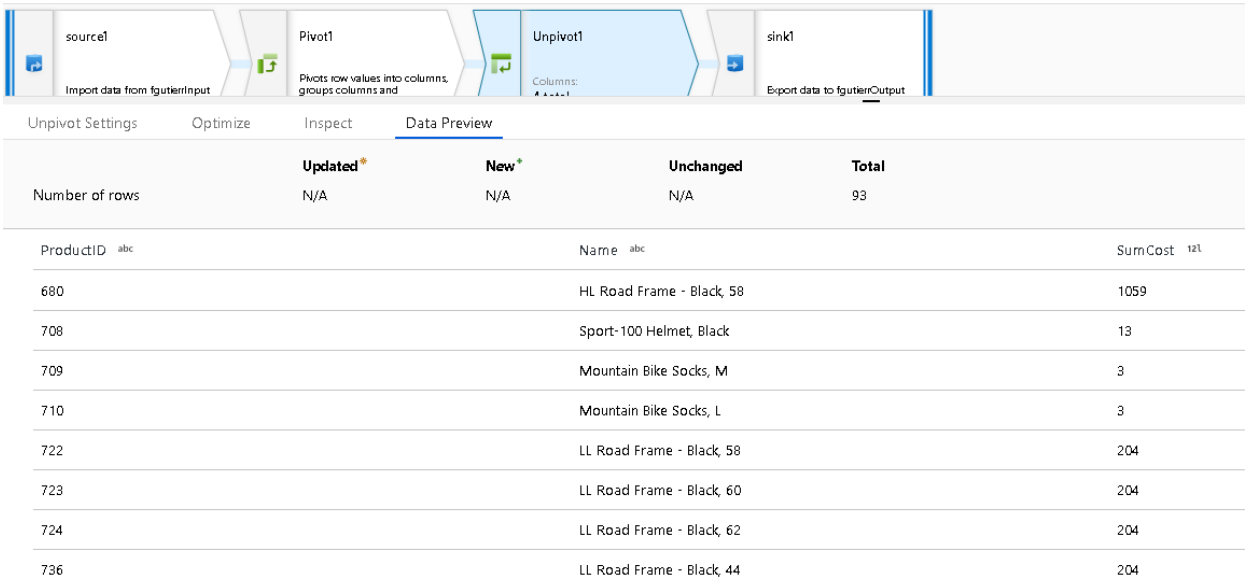
Lastly, choose the column name for storing the values for unpivoted columns that are transformed into rows.

(Optional) You can drop rows with Null values.

For instance, SumCost is the column name that is chosen in the example shared above.



Setting the Column Arrangement to "Normal" will group together all of the new unpivoted columns from a single value. Setting the columns arrangement to "Lateral" will group together new unpivoted columns generated from an existing column.



The final unpivoted data result set shows the column totals now unpivoted into separate row values.

Next steps

Use the Pivot transformation to pivot rows to columns.

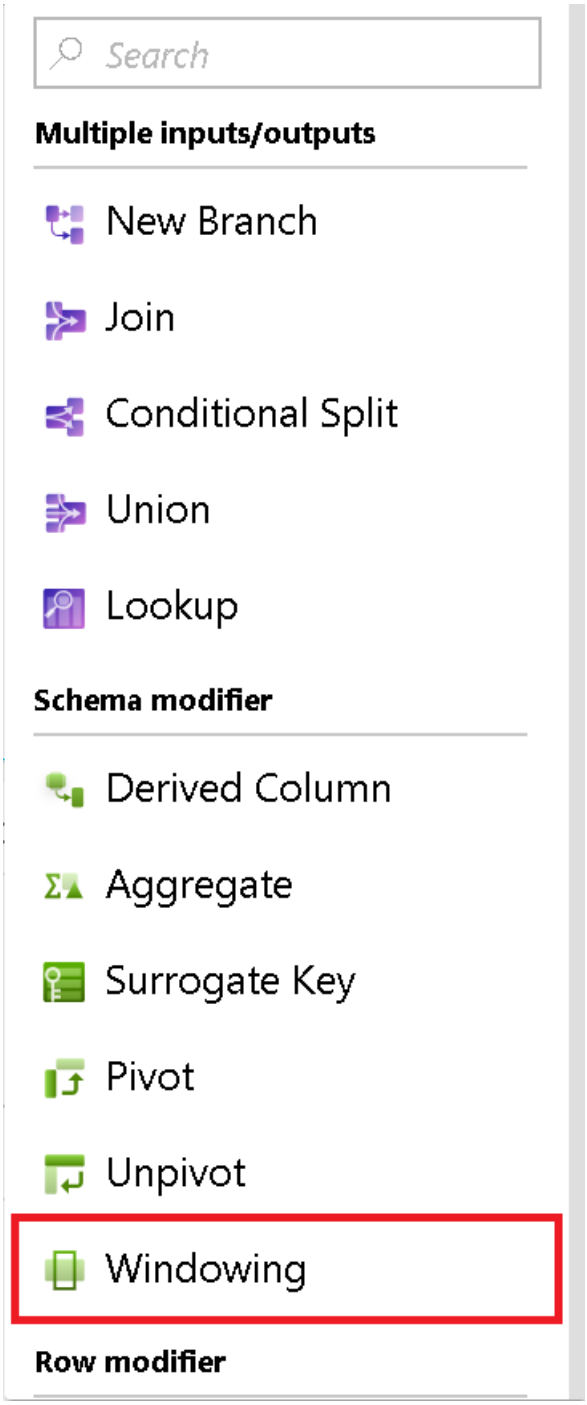
Window transformation in mapping data flow

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

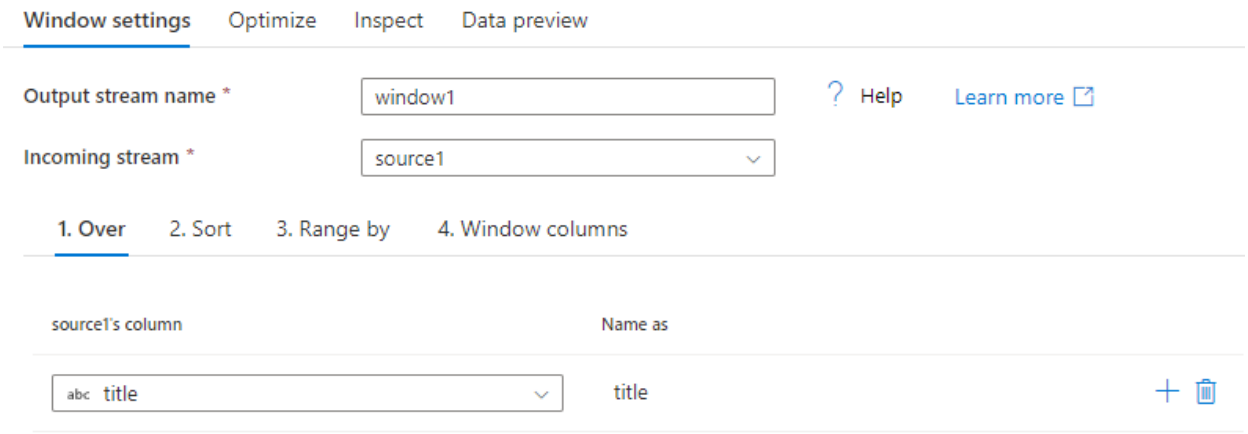
Data flows are available both in Azure Data Factory and Azure Synapse Pipelines. This article applies to mapping data flows. If you are new to transformations, please refer to the introductory article Transform data using a mapping data flow.

The Window transformation is where you will define window-based aggregations of columns in your data streams. In the Expression Builder, you can define different types of aggregations that are based on data or time windows (SQL OVER clause) such as LEAD, LAG, NTILE, CUMEDIST, RANK, etc.). A new field will be generated in your output that includes these aggregations. You can also include optional group-by fields.



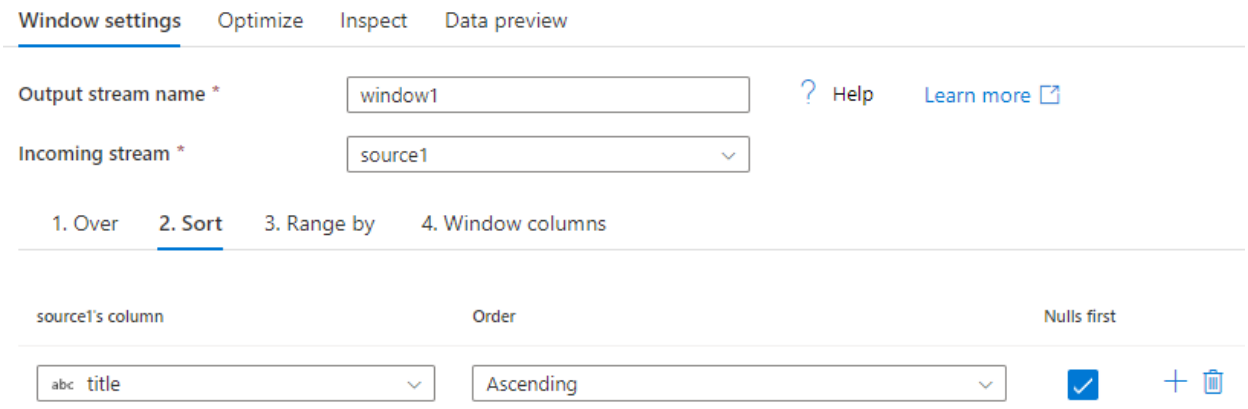
Over

Set the partitioning of column data for your window transformation. The SQL equivalent is the `Partition By` in the Over clause in SQL. If you wish to create a calculation or create an expression to use for the partitioning, you can do that by hovering over the column name and select "computed column".



Sort

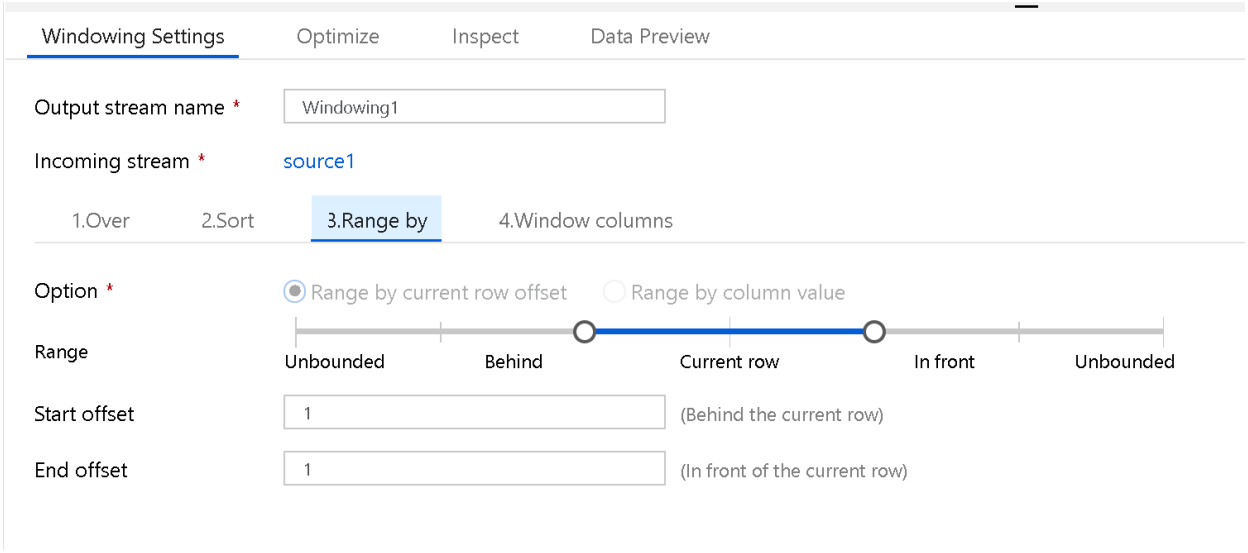
Another part of the Over clause is setting the `Order By`. This will set the data sort ordering. You can also create an expression for a calculate value in this column field for sorting.



Range By

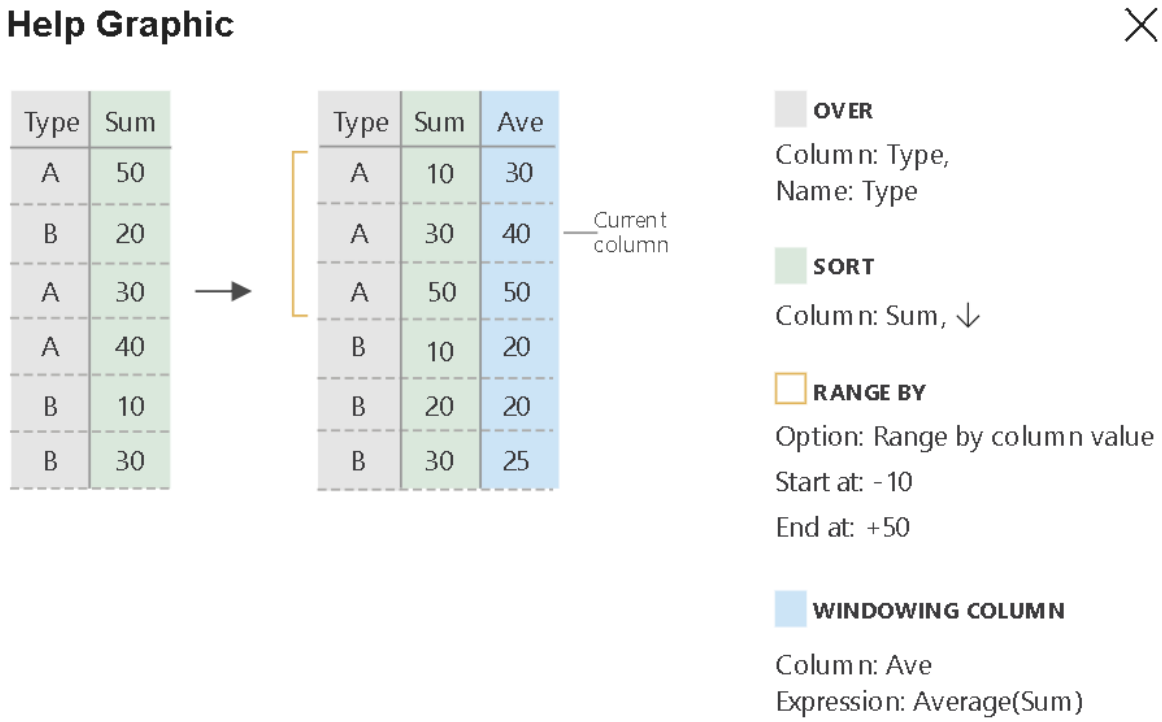
Next, set the window frame as Unbounded or Bounded. To set an unbounded window frame, set the slider to Unbounded on both ends. If you choose a setting between Unbounded and Current Row, then you must set the Offset start and end values. Both values will be positive integers. You can use either relative numbers or values from your data.

The window slider has two values to set: the values before the current row and the values after the current row. The Start and End offset matches the two selectors on the slider.



Window columns

Lastly, use the Expression Builder to define the aggregations you wish to use with the data windows such as RANK, COUNT, MIN, MAX, DENSE RANK, LEAD, LAG, etc.



The full list of aggregation and analytical functions available for you to use in the Data Flow Expression Language via the Expression Builder are listed in Data transformation expressions in mapping data flow.

Next steps

If you are looking for a simple group-by aggregation, use the Aggregate transformation

Parameterize linked services in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

You can now parameterize a linked service and pass dynamic values at run time. For example, if you want to connect to different databases on the same logical SQL server, you can now parameterize the database name in the linked service definition. This prevents you from having to create a linked service for each database on the logical SQL server. You can parameterize other properties in the linked service definition as well - for example, *User name*.

You can use the UI in the Azure portal or a programming interface to parameterize linked services.

> **TIP**
> We recommend not to parameterize passwords or secrets. Store all secrets in Azure Key Vault instead, and parameterize the *Secret Name*.

> **NOTE**
> There is open bug to use "-" in parameter names, we recommend to use names without "-" until the bug is resolved.

For a seven-minute introduction and demonstration of this feature, watch the following video:

Supported linked service types

All the linked service types are supported for parameterization.

Natively supported in UI: When authoring linked service on UI, the service provides built-in parameterization experience for the following types of linked services. In linked service creation/edit blade, you can find options to new parameters and add dynamic content. Refer to UI experience.

- Amazon Redshift
- Amazon S3
- Amazon S3 Compatible Storage
- Azure Blob Storage
- Azure Cosmos DB (SQL API)
- Azure Data Explorer
- Azure Data Lake Storage Gen1
- Azure Data Lake Storage Gen2
- Azure Database for MySQL
- Azure Database for PostgreSQL
- Azure Databricks
- Azure File Storage

- Azure Function
- Azure Key Vault
- Azure SQL Database
- Azure SQL Managed Instance
- Azure Synapse Analytics
- Azure Table Storage
- File System
- FTP
- Generic HTTP
- Generic REST
- Google AdWords
- Informix
- Microsoft Access
- MySQL
- OData
- ODBC
- Oracle
- Oracle Cloud Storage
- PostgreSQL
- Salesforce
- Salesforce Service Cloud
- SAP ODP
- SFTP
- SharePoint Online List
- Snowflake
- SQL Server

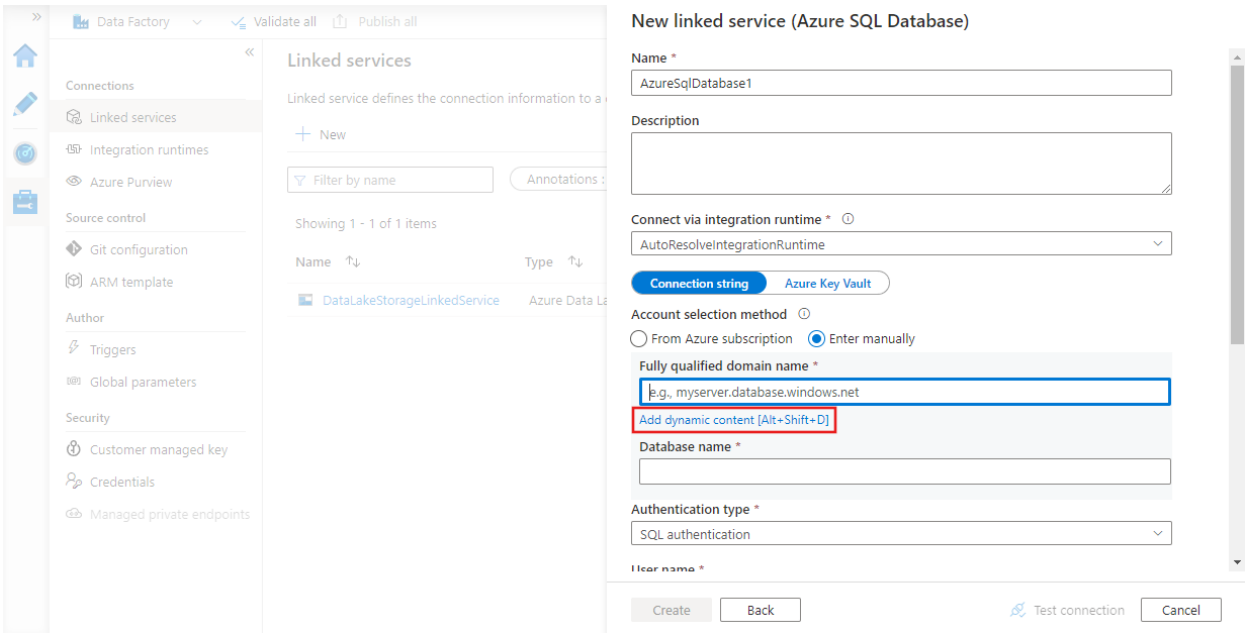
Advanced authoring: For other linked service types that are not in above list, you can parameterize the linked service by editing the JSON on UI:

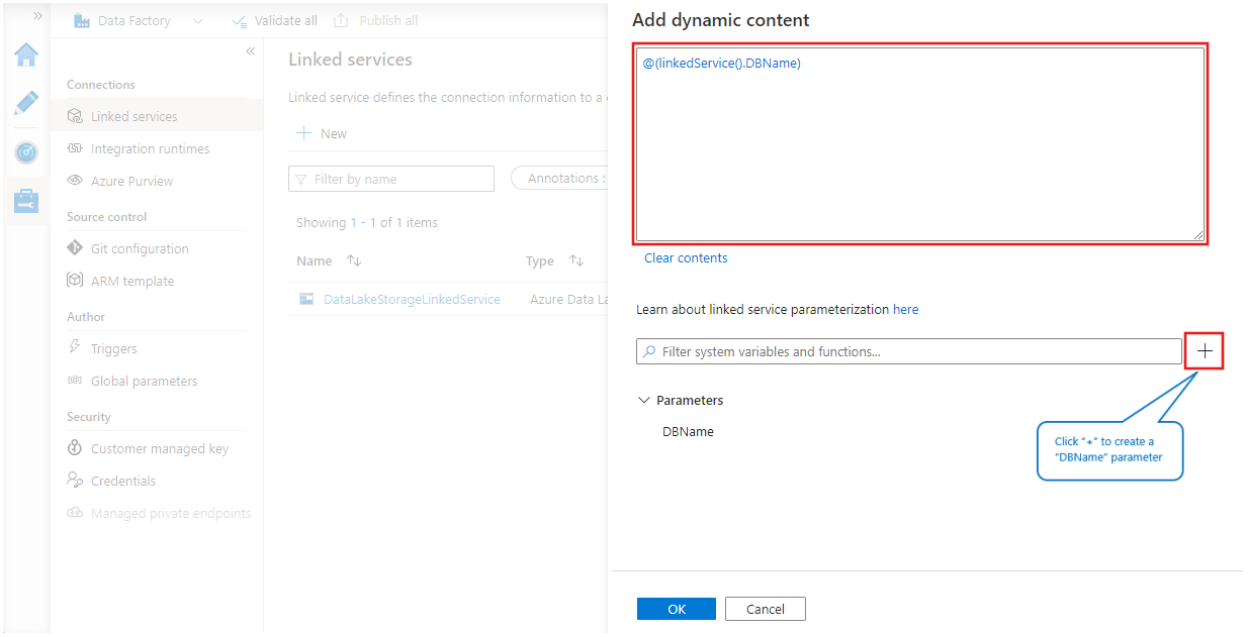
- In linked service creation/edit blade -> expand "Advanced" at the bottom -> check "Specify dynamic contents in JSON format" checkbox -> specify the linked service JSON payload.
- Or, after you create a linked service without parameterization, in Management hub -> Linked services -> find the specific linked service -> click "Code" (button "{}") to edit the JSON.

Refer to the JSON sample to add `parameters` section to define parameters and reference the parameter using `@{linkedService().paramName}`.

UI Experience

- Azure Data Factory
- Azure Synapse





JSON

```
{
 "name": "AzureSqlDatabase",
 "properties": {
  "type": "AzureSqlDatabase",
  "typeProperties": {
   "connectionString":
"Server=tcp:myserver.database.windows.net,1433;Database=@{linkedService().DBName};User
ID=user;Password=fake;Trusted_Connection=False;Encrypt=True;Connection Timeout=30"
  },
  "connectVia": null,
  "parameters": {
   "DBName": {
    "type": "String"
   }
  }
 }
}
```

Expressions and functions in Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 54 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides details about expressions and functions supported by Azure Data Factory and Azure Synapse Analytics.

Expressions

JSON values in the definition can be literal or expressions that are evaluated at runtime. For example:

```
"name": "value"
```

or

```
"name": "@pipeline().parameters.password"
```

Expressions can appear anywhere in a JSON string value and always result in another JSON value. If a JSON value is an expression, the body of the expression is extracted by removing the at-sign (@). If a literal string is needed that starts with @, it must be escaped by using @@. The following examples show how expressions are evaluated.

JSON VALUE	RESULT
"parameters"	The characters 'parameters' are returned.
"parameters[1]"	The characters 'parameters[1]' are returned.
"@@"	A 1 character string that contains '@' is returned.
" @"	A 2 character string that contains ' @' is returned.

Expressions can also appear inside strings, using a feature called *string interpolation* where expressions are wrapped in `@{ ... }`. For example:

```
"name" : "First Name: @{pipeline().parameters.firstName} Last Name: @{pipeline().parameters.lastName}"
```

Using string interpolation, the result is always a string. Say I have defined `myNumber` as `42` and `myString` as `foo`:

JSON VALUE	RESULT
"@pipeline().parameters.myString"	Returns `foo` as a string.
"@{pipeline().parameters.myString}"	Returns `foo` as a string.
"@pipeline().parameters.myNumber"	Returns `42` as a *number*.

JSON VALUE	RESULT
"@{pipeline().parameters.myNumber}"	Returns `42` as a *string*.
"Answer is: @{pipeline().parameters.myNumber}"	Returns the string `Answer is: 42`.
"@concat('Answer is: ', string(pipeline().parameters.myNumber))"	Returns the string `Answer is: 42`
"Answer is: @@{pipeline().parameters.myNumber}"	Returns the string `Answer is: @{pipeline().parameters.myNumber}`.

In the control flow activities like ForEach activity, you can provide an array to be iterated over for the property items and use @item() to iterate over a single enumeration in ForEach activity. For example, if items is an array: [1, 2, 3], @item() returns 1 in the first iteration, 2 in the second iteration, and 3 in the third iteration. You can also use @range(0,10) like expression to iterate ten times starting with 0 ending with 9.

You can use @activity('activity name') to capture output of activity and make decisions. Consider a web activity called Web1. For placing the output of the first activity in the body of the second, the expression generally looks like: @activity('Web1').output or @activity('Web1').output.data or something similar depending upon what the output of the first activity looks like.

Examples

Complex expression example

The below example shows a complex example that references a deep sub-field of activity output. To reference a pipeline parameter that evaluates to a sub-field, use [] syntax instead of dot(.) operator (as in case of subfield1 and subfield2), as part of an activity output.

```
@activity('*activityName*').output.*subfield1*.*subfield2*[pipeline().parameters.*subfield3*].*subfield4*
```

Creating files dynamically and naming them is common pattern. Let us explore few dynamic file naming examples.

1. Append Date to a filename: `@concat('Test_', formatDateTime(utcnow(), 'yyyy-dd-MM'))`
2. Append DateTime in customer timezone : `@concat('Test_', convertFromUtc(utcnow(), 'Pacific Standard Time'))`
3. Append Trigger Time : `@concat('Test_', pipeline().TriggerTime)`
4. Output a custom filename in a Mapping Data Flow when outputting to a single file with date : `'Test_' + toString(currentDate()) + '.csv'`

In above cases, 4 dynamic filenames are created starting with Test_.

Dynamic content editor

Dynamic content editor automatically escapes characters in your content when you finish editing. For example, the following content in content editor is a string interpolation with two expression functions.

```
{
  "type": "@{if(equals(1, 2), 'Blob', 'Table' )}",
  "name": "@{toUpper('myData')}"
}
```

Dynamic content editor converts above content to expression

`"{ \n \"type\": \"@{if(equals(1, 2), 'Blob', 'Table' )}\",\n \"name\": \"@{toUpper('myData')}\"\n}"` . The result of this expression is a JSON format string showed below.

```
{
  "type": "Table",
  "name": "MYDATA"
}
```

A dataset with a parameter

In the following example, the BlobDataset takes a parameter named **path**. Its value is used to set a value for the **folderPath** property by using the expression: `dataset().path` .

```
{
    "name": "BlobDataset",
    "properties": {
        "type": "AzureBlob",
        "typeProperties": {
            "folderPath": "@dataset().path"
        },
        "linkedServiceName": {
            "referenceName": "AzureStorageLinkedService",
            "type": "LinkedServiceReference"
        },
        "parameters": {
            "path": {
                "type": "String"
            }
        }
    }
}
```

A pipeline with a parameter

In the following example, the pipeline takes **inputPath** and **outputPath** parameters. The **path** for the parameterized blob dataset is set by using values of these parameters. The syntax used here is: `pipeline().parameters.parametername` .

```
{
    "name": "Adfv2QuickStartPipeline",
    "properties": {
        "activities": [
            {
                "name": "CopyFromBlobToBlob",
                "type": "Copy",
                "inputs": [
                    {
                        "referenceName": "BlobDataset",
                        "parameters": {
                            "path": "@pipeline().parameters.inputPath"
                        },
                        "type": "DatasetReference"
                    }
                ],
                "outputs": [
                    {
                        "referenceName": "BlobDataset",
                        "parameters": {
                            "path": "@pipeline().parameters.outputPath"
                        },
                        "type": "DatasetReference"
                    }
                ],
                "typeProperties": {
                    "source": {
                        "type": "BlobSource"
                    },
                    "sink": {
                        "type": "BlobSink"
                    }
                }
            }
        ],
        "parameters": {
            "inputPath": {
                "type": "String"
            },
            "outputPath": {
                "type": "String"
            }
        }
    }
}
```

Replacing special characters

Dynamic content editor automatically escapes characters like double quote, backslash in your content when you finish editing. This causes trouble if you want to replace line feed or tab by using **\n**, **\t** in replace() function. You can of edit your dynamic content in code view to remove the extra \ in the expression, or you can follow below steps to replace special characters using expression language:

1. URL encoding against the original string value
2. Replace URL encoded string, for example, line feed (%0A), carriage return(%0D), horizontal tab(%09).
3. URL decoding

For example, variable *companyName* with a newline character in its value, expression `@uriComponentToString(replace(uriComponent(variables('companyName')), '%0A', ''))` can remove the newline character.

```
Contoso-
Corporation
```

Escaping single quote character

Expression functions use single quote for string value parameters. Use two single quotes to escape a ' character in string functions. For example, expression `@concat('Baba', '''s ', 'book store')` will return below result.

```
Baba's book store
```

Tutorial

This tutorial walks you through how to pass parameters between a pipeline and activity as well as between the activities. The tutorial specifically demonstrates steps for an Azure Data Factory although steps for a Synapse workspace are nearly equivalent but with a slightly different user interface.

Functions

You can call functions within expressions. The following sections provide information about the functions that can be used in an expression.

Date functions

DATE OR TIME FUNCTION	TASK
addDays	Add a number of days to a timestamp.
addHours	Add a number of hours to a timestamp.
addMinutes	Add a number of minutes to a timestamp.
addSeconds	Add a number of seconds to a timestamp.
addToTime	Add a number of time units to a timestamp. See also getFutureTime.
convertFromUtc	Convert a timestamp from Universal Time Coordinated (UTC) to the target time zone.
convertTimeZone	Convert a timestamp from the source time zone to the target time zone.
convertToUtc	Convert a timestamp from the source time zone to Universal Time Coordinated (UTC).
dayOfMonth	Return the day of the month component from a timestamp.
dayOfWeek	Return the day of the week component from a timestamp.
dayOfYear	Return the day of the year component from a timestamp.
formatDateTime	Return the timestamp as a string in optional format.

DATE OR TIME FUNCTION	TASK
getFutureTime	Return the current timestamp plus the specified time units. See also addToTime.
getPastTime	Return the current timestamp minus the specified time units. See also subtractFromTime.
startOfDay	Return the start of the day for a timestamp.
startOfHour	Return the start of the hour for a timestamp.
startOfMonth	Return the start of the month for a timestamp.
subtractFromTime	Subtract a number of time units from a timestamp. See also getPastTime.
ticks	Return the `ticks` property value for a specified timestamp.
utcNow	Return the current timestamp as a string.

String functions

To work with strings, you can use these string functions and also some collection functions. String functions work only on strings.

STRING FUNCTION	TASK
concat	Combine two or more strings, and return the combined string.
endsWith	Check whether a string ends with the specified substring.
guid	Generate a globally unique identifier (GUID) as a string.
indexOf	Return the starting position for a substring.
lastIndexOf	Return the starting position for the last occurrence of a substring.
replace	Replace a substring with the specified string, and return the updated string.
split	Return an array that contains substrings, separated by commas, from a larger string based on a specified delimiter character in the original string.
startsWith	Check whether a string starts with a specific substring.
substring	Return characters from a string, starting from the specified position.
toLower	Return a string in lowercase format.

STRING FUNCTION	TASK
toUpper	Return a string in uppercase format.
trim	Remove leading and trailing whitespace from a string, and return the updated string.

Collection functions

To work with collections, generally arrays, strings, and sometimes, dictionaries, you can use these collection functions.

COLLECTION FUNCTION	TASK
contains	Check whether a collection has a specific item.
empty	Check whether a collection is empty.
first	Return the first item from a collection.
intersection	Return a collection that has *only* the common items across the specified collections.
join	Return a string that has *all* the items from an array, separated by the specified character.
last	Return the last item from a collection.
length	Return the number of items in a string or array.
skip	Remove items from the front of a collection, and return *all the other* items.
take	Return items from the front of a collection.
union	Return a collection that has *all* the items from the specified collections.

Logical functions

These functions are useful inside conditions, they can be used to evaluate any type of logic.

LOGICAL COMPARISON FUNCTION	TASK
and	Check whether all expressions are true.
equals	Check whether both values are equivalent.
greater	Check whether the first value is greater than the second value.
greaterOrEquals	Check whether the first value is greater than or equal to the second value.

LOGICAL COMPARISON FUNCTION	TASK
if	Check whether an expression is true or false. Based on the result, return a specified value.
less	Check whether the first value is less than the second value.
lessOrEquals	Check whether the first value is less than or equal to the second value.
not	Check whether an expression is false.
or	Check whether at least one expression is true.

Conversion functions

These functions are used to convert between each of the native types in the language:

- string
- integer
- float
- boolean
- arrays
- dictionaries

CONVERSION FUNCTION	TASK
array	Return an array from a single specified input. For multiple inputs, see createArray.
base64	Return the base64-encoded version for a string.
base64ToBinary	Return the binary version for a base64-encoded string.
base64ToString	Return the string version for a base64-encoded string.
binary	Return the binary version for an input value.
bool	Return the Boolean version for an input value.
coalesce	Return the first non-null value from one or more parameters.
createArray	Return an array from multiple inputs.
dataUri	Return the data URI for an input value.
dataUriToBinary	Return the binary version for a data URI.
dataUriToString	Return the string version for a data URI.
decodeBase64	Return the string version for a base64-encoded string.

CONVERSION FUNCTION	TASK
decodeDataUri	Return the binary version for a data URI.
decodeUriComponent	Return a string that replaces escape characters with decoded versions.
encodeUriComponent	Return a string that replaces URL-unsafe characters with escape characters.
float	Return a floating point number for an input value.
int	Return the integer version for a string.
json	Return the JavaScript Object Notation (JSON) type value or object for a string or XML.
string	Return the string version for an input value.
uriComponent	Return the URI-encoded version for an input value by replacing URL-unsafe characters with escape characters.
uriComponentToBinary	Return the binary version for a URI-encoded string.
uriComponentToString	Return the string version for a URI-encoded string.
xml	Return the XML version for a string.
xpath	Check XML for nodes or values that match an XPath (XML Path Language) expression, and return the matching nodes or values.

Math functions

These functions can be used for either types of numbers: **integers** and **floats**.

MATH FUNCTION	TASK
add	Return the result from adding two numbers.
div	Return the result from dividing two numbers.
max	Return the highest value from a set of numbers or an array.
min	Return the lowest value from a set of numbers or an array.
mod	Return the remainder from dividing two numbers.
mul	Return the product from multiplying two numbers.
rand	Return a random integer from a specified range.
range	Return an integer array that starts from a specified integer.

MATH FUNCTION	TASK
sub	Return the result from subtracting the second number from the first number.

Function reference

This section lists all the available functions in alphabetical order.

add

Return the result from adding two numbers.

```
add(<summand_1>, <summand_2>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*summand_1*>, <*summand_2*>	Yes	Integer, Float, or mixed	The numbers to add

RETURN VALUE	TYPE	DESCRIPTION
<*result-sum*>	Integer or Float	The result from adding the specified numbers

Example

This example adds the specified numbers:

```
add(1, 1.5)
```

And returns this result: `2.5`

addDays

Add a number of days to a timestamp.

```
addDays('<timestamp>', <days>, '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*days*>	Yes	Integer	The positive or negative number of days to add

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp plus the specified number of days

Example 1

This example adds 10 days to the specified timestamp:

```
addDays('2018-03-15T13:00:00Z', 10)
```

And returns this result: `"2018-03-25T00:00:0000000Z"`

Example 2

This example subtracts five days from the specified timestamp:

```
addDays('2018-03-15T00:00:00Z', -5)
```

And returns this result: `"2018-03-10T00:00:0000000Z"`

addHours

Add a number of hours to a timestamp.

```
addHours('<timestamp>', <hours>, '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*hours*>	Yes	Integer	The positive or negative number of hours to add

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp plus the specified number of hours

Example 1

This example adds 10 hours to the specified timestamp:

```
addHours('2018-03-15T00:00:00Z', 10)
```

And returns this result: `"2018-03-15T10:00:0000000Z"`

Example 2

This example subtracts five hours from the specified timestamp:

```
addHours('2018-03-15T15:00:00Z', -5)
```

And returns this result: `"2018-03-15T10:00:0000000Z"`

addMinutes

Add a number of minutes to a timestamp.

```
addMinutes('<timestamp>', <minutes>, '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*minutes*>	Yes	Integer	The positive or negative number of minutes to add

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp plus the specified number of minutes

Example 1

This example adds 10 minutes to the specified timestamp:

```
addMinutes('2018-03-15T00:10:00Z', 10)
```

And returns this result: `"2018-03-15T00:20:00.0000000Z"`

Example 2

This example subtracts five minutes from the specified timestamp:

```
addMinutes('2018-03-15T00:20:00Z', -5)
```

And returns this result: `"2018-03-15T00:15:00.0000000Z"`

addSeconds

Add a number of seconds to a timestamp.

```
addSeconds('<timestamp>', <seconds>, '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*seconds*>	Yes	Integer	The positive or negative number of seconds to add

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp plus the specified number of seconds

Example 1

This example adds 10 seconds to the specified timestamp:

```
addSeconds('2018-03-15T00:00:00Z', 10)
```

And returns this result: `"2018-03-15T00:00:10.0000000Z"`

Example 2

This example subtracts five seconds to the specified timestamp:

```
addSeconds('2018-03-15T00:00:30Z', -5)
```

And returns this result: `"2018-03-15T00:00:25.0000000Z"`

addToTime

Add a number of time units to a timestamp. See also getFutureTime().

```
addToTime('<timestamp>', <interval>, '<timeUnit>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*interval*>	Yes	Integer	The number of specified time units to add
<*timeUnit*>	Yes	String	The unit of time to use with *interval*: "Second", "Minute", "Hour", "Day", "Week", "Month", "Year"

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp plus the specified number of time units

Example 1

This example adds one day to the specified timestamp:

```
addToTime('2018-01-01T00:00:00Z', 1, 'Day')
```

And returns this result: `"2018-01-02T00:00:00.0000000Z"`

Example 2

This example adds one day to the specified timestamp:

```
addToTime('2018-01-01T00:00:00Z', 1, 'Day', 'D')
```

And returns the result using the optional "D" format: `"Tuesday, January 2, 2018"`

and

Check whether both expressions are true. Return true when both expressions are true, or return false when at least one expression is false.

```
and(<expression1>, <expression2>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*expression1*>, <*expression2*>	Yes	Boolean	The expressions to check

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when both expressions are true. Return false when at least one expression is false.

RETURN VALUE	TYPE	DESCRIPTION

Example 1

These examples check whether the specified Boolean values are both true:

```
and(true, true)
and(false, true)
and(false, false)
```

And returns these results:

- First example: Both expressions are true, so returns `true`.
- Second example: One expression is false, so returns `false`.
- Third example: Both expressions are false, so returns `false`.

Example 2

These examples check whether the specified expressions are both true:

```
and(equals(1, 1), equals(2, 2))
and(equals(1, 1), equals(1, 2))
and(equals(1, 2), equals(1, 3))
```

And returns these results:

- First example: Both expressions are true, so returns `true`.
- Second example: One expression is false, so returns `false`.
- Third example: Both expressions are false, so returns `false`.

array

Return an array from a single specified input. For multiple inputs, see createArray().

```
array('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string for creating an array

RETURN VALUE	TYPE	DESCRIPTION
[<*value*>]	Array	An array that contains the single specified input

Example

This example creates an array from the "hello" string:

```
array('hello')
```

And returns this result: `["hello"]`

base64

Return the base64-encoded version for a string.

```
base64('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The input string

RETURN VALUE	TYPE	DESCRIPTION
<*base64-string*>	String	The base64-encoded version for the input string

Example

This example converts the "hello" string to a base64-encoded string:

```
base64('hello')
```

And returns this result: `"aGVsbG8="`

base64ToBinary

Return the binary version for a base64-encoded string.

```
base64ToBinary('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The base64-encoded string to convert

RETURN VALUE	TYPE	DESCRIPTION
<*binary-for-base64-string*>	String	The binary version for the base64-encoded string

Example

This example converts the "aGVsbG8=" base64-encoded string to a binary string:

```
base64ToBinary('aGVsbG8=')
```

And returns this result:

```
"0110000101000111010101100111001101100010010001110011100000111101"
```

base64ToString

Return the string version for a base64-encoded string, effectively decoding the base64 string. Use this function rather than decodeBase64(). Although both functions work the same way, `base64ToString()` is preferred.

```
base64ToString('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The base64-encoded string to decode

RETURN VALUE	TYPE	DESCRIPTION
<*decoded-base64-string*>	String	The string version for a base64-encoded string

Example

This example converts the "aGVsbG8=" base64-encoded string to just a string:

```
base64ToString('aGVsbG8=')
```

And returns this result: `"hello"`

binary

Return the binary version for a string.

```
binary('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string to convert

RETURN VALUE	TYPE	DESCRIPTION
<*binary-for-input-value*>	String	The binary version for the specified string

Example

This example converts the "hello" string to a binary string:

```
binary('hello')
```

And returns this result:

`"0110100001100101011011000110110001101111"`

bool

Return the Boolean version for a value.

```
bool(<value>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	Any	The value to convert

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	The Boolean version for the specified value

Example

These examples convert the specified values to Boolean values:

```
bool(1)
bool(0)
```

And returns these results:

- First example: `true`
- Second example: `false`

coalesce

Return the first non-null value from one or more parameters. Empty strings, empty arrays, and empty objects are not null.

```
coalesce(<object_1>, <object_2>, ...)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*object_1*>, <*object_2*>, ...	Yes	Any, can mix types	One or more items to check for null

RETURN VALUE	TYPE	DESCRIPTION
<*first-non-null-item*>	Any	The first item or value that is not null. If all parameters are null, this function returns null.

Example

These examples return the first non-null value from the specified values, or null when all the values are null:

```
coalesce(null, true, false)
coalesce(null, 'hello', 'world')
coalesce(null, null, null)
```

And returns these results:

- First example: `true`
- Second example: `"hello"`
- Third example: `null`

concat

Combine two or more strings, and return the combined string.

```
concat('<text1>', '<text2>', ...)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text1*>, <*text2*>, ...	Yes	String	At least two strings to combine

RETURN VALUE	TYPE	DESCRIPTION
<*text1text2...*>	String	The string created from the combined input strings

Example

This example combines the strings "Hello" and "World":

```
concat('Hello', 'World')
```

And returns this result: `"HelloWorld"`

contains

Check whether a collection has a specific item. Return true when the item is found, or return false when not found. This function is case-sensitive.

```
contains('<collection>', '<value>')
contains([<collection>], '<value>')
```

Specifically, this function works on these collection types:

- A *string* to find a *substring*
- An *array* to find a *value*
- A *dictionary* to find a *key*

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String, Array, or Dictionary	The collection to check
<*value*>	Yes	String, Array, or Dictionary, respectively	The item to find

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the item is found. Return false when not found.

Example 1

This example checks the string "hello world" for the substring "world" and returns true:

```
contains('hello world', 'world')
```

Example 2

This example checks the string "hello world" for the substring "universe" and returns false:

```
contains('hello world', 'universe')
```

convertFromUtc

Convert a timestamp from Universal Time Coordinated (UTC) to the target time zone.

```
convertFromUtc('<timestamp>', '<destinationTimeZone>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*destinationTimeZone*>	Yes	String	The name for the target time zone. For time zone names, see Microsoft Time Zone Values, but you might have to remove any punctuation from the time zone name.
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*converted-timestamp*>	String	The timestamp converted to the target time zone

Example 1

This example converts a timestamp to the specified time zone:

```
convertFromUtc('2018-01-01T08:00:00.0000000Z', 'Pacific Standard Time')
```

And returns this result: `"2018-01-01T00:00:00Z"`

Example 2

This example converts a timestamp to the specified time zone and format:

```
convertFromUtc('2018-01-01T08:00:00.0000000Z', 'Pacific Standard Time', 'D')
```

And returns this result: `"Monday, January 1, 2018"`

convertTimeZone

Convert a timestamp from the source time zone to the target time zone.

```
convertTimeZone('<timestamp>', '<sourceTimeZone>', '<destinationTimeZone>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*sourceTimeZone*>	Yes	String	The name for the source time zone. For time zone names, see Microsoft Time Zone Values, but you might have to remove any punctuation from the time zone name.
<*destinationTimeZone*>	Yes	String	The name for the target time zone. For time zone names, see Microsoft Time Zone Values, but you might have to remove any punctuation from the time zone name.
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*converted-timestamp*>	String	The timestamp converted to the target time zone

Example 1

This example converts the source time zone to the target time zone:

```
convertTimeZone('2018-01-01T08:00:00.0000000Z', 'UTC', 'Pacific Standard Time')
```

And returns this result: `"2018-01-01T00:00:00.0000000"`

Example 2

This example converts a time zone to the specified time zone and format:

```
convertTimeZone('2018-01-01T08:00:00.0000000Z', 'UTC', 'Pacific Standard Time', 'D')
```

And returns this result: `"Monday, January 1, 2018"`

convertToUtc

Convert a timestamp from the source time zone to Universal Time Coordinated (UTC).

```
convertToUtc('<timestamp>', '<sourceTimeZone>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*sourceTimeZone*>	Yes	String	The name for the source time zone. For time zone names, see Microsoft Time Zone Values, but you might have to remove any punctuation from the time zone name.
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*converted-timestamp*>	String	The timestamp converted to UTC

Example 1

This example converts a timestamp to UTC:

```
convertToUtc('01/01/2018 00:00:00', 'Pacific Standard Time')
```

And returns this result: `"2018-01-01T08:00:00.0000000Z"`

Example 2

This example converts a timestamp to UTC:

```
convertToUtc('01/01/2018 00:00:00', 'Pacific Standard Time', 'D')
```

And returns this result: `"Monday, January 1, 2018"`

createArray

Return an array from multiple inputs. For single input arrays, see array().

```
createArray('<object1>', '<object2>', ...)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*object1*>, <*object2*>, ...	Yes	Any, but not mixed	At least two items to create the array

RETURN VALUE	TYPE	DESCRIPTION
[<*object1*>, <*object2*>, ...]	Array	The array created from all the input items

Example

This example creates an array from these inputs:

```
createArray('h', 'e', 'l', 'l', 'o')
```

And returns this result: `["h", "e", "l", "l", "o"]`

dataUri

Return a data uniform resource identifier (URI) for a string.

```
dataUri('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string to convert

RETURN VALUE	TYPE	DESCRIPTION
<*data-uri*>	String	The data URI for the input string

Example

This example creates a data URI for the "hello" string:

```
dataUri('hello')
```

And returns this result: `"data:text/plain;charset=utf-8; base64,aGVsbG8="`

dataUriToBinary

Return the binary version for a data uniform resource identifier (URI). Use this function rather than decodeDataUri(). Although both functions work the same way, `dataUriBinary()` is preferred.

```
dataUriToBinary('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The data URI to convert

RETURN VALUE	TYPE	DESCRIPTION
<*binary-for-data-uri*>	String	The binary version for the data URI

Example

This example creates a binary version for this data URI:

```
dataUriToBinary('data:text/plain;charset=utf-8; base64,aGVsbG8=')
```

And returns this result:

```
"01100100011000010111010001100001001110100111010001100101011110000111010000101111011100000
11011000110000101101001011011100011101101100011011010000110000101110010011100110110010101111
01000011110101110101011101000110011000101101001110000011101101100010011000010111001101100101
10011011000110100001011000110000101000111010101100111001101100010010001110011100000111101"
```

dataUriToString

Return the string version for a data uniform resource identifier (URI).

```
dataUriToString('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The data URI to convert

RETURN VALUE	TYPE	DESCRIPTION
<*string-for-data-uri*>	String	The string version for the data URI

Example

This example creates a string for this data URI:

```
dataUriToString('data:text/plain;charset=utf-8; base64,aGVsbG8=')
```

And returns this result: `"hello"`

dayOfMonth

Return the day of the month from a timestamp.

```
dayOfMonth('<timestamp>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

RETURN VALUE	TYPE	DESCRIPTION
<*day-of-month*>	Integer	The day of the month from the specified timestamp

Example

This example returns the number for the day of the month from this timestamp:

```
dayOfMonth('2018-03-15T13:27:36Z')
```

And returns this result: `15`

dayOfWeek

Return the day of the week from a timestamp.

```
dayOfWeek('<timestamp>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

RETURN VALUE	TYPE	DESCRIPTION
<*day-of-week*>	Integer	The day of the week from the specified timestamp where Sunday is 0, Monday is 1, and so on

Example

This example returns the number for the day of the week from this timestamp:

```
dayOfWeek('2018-03-15T13:27:36Z')
```

And returns this result: `3`

dayOfYear

Return the day of the year from a timestamp.

```
dayOfYear('<timestamp>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

RETURN VALUE	TYPE	DESCRIPTION
<*day-of-year*>	Integer	The day of the year from the specified timestamp

Example

This example returns the number of the day of the year from this timestamp:

```
dayOfYear('2018-03-15T13:27:36Z')
```

And returns this result: `74`

decodeBase64

Return the string version for a base64-encoded string, effectively decoding the base64 string. Consider using base64ToString() rather than `decodeBase64()`. Although both functions work the same way, `base64ToString()` is preferred.

```
decodeBase64('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The base64-encoded string to decode

RETURN VALUE	TYPE	DESCRIPTION
<*decoded-base64-string*>	String	The string version for a base64-encoded string

Example

This example creates a string for a base64-encoded string:

```
decodeBase64('aGVsbG8=')
```

And returns this result: `"hello"`

decodeDataUri

Return the binary version for a data uniform resource identifier (URI). Consider using dataUriToBinary(), rather than `decodeDataUri()`. Although both functions work the same way, `dataUriToBinary()` is preferred.

```
decodeDataUri('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	String	The data URI string to decode

RETURN VALUE	TYPE	DESCRIPTION
<binary-for-data-uri>	String	The binary version for a data URI string

Example

This example returns the binary version for this data URI:

```
decodeDataUri('data:text/plain;charset=utf-8; base64,aGVsbG8=')
```

And returns this result:

```
"01100100011000010111010001100001001110100111010001100101011110000111010000101111011100000
11011000110000101101001011011100011101101100011011010000110000101110010011100110110010101111
01000011110101110101011101000110011000101101001110000011101101100010011000010111001101100101
10011011000110100001011000110000101000111010101100111001101100010010001110011100000111101"
```

decodeUriComponent

Return a string that replaces escape characters with decoded versions.

```
decodeUriComponent('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	String	The string with the escape characters to decode

RETURN VALUE	TYPE	DESCRIPTION
<decoded-uri>	String	The updated string with the decoded escape characters

Example

This example replaces the escape characters in this string with decoded versions:

```
decodeUriComponent('http%3A%2F%2Fcontoso.com')
```

And returns this result: `"https://contoso.com"`

div

Return the integer result from dividing two numbers. To get the remainder result, see mod().

```
div(<dividend>, <divisor>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*dividend*>	Yes	Integer or Float	The number to divide by the *divisor*
<*divisor*>	Yes	Integer or Float	The number that divides the *dividend*, but cannot be 0

RETURN VALUE	TYPE	DESCRIPTION
<*quotient-result*>	Integer	The integer result from dividing the first number by the second number

Example

Both examples divide the first number by the second number:

```
div(10, 5)
div(11, 5)
```

And return this result: `2`

encodeUriComponent

Return a uniform resource identifier (URI) encoded version for a string by replacing URL-unsafe characters with escape characters. Consider using uriComponent(), rather than `encodeUriComponent()`. Although both functions work the same way, `uriComponent()` is preferred.

```
encodeUriComponent('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string to convert to URI-encoded format

RETURN VALUE	TYPE	DESCRIPTION
<*encoded-uri*>	String	The URI-encoded string with escape characters

Example

This example creates a URI-encoded version for this string:

```
encodeUriComponent('https://contoso.com')
```

And returns this result: `"http%3A%2F%2Fcontoso.com"`

empty

Check whether a collection is empty. Return true when the collection is empty, or return false when not empty.

```
empty('<collection>')
empty([<collection>])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String, Array, or Object	The collection to check

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the collection is empty. Return false when not empty.

Example

These examples check whether the specified collections are empty:

```
empty('')
empty('abc')
```

And returns these results:

- First example: Passes an empty string, so the function returns `true`.
- Second example: Passes the string "abc", so the function returns `false`.

endsWith

Check whether a string ends with a specific substring. Return true when the substring is found, or return false when not found. This function is not case-sensitive.

```
endsWith('<text>', '<searchText>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string to check
<*searchText*>	Yes	String	The ending substring to find

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the ending substring is found. Return false when not found.

Example 1

This example checks whether the "hello world" string ends with the "world" string:

```
endsWith('hello world', 'world')
```

And returns this result: `true`

Example 2

This example checks whether the "hello world" string ends with the "universe" string:

```
endsWith('hello world', 'universe')
```

And returns this result: `false`

equals

Check whether both values, expressions, or objects are equivalent. Return true when both are equivalent, or return false when they're not equivalent.

```
equals('<object1>', '<object2>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*object1*>, <*object2*>	Yes	Various	The values, expressions, or objects to compare

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when both are equivalent. Return false when not equivalent.

Example

These examples check whether the specified inputs are equivalent.

```
equals(true, 1)
equals('abc', 'abcd')
```

And returns these results:

- First example: Both values are equivalent, so the function returns `true`.
- Second example: Both values aren't equivalent, so the function returns `false`.

first

Return the first item from a string or array.

```
first('<collection>')
first([<collection>])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String or Array	The collection where to find the first item

RETURN VALUE	TYPE	DESCRIPTION
<*first-collection-item*>	Any	The first item in the collection

Example

These examples find the first item in these collections:

```
first('hello')
first(createArray(0, 1, 2))
```

And return these results:

- First example: `"h"`
- Second example: `0`

float

Convert a string version for a floating-point number to an actual floating point number.

```
float('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string that has a valid floating-point number to convert

RETURN VALUE	TYPE	DESCRIPTION
<*float-value*>	Float	The floating-point number for the specified string

Example

This example creates a string version for this floating-point number:

```
float('10.333')
```

And returns this result: `10.333`

formatDateTime

Return a timestamp in the specified format.

```
formatDateTime('<timestamp>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*reformatted-timestamp*>	String	The updated timestamp in the specified format

Example

This example converts a timestamp to the specified format:

```
formatDateTime('03/15/2018 12:00:00', 'yyyy-MM-ddTHH:mm:ss')
```

And returns this result: `"2018-03-15T12:00:00"`

getFutureTime

Return the current timestamp plus the specified time units.

```
getFutureTime(<interval>, <timeUnit>, <format>?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<interval>	Yes	Integer	The number of specified time units to add
<timeUnit>	Yes	String	The unit of time to use with *interval*: "Second", "Minute", "Hour", "Day", "Week", "Month", "Year"
<format>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<updated-timestamp>	String	The current timestamp plus the specified number of time units

Example 1

Suppose the current timestamp is "2018-03-01T00:00:00.0000000Z". This example adds five days to that timestamp:

```
getFutureTime(5, 'Day')
```

And returns this result: `"2018-03-06T00:00:00.0000000Z"`

Example 2

Suppose the current timestamp is "2018-03-01T00:00:00.0000000Z". This example adds five days and converts the result to "D" format:

```
getFutureTime(5, 'Day', 'D')
```

And returns this result: `"Tuesday, March 6, 2018"`

getPastTime

Return the current timestamp minus the specified time units.

```
getPastTime(<interval>, <timeUnit>, <format>?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*interval*>	Yes	Integer	The number of specified time units to subtract
<*timeUnit*>	Yes	String	The unit of time to use with *interval*: "Second", "Minute", "Hour", "Day", "Week", "Month", "Year"
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The current timestamp minus the specified number of time units

Example 1

Suppose the current timestamp is "2018-02-01T00:00:00.0000000Z". This example subtracts five days from that timestamp:

```
getPastTime(5, 'Day')
```

And returns this result: `"2018-01-27T00:00:00.0000000Z"`

Example 2

Suppose the current timestamp is "2018-02-01T00:00:00.0000000Z". This example subtracts five days and converts the result to "D" format:

```
getPastTime(5, 'Day', 'D')
```

And returns this result: `"Saturday, January 27, 2018"`

greater

Check whether the first value is greater than the second value. Return true when the first value is more, or return false when less.

```
greater(<value>, <compareTo>)
greater('<value>', '<compareTo>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	Integer, Float, or String	The first value to check whether greater than the second value
<compareTo>	Yes	Integer, Float, or String, respectively	The comparison value

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the first value is greater than the second value. Return false when the first value is equal to or less than the second value.

Example

These examples check whether the first value is greater than the second value:

```
greater(10, 5)
greater('apple', 'banana')
```

And return these results:

- First example: `true`
- Second example: `false`

greaterOrEquals

Check whether the first value is greater than or equal to the second value. Return true when the first value is greater or equal, or return false when the first value is less.

```
greaterOrEquals(<value>, <compareTo>)
greaterOrEquals('<value>', '<compareTo>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	Integer, Float, or String	The first value to check whether greater than or equal to the second value
<compareTo>	Yes	Integer, Float, or String, respectively	The comparison value

RETURN VALUE	TYPE	DESCRIPTION

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the first value is greater than or equal to the second value. Return false when the first value is less than the second value.

Example

These examples check whether the first value is greater or equal than the second value:

```
greaterOrEquals(5, 5)
greaterOrEquals('apple', 'banana')
```

And return these results:

- First example: `true`
- Second example: `false`

guid

Generate a globally unique identifier (GUID) as a string, for example, "c2ecc88d-88c8-4096-912c-d6f2e2b138ce":

```
guid()
```

Also, you can specify a different format for the GUID other than the default format, "D", which is 32 digits separated by hyphens.

```
guid('<format>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	A single format specifier for the returned GUID. By default, the format is "D", but you can use "N", "D", "B", "P", or "X".

RETURN VALUE	TYPE	DESCRIPTION
<*GUID-value*>	String	A randomly generated GUID

Example

This example generates the same GUID, but as 32 digits, separated by hyphens, and enclosed in parentheses:

```
guid('P')
```

And returns this result: `"(c2ecc88d-88c8-4096-912c-d6f2e2b138ce)"`

if

Check whether an expression is true or false. Based on the result, return a specified value.

```
if(<expression>, <valueIfTrue>, <valueIfFalse>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*expression*>	Yes	Boolean	The expression to check
<*valueIfTrue*>	Yes	Any	The value to return when the expression is true
<*valueIfFalse*>	Yes	Any	The value to return when the expression is false

RETURN VALUE	TYPE	DESCRIPTION
<*specified-return-value*>	Any	The specified value that returns based on whether the expression is true or false

Example

This example returns `"yes"` because the specified expression returns true. Otherwise, the example returns `"no"`:

```
if(equals(1, 1), 'yes', 'no')
```

indexOf

Return the starting position or index value for a substring. This function is not case-sensitive, and indexes start with the number 0.

```
indexOf('<text>', '<searchText>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string that has the substring to find
<*searchText*>	Yes	String	The substring to find

RETURN VALUE	TYPE	DESCRIPTION

RETURN VALUE	TYPE	DESCRIPTION
< *index-value* >	Integer	The starting position or index value for the specified substring. If the string is not found, return the number -1.

Example

This example finds the starting index value for the "world" substring in the "hello world" string:

```
indexOf('hello world', 'world')
```

And returns this result: `6`

int

Return the integer version for a string.

```
int('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
< *value* >	Yes	String	The string to convert

RETURN VALUE	TYPE	DESCRIPTION
< *integer-result* >	Integer	The integer version for the specified string

Example

This example creates an integer version for the string "10":

```
int('10')
```

And returns this result: `10`

json

Return the JavaScript Object Notation (JSON) type value or object for a string or XML.

```
json('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
< *value* >	Yes	String or XML	The string or XML to convert

PARAMETER	REQUIRED	TYPE	DESCRIPTION

RETURN VALUE	TYPE	DESCRIPTION
<JSON-result>	JSON native type or object	The JSON native type value or object for the specified string or XML. If the string is null, the function returns an empty object.

Example 1

This example converts this string to the JSON value:

```
json('[1, 2, 3]')
```

And returns this result: `[1, 2, 3]`

Example 2

This example converts this string to JSON:

```
json('{"fullName": "Sophia Owen"}')
```

And returns this result:

```
{
  "fullName": "Sophia Owen"
}
```

Example 3

This example converts this XML to JSON:

```
json(xml('<?xml version="1.0"?> <root> <person id='1'> <name>Sophia Owen</name>
<occupation>Engineer</occupation> </person> </root>'))
```

And returns this result:

```
{
   "?xml": { "@version": "1.0" },
   "root": {
      "person": [ {
         "@id": "1",
         "name": "Sophia Owen",
         "occupation": "Engineer"
      } ]
   }
}
```

intersection

Return a collection that has *only* the common items across the specified collections. To appear in the result, an item must appear in all the collections passed to this function. If one or more items have the same name, the last

item with that name appears in the result.

```
intersection([<collection1>], [<collection2>], ...)
intersection('<collection1>', '<collection2>', ...)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection1*>, <*collection2*>, ...	Yes	Array or Object, but not both	The collections from where you want *only* the common items

RETURN VALUE	TYPE	DESCRIPTION
<*common-items*>	Array or Object, respectively	A collection that has only the common items across the specified collections

Example

This example finds the common items across these arrays:

```
intersection(createArray(1, 2, 3), createArray(101, 2, 1, 10), createArray(6, 8, 1, 2))
```

And returns an array with *only* these items: `[1, 2]`

join

Return a string that has all the items from an array and has each character separated by a *delimiter*.

```
join([<collection>], '<delimiter>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	Array	The array that has the items to join
<*delimiter*>	Yes	String	The separator that appears between each character in the resulting string

RETURN VALUE	TYPE	DESCRIPTION
<*char1*> <*delimiter*> <*char2*> <*delimiter*> ...	String	The resulting string created from all the items in the specified array

Example

This example creates a string from all the items in this array with the specified character as the delimiter:

```
join(createArray('a', 'b', 'c'), '.')
```

And returns this result: `"a.b.c"`

last

Return the last item from a collection.

```
last('<collection>')
last([<collection>])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String or Array	The collection where to find the last item

RETURN VALUE	TYPE	DESCRIPTION
<*last-collection-item*>	String or Array, respectively	The last item in the collection

Example

These examples find the last item in these collections:

```
last('abcd')
last(createArray(0, 1, 2, 3))
```

And returns these results:

- First example: `"d"`
- Second example: `3`

lastIndexOf

Return the starting position or index value for the last occurrence of a substring. This function is not case-sensitive, and indexes start with the number 0.

```
lastIndexOf('<text>', '<searchText>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string that has the substring to find
<*searchText*>	Yes	String	The substring to find

RETURN VALUE	TYPE	DESCRIPTION
<*ending-index-value*>	Integer	The starting position or index value for the last occurrence of the specified substring. If the string is not found, return the number -1.

Example

This example finds the starting index value for the last occurrence of the "world" substring in the "hello world" string:

```
lastIndexOf('hello world', 'world')
```

And returns this result: `6`

length

Return the number of items in a collection.

```
length('<collection>')
length([<collection>])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String or Array	The collection with the items to count

RETURN VALUE	TYPE	DESCRIPTION
<*length-or-count*>	Integer	The number of items in the collection

Example

These examples count the number of items in these collections:

```
length('abcd')
length(createArray(0, 1, 2, 3))
```

And return this result: `4`

less

Check whether the first value is less than the second value. Return true when the first value is less, or return false when the first value is more.

```
less(<value>, <compareTo>)
less('<value>', '<compareTo>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	Integer, Float, or String	The first value to check whether less than the second value
<compareTo>	Yes	Integer, Float, or String, respectively	The comparison item

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the first value is less than the second value. Return false when the first value is equal to or greater than the second value.

Example

These examples check whether the first value is less than the second value.

```
less(5, 10)
less('banana', 'apple')
```

And return these results:

- First example: `true`
- Second example: `false`

lessOrEquals

Check whether the first value is less than or equal to the second value. Return true when the first value is less than or equal, or return false when the first value is more.

```
lessOrEquals(<value>, <compareTo>)
lessOrEquals('<value>', '<compareTo>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<value>	Yes	Integer, Float, or String	The first value to check whether less than or equal to the second value
<compareTo>	Yes	Integer, Float, or String, respectively	The comparison item

RETURN VALUE	TYPE	DESCRIPTION

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the first value is less than or equal to the second value. Return false when the first value is greater than the second value.

Example

These examples check whether the first value is less or equal than the second value.

```
lessOrEquals(10, 10)
lessOrEquals('apply', 'apple')
```

And return these results:

- First example: `true`
- Second example: `false`

max

Return the highest value from a list or array with numbers that is inclusive at both ends.

```
max(<number1>, <number2>, ...)
max([<number1>, <number2>, ...])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*number1*>, <*number2*>, ...	Yes	Integer, Float, or both	The set of numbers from which you want the highest value
[<*number1*>, <*number2*>, ...]	Yes	Array - Integer, Float, or both	The array of numbers from which you want the highest value

RETURN VALUE	TYPE	DESCRIPTION
<*max-value*>	Integer or Float	The highest value in the specified array or set of numbers

Example

These examples get the highest value from the set of numbers and the array:

```
max(1, 2, 3)
max(createArray(1, 2, 3))
```

And return this result: `3`

min

Return the lowest value from a set of numbers or an array.

```
min(<number1>, <number2>, ...)
min([<number1>, <number2>, ...])
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*number1*>, <*number2*>, ...	Yes	Integer, Float, or both	The set of numbers from which you want the lowest value
[<*number1*>, <*number2*>, ...]	Yes	Array - Integer, Float, or both	The array of numbers from which you want the lowest value

RETURN VALUE	TYPE	DESCRIPTION
<*min-value*>	Integer or Float	The lowest value in the specified set of numbers or specified array

Example

These examples get the lowest value in the set of numbers and the array:

```
min(1, 2, 3)
min(createArray(1, 2, 3))
```

And return this result: `1`

mod

Return the remainder from dividing two numbers. To get the integer result, see div().

```
mod(<dividend>, <divisor>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*dividend*>	Yes	Integer or Float	The number to divide by the *divisor*
<*divisor*>	Yes	Integer or Float	The number that divides the *dividend*, but cannot be 0.

RETURN VALUE	TYPE	DESCRIPTION
<*modulo-result*>	Integer or Float	The remainder from dividing the first number by the second number

Example

This example divides the first number by the second number:

```
mod(3, 2)
```

And return this result: `1`

mul

Return the product from multiplying two numbers.

```
mul(<multiplicand1>, <multiplicand2>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*multiplicand1*>	Yes	Integer or Float	The number to multiply by *multiplicand2*
<*multiplicand2*>	Yes	Integer or Float	The number that multiples *multiplicand1*

RETURN VALUE	TYPE	DESCRIPTION
<*product-result*>	Integer or Float	The product from multiplying the first number by the second number

Example

These examples multiple the first number by the second number:

```
mul(1, 2)
mul(1.5, 2)
```

And return these results:

- First example: `2`
- Second example `3`

not

Check whether an expression is false. Return true when the expression is false, or return false when true.

```
not(<expression>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*expression*>	Yes	Boolean	The expression to check

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the expression is false. Return false when the expression is true.

Example 1

These examples check whether the specified expressions are false:

```
not(false)
not(true)
```

And return these results:

- First example: The expression is false, so the function returns `true`.
- Second example: The expression is true, so the function returns `false`.

Example 2

These examples check whether the specified expressions are false:

```
not(equals(1, 2))
not(equals(1, 1))
```

And return these results:

- First example: The expression is false, so the function returns `true`.
- Second example: The expression is true, so the function returns `false`.

or

Check whether at least one expression is true. Return true when at least one expression is true, or return false when both are false.

```
or(<expression1>, <expression2>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*expression1*>, <*expression2*>	Yes	Boolean	The expressions to check

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when at least one expression is true. Return false when both expressions are false.

Example 1

These examples check whether at least one expression is true:

```
or(true, false)
or(false, false)
```

And return these results:

- First example: At least one expression is true, so the function returns `true`.
- Second example: Both expressions are false, so the function returns `false`.

Example 2

These examples check whether at least one expression is true:

```
or(equals(1, 1), equals(1, 2))
or(equals(1, 2), equals(1, 3))
```

And return these results:

- First example: At least one expression is true, so the function returns `true`.
- Second example: Both expressions are false, so the function returns `false`.

rand

Return a random integer from a specified range, which is inclusive only at the starting end.

```
rand(<minValue>, <maxValue>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*minValue*>	Yes	Integer	The lowest integer in the range
<*maxValue*>	Yes	Integer	The integer that follows the highest integer in the range that the function can return

RETURN VALUE	TYPE	DESCRIPTION
<*random-result*>	Integer	The random integer returned from the specified range

Example

This example gets a random integer from the specified range, excluding the maximum value:

```
rand(1, 5)
```

And returns one of these numbers as the result: `1`, `2`, `3`, or `4`

range

Return an integer array that starts from a specified integer.

```
range(<startIndex>, <count>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*startIndex*>	Yes	Integer	An integer value that starts the array as the first item
<*count*>	Yes	Integer	The number of integers in the array

RETURN VALUE	TYPE	DESCRIPTION
[<*range-result*>]	Array	The array with integers starting from the specified index

Example

This example creates an integer array that starts from the specified index and has the specified number of integers:

```
range(1, 4)
```

And returns this result: `[1, 2, 3, 4]`

replace

Replace a substring with the specified string, and return the result string. This function is case-sensitive.

```
replace('<text>', '<oldText>', '<newText>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string that has the substring to replace
<*oldText*>	Yes	String	The substring to replace
<*newText*>	Yes	String	The replacement string

RETURN VALUE	TYPE	DESCRIPTION
<*updated-text*>	String	The updated string after replacing the substring If the substring is not found, return the original string.

Example

This example finds the "old" substring in "the old string" and replaces "old" with "new":

```
replace('the old string', 'old', 'new')
```

And returns this result: `"the new string"`

skip

Remove items from the front of a collection, and return *all the other* items.

```
skip([<collection>], <count>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	Array	The collection whose items you want to remove
<*count*>	Yes	Integer	A positive integer for the number of items to remove at the front

RETURN VALUE	TYPE	DESCRIPTION
[<*updated-collection*>]	Array	The updated collection after removing the specified items

Example

This example removes one item, the number 0, from the front of the specified array:

```
skip(createArray(0, 1, 2, 3), 1)
```

And returns this array with the remaining items: `[1,2,3]`

split

Return an array that contains substrings, separated by commas, based on the specified delimiter character in the original string.

```
split('<text>', '<delimiter>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string to separate into substrings based on the specified delimiter in the original string

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*delimiter*>	Yes	String	The character in the original string to use as the delimiter

RETURN VALUE	TYPE	DESCRIPTION
[<*substring1*>,<*substring2*>,...]	Array	An array that contains substrings from the original string, separated by commas

Example

This example creates an array with substrings from the specified string based on the specified character as the delimiter:

```
split('a_b_c', '_')
```

And returns this array as the result: `["a","b","c"]`

startOfDay

Return the start of the day for a timestamp.

```
startOfDay('<timestamp>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The specified timestamp but starting at the zero-hour mark for the day

Example

This example finds the start of the day for this timestamp:

```
startOfDay('2018-03-15T13:30:30Z')
```

And returns this result: `"2018-03-15T00:00:00.0000000Z"`

startOfHour

Return the start of the hour for a timestamp.

```
startOfHour('<timestamp>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The specified timestamp but starting at the zero-minute mark for the hour

Example

This example finds the start of the hour for this timestamp:

```
startOfHour('2018-03-15T13:30:30Z')
```

And returns this result: `"2018-03-15T13:00:00.0000000Z"`

startOfMonth

Return the start of the month for a timestamp.

```
startOfMonth('<timestamp>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The specified timestamp but starting on the first day of the month at the zero-hour mark

Example

This example returns the start of the month for this timestamp:

```
startOfMonth('2018-03-15T13:30:30Z')
```

And returns this result: `"2018-03-01T00:00:00.0000000Z"`

startsWith

Check whether a string starts with a specific substring. Return true when the substring is found, or return false when not found. This function is not case-sensitive.

```
startsWith('<text>', '<searchText>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string to check
<*searchText*>	Yes	String	The starting string to find

RETURN VALUE	TYPE	DESCRIPTION
true or false	Boolean	Return true when the starting substring is found. Return false when not found.

Example 1

This example checks whether the "hello world" string starts with the "hello" substring:

```
startsWith('hello world', 'hello')
```

And returns this result: `true`

Example 2

This example checks whether the "hello world" string starts with the "greetings" substring:

```
startsWith('hello world', 'greetings')
```

And returns this result: `false`

string

Return the string version for a value.

```
string(<value>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	Any	The value to convert

RETURN VALUE	TYPE	DESCRIPTION
<*string-value*>	String	The string version for the specified value

Example 1

This example creates the string version for this number:

```
string(10)
```

And returns this result: `"10"`

Example 2

This example creates a string for the specified JSON object and uses the backslash character (\) as an escape character for the double-quotation mark (").

```
string( { "name": "Sophie Owen" } )
```

And returns this result: `"{ \\"name\\": \\"Sophie Owen\\" }"`

sub

Return the result from subtracting the second number from the first number.

```
sub(<minuend>, <subtrahend>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*minuend*>	Yes	Integer or Float	The number from which to subtract the *subtrahend*
<*subtrahend*>	Yes	Integer or Float	The number to subtract from the *minuend*

RETURN VALUE	TYPE	DESCRIPTION
<*result*>	Integer or Float	The result from subtracting the second number from the first number

Example

This example subtracts the second number from the first number:

```
sub(10.3, .3)
```

And returns this result: `10`

substring

Return characters from a string, starting from the specified position, or index. Index values start with the number 0.

```
substring('<text>', <startIndex>, <length>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string whose characters you want
<*startIndex*>	Yes	Integer	A positive number equal to or greater than 0 that you want to use as the starting position or index value
<*length*>	Yes	Integer	A positive number of characters that you want in the substring

RETURN VALUE	TYPE	DESCRIPTION
<*substring-result*>	String	A substring with the specified number of characters, starting at the specified index position in the source string

Example

This example creates a five-character substring from the specified string, starting from the index value 6:

```
substring('hello world', 6, 5)
```

And returns this result: `"world"`

subtractFromTime

Subtract a number of time units from a timestamp. See also getPastTime.

```
subtractFromTime('<timestamp>', <interval>, '<timeUnit>', '<format>'?)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string that contains the timestamp
<*interval*>	Yes	Integer	The number of specified time units to subtract
<*timeUnit*>	Yes	String	The unit of time to use with *interval*: "Second", "Minute", "Hour", "Day", "Week", "Month", "Year"
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*updated-timestamp*>	String	The timestamp minus the specified number of time units

Example 1

This example subtracts one day from this timestamp:

```
subtractFromTime('2018-01-02T00:00:00Z', 1, 'Day')
```

And returns this result: `"2018-01-01T00:00:00.0000000Z"`

Example 2

This example subtracts one day from this timestamp:

```
subtractFromTime('2018-01-02T00:00:00Z', 1, 'Day', 'D')
```

And returns this result using the optional "D" format: `"Monday, January, 1, 2018"`

take

Return items from the front of a collection.

```
take('<collection>', <count>)
take([<collection>], <count>)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection*>	Yes	String or Array	The collection whose items you want
<*count*>	Yes	Integer	A positive integer for the number of items that you want from the front

RETURN VALUE	TYPE	DESCRIPTION
<*subset*> or [<*subset*>]	String or Array, respectively	A string or array that has the specified number of items taken from the front of the original collection

Example

These examples get the specified number of items from the front of these collections:

```
take('abcde', 3)
take(createArray(0, 1, 2, 3, 4), 3)
```

And return these results:

- First example: `"abc"`
- Second example: `[0, 1, 2]`

ticks

Return the `ticks` property value for a specified timestamp. A *tick* is a 100-nanosecond interval.

```
ticks('<timestamp>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*timestamp*>	Yes	String	The string for a timestamp

RETURN VALUE	TYPE	DESCRIPTION
<*ticks-number*>	Integer	The number of ticks since the specified timestamp

toLower

Return a string in lowercase format. If a character in the string doesn't have a lowercase version, that character stays unchanged in the returned string.

```
toLower('<text>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string to return in lowercase format

RETURN VALUE	TYPE	DESCRIPTION
<*lowercase-text*>	String	The original string in lowercase format

Example

This example converts this string to lowercase:

```
toLower('Hello World')
```

And returns this result: `"hello world"`

toUpper

Return a string in uppercase format. If a character in the string doesn't have an uppercase version, that character stays unchanged in the returned string.

```
toUpper('<text>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string to return in uppercase format

RETURN VALUE	TYPE	DESCRIPTION
<*uppercase-text*>	String	The original string in uppercase format

Example

This example converts this string to uppercase:

```
toUpper('Hello World')
```

And returns this result: `"HELLO WORLD"`

trim

Remove leading and trailing whitespace from a string, and return the updated string.

```
trim('<text>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*text*>	Yes	String	The string that has the leading and trailing whitespace to remove

RETURN VALUE	TYPE	DESCRIPTION
<*updatedText*>	String	An updated version for the original string without leading or trailing whitespace

Example

This example removes the leading and trailing whitespace from the string " Hello World ":

```
trim(' Hello World  ')
```

And returns this result: `"Hello World"`

union

Return a collection that has *all* the items from the specified collections. To appear in the result, an item can appear in any collection passed to this function. If one or more items have the same name, the last item with that name appears in the result.

```
union('<collection1>', '<collection2>', ...)
union([<collection1>], [<collection2>], ...)
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*collection1*>, <*collection2*>, ...	Yes	Array or Object, but not both	The collections from where you want *all* the items

RETURN VALUE	TYPE	DESCRIPTION
<*updatedCollection*>	Array or Object, respectively	A collection with all the items from the specified collections - no duplicates

Example

This example gets *all* the items from these collections:

```
union(createArray(1, 2, 3), createArray(1, 2, 10, 101))
```

And returns this result: `[1, 2, 3, 10, 101]`

uriComponent

Return a uniform resource identifier (URI) encoded version for a string by replacing URL-unsafe characters with escape characters. Use this function rather than encodeUriComponent(). Although both functions work the same way, `uriComponent()` is preferred.

```
uriComponent('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string to convert to URI-encoded format

RETURN VALUE	TYPE	DESCRIPTION
<*encoded-uri*>	String	The URI-encoded string with escape characters

Example

This example creates a URI-encoded version for this string:

```
uriComponent('https://contoso.com')
```

And returns this result: `"http%3A%2F%2Fcontoso.com"`

uriComponentToBinary

Return the binary version for a uniform resource identifier (URI) component.

```
uriComponentToBinary('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The URI-encoded string to convert

RETURN VALUE	TYPE	DESCRIPTION
<*binary-for-encoded-uri*>	String	The binary version for the URI-encoded string. The binary content is base64-encoded and represented by `$content`.

Example

This example creates the binary version for this URI-encoded string:

```
uriComponentToBinary('http%3A%2F%2Fcontoso.com')
```

And returns this result:

```
"0010001001101000011101000111010001110000001001010011001101000001001001010011001001000110001001010011001000100010010100110010010001100010010100110010001
1001100011011011110110111001110100110111101110011011011 1100101110011000110110111101101101001000100"
```

uriComponentToString

Return the string version for a uniform resource identifier (URI) encoded string, effectively decoding the URI-encoded string.

```
uriComponentToString('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The URI-encoded string to decode

RETURN VALUE	TYPE	DESCRIPTION
<*decoded-uri*>	String	The decoded version for the URI-encoded string

Example

This example creates the decoded string version for this URI-encoded string:

```
uriComponentToString('http%3A%2F%2Fcontoso.com')
```

And returns this result: `"https://contoso.com"`

utcNow

Return the current timestamp.

```
utcNow('<format>')
```

Optionally, you can specify a different format with the <*format*> parameter.

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*format*>	No	String	Either a single format specifier or a custom format pattern. The default format for the timestamp is "o" (yyyy-MM-ddTHH:mm:ss:fffffffK), which complies with ISO 8601 and preserves time zone information.

RETURN VALUE	TYPE	DESCRIPTION
<*current-timestamp*>	String	The current date and time

Example 1

Suppose today is April 15, 2018 at 1:00:00 PM. This example gets the current timestamp:

```
utcNow()
```

And returns this result: `"2018-04-15T13:00:00.0000000Z"`

Example 2

Suppose today is April 15, 2018 at 1:00:00 PM. This example gets the current timestamp using the optional "D" format:

```
utcNow('D')
```

And returns this result: `"Sunday, April 15, 2018"`

xml

Return the XML version for a string that contains a JSON object.

```
xml('<value>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*value*>	Yes	String	The string with the JSON object to convert The JSON object must have only one root property, which can't be an array. Use the backslash character (\) as an escape character for the double quotation mark (\").

RETURN VALUE	TYPE	DESCRIPTION
<*xml-version*>	Object	The encoded XML for the specified string or JSON object

Example 1

This example creates the XML version for this string, which contains a JSON object:

```
xml(json('{ \"name\": \"Sophia Owen\" }'))
```

And returns this result XML:

```
<name>Sophia Owen</name>
```

Example 2

Suppose you have this JSON object:

```
{
  "person": {
    "name": "Sophia Owen",
    "city": "Seattle"
  }
}
```

This example creates XML for a string that contains this JSON object:

```
xml(json('{\"person\": {\"name\": \"Sophia Owen\", \"city\": \"Seattle\"}}'))
```

And returns this result XML:

```
<person>
  <name>Sophia Owen</name>
  <city>Seattle</city>
<person>
```

xpath

Check XML for nodes or values that match an XPath (XML Path Language) expression, and return the matching

nodes or values. An XPath expression, or just "XPath", helps you navigate an XML document structure so that you can select nodes or compute values in the XML content.

```
xpath('<xml>', '<xpath>')
```

PARAMETER	REQUIRED	TYPE	DESCRIPTION
<*xml*>	Yes	Any	The XML string to search for nodes or values that match an XPath expression value
<*xpath*>	Yes	Any	The XPath expression used to find matching XML nodes or values

RETURN VALUE	TYPE	DESCRIPTION
<*xml-node*>	XML	An XML node when only a single node matches the specified XPath expression
<*value*>	Any	The value from an XML node when only a single value matches the specified XPath expression
[<*xml-node1*>, <*xml-node2*>, ...] -or- [<*value1*>, <*value2*>, ...]	Array	An array with XML nodes or values that match the specified XPath expression

Example 1

Following on Example 1, this example finds nodes that match the `<count></count>` node and adds those node values with the `sum()` function:

```
xpath(xml(parameters('items')), 'sum(/produce/item/count)')
```

And returns this result: `30`

Example 2

For this example, both expressions find nodes that match the `<location></location>` node, in the specified arguments, which include XML with a namespace. The expressions use the backslash character (\) as an escape character for the double quotation mark (").

- *Expression 1*

  ```
  xpath(xml(body('Http')), '/*[name()=\"file\"]/*[name()=\"location\"]')
  ```

- *Expression 2*

  ```
  xpath(xml(body('Http')), '/*[local-name()=\"file\" and namespace-uri()=\"http://contoso.com\"]/*
  [local-name()=\"location\"]')
  ```

Here are the arguments:

- This XML, which includes the XML document namespace, `xmlns="http://contoso.com"`:

```
<?xml version="1.0"?> <file xmlns="http://contoso.com"> <location>Paris</location> </file>
```

- Either XPath expression here:
  - `/*[name()=\"file\"]/*[name()=\"location\"]`
  - `/*[local-name()=\"file\" and namespace-uri()=\"http://contoso.com\"]/*[local-name()=\"location\"]`

Here is the result node that matches the `<location></location>` node:

```
<location xmlns="https://contoso.com">Paris</location>
```

Example 3

Following on Example 3, this example finds the value in the `<location></location>` node:

```
xpath(xml(body('Http')), 'string(/*[name()=\"file\"]/*[name()=\"location\"])')
```

And returns this result: `"Paris"`

Next steps

For a list of system variables you can use in expressions, see System variables.

System variables supported by Azure Data Factory and Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes system variables supported by Azure Data Factory and Azure Synapse. You can use these variables in expressions when defining entities within either service.

Pipeline scope

These system variables can be referenced anywhere in the pipeline JSON.

VARIABLE NAME	DESCRIPTION
@pipeline().DataFactory	Name of the data or Synapse workspace the pipeline run is running in
@pipeline().Pipeline	Name of the pipeline
@pipeline().RunId	ID of the specific pipeline run
@pipeline().TriggerType	The type of trigger that invoked the pipeline (for example, `ScheduleTrigger`, `BlobEventsTrigger`). For a list of supported trigger types, see Pipeline execution and triggers. A trigger type of `Manual` indicates that the pipeline was triggered manually.
@pipeline().TriggerId	ID of the trigger that invoked the pipeline
@pipeline().TriggerName	Name of the trigger that invoked the pipeline
@pipeline().TriggerTime	Time of the trigger run that invoked the pipeline. This is the time at which the trigger **actually** fired to invoke the pipeline run, and it may differ slightly from the trigger's scheduled time.
@pipeline().GroupId	ID of the group to which pipeline run belongs.
@pipeline()?TriggeredByPipelineName	Name of the pipeline that triggers the pipeline run. Applicable when the pipeline run is triggered by an ExecutePipeline activity. Evaluate to *Null* when used in other circumstances. Note the question mark after @pipeline()
@pipeline()?TriggeredByPipelineRunId	Run ID of the pipeline that triggers the pipeline run. Applicable when the pipeline run is triggered by an ExecutePipeline activity. Evaluate to *Null* when used in other circumstances. Note the question mark after @pipeline()

> **NOTE**
> Trigger-related date/time system variables (in both pipeline and trigger scopes) return UTC dates in ISO 8601 format, for example, `2017-06-01T22:20:00.4061448Z`.

Schedule trigger scope

These system variables can be referenced anywhere in the trigger JSON for triggers of type ScheduleTrigger.

VARIABLE NAME	DESCRIPTION
@trigger().scheduledTime	Time at which the trigger was scheduled to invoke the pipeline run.
@trigger().startTime	Time at which the trigger **actually** fired to invoke the pipeline run. This may differ slightly from the trigger's scheduled time.

Tumbling window trigger scope

These system variables can be referenced anywhere in the trigger JSON for triggers of type TumblingWindowTrigger.

VARIABLE NAME	DESCRIPTION
@trigger().outputs.windowStartTime	Start of the window associated with the trigger run.
@trigger().outputs.windowEndTime	End of the window associated with the trigger run.
@trigger().scheduledTime	Time at which the trigger was scheduled to invoke the pipeline run.
@trigger().startTime	Time at which the trigger **actually** fired to invoke the pipeline run. This may differ slightly from the trigger's scheduled time.

Storage event trigger scope

These system variables can be referenced anywhere in the trigger JSON for triggers of type BlobEventsTrigger.

VARIABLE NAME	DESCRIPTION
@triggerBody().fileName	Name of the file whose creation or deletion caused the trigger to fire.
@triggerBody().folderPath	Path to the folder that contains the file specified by `@triggerBody().fileName`. The first segment of the folder path is the name of the Azure Blob Storage container.
@trigger().startTime	Time at which the trigger fired to invoke the pipeline run.

> **NOTE**
>
> If you are creating your pipeline and trigger in Azure Synapse Analytics, you must use `@trigger().outputs.body.fileName` and `@trigger().outputs.body.folderPath` as parameters. Those two properties capture blob information. Use those properties instead of using `@triggerBody().fileName` and `@triggerBody().folderPath`.

Custom event trigger scope

These system variables can be referenced anywhere in the trigger JSON for triggers of type CustomEventsTrigger.

> **NOTE**
>
> The service expects custom events to be formatted with Azure Event Grid event schema.

VARIABLE NAME	DESCRIPTION
@triggerBody().event.eventType	Type of events that triggered the Custom Event Trigger run. Event type is customer-defined field and take on any values of string type.
@triggerBody().event.subject	Subject of the custom event that caused the trigger to fire.
@triggerBody().event.data._keyName_	Data field in custom event is a free from JSON blob, which customer can use to send messages and data. Please use data.*keyName* to reference each field. For example, @triggerBody().event.data.callback returns the value for the *callback* field stored under *data*.
@trigger().startTime	Time at which the trigger fired to invoke the pipeline run.

- For information about how these variables are used in expressions, see Expression language & functions.
- To use trigger scope system variables in pipeline, see Reference trigger metadata in pipeline

Parameterizing mapping data flows

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

Mapping data flows in Azure Data Factory and Synapse pipelines support the use of parameters. Define parameters inside of your data flow definition and use them throughout your expressions. The parameter values are set by the calling pipeline via the Execute Data Flow activity. You have three options for setting the values in the data flow activity expressions:

- Use the pipeline control flow expression language to set a dynamic value
- Use the data flow expression language to set a dynamic value
- Use either expression language to set a static literal value

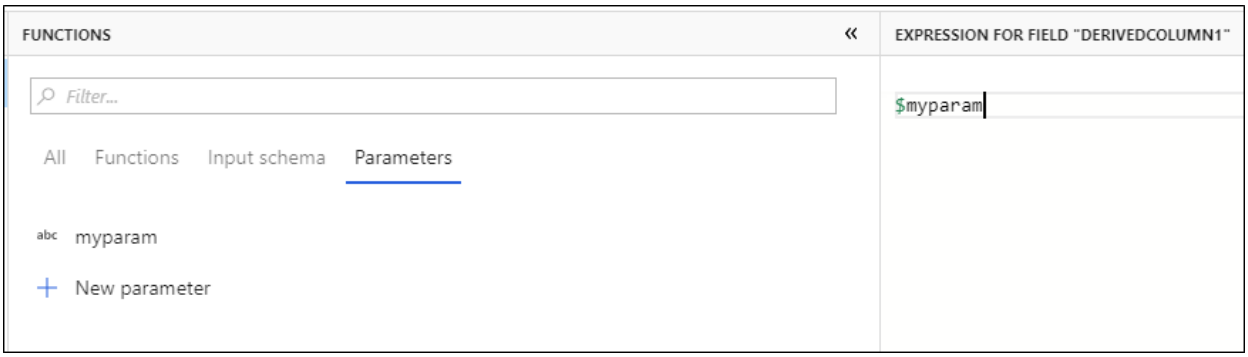
Use this capability to make your data flows general-purpose, flexible, and reusable. You can parameterize data flow settings and expressions with these parameters.

Create parameters in a mapping data flow

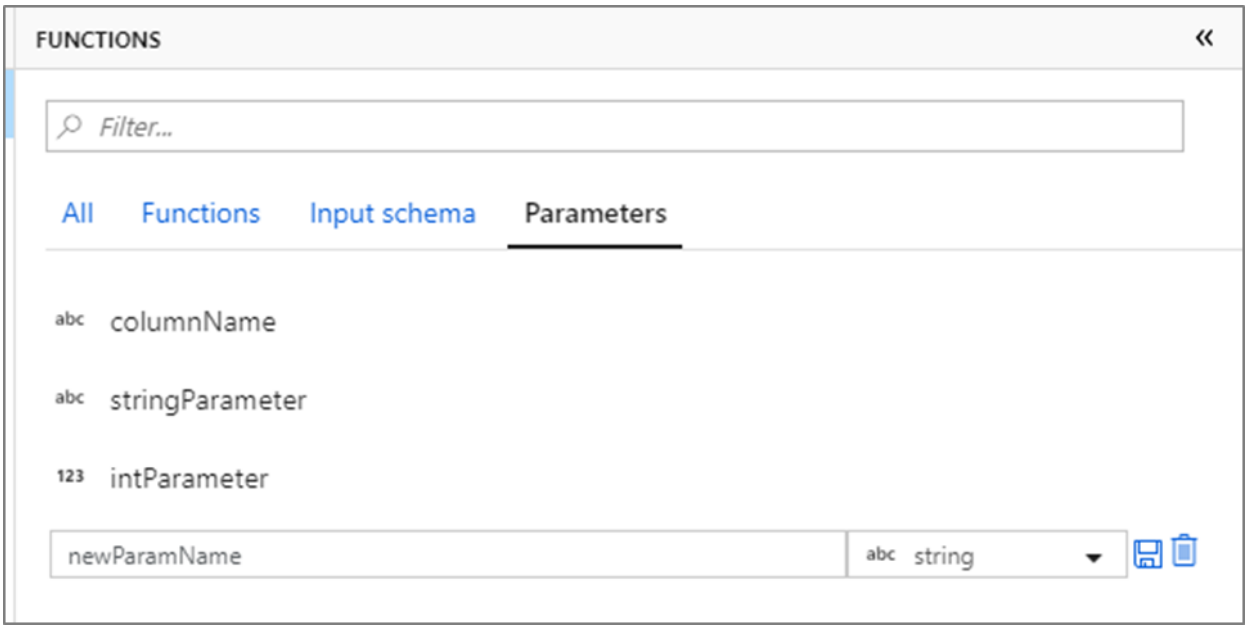
To add parameters to your data flow, click on the blank portion of the data flow canvas to see the general properties. In the settings pane, you will see a tab called **Parameter**. Select **New** to generate a new parameter. For each parameter, you must assign a name, select a type, and optionally set a default value.

Use parameters in a mapping data flow

Parameters can be referenced in any data flow expression. Parameters begin with $ and are immutable. You will find the list of available parameters inside of the Expression Builder under the **Parameters** tab.



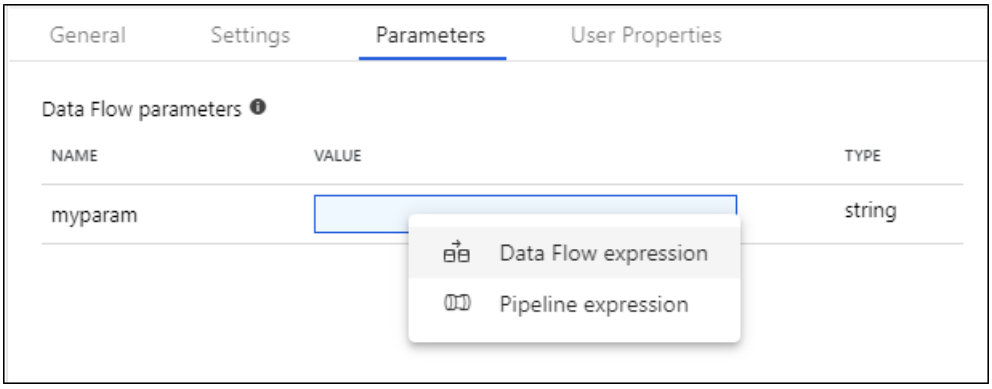
You can quickly add additional parameters by selecting **New parameter** and specifying the name and type.



Assign parameter values from a pipeline

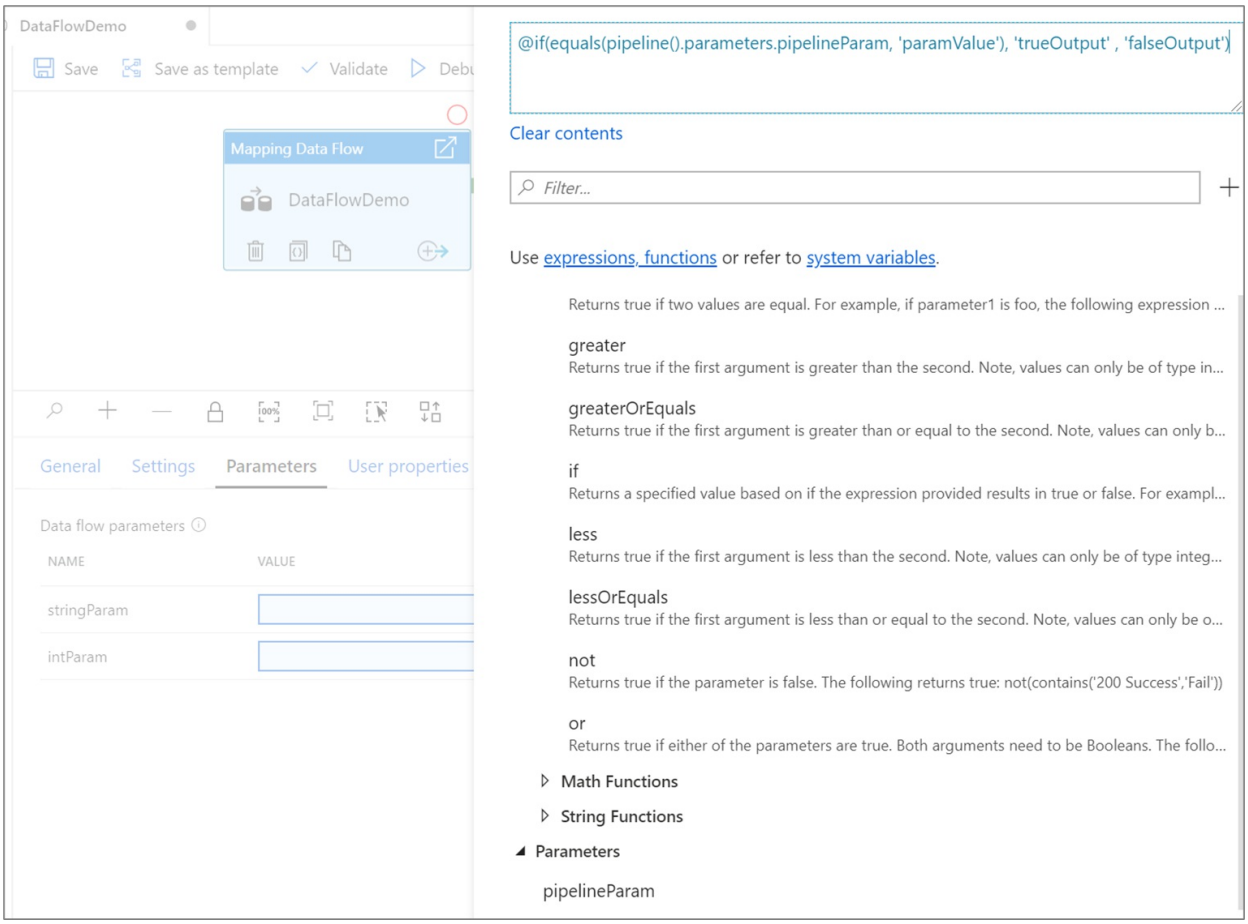
Once you've created a data flow with parameters, you can execute it from a pipeline with the Execute Data Flow Activity. After you add the activity to your pipeline canvas, you will be presented with the available data flow parameters in the activity's **Parameters** tab.

When assigning parameter values, you can use either the pipeline expression language or the data flow expression language based on spark types. Each mapping data flow can have any combination of pipeline and data flow expression parameters.



Pipeline expression parameters

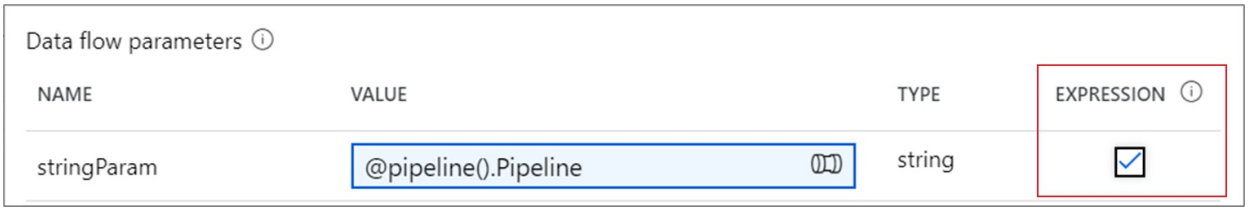
Pipeline expression parameters allow you to reference system variables, functions, pipeline parameters, and variables similar to other pipeline activities. When you click **Pipeline expression**, a side-nav will open allowing you to enter an expression using the expression builder.



When referenced, pipeline parameters are evaluated and then their value is used in the data flow expression language. The pipeline expression type doesn't need to match the data flow parameter type.

String literals vs expressions

When assigning a pipeline expression parameter of type string, by default quotes will be added and the value will be evaluated as a literal. To read the parameter value as a data flow expression, check the expression box next to the parameter.

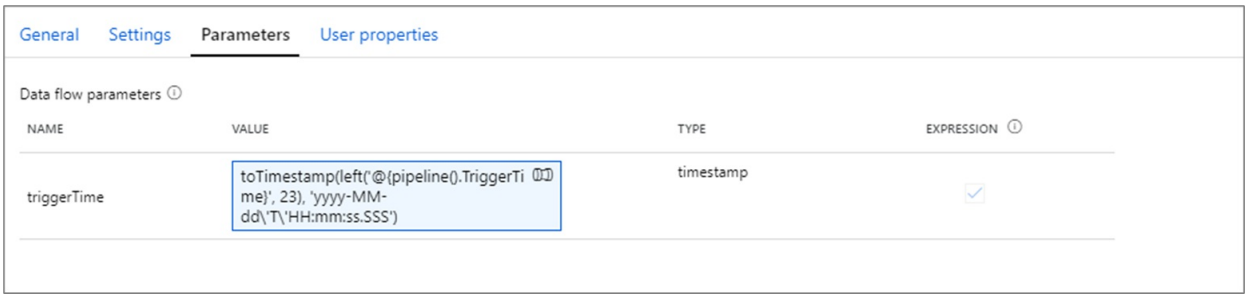


If data flow parameter `stringParam` references a pipeline parameter with value `upper(column1)`.

- If expression is checked, `$stringParam` evaluates to the value of column1 all uppercase.
- If expression is not checked (default behavior), `$stringParam` evaluates to `'upper(column1)'`

Passing in timestamps

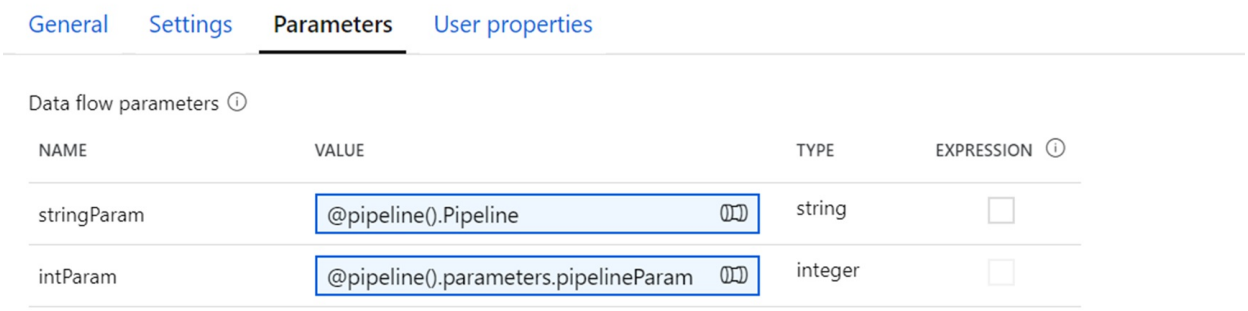
In the pipeline expression language, System variables such as `pipeline().TriggerTime` and functions like `utcNow()` return timestamps as strings in format 'yyyy-MM-dd'T'HH:mm:ss.SSSSSSZ'. To convert these into data flow parameters of type timestamp, use string interpolation to include the desired timestamp in a `toTimestamp()` function. For example, to convert the pipeline trigger time into a data flow parameter, you can use `toTimestamp(left('@{pipeline().TriggerTime}', 23), 'yyyy-MM-dd\'T\'HH:mm:ss.SSS')`.



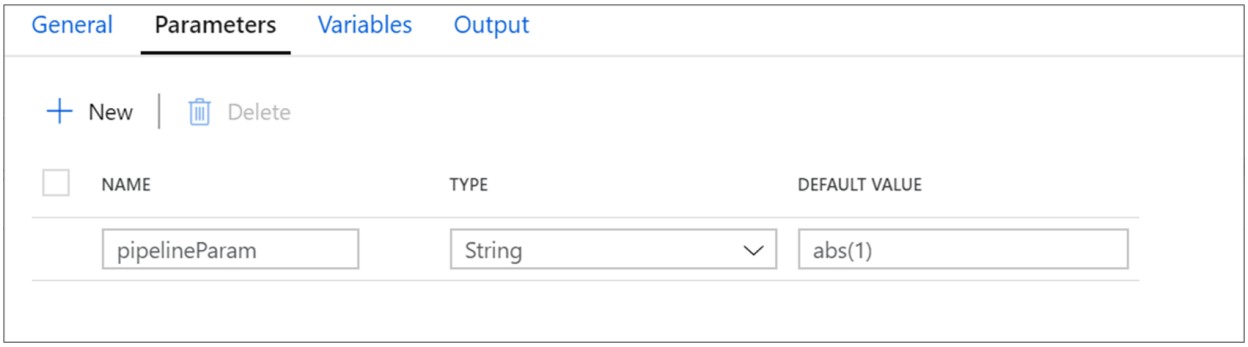
> **NOTE**
> Data Flows can only support up to 3 millisecond digits. The `left()` function is used trim off additional digits.

Pipeline parameter example

Say you have an integer parameter `intParam` that is referencing a pipeline parameter of type String, `@pipeline.parameters.pipelineParam`.



`@pipeline.parameters.pipelineParam` is assigned a value of `abs(1)` at runtime.



When `$intParam` is referenced in an expression such as a derived column, it will evaluate `abs(1)` return `1`.

Data flow expression parameters

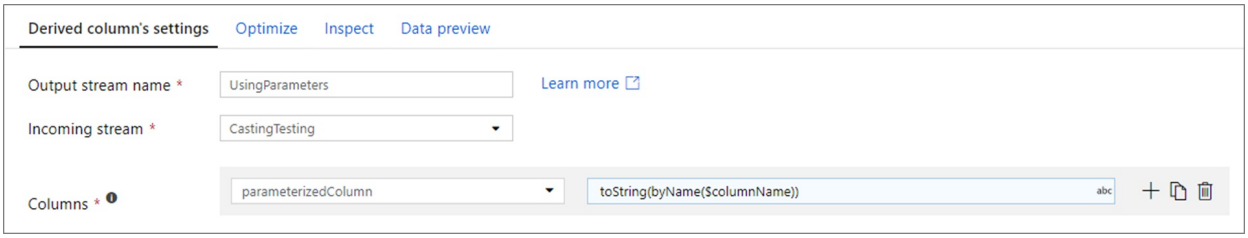
Select **Data flow expression** will open up the data flow expression builder. You will be able to reference functions, other parameters and any defined schema column throughout your data flow. This expression will be evaluated as is when referenced.

> **NOTE**
> If you pass in an invalid expression or reference a schema column that doesn't exist in that transformation, the parameter will evaluate to null.

Passing in a column name as a parameter

A common pattern is to pass in a column name as a parameter value. If the column is defined in the data flow schema, you can reference it directly as a string expression. If the column isn't defined in the schema, use the `byName()` function. Remember to cast the column to its appropriate type with a casting function such as `toString()`.

For example, if you wanted to map a string column based upon a parameter `columnName`, you can add a derived column transformation equal to `toString(byName($columnName))`.



Next steps

- Execute data flow activity
- Control flow expressions

Use Synapse Studio to monitor your workspace pipeline runs

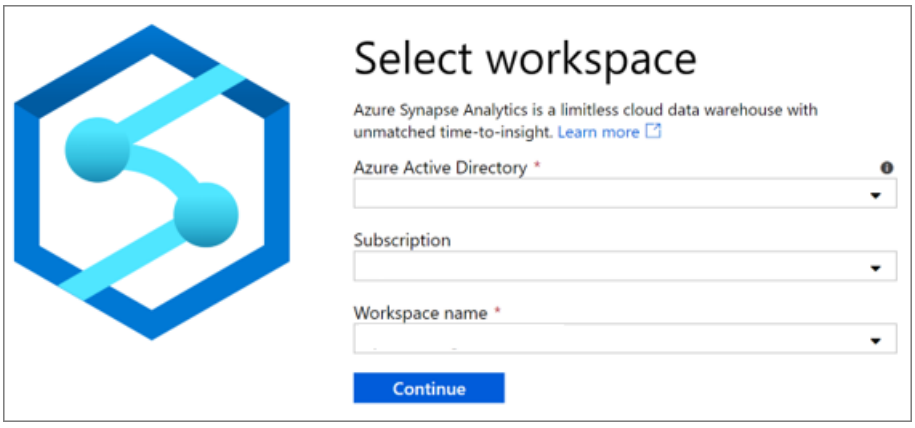
8/19/2022 • 2 minutes to read • Edit Online

With Azure Synapse Analytics, you can create complex pipelines that can automate and integrate your data movement, data transformation, and compute activities within your solution. You can author and monitor these pipelines using Synapse Studio.

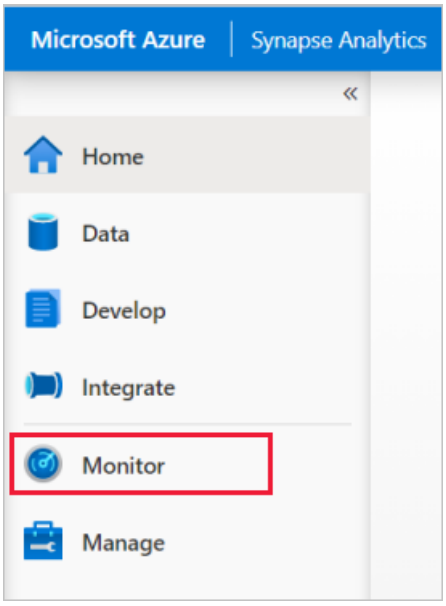
This article explains how to monitor your pipeline runs, which allows you to keep an eye on the latest status, issues, and progress of your pipelines.

Access pipeline runs list

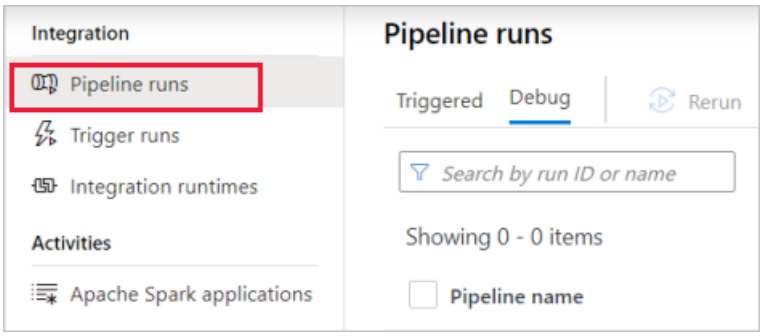
To see the list of pipeline runs in your workspace, first open the Synapse Studio and select your workspace.



Once you've opened your workspace, select the **Monitor** section on the left.



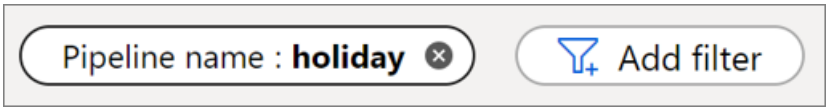
Select **Pipeline runs** to view the list of pipeline runs.



Filter your pipeline runs

You can filter the list of pipeline runs to the ones you're interested in. The filters at the top of the screen allow you to specify a field on which you'd like to filter.

For example, you can filter the view to see only the pipeline runs for the pipeline named "holiday":



View details about a specific pipeline run

To view details about your pipeline run, select the pipeline run. Then view the activity runs associated with the pipeline run. If the pipeline is still running, you can monitor the progress.

Next steps

To learn more about monitoring applications, see the Monitor Apache Spark applications article.

Send an email with an Azure Data Factory or Azure Synapse pipeline

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

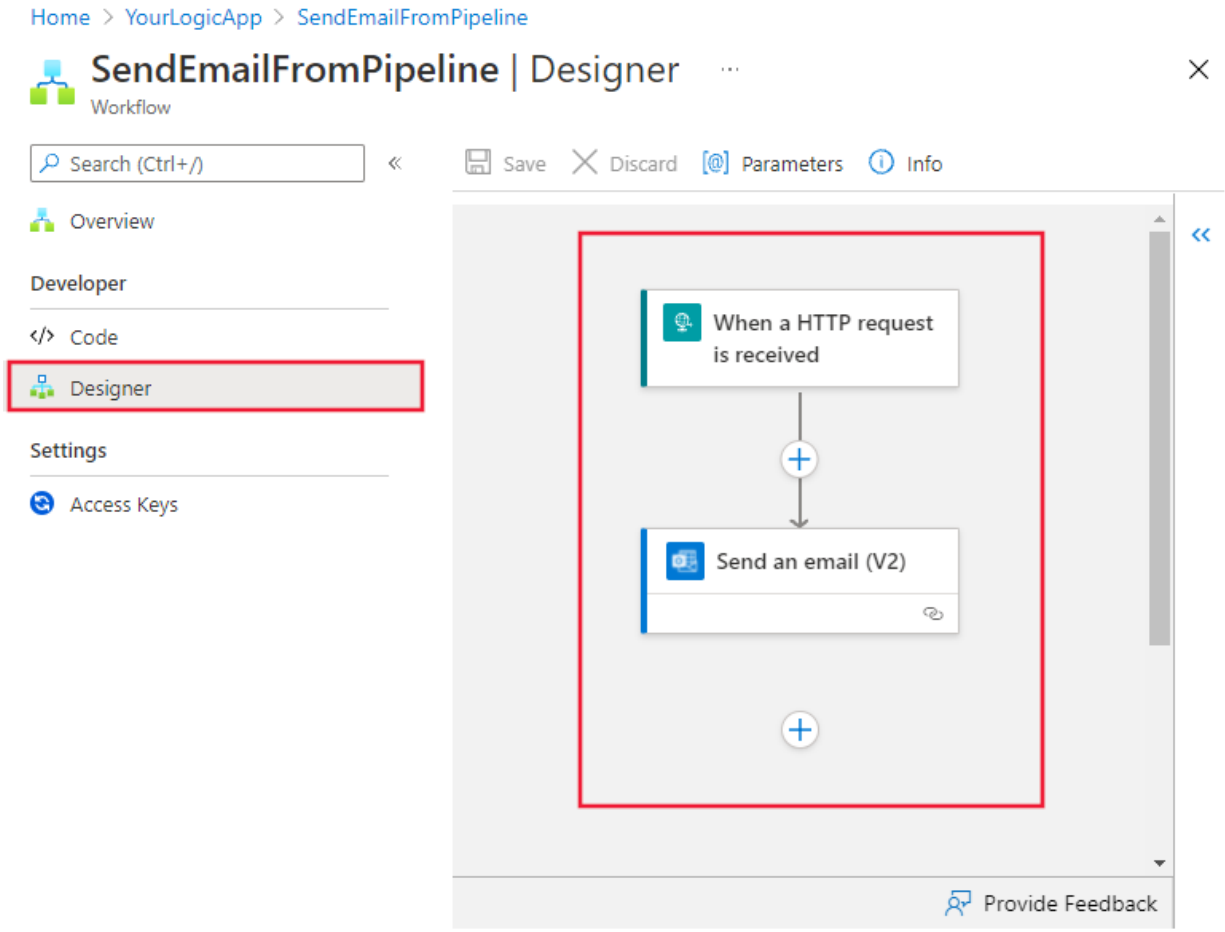
It's often necessary to send notifications during or after execution of a pipeline. Notification provides proactive alerting and reduces the need for reactive monitoring to discover issues. This article shows how to configure email notifications from an Azure Data Factory or Azure Synapse pipeline.

Prerequisites

- **Azure subscription**. If you don't have an Azure subscription, create a free account before you begin.
- **Logic App**. To trigger sending an email from the pipeline, you use Logic Apps to define the workflow. For details on creating a Logic App workflow, see How to create a logic app.

Create the email workflow in your Logic App

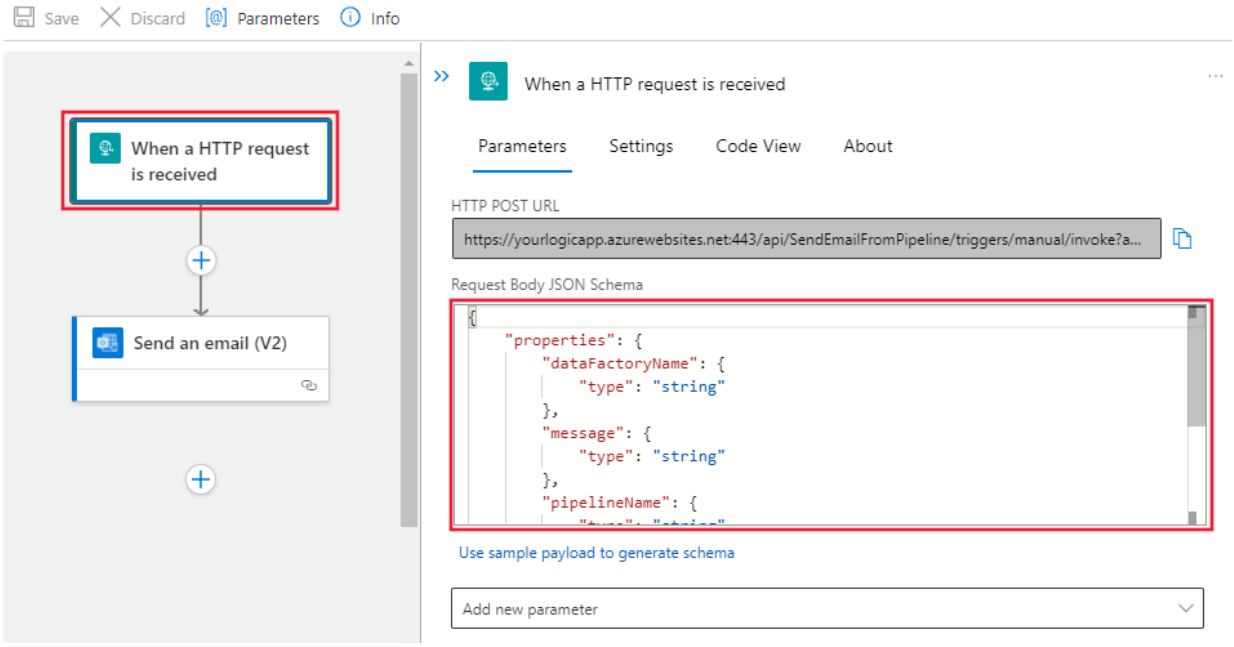
Create a Logic App workflow named `SendEmailFromPipeline`. Define the workflow trigger as `When an HTTP request is received`, and add an action of `Office 365 Outlook – Send an email (V2)`.



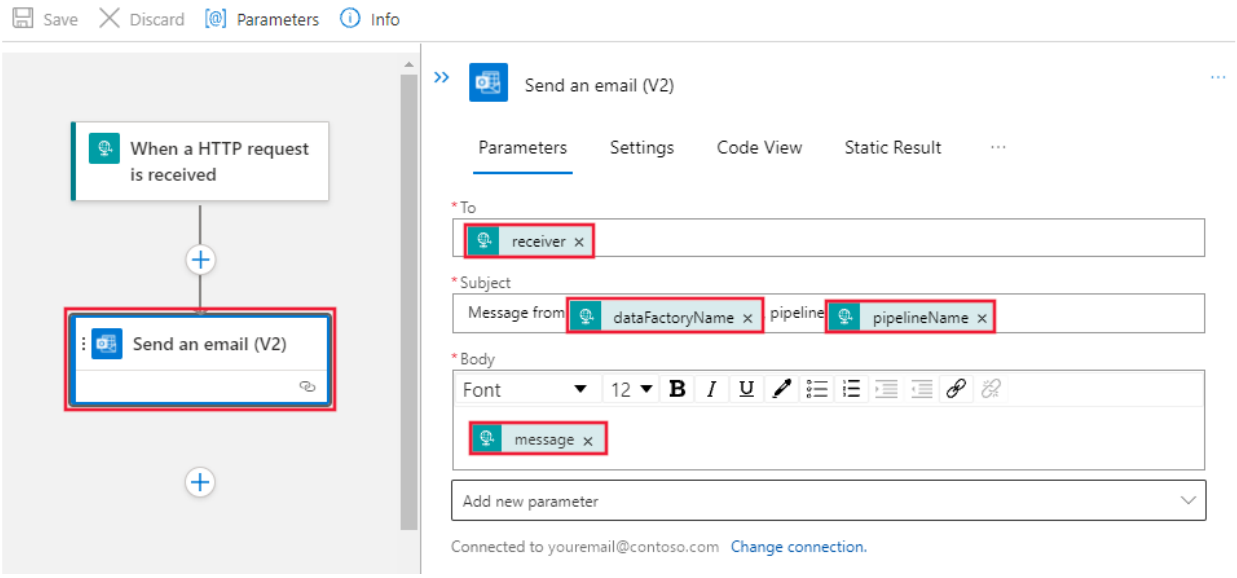
For the HTTP request trigger, provide this JSON for the `Request Body JSON Schema`:

```
{
    "properties": {
        "dataFactoryName": {
            "type": "string"
        },
        "message": {
            "type": "string"
        },
        "pipelineName": {
            "type": "string"
        },
        "receiver": {
            "type": "string"
        }
    },
    "type": "object"
}
```

The HTTP Request in the Logic App Designer should look like this:

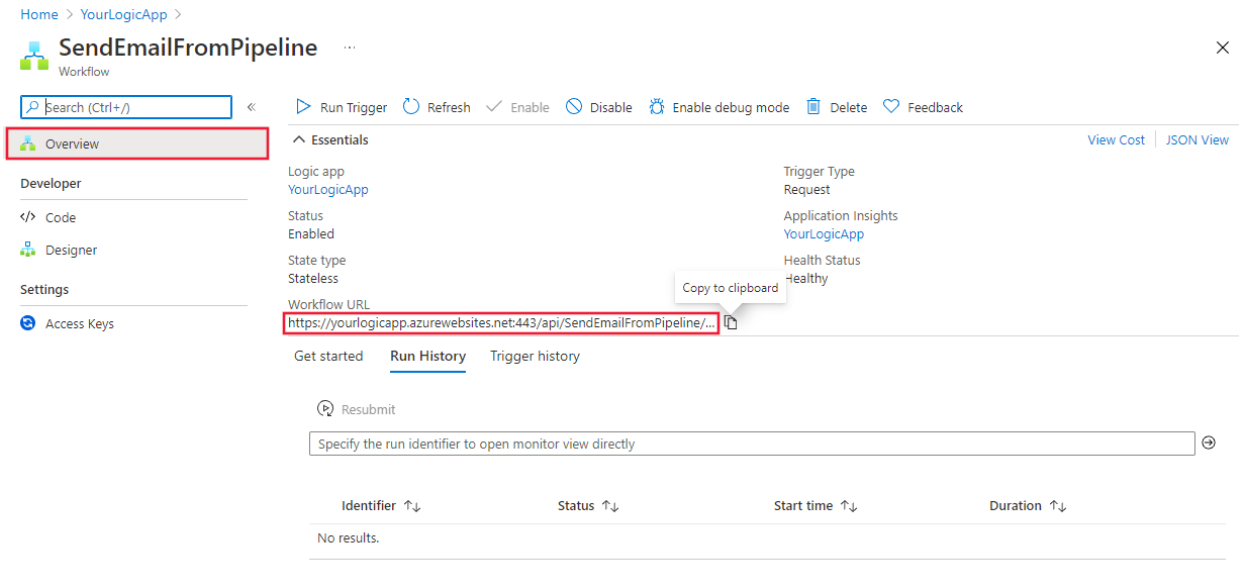


For the **Send Email (V2)** action, customize how you wish to format the email, using the properties from the request Body JSON schema:



Save the workflow. Browse to the Overview page for the workflow. Make a note of the Workflow URL for your

new workflow then, highlighted in the image below:



> **NOTE**
>
> To find the Workflow URL you must browse to the workflow itself, not just the logic app that contains it. From the Workflows page of your logic app instance, choose the workflow and then navigate to its Overview page.

Create a pipeline to trigger your Logic App email workflow

Once you create the Logic App workflow to send email, you can trigger it from a pipeline using a **Web** activity.

1. Create a new pipeline and find the **Web** activity under the **General** category, to drag it onto the editing canvas.

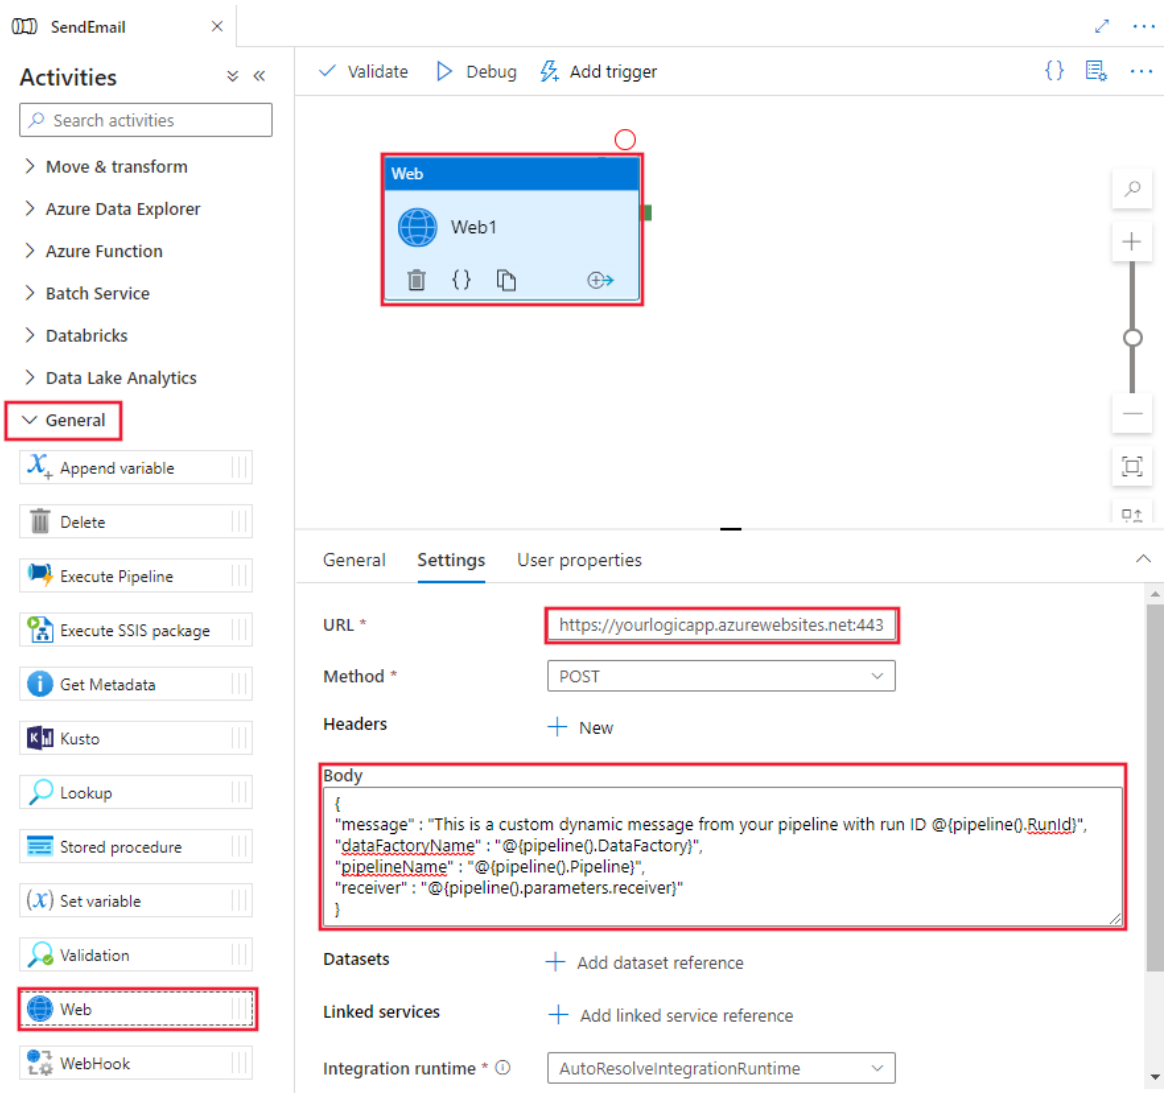
2. Select the new **Web1** activity, and then select the **Settings** tab.

   Provide the URL from the Logic App workflow you created previously in the **URL** field.

   Provide the following JSON for the **Body**:

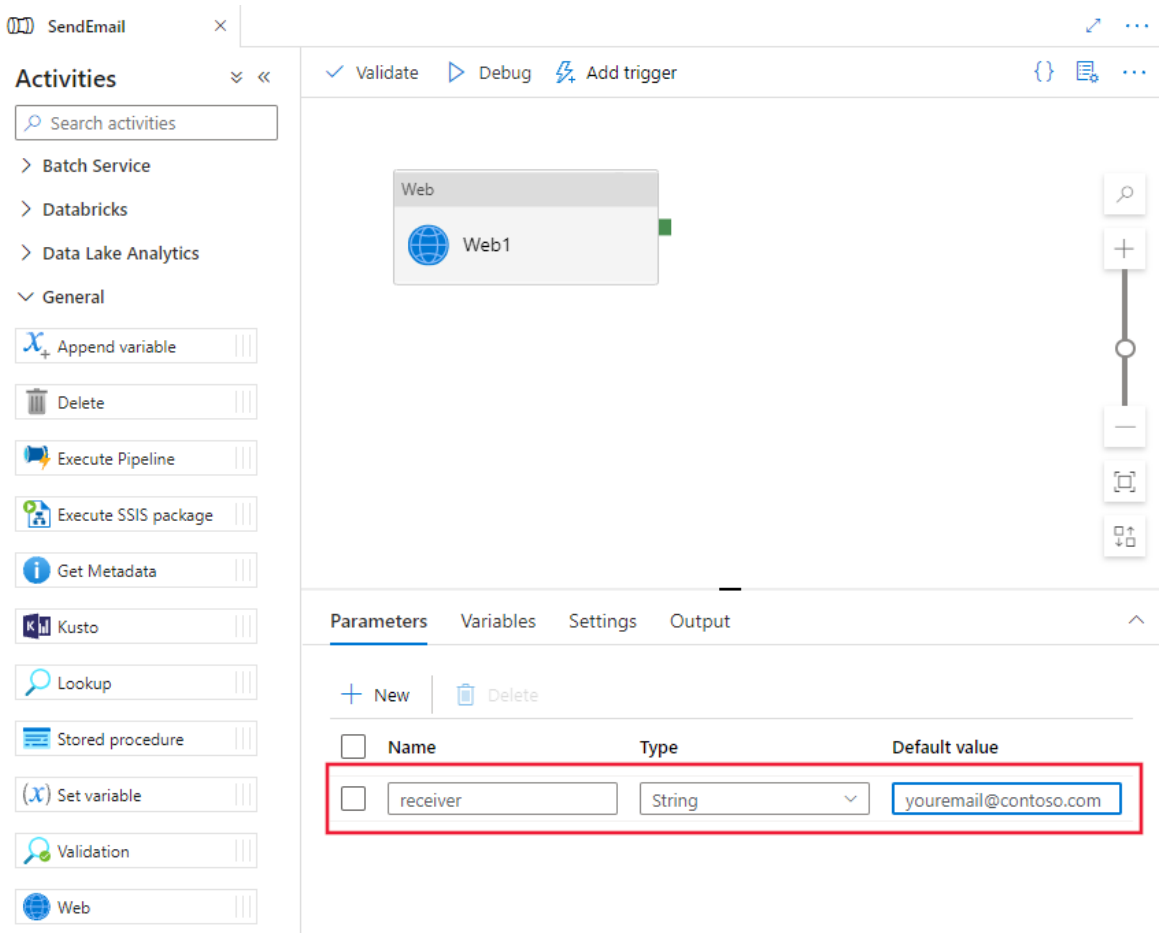
   ```
   {
    "message" : "This is a custom dynamic message from your pipeline with run ID
   @{pipeline().RunId}.",
    "dataFactoryName" : "@{pipeline().DataFactory}",
    "pipelineName" : "@{pipeline().Pipeline}",
    "receiver" : "@{pipeline().parameters.receiver}"
   }
   ```

   Use dynamic expressions to generate useful messages for events in your pipelines. Notice that the JSON format here matches the JSON format you defined in the Logic App, and you can also customize these as required.

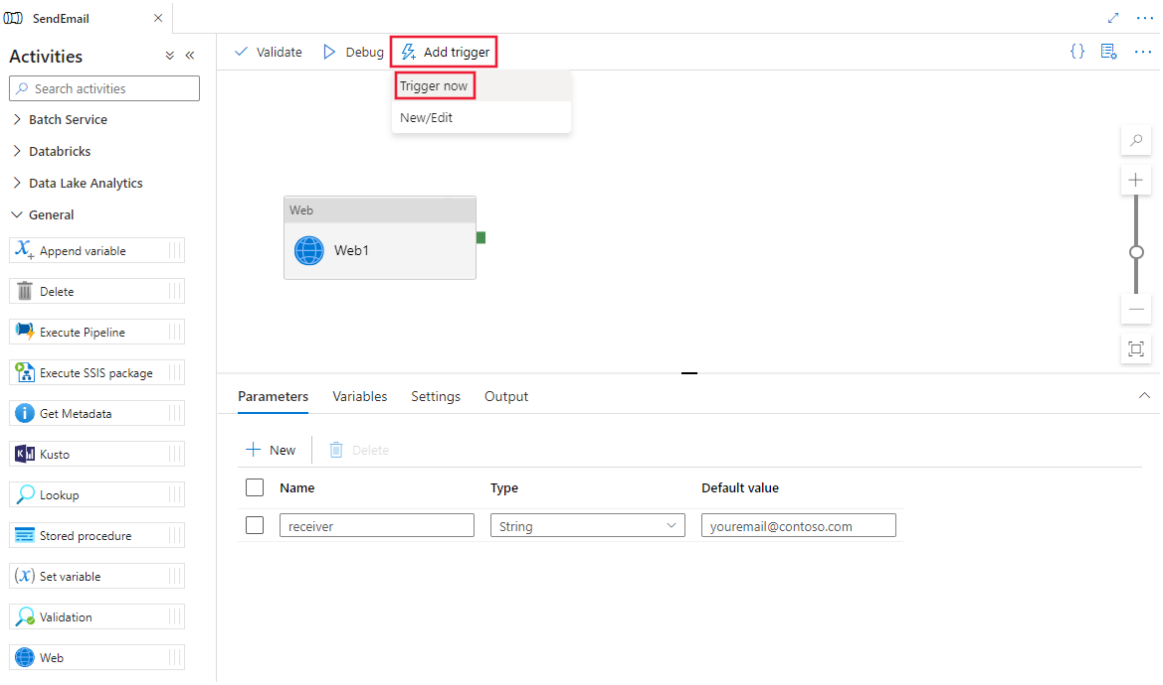


3. Select the background area of the pipeline designer to select the pipeline properties page and add a new parameter called receiver, providing an email address as its Default value.

   In this example, we provide the receiver email from a pipeline parameter we define arbitrarily. The receiver value could be taken from any expression, or even linked data sources.



4. Publish your pipeline, and then trigger it manually to confirm the email is sent as expected.



Add dynamic messages with system variables and expressions

You can use system variables and expressions to make your messages dynamic. For example:

- `@activity("CopyData").output.errors[0].Message`
- `@activity("DataFlow").error.Message`

The above expressions will return the relevant error messages from a Copy activity failure, which can be

redirected then to your Web activity that sends the email. Refer to the Copy activity output properties article for more details.

How to send Teams notifications from a pipeline

Send notifications to a Microsoft Teams channel from an Azure Data Factory or Synapse Analytics pipeline

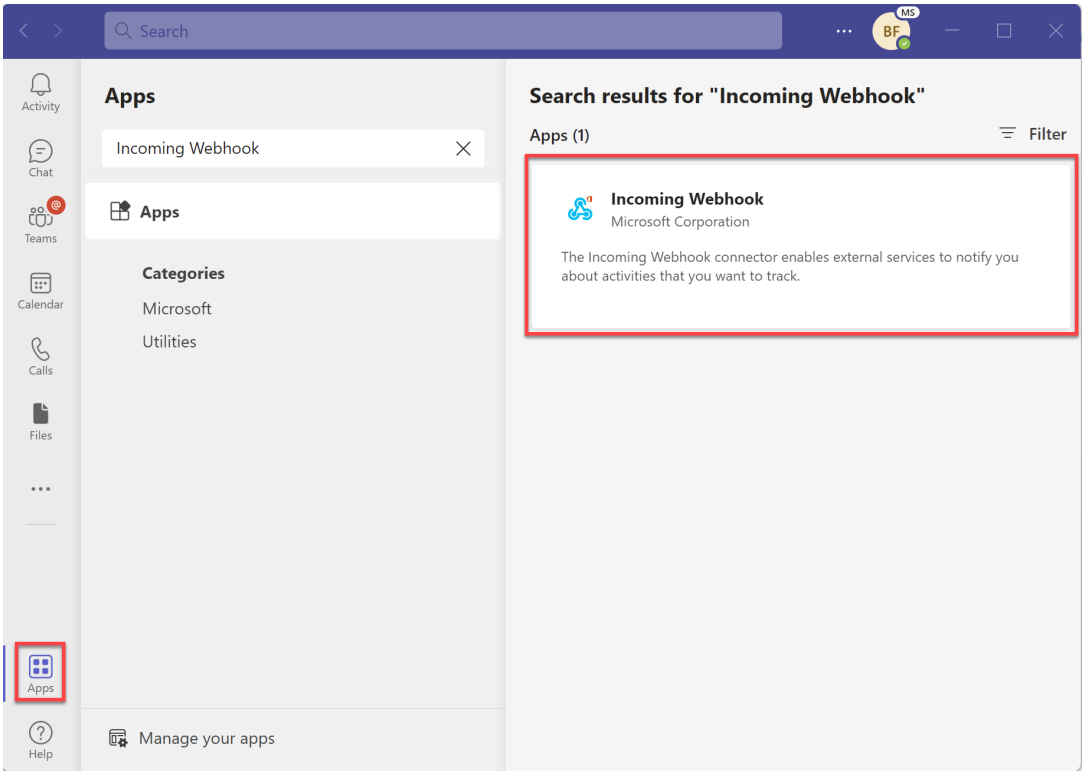
8/19/2022 • 11 minutes to read • Edit Online

It's often necessary to send notifications during or after execution of a pipeline. Notification provides proactive alerting and reduces the need for reactive monitoring to discover issues. You can learn about how to send email notifications using logic apps that a data factory or Synapse pipeline can invoke. Many enterprises are also increasingly using Microsoft Teams for collaboration. This article shows how to configure notifications from pipeline alerts into Microsoft Teams.

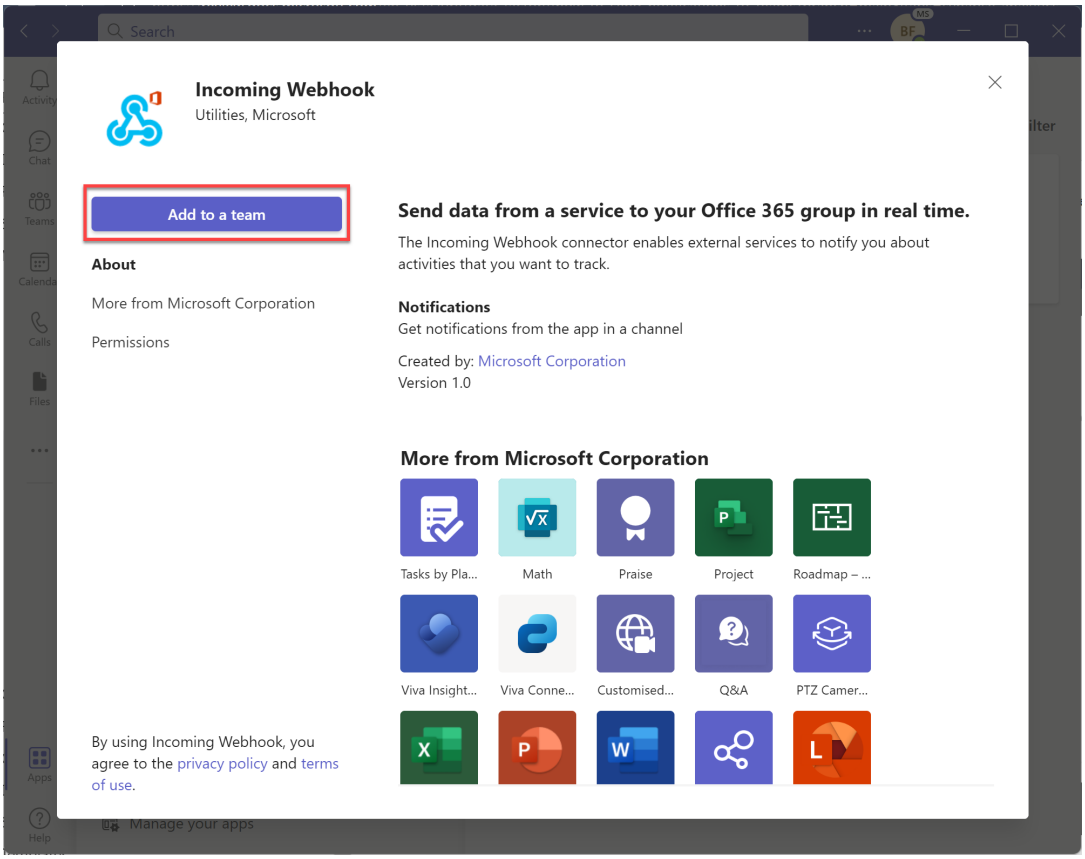
Prerequisites

Before you can send notifications to Teams from your pipelines, you must create an Incoming Webhook for your Teams channel. If you need to create a new Teams channel for this purpose, refer to the Teams documentation.

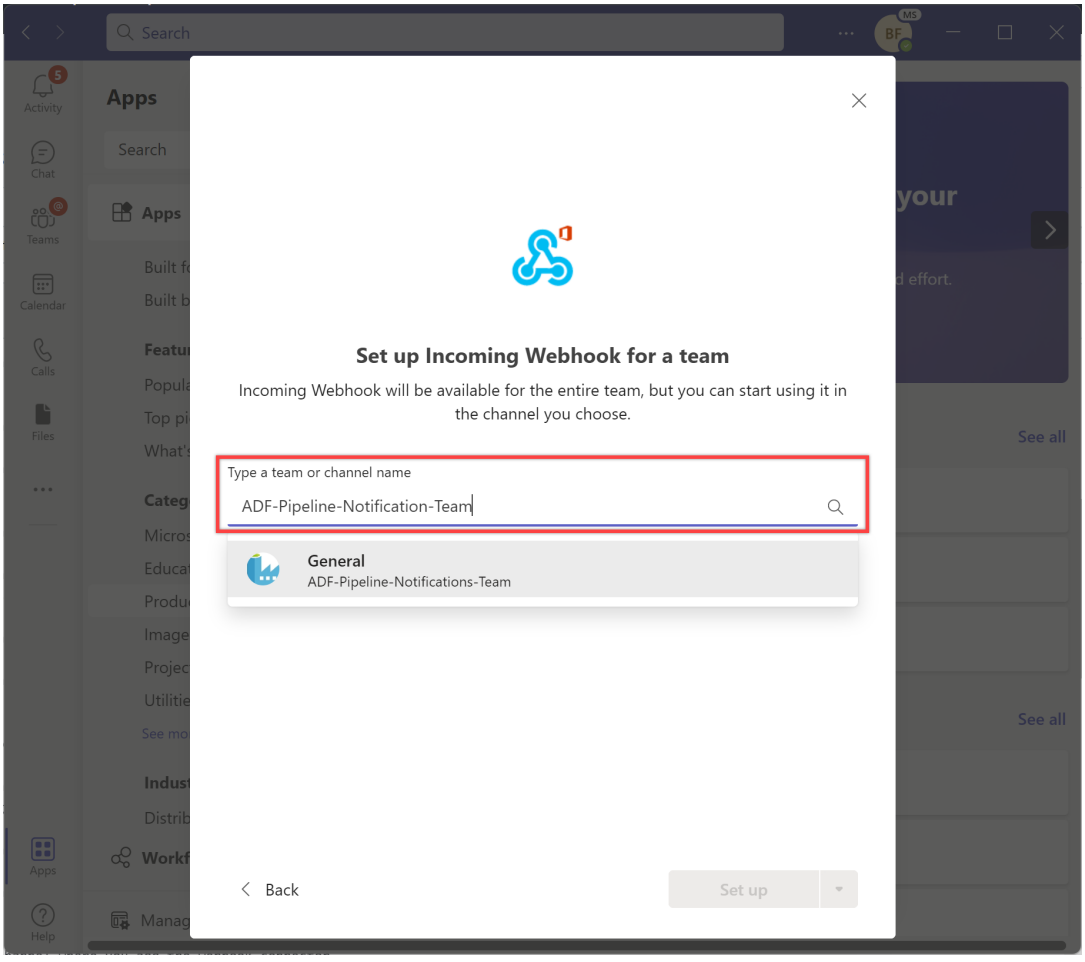
1. Open Microsoft Teams and go to the Apps tab. Search for "Incoming Webhook" and select the Incoming Webhook connector.



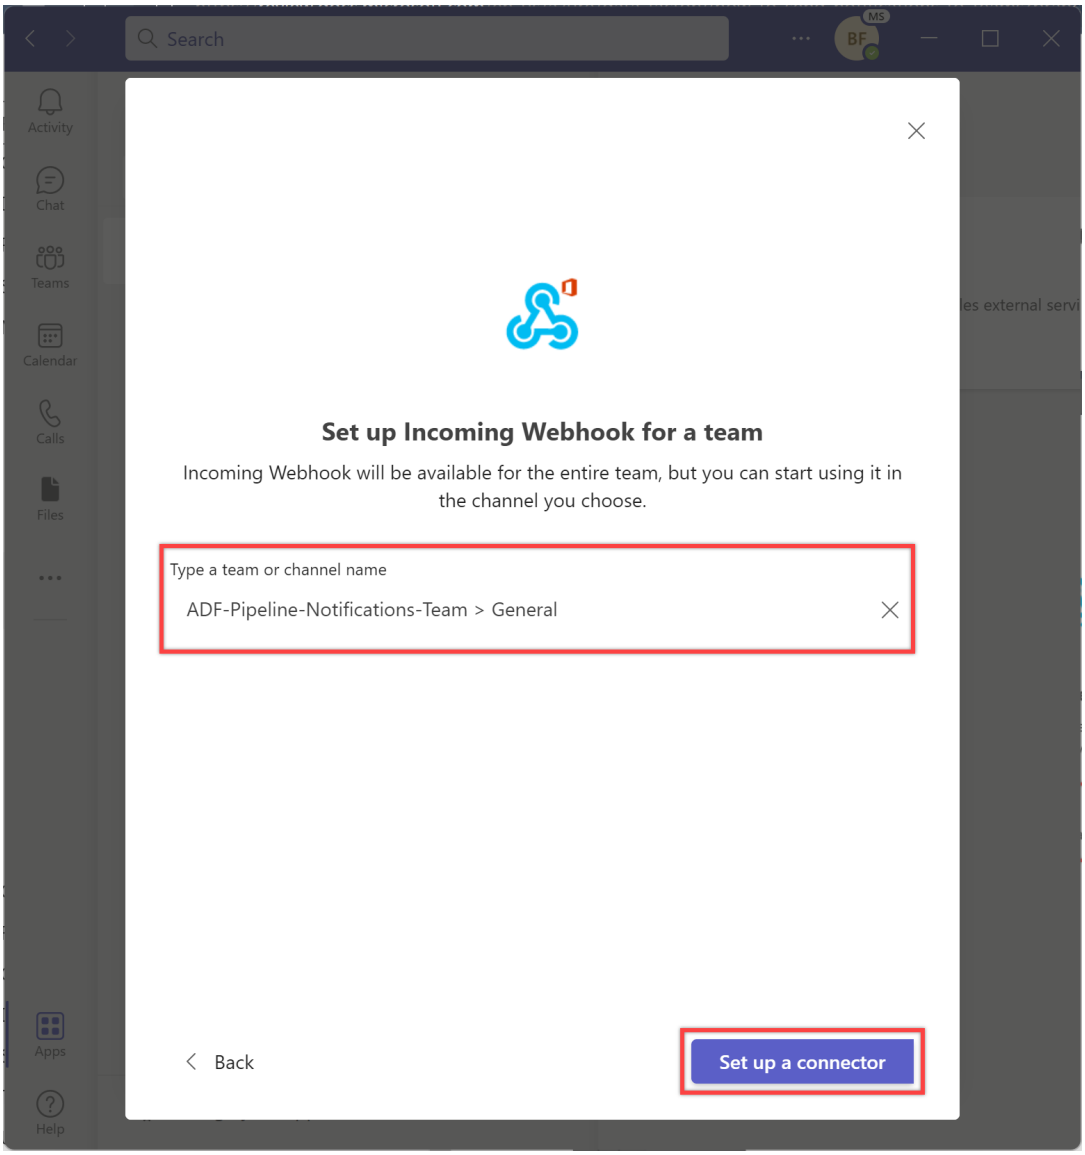
2. Select the "Add to a team" button to add the connector to the Team or Team channel name site where you want to send notifications.



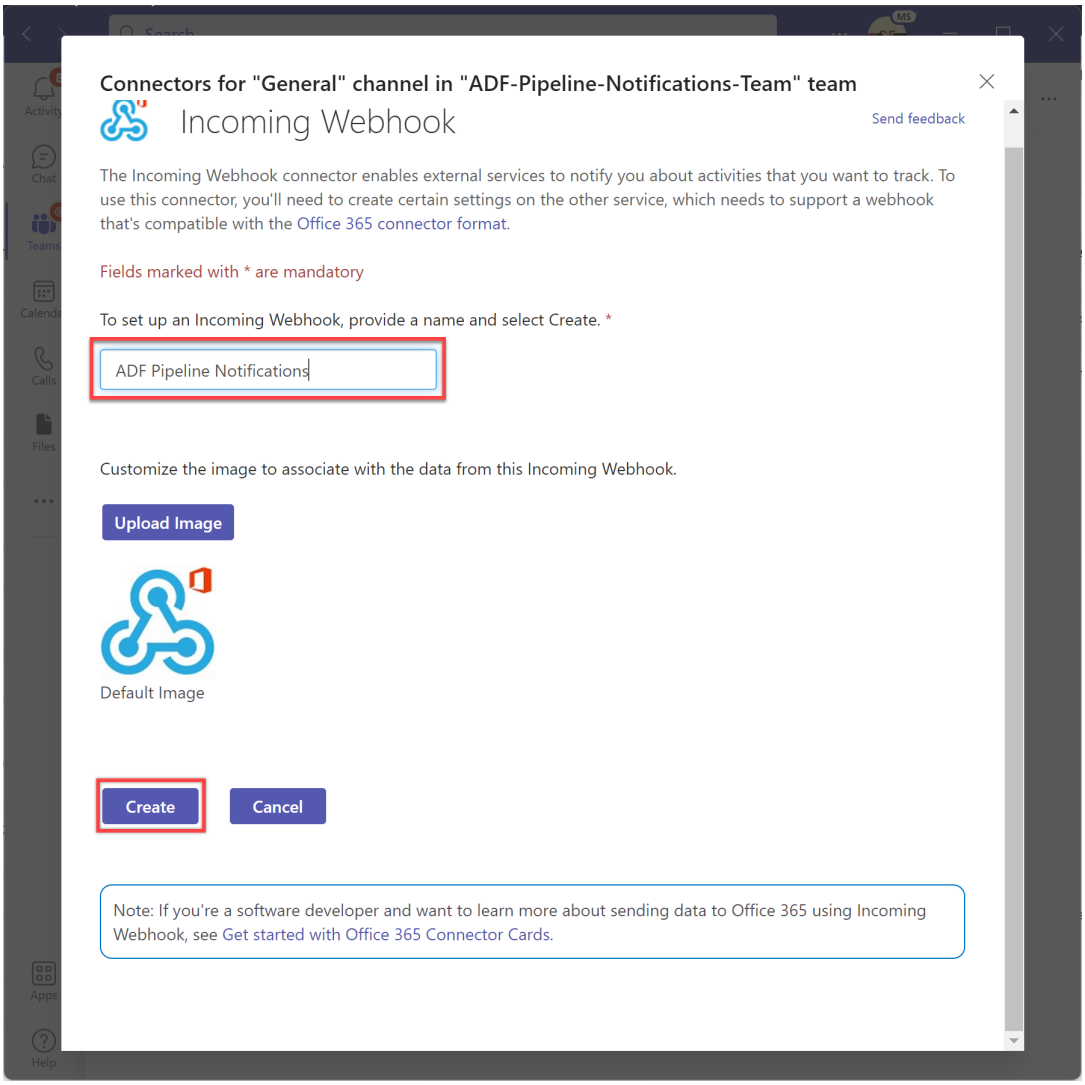
3. Type or select Team or Team channel name where you want to send the notifications.



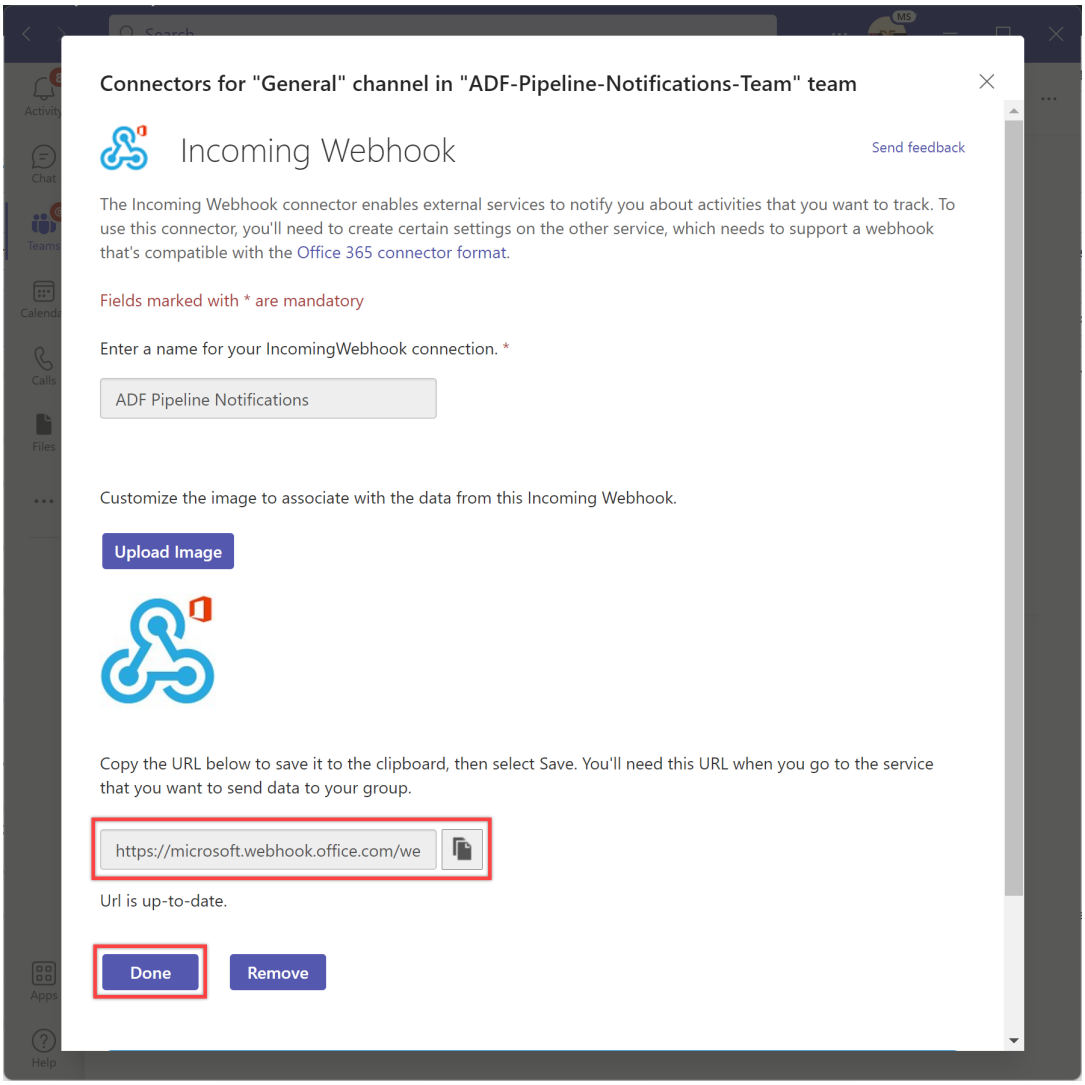
4. Select the "Set up a connector" button to set up the Incoming Webhook for the Team or Team channel name you selected in the previous step.



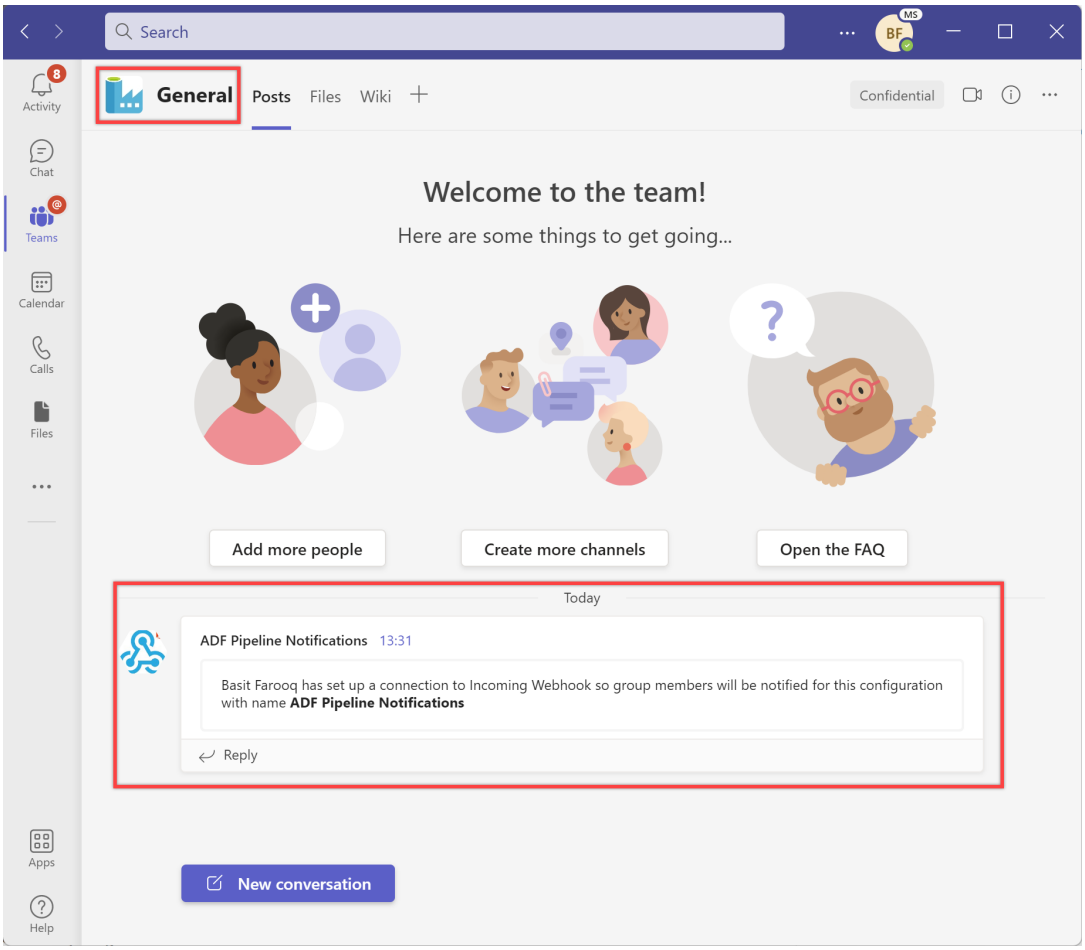
5. Name the Webhook as appropriate and optionally upload an icon to identify your messages. After that, select the "Create" button to create the Incoming Webhook.



6. Copy the Webhook URL that is generated on creation and save it for later use in pipeline. After that, select the "Done" button to complete the setup.



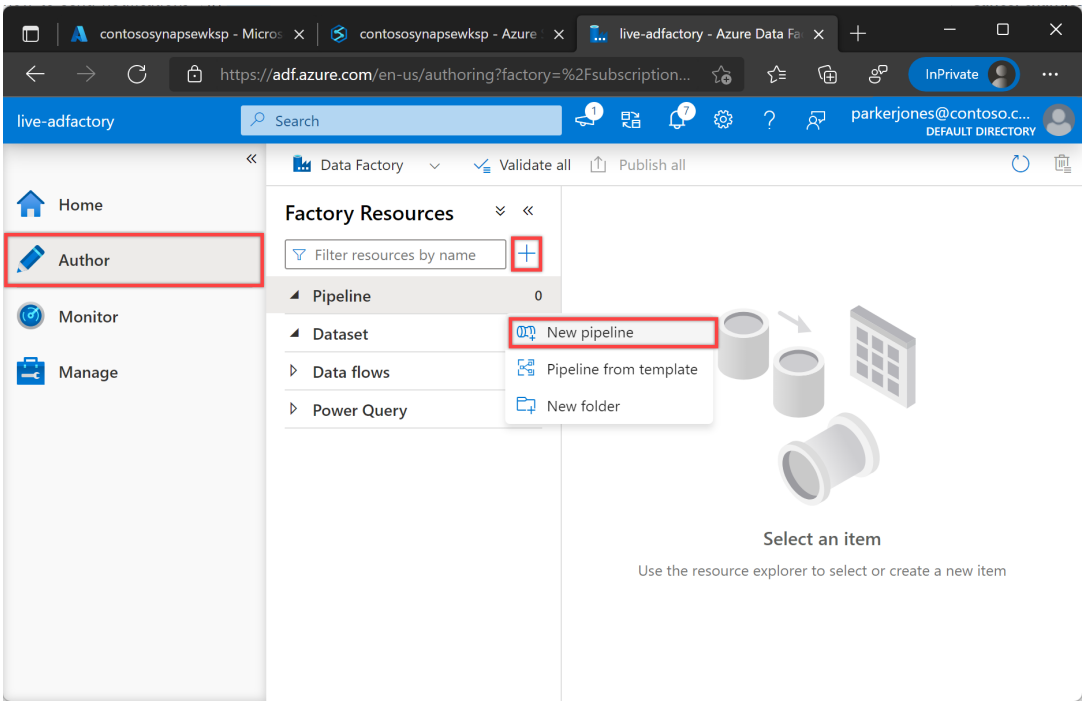
7. You can see the notification in the channel where you add the webhook connector.



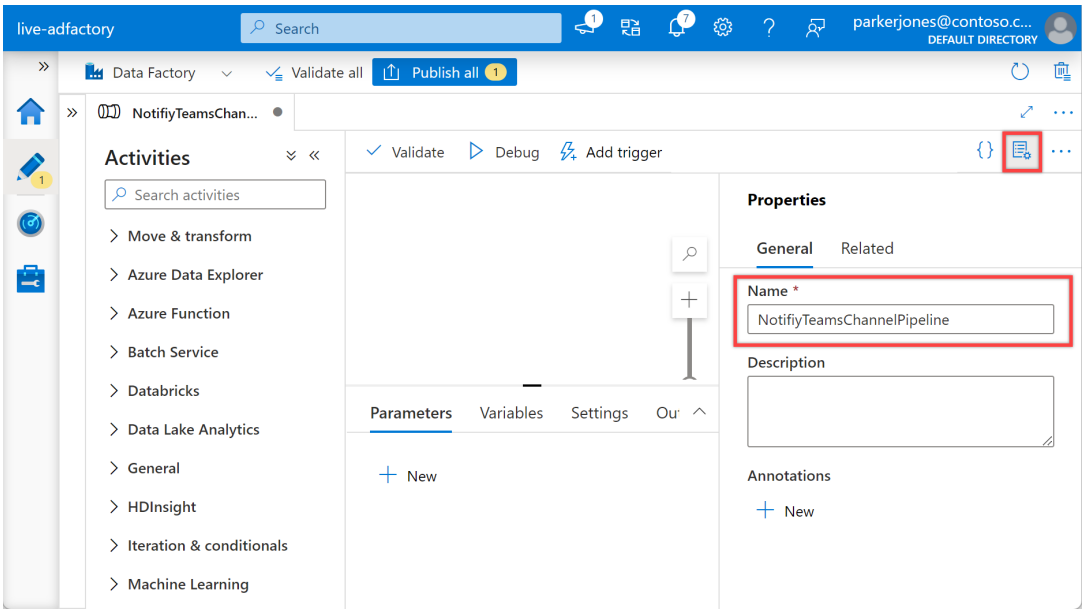
Steps to send notifications on Teams channel from a pipeline:

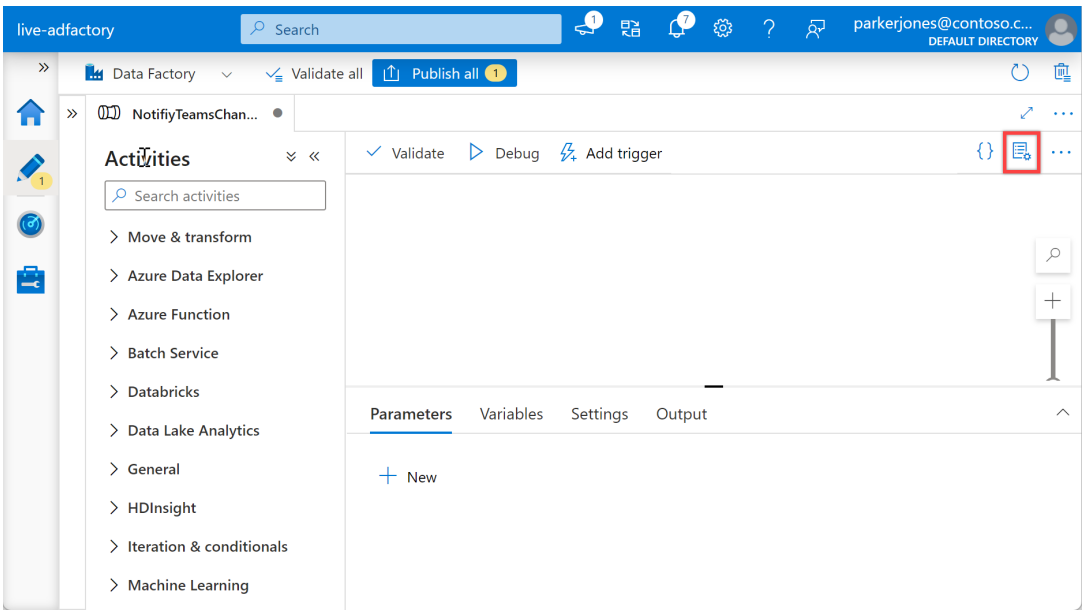
- Azure Data Factory
- Synapse Analytics

1. Select **Author** tab from the left pane.
2. Select the + (plus) button, and then select **New pipeline**.



3. In the "Properties" pane under "General", specify **NotifiyTeamsChannelPipeline** for **Name**. Then collapse the panel by clicking the **Properties** icon in the top-right corner.

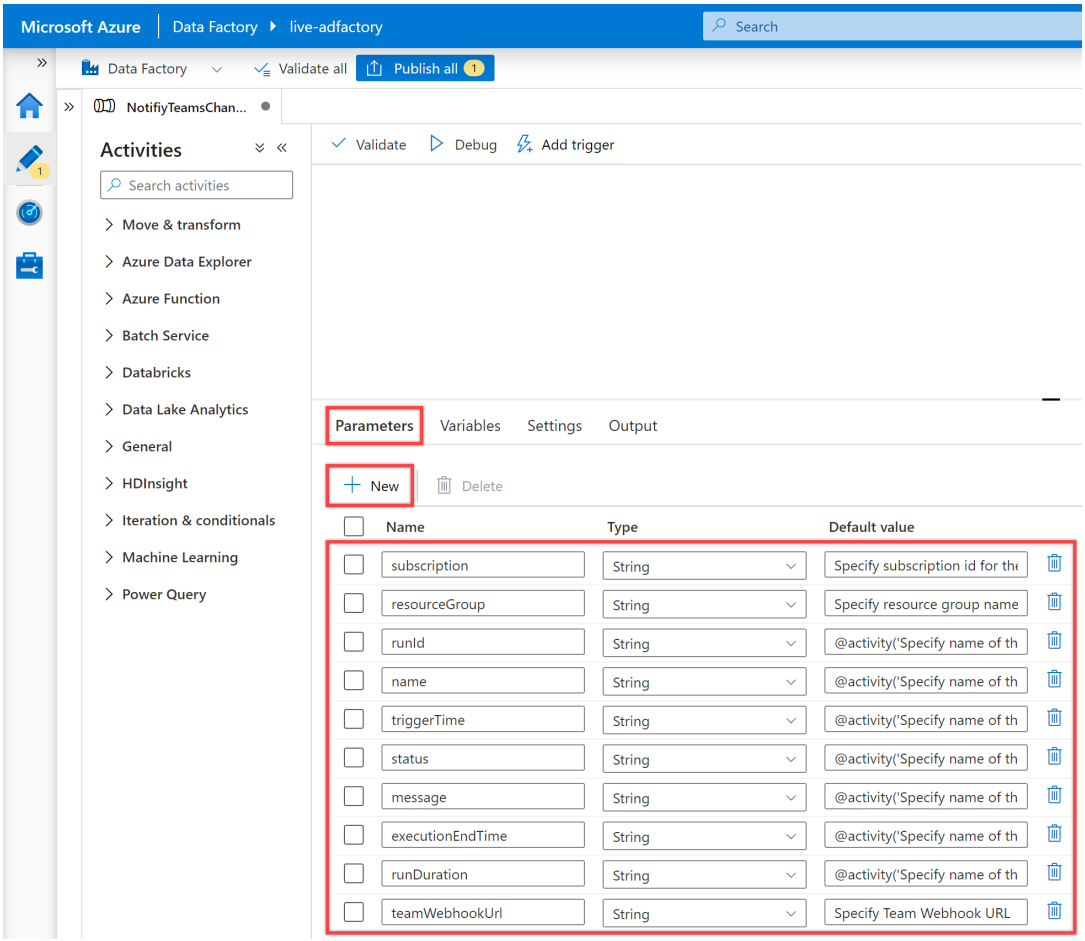




4. In the "Configurations" pane, select **Parameters**, and then select the **+ New** button define following parameters for your pipeline.

NAME	TYPE	DEFAULT VALUE
subscription	`String`	`Specify subscription id for the pipeline`
resourceGroup	`String`	`Specify resource group name for the pipeline`
runId	`String`	`@activity('Specify name of the calling pipeline').output['pipelineRunId']`
name	`String`	`@activity('Specify name of the calling pipeline').output['pipelineName']`
triggerTime	`String`	`@activity('Specify name of the calling pipeline').ExecutionStartTime`
status	`String`	`@activity('Specify name of the calling pipeline').Status`

NAME	TYPE	DEFAULT VALUE
message	`String`	`@activity('Specify name of the calling pipeline').Error['message']`
executionEndTime	`String`	`@activity('Specify name of the calling pipeline').ExecutionEndTime`
runDuration	`String`	`@activity('Specify name of the calling pipeline').Duration`
teamWebhookUrl	`String`	`Specify Team Webhook URL`



NOTE

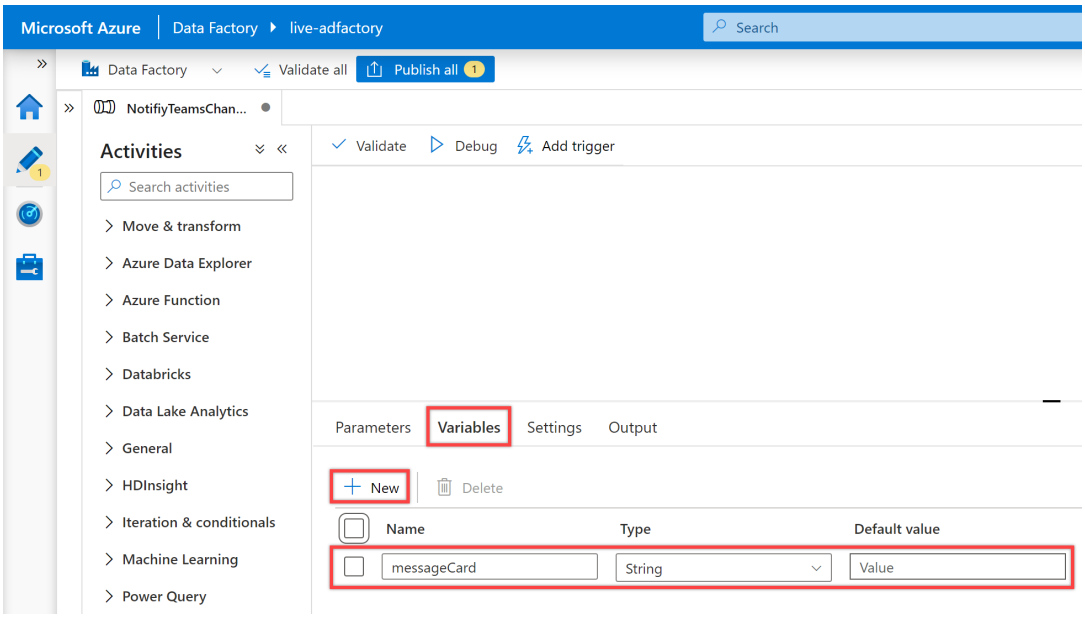
These parameters are used to construct the monitoring URL. Suppose you do not provide a valid subscription and resource group (of the same data factory where the pipelines belong). In that case, the notification will not contain a valid pipeline monitoring URL, but the messages will still work. Additionally, adding these parameters helps prevent the need to always pass those values from another pipeline. If you intend to control those values through a metadata-driven approach, then you should modify them accordingly.

TIP

We recommend adding the current Data Factory **Subscription ID**, **Resource Group**, and the **Teams webhook URL** (refer to prerequisites) for the default value of the relevant parameters.

5. In the "Configurations" pane, select **Variables**, and then select the **+ New** button define following variables for your pipeline.

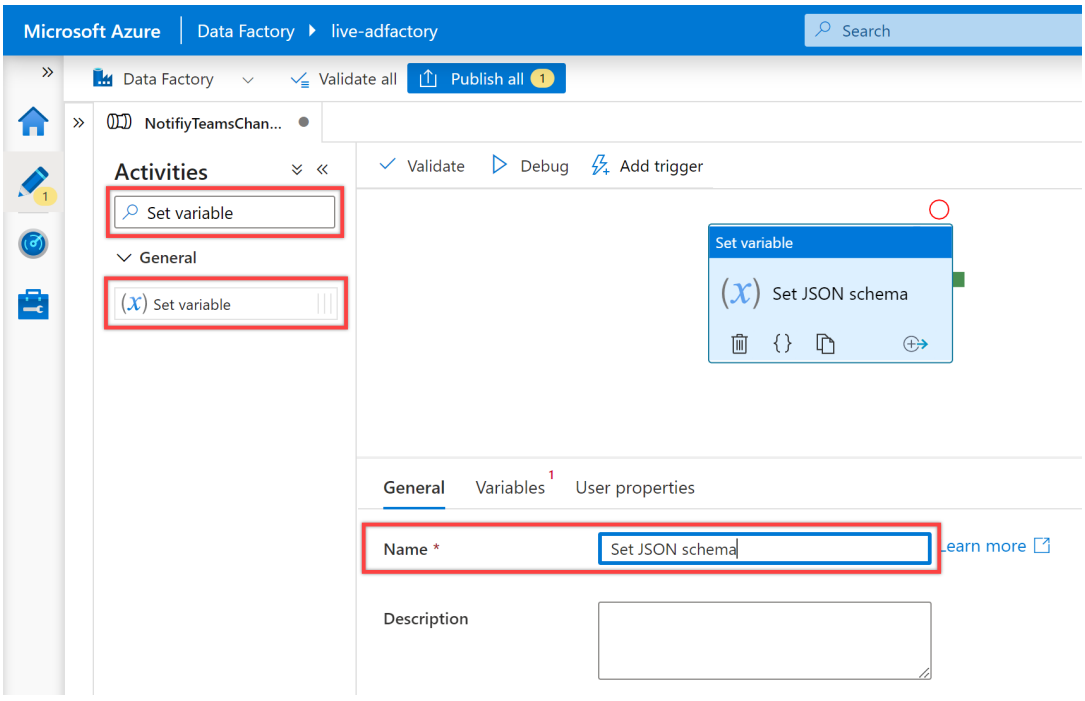
NAME	TYPE	DEFAULT VALUE
messageCard	`String`	



6. Search for "Set variable" in the pipeline "Activities" pane, and drag a **Set Variable** activity to the pipeline canvas.

7. Select the **Set Variable** activity on the canvas if it isn't already selected, and its "General" tab, to edit its details.

8. In the "General" tab, specify **Set JSON schema** for **Name** of the **Set Variable** activity.



9. In the "Variables" tab, select **messageCard** variable for the **Name** property and enter the following **JSON** for its **Value** property:

```
{
    "@type": "MessageCard",
    "@context": "http://schema.org/extensions",
    "themeColor": "0076D7",

                }
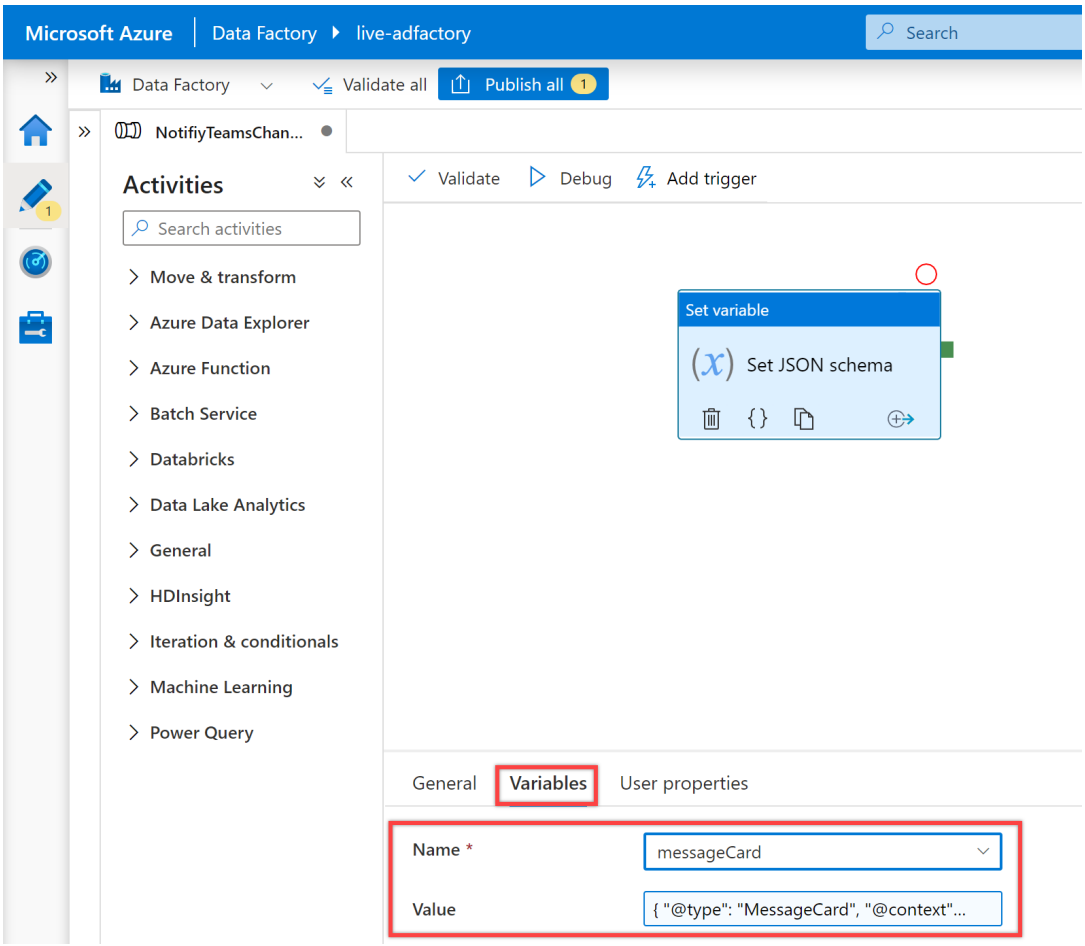
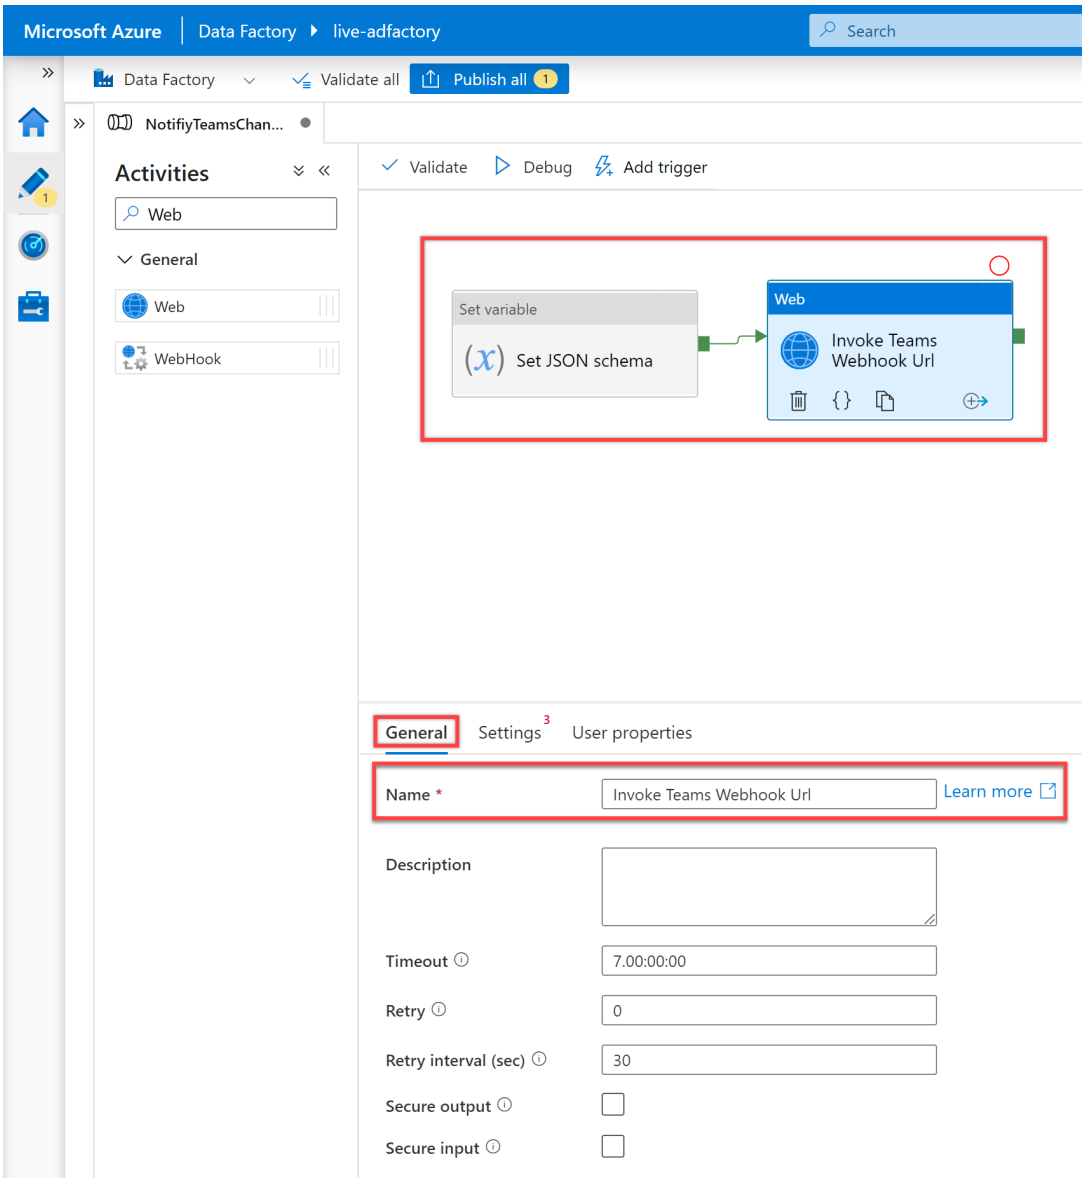
            ]
        }
    ]
}
```

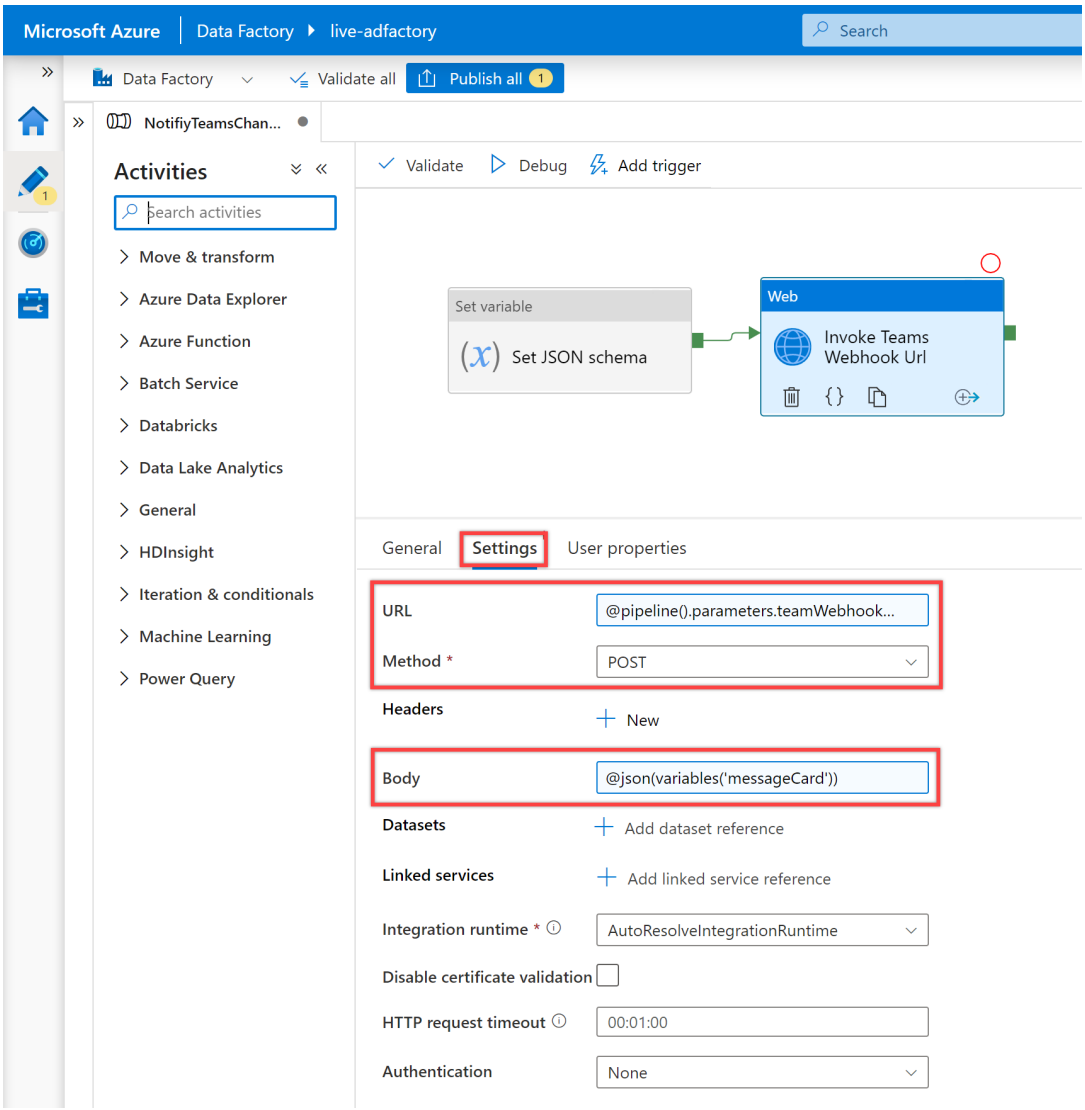


10. Search for "Web" in the pipeline "Activities" pane, and drag a **Web** activity to the pipeline canvas.
11. Create a dependency condition for the **Web** activity so that it only runs if the **Set Variable** activity succeeds. To create this dependency, select the green handle on the right side of the **Set Variable** activity, drag it, and connect it to the **Web** activity.
12. Select the new **Web** activity on the canvas if it isn't already selected, and its "General" tab, to edit its details.
13. In the "General" pane, specify **Invoke Teams Webhook Url** for **Name** of the **Web** activity.



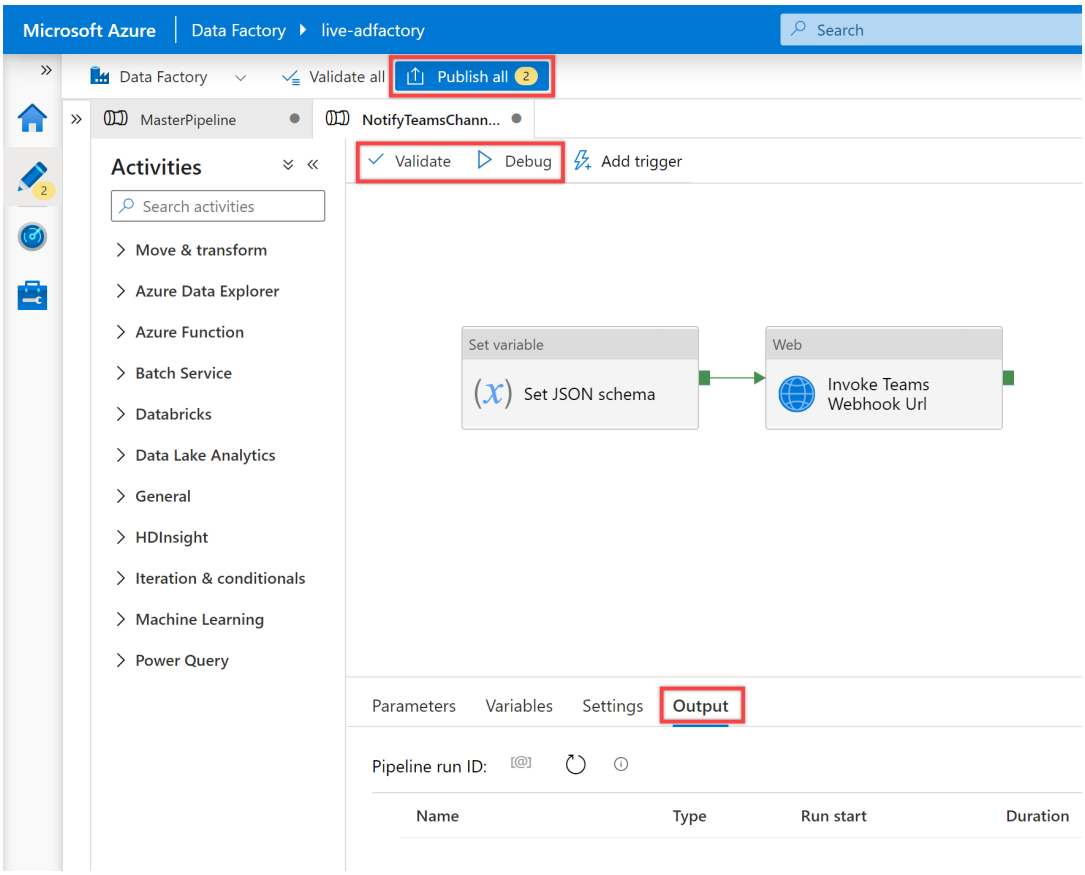
14. In the "Settings" pane, set following properties as follows:

PROPERTY	VALUE
URL	`@pipeline().parameters.teamWebhookUrl`
Method	`POST`
Body	`@json(variables('messageCard'))`



15. All set and now you're ready to validate, debug, and then publish your **NotifiyTeamsChannelPipeline** pipeline.

    - To validate the pipeline, select **Validate** from the tool bar.
    - To debug the pipeline, select **Debug** on the toolbar. You can see the status of the pipeline run in the "Output" tab at the bottom of the window.
    - Once the pipeline can run successfully, in the top toolbar, select **Publish all**. This action publishes entities you created to Data Factory. Wait until you see the **Successfully** published message.



Sample usage

In this sample usage scenario, we'll create a master pipeline with three **Execute Pipeline** activities. The first **Execute Pipeline** activity will invoke our ETL pipeline and the remaining two **Execute Pipeline** activities will invoke the "NotifiyTeamsChannelPipeline" pipeline to send relevant success or failure notifications to the Teams channel depending on the execution state of our ETL pipeline.

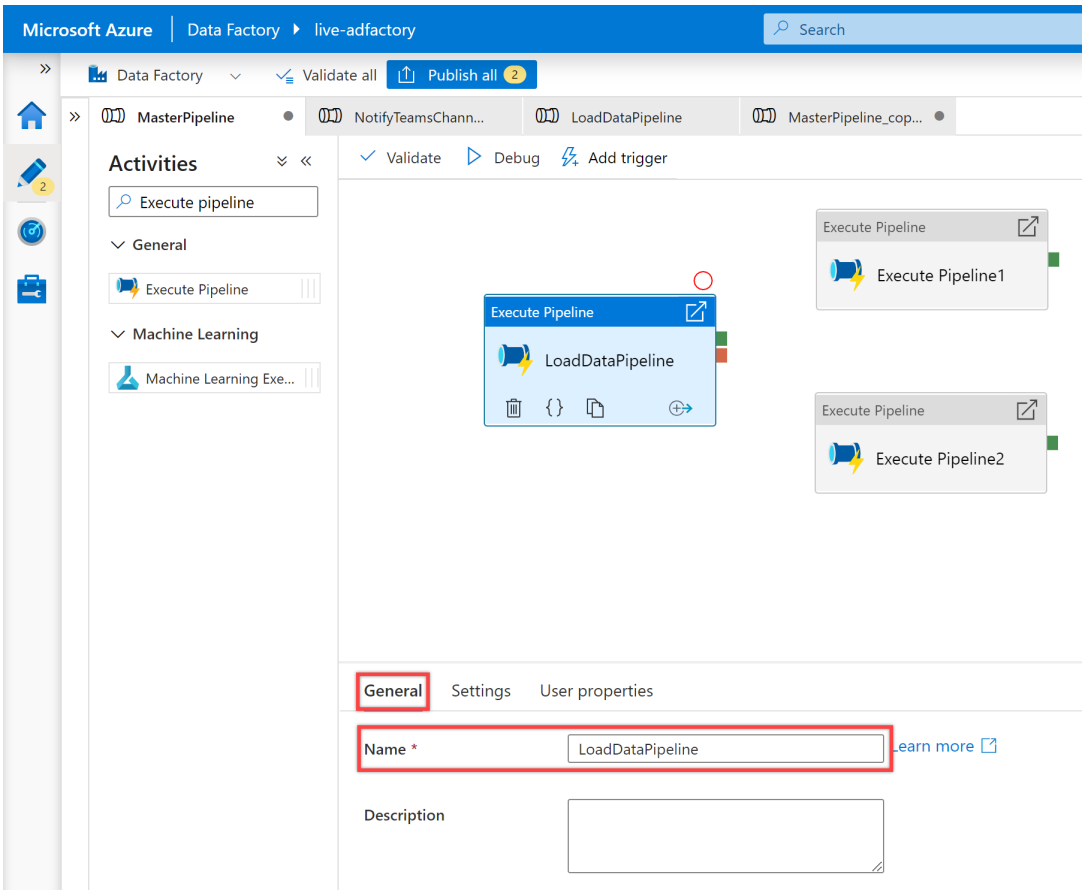
1. Select **Author** tab from the left pane in **Data Factory** or **Integrate** tab from the left pane in **Synapse Studio**. Next, select the + (plus) button, and then select **Pipeline** to create a new pipeline.

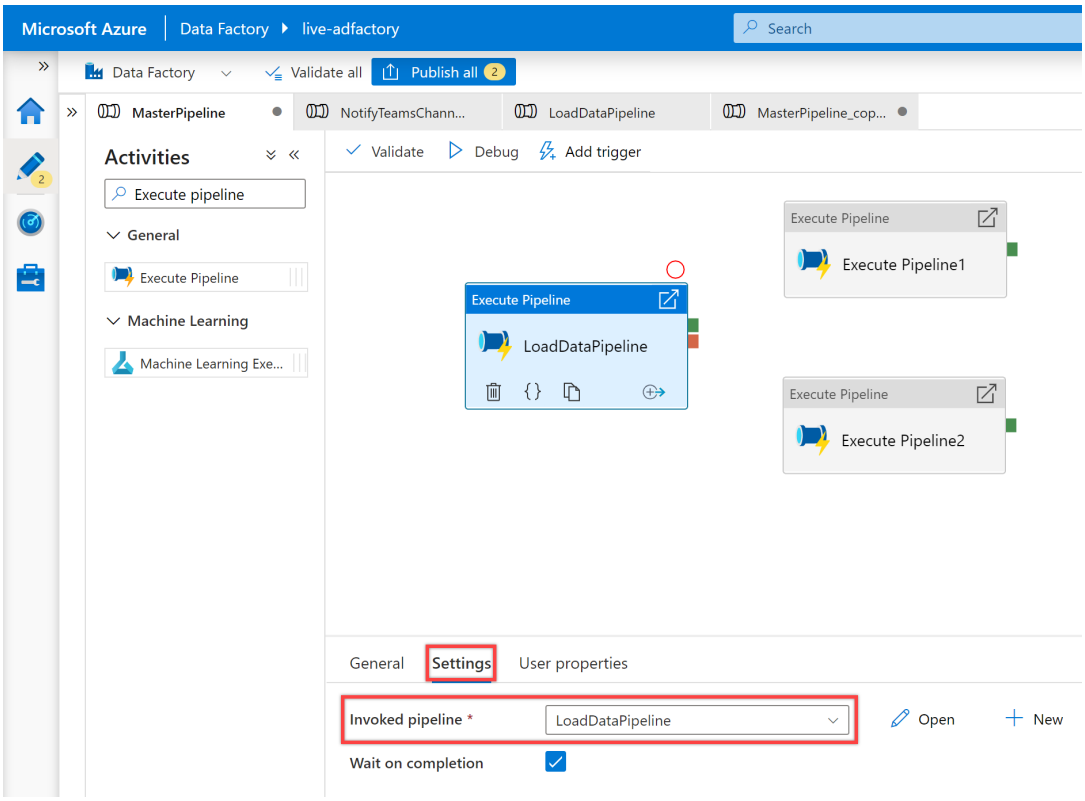
2. In the "General" panel under Properties, specify **MasterPipeline** for **Name**. Then collapse the panel by clicking the **Properties** icon in the top-right corner.

3. Search for pipeline in the pipeline "Activities" pane, and drag three **Execute Pipeline** activities to the pipeline canvas.

4. Select first **Execute Pipeline** activity on the canvas if it isn't already selected, and its "General" pane, to edit its details.

    - For **Name** property of the **Execute Pipeline** activity, we recommend using the name of your invoked ETL pipeline for which you want to send notifications. For example, we used **LoadDataPipeline** for the **Name** of our **Execute Pipeline** activity because it's the name of our invoked pipeline.
    - In the "Settings" pane, select an existing pipeline or create a new one using the **+ New** button for the **Invoked pipeline** property. For example, in our case, we selected **LoadDataPipeline** pipeline for the "Invoked pipeline" property. Select other options and configure any parameters for the pipeline as required to complete your configuration.

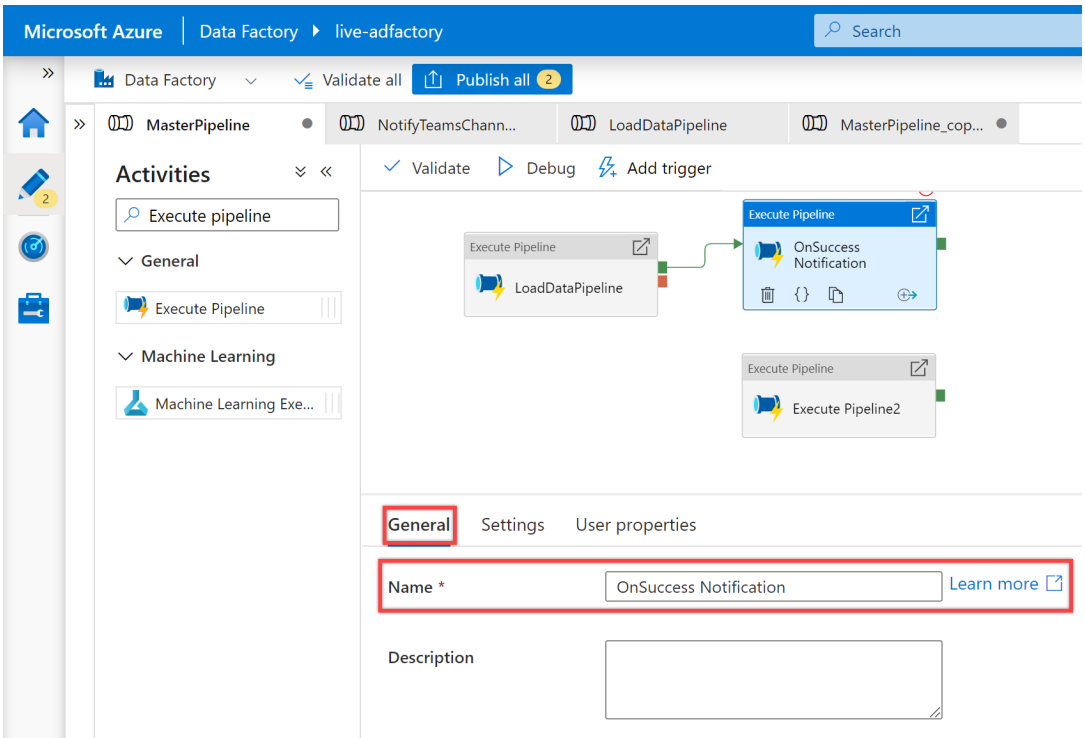


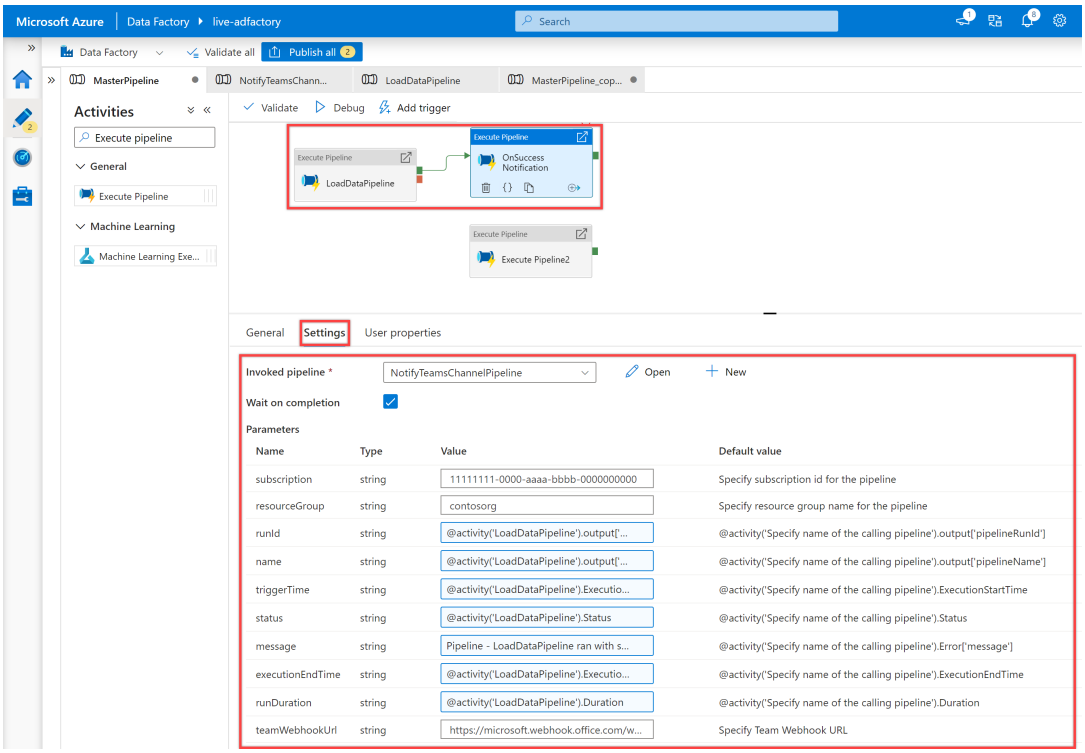


5. Select second **Execute Pipeline** activity on the canvas, and it's "General" pane, to edit its details.
   - Specify **OnSuccess Notification** for **Name** of the **Execute Pipeline** activity.
   - In the "Settings" pane, select **NotifiyTeamsChannelPipeline** pipeline, which we created earlier, for the **Invoked pipeline** property. Customize the parameters as required based on activity type. For example, I've customized the parameters as follows:

NAME	VALUE
subscription	`11111111-0000-aaaa-bbbb-0000000000`
resourceGroup	`contosorg`
runId	`@activity('LoadDataPipeline').output['pipelineRunId']`
name	`@activity('LoadDataPipeline').output['pipelineName']`
triggerTime	`@activity('LoadDataPipeline').ExecutionStartTime`
status	`@activity('LoadDataPipeline').Status`
message	`Pipeline - LoadDataPipeline ran with success.`
executionEndTime	`@activity('LoadDataPipeline').ExecutionEndTime`
runDuration	`@activity('LoadDataPipeline').Duration`
teamWebhookUrl	`https://microsoft.webhook.office.com/webhookb2/1234abcd-1x11-2ff1-a1234d0699a9e@72f988bf-32b1-41af-91ab-2d7cd011db47/IncomingWebhook/8212f66ad80040ab83cf68b554d9232a/17d52ed5c-44ed-98a0-35c12dd89a6d`

- Create a dependency condition for the second **Execute Pipeline** activity so that it only runs if the first **Execute Pipeline** activity succeeds. To create this dependency, select the green handle on the right side of the first **Execute Pipeline** activity, drag it, and connect it to the second **Execute Pipeline** activity.





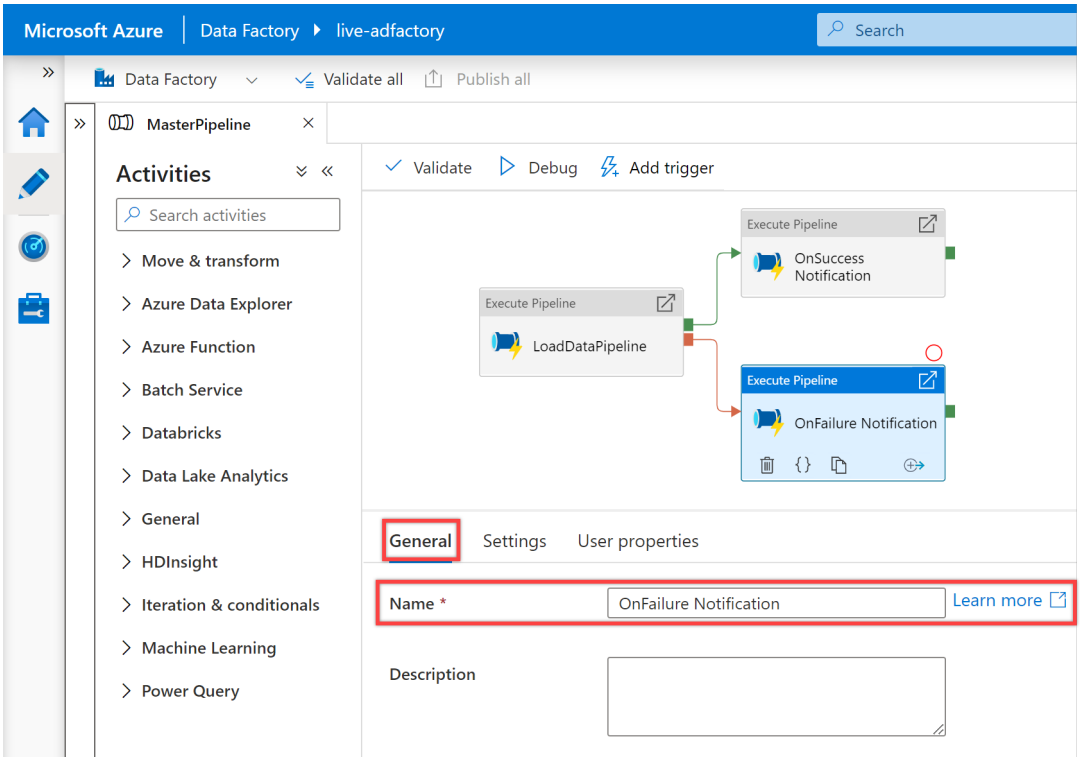
6. Select third **Execute Pipeline** activity on the canvas, and it's "General" pane, to edit its details.

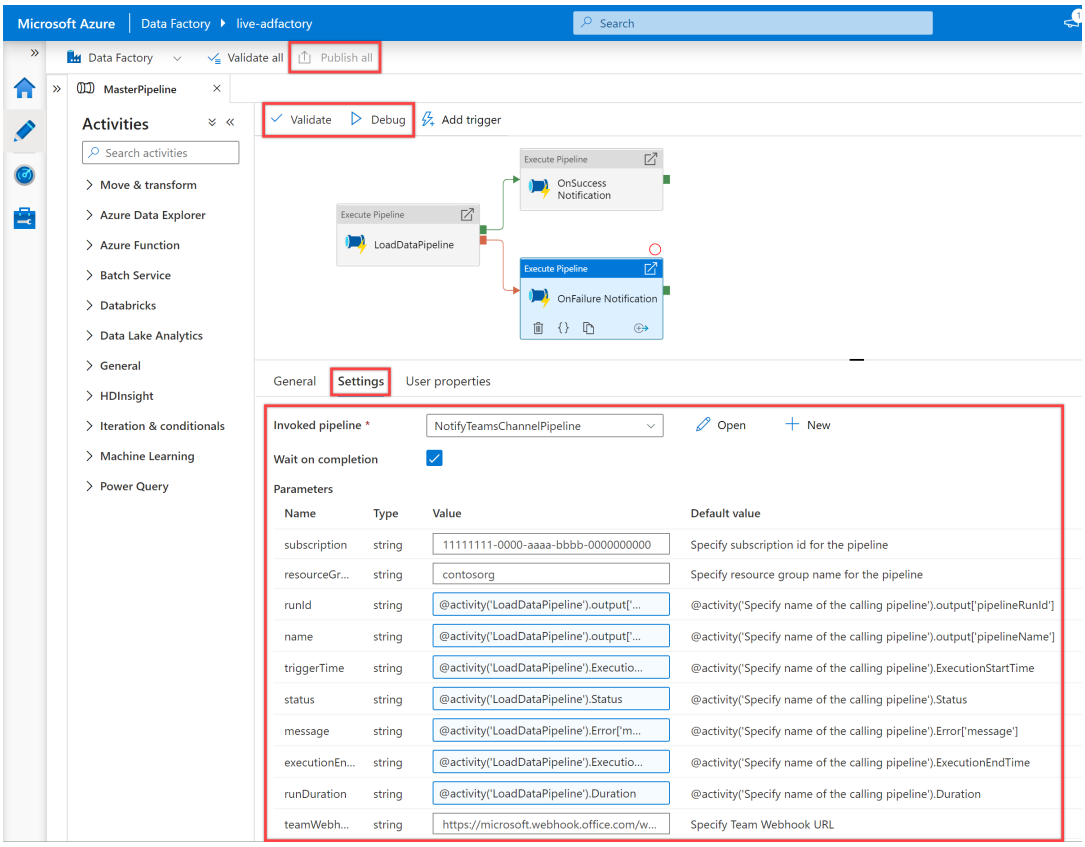
   - Specify **OnFailure Notification** for **Name** of the **Execute Pipeline** activity.
   - In the "Settings" pane, select **NotifiyTeamsChannelPipeline** pipeline for the **Invoked pipeline** property. Customize the parameters as required based on activity type. For example, I've customized the parameters this time as follows:

NAME	VALUE
subscription	`11111111-0000-aaaa-bbbb-0000000000`
resourceGroup	`contosorg`
runId	`@activity('LoadDataPipeline').output['pipelineRunId']`
name	`@activity('LoadDataPipeline').output['pipelineName']`
triggerTime	`@activity('LoadDataPipeline').ExecutionStartTime`
status	`@activity('LoadDataPipeline').Status`
message	`@activity('LoadDataPipeline').Error['message']`
executionEndTime	`@activity('LoadDataPipeline').ExecutionEndTime`
runDuration	`@activity('LoadDataPipeline').Duration`
teamWebhookUrl	`https://microsoft.webhook.office.com/webhookb2/1234abcd-1x11-2ff1-a1234d0699a9e@72f988bf-32b1-41af-91ab-2d7cd011db47/IncomingWebhook/8212f66ad80040ab83cf68b554d9232a/17d52ed5c-44ed-98a0-35c12dd89a6d`

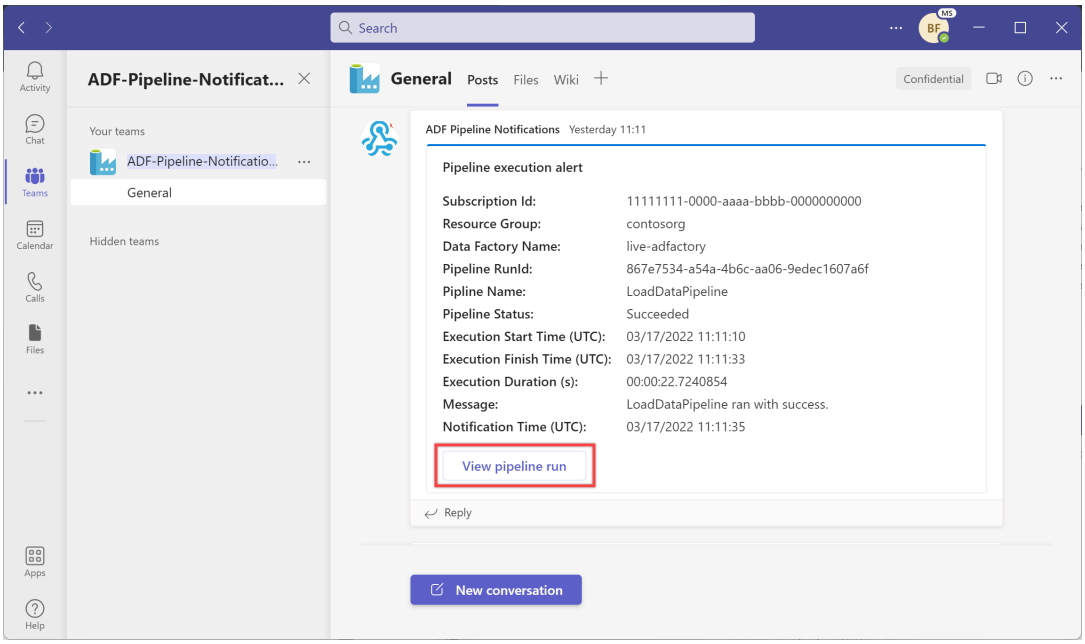
   - Create a dependency condition for the third **Execute Pipeline** activity so that it only runs if the first **Execute Pipeline** activity fails. To create this dependency, select the red handle on the right side of the first **Execute Pipeline** activity, drag it, and connect it to the third **Execute Pipeline** activity.

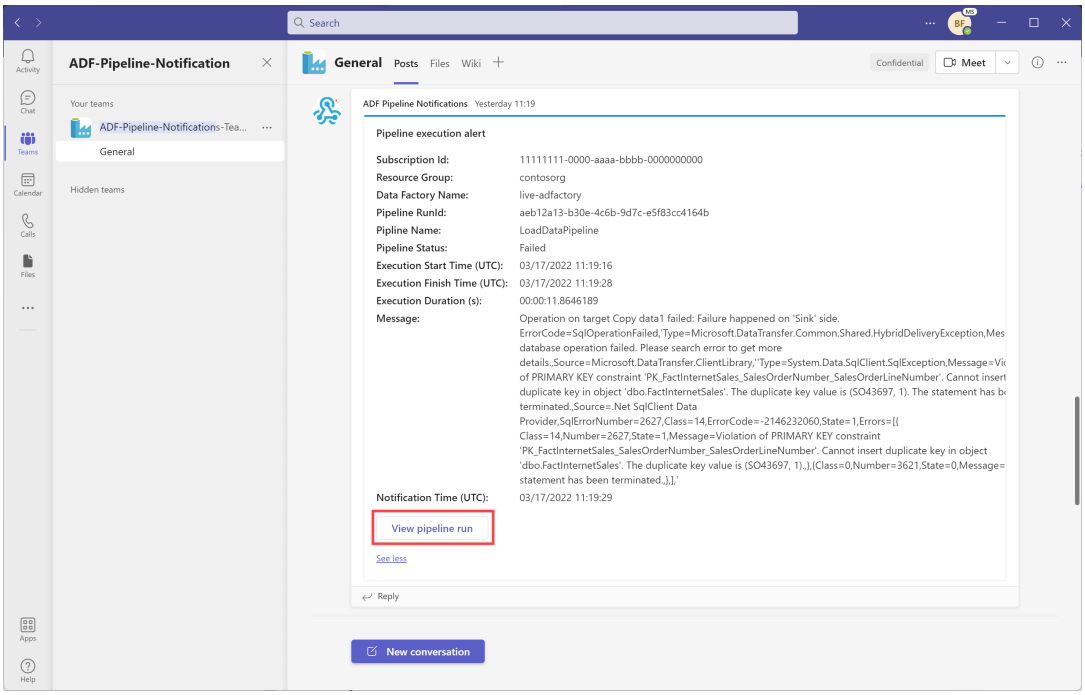
- Validate, debug, and then publish your **MasterPipeline** pipeline.





7. Run pipeline to receive notifications in Teams. For example, below are sample notifications, when my pipeline ran successfully and when it failed.





8. Select the "View pipeline run" button to view pipeline run.

Add dynamic messages with system variables and expressions

You can use system variables and expressions to make your messages dynamic. For example:

- `@activity("CopyData").output.errors[0].Message`
- `@activity("DataFlow").error.Message`

The above expressions will return the relevant error messages from a failure, which can be sent out as notification on a Teams channel. For more information about this topic, see the Copy activity output properties article.

We also encourage you to review the Microsoft Teams supported notification payload schema and further customize the above template to your needs.

How to send email from a pipeline

How to create and configure Azure Integration Runtime

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The Integration Runtime (IR) is the compute infrastructure used by Azure Data Factory and Synapse pipelines to provide data integration capabilities across different network environments. For more information about IR, see Integration runtime.

Azure IR provides a fully managed compute to natively perform data movement and dispatch data transformation activities to compute services like HDInsight. It is hosted in Azure environment and supports connecting to resources in public network environment with public accessible endpoints.

This document introduces how you can create and configure Azure Integration Runtime.

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Default Azure IR

By default, each data factory or Synapse workspace has an Azure IR in the backend that supports operations on cloud data stores and compute services in public network. The location of that Azure IR is autoresolve. If **connectVia** property is not specified in the linked service definition, the default Azure IR is used. You only need to explicitly create an Azure IR when you would like to explicitly define the location of the IR, or if you would like to virtually group the activity executions on different IRs for management purpose.

Create Azure IR

To create and set up an Azure IR, you can use the following procedures.

Create an Azure IR via Azure PowerShell

Integration Runtime can be created using the **Set-AzDataFactoryV2IntegrationRuntime** PowerShell cmdlet. To create an Azure IR, you specify the name, location, and type to the command. Here is a sample command to create an Azure IR with location set to "West Europe":

```
Set-AzDataFactoryV2IntegrationRuntime -DataFactoryName "SampleV2DataFactory1" -Name "MySampleAzureIR" -
ResourceGroupName "ADFV2SampleRG" -Type Managed -Location "West Europe"
```

For Azure IR, the type must be set to **Managed**. You do not need to specify compute details because it is fully managed elastically in cloud. Specify compute details like node size and node count when you would like to create Azure-SSIS IR. For more information, see Create and Configure Azure-SSIS IR.

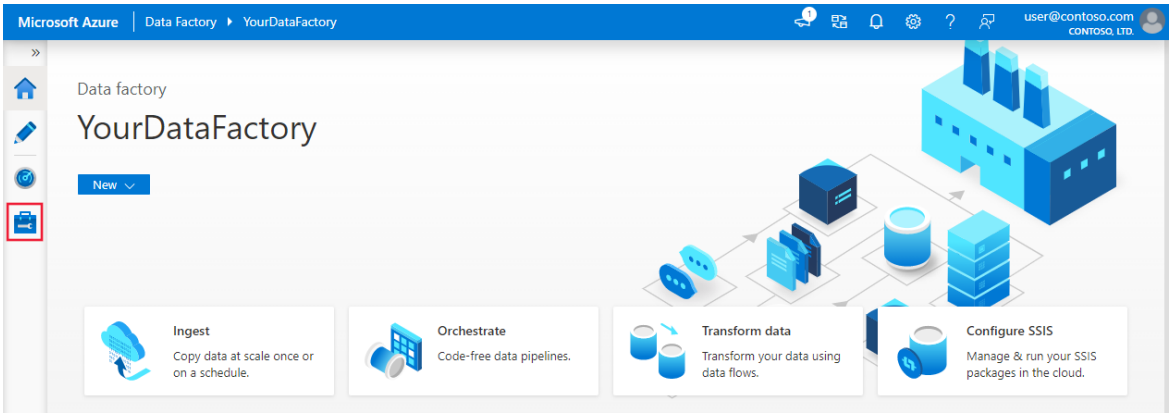
You can configure an existing Azure IR to change its location using the Set-AzDataFactoryV2IntegrationRuntime PowerShell cmdlet. For more information about the location of an Azure IR, see Introduction to integration runtime.

Create an Azure IR via UI

Use the following steps to create an Azure IR using UI.

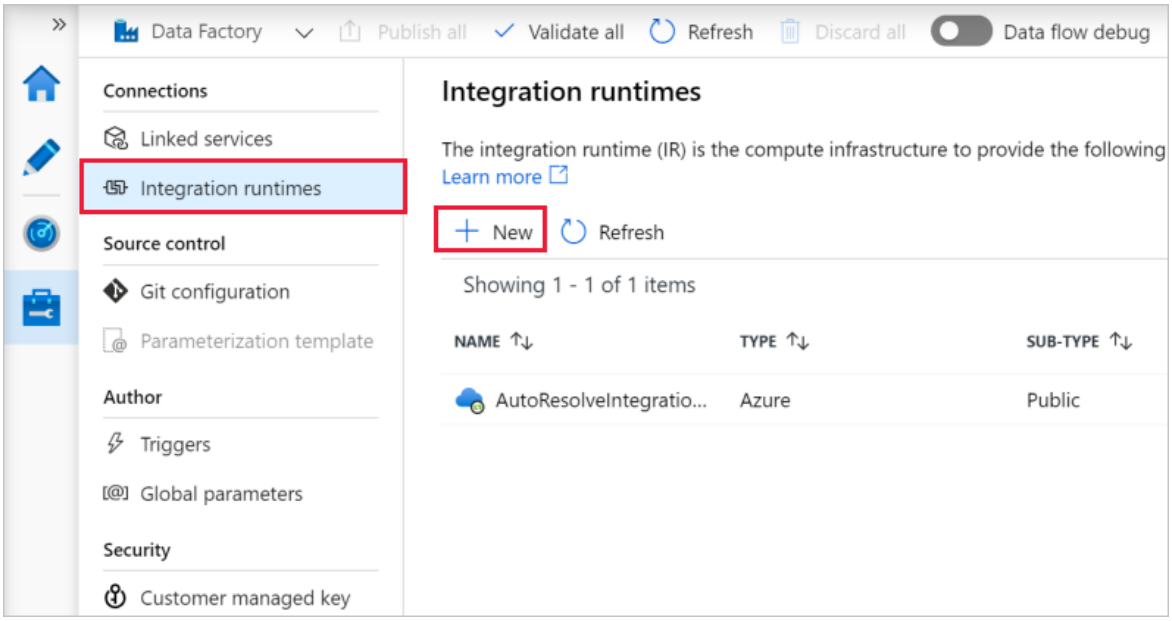
1. On the home page for the service, select the Manage tab from the leftmost pane.

   - Azure Data Factory
   - Azure Synapse



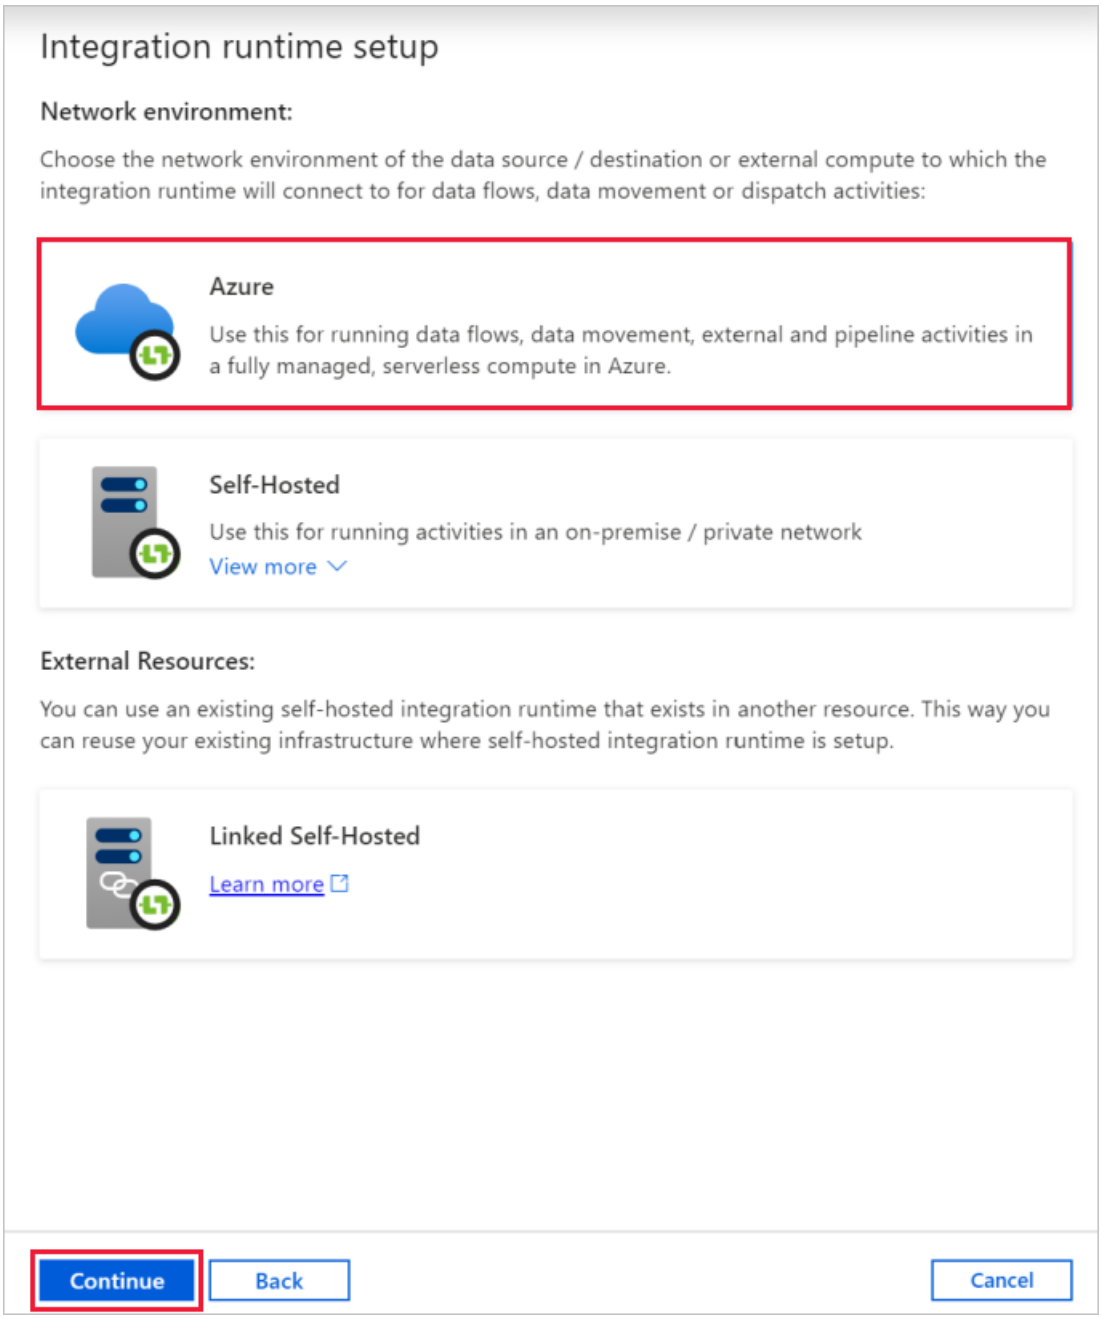
2. Select **Integration runtimes** on the left pane, and then select **+New**.

   - Azure Data Factory
   - Azure Synapse

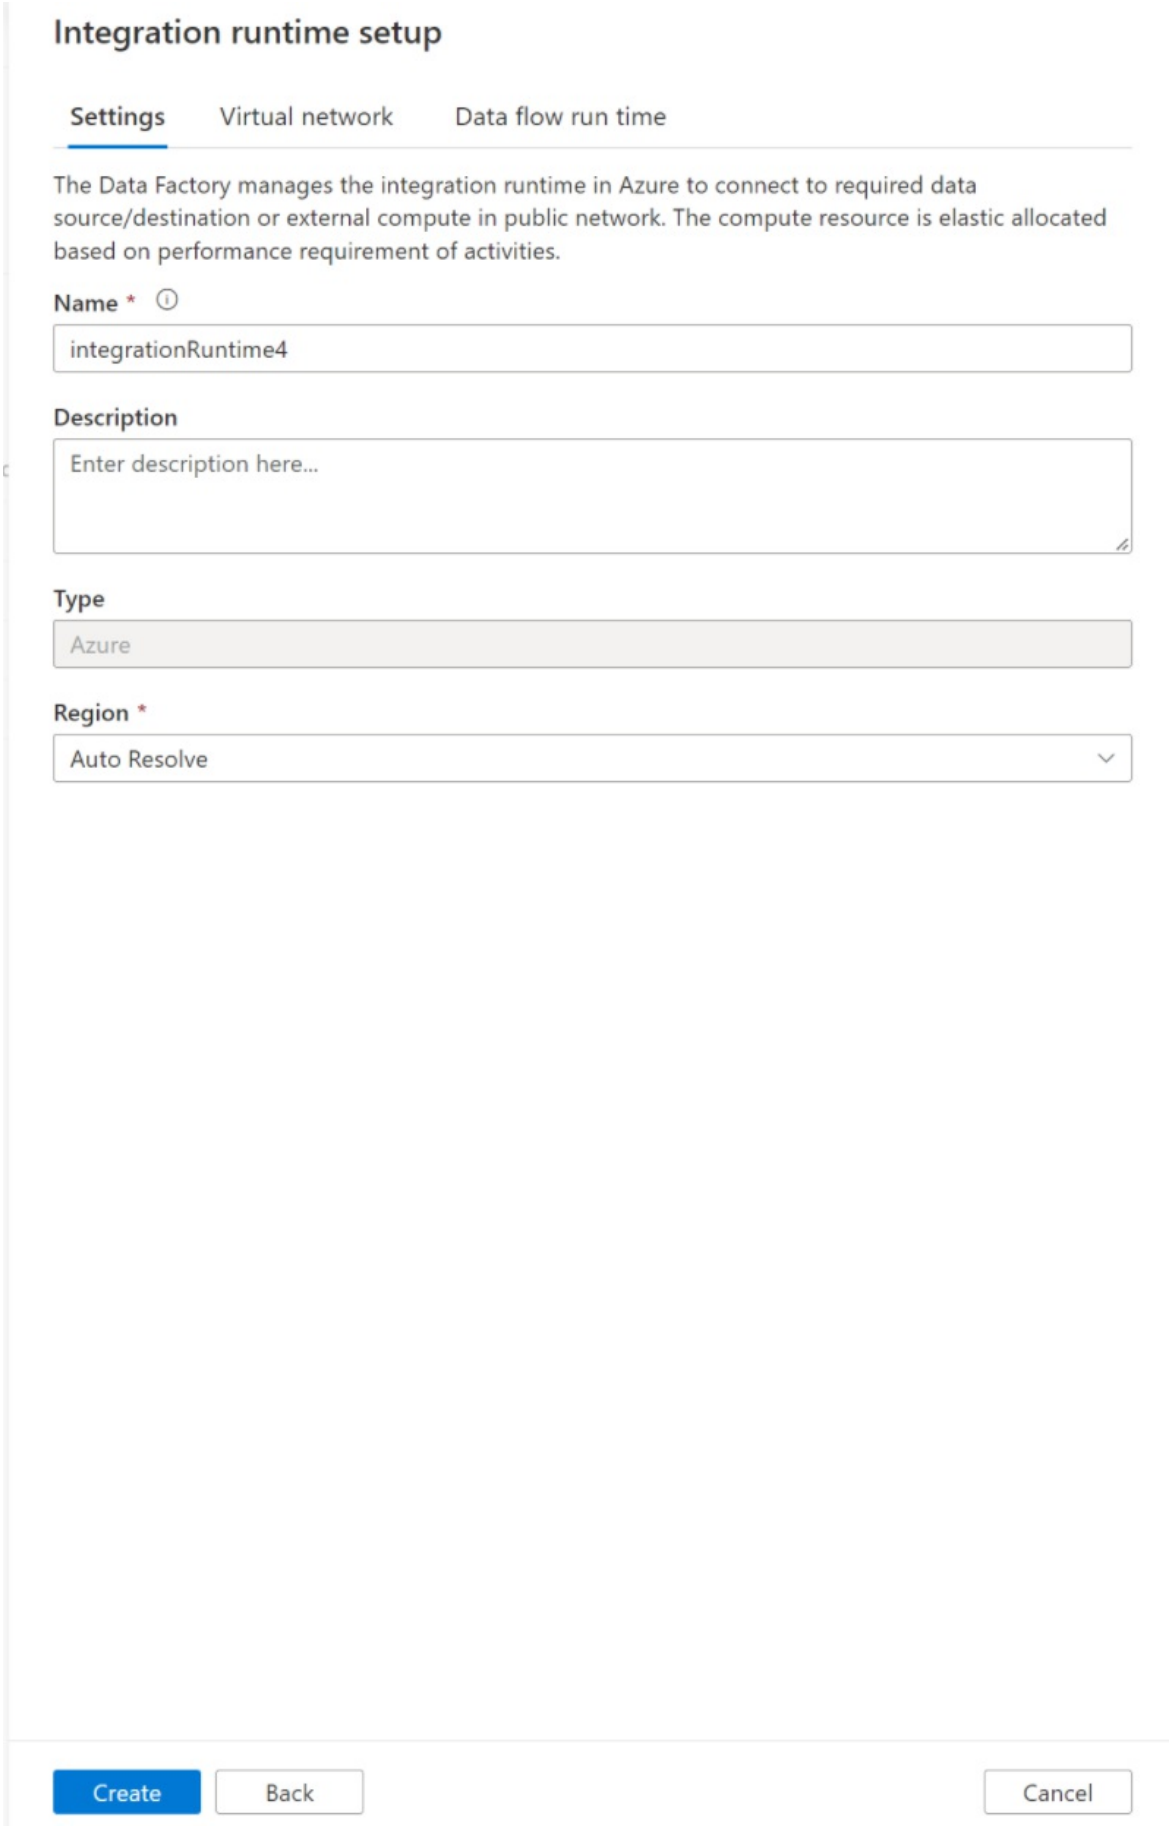


3. On the **Integration runtime setup** page, select **Azure, Self-Hosted**, and then select **Continue**.

4. On the following page, select **Azure** to create an Azure IR, and then select **Continue**.



5. Enter a name for your Azure IR, and select **Create**.



6. You'll see a pop-up notification when the creation completes. On the **Integration runtimes** page, make sure that you see the newly created IR in the list.

> **NOTE**
>
> If you want to enable managed virtual network on Azure IR, please see How to enable managed virtual network

Use Azure IR

Once an Azure IR is created, you can reference it in your Linked Service definition. Below is a sample of how you can reference the Azure Integration Runtime created above from an Azure Storage Linked Service:

```
{
    "name": "MyStorageLinkedService",
    "properties": {
      "type": "AzureStorage",
      "typeProperties": {
        "connectionString": "DefaultEndpointsProtocol=https;AccountName=myaccountname;AccountKey=..."
      },
      "connectVia": {
        "referenceName": "MySampleAzureIR",
        "type": "IntegrationRuntimeReference"
      }
    }
}
```

Next steps

See the following articles on how to create other types of integration runtimes:

- Create self-hosted integration runtime
- Create Azure-SSIS integration runtime

Create and configure a self-hosted integration runtime

8/19/2022 • 24 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

The integration runtime (IR) is the compute infrastructure that Azure Data Factory and Synapse pipelines use to provide data-integration capabilities across different network environments. For details about IR, see Integration runtime overview.

A self-hosted integration runtime can run copy activities between a cloud data store and a data store in a private network. It also can dispatch transform activities against compute resources in an on-premises network or an Azure virtual network. The installation of a self-hosted integration runtime needs an on-premises machine or a virtual machine inside a private network.

This article describes how you can create and configure a self-hosted IR.

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Considerations for using a self-hosted IR

- You can use a single self-hosted integration runtime for multiple on-premises data sources. You can also share it with another data factory within the same Azure Active Directory (Azure AD) tenant. For more information, see Sharing a self-hosted integration runtime.
- You can install only one instance of a self-hosted integration runtime on any single machine. If you have two data factories or Synapse workspaces that need to access on-premises data sources, either use the self-hosted IR sharing feature to share the self-hosted IR, or install the self-hosted IR on two on-premises computers, one for each data factory or Synapse workspace.
- The self-hosted integration runtime doesn't need to be on the same machine as the data source. However, having the self-hosted integration runtime close to the data source reduces the time for the self-hosted integration runtime to connect to the data source. We recommend that you install the self-hosted integration runtime on a machine that differs from the one that hosts the on-premises data source. When the self-hosted integration runtime and data source are on different machines, the self-hosted integration runtime doesn't compete with the data source for resources.
- You can have multiple self-hosted integration runtimes on different machines that connect to the same on-premises data source. For example, if you have two self-hosted integration runtimes that serve two data factories, the same on-premises data source can be registered with both data factories.
- Use a self-hosted integration runtime to support data integration within an Azure virtual network.
- Treat your data source as an on-premises data source that is behind a firewall, even when you use Azure ExpressRoute. Use the self-hosted integration runtime to connect the service to the data source.
- Use the self-hosted integration runtime even if the data store is in the cloud on an Azure Infrastructure as a Service (IaaS) virtual machine.
- Tasks might fail in a self-hosted integration runtime that you installed on a Windows server for which FIPS-compliant encryption is enabled. To work around this problem, you have two options: store credentials/secret

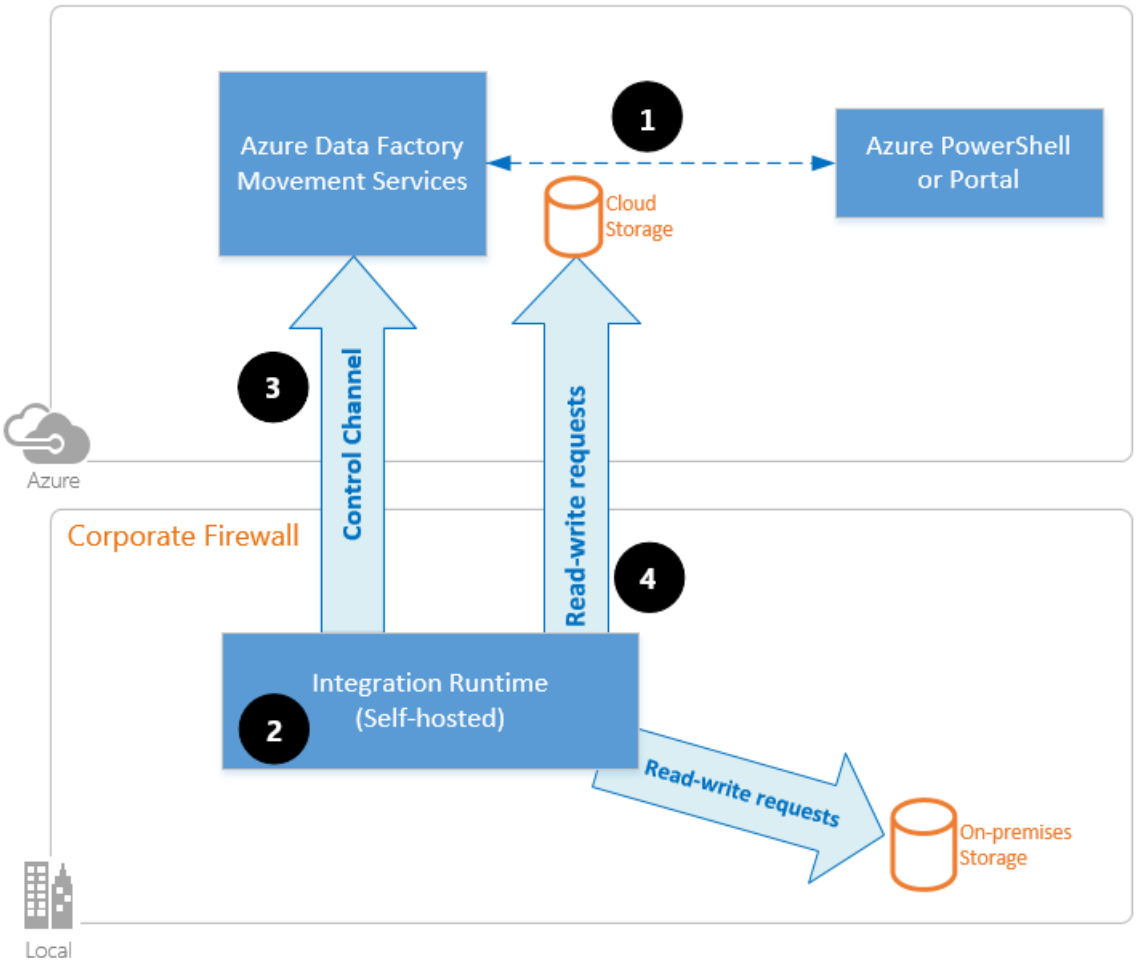
values in an Azure Key Vault or disable FIPS-compliant encryption on the server. To disable FIPS-compliant encryption, change the following registry subkey's value from 1 (enabled) to 0 (disabled): `HKLM\System\CurrentControlSet\Control\Lsa\FIPSAlgorithmPolicy\Enabled`. If you use the self-hosted integration runtime as a proxy for SSIS integration runtime, FIPS-compliant encryption can be enabled and will be used when moving data from on premises to Azure Blob Storage as a staging area.

> **NOTE**
> Currently self-hosted integration runtime can only be shared with multiple data factories, it can't be shared across Synapse workspaces or between data factory and Synapse workspace.

Command flow and data flow

When you move data between on-premises and the cloud, the activity uses a self-hosted integration runtime to transfer the data between an on-premises data source and the cloud.

Here is a high-level summary of the data-flow steps for copying with a self-hosted IR:



1. A data developer first creates a self-hosted integration runtime within an Azure data factory or Synapse workspace by using the Azure portal or the PowerShell cmdlet. Then the data developer creates a linked service for an on-premises data store, specifying the self-hosted integration runtime instance that the service should use to connect to data stores.

2. The self-hosted integration runtime node encrypts the credentials by using Windows Data Protection Application Programming Interface (DPAPI) and saves the credentials locally. If multiple nodes are set for high availability, the credentials are further synchronized across other nodes. Each node encrypts the credentials by using DPAPI and stores them locally. Credential synchronization is transparent to the data

developer and is handled by the self-hosted IR.

3. Azure Data Factory and Synapse pipelines communicate with the self-hosted integration runtime to schedule and manage jobs. Communication is via a control channel that uses a shared Azure Relay connection. When an activity job needs to be run, the service queues the request along with any credential information. It does so in case credentials aren't already stored on the self-hosted integration runtime. The self-hosted integration runtime starts the job after it polls the queue.

4. The self-hosted integration runtime copies data between an on-premises store and cloud storage. The direction of the copy depends on how the copy activity is configured in the data pipeline. For this step, the self-hosted integration runtime directly communicates with cloud-based storage services like Azure Blob storage over a secure HTTPS channel.

Prerequisites

- The supported versions of Windows are:
  - Windows 8.1
  - Windows 10
  - Windows 11
  - Windows Server 2012
  - Windows Server 2012 R2
  - Windows Server 2016
  - Windows Server 2019
  - Windows Server 2022

Installation of the self-hosted integration runtime on a domain controller isn't supported.

- Self-hosted integration runtime requires a 64-bit Operating System with .NET Framework 4.7.2 or above. See .NET Framework System Requirements for details.
- The recommended minimum configuration for the self-hosted integration runtime machine is a 2-GHz processor with 4 cores, 8 GB of RAM, and 80 GB of available hard drive space. For the details of system requirements, see Download.
- If the host machine hibernates, the self-hosted integration runtime doesn't respond to data requests. Configure an appropriate power plan on the computer before you install the self-hosted integration runtime. If the machine is configured to hibernate, the self-hosted integration runtime installer prompts with a message.
- You must be an administrator on the machine to successfully install and configure the self-hosted integration runtime.
- Copy-activity runs happen with a specific frequency. Processor and RAM usage on the machine follows the same pattern with peak and idle times. Resource usage also depends heavily on the amount of data that is moved. When multiple copy jobs are in progress, you see resource usage go up during peak times.
- Tasks might fail during extraction of data in Parquet, ORC, or Avro formats. For more on Parquet, see Parquet format in Azure Data Factory. File creation runs on the self-hosted integration machine. To work as expected, file creation requires the following prerequisites:
  - Visual C++ 2010 Redistributable Package (x64)
  - Java Runtime (JRE) version 8 from a JRE provider such as Adopt OpenJDK. Ensure that the JAVA_HOME environment variable is set to the JDK folder (and not just the JRE folder).

> **NOTE**
>
> It might be necessary to adjust the Java settings if memory errors occur, as described in the Parquet format documentation.

> **NOTE**
>
> If you are running in government cloud, please review Connect to government cloud.

Setting up a self-hosted integration runtime

To create and set up a self-hosted integration runtime, use the following procedures.

Create a self-hosted IR via Azure PowerShell

1. You can use Azure PowerShell for this task. Here is an example:

```
Set-AzDataFactoryV2IntegrationRuntime -ResourceGroupName $resourceGroupName -DataFactoryName
$dataFactoryName -Name $selfHostedIntegrationRuntimeName -Type SelfHosted -Description "selfhosted IR
description"
```

2. Download and install the self-hosted integration runtime on a local machine.

3. Retrieve the authentication key and register the self-hosted integration runtime with the key. Here is a PowerShell example:

```
Get-AzDataFactoryV2IntegrationRuntimeKey -ResourceGroupName $resourceGroupName -DataFactoryName
$dataFactoryName -Name $selfHostedIntegrationRuntimeName
```

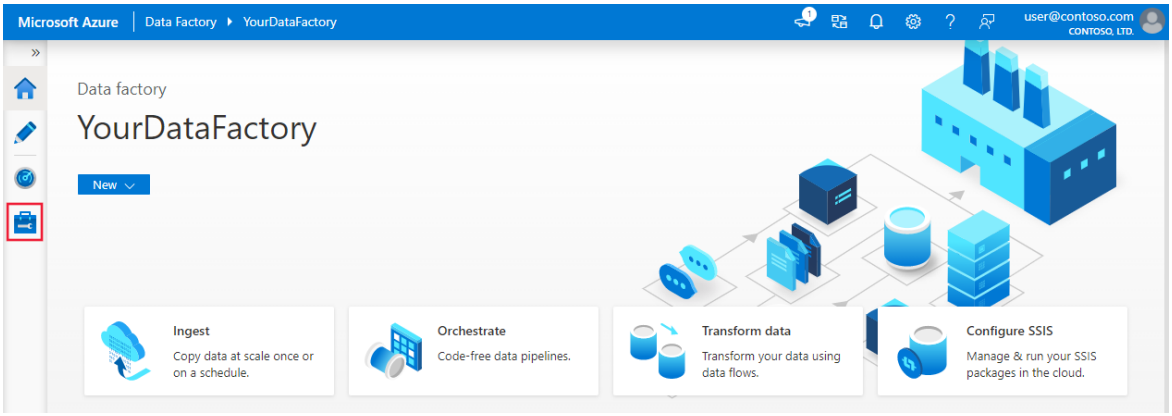
> **NOTE**
>
> Run PowerShell command in Azure government, please see Connect to Azure Government with PowerShell.

Create a self-hosted IR via UI

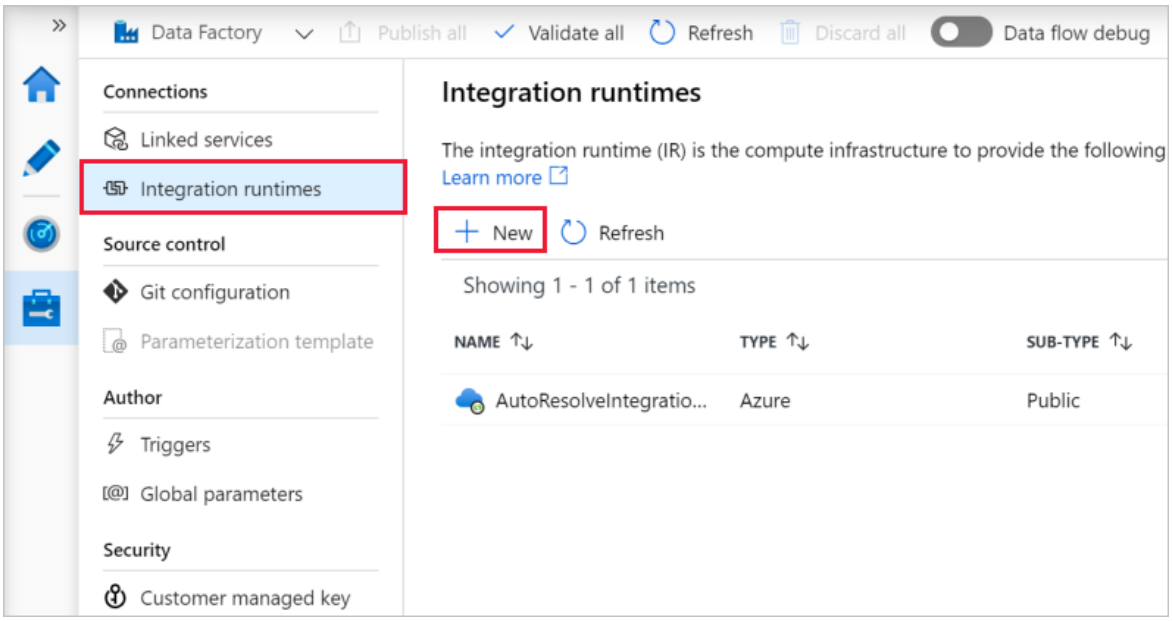
Use the following steps to create a self-hosted IR using the Azure Data Factory or Azure Synapse UI.

- Azure Data Factory
- Azure Synapse

1. On the home page of the Azure Data Factory UI, select the Manage tab from the leftmost pane.

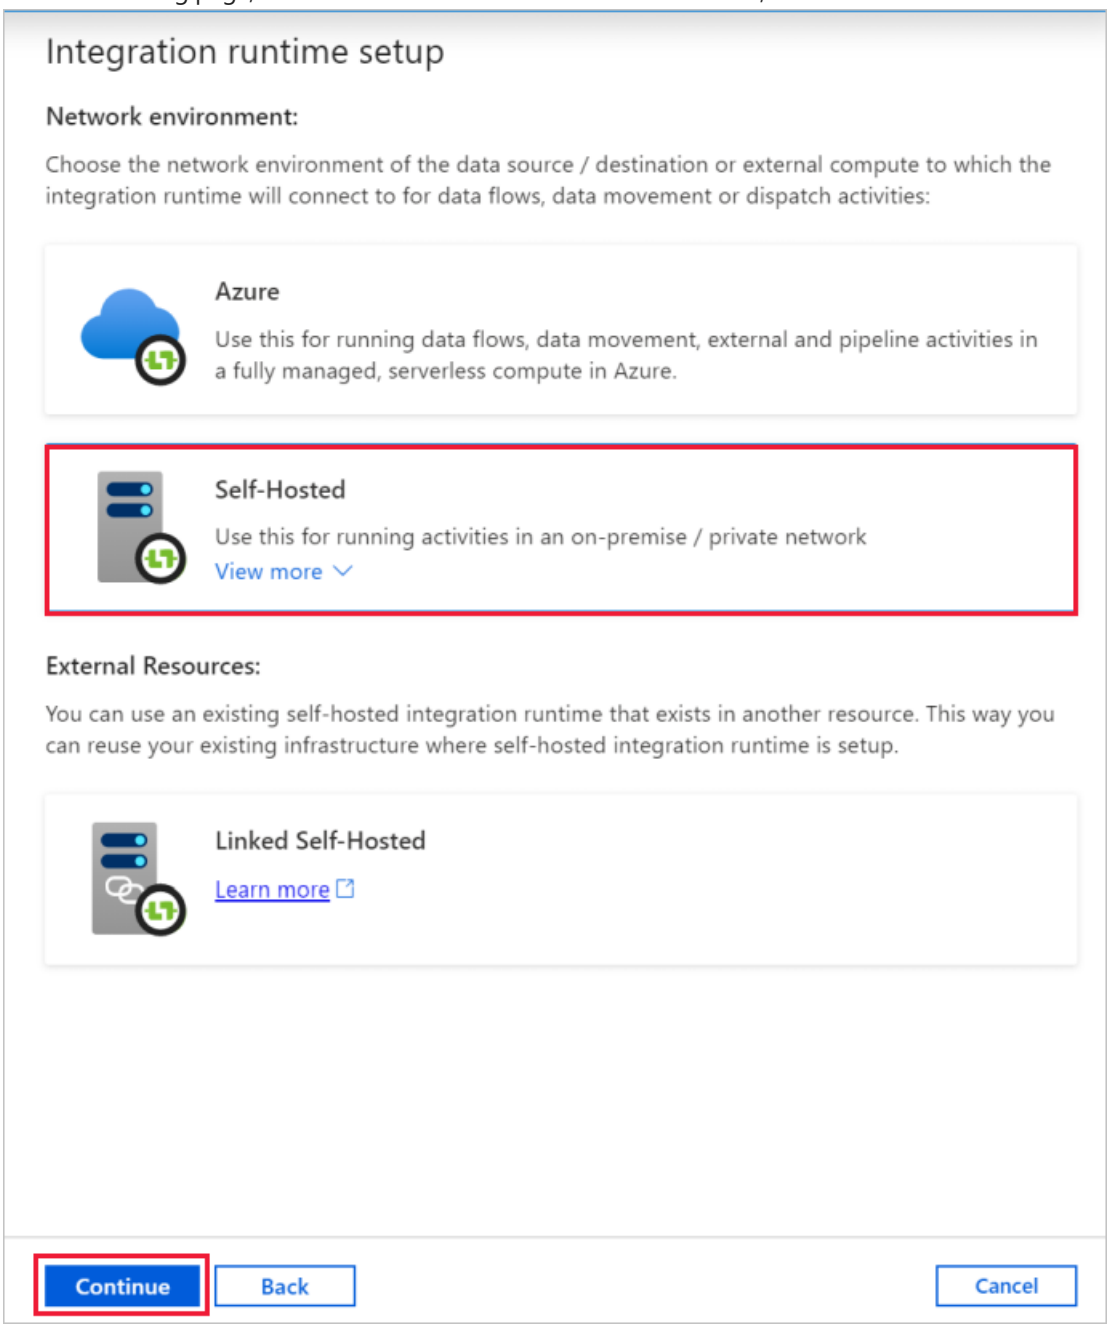


2. Select **Integration runtimes** on the left pane, and then select **+New**.



3. On the **Integration runtime setup** page, select **Azure, Self-Hosted**, and then select **Continue**.

4. On the following page, select **Self-Hosted** to create a Self-Hosted IR, and then select **Continue**.



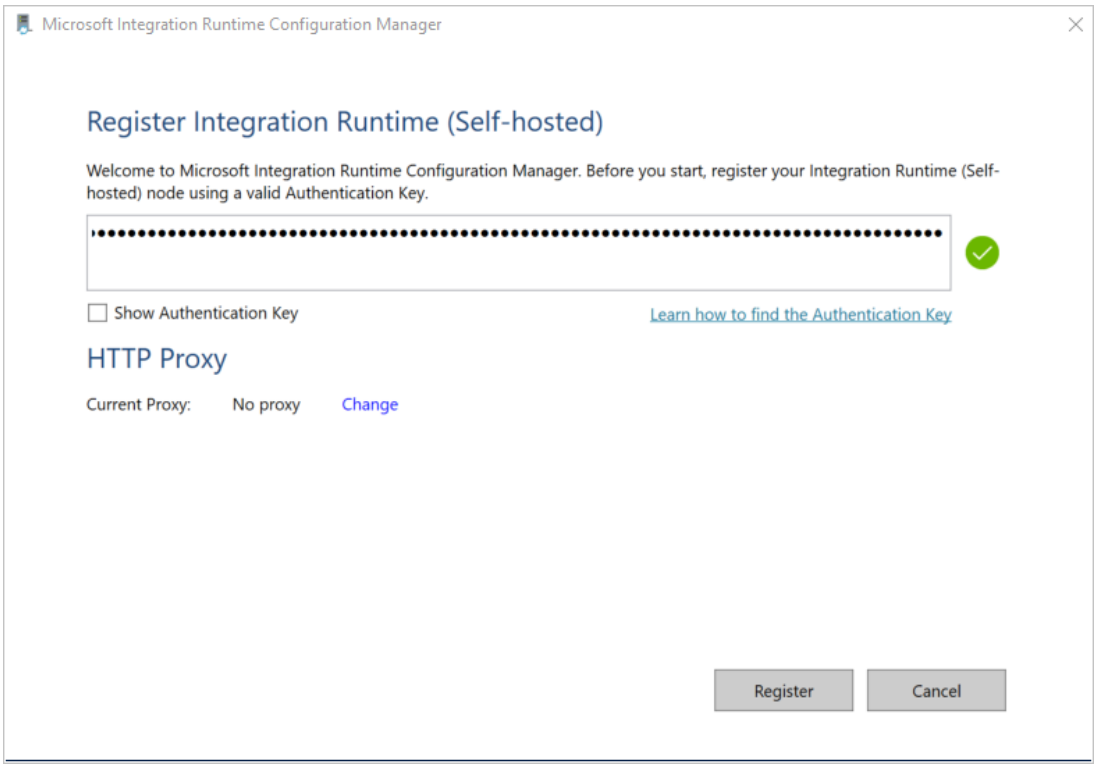
Configure a self-hosted IR via UI

1. Enter a name for your IR, and select **Create**.
2. On the **Integration runtime setup** page, select the link under **Option 1** to open the express setup on your computer. Or follow the steps under **Option 2** to set up manually. The following instructions are based on manual setup:

   a. Copy and paste the authentication key. Select **Download and install integration runtime**.

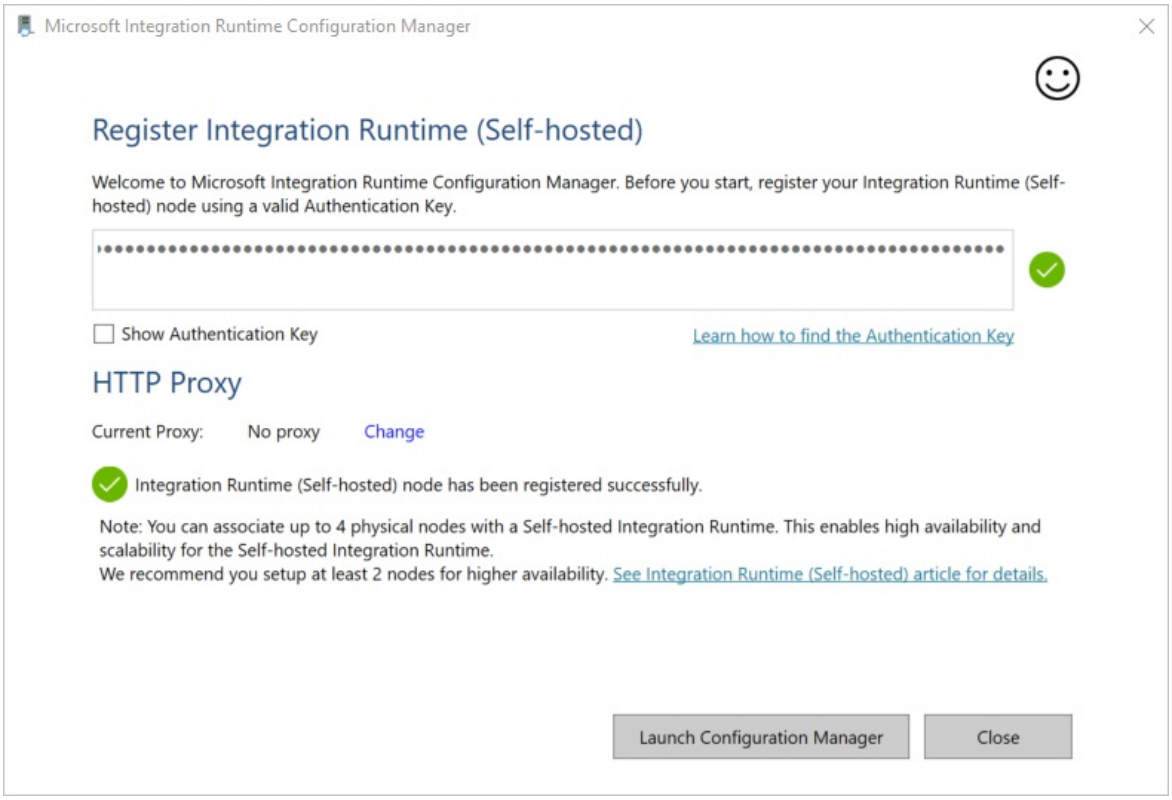
   b. Download the self-hosted integration runtime on a local Windows machine. Run the installer.

   c. On the **Register Integration Runtime (Self-hosted)** page, paste the key you saved earlier, and select **Register**.



d. On the **New Integration Runtime (Self-hosted) Node** page, select **Finish**.

3. After the self-hosted integration runtime is registered successfully, you see the following window:



Set up a self-hosted IR on an Azure VM via an Azure Resource Manager template

You can automate self-hosted IR setup on an Azure virtual machine by using the Create self host IR template. The template provides an easy way to have a fully functional self-hosted IR inside an Azure virtual network. The IR has high-availability and scalability features, as long as you set the node count to 2 or higher.

Set up an existing self-hosted IR via local PowerShell

You can use a command line to set up or manage an existing self-hosted IR. This usage can especially help to automate the installation and registration of self-hosted IR nodes.

Dmgcmd.exe is included in the self-hosted installer. It's typically located in the C:\Program Files\Microsoft Integration Runtime\4.0\Shared\ folder. This application supports various parameters and can be invoked via a command line using batch scripts for automation.

Use the application as follows:

```
dmgcmd ACTION args...
```

Here are details of the application's actions and arguments:

ACTION	ARGS	DESCRIPTION
`-rn`, `-RegisterNewNode`	"`<AuthenticationKey>`" ["`<NodeName>`"]	Register a self-hosted integration runtime node with the specified authentication key and node name.
`-era`, `-EnableRemoteAccess`	"`<port>`" ["`<thumbprint>`"]	Enable remote access on the current node to set up a high-availability cluster. Or enable setting credentials directly against the self-hosted IR without going through an Azure Data Factory or Azure Synapse workspace. You do the latter by using the **New-AzDataFactoryV2LinkedServiceEncryptedCredential** cmdlet from a remote machine in the same network.
`-erac`, `-EnableRemoteAccessInContainer`	"`<port>`" ["`<thumbprint>`"]	Enable remote access to the current node when the node runs in a container.
`-dra`, `-DisableRemoteAccess`		Disable remote access to the current node. Remote access is needed for multinode setup. The **New-AzDataFactoryV2LinkedServiceEncryptedCredential** PowerShell cmdlet still works even when remote access is disabled. This behavior is true as long as the cmdlet is executed on the same machine as the self-hosted IR node.
`-k`, `-Key`	"`<AuthenticationKey>`"	Overwrite or update the previous authentication key. Be careful with this action. Your previous self-hosted IR node can go offline if the key is of a new integration runtime.
`-gbf`, `-GenerateBackupFile`	"`<filePath>`" "`<password>`"	Generate a backup file for the current node. The backup file includes the node key and data-store credentials.
`-ibf`, `-ImportBackupFile`	"`<filePath>`" "`<password>`"	Restore the node from a backup file.
`-r`, `-Restart`		Restart the self-hosted integration runtime host service.

ACTION	ARGS	DESCRIPTION
`-s`, `-Start`		Start the self-hosted integration runtime host service.
`-t`, `-Stop`		Stop the self-hosted integration runtime host service.
`-sus`, `-StartUpgradeService`		Start the self-hosted integration runtime upgrade service.
`-tus`, `-StopUpgradeService`		Stop the self-hosted integration runtime upgrade service.
`-tonau`, `-TurnOnAutoUpdate`		Turn on the self-hosted integration runtime auto-update.
`-toffau`, `-TurnOffAutoUpdate`		Turn off the self-hosted integration runtime auto-update.
`-ssa`, `-SwitchServiceAccount`	" `<domain\user>` " [" `<password>` "]	Set DIAHostService to run as a new account. Use the empty password "" for system accounts and virtual accounts.
`-elma`, `-EnableLocalMachineAccess`		Enable local machine access (localhost, private IP) on the current self-hosted IR node. In self-hosted IR High Availability scenario, the action needs to be invoked on every self-hosted IR node.
`-dlma`, `-DisableLocalMachineAccess`		Disable local machine access (localhost, private IP) on the current self-hosted IR node. In self-hosted IR High Availability scenario, the action needs to be invoked on every self-hosted IR node.

Install and register a self-hosted IR from Microsoft Download Center

1. Go to the Microsoft integration runtime download page.
2. Select **Download**, select the 64-bit version, and select **Next**. The 32-bit version isn't supported.
3. Run the MSI file directly, or save it to your hard drive and run it.
4. On the **Welcome** window, select a language and select **Next**.
5. Accept the Microsoft Software License Terms and select **Next**.
6. Select **folder** to install the self-hosted integration runtime, and select **Next**.
7. On the **Ready to install** page, select **Install**.
8. Select **Finish** to complete installation.
9. Get the authentication key by using PowerShell. Here's a PowerShell example for retrieving the

authentication key:

```
Get-AzDataFactoryV2IntegrationRuntimeKey -ResourceGroupName $resourceGroupName -DataFactoryName
$dataFactoryName -Name $selfHostedIntegrationRuntimeName
```

10. On the **Register Integration Runtime (Self-hosted)** window of Microsoft Integration Runtime Configuration Manager running on your machine, take the following steps:

    a. Paste the authentication key in the text area.

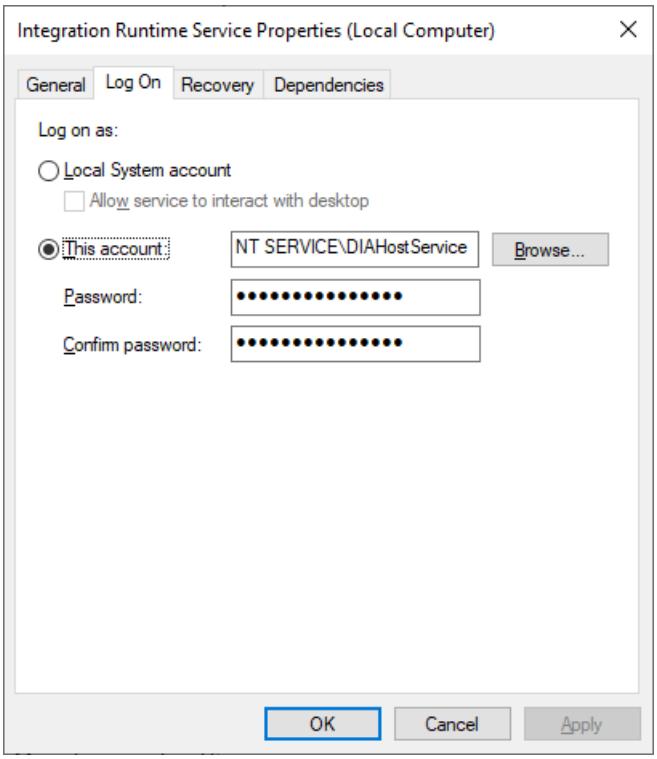
    b. Optionally, select **Show authentication key** to see the key text.

    c. Select **Register**.

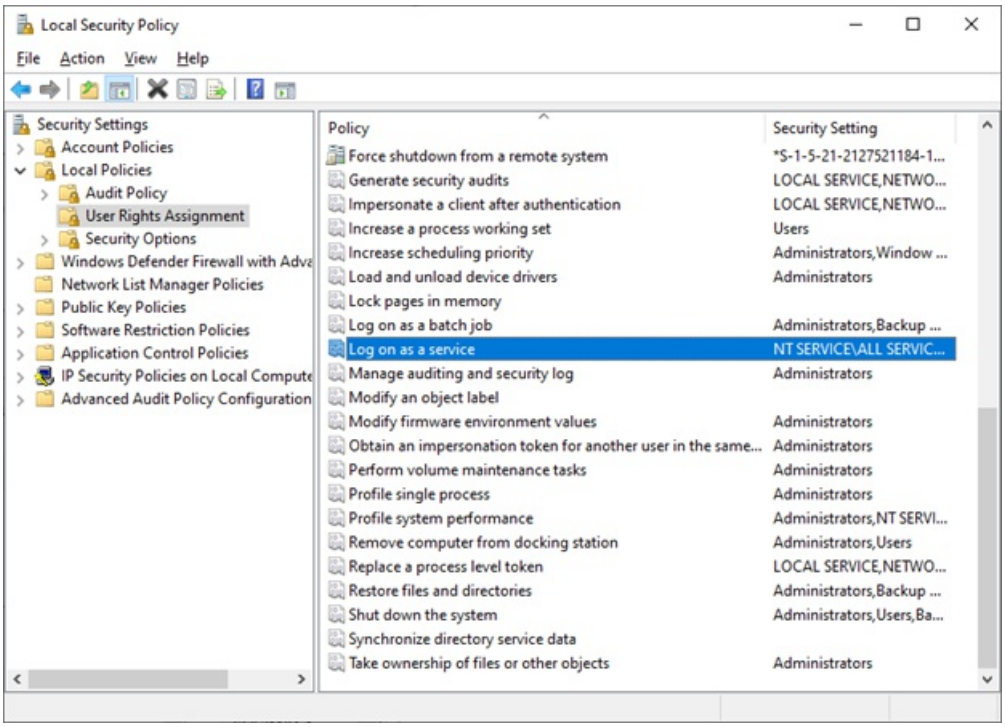
> **NOTE**
> Release Notes are available on the same Microsoft integration runtime download page.

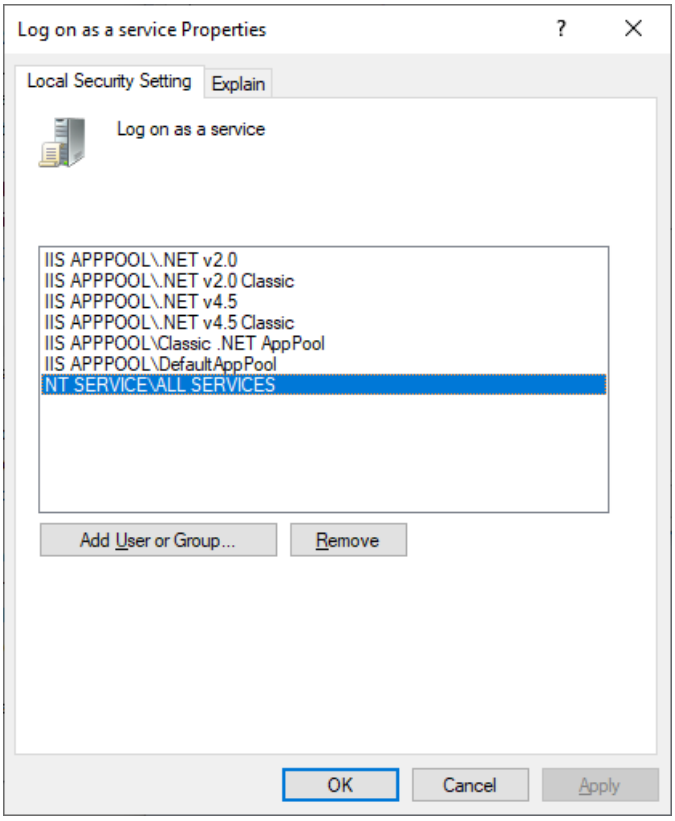
Service account for Self-hosted integration runtime

The default log on service account of Self-hosted integration runtime is **NT SERVICE\DIAHostService**. You can see it in **Services -> Integration Runtime Service -> Properties -> Log on**.



Make sure the account has the permission of Log on as a service. Otherwise self-hosted integration runtime can't start successfully. You can check the permission in **Local Security Policy -> Security Settings -> Local Policies -> User Rights Assignment -> Log on as a service**





Notification area icons and notifications

If you move your cursor over the icon or message in the notification area, you can see details about the state of the self-hosted integration runtime.

High availability and scalability

You can associate a self-hosted integration runtime with multiple on-premises machines or virtual machines in

Azure. These machines are called nodes. You can have up to four nodes associated with a self-hosted integration runtime. The benefits of having multiple nodes on on-premises machines that have a gateway installed for a logical gateway are:

- Higher availability of the self-hosted integration runtime so that it's no longer the single point of failure in your big data solution or cloud data integration. This availability helps ensure continuity when you use up to four nodes.
- Improved performance and throughput during data movement between on-premises and cloud data stores. Get more information on performance comparisons.

You can associate multiple nodes by installing the self-hosted integration runtime software from Download Center. Then, register it by using either of the authentication keys that were obtained from the **New-AzDataFactoryV2IntegrationRuntimeKey** cmdlet, as described in the tutorial.

> **NOTE**
> You don't need to create a new self-hosted integration runtime to associate each node. You can install the self-hosted integration runtime on another machine and register it by using the same authentication key.

> **NOTE**
> Before you add another node for high availability and scalability, ensure that the **Remote access to intranet** option is enabled on the first node. To do so, select **Microsoft Integration Runtime Configuration Manager** > **Settings** > **Remote access to intranet**.

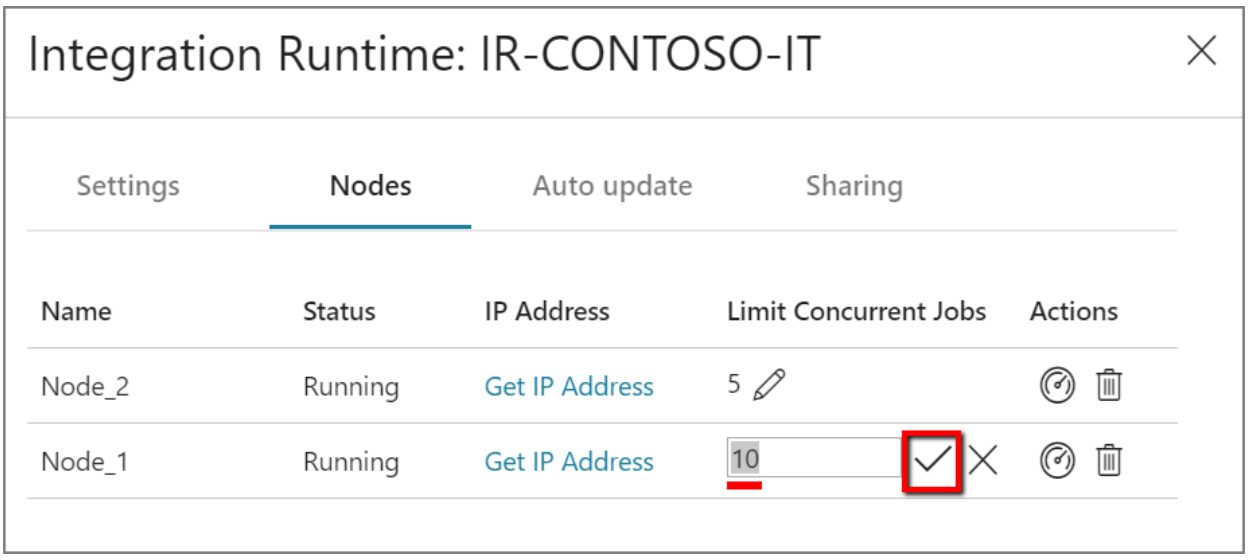
Scale considerations

Scale out

When processor usage is high and available memory is low on the self-hosted IR, add a new node to help scale out the load across machines. If activities fail because they time out or the self-hosted IR node is offline, it helps if you add a node to the gateway.

Scale up

When the processor and available RAM aren't well utilized, but the execution of concurrent jobs reaches a node's limits, scale up by increasing the number of concurrent jobs that a node can run. You might also want to scale up when activities time out because the self-hosted IR is overloaded. As shown in the following image, you can increase the maximum capacity for a node:



TLS/SSL certificate requirements

If you want to enable remote access from intranet with TLS/SSL certificate (Advanced) to secure communication between integration runtime nodes, you can follow steps in Enable remote access from intranet with TLS/SSL certificate.

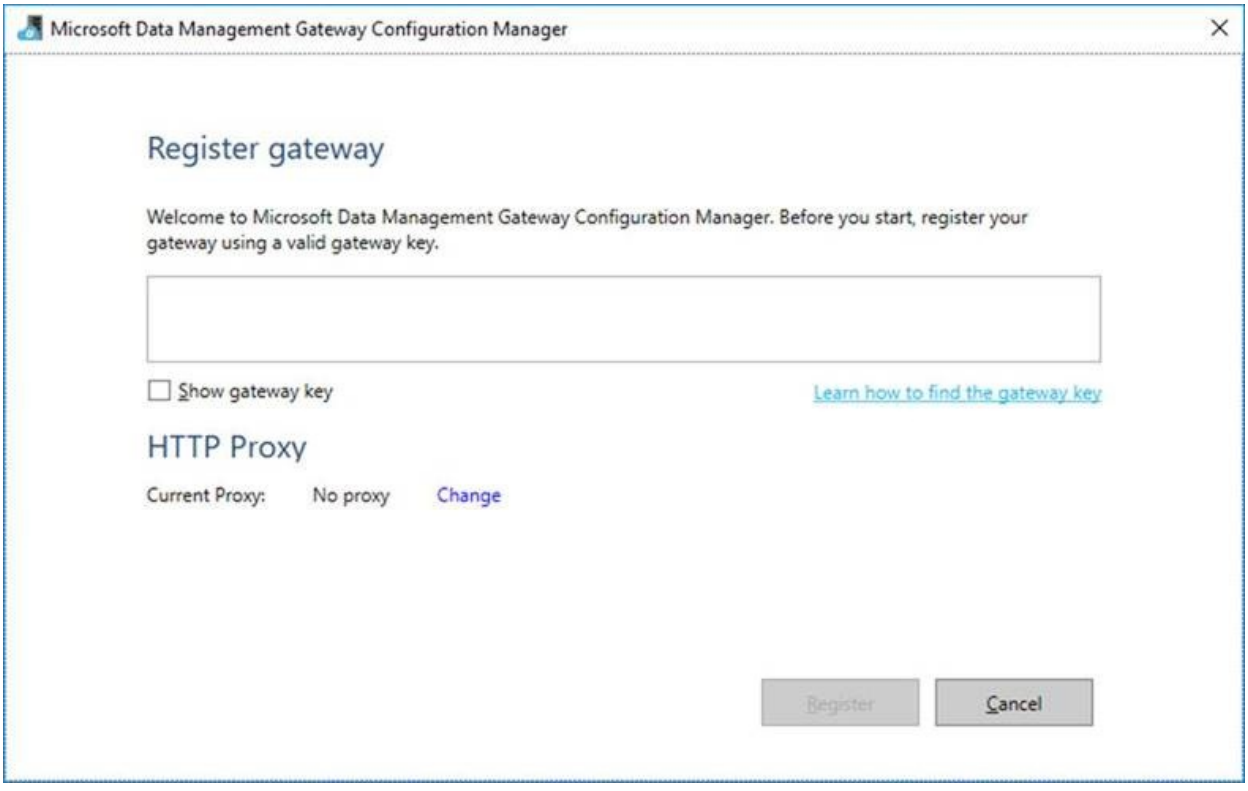
> **NOTE**
>
> This certificate is used:
>
> - To encrypt ports on a self-hosted IR node.
> - For node-to-node communication for state synchronization, which includes credentials synchronization of linked services across nodes.
> - When a PowerShell cmdlet is used for linked-service credential settings from within a local network.
>
> We suggest you use this certificate if your private network environment is not secure or if you want to secure the communication between nodes within your private network.
>
> Data movement in transit from a self-hosted IR to other data stores always happens within an encrypted channel, regardless of whether or not this certificate is set.

Credential Sync

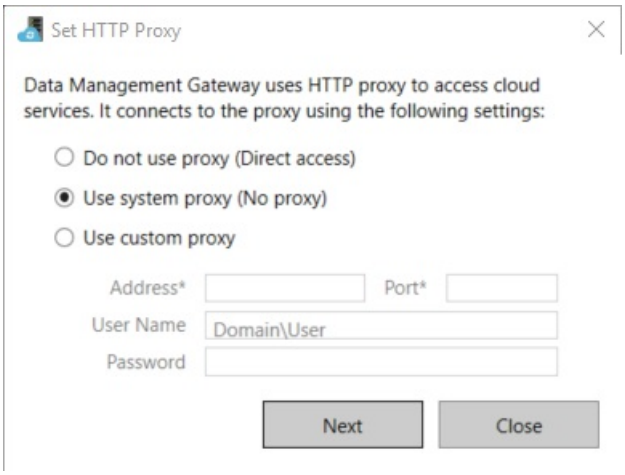
If you don't store credentials or secret values in an Azure Key Vault, the credentials or secret values will be stored in the machines where your self-hosted integration runtime locates. Each node will have a copy of credential with certain version. In order to make all nodes work together, the version number should be the same for all nodes.

Proxy server considerations

If your corporate network environment uses a proxy server to access the internet, configure the self-hosted integration runtime to use appropriate proxy settings. You can set the proxy during the initial registration phase.



When configured, the self-hosted integration runtime uses the proxy server to connect to the cloud service's source and destination (which use the HTTP or HTTPS protocol). This is why you select **Change link** during initial setup.



There are three configuration options:

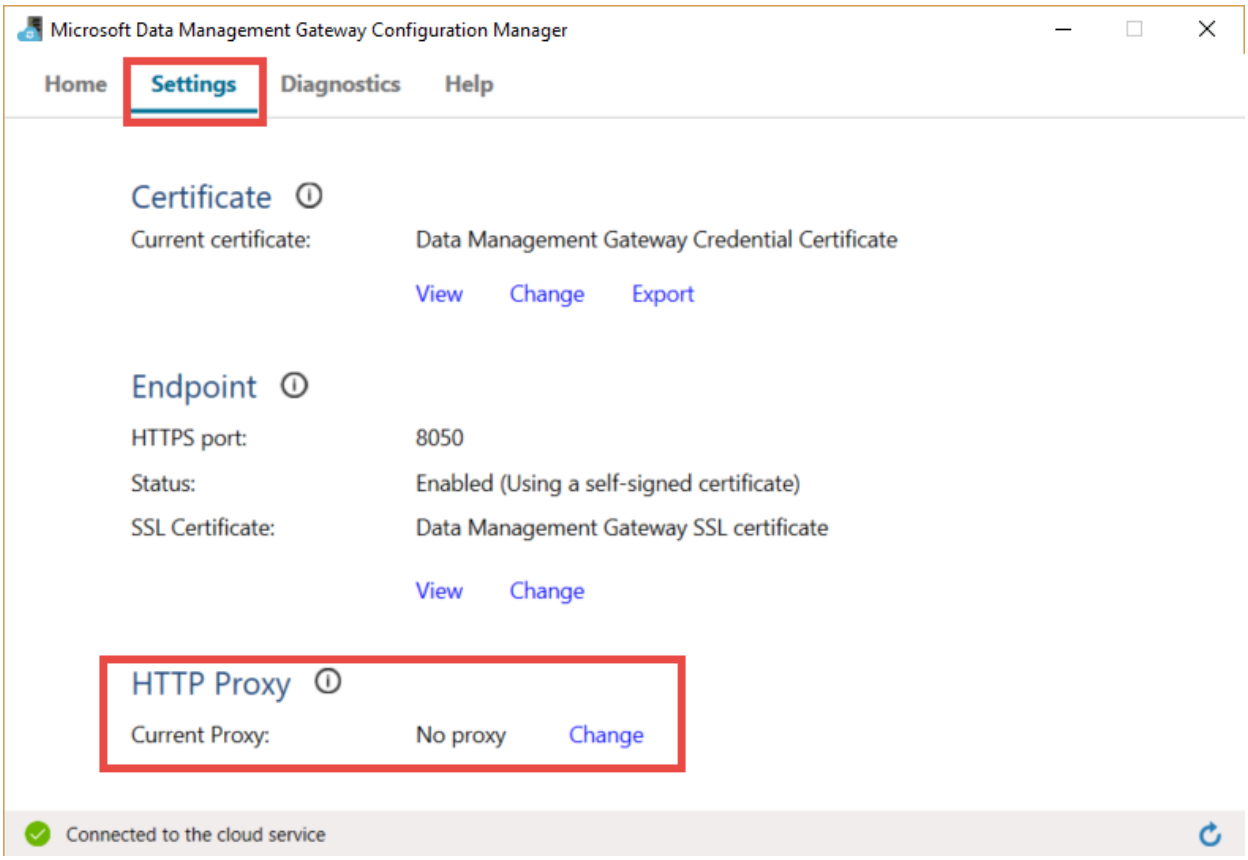
- **Do not use proxy**: The self-hosted integration runtime doesn't explicitly use any proxy to connect to cloud services.
- **Use system proxy**: The self-hosted integration runtime uses the proxy setting that is configured in diahost.exe.config and diawp.exe.config. If these files specify no proxy configuration, the self-hosted integration runtime connects to the cloud service directly without going through a proxy.
- **Use custom proxy**: Configure the HTTP proxy setting to use for the self-hosted integration runtime, instead of using configurations in diahost.exe.config and diawp.exe.config. **Address** and **Port** values are required. **User Name** and **Password** values are optional, depending on your proxy's authentication setting. All settings are encrypted with Windows DPAPI on the self-hosted integration runtime and stored locally on the machine.

The integration runtime host service restarts automatically after you save the updated proxy settings.

After you register the self-hosted integration runtime, if you want to view or update proxy settings, use Microsoft Integration Runtime Configuration Manager.

1. Open **Microsoft Integration Runtime Configuration Manager**.
2. Select the **Settings** tab.
3. Under **HTTP Proxy**, select the **Change** link to open the **Set HTTP Proxy** dialog box.
4. Select **Next**. You then see a warning that asks for your permission to save the proxy setting and restart the integration runtime host service.

You can use the configuration manager tool to view and update the HTTP proxy.



> **NOTE**
>
> If you set up a proxy server with NTLM authentication, the integration runtime host service runs under the domain account. If you later change the password for the domain account, remember to update the configuration settings for the service and restart the service. Because of this requirement, we suggest that you access the proxy server by using a dedicated domain account that doesn't require you to update the password frequently.

Configure proxy server settings

If you select the **Use system proxy** option for the HTTP proxy, the self-hosted integration runtime uses the proxy settings in diahost.exe.config and diawp.exe.config. When these files specify no proxy, the self-hosted integration runtime connects to the cloud service directly without going through a proxy. The following procedure provides instructions for updating the diahost.exe.config file:

1. In File Explorer, make a safe copy of C:\Program Files\Microsoft Integration Runtime\4.0\Shared\diahost.exe.config as a backup of the original file.
2. Open Notepad running as administrator.
3. In Notepad, open the text file C:\Program Files\Microsoft Integration Runtime\4.0\Shared\diahost.exe.config.
4. Find the default **system.net** tag as shown in the following code:

```
<system.net>
    <defaultProxy useDefaultCredentials="true" />
</system.net>
```

   You can then add proxy server details as shown in the following example:

```
<system.net>
    <defaultProxy enabled="true">
          <proxy bypassonlocal="true" proxyaddress="http://proxy.domain.org:8888/" />
    </defaultProxy>
</system.net>
```

The proxy tag allows additional properties to specify required settings like `scriptLocation`. See <proxy> Element (Network Settings) for syntax.

```
<proxy autoDetect="true|false|unspecified" bypassonlocal="true|false|unspecified"
proxyaddress="uriString" scriptLocation="uriString" usesystemdefault="true|false|unspecified "/>
```

5. Save the configuration file in its original location. Then restart the self-hosted integration runtime host service, which picks up the changes.

   To restart the service, use the services applet from Control Panel. Or from Integration Runtime Configuration Manager, select the **Stop Service** button, and then select **Start Service**.

   If the service doesn't start, you likely added incorrect XML tag syntax in the application configuration file that you edited.

> **IMPORTANT**
> Don't forget to update both diahost.exe.config and diawp.exe.config.

You also need to make sure that Microsoft Azure is in your company's allowlist. You can download the list of valid Azure IP addresses. IP Ranges for each cloud, broken down by region and by the tagged services in that cloud are now available on MS Download:

- Public: https://www.microsoft.com/download/details.aspx?id=56519
- US Gov: https://www.microsoft.com/download/details.aspx?id=57063
- Germany: https://www.microsoft.com/download/details.aspx?id=57064
- China: https://www.microsoft.com/download/details.aspx?id=57062

Possible symptoms for issues related to the firewall and proxy server

If you see error messages like the following ones, the likely reason is improper configuration of the firewall or proxy server. Such configuration prevents the self-hosted integration runtime from connecting to Data Factory or Synapse pipelines to authenticate itself. To ensure that your firewall and proxy server are properly configured, refer to the previous section.

- When you try to register the self-hosted integration runtime, you receive the following error message: "Failed to register this Integration Runtime node! Confirm that the Authentication key is valid and the integration service host service is running on this machine."
- When you open Integration Runtime Configuration Manager, you see a status of **Disconnected** or **Connecting**. When you view Windows event logs, under **Event Viewer** > **Application and Services Logs** > **Microsoft Integration Runtime**, you see error messages like this one:

```
Unable to connect to the remote server
A component of Integration Runtime has become unresponsive and restarts automatically. Component
name: Integration Runtime (Self-hosted).
```

Enable remote access from an intranet

If you use PowerShell to encrypt credentials from a networked machine other than where you installed the self-hosted integration runtime, you can enable the **Remote Access from Intranet** option. If you run PowerShell to encrypt credentials on the machine where you installed the self-hosted integration runtime, you can't enable **Remote Access from Intranet**.

Enable **Remote Access from Intranet** before you add another node for high availability and scalability.

When you run the self-hosted integration runtime setup version 3.3 or later, by default the self-hosted integration runtime installer disables **Remote Access from Intranet** on the self-hosted integration runtime machine.

When you use a firewall from a partner or others, you can manually open port 8060 or the user-configured port. If you have a firewall problem while setting up the self-hosted integration runtime, use the following command to install the self-hosted integration runtime without configuring the firewall:

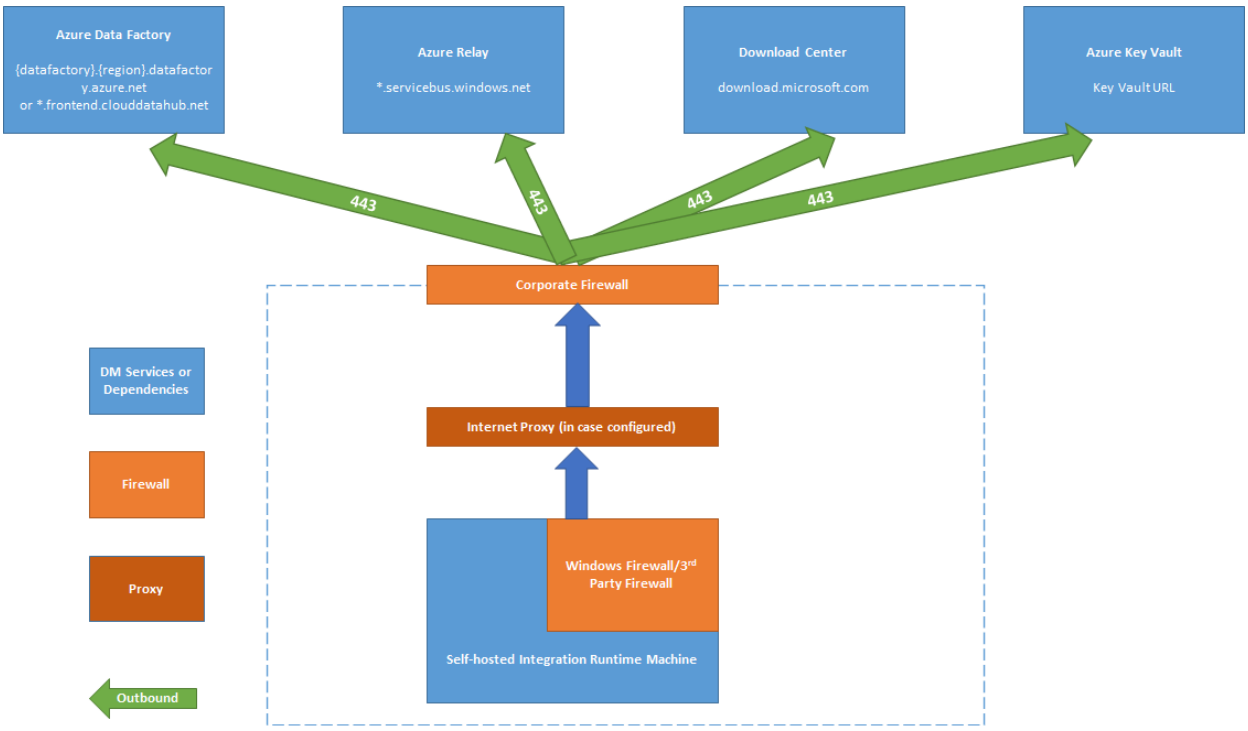
```
msiexec /q /i IntegrationRuntime.msi NOFIREWALL=1
```

If you choose not to open port 8060 on the self-hosted integration runtime machine, use mechanisms other than the Setting Credentials application to configure data-store credentials. For example, you can use the **New-AzDataFactoryV2LinkedServiceEncryptCredential** PowerShell cmdlet.

Ports and firewalls

There are two firewalls to consider:

- The *corporate firewall* that runs on the central router of the organization
- The *Windows firewall* that is configured as a daemon on the local machine where the self-hosted integration runtime is installed



At the corporate firewall level, you need to configure the following domains and outbound ports:

DOMAIN NAMES	OUTBOUND PORTS	DESCRIPTION
Public Cloud: `*.servicebus.windows.net` Azure Government: `*.servicebus.usgovcloudapi.net` China: `*.servicebus.chinacloudapi.cn`	443	Required by the self-hosted integration runtime for interactive authoring.
Public Cloud: `{datafactory}.{region}.datafactory.azure.net` or `*.frontend.clouddatahub.net` Azure Government: `{datafactory}.{region}.datafactory.azure.us` China: `{datafactory}.{region}.datafactory.azure.cn`	443	Required by the self-hosted integration runtime to connect to the Data Factory service. For new created Data Factory in public cloud, please find the FQDN from your Self-hosted Integration Runtime key which is in format {datafactory}.{region}.datafactory.azure.net. For old Data factory and Azure Synapse Analytics, if you don't see the FQDN in your Self-hosted Integration key, please use *.frontend.clouddatahub.net instead.
`download.microsoft.com`	443	Required by the self-hosted integration runtime for downloading the updates. If you have disabled auto-update, you can skip configuring this domain.
Key Vault URL	443	Required by Azure Key Vault if you store the credential in Key Vault.

At the Windows firewall level or machine level, these outbound ports are normally enabled. If they aren't, you can configure the domains and ports on a self-hosted integration runtime machine.

> **NOTE**
> As currently Azure Relay doesn't support service tag, you have to use service tag **AzureCloud** or **Internet** in NSG rules for the communication to Azure Relay. For the communication to Azure Data Factory and Synapse workspaces, you can use service tag **DataFactoryManagement** in the NSG rule setup.

Based on your source and sinks, you might need to allow additional domains and outbound ports in your corporate firewall or Windows firewall.

DOMAIN NAMES	OUTBOUND PORTS	DESCRIPTION
`*.core.windows.net`	443	Used by the self-hosted integration runtime to connect to the Azure storage account when you use the staged copy feature.
`*.database.windows.net`	1433	Required only when you copy from or to Azure SQL Database or Azure Synapse Analytics and optional otherwise. Use the staged-copy feature to copy data to SQL Database or Azure Synapse Analytics without opening port 1433.

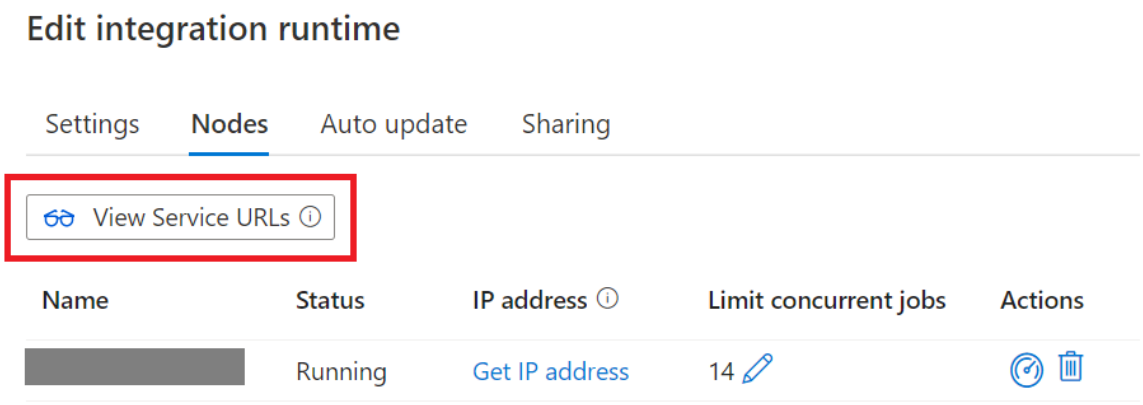
DOMAIN NAMES	OUTBOUND PORTS	DESCRIPTION
`*.azuredatalakestore.net` `login.microsoftonline.com/<tenant>/oauth2/token`	443	Required only when you copy from or to Azure Data Lake Store and optional otherwise.

For some cloud databases, such as Azure SQL Database and Azure Data Lake, you might need to allow IP addresses of self-hosted integration runtime machines on their firewall configuration.

Get URL of Azure Relay

One required domain and port that need to be put in the allowlist of your firewall is for the communication to Azure Relay. The self-hosted integration runtime uses it for interactive authoring such as test connection, browse folder list and table list, get schema, and preview data. If you don't want to allow **.servicebus.windows.net** and would like to have more specific URLs, then you can see all the FQDNs that are required by your self-hosted integration runtime from the service portal. Follow these steps:

1. Go to the service portal and select your self-hosted integration runtime.
2. In Edit page, select **Nodes**.
3. Select **View Service URLs** to get all FQDNs.



4. You can add these FQDNs in the allowlist of firewall rules.

> **NOTE**
> For the details related to Azure Relay connections protocol, see Azure Relay Hybrid Connections protocol.

Copy data from a source to a sink

Ensure that you properly enable firewall rules on the corporate firewall, the Windows firewall of the self-hosted integration runtime machine, and the data store itself. Enabling these rules lets the self-hosted integration runtime successfully connect to both source and sink. Enable rules for each data store that is involved in the copy operation.

For example, to copy from an on-premises data store to a SQL Database sink or an Azure Synapse Analytics sink, take the following steps:

1. Allow outbound TCP communication on port 1433 for both the Windows firewall and the corporate firewall.
2. Configure the firewall settings of the SQL Database to add the IP address of the self-hosted integration runtime machine to the list of allowed IP addresses.

> **NOTE**
> If your firewall doesn't allow outbound port 1433, the self-hosted integration runtime can't access the SQL database directly. In this case, you can use a staged copy to SQL Database and Azure Synapse Analytics. In this scenario, you require only HTTPS (port 443) for the data movement.

Credentials store

There are two ways to store the credentials when using self-hosted integration runtime:

1. Use Azure Key Vault. This is the recommended way to store your credentials in Azure. The self-hosted integration runtime can directly get the credentials from Azure Key Vault which can highly avoid some potential security issues or any credential in-sync problems between self-hosted integration runtime nodes.
2. Store credentials locally. The credentials will be push to the machine of your self-hosted integration runtime and be encrypted. When your self-hosted integration runtime is recovered from crash, you can either recover credential from the one you backup before or edit linked service and let the credential be pushed to self-hosted integration runtime again. Otherwise, the pipeline doesn't work due to the lack of credential when running via self-hosted integration runtime.

> **NOTE**
> If you prefer to store the credential locally, your need to put the domain for interactive authoring in the allowlist of your firewall and open the port. This channel is also for the self-hosted integration runtime to get the credentials. For the domain and port needed for interactive authoring, refer to Ports and firewalls

Installation best practices

You can install the self-hosted integration runtime by downloading a Managed Identity setup package from Microsoft Download Center. See the article Move data between on-premises and cloud for step-by-step instructions.

- Configure a power plan on the host machine for the self-hosted integration runtime so that the machine doesn't hibernate. If the host machine hibernates, the self-hosted integration runtime goes offline.
- Regularly back up the credentials associated with the self-hosted integration runtime.
- To automate self-hosted IR setup operations, refer to Set up an existing self hosted IR via PowerShell.

Next steps

For step-by-step instructions, see Tutorial: Copy on-premises data to cloud.

Create a trigger that runs a pipeline in response to a storage event

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes the Storage Event Triggers that you can create in your Data Factory or Synapse pipelines.

Event-driven architecture (EDA) is a common data integration pattern that involves production, detection, consumption, and reaction to events. Data integration scenarios often require customers to trigger pipelines based on events happening in storage account, such as the arrival or deletion of a file in Azure Blob Storage account. Data Factory and Synapse pipelines natively integrate with Azure Event Grid, which lets you trigger pipelines on such events.

> **NOTE**
> The integration described in this article depends on Azure Event Grid. Make sure that your subscription is registered with the Event Grid resource provider. For more info, see Resource providers and types. You must be able to do the *Microsoft.EventGrid/eventSubscriptions/** action. This action is part of the EventGrid EventSubscription Contributor built-in role.

> **IMPORTANT**
> If you are using this feature in Azure Synapse Analytics, please ensure that your subscription is also registered with Data Factory resource provider, or otherwise you will get an error stating that *the creation of an "Event Subscription" failed*.

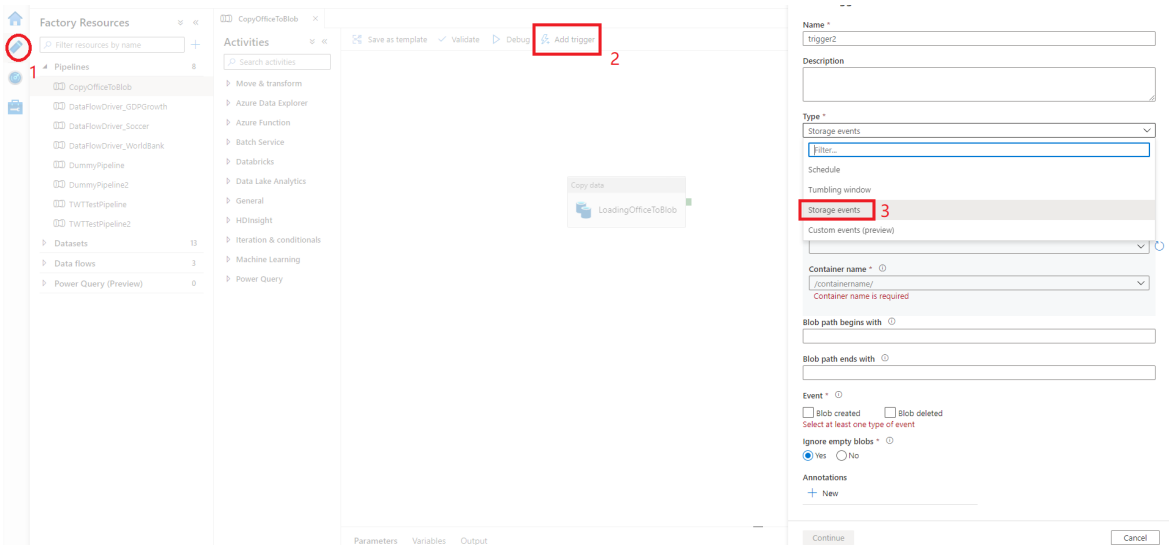
> **NOTE**
> If the blob storage account resides behind a private endpoint and blocks public network access, you need to configure network rules to allow communications from blob storage to Azure Event Grid. You can either grant storage access to trusted Azure services, such as Event Grid, following Storage documentation, or configure private endpoints for Event Grid that map to VNet address space, following Event Grid documentation

Create a trigger with UI

This section shows you how to create a storage event trigger within the Azure Data Factory and Synapse pipeline User Interface.

1. Switch to the **Edit** tab in Data Factory, or the **Integrate** tab in Azure Synapse.
2. Select **Trigger** on the menu, then select **New/Edit**.
3. On the **Add Triggers** page, select **Choose trigger...**, then select **+New**.
4. Select trigger type **Storage Event**

   - Azure Data Factory
   - Azure Synapse



5. Select your storage account from the Azure subscription dropdown or manually using its Storage account resource ID. Choose which container you wish the events to occur on. Container selection is required, but be mindful that selecting all containers can lead to a large number of events.

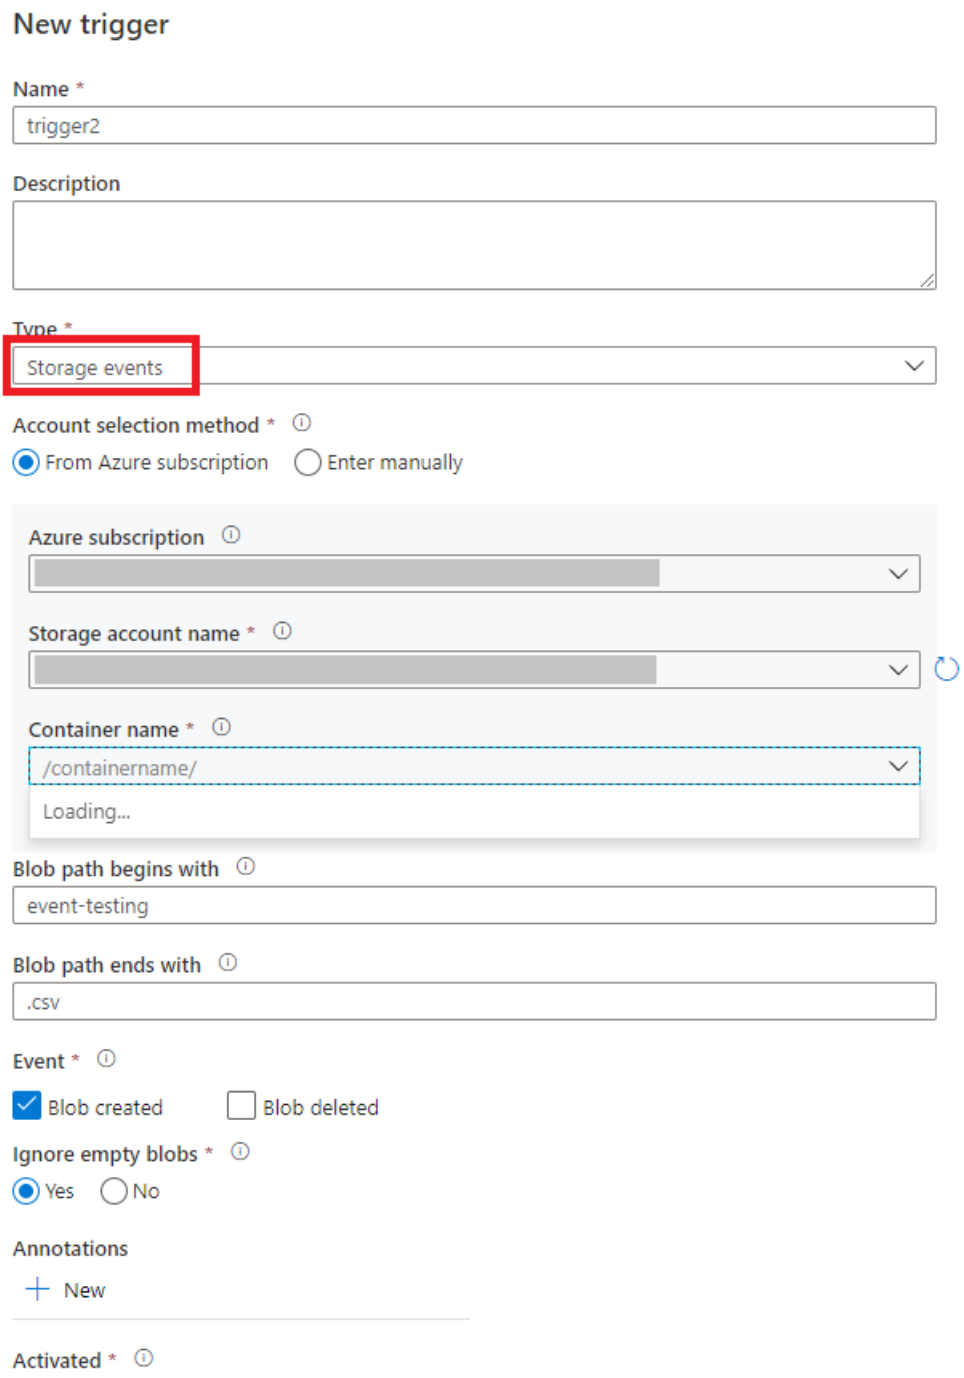
> **NOTE**
>
> The Storage Event Trigger currently supports only Azure Data Lake Storage Gen2 and General-purpose version 2 storage accounts. Due to an Azure Event Grid limitation, Azure Data Factory only supports a maximum of 500 storage event triggers per storage account. If you hit the limit, please contact support for recommendations and increasing the limit upon evaluation by Event Grid team.

> **NOTE**
>
> To create a new or modify an existing Storage Event Trigger, the Azure account used to log into the service and publish the storage event trigger must have appropriate role based access control (Azure RBAC) permission on the storage account. No additional permission is required: Service Principal for the Azure Data Factory and Azure Synapse does *not* need special permission to either the Storage account or Event Grid. For more information about access control, see Role based access control section.

6. The **Blob path begins with** and **Blob path ends with** properties allow you to specify the containers, folders, and blob names for which you want to receive events. Your storage event trigger requires at least one of these properties to be defined. You can use variety of patterns for both **Blob path begins with** and **Blob path ends with** properties, as shown in the examples later in this article.

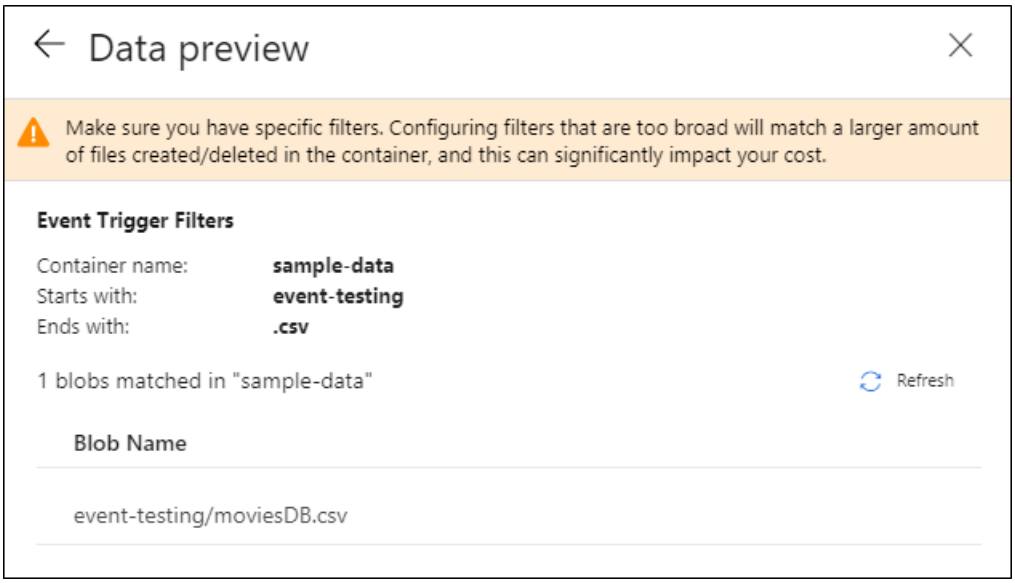
   - **Blob path begins with:** The blob path must start with a folder path. Valid values include `2018/` and `2018/april/shoes.csv`. This field can't be selected if a container isn't selected.
   - **Blob path ends with:** The blob path must end with a file name or extension. Valid values include `shoes.csv` and `.csv`. Container and folder names, when specified, they must be separated by a `/blobs/` segment. For example, a container named 'orders' can have a value of `/orders/blobs/2018/april/shoes.csv`. To specify a folder in any container, omit the leading '/' character. For example, `april/shoes.csv` will trigger an event on any file named `shoes.csv` in folder a called 'april' in any container.
   - Note that Blob path **begins with** and **ends with** are the only pattern matching allowed in Storage Event Trigger. Other types of wildcard matching aren't supported for the trigger type.

7. Select whether your trigger will respond to a **Blob created** event, **Blob deleted** event, or both. In your specified storage location, each event will trigger the Data Factory and Synapse pipelines associated with the trigger.



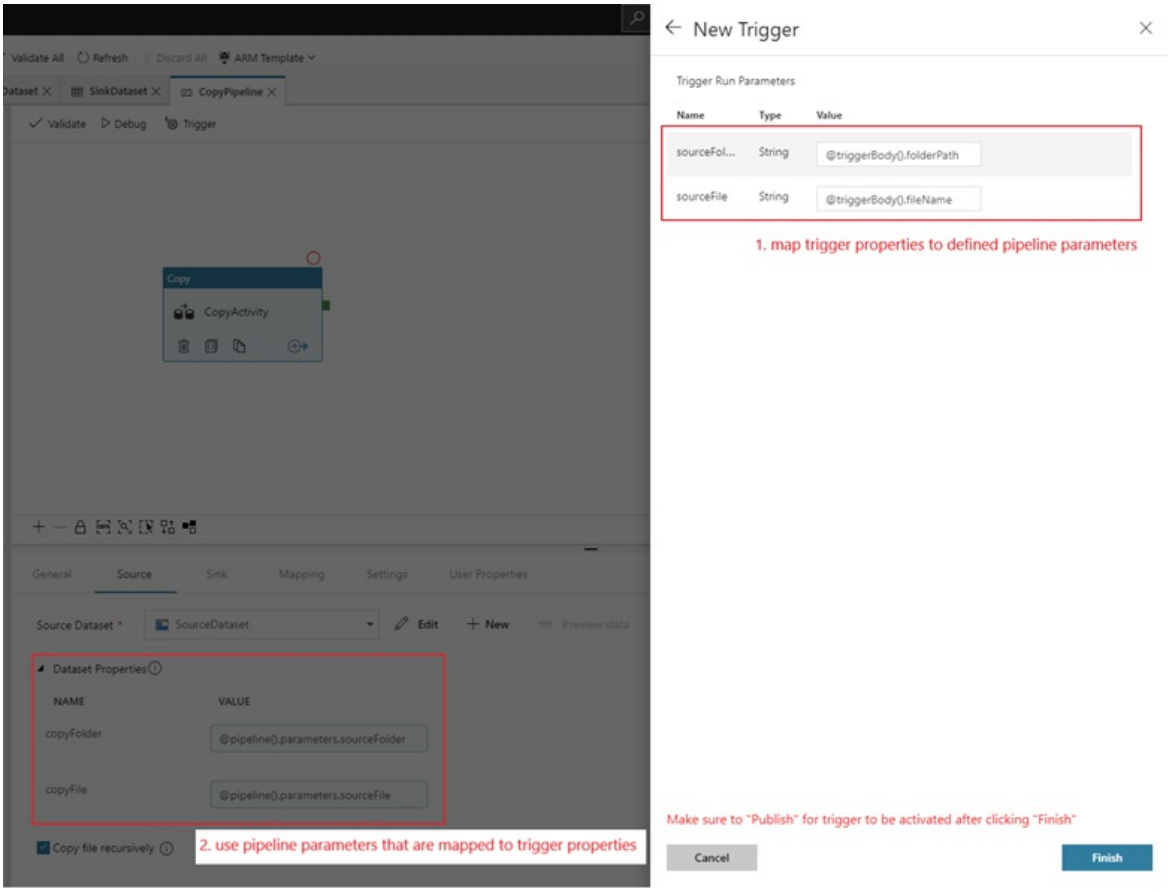
8. Select whether or not your trigger ignores blobs with zero bytes.

9. After you configure you trigger, click on **Next: Data preview**. This screen shows the existing blobs matched by your storage event trigger configuration. Make sure you've specific filters. Configuring filters that are too broad can match a large number of files created/deleted and may significantly impact your cost. Once your filter conditions have been verified, click **Finish**.



10. To attach a pipeline to this trigger, go to the pipeline canvas and click **Trigger** and select **New/Edit**. When the side nav appears, click on the **Choose trigger...** dropdown and select the trigger you created. Click **Next: Data preview** to confirm the configuration is correct and then **Next** to validate the Data preview is correct.

11. If your pipeline has parameters, you can specify them on the trigger runs parameter side nav. The storage event trigger captures the folder path and file name of the blob into the properties `@triggerBody().folderPath` and `@triggerBody().fileName`. To use the values of these properties in a pipeline, you must map the properties to pipeline parameters. After mapping the properties to parameters, you can access the values captured by the trigger through the `@pipeline().parameters.parameterName` expression throughout the pipeline. For detailed explanation, see Reference Trigger Metadata in Pipelines



In the preceding example, the trigger is configured to fire when a blob path ending in .csv is created in the folder *event-testing* in the container *sample-data*. The **folderPath** and **fileName** properties capture the

location of the new blob. For example, when MoviesDB.csv is added to the path sample-data/event-testing, `@triggerBody().folderPath` has a value of `sample-data/event-testing` and `@triggerBody().fileName` has a value of `moviesDB.csv`. These values are mapped, in the example, to the pipeline parameters `sourceFolder` and `sourceFile`, which can be used throughout the pipeline as `@pipeline().parameters.sourceFolder` and `@pipeline().parameters.sourceFile` respectively.

> **NOTE**
>
> If you are creating your pipeline and trigger in Azure Synapse Analytics, you must use `@trigger().outputs.body.fileName` and `@trigger().outputs.body.folderPath` as parameters. Those two properties capture blob information. Use those properties instead of using `@triggerBody().fileName` and `@triggerBody().folderPath`.

12. Click **Finish** once you are done.

JSON schema

The following table provides an overview of the schema elements that are related to storage event triggers:

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED
scope	The Azure Resource Manager resource ID of the Storage Account.	String	Azure Resource Manager ID	Yes
events	The type of events that cause this trigger to fire.	Array	Microsoft.Storage.BlobCreated, Microsoft.Storage.BlobDeleted	Yes, any combination of these values.
blobPathBeginsWith	The blob path must begin with the pattern provided for the trigger to fire. For example, `/records/blobs/december/` only fires the trigger for blobs in the `december` folder under the `records` container.	String		Provide a value for at least one of these properties: `blobPathBeginsWith` or `blobPathEndsWith`.
blobPathEndsWith	The blob path must end with the pattern provided for the trigger to fire. For example, `december/boxes.csv` only fires the trigger for blobs named `boxes` in a `december` folder.	String		Provide a value for at least one of these properties: `blobPathBeginsWith` or `blobPathEndsWith`.

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED
ignoreEmptyBlobs	Whether or not zero-byte blobs will trigger a pipeline run. By default, this is set to true.	Boolean	true or false	No

Examples of storage event triggers

This section provides examples of storage event trigger settings.

> **IMPORTANT**
> You have to include the `/blobs/` segment of the path, as shown in the following examples, whenever you specify container and folder, container and file, or container, folder, and file. For **blobPathBeginsWith**, the UI will automatically add `/blobs/` between the folder and container name in the trigger JSON.

PROPERTY	EXAMPLE	DESCRIPTION
Blob path begins with	`/containername/`	Receives events for any blob in the container.
Blob path begins with	`/containername/blobs/foldername/`	Receives events for any blobs in the `containername` container and `foldername` folder.
Blob path begins with	`/containername/blobs/foldername/subfoldername/`	You can also reference a subfolder.
Blob path begins with	`/containername/blobs/foldername/file.txt`	Receives events for a blob named `file.txt` in the `foldername` folder under the `containername` container.
Blob path ends with	`file.txt`	Receives events for a blob named `file.txt` in any path.
Blob path ends with	`/containername/blobs/file.txt`	Receives events for a blob named `file.txt` under container `containername`.
Blob path ends with	`foldername/file.txt`	Receives events for a blob named `file.txt` in `foldername` folder under any container.

Role-based access control

Azure Data Factory and Synapse pipelines use Azure role-based access control (Azure RBAC) to ensure that unauthorized access to listen to, subscribe to updates from, and trigger pipelines linked to blob events, are strictly prohibited.

- To successfully create a new or update an existing Storage Event Trigger, the Azure account signed into the service needs to have appropriate access to the relevant storage account. Otherwise, the operation will fail with *Access Denied*.

- Azure Data Factory and Azure Synapse need no special permission to your Event Grid, and you do *not* need to assign special RBAC permission to the Data Factory or Azure Synapse service principal for the operation.

Any of following RBAC settings works for storage event trigger:

- Owner role to the storage account
- Contributor role to the storage account
- *Microsoft.EventGrid/EventSubscriptions/Write* permission to storage account */subscriptions/####/resourceGroups/####/providers/Microsoft.Storage/storageAccounts/storageAccountName*

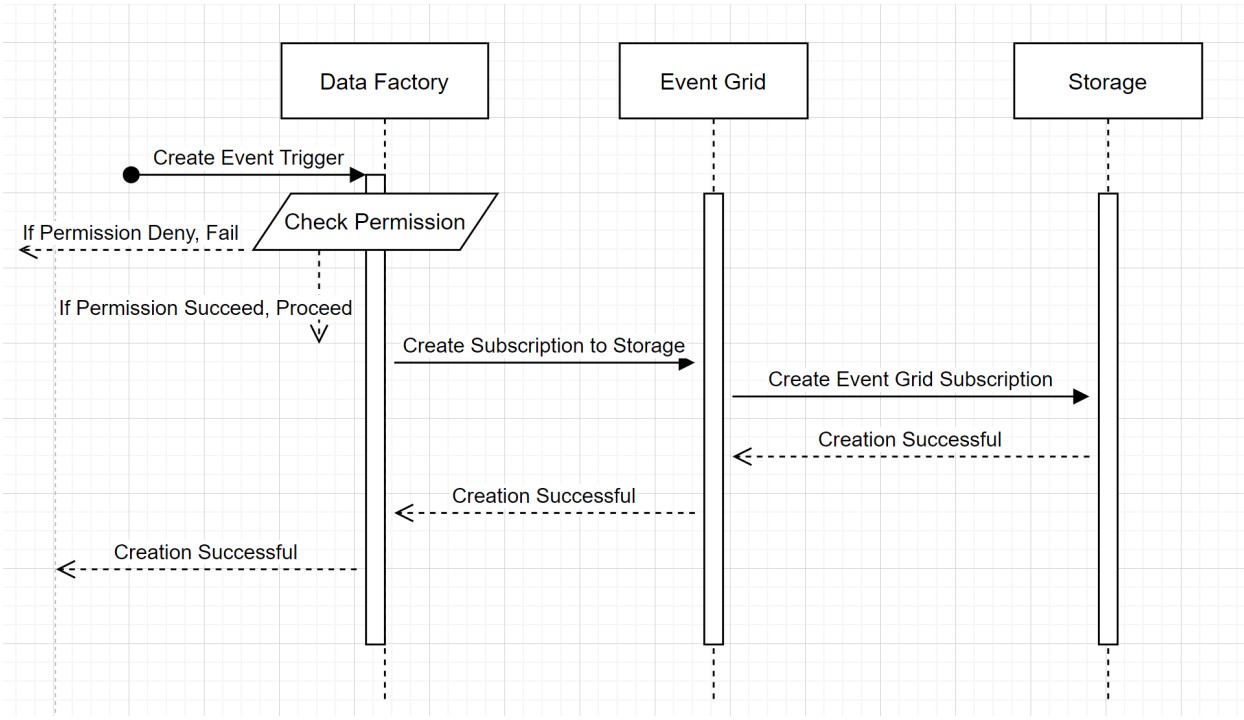
Specifically,

- When authoring in the data factory (in the development environment for instance), the Azure account signed in needs to have the above permission
- When publishing through CI/CD, the account used to publish the ARM template into the testing or production factory needs to have the above permission.

In order to understand how the service delivers the two promises, let's take back a step and take a peek behind the scenes. Here are the high-level work flows for integration between Azure Data Factory/Azure Synapse, Storage, and Event Grid.

Create a new Storage Event Trigger

This high-level work flow describes how Azure Data Factory interacts with Event Grid to create a Storage Event Trigger. For Azure Synapse the data flow is the same, with Synapse pipelines taking the role of the Data Factory in the diagram below.



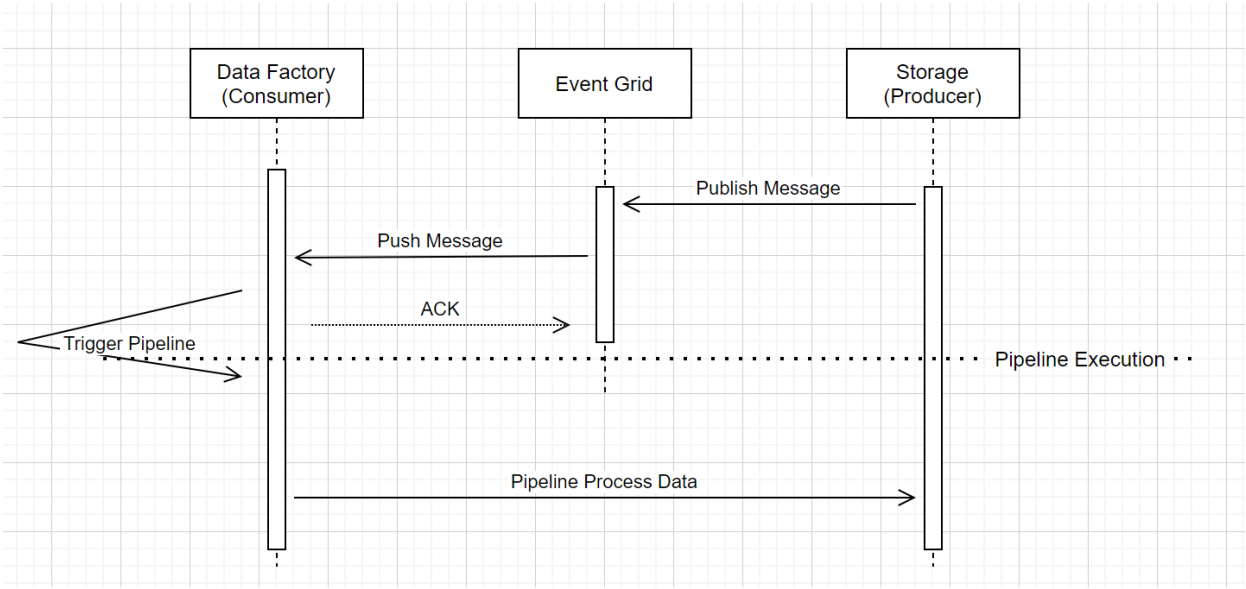
Two noticeable call outs from the work flows:

- Azure Data Factory and Azure Synapse make *no* direct contact with Storage account. Request to create a subscription is instead relayed and processed by Event Grid. Hence, the service needs no permission to Storage account for this step.

- Access control and permission checking happen within the service. Before the service sends a request to subscribe to storage event, it checks the permission for the user. More specifically, it checks whether the Azure account signed in and attempting to create the Storage Event trigger has appropriate access to the relevant storage account. If the permission check fails, trigger creation also fails.

Storage event trigger pipeline run

This high-level work flows describe how Storage event triggers pipeline run through Event Grid. For Azure Synapse the data flow is the same, with Synapse pipelines taking the role of the Data Factory in the diagram below.



There are three noticeable call outs in the workflow related to Event triggering pipelines within the service:

- Event Grid uses a Push model that relays the message as soon as possible when storage drops the message into the system. This is different from messaging system, such as Kafka where a Pull system is used.
- Event Trigger serves as an active listener to the incoming message and it properly triggers the associated pipeline.
- Storage Event Trigger itself makes no direct contact with Storage account
    - That said, if you have a Copy or other activity inside the pipeline to process the data in Storage account, the service will make direct contact with Storage, using the credentials stored in the Linked Service. Ensure that Linked Service is set up appropriately
    - However, if you make no reference to the Storage account in the pipeline, you do not need to grant permission to the service to access Storage account

Next steps

- For detailed information about triggers, see Pipeline execution and triggers.
- Learn how to reference trigger metadata in pipeline, see Reference Trigger Metadata in Pipeline Runs

Create a trigger that runs a pipeline on a schedule

8/19/2022 • 24 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides information about the schedule trigger and the steps to create, start, and monitor a schedule trigger. For other types of triggers, see Pipeline execution and triggers.

When creating a schedule trigger, you specify a schedule (start date, recurrence, end date etc.) for the trigger, and associate with a pipeline. Pipelines and triggers have a many-to-many relationship. Multiple triggers can kick off a single pipeline. A single trigger can kick off multiple pipelines.

The following sections provide steps to create a schedule trigger in different ways.

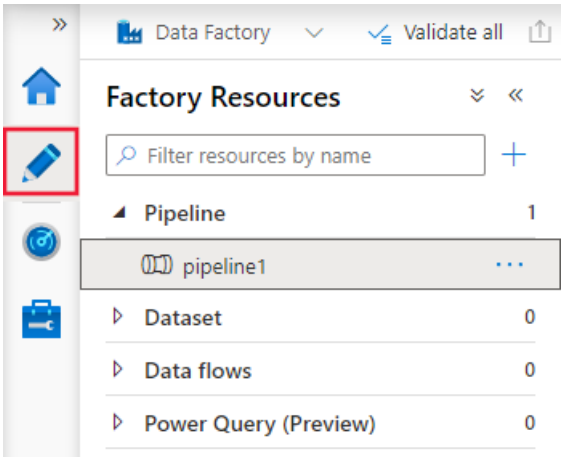
Azure Data Factory and Synapse portal experience

You can create a **schedule trigger** to schedule a pipeline to run periodically (hourly, daily, etc.).

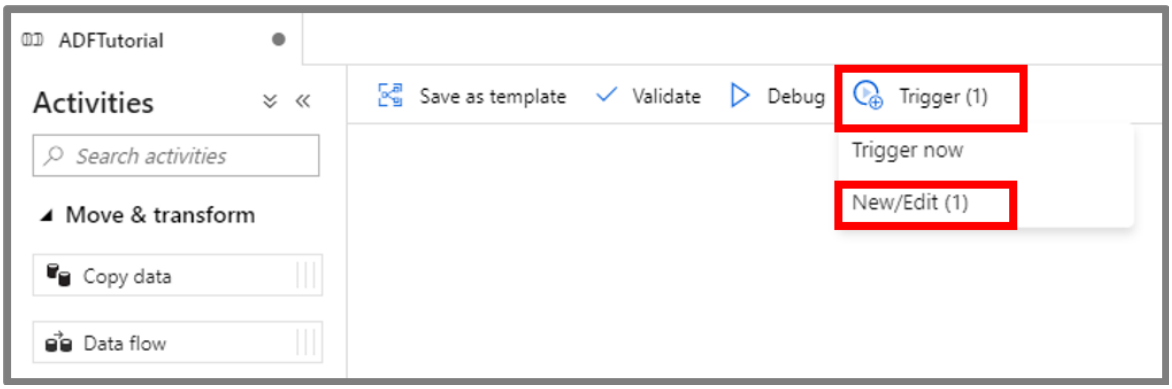
> **NOTE**
> For a complete walkthrough of creating a pipeline and a schedule trigger, which associates the trigger with the pipeline, and runs and monitors the pipeline, see Quickstart: create a data factory using Data Factory UI.

1. Switch to the **Edit** tab in Data Factory or the Integrate tab in Azure Synapse.

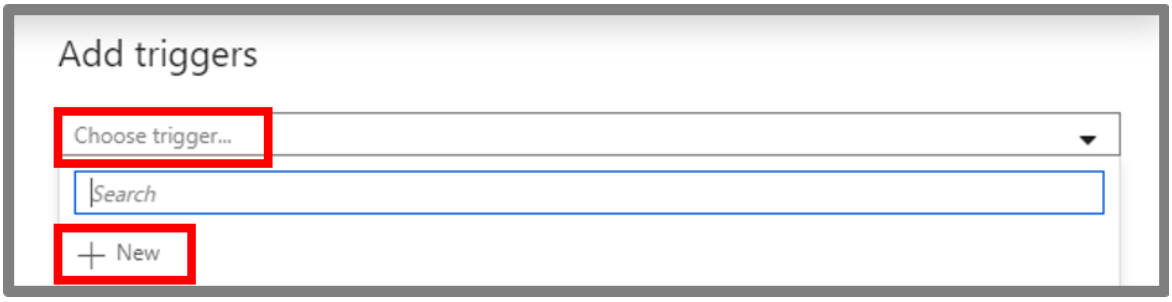
   - Azure Data Factory
   - Azure Synapse



2. Select **Trigger** on the menu, then select **New/Edit**.



3. On the **Add Triggers** page, select **Choose trigger...**, then select **+New**.



4. On the **New Trigger** page, do the following steps:

   a. Confirm that **Schedule** is selected for **Type**.

   b. Specify the start datetime of the trigger for **Start Date**. It's set to the current datetime in Coordinated Universal Time (UTC) by default.

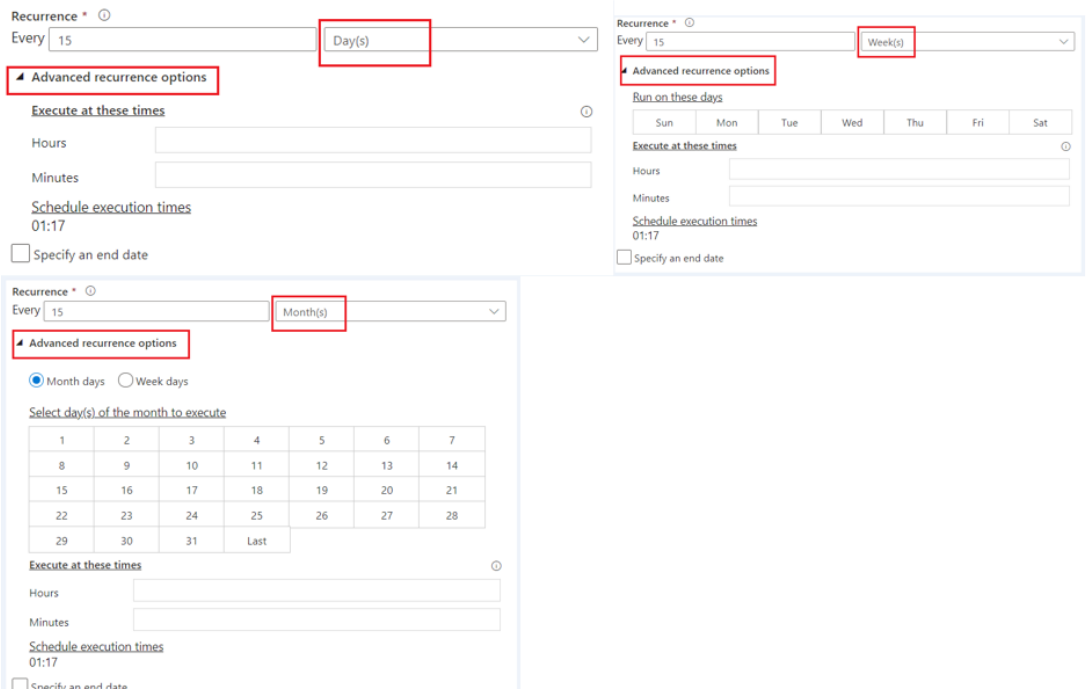
   c. Specify the time zone that the trigger will be created in. The time zone setting will apply to **Start Date**, **End Date**, and **Schedule Execution Times** in Advanced recurrence options. Changing Time Zone setting will not automatically change your start date. Make sure the Start Date is correct in the specified time zone. Please note that Scheduled Execution time of Trigger will be considered post the Start Date (Ensure Start Date is at least 1 minute lesser than the Execution time else it will trigger pipeline in next recurrence).

   > **NOTE**
   > For time zones that observe daylight saving, trigger time will auto-adjust for the twice a year change, if the recurrence is set to *Days* or above. To opt out of the daylight saving change, please select a time zone that does not observe daylight saving, for instance UTC

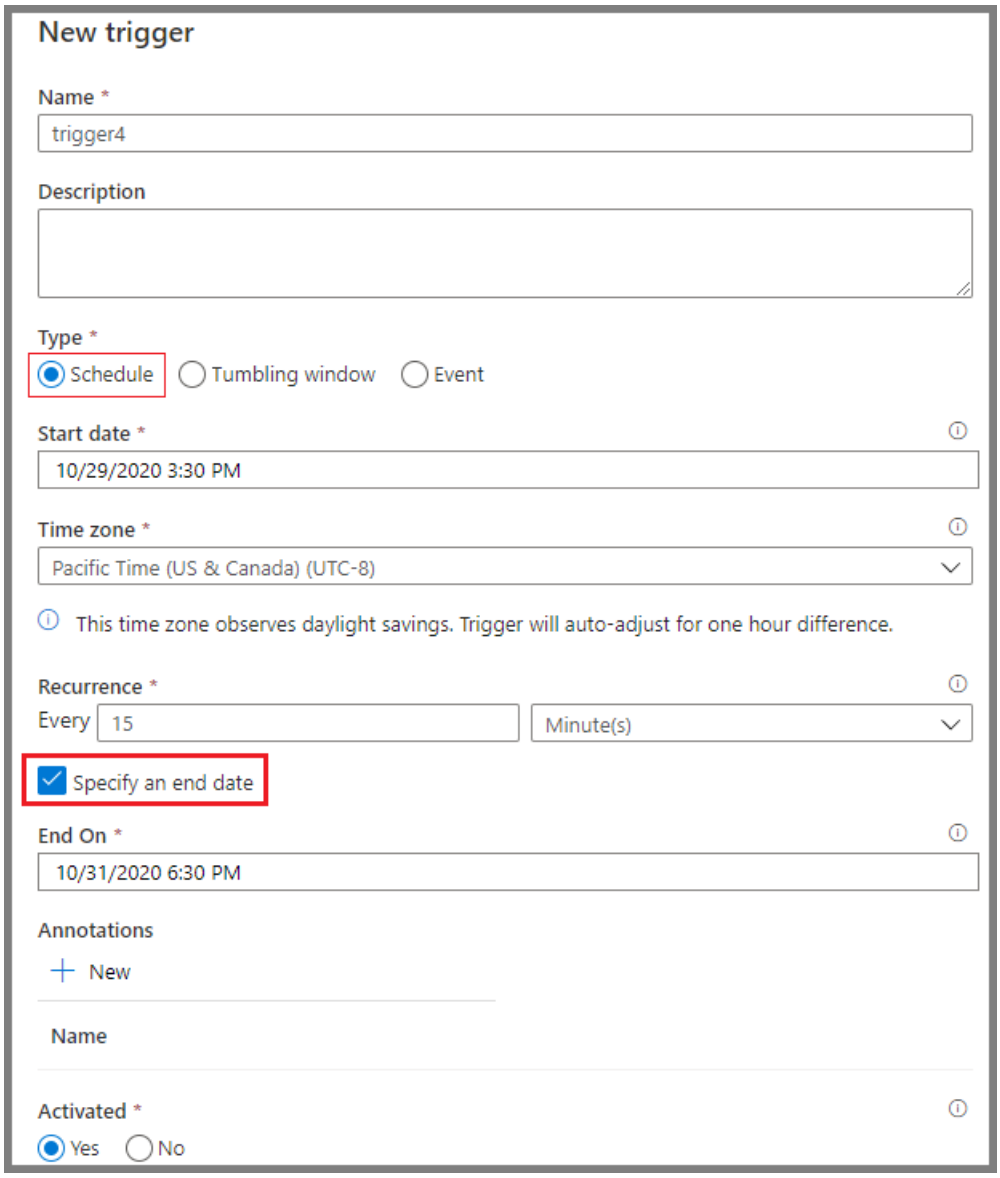
   > **IMPORTANT**
   > Daylight saving adjustment only happens for trigger with recurrence set to *Days* or above. If the trigger is set to *Hours* or *Minutes* frequency, it will continue to fire at regular intervals.

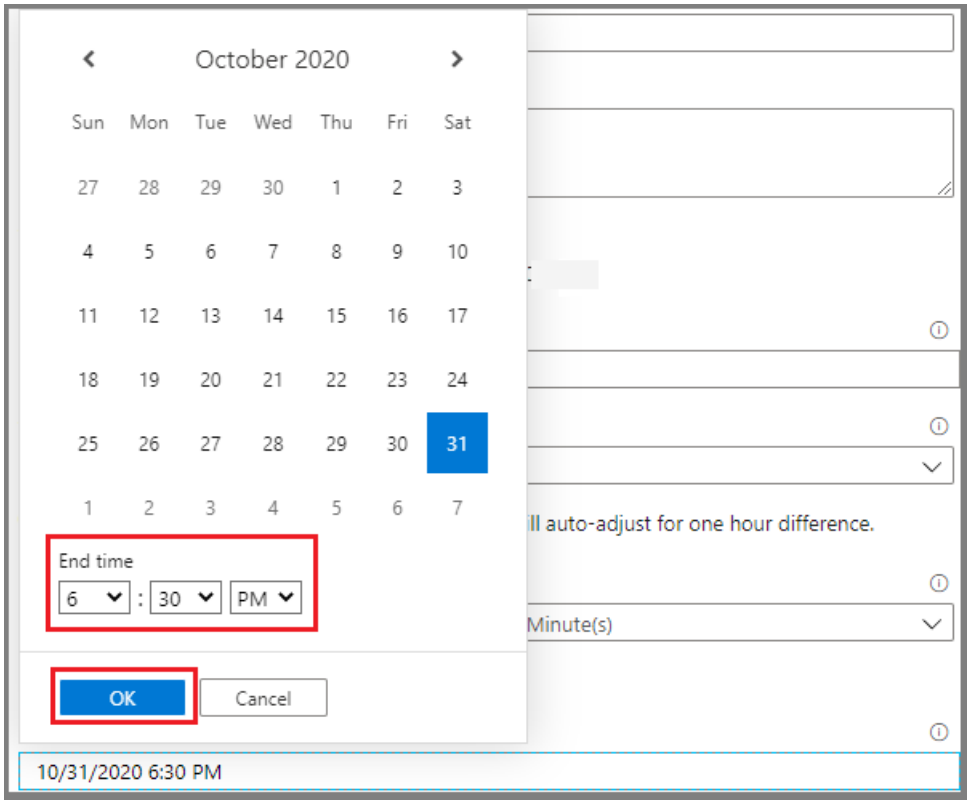
   d. Specify **Recurrence** for the trigger. Select one of the values from the drop-down list (Every minute, Hourly, Daily, Weekly, and Monthly). Enter the multiplier in the text box. For example, if you want the trigger to run once for every 15 minutes, you select **Every Minute**, and enter **15** in the text box.

   e. In the **Recurrence**, if you choose "Day(s), Week(s) or Month(s)" from the drop-down, you can find "Advanced recurrence options".



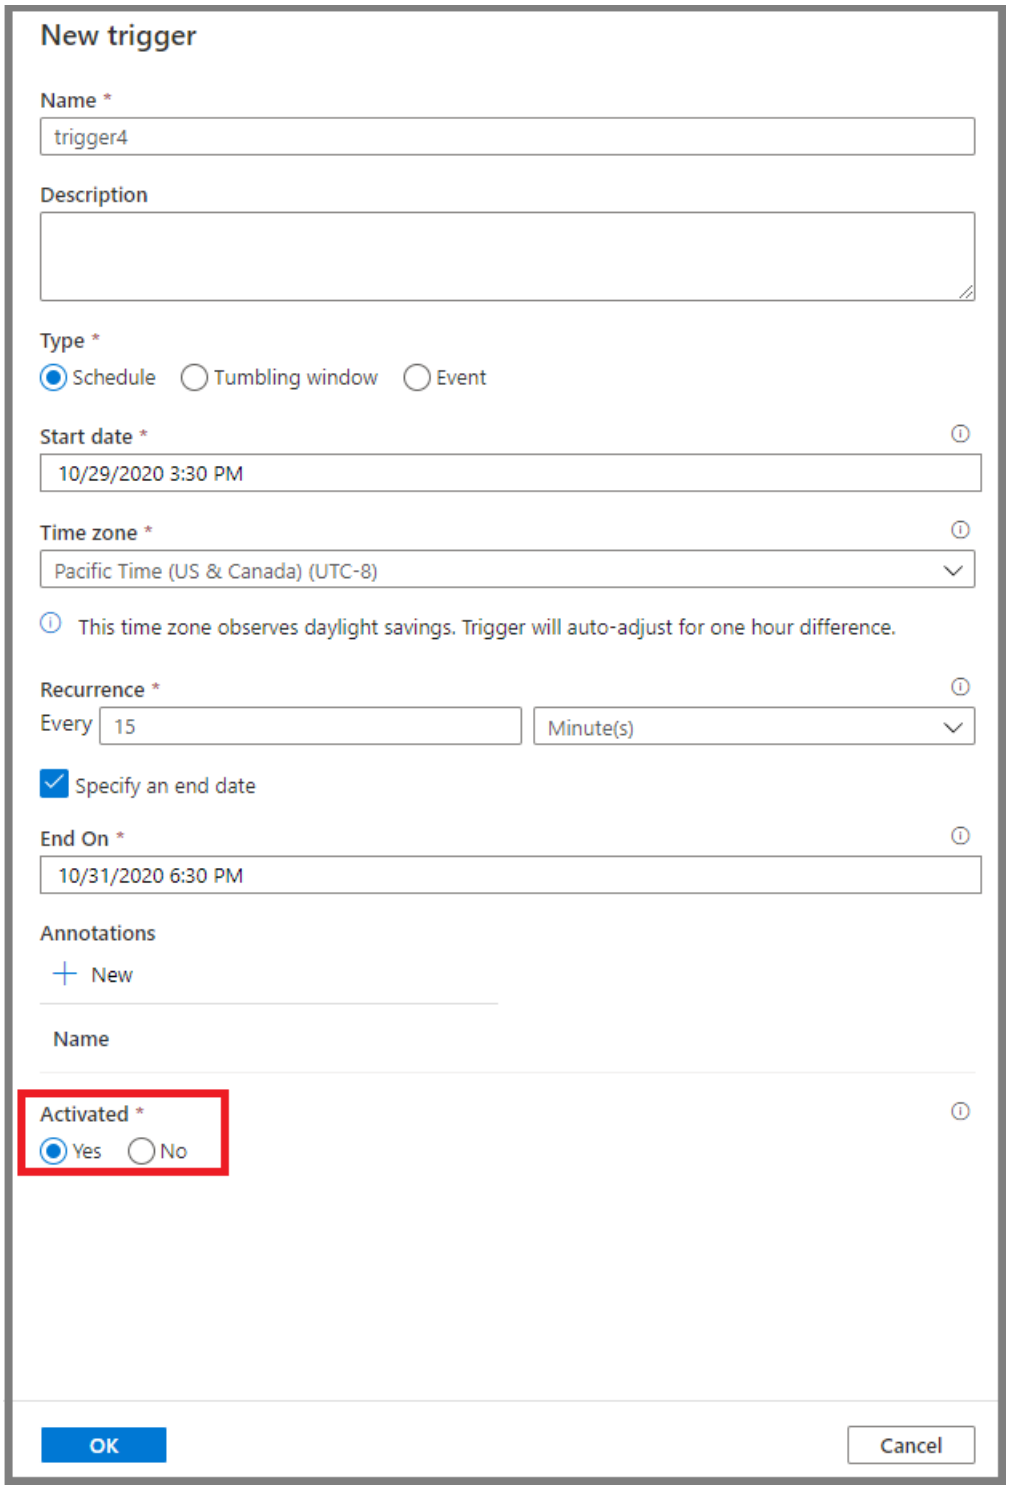
f. To specify an end date time, select **Specify an End Date**, and specify *Ends On*, then select **OK**. There is a cost associated with each pipeline run. If you are testing, you may want to ensure that the pipeline is triggered only a couple of times. However, ensure that there is enough time for the pipeline to run between the publish time and the end time. The trigger comes into effect only after you publish the solution, not when you save the trigger in the UI.



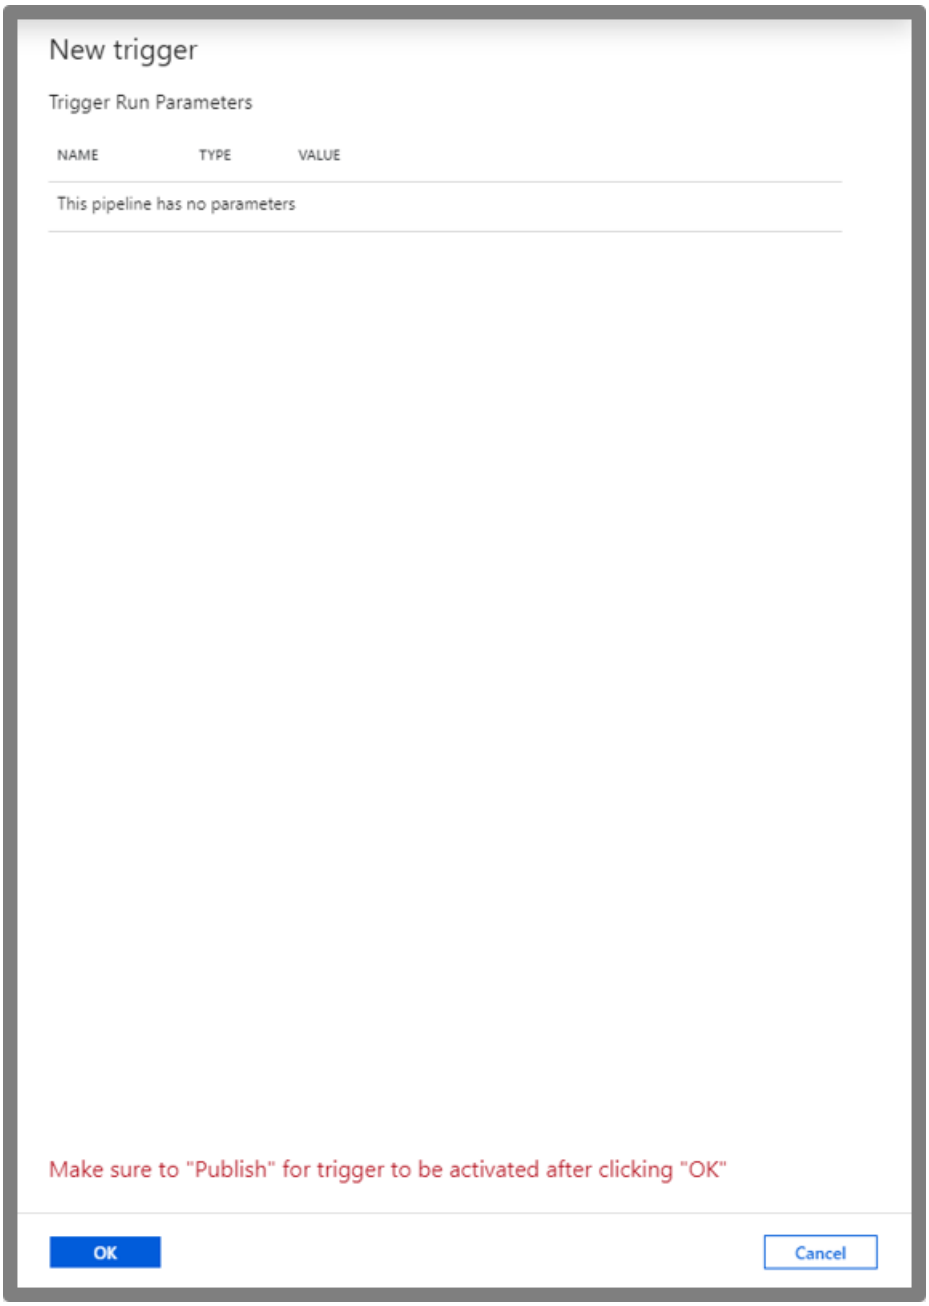


5. In the **New Trigger** window, select **Yes** in the **Activated** option, then select **OK**. You can use this

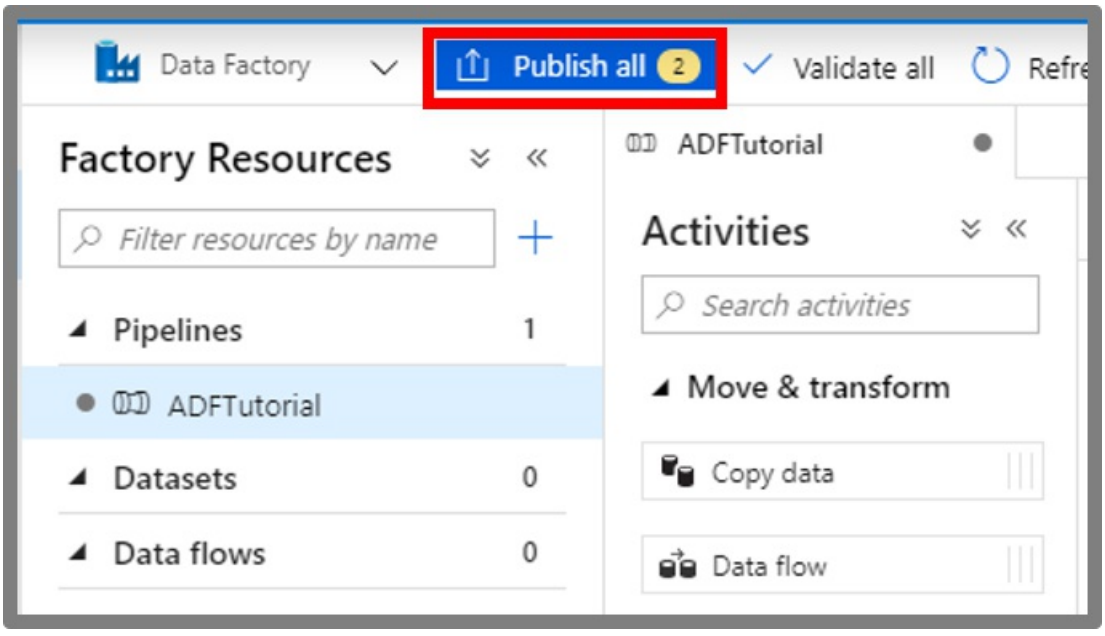
checkbox to deactivate the trigger later.



6. In the **New Trigger** window, review the warning message, then select **OK**.

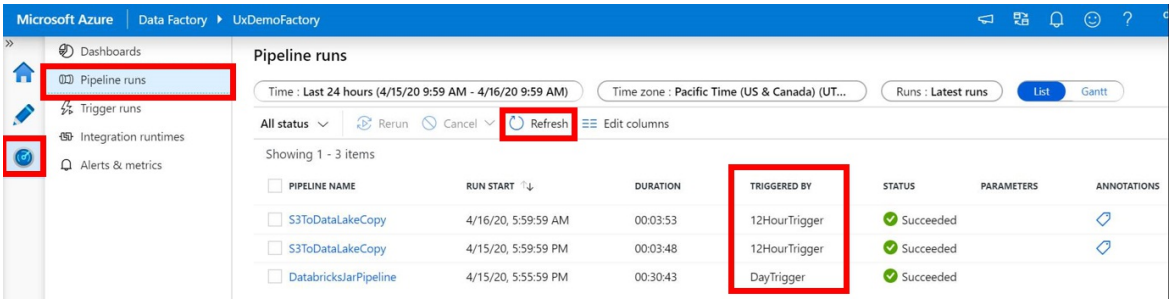


7. Select **Publish all** to publish the changes. Until you publish the changes, the trigger doesn't start triggering the pipeline runs.



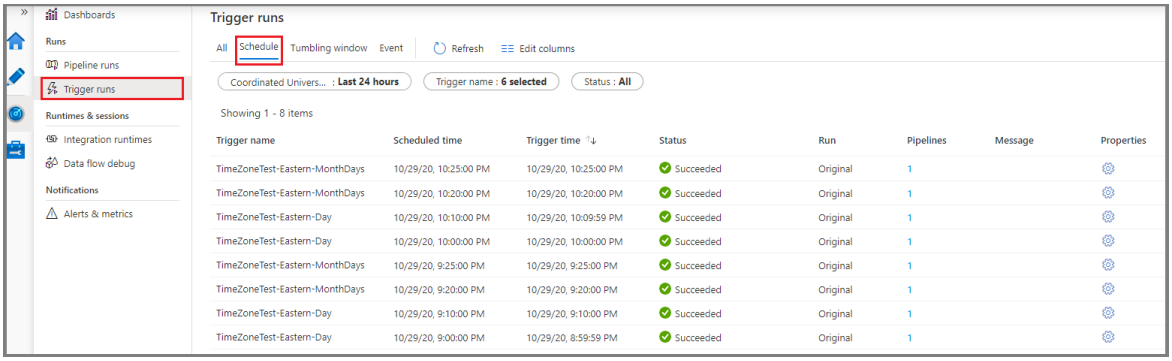
8. Switch to the **Pipeline runs** tab on the left, then select **Refresh** to refresh the list. You will see the pipeline runs triggered by the scheduled trigger. Notice the values in the **Triggered By** column. If you use the **Trigger Now** option, you will see the manual trigger run in the list.

   - Azure Data Factory
   - Azure Synapse



9. Switch to the **Trigger Runs \ Schedule** view.

   - Azure Data Factory
   - Azure Synapse



Azure PowerShell

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

This section shows you how to use Azure PowerShell to create, start, and monitor a schedule trigger. To see this sample working, first go through the Quickstart: Create a data factory by using Azure PowerShell. Then, add the following code to the main method, which creates and starts a schedule trigger that runs every 15 minutes. The trigger is associated with a pipeline named **Adfv2QuickStartPipeline** that you create as part of the Quickstart.

Prerequisites

- **Azure subscription**. If you don't have an Azure subscription, create a free account before you begin.
- **Azure PowerShell**. Follow the instructions in Install Azure PowerShell on Windows with PowerShellGet.

Sample Code

1. Create a JSON file named **MyTrigger.json** in the C:\ADFv2QuickStartPSH\ folder with the following content:

> **IMPORTANT**
>
> Before you save the JSON file, set the value of the **startTime** element to the current UTC time. Set the value of the **endTime** element to one hour past the current UTC time.

```
{
    "properties": {
        "name": "MyTrigger",
        "type": "ScheduleTrigger",
        "typeProperties": {
            "recurrence": {
                "frequency": "Minute",
                "interval": 15,
                "startTime": "2017-12-08T00:00:00Z",
                "endTime": "2017-12-08T01:00:00Z",
                "timeZone": "UTC"
            }
        },
        "pipelines": [{
                "pipelineReference": {
                    "type": "PipelineReference",
                    "referenceName": "Adfv2QuickStartPipeline"
                },
                "parameters": {
                    "inputPath": "adftutorial/input",
                    "outputPath": "adftutorial/output"
                }
            }
        ]
    }
}
```

In the JSON snippet:

- The **type** element of the trigger is set to "ScheduleTrigger".
- The **frequency** element is set to "Minute" and the **interval** element is set to 15. As such, the trigger runs the pipeline every 15 minutes between the start and end times.
- The **timeZone** element specifies the time zone that the trigger is created in. This setting affects both **startTime** and **endTime**.
- The **endTime** element is one hour after the value of the **startTime** element. As such, the trigger runs the pipeline 15 minutes, 30 minutes, and 45 minutes after the start time. Don't forget to update the start time to the current UTC time, and the end time to one hour past the start time.

  > **IMPORTANT**
  >
  > For UTC timezone, the startTime and endTime need to follow format 'yyyy-MM-ddTHH:mm:ssZ', while for other timezones, startTime and endTime follow 'yyyy-MM-ddTHH:mm:ss'.
  >
  > Per ISO 8601 standard, the *Z* suffix to timestamp mark the datetime to UTC timezone, and render timeZone field useless. While missing *Z* suffix for UTC time zone will result in an error upon trigger *activation*.

- The trigger is associated with the **Adfv2QuickStartPipeline** pipeline. To associate multiple pipelines with a trigger, add more **pipelineReference** sections.
- The pipeline in the Quickstart takes two **parameters** values: **inputPath** and **outputPath**. And you

pass values for these parameters from the trigger.

2. Create a trigger by using the Set-AzDataFactoryV2Trigger cmdlet:

```
Set-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
Name "MyTrigger" -DefinitionFile "C:\ADFv2QuickStartPSH\MyTrigger.json"
```

3. Confirm that the status of the trigger is **Stopped** by using the Get-AzDataFactoryV2Trigger cmdlet:

```
Get-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
Name "MyTrigger"
```

4. Start the trigger by using the Start-AzDataFactoryV2Trigger cmdlet:

```
Start-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName
-Name "MyTrigger"
```

5. Confirm that the status of the trigger is **Started** by using the Get-AzDataFactoryV2Trigger cmdlet:

```
Get-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
Name "MyTrigger"
```

6. Get the trigger runs in Azure PowerShell by using the Get-AzDataFactoryV2TriggerRun cmdlet. To get the information about the trigger runs, execute the following command periodically. Update the **TriggerRunStartedAfter** and **TriggerRunStartedBefore** values to match the values in your trigger definition:

```
Get-AzDataFactoryV2TriggerRun -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName
-TriggerName "MyTrigger" -TriggerRunStartedAfter "2017-12-08T00:00:00" -TriggerRunStartedBefore
"2017-12-08T01:00:00"
```

> **NOTE**
> Trigger time of Schedule triggers are specified in UTC timestamp. *TriggerRunStartedAfter* and *TriggerRunStartedBefore* also expects UTC timestamp

To monitor the trigger runs and pipeline runs in the Azure portal, see Monitor pipeline runs.

Azure CLI

This section shows you how to use Azure CLI to create, start, and monitor a schedule trigger. To see this sample working, first go through the Quickstart: Create an Azure Data Factory using Azure CLI. Then, follow the steps below to create and start a schedule trigger that runs every 15 minutes. The trigger is associated with a pipeline named **Adfv2QuickStartPipeline** that you create as part of the Quickstart.

Prerequisites

- Use the Bash environment in Azure Cloud Shell. For more information, see Azure Cloud Shell Quickstart - Bash.

  Launch Cloud Shell

- If you prefer to run CLI reference commands locally, install the Azure CLI. If you're running on Windows

or macOS, consider running Azure CLI in a Docker container. For more information, see How to run the Azure CLI in a Docker container.

- If you're using a local installation, sign in to the Azure CLI by using the az login command. To finish the authentication process, follow the steps displayed in your terminal. For other sign-in options, see Sign in with the Azure CLI.
- When you're prompted, install the Azure CLI extension on first use. For more information about extensions, see Use extensions with the Azure CLI.
- Run az version to find the version and dependent libraries that are installed. To upgrade to the latest version, run az upgrade.

Sample Code

1. In your working directory, create a JSON file named **MyTrigger.json** with the trigger's properties. For this example use the following content:

> **IMPORTANT**
> Before you save the JSON file, set the value of the **startTime** element to the current UTC time. Set the value of the **endTime** element to one hour past the current UTC time.

```
{
    "name": "MyTrigger",
    "type": "ScheduleTrigger",
    "typeProperties": {
        "recurrence": {
            "frequency": "Minute",
            "interval": 15,
            "startTime": "2017-12-08T00:00:00Z",
            "endTime": "2017-12-08T01:00:00Z",
            "timeZone": "UTC"
        }
    },
    "pipelines": [{
            "pipelineReference": {
                "type": "PipelineReference",
                "referenceName": "Adfv2QuickStartPipeline"
            },
            "parameters": {
                "inputPath": "adftutorial/input",
                "outputPath": "adftutorial/output"
            }
        }
    ]
}
```

In the JSON snippet:

- The **type** element of the trigger is set to "ScheduleTrigger".
- The **frequency** element is set to "Minute" and the **interval** element is set to 15. As such, the trigger runs the pipeline every 15 minutes between the start and end times.
- The **timeZone** element specifies the time zone that the trigger is created in. This setting affects both **startTime** and **endTime**.
- The **endTime** element is one hour after the value of the **startTime** element. As such, the trigger runs the pipeline 15 minutes, 30 minutes, and 45 minutes after the start time. Don't forget to update the start time to the current UTC time, and the end time to one hour past the start time.

> **IMPORTANT**
>
> For UTC timezone, the startTime and endTime need to follow format 'yyyy-MM-ddTHH:mm:ssZ', while for other timezones, startTime and endTime follow 'yyyy-MM-ddTHH:mm:ss'.
>
> Per ISO 8601 standard, the *Z* suffix to timestamp mark the datetime to UTC timezone, and render timeZone field useless. While missing *Z* suffix for UTC time zone will result in an error upon trigger *activation*.

- The trigger is associated with the **Adfv2QuickStartPipeline** pipeline. To associate multiple pipelines with a trigger, add more **pipelineReference** sections.
- The pipeline in the Quickstart takes two **parameters** values: **inputPath** and **outputPath**. And you pass values for these parameters from the trigger.

2. Create a trigger by using the az datafactory trigger create command:

```
az datafactory trigger create --resource-group "ADFQuickStartRG" --factory-name "ADFTutorialFactory"
--name "MyTrigger" --properties @MyTrigger.json
```

3. Confirm that the status of the trigger is **Stopped** by using the az datafactory trigger show command:

```
az datafactory trigger show --resource-group "ADFQuickStartRG" --factory-name "ADFTutorialFactory" --
name "MyTrigger"
```

4. Start the trigger by using the az datafactory trigger start command:

```
az datafactory trigger start --resource-group "ADFQuickStartRG" --factory-name "ADFTutorialFactory" -
-name "MyTrigger"
```

5. Confirm that the status of the trigger is **Started** by using the az datafactory trigger show command:

```
az datafactory trigger show --resource-group "ADFQuickStartRG" --factory-name "ADFTutorialFactory" --
name "MyTrigger"
```

6. Get the trigger runs in Azure CLI by using the az datafactory trigger-run query-by-factory command. To get information about the trigger runs, execute the following command periodically. Update the **last-updated-after** and **last-updated-before** values to match the values in your trigger definition:

```
az datafactory trigger-run query-by-factory --resource-group "ADFQuickStartRG" --factory-name
"ADFTutorialFactory" --filters operand="TriggerName" operator="Equals" values="MyTrigger" --last-
updated-after "2017-12-08T00:00:00" --last-updated-before "2017-12-08T01:00:00"
```

> **NOTE**
>
> Trigger time of Schedule triggers are specified in UTC timestamp. *last-updated-after* and *last-updated-before* also expects UTC timestamp

To monitor the trigger runs and pipeline runs in the Azure portal, see Monitor pipeline runs.

.NET SDK

This section shows you how to use the .NET SDK to create, start, and monitor a trigger. To see this sample working, first go through the Quickstart: Create a data factory by using the .NET SDK. Then, add the following code to the main method, which creates and starts a schedule trigger that runs every 15 minutes. The trigger is associated with a pipeline named **Adfv2QuickStartPipeline** that you create as part of the Quickstart.

To create and start a schedule trigger that runs every 15 minutes, add the following code to the main method:

```
            // Create the trigger
            Console.WriteLine("Creating the trigger");

            // Set the start time to the current UTC time
            DateTime startTime = DateTime.UtcNow;

            // Specify values for the inputPath and outputPath parameters
            Dictionary<string, object> pipelineParameters = new Dictionary<string, object>();
            pipelineParameters.Add("inputPath", "adftutorial/input");
            pipelineParameters.Add("outputPath", "adftutorial/output");

            // Create a schedule trigger
            string triggerName = "MyTrigger";
            ScheduleTrigger myTrigger = new ScheduleTrigger()
            {
                Pipelines = new List<TriggerPipelineReference>()
                {
                    // Associate the Adfv2QuickStartPipeline pipeline with the trigger
                    new TriggerPipelineReference()
                    {
                        PipelineReference = new PipelineReference(pipelineName),
                        Parameters = pipelineParameters,
                    }
                },
                Recurrence = new ScheduleTriggerRecurrence()
                {
                    // Set the start time to the current UTC time and the end time to one hour after the
start time
                    StartTime = startTime,
                    TimeZone = "UTC",
                    EndTime = startTime.AddHours(1),
                    Frequency = RecurrenceFrequency.Minute,
                    Interval = 15,
                }
            };

            // Now, create the trigger by invoking the CreateOrUpdate method
            TriggerResource triggerResource = new TriggerResource()
            {
                Properties = myTrigger
            };
            client.Triggers.CreateOrUpdate(resourceGroup, dataFactoryName, triggerName, triggerResource);

            // Start the trigger
            Console.WriteLine("Starting the trigger");
            client.Triggers.Start(resourceGroup, dataFactoryName, triggerName);
```

To create triggers in a different time zone, other than UTC, following settings are required:

```
<<ClientInstance>>.SerializationSettings.DateFormatHandling =
Newtonsoft.Json.DateFormatHandling.IsoDateFormat;
<<ClientInstance>>.SerializationSettings.DateTimeZoneHandling =
Newtonsoft.Json.DateTimeZoneHandling.Unspecified;
<<ClientInstance>>.SerializationSettings.DateParseHandling = DateParseHandling.None;
<<ClientInstance>>.DeserializationSettings.DateParseHandling = DateParseHandling.None;
<<ClientInstance>>.DeserializationSettings.DateFormatHandling =
Newtonsoft.Json.DateFormatHandling.IsoDateFormat;
<<ClientInstance>>.DeserializationSettings.DateTimeZoneHandling =
Newtonsoft.Json.DateTimeZoneHandling.Unspecified;
```

To monitor a trigger run, add the following code before the last `Console.WriteLine` statement in the sample:

```
            // Check that the trigger runs every 15 minutes
            Console.WriteLine("Trigger runs. You see the output every 15 minutes");

            for (int i = 0; i < 3; i++)
            {
                System.Threading.Thread.Sleep(TimeSpan.FromMinutes(15));
                List<TriggerRun> triggerRuns = client.Triggers.ListRuns(resourceGroup, dataFactoryName,
triggerName, DateTime.UtcNow.AddMinutes(-15 * (i + 1)), DateTime.UtcNow.AddMinutes(2)).ToList();
                Console.WriteLine("{0} trigger runs found", triggerRuns.Count);

                foreach (TriggerRun run in triggerRuns)
                {
                    foreach (KeyValuePair<string, string> triggeredPipeline in run.TriggeredPipelines)
                    {
                        PipelineRun triggeredPipelineRun = client.PipelineRuns.Get(resourceGroup,
dataFactoryName, triggeredPipeline.Value);
                        Console.WriteLine("Pipeline run ID: {0}, Status: {1}", triggeredPipelineRun.RunId,
triggeredPipelineRun.Status);
                        List<ActivityRun> runs = client.ActivityRuns.ListByPipelineRun(resourceGroup,
dataFactoryName, triggeredPipelineRun.RunId, run.TriggerRunTimestamp.Value,
run.TriggerRunTimestamp.Value.AddMinutes(20)).ToList();
                    }
                }
            }
```

To monitor the trigger runs and pipeline runs in the Azure portal, see Monitor pipeline runs.

Python SDK

This section shows you how to use the Python SDK to create, start, and monitor a trigger. To see this sample working, first go through the Quickstart: Create a data factory by using the Python SDK. Then, add the following code block after the "monitor the pipeline run" code block in the Python script. This code creates a schedule trigger that runs every 15 minutes between the specified start and end times. Update the **start_time** variable to the current UTC time, and the **end_time** variable to one hour past the current UTC time.

```
    # Create a trigger
    tr_name = 'mytrigger'
    scheduler_recurrence = ScheduleTriggerRecurrence(frequency='Minute', interval='15',start_time='2017-12-
12T04:00:00Z', end_time='2017-12-12T05:00:00Z', time_zone='UTC')
    pipeline_parameters = {'inputPath':'adftutorial/input', 'outputPath':'adftutorial/output'}
    pipelines_to_run = []
    pipeline_reference = PipelineReference('copyPipeline')
    pipelines_to_run.append(TriggerPipelineReference(pipeline_reference, pipeline_parameters))
    tr_properties = TriggerResource(properties=ScheduleTrigger(description='My scheduler trigger', pipelines
= pipelines_to_run, recurrence=scheduler_recurrence))
    adf_client.triggers.create_or_update(rg_name, df_name, tr_name, tr_properties)

    # Start the trigger
    adf_client.triggers.start(rg_name, df_name, tr_name)
```

To monitor the trigger runs and pipeline runs in the Azure portal, see Monitor pipeline runs.

Azure Resource Manager template

You can use an Azure Resource Manager template to create a trigger. For step-by-step instructions, see Create an Azure data factory by using a Resource Manager template.

Pass the trigger start time to a pipeline

Azure Data Factory version 1 supports reading or writing partitioned data by using the system variables: **SliceStart**, **SliceEnd**, **WindowStart**, and **WindowEnd**. In the current version of Azure Data Factory and Synapse pipelines, you can achieve this behavior by using a pipeline parameter. The start time and scheduled time for the trigger are set as the value for the pipeline parameter. In the following example, the scheduled time for the trigger is passed as a value to the pipeline **scheduledRunTime** parameter:

```
"parameters": {
    "scheduledRunTime": "@trigger().scheduledTime"
}
```

JSON schema

The following JSON definition shows you how to create a schedule trigger with scheduling and recurrence:

```
{
  "properties": {
    "type": "ScheduleTrigger",
    "typeProperties": {
      "recurrence": {
        "frequency": <<Minute, Hour, Day, Week, Month>>,
        "interval": <<int>>,             // Optional, specifies how often to fire (default to 1)
        "startTime": <<datetime>>,
        "endTime": <<datetime - optional>>,
        "timeZone": "UTC"
        "schedule": {                    // Optional (advanced scheduling specifics)
          "hours": [<<0-23>>],
          "weekDays": [<<Monday-Sunday>>],
          "minutes": [<<0-59>>],
          "monthDays": [<<1-31>>],
          "monthlyOccurrences": [
               {
                    "day": <<Monday-Sunday>>,
                    "occurrence": <<1-5>>
               }
           ]
        }
      }
    },
   "pipelines": [
           {
               "pipelineReference": {
                   "type": "PipelineReference",
                   "referenceName": "<Name of your pipeline>"
               },
               "parameters": {
                   "<parameter 1 Name>": {
                       "type": "Expression",
                       "value": "<parameter 1 Value>"
                   },
                   "<parameter 2 Name>" : "<parameter 2 Value>"
               }
           }
      ]
  }
}
```

IMPORTANT

The **parameters** property is a mandatory property of the **pipelines** element. If your pipeline doesn't take any parameters, you must include an empty JSON definition for the **parameters** property.

Schema overview

The following table provides a high-level overview of the major schema elements that are related to recurrence and scheduling of a trigger:

JSON PROPERTY	DESCRIPTION
startTime	A Date-Time value. For simple schedules, the value of the **startTime** property applies to the first occurrence. For complex schedules, the trigger starts no sooner than the specified **startTime** value. For UTC time zone, format is `'yyyy-MM-ddTHH:mm:ssZ'`, for other time zone, format is `'yyyy-MM-ddTHH:mm:ss'`.

JSON PROPERTY	DESCRIPTION
endTime	The end date and time for the trigger. The trigger doesn't execute after the specified end date and time. The value for the property can't be in the past. This property is optional. For UTC time zone, format is `'yyyy-MM-ddTHH:mm:ssZ'`, for other time zone, format is `'yyyy-MM-ddTHH:mm:ss'`.
timeZone	The time zone the trigger is created in. This setting affects **startTime**, **endTime**, and **schedule**. See list of supported time zone
recurrence	A recurrence object that specifies the recurrence rules for the trigger. The recurrence object supports the **frequency**, **interval**, **endTime**, **count**, and **schedule** elements. When a recurrence object is defined, the **frequency** element is required. The other elements of the recurrence object are optional.
frequency	The unit of frequency at which the trigger recurs. The supported values include "minute," "hour," "day," "week," and "month."
interval	A positive integer that denotes the interval for the **frequency** value, which determines how often the trigger runs. For example, if the **interval** is 3 and the **frequency** is "week," the trigger recurs every 3 weeks.
schedule	The recurrence schedule for the trigger. A trigger with a specified **frequency** value alters its recurrence based on a recurrence schedule. The **schedule** property contains modifications for the recurrence that are based on minutes, hours, weekdays, month days, and week number.

IMPORTANT

For UTC timezone, the startTime and endTime need to follow format 'yyyy-MM-ddTHH:mm:ssZ', while for other timezones, startTime and endTime follow 'yyyy-MM-ddTHH:mm:ss'.

Per ISO 8601 standard, the *Z* suffix to timestamp mark the datetime to UTC timezone, and render timeZone field useless. While missing *Z* suffix for UTC time zone will result in an error upon trigger *activation*.

Schema defaults, limits, and examples

JSON PROPERTY	TYPE	REQUIRED	DEFAULT VALUE	VALID VALUES	EXAMPLE
startTime	String	Yes	None	ISO-8601 Date-Times	for UTC time zone `"startTime" : "2013-01-09T09:30:00-08:00Z"` for other time zone `"2013-01-09T09:30:00-08:00"`

JSON PROPERTY	TYPE	REQUIRED	DEFAULT VALUE	VALID VALUES	EXAMPLE
timeZone	String	Yes	None	Time Zone Values	`"UTC"`
recurrence	Object	Yes	None	Recurrence object	`"recurrence" : { "frequency" : "monthly", "interval" : 1 }`
interval	Number	No	1	1 to 1,000	`"interval":10`
endTime	String	Yes	None	A Date-Time value that represents a time in the future.	for UTC time zone `"endTime" : "2013-02-09T09:30:00-08:00Z"` for other time zone `"endTime" : "2013-02-09T09:30:00-08:00"`
schedule	Object	No	None	Schedule object	`"schedule" : { "minute" : [30], "hour" : [8,17] }`

Time zone option

Here are some of time zones supported for Schedule triggers:

TIME ZONE	UTC OFFSET (NON-DAYLIGHT SAVING)	TIMEZONE VALUE	OBSERVE DAYLIGHT SAVING	TIME STAMP FORMAT
Coordinated Universal Time	0	`UTC`	No	`'yyyy-MM-ddTHH:mm:ssZ'`
Pacific Time (PT)	-8	`Pacific Standard Time`	Yes	`'yyyy-MM-ddTHH:mm:ss'`
Central Time (CT)	-6	`Central Standard Time`	Yes	`'yyyy-MM-ddTHH:mm:ss'`
Eastern Time (ET)	-5	`Eastern Standard Time`	Yes	`'yyyy-MM-ddTHH:mm:ss'`
Greenwich Mean Time (GMT)	0	`GMT Standard Time`	Yes	`'yyyy-MM-ddTHH:mm:ss'`
Central European Standard Time	+1	`W. Europe Standard Time`	Yes	`'yyyy-MM-ddTHH:mm:ss'`
India Standard Time (IST)	+5:30	`India Standard Time`	No	`'yyyy-MM-ddTHH:mm:ss'`

TIME ZONE	UTC OFFSET (NON-DAYLIGHT SAVING)	TIMEZONE VALUE	OBSERVE DAYLIGHT SAVING	TIME STAMP FORMAT
China Standard Time	+8	`China Standard Time`	No	`'yyyy-MM-ddTHH:mm:ss'`

This list is incomplete. For complete list of time zone options, explore in the portal Trigger creation page

startTime property

The following table shows you how the **startTime** property controls a trigger run:

STARTTIME VALUE	RECURRENCE WITHOUT SCHEDULE	RECURRENCE WITH SCHEDULE
Start time in past	Calculates the first future execution time after the start time and runs at that time. Runs subsequent executions based on calculating from the last execution time. See the example that follows this table.	The trigger starts *no sooner than* the specified start time. The first occurrence is based on the schedule that's calculated from the start time. Runs subsequent executions based on the recurrence schedule.
Start time in future or at present	Runs once at the specified start time. Runs subsequent executions based on calculating from the last execution time.	The trigger starts *no sooner* than the specified start time. The first occurrence is based on the schedule that's calculated from the start time. Runs subsequent executions based on the recurrence schedule.

Let's see an example of what happens when the start time is in the past, with a recurrence, but no schedule. Assume that the current time is `2017-04-08 13:00`, the start time is `2017-04-07 14:00`, and the recurrence is every two days. (The **recurrence** value is defined by setting the **frequency** property to "day" and the **interval** property to 2.) Notice that the **startTime** value is in the past and occurs before the current time.

Under these conditions, the first execution is at `2017-04-09` at `14:00`. The Scheduler engine calculates execution occurrences from the start time. Any instances in the past are discarded. The engine uses the next instance that occurs in the future. In this scenario, the start time is `2017-04-07` at `2:00pm`, so the next instance is two days from that time, which is `2017-04-09` at `2:00pm`.

The first execution time is the same even if the **startTime** value is `2017-04-05 14:00` or `2017-04-01 14:00`. After the first execution, subsequent executions are calculated by using the schedule. Therefore, the subsequent executions are at `2017-04-11` at `2:00pm`, then `2017-04-13` at `2:00pm`, then `2017-04-15` at `2:00pm`, and so on.

Finally, when the hours or minutes aren't set in the schedule for a trigger, the hours or minutes of the first execution are used as the defaults.

schedule property

On one hand, the use of a schedule can limit the number of trigger executions. For example, if a trigger with a monthly frequency is scheduled to run only on day 31, the trigger runs only in those months that have a 31st day.

Whereas, a schedule can also expand the number of trigger executions. For example, a trigger with a monthly frequency that's scheduled to run on month days 1 and 2, runs on the 1st and 2nd days of the month, rather than once a month.

If multiple **schedule** elements are specified, the order of evaluation is from the largest to the smallest schedule

setting. The evaluation starts with week number, and then month day, weekday, hour, and finally, minute.

The following table describes the **schedule** elements in detail:

JSON ELEMENT	DESCRIPTION	VALID VALUES
minutes	Minutes of the hour at which the trigger runs.	• Integer • Array of integers
hours	Hours of the day at which the trigger runs.	• Integer • Array of integers
weekDays	Days of the week on which the trigger runs. The value can be specified with a weekly frequency only.	• Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, Sunday • Array of day values (maximum array size is 7) • Day values are not case-sensitive
monthlyOccurrences	Days of the month on which the trigger runs. The value can be specified with a monthly frequency only.	• Array of **monthlyOccurrence** objects: `{ "day": day, "occurrence": occurrence }`. • The **day** attribute is the day of the week on which the trigger runs. For example, a **monthlyOccurrences** property with a **day** value of `{Sunday}` means every Sunday of the month. The **day** attribute is required. • The **occurrence** attribute is the occurrence of the specified **day** during the month. For example, a **monthlyOccurrences** property with **day** and **occurrence** values of `{Sunday, -1}` means the last Sunday of the month. The **occurrence** attribute is optional.
monthDays	Day of the month on which the trigger runs. The value can be specified with a monthly frequency only.	• Any value <= -1 and >= -31 • Any value >= 1 and <= 31 • Array of values

Examples of trigger recurrence schedules

This section provides examples of recurrence schedules and focuses on the **schedule** object and its elements.

The examples assume that the **interval** value is 1, and that the **frequency** value is correct according to the schedule definition. For example, you can't have a **frequency** value of "day" and also have a "monthDays" modification in the **schedule** object. Restrictions such as these are mentioned in the table in the previous

section.

EXAMPLE	DESCRIPTION
`{"hours":[5]}`	Run at 5:00 AM every day.
`{"minutes":[15], "hours":[5]}`	Run at 5:15 AM every day.
`{"minutes":[15], "hours":[5,17]}`	Run at 5:15 AM and 5:15 PM every day.
`{"minutes":[15,45], "hours":[5,17]}`	Run at 5:15 AM, 5:45 AM, 5:15 PM, and 5:45 PM every day.
`{"minutes":[0,15,30,45]}`	Run every 15 minutes.
`{hours":[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23]}`	Run every hour. This trigger runs every hour. The minutes are controlled by the **startTime** value, when a value is specified. If a value not specified, the minutes are controlled by the creation time. For example, if the start time or creation time (whichever applies) is 12:25 PM, the trigger runs at 00:25, 01:25, 02:25, ..., and 23:25. This schedule is equivalent to having a trigger with a **frequency** value of "hour," an **interval** value of 1, and no **schedule**. This schedule can be used with different **frequency** and **interval** values to create other triggers. For example, when the **frequency** value is "month," the schedule runs only once a month, rather than every day, when the **frequency** value is "day."
`{"minutes":[0]}`	Run every hour on the hour. This trigger runs every hour on the hour starting at 12:00 AM, 1:00 AM, 2:00 AM, and so on. This schedule is equivalent to a trigger with a **frequency** value of "hour" and a **startTime** value of zero minutes, or no **schedule** but a **frequency** value of "day." If the **frequency** value is "week" or "month," the schedule executes one day a week or one day a month only, respectively.
`{"minutes":[15]}`	Run at 15 minutes past every hour. This trigger runs every hour at 15 minutes past the hour starting at 00:15 AM, 1:15 AM, 2:15 AM, and so on, and ending at 11:15 PM.
`{"hours":[17], "weekDays":["saturday"]}`	Run at 5:00 PM on Saturdays every week.
`{"hours":[17], "weekDays":["monday", "wednesday", "friday"]}`	Run at 5:00 PM on Monday, Wednesday, and Friday every week.
`{"minutes":[15,45], "hours":[17], "weekDays": ["monday", "wednesday", "friday"]}`	Run at 5:15 PM and 5:45 PM on Monday, Wednesday, and Friday every week.
`{"minutes":[0,15,30,45], "weekDays":["monday", "tuesday", "wednesday", "thursday", "friday"]}`	Run every 15 minutes on weekdays.
`{"minutes":[0,15,30,45], "hours": [9, 10, 11, 12, 13, 14, 15, 16] "weekDays":["monday", "tuesday", "wednesday", "thursday", "friday"]}`	Run every 15 minutes on weekdays between 9:00 AM and 4:45 PM.

EXAMPLE	DESCRIPTION
`{"weekDays":["tuesday", "thursday"]}`	Run on Tuesdays and Thursdays at the specified start time.
`{"minutes":[0], "hours":[6], "monthDays":[28]}`	Run at 6:00 AM on the 28th day of every month (assuming a **frequency** value of "month").
`{"minutes":[0], "hours":[6], "monthDays":[-1]}`	Run at 6:00 AM on the last day of the month. To run a trigger on the last day of a month, use -1 instead of day 28, 29, 30, or 31.
`{"minutes":[0], "hours":[6], "monthDays":[1,-1]}`	Run at 6:00 AM on the first and last day of every month.
`{monthDays":[1,14]}`	Run on the first and 14th day of every month at the specified start time.
`{"minutes":[0], "hours":[5], "monthlyOccurrences": [{"day":"friday", "occurrence":1}]}`	Run on the first Friday of every month at 5:00 AM.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":1}]}`	Run on the first Friday of every month at the specified start time.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":-3}]}`	Run on the third Friday from the end of the month, every month, at the specified start time.
`{"minutes":[15], "hours":[5], "monthlyOccurrences": [{"day":"friday", "occurrence":1},{"day":"friday", "occurrence":-1}]}`	Run on the first and last Friday of every month at 5:15 AM.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":1},{"day":"friday", "occurrence":-1}]}`	Run on the first and last Friday of every month at the specified start time.
`{"monthlyOccurrences":[{"day":"friday", "occurrence":5}]}`	Run on the fifth Friday of every month at the specified start time. When there's no fifth Friday in a month, the pipeline doesn't run, since it's scheduled to run only on fifth Fridays. To run the trigger on the last occurring Friday of the month, consider using -1 instead of 5 for the **occurrence** value.
`{"minutes":[0,15,30,45], "monthlyOccurrences": [{"day":"friday", "occurrence":-1}]}`	Run every 15 minutes on the last Friday of the month.
`{"minutes":[15,45], "hours":[5,17], "monthlyOccurrences":[{"day":"wednesday", "occurrence":3}]}`	Run at 5:15 AM, 5:45 AM, 5:15 PM, and 5:45 PM on the third Wednesday of every month.

Create a trigger that runs a pipeline on a tumbling window

8/19/2022 • 10 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

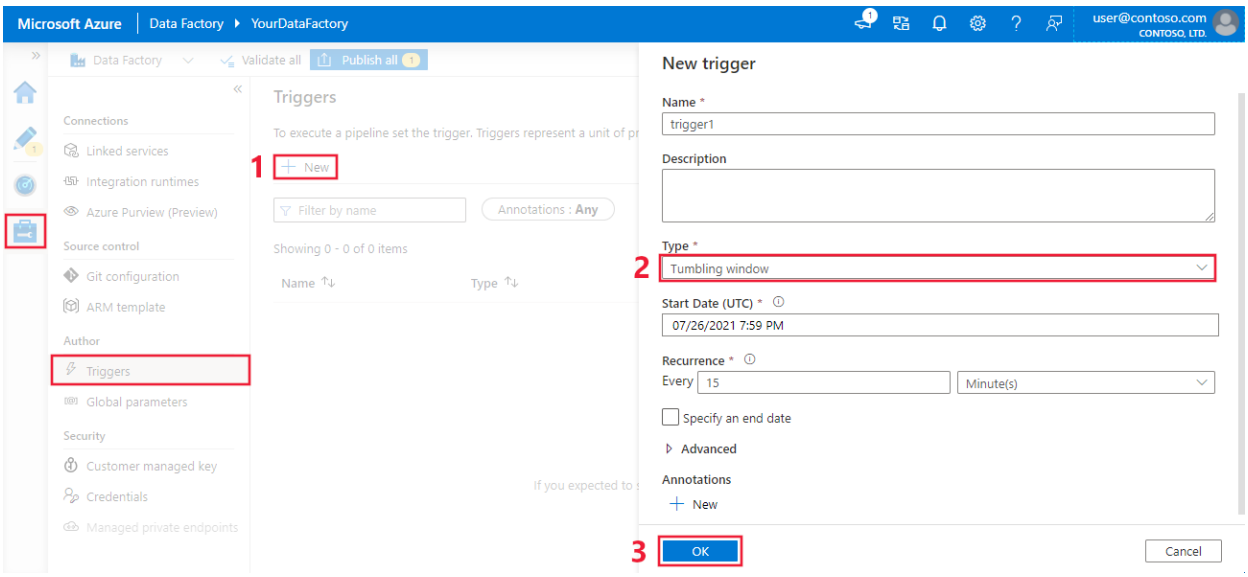
This article provides steps to create, start, and monitor a tumbling window trigger. For general information about triggers and the supported types, see Pipeline execution and triggers.

Tumbling window triggers are a type of trigger that fires at a periodic time interval from a specified start time, while retaining state. Tumbling windows are a series of fixed-sized, non-overlapping, and contiguous time intervals. A tumbling window trigger has a one-to-one relationship with a pipeline and can only reference a singular pipeline. Tumbling window trigger is a more heavy weight alternative for schedule trigger offering a suite of features for complex scenarios(dependency on other tumbling window triggers, rerunning a failed job and set user retry for pipelines). To further understand the difference between schedule trigger and tumbling window trigger, please visit here.

Azure Data Factory and Synapse portal experience

1. To create a tumbling window trigger in the Azure portal, select the **Triggers** tab, and then select **New**.
2. After the trigger configuration pane opens, select **Tumbling Window**, and then define your tumbling window trigger properties.
3. When you're done, select **Save**.

- Azure Data Factory
- Azure Synapse



Tumbling window trigger type properties

A tumbling window has the following trigger type properties:

```
{
    "name": "MyTriggerName",
    "properties": {
        "type": "TumblingWindowTrigger",
        "runtimeState": "<<Started/Stopped/Disabled - readonly>>",
        "typeProperties": {
            "frequency": <<Minute/Hour>>,
            "interval": <<int>>,
            "startTime": "<<datetime>>",
            "endTime": <<datetime – optional>>,
            "delay": <<timespan – optional>>,
            "maxConcurrency": <<int>> (required, max allowed: 50),
            "retryPolicy": {
                "count": <<int - optional, default: 0>>,
                "intervalInSeconds": <<int>>,
            },
            "dependsOn": [
                {
                    "type": "TumblingWindowTriggerDependencyReference",
                    "size": <<timespan – optional>>,
                    "offset": <<timespan – optional>>,
                    "referenceTrigger": {
                        "referenceName": "MyTumblingWindowDependency1",
                        "type": "TriggerReference"
                    }
                },
                {
                    "type": "SelfDependencyTumblingWindowTriggerReference",
                    "size": <<timespan – optional>>,
                    "offset": <<timespan>>
                }
            ]
        },
        "pipeline": {
            "pipelineReference": {
                "type": "PipelineReference",
                "referenceName": "MyPipelineName"
            },
            "parameters": {
                "parameter1": {
                    "type": "Expression",
                    "value": "@{concat('output',formatDateTime(trigger().outputs.windowStartTime,'-dd-MM-
yyyy-HH-mm-ss-ffff'))}"
                },
                "parameter2": {
                    "type": "Expression",
                    "value": "@{concat('output',formatDateTime(trigger().outputs.windowEndTime,'-dd-MM-yyyy-
HH-mm-ss-ffff'))}"
                },
                "parameter3": "https://mydemo.azurewebsites.net/api/demoapi"
            }
        }
    }
}
```

The following table provides a high-level overview of the major JSON elements that are related to recurrence and scheduling of a tumbling window trigger:

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED
type	The type of the trigger. The type is the fixed value "TumblingWindowTrigger".	String	"TumblingWindowTrigger"	Yes
runtimeState	The current state of the trigger run time. **Note**: This element is <readOnly>.	String	"Started," "Stopped," "Disabled"	Yes
frequency	A string that represents the frequency unit (minutes or hours) at which the trigger recurs. If the **startTime** date values are more granular than the **frequency** value, the **startTime** dates are considered when the window boundaries are computed. For example, if the **frequency** value is hourly and the **startTime** value is 2017-09-01T10:10:10Z, the first window is (2017-09-01T10:10:10Z, 2017-09-01T11:10:10Z).	String	"minute," "hour"	Yes
interval	A positive integer that denotes the interval for the **frequency** value, which determines how often the trigger runs. For example, if the **interval** is 3 and the **frequency** is "hour," the trigger recurs every 3 hours. **Note**: The minimum window interval is 5 minutes.	Integer	A positive integer.	Yes
startTime	The first occurrence, which can be in the past. The first trigger interval is (**startTime**, **startTime** + **interval**).	DateTime	A DateTime value.	Yes

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED
endTime	The last occurrence, which can be in the past.	DateTime	A DateTime value.	Yes
delay	The amount of time to delay the start of data processing for the window. The pipeline run is started after the expected execution time plus the amount of **delay**. The **delay** defines how long the trigger waits past the due time before triggering a new run. The **delay** doesn't alter the window **startTime**. For example, a **delay** value of 00:10:00 implies a delay of 10 minutes.	Timespan (hh:mm:ss)	A timespan value where the default is 00:00:00.	No
maxConcurrency	The number of simultaneous trigger runs that are fired for windows that are ready. For example, to back fill hourly runs for yesterday results in 24 windows. If **maxConcurrency** = 10, trigger events are fired only for the first 10 windows (00:00-01:00 - 09:00-10:00). After the first 10 triggered pipeline runs are complete, trigger runs are fired for the next 10 windows (10:00-11:00 - 19:00-20:00). Continuing with this example of **maxConcurrency** = 10, if there are 10 windows ready, there are 10 total pipeline runs. If there's only 1 window ready, there's only 1 pipeline run.	Integer	An integer between 1 and 50.	Yes
retryPolicy: Count	The number of retries before the pipeline run is marked as "Failed."	Integer	An integer, where the default is 0 (no retries).	No

JSON ELEMENT	DESCRIPTION	TYPE	ALLOWED VALUES	REQUIRED
retryPolicy: intervalInSeconds	The delay between retry attempts specified in seconds.	Integer	The number of seconds, where the default is 30.	No
dependsOn: type	The type of TumblingWindowTriggerReference. Required if a dependency is set.	String	"TumblingWindowTriggerDependencyReference", "SelfDependencyTumblingWindowTriggerReference"	No
dependsOn: size	The size of the dependency tumbling window.	Timespan (hh:mm:ss)	A positive timespan value where the default is the window size of the child trigger	No
dependsOn: offset	The offset of the dependency trigger.	Timespan (hh:mm:ss)	A timespan value that must be negative in a self-dependency. If no value specified, the window is the same as the trigger itself.	Self-Dependency: Yes Other: No

> **NOTE**
> After a tumbling window trigger is published, **interval** and **frequency** can't be edited.

WindowStart and WindowEnd system variables

You can use the **WindowStart** and **WindowEnd** system variables of the tumbling window trigger in your **pipeline** definition (that is, for part of a query). Pass the system variables as parameters to your pipeline in the **trigger** definition. The following example shows you how to pass these variables as parameters:

```
{
    "name": "MyTriggerName",
    "properties": {
        "type": "TumblingWindowTrigger",
            ...
        "pipeline": {
            "pipelineReference": {
                "type": "PipelineReference",
                "referenceName": "MyPipelineName"
            },
            "parameters": {
                "MyWindowStart": {
                    "type": "Expression",
                    "value": "@{concat('output',formatDateTime(trigger().outputs.windowStartTime,'-dd-MM-
yyyy-HH-mm-ss-ffff'))}"
                },
                "MyWindowEnd": {
                    "type": "Expression",
                    "value": "@{concat('output',formatDateTime(trigger().outputs.windowEndTime,'-dd-MM-yyyy-
HH-mm-ss-ffff'))}"
                }
            }
        }
    }
}
```

To use the **WindowStart** and **WindowEnd** system variable values in the pipeline definition, use your "MyWindowStart" and "MyWindowEnd" parameters, accordingly.

Execution order of windows in a backfill scenario

If the startTime of trigger is in the past, then based on this formula, M=(CurrentTime-TriggerStartTime)/TumblingWindowSize, the trigger will generate {M} backfill(past) runs in parallel, honoring trigger concurrency, before executing the future runs. The order of execution for windows is deterministic, from oldest to newest intervals. Currently, this behavior can't be modified.

Existing TriggerResource elements

The following points apply to update of existing **TriggerResource** elements:

- The value for the **frequency** element (or window size) of the trigger along with **interval** element cannot be changed once the trigger is created. This is required for proper functioning of triggerRun reruns and dependency evaluations
- If the value for the **endTime** element of the trigger changes (added or updated), the state of the windows that are already processed is *not* reset. The trigger honors the new **endTime** value. If the new **endTime** value is before the windows that are already executed, the trigger stops. Otherwise, the trigger stops when the new **endTime** value is encountered.

User assigned retries of pipelines

In case of pipeline failures, tumbling window trigger can retry the execution of the referenced pipeline automatically, using the same input parameters, without the user intervention. This can be specified using the property "retryPolicy" in the trigger definition.

Tumbling window trigger dependency

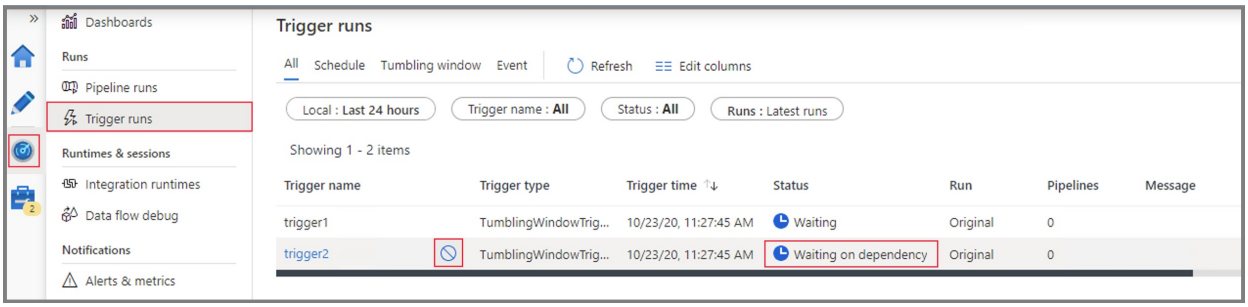
If you want to make sure that a tumbling window trigger is executed only after the successful execution of another tumbling window trigger in the data factory, create a tumbling window trigger dependency.

Cancel tumbling window run

You can cancel runs for a tumbling window trigger, if the specific window is in *Waiting*, *Waiting on Dependency*, or *Running* state

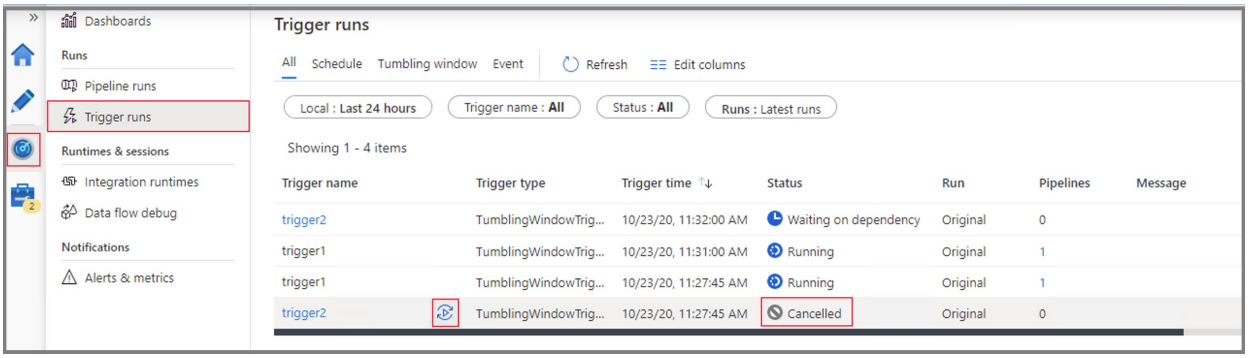
- If the window is in **Running** state, cancel the associated *Pipeline Run*, and the trigger run will be marked as *Canceled* afterwards
- If the window is in **Waiting** or **Waiting on Dependency** state, you can cancel the window from Monitoring:

- Azure Data Factory
- Azure Synapse



You can also rerun a canceled window. The rerun will take the *latest* published definitions of the trigger, and dependencies for the specified window will be *re-evaluated* upon rerun

- Azure Data Factory
- Azure Synapse



Sample for Azure PowerShell and Azure CLI

- Azure PowerShell
- Azure CLI

This section shows you how to use Azure PowerShell to create, start, and monitor a trigger.

> **NOTE**
> This article uses the Azure Az PowerShell module, which is the recommended PowerShell module for interacting with Azure. To get started with the Az PowerShell module, see Install Azure PowerShell. To learn how to migrate to the Az PowerShell module, see Migrate Azure PowerShell from AzureRM to Az.

Prerequisites

- **Azure subscription**. If you don't have an Azure subscription, create a free account before you begin.
- **Azure PowerShell**. Follow the instructions in Install Azure PowerShell on Windows with PowerShellGet.
- **Azure Data Factory**. Follow the instructions in Create an Azure Data Factory using PowerShell to create a data factory and a pipeline.

Sample Code

1. Create a JSON file named **MyTrigger.json** in the C:\ADFv2QuickStartPSH\ folder with the following content:

   > **IMPORTANT**
   >
   > Before you save the JSON file, set the value of the **startTime** element to the current UTC time. Set the value of the **endTime** element to one hour past the current UTC time.

   ```
   {
     "name": "PerfTWTrigger",
     "properties": {
       "type": "TumblingWindowTrigger",
       "typeProperties": {
         "frequency": "Minute",
         "interval": "15",
         "startTime": "2017-09-08T05:30:00Z",
         "endTime" : "2017-09-08T06:30:00Z",
         "delay": "00:00:01",
         "retryPolicy": {
           "count": 2,
           "intervalInSeconds": 30
         },
         "maxConcurrency": 50
       },
       "pipeline": {
         "pipelineReference": {
           "type": "PipelineReference",
           "referenceName": "DynamicsToBlobPerfPipeline"
         },
         "parameters": {
           "windowStart": "@trigger().outputs.windowStartTime",
           "windowEnd": "@trigger().outputs.windowEndTime"
         }
       },
       "runtimeState": "Started"
     }
   }
   ```

2. Create a trigger by using the Set-AzDataFactoryV2Trigger cmdlet:

   ```
   Set-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
   Name "MyTrigger" -DefinitionFile "C:\ADFv2QuickStartPSH\MyTrigger.json"
   ```

3. Confirm that the status of the trigger is **Stopped** by using the Get-AzDataFactoryV2Trigger cmdlet:

   ```
   Get-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
   Name "MyTrigger"
   ```

4. Start the trigger by using the Start-AzDataFactoryV2Trigger cmdlet:

   ```
   Start-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName
   -Name "MyTrigger"
   ```

5. Confirm that the status of the trigger is **Started** by using the Get-AzDataFactoryV2Trigger cmdlet:

```
Get-AzDataFactoryV2Trigger -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName -
Name "MyTrigger"
```

6. Get the trigger runs in Azure PowerShell by using the Get-AzDataFactoryV2TriggerRun cmdlet. To get information about the trigger runs, execute the following command periodically. Update the **TriggerRunStartedAfter** and **TriggerRunStartedBefore** values to match the values in your trigger definition:

```
Get-AzDataFactoryV2TriggerRun -ResourceGroupName $ResourceGroupName -DataFactoryName $DataFactoryName
-TriggerName "MyTrigger" -TriggerRunStartedAfter "2017-12-08T00:00:00" -TriggerRunStartedBefore
"2017-12-08T01:00:00"
```

To monitor trigger runs and pipeline runs in the Azure portal, see Monitor pipeline runs.

Create a tumbling window trigger dependency

8/19/2022 • 4 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

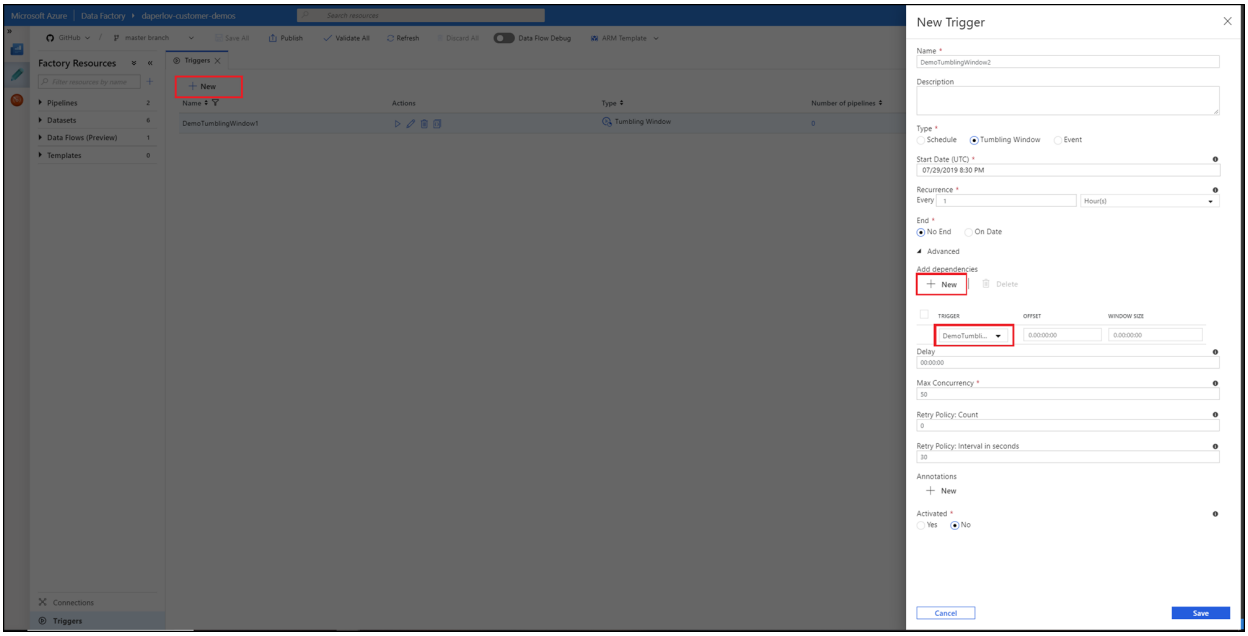
This article provides steps to create a dependency on a tumbling window trigger. For general information about Tumbling Window triggers, see How to create tumbling window trigger.

In order to build a dependency chain and make sure that a trigger is executed only after the successful execution of another trigger within the service, use this advanced feature to create a tumbling window dependency.

For a demonstration on how to create dependent pipelines using tumbling window trigger, watch the following video:

Create a dependency in the UI

To create dependency on a trigger, select **Trigger** > **Advanced** > **New**, and then choose the trigger to depend on with the appropriate offset and size. Select **Finish** and publish the changes for the dependencies to take effect.



Tumbling window dependency properties

A tumbling window trigger with a dependency has the following properties:

```
{
    "name": "MyTriggerName",
    "properties": {
        "type": "TumblingWindowTrigger",
        "runtimeState": <<Started/Stopped/Disabled - readonly>>,
        "typeProperties": {
            "frequency": <<Minute/Hour>>,
            "interval": <<int>>,
            "startTime": <<datetime>>,
            "endTime": <<datetime – optional>>,
            "delay": <<timespan – optional>>,
            "maxConcurrency": <<int>> (required, max allowed: 50),
            "retryPolicy": {
                "count": <<int - optional, default: 0>>,
                "intervalInSeconds": <<int>>,
            },
            "dependsOn": [
                {
                    "type": "TumblingWindowTriggerDependencyReference",
                    "size": <<timespan – optional>>,
                    "offset": <<timespan – optional>>,
                    "referenceTrigger": {
                        "referenceName": "MyTumblingWindowDependency1",
                        "type": "TriggerReference"
                    }
                },
                {
                    "type": "SelfDependencyTumblingWindowTriggerReference",
                    "size": <<timespan – optional>>,
                    "offset": <<timespan>>
                }
            ]
        }
    }
}
```

The following table provides the list of attributes needed to define a Tumbling Window dependency.

PROPERTY NAME	DESCRIPTION	TYPE	REQUIRED
type	All the existing tumbling window triggers are displayed in this drop down. Choose the trigger to take dependency on.	TumblingWindowTriggerDependencyReference or SelfDependencyTumblingWindowTriggerReference	Yes
offset	Offset of the dependency trigger. Provide a value in time span format and both negative and positive offsets are allowed. This property is mandatory if the trigger is depending on itself and in all other cases it is optional. Self-dependency should always be a negative offset. If no value specified, the window is the same as the trigger itself.	Timespan (hh:mm:ss)	Self-Dependency: Yes Other: No

PROPERTY NAME	DESCRIPTION	TYPE	REQUIRED
size	Size of the dependency tumbling window. Provide a positive timespan value. This property is optional.	Timespan (hh:mm:ss)	No

> **NOTE**
> A tumbling window trigger can depend on a maximum of five other triggers.

Tumbling window self-dependency properties

In scenarios where the trigger shouldn't proceed to the next window until the preceding window is successfully completed, build a self-dependency. A self-dependency trigger that's dependent on the success of earlier runs of itself within the preceding hour will have the properties indicated in the following code.

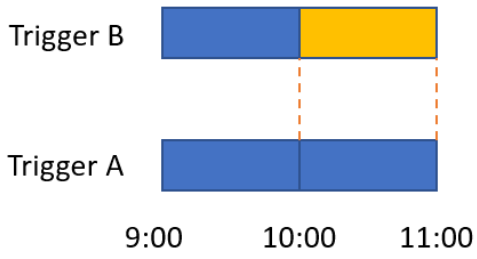
> **NOTE**
> If your triggered pipeline relies on the output of pipelines in previously triggered windows, we recommend using only tumbling window trigger self-dependency. To limit parallel trigger runs, set the maximimum trigger concurrency.

```
{
    "name": "DemoSelfDependency",
    "properties": {
        "runtimeState": "Started",
        "pipeline": {
            "pipelineReference": {
                "referenceName": "Demo",
                "type": "PipelineReference"
            }
        },
        "type": "TumblingWindowTrigger",
        "typeProperties": {
            "frequency": "Hour",
            "interval": 1,
            "startTime": "2018-10-04T00:00:00Z",
            "delay": "00:01:00",
            "maxConcurrency": 50,
            "retryPolicy": {
                "intervalInSeconds": 30
            },
            "dependsOn": [
                {
                    "type": "SelfDependencyTumblingWindowTriggerReference",
                    "size": "01:00:00",
                    "offset": "-01:00:00"
                }
            ]
        }
    }
}
```

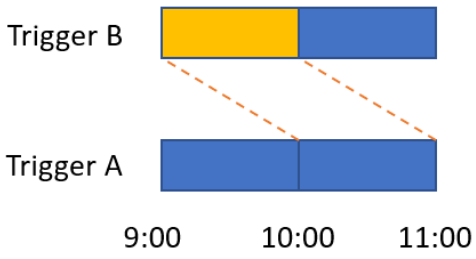
Usage scenarios and examples

Below are illustrations of scenarios and usage of tumbling window dependency properties.

Dependency offset

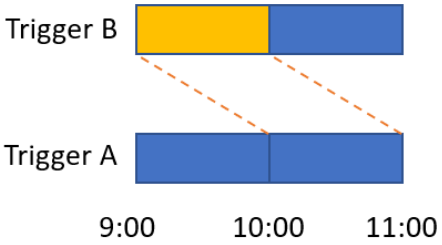


Dependency: A -> B
Offset: 0

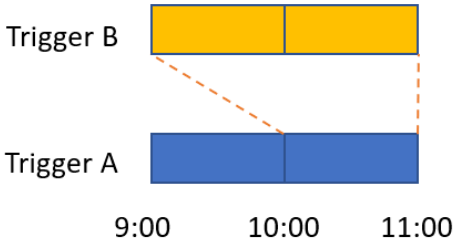


Dependency: A -> B
Offset: -1 hour

Dependency size

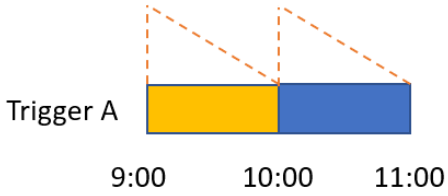


Dependency: A -> B
Offset: -1 hour
Size: unspecified

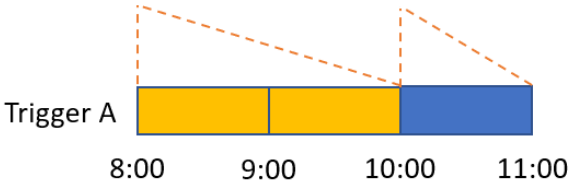


Dependency: A -> B
Offset: -1 hour
Size: 2 hours

Self-dependency



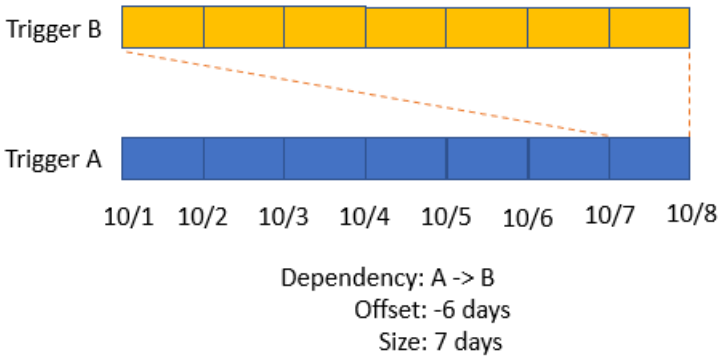
Dependency: A -> A
Offset: -1 hour
Size: unspecified



Dependency: A -> A
Offset: -2 hour
Size: 2 hours

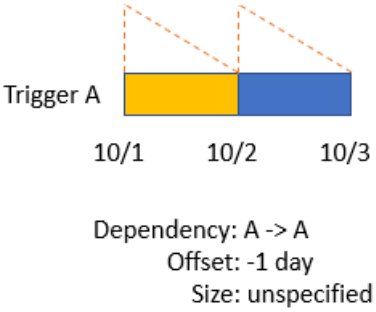
Dependency on another tumbling window trigger

A daily telemetry processing job depending on another daily job aggregating the last seven days output and generates seven day rolling window streams:



Dependency on itself

A daily job with no gaps in the output streams of the job:

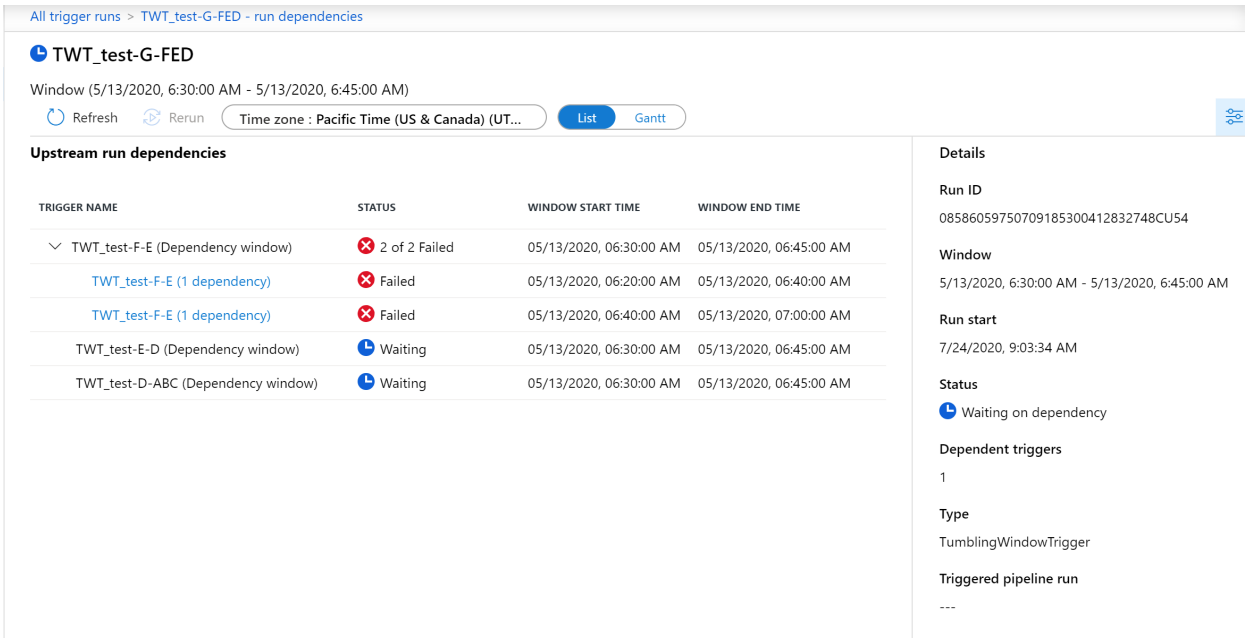


Monitor dependencies

You can monitor the dependency chain and the corresponding windows from the trigger run monitoring page. Navigate to **Monitoring** > **Trigger Runs**. If a Tumbling Window trigger has dependencies, Trigger Name will bear a hyperlink to dependency monitoring view.

TRIGGER NAME	TRIGGER TYPE	TRIGGER TIME	STATUS
TWT_test-D-ABC	TumblingWindowTrigger	7/24/20, 4:03:54 PM	Waiting on dependency
TWT_test-C	TumblingWindowTrigger	7/24/20, 4:03:54 PM	Waiting
TWT_test-D-ABC	TumblingWindowTrigger	7/24/20, 4:03:53 PM	Waiting on dependency
TWT_test-A	TumblingWindowTrigger	7/24/20, 4:03:53 PM	Waiting

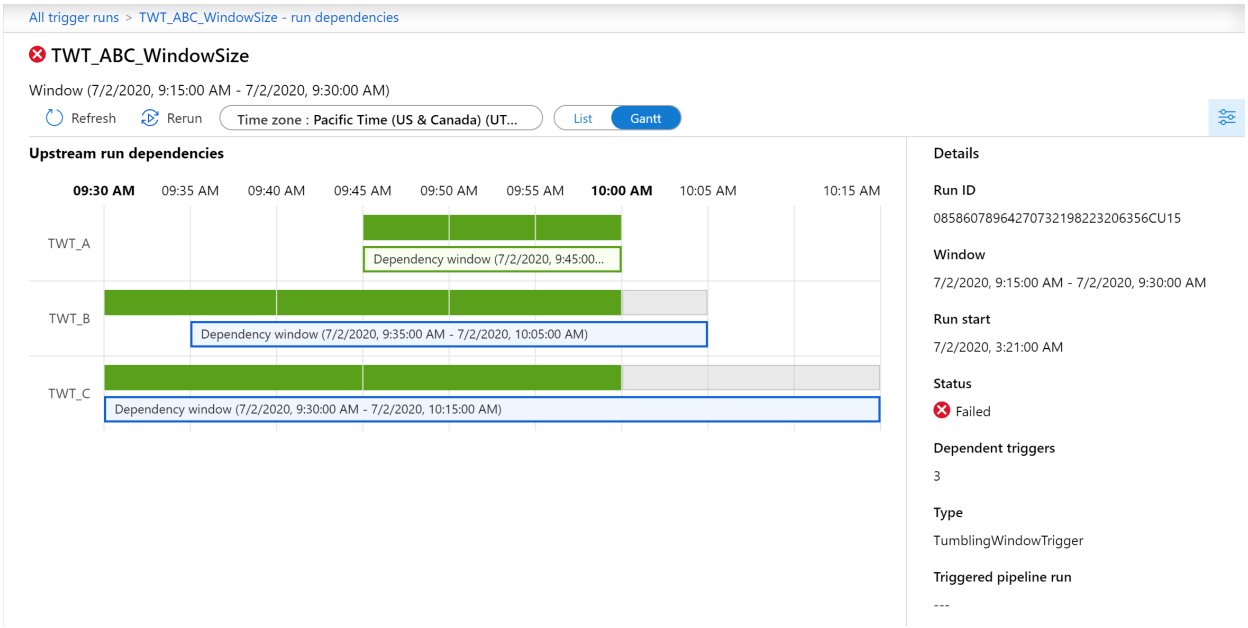
Click through the trigger name to view trigger dependencies. Right-hand panel shows detailed trigger run information, such as RunID, window time, status, and so on.



You can see the status of the dependencies, and windows for each dependent trigger. If one of the dependencies triggers fails, you must successfully rerun it in order for the dependent trigger to run.

A tumbling window trigger will wait on dependencies for *seven days* before timing out. After seven days, the trigger run will fail.

For a more visual to view the trigger dependency schedule, select the Gantt view.



Transparent boxes show the dependency windows for each down stream-dependent trigger, while solid colored boxes above show individual window runs. Here are some tips for interpreting the Gantt chart view:

- Transparent box renders blue when dependent windows are in pending or running state
- After all windows succeeds for a dependent trigger, the transparent box will turn green
- Transparent box renders red when some dependent window fails. Look for a solid red box to identify the failure window run

To rerun a window in Gantt chart view, select the solid color box for the window, and an action panel will pop up with details and rerun options

Next steps

- Review How to create a tumbling window trigger

Troubleshoot Azure Data Factory and Synapse pipelines

8/19/2022 • 38 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article explores common troubleshooting methods for external control activities in Azure Data Factory and Synapse pipelines.

Connector and copy activity

For connector issues such as an encounter error using the copy activity, refer to the Troubleshoot Connectors article.

Azure Databricks

Error code: 3200

- **Message**: Error 403.
- **Cause**: `The Databricks access token has expired.`
- **Recommendation**: By default, the Azure Databricks access token is valid for 90 days. Create a new token and update the linked service.

Error code: 3201

- **Message**: `Missing required field: settings.task.notebook_task.notebook_path.`
- **Cause**: `Bad authoring: Notebook path not specified correctly.`
- **Recommendation**: Specify the notebook path in the Databricks activity.

- **Message**: `Cluster... does not exist.`
- **Cause**: `Authoring error: Databricks cluster does not exist or has been deleted.`
- **Recommendation**: Verify that the Databricks cluster exists.

- **Message**: `Invalid Python file URI... Please visit Databricks user guide for supported URI schemes.`
- **Cause**: `Bad authoring.`
- **Recommendation**: Specify either absolute paths for workspace-addressing schemes, or `dbfs:/folder/subfolder/foo.py` for files stored in the Databricks File System (DFS).

- **Message**: `{0} LinkedService should have domain and accessToken as required properties.`
- **Cause**: `Bad authoring.`
- **Recommendation**: Verify the linked service definition.

- **Message**:
  `{0} LinkedService should specify either existing cluster ID or new cluster information for creation.`
- **Cause**: `Bad authoring.`
- **Recommendation**: Verify the linked service definition.

- **Message**:
  ```
  Node type Standard_D16S_v3 is not supported. Supported node types: Standard_DS3_v2, Standard_DS4_v2,
  Standard_DS5_v2, Standard_D8s_v3, Standard_D16s_v3, Standard_D32s_v3, Standard_D64s_v3,
  Standard_D3_v2, Standard_D8_v3, Standard_D16_v3, Standard_D32_v3, Standard_D64_v3, Standard_D12_v2,
  Standard_D13_v2, Standard_D14_v2, Standard_D15_v2, Standard_DS12_v2, Standard_DS13_v2,
  Standard_DS14_v2, Standard_DS15_v2, Standard_E8s_v3, Standard_E16s_v3, Standard_E32s_v3,
  Standard_E64s_v3, Standard_L4s, Standard_L8s, Standard_L16s, Standard_L32s, Standard_F4s,
  Standard_F8s, Standard_F16s, Standard_H16, Standard_F4s_v2, Standard_F8s_v2, Standard_F16s_v2,
  Standard_F32s_v2, Standard_F64s_v2, Standard_F72s_v2, Standard_NC12, Standard_NC24, Standard_NC6s_v3,
  Standard_NC12s_v3, Standard_NC24s_v3, Standard_L8s_v2, Standard_L16s_v2, Standard_L32s_v2,
  Standard_L64s_v2, Standard_L80s_v2.
  ```
- **Cause**: `Bad authoring.`
- **Recommendation**: Refer to the error message.

Error code: 3202

- **Message**:
  ```
  There were already 1000 jobs created in past 3600 seconds, exceeding rate limit: 1000 job creations
  per 3600 seconds.
  ```
- **Cause**: `Too many Databricks runs in an hour.`
- **Recommendation**: Check all pipelines that use this Databricks workspace for their job creation rate. If pipelines launched too many Databricks runs in aggregate, migrate some pipelines to a new workspace.

- **Message**:
  ```
  Could not parse request object: Expected 'key' and 'value' to be set for JSON map field
  base_parameters, got 'key: "..."' instead.
  ```
- **Cause**: `Authoring error: No value provided for the parameter.`
- **Recommendation**: Inspect the pipeline JSON and ensure all parameters in the baseParameters notebook specify a nonempty value.

- **Message**: `User:` SimpleUserContext{userId=..., name=user@company.com, orgId=...}
  `is not authorized to access cluster.`
- **Cause**: The user who generated the access token isn't allowed to access the Databricks cluster specified in the linked service.
- **Recommendation**: Ensure the user has the required permissions in the workspace.

- **Message**: `Job is not fully initialized yet. Please retry later.`
- **Cause**: The job has not initialized.
- **Recommendation**: Wait and try again later.

Error code: 3203

- **Message**:
  ```
  The cluster is in Terminated state, not available to receive jobs. Please fix the cluster or retry later.
  ```
- **Cause**: The cluster was terminated. For interactive clusters, this issue might be a race condition.
- **Recommendation**: To avoid this error, use job clusters.

Error code: 3204

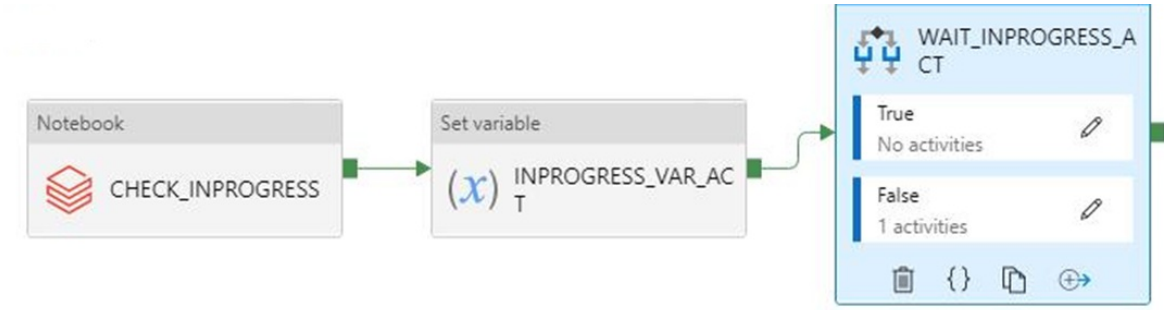
- **Message**: `Job execution failed.`
- **Cause**: Error messages indicate various issues, such as an unexpected cluster state or a specific activity. Often, no error message appears.
- **Recommendation**: N/A

Error code: 3208

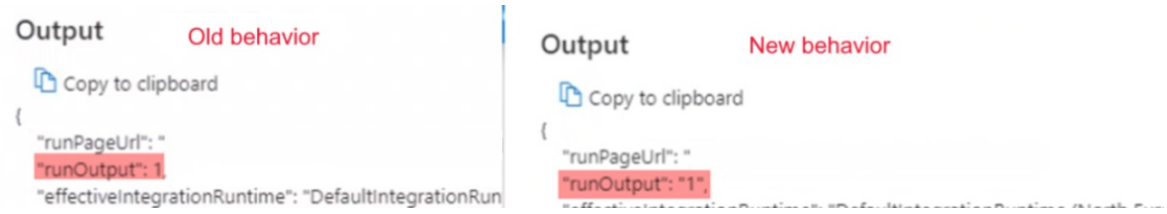
- **Message**: `An error occurred while sending the request.`
- **Cause**: The network connection to the Databricks service was interrupted.
- **Recommendation**: If you're using a self-hosted integration runtime, make sure that the network connection is reliable from the integration runtime nodes. If you're using Azure integration runtime, retry usually works.

The Boolean run output starts coming as string instead of expected int

- **Symptoms**: Your Boolean run output starts coming as string (for example, `"0"` or `"1"`) instead of expected int (for example, `0` or `1`).



You noticed this change on September 28, 2021 at around 9 AM IST when your pipeline relying on this output started failing. No change was made on the pipeline, and the Boolean output had been coming as expected before the failure.



- **Cause**: This issue is caused by a recent change, which is by design. After the change, if the result is a number that starts with zero, Azure Data Factory will convert the number to the octal value, which is a bug. This number is always 0 or 1, which never caused issues before the change. So to fix the octal conversion, the string output is passed from the Notebook run as is.
- **Recommendation**: Change the **if** condition to something like `if(value=="0")`.

Azure Data Lake Analytics

The following table applies to U-SQL.

Error code: 2709

- **Message**: `The access token is from the wrong tenant.`
- **Cause**: Incorrect Azure Active Directory (Azure AD) tenant.
- **Recommendation**: Incorrect Azure Active Directory (Azure AD) tenant.

- **Message**:
  ```
  We cannot accept your job at this moment. The maximum number of queued jobs for your account is 200.
  ```
- **Cause**: This error is caused by throttling on Data Lake Analytics.
- **Recommendation**: Reduce the number of submitted jobs to Data Lake Analytics. Either change triggers and concurrency settings on activities, or increase the limits on Data Lake Analytics.

- **Message**:
  ```
  This job was rejected because it requires 24 AUs. This account's administrator-defined policy prevents a job from using more than 5 AUs.
  ```
- **Cause**: This error is caused by throttling on Data Lake Analytics.
- **Recommendation**: Reduce the number of submitted jobs to Data Lake Analytics. Either change triggers and concurrency settings on activities, or increase the limits on Data Lake Analytics.

Error code: 2705

- **Message**:
  ```
  Forbidden. ACL verification failed. Either the resource does not exist or the user is not authorized to perform the requested operation.<br/> <br/> User is not able to access Data Lake Store. <br/> <br/> User is not authorized to use Data Lake Analytics.
  ```
- **Cause**: The service principal or certificate doesn't have access to the file in storage.
- **Recommendation**: Verify that the service principal or certificate that the user provides for Data Lake Analytics jobs has access to both the Data Lake Analytics account, and the default Data Lake Storage instance from the root folder.

Error code: 2711

- **Message**:
  ```
  Forbidden. ACL verification failed. Either the resource does not exist or the user is not authorized to perform the requested operation.<br/> <br/> User is not able to access Data Lake Store. <br/> <br/> User is not authorized to use Data Lake Analytics.
  ```
- **Cause**: The service principal or certificate doesn't have access to the file in storage.
- **Recommendation**: Verify that the service principal or certificate that the user provides for Data Lake Analytics jobs has access to both the Data Lake Analytics account, and the default Data Lake Storage instance from the root folder.

- **Message**: `Cannot find the 'Azure Data Lake Store' file or folder.`
- **Cause**: The path to the U-SQL file is wrong, or the linked service credentials don't have access.
- **Recommendation**: Verify the path and credentials provided in the linked service.

Error code: 2704

- **Message**:

```
Forbidden. ACL verification failed. Either the resource does not exist or the user is not authorized
to perform the requested operation.<br/> <br/> User is not able to access Data Lake Store. <br/> <br/>
User is not authorized to use Data Lake Analytics.
```

- **Cause**: The service principal or certificate doesn't have access to the file in storage.
- **Recommendation**: Verify that the service principal or certificate that the user provides for Data Lake Analytics jobs has access to both the Data Lake Analytics account, and the default Data Lake Storage instance from the root folder.

Error code: 2707

- **Message**:
  ```
  Cannot resolve the account of AzureDataLakeAnalytics. Please check 'AccountName' and
  'DataLakeAnalyticsUri'.
  ```
- **Cause**: The Data Lake Analytics account in the linked service is wrong.
- **Recommendation**: Verify that the right account is provided.

Error code: 2703

- **Message**: `Error Id: E_CQO_SYSTEM_INTERNAL_ERROR (or any error that starts with "Error Id:").`
- **Cause**: The error is from Data Lake Analytics.
- **Recommendation**: The job was submitted to Data Lake Analytics, and the script there, both failed. Investigate in Data Lake Analytics. In the portal, go to the Data Lake Analytics account and look for the job by using the Data Factory activity run ID (don't use the pipeline run ID). The job there provides more information about the error, and will help you troubleshoot.

  If the resolution isn't clear, contact the Data Lake Analytics support team and provide the job Universal Resource Locator (URL), which includes your account name and the job ID.

Azure functions

Error code: 3602

- **Message**: `Invalid HttpMethod: '%method;'.`
- **Cause**: The Httpmethod specified in the activity payload isn't supported by Azure Function Activity.
- **Recommendation**: The supported Httpmethods are: PUT, POST, GET, DELETE, OPTIONS, HEAD, and TRACE.

Error code: 3603

- **Message**: `Response Content is not a valid JObject.`
- **Cause**: The Azure function that was called didn't return a JSON Payload in the response. Azure Data Factory and Synapse pipeline Azure function activity only support JSON response content.
- **Recommendation**: Update the Azure function to return a valid JSON Payload such as a C# function may return `(ActionResult)new OkObjectResult("{\"Id\":\"123\"}");`

Error code: 3606

- **Message**: Azure function activity missing function key.
- **Cause**: The Azure function activity definition isn't complete.
- **Recommendation**: Check that the input Azure function activity JSON definition has a property named `functionKey`.

Error code: 3607

- **Message**: `Azure function activity missing function name.`
- **Cause**: The Azure function activity definition isn't complete.
- **Recommendation**: Check that the input Azure function activity JSON definition has a property named `functionName`.

Error code: 3608

- **Message**:
  ```
  Call to provided Azure function '%FunctionName;' failed with status-'%statusCode;' and message -
  '%message;'.
  ```
- **Cause**: The Azure function details in the activity definition may be incorrect.
- **Recommendation**: Fix the Azure function details and try again.

Error code: 3609

- **Message**: `Azure function activity missing functionAppUrl.`
- **Cause**: The Azure function activity definition isn't complete.
- **Recommendation**: Check that the input Azure Function activity JSON definition has a property named `functionAppUrl`.

Error code: 3610

- **Message**: `There was an error while calling endpoint.`
- **Cause**: The function URL may be incorrect.
- **Recommendation**: Verify that the value for `functionAppUrl` in the activity JSON is correct and try again.

Error code: 3611

- **Message**: `Azure function activity missing Method in JSON.`
- **Cause**: The Azure function activity definition isn't complete.
- **Recommendation**: Check that the input Azure function activity JSON definition has a property named `method`.

Error code: 3612

- **Message**: `Azure function activity missing LinkedService definition in JSON.`
- **Cause**: The Azure function activity definition isn't complete.
- **Recommendation**: Check that the input Azure function activity JSON definition has linked service details.

Azure Machine Learning

Error code: 4101

- **Message**:
  ```
  AzureMLExecutePipeline activity '%activityName;' has invalid value for property '%propertyName;'.
  ```
- **Cause**: Bad format or missing definition of property `%propertyName;`.
- **Recommendation**: Check if the activity `%activityName;` has the property `%propertyName;` defined with correct data.

Error code: 4110

- **Message**: `AzureMLExecutePipeline activity missing LinkedService definition in JSON.`
- **Cause**: The AzureMLExecutePipeline activity definition isn't complete.
- **Recommendation**: Check that the input AzureMLExecutePipeline activity JSON definition has correctly linked service details.

Error code: 4111

- **Message**:
  ```
  AzureMLExecutePipeline activity has wrong LinkedService type in JSON. Expected LinkedService type:
  '%expectedLinkedServiceType;', current LinkedService type: Expected LinkedService type:
  '%currentLinkedServiceType;'.
  ```
- **Cause**: Incorrect activity definition.
- **Recommendation**: Check that the input AzureMLExecutePipeline activity JSON definition has correctly linked service details.

Error code: 4112

- **Message**: `AzureMLService linked service has invalid value for property '%propertyName;'.`
- **Cause**: Bad format or missing definition of property '%propertyName;'.
- **Recommendation**: Check if the linked service has the property `%propertyName;` defined with correct data.

Error code: 4121

- **Message**:
  ```
  Request sent to Azure Machine Learning for operation '%operation;' failed with http status code
  '%statusCode;'. Error message from Azure Machine Learning: '%externalMessage;'.
  ```
- **Cause**: The Credential used to access Azure Machine Learning has expired.
- **Recommendation**: Verify that the credential is valid and retry.

Error code: 4122

- **Message**:
  ```
  Request sent to Azure Machine Learning for operation '%operation;' failed with http status code
  '%statusCode;'. Error message from Azure Machine Learning: '%externalMessage;'.
  ```
- **Cause**: The credential provided in Azure Machine Learning Linked Service is invalid, or doesn't have permission for the operation.
- **Recommendation**: Verify that the credential in Linked Service is valid, and has permission to access Azure Machine Learning.

Error code: 4123

- **Message**:
  ```
  Request sent to Azure Machine Learning for operation '%operation;' failed with http status code
  '%statusCode;'. Error message from Azure Machine Learning: '%externalMessage;'.
  ```
- **Cause**: The properties of the activity such as `pipelineParameters` are invalid for the Azure Machine Learning (ML) pipeline.
- **Recommendation**: Check that the value of activity properties matches the expected payload of the published Azure ML pipeline specified in Linked Service.

Error code: 4124

- **Message**:
  ```
  Request sent to Azure Machine Learning for operation '%operation;' failed with http status code
  '%statusCode;'. Error message from Azure Machine Learning: '%externalMessage;'.
  ```

- **Cause**: The published Azure ML pipeline endpoint doesn't exist.
- **Recommendation**: Verify that the published Azure Machine Learning pipeline endpoint specified in Linked Service exists in Azure Machine Learning.

Error code: 4125

- **Message**:
  ```
  Request sent to Azure Machine Learning for operation '%operation;' failed with http status code
  '%statusCode;'. Error message from Azure Machine Learning: '%externalMessage;'.
  ```
- **Cause**: There is a server error on Azure Machine Learning.
- **Recommendation**: Retry later. Contact the Azure Machine Learning team for help if the issue continues.

Error code: 4126

- **Message**:
  ```
  Azure ML pipeline run failed with status: '%amlPipelineRunStatus;'. Azure ML pipeline run Id:
  '%amlPipelineRunId;'. Please check in Azure Machine Learning for more error logs.
  ```
- **Cause**: The Azure ML pipeline run failed.
- **Recommendation**: Check Azure Machine Learning for more error logs, then fix the ML pipeline.

Azure Synapse Analytics

Error code: 3250

- **Message**: `There are not enough resources available in the workspace, details: '%errorMessage;'`
- **Cause**: Insufficient resources
- **Recommendation**: Try ending the running job(s) in the workspace, reducing the numbers of vCores requested, increasing the workspace quota or using another workspace.

Error code: 3251

- **Message**: `There are not enough resources available in the pool, details: '%errorMessage;'`
- **Cause**: Insufficient resources
- **Recommendation**: Try ending the running job(s) in the pool, reducing the numbers of vCores requested, increasing the pool maximum size or using another pool.

Error code: 3252

- **Message**: `There are not enough vcores available for your spark job, details: '%errorMessage;'`
- **Cause**: Insufficient vcores
- **Recommendation**: Try reducing the numbers of vCores requested or increasing your vCore quota. For more information, see Apache Spark core concepts.

Error code: 3253

- **Message**:
  ```
  There are substantial concurrent MappingDataflow executions which is causing failures due to
  throttling under the Integration Runtime used for ActivityId: '%activityId;'.
  ```
- **Cause**: Throttling threshold was reached.
- **Recommendation**: Retry the request after a wait period.

Error code: 3254

- **Message**: `AzureSynapseArtifacts linked service has invalid value for property '%propertyName;'.`

- **Cause**: Bad format or missing definition of property '%propertyName;'.
- **Recommendation**: Check if the linked service has property '%propertyName;' defined with correct data.

Common

Error code: 2103

- **Message**: `Please provide value for the required property '%propertyName;'.`
- **Cause**: The required value for the property has not been provided.
- **Recommendation**: Provide the value from the message and try again.

Error code: 2104

- **Message**: `The type of the property '%propertyName;' is incorrect.`
- **Cause**: The provided property type isn't correct.
- **Recommendation**: Fix the type of the property and try again.

Error code: 2105

- **Message**:
  ```
  An invalid json is provided for property '%propertyName;'. Encountered an error while trying to parse:
  '%message;'.
  ```
- **Cause**: The value for the property is invalid or isn't in the expected format.
- **Recommendation**: Refer to the documentation for the property and verify that the value provided includes the correct format and type.

Error code: 2106

- **Message**: `The storage connection string is invalid. %errorMessage;`
- **Cause**: The connection string for the storage is invalid or has incorrect format.
- **Recommendation**: Go to the Azure portal and find your storage, then copy-and-paste the connection string into your linked service and try again.

Error code: 2110

- **Message**:
  ```
  The linked service type '%linkedServiceType;' is not supported for '%executorType;' activities.
  ```
- **Cause**: The linked service specified in the activity is incorrect.
- **Recommendation**: Verify that the linked service type is one of the supported types for the activity. For example, the linked service type for HDI activities can be HDInsight or HDInsightOnDemand.

Error code: 2111

- **Message**:
  ```
  The type of the property '%propertyName;' is incorrect. The expected type is %expectedType;.
  ```
- **Cause**: The type of the provided property isn't correct.
- **Recommendation**: Fix the property type and try again.

Error code: 2112

- **Message**:
  ```
  The cloud type is unsupported or could not be determined for storage from the EndpointSuffix
  '%endpointSuffix;'.
  ```

- **Cause**: The cloud type is unsupported or couldn't be determined for storage from the EndpointSuffix.
- **Recommendation**: Use storage in another cloud and try again.

Custom

The following table applies to Azure Batch.

Error code: 2500

- **Message**: `Hit unexpected exception and execution failed.`
- **Cause**: `Can't launch command, or the program returned an error code.`
- **Recommendation**: Ensure that the executable file exists. If the program started, verify that *stdout.txt* and *stderr.txt* were uploaded to the storage account. It's a good practice to include logs in your code for debugging.

Error code: 2501

- **Message**: `Cannot access user batch account; please check batch account settings.`
- **Cause**: Incorrect Batch access key or pool name.
- **Recommendation**: Verify the pool name and the Batch access key in the linked service.

Error code: 2502

- **Message**: `Cannot access user storage account; please check storage account settings.`
- **Cause**: Incorrect storage account name or access key.
- **Recommendation**: Verify the storage account name and the access key in the linked service.

Error code: 2504

- **Message**: `Operation returned an invalid status code 'BadRequest'.`
- **Cause**: Too many files in the `folderPath` of the custom activity. The total size of `resourceFiles` can't be more than 32,768 characters.
- **Recommendation**: Remove unnecessary files, or Zip them and add an unzip command to extract them.

  For example, use

  ```
  powershell.exe -nologo -noprofile -command "& { Add-Type -A 'System.IO.Compression.FileSystem';
  [IO.Compression.ZipFile]::ExtractToDirectory($zipFile, $folder); }" ; $folder\yourProgram.exe
  ```

Error code: 2505

- **Message**: `Cannot create Shared Access Signature unless Account Key credentials are used.`
- **Cause**: Custom activities support only storage accounts that use an access key.
- **Recommendation**: Refer to the error description.

Error code: 2507

- **Message**: `The folder path does not exist or is empty: ...`
- **Cause**: No files are in the storage account at the specified path.
- **Recommendation**: The folder path must contain the executable files you want to run.

Error code: 2508

- **Message**: `There are duplicate files in the resource folder.`

- **Cause**: Multiple files of the same name are in different subfolders of folderPath.
- **Recommendation**: Custom activities flatten folder structure under folderPath. If you need to preserve the folder structure, zip the files and extract them in Azure Batch by using an unzip command.

  For example, use

  ```
  powershell.exe -nologo -noprofile -command "& { Add-Type -A 'System.IO.Compression.FileSystem';
  [IO.Compression.ZipFile]::ExtractToDirectory($zipFile, $folder); }" ; $folder\yourProgram.exe
  ```

Error code: 2509

- **Message**: `Batch url ... is invalid; it must be in Uri format.`
- **Cause**: Batch URLs must be similar to `https://mybatchaccount.eastus.batch.azure.com`
- **Recommendation**: Refer to the error description.

Error code: 2510

- **Message**: `An error occurred while sending the request.`
- **Cause**: The batch URL is invalid.
- **Recommendation**: Verify the batch URL.

HDInsight

Error code: 206

- **Message**: `The batch ID for Spark job is invalid. Please retry your job.`
- **Cause**: There was an internal problem with the service that caused this error.
- **Recommendation**: This issue could be transient. Retry your job after sometime.

Error code: 207

- **Message**:

  ```
  Could not determine the region from the provided storage account. Please try using another primary
  storage account for the on demand HDI.
  ```

- **Cause**: There was an internal error while trying to determine the region from the primary storage account.
- **Recommendation**: Try another storage.

Error code: 208

- **Message**:

  ```
  Service Principal or the MSI authenticator are not instantiated. Please consider providing a Service
  Principal in the HDI on demand linked service which has permissions to create an HDInsight cluster in
  the provided subscription and try again.
  ```

- **Cause**: There was an internal error while trying to read the Service Principal or instantiating the MSI authentication.
- **Recommendation**: Consider providing a service principal, which has permissions to create an HDInsight cluster in the provided subscription and try again. Verify that the Manage Identities are set up correctly.

Error code: 2300

- **Message**: `Failed to submit the job '%jobId;' to the cluster '%cluster;'. Error: %errorMessage;.`
- **Cause**: The error message contains a message similar to `The remote name could not be resolved.`. The provided cluster URI might be invalid.
- **Recommendation**: Verify that the cluster hasn't been deleted, and that the provided URI is correct. When

you open the URI in a browser, you should see the Ambari UI. If the cluster is in a virtual network, the URI should be the private URI. To open it, use a Virtual Machine (VM) that is part of the same virtual network.

For more information, see Directly connect to Apache Hadoop services.

- **Cause**: If the error message contains a message similar to `A task was canceled.`, the job submission timed out.
- **Recommendation**: The problem could be either general HDInsight connectivity or network connectivity. First confirm that the HDInsight Ambari UI is available from any browser. Then check that your credentials are still valid.

  If you're using a self-hosted integrated runtime (IR), perform this step from the VM or machine where the self-hosted IR is installed. Then try submitting the job again.

  For more information, read Ambari Web UI.

- **Cause**: When the error message contains a message similar to `User admin is locked out in Ambari` or `Unauthorized: Ambari user name or password is incorrect`, the credentials for HDInsight are incorrect or have expired.
- **Recommendation**: Correct the credentials and redeploy the linked service. First verify that the credentials work on HDInsight by opening the cluster URI on any browser and trying to sign in. If the credentials don't work, you can reset them from the Azure portal.

  For ESP cluster, reset the password through self service password reset.

- **Cause**: When the error message contains a message similar to `502 - Web server received an invalid response while acting as a gateway or proxy server`, this error is returned by HDInsight service.
- **Recommendation**: A 502 error often occurs when your Ambari Server process was shut down. You can restart the Ambari Services by rebooting the head node.

  1. Connect to one of your nodes on HDInsight using SSH.
  2. Identify your active head node host by running `ping headnodehost`.
  3. Connect to your active head node as Ambari Server sits on the active head node using SSH.
  4. Reboot the active head node.

     For more information, look through the Azure HDInsight troubleshooting documentation. For example:

     - Ambari UI 502 error
     - RpcTimeoutException for Apache Spark thrift server
     - Troubleshooting bad gateway errors in Application Gateway.

- **Cause**: When the error message contains a message similar to `Unable to service the submit job request as templeton service is busy with too many submit job requests` or `Queue root.joblauncher already has 500 applications, cannot accept submission of application`, too many jobs are being submitted to HDInsight at the same time.

- **Recommendation**: Limit the number of concurrent jobs submitted to HDInsight. Refer to activity concurrency if the jobs are being submitted by the same activity. Change the triggers so the concurrent pipeline runs are spread out over time.

  Refer to HDInsight documentation to adjust `templeton.parallellism.job.submit` as the error suggests.

Error code: 2301

- **Message**:
  ```
  Could not get the status of the application '%physicalJobId;' from the HDInsight service. Received the following error: %message;. Please refer to HDInsight troubleshooting documentation or contact their support for further assistance.
  ```
- **Cause**: HDInsight cluster or service has issues.
- **Recommendation**: This error occurs when the service doesn't receive a response from HDInsight cluster when attempting to request the status of the running job. This issue might be on the cluster itself, or HDInsight service might have an outage.

  Refer to HDInsight troubleshooting documentation, or contact Microsoft support for further assistance.

Error code: 2302

- **Message**:
  ```
  Hadoop job failed with exit code '%exitCode;'. See '%logPath;/stderr' for more details. Alternatively, open the Ambari UI on the HDI cluster and find the logs for the job '%jobId;'. Contact HDInsight team for further support.
  ```
- **Cause**: The job was submitted to the HDI cluster and failed there.
- **Recommendation**:

1. Check Ambari UI:
   a. Ensure that all services are still running.
   b. From Ambari UI, check the alert section in your dashboard.
      a. For more information on alerts and resolutions to alerts, see Managing and Monitoring a Cluster.
   c. Review your YARN memory. If your YARN memory is high, the processing of your jobs may be delayed. If you do not have enough resources to accommodate your Spark application/job, scale up the cluster to ensure the cluster has enough memory and cores.
2. Run a Sample test job.
   a. If you run the same job on HDInsight backend, check that it succeeded. For examples of sample runs, see Run the MapReduce examples included in HDInsight
3. If the job still failed on HDInsight, check the application logs and information, which to provide to Support:
   a. Check whether the job was submitted to YARN. If the job wasn't submitted to yarn, use `--master yarn`.
   b. If the application finished execution, collect the start time and end time of the YARN Application. If the application didn't complete the execution, collect Start time/Launch time.
   c. Check and collect application log with `yarn logs -applicationId <Insert_Your_Application_ID>`.
   d. Check and collect the yarn Resource Manager logs under the `/var/log/hadoop-yarn/yarn` directory.
   e. If these steps are not enough to resolve the issue, contact Azure HDInsight team for support and provide the above logs and timestamps.

Error code: 2303

- **Message**:
  ```
  Hadoop job failed with transient exit code '%exitCode;'. See '%logPath;/stderr' for more details. Alternatively, open the Ambari UI on the HDI cluster and find the logs for the job '%jobId;'. Try again or contact HDInsight team for further support.
  ```
- **Cause**: The job was submitted to the HDI cluster and failed there.

- **Recommendation**:

1. Check Ambari UI:
   a. Ensure that all services are still running.
   b. From Ambari UI, check the alert section in your dashboard.
      a. For more information on alerts and resolutions to alerts, see Managing and Monitoring a Cluster.
   c. Review your YARN memory. If your YARN memory is high, the processing of your jobs may be delayed. If you do not have enough resources to accommodate your Spark application/job, scale up the cluster to ensure the cluster has enough memory and cores.
2. Run a Sample test job.
   a. If you run the same job on HDInsight backend, check that it succeeded. For examples of sample runs, see Run the MapReduce examples included in HDInsight
3. If the job still failed on HDInsight, check the application logs and information, which to provide to Support:
   a. Check whether the job was submitted to YARN. If the job wasn't submitted to yarn, use `--master yarn`.
   b. If the application finished execution, collect the start time and end time of the YARN Application. If the application didn't complete the execution, collect Start time/Launch time.
   c. Check and collect application log with `yarn logs -applicationId <Insert_Your_Application_ID>`.
   d. Check and collect the yarn Resource Manager logs under the `/var/log/hadoop-yarn/yarn` directory.
   e. If these steps are not enough to resolve the issue, contact Azure HDInsight team for support and provide the above logs and timestamps.

Error code: 2304

- **Message**: `MSI authentication is not supported on storages for HDI activities.`
- **Cause**: The storage linked services used in the HDInsight (HDI) linked service or HDI activity, are configured with an MSI authentication that isn't supported.
- **Recommendation**: Provide full connection strings for storage accounts used in the HDI linked service or HDI activity.

Error code: 2305

- **Message**: `Failed to initialize the HDInsight client for the cluster '%cluster;'. Error: '%message;'`
- **Cause**: The connection information for the HDI cluster is incorrect, the provided user doesn't have permissions to perform the required action, or the HDInsight service has issues responding to requests from the service.
- **Recommendation**: Verify that the user information is correct, and that the Ambari UI for the HDI cluster can be opened in a browser from the VM where the IR is installed (for a self-hosted IR), or can be opened from any machine (for Azure IR).

Error code: 2306

- **Message**: `An invalid json is provided for script action '%scriptActionName;'. Error: '%message;'`
- **Cause**: The JSON provided for the script action is invalid.
- **Recommendation**: The error message should help to identify the issue. Fix the json configuration and try again.

  Check Azure HDInsight on-demand linked service for more information.

Error code: 2310

- **Message**: `Failed to submit Spark job. Error: '%message;'`

- **Cause**: The service tried to create a batch on a Spark cluster using Livy API (livy/batch), but received an error.
- **Recommendation**: Follow the error message to fix the issue. If there isn't enough information to get it resolved, contact the HDI team and provide them the batch ID and job ID, which can be found in the activity run Output in the service Monitoring page. To troubleshoot further, collect the full log of the batch job.

  For more information on how to collect the full log, see Get the full log of a batch job.

Error code: 2312

- **Message**:
  ```
  Spark job failed, batch id:%batchId;. Please follow the links in the activity run Output from the service Monitoring page to troubleshoot the run on HDInsight Spark cluster. Please contact HDInsight support team for further assistance.
  ```
- **Cause**: The job failed on the HDInsight Spark cluster.
- **Recommendation**: Follow the links in the activity run Output in the service Monitoring page to troubleshoot the run on HDInsight Spark cluster. Contact HDInsight support team for further assistance.

  For more information on how to collect the full log, see Get the full log of a batch job.

Error code: 2313

- **Message**:
  ```
  The batch with ID '%batchId;' was not found on Spark cluster. Open the Spark History UI and try to find it there. Contact HDInsight support for further assistance.
  ```
- **Cause**: The batch was deleted on the HDInsight Spark cluster.
- **Recommendation**: Troubleshoot batches on the HDInsight Spark cluster. Contact HDInsight support for further assistance.

  For more information on how to collect the full log, see Get the full log of a batch job, and share the full log with HDInsight support for further assistance.

Error code: 2328

- **Message**:
  ```
  Failed to create the on demand HDI cluster. Cluster or linked service name: '%clusterName;', error: '%message;'
  ```
- **Cause**: The error message should show the details of what went wrong.
- **Recommendation**: The error message should help to troubleshoot the issue.

Error code: 2329

- **Message**:
  ```
  Failed to delete the on demand HDI cluster. Cluster or linked service name: '%clusterName;', error: '%message;'
  ```
- **Cause**: The error message should show the details of what went wrong.
- **Recommendation**: The error message should help to troubleshoot the issue.

Error code: 2331

- **Message**: `The file path should not be null or empty.`
- **Cause**: The provided file path is empty.
- **Recommendation**: Provide a path for a file that exists.

Error code: 2340

- **Message**:
  ```
  HDInsightOnDemand linked service does not support execution via SelfHosted IR. Your IR name is '%IRName;'. Please select an Azure IR instead.
  ```
- **Cause**: The HDInsightOnDemand linked service doesn't support execution via SelfHosted IR.
- **Recommendation**: Select an Azure IR and try again.

Error code: 2341

- **Message**:
  ```
  HDInsight cluster URL '%clusterUrl;' is incorrect, it must be in URI format and the scheme must be 'https'.
  ```
- **Cause**: The provided URL isn't in correct format.
- **Recommendation**: Fix the cluster URL and try again.

Error code: 2342

- **Message**: `Failed to connect to HDInsight cluster: '%errorMessage;'.`
- **Cause**: Either the provided credentials are wrong for the cluster, or there was a network configuration or connection issue, or the IR is having problems connecting to the cluster.
- **Recommendation**:

  1. Verify that the credentials are correct by opening the HDInsight cluster's Ambari UI in a browser.
  2. If the cluster is in Virtual Network (VNet) and a self-hosted IR is being used, the HDI URL must be the private URL in VNets, and should have `-int` listed after the cluster name.

     For example, change `https://mycluster.azurehdinsight.net/` to `https://mycluster-int.azurehdinsight.net/`. Note the `-int` after `mycluster`, but before `.azurehdinsight.net`
  3. If the cluster is in VNet, the self-hosted IR is being used, and the private URL was used, and yet the connection still failed, then the VM where the IR is installed had problems connecting to the HDI.

     Connect to the VM where the IR is installed and open the Ambari UI in a browser. Use the private URL for the cluster. This connection should work from the browser. If it doesn't, contact HDInsight support team for further assistance.
  4. If self-hosted IR isn't being used, then the HDI cluster should be accessible publicly. Open the Ambari UI in a browser and check that it opens up. If there are any issues with the cluster or the services on it, contact HDInsight support team for assistance.

     The HDI cluster URL used in the linked service must be accessible for the IR (self-hosted or Azure) in order for the test connection to pass, and for runs to work. This state can be verified by opening the URL from a browser either from VM, or from any public machine.

Error code: 2343

- **Message**: `User name and password cannot be null or empty to connect to the HDInsight cluster.`
- **Cause**: Either the user name or the password is empty.
- **Recommendation**: Provide the correct credentials to connect to HDI and try again.

Error code: 2345

- **Message**: `Failed to read the content of the hive script. Error: '%message;'`
- **Cause**: The script file doesn't exist or the service couldn't connect to the location of the script.

- **Recommendation**: Verify that the script exists, and that the associated linked service has the proper credentials for a connection.

Error code: 2346

- **Message**: `Failed to create ODBC connection to the HDI cluster with error message '%message;'.`
- **Cause**: The service tried to establish an Open Database Connectivity (ODBC) connection to the HDI cluster, and it failed with an error.
- **Recommendation**:

  1. Confirm that you correctly set up your ODBC/Java Database Connectivity (JDBC) connection.
     a. For JDBC, if you're using the same virtual network, you can get this connection from: `Hive -> Summary -> HIVESERVER2 JDBC URL`
     b. To ensure that you have the correct JDBC set up, see Query Apache Hive through the JDBC driver in HDInsight.
     c. For Open Database (ODB), see Tutorial: Query Apache Hive with ODBC and PowerShell to ensure that you have the correct setup.
  2. Verify that Hiveserver2, Hive Metastore, and Hiveserver2 Interactive are active and working.
  3. Check the Ambari user interface (UI):
     a. Ensure that all services are still running.
     b. From the Ambari UI, check the alert section in your dashboard.
        a. For more information on alerts and resolutions to alerts, see Managing and Monitoring a Cluster .
  4. If these steps are not enough to resolve the issue, contact the Azure HDInsight team.

Error code: 2347

- **Message**: `Hive execution through ODBC failed with error message '%message;'.`
- **Cause**: The service submitted the hive script for execution to the HDI cluster via ODBC connection, and the script has failed on HDI.
- **Recommendation**:

  1. Confirm that you correctly set up your ODBC/Java Database Connectivity (JDBC) connection.
     a. For JDBC, if you're using the same virtual network, you can get this connection from: `Hive -> Summary -> HIVESERVER2 JDBC URL`
     b. To ensure that you have the correct JDBC set up, see Query Apache Hive through the JDBC driver in HDInsight.
     c. For Open Database (ODB), see Tutorial: Query Apache Hive with ODBC and PowerShell to ensure that you have the correct setup.
  2. Verify that Hiveserver2, Hive Metastore, and Hiveserver2 Interactive are active and working.
  3. Check the Ambari user interface (UI):
     a. Ensure that all services are still running.
     b. From the Ambari UI, check the alert section in your dashboard.
        a. For more information on alerts and resolutions to alerts, see Managing and Monitoring a Cluster .
  4. If these steps are not enough to resolve the issue, contact the Azure HDInsight team.

Error code: 2348

- **Message**:

```
The main storage has not been initialized. Please check the properties of the storage linked service
in the HDI linked service.
```

- **Cause**: The storage linked service properties are not set correctly.
- **Recommendation**: Only full connection strings are supported in the main storage linked service for HDI activities. Verify that you are not using MSI authorizations or applications.

Error code: 2350

- **Message**:
  ```
  Failed to prepare the files for the run '%jobId;'. HDI cluster: '%cluster;', Error: '%errorMessage;'
  ```
- **Cause**: The credentials provided to connect to the storage where the files should be located are incorrect, or the files do not exist there.
- **Recommendation**: This error occurs when the service prepares for HDI activities, and tries to copy files to the main storage before submitting the job to HDI. Check that files exist in the provided location, and that the storage connection is correct. As HDI activities do not support MSI authentication on storage accounts related to HDI activities, verify that those linked services have full keys or are using Azure Key Vault.

Error code: 2351

- **Message**: `Could not open the file '%filePath;' in container/fileSystem '%container;'.`
- **Cause**: The file doesn't exist at specified path.
- **Recommendation**: Check whether the file actually exists, and that the linked service with connection info pointing to this file has the correct credentials.

Error code: 2352

- **Message**:
  ```
  The file storage has not been initialized. Please check the properties of the file storage linked
  service in the HDI activity.
  ```
- **Cause**: The file storage linked service properties are not set correctly.
- **Recommendation**: Verify that the properties of the file storage linked service are properly configured.

Error code: 2353

- **Message**:
  ```
  The script storage has not been initialized. Please check the properties of the script storage linked
  service in the HDI activity.
  ```
- **Cause**: The script storage linked service properties are not set correctly.
- **Recommendation**: Verify that the properties of the script storage linked service are properly configured.

Error code: 2354

- **Message**:
  ```
  The storage linked service type '%linkedServiceType;' is not supported for '%executorType;' activities
  for property '%linkedServicePropertyName;'.
  ```
- **Cause**: The storage linked service type isn't supported by the activity.
- **Recommendation**: Verify that the selected linked service has one of the supported types for the activity. HDI activities support AzureBlobStorage and AzureBlobFSStorage linked services.

  For more information, read Compare storage options for use with Azure HDInsight clusters

Error code: 2355

- **Message**:
  ```
  The '%value' provided for commandEnvironment is incorrect. The expected value should be an array of
  strings where each string has the format CmdEnvVarName=CmdEnvVarValue.
  ```

- **Cause**: The provided value for `commandEnvironment` is incorrect.
- **Recommendation**: Verify that the provided value is similar to:

  ```
  \"variableName=variableValue\"
  ]
  ```

  Also verify that each variable appears in the list only once.

Error code: 2356

- **Message**: `The commandEnvironment already contains a variable named '%variableName;'.`
- **Cause**: The provided value for `commandEnvironment` is incorrect.
- **Recommendation**: Verify that the provided value is similar to:

  ```
  \"variableName=variableValue\"
  ]
  ```

  Also verify that each variable appears in the list only once.

Error code: 2357

- **Message**: `The certificate or password is wrong for ADLS Gen 1 storage.`
- **Cause**: The provided credentials are incorrect.
- **Recommendation**: Verify that the connection information in ADLS Gen 1 linked to the service, and verify that the test connection succeeds.

Error code: 2358

- **Message**:

  ```
  The value '%value;' for the required property 'TimeToLive' in the on demand HDInsight linked service
  '%linkedServiceName;' has invalid format. It should be a timespan between '00:05:00' and '24:00:00'.
  ```

- **Cause**: The provided value for the required property `TimeToLive` has an invalid format.
- **Recommendation**: Update the value to the suggested range and try again.

Error code: 2359

- **Message**:

  ```
  The value '%value;' for the property 'roles' is invalid. Expected types are 'zookeeper', 'headnode',
  and 'workernode'.
  ```

- **Cause**: The provided value for the property `roles` is invalid.
- **Recommendation**: Update the value to be one of the suggestions and try again.

Error code: 2360

- **Message**:

  ```
  The connection string in HCatalogLinkedService is invalid. Encountered an error while trying to parse:
  '%message;'.
  ```

- **Cause**: The provided connection string for the `HCatalogLinkedService` is invalid.
- **Recommendation**: Update the value to a correct Azure SQL connection string and try again.

Error code: 2361

- **Message**: `Failed to create on demand HDI cluster. Cluster name is '%clusterName;'.`

- **Cause**: The cluster creation failed, and the service did not get an error back from HDInsight service.
- **Recommendation**: Open the Azure portal and try to find the HDI resource with provided name, then check the provisioning status. Contact HDInsight support team for further assistance.

Error code: 2362

- **Message**:

```
Only Azure Blob storage accounts are supported as additional storages for HDInsight on demand linked service.
```

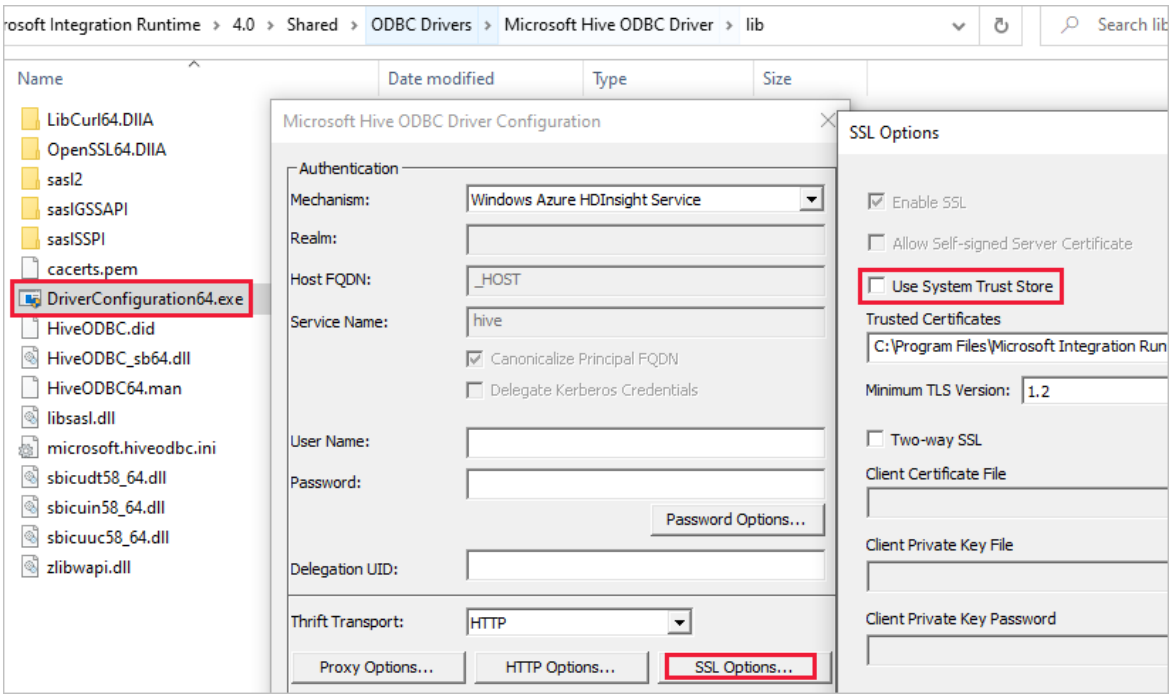
- **Cause**: The provided additional storage was not Azure Blob storage.
- **Recommendation**: Provide an Azure Blob storage account as an additional storage for HDInsight on-demand linked service.

SSL error when linked service using HDInsight ESP cluster

- **Message**:

```
Failed to connect to HDInsight cluster: 'ERROR [HY000] [Microsoft][DriverSupport] (1100) SSL certificate verification failed because the certificate is missing or incorrect.
```

- **Cause**: The issue is most likely related with System Trust Store.
- **Resolution**: You can navigate to the path **Microsoft Integration Runtime\4.0\Shared\ODBC Drivers\Microsoft Hive ODBC Driver\lib** and open DriverConfiguration64.exe to change the setting.



HDI activity stuck in preparing for cluster

If the HDI activity is stuck in preparing for cluster, follow the guidelines below:

1. Make sure the timeout is greater than what is described below and wait for the execution to complete or until it is timed out, and wait for Time To Live (TTL) time before submitting new jobs.

   The max default time that it takes to spin up a cluster is 2 hours, and if you have any init script, it will add up, up to another 2 hours.

2. Make sure the storage and HDI are provisioned in the same region.
3. Make sure that the service principal used for accessing the HDI cluster is valid.
4. If the issue still persists, as a workaround, delete the HDI linked service and re-create it with a new name.

Web Activity

Error code: 2128

- **Message**:
  ```
  No response from the endpoint. Possible causes: network connectivity, DNS failure, server certificate validation or timeout.
  ```
- **Cause**: This issue is due to either Network connectivity, a DNS failure, a server certificate validation, or a timeout.
- **Recommendation**: Validate that the endpoint you are trying to hit is responding to requests. You may use tools like **Fiddler/Postman/Netmon/Wireshark**.

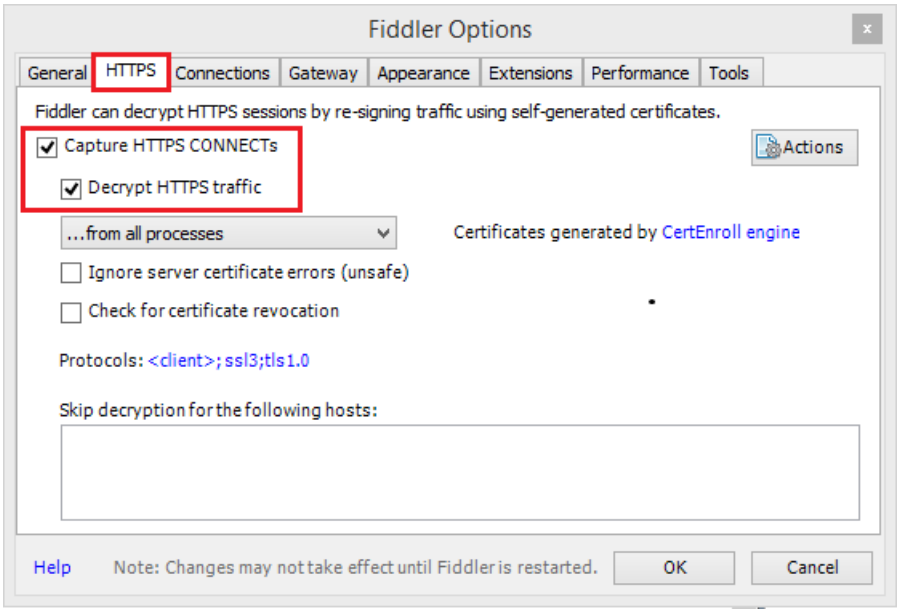
Error code: 2108

- **Message**: `Error calling the endpoint '%url;'. Response status code: '%code;'`
- **Cause**: The request failed due to an underlying issue such as network connectivity, a DNS failure, a server certificate validation, or a timeout.
- **Recommendation**: Use Fiddler/Postman/Netmon/Wireshark to validate the request.

More details

To use **Fiddler** to create an HTTP session of the monitored web application:

1. Download, install, and open Fiddler.
2. If your web application uses HTTPS, go to **Tools** > **Fiddler Options** > **HTTPS**.
   a. In the HTTPS tab, select both **Capture HTTPS CONNECTs** and **Decrypt HTTPS traffic**.



3. If your application uses TLS/SSL certificates, add the Fiddler certificate to your device.

   Go to: **Tools** > **Fiddler Options** > **HTTPS** > **Actions** > **Export Root Certificate to Desktop**.
4. Turn off capturing by going to **File** > **Capture Traffic**. Or press **F12**.
5. Clear your browser's cache so that all cached items are removed and must be downloaded again.
6. Create a request:
7. Select the **Composer** tab.
   a. Set the HTTP method and URL.

b. If needed, add headers and a request body.

c. Select **Execute**.

8. Turn on traffic capturing again, and complete the problematic transaction on your page.

9. Go to: **File** > **Save** > **All Sessions**.

For more information, see Getting started with Fiddler.

General

REST continuation token NULL error

Error message: {"token":null,"range":{"min":...}

Cause: When querying across multiple partitions/pages, backend service returns continuation token in JObject format with 3 properties: **token, min and max key ranges**, for instance, {"token":null,"range":{"min":"05C1E9AB0DAD76","max":"05C1E9CD673398"}}). Depending on source data, querying can result 0 indicating missing token though there is more data to fetch.

Recommendation: When the continuationToken is non-null, as the string {"token":null,"range":{"min":"05C1E9AB0DAD76","max":"05C1E9CD673398"}}, it is required to call queryActivityRuns API again with the continuation token from the previous response. You need to pass the full string for the query API again. The activities will be returned in the subsequent pages for the query result. You should ignore that there is empty array in this page, as long as the full continuationToken value != null, you need continue querying. For more details, please refer to REST api for pipeline run query.

Activity stuck issue

When you observe that the activity is running much longer than your normal runs with barely no progress, it may happen to be stuck. You can try canceling it and retry to see if it helps. If it's a copy activity, you can learn about the performance monitoring and troubleshooting from Troubleshoot copy activity performance; if it's a data flow, learn from Mapping data flows performance and tuning guide.

Payload is too large

Error message:

```
The payload including configurations on activity/dataSet/linked service is too large. Please check if you
have settings with very large value and try to reduce its size.
```

Cause: The payload for each activity run includes the activity configuration, the associated dataset(s), and linked service(s) configurations if any, and a small portion of system properties generated per activity type. The limit of such payload size is 896 KB as mentioned in the Azure limits documentation for Data Factory and Azure Synapse Analytics.

Recommendation: You hit this limit likely because you pass in one or more large parameter values from either upstream activity output or external, especially if you pass actual data across activities in control flow. Check if you can reduce the size of large parameter values, or tune your pipeline logic to avoid passing such values across activities and handle it inside the activity instead.

Unsupported compression causes files to be corrupted

Symptoms: You try to unzip a file that is stored in a blob container. A single copy activity in a pipeline has a source with the compression type set to "deflate64" (or any unsupported type). This activity runs successfully and produces the text file contained in the zip file. However, there is a problem with the text in the file, and this file appears corrupted. When this file is unzipped locally, it is fine.

Cause: Your zip file is compressed by the algorithm of "deflate64", while the internal zip library of Azure Data Factory only supports "deflate". If the zip file is compressed by the Windows system and the overall file size exceeds a certain number, Windows will use "deflate64" by default, which is not supported in Azure Data

Factory. On the other hand, if the file size is smaller or you use some third party zip tools that support specifying the compress algorithm, Windows will use "deflate" by default.

> **TIP**
>
> Actually, both Binary format in Azure Data Factory and Synapse Analytics and Delimited text format in Azure Data Factory and Azure Synapse Analytics clearly state that the "deflate64" format is not supported in Azure Data Factory.

Troubleshoot Azure Data Factory and Azure Synapse Analytics connectors

8/19/2022 • 6 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article describes how to troubleshoot connectors in Azure Data Factory and Azure Synapse Analytics.

Connector specific problems

You can refer to the troubleshooting pages for each connector to see problems specific to it with explanations of their causes and recommendations to resolve them.

- Azure Blob Storage
- Azure Cosmos DB (including SQL API connector)
- Azure Data Lake (Gen1 and Gen2)
- Azure Database for PostgreSQL
- Azure Files storage
- Azure Synapse Analytics, Azure SQL Database, and SQL Server
- DB2
- Delimited text format
- Dynamics 365, Dataverse (Common Data Service), and Dynamics CRM
- FTP, SFTP and HTTP
- Hive
- Oracle
- ORC format
- Parquet format
- REST
- SharePoint Online list
- XML format

General copy activity errors

The errors below are general to the copy activity and could occur with any connector.

Error code: JreNotFound

- **Message**:

  ```
  Java Runtime Environment cannot be found on the Self-hosted Integration Runtime machine. It is required for parsing or writing to Parquet/ORC files. Make sure Java Runtime Environment has been installed on the Self-hosted Integration Runtime machine.
  ```

- **Cause**: The self-hosted IR can't find Java Runtime. Java Runtime is required for reading particular sources.

- **Recommendation**: Check your integration runtime environment, see Use Self-hosted Integration Runtime.

Error code: WildcardPathSinkNotSupported

- **Message**: `Wildcard in path is not supported in sink dataset. Fix the path: '%setting;'.`

- **Cause**: The sink dataset doesn't support wildcard values.
- **Recommendation**: Check the sink dataset, and rewrite the path without using a wildcard value.

FIPS issue

- **Symptoms**: Copy activity fails on a FIPS-enabled self-hosted IR machine with the following error message:

  ```
  This implementation is not part of the Windows Platform FIPS validated cryptographic algorithms.
  ```

- **Cause**: This error might occur when you copy data with connectors such as Azure Blob, SFTP, and so on. Federal Information Processing Standards (FIPS) defines a certain set of cryptographic algorithms that are allowed to be used. When FIPS mode is enabled on the machine, some cryptographic classes that copy activity depends on are blocked in some scenarios.
- **Resolution**: Learn why we're not recommending "FIPS Mode" anymore, and evaluate whether you can disable FIPS on your self-hosted IR machine.

  Alternatively, if you only want to bypass FIPS and make the activity runs succeed, do the following:

  1. Open the folder where Self-hosted IR is installed. The path is usually *C:\Program Files\Microsoft Integration Runtime <IR version>\Shared*.
  2. Open the *diawp.exe.config* file and then, at the end of the `<runtime>` section, add `<enforceFIPSPolicy enabled="false"/>`, as shown here:

     ```
     <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
       <dependentAssembly>
         <assemblyIdentity name="BouncyCastle.Crypto" publicKeyToken="0e99375e54769942" culture="neutral" />
         <bindingRedirect oldVersion="0.0.0.0-1.8.5.0" newVersion="1.8.5.0" />
       </dependentAssembly>
     </assemblyBinding>
     <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
       <dependentAssembly>
         <assemblyIdentity name="YamlDotNet" publicKeyToken="ec19458f3c15af5e" culture="neutral" />
         <bindingRedirect oldVersion="0.0.0.0-6.0.0.0" newVersion="6.0.0.0" />
       </dependentAssembly>
     </assemblyBinding>
     <assemblyBinding xmlns="urn:schemas-microsoft-com:asm.v1">
       <dependentAssembly>
         <assemblyIdentity name="Microsoft.Cloud.InstrumentationFramework.Metrics" publicKeyToken="31bf3856ad364e35" culture="neutral" />
         <bindingRedirect oldVersion="0.0.0.0-3.0.0.0" newVersion="3.0.0.0" />
       </dependentAssembly>
     </assemblyBinding>
     <enforceFIPSPolicy enabled="false"/>
   </runtime>
 </configuration>
     ```

  3. Save the file, and then restart the Self-hosted IR machine.

Error code: JniException

- **Message**: `An error occurred when invoking Java Native Interface.`
- **Cause**: If the error message contains "Cannot create JVM: JNI return code [-6][JNI call failed: Invalid arguments.]", the possible cause is that JVM can't be created because some illegal (global) arguments are set.
- **Recommendation**: Log in to the machine that hosts *each node* of your self-hosted integration runtime. Check to ensure that the system variable is set correctly, as follows: `_JAVA_OPTIONS "-Xms256m -Xmx16g" with memory bigger than 8G`. Restart all the integration runtime nodes, and then rerun the pipeline.

Error code: GetOAuth2AccessTokenErrorResponse

- **Message**:

  ```
  Failed to get access token from your token endpoint. Error returned from your authorization server: %errorResponse;.
  ```

- **Cause**: Your client ID or client secret is invalid, and the authentication failed in your authorization server.
- **Recommendation**: Correct all OAuth2 client credential flow settings of your authorization server.

Error code: FailedToGetOAuth2AccessToken

- **Message**: `Failed to get access token from your token endpoint. Error message: %errorMessage;.`
- **Cause**: OAuth2 client credential flow settings are invalid.
- **Recommendation**: Correct all OAuth2 client credential flow settings of your authorization server.

Error code: OAuth2AccessTokenTypeNotSupported

- **Message**:
  ```
  The toke type '%tokenType;' from your authorization server is not supported, supported types: '%tokenTypes;'.
  ```
- **Cause**: Your authorization server is not supported.
- **Recommendation**: Use an authorization server that can return tokens with supported token types.

Error code: OAuth2ClientIdColonNotAllowed

- **Message**:
  ```
  The character colon(:) is not allowed in clientId for OAuth2ClientCredential authentication.
  ```
- **Cause**: Your client ID includes the invalid character colon (`:`).
- **Recommendation**: Use a valid client ID.

Error code: ManagedIdentityCredentialObjectNotSupported

- **Message**:
  ```
  Managed identity credential is not supported in this version ('%version;') of Self Hosted Integration Runtime.
  ```
- **Recommendation**: Check the supported version and upgrade the integration runtime to a higher version.

Error code: QueryMissingFormatSettingsInDataset

- **Message**: `The format settings are missing in dataset %dataSetName;.`
- **Cause**: The dataset type is Binary, which is not supported.
- **Recommendation**: Use the DelimitedText, Json, Avro, Orc, or Parquet dataset instead.
- **Cause**: For the file storage, the format settings are missing in the dataset.
- **Recommendation**: Deselect the "Binary copy" in the dataset, and set correct format settings.

Error code: QueryUnsupportedCommandBehavior

- **Message**: `The command behavior "%behavior;" is not supported.`
- **Recommendation**: Don't add the command behavior as a parameter for preview or GetSchema API request URL.

Error code: DataConsistencyFailedToGetSourceFileMetadata

- **Message**: `Failed to retrieve source file ('%name;') metadata to validate data consistency.`
- **Cause**: There is a transient issue on the sink data store, or retrieving metadata from the sink data store is not allowed.

Error code: DataConsistencyFailedToGetSinkFileMetadata

- **Message**: `Failed to retrieve sink file ('%name;') metadata to validate data consistency.`
- **Cause**: There is a transient issue on the sink data store, or retrieving metadata from the sink data store is not allowed.

Error code: DataConsistencyValidationNotSupportedForNonDirectBinaryCopy

- **Message**: `Data consistency validation is not supported in current copy activity settings.`
- **Cause**: The data consistency validation is only supported in the direct binary copy scenario.
- **Recommendation**: Remove the 'validateDataConsistency' property in the copy activity payload.

Error code: DataConsistencyValidationNotSupportedForLowVersionSelfHostedIntegrationRuntime

- **Message**:
  ```
  'validateDataConsistency' is not supported in this version ('%version;') of Self Hosted Integration Runtime.
  ```
- **Recommendation**: Check the supported integration runtime version and upgrade it to a higher version, or remove the 'validateDataConsistency' property from copy activities.

Error code: SkipMissingFileNotSupportedForNonDirectBinaryCopy

- **Message**:
  ```
  Skip missing file is not supported in current copy activity settings, it's only supported with direct binary copy with folder.
  ```
- **Recommendation**: Remove 'fileMissing' of the skipErrorFile setting in the copy activity payload.

Error code: SkipInconsistencyDataNotSupportedForNonDirectBinaryCopy

- **Message**:
  ```
  Skip inconsistency is not supported in current copy activity settings, it's only supported with direct binary copy when validateDataConsistency is true.
  ```
- **Recommendation**: Remove 'dataInconsistency' of the skipErrorFile setting in the copy activity payload.

Error code: SkipForbiddenFileNotSupportedForNonDirectBinaryCopy

- **Message**:
  ```
  Skip forbidden file is not supported in current copy activity settings, it's only supported with direct binary copy with folder.
  ```
- **Recommendation**: Remove 'fileForbidden' of the skipErrorFile setting in the copy activity payload.

Error code: SkipForbiddenFileNotSupportedForThisConnector

- **Message**: `Skip forbidden file is not supported for this connector: ('%connectorName;').`
- **Recommendation**: Remove 'fileForbidden' of the skipErrorFile setting in the copy activity payload.

Error code: SkipInvalidFileNameNotSupportedForNonDirectBinaryCopy

- **Message**:
  ```
  Skip invalid file name is not supported in current copy activity settings, it's only supported with direct binary copy with folder.
  ```
- **Recommendation**: Remove 'invalidFileName' of the skipErrorFile setting in the copy activity payload.

Error code: SkipInvalidFileNameNotSupportedForSource

- **Message**: `Skip invalid file name is not supported for '%connectorName;' source.`
- **Recommendation**: Remove 'invalidFileName' of the skipErrorFile setting in the copy activity payload.

Error code: SkipInvalidFileNameNotSupportedForSink

- **Message**: `Skip invalid file name is not supported for '%connectorName;' sink.`
- **Recommendation**: Remove 'invalidFileName' of the skipErrorFile setting in the copy activity payload.

Error code: SkipAllErrorFileNotSupportedForNonBinaryCopy

- **Message**:

```
Skip all error file is not supported in current copy activity settings, it's only supported with
binary copy with folder.
```

- **Recommendation**: Remove 'allErrorFile' in the skipErrorFile setting in the copy activity payload.

Error code: DeleteFilesAfterCompletionNotSupportedForNonDirectBinaryCopy

- **Message**:
  ```
  'deleteFilesAfterCompletion' is not support in current copy activity settings, it's only supported
  with direct binary copy.
  ```
- **Recommendation**: Remove the 'deleteFilesAfterCompletion' setting or use direct binary copy.

Error code: DeleteFilesAfterCompletionNotSupportedForThisConnector

- **Message**: `'deleteFilesAfterCompletion' is not supported for this connector: ('%connectorName;').`
- **Recommendation**: Remove the 'deleteFilesAfterCompletion' setting in the copy activity payload.

Error code: FailedToDownloadCustomPlugins

- **Message**: `Failed to download custom plugins.`
- **Cause**: Invalid download links or transient connectivity issues.
- **Recommendation**: Retry if the message shows that it's a transient issue. If the problem persists, contact the support team.

General connector errors

Error code: UserErrorOdbcInvalidQueryString

- **Message**: `The following ODBC Query is not valid: '%'.`
- **Cause**: You provide a wrong or invalid query to fetch the data/schemas.
- **Recommendation**: Verify your query is valid and can return data/schemas. Use Script activity if you want to execute non-query scripts and your data store is supported. Alternatively, consider to use stored procedure that returns a dummy result to execute your non-query scripts.

Troubleshoot the Azure Blob Storage connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Blob Storage connector in Azure Data Factory and Azure Synapse.

Error code: AzureBlobOperationFailed

- **Message**: "Blob operation Failed. ContainerName: %containerName;, path: %path;."
- **Cause**: A problem with the Blob Storage operation.
- **Recommendation**: To check the error details, see Blob Storage error codes. For further help, contact the Blob Storage team.

Invalid property during copy activity

- **Message**:

```
Copy activity \<Activity Name> has an invalid "source" property. The source type is not compatible with the dataset \<Dataset Name> and its linked service \<Linked Service Name>. Please verify your input against.
```

- **Cause**: The type defined in the dataset is inconsistent with the source or sink type that's defined in the copy activity.
- **Resolution**: Edit the dataset or pipeline JSON definition to make the types consistent, and then rerun the deployment.

Error code: FIPSModeIsNotSupport

- **Message**:

```
Fail to read data form Azure Blob Storage for Azure Blob connector needs MD5 algorithm which can't co-work with FIPS mode. Please change diawp.exe.config in self-hosted integration runtime install directory to disable FIPS policy following https://docs.microsoft.com/dotnet/framework/configure-apps/file-schema/runtime/enforcefipspolicy-element.
```

- **Cause**: Then FIPS policy is enabled on the VM where the self-hosted integration runtime was installed.
- **Recommendation**: Disable the FIPS mode on the VM where the self-hosted integration runtime was installed. Windows doesn't recommend the FIPS mode.

Error code: AzureBlobInvalidBlockSize

- **Message**: `Block size should between %minSize; MB and 100 MB.`
- **Cause**: The block size is over the blob limitation.

Error code: AzureStorageOperationFailedConcurrentWrite

- **Message**:

```
Error occurred when trying to upload a file. It's possible because you have multiple concurrent copy activities runs writing to the same file '%name;'. Check your ADF configuration.
```

- **Cause**: You have multiple concurrent copy activity runs or applications writing to the same file.

Error code: AzureAppendBlobConcurrentWriteConflict

- **Message**:

```
Detected concurrent write to the same append blob file, it's possible because you have multiple concurrent copy activities runs or applications writing to the same file '%name;'. Please check your ADF configuration and retry.
```

- **Cause**: Multiple concurrent writing requests occur, which causes conflicts on file content.

Error code: AzureBlobFailedToCreateContainer

- **Message**:

```
Unable to create Azure Blob container. Endpoint: '%endpoint;', Container Name: '%containerName;'.
```

- **Cause**: This error happens when copying data with Azure Blob Storage account public access.
- **Recommendation**: For more information about connection errors in the public endpoint, see Connection error in public endpoint.

Troubleshoot the Azure Cosmos DB connector in Azure Data Factory and Azure Synapse

8/19/2022 • 3 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Cosmos DB and Azure Cosmos DB (SQL API) connectors in Azure Data Factory and Azure Synapse.

Error message: Request size is too large

- **Symptoms**: When you copy data into Azure Cosmos DB with a default write batch size, you receive the following error: `Request size is too large.`
- **Cause**: Azure Cosmos DB limits the size of a single request to 2 MB. The formula is *request size = single document size * write batch size*. If your document size is large, the default behavior will result in a request size that's too large. You can tune the write batch size.
- **Resolution**: In the copy activity sink, reduce the *write batch size* value (the default value is 10000).

Error message: Unique index constraint violation

- **Symptoms**: When you copy data into Azure Cosmos DB, you receive the following error:

```
Message=Partition range id 0 | Failed to import mini-batch. Exception was Message: {"Errors":
["Encountered exception while executing function. Exception = Error: {\"Errors\":[\"Unique index
constraint violation.\"]}...
```

- **Cause**: There are two possible causes:
  - Cause 1: If you use **Insert** as the write behavior, this error means that your source data has rows or objects with same ID.
  - Cause 2: If you use **Upsert** as the write behavior and you set another unique key to the container, this error means that your source data has rows or objects with different IDs but the same value for the defined unique key.
- **Resolution**:
  - For cause 1, set **Upsert** as the write behavior.
  - For cause 2, make sure that each document has a different value for the defined unique key.

Error message: Request rate is large

- **Symptoms**: When you copy data into Azure Cosmos DB, you receive the following error:

```
Type=Microsoft.Azure.Documents.DocumentClientException, Message=Message: {"Errors":["Request rate is
large"]}
```

- **Cause**: The number of used request units (RUs) is greater than the available RUs configured in Azure Cosmos DB. To learn how Azure Cosmos DB calculates RUs, see Request units in Azure Cosmos DB.
- **Resolution**: Try either of the following two solutions:
  - Increase the *container RUs* number to a greater value in Azure Cosmos DB. This solution will improve the copy activity performance, but it will incur more cost in Azure Cosmos DB.

- Decrease *writeBatchSize* to a lesser value, such as 1000, and decrease *parallelCopies* to a lesser value, such as 1. This solution will reduce copy run performance, but it won't incur more cost in Azure Cosmos DB.

Columns missing in column mapping

- **Symptoms**: When you import a schema for Azure Cosmos DB for column mapping, some columns are missing.
- **Cause**: Azure Data Factory and Synapse pipelines infer the schema from the first 10 Azure Cosmos DB documents. If some document columns or properties don't contain values, the schema isn't detected and consequently isn't displayed.
- **Resolution**: You can tune the query as shown in the following code to force the column values to be displayed in the result set with empty values. Assume that the *impossible* column is missing in the first 10 documents). Alternatively, you can manually add the column for mapping.

```
select c.company, c.category, c.comments, (c.impossible??'') as impossible from c
```

Error message: The GuidRepresentation for the reader is CSharpLegacy

- **Symptoms**: When you copy data from Azure Cosmos DB MongoAPI or MongoDB with the universally unique identifier (UUID) field, you receive the following error:

```
Failed to read data via MongoDB client.,
Source=Microsoft.DataTransfer.Runtime.MongoDbV2Connector,Type=System.FormatException, Message=The
GuidRepresentation for the reader is CSharpLegacy which requires the binary sub type to be UuidLegacy
not UuidStandard.,Source=MongoDB.Bson,’“,
```

- **Cause**: There are two ways to represent the UUID in Binary JSON (BSON): UuidStardard and UuidLegacy. By default, UuidLegacy is used to read data. You will receive an error if your UUID data in MongoDB is UuidStandard.
- **Resolution**: In the MongoDB connection string, add the *uuidRepresentation=standard* option. For more information, see MongoDB connection string.

Error code: CosmosDbSqlApiOperationFailed

- **Message**: `CosmosDbSqlApi operation Failed. ErrorMessage: %msg;.`
- **Cause**: A problem with the CosmosDbSqlApi operation. This applies to the Cosmos DB (SQL API) connector specifically.
- **Recommendation**: To check the error details, see Azure Cosmos DB help document. For further help, contact the Azure Cosmos DB team.

Error code: CosmosDbSqlApiPartitionKeyExceedStorage

- **Message**:

```
The size of data each logical partition can store is limited, current partitioning design and workload
failed to store more than the allowed amount of data for a given partition key value.
```

- **Cause**: The data size of each logical partition is limited, and the partition key reached the maximum size of your logical partition.
- **Recommendation**: Check your Azure Cosmos DB partition design. For more information, see Logical

partitions.

Troubleshoot the Azure Data Explorer connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Data Explorer connector in Azure Data Factory and Azure Synapse.

Error code: KustoMappingReferenceHasWrongKind

- **Message**: `Mapping reference should be of kind 'Csv'. Mapping reference: '%reference;'. Kind '%kind;'.`
- **Cause**: The ingestion mapping reference is not CSV type.
- **Recommendation**: Create a CSV ingestion mapping reference.

Error code: KustoWriteFailed

- **Message**: `Write to Kusto failed with following error: '%message;'.`
- **Cause**: Wrong configuration or transient errors when the sink reads data from the source.
- **Recommendation**: For transient failures, set retries for the activity. For permanent failures, check your configuration and contact support.

Troubleshoot the Azure Data Lake Storage connectors in Azure Data Factory and Azure Synapse

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Data Lake Storage Gen1 and Gen2 connectors in Azure Data Factory and Azure Synapse.

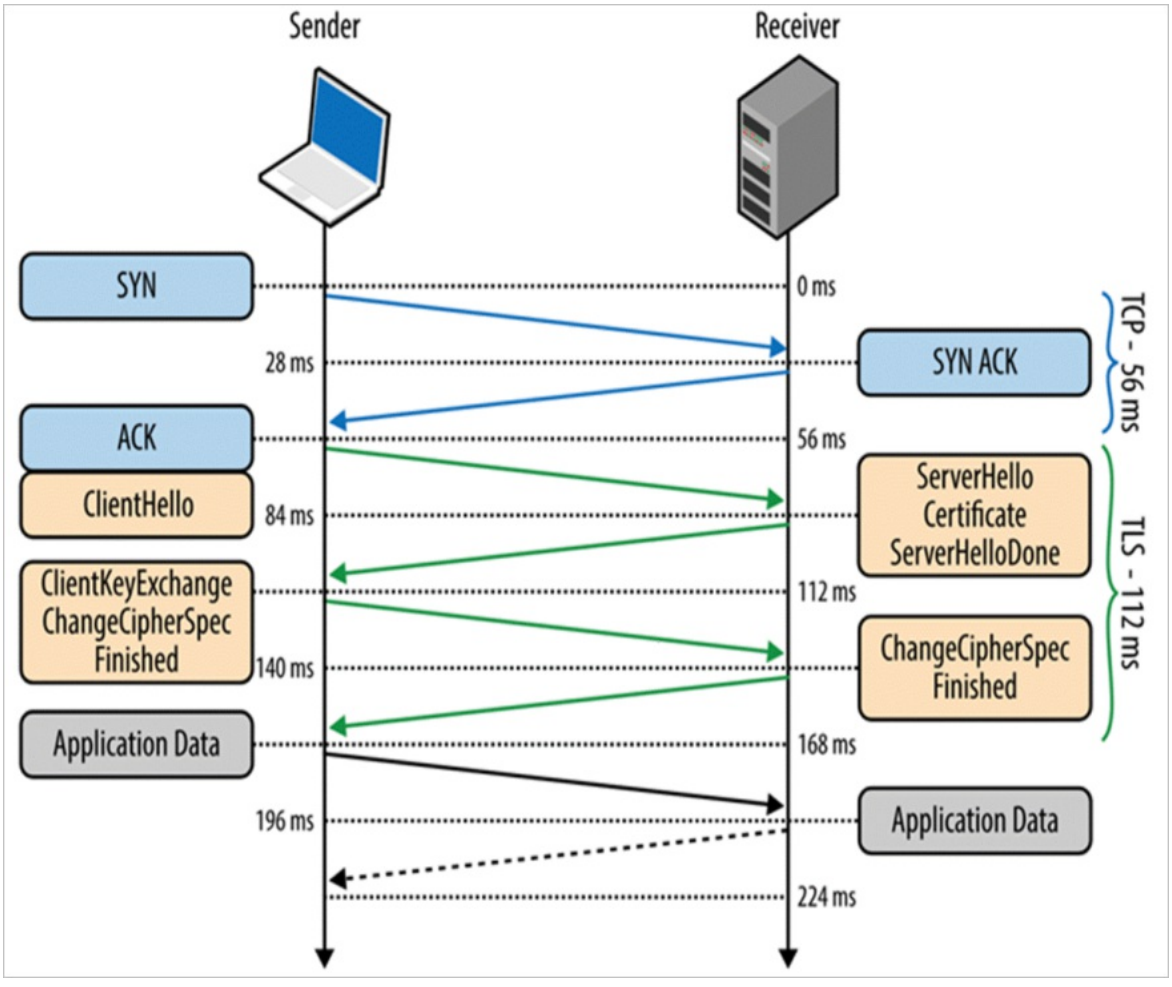
Azure Data Lake Storage Gen1

Error message: The underlying connection was closed: Could not establish trust relationship for the SSL/TLS secure channel.

- **Symptoms**: Copy activity fails with the following error:

```
Message: ErrorCode = UserErrorFailedFileOperation, Error Message = The underlying connection was
closed: Could not establish trust relationship for the SSL/TLS secure channel.
```

- **Cause**: The certificate validation failed during the TLS handshake.
- **Resolution**: As a workaround, use the staged copy to skip the Transport Layer Security (TLS) validation for Azure Data Lake Storage Gen1. You need to reproduce this issue and gather the network monitor (netmon) trace, and then engage your network team to check the local network configuration.



Error message: The remote server returned an error: (403) Forbidden

- **Symptoms**: Copy activity fail with the following error:

```
Message: The remote server returned an error: (403) Forbidden. Response details: {"RemoteException":
{"exception":"AccessControlException""message":"CREATE failed with error 0x83090aa2 (Forbidden. ACL
verification failed. Either the resource does not exist or the user is not authorized to perform the
requested operation.)....
```

- **Cause**: One possible cause is that the service principal or managed identity you use doesn't have permission to access certain folders or files.
- **Resolution**: Grant appropriate permissions to all the folders and subfolders you need to copy. For more information, see Copy data to or from Azure Data Lake Storage Gen1.

Error message: Failed to get access token by using service principal. ADAL Error: service_unavailable

- **Symptoms**: Copy activity fails with the following error:

```
Failed to get access token by using service principal. ADAL Error: service_unavailable, The remote
server returned an error: (503) Server Unavailable.
```

- **Cause**: When the Service Token Server (STS) that's owned by Azure Active Directory is not available, that means it's too busy to handle requests, and it returns HTTP error 503.
- **Resolution**: Rerun the copy activity after several minutes.

Azure Data Lake Storage Gen2

Error code: ADLSGen2OperationFailed

- **Message**: `ADLS Gen2 operation failed for: %adlsGen2Message;.%exceptionData;.`
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
If Azure Data Lake Storage Gen2 throws error indicating some operation failed.	Check the detailed error message thrown by Azure Data Lake Storage Gen2. If the error is a transient failure, retry the operation. For further help, contact Azure Storage support, and provide the request ID in error message.
If the error message contains the string "Forbidden", the service principal or managed identity you use might not have sufficient permission to access Azure Data Lake Storage Gen2.	To troubleshoot this error, see Copy and transform data in Azure Data Lake Storage Gen2.
If the error message contains the string "InternalServerError", the error is returned by Azure Data Lake Storage Gen2.	The error might be caused by a transient failure. If so, retry the operation. If the issue persists, contact Azure Storage support and provide the request ID from the error message.
If the error message is `Unable to read data from the transport connection: An existing connection was forcibly closed by the remote host`, your integration runtime has a network issue in connecting to Azure Data Lake Storage Gen2.	In the firewall rule setting of Azure Data Lake Storage Gen2, make sure Azure Data Factory IP addresses are in the allowed list. For more information, see Configure Azure Storage firewalls and virtual networks.

CAUSE ANALYSIS	RECOMMENDATION
If the error message is `This endpoint does not support BlobStorageEvents or SoftDelete`, you are using an Azure Data Lake Storage Gen2 linked service to connect to an Azure Blob Storage account that enables Blob storage events or soft delete.	Try the following options: 1. If you still want to use an Azure Data Lake Storage Gen2 linked service, upgrade your Azure Blob Storage to Azure Data Lake Storage Gen2. For more information, see Upgrade Azure Blob Storage with Azure Data Lake Storage Gen2 capabilities. 2. Switch your linked service to Azure Blob Storage. 3. Disable Blob storage events or soft delete in your Azure Blob Storage account.

Request to Azure Data Lake Storage Gen2 account caused a timeout error

- **Message**:
  - Error Code = `UserErrorFailedBlobFSOperation`
  - Error Message = `BlobFS operation failed for: A task was canceled.`
- **Cause**: The issue is caused by the Azure Data Lake Storage Gen2 sink timeout error, which usually occurs on the Self-hosted Integration Runtime (IR) machine.
- **Recommendation**:
  - Place your Self-hosted IR machine and target Azure Data Lake Storage Gen2 account in the same region, if possible. This can help avoid a random timeout error and produce better performance.
  - Check whether there's a special network setting, such as ExpressRoute, and ensure that the network has enough bandwidth. We suggest that you lower the Self-hosted IR concurrent jobs setting when the overall bandwidth is low. Doing so can help avoid network resource competition across multiple concurrent jobs.
  - If the file size is moderate or small, use a smaller block size for nonbinary copy to mitigate such a timeout error. For more information, see Blob Storage Put Block.

    To specify the custom block size, edit the property in your JSON file editor as shown here:

    ```
    "sink": {
        "type": "DelimitedTextSink",
        "storeSettings": {
            "type": "AzureBlobFSWriteSettings",
            "blockSizeInMB": 8
        }
    }
    ```

The copy activity is not able to pick files from Azure Data Lake Storage Gen2

- **Symptoms**: The copy activity is not able to pick files from Azure Data Lake Storage Gen2 when the file name is "Asset_Metadata". The issue only occurs in the Parquet type dataset. Other types of datasets with the same file name work correctly.
- **Cause**: For the backward compatibility, `_metadata` is treated as a reserved substring in the file name.
- **Recommendation**: Change the file name to avoid the reserved list for Parquet below:
  1. The file name contains `_metadata`.
  2. The file name starts with `.` (dot).

Troubleshoot the Azure Database for PostgreSQL connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Database for PostgreSQL connector in Azure Data Factory and Azure Synapse.

Error code: AzurePostgreSqlNpgsqlDataTypeNotSupported

- **Message**:

  ```
  The data type of the chosen Partition Column, '%partitionColumn;', is '%dataType;' and this data type is not supported for partitioning.
  ```

- **Recommendation**: Pick a partition column with int, bigint, smallint, serial, bigserial, smallserial, timestamp with or without time zone, time without time zone or date data type.

Error code: AzurePostgreSqlNpgsqlPartitionColumnNameNotProvided

- **Message**: `Partition column name must be specified.`
- **Cause**: No partition column name is provided, and it couldn't be decided automatically.

Troubleshoot the Azure Files connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Files connector in Azure Data Factory and Azure Synapse.

Error code: AzureFileOperationFailed

- **Message**: `Azure File operation Failed. Path: %path;. ErrorMessage: %msg;.`
- **Cause**: A problem with the Azure Files storage operation.
- **Recommendation**: To check the error details, see Azure Files help. For further help, contact the Azure Files team.

Troubleshoot the Azure Synapse Analytics, Azure SQL Database, and SQL Server connectors in Azure Data Factory and Azure Synapse

8/19/2022 • 11 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Synapse Analytics, Azure SQL Database, and SQL Server connectors in Azure Data Factory and Azure Synapse.

Error code: SqlFailedToConnect

- **Message**:

```
Cannot connect to SQL Database: '%server;', Database: '%database;', User: '%user;'. Check the linked service configuration is correct, and make sure the SQL Database firewall allows the integration runtime to access.
```

- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
For Azure SQL, if the error message contains the string "SqlErrorNumber=47073", it means that public network access is denied in the connectivity setting.	On the Azure SQL firewall, set the **Deny public network access** option to *No*. For more information, see Azure SQL connectivity settings.
For Azure SQL, if the error message contains an SQL error code such as "SqlErrorNumber=[errorcode]", see the Azure SQL troubleshooting guide.	For a recommendation, see Troubleshoot connectivity issues and other errors with Azure SQL Database and Azure SQL Managed Instance.
Check to see whether port 1433 is in the firewall allowlist.	For more information, see Ports used by SQL Server.
If the error message contains the string "SqlException", SQL Database the error indicates that some specific operation failed.	For more information, search by SQL error code in Database engine errors. For further help, contact Azure SQL support.
If this is a transient issue (for example, an instable network connection), add retry in the activity policy to mitigate.	For more information, see Pipelines and activities.
If the error message contains the string "Client with IP address '...' is not allowed to access the server", and you're trying to connect to Azure SQL Database, the error is usually caused by an Azure SQL Database firewall issue.	In the Azure SQL Server firewall configuration, enable the **Allow Azure services and resources to access this server** option. For more information, see Azure SQL Database and Azure Synapse IP firewall rules.

Error code: SqlOperationFailed

- **Message**: `A database operation failed. Please search error to get more details.`
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible

cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
If the error message contains the string "SqlException", SQL Database throws an error indicating some specific operation failed.	If the SQL error is not clear, try to alter the database to the latest compatibility level '150'. It can throw the latest version SQL errors. For more information, see the documentation. For more information about troubleshooting SQL issues, search by SQL error code in Database engine errors. For further help, contact Azure SQL support.
If the error message contains the string "PdwManagedToNativeInteropException", it's usually caused by a mismatch between the source and sink column sizes.	Check the size of both the source and sink columns. For further help, contact Azure SQL support.
If the error message contains the string "InvalidOperationException", it's usually caused by invalid input data.	To identify which row has encountered the problem, enable the fault tolerance feature on the copy activity, which can redirect problematic rows to the storage for further investigation. For more information, see Fault tolerance of copy activity.
If the error message contains "Execution Timeout Expired", it's usually caused by query timeout.	Configure **Query timeout** in the source and **Write batch timeout** in the sink to increase timeout.

Error code: SqlUnauthorizedAccess

- **Message**: `Cannot connect to '%connectorName;'. Detail Message: '%message;'`
- **Cause**: The credentials are incorrect or the login account can't access the SQL database.
- **Recommendation**: Check to ensure that the login account has sufficient permissions to access the SQL database.

Error code: SqlOpenConnectionTimeout

- **Message**: `Open connection to database timeout after '%timeoutValue;' seconds.`
- **Cause**: The problem could be a SQL database transient failure.
- **Recommendation**: Retry the operation to update the linked service connection string with a larger connection timeout value.

Error code: SqlAutoCreateTableTypeMapFailed

- **Message**:
  ```
  Type '%dataType;' in source side cannot be mapped to a type that supported by sink side(column name:'%columnName;') in autocreate table.
  ```
- **Cause**: The autocreation table can't meet the source requirement.
- **Recommendation**: Update the column type in *mappings*, or manually create the sink table in the target server.

Error code: SqlDataTypeNotSupported

- **Message**: `A database operation failed. Check the SQL errors.`

- **Cause**: If the issue occurs in the SQL source and the error is related to SqlDateTime overflow, the data value exceeds the logic type range (1/1/1753 12:00:00 AM - 12/31/9999 11:59:59 PM).
- **Recommendation**: Cast the type to the string in the source SQL query or, in the copy activity column mapping, change the column type to *String*.
- **Cause**: If the issue occurs on the SQL sink and the error is related to SqlDateTime overflow, the data value exceeds the allowed range in the sink table.
- **Recommendation**: Update the corresponding column type to the *datetime2* type in the sink table.

Error code: SqlInvalidDbStoredProcedure

- **Message**:
  ```
  The specified Stored Procedure is not valid. It could be caused by that the stored procedure doesn't return any data. Invalid Stored Procedure script: '%scriptName;'.
  ```
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
The specified stored procedure is invalid.	Validate the stored procedure by using SQL Tools. Make sure that the stored procedure can return data.
The Lookup activity requires the stored procedure to return some value, but the stored procedure code doesn't return any value.	Use the Stored Procedure Activity if the stored procedure is expected to return no data.

Error code: SqlInvalidDbQueryString

- **Message**:
  ```
  The specified SQL Query is not valid. It could be caused by that the query doesn't return any data. Invalid query: '%query;'
  ```
- **Cause**: The specified SQL query is invalid. The cause might be that the query doesn't return any data.
- **Recommendation**: Validate the SQL query by using SQL Tools. Make sure that the query can return data.

Error code: SqlInvalidColumnName

- **Message**:
  ```
  Column '%column;' does not exist in the table '%tableName;', ServerName: '%serverName;', DatabaseName: '%dbName;'.
  ```
- **Cause**: The column can't be found because the configuration might be incorrect.
- **Recommendation**: Verify the column in the query, *structure* in the dataset, and *mappings* in the activity.

Error code: SqlBatchWriteTimeout

- **Message**: `Timeouts in SQL write operation.`
- **Cause**: The problem could be caused by a SQL database transient failure.
- **Recommendation**: Retry the operation. If the problem persists, contact Azure SQL support.

Error code: SqlBatchWriteTransactionFailed

- **Message**: `SQL transaction commits failed.`
- **Cause**: If exception details constantly indicate a transaction timeout, the network latency between the integration runtime and the database is greater than the default threshold of 30 seconds.
- **Recommendation**: Update the SQL-linked service connection string with a *connection timeout* value that's equal to or greater than 120 and rerun the activity.
- **Cause**: If the exception details intermittently indicate that the SQL connection is broken, it might be a transient network failure or a SQL database side issue.
- **Recommendation**: Retry the activity and review the SQL database side metrics.

Error code: SqlBulkCopyInvalidColumnLength

- **Message**: `SQL Bulk Copy failed due to receive an invalid column length from the bcp client.`
- **Cause**: SQL Bulk Copy failed because it received an invalid column length from the bulk copy program utility (bcp) client.
- **Recommendation**: To identify which row has encountered the problem, enable the fault tolerance feature on the copy activity. This can redirect problematic rows to the storage for further investigation. For more information, see Fault tolerance of copy activity.

Error code: SqlConnectionIsClosed

- **Message**: `The connection is closed by SQL Database.`
- **Cause**: The SQL connection is closed by the SQL database when a high concurrent run and the server terminate the connection.
- **Recommendation**: Retry the connection. If the problem persists, contact Azure SQL support.

Error code: SqlServerInvalidLinkedServiceCredentialMissing

- **Message**: `The SQL Server linked service is invalid with its credential being missing.`
- **Cause**: The linked service was not configured properly.
- **Recommendation**: Validate and fix the SQL server linked service.

Error code: SqlParallelFailedToDetectPartitionColumn

- **Message**: `Failed to detect the partition column with command '%command;', %message;.`
- **Cause**: There is no primary key or unique key in the table.
- **Recommendation**: Check the table to make sure that a primary key or a unique index is created.

Error code: SqlParallelFailedToDetectPhysicalPartitions

- **Message**: `Failed to detect the physical partitions with command '%command;', %message;.`
- **Cause**: No physical partitions are created for the table. Check your database.
- **Recommendation**: Reference Create Partitioned Tables and Indexes to solve this issue.

Error code: SqlParallelFailedToGetPartitionRangeSynapse

- **Message**: `Failed to get the partitions for azure synapse with command '%command;', %message;.`
- **Cause**: No physical partitions are created for the table. Check your database.
- **Recommendation**: Reference Partitioning tables in dedicated SQL pool to solve this issue.

Error message: Conversion failed when converting from a character string to uniqueidentifier

- **Symptoms**: When you copy data from a tabular data source (such as SQL Server) into Azure Synapse Analytics using staged copy and PolyBase, you receive the following error:

```
ErrorCode=FailedDbOperation,Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,
Message=Error happened when loading data into Azure Synapse Analytics.,
Source=Microsoft.DataTransfer.ClientLibrary,Type=System.Data.SqlClient.SqlException,
Message=Conversion failed when converting from a character string to uniqueidentifier...
```

- **Cause**: Azure Synapse Analytics PolyBase can't convert an empty string to a GUID.
- **Resolution**: In the copy activity sink, under PolyBase settings, set the **use type default** option to *false*.

Error message: Expected data type: DECIMAL(x,x), Offending value

- **Symptoms**: When you copy data from a tabular data source (such as SQL Server) into Azure Synapse Analytics by using staged copy and PolyBase, you receive the following error:

```
ErrorCode=FailedDbOperation,Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,
Message=Error happened when loading data into Azure Synapse Analytics.,
Source=Microsoft.DataTransfer.ClientLibrary,Type=System.Data.SqlClient.SqlException, Message=Query
aborted-- the maximum reject threshold (0 rows) was reached while reading from an external source: 1
rows rejected out of total 415 rows processed. (/file_name.txt) Column ordinal: 18, Expected data
type: DECIMAL(x,x), Offending value:..
```

- **Cause**: Azure Synapse Analytics PolyBase can't insert an empty string (null value) into a decimal column.
- **Resolution**: In the copy activity sink, under PolyBase settings, set the **use type default** option to false.

Error message: Java exception message: HdfsBridge::CreateRecordReader

- **Symptoms**: You copy data into Azure Synapse Analytics by using PolyBase and receive the following error:

```
Message=110802;An internal DMS error occurred that caused this operation to fail. Details: Exception:
Microsoft.SqlServer.DataWarehouse.DataMovement.Common.ExternalAccess.HdfsAccessException, Message:
Java exception raised on call to HdfsBridge_CreateRecordReader. Java exception
message:HdfsBridge::CreateRecordReader - Unexpected error encountered creating the record reader.:
Error [HdfsBridge::CreateRecordReader - Unexpected error encountered creating the record reader.]
occurred while accessing external file.....
```

- **Cause**: The cause might be that the schema (total column width) is too large (larger than 1 MB). Check the schema of the target Azure Synapse Analytics table by adding the size of all columns:
  - Int = 4 bytes
  - Bigint = 8 bytes
  - Varchar(n), char(n), binary(n), varbinary(n) = n bytes
  - Nvarchar(n), nchar(n) = n*2 bytes
  - Date = 6 bytes
  - Datetime/(2), smalldatetime = 16 bytes

    - Datetimeoffset = 20 bytes
    - Decimal = 19 bytes
    - Float = 8 bytes
    - Money = 8 bytes
    - Smallmoney = 4 bytes
    - Real = 4 bytes
    - Smallint = 2 bytes
    - Time = 12 bytes
    - Tinyint = 1 byte
- **Resolution**:
    - Reduce column width to less than 1 MB.
    - Or use a bulk insert approach by disabling PolyBase.

Error message: The condition specified using HTTP conditional header(s) is not met

- **Symptoms**: You use SQL query to pull data from Azure Synapse Analytics and receive the following error:

  ```
  ...StorageException: The condition specified using HTTP conditional header(s) is not met...
  ```

- **Cause**: Azure Synapse Analytics encountered an issue while querying the external table in Azure Storage.
- **Resolution**: Run the same query in SQL Server Management Studio (SSMS) and check to see whether you get the same result. If you do, open a support ticket to Azure Synapse Analytics and provide your Azure Synapse Analytics server and database name.

Performance tier is low and leads to copy failure

- **Symptoms**: You copy data into Azure SQL Database and receive the following error:

  ```
  Database operation failed. Error message from database execution : ExecuteNonQuery requires an open and available Connection. The connection's current state is closed.
  ```

- **Cause**: Azure SQL Database s1 has hit input/output (I/O) limits.
- **Resolution**: Upgrade the Azure SQL Database performance tier to fix the issue.

SQL table can't be found

- **Symptoms**: You copy data from hybrid into an on-premises SQL Server table and receive the following error: `Cannot find the object "dbo.Contoso" because it does not exist or you do not have permissions.`
- **Cause**: The current SQL account doesn't have sufficient permissions to execute requests issued by .NET SqlBulkCopy.WriteToServer.
- **Resolution**: Switch to a more privileged SQL account.

Error message: String or binary data is truncated

- **Symptoms**: An error occurs when you copy data into an on-premises Azure SQL Server table.
- **Cause**: The Cx SQL table schema definition has one or more columns with less length than expected.
- **Resolution**: To resolve the issue, try the following:

1. To troubleshoot which rows have the issue, apply SQL sink fault tolerance, especially "redirectIncompatibleRowSettings."

   > **NOTE**
   > Fault tolerance might require additional execution time, which could lead to higher costs.

2. Double-check the redirected data against the SQL table schema column length to see which columns need to be updated.
3. Update the table schema accordingly.

Error code: FailedDbOperation

- **Message**: `User does not have permission to perform this action.`
- **Recommendation**: Make sure the user configured in the Azure Synapse Analytics connector must have 'CONTROL' permission on the target database while using PolyBase to load data. For more detailed information, refer to this document.

Troubleshoot the Azure Table Storage connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Table Storage connector in Azure Data Factory and Azure Synapse.

Error code: AzureTableDuplicateColumnsFromSource

- **Message**:

  ```
  Duplicate columns with same name '%name;' are detected from source. This is NOT supported by Azure Table Storage sink.
  ```

- **Cause**: Duplicated source columns might occur for one of the following reasons:
  - You're using the database as a source and applied table joins.
  - You have unstructured CSV files with duplicated column names in the header row.
- **Recommendation**: Double-check and fix the source columns, as necessary.

Next steps

Troubleshoot the DB2 connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Azure Database for PostgreSQL connector in Azure Data Factory and Azure Synapse.

Error code: DB2DriverRunFailed

- **Message**: `Error thrown from driver. Sql code: '%code;'`
- **Cause**: If the error message contains the string "SQLSTATE=51002 SQLCODE=-805", follow the "Tip" in Copy data from DB2.
- **Recommendation**: Try to set "NULLID" in the `packageCollection` property.

Next steps

For more troubleshooting help, try these resources:

Troubleshoot the delimited text format connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the delimited text formatL connector in Azure Data Factory and Azure Synapse.

Error code: DelimitedTextColumnNameNotAllowNull

- **Message**:

  ```
  The name of column index %index; is empty. Make sure column name is properly specified in the header row.
  ```

- **Cause**: When 'firstRowAsHeader' is set in the activity, the first row is used as the column name. This error means that the first row contains an empty value (for example, 'ColumnA, ColumnB').

- **Recommendation**: Check the first row, and fix the value if it is empty.

Error code: DelimitedTextMoreColumnsThanDefined

- **Message**:

  ```
  Error found when processing '%function;' source '%name;' with row number %rowCount;: found more columns than expected column count: %expectedColumnCount;.
  ```

- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
The problematic row's column count is larger than the first row's column count. It might be caused by a data issue or incorrect column delimiter or quote char settings.	Get the row count from the error message, check the row's column, and fix the data.
If the expected column count is "1" in an error message, you might have specified wrong compression or format settings, which caused the files to be parsed incorrectly.	Check the format settings to make sure they match your source files.
If your source is a folder, the files under the specified folder might have a different schema.	Make sure that the files in the specified folder have an identical schema.

Troubleshoot the Dynamics 365, Dataverse (Common Data Service), and Dynamics CRM connectors in Azure Data Factory and Azure Synapse

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Dynamics 365, Dataverse (Common Data Service), and Dynamics CRM connectors in Azure Data Factory and Azure Synapse.

Error code: DynamicsCreateServiceClientError

- **Message**: `This is a transient issue on Dynamics server side. Try to rerun the pipeline.`
- **Cause**: The problem is a transient issue on the Dynamics server side.
- **Recommendation**: Rerun the pipeline. If it fails again, try to reduce the parallelism. If the problem persists, contact Dynamics support.

Missing columns when you import a schema or preview data

- **Symptoms**: Some columns are missing when you import a schema or preview data. Error message: `The valid structure information (column name and type) are required for Dynamics source.`
- **Cause**: This issue is by design, because Data Factory and Synapse pipelines are unable to show columns that contain no values in the first 10 records. Make sure that the columns you've added are in the correct format.
- **Recommendation**: Manually add the columns in the mapping tab. For more details, refer to Explicit mapping.

Error code: DynamicsMissingTargetForMultiTargetLookupField

- **Message**: `Cannot find the target column for multi-target lookup field: '%fieldName;'.`
- **Cause**: The target column doesn't exist in the source or in the column mapping.
- **Recommendation**:

  1. Make sure that the source contains the target column.
  2. Add the target column in the column mapping. Ensure that the sink column is in the format *{fieldName}@EntityReference*.

Error code: DynamicsInvalidTargetForMultiTargetLookupField

- **Message**:

```
The provided target: '%targetName;' is not a valid target of field: '%fieldName;'. Valid targets are: '%validTargetNames;'
```

- **Cause**: A wrong entity name is provided as target entity of a multi-target lookup field.

- **Recommendation**: Provide a valid entity name for the multi-target lookup field.

Error code: DynamicsInvalidTypeForMultiTargetLookupField

- **Message**: `The provided target type is not a valid string. Field: '%fieldName;'.`
- **Cause**: The value in the target column is not a string.
- **Recommendation**: Provide a valid string in the multi-target lookup target column.

Error code: DynamicsFailedToRequetServer

- **Message**:
  ```
  The Dynamics server or the network is experiencing issues. Check network connectivity or check
  Dynamics server log for more details.
  ```
- **Cause**: The Dynamics server is instable or inaccessible, or the network is experiencing issues.
- **Recommendation**: For more details, check network connectivity or check the Dynamics server log. For further help, contact Dynamics support.

Error code: DynamicsFailedToConnect

- **Message**: `Failed to connect to Dynamics: %message;`
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION

You are seeing
`ERROR REQUESTING ORGS FROM THE DISCOVERY SERVERFCB 'EnableRegionalDisco' is disabled.`
or otherwise
`Unable to Login to Dynamics CRM, message:ERROR REQUESTING Token FROM THE Authentication context - USER intervention required but not permitted by prompt behavior AADSTS50079: Due to a configuration change made by your administrator, or because you moved to a new location, you must enroll in multi-factor authentication to access '00000007-0000-0000-c000-000000000000'`
If your use case meets **all** of the following three conditions:
• You are connecting to Dynamics 365, Common Data Service, or Dynamics CRM.
• You are using Office365 Authentication.
• Your tenant and user is configured in Azure Active Directory for conditional access and/or Multi-Factor Authentication is required (see this link to Dataverse doc).
Under these circumstances, the connection used to succeed before 6/8/2021. Starting 6/9/2021 connection will start to fail because of the deprecation of regional Discovery Service (see this link).
	If your tenant and user is configured in Azure Active Directory for conditional access and/or Multi-Factor Authentication is required, you must use 'Azure AD service-principal' to authenticate after 6/8/2021. Refer this link for detailed steps.

If you see `Office 365 auth with OAuth failed` in the error message, it means that your server might have some configurations not compatible with OAuth.	• Contact Dynamics support team with the detailed error message for help. • Use the service principal authentication, and you can refer to this article: Example: Dynamics online using Azure AD service-principal and certificate authentication.

CAUSE ANALYSIS	RECOMMENDATION
If you see `Unable to retrieve authentication parameters from the serviceUri` in the error message, it means that either you input the wrong Dynamics service URL or proxy/firewall to intercept the traffic.	• Make sure you have put the correct service URI in the linked service. • If you use the Self Hosted IR, make sure that the firewall/proxy does not intercept the requests to the Dynamics server.
If you see `An unsecured or incorrectly secured fault was received from the other party` in the error message, it means that unexpected responses were gotten from the server side.	• Make sure your username and password are correct if you use the Office 365 authentication. • Make sure you have input the correct service URI. • If you use regional CRM URL (URL has a number after 'crm'), make sure you use the correct regional identifier. • Contact the Dynamics support team for help.
If you see `No Organizations Found` in the error message, it means that either your organization name is wrong or you used a wrong CRM region identifier in the service URL.	• Make sure you have input the correct service URI. • If you use the regional CRM URL (URL has a number after 'crm'), make sure that you use the correct regional identifier. • Contact the Dynamics support team for help.
If you see `401 Unauthorized` and AAD-related error message, it means that there's an issue with the service principal.	Follow the guidance in the error message to fix the service principal issue.
For other errors, usually the issue is on the server side.	Use XrmToolBox to make connection. If the error persists, contact the Dynamics support team for help.

Error code: DynamicsOperationFailed

- **Message**: `Dynamics operation failed with error code: %code;, error message: %message;.`
- **Cause**: The operation failed on the server side.
- **Recommendation**: Extract the error code of the dynamics operation from the error message: `Dynamics operation failed with error code: {code}`, and refer to the article Web service error codes for more detailed information. You can contact the Dynamics support team if necessary.

Error code: DynamicsInvalidFetchXml

- **Message**: `The Fetch Xml query specified is invalid.`
- **Cause**: There is an error existed in the fetch XML.
- **Recommendation**: Fix the error in the fetch XML.

Error code: DynamicsMissingKeyColumns

- **Message**:
  `Input DataSet must contain keycolumn(s) in Upsert/Update scenario. Missing key column(s): %column;`
- **Cause**: The source data does not contain the key column for the sink entity.
- **Recommendation**: Confirm that key columns are in the source data or map a source column to the key column on the sink entity.

Error code: DynamicsPrimaryKeyMustBeGuid

- **Message**: `The primary key attribute '%attribute;' must be of type guid.`
- **Cause**: The type of the primary key column is not 'Guid'.
- **Recommendation**: Make sure that the primary key column in the source data is of 'Guid' type.

Error code: DynamicsAlternateKeyNotFound

- **Message**: `Cannot retrieve key information of alternate key '%key;' for entity '%entity;'.`
- **Cause**: The provided alternate key does not exist, which may be caused by wrong key names or insufficient permissions.
- **Recommendation**:
  - Fix typos in the key name.
  - Make sure that you have sufficient permissions on the entity.

Error code: DynamicsInvalidSchemaDefinition

- **Message**: `The valid structure information (column name and type) are required for Dynamics source.`
- **Cause**: Sink columns in the column mapping miss the 'type' property.
- **Recommendation**: You can add the 'type' property to those columns in the column mapping by using JSON editor on the portal.

Error code: UserErrorUnsupportedAttributeType

- **Message**: `The attribute type 'Lookup' of field %attributeName; is not supported`
- **Cause**: When loading data to Dynamics sink, Azure Data Factory imposes validation on lookup attribute's metadata. However, there's the known issue of certain Dynamics entities not having valid lookup attribute metadata that holds a list of targets, which would fail the validation.
- **Recommendation**: Contact Dynamics support team to mitigate the issue.

The copy activity from the Dynamics 365 reads more rows than the actual number

- **Symptoms**: The copy activity from the Dynamics 365 reads more rows than the actual number.
- **Cause**: The Dynamics 365 server always indicates more available records.
- **Recommendation**: Use **XrmToolBox** to test the FetchXML with paging. **XrmToolBox** with some installed tools can get records count. For more information, see XrmToolBox.

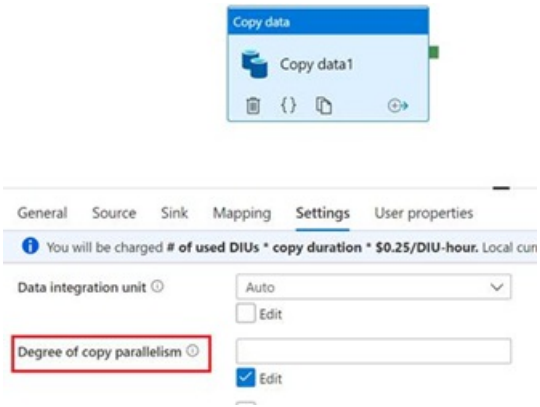
Cannot access virtual columns from Dynamics sources in the copy activity

- **Symptoms**: You cannot access virtual columns from Dynamics sources in the copy activity.
- **Cause**: The virtual column is not supported now.
- **Recommendation**: For the Option Set value, follow the options below to get it:

- You can get the object type code by referring to How to Find the Object Type Code for Any Entity and Dynamics 365 blog.
- You can link the StringMap entity to your target entity and get the associated values.

The parallel copy in a Dynamics CRM data store

- **Symptoms**: You don't know if it is possible to configure the parallel copy in a Dynamics CRM data store, and you also don't know the range of values that can be set in the "Degree of copy parallelism" section.
- **Recommendation**: The parallel copy controls parallelism, and the "Degree of copy parallelism" section can be set to non-zero value. Large number may cause throttling on dynamics server side, which may reduce the throughput, but now the throttling is handled by taking the public SDK.



Dynamics type conversion

- **Symptoms**: You try to convert the GUID to a string in the Dynamics source, but you encounter an error.
- **Cause**: When Dynamics is used as the source, the type conversion is not supported.
- **Recommendation**: Enable the staging and retry.

Troubleshoot the FTP, SFTP and HTTP connectors in Azure Data Factory and Azure Synapse

8/19/2022 • 7 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the FTP, SFTP and HTTP connectors in Azure Data Factory and Azure Synapse.

FTP

Error code: FtpFailedToConnectToFtpServer

- **Message**:
  ```
  Failed to connect to FTP server. Please make sure the provided server information is correct, and try again.
  ```
- **Cause**: An incorrect linked service type might be used for the FTP server, such as using the Secure FTP (SFTP) linked service to connect to an FTP server.
- **Recommendation**: Check the port of the target server. FTP uses port 21.

Error code: FtpFailedToReadFtpData

- **Message**:
  ```
  Failed to read data from ftp: The remote server returned an error: 227 Entering Passive Mode (*,*,*,*,*,*).
  ```
- **Cause**: Port range between 1024 to 65535 is not open for data transfer under passive mode supported by the data factory or Synapse pipeline.
- **Recommendation**: Check the firewall settings of the target server. Open port 1024-65535 or port range specified in FTP server to SHIR/Azure IR IP address.

SFTP

Error code: SftpOperationFail

- **Message**: `Failed to '%operation;'. Check detailed error from SFTP.`
- **Cause**: A problem with the SFTP operation.
- **Recommendation**: Check the error details from SFTP.

Error code: SftpRenameOperationFail

- **Message**:
  ```
  Failed to rename the temp file. Your SFTP server doesn't support renaming temp file, set "useTempFileRename" as false in copy sink to disable uploading to temp file.
  ```
- **Cause**: Your SFTP server doesn't support renaming the temp file.
- **Recommendation**: Set "useTempFileRename" as false in the copy sink to disable uploading to the temp file.

Error code: SftpInvalidSftpCredential

- **Message**: `Invalid SFTP credential provided for '%type;' authentication type.`

- **Cause**: Private key content is fetched from the Azure key vault or SDK, but it's not encoded correctly.
- **Recommendation**:

  If the private key content is from your key vault, the original key file can work if you upload it directly to the SFTP linked service.

  For more information, see Copy data from and to the SFTP server by using data factory or Synapse pipelines. The private key content is base64 encoded SSH private key content.

  Encode *entire* original private key file with base64 encoding, and store the encoded string in your key vault. The original private key file is the one that can work on the SFTP linked service if you select **Upload** from the file.

  Here are some samples you can use to generate the string:

  - Use C# code:

    ```
    byte[] keyContentBytes = File.ReadAllBytes(Private Key Path);
    string keyContent = Convert.ToBase64String(keyContentBytes, Base64FormattingOptions.None);
    ```

  - Use Python code:

    ```
    import base64
    rfd = open(r'{Private Key Path}', 'rb')
    keyContent = rfd.read()
    rfd.close()
    print base64.b64encode(Key Content)
    ```

  - Use a third-party base64 conversion tool. We recommend the Encode to Base64 format tool.

- **Cause**: The wrong key content format was chosen.
- **Recommendation**:

  PKCS#8 format SSH private key (start with "-----BEGIN ENCRYPTED PRIVATE KEY-----") is currently not supported to access the SFTP server.

  To convert the key to traditional SSH key format, starting with "-----BEGIN RSA PRIVATE KEY-----", run the following commands:

  ```
  openssl pkcs8 -in pkcs8_format_key_file -out traditional_format_key_file
  chmod 600 traditional_format_key_file
  ssh-keygen -f traditional_format_key_file -p
  ```

- **Cause**: Invalid credentials or private key content.
- **Recommendation**: To see whether your key file or password is correct, double-check with tools such as WinSCP.

SFTP copy activity failed

- **Symptoms**:
  - Error code: UserErrorInvalidColumnMappingColumnNotFound
  - Error message: `Column 'AccMngr' specified in column mapping cannot be found in source data.`
- **Cause**: The source doesn't include a column named "AccMngr."
- **Resolution**: To determine whether the "AccMngr" column exists, double-check your dataset

configuration by mapping the destination dataset column.

Error code: SftpFailedToConnectToSftpServer

- **Message**: `Failed to connect to SFTP server '%server;'.`
- **Cause**: If the error message contains the string "Socket read operation has timed out after 30,000 milliseconds", one possible cause is that an incorrect linked service type is used for the SFTP server. For example, you might be using the FTP linked service to connect to the SFTP server.
- **Recommendation**: Check the port of the target server. By default, SFTP uses port 22.
- **Cause**: If the error message contains the string "Server response does not contain SSH protocol identification", one possible cause is that the SFTP server throttled the connection. Multiple connections are created to download from the SFTP server in parallel, and sometimes it will encounter SFTP server throttling. Ordinarily, different servers return different errors when they encounter throttling.
- **Recommendation**:

  Specify the maximum number of concurrent connections of the SFTP dataset as 1 and rerun the copy activity. If the activity succeeds, you can be sure that throttling is the cause.

  If you want to promote the low throughput, contact your SFTP administrator to increase the concurrent connection count limit, or you can do one of the following:

  - If you're using Self-hosted IR, add the Self-hosted IR machine's IP to the allowlist.
  - If you're using Azure IR, add Azure Integration Runtime IP addresses. If you don't want to add a range of IPs to the SFTP server allowlist, use Self-hosted IR instead.

Error code: SftpPermissionDenied

- **Message**: `Permission denied to access '%path;'`
- **Cause**: The specified user does not have read or write permission to the folder or file when operating.
- **Recommendation**: Grant the user with permission to read or write to the folder or files on SFTP server.

Error code: SftpAuthenticationFailure

- **Message**:

  ```
  Meet authentication failure when connect to Sftp server '%server;' using '%type;' authentication type.
  Please make sure you are using the correct authentication type and the credential is valid. For more
  details, see our troubleshooting docs.
  ```

- **Cause**: The specified credential (your password or private key) is invalid.
- **Recommendation**: Check your credential.
- **Cause**: The specified authentication type is not allowed or not sufficient to complete the authentication in your SFTP server.
- **Recommendation**: Apply the following options to use the correct authentication type:

  - If your server requires a password, use "Basic".
  - If your server requires a private key, use "SSH public key authentication".
  - If your server requires both "password" and "private key", use "Multiple factor authentication".
- **Cause**: Your SFTP server requires "keyboard-interactive" for authentication, but you provided "password".
- **Recommendation**:

  "keyboard-interactive" is a special authentication method, which is different from "password". It means that when logging into a server, you must enter the password manually, and you cannot use the

previously saved password. But Azure Data Factory (ADF) is a scheduled data transfer service, and there is no pop-up input box allowing you to provide the password at the runtime.

As a compromise, an option is provided to simulate the input in the background instead of your real manual input, which is equivalent to changing the "keyboard-interactive" to "password". If you can accept this security concern, follow the steps below to enable it:

1. On the ADF portal, hover on the SFTP linked service, and open its payload by selecting the code button.
2. Add `"allowKeyboardInteractiveAuth": true` in the "typeProperties" section.

Unable to connect to SFTP due to key exchange algorithms provided by SFTP are not supported in ADF

- **Symptoms**: You are unable to connect to SFTP via ADF and meet the following error message: `Failed to negotiate key exchange algorithm.`
- **Cause**: The key exchange algorithms provided by the SFTP server are not supported in ADF. The key exchange algorithms supported by ADF are:
  - curve25519-sha256
  - curve25519-sha256@libssh.org
  - ecdh-sha2-nistp256
  - ecdh-sha2-nistp384
  - ecdh-sha2-nistp521
  - diffie-hellman-group-exchange-sha256
  - diffie-hellman-group-exchange-sha1
  - diffie-hellman-group16-sha512
  - diffie-hellman-group14-sha256
  - diffie-hellman-group14-sha1
  - diffie-hellman-group1-sha1

  The latest version to support above key exchange algorithms on SHIR is version 5.19.

Error Code: SftpInvalidHostKeyFingerprint

- **Message**:
  ```
  Host key finger-print validation failed. Expected fingerprint is '<value in linked service>', real finger-print is '<server real value>'
  ```
- **Cause**: Azure Data Factory now supports more secure host key algorithms in SFTP connector. For the newly added algorithms, it requires to get the corresponding fingerprint in the SFTP server.

  The newly supported algorithms are:
  - ssh-ed25519
  - ecdsa-sha2-nistp256
  - ecdsa-sha2-nistp384
  - ecdsa-sha2-nistp521
- **Recommendation**: Get a valid fingerprint using the Host Key Name in `real finger-print` from the error message in the SFTP server. You can run the command to get the fingerprint on your SFTP server. For example: run `ssh-keygen -E md5 -lf <keyFilePath>` in Linux server to get the fingerprint. The command may vary among different server types.

HTTP

Error code: HttpFileFailedToRead

- **Message**: `Failed to read data from http server. Check the error from http server:%message;`

- **Cause**: This error occurs when a data factory or a Synapse pipeline talks to the HTTP server, but the HTTP request operation fails.
- **Recommendation**: Check the HTTP status code in the error message, and fix the remote server issue.

Error code: HttpSourceUnsupportedStatusCode

- **Message**: `Http source doesn't support HTTP Status Code '%code;'.`
- **Cause**: This error happens when Azure Data Factory requests HTTP source but gets unexpected status code.
- **Recommendation**: For more information about HTTP status code, see this document.

Troubleshoot the Hive connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Hive connector in Azure Data Factory and Azure Synapse.

The performance difference between the ODBC connector and the Hive connector

- **Symptoms**: The concern about the performance difference between the ODBC connector and the Hive connector.
- **Cause**: The ODBC connector needs its own driver, which may cause the performance difference due to the third-party driver quality.
- **Recommendation**: Use the Hive connector firstly.

Unexpected response received from the server when connecting to the Hive server via ODBC

- **Symptoms**: When connecting to the Hive server using ODBC linked service, you meet this error message:

  ```
  ERROR [HY000] [Cloudera][DriverSupport] (1110) Unexpected response received from server. Please ensure the server host and port specified for the connection are correct and confirm if SSL should be enabled for the connection.
  ```

- **Cause**: You use the Kerberos authentication that is not supported in Azure Data Factory.
- **Recommendation**: Try the following steps. If they do not work, check the provided driver to resolve this issue.

  1. The **kr5.ini** file is in the **C:\Program Files\MIT\Kerberos\bin** folder.
  2. Add the `KRB5_CONFIG` and `KRB5CCNAME` to the system variable as well.
  3. Edit the **krb.ini** file.
  4. Shut down and restart the VM and the SHIR from the machine.

Troubleshoot the Oracle connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Oracle connector in Azure Data Factory and Azure Synapse.

Oracle

Error code: ArgumentOutOfRangeException

- **Message**: `Hour, Minute, and Second parameters describe an un-representable DateTime.`
- **Cause**: In Azure Data Factory and Synapse pipelines, DateTime values are supported in the range from 0001-01-01 00:00:00 to 9999-12-31 23:59:59. However, Oracle supports a wider range of DateTime values, such as the BC century or min/sec>59, which leads to failure.
- **Recommendation**:

  To see whether the value in Oracle is in the supported range of dates, run `select dump(<column name>)`.

  To learn the byte sequence in the result, see How are dates stored in Oracle?.

Troubleshoot the ORC format connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the ORC format connector in Azure Data Factory and Azure Synapse.

Error code: OrcJavaInvocationException

- **Message**: `An error occurred when invoking Java, message: %javaException;.`
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
When the error message contains the strings "java.lang.OutOfMemory", "Java heap space", and "doubleCapacity", it's usually a memory management issue in an old version of integration runtime.	If you're using Self-hosted Integration Runtime, we recommend that you upgrade to the latest version.
When the error message contains the string "java.lang.OutOfMemory", the integration runtime doesn't have enough resources to process the files.	Limit the concurrent runs on the integration runtime. For Self-hosted IR, scale up to a powerful machine with memory equal to or larger than 8 GB.
When the error message contains the string "NullPointerReference", the cause might be a transient error.	Retry the operation. If the problem persists, contact support.
When the error message contains the string "BufferOverflowException", the cause might be a transient error.	Retry the operation. If the problem persists, contact support.
When the error message contains the string "java.lang.ClassCastException:org.apache.hadoop.hive.serde2.io.HiveCharWritable can't be cast to org.apache.hadoop.io.Text", the cause might be a type conversion issue inside Java Runtime. Usually, it means that the source data can't be handled well in Java Runtime.	This is a data issue. Try to use a string instead of char or varchar in ORC format data.

Error code: OrcDateTimeExceedLimit

- **Message**:

```
The Ticks value '%ticks;' for the datetime column must be between valid datetime ticks range -
621355968000000000 and 2534022144000000000.
```

- **Cause**: If the datetime value is '0001-01-01 00:00:00', it could be caused by the differences between the Julian calendar and the Gregorian calendar.
- **Recommendation**: Check the ticks value and avoid using the datetime value '0001-01-01 00:00:00'.

Troubleshoot the Parquet format connector in Azure Data Factory and Azure Synapse

8/19/2022 • 5 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Parquet format connector in Azure Data Factory and Azure Synapse.

Error code: ParquetJavaInvocationException

- **Message**: `An error occurred when invoking java, message: %javaException;.`
- **Causes and recommendations**: Different causes may lead to this error. Check below list for possible cause analysis and related recommendation.

CAUSE ANALYSIS	RECOMMENDATION
When the error message contains the strings "java.lang.OutOfMemory", "Java heap space", and "doubleCapacity", it's usually a memory management issue in an old version of Integration Runtime.	If you are using Self-hosted IR and the version is earlier than 3.20.7159.1, we recommend that you upgrade to the latest version.
When the error message contains the string "java.lang.OutOfMemory", the integration runtime doesn't have enough resources to process the files.	Limit the concurrent runs on the integration runtime. For Self-hosted IR, scale up to a powerful machine with memory that's equal to or greater than 8 GB.
When the error message contains the string "NullPointerReference", it might be a transient error.	Retry the operation. If the problem persists, contact support.

Error code: ParquetInvalidFile

- **Message**: `File is not a valid Parquet file.`
- **Cause**: This is a Parquet file issue.
- **Recommendation**: Check to see whether the input is a valid Parquet file.

Error code: ParquetNotSupportedType

- **Message**: `Unsupported Parquet type. PrimitiveType: %primitiveType; OriginalType: %originalType;.`
- **Cause**: The Parquet format is not supported in Azure Data Factory and Synapse pipelines.
- **Recommendation**: Double-check the source data by going to Supported file formats and compression codecs by copy activity.

Error code: ParquetMissedDecimalPrecisionScale

- **Message**: `Decimal Precision or Scale information is not found in schema for column: %column;.`
- **Cause**: The number precision and scale were parsed, but no such information was provided.

- **Recommendation**: The source doesn't return the correct precision and scale information. Check the issue column for the information.

Error code: ParquetInvalidDecimalPrecisionScale

- **Message**: `Invalid Decimal Precision or Scale. Precision: %precision; Scale: %scale;.`
- **Cause**: The schema is invalid.
- **Recommendation**: Check the issue column for precision and scale.

Error code: ParquetColumnNotFound

- **Message**: `Column %column; does not exist in Parquet file.`
- **Cause**: The source schema is a mismatch with the sink schema.
- **Recommendation**: Check the mappings in the activity. Make sure that the source column can be mapped to the correct sink column.

Error code: ParquetInvalidDataFormat

- **Message**: `Incorrect format of %srcValue; for converting to %dstType;.`
- **Cause**: The data can't be converted into the type that's specified in mappings.source.
- **Recommendation**: Double-check the source data or specify the correct data type for this column in the copy activity column mapping. For more information, see Supported file formats and compression codecs by the copy activity.

Error code: ParquetDataCountNotMatchColumnCount

- **Message**:
  ```
  The data count in a row '%sourceColumnCount;' does not match the column count '%sinkColumnCount;' in given schema.
  ```
- **Cause**: A mismatch between the source column count and the sink column count.
- **Recommendation**: Double-check to ensure that the source column count is same as the sink column count in 'mapping'.

Error code: ParquetDataTypeNotMatchColumnType

- **Message**: `The data type %srcType; is not match given column type %dstType; at column '%columnIndex;'.`
- **Cause**: The data from the source can't be converted to the type that's defined in the sink.
- **Recommendation**: Specify a correct type in mapping.sink.

Error code: ParquetBridgeInvalidData

- **Message**: `%message;`
- **Cause**: The data value has exceeded the limit.
- **Recommendation**: Retry the operation. If the issue persists, contact us.

Error code: ParquetUnsupportedInterpretation

- **Message**: `The given interpretation '%interpretation;' of Parquet format is not supported.`
- **Cause**: This scenario isn't supported.
- **Recommendation**: 'ParquetInterpretFor' should not be 'sparkSql'.

Error code: ParquetUnsupportFileLevelCompressionOption

- **Message**: `File level compression is not supported for Parquet.`
- **Cause**: This scenario isn't supported.
- **Recommendation**: Remove 'CompressionType' in the payload.

Error code: UserErrorJniException

- **Message**: `Cannot create JVM: JNI return code [-6][JNI call failed: Invalid arguments.]`
- **Cause**: A Java Virtual Machine (JVM) can't be created because some illegal (global) arguments are set.
- **Recommendation**: Log in to the machine that hosts *each node* of your self-hosted IR. Check to ensure that the system variable is set correctly, as follows: `_JAVA_OPTIONS "-Xms256m -Xmx16g" with memory bigger than 8 G`. Restart all the IR nodes, and then rerun the pipeline.

Arithmetic overflow

- **Symptoms**: Error message occurred when you copy Parquet files: `Message = Arithmetic Overflow., Source = Microsoft.DataTransfer.Common`
- **Cause**: Currently only the decimal of precision <= 38 and length of integer part <= 20 are supported when you copy files from Oracle to Parquet.
- **Resolution**: As a workaround, you can convert any columns with this problem into VARCHAR2.

No enum constant

- **Symptoms**: Error message occurred when you copy data to Parquet format: `java.lang.IllegalArgumentException:field ended by ';'`, or: `java.lang.IllegalArgumentException:No enum constant org.apache.parquet.schema.OriginalType.test`.
- **Cause**:

  The issue could be caused by white spaces or unsupported special characters (such as,;{}()\n\t=) in the column name, because Parquet doesn't support such a format.

  For example, a column name such as *contoso(test)* will parse the type in brackets from code `Tokenizer st = new Tokenizer(schemaString, " ;{}()\n\t");`. The error is thrown because there is no such "test" type.

  To check supported types, go to the GitHub apache/parquet-mr site.

- **Resolution**:

  Double-check to see whether:

  - There are white spaces in the sink column name.
  - The first row with white spaces is used as the column name.
  - The type OriginalType is supported. Try to avoid using these special characters: `,;{}()\n\t=`.

Error code: ParquetDateTimeExceedLimit

- **Message**:
  ```
  The Ticks value '%ticks;' for the datetime column must be between valid datetime ticks range -
  621355968000000000 and 2534022144000000000.
  ```
- **Cause**: If the datetime value is '0001-01-01 00:00:00', it could be caused by the difference between Julian Calendar and Gregorian Calendar. For more details, reference Difference between Julian and proleptic Gregorian calendar dates.
- **Resolution**: Check the ticks value and avoid using the datetime value '0001-01-01 00:00:00'.

Error code: ParquetInvalidColumnName

- **Message**: `The column name is invalid. Column name cannot contain these character:[,;{}()\n\t=]`
- **Cause**: The column name contains invalid characters.
- **Resolution**: Add or modify the column mapping to make the sink column name valid.

The file created by the copy data activity extracts a table that contains a varbinary (max) column

- **Symptoms**: The Parquet file created by the copy data activity extracts a table that contains a varbinary (max) column.
- **Cause**: This issue is caused by the Parquet-mr library bug of reading large column.
- **Resolution**: Try to generate smaller files (size < 1G) with a limitation of 1000 rows per file.

Troubleshoot the REST connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the REST connector in Azure Data Factory and Azure Synapse.

Error code: RestSinkCallFailed

- **Message**: `Rest Endpoint responded with Failure from server. Check the error from server:%message;`
- **Cause**: This error occurs when a data factory or Synapse pipeline talks to the REST endpoint over HTTP protocol, and the request operation fails.
- **Recommendation**: Check the HTTP status code or the message in the error message and fix the remote server issue.

Error code: RestSourceCallFailed

- **Message**:

  ```
  The HttpStatusCode %statusCode; indicates failure.&#xA;Request URL: %requestUri;&#xA;Response payload:%payload;
  ```

- **Cause**: This error occurs when Azure Data Factory talks to the REST endpoint over HTTP protocol, and the request operation fails.
- **Recommendation**: Check the HTTP status code or the request URL or the response payload in the error message and fix the remote server issue.

Error code: RestSinkUNSupportedCompressionType

- **Message**: `User Configured CompressionType is Not Supported By Azure Data Factory:%message;`
- **Recommendation**: Check the supported compression types for the REST sink.

Unexpected network response from the REST connector

- **Symptoms**: The endpoint sometimes receives an unexpected response (400, 401, 403, 500) from the REST connector.
- **Cause**: The REST source connector uses the URL and HTTP method/header/body from the linked service/dataset/copy source as parameters when it constructs an HTTP request. The issue is most likely caused by some mistakes in one or more specified parameters.
- **Resolution**:
  - Use 'curl' in a Command Prompt window to see whether the parameter is the cause (**Accept** and **User-Agent** headers should always be included):

    ```
    curl -i -X <HTTP method> -H <HTTP header1> -H <HTTP header2> -H "Accept: application/json" -H "User-Agent: azure-data-factory/2.0" -d '<HTTP body>' <URL>
    ```

If the command returns the same unexpected response, fix the preceding parameters with 'curl' until it returns the expected response.

You can also use 'curl--help' for more advanced usage of the command.

- If only the REST connector returns an unexpected response, contact Microsoft support for further troubleshooting.
- Note that 'curl' might not be suitable to reproduce an SSL certificate validation issue. In some scenarios, the 'curl' command was executed successfully without encountering any SSL certificate validation issues. But when the same URL is executed in a browser, no SSL certificate is actually returned for the client to establish trust with server.

  Tools like **Postman** and **Fiddler** are recommended for the preceding case.

Troubleshoot the SharePoint Online list connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the SharePoint Online list connector in Azure Data Factory and Azure Synapse.

Error code: SharePointOnlineAuthFailed

- **Message**: `The access token generated failed, status code: %code;, error message: %message;.`
- **Cause**: The service principal ID and key might not be set correctly.
- **Recommendation**: Check your registered application (service principal ID) and key to see whether they're set correctly.

Connection failed after granting permission in SharePoint Online List

Symptoms

You granted permission to your data factory in SharePoint Online List, but you still fail with the following error message:

```
Failed to get metadata of odata service, please check if service url and credential is correct and your application has permission to the resource. Expected status code: 200, actual status code: Unauthorized, response is : {"error":"invalid_request","error_description":"Token type is not allowed."}.
```

Cause

The SharePoint Online List uses ACS to acquire the access token to grant access to other applications. But for the tenant built after November 7, 2018, ACS is disabled by default.

Recommendation

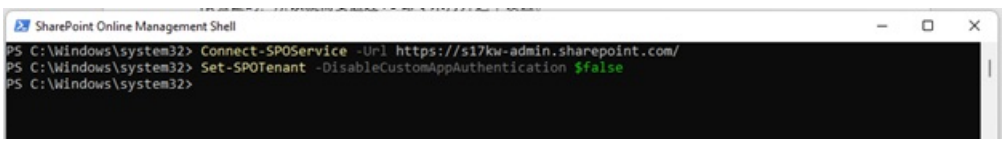
You need to enable ACS to acquire the access token. Take the following steps:

1. Download SharePoint Online Management Shell, and ensure that you have a tenant admin account.
2. Run the following command in the SharePoint Online Management Shell. Replace `<tenant name>` with your tenant name and add `-admin` after it.

   ```
   Connect-SPOService -Url https://<tenant name>-admin.sharepoint.com/
   ```

3. Enter your tenant admin information in the pop-up authentication window.
4. Run the following command:

   ```
   Set-SPOTenant -DisableCustomAppAuthentication $false
   ```



5. Use ACS to get the access token.

Troubleshoot the Snowflake connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the Snowflake connector in Azure Data Factory and Azure Synapse.

Error message: IP % is not allowed to access Snowflake. Contact your local security administrator.

- **Symptoms**: The copy activity fails with the following error:

```
Job failed due to reason: net.snowflake.client.jdbc.SnowflakeSQLException: IP % is not allowed to
access Snowflake. Contact your local security administrator.
```

- **Cause**: It's a connectivity issue and usually caused by firewall IP issues when integration runtimes access your Snowflake.

- **Recommendation**:

  - If you configure a self-hosted integration runtime to connect to Snowflake, make sure to add your self-hosted integration runtime IPs to the allowed list in Snowflake.
  - If you use an Azure Integration Runtime and the access is restricted to IPs approved in the firewall rules, you can add Azure Integration Runtime IPs to the allowed list in Snowflake.
  - If you use a managed private endpoint and a network policy is in place on your Snowflake account, ensure Managed VNet CIDR is allowed. For more steps, refer to How To: Set up a managed private endpoint from Azure Data Factory or Synapse to Snowflake.

Error message: Failed to access remote file: access denied.

- **Symptoms**: The copy activity fails with the following error:

```
ERROR [42501] Failed to access remote file: access denied. Please check your credentials,Source
=SnowflakeODBC_sb64.dll..
```

- **Cause**: The error pops up by the Snowflake COPY command and is caused by missing access permission on source/sink when execute Snowflake COPY commands.

- **Recommendation**: Check your source/sink to make sure that you have granted proper access permission to Snowflake.

  - Direct copy: Make sure to grant access permission to Snowflake in the other source/sink.
  - Staged copy: The staging Azure Blob storage linked service must use shared access signature authentication. When you generate the shared access signature, make sure to set the allowed permissions and IP addresses to Snowflake in the staging Azure Blob storage. To learn more about this, see this article.

Troubleshoot the XML format connector in Azure Data Factory and Azure Synapse

8/19/2022 • 2 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article provides suggestions to troubleshoot common problems with the XML format connector in Azure Data Factory and Azure Synapse.

Error code: XmlSinkNotSupported

- **Message**: `Write data in XML format is not supported yet, choose a different format!`
- **Cause**: An XML dataset was used as a sink dataset in your copy activity.
- **Recommendation**: Use a dataset in a different format from that of the sink dataset.

Error code: XmlAttributeColumnNameConflict

- **Message**:

  ```
  Column names %attrNames;' for attributes of element '%element;' conflict with that for corresponding child elements, and the attribute prefix used is '%prefix;'.
  ```

- **Cause**: An attribute prefix was used, which caused the conflict.
- **Recommendation**: Set a different value for the "attributePrefix" property.

Error code: XmlValueColumnNameConflict

- **Message**:

  ```
  Column name for the value of element '%element;' is '%columnName;' and it conflicts with the child element having the same name.
  ```

- **Cause**: One of the child element names was used as the column name for the element value.
- **Recommendation**: Set a different value for the "valueColumn" property.

Error code: XmlInvalid

- **Message**: `Input XML file '%file;' is invalid with parsing error '%error;'.`
- **Cause**: The input XML file is not well formed.
- **Recommendation**: Correct the XML file to make it well formed.

Next steps

Troubleshoot CI-CD, Azure DevOps, and GitHub issues in Azure Data Factory and Synapse Analytics

8/19/2022 • 15 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

In this article, let us explore common troubleshooting methods for Continuous Integration-Continuous Deployment (CI-CD), Azure DevOps and GitHub issues in Azure Data Factory and Synapse Analytics.

If you have questions or issues in using source control or DevOps techniques, here are a few articles you may find useful:

- Refer to Source Control to learn how source control is practiced in the service.
- Refer to CI-CD to learn more about how DevOps CI-CD is practiced in the service.

Common errors and messages

Connect to Git repository failed due to different tenant

Issue

Sometimes you encounter Authentication issues like HTTP status 401. Especially when you have multiple tenants with guest account, things could become more complicated.

Cause

The token was obtained from the original tenant, but the service is in guest tenant trying to use the token to visit DevOps in guest tenant. This type of token access isn't the expected behavior.

Recommendation

You should use the token issued from guest tenant. For example, you have to assign the same Azure Active Directory to be your guest tenant and your DevOps, so it can correctly set token behavior and use the correct tenant.

Template parameters in the parameters file aren't valid

Issue

If we delete a trigger in Dev branch, which is already available in Test or Production branch with **same** configuration (like frequency and interval), then release pipeline deployment succeeds and corresponding trigger will be deleted in respective environments. But if you have **different** configuration (like frequency and interval) for trigger in Test/Production environments and if you delete the same trigger in Dev, then deployment fails with an error.

Cause

CI/CD Pipeline fails with the following error:

```
2020-07-20T11:19:02.1276769Z ##[error]Deployment template validation failed: 'The template parameters
'Trigger_Salesforce_properties_typeProperties_recurrence_frequency,
Trigger_Salesforce_properties_typeProperties_recurrence_interval,
Trigger_Salesforce_properties_typeProperties_recurrence_startTime,
Trigger_Salesforce_properties_typeProperties_recurrence_timeZone' in the parameters file are not valid; they
are not present in the original template and can therefore not be provided at deployment time. The only
supported parameters for this template are 'factoryName, PlanonDWH_connectionString,
PlanonKeyVault_properties_typeProperties_baseUrl
```

Recommendation

The error occurs because we often delete a trigger, which is parameterized, therefore, the parameters will not be available in the Azure Resource Manager (ARM) template (because the trigger does not exist anymore). Since

the parameter is not in the ARM template anymore, we have to update the overridden parameters in the DevOps pipeline. Otherwise, each time the parameters in the ARM template change, they must update the overridden parameters in the DevOps pipeline (in the deployment task).

Updating property type is not supported

Issue

CI/CD release pipeline failing with the following error:

```
2020-07-06T09:50:50.8716614Z There were errors in your deployment. Error code: DeploymentFailed.
2020-07-06T09:50:50.8760242Z ##[error]At least one resource deployment operation failed. Please list
deployment operations for details. Please see https://aka.ms/DeployOperations for usage details.
2020-07-06T09:50:50.8771655Z ##[error]Details:
2020-07-06T09:50:50.8772837Z ##[error]DataFactoryPropertyUpdateNotSupported: Updating property type is not
supported.
2020-07-06T09:50:50.8774148Z ##[error]DataFactoryPropertyUpdateNotSupported: Updating property type is not
supported.
2020-07-06T09:50:50.8775530Z ##[error]Check out the troubleshooting guide to see if your issue is addressed:
https://docs.microsoft.com/azure/devops/pipelines/tasks/deploy/azure-resource-group-
deployment#troubleshooting
2020-07-06T09:50:50.8776801Z ##[error]Task failed while creating or updating the template deployment.
```

Cause

This error is due to an integration runtime with the same name in the target service instance, but with a different type. Integration Runtime needs to be of the same type during deployment.

Recommendation

- Refer to the Best Practices for CI/CD
- Integration runtimes don't change often and are similar across all stages in your CI/CD, so the service expects you to have the same name and type of integration runtime across all stages of CI/CD. If the name and types & properties are different, make sure to match the source and target integration runtime configuration and then deploy the release pipeline.
- If you want to share integration runtimes across all stages, consider using a ternary factory just to contain the shared integration runtimes. You can use this shared factory in all of your environments as a linked integration runtime type.

Document creation or update failed because of invalid reference

Issue

When trying to publish changes, you get following error message:

```
"error": { "code": "BadRequest", "message": "The document creation or update failed because of invalid reference
'<entity>'.", "target": "/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/<rgname>/providers/Microsoft.DataFactory/factories/<datafactory>/pipelines/<pipeline>",
"details": null }
```

Cause

You have detached the Git configuration and set it up again with the "Import resources" flag selected, which sets the service as "in sync". This means no change during publication.

Resolution

Detach Git configuration and set it up again, and make sure NOT to check the "import existing resources" checkbox.

Data factory move failing from one resource group to another

Issue

You are unable to move a data factory from one Resource Group to another, failing with the following error:

```
{ "code": "ResourceMoveProviderValidationFailed", "message": "Resource move validation failed. Please see
details. Diagnostic information: timestamp 'xxxxxxxxxxxxZ', subscription id 'xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx', tracking id 'xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx', request correlation id 'xxxxxxxx-xxxx-
xxxx-xxxx-xxxxxxxxxxxx'.", "details": [ { "code": "BadRequest", "target": "Microsoft.DataFactory/factories",
"message": "One of the resources contain integration runtimes that are either SSIS-IRs in
starting/started/stopping state, or Self-Hosted IRs which are shared with other resources. Resource move is
not supported for those resources." } ] }
```

Resolution

You can delete the SSIS-IR and Shared IRs to allow the move operation. If you don't want to delete the integration runtimes, then the best way is to follow the copy and clone document to do the copy and after it's done, delete the old data factory.

Unable to export and import ARM template

Issue

Unable to export and import ARM template. No error was on the portal, however, in the browser trace, you could see the following error:

```
Failed to load resource: the server responded with a status code of 401 (Unauthorized)
```

Cause

You have created a customer role as the user and it did not have the necessary permission. When the UI is loaded, a series of exposure control values is checked. In this case, the user's access role does not have permission to access *queryFeaturesValue* API. To access this API, the global parameters feature is turned off. The ARM export code path is partly relying on the global parameters feature.

Resolution

In order to resolve the issue, you need to add the following permission to your role: *Microsoft.DataFactory/factories/queryFeaturesValue/action*. This permission is included by default in the **Data Factory Contributor** role for Data Factory, and the **Contributor** role In Synapse Analytics.

Cannot automate publishing for CI/CD

Cause

Until recently, the it was only possible to publish a pipeline for deployments by clicking the UI in the Portal. Now, this process can be automated.

Resolution

CI/CD process has been enhanced. The **Automated** publish feature takes, validates, and exports all ARM template features from the UI. It makes the logic consumable via a publicly available npm package @microsoft/azure-data-factory-utilities. This method allows you to programmatically trigger these actions instead of having to go to the UI and click a button. This method gives your CI/CD pipelines a **true** continuous integration experience. Follow CI/CD Publishing Improvements for details.

Cannot publish because of 4-MB ARM template limit

Issue

You can't deploy because you hit Azure Resource Manager limit of 4-MB total template size. You need a solution to deploy after crossing the limit.

Cause

Azure Resource Manager restricts template size to be 4 MB. Limit the size of your template to 4 MB, and each parameter file to 64 KB. The 4-MB limit applies to the final state of the template after it has been expanded with iterative resource definitions, and values for variables and parameters. But, you have crossed the limit.

Resolution

For small to medium solutions, a single template is easier to understand and maintain. You can see all the resources and values in a single file. For advanced scenarios, linked templates enable you to break down the solution into targeted components. Follow best practice at Using Linked and Nested Templates.

DevOps API limit of 20 MB causes ADF trigger twice or more instead of once

Issue

While publishing ADF resources, the azure pipeline triggers twice or more instead of once.

Cause

Azure DevOps has the 20 MB REST API limit. When the ARM template exceeds this size, ADF internally splits the template file into multiple files with linked templates to solve this issue. As a side effect, this split could result in customer's triggers being run more than once.

Resolution

Use ADF **Automated publish** (preferred) or **manual trigger** method to trigger once instead of twice or more.

Cannot connect to GIT Enterprise

Issue

You can't connect to GIT Enterprise because of permission issues. You can see error like **422 - Unprocessable Entity.**

Cause

- You haven't configured Oauth for the service.
- Your URL is misconfigured. The repoConfiguration should be of type FactoryGitHubConfiguration

Resolution

You grant Oauth access to the service at first. Then, you have to use correct URL to connect to GIT Enterprise. The configuration must be set to the customer organization(s). For example, the service will try *https://hostname/api/v3/search/repositories?q=user%3<customer credential>...*. at first and fail. Then, it will try *https://hostname/api/v3/orgs/<org>/<repo>...*, and succeed.

Cannot recover from a deleted instance

Issue

An instance of the service, or the resource group containing it, was deleted and needs to be recovered.

Cause

It is possible to recover the instance only if source control was configured for it with DevOps or Git. This action will bring all the latest published resources, but **will not** restore any unpublished pipelines, datasets, or linked services. If there is no Source control, recovering a deleted instance from the Azure backend isn't possible because once the service receives the delete command, the instance is permanently deleted without any backup.

Resolution

To recover a deleted service instance that has source control configured, refer the steps below:

- Create a new instance of the service.
- Reconfigure Git with the same settings, but make sure to import existing resources to the selected repository, and choose New branch.
- Create a pull request to merge the changes to the collaboration branch and publish.
- If there was a Self-hosted Integration Runtime in a deleted data factory or Synapse workspace, a new instance of the IR must be created in a new factory or workspace. The on-premises or virtual machine IR instance must be uninstalled and reinstalled, and a new key obtained. After setup of the new IR is completed, the Linked Service must be updated to point to new IR and the connected tested again, or it will fail with error **invalid reference.**

Can't deploy to different stage using automatic publish method

Issue

Customer followed all necessary steps like installing NPM package and setting up a higher stage using Azure DevOps, but deployment still fails.

Cause

While npm packages can be consumed in various ways, one of the primary benefits is being consumed via

Azure Pipeline. On each merge into your collaboration branch, a pipeline can be triggered that first validates all of the code and then exports the ARM template into a build artifact that can be consumed by a release pipeline. In Starter pipeline, YAML file should be valid and complete.

Resolution

Following section is not valid because package.json folder is not valid.

```
- task: Npm@1
  inputs:
    command: 'custom'
    workingDir: '$(Build.Repository.LocalPath)/<folder-of-the-package.json-file>' #replace with the
package.json folder
    customCommand: 'run build validate $(Build.Repository.LocalPath) /subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-
xxxxxxxxxxxx/resourceGroups/testResourceGroup/providers/Microsoft.DataFactory/factories/yourFactoryName'
  displayName: 'Validate'
```

It should have DataFactory included in customCommand like *'run build validate $(Build.Repository.LocalPath)/DataFactory/subscriptions/xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx/resourceGroups/testResourceGroup/providers/Microsoft.DataFactory/factories/yourFactoryName'*. Make sure the generated YAML file for higher stage should have required JSON artifacts.

Extra left "[" displayed in published JSON file

Issue

When publishing with DevOps, there is an extra "[" displayed. The service adds one more "[" in an ARMTemplate in DevOps automatically. You will see an expression like "[[" in JSON file.

Cause

Because [is a reserved character for ARM, an extra [is added automatically to escape "[".

Resolution

This is normal behavior during the publishing process for CI/CD.

Perform CI/CD during progress/queued stage of pipeline run

Issue

You want to perform CI/CD during progress and queuing stage of pipeline run.

Cause

When pipeline is in progress/queued stage, you have to monitor the pipeline and activities at first. Then, you can decide to wait until pipeline to finish or you can cancel the pipeline run.

Resolution

You can monitor the pipeline using **SDK**, **Azure Monitor** or Monitor. Then, you can follow CI/CD Best Practices to guide you further.

Perform UNIT TESTING during development and deployment

Issue

You want to perform unit testing during development and deployment of your pipelines.

Cause

During development and deployment cycles, you may want to unit test your pipeline before you manually or automatically publish your pipeline. Test automation allows you to run more tests, in less time, with guaranteed repeatability. Automatically retesting all your pipelines before deployment gives you some protection against regression faults. Automated testing is a key component of CI/CD software development approaches: inclusion of automated tests in CI/CD deployment pipelines can significantly improve quality. In long run, tested pipeline artifacts are reused saving you cost and time.

Resolution

Because customers may have different unit testing requirements with different skillsets, usual practice is to

follow following steps:

1. Setup Azure DevOps CI/CD project or develop .NET/PYTHON/REST type SDK driven test strategy.
2. For CI/CD, create a build artifact containing all scripts and deploy resources in release pipeline. For an SDK driven approach, develop Test units using PyTest in Python, Nunit in C# using .NET SDK and so on.
3. Run unit tests as part of release pipeline or independently with ADF Python/PowerShell/.NET/REST SDK.

For example, you want to delete duplicates in a file and then store curated file as table in a database. To test the pipeline, you set up a CI/CD project using Azure DevOps. You set up a TEST pipeline stage where you deploy your developed pipeline. You configure TEST stage to run Python tests for making sure table data is what you expected. If you do not use CI/CD, you use **Nunit** to trigger deployed pipelines with tests you want. Once you are satisfied with the results, you can finally publish the pipeline to a production instance.

Pipeline runs temporarily fail after CI/CD deployment or authoring updates

Issue

After some amount of time, new pipeline runs begin to succeed without any user action after temporary failures.

Cause

There are several scenarios, which can trigger this behavior, all of which involve a new version of a dependent resource being called by the old version of the parent resource. For example, suppose an existing child pipeline called by "Execute pipeline" is updated to have required parameters and the existing parent pipeline is updated to pass these parameters. If the deployment occurs during a parent pipeline execution, but before the **Execute Pipeline** activity, the old version of the pipeline will call the new version of the child pipeline, and the expected parameters will not be passed. This will cause the pipeline to fail with a *UserError*. This can also occur with other types of dependencies, such as if a breaking change is made to linked service during a pipeline run that references it.

Resolution

New runs of the parent pipeline will automatically begin succeeding, so typically no action is needed. However, to prevent these errors, customers should consider dependencies while authoring and planning deployments to avoid breaking changes.

Cannot parameterize integration run time in linked service

Issue

Need to parameterize linked service integration run time

Cause

This feature isn't supported.

Resolution

You have to select manually and set an integration runtime. You can use PowerShell API to change as well. This change can have downstream implications.

Update/change Integration runtime during CI/CD.

Issue

Changing Integration runtime name during CI/CD deployment.

Cause

Parameterizing an entity reference (Integration runtime in Linked service, Dataset in activity, Linked Service in dataset) isn't supported. Changing the runtime name during deployment will cause the depended resource (Resource referencing the Integration runtime) to become malformed with invalid reference.

Resolution

Data Factory requires you to have the same name and type of integration runtime across all stages of CI/CD.

ARM template deployment failing with error DataFactoryPropertyUpdateNotSupported

Issue

ARM template deployment fails with an error such as DataFactoryPropertyUpdateNotSupported: Updating

property type isn't supported.

Cause

The ARM template deployment is attempting to change the type of an existing integration runtime. This isn't allowed and will cause a deployment failure because data factory requires the same name and type of integration runtime across all stages of CI/CD.

Resolution

If you want to share integration runtimes across all stages, consider using a ternary factory just to contain the shared integration runtimes. You can use this shared factory in all of your environments as a linked integration runtime type. For more information, refer to Continuous integration and delivery - Azure Data Factory

GIT publish may fail because of PartialTempTemplates files

Issue

When you've 1000 s of old temporary ARM json files in PartialTemplates folder, publish may fail.

Cause

On publish, ADF fetches every file inside each folder in the collaboration branch. In the past, publishing generated two folders in the publish branch: PartialArmTemplates and LinkedTemplates. PartialArmTemplates files are no longer generated. However, because there can be many old files (thousands) in the PartialArmTemplates folder, this may result in many requests being made to GitHub on publish and the rate limit being hit.

Resolution

Delete the PartialTemplates folder and republish. You can delete the temporary files in that folder as well.

Include global parameters in ARM template option does not work

Issue

If you are using old default parameterization template, new way to include global paramaters from **Manage Hub** will not work.

Cause

Default parameterization template should include all values from global parameter list.

Resolution

Use updated default parameterization template. as one time migration to new method of including global parameters. This template references to all values in global parameter list.

Error code: InvalidTemplate

Issue

Message says *Unable to parse expression.* The expression passed in the dynamic content of an activity isn't being processed correctly because of a syntax error.

Cause

Dynamic content is not written as per expression language requirements.

Resolution

- For debug run, check expressions in pipeline within current git branch.
- For Triggered run, check expressions in pipeline within *Live* mode .

Troubleshoot Azure Data Factory and Synapse Analytics security and access control issues

8/19/2022 • 9 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

This article explores common troubleshooting methods for security and access control in Azure Data Factory and Synapse Analytics pipelines.

Common errors and messages

Connectivity issue in the copy activity of the cloud datastore

Symptoms

Various error messages might be returned when connectivity issues occur in the source or sink datastore.

Cause

The problem is usually caused by one of the following factors:

- The proxy setting in the self-hosted integration runtime (IR) node, if you're using a self-hosted IR.
- The firewall setting in the self-hosted IR node, if you're using a self-hosted IR.
- The firewall setting in the cloud datastore.

Resolution

- To ensure that this is a connectivity issue, check the following points:
  - The error is thrown from the source or sink connectors.
  - The failure is at the start of the copy activity.
  - The failure is consistent for Azure IR or the self-hosted IR with one node, because it could be a random failure in a multiple-node self-hosted IR if only some of the nodes have the issue.
- If you're using a **self-hosted IR**, check your proxy, firewall, and network settings, because connecting to the same datastore could succeed if you're using an Azure IR. To troubleshoot this scenario, see:
  - Self-hosted IR ports and firewalls
  - Azure Data Lake Storage connector
- If you're using an **Azure IR**, try to disable the firewall setting of the datastore. This approach can resolve the issues in the following two situations:
  - Azure IR IP addresses are not in the allow list.
  - The *Allow trusted Microsoft services to access this storage account* feature is turned off for Azure Blob Storage and Azure Data Lake Storage Gen 2.
  - The *Allow access to Azure services* setting isn't enabled for Azure Data Lake Storage Gen1.

If none of the preceding methods works, contact Microsoft for help.

Invalid or empty authentication key issue after public network access is disabled

Symptoms

After you disable public network access for the service, the self-hosted integration runtime throws following errors: `The Authentication key is invalid or empty.` or

```
Cannot connect to the data factory. Please check whether the factory has enabled public network access or the machine is hosted in a approved private endpoint Virtual Network.
```

Cause

The problem is most likely caused by a Domain Name System (DNS) resolution issue, because disabling public connectivity and establishing a private endpoint prevents reconnection.

To verify whether the service's fully qualified domain name (FQDN) is resolved to the public IP address, do the following:

1. Confirm that you've created the Azure virtual machine (VM) in the same virtual network as the service's private endpoint.
2. Run PsPing and Ping from the Azure VM to the service FQDN:

```
psping.exe <dataFactoryName>.<region>.datafactory.azure.net:443
ping <dataFactoryName>.<region>.datafactory.azure.net
```

> **NOTE**
> You must specify a port for the PsPing command. Port 443 is shown here but is not required.

3. Check to see whether both commands resolve to an Azure Data Factory public IP that's based on a specified region. The IP should be in the following format: `xxx.xxx.xxx.0`

Resolution

To resolve the issue, do the following:

- As option, we would like to suggest you to manually add a "Virtual Network link" under the "Private link DNS Zone" for the service. For details, refer to the Azure Private Link article. The instruction is for configuring the private DNS zone or custom DNS server to resolve the service FQDN to a private IP address.
- However, if you don't want to configure the private DNS zone or custom DNS server, try the following temporary solution:

  1. Change the host file in Windows, and map the private IP (the service's private endpoint) to the service FQDN.

     In the Azure VM, go to `C:\Windows\System32\drivers\etc`, and then open the *host* file in Notepad. Add the line that maps the private IP to the FQDN at the end of the file, and save the change.

     ```
     # localhost name resolution is handled within DNS itself.
     #       127.0.0.1       localhost
     #       ::1             localhost

           10.0.0.1        <dataFactoryName>.<region>.datafactory.azure.net
     ```

  2. Rerun the same commands as in the preceding verification steps to check the response, which should contain the private IP.

  3. Re-register the self-hosted integration runtime, and the issue should be resolved.

Unable to register IR authentication key on Self-hosted VMs due to private link

Symptoms

You're unable to register the IR authentication key on the self-hosted VM because the private link is enabled. You receive the following error message:

"Failed to get service token from ADF service with key ********** and time cost is: 0.1250079 second, the error code is: InvalidGatewayKey, activityId is: XXXXXXX and detailed error message is Client IP address is not valid private ip Cause Data factory couldn't access the public network thereby not able to reach out to the cloud to make the successful connection."

Cause

The issue could be caused by the VM in which you're trying to install the self-hosted IR. To connect to the cloud, ensure that public network access is enabled.

Resolution

Solution 1

To resolve the issue, do the following:

1. Go to the Factories - Update page.
2. At the upper right, select the **Try it** button.
3. Under **Parameters**, complete the required information.
4. Under **Body**, paste the following property:

   ```
   { "tags": { "publicNetworkAccess":"Enabled" } }
   ```

5. Select **Run** to run the function.
6. Under **Parameters**, complete the required information.
7. Under **Body**, paste the following property:

   ```
   { "tags": { "publicNetworkAccess":"Enabled" } }
   ```

8. Select **Run** to run the function.
9. Confirm that **Response Code: 200** is displayed. The property you pasted should be displayed in the

JSON definition as well.

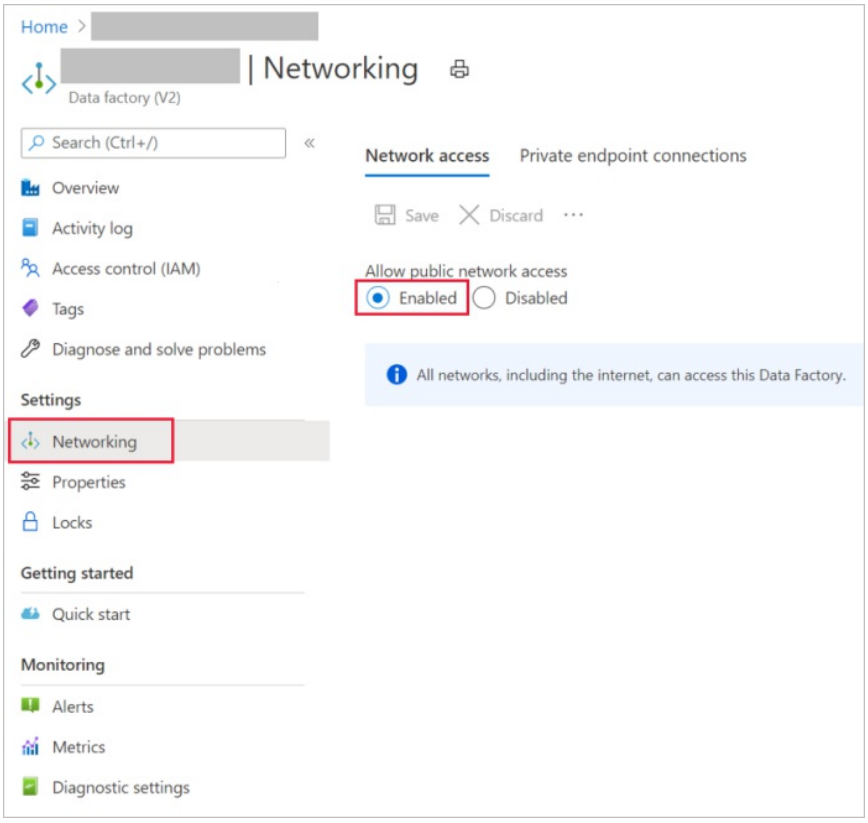
10. Add the IR authentication key again in the integration runtime.

Solution 2

To resolve the issue, go to Azure Private Link.

Try to enable public network access on the user interface, as shown in the following screenshot:

- Azure Data Factory
- Synapse Analytics



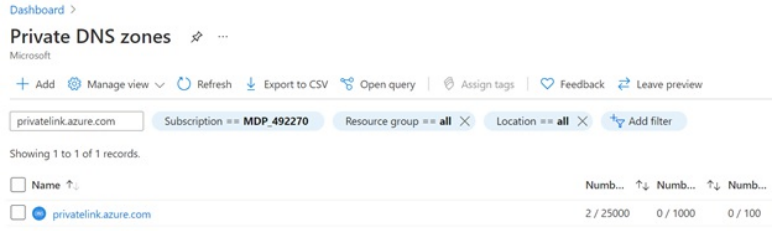
Service private DNS zone overrides Azure Resource Manager DNS resolution causing 'Not found' error

Cause

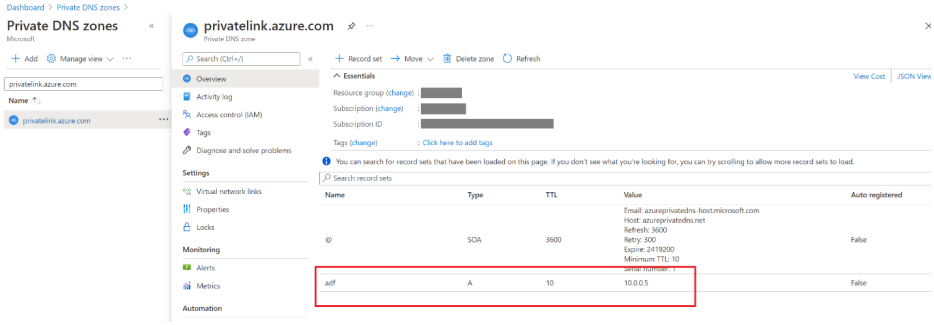
Both Azure Resource Manager and the service are using the same private zone creating a potential conflict on customer's private DNS with a scenario where the Azure Resource Manager records will not be found.

Solution

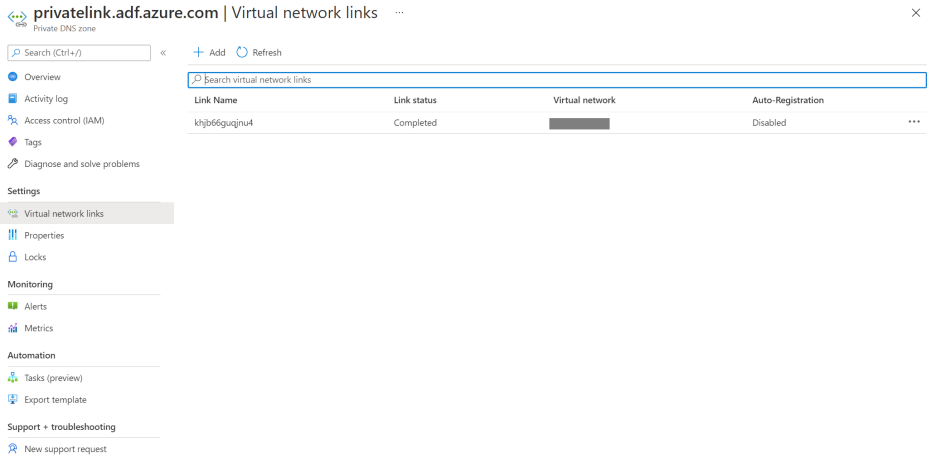
1. Find Private DNS zones **privatelink.azure.com** in Azure portal.



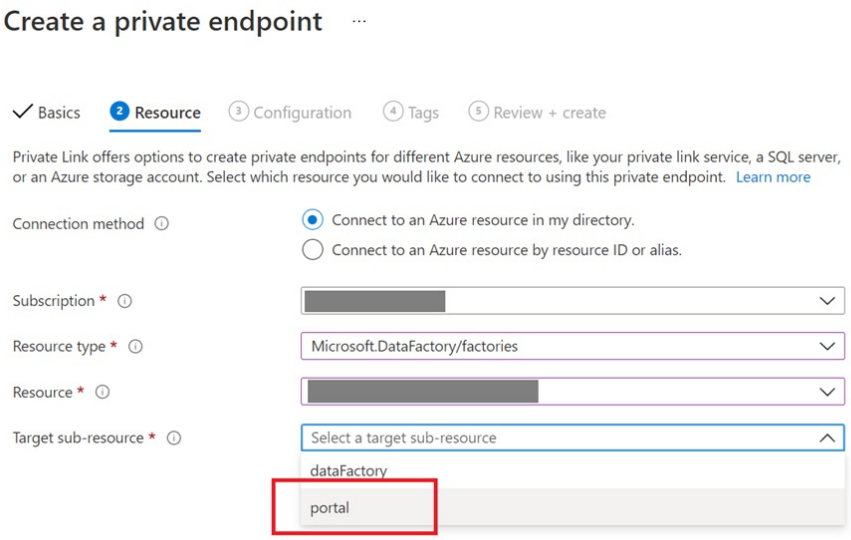
2. Check if there is an A record **adf**.



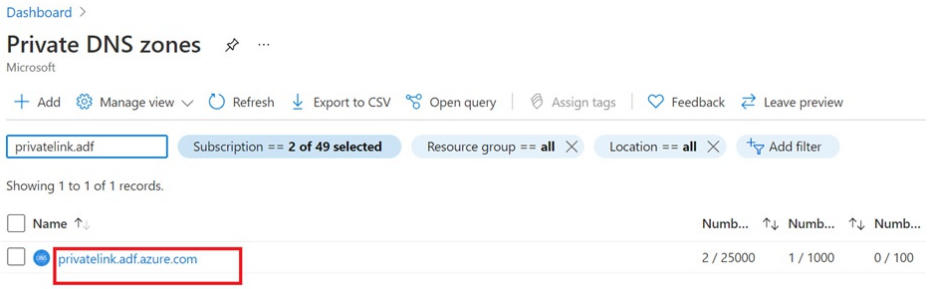
3. Go to **Virtual network links**, delete all records.



4. Navigate to your service in Azure portal and recreate the private endpoint for the portal.



5. Go back to Private DNS zones, and check if there is a new private DNS zone **privatelink.adf.azure.com**.



Connection error in public endpoint

Symptoms

When copying data with Azure Blob Storage account public access, pipeline runs randomly fail with following error.

For example: The Azure Blob Storage sink was using Azure IR (public, not Managed VNet) and the Azure SQL Database source was using the Managed VNet IR. Or source/sink use Managed VNet IR only with storage public access.

```
<LogProperties><Text>Invoke callback url with req:
"ErrorCode=AzureBlobFailedToCreateContainer,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Message=Unable
to create Azure Blob container. Endpoint: XXXXXXX/, Container Name:
test.,Source=Microsoft.DataTransfer.ClientLibrary,''Type=Microsoft.WindowsAzure.Storage.StorageException,Message=Unable to
connect to the remote server,Source=Microsoft.WindowsAzure.Storage,''Type=System.Net.WebException,Message=Unable to connect
to the remote server,Source=System,''Type=System.Net.Sockets.SocketException,Message=A connection attempt failed because the
connected party did not properly respond after a period of time, or established connection failed because connected host has
failed to respond public ip:443,Source=System,'","Details":null}}</Text></LogProperties>.
```

Cause

The service may still use Managed VNet IR, but you could encounter such error because the public endpoint to Azure Blob Storage in Managed VNet is not reliable based on the testing result, and Azure Blob Storage and Azure Data Lake Gen2 are not supported to be connected through public endpoint from the service's Managed Virtual Network according to Managed virtual network & managed private endpoints.

Solution

- Having private endpoint enabled on the source and also the sink side when using the Managed VNet IR.
- If you still want to use the public endpoint, you can switch to public IR only instead of using the Managed VNet IR for the source and the sink. Even if you switch back to public IR, the service may still use the Managed VNet IR if the Managed VNet IR is still there.

Internal error while trying to Delete a data factory or Synapse workspace with Customer Managed Key (CMK) and User Assigned Managed Identity (UA-MI)

Symptoms

```
{\"error\":{\"code\":\"InternalError\",\"message\":\"Internal error has occurred.\"}}
```

Cause

If you are performing any operations related to CMK, you should complete all operations related to the service first, and then external operations (like Managed Identities or Key Vault operations). For example, if you want to delete all resources, you need to delete the service instance first, and then delete the key vault. If you delete the key vault first, this error will occur since the service can't read the required objects anymore, and it won't be able to validate if deletion is possible or not.

Solution

There are three possible ways to solve the issue. They are as follows:

- You revoked the service's access to Key vault where the CMK key was stored. You can reassign access to the following permissions: **Get, Unwrap Key, and Wrap Key**. These permissions are required to enable customer-managed keys. Please refer to Grant access to customer-managed keys. Once the permission is provided, you should be able to delete the service.
- Customer deleted Key Vault / CMK before deleting the service. CMK in the service should have "Soft Delete" enabled and "Purge Protect" enabled which has default retention policy of 90 days. You can restore the deleted key.
  Please review Recover deleted Key and Deleted Key Value
- User Assigned Managed Identity (UA-MI) was deleted before the service. You can recover from this by using REST API calls, you can do this in an http client of your choice in any programming language. If you have not anything already set up for REST API calls with Azure authentication, the easiest way to do this would be by using POSTMAN/Fiddler. Please follow following steps.

  1. Make a GET call using Method: GET Url like
     ```
     https://management.azure.com/subscriptions/YourSubscription/resourcegroups/YourResourceGroup/providers/Microsoft.DataFactory/factorie
     api-version=2018-06-01
     ```
  2. You need to create a new User Managed Identity with a different Name (same name may work, but just to be sure, it's safer to use a different name than the one in the GET response)
  3. Modify the encryption.identity property and identity.userassignedidentities to point to the newly created managed identity. Remove the clientId and principalId from the userAssignedIdentity object.
  4. Make a PUT call to the same url passing the new body. It is very important that you are passing whatever you got in the GET response, and only modify the identity. Otherwise they would override other settings unintentionally.
  5. After the call succeeds, you will be able to see the entities again and retry deleting.

Sharing Self-hosted Integration Runtime

Sharing a self-hosted IR from a different tenant is not supported

Symptoms

You might notice other data factories (on different tenants) as you're attempting to share the self-hosted IR from the UI, but you can't share it across data factories that are on different tenants.

Cause

The self-hosted IR can't be shared across tenants.

Troubleshoot self-hosted integration runtime

8/19/2022 • 32 minutes to read • Edit Online

APPLIES TO: Azure Data Factory Azure Synapse Analytics

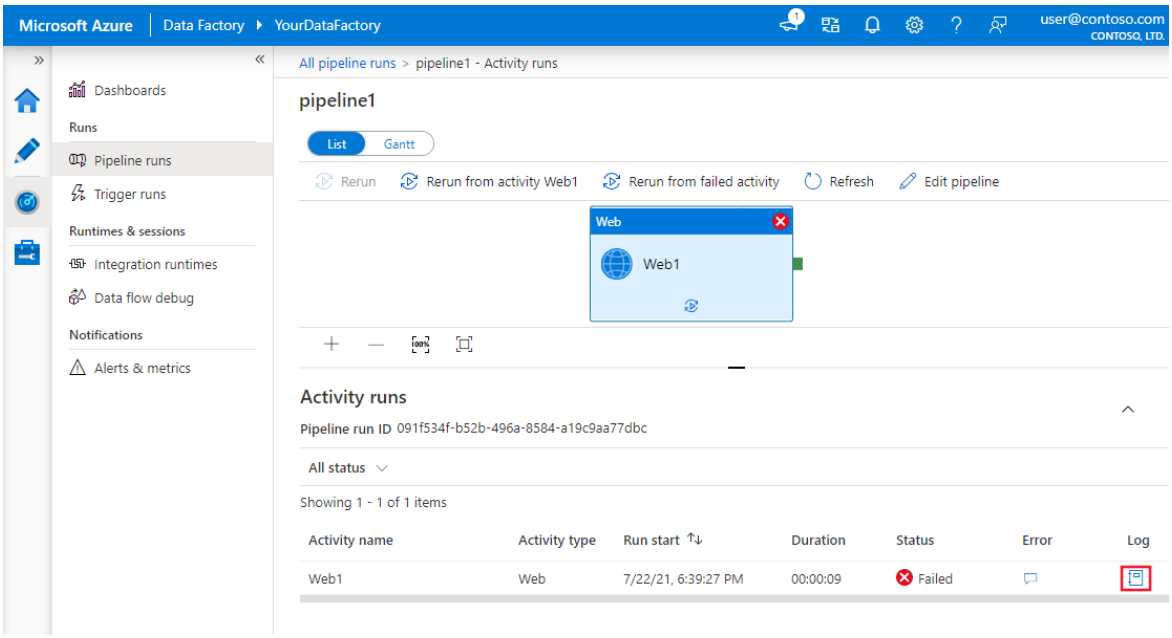
This article explores common troubleshooting methods for self-hosted integration runtime (IR) in Azure Data Factory and Synapse workspaces.

Gather self-hosted IR logs

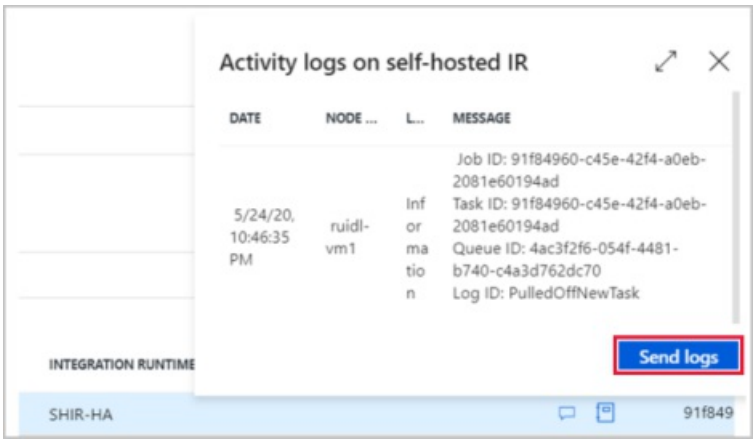
For failed activities that are running on a self-hosted IR or a shared IR, the service supports viewing and uploading error logs. To get the error report ID, follow the instructions here, and then enter the report ID to search for related known issues.

1. On the Monitor page for the service UI, select **Pipeline runs**.
2. Under **Activity runs**, in the **Error** column, select the highlighted button to display the activity logs, as shown in the following screenshot:

   - Azure Data Factory
   - Azure Synapse

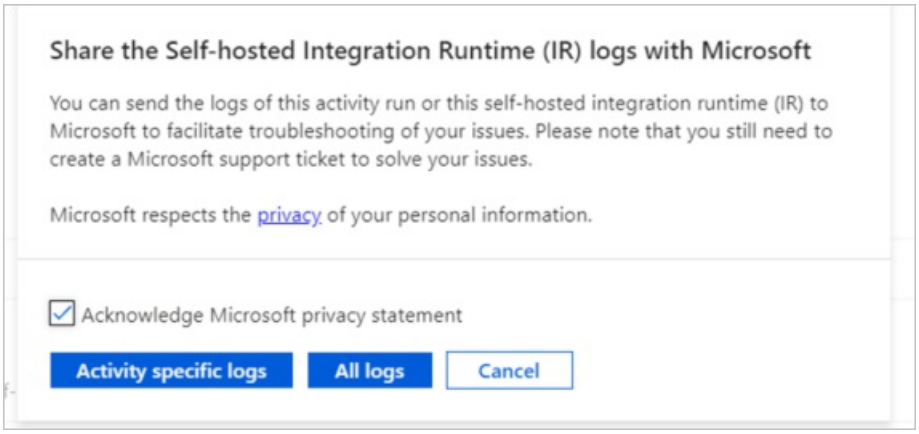


The activity logs are displayed for the failed activity run.



3. For further assistance, select **Send logs**.

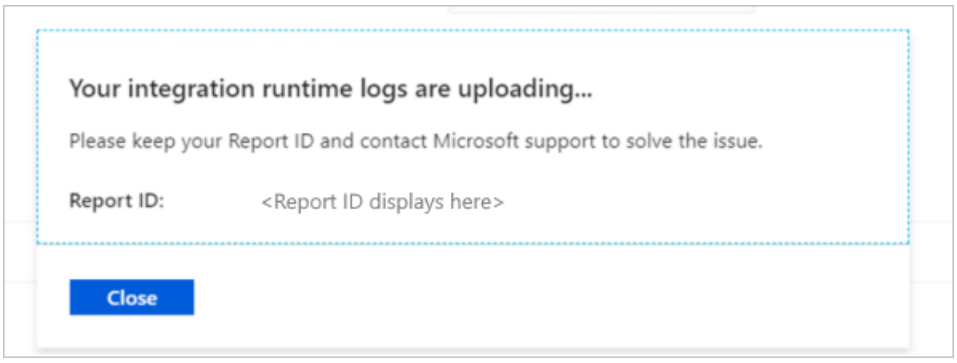
   The **Share the self-hosted integration runtime (IR) logs with Microsoft** window opens.



4. Select which logs you want to send.

   - For a *self-hosted IR*, you can upload logs that are related to the failed activity or all logs on the self-hosted IR node.
   - For a *shared IR*, you can upload only logs that are related to the failed activity.

5. When the logs are uploaded, keep a record of the Report ID for later use if you need further assistance to solve the issue.



> **NOTE**
>
> Log viewing and uploading requests are executed on all online self-hosted IR instances. If any logs are missing, make sure that all the self-hosted IR instances are online.

Self-hosted IR general failure or error

Out of memory issue

- Symptoms

  An OutOfMemoryException (OOM) error occurs when you try to run a lookup activity with a linked IR or a self-hosted IR.

- Cause

  A new activity can throw an OOM error if the IR machine experiences momentary high memory usage. The issue might be caused by a large volume of concurrent activity, and the error is by design.

- Resolution

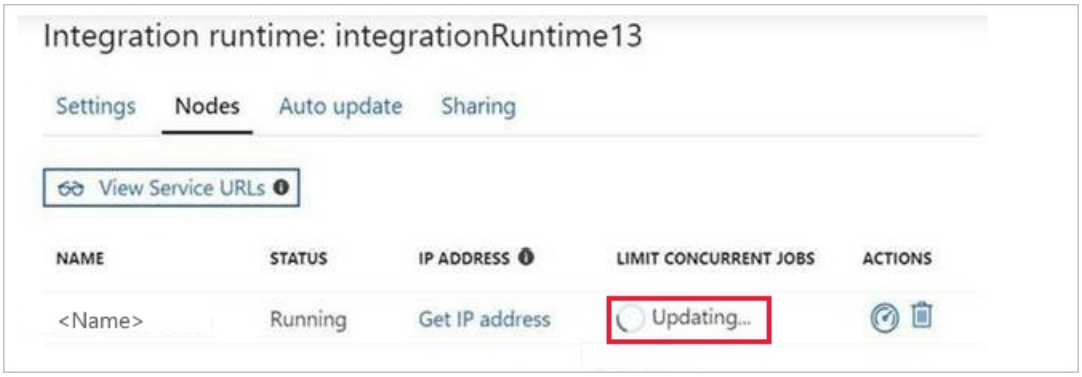
  Check the resource usage and concurrent activity execution on the IR node. Adjust the internal and trigger time of activity runs to avoid too much execution on a single IR node at the same time.

Concurrent jobs limit issue

- Symptoms

  When you try to increase the concurrent jobs limit from UI, the process hangs in *Updating* status.

  Example scenario: The maximum concurrent jobs value is currently set to 24, and you want to increase the count so that your jobs can run faster. The minimum value that you can enter is 3, and the maximum value is 32. You increase the value from 24 to 32 and then select the **Update** button. The process gets stuck in *Updating* status, as shown in the following screenshot. You refresh the page, and the value is still displayed as 24. It hasn't been updated to 32 as you had expected.



- Cause

  The limit on the number of concurrent jobs depends on the computer's logic core and memory. Try to adjust the value downward to a value such as 24, and then view the result.

  > **TIP**
  > - To learn more about logic core count and to determine your machine's logic core count, see Four ways to find the number of cores in your CPU on Windows 10.
  > - To learn how to calculate the math.log, go to the Logarithm calculator.

Self-hosted IR high availability (HA) SSL certificate issue

- Symptoms

  The self-hosted IR work node has reported the following error:

  "Failed to pull shared states from primary node net.tcp://abc.cloud.corp.Microsoft.com:8060/ExternalService.svc/. Activity ID: XXXXX The X.509 certificate CN=abc.cloud.corp.Microsoft.com, OU=test, O=Microsoft chain building failed. The certificate that was used has a trust chain that cannot be verified. Replace the certificate or change the certificateValidationMode. The revocation function was unable to check revocation because the

revocation server was offline."

- **Cause**

  When you handle cases that are related to an SSL/TLS handshake, you might encounter some issues related to certificate chain verification.

- **Resolution**

  - Here's a quick, intuitive way to troubleshoot an X.509 certificate chain build failure:

    1. Export the certificate, which needs to be verified. To do so, do the following:

       a. In Windows, select **Start**, start typing **certificates**, and then select **Manage computer certificates**.

       b. In File Explorer, on the left pane, search for the certificate that you want to check, right-click it, and then select **All tasks** > **Export**.

       
    2. Copy the exported certificate to the client machine.

    3. On the client side, in a Command Prompt window, run the following command. Be sure to replace *<certificate path>* and *<output txt file path>* with the actual paths.

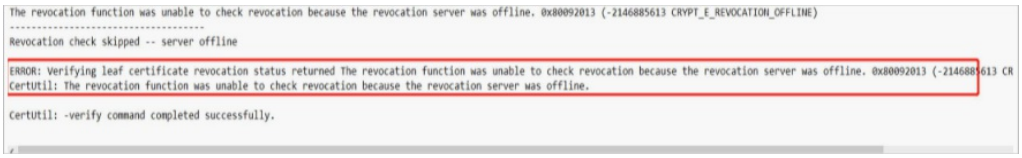
       ```
       Certutil -verify -urlfetch    <certificate path>    >     <output txt file path>
       ```

       For example:

       ```
       Certutil -verify -urlfetch c:\users\test\desktop\servercert02.cer >
       c:\users\test\desktop\Certinfo.txt
       ```

    4. Check for errors in the output TXT file. You can find the error summary at the end of the TXT file.

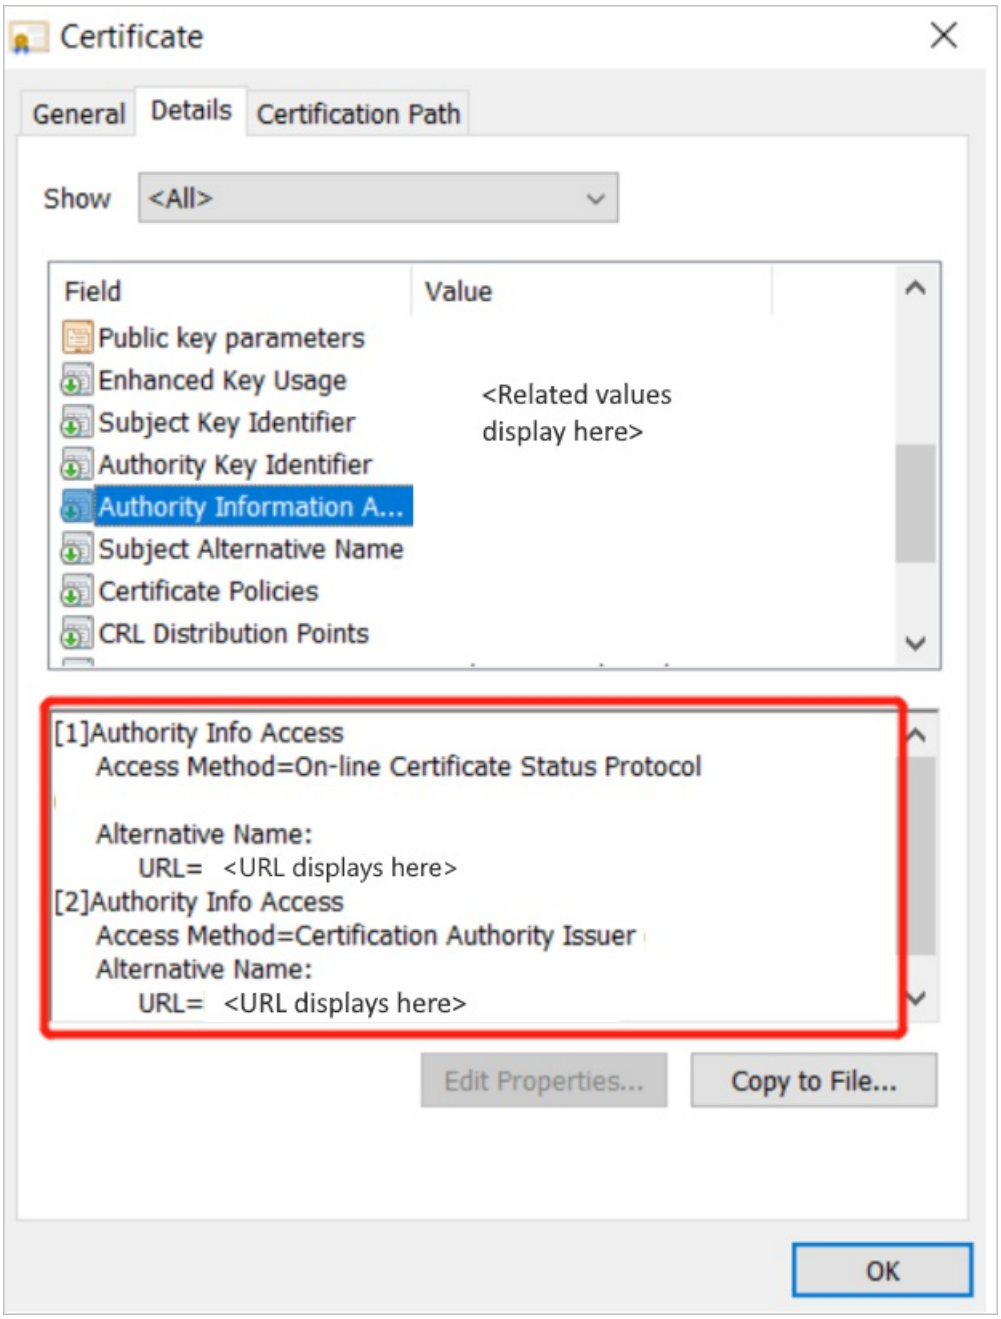
       For example:



If you don't see an error at the end of the log file, as shown in the following screenshot, you can consider that the certificate chain has been built successfully on the client machine.

- If an AIA (Authority Information Access), CDP (CRL Distribution Point), or OCSP (Online Certificate Status Protocol) file name extension is configured in the certificate file, you can check it in a more intuitive way:

  1. Get this information by checking the certificate details, as shown in the following screenshot:

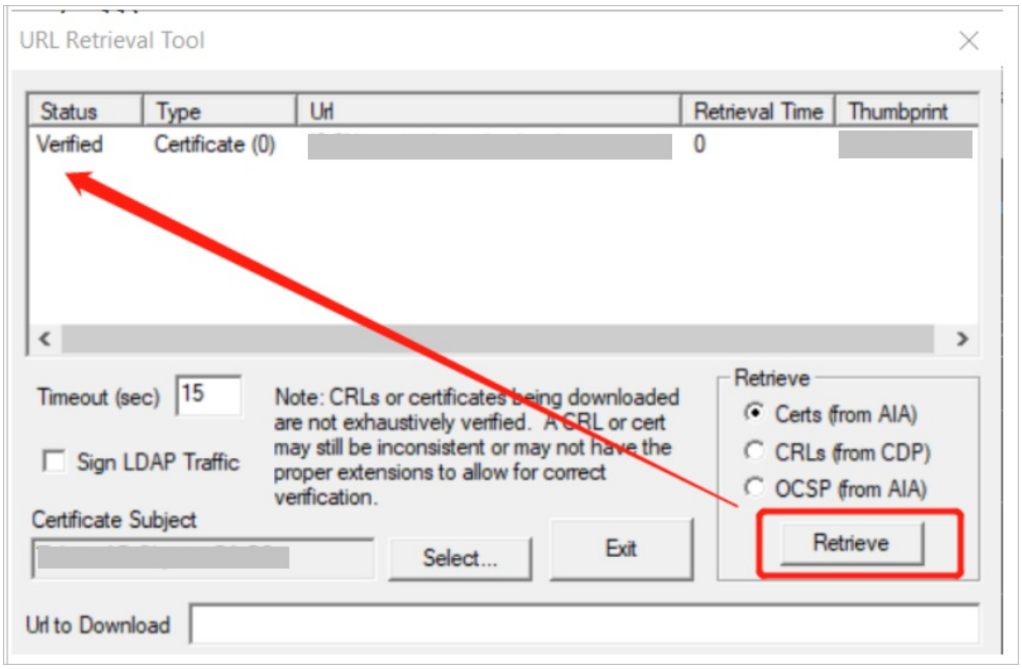


2. Run the following command. Be sure to replace *<certificate path>* with the actual path of the certificate.

```
Certutil   -URL    <certificate path>
```

   The URL Retrieval tool opens.

3. To verify certificates with AIA, CDP, and OCSP file name extensions, select **Retrieve**.



You've built the certificate chain successfully if the certificate status from AIA is *Verified* and the certificate status from CDP or OCSP is *Verified*.

If you fail when you try to retrieve AIA or CDP, work with your network team to get the client machine ready to connect to the target URL. It will be enough if either the HTTP path or the Lightweight Directory Access Protocol (LDAP) path can be verified.

Self-hosted IR could not load file or assembly

- Symptoms

  You get the following error message:

  "Could not load file or assembly 'XXXXXXXXXXXXXXXX, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find the file specified. Activity ID: 92693b45-b4bf-4fc8-89da-2d3dc56f27c3"

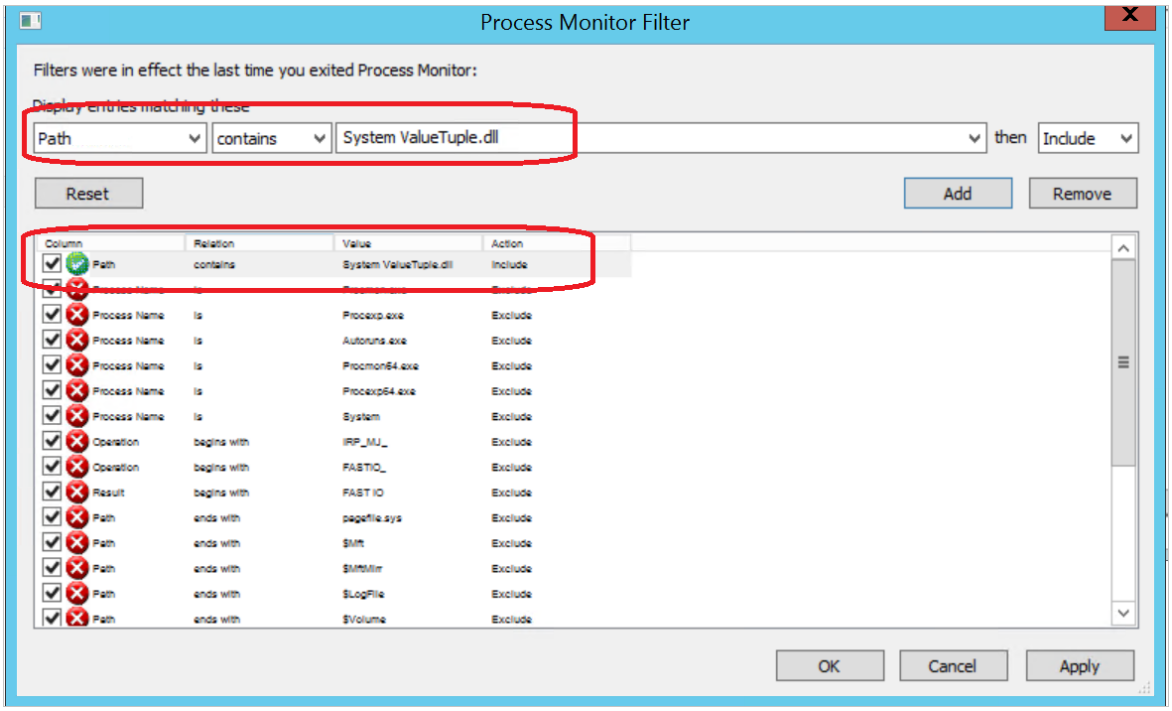
  Here is a more specific error message:

  "Could not load file or assembly 'System.ValueTuple, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find the file specified. Activity ID: 92693b45-b4bf-4fc8-89da-2d3dc56f27c3"

- Cause

  In Process Monitor, you can view the following result:

  > **TIP**
  > In Process Monitor, you can set filters as shown in following screenshot.
  >
  > The preceding error message says that the DLL System.ValueTuple is not located in the related *Global Assembly Cache* (GAC) folder, in the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway* folder, or in the *C:\Program Files\Microsoft Integration Runtime\4.0\Shared* folder.
  >
  > Basically, the process loads the DLL first from the *GAC* folder, then from the *Shared* folder, and finally from the *Gateway* folder. Therefore, you can load the DLL from any path that's helpful.



- **Resolution**

  You'll find the *System.ValueTuple.dll* file in the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway\DataScan* folder. To resolve the issue, copy the *System.ValueTuple.dll* file to the *C:\Program Files\Microsoft Integration Runtime\4.0\Gateway* folder.

  You can use the same method to resolve other missing file or assembly issues.

- **More information about this issue**

  The reason why you see the *System.ValueTuple.dll* under *%windir%\Microsoft.NET\assembly* and *%windir%\assembly* is that this is a .NET behavior.

  In the following error, you can clearly see that the *System.ValueTuple* assembly is missing. This issue arises when the application tries to check the *System.ValueTuple.dll* assembly.

  "<LogProperties><ErrorInfo>[{"Code":0,"Message":"The type initializer for 'Npgsql.PoolManager' threw an exception.","EventType":0,"Category":5,"Data":{},"MsgId":null,"ExceptionType":"System.TypeInitializationException","Source":"Npgsql","StackTrace":"","InnerEventInfos":[{"Code":0,"Message":"Could not load file or assembly 'System.ValueTuple, Version=4.0.2.0, Culture=neutral, PublicKeyToken=XXXXXXXXX' or one of its dependencies. The system cannot find the file specified.","EventType":0,"Category":5,"Data":{},"MsgId":null,"ExceptionType":"System.IO.FileNotFoundException","Source":"Npgsql","StackTrace":"","InnerEventInfos":[]}]}]</ErrorInfo></LogProperties>"

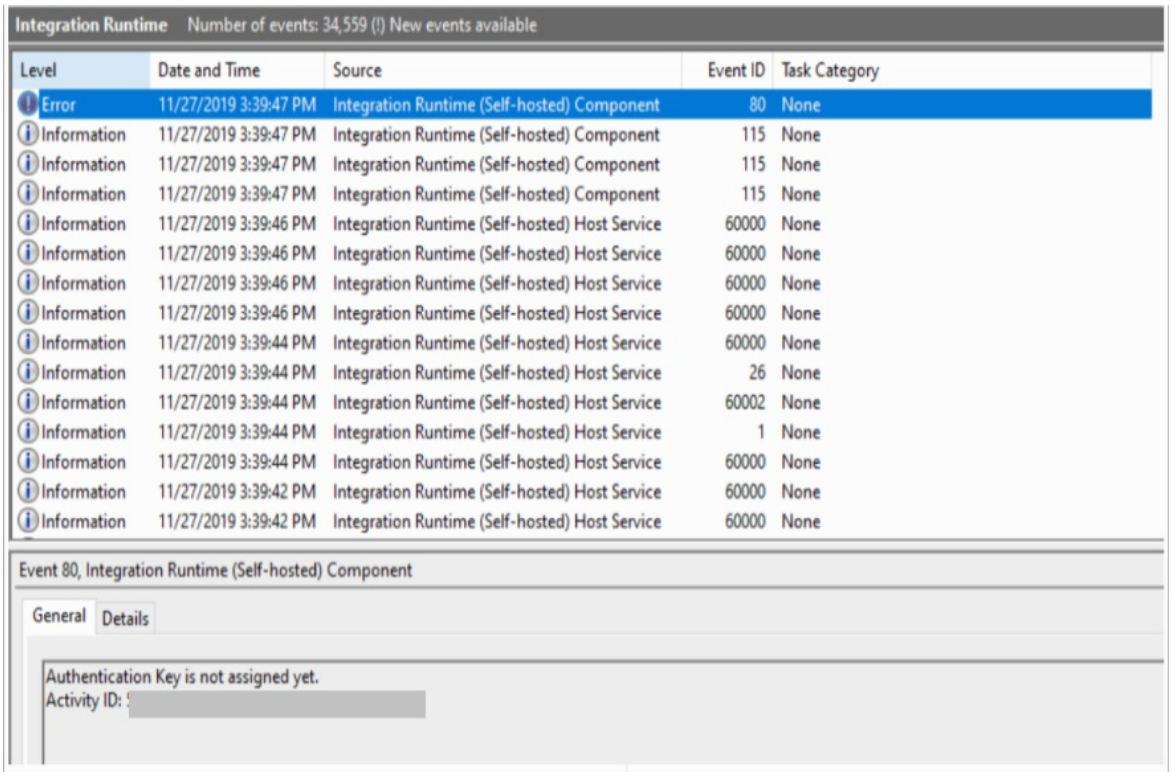
  For more information about GAC, see Global Assembly Cache.

Self-hosted integration runtime Authentication Key is missing

- **Symptoms**

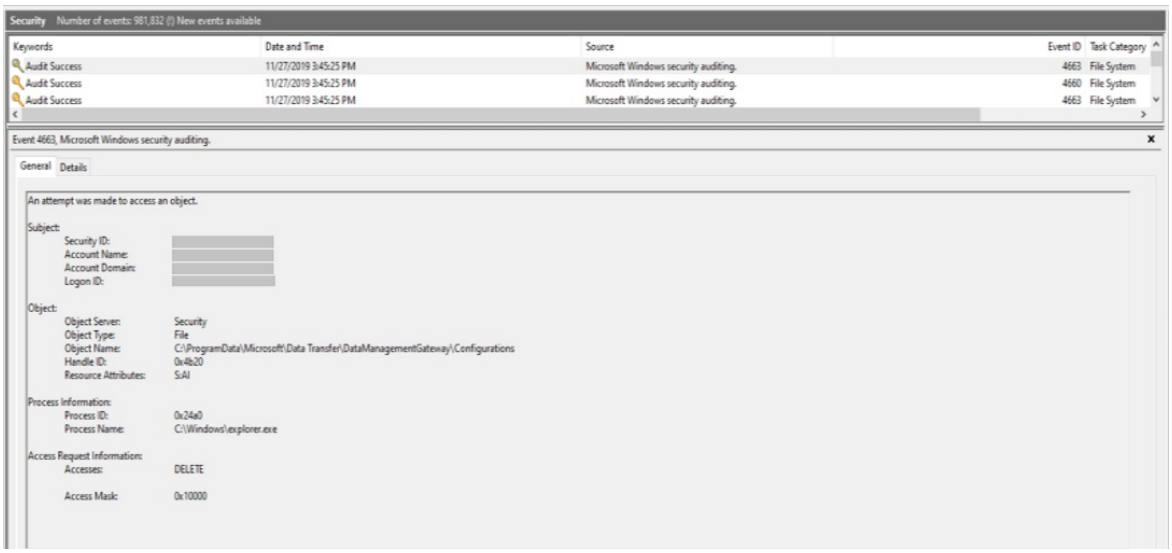
  The self-hosted integration runtime suddenly goes offline without an Authentication Key, and the Event Log displays the following error message:

  "Authentication Key is not assigned yet"



- **Cause**
  - The self-hosted IR node or logical self-hosted IR in the Azure portal was deleted.
  - A clean uninstall was performed.
- **Resolution**

  If neither of the preceding causes applies, you can go to the *%programdata%\Microsoft\Data Transfer\DataManagementGateway* folder to see whether the *Configurations* file has been deleted. If it was deleted, follow the instructions in the Netwrix article Detect who deleted a file from your Windows file servers.



Can't use self-hosted IR to bridge two on-premises datastores

- **Symptoms**

  After you create self-hosted IRs for both the source and destination datastores, you want to connect the two IRs to finish a copy activity. If the datastores are configured in different virtual networks, or the datastores can't understand the gateway mechanism, you receive either of the following errors:

  - "The driver of source cannot be found in destination IR"

- "The source cannot be accessed by the destination IR"

- **Cause**

  The self-hosted IR is designed as a central node of a copy activity, not a client agent that needs to be installed for each datastore.

  In this case, you should create the linked service for each datastore with the same IR, and the IR should be able to access both datastore through the network. It doesn't matter whether the IR is installed at the source datastore or the destination datastore, or on a third machine. If two linked services are created with different IRs but used in the same copy activity, the destination IR is used, and you need to install the drivers for both datastores on the destination IR machine.

- **Resolution**

  Install drivers for both the source and destination datastores on the destination IR, and make sure that it can access the source datastore.

  If the traffic can't pass through the network between two datastores (for example, they're configured in two virtual networks), you might not finish copying in one activity even with the IR installed. If you can't finish copying in a single activity, you can create two copy activities with two IRs, each in a VENT:

  - Copy one IR from datastore 1 to Azure Blob Storage
  - Copy another IR from Azure Blob Storage to datastore 2.

  This solution could simulate the requirement to use the IR to create a bridge that connects two disconnected datastores.

Credential sync issue causes credential loss from HA

- **Symptoms**

  If the data source credential "XXXXXXXXXX" is deleted from the current integration runtime node with payload, you receive the following error message:

  "When you delete the link service on Azure portal, or the task has the wrong payload, please create new link service with your credential again."

- **Cause**

  Your self-hosted IR is built in HA mode with two nodes, but the nodes aren't in a credentials sync state. This means that the credentials stored in the dispatcher node aren't synced to other worker nodes. If any failover happens from the dispatcher node to the worker node, and the credentials exist only in the previous dispatcher node, the task will fail when you're trying to access credentials, and you'll receive the preceding error.

- **Resolution**

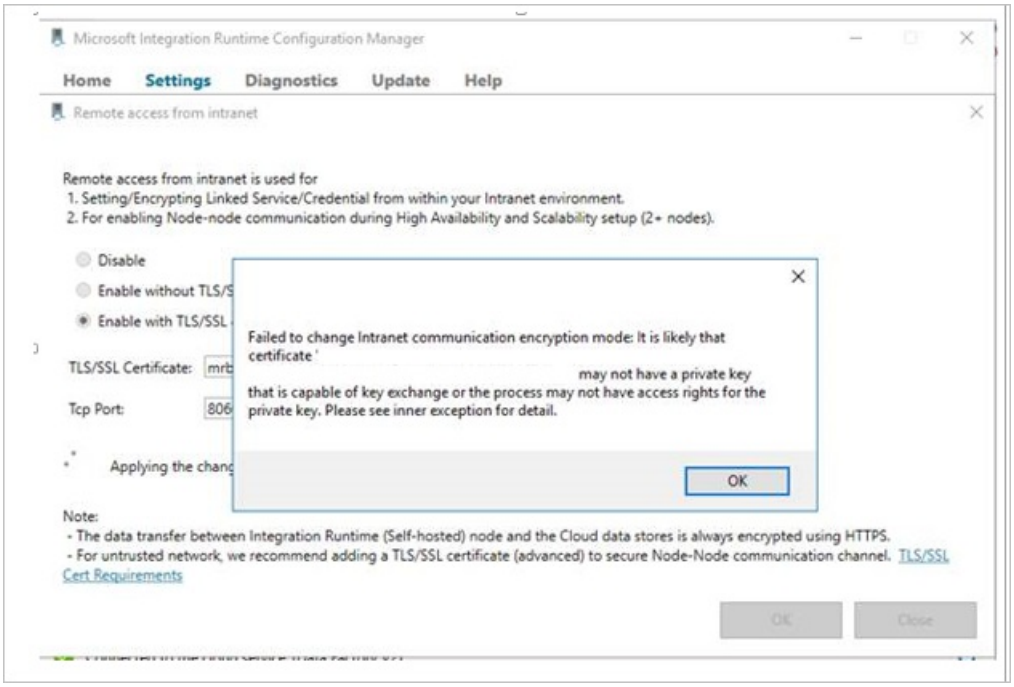
  The only way to avoid this issue is to make sure that the two nodes are in credentials sync state. If they aren't in sync, you have to reenter the credentials for the new dispatcher.

Can't choose the certificate because the private key is missing

- **Symptoms**

  - You've imported a PFX file to the certificate store.
  - When you selected the certificate through the IR Configuration Manager UI, you received the following error message:

    "Failed to change intranet communication encryption mode. It is likely that certificate '<*certificate name*>' may not have a private key that is capable of key exchange or the process may not have access rights for the private key. Please see inner exception for detail."



- Cause
  - The user account has a low privilege level and can't access the private key.
  - The certificate was generated as a signature but not as a key exchange.
- Resolution
  - To operate the UI, use an account with appropriate privileges for accessing the private key.
  - Import the certificate by running the following command:

```
certutil -importpfx FILENAME.pfx AT_KEYEXCHANGE
```

Self-hosted integration runtime nodes out of the sync issue

- Symptoms

  Self-hosted integration runtime nodes try to sync the credentials across nodes but get stuck in the process and encounter the error message below after a while:

  "The Integration Runtime (Self-hosted) node is trying to sync the credentials across nodes. It may take several minutes."

  > **NOTE**
  > If this error appears for over 10 minutes, please check the connectivity with the dispatcher node.

- Cause

  The reason is that the worker nodes do not have access to the private keys. This can be confirmed from the self-hosted integration runtime logs below:

```
[14]0460.3404::05/07/21-00:23:32.2107988 [System] A fatal error occurred when attempting to access the TLS server credential private key. The error code returned from the cryptographic module is 0x8009030D. The internal error state is 10001.
```

  You have no issue with the sync process when you use the service principal authentication in the linked service. However, when you switch the authentication type to account key, the syncing issue started. This is because the self-hosted integration runtime service runs under a service account (NT

SERVICE\DIAHostService) and it need to be added to the private key permissions.

- **Resolution**

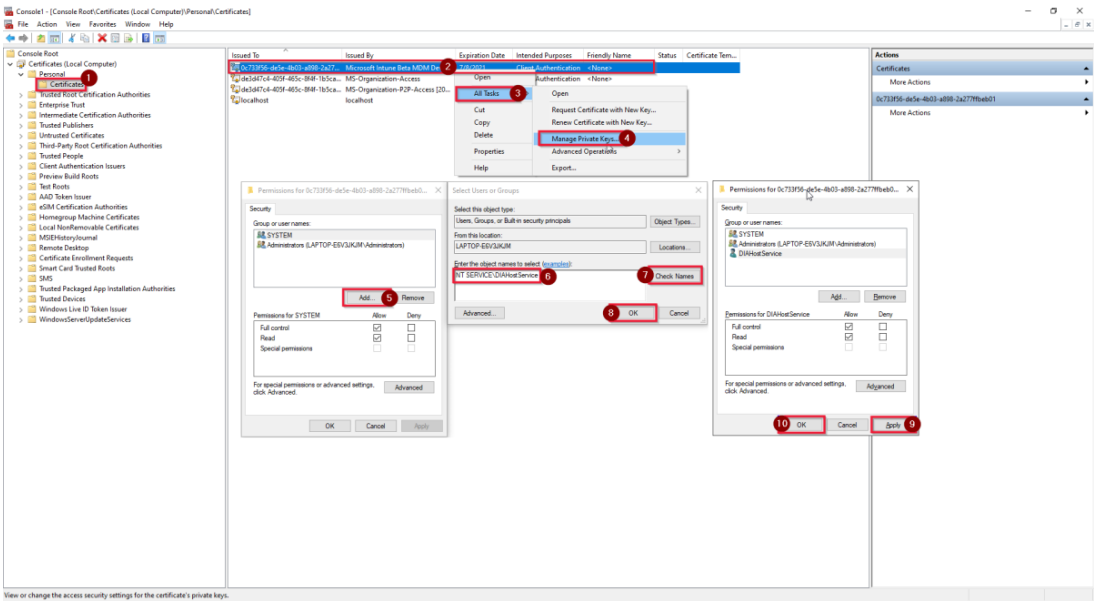
  To solve this issue, you need to add the self-hosted integration runtime service account (NT SERVICE\DIAHostService) to the private key permissions. You can apply the following steps:

  1. Open your Microsoft Management Console (MMC) Run Command.

     
  2. In the MMC pane, apply the following steps:

     
     a. Select **File**.
     b. Choose **Add/Remove Snap-in** in th drop-down menu.
     c. Select **Certificates** in the "Available snap-ins" pane.
     d. Select **Add**.
     e. In the pop-up "Certificates snap-in" pane, choose **Computer account**.
     f. Select **Next**.
     g. In the "Select Computer" pane, choose **Local computer: the computer this console is running on**.
     h. Select **Finish**.
     i. Select **OK** in the "Add or Remove Snap-ins" pane.

  3. In the pane of MMC, move on with the following steps:



a. From the left folder list, select **Console Root -> Certificates (Local Computer) -> Personal -> Certificates**.
b. Right-click the **Microsoft Intune Beta MDM**.
c. Select **All Tasks** in the drop-down list.
d. Select **Manage Private Keys**.
e. Select **Add** under "Group or user names".
f. Select **NT SERVICE\DIAHostService** to grant it full control access to this certificate, apply and safe.
g. Select **Check Names** and then select **OK**.
h. In the "Permissions" pane, select **Apply** and then select **OK**.

UserErrorJreNotFound error message when you run a copy activity to Azure

- **Symptoms**

  When you try to copy content to Microsoft Azure by using a Java-based tool or program (for example, copying ORC or Parquet format files), you receive an error message that resembles the following:

  > ErrorCode=UserErrorJreNotFound,'Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Message=Java Runtime Environment is not found. Go to `http://go.microsoft.com/fwlink/?LinkId=808605` to download and install on your Integration Runtime (Self-hosted) node machine. Note 64-bit Integration Runtime requires 64-bit JRE and 32-bit Integration Runtime requires 32-bit JRE.,Source=Microsoft.DataTransfer.Common,''Type=System.DllNotFoundException,Message=Unable to load DLL 'jvm.dll': The specified module could not be found. (Exception from HRESULT: 0x8007007E),Source=Microsoft.DataTransfer.Richfile.HiveOrcBridge

- **Cause**

  This issue occurs for either of the following reasons:

  - Java Runtime Environment (JRE) isn't installed correctly on your Integration Runtime server.
  - Your Integration Runtime server lacks the required dependency for JRE.

  By default, Integration Runtime resolves the JRE path by using registry entries. Those entries should be automatically set during JRE installation.

- **Resolution**

Follow the steps in this section carefully. Serious problems might occur if you modify the registry incorrectly. Before you modify it, back up the registry for restoration in case problems occur.

To fix this issue, follow these steps to verify the status of the JRE installation:

1. Make sure that Integration Runtime (Diahost.exe) and JRE are installed on the same platform. Check the following conditions:

   - 64-bit JRE for 64-bit ADF Integration Runtime should be installed in the folder: `C:\Program Files\Java\`

     > **NOTE**
     > The folder is not `C:\Program Files (x86)\Java\`

   - JRE 7 and JRE 8 are both compatible for this copy activity. JRE 6 and versions that are earlier than JRE 6 have not been validated for this use.

2. Check the registry for the appropriate settings. To do this, follow these steps:

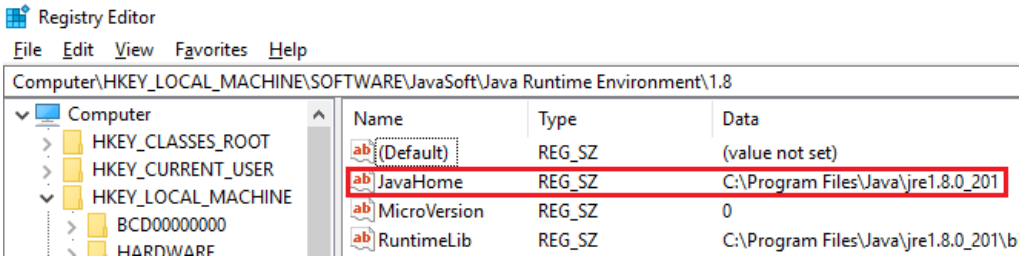
   a. In the **Run** menu, type **Regedit**, and then press Enter.

   b. In the navigation pane, locate the following subkey:

   `HKEY_LOCAL_MACHINE\SOFTWARE\JavaSoft\Java Runtime Environment`.

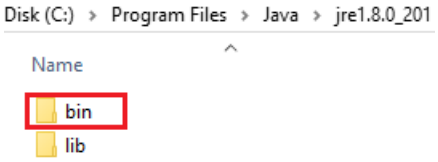
   In the **Details** pane, there should be a Current Version entry that shows the JRE version (for example, 1.8).

   c. In the navigation pane, locate a subkey that is an exact match for the version (for example 1.8) under the JRE folder. In the details pane, there should be a **JavaHome** entry. The value of this entry is the JRE installation path.



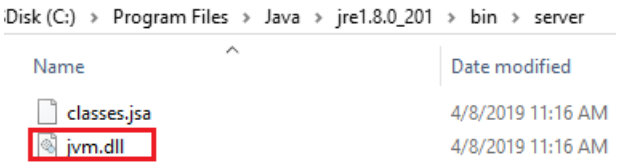
3. Locate the bin\server folder in the following path:

   `C:\Program Files\Java\jre1.8.0_74`



4. Check whether this folder contains a jvm.dll file. If it does not, check for the file in the `bin\client`

folder.



NOTE

- If any of these configurations are not as described in these steps, use the JRE windows installer to fix the problems.
- If all the configurations in these steps are correct as described, there may be a VC++ runtime library missing in the system. You can fix this problem by installing the VC++ 2010 Redistributable Package.

Self-hosted IR setup

Integration runtime registration error

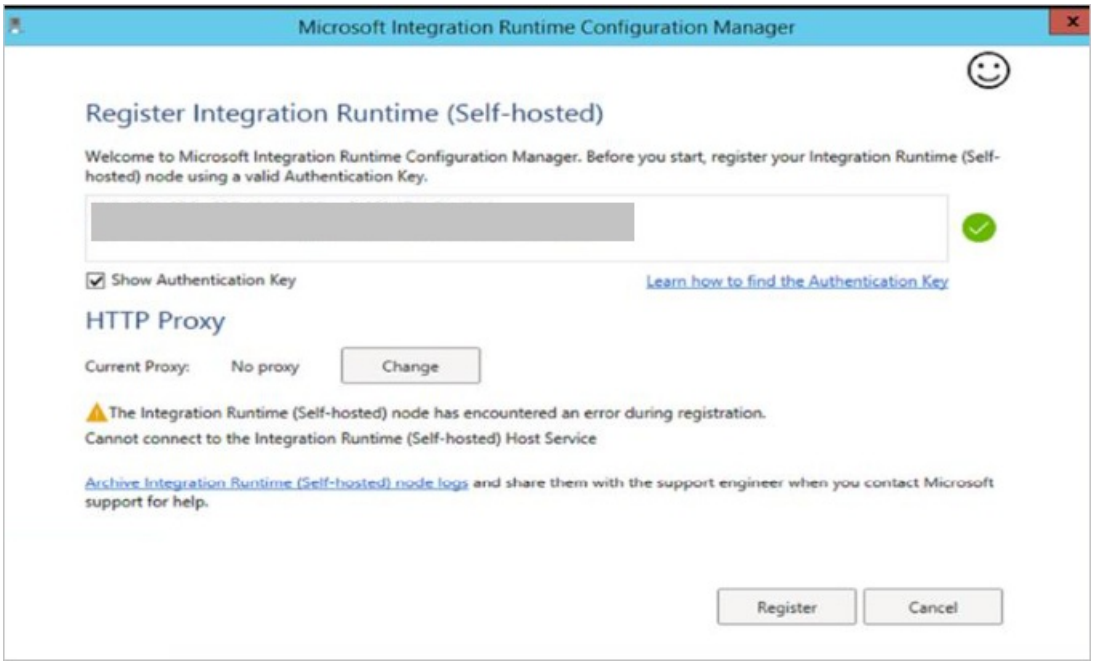
- Symptoms

  You might occasionally want to run a self-hosted IR in a different account for either of the following reasons:

  - Company policy disallows the service account.
  - Some authentication is required.

  After you change the service account on the service pane, you might find that the integration runtime stops working, and you get the following error message:

  "The Integration Runtime (Self-hosted) node has encountered an error during registration. Cannot connect to the Integration Runtime (Self-hosted) Host Service."



- Cause

  Many resources are granted only to the service account. When you change the service account to another account, the permissions of all dependent resources remain unchanged.

- Resolution

Go to the integration runtime event log to check the error.

```
DEBUG:
A runtime error has occurred
Access to the path 'C:\ProgramData\Microsoft\Data Transfer\DataManagementGateway\5s0u2ut1.ecv' is denied.

Exception detail:

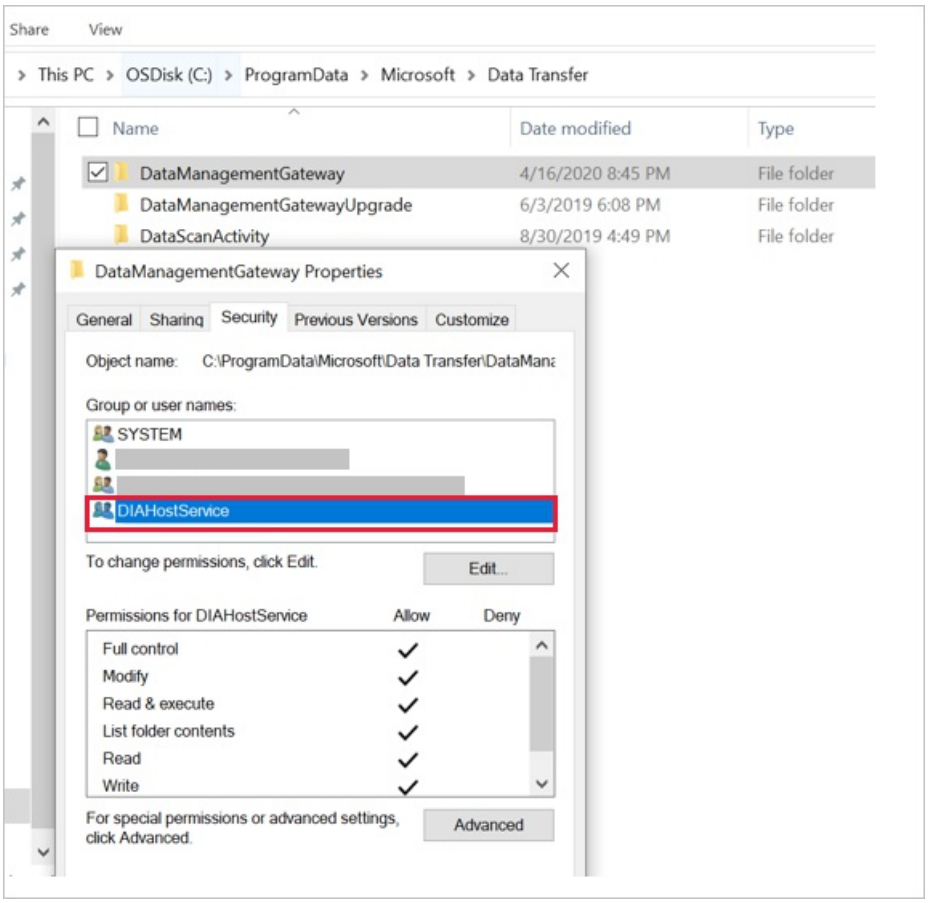
System.UnauthorizedAccessException: Access to the path 'C:\ProgramData\Microsoft\Data Transfer\DataManagementGateway\5s0u2ut1.ecv' is denied.
  at System.IO.__Error.WinIOError(Int32 errorCode, String maybeFullPath)
  at System.IO.FileStream.Init(String path, FileMode mode, FileAccess access, Int32 rights, Boolean useRights, FileShare share, Int32 bufferSize, FileOptions options,
SECURITY_ATTRIBUTES secAttrs, String msgPath, Boolean bFromProxy, Boolean useLongPath, Boolean checkHost)
  at System.IO.FileStream..ctor(String path, FileMode mode, FileAccess access, FileShare share)
  at Microsoft.DataTransfer.GatewayCommon.EncryptedSerializer.WriteToFile(Byte[] encryptedData)
  at Microsoft.DataTransfer.GatewayCommon.PropertiesPersistent.SetProperty(PropertyValue value, Boolean notify)
  at Microsoft.DataTransfer.DIAgentHost.HostService.OnStart(Boolean isRestart, String gatewayDll, Action exit)
```

- If the error in the event log is "UnauthorizedAccessException," do the following:

  1. Check the *DIAHostService* logon service account in the Windows service panel.

  2. Check to see whether the logon service account has read/write permissions for the *%programdata%\Microsoft\DataTransfer\DataManagementGateway* folder.

     - By default, if the service logon account hasn't been changed, it should have read/write permissions.



- If you've changed the service logon account, mitigate the issue by doing the following:

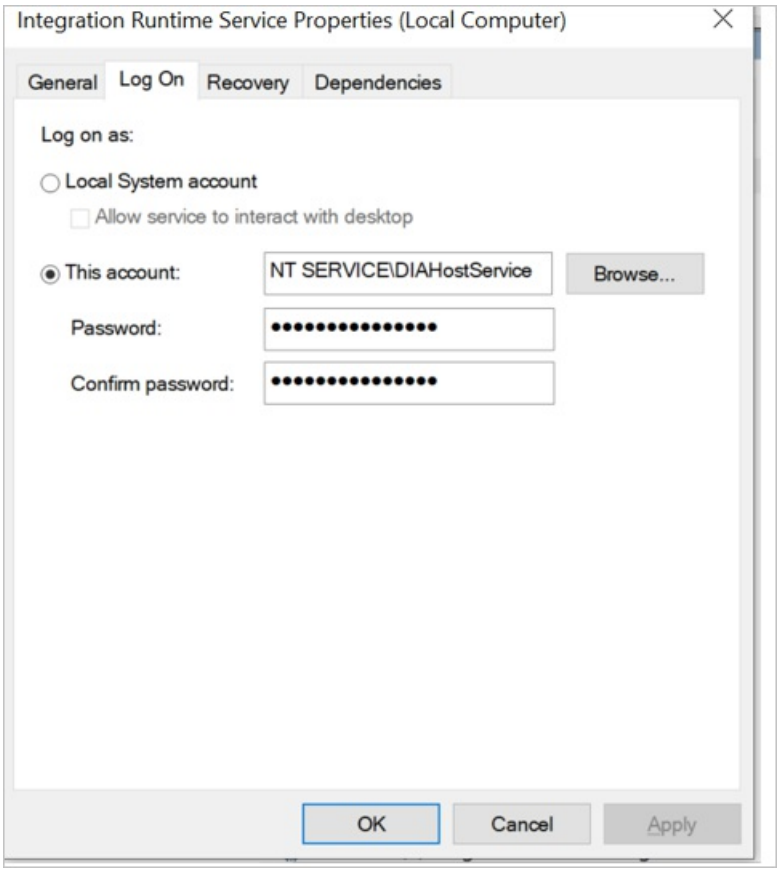
  a. Perform a clean uninstallation of the current self-hosted IR.
  b. Install the self-hosted IR bits.
  c. Change the service account by doing the following:

  i. Go to the self-hosted IR installation folder, and then switch to the *Microsoft Integration Runtime\4.0\Shared* folder.
  ii. Open a Command Prompt window by using elevated privileges. Replace *<user>* and *<password>* with your own username and password, and then run the following command:
  `dmgcmd.exe -SwitchServiceAccount "<user>" "<password>"`
  iii. If you want to change to the LocalSystem account, be sure to use the correct format for this account: `dmgcmd.exe -SwitchServiceAccount "NT Authority\System" ""`
  Do *not* use this format: `dmgcmd.exe -SwitchServiceAccount "LocalSystem" ""`
  iv. Optionally, because Local System has higher privileges than Administrator, you can also directly change it in "Services".
  v. You can use a local/domain user for the IR service logon account.

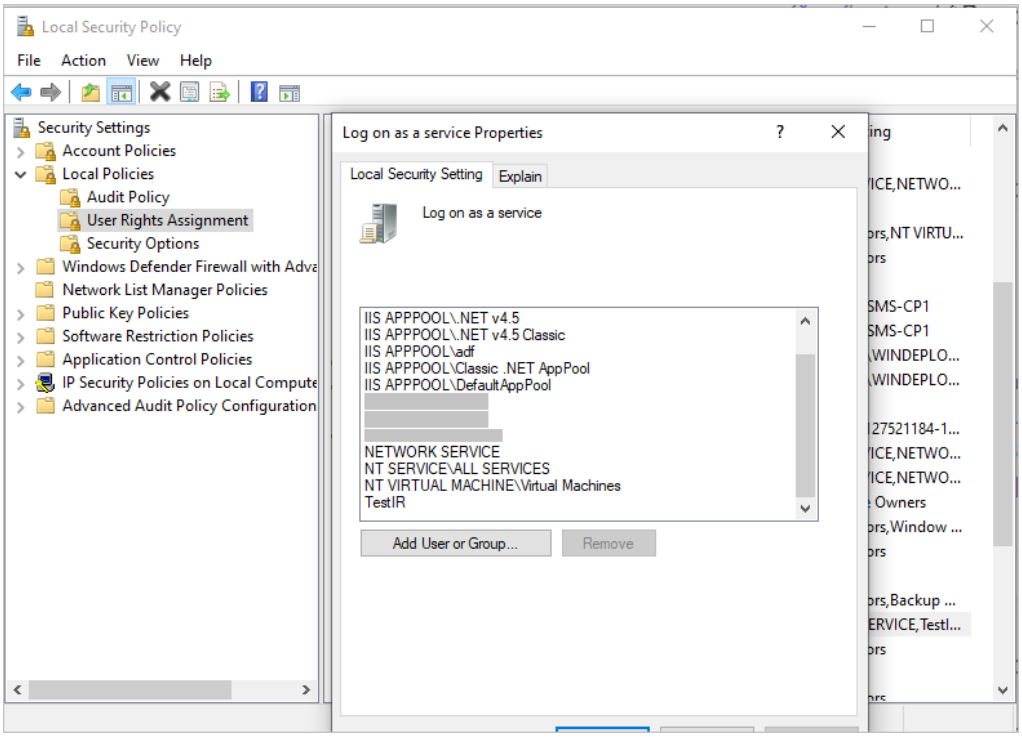
  d. Register the integration runtime.

- If the error is "Service 'Integration Runtime Service' (DIAHostService) failed to start. Verify that you have sufficient privileges to start system services," do the following:

  1. Check the *DIAHostService* logon service account in the Windows service panel.



2. Check to see whether the logon service account has **Log on as a service** permission to start the Windows service:



- **More information**

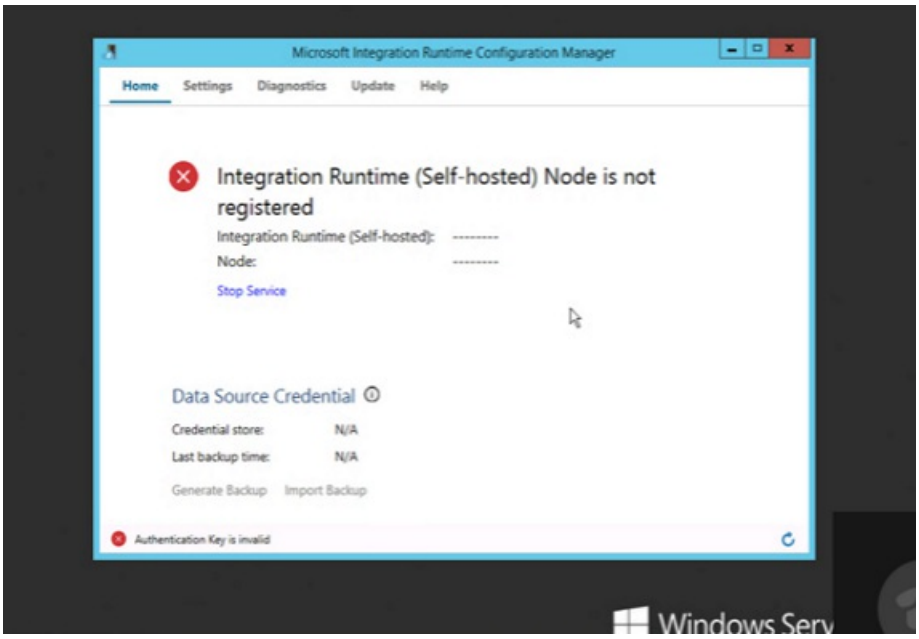
  If neither of the preceding two resolution patterns applies in your case, try to collect the following Windows event logs:

  - Applications and Services Logs > Integration Runtime
  - Windows Logs > Application

Can't find the Register button to register a self-hosted IR

- Symptoms

  When you register a self-hosted IR, the **Register** button isn't displayed on the Configuration Manager pane.



- Cause

  As of the release of Integration Runtime 3.0, the **Register** button on existing integration runtime nodes has been removed to enable a cleaner and more secure environment. If a node has been registered to an integration runtime, whether it's online or not, re-register it to another integration runtime by uninstalling the previous node, and then install and register the node.

- Resolution

  1. In Control Panel, uninstall the existing integration runtime.

     > **IMPORTANT**
     > In the following process, select **Yes**. Do not keep data during the uninstallation process.

     
  2. If you don't have the integration runtime installer MSI file, go to download center to download the latest integration runtime.
  3. Install the MSI file, and register the integration runtime.

Unable to register the self-hosted IR because of localhost

- Symptoms

You're unable to register the self-hosted IR on a new machine when you use get_LoopbackIpOrName.

Debug: A runtime error has occurred. The type initializer for 'Microsoft.DataTransfer.DIAgentHost.DataSourceCache' threw an exception. A non-recoverable error occurred during a database lookup.

Exception detail: System.TypeInitializationException: The type initializer for 'Microsoft.DataTransfer.DIAgentHost.DataSourceCache' threw an exception. ---> System.Net.Sockets.SocketException: A non-recoverable error occurred during a database lookup at System.Net.Dns.GetAddrInfo(String name).

- **Cause**

  The issue usually occurs when the localhost is being resolved.

- **Resolution**

  Use localhost IP address 127.0.0.1 to host the file and resolve the issue.

Self-hosted setup failed

- **Symptoms**

  You're unable to uninstall an existing IR, install a new IR, or upgrade an existing IR to a new IR.

- **Cause**

  The integration runtime installation depends on the Windows Installer service. You might experience installation problems for the following reasons:

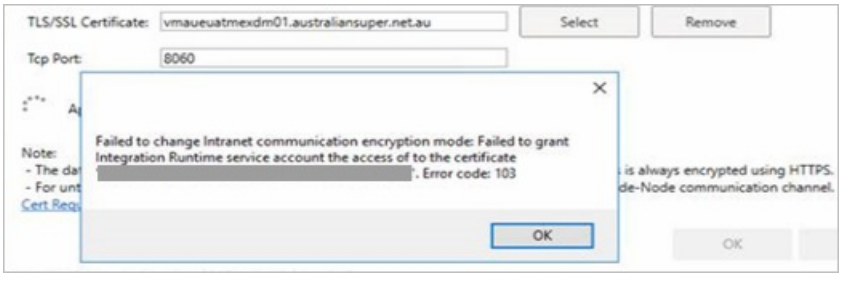
  - Insufficient available disk space.
  - Lack of permissions.
  - The Windows NT service is locked.
  - CPU utilization is too high.
  - The MSI file is hosted in a slow network location.
  - Some system files or registries were touched unintentionally.

The IR service account failed to fetch certificate access

- **Symptoms**

  When you install a self-hosted IR via Microsoft Integration Runtime Configuration Manager, a certificate with a trusted certificate authority (CA) is generated. The certificate couldn't be applied to encrypt communication between two nodes, and the following error message is displayed:

  "Failed to change Intranet communication encryption mode: Failed to grant Integration Runtime service account the access of to the certificate '<*certificate name*>'. Error code 103"



- **Cause**

  The certificate is using key storage provider (KSP) storage, which is not supported yet. To date, self-hosted IR supports only cryptographic service provider (CSP) storage.

- **Resolution**

  We recommend that you use CSP certificates in this case.

  Solution 1

  To import the certificate, run the following command:

  ```
  Certutil.exe -CSP "CSP or KSP" -ImportPFX FILENAME.pfx
  ```

  
  Solution 2

  To convert the certificate, run the following commands:

  ```
  openssl pkcs12 -in .\xxxx.pfx -out .\xxxx_new.pem -password pass: <EnterPassword>
  openssl pkcs12 -export -in .\xxxx_new.pem -out xxxx_new.pfx
  ```

  Before and after conversion:

Self-hosted integration runtime version 5.x

For the upgrade to version 5.x of the self-hosted integration runtime, we require **.NET Framework Runtime 4.7.2** or later. On the download page, you'll find download links for the latest 4.x version and the latest two 5.x versions.

For Azure Data Factory v2 and Azure Synapse customers:

- If automatic update is on and you've already upgraded your .NET Framework Runtime to 4.7.2 or later, the self-hosted integration runtime will be automatically upgraded to the latest 5.x version.
- If automatic update is on and you haven't upgraded your .NET Framework Runtime to 4.7.2 or later, the self-hosted integration runtime won't be automatically upgraded to the latest 5.x version. The self-hosted integration runtime will stay in the current 4.x version. You can see a warning for a .NET Framework Runtime upgrade in the portal and the self-hosted integration runtime client.
- If automatic update is off and you've already upgraded your .NET Framework Runtime to 4.7.2 or later, you can manually download the latest 5.x and install it on your machine.
- If automatic update is off and you haven't upgraded your .NET Framework Runtime to 4.7.2 or later. When you try to manually install self-hosted integration runtime 5.x and register the key, you will be required to upgrade your .NET Framework Runtime version first.

For Azure Data Factory v1 customers:

- Self-hosted integration runtime 5.X doesn't support Azure Data Factory v1.
- The self-hosted integration runtime will be automatically upgraded to the latest version of 4.x. And the latest version of 4.x won't expire.
- If you try to manually install self-hosted integration runtime 5.x and register the key, you'll be notified that self-hosted integration runtime 5.x doesn't support Azure Data Factory v1.

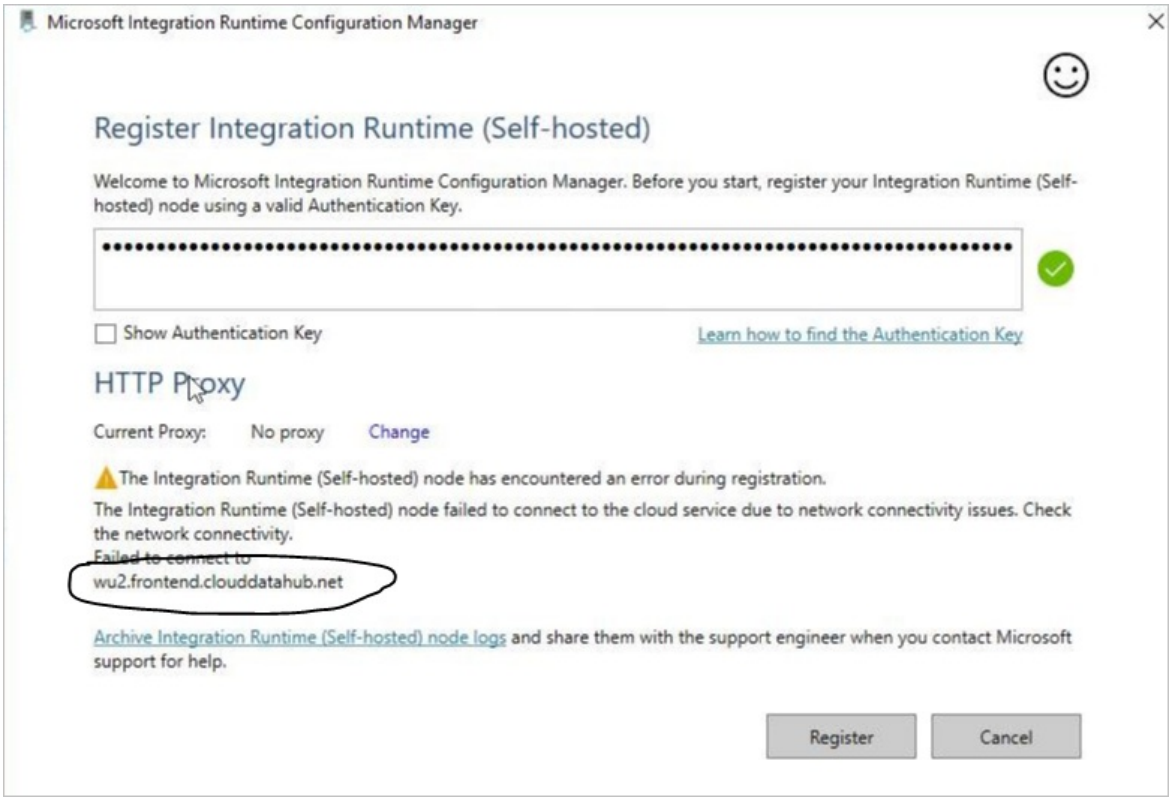
Self-hosted IR connectivity issues

Self-hosted integration runtime can't connect to the cloud service

- Symptoms

  When you attempt to register the self-hosted integration runtime, Configuration Manager displays the following error message:

  "The Integration Runtime (Self-hosted) node has encountered an error during registration."



- Cause

  The self-hosted IR can't connect to the service back end. This issue is usually caused by network settings in the firewall.

- Resolution

  1. Check to see whether the integration runtime service is running. If it is, go to step 2.

  2. If no proxy is configured on the self-hosted IR, which is the default setting, run the following PowerShell command on the machine where the self-hosted integration runtime is installed:

```
(New-Object System.Net.WebClient).DownloadString("https://wu2.frontend.clouddatahub.net/")
```

> **NOTE**
> The service URL might vary, depending on the location of your data factory or Synapse workspace instance. To find the service URL, use the Manage page of the UI in your data factory or Azure Synapse instance to find **Integration runtimes** and click your self-hosted IR to edit it. There select the **Nodes** tab and click **View Service URLs**.

The following is the expected response:

```
Exception calling "DownloadString" with "1" argument(s): "The remote server returned an error: (403) Forbidden."
At line:1 char:2
+  (New-Object System.Net.WebClient).DownloadString("https://eu.fronten ...
+  ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
    + CategoryInfo          : NotSpecified: (:) [], MethodInvocationException
    + FullyQualifiedErrorId : WebException
```

3. If you don't receive the response you had expected, use one of the following methods, as appropriate:

   - If you receive a "Remote name could not be resolved" message, there's a Domain Name System (DNS) issue. Contact your network team to fix the issue.
   - If you receive an "ssl/tls cert is not trusted" message, check the certificate to see whether it's trusted on the machine, and then install the public certificate by using Certificate Manager. This action should mitigate the issue.
   - Go to **Windows** > **Event viewer (logs)** > **Applications and Services Logs** > **Integration Runtime**, and check for any failure that's caused by DNS, a firewall rule, or company network settings. If you find such a failure, forcibly close the connection. Because every company has its own customized network settings, contact your network team to troubleshoot these issues.

4. If "proxy" has been configured on the self-hosted integration runtime, verify that your proxy server can access the service endpoint. For a sample command, see PowerShell, web requests, and proxies.

```
$user = $env:username
$webproxy = (get-itemproperty 'HKCU:\Software\Microsoft\Windows\CurrentVersion\Internet
Settings').ProxyServer
$pwd = Read-Host "Password?" -assecurestring
$proxy = new-object System.Net.WebProxy
$proxy.Address = $webproxy
$account = new-object System.Net.NetworkCredential($user,
[Runtime.InteropServices.Marshal]::PtrToStringAuto([Runtime.InteropServices.Marshal]::SecureSt
ringToBSTR($pwd)), "")
$proxy.credentials = $account
$url = "https://wu2.frontend.clouddatahub.net/"
$wc = new-object system.net.WebClient
$wc.proxy = $proxy
$webpage = $wc.DownloadData($url)
$string = [System.Text.Encoding]::ASCII.GetString($webpage)
$string
```

The following is the expected response:

```
Exception calling "DownloadString" with "1" argument(s): "The remote server returned an error: (403) Forbidden."
At line:1 char:2
+  (New-Object System.Net.WebClient).DownloadString("https://eu.fronten ...
+  ~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~
    + CategoryInfo          : NotSpecified: (:) [], MethodInvocationException
    + FullyQualifiedErrorId : WebException
```

> **NOTE**
>
> Proxy considerations:
>
> - Check to see whether the proxy server needs to be put on the Safe Recipients list. If so, make sure these domains are on the Safe Recipients list.
> - Check to see whether SSL/TLS certificate "wu2.frontend.clouddatahub.net/" is trusted on the proxy server.
> - If you're using Active Directory authentication on the proxy, change the service account to the user account that can access the proxy as "Integration Runtime Service."

Error message: Self-hosted integration runtime node/logical self-hosted IR is in Inactive/ "Running (Limited)"

state

- Cause

  The self-hosted integrated runtime node might have a status of **Inactive**, as shown in the following screenshot:

  This behavior occurs when nodes can't communicate with each other.

- Resolution

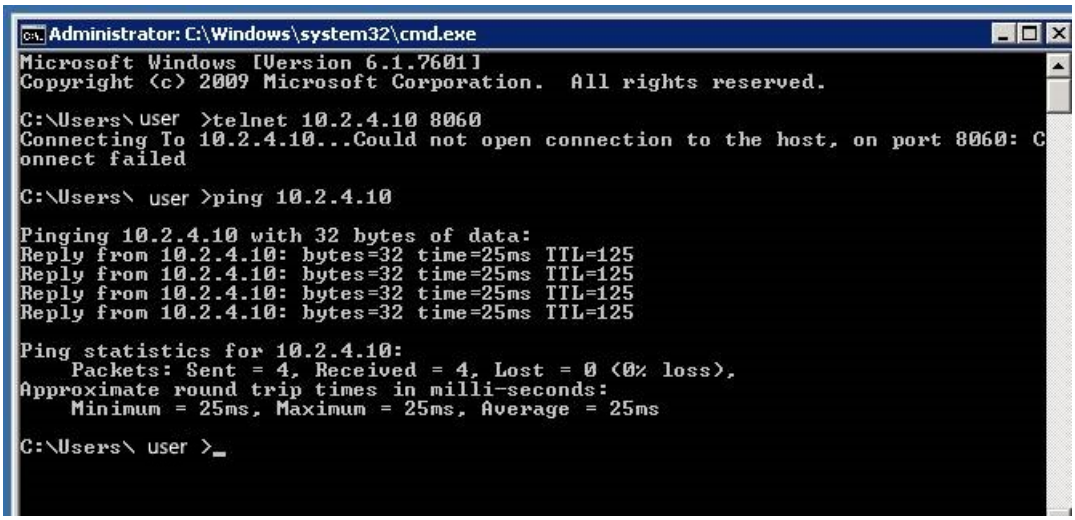
  1. Log in to the node-hosted virtual machine (VM). Under **Applications and Services Logs** > **Integration Runtime**, open Event Viewer, and filter the error logs.
  2. Check to see whether an error log contains the following error:

     ```
     System.ServiceModel.EndpointNotFoundException: Could not connect to
     net.tcp://xxxxxxx.bwld.com:8060/ExternalService.svc/WorkerManager. The connection attempt
     lasted for a time span of 00:00:00.9940994. TCP error code 10061: No connection could be made
     because the target machine actively refused it 10.2.4.10:8060.
     System.Net.Sockets.SocketException: No connection could be made because the target machine
     actively refused it.
     10.2.4.10:8060
     at System.Net.Sockets.Socket.DoConnect(EndPoint endPointSnapshot, SocketAddress socketAddress)
     at System.Net.Sockets.Socket.Connect(EndPoint remoteEP)
     at System.ServiceModel.Channels.SocketConnectionInitiator.Connect(Uri uri, TimeSpan timeout)
     ```

  3. If you see this error, run the following command in a Command Prompt window:

     ```
     telnet 10.2.4.10 8060
     ```

  4. If you receive the "Could not open connection to the host" command-line error that's shown in the following screenshot, contact your IT department for help to fix this issue. After you can successfully telnet, contact Microsoft Support if you still have issues with the integration runtime node status.



5. Check to see whether the error log contains the following entry:

```
Error log: Cannot connect to worker manager: net.tcp://xxxxxx:8060/ExternalService.svc/ No DNS
entries exist for host azranlcir01r1. No such host is known Exception detail:
System.ServiceModel.EndpointNotFoundException: No DNS entries exist for host xxxxx. --->
System.Net.Sockets.SocketException: No such host is known at System.Net.Dns.GetAddrInfo(String
name) at System.Net.Dns.InternalGetHostByName(String hostName, Boolean includeIPv6) at
System.Net.Dns.GetHostEntry(String hostNameOrAddress) at
System.ServiceModel.Channels.DnsCache.Resolve(Uri uri) --- End of inner exception stack trace
--- Server stack trace: at System.ServiceModel.Channels.DnsCache.Resolve(Uri uri)
```

6. To resolve the issue, try one or both of the following methods:
    - Put all the nodes in the same domain.
    - Add the IP to host mapping in all the hosted VM's host files.

Connectivity issue between the self-hosted IR and your data factory or Azure Synapse instance or the self-hosted IR and the data source or sink

To troubleshoot the network connectivity issue, you should know how to collect the network trace, understand how to use it, and analyze the Microsoft Network Monitor (Netmon) trace before applying the Netmon Tools in real cases from the self-hosted IR.

- Symptoms

  You might occasionally need to troubleshoot certain connectivity issues between the self-hosted IR and your data factory or Azure Synapse instance, as shown in the following screenshot, or between the self-hosted IR and the data source or sink.

  In either instance, you might encounter the following errors:

    - "Copy failed with error:Type=Microsoft.DataTransfer.Common.Shared.HybridDeliveryException,Message=Cannot connect to SQL Server: 'IP address'"

- "One or more errors occurred. An error occurred while sending the request. The underlying connection was closed: An unexpected error occurred on a receive. Unable to read data from the transport connection: An existing connection was forcibly closed by the remote host. An existing connection was forcibly closed by the remote host Activity ID."

- **Resolution**

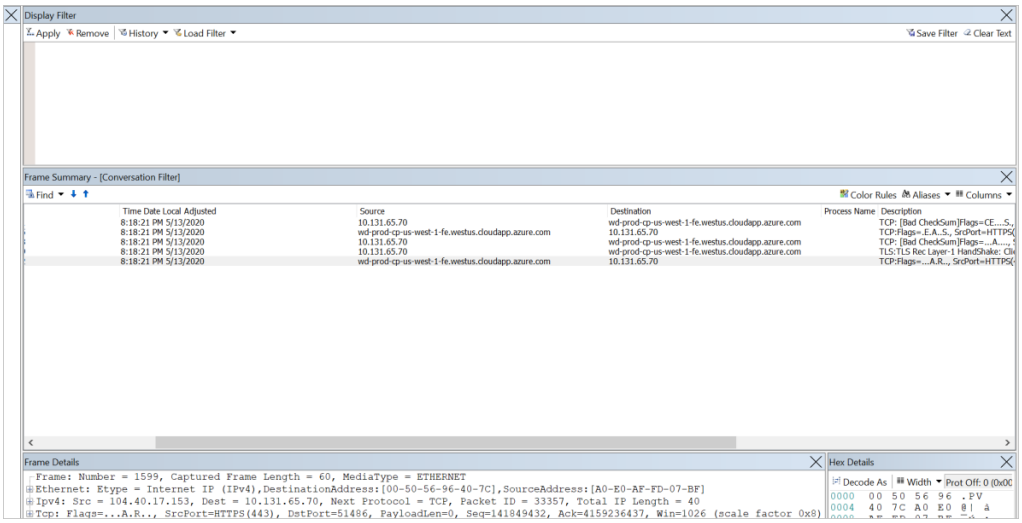
  When you encounter the preceding errors, troubleshoot them by following the instructions in this section.

  - Collect a Netmon trace for analysis:

    1. You can set the filter to see a reset from the server to the client side. In the following example screenshot, you can see that the server side is the Data Factory server.

    2. When you get the reset package, you can find the conversation by following Transmission Control Protocol (TCP).

    3. Get the conversation between the client and the Data Factory server below by removing the filter.



- An analysis of the Netmon trace you've collected shows that the Time to Live (TTL)) total is 64. According to the values mentioned in the IP Time to Live (TTL) and Hop Limit Basics article, extracted in the following list, you can see that it's the Linux System that resets the package and causes the disconnection.

  Default TTL and Hop Limit values vary between different operating systems, as listed here:

  - Linux kernel 2.4 (circa 2001): 255 for TCP, User Datagram Protocol (UDP), and Internet Control Message Protocol (ICMP)
  - Linux kernel 4.10 (2015): 64 for TCP, UDP, and ICMP
  - Windows XP (2001): 128 for TCP, UDP, and ICMP
  - Windows 10 (2015): 128 for TCP, UDP, and ICMP
  - Windows Server 2008: 128 for TCP, UDP, and ICMP
  - Windows Server 2019 (2018): 128 for TCP, UDP, and ICMP
  - macOS (2001): 64 for TCP, UDP, and ICMP

  In the preceding example, the TTL is shown as 61 instead of 64, because when the network package reaches its destination, it needs to go through various hops, such as routers or network devices. The number of routers or network devices is deducted to produce the final TTL.

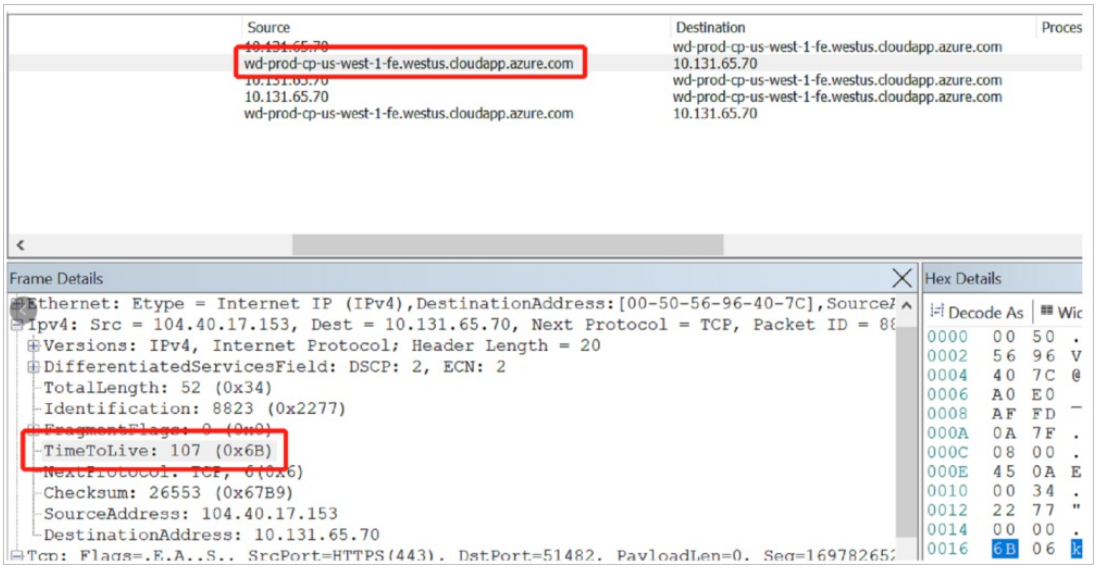
  In this case, you can see that a reset can be sent from the Linux System with TTL 64.

- To confirm where the reset device might come from, check the fourth hop from self-hosted IR.

  Network package from Linux System A with TTL 64 -> B TTL 64 minus 1 = 63 -> C TTL 63 minus 1 = 62 -> TTL 62 minus 1 = 61 self-hosted IR

- In an ideal situation, the TTL hops number would be 128, which means that the Windows

operating system is running your data factory instance. As shown in the following example, *128 minus 107 = 21 hops*, which means that 21 hops for the package were sent from the data factory instance to the self-hosted IR during the TCP 3 handshake.



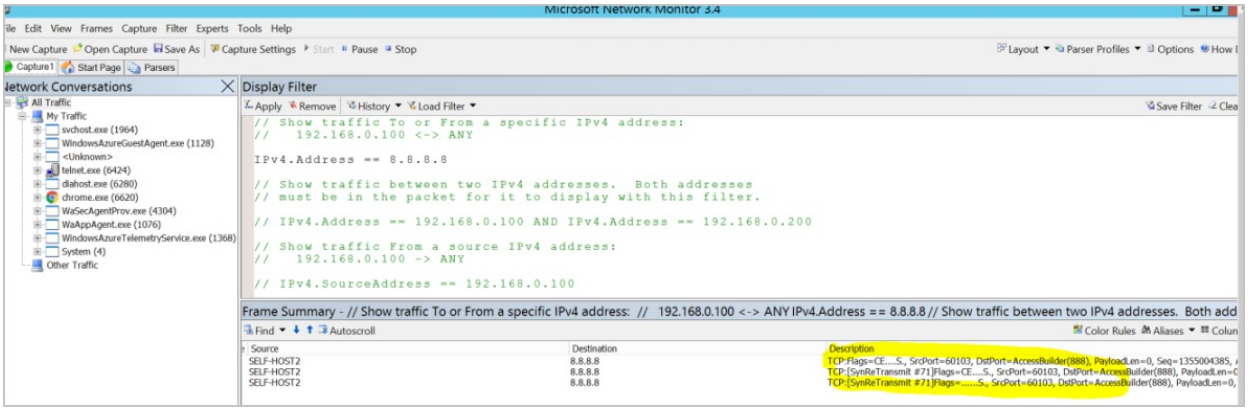
Therefore, you need to engage the network team to check to see what the fourth hop is from the self-hosted IR. If it's the firewall, as with the Linux System, check any logs to see why that device resets the package after the TCP 3 handshake.

If you're unsure where to investigate, try to get the Netmon trace from both the self-hosted IR and the firewall during the problematic time. This approach will help you figure out which device might have reset the package and caused the disconnection. In this case, you also need to engage your network team to move forward.

Analyze the Netmon trace

> **NOTE**
>
> The following instructions apply to the Netmon trace. Because Netmon trace is currently out of support, you can use Wireshark for this purpose.

When you try to telnet **8.8.8.8 888** with the collected Netmon trace, you should see the trace in the following screenshots:

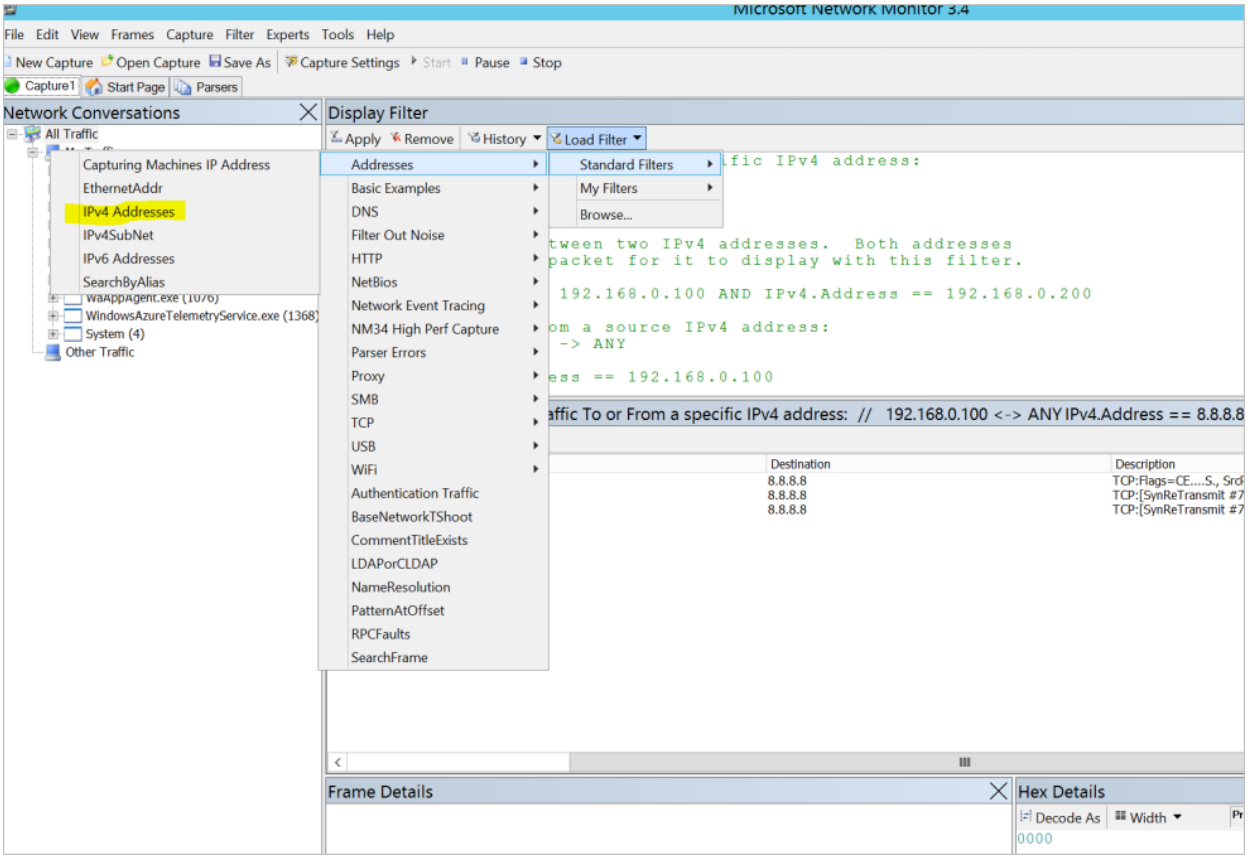


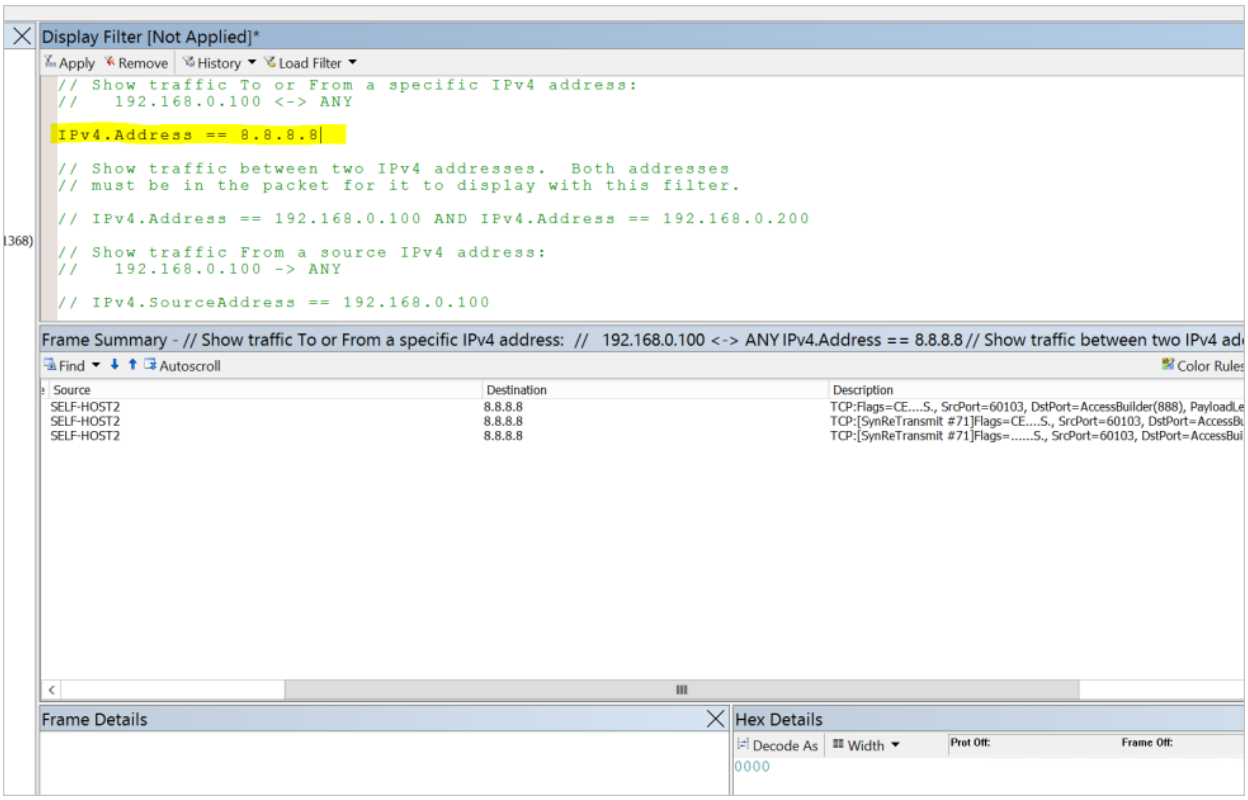
The preceding images show that you couldn't make a TCP connection to the **8.8.8.8** server side on port **888**, so you see two **SynReTransmit** additional packages there. Because source **SELF-HOST2** couldn't connect to **8.8.8.8** with the first package, it will keep trying to make the connection.

TIP

To make this connection, try the following solution:

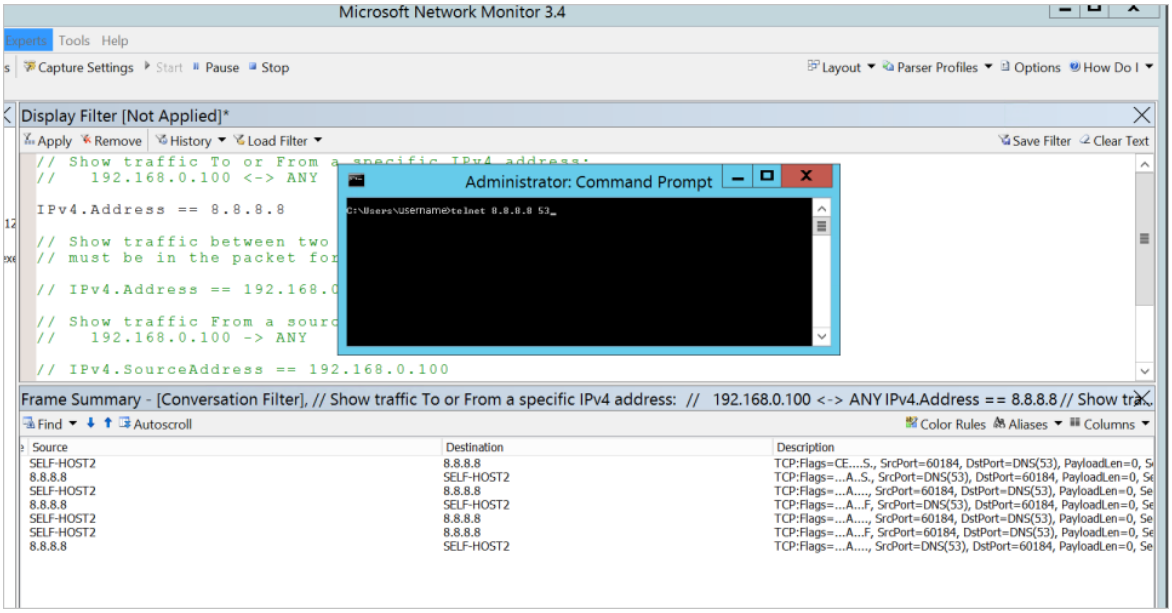
1. Select **Load Filter** > **Standard Filter** > **Addresses** > **IPv4 Addresses**.
2. To apply the filter, enter **IPv4.Address == 8.8.8.8**, and then select **Apply**. You should then see the communication from the local machine to destination **8.8.8.8**.





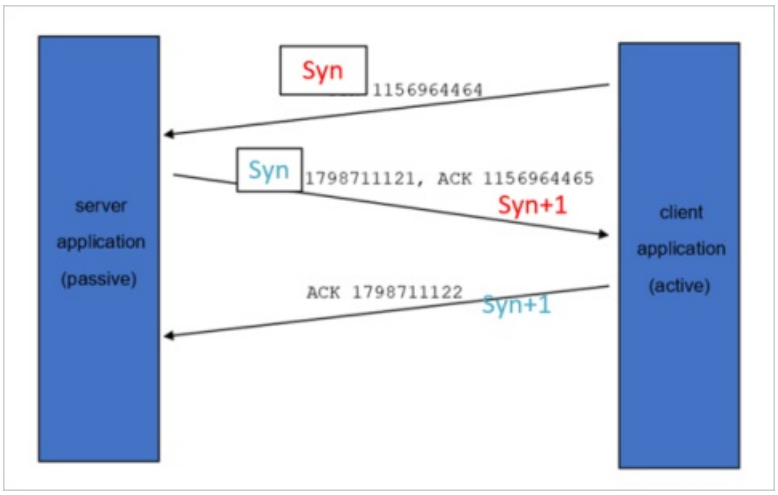
Successful scenarios are shown in the following examples:

- If you can telnet `8.8.8.8 53` without any issues, there's a successful TCP 3 handshake, and the session finishes with a TCP 4 handshake.



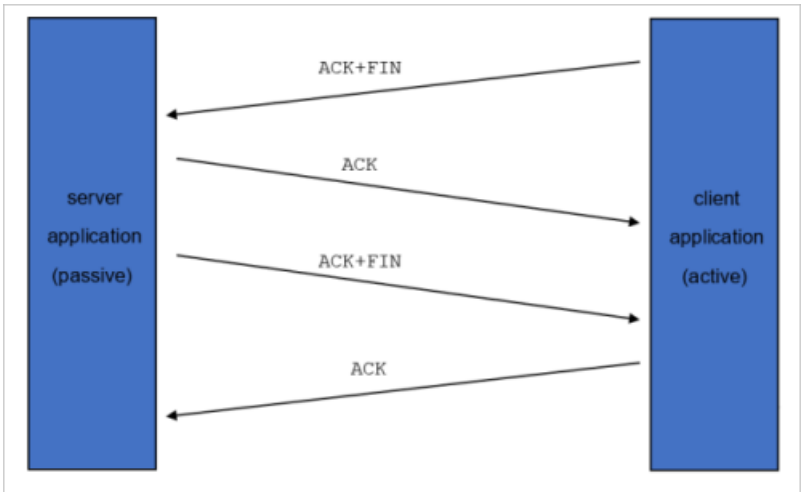
```
TCP:Flags=CE....S., SrcPort=60184, DstPort=DNS(53), PayloadLen=0, Seq=1156964464, Ack=0, Win=8192 (
TCP:Flags=...A..S., SrcPort=DNS(53), DstPort=60184, PayloadLen=0, Seq=1798711121, Ack=1156964465, W
TCP:Flags=...A...., SrcPort=60184, DstPort=DNS(53), PayloadLen=0, Seq=1156964465, Ack=1798711122, Wi
```

- The preceding TCP 3 handshake produces the following workflow:



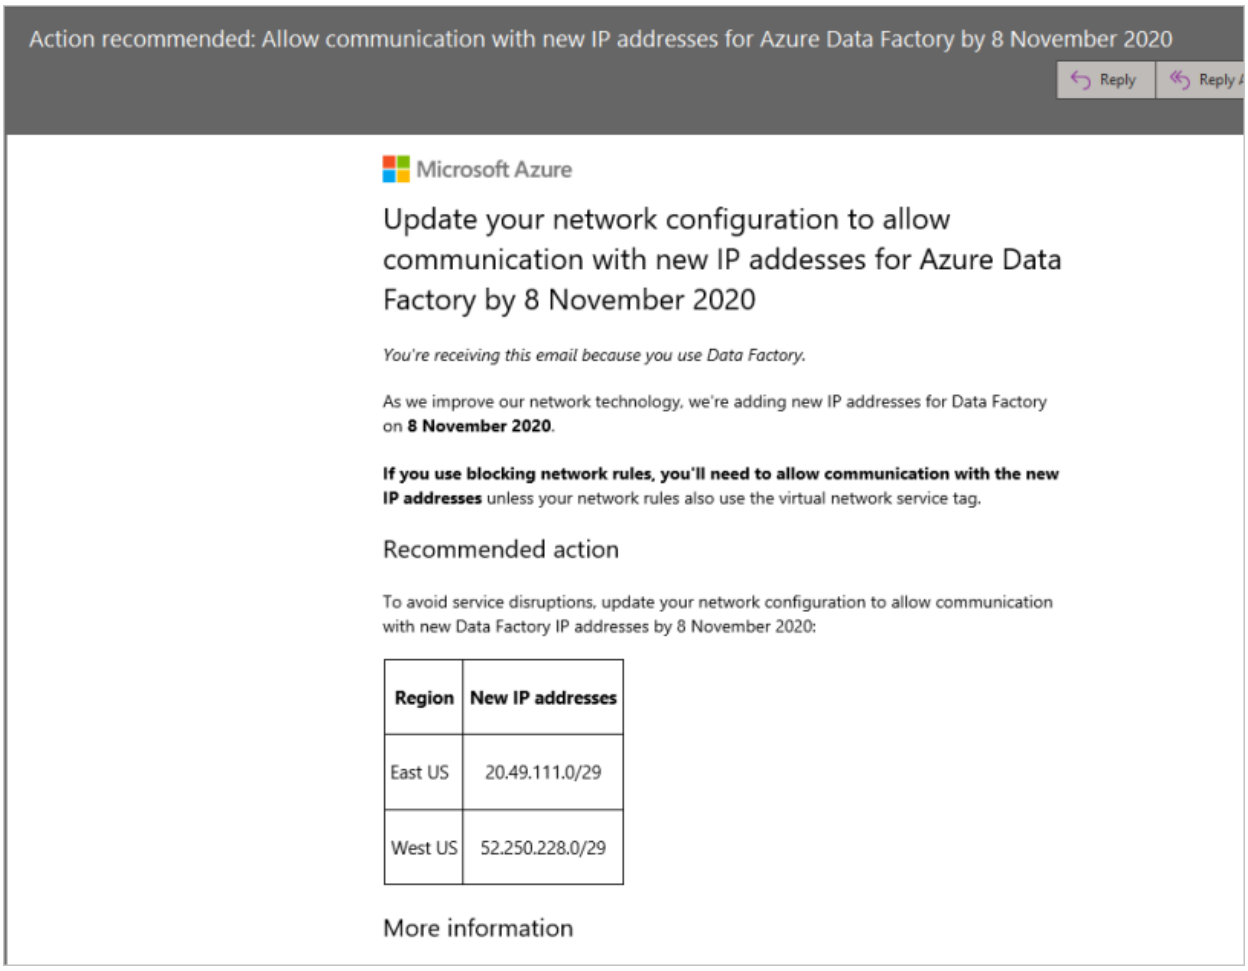
- The TCP 4 handshake to finish the session is illustrated by the following workflows:

```
TCP:Flags=...A...F, SrcPort=DNS(53), DstPort=60184, PayloadLen=0, Seq=1798711122, Ack=1156964465, Win
TCP:Flags=...A...., SrcPort=60184, DstPort=DNS(53), PayloadLen=0, Seq=1156964465, Ack=1798711123, Win
TCP:Flags=...A...F, SrcPort=60184, DstPort=DNS(53), PayloadLen=0, Seq=1156964465, Ack=1798711123, Win
TCP:Flags=...A...., SrcPort=DNS(53), DstPort=60184, PayloadLen=0, Seq=1798711123, Ack=1156964466, Win
```



Microsoft email notification about updating your network configuration

You might receive the following email notification, which recommends that you update your network configuration to allow communication with new IP addresses for Azure Data Factory by 8 November 2020:



Action recommended: Allow communication with new IP addresses for Azure Data Factory by 8 November 2020

Reply

Microsoft Azure

Update your network configuration to allow communication with new IP addesses for Azure Data Factory by 8 November 2020

You're receiving this email because you use Data Factory.

As we improve our network technology, we're adding new IP addresses for Data Factory on **8 November 2020**.

If you use blocking network rules, you'll need to allow communication with the new IP addresses unless your network rules also use the virtual network service tag.

Recommended action

To avoid service disruptions, update your network configuration to allow communication with new Data Factory IP addresses by 8 November 2020:

Region	New IP addresses
East US	20.49.111.0/29
West US	52.250.228.0/29

More information

Determine whether this notification affects you

This notification applies to the following scenarios:

Scenario 1: Outbound communication from a self-hosted integration runtime that's running on-premises behind a corporate firewall

How to determine whether you're affected:

- You *are not* affected if you're defining firewall rules based on fully qualified domain names (FQDNs) that use the approach described in Set up a firewall configuration and allowlist for IP addresses.
- You *are* affected if you're explicitly enabling the allowlist for outbound IPs on your corporate firewall.

  If you're affected, take the following action: by November 8, 2020, notify your network infrastructure team to update your network configuration to use the latest data factory IP addresses. To download the

latest IP addresses, go to Discover service tags by using downloadable JSON files.

Scenario 2: Outbound communication from a self-hosted integration runtime that's running on an Azure VM inside a customer-managed Azure virtual network

How to determine whether you're affected:

- Check to see whether you have any outbound network security group (NSG) rules in a private network that contains self-hosted integration runtime. If there are no outbound restrictions, you aren't affected.
- If you have outbound rule restrictions, check to see whether you're using service tags. If you're using service tags, you're not affected. There's no need to change or add anything, because the new IP range is under your existing service tags.

Port	Protocol	Source	Destination	Action
443	Any	VirtualNetwork	DataFactory	Allow

- You *are* affected if you're explicitly enabling the allowlist for outbound IP addresses on your NSG rules setting on the Azure virtual network.

  If you're affected, take the following action: by November 8, 2020, notify your network infrastructure team to update the NSG rules on your Azure virtual network configuration to use the latest data factory IP addresses. To download the latest IP addresses, go to Discover service tags by using downloadable JSON files.

Scenario 3: Outbound communication from SSIS Integration Runtime in a customer-managed Azure virtual network

How to determine whether you're affected:

- Check to see whether you have any outbound NSG rules in a private network that contains SQL Server Integration Services (SSIS) Integration Runtime. If there are no outbound restrictions, you aren't affected.
- If you have outbound rule restrictions, check to see whether you're using service tags. If you're using service tags, you're not affected. There's no need to change or add anything because the new IP range is under your existing service tags.
- You *are* affected if you're explicitly enabling the allowlist for outbound IP addresses on your NSG rules setting on the Azure virtual network.

  If you're affected, take the following action: by November 8, 2020, notify your network infrastructure team to update the NSG rules on your Azure virtual network configuration to use the latest data factory IP addresses. To download the latest IP addresses, go to Discover service tags by using downloadable JSON files.

Couldn't establish a trust relationship for the SSL/TLS secure channel

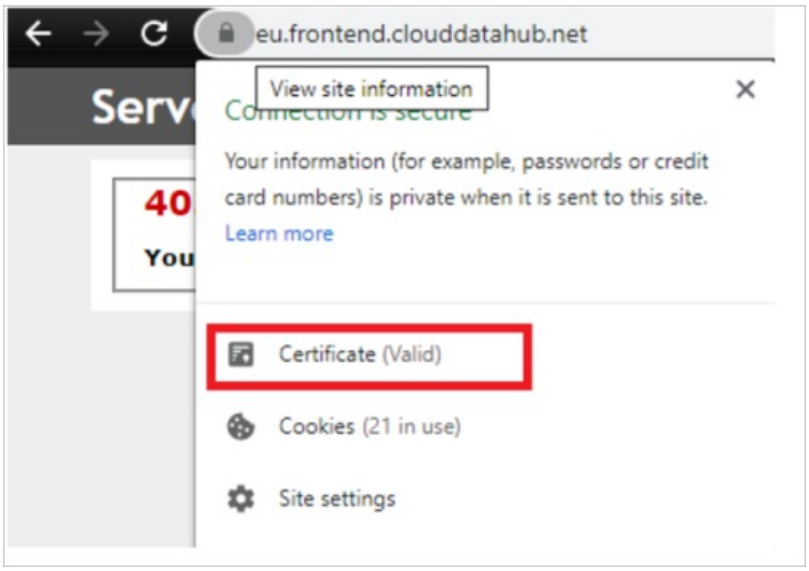
- **Symptoms**

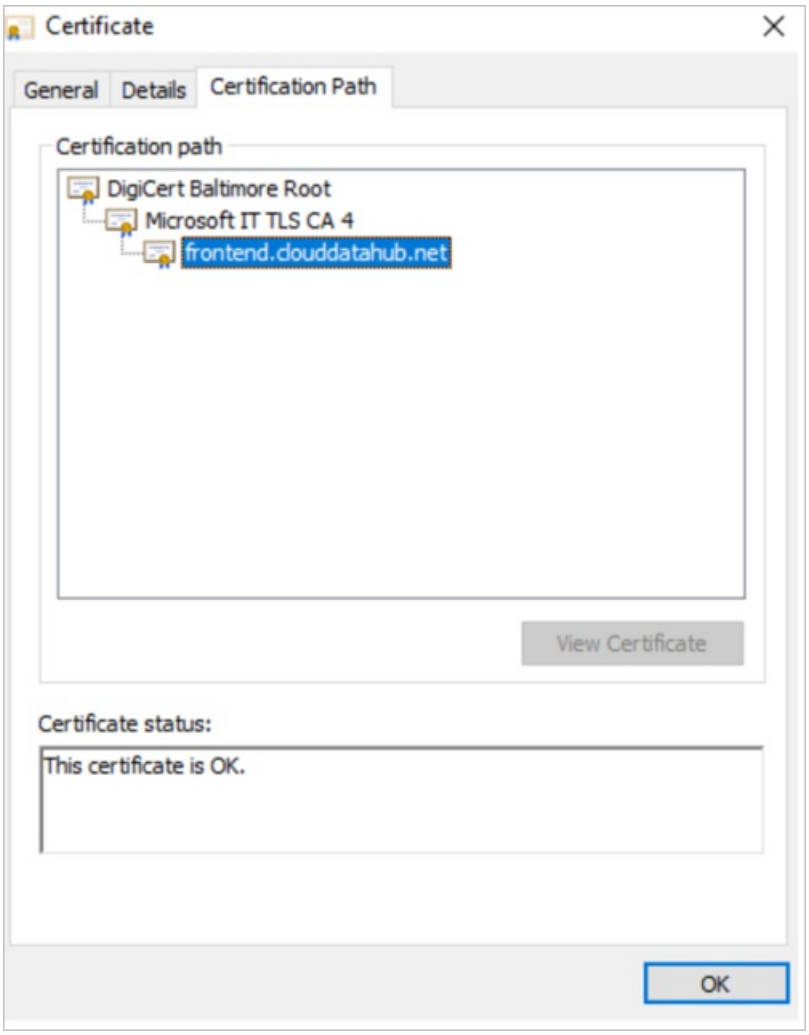
  The self-hosted IR couldn't connect to the Azure Data Factory or Azure Synapse service.

  When you check the self-hosted IR event log or the client notification logs in the CustomLogEvent table, you'll find the following error message:

  "The underlying connection was closed: Could not establish trust relationship for the SSL/TLS secure channel. The remote certificate is invalid according to the validation procedure."

  The simplest way to check the server certificate of the service is to open the service URL in your browser. For example, open the check server certificate link on the machine where the self-hosted IR is installed, and then view the server certificate information.





- **Cause**

  There are two possible reasons for this issue:

  - Reason 1: The root CA of the service's server certificate isn't trusted on the machine where the self-hosted IR is installed.
  - Reason 2: You're using a proxy in your environment, the server certificate of the service is replaced by the proxy, and the replaced server certificate isn't trusted by the machine where the self-hosted IR is installed.

- **Resolution**

  - For reason 1: Make sure that the service's server certificate and its certificate chain are trusted by the

machine where the self-hosted IR is installed.

- For reason 2: Either trust the replaced root CA on the self-hosted IR machine, or configure the proxy not to replace the service's server certificate.

For more information about trusting certificates on Windows, see Installing the trusted root certificate.

- **Additional information**
  We've rolled out a new SSL certificate, which is signed from DigiCert. Check to see whether the DigiCert Global Root G2 is in the trusted root CA.

If it isn't in the trusted root CA, download it here.

Machine Learning capabilities in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Azure Synapse Analytics offers various machine learning capabilities. This article provides an overview of how you can apply Machine Learning in the context of Azure Synapse.

This overview covers the different capabilities in Synapse related to machine learning, from a data science process perspective.

You may be familiar with how a typical data science process looks. It's a well-known process, which most machine learning projects follow.

At a high level, the process contains the following steps:

- Business understanding (not discussed in this article)
- Data acquisition and understanding
- Modeling
- Model deployment and scoring

This article describes the Azure Synapse machine learning capabilities in different analytics engines, from a data science process perspective. For each step in the data science process, the Azure Synapse capabilities that can help are summarized.

Data acquisition and understanding

Most machine learning projects involve well-established steps, and one of these steps is to access and understand the data.

Data source and pipelines

Thanks to Azure Data Factory, a natively integrated part of Azure Synapse, there is a powerful set of tools available for data ingestion and data orchestration pipelines. This allows you to easily build data pipelines to access and transform the data into a format that can be consumed for machine learning. Learn more about data pipelines in Synapse.

Data preparation and exploration/visualization

An important part of the machine learning process is to understand the data by exploration and visualizations.

Depending on where the data is stored, Synapse offers a set of different tools to explore and prepare it for analytics and machine learning. One of the quickest ways to get started with data exploration is using Apache Spark or serverless SQL pools directly over data in the data lake.

- Apache Spark for Azure Synapse offers capabilities to transform, prepare, and explore your data at scale. These spark pools offer tools like PySpark/Python, Scala, and .NET for data processing at scale. Using powerful visualization libraries, the data exploration experience can be enhanced to help understand the data better. Learn more about how to explore and visualize data in Synapse using Spark.
- Serverless SQL pools offer a way to explore data using TSQL directly over the data lake. Serverless SQL pools also offer some built-in visualizations in Synapse Studio. Learn more about how to explore data with serverless SQL pools.

Modeling

In Azure Synapse, training machine learning models can be performed on the Apache Spark Pools with tools like PySpark/Python, Scala, or .NET.

Train models on Spark Pools with MLlib

Machine learning models can be trained with help from various algorithms and libraries. Spark MLlib offers scalable machine learning algorithms that can help solving most classical machine learning problems. For a tutorial on how to train a model using MLlib in Synapse, see Build a machine learning app with Apache Spark MLlib and Azure Synapse Analytics.

In addition to MLlib, popular libraries such as Scikit Learn can also be used to develop models. See Manage libraries for Apache Spark in Azure Synapse Analytics for details on how to install libraries on Synapse Spark Pools.

Train models with Azure Machine Learning automated ML

Another way to train machine learning models, that does not require much prior familiarity with machine learning, is to use automated ML. Automated ML is a feature that automatically trains a set of machine learning models and allows the user to select the best model based on specific metrics. Thanks to a seamless integration with Azure Machine Learning from Azure Synapse Notebooks, users can easily leverage automated ML in Synapse with passthrough Azure Active Directory authentication. This means that you only need to point to your Azure Machine Learning workspace and do not need to enter any credentials. The tutorial, Train a model in Python with automated machine learning, describes how to train models using Azure Machine Learning automated ML on Synapse Spark Pools.

Model deployment and scoring

Models that have been trained either in Azure Synapse or outside Azure Synapse can easily be used for batch scoring. Currently in Synapse, there are two ways in which you can run batch scoring.

- You can use the TSQL PREDICT function in Synapse SQL pools to run your predictions right where your data lives. This powerful and scalable function allows you to enrich your data without moving any data out of your data warehouse. A new guided machine learning model experience in Synapse Studio was introduced where you can deploy an ONNX model from the Azure Machine Learning model registry in Synapse SQL Pools for batch scoring using PREDICT.
- Another option for batch scoring machine learning models in Azure Synapse is to leverage the Apache Spark Pools for Azure Synapse. Depending on the libraries used to train the models, you can use a code experience to run your batch scoring.

Next steps

- Get started with Azure Synapse Analytics
- Create a workspace
- Quickstart: Create a new Azure Machine Learning linked service in Synapse
- Tutorial: Machine learning model scoring wizard - dedicated SQL pool

Quickstart: Use a sample notebook from the Synapse Analytics gallery

8/19/2022 • 3 minutes to read • Edit Online

In this quickstart, you'll learn how to copy a sample machine learning notebook from the Synapse Analytics gallery into your workspace, modify it, and run it. The sample notebook ingests an Open Dataset of NYC Taxi trips and uses visualization to help you prepare the data. It then trains a model to predict whether there will be a tip on a given trip.

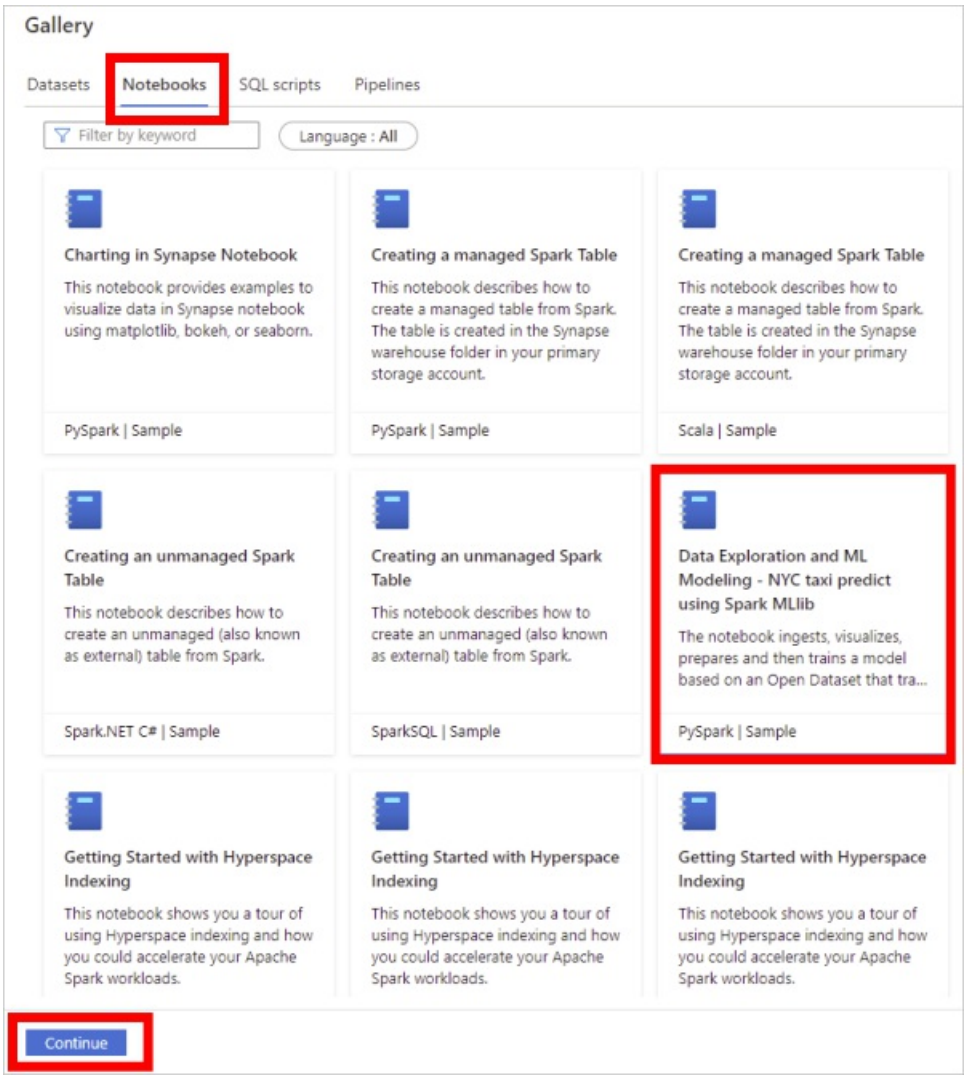
This notebook demonstrates the basic steps used in creating a model: **data import**, **data prep**, **model training**, and **evaluation**. You can use this sample as a starting point for creating a model with your own data.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace.

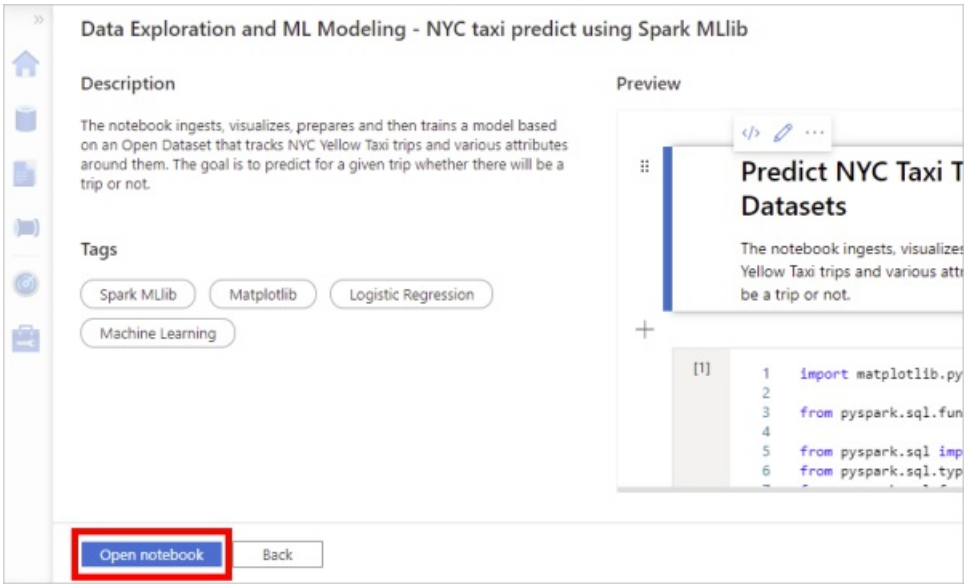
Copy the notebook to your workspace

1. Open your workspace and select **Learn** from the home page.
2. In the **Knowledge center**, select **Browse gallery**.
3. In the gallery, select **Notebooks**.
4. Find and select the notebook "Data Exploration and ML Modeling - NYC taxi predict using Spark MLib".



5. Select **Continue**.

6. On the notebook preview page, select **Open notebook**. The sample notebook is copied into your workspace and opened.



7. In the **Attach to** menu in the open notebook, select your Apache Spark pool.

Run the notebook

The notebook is divided into multiple cells that each perform a specific function. You can manually run each cell,

running cells sequentially, or select **Run all** to run all the cells.

Here are descriptions for each of the cells in the notebook:

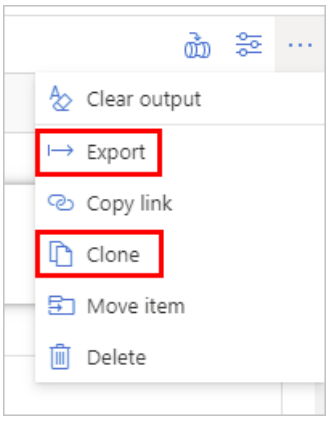
1. Import PySpark functions that the notebook uses.
2. **Ingest Date** - Ingest data from the Azure Open Dataset **NycTlcYellow** into a local dataframe for processing. The code extracts data within a specific time period - you can modify the start and end dates to get different data.
3. Downsample the dataset to make development faster. You can modify this step to change the sample size or the sampling seed.
4. **Exploratory Data Analysis** - Display charts to view the data. This can give you an idea what data prep might be needed before creating the model.
5. **Data Prep and Featurization** - Filter out outlier data discovered through visualization and create some useful derived variables.
6. **Data Prep and Featurization Part 2** - Drop unneeded columns and create some additional features.
7. **Encoding** - Convert string variables to numbers that the Logistic Regression model is expecting.
8. **Generation of Testing and Training Data Sets** - Split the data into separate testing and training data sets. You can modify the fraction and randomizing seed used to split the data.
9. **Train the Model** - Train a Logistic Regression model and display its "Area under ROC" metric to see how well the model is working. This step also saves the trained model in case you want to use it elsewhere.
10. **Evaluate and Visualize** - Plot the model's ROC curve to further evaluate the model.

Save the notebook

To save your notebook by selecting **Publish** on the workspace command bar.

Copying the sample notebook

To make a copy of this notebook, click the ellipsis in the top command bar and select **Clone** to create a copy in your workspace or **Export** to download a copy of the notebook (`.ipynb`) file.



Clean up resources

To ensure the Spark instance is shut down when you're finished, end any connected sessions (notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **stop session** from the status bar at the upper right of the notebook.

Industry AI solutions

8/19/2022 • 2 minutes to read • Edit Online

Every industry has common industry specific problems to solve. This article will cover the industry solutions available in Azure Synapse Workspaces for quickly getting started solving common industry problems. At this time, the AI solution offered is a Retail solution for product recommendation. You can find more details below on how to use this solution as a retailer, in order to get started.

Target user

The recommendation solution targets existing data scientists and emerging data scientists who are comfortable with code and are familiar with machine learning concepts. This solution is meant to accelerate the productivity of these users for solving a specific problem in the Retail domain.

Retail product recommendation solution

The **Retail - Product recommendations** solution provides a robust and scalable recommendation engine for out-of-the-box development in Synapse. When using this solution, you will get a Notebook training a machine learning model for product recommendation.

You may need to customize the pre-configured Notebook to ensure it meets your unique business requirements.

This Retail recommendation solution can be deployed in two different modes. You can try it out with sample data, or use a database modeled using the Database Template for Retail in Synapse.

The **Retail - Product recommendations** solution provides a recommendation pipeline for content-based filtering recommendations. The content-based filtering pipeline uses the LightGBM algorithm to train a model for predicting the user preferences based on user and item features. The features can be static features like user profile and item profile, as well as dynamic features like the aggregated user behavior patterns. The content-based filtering typed recommendation system is often used for recommendations such as "personalized recommendation" or "new products you may like".

Get started

1. Open your Synapse workspace
2. From your Home screen, select **Knowledge center** in the **Discover more** section
3. In the Knowledge center, select **Browse gallery**
4. In the Gallery, select the **Database Templates** tab, scroll down to the **AI solutions** section, and select the "Retail - Product recommendations" solution. Click **Continue**.
5. You can choose between two options:
   - "Use sample data"
   - "Use my own data from a workspace database". This option can for example be a database modeled with the Retail Database template.

   Clicking **Deploy** will open a Notebook in your Synapse workspace.
6. A Notebook will now be opened in your workspace. You can attach this Notebook to a Spark pool and start exploring it. Please be aware that this Notebook is meant to be customized to your specific needs.

> **NOTE**
>
> If you choose your own database, you need to customize the Notebook to use your own table and column names.

Next steps

- Get started with Azure Synapse Analytics
- Create a workspace

Quickstart: Create a new Azure Machine Learning linked service in Synapse

8/19/2022 • 4 minutes to read • Edit Online

IMPORTANT, PLEASE NOTE THE BELOW LIMITATIONS:

- **The Azure ML integration is not currently supported in Synapse Workspaces with Data Exfiltration Protection.** If you are **not** using data exfiltration protection and want to connect to Azure ML using private endpoints, you can set up a managed AzureML private endpoint in your Synapse workspace. Read more about managed private endpoints
- **AzureML linked service is not supported with self hosted integration runtimes.** This applies to Synapse workspaces with and without Data Exfiltration Protection.

In this quickstart, you'll link an Azure Synapse Analytics workspace to an Azure Machine Learning workspace. Linking these workspaces allows you to leverage Azure Machine Learning from various experiences in Synapse.

For example, this linking to an Azure Machine Learning workspace enables these experiences:

- Run your Azure Machine Learning pipelines as a step in your Synapse pipelines. To learn more, see Execute Azure Machine Learning pipelines.
- Enrich your data with predictions by bringing a machine learning model from the Azure Machine Learning model registry and score the model in Synapse SQL pools. For more details, see Tutorial: Machine learning model scoring wizard for Synapse SQL pools.

Two types of authentication

There are two types of identities you can use when creating an Azure Machine Learning linked service in Azure Synapse.

- Synapse workspace Managed Identity
- Service Principal

In the following sections, you'll find guidance on how to create an Azure Machine Learning linked service using these two different types of authentication.

Prerequisites

- Azure subscription - Create one for free.
- Synapse Analytics workspace with an ADLS Gen2 storage account configured as the default storage. You need to be the **Storage Blob Data Contributor** of the ADLS Gen2 filesystem that you work with.
- Azure Machine Learning workspace.
- If you chose to use a Service principal, you need permissions (or request from someone who has permissions) to create a service principal and secret which you can use to create the linked service. Note that this service principal needs to be assigned the contributor role in the Azure Machine Learning workspace.
- Sign in to the Azure portal

Create a linked service using the Synapse workspace Managed identity

This section will guide you on how to create an Azure Machine Learning linked service in Azure Synapse, using the Azure Synapse workspace Managed Identity

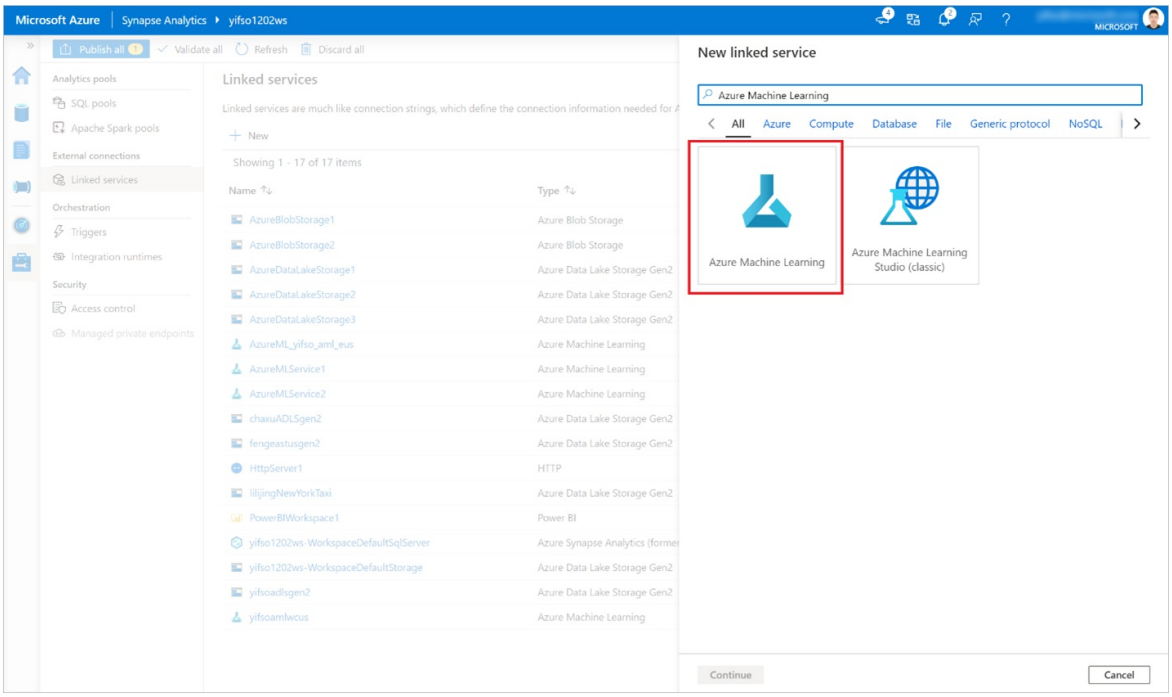
Give MSI permission to the Azure ML workspace

1. Navigate to your Azure Machine Learning workspace resource in the Azure portal and select **Access Control**

2. Create a role assignment and add your Synapse workspace Managed Service identity (MSI) as a *contributor* of the Azure Machine Learning workspace. Note that this will require being an owner of the resource group that the Azure Machine Learning workspace belongs to. If you have trouble finding your Synapse workspace MSI, search for the name of the Synapse workspace.

Create an Azure ML linked service

1. In the Synapse workspace where you want to create the new Azure Machine Learning linked service, go to **Management** > **Linked service**, and create a new linked service with type "Azure Machine Learning".



2. Fill out the form:

   - Provide the details about the Azure Machine Learning workspace you want to link to. This includes details about subscription and workspace name.

   - Select Authentication Method: **Managed Identity**

3. Click **Test Connection** to verify if the configuration is correct. If the connection test passes, click **Save**.

   If the connection test fails, make sure that the Azure Synapse workspace MSI has permissions to access this Azure Machine Learning workspace, and try again.

Create a linked service using a service principal

This section will guide you on how to create an Azure Machine Learning linked service with a service principal.

Create a service principal

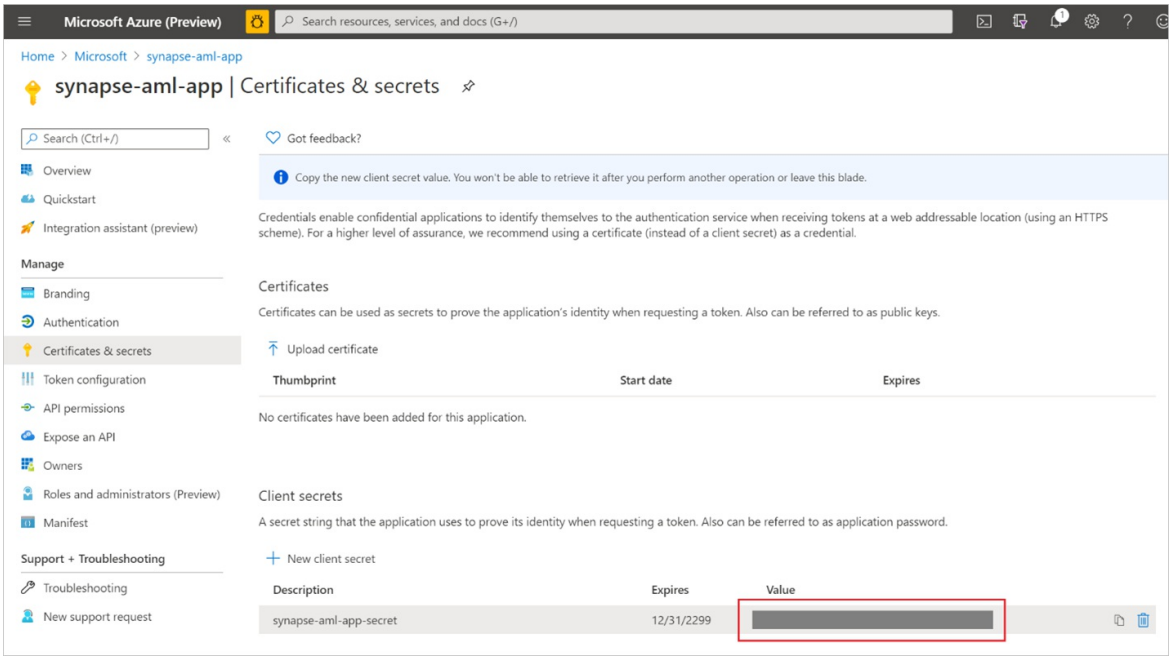
This step will create a new Service Principal. If you want to use an existing Service Principal, you can skip this step.

1. Open Azure portal.

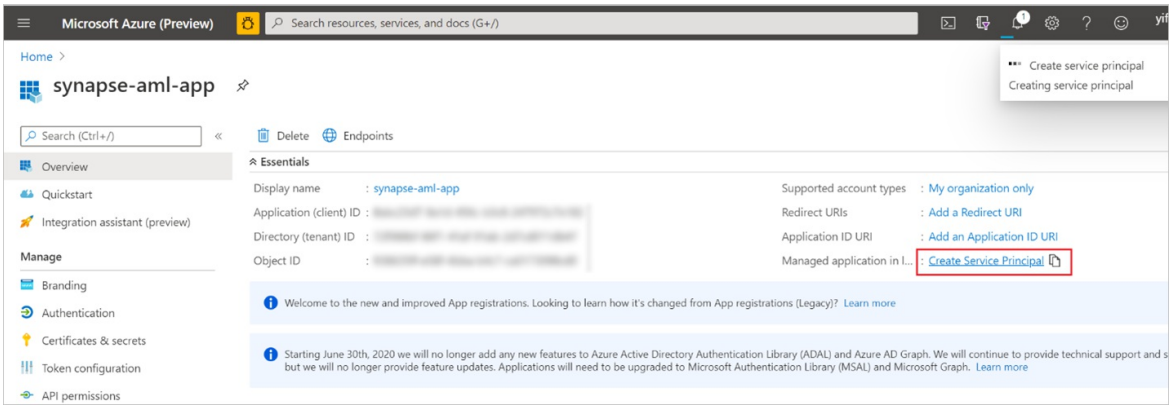
2. Go to **Azure Active Directory** -> **App registrations**.

3. Click **New registration**. Then, follow instructions to register a new application.

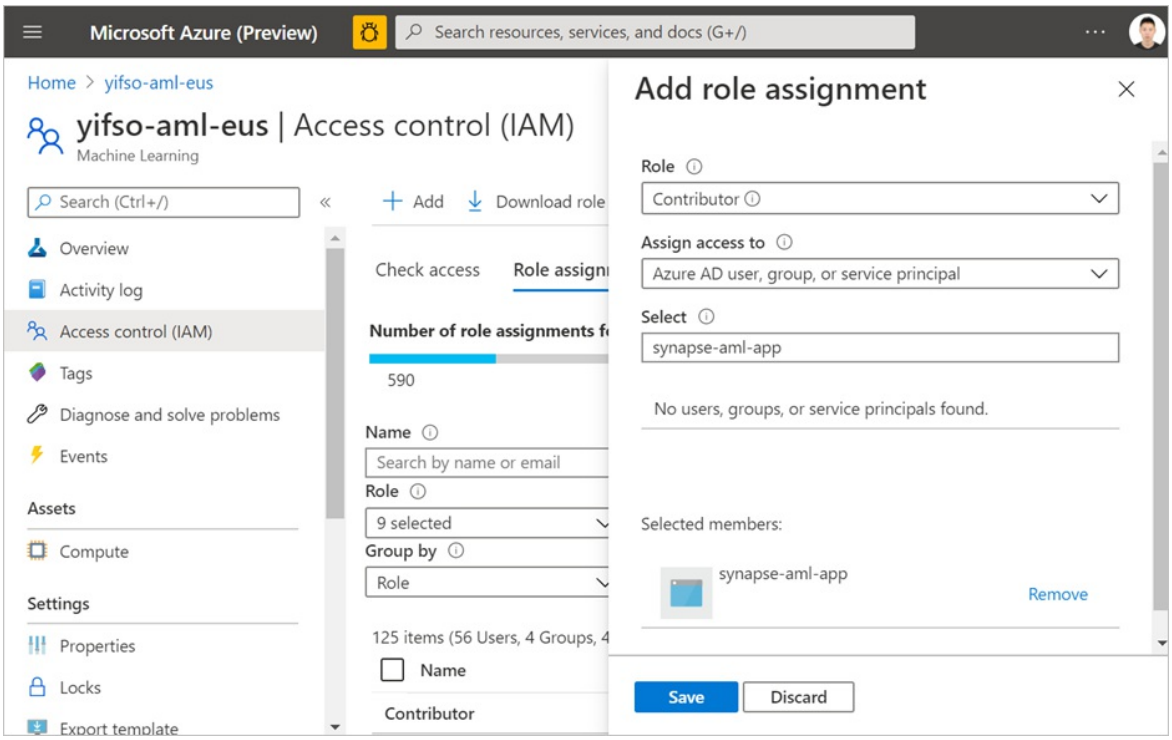
4. After the application is registered, generate a secret for the application. Go to **Your application** -> **Certificate & Secret**. Click **Add client secret** to generate a secret. Keep the secret safe and it will be used later.



5. Create a service principal for the application. Go to **Your application** -> **Overview** and then click **Create service principal**. In some cases, this service principal is automatically created.

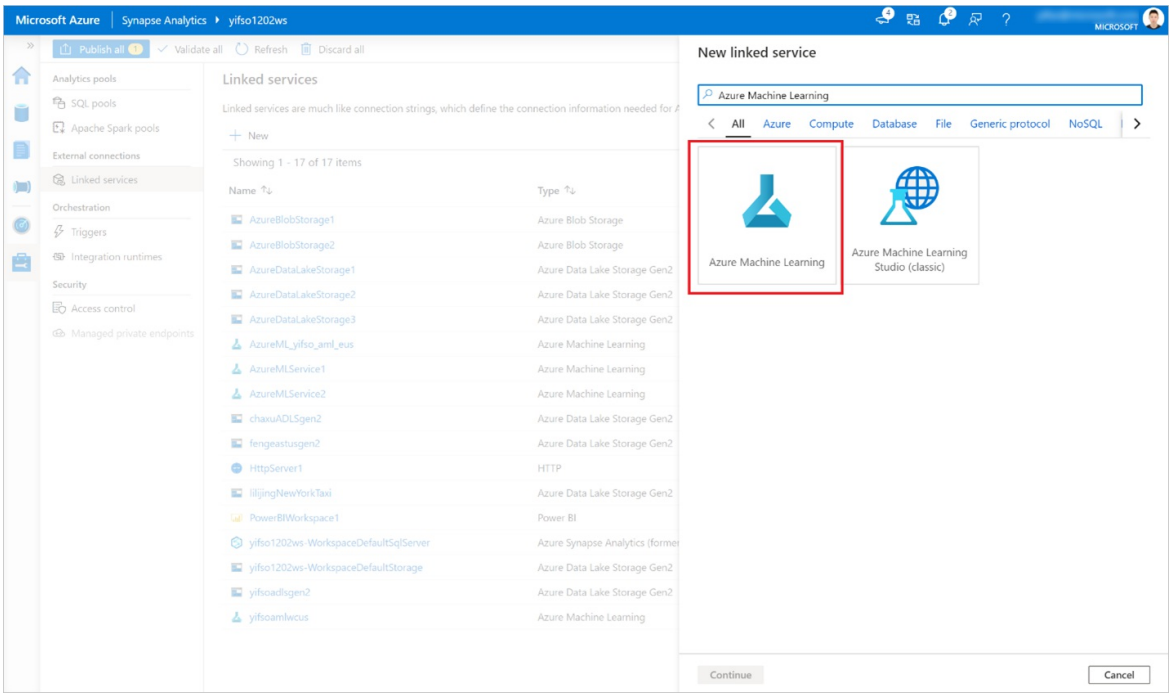


6. Add the service principal as "contributor" of the Azure Machine Learning workspace. Note that this will require being an owner of the resource group that the Azure Machine Learning workspace belongs to.



Create an Azure ML linked service

1. In the Synapse workspace where you want to create the new Azure Machine Learning linked service, go to **Management** -> **Linked service**, create a new linked service with type "Azure Machine Learning".



2. Fill out the form:

   - Provide the details about the Azure Machine Learning workspace you want to link to. This includes details about subscription and workspace name.
   - Select Authentication Method: **Service Principal**
   - Service principal ID: This is the **application (client) ID** of the Application.

> **NOTE**
>
> The ID is NOT the name of the application. You can find this ID in the overview page of the application. It should be a long string looking similar to this "81707eac-ab38-406u-8f6c-10ce76a568d5".

- Service principal key: The secret you generated in the previous section.

3. Click **Test Connection** to verify if the configuration is correct. If the connection test passes, click **Save**.

   If the connection test fails, make sure that the service principal ID and secret are correct and try again.

Quickstart: Configure prerequisites for using Cognitive Services in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

In this quickstart, you'll learn how set up the prerequisites for securely using Azure Cognitive Services in Azure Synapse Analytics. Linking these Azure Cognitive Services allows you to leverage Azure Cognitive Services from various experiences in Synapse.

This quickstart covers:

- Create a Cognitive Services resource like Text Analytics or Anomaly Detector.
- Store an authentication key to Cognitive Services resources as secrets in Azure Key Vault, and configure access for an Azure Synapse Analytics workspace.
- Create an Azure Key Vault linked service in your Azure Synapse Analytics workspace.
- Create an Azure Cognitive Services linked service in your Azure Synapse Analytics workspace.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Azure Data Lake Storage Gen2 file system that you work with.

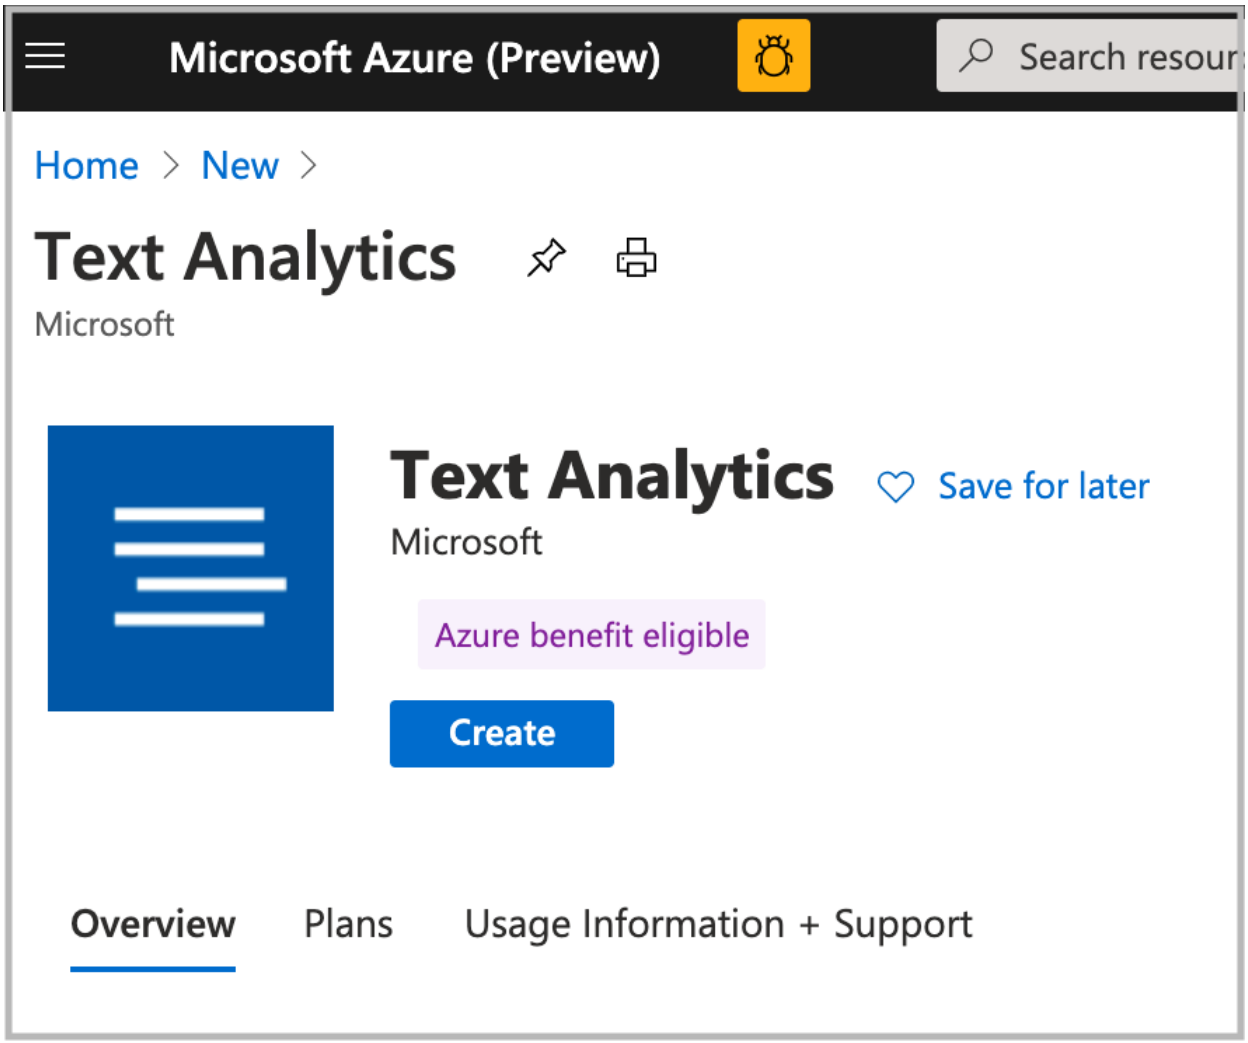
Sign in to the Azure portal

Sign in to the Azure portal.

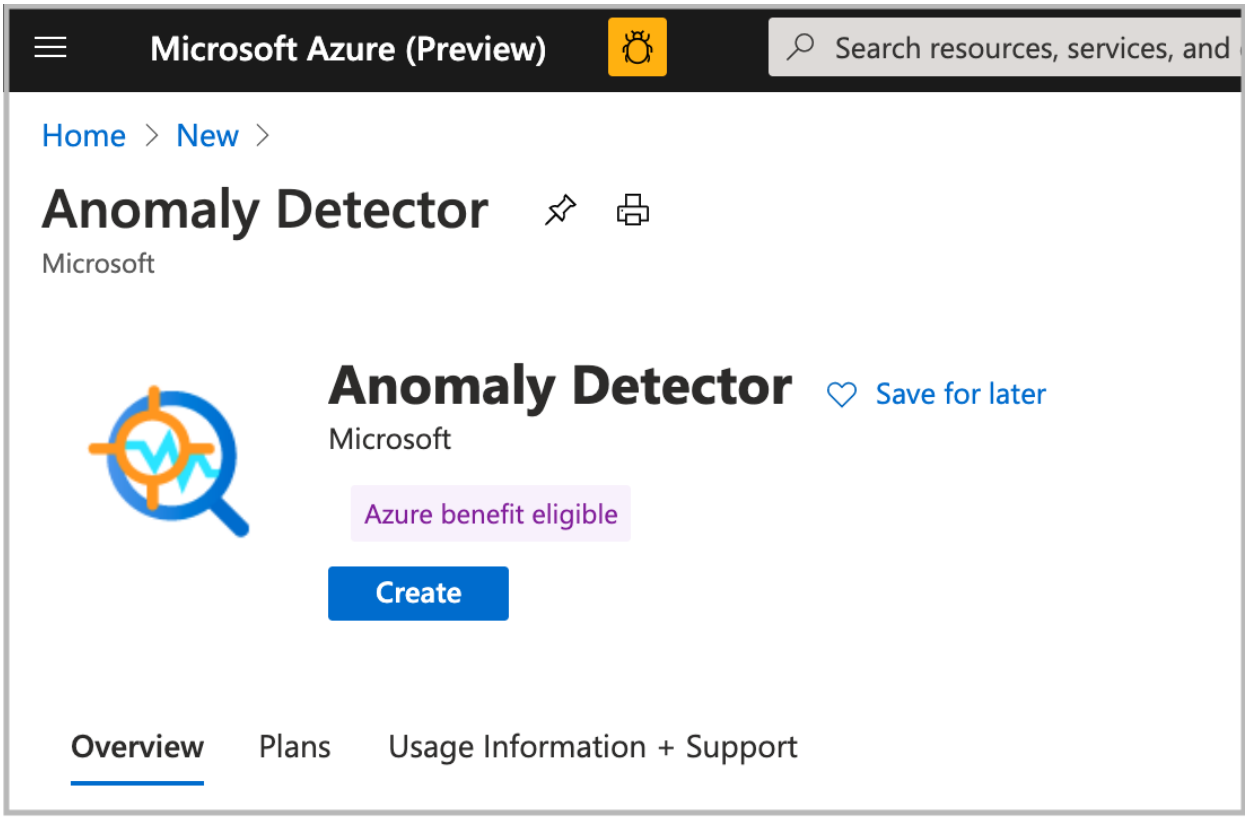
Create a Cognitive Services resource

Azure Cognitive Services includes many types of services. Follow services are examples used in the Azure Synapse tutorials.

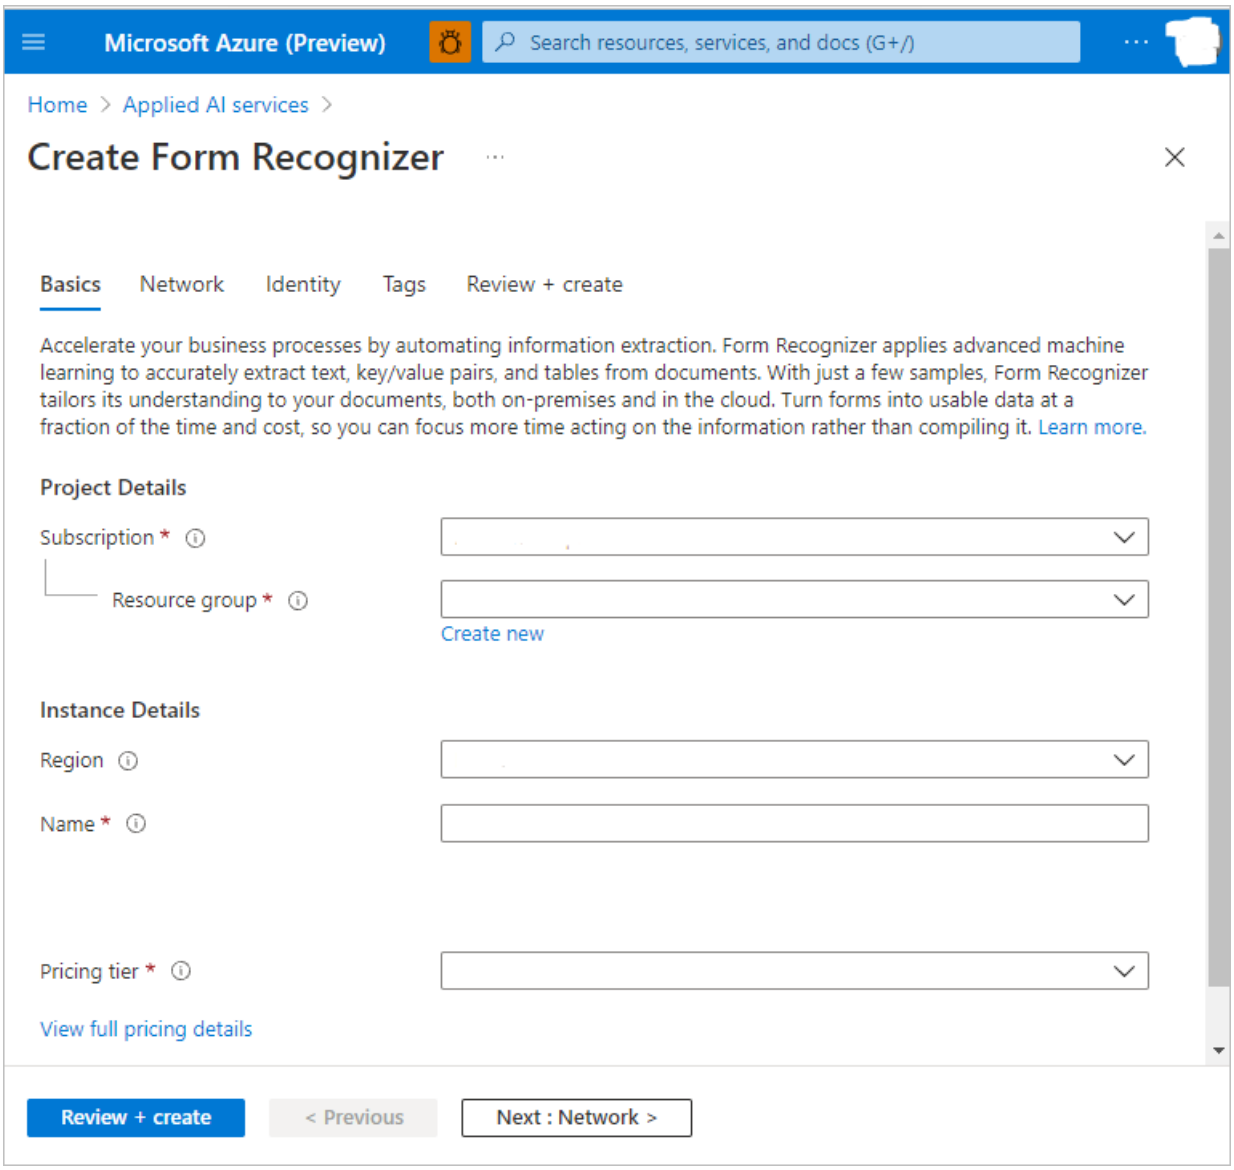
You can create a Text Analytics resource in the Azure portal:



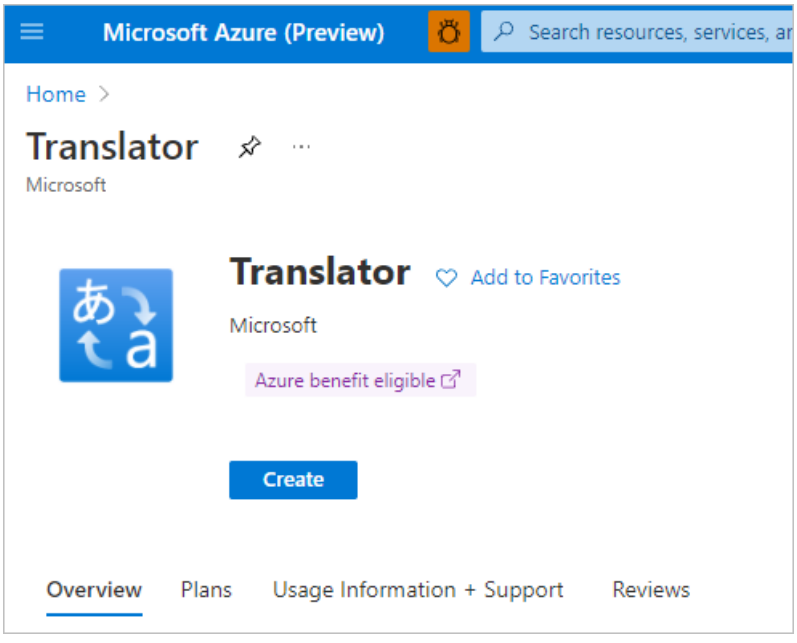
You can create an Anomaly Detector resource in the Azure portal:



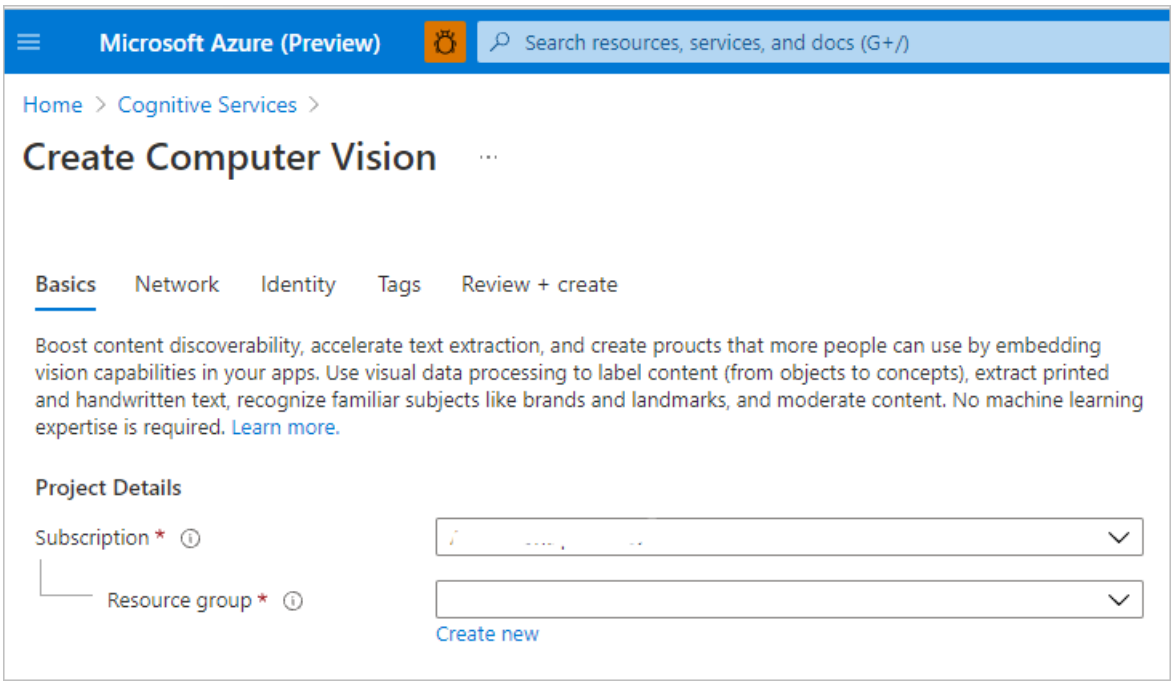
You can create an Form Recognizer resource in the Azure portal:



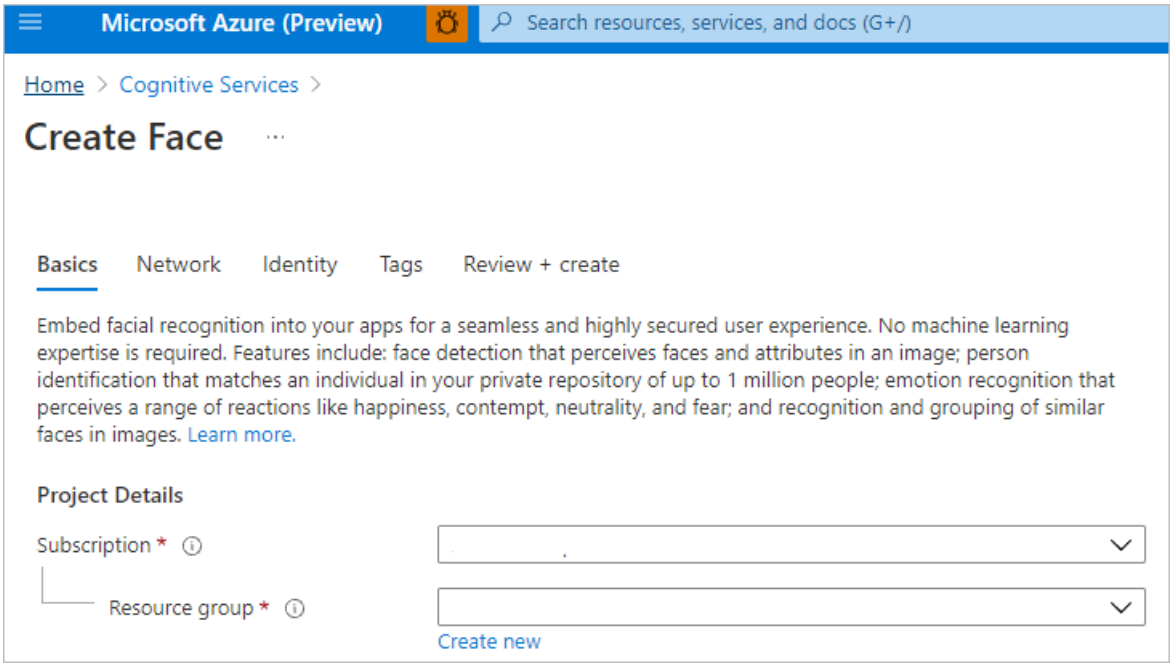
You can create a Translator resource in the Azure portal:



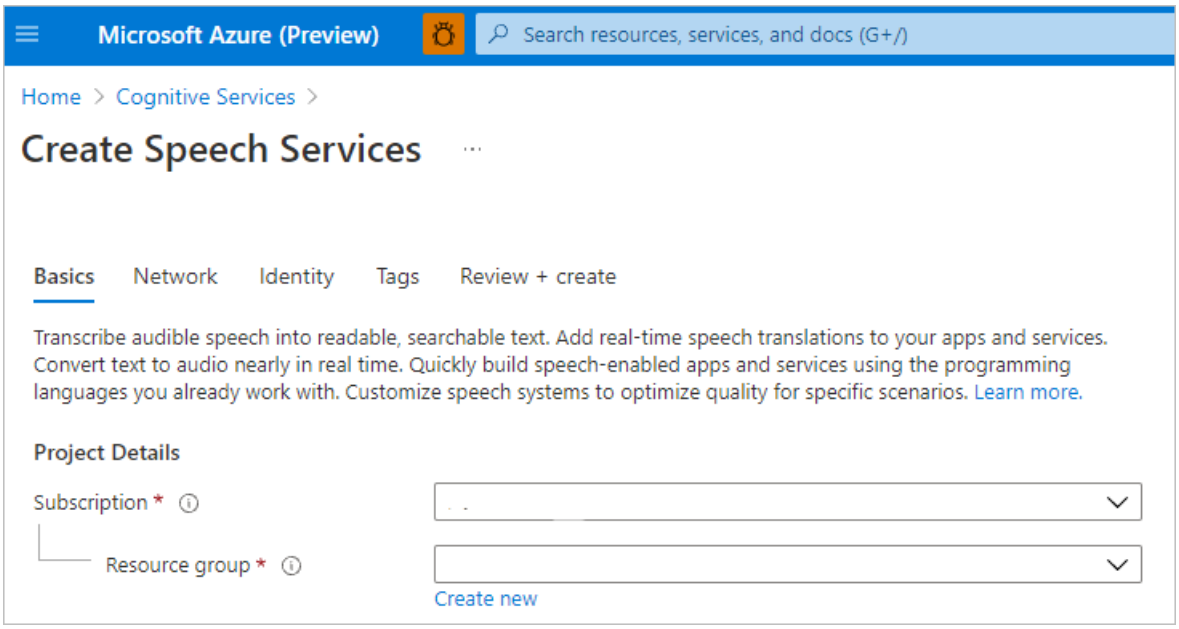
You can create a Computer Vision resource in the Azure portal:



You can create a Face resource in the Azure portal:



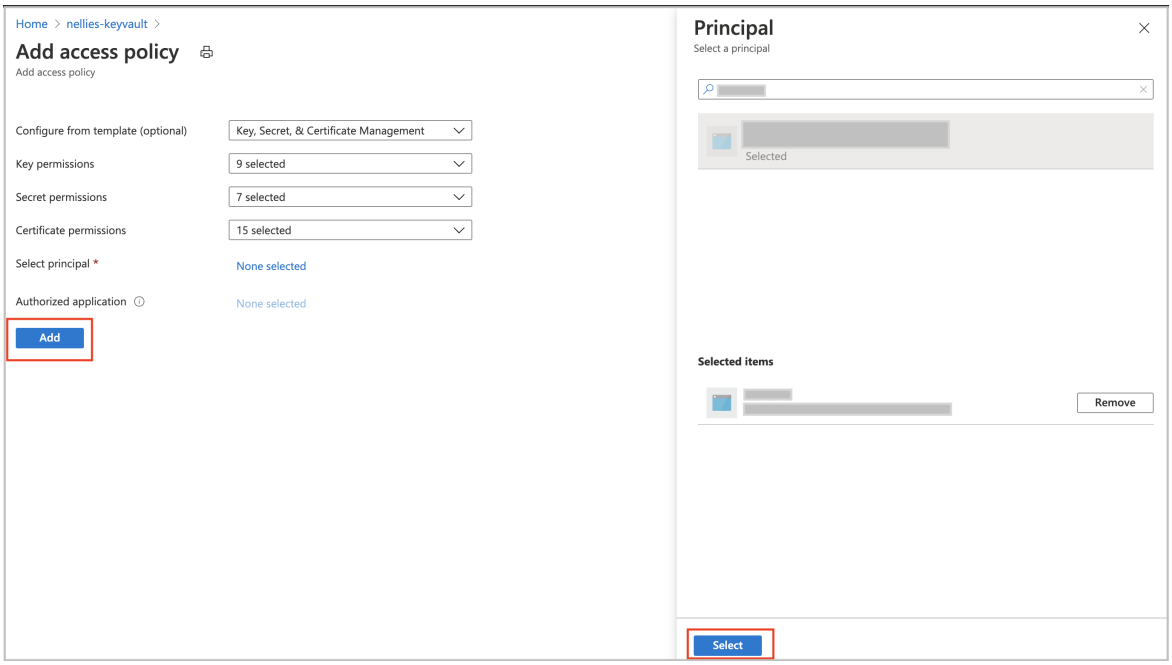
You can create a Speech resource in the Azure portal:



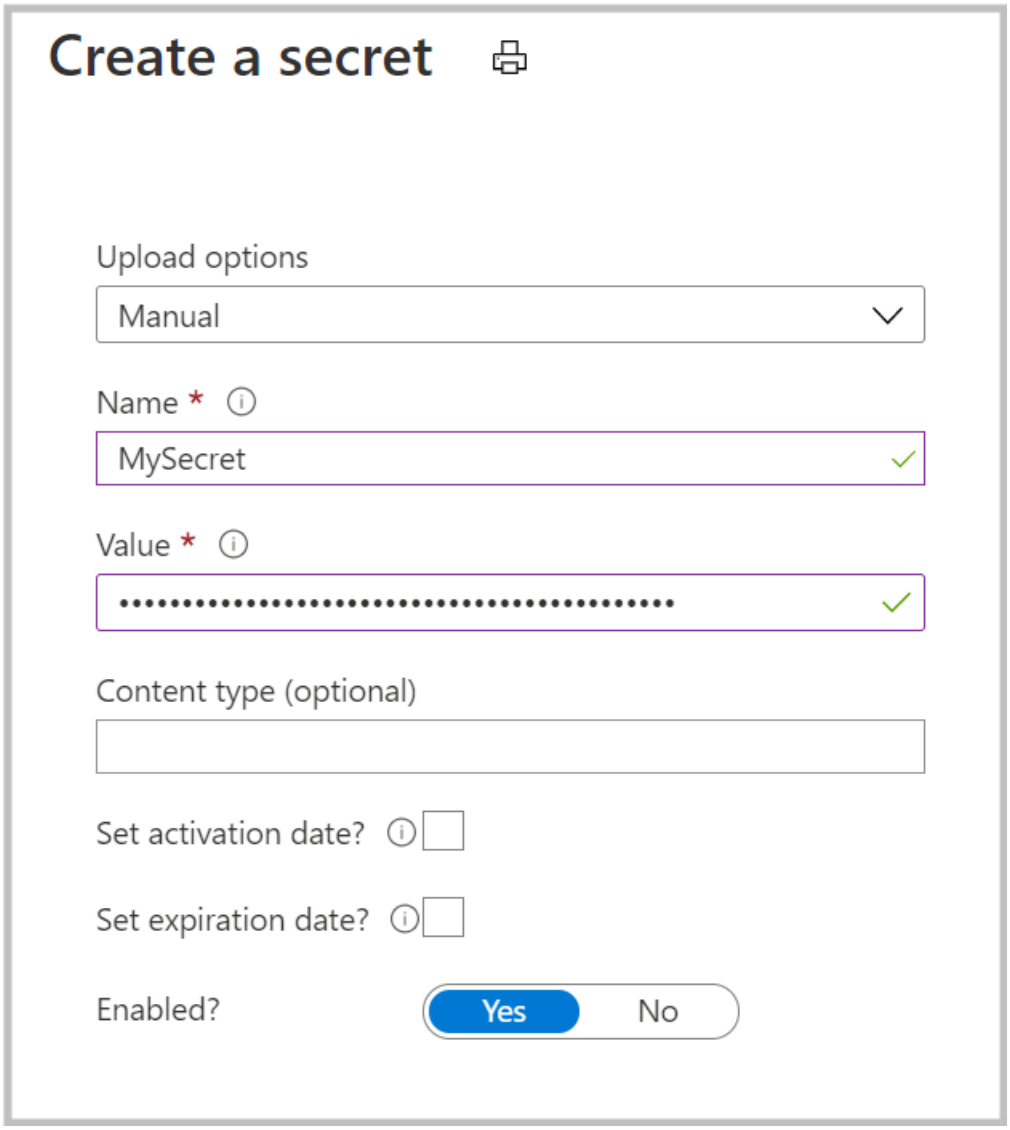
Create a key vault and configure secrets and access

1. Create a key vault in the Azure portal.
2. Go to **Key Vault** > **Access policies**, and grant the Azure Synapse workspace MSI permissions to read secrets from Azure Key Vault.

> **NOTE**
>
> Make sure that the policy changes are saved. This step is easy to miss.



3. Go to your Cognitive Services resource. For example, go to **Anomaly Detector** > **Keys and Endpoint**. Then copy either of the two keys to the clipboard.
4. Go to **Key Vault** > **Secret** to create a new secret. Specify the name of the secret, and then paste the key from the previous step into the **Value** field. Finally, select **Create**.

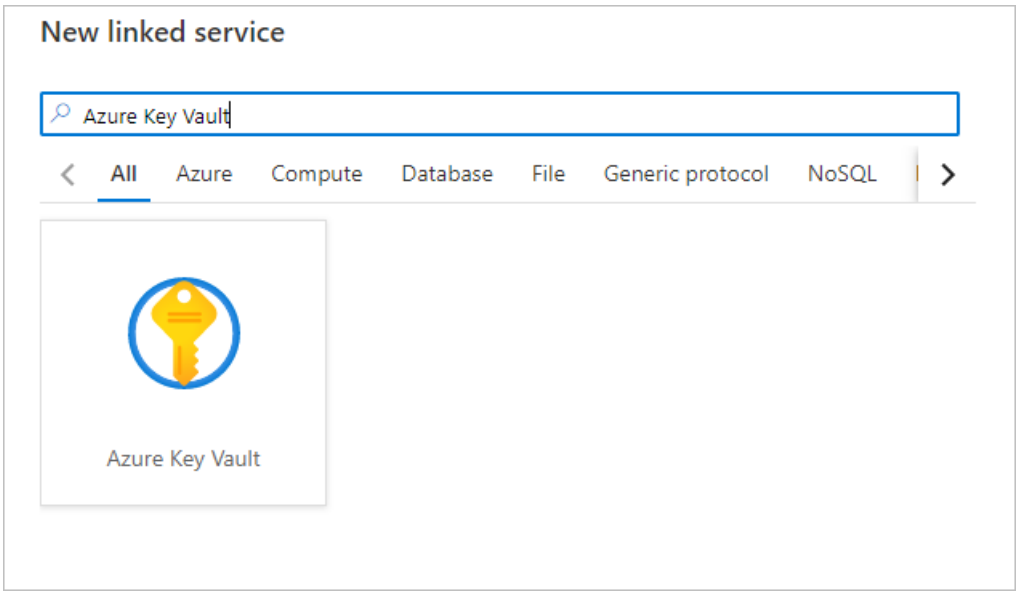


IMPORTANT

Make sure you remember or note down this secret name. You'll use it later when you create the Azure Cognitive Services linked service.

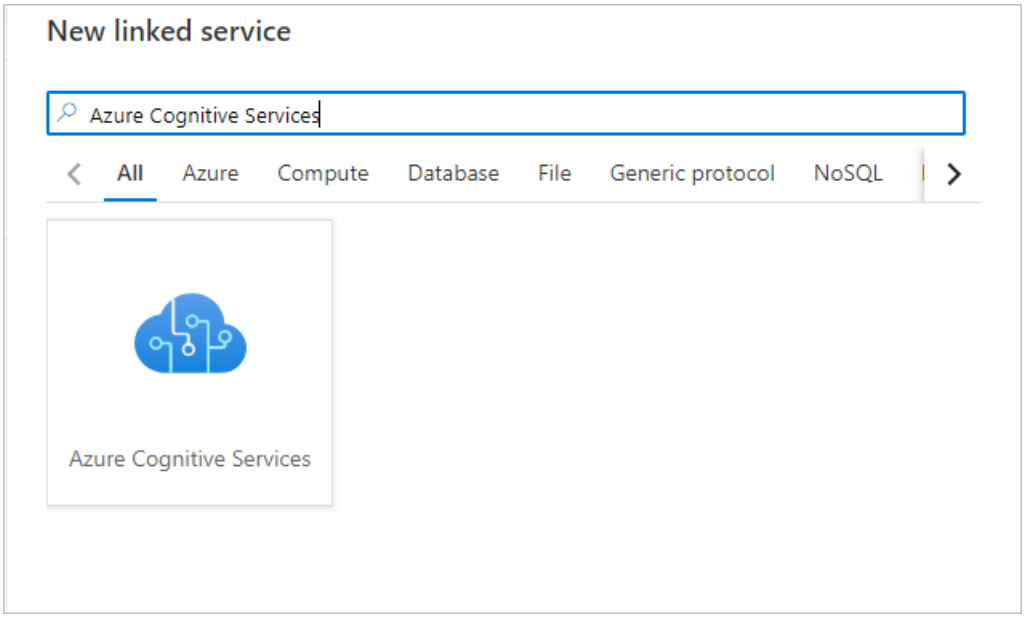
Create an Azure Key Vault linked service in Azure Synapse

1. Open your workspace in Synapse Studio.
2. Go to **Manage** > **Linked Services**. Create an **Azure Key Vault** linked service by pointing to the key vault that you just created.
3. Verify the connection by selecting the **Test connection** button. If the connection is green, select **Create** and then select **Publish all** to save your change.



Create an Azure Cognitive Service linked service in Azure Synapse

1. Open your workspace in Synapse Studio.
2. Go to **Manage** > **Linked Services**. Create an **Azure Cognitive Services** linked service by pointing to the Cognitive Service that you just created.
3. Verify the connection by selecting the **Test connection** button. If the connection is green, select **Create** and then select **Publish all** to save your change.



You're now ready to continue with one of the tutorials for using the Azure Cognitive Services experience in Synapse Studio.

Train machine learning models

8/19/2022 • 3 minutes to read • Edit Online

Apache Spark in Azure Synapse Analytics enables machine learning with big data, providing the ability to obtain valuable insight from large amounts of structured, unstructured, and fast-moving data. There are several options when training machine learning models using Azure Spark in Azure Synapse Analytics: Apache Spark MLlib, Azure Machine Learning, and various other open-source libraries.

Apache SparkML and MLlib

Apache Spark in Azure Synapse Analytics is one of Microsoft's implementations of Apache Spark in the cloud. It provides a unified, open-source, parallel data processing framework supporting in-memory processing to boost big data analytics. The Spark processing engine is built for speed, ease of use, and sophisticated analytics. Spark's in-memory distributed computation capabilities make it a good choice for the iterative algorithms used in machine learning and graph computations.

There are two scalable machine learning libraries that bring algorithmic modeling capabilities to this distributed environment: MLlib and SparkML. MLlib contains the original API built on top of RDDs. SparkML is a newer package that provides a higher-level API built on top of DataFrames for constructing ML pipelines. SparkML doesn't yet support all of the features of MLlib, but is replacing MLlib as Spark's standard machine learning library.

> **NOTE**
> You can learn more about creating a SparkML model by following this tutorial.

Popular libraries

Every Apache Spark pool in Azure Synapse Analytics comes with a set of pre-loaded and popular machine learning libraries. These libraries provide reusable code that you may want to include in your programs or projects. Some of the relevant machine learning libraries that are included by default include:

- Scikit-learn is one of the most popular single-node machine learning libraries for classical ML algorithms. Scikit-learn supports most of the supervised and unsupervised learning algorithms and can also be used for data-mining and data-analysis.
- XGBoost is a popular machine learning library that contains optimized algorithms for training decision trees and random forests.
- PyTorch & Tensorflow are powerful Python deep learning libraries. Within an Apache Spark pool in Azure Synapse Analytics, you can use these libraries to build single-machine models by setting the number of executors on your pool to zero. Even though Apache Spark is not functional under this configuration, it is a simple and cost-effective way to create single-machine models.

You can learn more about the available libraries and related versions by viewing the published Azure Synapse Analytics runtime.

MMLSpark

The Microsoft Machine Learning library for Apache Spark is MMLSpark. This library is designed to make data scientists more productive on Spark, increase the rate of experimentation, and leverage cutting-edge machine

learning techniques, including deep learning, on large datasets.

MMLSpark provides a layer on top of SparkML's low-level APIs when building scalable ML models, such as indexing strings, coercing data into a layout expected by machine learning algorithms, and assembling feature vectors. The MMLSpark library simplifies these and other common tasks for building models in PySpark.

Automated ML in Azure Machine Learning

Azure Machine Learning is a cloud-based environment that allows you to train, deploy, automate, manage, and track machine learning models. Automated ML in Azure Machine Learning accepts training data and configuration settings and automatically iterates through combinations of different feature normalization/standardization methods, models, and hyperparameter settings to arrive at the best model.

When using automated ML within Azure Synapse Analytics, you can leverage the deep integration between the different services to simplify authentication & model training.

> **NOTE**
> You can learn more about creating an Azure Machine Learning automated ML experiment by following this tutorial.

Azure Cognitive Services

Azure Cognitive Services provides machine learning capabilities to solve general problems such as analyzing text for emotional sentiment or analyzing images to recognize objects or faces. You don't need special machine learning or data science knowledge to use these services. A Cognitive Service provides part or all of the components in a machine learning solution: data, algorithm, and trained model. These services are meant to require general knowledge about your data without needing experience with machine learning or data science. You can leverage these pre-trained Cognitive Services automatically within Azure Synapse Analytics.

Deep learning (Preview)

8/19/2022 • 2 minutes to read • Edit Online

Apache Spark in Azure Synapse Analytics enables machine learning with big data, providing the ability to obtain valuable insight from large amounts of structured, unstructured, and fast-moving data. There are several options when training machine learning models using Azure Spark in Azure Synapse Analytics: Apache Spark MLlib, Azure Machine Learning, and various other open-source libraries.

GPU-enabled Apache Spark pools

To simplify the process for creating and managing pools, Azure Synapse takes care of pre-installing low-level libraries and setting up all the complex networking requirements between compute nodes. This integration allows users to get started with GPU- accelerated pools within just a few minutes. To learn more about how to create a GPU-accelerated pool, you can visit the quickstart on how to create a GPU-accelerated pool.

NOTE

- GPU-accelerated pools can be created in workspaces located in East US, Australia East, and North Europe.
- GPU-accelerated pools are only available with the Apache Spark 3.1 and 3.2 runtime.
- You might need to request a limit increase in order to create GPU-enabled clusters.

GPU ML Environment

Azure Synapse Analytics provides built-in support for deep learning infrastructure. The Azure Synapse Analytics runtimes for Apache Spark 3 include support for the most common deep learning libraries like TensorFlow and PyTorch. The Azure Synapse runtime also includes supporting libraries like Petastorm and Horovod which are commonly used for distributed training.

Tensorflow

TensorFlow is an open source machine learning framework for all developers. It is used for implementing machine learning and deep learning applications.

For more information about Tensorflow, you can visit the Tensorflow API documentation.

PyTorch

PyTorch is an optimized tensor library for deep learning using GPUs and CPUs.

For more information about PyTorch, you can visit the PyTorch documentation.

Horovod

Horovod is a distributed deep learning training framework for TensorFlow, Keras, and PyTorch. Horovod was developed to make distributed deep learning fast and easy to use. With this framework, an existing training script can be scaled up to run on hundreds of GPUs in just a few lines of code. In addition, Horovod can run on top of Apache Spark, making it possible to unify data processing and model training into a single pipeline.

To learn more about how to run distributed training jobs in Azure Synapse Analytics, you can visit the following tutorials: - Tutorial: Distributed training with Horovod and PyTorch - Tutorial: Distributed training with Horovod and Tensorflow

For more information about Horovod, you can visit the Horovod documentation,

Petastorm

Petastorm is an open source data access library which enables single-node or distributed training of deep learning models. This library enables training directly from datasets in Apache Parquet format and datasets that have already been loaded as an Apache Spark DataFrame. Petastorm supports popular training frameworks such as Tensorflow and PyTorch.

For more information about Petastorm, you can visit the Petastorm GitHub page or the Petastorm API documentation.

Analyze data with Apache Spark

8/19/2022 • 5 minutes to read • Edit Online

In this tutorial, you'll learn how to perform exploratory data analysis by using Azure Open Datasets and Apache Spark. You can then visualize the results in a Synapse Studio notebook in Azure Synapse Analytics.

In particular, we'll analyze the New York City (NYC) Taxi dataset. The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips: information about each trip, the start and end time and locations, the cost, and other interesting attributes.

Before you begin

Create an Apache Spark Pool by following the Create an Apache Spark pool tutorial.

Download and prepare the data

1. Create a notebook by using the PySpark kernel. For instructions, see Create a notebook.

   > **NOTE**
   > Because of the PySpark kernel, you don't need to create any contexts explicitly. The Spark context is automatically created for you when you run the first code cell.

2. In this tutorial, we'll use several different libraries to help us visualize the dataset. To do this analysis, import the following libraries:

   ```
   import matplotlib.pyplot as plt
   import seaborn as sns
   import pandas as pd
   ```

3. Because the raw data is in a Parquet format, you can use the Spark context to pull the file into memory as a DataFrame directly. Create a Spark DataFrame by retrieving the data via the Open Datasets API. Here, we use the Spark DataFrame *schema on read* properties to infer the datatypes and schema.

   ```
   from azureml.opendatasets import NycTlcYellow
   from datetime import datetime
   from dateutil import parser

   end_date = parser.parse('2018-06-06')
   start_date = parser.parse('2018-05-01')
   nyc_tlc = NycTlcYellow(start_date=start_date, end_date=end_date)
   df = nyc_tlc.to_spark_dataframe()
   ```

4. After the data is read, we'll want to do some initial filtering to clean the dataset. We might remove unneeded columns and add columns that extract important information. In addition, we'll filter out anomalies within the dataset.

```
# Filter the dataset
from pyspark.sql.functions import *

filtered_df = df.select('vendorID', 'passengerCount', 'tripDistance','paymentType', 'fareAmount',
'tipAmount'\
                                , date_format('tpepPickupDateTime', 'hh').alias('hour_of_day')\
                                , dayofweek('tpepPickupDateTime').alias('day_of_week')\
                                , dayofmonth(col('tpepPickupDateTime')).alias('day_of_month'))\
                            .filter((df.passengerCount > 0)\
                                & (df.tipAmount >= 0)\
                                & (df.fareAmount >= 1) & (df.fareAmount <= 250)\
                                & (df.tripDistance > 0) & (df.tripDistance <= 200))

filtered_df.createOrReplaceTempView("taxi_dataset")
```

Analyze data

As a data analyst, you have a wide range of tools available to help you extract insights from the data. In this part of the tutorial, we'll walk through a few useful tools available within Azure Synapse Analytics notebooks. In this analysis, we want to understand the factors that yield higher taxi tips for our selected period.

Apache Spark SQL Magic

First, we'll perform exploratory data analysis by Apache Spark SQL and magic commands with the Azure Synapse notebook. After we have our query, we'll visualize the results by using the built-in `chart options` capability.

1. Within your notebook, create a new cell and copy the following code. By using this query, we want to understand how the average tip amounts have changed over the period we've selected. This query will also help us identify other useful insights, including the minimum/maximum tip amount per day and the average fare amount.

   ```
   %%sql
   SELECT
       day_of_month
       , MIN(tipAmount) AS minTipAmount
       , MAX(tipAmount) AS maxTipAmount
       , AVG(tipAmount) AS avgTipAmount
       , AVG(fareAmount) as fareAmount
   FROM taxi_dataset
   GROUP BY day_of_month
   ORDER BY day_of_month ASC
   ```

2. After our query finishes running, we can visualize the results by switching to the chart view. This example creates a line chart by specifying the `day_of_month` field as the key and `avgTipAmount` as the value. After you've made the selections, select **Apply** to refresh your chart.

Visualize data

In addition to the built-in notebook charting options, you can use popular open-source libraries to create your own visualizations. In the following examples, we'll use Seaborn and Matplotlib. These are commonly used Python libraries for data visualization.

NOTE

By default, every Apache Spark pool in Azure Synapse Analytics contains a set of commonly used and default libraries. You can view the full list of libraries in the Azure Synapse runtime documentation. In addition, to make third-party or locally built code available to your applications, you can install a library onto one of your Spark pools.

1. To make development easier and less expensive, we'll downsample the dataset. We'll use the built-in Apache Spark sampling capability. In addition, both Seaborn and Matplotlib require a Pandas DataFrame or NumPy array. To get a Pandas DataFrame, use the `toPandas()` command to convert the DataFrame.

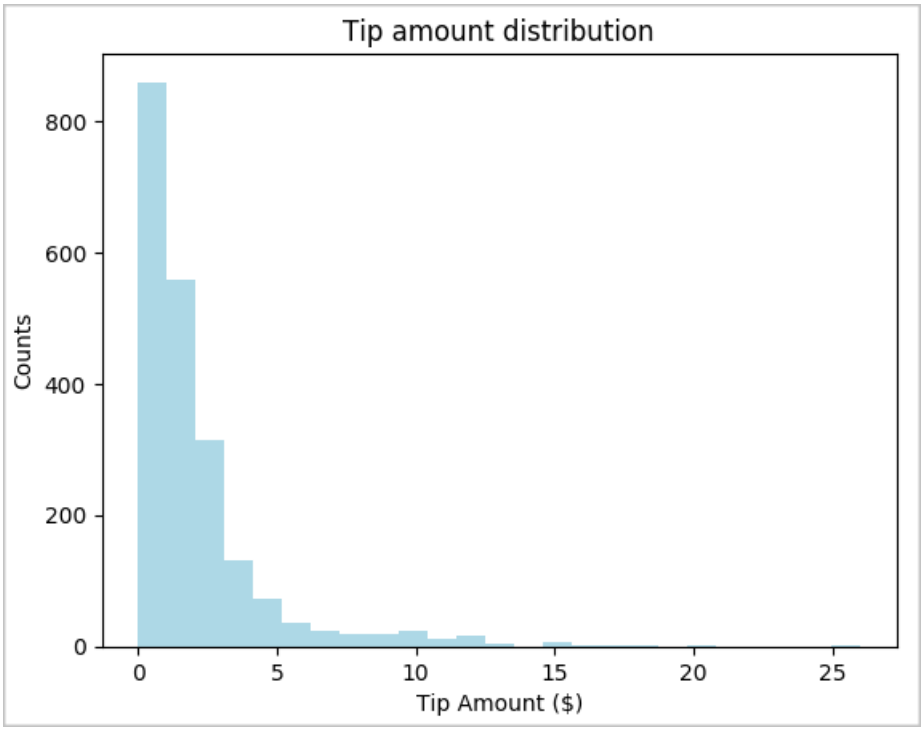
```
# To make development easier, faster, and less expensive, downsample for now
sampled_taxi_df = filtered_df.sample(True, 0.001, seed=1234)

# The charting package needs a Pandas DataFrame or NumPy array to do the conversion
sampled_taxi_pd_df = sampled_taxi_df.toPandas()
```

2. We want to understand the distribution of tips in our dataset. We'll use Matplotlib to create a histogram that shows the distribution of tip amount and count. Based on the distribution, we can see that tips are skewed toward amounts less than or equal to $10.

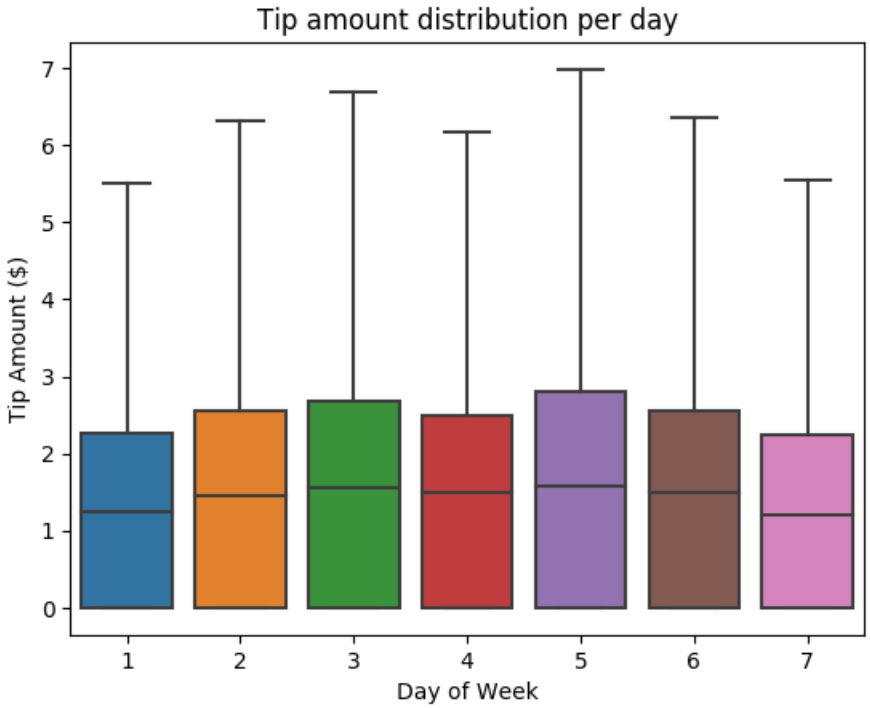
```
# Look at a histogram of tips by count by using Matplotlib

ax1 = sampled_taxi_pd_df['tipAmount'].plot(kind='hist', bins=25, facecolor='lightblue')
ax1.set_title('Tip amount distribution')
ax1.set_xlabel('Tip Amount ($)')
ax1.set_ylabel('Counts')
plt.suptitle('')
plt.show()
```



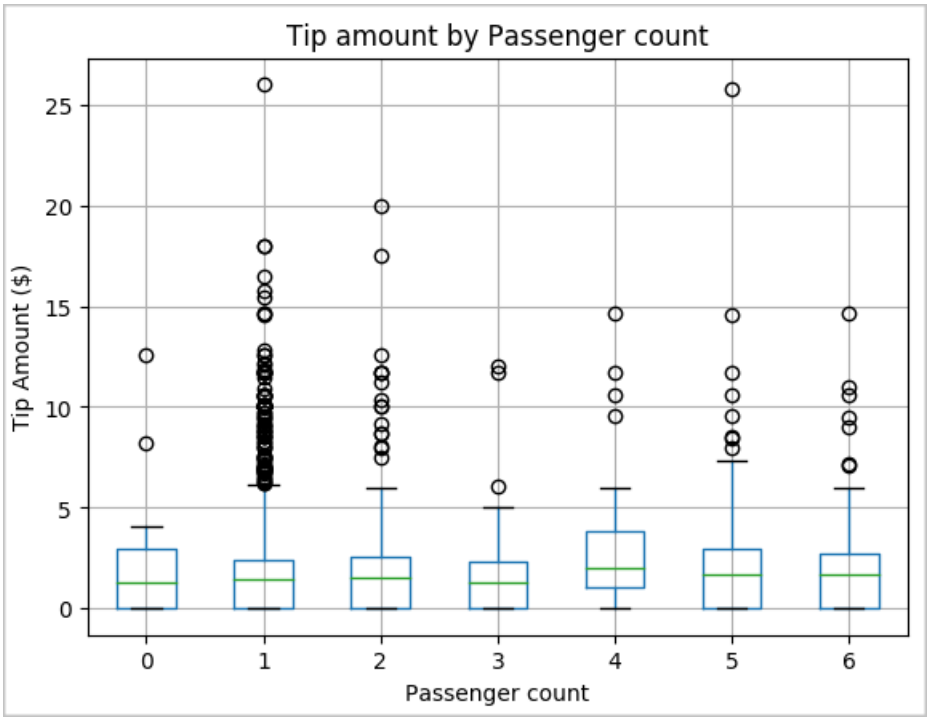
3. Next, we want to understand the relationship between the tips for a given trip and the day of the week. Use Seaborn to create a box plot that summarizes the trends for each day of the week.

```
# View the distribution of tips by day of week using Seaborn
ax = sns.boxplot(x="day_of_week", y="tipAmount",data=sampled_taxi_pd_df, showfliers = False)
ax.set_title('Tip amount distribution per day')
ax.set_xlabel('Day of Week')
ax.set_ylabel('Tip Amount ($)')
plt.show()
```



4. Another hypothesis of ours might be that there's a positive relationship between the number of passengers and the total taxi tip amount. To verify this relationship, run the following code to generate a box plot that illustrates the distribution of tips for each passenger count.

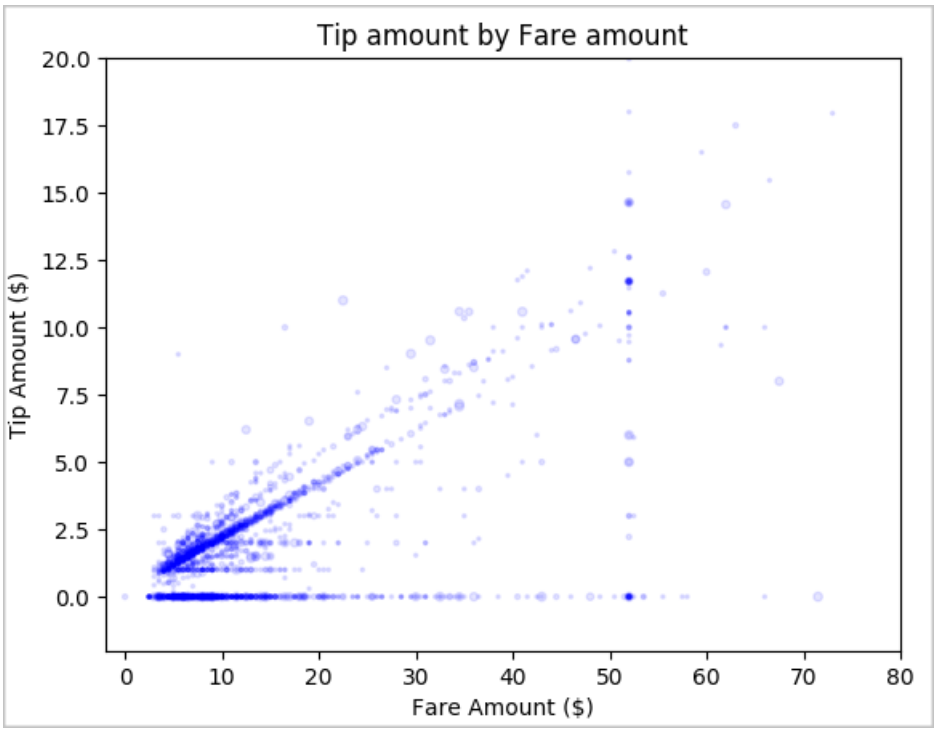
```
# How many passengers tipped by various amounts
ax2 = sampled_taxi_pd_df.boxplot(column=['tipAmount'], by=['passengerCount'])
ax2.set_title('Tip amount by Passenger count')
ax2.set_xlabel('Passenger count')
ax2.set_ylabel('Tip Amount ($)')
ax2.set_ylim(0,30)
plt.suptitle('')
plt.show()
```



5. Last, we want to understand the relationship between the fare amount and the tip amount. Based on the results, we can see that there are several observations where people don't tip. However, we also see a positive relationship between the overall fare and tip amounts.

```
# Look at the relationship between fare and tip amounts

ax = sampled_taxi_pd_df.plot(kind='scatter', x= 'fareAmount', y = 'tipAmount', c='blue', alpha =
0.10, s=2.5*(sampled_taxi_pd_df['passengerCount']))
ax.set_title('Tip amount by Fare amount')
ax.set_xlabel('Fare Amount ($)')
ax.set_ylabel('Tip Amount ($)')
plt.axis([-2, 80, -2, 20])
plt.suptitle('')
plt.show()
```



Shut down the Spark instance

After you finish running the application, shut down the notebook to release the resources. Either close the tab or select **End Session** from the status panel at the bottom of the notebook.

Tutorial: Build a machine learning app with Apache Spark MLlib and Azure Synapse Analytics

8/19/2022 • 8 minutes to read • Edit Online

In this article, you'll learn how to use Apache Spark MLlib to create a machine learning application that does simple predictive analysis on an Azure open dataset. Spark provides built-in machine learning libraries. This example uses *classification* through logistic regression.

SparkML and MLlib are core Spark libraries that provide many utilities that are useful for machine learning tasks, including utilities that are suitable for:

- Classification
- Regression
- Clustering
- Topic modeling
- Singular value decomposition (SVD) and principal component analysis (PCA)
- Hypothesis testing and calculating sample statistics

Understand classification and logistic regression

Classification, a popular machine learning task, is the process of sorting input data into categories. It's the job of a classification algorithm to figure out how to assign *labels* to input data that you provide. For example, you can think of a machine learning algorithm that accepts stock information as input and divide the stock into two categories: stocks that you should sell and stocks that you should keep.

Logistic regression is an algorithm that you can use for classification. Spark's logistic regression API is useful for *binary classification*, or classifying input data into one of two groups. For more information about logistic regression, see Wikipedia.

In summary, the process of logistic regression produces a *logistic function* that you can use to predict the probability that an input vector belongs in one group or the other.

Predictive analysis example on NYC taxi data

In this example, you use Spark to perform some predictive analysis on taxi-trip tip data from New York. The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips, including information about each trip, the start and end time and locations, the cost, and other interesting attributes.

> **IMPORTANT**
> There might be additional charges for pulling this data from its storage location.

In the following steps, you develop a model to predict whether a particular trip includes a tip or not.

Create an Apache Spark machine learning model

1. Create a notebook by using the PySpark kernel. For instructions, see Create a notebook.

2. Import the types required for this application. Copy and paste the following code into an empty cell, and

then press Shift+Enter. Or run the cell by using the blue play icon to the left of the code.

```
import matplotlib.pyplot as plt
from datetime import datetime
from dateutil import parser
from pyspark.sql.functions import unix_timestamp, date_format, col, when
from pyspark.ml import Pipeline
from pyspark.ml import PipelineModel
from pyspark.ml.feature import RFormula
from pyspark.ml.feature import OneHotEncoder, StringIndexer, VectorIndexer
from pyspark.ml.classification import LogisticRegression
from pyspark.mllib.evaluation import BinaryClassificationMetrics
from pyspark.ml.evaluation import BinaryClassificationEvaluator
```

Because of the PySpark kernel, you don't need to create any contexts explicitly. The Spark context is automatically created for you when you run the first code cell.

Construct the input DataFrame

Because the raw data is in a Parquet format, you can use the Spark context to pull the file into memory as a DataFrame directly. Although the code in the following steps uses the default options, it's possible to force mapping of data types and other schema attributes if needed.

1. Run the following lines to create a Spark DataFrame by pasting the code into a new cell. This step retrieves the data via the Open Datasets API. Pulling all of this data generates about 1.5 billion rows.

   Depending on the size of your serverless Apache Spark pool, the raw data might be too large or take too much time to operate on. You can filter this data down to something smaller. The following code example uses `start_date` and `end_date` to apply a filter that returns a single month of data.

   ```
   from azureml.opendatasets import NycTlcYellow

   end_date = parser.parse('2018-06-06')
   start_date = parser.parse('2018-05-01')
   nyc_tlc = NycTlcYellow(start_date=start_date, end_date=end_date)
   filtered_df = nyc_tlc.to_spark_dataframe()
   ```

2. The downside to simple filtering is that, from a statistical perspective, it might introduce bias into the data. Another approach is to use the sampling built into Spark.

   The following code reduces the dataset to about 2,000 rows, if it's applied after the preceding code. You can use this sampling step instead of the simple filter or in conjunction with the simple filter.

   ```
   # To make development easier, faster, and less expensive, downsample for now
   sampled_taxi_df = filtered_df.sample(True, 0.001, seed=1234)
   ```

3. It's now possible to look at the data to see what was read. It's normally better to review data with a subset rather than the full set, depending on the size of the dataset.

   The following code offers two ways to view the data. The first way is basic. The second way provides a much richer grid experience, along with the capability to visualize the data graphically.

   ```
   #sampled_taxi_df.show(5)
   display(sampled_taxi_df)
   ```

4. Depending on the size of the generated dataset, and your need to experiment or run the notebook many

times, you might want to cache the dataset locally in the workspace. There are three ways to perform explicit caching:

- Save the DataFrame locally as a file.
- Save the DataFrame as a temporary table or view.
- Save the DataFrame as a permanent table.

The first two of these approaches are included in the following code examples.

Creating a temporary table or view provides different access paths to the data, but it lasts only for the duration of the Spark instance session.

```
sampled_taxi_df.createOrReplaceTempView("nytaxi")
```

Prepare the data

The data in its raw form is often not suitable for passing directly to a model. You must perform a series of actions on the data to get it into a state where the model can consume it.

In the following code, you perform four classes of operations:

- The removal of outliers or incorrect values through filtering.
- The removal of columns, which are not needed.
- The creation of new columns derived from the raw data to make the model work more effectively. This operation is sometimes called featurization.
- Labeling. Because you're undertaking binary classification (will there be a tip or not on a given trip), there's a need to convert the tip amount into a 0 or 1 value.

```
taxi_df = sampled_taxi_df.select('totalAmount', 'fareAmount', 'tipAmount', 'paymentType', 'rateCodeId',
'passengerCount'\
                                , 'tripDistance', 'tpepPickupDateTime', 'tpepDropoffDateTime'\
                                , date_format('tpepPickupDateTime', 'hh').alias('pickupHour')\
                                , date_format('tpepPickupDateTime', 'EEEE').alias('weekdayString')\
                                , (unix_timestamp(col('tpepDropoffDateTime')) -
unix_timestamp(col('tpepPickupDateTime'))).alias('tripTimeSecs')\
                                , (when(col('tipAmount') > 0, 1).otherwise(0)).alias('tipped')
                                )\
                        .filter((sampled_taxi_df.passengerCount > 0) & (sampled_taxi_df.passengerCount < 8)\
                                & (sampled_taxi_df.tipAmount >= 0) & (sampled_taxi_df.tipAmount <= 25)\
                                & (sampled_taxi_df.fareAmount >= 1) & (sampled_taxi_df.fareAmount <= 250)\
                                & (sampled_taxi_df.tipAmount < sampled_taxi_df.fareAmount)\
                                & (sampled_taxi_df.tripDistance > 0) & (sampled_taxi_df.tripDistance <=
100)\
                                & (sampled_taxi_df.rateCodeId <= 5)
                                & (sampled_taxi_df.paymentType.isin({"1", "2"}))
                                )
```

You then make a second pass over the data to add the final features.

```
taxi_featurised_df = taxi_df.select('totalAmount', 'fareAmount', 'tipAmount', 'paymentType',
'passengerCount'\
                                                , 'tripDistance', 'weekdayString',
'pickupHour','tripTimeSecs','tipped'\
                                                , when((taxi_df.pickupHour <= 6) | (taxi_df.pickupHour >=
20),"Night")\
                                                .when((taxi_df.pickupHour >= 7) & (taxi_df.pickupHour <=
10), "AMRush")\
                                                .when((taxi_df.pickupHour >= 11) & (taxi_df.pickupHour <=
15), "Afternoon")\
                                                .when((taxi_df.pickupHour >= 16) & (taxi_df.pickupHour <=
19), "PMRush")\
                                                .otherwise(0).alias('trafficTimeBins')
                                              )\
                                       .filter((taxi_df.tripTimeSecs >= 30) & (taxi_df.tripTimeSecs <=
7200))
```

Create a logistic regression model

The final task is to convert the labeled data into a format that can be analyzed through logistic regression. The input to a logistic regression algorithm needs to be a set of *label/feature vector pairs*, where the *feature vector* is a vector of numbers that represent the input point.

So, you need to convert the categorical columns into numbers. Specifically, you need to convert the `trafficTimeBins` and `weekdayString` columns into integer representations. There are multiple approaches to performing the conversion. The following example takes the `OneHotEncoder` approach, which is common.

```
# Because the sample uses an algorithm that works only with numeric features, convert them so they can be
consumed
sI1 = StringIndexer(inputCol="trafficTimeBins", outputCol="trafficTimeBinsIndex")
en1 = OneHotEncoder(dropLast=False, inputCol="trafficTimeBinsIndex", outputCol="trafficTimeBinsVec")
sI2 = StringIndexer(inputCol="weekdayString", outputCol="weekdayIndex")
en2 = OneHotEncoder(dropLast=False, inputCol="weekdayIndex", outputCol="weekdayVec")

# Create a new DataFrame that has had the encodings applied
encoded_final_df = Pipeline(stages=[sI1, en1, sI2,
en2]).fit(taxi_featurised_df).transform(taxi_featurised_df)
```

This action results in a new DataFrame with all columns in the right format to train a model.

Train a logistic regression model

The first task is to split the dataset into a training set and a testing or validation set. The split here is arbitrary. Experiment with different split settings to see if they affect the model.

```
# Decide on the split between training and testing data from the DataFrame
trainingFraction = 0.7
testingFraction = (1-trainingFraction)
seed = 1234

# Split the DataFrame into test and training DataFrames
train_data_df, test_data_df = encoded_final_df.randomSplit([trainingFraction, testingFraction], seed=seed)
```

Now that there are two DataFrames, the next task is to create the model formula and run it against the training DataFrame. Then you can validate against the testing DataFrame. Experiment with different versions of the model formula to see the impact of different combinations.

> **NOTE**
>
> To save the model, assign the *Storage Blob Data Contributor* role to the Azure SQL Database server resource scope. For detailed steps, see Assign Azure roles using the Azure portal. Only members with owner privileges can perform this step.

```
## Create a new logistic regression object for the model
logReg = LogisticRegression(maxIter=10, regParam=0.3, labelCol = 'tipped')

## The formula for the model
classFormula = RFormula(formula="tipped ~ pickupHour + weekdayVec + passengerCount + tripTimeSecs +
tripDistance + fareAmount + paymentType+ trafficTimeBinsVec")

## Undertake training and create a logistic regression model
lrModel = Pipeline(stages=[classFormula, logReg]).fit(train_data_df)

## Saving the model is optional, but it's another form of inter-session cache
datestamp = datetime.now().strftime('%m-%d-%Y-%s')
fileName = "lrModel_" + datestamp
logRegDirfilename = fileName
lrModel.save(logRegDirfilename)

## Predict tip 1/0 (yes/no) on the test dataset; evaluation using area under ROC
predictions = lrModel.transform(test_data_df)
predictionAndLabels = predictions.select("label","prediction").rdd
metrics = BinaryClassificationMetrics(predictionAndLabels)
print("Area under ROC = %s" % metrics.areaUnderROC)
```

The output from this cell is:

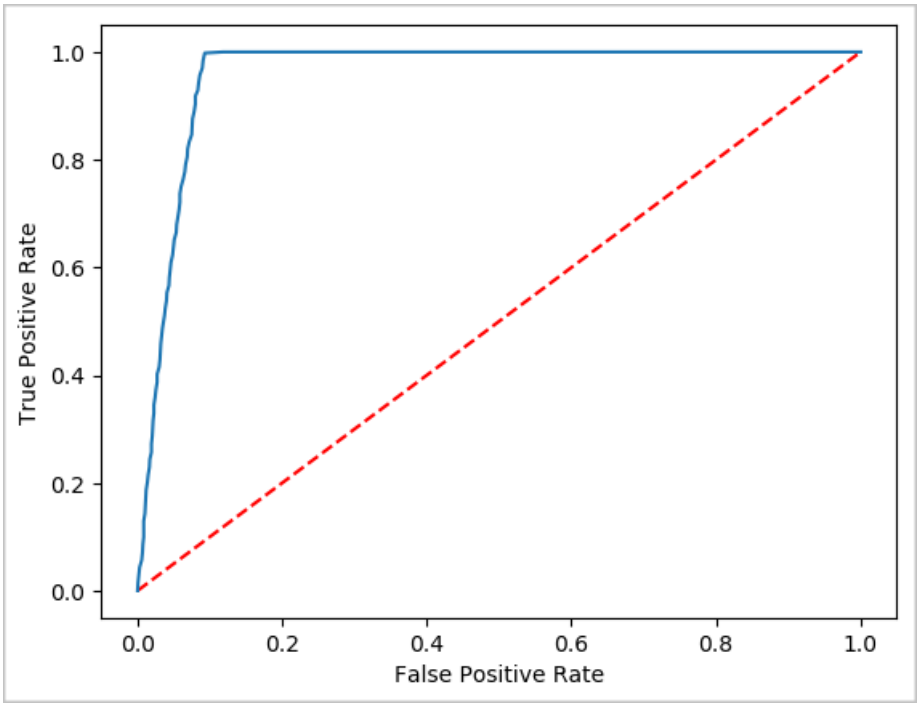
```
Area under ROC = 0.9779470729751403
```

Create a visual representation of the prediction

You can now construct a final visualization to help you reason about the results of this test. An ROC curve is one way to review the result.

```
## Plot the ROC curve; no need for pandas, because this uses the modelSummary object
modelSummary = lrModel.stages[-1].summary

plt.plot([0, 1], [0, 1], 'r--')
plt.plot(modelSummary.roc.select('FPR').collect(),
         modelSummary.roc.select('TPR').collect())
plt.xlabel('False Positive Rate')
plt.ylabel('True Positive Rate')
plt.show()
```



Shut down the Spark instance

After you finish running the application, shut down the notebook to release the resources by closing the tab. Or select **End Session** from the status panel at the bottom of the notebook.

Tutorial: Train a machine learning model without code

8/19/2022 • 5 minutes to read • Edit Online

You can enrich your data in Spark tables with new machine learning models that you train by using automated machine learning. In Azure Synapse Analytics, you can select a Spark table in the workspace to use as a training dataset for building machine learning models, and you can do this in a code-free experience.

In this tutorial, you learn how to train machine learning models by using a code-free experience in Synapse Studio. Synapse Studio is a feature of Azure Synapse Analytics.

You'll use automated machine learning in Azure Machine Learning, instead of coding the experience manually. The type of model that you train depends on the problem you're trying to solve. For this tutorial, you'll use a regression model to predict taxi fares from the New York City taxi dataset.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- An Azure Synapse Analytics workspace. Ensure that it has an Azure Data Lake Storage Gen2 storage account configured as the default storage. For the Data Lake Storage Gen2 file system that you work with, ensure that you're the *Storage Blob Data Contributor*.
- An Apache Spark pool (version 2.4) in your Azure Synapse Analytics workspace. For details, see Quickstart: Create a serverless Apache Spark pool using Synapse Studio.
- An Azure Machine Learning linked service in your Azure Synapse Analytics workspace. For details, see Quickstart: Create a new Azure Machine Learning linked service in Azure Synapse Analytics.

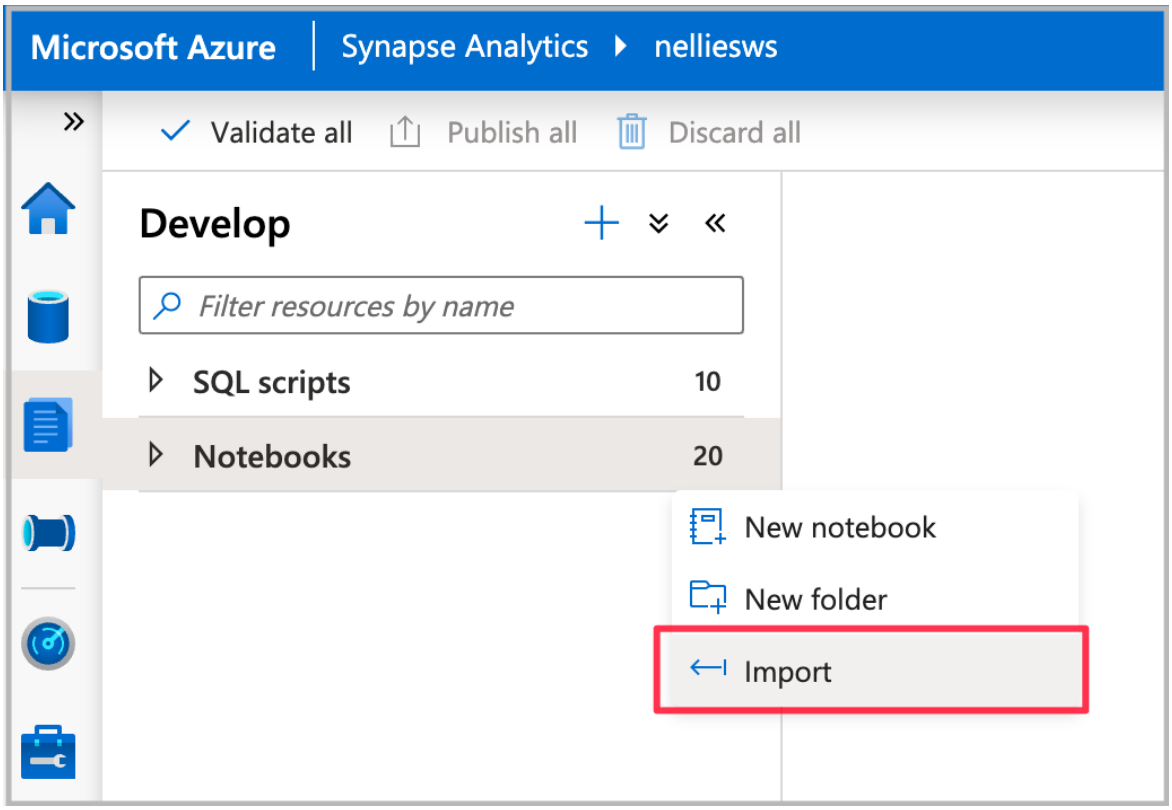
Sign in to the Azure portal

Sign in to the Azure portal.

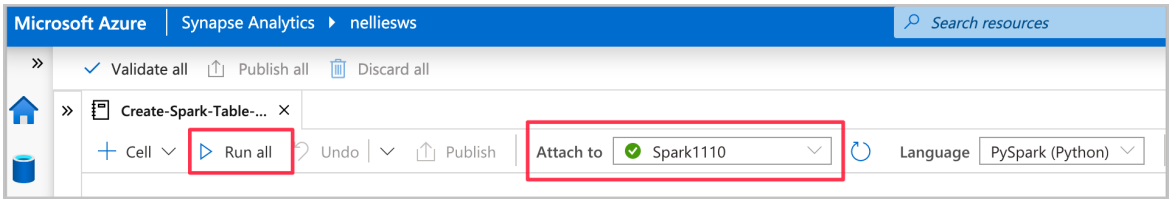
Create a Spark table for the training dataset

For this tutorial, you need a Spark table. The following notebook creates one:

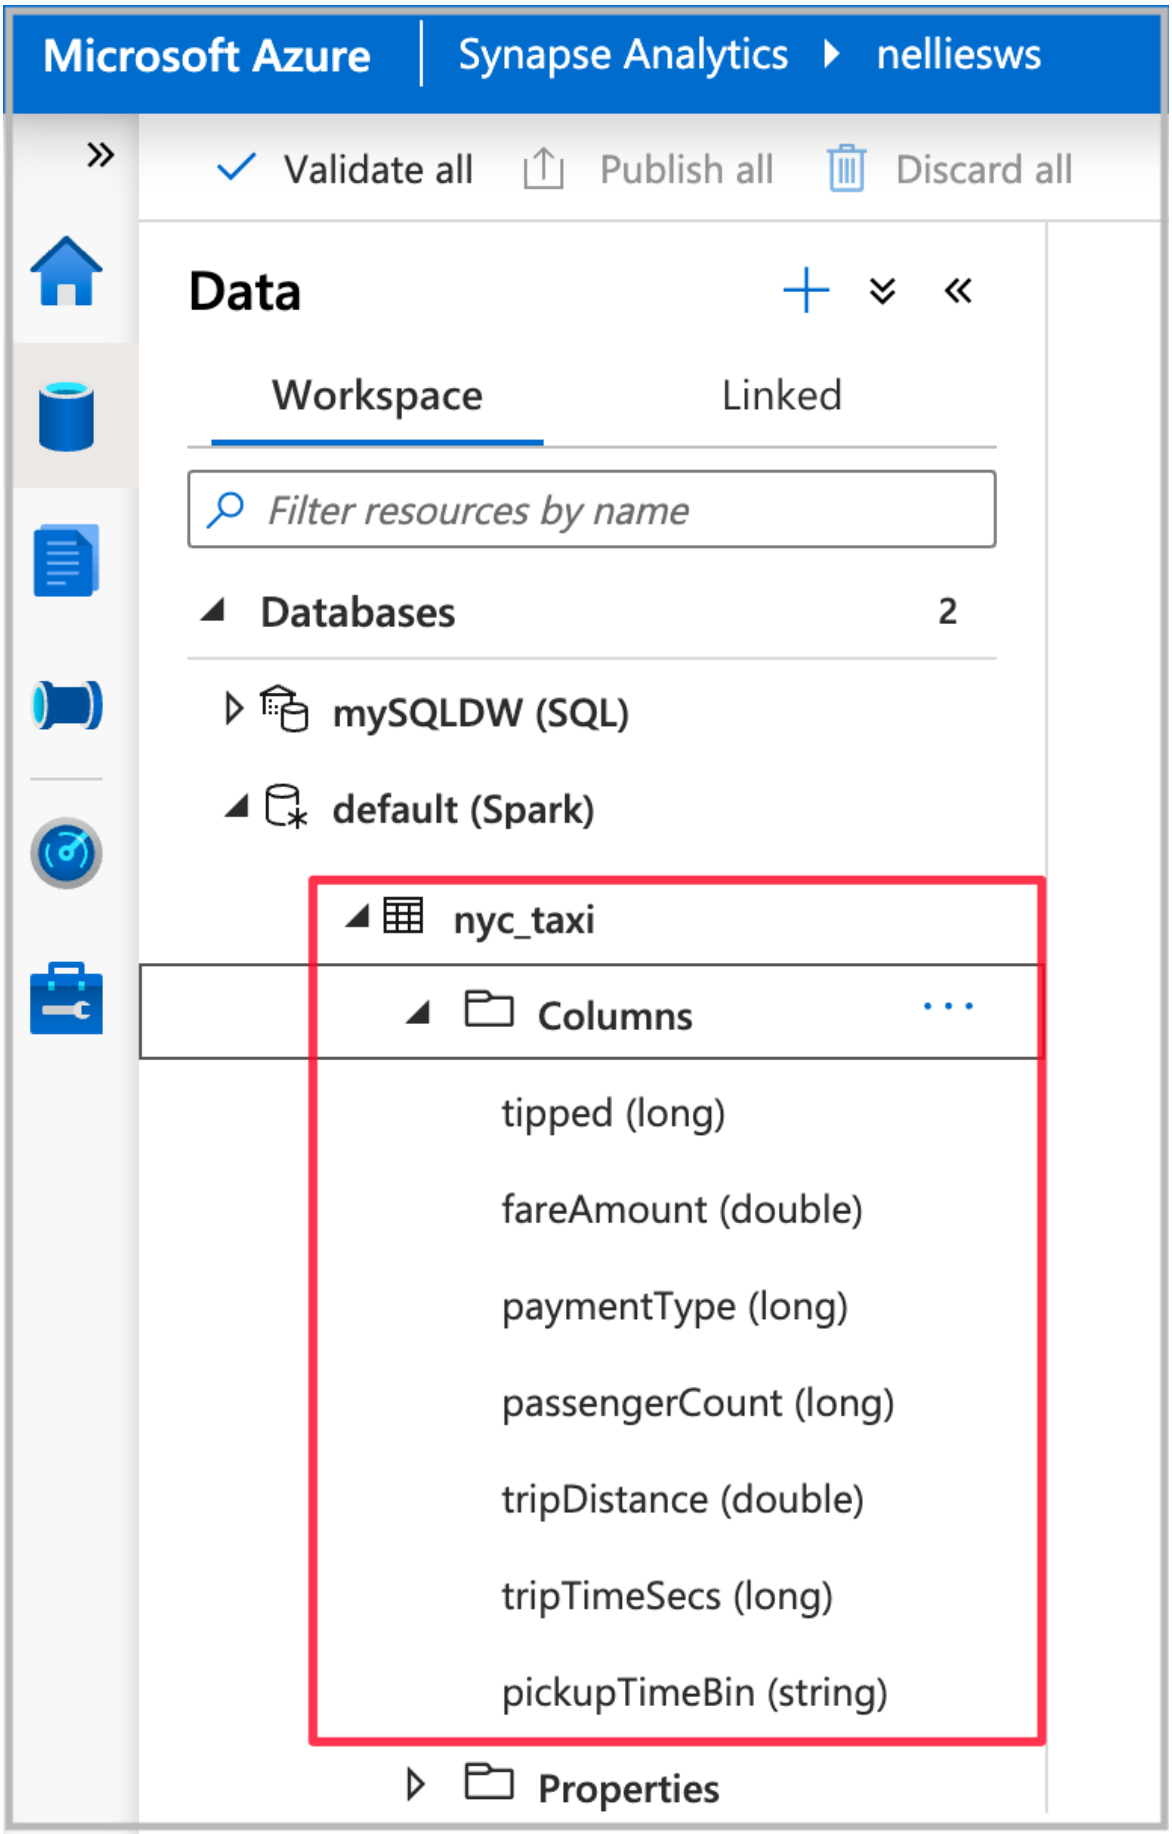
1. Download the notebook Create-Spark-Table-NYCTaxi- Data.ipynb.
2. Import the notebook to Synapse Studio.



3. Select the Spark pool that you want to use, and then select **Run all**. This step gets New York taxi data from the open dataset and saves the data to your default Spark database.

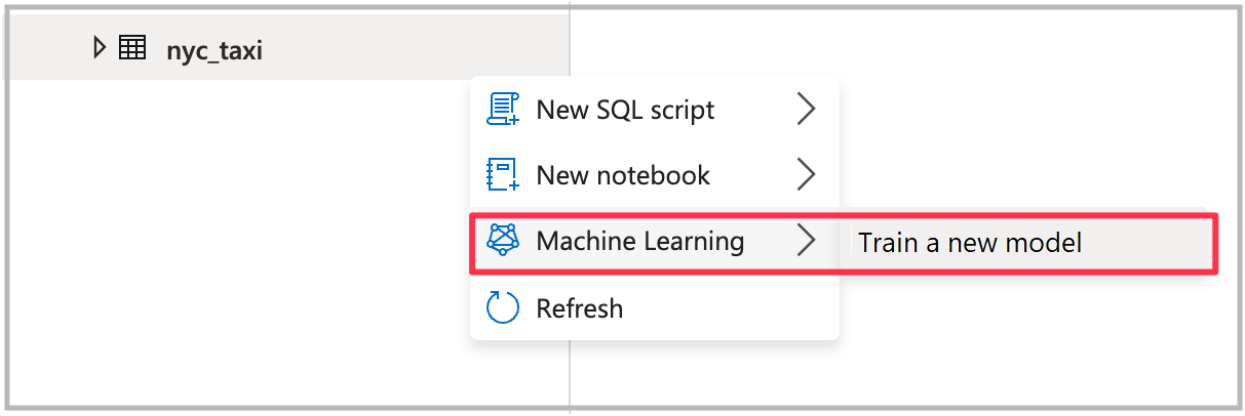


4. After the notebook run has completed, you see a new Spark table under the default Spark database. From **Data**, find the table named **nyc_taxi**.



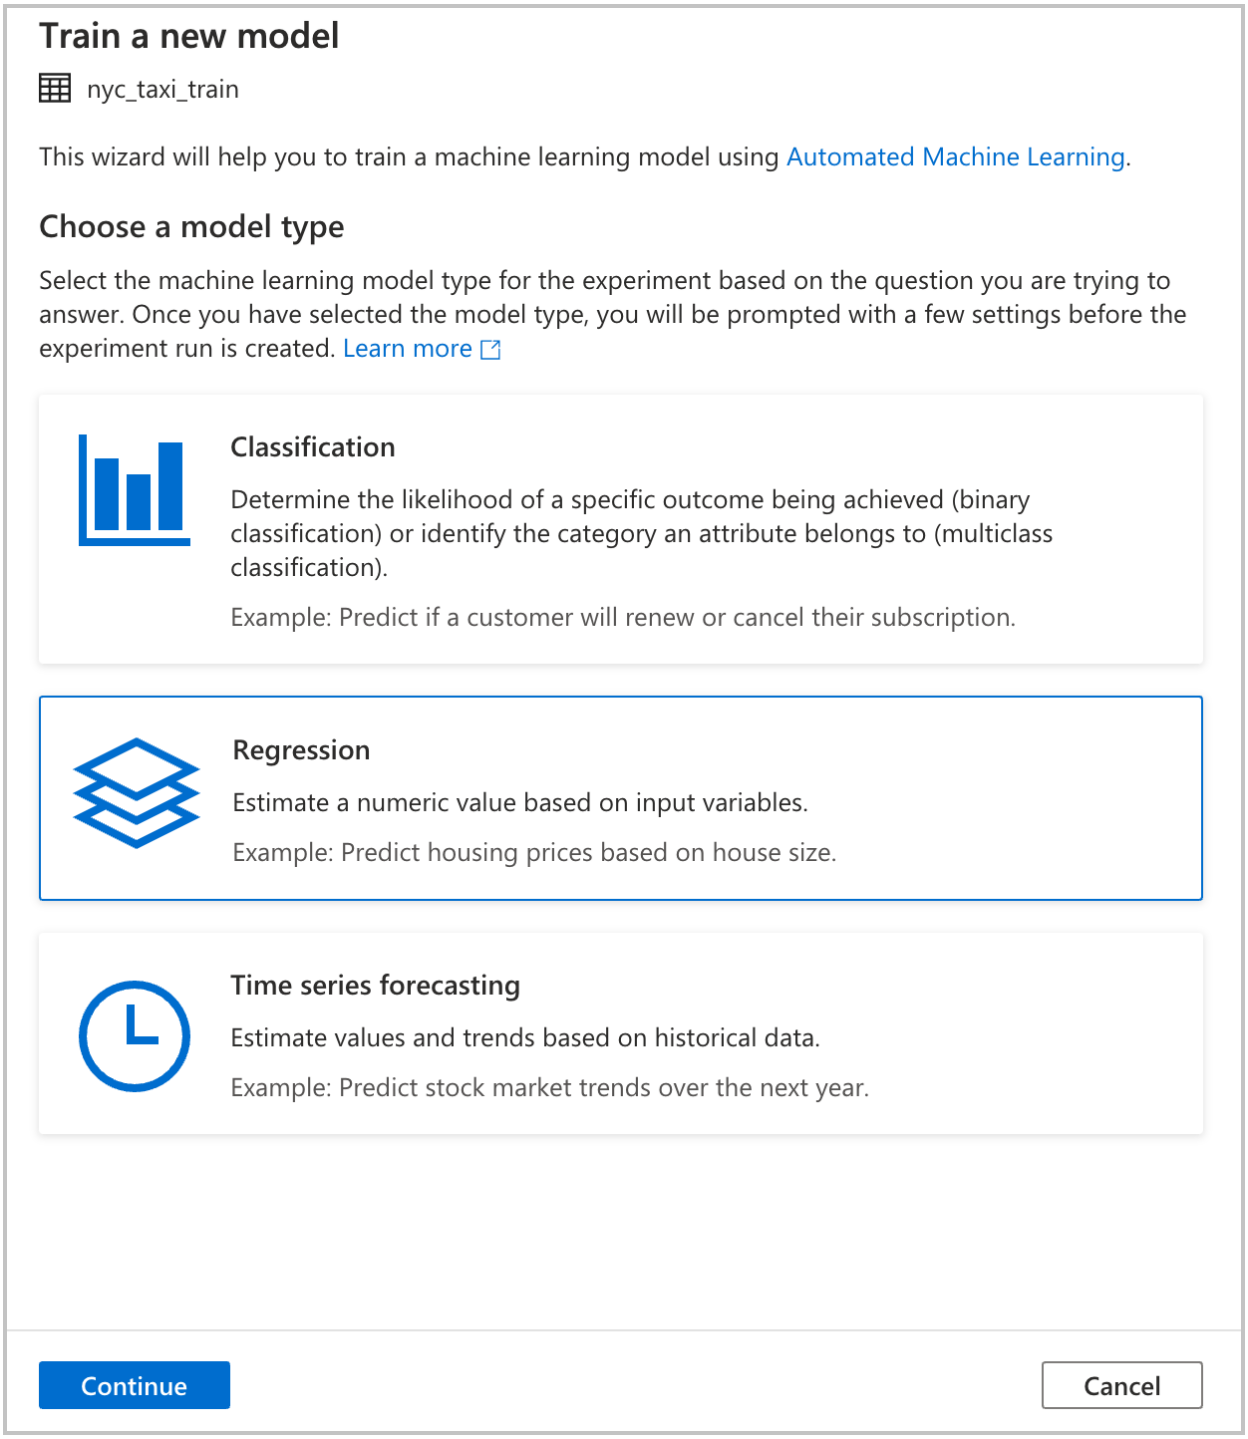
Open the automated machine learning wizard

To open the wizard, right-click the Spark table that you created in the previous step. Then select **Machine Learning** > **Train a new model**.



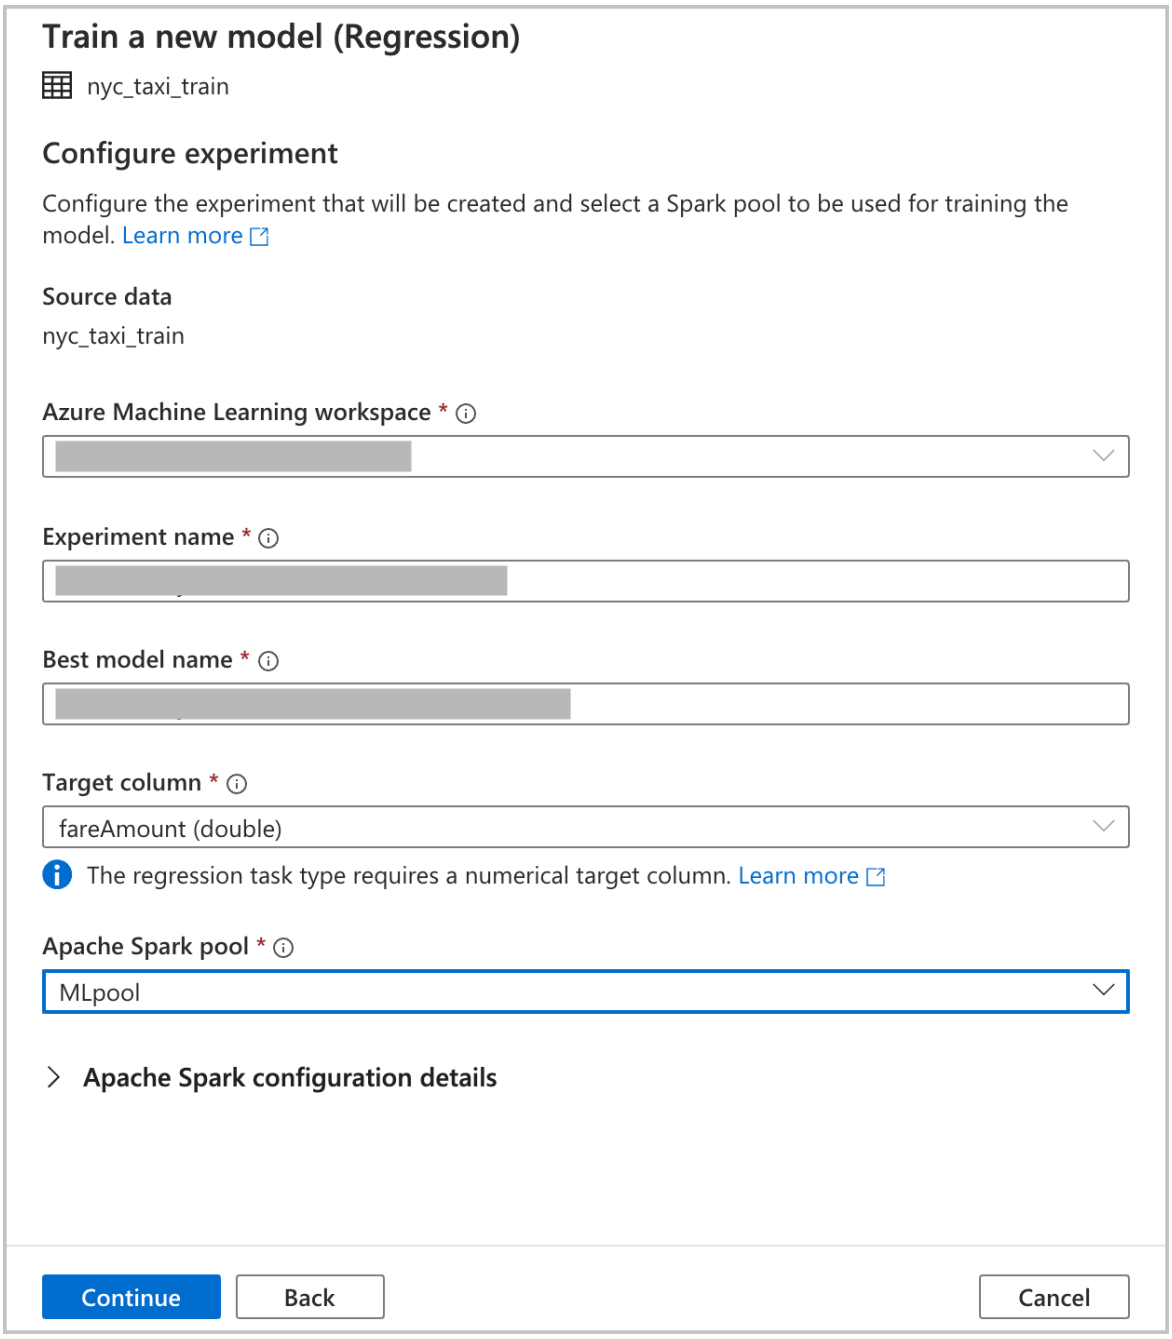
Choose a model type

Select the machine learning model type for the experiment, based on the question you're trying to answer. Because the value you're trying to predict is numeric (taxi fares), select **Regression** here. Then select **Continue**.



Configure the experiment

1. Provide configuration details for creating an automated machine learning experiment run in Azure Machine Learning. This run trains multiple models. The best model from a successful run is registered in the Azure Machine Learning model registry.



- **Azure Machine Learning workspace**: An Azure Machine Learning workspace is required for creating an automated machine learning experiment run. You also need to link your Azure Synapse Analytics workspace with the Azure Machine Learning workspace by using a linked service. After you've fulfilled all the prerequisites, you can specify the Azure Machine Learning workspace that you want to use for this automated run.
- **Experiment name**: Specify the experiment name. When you submit an automated machine learning run, you provide an experiment name. Information for the run is stored under that experiment in the Azure Machine Learning workspace. This experience creates a new experiment by default and generates a proposed name, but you can also provide the name of an existing experiment.
- **Best model name**: Specify the name of the best model from the automated run. The best model

is given this name and saved in the Azure Machine Learning model registry automatically after this run. An automated machine learning run creates many machine learning models. Based on the primary metric that you select in a later step, those models can be compared and the best model can be selected.

- **Target column**: This is what the model will be trained to predict. Choose the column in the dataset that contains the data you want to predict. For this tutorial, select the numeric column `fareAmount` as the target column.
- **Spark pool**: Specify the Spark pool that you want to use for the automated experiment run. The computations are run on the pool that you specify.
- **Spark configuration details**: In addition to the Spark pool, you have the option to provide session configuration details.

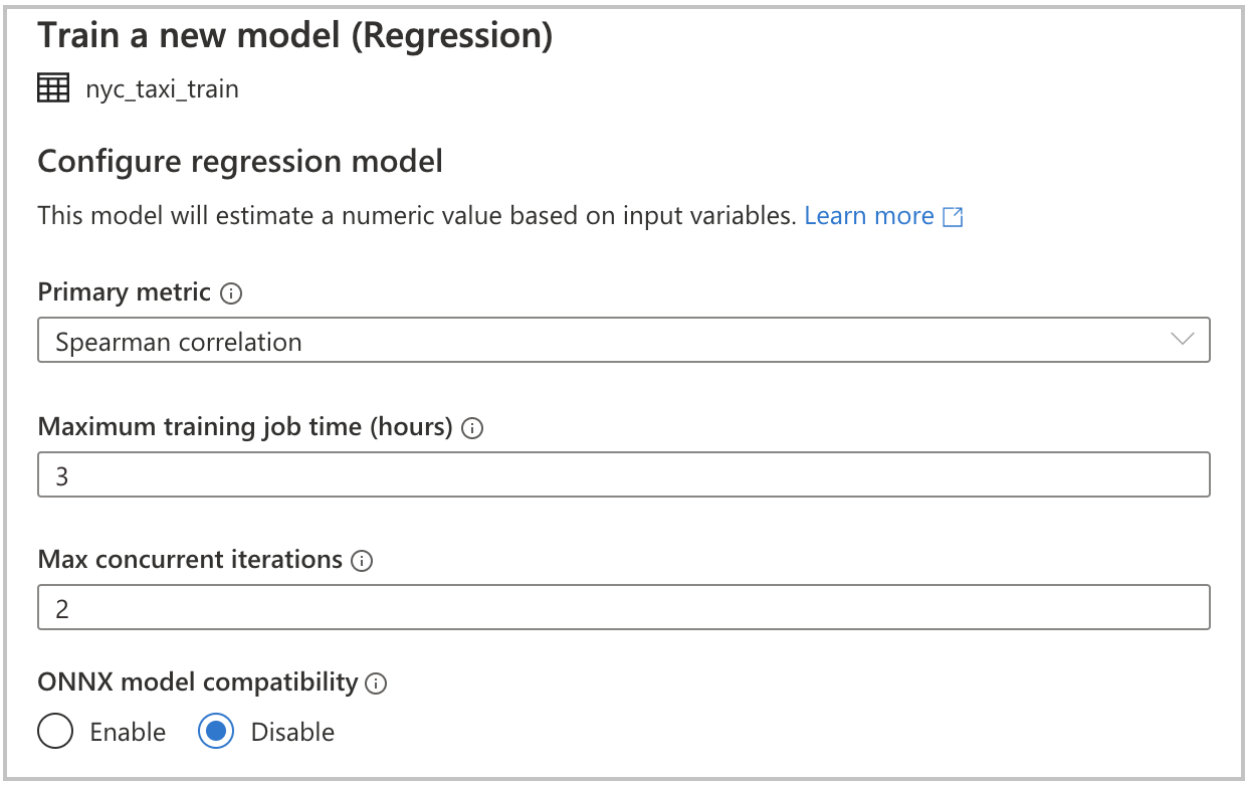
2. Select **Continue**.

Configure the model

Because you selected **Regression** as your model type in the previous section, the following configurations are available (these are also available for the **Classification** model type):

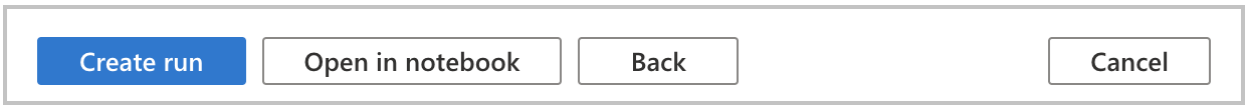
- **Primary metric**: Enter the metric that measures how well the model is doing. You use this metric to compare different models created in the automated run and determine which model performed best.
- **Training job time (hours)**: Specify the maximum amount of time, in hours, for an experiment to run and train models. Note that you can also provide values less than 1 (for example, **0.5**).
- **Max concurrent iterations**: Choose the maximum number of iterations that run in parallel.
- **ONNX model compatibility**: If you enable this option, the models trained by automated machine learning are converted to the ONNX format. This is particularly relevant if you want to use the model for scoring in Azure Synapse Analytics SQL pools.

These settings all have a default value that you can customize.



Start a run

After all the required configurations are done, you can start your automated run. You can choose to create a run directly by selecting **Create run** - this starts the run without code. Alternatively, if you prefer code, you can select **Open in notebook** - this opens a notebook containing the code that creates the run so you can view the code and start the run yourself.



> **NOTE**
> If you selected **Time series forecasting** as your model type in the previous section, you must make additional configurations. Forecasting also doesn't support ONNX model compatibility.

Create a run directly

To start your automated machine learning run directly, select **Create Run**. You see a notification that indicates the run is starting. Then you see another notification that indicates success. You can also check the status in Azure Machine Learning by selecting the link in the notification.

Create a run with a notebook

To generate a notebook, select **Open In Notebook**. This gives you an opportunity to add settings or otherwise modify the code for your automated machine learning run. When you're ready to run the code, select **Run all**.

Monitor the run

After you've successfully submitted the run, you see a link to the experiment run in the Azure Machine Learning workspace in the notebook output. Select the link to monitor your automated run in Azure Machine Learning.

Tutorial: Train a model in Python with automated machine learning

8/19/2022 • 10 minutes to read • Edit Online

Azure Machine Learning is a cloud-based environment that allows you to train, deploy, automate, manage, and track machine learning models.

In this tutorial, you use automated machine learning in Azure Machine Learning to create a regression model to predict taxi fare prices. This process arrives at the best model by accepting training data and configuration settings, and automatically iterating through combinations of different methods, models, and hyperparameter settings.

In this tutorial, you learn how to:

- Download the data by using Apache Spark and Azure Open Datasets.
- Transform and clean data by using Apache Spark DataFrames.
- Train a regression model in automated machine learning.
- Calculate model accuracy.

Before you begin

- Create a serverless Apache Spark pool by following the Create a serverless Apache Spark pool quickstart.
- Complete the Azure Machine Learning workspace setup tutorial if you don't have an existing Azure Machine Learning workspace.

Understand regression models

Regression models predict numerical output values based on independent predictors. In regression, the objective is to help establish the relationship among those independent predictor variables by estimating how one variable affects the others.

Example based on New York City taxi data

In this example, you use Spark to perform some analysis on taxi-trip tip data from New York City (NYC). The data is available through Azure Open Datasets. This subset of the dataset contains information about yellow taxi trips, including information about each trip, the start and end time and locations, and the cost.

> **IMPORTANT**
> There might be additional charges for pulling this data from its storage location. In the following steps, you develop a model to predict NYC taxi fare prices.

Download and prepare the data

Here's how:

1. Create a notebook by using the PySpark kernel. For instructions, see Create a notebook.

> **NOTE**
>
> Because of the PySpark kernel, you don't need to create any contexts explicitly. The Spark context is automatically created for you when you run the first code cell.

2. Because the raw data is in a Parquet format, you can use the Spark context to pull the file directly into memory as a DataFrame. Create a Spark DataFrame by retrieving the data via the Open Datasets API. Here, you use the Spark DataFrame `schema on read` properties to infer the datatypes and schema.

```
blob_account_name = "azureopendatastorage"
blob_container_name = "nyctlc"
blob_relative_path = "yellow"
blob_sas_token = r""

# Allow Spark to read from the blob remotely
wasbs_path = 'wasbs://%s@%s.blob.core.windows.net/%s' % (blob_container_name, blob_account_name,
blob_relative_path)
spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name,
blob_account_name),blob_sas_token)

# Spark read parquet; note that it won't load any data yet
df = spark.read.parquet(wasbs_path)
```

3. Depending on the size of your Spark pool, the raw data might be too large or take too much time to operate on. You can filter this data down to something smaller, like a month of data, by using the `start_date` and `end_date` filters. After you filter a DataFrame, you also run the `describe()` function on the new DataFrame to see summary statistics for each field.

   Based on the summary statistics, you can see that there are some irregularities in the data. For example, the statistics show that the minimum trip distance is less than 0. You need to filter out these irregular data points.

```
# Create an ingestion filter
start_date = '2015-01-01 00:00:00'
end_date = '2015-12-31 00:00:00'

filtered_df = df.filter('tpepPickupDateTime > "' + start_date + '" and tpepPickupDateTime< "' +
end_date + '"')

filtered_df.describe().show()
```

4. Generate features from the dataset by selecting a set of columns and creating various time-based features from the pickup `datetime` field. Filter out the outliers that were identified from the earlier step, and then remove the last few columns because they're unnecessary for training.

```
from datetime import datetime
from pyspark.sql.functions import *

# To make development easier, faster, and less expensive, downsample for now
sampled_taxi_df = filtered_df.sample(True, 0.001, seed=1234)

taxi_df = sampled_taxi_df.select('vendorID', 'passengerCount', 'tripDistance',  'startLon',
'startLat', 'endLon' \
                                 , 'endLat', 'paymentType', 'fareAmount', 'tipAmount'\
                                 , column('puMonth').alias('month_num') \
                                 , date_format('tpepPickupDateTime', 'hh').alias('hour_of_day')\
                                 , date_format('tpepPickupDateTime', 'EEEE').alias('day_of_week')\
                                 , dayofmonth(col('tpepPickupDateTime')).alias('day_of_month')
                                 ,(unix_timestamp(col('tpepDropoffDateTime')) -
unix_timestamp(col('tpepPickupDateTime'))).alias('trip_time'))\
                          .filter((sampled_taxi_df.passengerCount > 0) &
(sampled_taxi_df.passengerCount < 8)\
                                 & (sampled_taxi_df.tipAmount >= 0)\
                                 & (sampled_taxi_df.fareAmount >= 1) & (sampled_taxi_df.fareAmount <=
250)\
                                 & (sampled_taxi_df.tipAmount < sampled_taxi_df.fareAmount)\
                                 & (sampled_taxi_df.tripDistance > 0) & (sampled_taxi_df.tripDistance
<= 200)\
                                 & (sampled_taxi_df.rateCodeId <= 5)\
                                 & (sampled_taxi_df.paymentType.isin({"1", "2"})))
taxi_df.show(10)
```

As you can see, this will create a new DataFrame with additional columns for the day of the month, pickup hour, weekday, and total trip time.

Generate test and validation datasets

After you have your final dataset, you can split the data into training and test sets by using the `random_ split` function in Spark. By using the provided weights, this function randomly splits the data into the training dataset for model training and the validation dataset for testing.

```
# Random split dataset using Spark; convert Spark to pandas
training_data, validation_data = taxi_df.randomSplit([0.8,0.2], 223)
```

This step ensures that the data points to test the finished model haven't been used to train the model.

Connect to an Azure Machine Learning workspace

In Azure Machine Learning, a workspace is a class that accepts your Azure subscription and resource information. It also creates a cloud resource to monitor and track your model runs. In this step, you create a workspace object from the existing Azure Machine Learning workspace.

```
from azureml.core import Workspace

# Enter your subscription id, resource group, and workspace name.
subscription_id = "<enter your subscription ID>" #you should be owner or contributor
resource_group = "<enter your resource group>" #you should be owner or contributor
workspace_name = "<enter your workspace name>" #your workspace name

ws = Workspace(workspace_name = workspace_name,
               subscription_id = subscription_id,
               resource_group = resource_group)
```

Convert a DataFrame to an Azure Machine Learning dataset

To submit a remote experiment, convert your dataset into an Azure Machine Learning `TabularDatset` instance. TabularDataset represents data in a tabular format by parsing the provided files.

The following code gets the existing workspace and the default Azure Machine Learning datastore. It then passes the datastore and file locations to the path parameter to create a new `TabularDataset` instance.

```
import pandas
from azureml.core import Dataset

# Get the Azure Machine Learning default datastore
datastore = ws.get_default_datastore()
training_pd = training_data.toPandas().to_csv('training_pd.csv', index=False)

# Convert into an Azure Machine Learning tabular dataset
datastore.upload_files(files = ['training_pd.csv'],
                       target_path = 'train-dataset/tabular/',
                       overwrite = True,
                       show_progress = True)
dataset_training = Dataset.Tabular.from_delimited_files(path = [(datastore, 'train-
dataset/tabular/training_pd.csv')])
```

```
Uploading an estimated of 1 files
Uploading training_pd.csv
Uploaded training_pd.csv, 1 files out of an estimated total of 1
Uploaded 1 files
```

Submit an automated experiment

The following sections walk you through the process of submitting an automated machine learning experiment.

Define training settings

1. To submit an experiment, you need to define the experiment parameter and model settings for training. For the full list of settings, see Configure automated machine learning experiments in Python.

```
import logging

automl_settings = {
    "iteration_timeout_minutes": 10,
    "experiment_timeout_minutes": 30,
    "enable_early_stopping": True,
    "primary_metric": 'r2_score',
    "featurization": 'auto',
    "verbosity": logging.INFO,
    "n_cross_validations": 2}
```

2. Pass the defined training settings as a `kwargs` parameter to an `AutoMLConfig` object. Because you're using Spark, you must also pass the Spark context, which is automatically accessible by the `sc` variable. Additionally, you specify the training data and the type of model, which is regression in this case.

```
from azureml.train.automl import AutoMLConfig

automl_config = AutoMLConfig(task='regression',
                             debug_log='automated_ml_errors.log',
                             training_data = dataset_training,
                             spark_context = sc,
                             model_explainability = False,
                             label_column_name ="fareAmount",**automl_settings)
```

> **NOTE**
> Automated machine learning pre-processing steps become part of the underlying model. These steps include feature normalization, handling missing data, and converting text to numeric. When you're using the model for predictions, the same pre-processing steps applied during training are applied to your input data automatically.

Train the automatic regression model

Next, you create an experiment object in your Azure Machine Learning workspace. An experiment acts as a container for your individual runs.

```
from azureml.core.experiment import Experiment

# Start an experiment in Azure Machine Learning
experiment = Experiment(ws, "aml-synapse-regression")
tags = {"Synapse": "regression"}
local_run = experiment.submit(automl_config, show_output=True, tags = tags)

# Use the get_details function to retrieve the detailed output for the run.
run_details = local_run.get_details()
```

When the experiment has finished, the output returns details about the completed iterations. For each iteration, you see the model type, the run duration, and the training accuracy. The `BEST` field tracks the best-running training score based on your metric type.

```

        11    StackEnsemble                                 0:02:52       0.9600    0.9602
```

> **NOTE**
>
> After you submit the automated machine learning experiment, it runs various iterations and model types. This run typically takes 60 to 90 minutes.

Retrieve the best model

To select the best model from your iterations, use the `get_output` function to return the best run and fitted model. The following code retrieves the best run and fitted model for any logged metric or a particular iteration.

```
# Get best model
best_run, fitted_model = local_run.get_output()
```

Test model accuracy

1. To test the model accuracy, use the best model to run taxi fare predictions on the test dataset. The `predict` function uses the best model and predicts the values of `y` (fare amount) from the validation dataset.

   ```
   # Test best model accuracy
   validation_data_pd = validation_data.toPandas()
   y_test = validation_data_pd.pop("fareAmount").to_frame()
   y_predict = fitted_model.predict(validation_data_pd)
   ```

2. The root-mean-square error is a frequently used measure of the differences between sample values predicted by a model and the values observed. You calculate the root-mean-square error of the results by comparing the `y_test` DataFrame to the values predicted by the model.

   The function `mean_squared_error` takes two arrays and calculates the average squared error between

them. You then take the square root of the result. This metric indicates roughly how far the taxi fare predictions are from the actual fare values.

```
from sklearn.metrics import mean_squared_error
from math import sqrt

# Calculate root-mean-square error
y_actual = y_test.values.flatten().tolist()
rmse = sqrt(mean_squared_error(y_actual, y_predict))

print("Root Mean Square Error:")
print(rmse)
```

```
Root Mean Square Error:
2.309997102577151
```

The root-mean-square error is a good measure of how accurately the model predicts the response. From the results, you see that the model is fairly good at predicting taxi fares from the dataset's features, typically within $2.00.

3. Run the following code to calculate the mean-absolute-percent error. This metric expresses accuracy as a percentage of the error. It does this by calculating an absolute difference between each predicted and actual value and then summing all the differences. Then, it expresses that sum as a percentage of the total of the actual values.

```
# Calculate mean-absolute-percent error and model accuracy
sum_actuals = sum_errors = 0

for actual_val, predict_val in zip(y_actual, y_predict):
    abs_error = actual_val - predict_val
    if abs_error < 0:
        abs_error = abs_error * -1

    sum_errors = sum_errors + abs_error
    sum_actuals = sum_actuals + actual_val

mean_abs_percent_error = sum_errors / sum_actuals

print("Model MAPE:")
print(mean_abs_percent_error)
print()
print("Model Accuracy:")
print(1 - mean_abs_percent_error)
```

```
Model MAPE:
0.03655071038487368

Model Accuracy:
0.9634492896151263
```

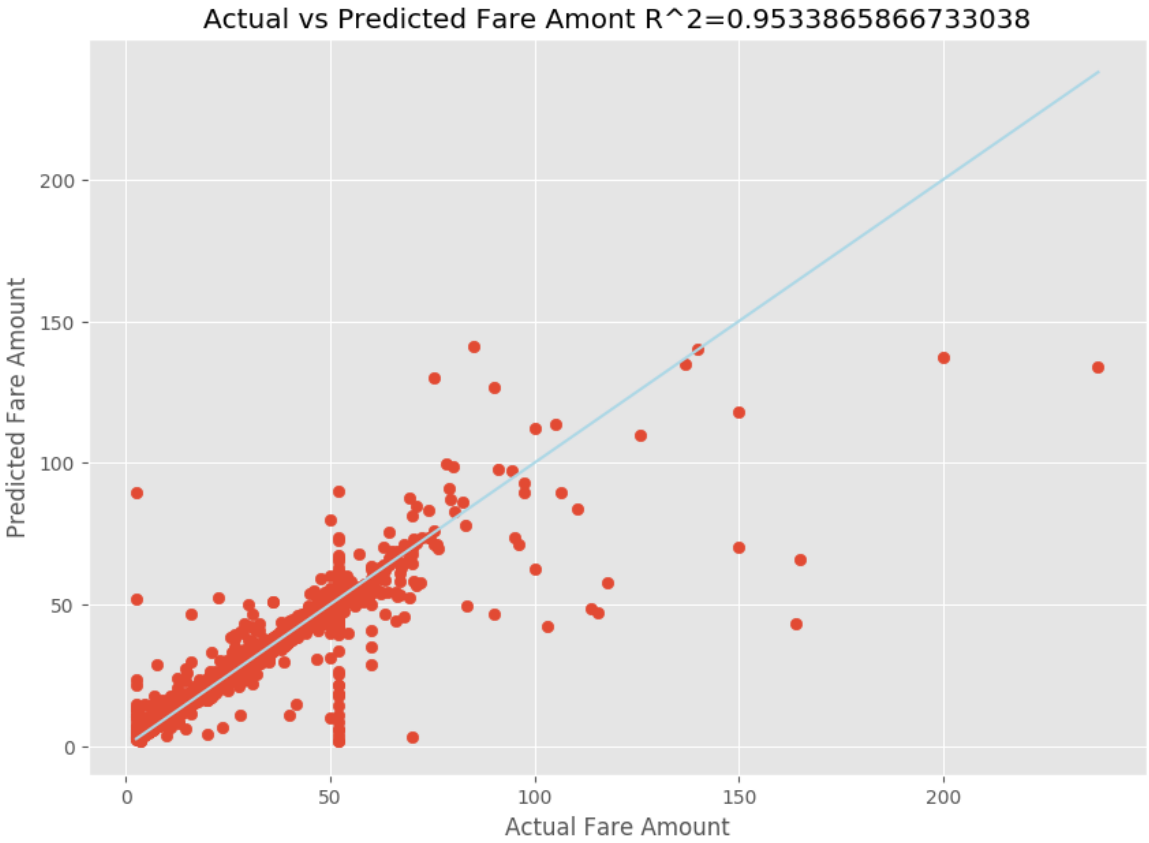
From the two prediction accuracy metrics, you see that the model is fairly good at predicting taxi fares from the dataset's features.

4. After fitting a linear regression model, you now need to determine how well the model fits the data. To do this, you plot the actual fare values against the predicted output. In addition, you calculate the R-squared measure to understand how close the data is to the fitted regression line.

```
import matplotlib.pyplot as plt
import numpy as np
from sklearn.metrics import mean_squared_error, r2_score

# Calculate the R2 score by using the predicted and actual fare prices
y_test_actual = y_test["fareAmount"]
r2 = r2_score(y_test_actual, y_predict)

# Plot the actual versus predicted fare amount values
plt.style.use('ggplot')
plt.figure(figsize=(10, 7))
plt.scatter(y_test_actual,y_predict)
plt.plot([np.min(y_test_actual), np.max(y_test_actual)], [np.min(y_test_actual),
np.max(y_test_actual)], color='lightblue')
plt.xlabel("Actual Fare Amount")
plt.ylabel("Predicted Fare Amount")
plt.title("Actual vs Predicted Fare Amount R^2={}".format(r2))
plt.show()
```



From the results, you can see that the R-squared measure accounts for 95 percent of the variance. This is also validated by the actual plot versus the observed plot. The more variance that the regression model accounts for, the closer the data points will fall to the fitted regression line.

Register the model to Azure Machine Learning

After you've validated your best model, you can register it to Azure Machine Learning. Then, you can download or deploy the registered model and receive all the files that you registered.

```
description = 'My automated ML model'
model_path='outputs/model.pkl'
model = best_run.register_model(model_name = 'NYCYellowTaxiModel', model_path = model_path, description =
description)
print(model.name, model.version)
```

```
NYCYellowTaxiModel 1
```

View results in Azure Machine Learning

You can also access the results of the iterations by going to the experiment in your Azure Machine Learning workspace. Here, you can get additional details on the status of your run, attempted models, and other model metrics.

Tutorial: Distributed Training with Horovod Estimator and PyTorch (Preview)

8/19/2022 • 5 minutes to read • Edit Online

Horovod is a distributed training framework for libraries like TensorFlow and PyTorch. With Horovod, users can scale up an existing training script to run on hundreds of GPUs in just a few lines of code.

Within Azure Synapse Analytics, users can quickly get started with Horovod using the default Apache Spark 3 runtime.For Spark ML pipeline applications using PyTorch, users can use the horovod.spark estimator API. This notebook uses an Apache Spark dataframe to perform distributed training of a distributed neural network (DNN) model on MNIST dataset. This tutorial leverages PyTorch and the Horovod Estimator to run the training process.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Create a GPU-enabled Apache Spark pool in your Azure Synapse Analytics workspace. For details, see Create a GPU-enabled Apache Spark pool in Azure Synapse. For this tutorial, we suggest using the GPU-Large cluster size with 3 nodes.

Configure the Apache Spark session

At the start of the session, we will need to configure a few Apache Spark settings. In most cases, we only needs to set the numExecutors and spark.rapids.memory.gpu.reserve. For very large models, users may also need to configure the `spark.kryoserializer.buffer.max` setting. For Tensorflow models, users will need to set the `spark.executorEnv.TF_FORCE_GPU_ALLOW_GROWTH` to be true.

In the example below, you can see how the Spark configurations can be passed with the `%%configure` command. The detailed meaning of each parameter is explained in the Apache Spark configuration documentation. The values provided below are the suggested, best practice values for Azure Synapse GPU-large pools.

```
%%configure -f
{
    "driverMemory": "30g",
    "driverCores": 4,
    "executorMemory": "60g",
    "executorCores": 12,
    "numExecutors": 3,
    "conf":{
        "spark.rapids.memory.gpu.reserve": "10g",
        "spark.executorEnv.TF_FORCE_GPU_ALLOW_GROWTH": "true",
        "spark.kryoserializer.buffer.max": "2000m"
   }
}
```

For this tutorial, we will use the following configurations:

```
%%configure -f
{
    "numExecutors": 3,
    "conf":{
        "spark.rapids.memory.gpu.reserve": "10g"
   }
}
```

NOTE

When training with Horovod, users should set the Spark configuration for `numExecutors` to be less or equal to the number of nodes.

Import dependencies

In this tutorial, we will leverage PySpark to read and process the dataset. We will then use PyTorch and Horovod to build the distributed neural network (DNN) model and run the training process. To get started, we will need to import the following dependencies:

```
# base libs
import sys
import uuid

# numpy
import numpy as np

# pyspark related
import pyspark
import pyspark.sql.types as T
from pyspark.ml.evaluation import MulticlassClassificationEvaluator
from pyspark.sql import SparkSession
from pyspark.sql.functions import udf

# pytorch related
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim

# horovod related
import horovod.spark.torch as hvd
from horovod.spark.common.backend import SparkBackend
from horovod.spark.common.store import Store

# azure related
from azure.synapse.ml.horovodutils import AdlsStore
```

Connect to alternative storage account

We will need the Azure Data Lake Storage (ADLS) account for storing intermediate and model data. If you are using an alternative storage account, be sure to set up the linked service to automatically authenticate and read from the account. In addition, you will need to modify the following properties below: `remote_url`, `account_name`, and `linked_service_name`.

```
num_proc = 3  # equal to numExecutors
batch_size = 128
epochs = 3
lr_single_node = 0.01  # learning rate for single node code

uuid_str = str(uuid.uuid4())  # with uuid, each run will use a new directory
work_dir = '/tmp/' + uuid_str

# create adls store for model training, use your own adls account info
remote_url = "<<ABFS path to storage account>>"
account_name = "<<name of storage account>>"
linked_service_name = "<<name of linked service>>"
sas_token = TokenLibrary.getConnectionString(linked_service_name)
adls_store_path = remote_url + work_dir

store = AdlsStore.create(adls_store_path,
                         storage_options={
                             'account_name': account_name,
                             'sas_token': sas_token
                         },
                         save_runs=True)

print(adls_store_path)
```

Prepare dataset

Next, we will prepare the dataset for training. In this tutorial, we will use the MNIST dataset from Azure Open Datasets.

```
# Initialize SparkSession
spark = SparkSession.builder.getOrCreate()

# Download MNIST dataset from Azure Open Datasets
from azureml.opendatasets import MNIST

mnist = MNIST.get_tabular_dataset()
mnist_df = mnist.to_pandas_dataframe()
mnist_df.info()

# Preprocess dataset
mnist_df['features'] = mnist_df.iloc[:, :784].values.tolist()
mnist_df.drop(mnist_df.iloc[:, :784], inplace=True, axis=1)
mnist_df.head()
```

Process data with Apache Spark

Now, we will create an Apache Spark dataframe. This dataframe will be used with the `HorovodEstimator` for training.

```
# Create Spark DataFrame for training
df = spark.createDataFrame(mnist_df)

# repartition DataFrame for training
train_df = df.repartition(num_proc)

# Train/test split
train_df, test_df = train_df.randomSplit([0.9, 0.1])

# show the dataset
train_df.show()
train_df.count()
```

Define DNN model

Once we have finished processing our dataset, we can now define our PyTorch model. The same code could also be used to train a single-node PyTorch model.

```
# Define the PyTorch model without any Horovod-specific parameters
class Net(nn.Module):

    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 10, kernel_size=5)
        self.conv2 = nn.Conv2d(10, 20, kernel_size=5)
        self.conv2_drop = nn.Dropout2d()
        self.fc1 = nn.Linear(320, 50)
        self.fc2 = nn.Linear(50, 10)

    def forward(self, x):
        x = x.float()
        x = F.relu(F.max_pool2d(self.conv1(x), 2))
        x = F.relu(F.max_pool2d(self.conv2_drop(self.conv2(x)), 2))
        x = x.view(-1, 320)
        x = F.relu(self.fc1(x))
        x = F.dropout(x, training=self.training)
        x = self.fc2(x)
        return F.log_softmax(x)

model = Net()
optimizer = optim.SGD(model.parameters(),
                      lr=lr_single_node * num_proc,
                      momentum=0.5)  # notice the lr is scaled up
loss = nn.NLLLoss()
```

Train model

Now, we can train a Horovod Spark estimator on top of our Apache Spark dataframe.

```
# Train a Horovod Spark Estimator on the DataFrame
backend = SparkBackend(num_proc=num_proc,
                       stdout=sys.stdout,
                       stderr=sys.stderr,
                       prefix_output_with_timestamp=True)

torch_estimator = hvd.TorchEstimator(
    backend=backend,
    store=store,
    partitions_per_process=1,  # important for GPU training
    model=model,
    optimizer=optimizer,
    loss=lambda input, target: loss(input, target.long()),
    input_shapes=[[-1, 1, 28, 28]],
    feature_cols=['features'],
    label_cols=['label'],
    batch_size=batch_size,
    epochs=epochs,
    validation=0.1,
    verbose=2)

torch_model = torch_estimator.fit(train_df).setOutputCols(['label_prob'])
```

Evaluate trained model

Once the training process has finished, we can then evaluate the model on the test dataset.

```
# Evaluate the model on the held-out test DataFrame
pred_df = torch_model.transform(test_df)

argmax = udf(lambda v: float(np.argmax(v)), returnType=T.DoubleType())
pred_df = pred_df.withColumn('label_pred', argmax(pred_df.label_prob))
evaluator = MulticlassClassificationEvaluator(predictionCol='label_pred',
                                              labelCol='label',
                                              metricName='accuracy')

print('Test accuracy:', evaluator.evaluate(pred_df))
```

Clean up resources

To ensure the Spark instance is shut down, end any connected sessions(notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **stop session** from the status bar at the upper right of the notebook.

Tutorial: Distributed Training with Horovod Runner and Tensorflow (Preview)

8/19/2022 • 6 minutes to read • Edit Online

Horovod is a distributed training framework for libraries like TensorFlow and PyTorch. With Horovod, users can scale up an existing training script to run on hundreds of GPUs in just a few lines of code.

Within Azure Synapse Analytics, users can quickly get started with Horovod using the default Apache Spark 3 runtime.For Spark ML pipeline applications using Tensorflow, users can use `HorovodRunner`. This notebook uses an Apache Spark dataframe to perform distributed training of a distributed neural network (DNN) model on MNIST dataset. This tutorial leverages Tensorflow and the `HorovodRunner` to run the training process.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Create a GPU-enabled Apache Spark pool in your Azure Synapse Analytics workspace. For details, see Create a GPU-enabled Apache Spark pool in Azure Synapse. For this tutorial, we suggest using the GPU-Large cluster size with 3 nodes.

Configure the Apache Spark session

At the start of the session, we will need to configure a few Apache Spark settings. In most cases, we only needs to set the `numExecutors` and `spark.rapids.memory.gpu.reserve`. For very large models, users may also need to configure the `spark.kryoserializer.buffer.max` setting. For Tensorflow models, users will need to set the `spark.executorEnv.TF_FORCE_GPU_ALLOW_GROWTH` to be true.

In the example below, you can see how the Spark configurations can be passed with the `%%configure` command. The detailed meaning of each parameter is explained in the Apache Spark configuration documentation. The values provided below are the suggested, best practice values for Azure Synapse GPU-large pools.

```
%%configure -f
{
    "driverMemory": "30g",
    "driverCores": 4,
    "executorMemory": "60g",
    "executorCores": 12,
    "numExecutors": 3,
    "conf":{
        "spark.rapids.memory.gpu.reserve": "10g",
        "spark.executorEnv.TF_FORCE_GPU_ALLOW_GROWTH": "true",
        "spark.kryoserializer.buffer.max": "2000m"
   }
}
```

For this tutorial, we will use the following configurations:

```
%%configure -f
{
    "numExecutors": 3,
    "conf":{
        "spark.rapids.memory.gpu.reserve": "10g",
        "spark.executorEnv.TF_FORCE_GPU_ALLOW_GROWTH": "true"
   }
}
```

NOTE

When training with Horovod, users should set the Spark configuration for `numExecutors` to be less or equal to the number of nodes.

Setup primary storage account

We will need the Azure Data Lake Storage (ADLS) account for storing intermediate and model data. If you are using an alternative storage account, be sure to set up the linked service to automatically authenticate and read from the account.

In this example, we will read from the primary Azure Synapse Analytics storage account. To do this, you will need to modify the following properties below: `remote_url`.

```
# Specify training parameters
num_proc = 3  # equal to numExecutors
batch_size = 128
epochs = 3
lr_single_node = 0.1  # learning rate for single node code

# configure adls store remote url
remote_url = "<<abfss path to storage account>>
```

Prepare dataset

Next, we will prepare the dataset for training. In this tutorial, we will use the MNIST dataset from Azure Open Datasets.

```
def get_dataset(rank=0, size=1):
    # import dependency libs
    from azureml.opendatasets import MNIST
    from sklearn.preprocessing import OneHotEncoder
    import numpy as np

    # Download MNIST dataset from Azure Open Datasets
    mnist = MNIST.get_tabular_dataset()
    mnist_df = mnist.to_pandas_dataframe()

    # Preprocess dataset
    mnist_df['features'] = mnist_df.iloc[:, :784].values.tolist()
    mnist_df.drop(mnist_df.iloc[:, :784], inplace=True, axis=1)

    x = np.array(mnist_df['features'].values.tolist())
    y = np.array(mnist_df['label'].values.tolist()).reshape(-1, 1)

    enc = OneHotEncoder()
    enc.fit(y)
    y = enc.transform(y).toarray()

    (x_train, y_train), (x_test, y_test) = (x[:60000], y[:60000]), (x[60000:],
                                                                    y[60000:])

    # Prepare dataset for distributed training
    x_train = x_train[rank::size]
    y_train = y_train[rank::size]
    x_test = x_test[rank::size]
    y_test = y_test[rank::size]

    # Reshape and Normalize data for model input
    x_train = x_train.reshape(x_train.shape[0], 28, 28, 1)
    x_test = x_test.reshape(x_test.shape[0], 28, 28, 1)
    x_train = x_train.astype('float32')
    x_test = x_test.astype('float32')
    x_train /= 255.0
    x_test /= 255.0

    return (x_train, y_train), (x_test, y_test)
```

Define DNN model

Once we have finished processing our dataset, we can now define our Tensorflow model. The same code could also be used to train a single-node Tensorflow model.

```
# Define the TensorFlow model without any Horovod-specific parameters
def get_model():
    from tensorflow.keras import models
    from tensorflow.keras import layers

    model = models.Sequential()
    model.add(
        layers.Conv2D(32,
                      kernel_size=(3, 3),
                      activation='relu',
                      input_shape=(28, 28, 1)))
    model.add(layers.Conv2D(64, (3, 3), activation='relu'))
    model.add(layers.MaxPooling2D(pool_size=(2, 2)))
    model.add(layers.Dropout(0.25))
    model.add(layers.Flatten())
    model.add(layers.Dense(128, activation='relu'))
    model.add(layers.Dropout(0.5))
    model.add(layers.Dense(10, activation='softmax'))
    return model
```

Define a training function for a single node

First, we will train our Tensorflow model on the driver node of the Apache Spark pool. Once we have finished the training process, we will evaluate the model and print the loss and accuracy scores.

```
def train(learning_rate=0.1):
    import tensorflow as tf
    from tensorflow import keras

    gpus = tf.config.experimental.list_physical_devices('GPU')
    for gpu in gpus:
        tf.config.experimental.set_memory_growth(gpu, True)

    # Prepare dataset
    (x_train, y_train), (x_test, y_test) = get_dataset()

    # Initialize model
    model = get_model()

    # Specify the optimizer (Adadelta in this example)
    optimizer = keras.optimizers.Adadelta(learning_rate=learning_rate)

    model.compile(optimizer=optimizer,
                  loss='categorical_crossentropy',
                  metrics=['accuracy'])

    model.fit(x_train,
              y_train,
              batch_size=batch_size,
              epochs=epochs,
              verbose=2,
              validation_data=(x_test, y_test))
    return model

# Run the training process on the driver
model = train(learning_rate=lr_single_node)

# Evaluate the single node, trained model
_, (x_test, y_test) = get_dataset()
loss, accuracy = model.evaluate(x_test, y_test, batch_size=128)
print("loss:", loss)
print("accuracy:", accuracy)
```

Migrate to HorovodRunner for distributed training

Next, we will take a look at how the same code could be re-run using `HorovodRunner` for distributed training.

Define training function

To do this, we will first define a training function for `HorovodRunner`.

```
# Define training function for Horovod runner
def train_hvd(learning_rate=0.1):
    # Import base libs
    import tempfile
    import os
    import shutil
    import atexit

    # Import tensorflow modules to each worker
    import tensorflow as tf
    from tensorflow import keras
    import horovod.tensorflow.keras as hvd

    # Initialize Horovod
    hvd.init()

    # Pin GPU to be used to process local rank (one GPU per process)
```

```
    # These steps are skipped on a CPU cluster
    gpus = tf.config.experimental.list_physical_devices('GPU')
    for gpu in gpus:
        tf.config.experimental.set_memory_growth(gpu, True)
    if gpus:
        tf.config.experimental.set_visible_devices(gpus[hvd.local_rank()],
                                                   'GPU')

    # Call the get_dataset function you created, this time with the Horovod rank and size
    (x_train, y_train), (x_test, y_test) = get_dataset(hvd.rank(), hvd.size())

    # Initialize model with random weights
    model = get_model()

    # Adjust learning rate based on number of GPUs
    optimizer = keras.optimizers.Adadelta(learning_rate=learning_rate *
                                          hvd.size())

    # Use the Horovod Distributed Optimizer
    optimizer = hvd.DistributedOptimizer(optimizer)

    model.compile(optimizer=optimizer,
                  loss='categorical_crossentropy',
                  metrics=['accuracy'])

    # Create a callback to broadcast the initial variable states from rank 0 to all other processes.
    # This is required to ensure consistent initialization of all workers when training is started with
random weights or restored from a checkpoint.
    callbacks = [
        hvd.callbacks.BroadcastGlobalVariablesCallback(0),
    ]

    # Model checkpoint location.
    ckpt_dir = tempfile.mkdtemp()
    ckpt_file = os.path.join(ckpt_dir, 'checkpoint.h5')
    atexit.register(lambda: shutil.rmtree(ckpt_dir))

    # Save checkpoints only on worker 0 to prevent conflicts between workers
    if hvd.rank() == 0:
        callbacks.append(
            keras.callbacks.ModelCheckpoint(ckpt_file,
                                            monitor='val_loss',
                                            mode='min',
                                            save_best_only=True))

    model.fit(x_train,
              y_train,
              batch_size=batch_size,
              callbacks=callbacks,
              epochs=epochs,
              verbose=2,
              validation_data=(x_test, y_test))

    # Return model bytes only on worker 0
    if hvd.rank() == 0:
        with open(ckpt_file, 'rb') as f:
            return f.read()
```

Run training

Once we have defined the model, we will run the training process.

```
# Run training
import os
import sys
import horovod.spark

best_model_bytes = \
    horovod.spark.run(train_hvd, args=(lr_single_node, ), num_proc=num_proc,
                      env=os.environ.copy(),
                      stdout=sys.stdout, stderr=sys.stderr, verbose=2,
                      prefix_output_with_timestamp=True)[0]
```

Save checkpoints to ADLS storage

The code below shows how to save the checkpoints to the Azure Data Lake Storage (ADLS) account.

```
import tempfile
import fsspec
import os

local_ckpt_dir = tempfile.mkdtemp()
local_ckpt_file = os.path.join(local_ckpt_dir, 'mnist-ckpt.h5')
adls_ckpt_file = remote_url + local_ckpt_file

with open(local_ckpt_file, 'wb') as f:
    f.write(best_model_bytes)

## Upload local file to ADLS
fs = fsspec.filesystem('abfss')
fs.upload(local_ckpt_file, adls_ckpt_file)

print(adls_ckpt_file)
```

Evaluate Horovod trained model

Once we have finished training our model, we can then take a look at the loss and accuracy for the final model.

```
import tensorflow as tf

hvd_model = tf.keras.models.load_model(local_ckpt_file)

_, (x_test, y_test) = get_dataset()
loss, accuracy = hvd_model.evaluate(x_test, y_test, batch_size=128)
print("loaded model loss and accuracy:", loss, accuracy)
```

Clean up resources

To ensure the Spark instance is shut down, end any connected sessions(notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **stop session** from the status bar at the upper right of the notebook.

Load data with Petastorm (Preview)

8/19/2022 • 6 minutes to read • Edit Online

Petastorm is an open source data access library which enables single-node or distributed training of deep learning models. This library enables training directly from datasets in Apache Parquet format and datasets that have already been loaded as an Apache Spark DataFrame. Petastorm supports popular training frameworks such as Tensorflow and PyTorch.

For more information about Petastorm, you can visit the Petastorm GitHub page or the Petastorm API documentation.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Create a GPU-enabled Apache Spark pool in your Azure Synapse Analytics workspace. For details, see Create a GPU-enabled Apache Spark pool in Azure Synapse. For this tutorial, we suggest using the GPU-Large cluster size with 3 nodes.

Configure the Apache Spark session

At the start of the session, we will need to configure a few Apache Spark settings. In most cases, we only needs to set the `numExecutors` and `spark.rapids.memory.gpu.reserve`. In the example below, you can see how the Spark configurations can be passed with the `%%configure` command. The detailed meaning of each parameter is explained in the Apache Spark configuration documentation.

```
%%configure -f
{
    "numExecutors": 3,
    "conf":{
        "spark.rapids.memory.gpu.reserve": "10g"
   }
}
```

Petastorm write APIs

A dataset created using Petastorm is stored in an Apache Parquet format. On top of a Parquet schema, Petastorm also stores higher-level schema information that makes multidimensional arrays into a native part of a Petastorm dataset.

In the sample below, we create a dataset using PySpark. We write the dataset to an Azure Data Lake Storage Gen2 account.

```
import numpy as np
from pyspark.sql import SparkSession
from pyspark.sql.types import IntegerType

from petastorm.codecs import ScalarCodec, CompressedImageCodec, NdarrayCodec
from petastorm.etl.dataset_metadata import materialize_dataset
from petastorm.unischema import dict_to_spark_row, Unischema, UnischemaField

# The schema defines how the dataset schema looks like
HelloWorldSchema = Unischema('HelloWorldSchema', [
    UnischemaField('id', np.int32, (), ScalarCodec(IntegerType()), False),
    UnischemaField('image1', np.uint8, (128, 256, 3), CompressedImageCodec('png'), False),
    UnischemaField('array_4d', np.uint8, (None, 128, 30, None), NdarrayCodec(), False),
])

def row_generator(x):
    """Returns a single entry in the generated dataset. Return a bunch of random values as an example."""
    return {'id': x,
            'image1': np.random.randint(0, 255, dtype=np.uint8, size=(128, 256, 3)),
            'array_4d': np.random.randint(0, 255, dtype=np.uint8, size=(4, 128, 30, 3))}

def generate_petastorm_dataset(output_url):
    rowgroup_size_mb = 256

    spark = SparkSession.builder.config('spark.driver.memory', '2g').master('local[2]').getOrCreate()
    sc = spark.sparkContext

    # Wrap dataset materialization portion. Will take care of setting up spark environment variables as
    # well as save petastorm specific metadata
    rows_count = 10
    with materialize_dataset(spark, output_url, HelloWorldSchema, rowgroup_size_mb):

        rows_rdd = sc.parallelize(range(rows_count))\
            .map(row_generator)\
            .map(lambda x: dict_to_spark_row(HelloWorldSchema, x))

        spark.createDataFrame(rows_rdd, HelloWorldSchema.as_spark_schema()) \
            .coalesce(10) \
            .write \
            .mode('overwrite') \
            .parquet(output_url)

output_url = 'abfs://container_name@storage_account_url/data_dir' #use your own adls account info
generate_petastorm_dataset(output_url)
```

Petastorm read APIs

Read dataset from a primary storage account

The `petastorm.reader.Reader` class is the main entry point for user code that accesses the data from an ML framework such as Tensorflow or Pytorch. You can read a dataset using the `petastorm.reader.Reader` class and the `petastorm.make_reader` factory method.

In the example below, you can see how you can pass an `abfs` URL protocol.

```
from petastorm import make_reader

#on primary storage associated with the workspace, url can be abbreviated with container path for data
directory
with make_reader('abfs://<container_name>/<data directory path>/') as reader:
    for row in reader:
        print(row)
```

Read dataset from secondary storage account

If you are using an alternative storage account, be sure to set up the linked service to automatically authenticate and read from the account. In addition, you will need to modify the following properties below: `remote_url`, `account_name`, and `linked_service_name`.

```
from petastorm import make_reader

# create sas token for storage account access, use your own adls account info
remote_url = "abfs://container_name@storage_account_url"
account_name = "<<adls account name>>"
linked_service_name = '<<linked service name>>'
TokenLibrary = spark._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
sas_token = TokenLibrary.getConnectionString(linked_service_name)

with make_reader('{}/data_directory'.format(remote_url), storage_options = {'sas_token' : sas_token}) as
reader:
    for row in reader:
        print(row)
```

Read dataset in batches

In the example below, you can see how you can pass an `abfs` URL protocol to read data in batches. This example uses the `make_batch_reader` class.

```
from petastorm import make_batch_reader

with make_batch_reader('abfs://<container_name>/<data directory path>/', schema_fields=["value1", "value2"])
as reader:
    for schema_view in reader:
        print("Batched read:\nvalue1: {0} value2: {1}".format(schema_view.value1, schema_view.value2))
```

PyTorch API

To read a Petastorm dataset from PyTorch, you can use the adapter `petastorm.pytorch.DataLoader` class. This allows for custom PyTorch collating functions and transforms to be supplied.

In this example, we will show how Petastorm DataLoader can be used to load a Petastorm dataset with the help of make_reader API. This first section creates the definition of a `Net` class and `train` and `test` function.

```
from __future__ import division, print_function

import argparse
import pyarrow
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torchvision import transforms

from petastorm import make_reader, TransformSpec
from petastorm.pytorch import DataLoader
```

```
from pyspark.sql.functions import col

class Net(nn.Module):
    def __init__(self):
        super(Net, self).__init__()
        self.conv1 = nn.Conv2d(1, 10, kernel_size=5)
        self.conv2 = nn.Conv2d(10, 20, kernel_size=5)
        self.conv2_drop = nn.Dropout2d()
        self.fc1 = nn.Linear(320, 50)
        self.fc2 = nn.Linear(50, 10)

    def forward(self, x):
        x = F.relu(F.max_pool2d(self.conv1(x), 2))
        x = F.relu(F.max_pool2d(self.conv2_drop(self.conv2(x)), 2))
        x = x.view(-1, 320)
        x = F.relu(self.fc1(x))
        x = F.dropout(x, training=self.training)
        x = self.fc2(x)
        return F.log_softmax(x, dim=1)

def train(model, device, train_loader, log_interval, optimizer, epoch):
    model.train()
    for batch_idx, row in enumerate(train_loader):
        data, target = row['image'].to(device), row['digit'].to(device)
        optimizer.zero_grad()
        output = model(data)
        loss = F.nll_loss(output, target)
        loss.backward()
        optimizer.step()
        if batch_idx % log_interval == 0:
            print('Train Epoch: {} [{}]\tLoss: {:.6f}'.format(
                epoch, batch_idx * len(data), loss.item()))

def test(model, device, test_loader):
    model.eval()
    test_loss = 0
    correct = 0
    count = 0
    with torch.no_grad():
        for row in test_loader:
            data, target = row['image'].to(device), row['digit'].to(device)
            output = model(data)
            test_loss += F.nll_loss(output, target, reduction='sum').item()  # sum up batch loss
            pred = output.max(1, keepdim=True)[1]  # get the index of the max log-probability
            correct += pred.eq(target.view_as(pred)).sum().item()
            count += data.shape[0]
    test_loss /= count
    print('\nTest set: Average loss: {:.4f}, Accuracy: {}/{} ({:.0f}%)\n'.format(
        test_loss, correct, count, 100. * correct / count))

def _transform_row(mnist_row):
    # For this example, the images are stored as simpler ndarray (28,28), but the
    # training network expects 3-dim images, hence the additional lambda transform.
    transform = transforms.Compose([
        transforms.Lambda(lambda nd: nd.reshape(28, 28, 1)),
        transforms.ToTensor(),
        transforms.Normalize((0.1307,), (0.3081,))
    ])
    # In addition, the petastorm pytorch DataLoader does not distinguish the notion of
    # data or target transform, but that actually gives the user more flexibility
    # to make the desired partial transform, as shown here.
    result_row = {
        'image': transform(mnist_row['image']),
        'digit': mnist_row['digit']
    }

    return result_row
```

In this example, an Azure Data Lake Storage account is used to store intermediate data. To store this data, you must set up a Linked Service to the storage account and retrieve the following pieces of information: `remote_url`, `account_name`, and `linked_service_name`.

```
from petastorm import make_reader

# create sas token for storage account access, use your own adls account info
remote_url = "abfs://container_name@storage_account_url"
account_name = "<account name>"
linked_service_name = '<linked service name>'
TokenLibrary = spark._jvm.com.microsoft.azure.synapse.tokenlibrary.TokenLibrary
sas_token = TokenLibrary.getConnectionString(linked_service_name)

# Read Petastorm dataset and apply custom PyTorch transformation functions

device = torch.device('cpu') #For GPU, it will be torch.device('cuda'). More details:
https://pytorch.org/docs/stable/tensor_attributes.html#torch-device

model = Net().to(device)
optimizer = optim.SGD(model.parameters(), lr=0.01, momentum=0.5)

loop_epochs = 1
reader_epochs = 1

transform = TransformSpec(_transform_row, removed_fields=['idx'])

for epoch in range(1, loop_epochs + 1):
    with DataLoader(make_reader('{}/train'.format(remote_url), num_epochs=reader_epochs,
transform_spec=transform),batch_size=5) as train_loader:
        train(model, device, train_loader, 10, optimizer, epoch)
    with DataLoader(make_reader('{}/test'.format(remote_url), num_epochs=reader_epochs,
transform_spec=transform), batch_size=5) as test_loader:
        test(model, device, test_loader)
```

Tutorial: Machine learning model scoring wizard (preview) for dedicated SQL pools

8/19/2022 • 4 minutes to read • Edit Online

Learn how to easily enrich your data in dedicated SQL pools with predictive machine learning models. The models that your data scientists create are now easily accessible to data professionals for predictive analytics. A data professional in Azure Synapse Analytics can simply select a model from the Azure Machine Learning model registry for deployment in Azure Synapse SQL pools and launch predictions to enrich the data.

In this tutorial, you'll learn how to:

- Train a predictive machine learning model and register the model in the Azure Machine Learning model registry.
- Use the SQL scoring wizard to launch predictions in a dedicated SQL pool.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Dedicated SQL pool in your Azure Synapse Analytics workspace. For details, see Create a dedicated SQL pool.
- Azure Machine Learning linked service in your Azure Synapse Analytics workspace. For details, see Create an Azure Machine Learning linked service in Azure Synapse.

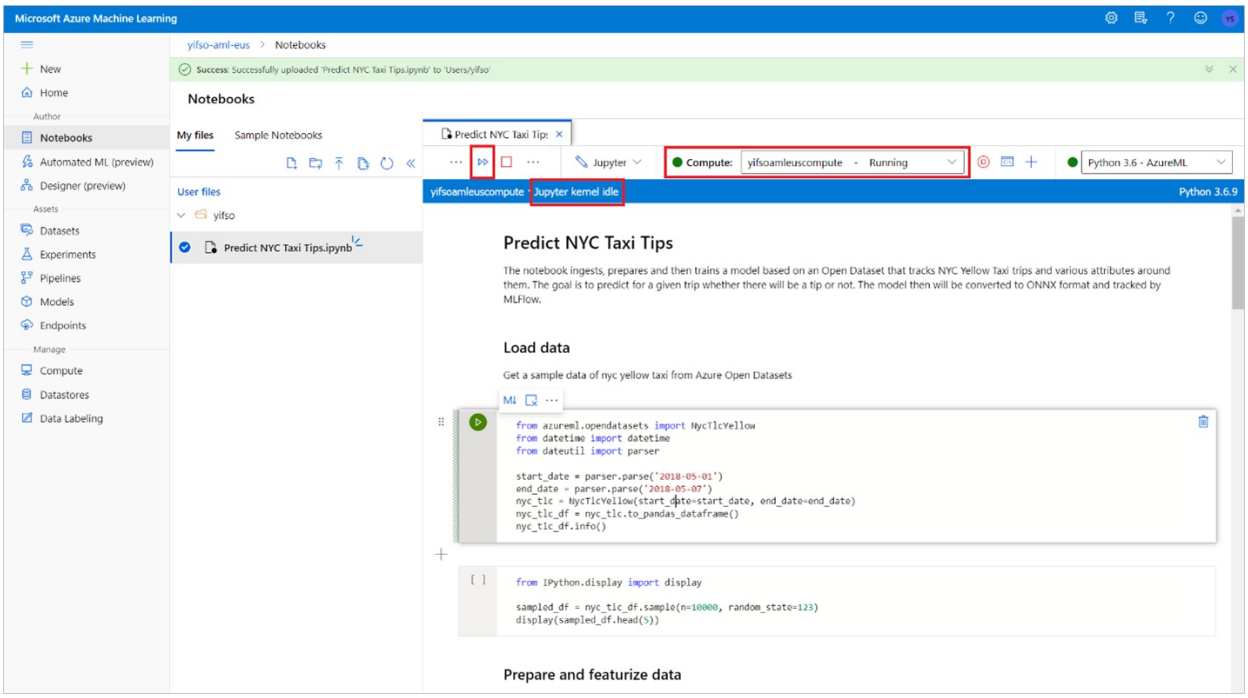
Sign in to the Azure portal

Sign in to the Azure portal.

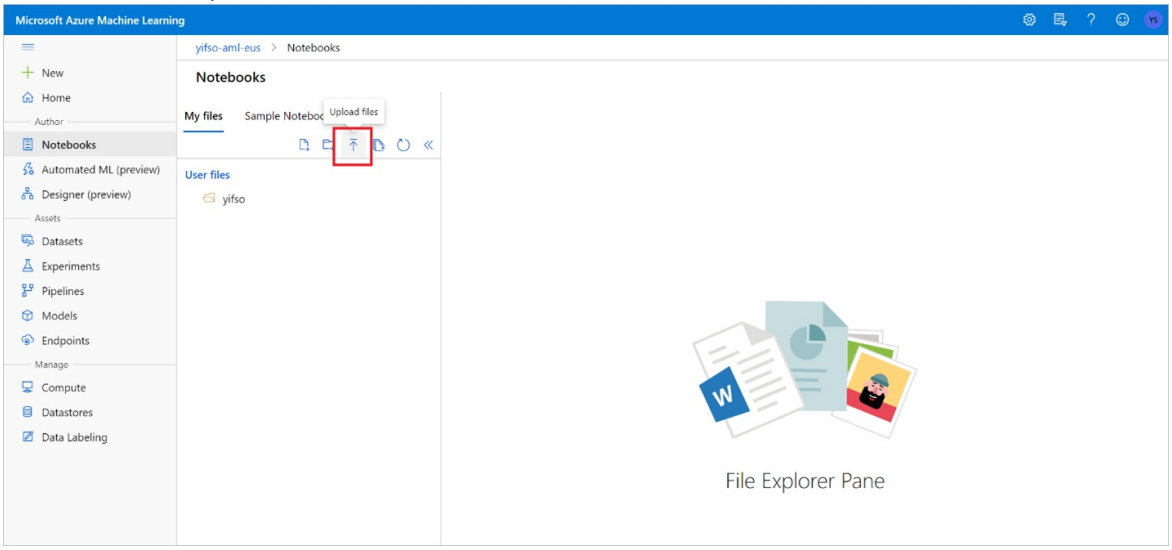
Train a model in Azure Machine Learning

Before you begin, verify that your version of sklearn is 0.20.3.

Before you run all cells in the notebook, check that the compute instance is running.



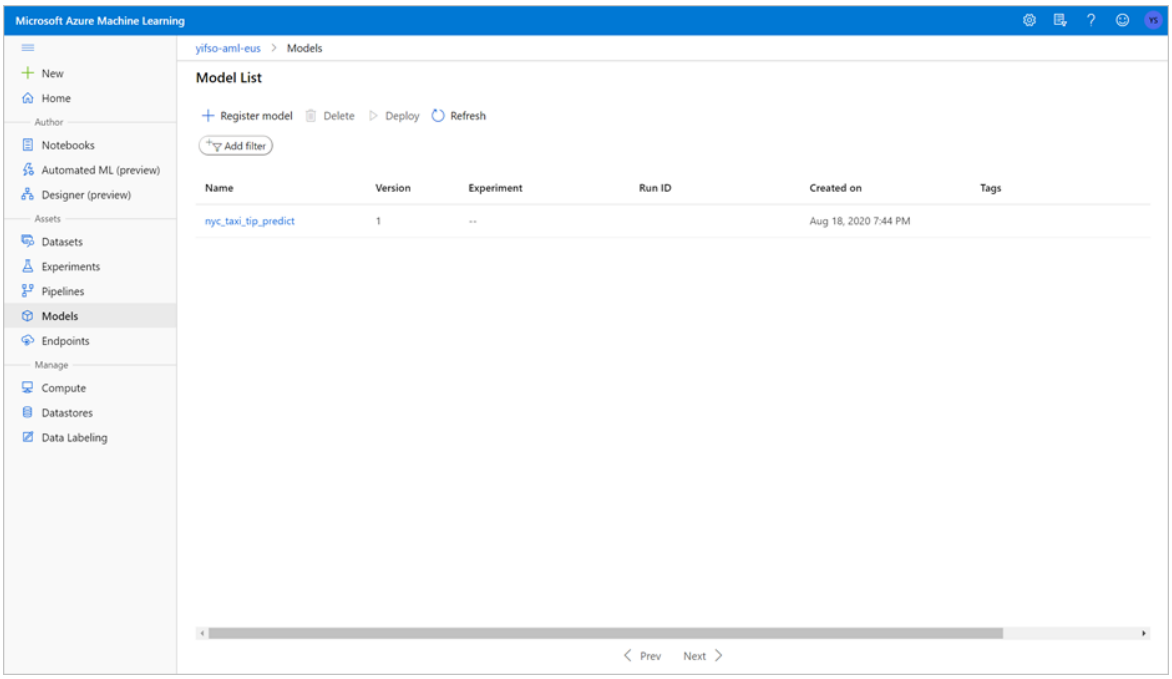
1. Go to your Azure Machine Learning workspace.
2. Download Predict NYC Taxi Tips.ipynb.
3. Open the Azure Machine Learning workspace in Azure Machine Learning Studio.
4. Go to **Notebooks** > **Upload files**. Then select the **Predict NYC Taxi Tips.ipynb** file that you downloaded and upload it.



5. After the notebook is uploaded and opened, select **Run all cells**.

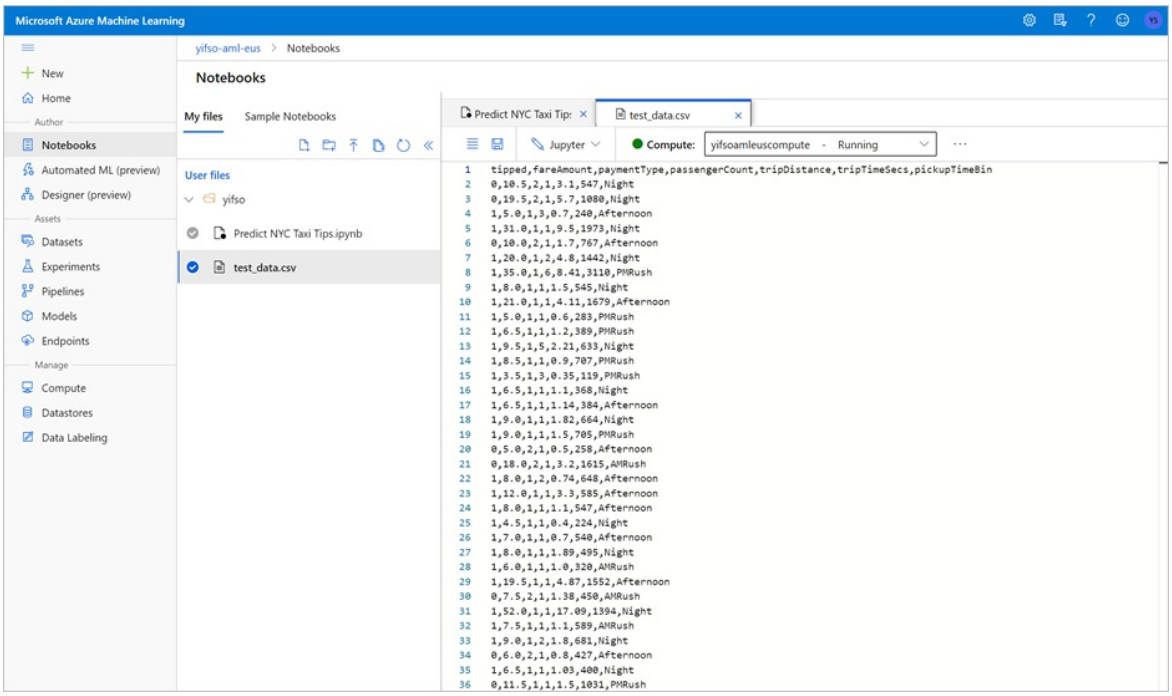
   One of the cells might fail and ask you to authenticate to Azure. Watch for this in the cell outputs, and authenticate in your browser by following the link and entering the code. Then re-run the notebook.

6. The notebook will train an ONNX model and register it with MLflow. Go to **Models** to check that the new model is registered properly.



7. Running the notebook will also export the test data into a CSV file. Download the CSV file to your local system. Later, you'll import the CSV file into a dedicated SQL pool and use the data to test the model.

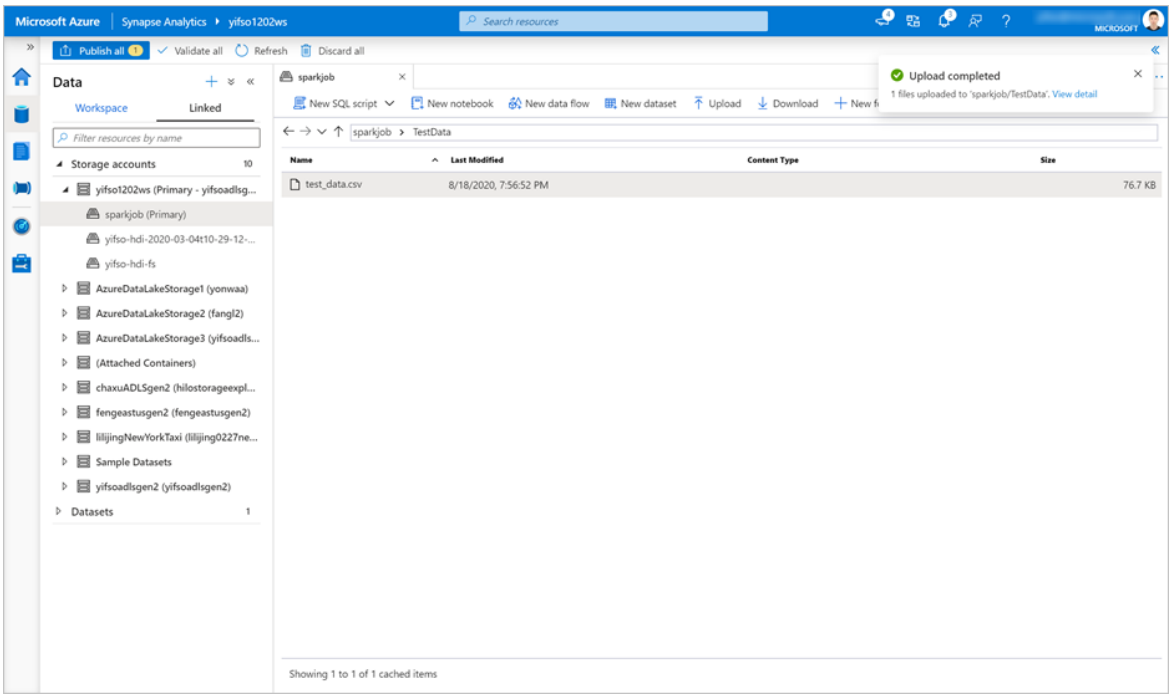
   The CSV file is created in the same folder as your notebook file. Select **Refresh** in File Explorer if you don't see it right away.



Launch predictions with the SQL scoring wizard

1. Open the Azure Synapse workspace with Synapse Studio.

2. Go to **Data** > **Linked** > **Storage Accounts**. Upload `test_data.csv` to the default storage account.



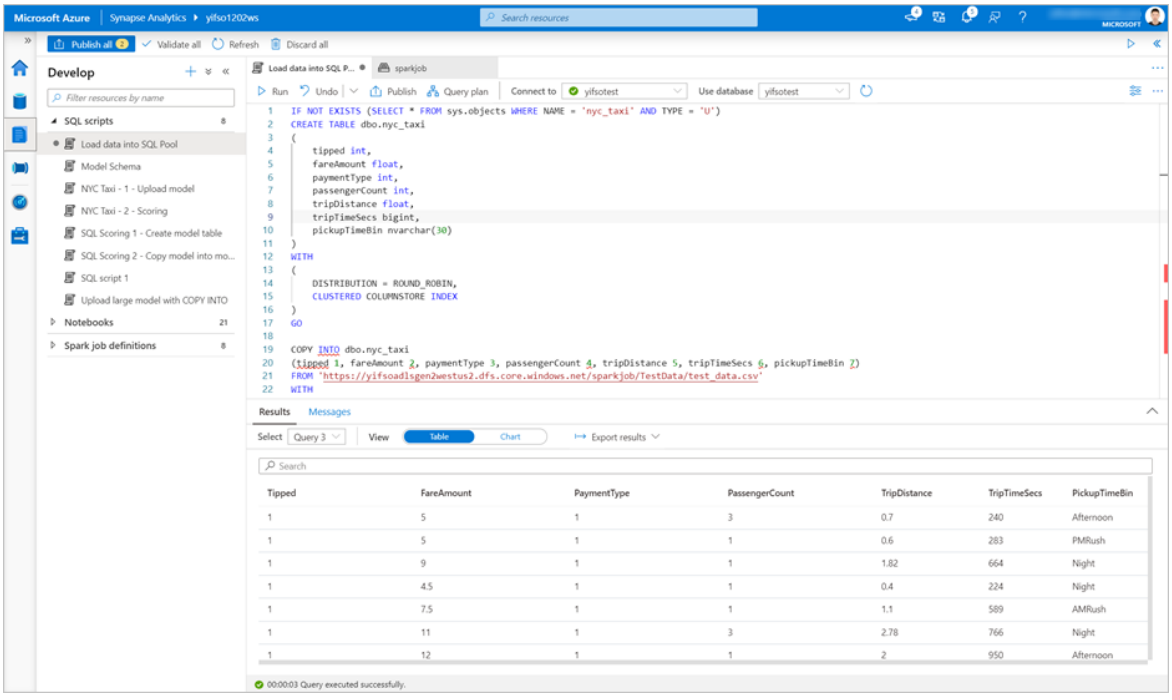
3. Go to **Develop** > **SQL scripts**. Create a new SQL script to load `test_data.csv` into your dedicated SQL pool.

> **NOTE**
>
> Update the file URL in this script before running it.

```
IF NOT EXISTS (SELECT * FROM sys.objects WHERE NAME = 'nyc_taxi' AND TYPE = 'U')
CREATE TABLE dbo.nyc_taxi
(
    tipped int,
    fareAmount float,
    paymentType int,
    passengerCount int,
    tripDistance float,
    tripTimeSecs bigint,
    pickupTimeBin nvarchar(30)
)
WITH
(
    DISTRIBUTION = ROUND_ROBIN,
    CLUSTERED COLUMNSTORE INDEX
)
GO

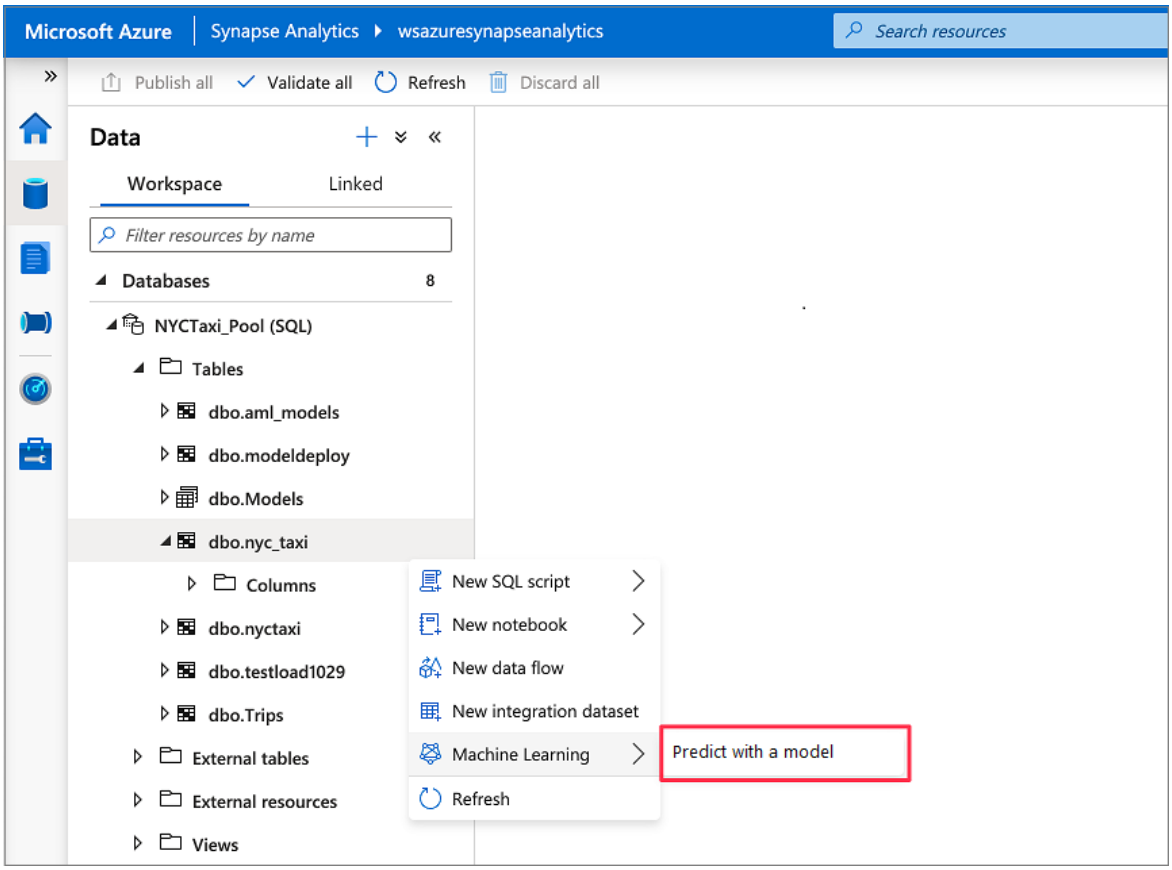
COPY INTO dbo.nyc_taxi
(tipped 1, fareAmount 2, paymentType 3, passengerCount 4, tripDistance 5, tripTimeSecs 6,
pickupTimeBin 7)
FROM '<URL to linked storage account>/test_data.csv'
WITH
(
    FILE_TYPE = 'CSV',
    ROWTERMINATOR='0x0A',
    FIELDQUOTE = '"',
    FIELDTERMINATOR = ',',
    FIRSTROW = 2
)
GO

SELECT TOP 100 * FROM nyc_taxi
GO
```



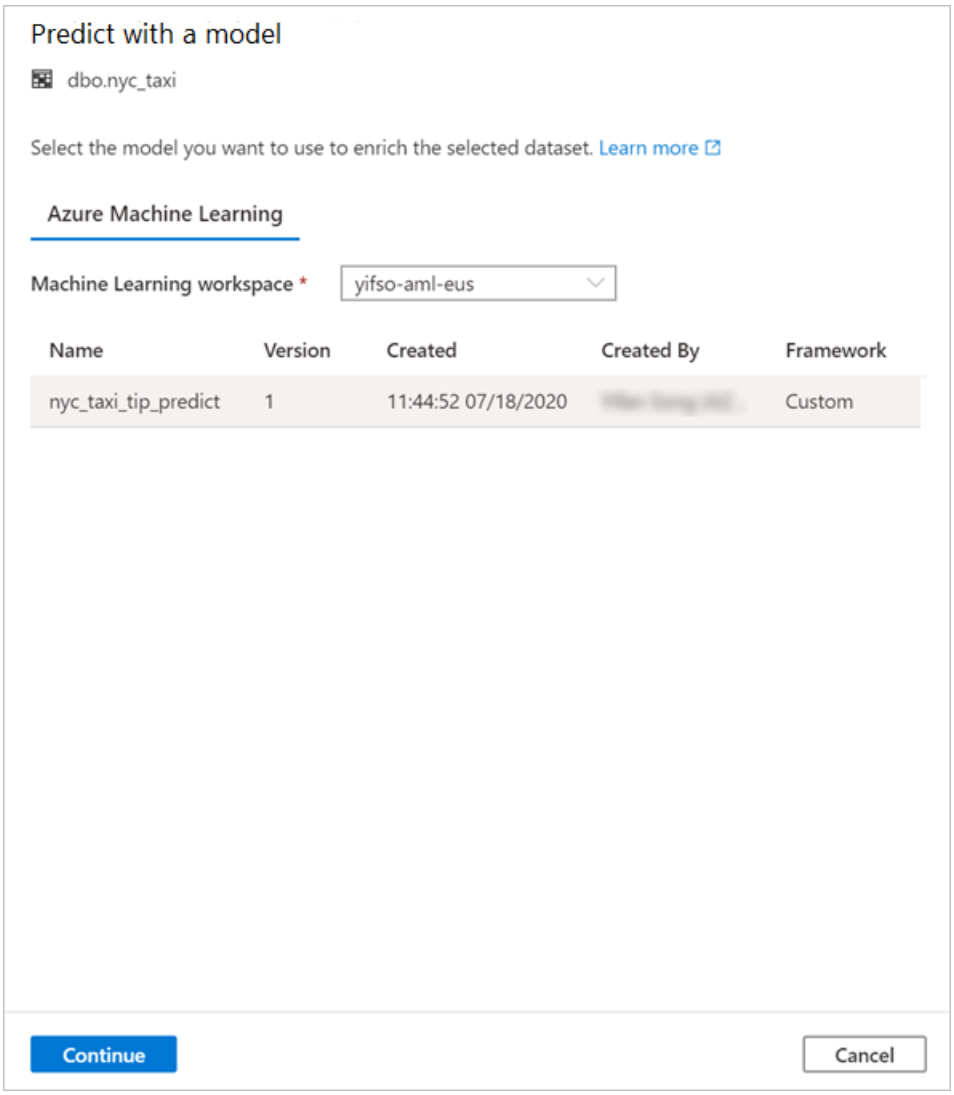
4. Go to **Data** > **Workspace**. Open the SQL scoring wizard by right-clicking the dedicated SQL pool table. Select **Machine Learning** > **Predict with a model**.

> **NOTE**
>
> The machine learning option does not appear unless you have a linked service created for Azure Machine Learning. (See Prerequisites at the beginning of this tutorial.)



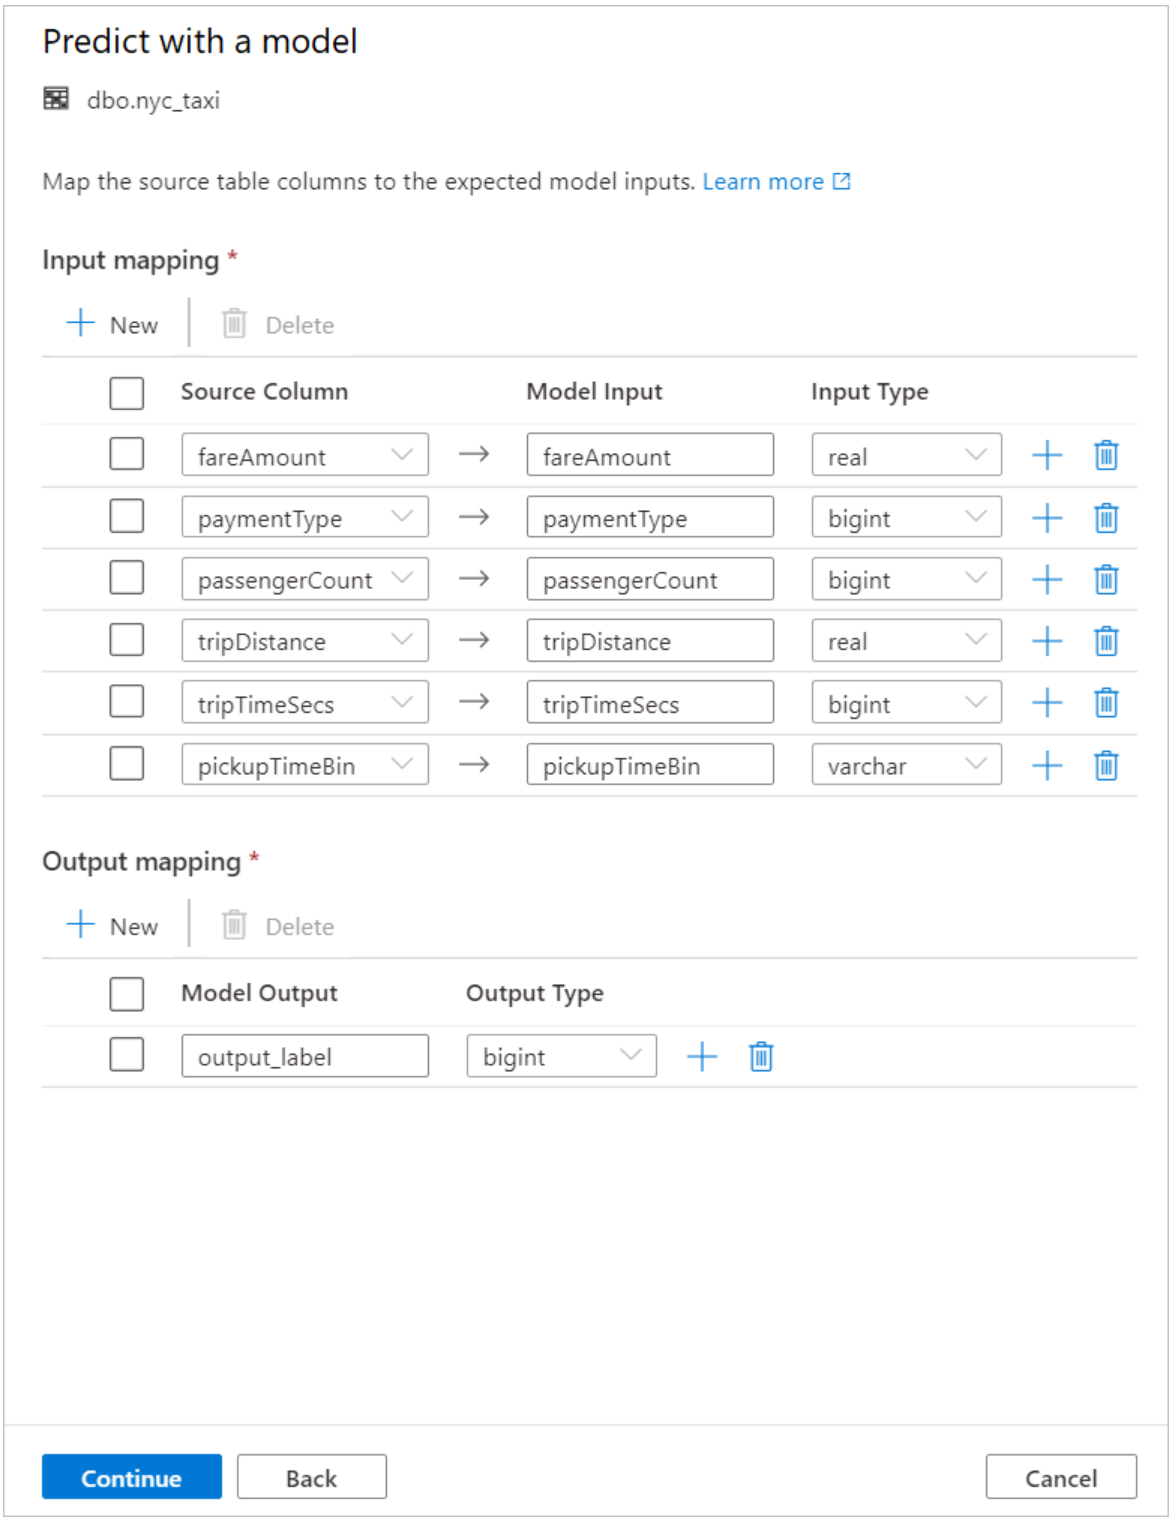
5. Select a linked Azure Machine Learning workspace in the drop-down box. This step loads a list of machine learning models from the model registry of the chosen Azure Machine Learning workspace. Currently, only ONNX models are supported, so this step will display only ONNX models.

6. Select the model that you just trained, and then select **Continue**.



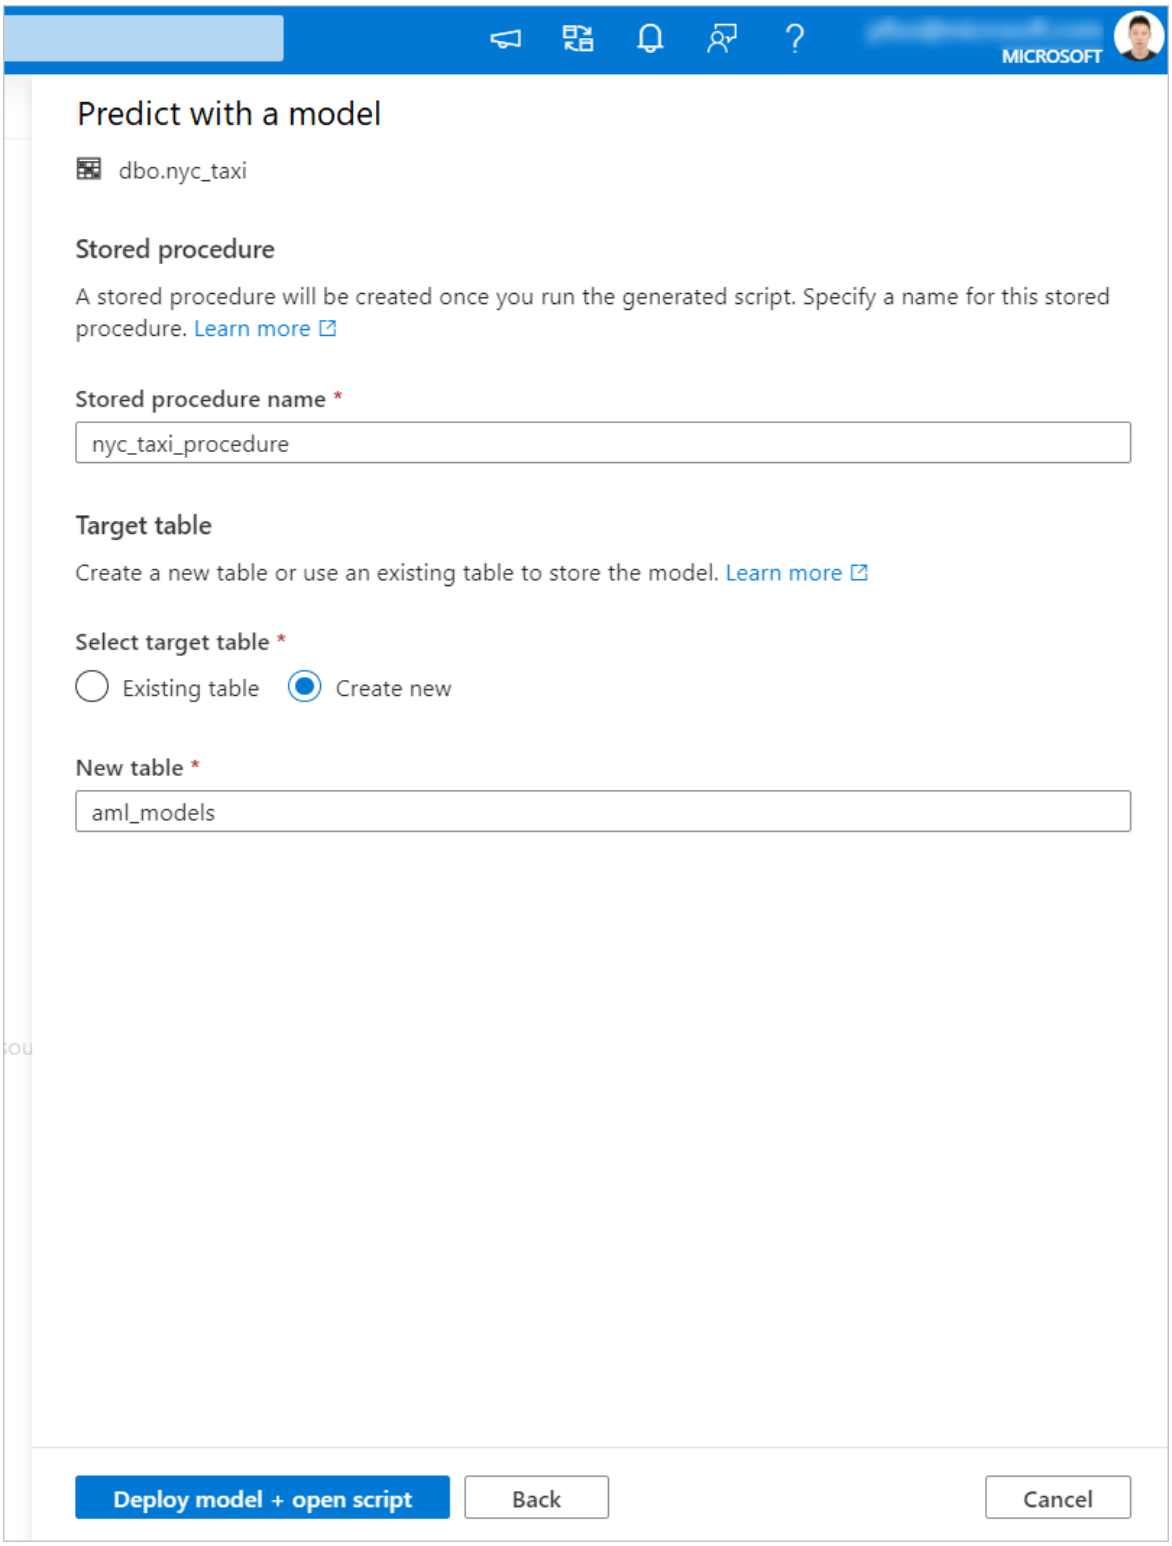
7. Map the table columns to the model inputs and specify the model outputs. If the model is saved in the MLflow format and the model signature is populated, the mapping will be done automatically for you by using a logic based on the similarity of names. The interface also supports manual mapping.

   Select **Continue**.



8. The generated T-SQL code is wrapped inside a stored procedure. This is why you need to provide a stored procedure name. The model binary, including metadata (version, description, and other information), will be physically copied from Azure Machine Learning to a dedicated SQL pool table. So you need to specify which table to save the model in.

   You can choose either **Existing table** or **Create new**. When you're done, select **Deploy model + open script** to deploy the model and generate a T-SQL prediction script.



9. After the script is generated, select **Run** to execute the scoring and get predictions.

- Machine Learning capabilities in Azure Synapse Analytics

Tutorial: Score machine learning models with PREDICT in serverless Apache Spark pools

8/19/2022 • 8 minutes to read • Edit Online

Learn how to use PREDICT functionality in serverless Apache Spark pools in Azure Synapse Analytics for score prediction. You can use a trained model registered in Azure Machine Learning (AML) or in the default Azure Data Lake Storage (ADLS) in your Synapse workspace.

PREDICT in a Synapse PySpark notebook provides you the capability to score machine learning models using the SQL language, user defined functions (UDF), or Transformers. With PREDICT, you can bring your existing machine learning models trained outside Synapse and registered in Azure Data Lake Storage Gen2 or Azure Machine Learning, to score historical data within the secure boundaries of Azure Synapse Analytics. The PREDICT function takes a model and data as inputs. This feature eliminates the step of moving valuable data outside of Synapse for scoring. The goal is to empower model consumers to easily infer machine learning models in Synapse as well as collaborate seamlessly with model producers working with the right framework for their task.

In this tutorial, you'll learn how to:

- Predict scores for data in a serverless Apache Spark pool using machine learning models which are trained outside Synapse and registered in Azure Machine Learning or Azure Data Lake Storage Gen2.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Serverless Apache Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Azure Machine Learning workspace is needed if you want to train or register model in Azure Machine Learning. For details, see Manage Azure Machine Learning workspaces in the portal or with the Python SDK.
- If your model is registered in Azure Machine Learning then you need a linked service. In Azure Synapse Analytics, a linked service defines your connection information to the service. In this tutorial, you'll add an Azure Synapse Analytics and Azure Machine Learning linked service. To learn more, see Create a new Azure Machine Learning linked service in Synapse.
- The PREDICT functionality requires that you already have a trained model which is either registered in Azure Machine Learning or uploaded in Azure Data Lake Storage Gen2.

NOTE

- PREDICT feature is supported on **Spark3** serverless Apache Spark pool in Azure Synapse Analytics. **Python 3.8** is recommended version for model creation and training.
- PREDICT supports most machine learning models packages in **MLflow** format: **TensorFlow, ONNX, PyTorch, SkLearn and pyfunc** are supported in this preview.
- PREDICT supports **AML and ADLS** model source. Here ADLS account refers to **default Synapse workspace ADLS account**.

Sign in to the Azure portal

Sign in to the Azure portal.

Use PREDICT for MLFLOW packaged models

Make sure all prerequisites are in place before following these steps for using PREDICT.

1. **Import libraries:** Import the following libraries to use PREDICT in spark session.

```
#Import libraries
from pyspark.sql.functions import col, pandas_udf,udf,lit
from azureml.core import Workspace
from azureml.core.authentication import ServicePrincipalAuthentication
import azure.synapse.ml.predict as pcontext
import azure.synapse.ml.predict.utils._logger as synapse_predict_logger
```

2. **Set parameters using variables:** Synapse ADLS data path and model URI need to be set using input variables. You also need to define runtime which is "mlflow" and the data type of model output return. Please note that all data types which are supported in PySpark are supported through PREDICT also.

> **NOTE**
> Before running this script, update it with the URI for ADLS Gen2 data file along with model output return data type and ADLS/AML URI for the model file.

```
#Set input data path
DATA_FILE = "abfss://<filesystemname>@<account name>.dfs.core.windows.net/<file path>"

#Set model URI
    #Set AML URI, if trained model is registered in AML
       AML_MODEL_URI = "<aml model uri>" #In URI ":x" signifies model version in AML. You can
choose which model version you want to run. If ":x" is not provided then by default   latest version
will be picked.

    #Set ADLS URI, if trained model is uploaded in ADLS
       ADLS_MODEL_URI = "abfss://<filesystemname>@<account name>.dfs.core.windows.net/<model
mlflow folder path>"

#Define model return type
RETURN_TYPES = "<data_type>" # for ex: int, float etc. PySpark data types are supported

#Define model runtime. This supports only mlflow
RUNTIME = "mlflow"
```

3. **Ways to authenticate AML workspace:** If the model is stored in the default ADLS account of Synapse workspace, then you do not need any further authentication setup. If the model is registered in Azure Machine Learning, then you can choose either of the following two supported ways of authentication.

> **NOTE**
> Update tenant, client, subscription, resource group, AML workspace and linked service details in this script before running it.

- **Through service principal:** You can use service principal client ID and secret directly to authenticate to AML workspace. Service principal must have "Contributor" access to the AML workspace.

```
    #AML workspace authentication using service principal
    AZURE_TENANT_ID = "<tenant_id>"
    AZURE_CLIENT_ID = "<client_id>"
    AZURE_CLIENT_SECRET = "<client_secret>"

    AML_SUBSCRIPTION_ID = "<subscription_id>"
    AML_RESOURCE_GROUP = "<resource_group_name>"
    AML_WORKSPACE_NAME = "<aml_workspace_name>"

    svc_pr = ServicePrincipalAuthentication(
        tenant_id=AZURE_TENANT_ID,
        service_principal_id=AZURE_CLIENT_ID,
        service_principal_password=AZURE_CLIENT_SECRET
    )

    ws = Workspace(
        workspace_name = AML_WORKSPACE_NAME,
        subscription_id = AML_SUBSCRIPTION_ID,
        resource_group = AML_RESOURCE_GROUP,
        auth=svc_pr
    )
```

- **Through linked service:** You can use linked service to authenticate to AML workspace. Linked service can use "service principal" or Synapse workspace's "Managed Service Identity (MSI)" for authentication. "Service principal" or "Managed Service Identity (MSI)" must have "Contributor" access to the AML workspace.

```
    #AML workspace authentication using linked service
    from notebookutils.mssparkutils import azureML
    ws = azureML.getWorkspace("<linked_service_name>") #   "
<linked_service_name>" is the linked service name, not AML workspace name. Also, linked
service supports MSI and service principal both
```

4. **Enable PREDICT in spark session:** Set the spark configuration `spark.synapse.ml.predict.enabled` to `true` to enable the library.

```
   #Enable SynapseML predict
   spark.conf.set("spark.synapse.ml.predict.enabled","true")
```

5. **Bind model in spark session:** Bind model with required inputs so that the model can be referred in the spark session. Also define alias so that you can use same alias in the PREDICT call.

> **NOTE**
> Update model alias and model uri in this script before running it.

```
   #Bind model within Spark session
    model = pcontext.bind_model(
     return_types=RETURN_TYPES,
     runtime=RUNTIME,
     model_alias="<random_alias_name>", #This alias will be used in PREDICT call to refer  this
model
     model_uri=ADLS_MODEL_URI, #In case of AML, it will be AML_MODEL_URI
     aml_workspace=ws #This is only for AML. In case of ADLS, this parameter can be removed
     ).register()
```

6. **Read data from ADLS:** Read data from ADLS. Create spark dataframe and a view on top of data frame.

> **NOTE**
>
> Update view name in this script before running it.

```
#Read data from ADLS
df = spark.read \
 .format("csv") \
 .option("header", "true") \
 .csv(DATA_FILE,
     inferSchema=True)
df.createOrReplaceTempView('<view_name>')
```

7. **Generate score using PREDICT:** You can call PREDICT three ways, using Spark SQL API, using User define function (UDF), and using Transformer API. Following are examples.

> **NOTE**
>
> Update the model alias name, view name, and comma separated model input column name in this script before running it. Comma separated model input columns are the same as those used while training the model.

```
#Call PREDICT using Spark SQL API

predictions = spark.sql(
               """
                   SELECT PREDICT('<random_alias_name>',
                             <comma_separated_model_input_column_name>) AS predict
                   FROM <view_name>
               """
           ).show()
```

```
#Call PREDICT using user defined function (UDF)

df = df[<comma_separated_model_input_column_name>] # for ex. df["empid","empname"]

df.withColumn("PREDICT",model.udf(lit("<random_alias_name>"),*df.columns)).show()
```

```
#Call PREDICT using Transformer API

columns = [<comma_separated_model_input_column_name>] # for ex. df["empid","empname"]

tranformer = model.create_transformer().setInputCols(columns).setOutputCol("PREDICT")

tranformer.transform(df).show()
```

Sklearn example using PREDICT

1. Import libraries and read the training dataset from ADLS.

```
# Import libraries and read training dataset from ADLS

import fsspec
import pandas
from fsspec.core import split_protocol

adls_account_name = 'xyz' #Provide exact ADLS account name
adls_account_key = 'xyz' #Provide exact ADLS account key

fsspec_handle = fsspec.open('abfs[s]://<container>/<path-to-file>',
account_name=adls_account_name, account_key=adls_account_key)

with fsspec_handle.open() as f:
    train_df = pandas.read_csv(f)
```

2. Train model and generate mlflow artifacts.

```
# Train model and generate mlflow artifacts

import os
import shutil
import mlflow
import json
from mlflow.utils import model_utils
import numpy as np
import pandas as pd
from sklearn.linear_model import LinearRegression

class LinearRegressionModel():
  _ARGS_FILENAME = 'args.json'
  FEATURES_KEY = 'features'
  TARGETS_KEY = 'targets'
  TARGETS_PRED_KEY = 'targets_pred'

  def __init__(self, fit_intercept, nb_input_features=9, nb_output_features=1):
    self.fit_intercept = fit_intercept
    self.nb_input_features = nb_input_features
    self.nb_output_features = nb_output_features

  def get_args(self):
    args = {
        'nb_input_features': self.nb_input_features,
        'nb_output_features': self.nb_output_features,
        'fit_intercept': self.fit_intercept
    }
    return args

  def create_model(self):
    self.model = LinearRegression(fit_intercept=self.fit_intercept)

  def train(self, dataset):

    features = np.stack([sample for sample in iter(
        dataset[LinearRegressionModel.FEATURES_KEY])], axis=0)

    targets = np.stack([sample for sample in iter(
        dataset[LinearRegressionModel.TARGETS_KEY])], axis=0)

    self.model.fit(features, targets)

  def predict(self, dataset):
    features = np.stack([sample for sample in iter(
        dataset[LinearRegressionModel.FEATURES_KEY])], axis=0)
    targets_pred = self.model.predict(features)
```

```
        return targets_pred

    def save(self, path):
        if os.path.exists(path):
            shutil.rmtree(path)

        # save the sklearn model with mlflow
        mlflow.sklearn.save_model(self.model, path)

        # save args
        self._save_args(path)

    def _save_args(self, path):
        args_filename = os.path.join(path, LinearRegressionModel._ARGS_FILENAME)
        with open(args_filename, 'w') as f:
            args = self.get_args()
            json.dump(args, f)

def train(train_df, output_model_path):
    print(f"Start to train LinearRegressionModel.")

    # Initialize input dataset
    dataset = train_df.to_numpy()
    datasets = {}
    datasets['targets'] = dataset[:, -1]
    datasets['features'] = dataset[:, :9]

    # Initialize model class obj
    model_class = LinearRegressionModel(fit_intercept=10)
    with mlflow.start_run(nested=True) as run:
        model_class.create_model()
        model_class.train(datasets)
        model_class.save(output_model_path)
        print(model_class.predict(datasets))

train(train_df, './artifacts/output')
```

3. Store model MLFLOW artifacts in ADLS or register in AML.

```
# Store model MLFLOW artifacts in ADLS

STORAGE_PATH = 'abfs[s]://<container>/<path-to-store-folder>'

protocol, _ = split_protocol(STORAGE_PATH)
print (protocol)

storage_options = {
    'account_name': adls_account_name,
    'account_key': adls_account_key
}
fs = fsspec.filesystem(protocol, **storage_options)
fs.put(
    './artifacts/output',
    STORAGE_PATH,
    recursive=True, overwrite=True)
```

```
    # Register model MLFLOW artifacts in AML

    from azureml.core import Workspace, Model
    from azureml.core.authentication import ServicePrincipalAuthentication

    AZURE_TENANT_ID = "xyz"
    AZURE_CLIENT_ID = "xyz"
    AZURE_CLIENT_SECRET = "xyz"

    AML_SUBSCRIPTION_ID = "xyz"
    AML_RESOURCE_GROUP = "xyz"
    AML_WORKSPACE_NAME = "xyz"

    svc_pr = ServicePrincipalAuthentication(
        tenant_id=AZURE_TENANT_ID,
        service_principal_id=AZURE_CLIENT_ID,
        service_principal_password=AZURE_CLIENT_SECRET
    )

    ws = Workspace(
        workspace_name = AML_WORKSPACE_NAME,
        subscription_id = AML_SUBSCRIPTION_ID,
        resource_group = AML_RESOURCE_GROUP,
        auth=svc_pr
    )

    model = Model.register(
        model_path="./artifacts/output",
        model_name="xyz",
        workspace=ws,
    )
```

4. Set required parameters using variables.

```
    # If using ADLS uploaded model

    import pandas as pd
    from pyspark.sql import SparkSession
    from pyspark.sql.functions import col, pandas_udf,udf,lit
    import azure.synapse.ml.predict as pcontext
    import azure.synapse.ml.predict.utils._logger as synapse_predict_logger

    DATA_FILE = "abfss://xyz@xyz.dfs.core.windows.net/xyz.csv"
    ADLS_MODEL_URI_SKLEARN = "abfss://xyz@xyz.dfs.core.windows.net/mlflow/sklearn/
e2e_linear_regression/"
    RETURN_TYPES = "INT"
    RUNTIME = "mlflow"
```

```
    # If using AML registered model

    from pyspark.sql.functions import col, pandas_udf,udf,lit
    from azureml.core import Workspace
    from azureml.core.authentication import ServicePrincipalAuthentication
    import azure.synapse.ml.predict as pcontext
    import azure.synapse.ml.predict.utils._logger as synapse_predict_logger

    DATA_FILE = "abfss://xyz@xyz.dfs.core.windows.net/xyz.csv"
    AML_MODEL_URI_SKLEARN = "aml://xyz"
    RETURN_TYPES = "INT"
    RUNTIME = "mlflow"
```

5. Enable SynapseML PREDICT functionality in spark session.

```
spark.conf.set("spark.synapse.ml.predict.enabled","true")
```

6. Bind model in spark session.

```
# If using ADLS uploaded model

model = pcontext.bind_model(
 return_types=RETURN_TYPES,
 runtime=RUNTIME,
 model_alias="sklearn_linear_regression",
 model_uri=ADLS_MODEL_URI_SKLEARN,
 ).register()
```

```
# If using AML registered model

model = pcontext.bind_model(
 return_types=RETURN_TYPES,
 runtime=RUNTIME,
 model_alias="sklearn_linear_regression",
 model_uri=AML_MODEL_URI_SKLEARN,
 aml_workspace=ws
 ).register()
```

7. Load test data from ADLS.

```
# Load data from ADLS

df = spark.read \
    .format("csv") \
    .option("header", "true") \
    .csv(DATA_FILE,
        inferSchema=True)
df = df.select(df.columns[:9])
df.createOrReplaceTempView('data')
df.show(10)
```

8. Call PREDICT to generate the score.

```
# Call PREDICT

predictions = spark.sql(
                    """
                        SELECT PREDICT('sklearn_linear_regression', *) AS predict FROM data
                    """
                ).show()
```

Cognitive Services in Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

Using pretrained models from Azure Cognitive Services, you can enrich your data with artificial intelligence (AI) in Azure Synapse Analytics.

Azure Cognitive Services are cloud-based services that add cognitive intelligence to your data even if you don't have AI or data science skills. There are a few ways you can use these services with your data in Synapse Analytics:

- The Cognitive Services wizard in Synapse Analytics generates PySpark code in a Synapse notebook that connects to a cognitive service using data in a Spark table. Then, using pretrained machine learning models, the service does the work for you to add AI to your data. Check out Sentiment analysis wizard and Anomaly detection wizard for more details.
- Synapse Machine Learning (SynapseML) allows you to build powerful and highly scalable predictive and analytical models from various Spark data sources. Synapse Spark provide built-in SynapseML libraries including Cognitive Services on Spark. Check out Tutorials for more details.
- Starting from the PySpark code generated by the wizard, or the example SynapseML code provided in the tutorial, you can write your own code to use other cognitive services with your data. See What are Azure Cognitive Services? for more information about available services.

Get started

The tutorial, Pre-requisites for using Cognitive Services in Azure Synapse, walks you through a couple steps you need to perform before using Cognitive Services in Synapse Analytics.

Tutorials

The following tutorials provide complete examples of using Cognitive Services in Synapse Analytics.

- Sentiment analysis with Cognitive Services - Using an example data set of customer comments, you build a Spark table with a column that indicates the sentiment of the comments in each row.
- Anomaly detection with Cognitive Services - Using an example data set of time series data, you build a Spark table with a column that indicates whether the data in each row is an anomaly.
- Build machine learning applications using Microsoft Machine Learning for Apache Spark - This tutorial demonstrates how to use SynapseML to access several models from Cognitive Services.
- Form recognizer with Applied AI Service demonstrates how to use Form Recognizer to analyze your forms and documents, extracts text and data on Azure Synapse Analytics.
- Text Analytics with Cognitive Service shows how to use Text Analytics to analyze unstructured text on Azure Synapse Analytics.
- Translator with Cognitive Service shows how to use Translator to build intelligent, multi-language solutions on Azure Synapse Analytics
- Computer Vision with Cognitive Service demonstrates how to use Computer Vision to analyze images on Azure Synapse Analytics.

Available Cognitive Services APIs

Bing Image Search

API TYPE	SYNAPSEML APIS	COGNITIVE SERVICE APIS (VERSIONS)	DEP VNET SUPPORT
Bing Image Search	BingImageSearch	Images - Visual Search V7.0	Not Supported

Anomaly Detector

Tutorial: Sentiment analysis with Cognitive Services

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to easily enrich your data in Azure Synapse Analytics with Azure Cognitive Services. You'll use the Text Analytics capabilities to perform sentiment analysis.

A user in Azure Synapse can simply select a table that contains a text column to enrich with sentiments. These sentiments can be positive, negative, mixed, or neutral. A probability will also be returned.

This tutorial covers:

- Steps for getting a Spark table dataset that contains a text column for sentiment analysis.
- Using a wizard experience in Azure Synapse to enrich data by using Text Analytics in Cognitive Services.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Pre-configuration steps described in the tutorial Configure Cognitive Services in Azure Synapse.

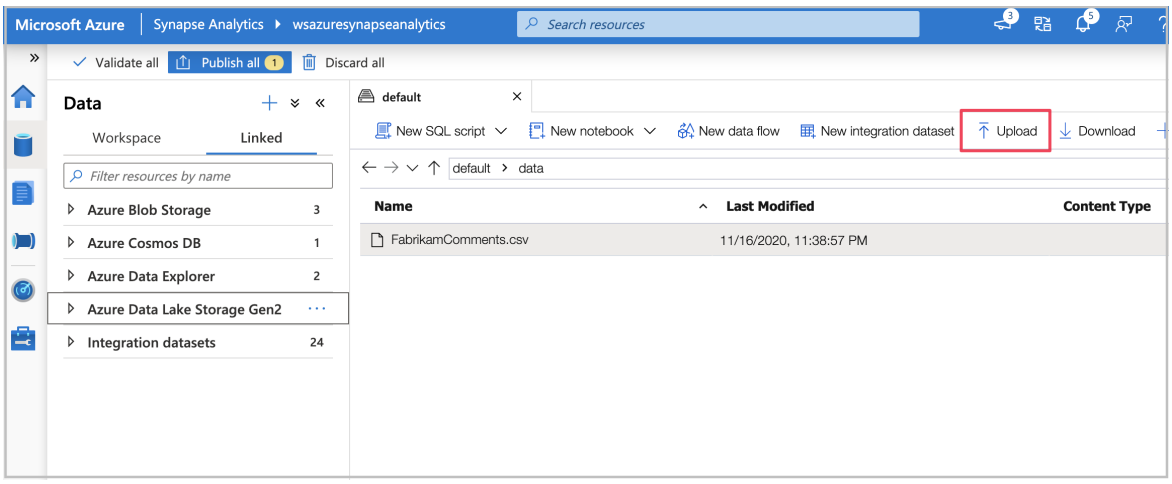
Sign in to the Azure portal

Sign in to the Azure portal.

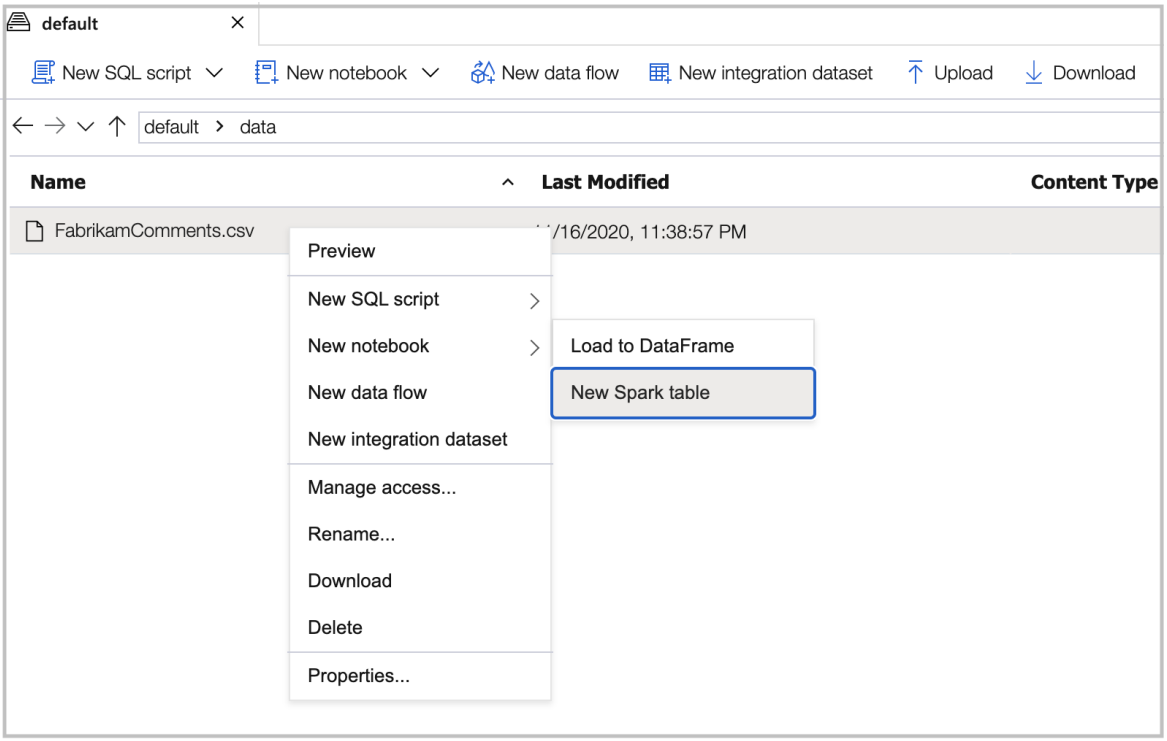
Create a Spark table

You'll need a Spark table for this tutorial.

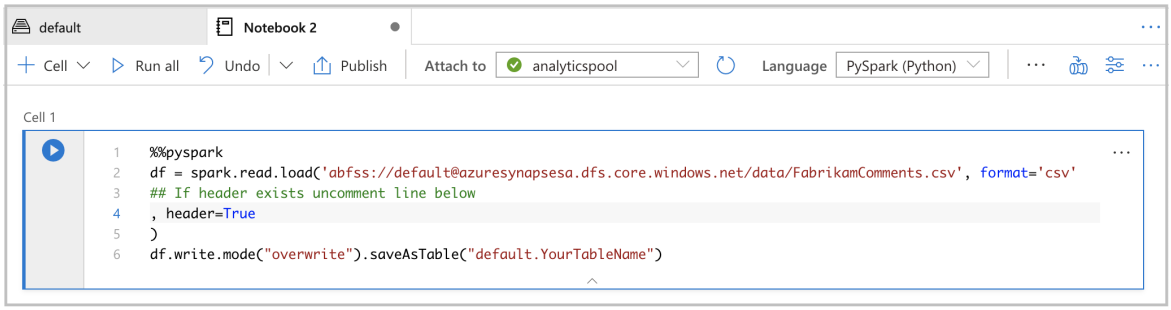
1. Download the FabrikamComments.csv file, which contains a dataset for text analytics.
2. Upload the file to your Azure Synapse storage account in Data Lake Storage Gen2.



3. Create a Spark table from the .csv file by right-clicking the file and selecting **New Notebook** > **Create Spark table**.



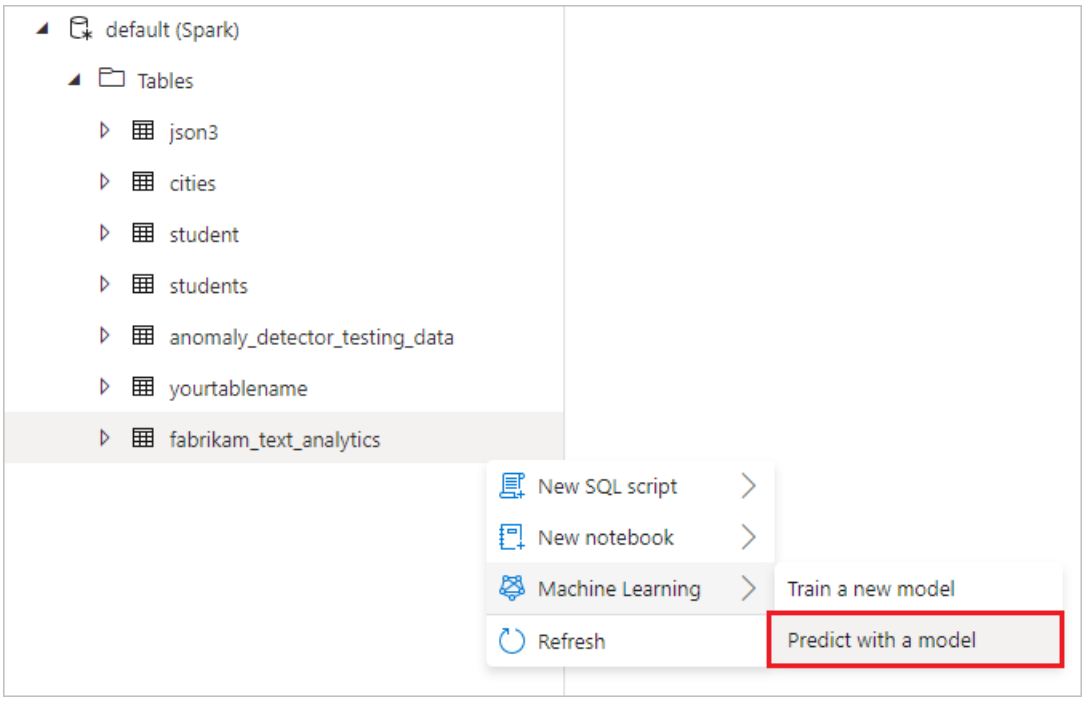
4. Name the table in the code cell and run the notebook on a Spark pool. Remember to set `header=True`.



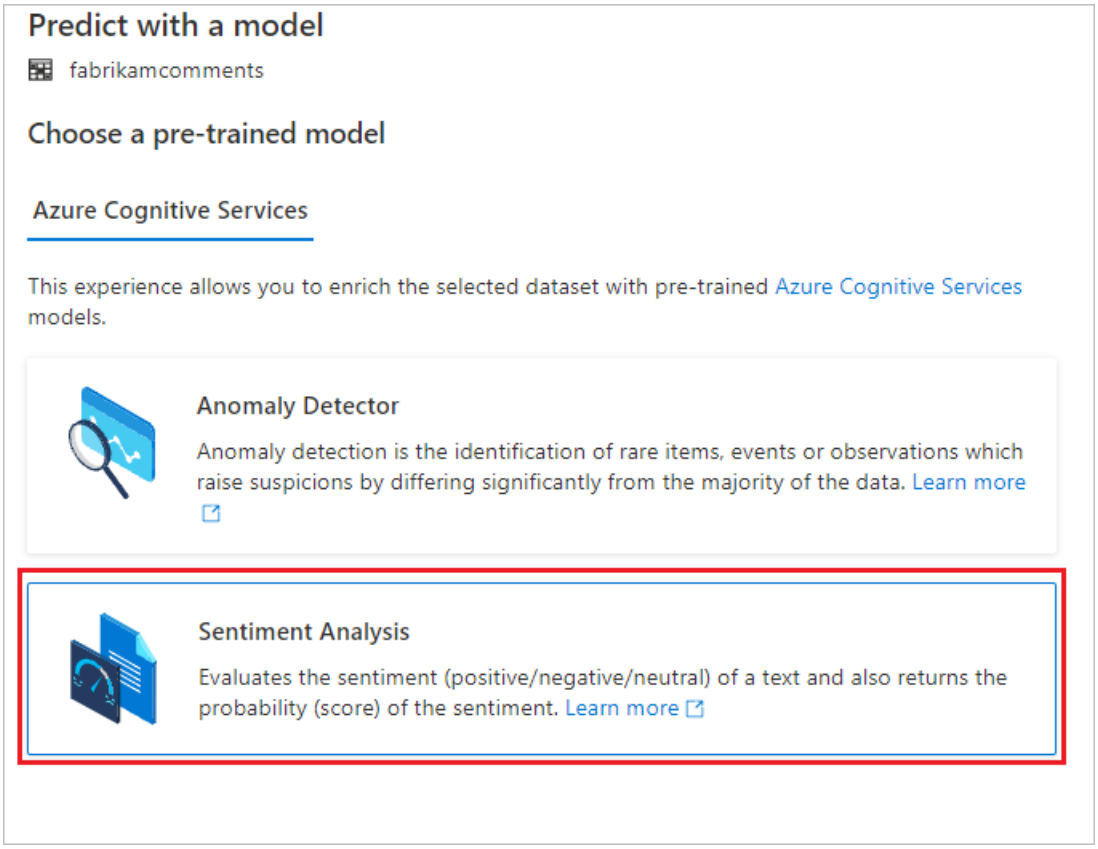
```
%%pyspark
df = spark.read.load('abfss://default@azuresynapsesa.dfs.core.windows.net/data/FabrikamComments.csv',
format='csv'
## Ifa headerexists,uncommentthe linebelow
, header=True
)
df.write.mode("overwrite").saveAsTable("default.YourTableName")
```

Open the Cognitive Services wizard

1. Right-click the Spark table created in the previous procedure. Select **Machine Learning** > **Predict with a model** to open the wizard.



2. A configuration panel appears, and you're asked to select a Cognitive Services model. Select **Sentiment Analysis**.

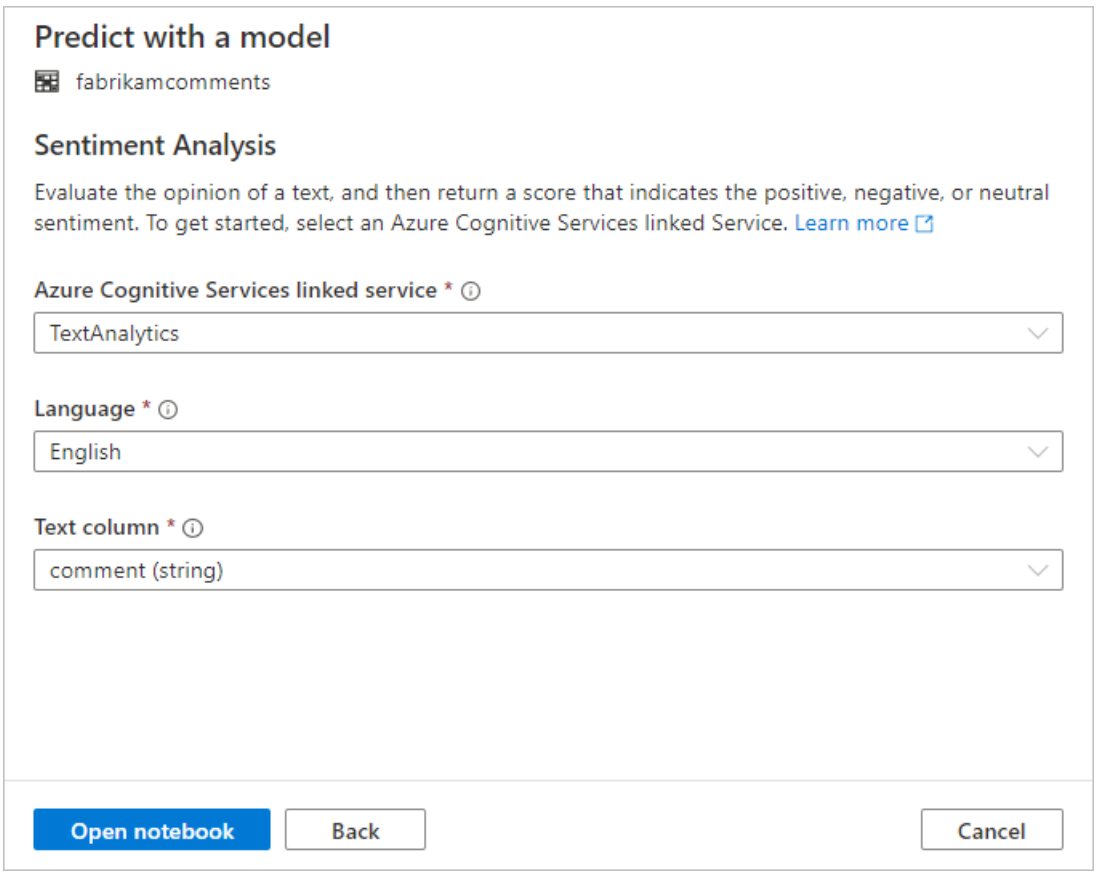


Configure sentiment analysis

Next, configure the sentiment analysis. Select the following details:

- **Azure Cognitive Services linked service**: As part of the prerequisite steps, you created a linked service to your Cognitive Services . Select it here.
- **Language**: Select **English** as the language of the text that you want to perform sentiment analysis on.
- **Text column**: Select **comment (string)** as the text column in your dataset that you want to analyze to determine the sentiment.

When you're done, select **Open notebook**. This generates a notebook for you with PySpark code that performs the sentiment analysis with Azure Cognitive Services.



Run the notebook

The notebook that you just opened uses the SynapseML library to connect to Cognitive Services. The Azure Cognitive Services linked service that you provided allow you to securely reference your cognitive service from this experience without revealing any secrets.

You can now run all cells to enrich your data with sentiments. Select **Run all**.

The sentiments are returned as **positive**, **negative**, **neutral**, or **mixed**. You also get probabilities per sentiment. Learn more about sentiment analysis in Cognitive Services.

Tutorial: Anomaly detection with Cognitive Services

8/19/2022 • 2 minutes to read • Edit Online

In this tutorial, you'll learn how to easily enrich your data in Azure Synapse Analytics with Azure Cognitive Services. You'll use Anomaly Detector to find anomalies. A user in Azure Synapse can simply select a table to enrich for detection of anomalies.

This tutorial covers:

- Steps for getting a Spark table dataset that contains time series data.
- Use of a wizard experience in Azure Synapse to enrich data by using Anomaly Detector in Cognitive Services.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Completion of the pre-configuration steps in the Configure Cognitive Services in Azure Synapse tutorial.

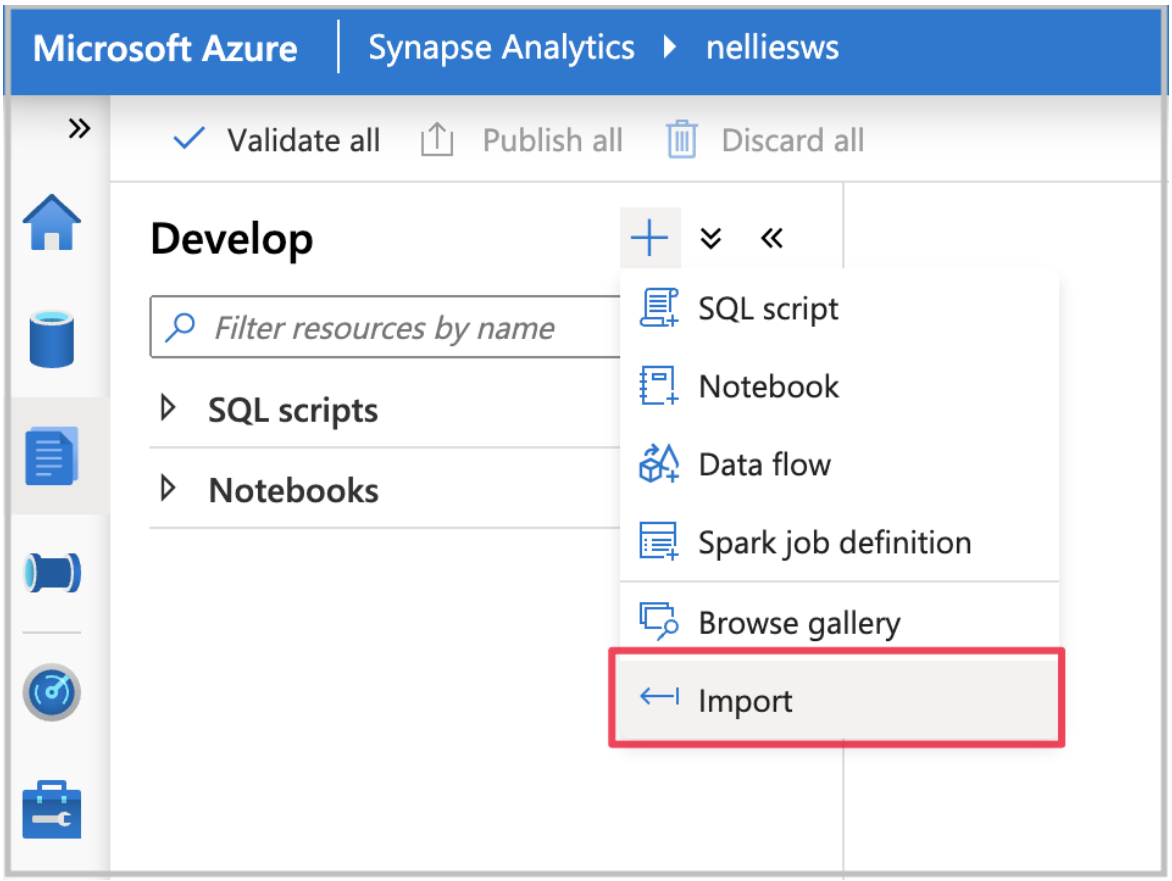
Sign in to the Azure portal

Sign in to the Azure portal.

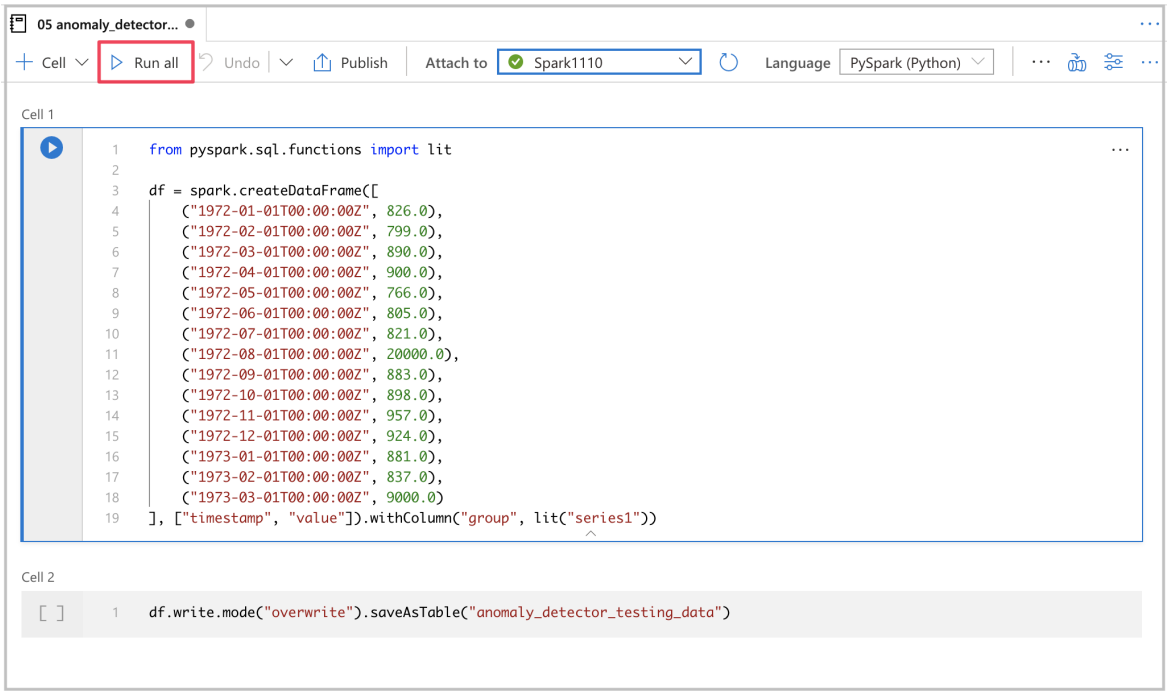
Create a Spark table

You need a Spark table for this tutorial.

1. Download the following notebook file that contains code to generate a Spark table: prepare_anomaly_detector_data.ipynb.
2. Upload the file to your Azure Synapse workspace.



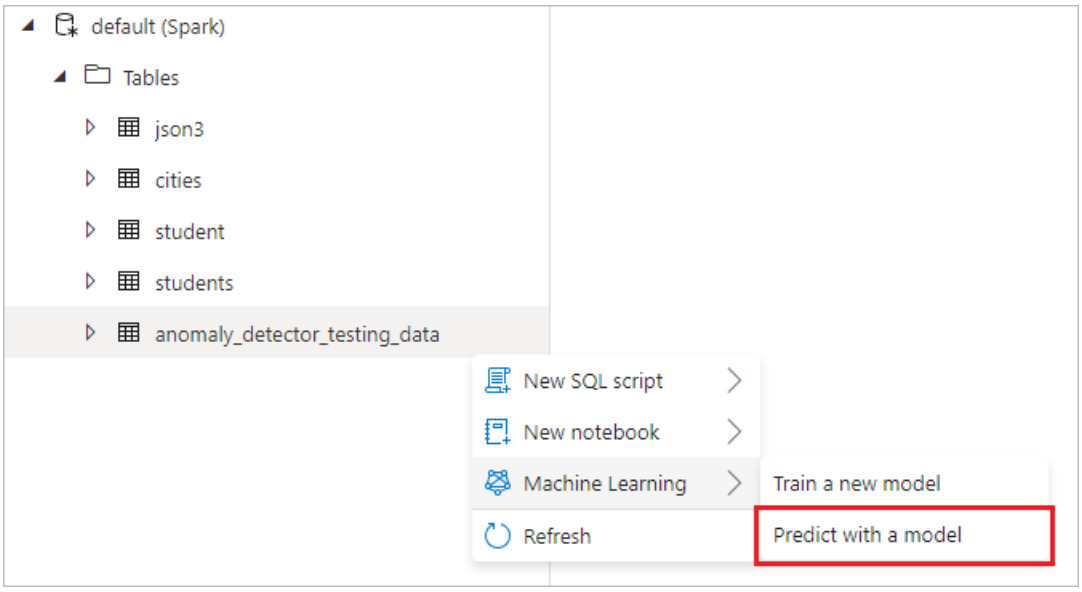
3. Open the notebook file and select **Run All** to run all cells.



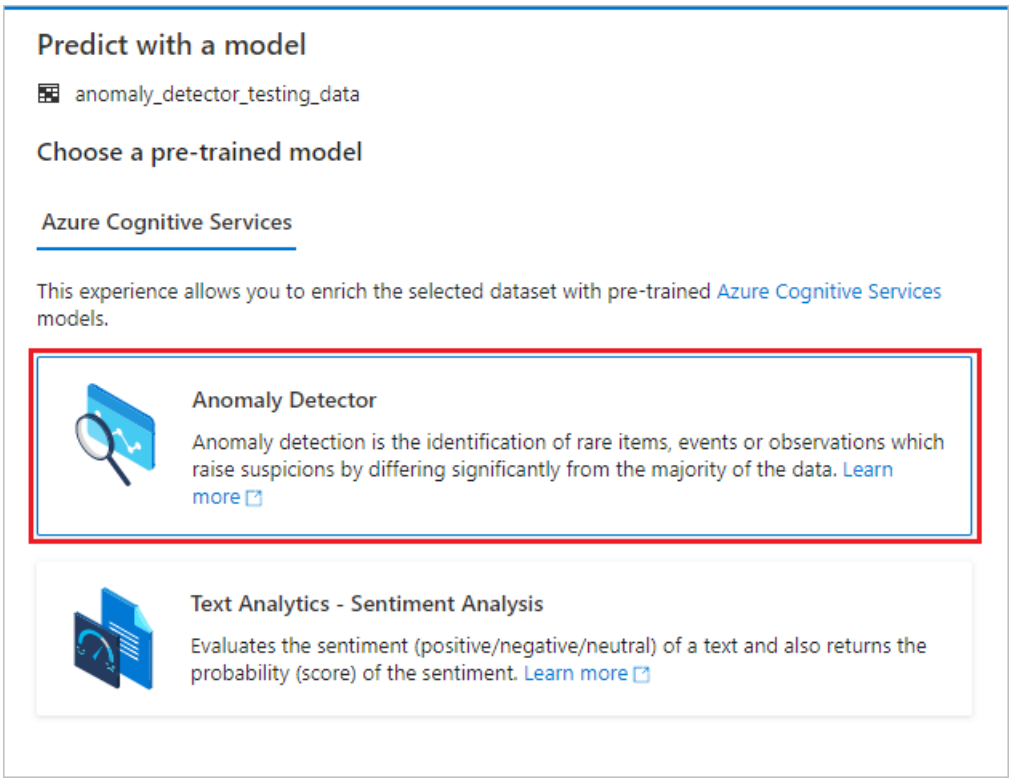
4. A Spark table named **anomaly_detector_testing_data** should now appear in the default Spark database.

Open the Cognitive Services wizard

1. Right-click the Spark table created in the previous step. Select **Machine Learning** > **Predict with a model** to open the wizard.



2. A configuration panel appears, and you're asked to select a Cognitive Services model. Select **Anomaly Detector**.

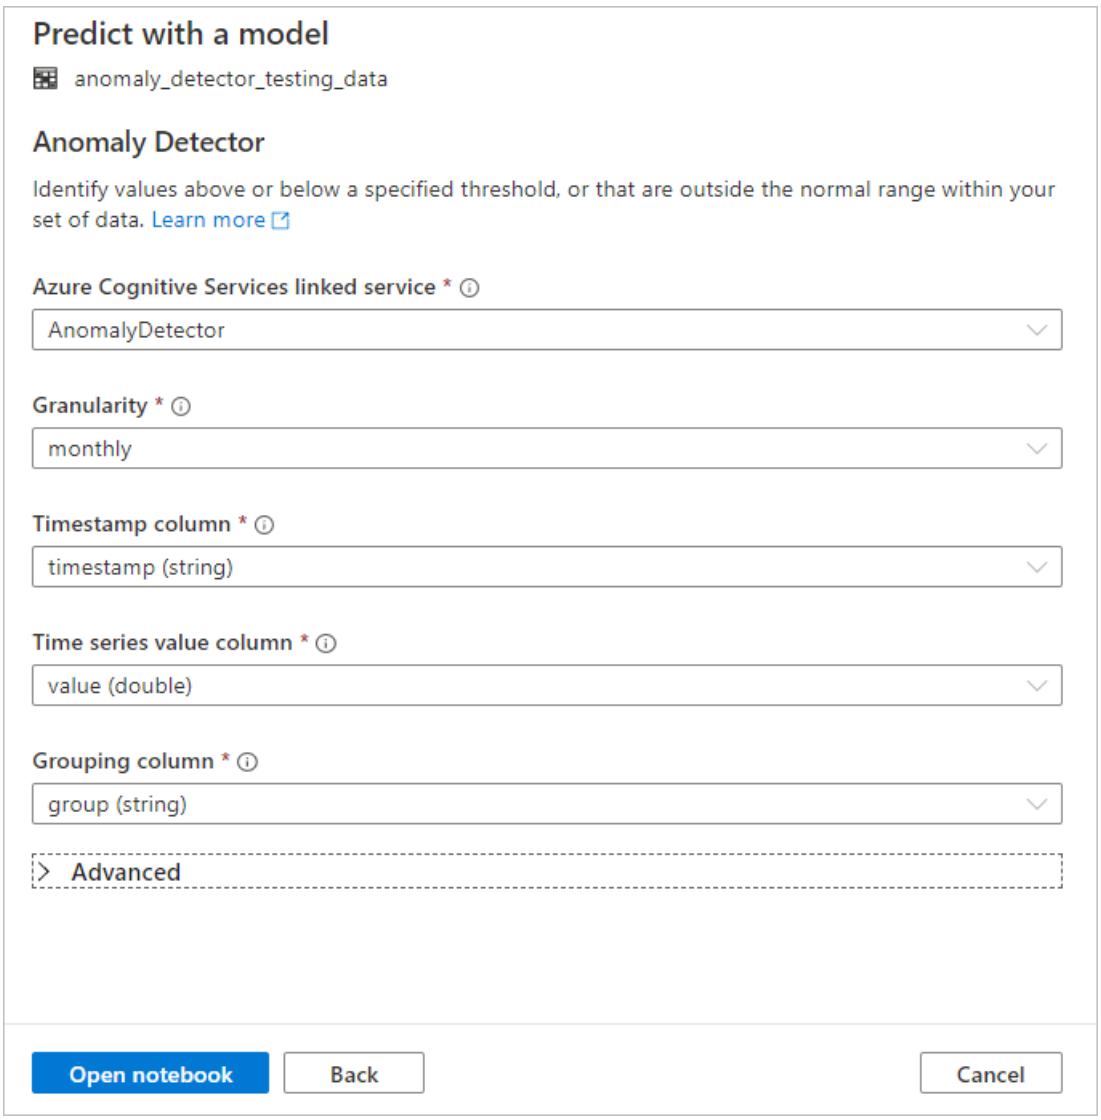


Configure Anomaly Detector

Provide the following details to configure Anomaly Detector:

- **Azure Cognitive Services linked service**: As part of the prerequisite steps, you created a linked service to your Cognitive Services . Select it here.
- **Granularity**: The rate at which your data is sampled. Choose **monthly**.
- **Timestamp column**: The column that represents the time of the series. Choose **timestamp (string)**.
- **Time series value column**: The column that represents the value of the series at the time specified by the Timestamp column. Choose **value (double)**.
- **Grouping column**: The column that groups the series. That is, all rows that have the same value in this column should form one time series. Choose **group (string)**.

When you're done, select **Open notebook**. This will generate a notebook for you with PySpark code that uses Azure Cognitive Services to detect anomalies.



Run the notebook

The notebook that you just opened uses the SynapseML library to connect to Cognitive Services. The Azure Cognitive Services linked service that you provided allow you to securely reference your cognitive service from this experience without revealing any secrets.

You can now run all cells to perform anomaly detection. Select **Run All**. Learn more about Anomaly Detector in Cognitive Services.

Tutorial: Text Analytics with Cognitive Service

8/19/2022 • 6 minutes to read • Edit Online

Text Analytics is an Azure Cognitive Service that enables you to perform text mining and text analysis with Natural Language Processing (NLP) features. In this tutorial, you'll learn how to use Text Analytics to analyze unstructured text on Azure Synapse Analytics.

This tutorial demonstrates using text analytics with SynapseML to:

- Detect sentiment labels at the sentence or document level
- Identify the language for a given text input
- Recognize entities from a text with links to a well-known knowledge base
- Extract key phases from a text
- Identify different entities in text and categorize them into pre-defined classes or types
- Identify and redact sensitive entities in a given text

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Pre-configuration steps described in the tutorial Configure Cognitive Services in Azure Synapse.

Get started

Open Synapse Studio and create a new notebook. To get started, import SynapseML.

```
import synapse.ml
from synapse.ml.cognitive import *
from pyspark.sql.functions import col
```

Configure text analytics

Use the linked text analytics you configured in the pre-configuration steps .

```
cognitive_service_name = "<Your linked service for text analytics>"
```

Text Sentiment

The Text Sentiment Analysis provides a way for detecting the sentiment labels (such as "negative", "neutral" and "positive") and confidence scores at the sentence and document-level. See the Supported languages in Text Analytics API for the list of enabled languages.

V2

```
# Create a dataframe that's tied to it's column names
df = spark.createDataFrame([
  ("I am so happy today, its sunny!", "en-US"),
  ("I am frustrated by this rush hour traffic", "en-US"),
  ("The cognitive services on spark aint bad", "en-US"),
], ["text", "language"])

# Run the Text Analytics service with options
sentimentv2 = (TextSentimentV2()
    .setLinkedService(linked_service_name)
    .setTextCol("text")
    .setOutputCol("sentiment")
    .setErrorCol("error")
    .setLanguageCol("language"))

# Show the results of your text query in a table format
display(sentimentv2.transform(df).select("text", col("sentiment")[0].getItem("score").alias("positive
score")))
```

Expected results

TEXT	POSITIVE SCORE
I am so happy today, its sunny!	0.99511755
I am frustrated by this rush hour traffic	0.007274598
The cognitive services on spark aint bad	0.9144157

V3.1

```
# Create a dataframe that's tied to it's column names
df = spark.createDataFrame([
  ("I am so happy today, its sunny!", "en-US"),
  ("I am frustrated by this rush hour traffic", "en-US"),
  ("The cognitive services on spark aint bad", "en-US"),
], ["text", "language"])

# Run the Text Analytics service with options
sentiment = (TextSentiment()
    .setLinkedService(linked_service_name)
    .setTextCol("text")
    .setOutputCol("sentiment")
    .setErrorCol("error")
    .setLanguageCol("language"))

# Show the results of your text query in a table format
display(sentiment.transform(df).select("text", col("sentiment")[0].getItem("sentiment").alias("sentiment")))
```

Expected results

TEXT	SENTIMENT
I am so happy today, its sunny!	positive
I am frustrated by this rush hour traffic	negative

TEXT	SENTIMENT
The cognitive services on spark aint bad	positive

Language Detector

The Language Detector evaluates text input for each document and returns language identifiers with a score that indicates the strength of the analysis. This capability is useful for content stores that collect arbitrary text, where language is unknown. See the Supported languages in Text Analytics API for the list of enabled languages.

V2

```
# Create a dataframe that's tied to it's column names
df = spark.createDataFrame([
  ("Hello World",),
  ("Bonjour tout le monde",),
  ("La carretera estaba atascada. Había mucho tráfico el día de ayer.",),
  ("你好",),
  ("こんにちは",),
  (":) :( :D",)
], ["text",])

# Run the Text Analytics service with options
languagev2 = (LanguageDetectorV2()
    .setLinkedService(linked_service_name)
    .setTextCol("text")
    .setOutputCol("language")
    .setErrorCol("error"))

# Show the results of your text query in a table format
display(languagev2.transform(df))
```

Expected results

Key Phrase Extractor

The Key Phrase Extraction evaluates unstructured text and returns a list of key phrases. This capability is useful if you need to quickly identify the main points in a collection of documents. See the Supported languages in Text Analytics API for the list of enabled languages.

V2

```
df = spark.createDataFrame([
    ("en", "Hello world. This is some input text that I love."),
    ("fr", "Bonjour tout le monde"),
    ("es", "La carretera estaba atascada. Había mucho tráfico el día de ayer.")
], ["lang", "text"])

keyPhrasesv2 = (KeyPhraseExtractorV2()
    .setLinkedService(linked_service_name)
    .setLanguageCol("lang")
    .setOutputCol("replies")
    .setErrorCol("error"))

display(keyPhrasesv2.transform(df).select("text", col("replies")
[0].getItem("keyPhrases").alias("keyPhrases")))
```

Expected results

TEXT	KEYPHRASES
Hello world. This is some input text that I love.	"["input text","world"]"
Bonjour tout le monde	"["monde"]"
La carretera estaba atascada. Había mucho tráfico el día de ayer.	"["carretera","tráfico","día"]"

V3.1

```
df = spark.createDataFrame([
    ("en", "Hello world. This is some input text that I love."),
    ("fr", "Bonjour tout le monde"),
    ("es", "La carretera estaba atascada. Había mucho tráfico el día de ayer.")
], ["lang", "text"])

keyPhrase = (KeyPhraseExtractor()
    .setLinkedService(linked_service_name)
    .setLanguageCol("lang")
    .setOutputCol("replies")
    .setErrorCol("error"))

display(keyPhrase.transform(df).select("text", col("replies")[0].getItem("keyPhrases").alias("keyPhrases")))
```

Expected results

TEXT	KEYPHRASES
Hello world. This is some input text that I love.	"["Hello world","input text"]"
Bonjour tout le monde	"["Bonjour","monde"]"
La carretera estaba atascada. Había mucho tráfico el día de ayer.	"["mucho tráfico","día","carretera","ayer"]"

Named Entity Recognition (NER)

Named Entity Recognition (NER) is the ability to identify different entities in text and categorize them into pre-defined classes or types such as: person, location, event, product, and organization. See the Supported languages in Text Analytics API for the list of enabled languages.

V2

```
df = spark.createDataFrame([
    ("1", "en", "I had a wonderful trip to Seattle last week."),
    ("2", "en", "I visited Space Needle 2 times.")
], ["id", "language", "text"])

nerv2 = (NERV2()
    .setLinkedService(linked_service_name)
    .setLanguageCol("language")

Tutorial: Computer Vision with Cognitive Service

8/19/2022 • 3 minutes to read • Edit Online

Computer Vision is an Azure Cognitive Service that enables you to process images and return information based on the visual features. In this tutorial, you'll learn how to use Computer Vision to analyze images on Azure Synapse Analytics.

This tutorial demonstrates using text analytics with SynapseML to:

- Extract visual features from the image content
- Recognize characters from images (OCR)
- Analyze image content and generate thumbnail
- Detect and identify domain-specific content in an image
- Generate tags related to an image
- Generate a description of an entire image in human-readable language

Analyze image

Extracts a rich set of visual features based on the image content, such as objects, faces, adult content, and autogenerated text descriptions.

Example input

```
# Create a dataframe with the image URLs
df = spark.createDataFrame([
        ("<replace with your file path>/dog.jpg", )
    ], ["image", ])

# Run the Computer Vision service. Analyze Image extracts infortmation from/about the images.
analysis = (AnalyzeImage()
    .setLinkedService(cognitive_service_name)
    .setVisualFeatures(["Categories","Color","Description","Faces","Objects","Tags"])
    .setOutputCol("analysis_results")
    .setImageUrlCol("image")
    .setErrorCol("error"))

# Show the results of what you wanted to pull out of the images.
display(analysis.transform(df).select("image", "analysis_results.description.tags"))
```

Expected results

```
["dog","outdoor","fence","wooden","small","brown","building","sitting","front","bench","standing","table","w
alking","board","beach","holding","bridge"]
```

Optical character recognition (OCR)

Extract printed text, handwritten text, digits, and currency symbols from images, such as photos of street signs and products, as well as from documents—invoices, bills, financial reports, articles, and more. It's optimized to extract text from text-heavy images and multi-page PDF documents with mixed languages. It supports detecting both printed and handwritten text in the same image or document.

Example input

```
df = spark.createDataFrame([
        ("<replace with your file path>/ocr.jpg", )
    ], ["url", ])

ri = (ReadImage()
    .setLinkedService(cognitive_service_name)
    .setImageUrlCol("url")
    .setOutputCol("ocr"))

display(ri.transform(df))
```

Expected results

url ↓	ReadImage_ececcae91fa0_er...	ocr
https://mmlspark.bl...	undefined	▼ "{"status":"succeeded","createdDateTime":"2021-10-2..." status: ""succeeded"" createdDateTime: ""2021-10-21T10:39:29Z"" lastUpdatedDateTime: ""2021-10-21T10:39:30Z"" ▼ analyzeResult: "{"version":"3.0.0","readResults":[{"angle":20.4048..." version: ""3.0.0"" ▼ readResults: "[{"angle":20.4048,"page":1,"height":1008,"unit":"p..." ▼ 0: "{"angle":20.4048,"page":1,"height":1008,"unit":"pi..." angle: "20.4048" page: "1" height: "1008" unit: ""pixel"" ▼ lines: "[{"boundingBox":[182,511,652,677,609,796,140,630],..." ▼ 0: "{"boundingBox":[182,511,652,677,609,796,140,630],"..." ▶ boundingBox: "[182,511,652,677,609,796,140,630]" text: ""CLOSED"" ▶ words: "[{"boundingBox":[181,512,652,681,601,796,140,630],..." ▼ 1: "{"boundingBox":[146,643,603,813,593,841,136,671],"..." ▶ boundingBox: "[146,643,603,813,593,841,136,671]" text: ""WHEN ONE DOOR CLOSES, ANOTHER"" ▶ words: "[{"boundingBox":[146,644,220,672,210,699,136,671],..." ▼ 2: "{"boundingBox":[75,676,644,887,633,919,65,706],"te..." ▶ boundingBox: "[75,676,644,887,633,919,65,706]" text: ""OPENS. ALL YOU HAVE TO DO IS WALK IN"" ▶ words: "[{"boundingBox":[75,677,161,710,152,739,65,706],"t..." width: "756"

Generate thumbnails

Analyze the contents of an image to generate an appropriate thumbnail for that image. Computer Vision first generates a high-quality thumbnail and then analyzes the objects within the image to determine the area of interest. Computer Vision then crops the image to fit the requirements of the area of interest. The generated thumbnail can be presented using an aspect ratio that is different from the aspect ratio of the original image, depending on your needs.

Example input

```
df = spark.createDataFrame([
        ("<replace with your file path>/satya.jpeg", )
    ], ["url", ])

gt =  (GenerateThumbnails()
    .setLinkedService(cognitive_service_name)
    .setHeight(50)
    .setWidth(50)
    .setSmartCropping(True)
    .setImageUrlCol("url")
    .setOutputCol("thumbnails"))

thumbnails = gt.transform(df).select("thumbnails").toJSON().first()

import json
img = json.loads(thumbnails)["thumbnails"]

displayHTML("<img src='" + img + "'>")
```

Expected results

Tag image

Generates a list of words, or tags, that are relevant to the content of the supplied image. Tags are returned based on thousands of recognizable objects, living beings, scenery, or actions found in images. Tags may contain hints to avoid ambiguity or provide context, for example the tag "ascomycete" may be accompanied by the hint "fungus".

Let continue using Satya's image as an example.

```
df = spark.createDataFrame([
        ("<replace with your file path>/satya.jpeg", )
    ], ["url", ])

ti = (TagImage()
    .setLinkedService(cognitive_service_name)
    .setImageUrlCol("url")
    .setOutputCol("tags"))

display(ti.transform(df))
```

Expected result

url	TagImage_b02b2481c189_error	tags
https://docs.mi...	undefined	▼ "{"tags":[{"name":"person","confidence":0.999554514..." ▼ tags: "[{"name":"person","confidence":0.9995545148849487}..." ▶ 0: "{"name":"person","confidence":0.9995545148849487}" ▶ 1: "{"name":"suit","confidence":0.9894102215766907}" ▶ 2: "{"name":"man","confidence":0.9881249666213989}" ▶ 3: "{"name":"tie","confidence":0.9581113457679749}" ▶ 4: "{"name":"human face","confidence":0.95434975624084..." ▶ 5: "{"name":"clothing","confidence":0.8706792593002319..." ▶ 6: "{"name":"outdoor","confidence":0.8646519184112549}" ▶ 7: "{"name":"smile","confidence":0.8594179749488831}" ▶ 8: "{"name":"glasses","confidence":0.6877670288085938}" requestId: ""d8625b53-ed72-4a35-a3f2-ba9825d88142""

Describe image

Generate a description of an entire image in human-readable language, using complete sentences. Computer Vision's algorithms generate various descriptions based on the objects identified in the image. The descriptions are each evaluated and a confidence score generated. A list is then returned ordered from highest confidence score to lowest.

Let continue using Satya's image as an example.

```
df = spark.createDataFrame([
        ("<replace with your file path>/satya.jpeg", )
    ], ["url", ])

di = (DescribeImage()
    .setLinkedService(cognitive_service_name)
    .setMaxCandidates(3)
    .setImageUrlCol("url")
    .setOutputCol("descriptions"))

display(di.transform(df))
```

Expected result

Recognize domain-specific content

Use domain models to detect and identify domain-specific content in an image, such as celebrities and landmarks. For example, if an image contains people, Computer Vision can use a domain model for celebrities to determine if the people detected in the image are known celebrities.

Let continue using Satya's image as an example.

```
df = spark.createDataFrame([
        ("<replace with your file path>/satya.jpeg", )
    ], ["url", ])

celeb =  (RecognizeDomainSpecificContent()
    .setLinkedService(cognitive_service_name)
    .setModel("celebrities")
    .setImageUrlCol("url")
    .setOutputCol("celebs"))

display(celeb.transform(df))
```

Expected result

url	RecognizeDomain...	celebs
https://d...	undefined	▼ "{"requestId":"295bc3d5-31b9-4870-88b2-3f8f0f23bec6..." requestId: ""295bc3d5-31b9-4870-88b2-3f8f0f23bec6"" ▶ metadata: "{"width":600,"height":900,"format":"Jpeg"}" ▼ result: "{"celebrities":[{"name":"Satya Nadella","faceRecta..." ▼ celebrities: "[{"name":"Satya Nadella","faceRectangle":{"left":2..." ▼ 0: "{"name":"Satya Nadella","faceRectangle":{"left":23..." name: ""Satya Nadella"" ▶ faceRectangle: "{"left":239,"top":293,"width":138,"height":138}" confidence: "0.9998459815979004"

Clean up resources

To ensure the Spark instance is shut down, end any connected sessions(notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **stop session** from the status bar at the upper right of the notebook.

Tutorial: Form Recognizer with Applied AI Service

8/19/2022 • 3 minutes to read • Edit Online

Azure Form Recognizer is an Azure Applied AI Service that enables you to build automated data processing application using machine learning technology. In this tutorial, you'll learn how to easily enrich your data in Azure Synapse Analytics. You'll use Form Recognizer to analyze your forms and documents, extracts text and data, and returns a structured JSON output. You quickly get accurate results that are tailored to your specific content without excessive manual intervention or extensive data science expertise.

This tutorial demonstrates using form recognizer with SynapseML to:

- Extract text and layout from a given document
- Detect and extract data from receipts
- Detect and extract data from business cards
- Detect and extract data from invoices
- Detect and extract data from identification documents

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Pre-configuration steps described in the tutorial Configure Cognitive Services in Azure Synapse.

Get started

Open Synapse Studio and create a new notebook. To get started, import SynapseML.

```
import synapse.ml
from synapse.ml.cognitive import *
```

Configure form recognizer

Use the linked form recognizer you configured in the pre-configuration steps .

```
cognitive_service_name = "<Your linked service for form recognizer>"
```

Analyze Layout

Extract text and layout information from a given document. The input document must be of one of the supported content types - 'application/pdf', 'image/jpeg', 'image/png' or 'image/tiff'.

Example input

Tutorial: Translator with Cognitive Service

8/19/2022 • 3 minutes to read • Edit Online

Translator is an Azure Cognitive Service that enables you to perform language translation and other language-related operations. In this tutorial, you'll learn how to use Translator to build intelligent, multi-language solutions on Azure Synapse Analytics.

This tutorial demonstrates using translator with MMLSpark to:

- Translate text
- Transliterate text
- Detect language
- Break sentence
- Dictionary lookup
- Dictionary example

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Pre-configuration steps described in the tutorial Configure Cognitive Services in Azure Synapse.

Get started

Open Synapse Studio and create a new notebook. To get started, import MMLSpark.

```
import mmlspark
from mmlspark.cognitive import *
from notebookutils import mssparkutils
from pyspark.sql.functions import col, flatten
```

Configure translator

Use the linked translator you configured in the pre-configuration steps .

```
cognitive_service_name = "<Your linked service for translator>"
```

Translate Text

The core operation of the Translator service is to translate text.

```
df = spark.createDataFrame([
  (["Hello, what is your name?", "Bye"],)
], ["text",])

translate = (Translate()
    .setLinkedService(cognitive_service_name)
    .setTextCol("text")
    .setToLanguage(["zh-Hans", "fr"])
    .setOutputCol("translation")
    .setConcurrency(5))

display(translate
      .transform(df)
      .withColumn("translation", flatten(col("translation.translations")))
      .withColumn("translation", col("translation.text"))
      .select("translation"))
```

Expected results

```
["你好，你叫什么名字？","Bonjour, quel est votre nom?","再见","Au revoir"]
```

Transliterate Text

Transliteration is the process of converting a word or phrase from the script (alphabet) of one language to another based on phonetic similarity.

```
transliterateDf =  spark.createDataFrame([
  (["こんにちは", "さようなら"],)
], ["text",])

transliterate = (Transliterate()
    .setLinkedService(cognitive_service_name)
    .setLanguage("ja")
    .setFromScript("Jpan")
    .setToScript("Latn")
    .setTextCol("text")
    .setOutputCol("result"))

display(transliterate
    .transform(transliterateDf)
    .withColumn("text", col("result.text"))
    .withColumn("script", col("result.script"))
    .select("text", "script"))
```

Expected results

TEXT	SCRIPT
"["Kon'nichiwa","sayonara"]"	"["Latn","Latn"]"

Detect Language

If you know that you'll need translation, but don't know the language of the text that will be sent to the Translator service, you can use the language detection operation.

```
detectDf =  spark.createDataFrame([
  (["Hello, what is your name?"],)
], ["text",])

detect = (Detect()
    .setLinkedService(cognitive_service_name)
    .setTextCol("text")
    .setOutputCol("result"))

display(detect
    .transform(detectDf)
    .withColumn("language", col("result.language"))
    .select("language"))
```

Expected results

```
"["en"]"
```

Break Sentence

Identifies the positioning of sentence boundaries in a piece of text.

```
bsDf =  spark.createDataFrame([
  (["Hello, what is your name?"],)
], ["text",])

breakSentence = (BreakSentence()
    .setLinkedService(cognitive_service_name)
    .setTextCol("text")
    .setOutputCol("result"))

display(breakSentence
    .transform(bsDf)
    .withColumn("sentLen", flatten(col("result.sentLen")))
    .select("sentLen"))
```

Expected results

```
"[25]"
```

Dictionary lookup (alternate translations)

With the endpoint, you can get alternate translations for a word or phrase.

```
dictDf = spark.createDataFrame([
  (["fly"],)
], ["text",])

dictionaryLookup = (DictionaryLookup()
    .setLinkedService(cognitive_service_name)
    .setFromLanguage("en")
    .setToLanguage("es")
    .setTextCol("text")
    .setOutputCol("result"))

display(dictionaryLookup
    .transform(dictDf)
    .withColumn("translations", flatten(col("result.translations")))
    .withColumn("normalizedTarget", col("translations.normalizedTarget"))
    .select("normalizedTarget"))
```

Expected results

NORMALIZEDTARGET
"["volar","mosca","operan","pilotar","moscas","marcha"]"

Dictionary examples (translations in context)

After you've performed a dictionary lookup, you can pass the source text and translation to the dictionary/examples endpoint to get a list of examples that show both terms in the context of a sentence or phrase.

```
dictDf = spark.createDataFrame([
  ([("fly", "volar")],)
], ["textAndTranslation",])

dictionaryExamples = (DictionaryExamples()
    .setLinkedService(cognitive_service_name)
    .setFromLanguage("en")
    .setToLanguage("es")
    .setTextAndTranslationCol("textAndTranslation")
    .setOutputCol("result"))

display(dictionaryExamples
    .transform(dictDf)
    .withColumn("examples", flatten(col("result.examples")))
    .select("examples"))
```

Expected results

```
[{"sourcePrefix":"I mean, for a guy who could ","sourceSuffix":".","targetPrefix":"Quiero decir, para un
tipo que podía ","targetTerm":"volar","sourceTerm":"fly","targetSuffix":"."},{"sourcePrefix":"Now it's time
to make you ","sourceSuffix":".","targetPrefix":"Ahora es hora de que te haga

Tutorial: Build machine learning applications using Synapse Machine Learning

8/19/2022 • 6 minutes to read • Edit Online

In this article, you will learn how to use Synapse Machine Learning (SynapseML) to create machine learning applications. SynapseML expands the distributed machine learning solution of Apache Spark by adding many deep learning and data science tools, such as Azure Cognitive Services, OpenCV, LightGBM and more. SynapseML allows you to build powerful and highly scalable predictive and analytical models from various Spark data sources. Synapse Spark provide built-in SynapseML libraries including:

- Vowpal Wabbit – Library services for Machine learning to enable Text analytics like sentiment analysis in tweets.
- Cognitive Services on Spark – To combine the feature of Azure Cognitive Services in SparkML pipelines in order to derive solution design for cognitive data modeling services like anomaly detection.
- LightGBM – LightGBM is a gradient boosting framework that uses tree based learning algorithms. It is designed to be distributed and higher efficiency.
- Conditional KNN - Scalable KNN Models with Conditional Queries.
- HTTP on Spark – Enables distributed Microservices orchestration in integrating Spark and HTTP protocol-based accessibility.

This tutorial covers samples using Azure Cognitive Services in SynapseML for

- Text Analytics - get the sentiment (or mood) of a set of sentences.
- Computer Vision - get the tags (one-word descriptions) associated with a set of images.
- Bing Image Search - search the web for images related to a natural language query.
- Anomaly Detector - detect anomalies within a time series data.

If you don't have an Azure subscription, create a free account before you begin.

Prerequisites

- Azure Synapse Analytics workspace with an Azure Data Lake Storage Gen2 storage account configured as the default storage. You need to be the *Storage Blob Data Contributor* of the Data Lake Storage Gen2 file system that you work with.
- Spark pool in your Azure Synapse Analytics workspace. For details, see Create a Spark pool in Azure Synapse.
- Pre-configuration steps described in the tutorial Configure Cognitive Services in Azure Synapse.

Get started

To get started, import SynapseML and configurate service keys.

```
import synapse.ml

from synapse.ml.cognitive import *
from notebookutils import mssparkutils

# A general Cognitive Services key for Text Analytics and Computer Vision (or use separate keys that belong
to each service)
cognitive_service_key = mssparkutils.credentials.getSecret("ADD_YOUR_KEY_VAULT_NAME",
"ADD_YOUR_SERVICE_KEY","ADD_YOUR_KEY_VAULT_LINKED_SERVICE_NAME")
# A Bing Search v7 subscription key
bingsearch_service_key = mssparkutils.credentials.getSecret("ADD_YOUR_KEY_VAULT_NAME",
"ADD_YOUR_BING_SEARCH_KEY","ADD_YOUR_KEY_VAULT_LINKED_SERVICE_NAME")
# An Anomaly Dectector subscription key
anomalydetector_key = mssparkutils.credentials.getSecret("ADD_YOUR_KEY_VAULT_NAME",
"ADD_YOUR_ANOMALY_KEY","ADD_YOUR_KEY_VAULT_LINKED_SERVICE_NAME")
```

Text analytics sample

The Text Analytics service provides several algorithms for extracting intelligent insights from text. For example, we can find the sentiment of given input text. The service will return a score between 0.0 and 1.0 where low scores indicate negative sentiment and high score indicates positive sentiment. This sample uses three simple sentences and returns the sentiment for each.

```
from pyspark.sql.functions import col

# Create a dataframe that's tied to it's column names
df_sentences = spark.createDataFrame([
  ("I am so happy today, its sunny!", "en-US"),
  ("this is a dog", "en-US"),
  ("I am frustrated by this rush hour traffic!", "en-US")
], ["text", "language"])

# Run the Text Analytics service with options
sentiment = (TextSentiment()
    .setTextCol("text")
    .setLocation("eastasia") # Set the location of your cognitive service
    .setSubscriptionKey(cognitive_service_key)
    .setOutputCol("sentiment")
    .setErrorCol("error")
    .setLanguageCol("language"))

# Show the results of your text query in a table format

display(sentiment.transform(df_sentences).select("text", col("sentiment")
[0].getItem("sentiment").alias("sentiment")))
```

Expected results

TEXT	SENTIMENT
I am frustrated by this rush hour traffic!	negative
this is a dog	neutral
I am so happy today, its sunny!	positive

Computer vision sample

Computer Vision analyzes images to identify structure such as faces, objects, and natural-language descriptions. In this sample, we tag the follow image. Tags are one-word descriptions of things in the image like recognizable objects, people, scenery, and actions.

```
# Create a dataframe with the image URL
df_images = spark.createDataFrame([
        ("https://raw.githubusercontent.com/Azure-Samples/cognitive-services-sample-data-
files/master/ComputerVision/Images/objects.jpg", )
    ], ["image", ])

# Run the Computer Vision service. Analyze Image extracts information from/about the images.
analysis = (AnalyzeImage()
    .setLocation("eastasia") # Set the location of your cognitive service
    .setSubscriptionKey(cognitive_service_key)
    .setVisualFeatures(["Categories","Color","Description","Faces","Objects","Tags"])
    .setOutputCol("analysis_results")
    .setImageUrlCol("image")
    .setErrorCol("error"))

# Show the results of what you wanted to pull out of the images.
display(analysis.transform(df_images).select("image", "analysis_results.description.tags"))
```

Expected results

IMAGE	TAGS
`https://raw.githubusercontent.com/Azure-Samples/cognitive-services-sample-data-files/master/ComputerVision/Images/objects.jpg`	[skating, person, man, outdoor, riding, sport, skateboard, young, board, shirt, air, park, boy, side, jumping, ramp, trick, doing, flying]

Bing image search sample

Bing Image Search searches the web to retrieve images related to a user's natural language query. In this sample, we use a text query that looks for images with quotes. It returns a list of image URLs that contain photos related to our query.

```
from pyspark.ml import PipelineModel

# Number of images Bing will return per query
imgsPerBatch = 2
# A list of offsets, used to page into the search results
offsets = [(i*imgsPerBatch,) for i in range(10)]
# Since web content is our data, we create a dataframe with options on that data: offsets
bingParameters = spark.createDataFrame(offsets, ["offset"])

# Run the Bing Image Search service with our text query
bingSearch = (BingImageSearch()
    .setSubscriptionKey(bingsearch_service_key)
    .setOffsetCol("offset")
    .setQuery("Martin Luther King Jr. quotes")
    .setCount(imgsPerBatch)
    .setOutputCol("images"))

# Transformer that extracts and flattens the richly structured output of Bing Image Search into a simple URL
column
getUrls = BingImageSearch.getUrlTransformer("images", "url")
pipeline_bingsearch = PipelineModel(stages=[bingSearch, getUrls])

# Show the results of your search: image URLs
res_bingsearch = pipeline_bingsearch.transform(bingParameters)
display(res_bingsearch.dropDuplicates())
```

Expected results

Anomaly detector sample

Anomaly Detector is great for detecting irregularities in your time series data. In this sample, we use the service to find anomalies in the entire time series.

```
from pyspark.sql.functions import lit

# Create a dataframe with the point data that Anomaly Detector requires
df_timeseriesdata = spark.createDataFrame([
    ("1972-01-01T00:00:00Z", 826.0),
    ("1972-02-01T00:00:00Z", 799.0),
    ("1972-03-01T00:00:00Z", 890.0),
    ("1972-04-01T00:00:00Z", 900.0),
    ("1972-05-01T00:00:00Z", 766.0),
    ("1972-06-01T00:00:00Z", 805.0),
    ("1972-07-01T00:00:00Z", 821.0),
    ("1972-08-01T00:00:00Z", 20000.0), # anomaly
    ("1972-09-01T00:00:00Z", 883.0),
    ("1972-10-01T00:00:00Z", 898.0),
    ("1972-11-01T00:00:00Z", 957.0),
    ("1972-12-01T00:00:00Z", 924.0),
    ("1973-01-01T00:00:00Z", 881.0),
    ("1973-02-01T00:00:00Z", 837.0),
    ("1973-03-01T00:00:00Z", 9000.0) # anomaly
], ["timestamp", "value"]).withColumn("group", lit("series1"))

# Run the Anomaly Detector service to look for irregular data
anamoly_detector = (SimpleDetectAnomalies()
  .setSubscriptionKey(anomalydetector_key)
  .setLocation("eastasia")
  .setTimestampCol("timestamp")
  .setValueCol("value")
  .setOutputCol("anomalies")
  .setGroupbyCol("group")
  .setGranularity("monthly"))

# Show the full results of the analysis with the anomalies marked as "True"
display(anamoly_detector.transform(df_timeseriesdata).select("timestamp", "value", "anomalies.isAnomaly"))
```

Expected results

TIMESTAMP	VALUE	ISANOMALY
1972-01-01T00:00:00Z	826.0	false
1972-02-01T00:00:00Z	799.0	false
1972-03-01T00:00:00Z	890.0	false
1972-04-01T00:00:00Z	900.0	false
1972-05-01T00:00:00Z	766.0	false
1972-06-01T00:00:00Z	805.0	false

TIMESTAMP	VALUE	ISANOMALY
1972-07-01T00:00:00Z	821.0	false

1972-09-01T00:00:00Z	883.0	false
1972-10-01T00:00:00Z	898.0	false
1972-11-01T00:00:00Z	957.0	false
1972-12-01T00:00:00Z	924.0	false
1973-01-01T00:00:00Z	881.0	false
1973-02-01T00:00:00Z	837.0	false
1973-03-01T00:00:00Z	9000.0	true

Speech-to-text sample

The Speech-to-text service converts streams or files of spoken audio to text. In this sample, we transcribe one audio file to text.

```
# Create a dataframe with our audio URLs, tied to the column called "url"
df = spark.createDataFrame([("https://mmlspark.blob.core.windows.net/datasets/Speech/audio2.wav",)
                            ], ["url"])

# Run the Speech-to-text service to translate the audio into text
speech_to_text = (SpeechToTextSDK()
    .setSubscriptionKey(service_key)
    .setLocation("northeurope") # Set the location of your cognitive service
    .setOutputCol("text")
    .setAudioDataCol("url")
    .setLanguage("en-US")
    .setProfanity("Masked"))

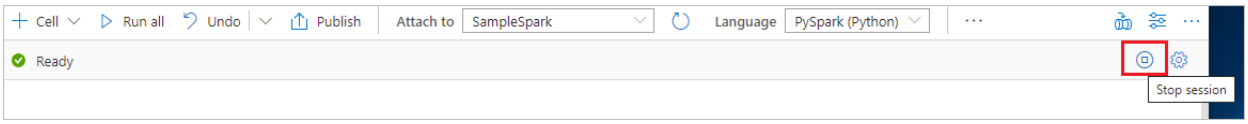
# Show the results of the translation
display(speech_to_text.transform(df).select("url", "text.DisplayText"))
```

Expected results

URL	DISPLAYTEXT
`https://mmlspark.blob.core.windows.net/datasets/Speech/audio2.wav`	Custom Speech provides tools that allow you to visually inspect the recognition quality of a model by comparing audio data with the corresponding recognition result from the custom speech portal. You can playback uploaded audio and determine if the provided recognition result is correct. This tool allows you to quickly inspect quality of Microsoft's baseline speech to text model or a trained custom model without having to transcribe any audio data.

Clean up resources

To ensure the Spark instance is shut down, end any connected sessions(notebooks). The pool shuts down when the **idle time** specified in the Apache Spark pool is reached. You can also select **stop session** from the status bar at the upper right of the notebook.



Next steps

- Check out Synapse sample notebooks
- SynapseML GitHub Repo

QuickStart:Connect a Synapse workspace to a Microsoft Purview account

8/19/2022 • 4 minutes to read • Edit Online

In this quickstart, you will register a Microsoft Purview Account to a Synapse workspace. That connection allows you to discover Microsoft Purview assets, interact with them through Synapse capabilities, and push lineage information to Microsoft Purview.

You can perform the following tasks in Synapse:

- Use the search box at the top to find Microsoft Purview assets based on keywords
- Understand the data based on metadata, lineage, annotations
- Connect those data to your workspace with linked services or integration datasets
- Analyze those datasets with Synapse Apache Spark, Synapse SQL, and Data Flow
- Execute pipelines and push lineage information to Microsoft Purview

Prerequisites

- Microsoft Purview account
- Synapseworkspace

Permissions for connecting a Microsoft Purview account

To connect a Microsoft Purview Account to a Synapse workspace, you need a **Contributor** role in Synapse workspace from Azure portal IAM and you need access to that Microsoft Purview Account. For more information, see Microsoft Purview permissions.

Connect a Microsoft Purview account

Follow the steps to connect a Microsoft Purview account:

1. Gotohttps://web.azuresynapse.net and sign in to your Synapse workspace.
2. Go to **Manage** -> **Microsoft Purview**, select **Connect to a Microsoft Purview account**.
3. You can choose **From Azure subscription** or **Enter manually**. **From Azure subscription**, you can select the account that you have access to.
4. Once connected, you can see the name of the Microsoft Purview account in the tab **Microsoft Purview account**.

If your Microsoft Purview account is protected by firewall, create the managed private endpoints for Microsoft Purview. Learn more about how to let Azure Synapse access a secured Microsoft Purview account. You can either do it during the initial connection or edit an existing connection later.

The Microsoft Purview connection information is stored in the Synapse workspace resource like the following. To establish the connection programmatically, you can update the Synapse workspace and add the `purviewConfiguration` settings.

```
{
    "name": "ContosoSynapseWorkspace",
    "type": "Microsoft.Synapse/workspaces",
    "location": "<region>",
    "properties": {
        ...
        "purviewConfiguration": {
            "purviewResourceId":
"/subscriptions/<subscriptionId>/resourceGroups/<resourceGroupname>/providers/Microsoft.Purview/accounts/<Pu
rviewAccountName>"
        }
    },
    "identity": {...},
    ...
}
```

Set up authentication

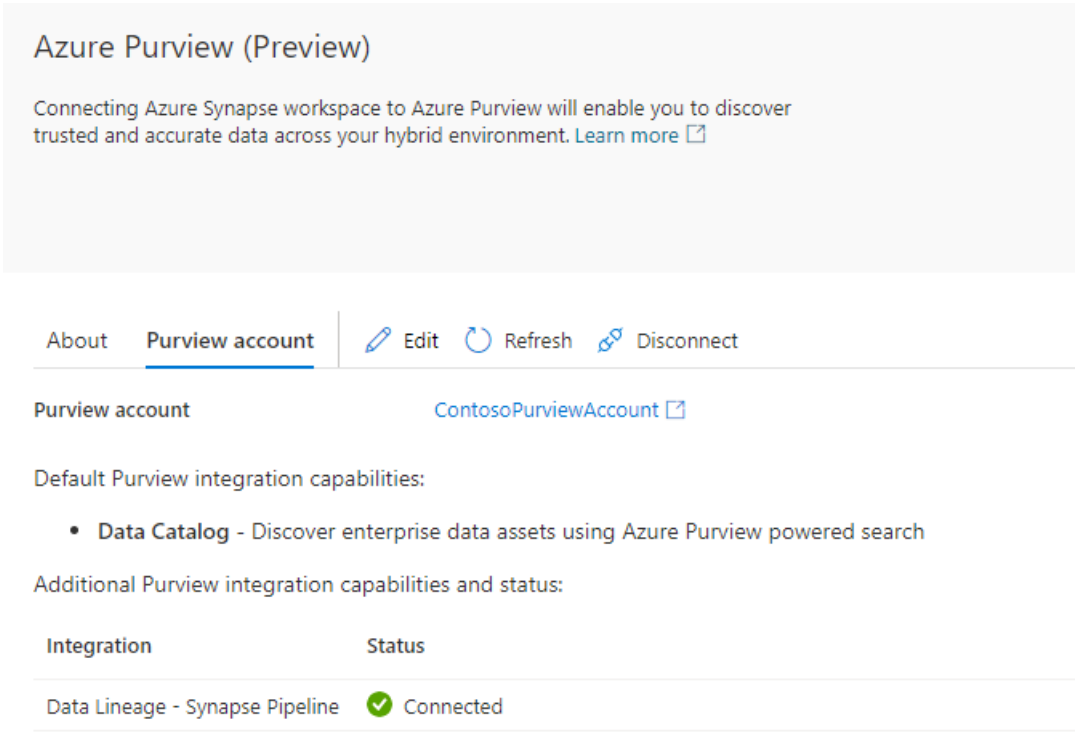
Synapse workspace's managed identity is used to authenticate lineage push operations from Synapse workspace to Microsoft Purview.

Grant the Synapse workspace's managed identity **Data Curator** role on your Microsoft Purview **root collection**. Learn more about Access control in Microsoft Purview and Add roles and restrict access through collections.

When connecting Synapse workspace to Microsoft Purview in Synapse Studio, Synapse tries to add such role assignment automatically. If you have **Collection admins** role on the Microsoft Purview root collection and have access to Microsoft Purview account from your network, this operation is done successfully.

Monitor Microsoft Purview connection

Once you connect the Synapse workspace to a Microsoft Purview account, you see the following page with details on the enabled integration capabilities.



For **Data Lineage - Synapse Pipeline**, you may see one of below status:

- **Connected**: The Synapse workspace is successfully connected to the Microsoft Purview account. Note this indicates Synapse workspace is associated with a Microsoft Purview account and has permission to push lineage to it. If your Microsoft Purview account is protected by firewall, you also need to make sure the integration runtime used to execute the activities and conduct lineage push can reach the Microsoft Purview account. Learn more from Access a secured Microsoft Purview account.
- **Disconnected**: The Synapse workspace cannot push lineage to Microsoft Purview because Microsoft Purview Data Curator role is not granted to Synapse workspace's managed identity. To fix this issue, go to your Microsoft Purview account to check the role assignments, and manually grant the role as needed. Learn more from Set up authentication section.
- **Unknown**: Azure Synapse cannot check the status. Possible reasons are:
  - Cannot reach the Microsoft Purview account from your current network because the account is protected by firewall. You can launch the Synapse Studio from a private network that has connectivity to your Microsoft Purview account instead.
  - You don't have permission to check role assignments on the Microsoft Purview account. You can contact the Microsoft Purview account admin to check the role assignments for you. Learn about the needed Microsoft Purview role from Set up authentication section.

Report lineage to Microsoft Purview

Once you connect the Synapse workspace to a Microsoft Purview account, when you execute pipelines, Synapse reports lineage information to the Microsoft Purview account. For detailed supported capabilities and an end to end walkthrough, see Metadata and lineage from Azure Synapse Analytics.

Discover and explore data using Microsoft Purview

Once you connect the Synapse workspace to a Microsoft Purview account, you can use the search bar at the top center of Synapse workspace to search for data and perform actions. Learn more from Discover, connect and explore data in Synapse using Microsoft Purview.

Access a secured Microsoft Purview account from Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

This article describes how to access a secured Microsoft Purview account from Azure Synapse Analytics for different integration scenarios.

Microsoft Purview private endpoint deployment scenarios

You can use Azure private endpoints for your Microsoft Purview accounts to allow secure access from a virtual network (VNet) to the catalog over a Private Link. Microsoft Purview provides different types of private points for various access need: *account* private endpoint, *portal* private endpoint, and *ingestion* private endpoints. Learn more from Microsoft Purview private endpoints conceptual overview.

If your Microsoft Purview account is protected by firewall and denies public access, make sure you follow below checklist to set up the private endpoints so Synapse can successfully connect to Microsoft Purview.

SCENARIO	REQUIRED MICROSOFT PURVIEW PRIVATE ENDPOINTS
Run pipeline and report lineage to Microsoft Purview	For Synapse pipeline to push lineage to Microsoft Purview, Microsoft Purview ***account*** and ***ingestion*** private endpoints are required. - When using **Azure Integration Runtime**, follow the steps in Managed private endpoints for Microsoft Purview section to create managed private endpoints in the Synapse managed virtual network. - When using **Self-hosted Integration Runtime**, follow the steps in this section to create the *account* and *ingestion* private endpoints in your integration runtime's virtual network.
Discover and explore data using Microsoft Purview on Synapse Studio	To use the search bar at the top center of Synapse Studio to search for Microsoft Purview data and perform actions, you need to create Microsoft Purview ***account*** and ***portal*** private endpoints in the virtual network that you launch the Synapse Studio. Follow the steps in Enable *account* and *portal* private endpoint.

Managed private endpoints for Microsoft Purview

Managed private endpoints are private endpoints created a Managed Virtual Network associated with your Azure Synapse workspace. When you run pipeline and report lineage to a firewall protected Microsoft Purview account, make sure your Synapse workspace is created with "Managed virtual network" option enabled, then create the Microsoft Purview ***account*** and ***ingestion*** managed private endpoints as follows.

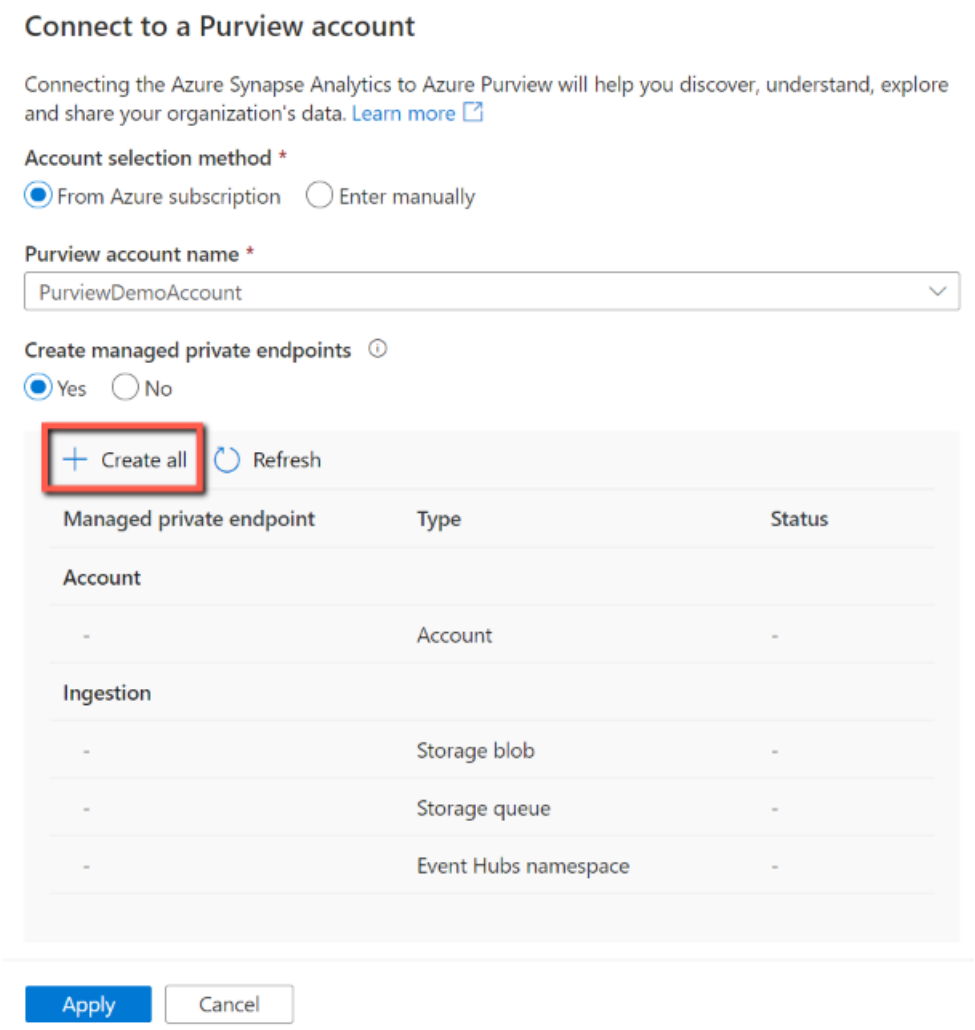
Create managed private endpoints

To create managed private endpoints for Microsoft Purview on Synapse Studio:

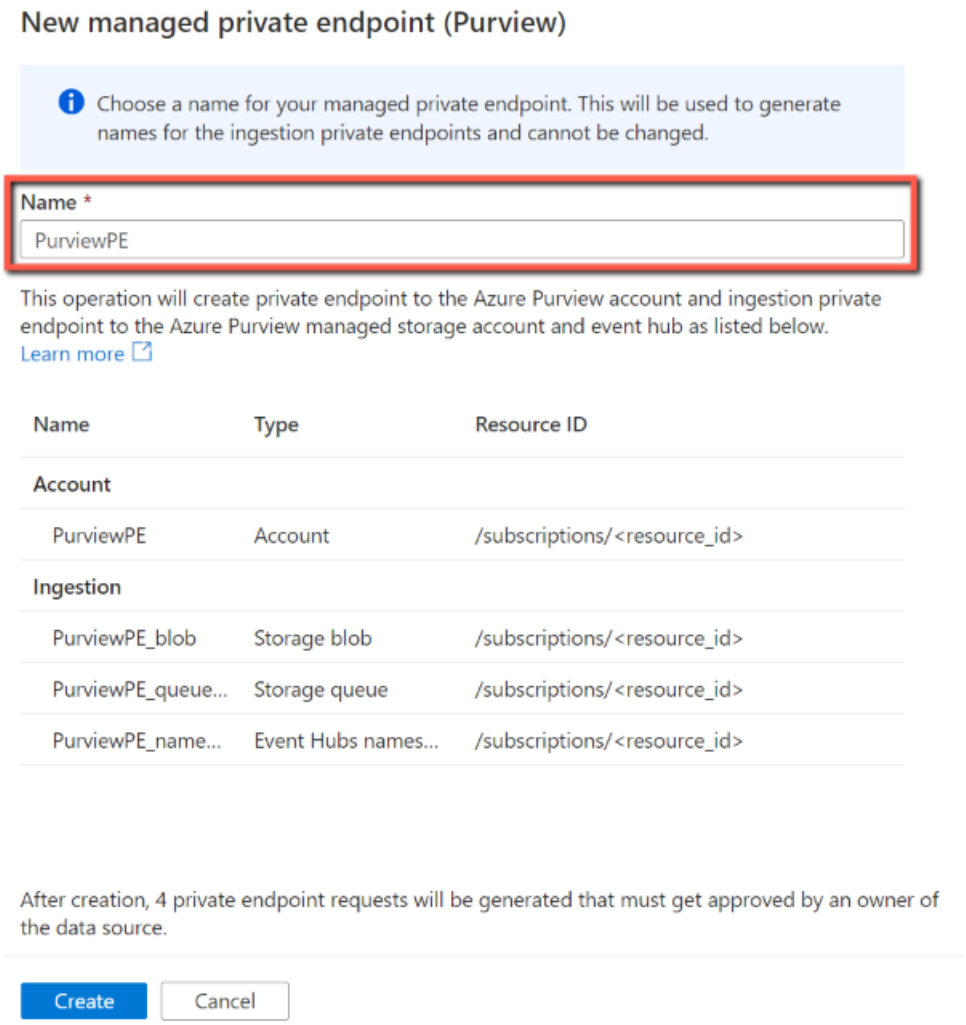
1. Go to **Manage** -> **Microsoft Purview**, and click **Edit** to edit your existing connected Microsoft Purview account or click **Connect to a Microsoft Purview account** to connect to a new Microsoft Purview account.

2. Select **Yes** for **Create managed private endpoints**. You need to have "**workspaces/managedPrivateEndpoint/write**" permission, e.g. Synapse Administrator or Synapse Linked Data Manager role.

3. Click **+ Create all** button to batch create the needed Microsoft Purview private endpoints, including the ***account*** private endpoint and the ***ingestion*** private endpoints for the Microsoft Purview managed resources - Blob storage, Queue storage, and Event Hubs namespace. You need to have at least **Reader** role on your Microsoft Purview account for Synapse to retrieve the Microsoft Purview managed resources' information.



4. In the next page, specify a name for the private endpoint. It will be used to generate names for the ingestion private endpoints as well with suffix.



5. Click **Create** to create the private endpoints. After creation, 4 private endpoint requests will be generated that must get approved by an owner of Microsoft Purview.

Such batch managed private endpoint creation is provided on the Synapse Studio only. If you want to create the managed private endpoints programmatically, you need to create those PEs individually. You can find Microsoft Purview managed resources' information from Azure portal -> your Microsoft Purview account -> Managed resources.

Approve private endpoint connections

After you create the managed private endpoints for Microsoft Purview, you see "Pending" state first. The Microsoft Purview owner need to approve the private endpoint connections for each resource.

If you have permission to approve the Microsoft Purview private endpoint connection, from Synapse Studio:

1. Go to **Manage** -> **Microsoft Purview** -> **Edit**
2. In the private endpoint list, click the **Edit** (pencil) button next to each private endpoint name
3. Click **Manage approvals in Azure portal** which will bring you to the resource.
4. On the given resource, go to **Networking** -> **Private endpoint connection** to approve it. The private endpoint is named as `data_factory_name.your_defined_private_endpoint_name` with description as "Requested by data_factory_name".
5. Repeat this operation for all private endpoints.

If you don't have permission to approve the Microsoft Purview private endpoint connection, ask the Microsoft Purview account owner to do as follows.

- For *account* private endpoint, go to Azure portal -> your Microsoft Purview account -> Networking -> Private endpoint connection to approve.

- For *ingestion* private endpoints, go to Azure portal -> your Microsoft Purview account -> Managed resources, click into the Storage account and Event Hubs namespace respectively, and approve the private endpoint connection in Networking -> Private endpoint connection page.

Monitor managed private endpoints

You can monitor the created managed private endpoints for Microsoft Purview at two places:

- Go to **Manage** -> **Microsoft Purview** -> **Edit** to open your existing connected Microsoft Purview account. To see all the relevant private endpoints, you need to have at least **Reader** role on your Microsoft Purview account for Synapse to retrieve the Microsoft Purview managed resources' information. Otherwise, you only see *account* private endpoint with warning.
- Go to **Manage** -> **Managed private endpoints** where you see all the managed private endpoints created under the Synapse workspace. If you have at least **Reader** role on your Microsoft Purview account, you see Microsoft Purview relevant private endpoints being grouped together. Otherwise, they show up separately in the list.

Nextsteps

- Connect Synapse workspace to Microsoft Purview
- Metadata and lineage from Azure Synapse Analytics
- Discover, connect and explore data in Synapse using Microsoft Purview

Discover, connect, and explore data in Synapse using Microsoft Purview

8/19/2022 • 2 minutes to read • Edit Online

In this document,you will learn the type of interactions that you can perform when registering a Microsoft Purview Account into Synapse.

Prerequisites

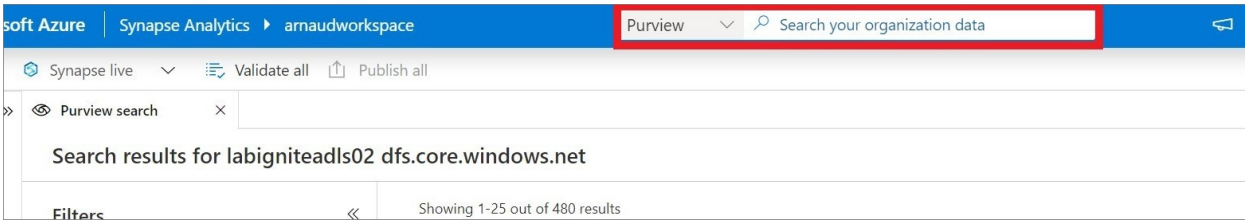
- Microsoft Purview account
- Synapseworkspace
- Connect a Microsoft Purview Account into Synapse

Using Microsoft Purview in Synapse

The use Microsoft Purview in Synapse requires you to have access to that Microsoft Purview account. Synapse passes-through your Microsoft Purview permission. As an example, if you have a curator permission role, you will be able to edit metadata scanned by Microsoft Purview.

Data discovery: search datasets

To discover data registered and scanned by Microsoft Purview, you can use the Search bar at the top center of Synapse workspace. Make sure that you select Microsoft Purview to search for all of your organization data.



Microsoft Purview actions

Here is a list of the Microsoft Purview features that are available in Synapse:

- **Overview** of the metadata
- View and edit **schema** of the metadata with classifications, glossary terms, data types, and descriptions
- View **lineage** to understand dependencies and do impact analysis. For more information about, see lineage
- View and edit **Contacts** to know who is an owner or expert over a dataset
- **Related** to understand the hierarchical dependencies of a specific dataset. This experience is helpful to browse through data hierarchy.
- Click **Request Access** to request access to the data by triggering the self-service data access workflow configured by Workflow Admin in Microsoft Purview. For more information see Request access and Self-Service data access workflow.

Actions that you can perform over datasets with Synapse resources

Connect data to Synapse

- You can create a **new linked service** to Synapse. That action will be required to copy data to Synapse or have them in your data hub (for supported data sources like ADLSg2)

- For objects like files, folders, or tables, you can directly create a **new integration dataset** and leverage an existing linked service if already created

We are not yet able to infer if there is an existing linked service or integration dataset.

Develop in Synapse

There are three actions that you can perform: **New SQL Script**, **New Notebook**, and **New Data Flow**.

With **New SQL Script**, depending on the type of support, you can:

- View the top 100 rows in order to understand the shape of the data.
- Create an external table from Synapse SQL database
- Load the data into a Synapse SQL database

With **New notebook**, you can:

- Load data into a Spark DataFrame
- Create a Spark Table (if you do that over Parquet format, it also creates a serverless SQL pool table).

With **New data flow**, you can create an integration dataset that can be used a source in a data flow pipeline. Data flow is a no-code developer capability to perform data transformation. For more information about using data flow in Synapse.

Nextsteps

- Register and scan Azure Synapse assets in Microsoft Purview
- How to Search Data in Microsoft Purview Data Catalog

Plan and manage costs for Azure Synapse Analytics

8/19/2022 • 7 minutes to read • Edit Online

This article describes how you plan for and manage costs for Azure Synapse Analytics. First, you use the Azure pricing calculator to help plan forAzure Synapse Analytics costs before you add any resources for the service to estimate costs. Next, as you add Azure resources, review the estimated costs. After you've started using Azure Synapse Analytics resources, use Cost Management features to set budgets and monitor costs. You can also review forecasted costs and identify spending trends to identify areas where you might want to act. Costs for Azure Synapse Analytics are only a portion of the monthly costs in your Azure bill. Although this article explains how to plan for and manage costs for Azure Synapse Analytics, you're billed for all Azure services and resources used in your Azure subscription, including the third-party services.

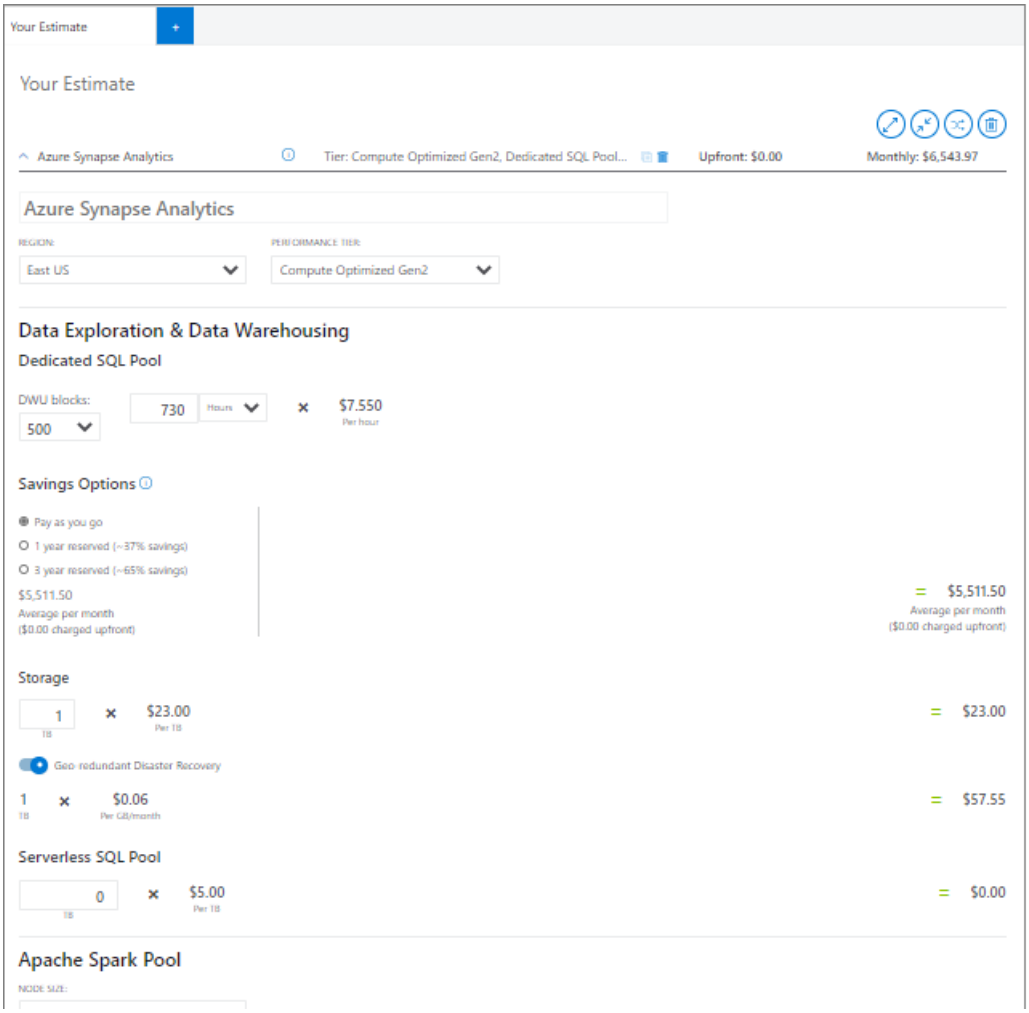
Prerequisites

Cost analysis in Cost Management supports most Azure account types, but not all of them. To view the full list of supported account types, see Understand Cost Management data. To view cost data, you need at least read access for an Azure account. For information about assigning access to Azure Cost Management data, see Assign access to data.

Estimate costs before using Azure Synapse Analytics

Use the Azure pricing calculator to estimate costs before you add Azure Synapse Analytics.

Azure Synapse has various resources that have different charges as seen in the cost estimate below.



Small (4 vCPU(s) / 32 GB)

2 Instances × 730 Hours × $0.16 Per vCore-hour = $951.92

Data Integration

Data Pipelines

Azure-Hosted $183.50

Orchestration

1 Activity Runs (X 1,000) × $1.00 Per 1,000 runs = $1.00

Data Movement

1 Data Integration Unit × 730 Hours × $0.25 Per DIU-hour = $182.50

Pipeline Activity Executions

Integration Runtime

1 Integration Hours × $0.00 Per hour = $0.00

External Integration Runtime

1 Integration Hours × $0.00 Per hour = $0.00

Azure-Hosted Managed VNET $343.50

Orchestration

1 Activity Runs (X 1,000) × $1.00 Per 1,000 runs = $1.00

Data Movement

1 Data Integration Unit × 730 Hours × $0.25 Per DIU-hour = $182.50

Pipeline Activity Executions

Integration Runtime

80 Integration Hours × $1.00 Per hour = $80.00

External Integration Runtime

80 Integration Hours × $1.00 Per hour = $80.00

Self-Hosted $15.50

Orchestration

5 Activity Runs (X 1,000) × $1.50 Per 1,000 runs = $7.50

Data Movement

80 Hours × $0.10 Per hour = $8.00

Pipeline Activity Executions

Integration Runtime

80 Integration Hours × $0.00 Per hour = $0.00

External Integration Runtime

80 Integration Hours × $0.00 Per hour = $0.00

Data Flows

Data Flows $9,617.02

Compute Optimized vCores

INSTANCE:

8 vCores

5 Instances × 730 Hours = $5,613.70

General Purpose vCores

INSTANCE:

8 vCores

0 Instances × 730 Hours = $0.00

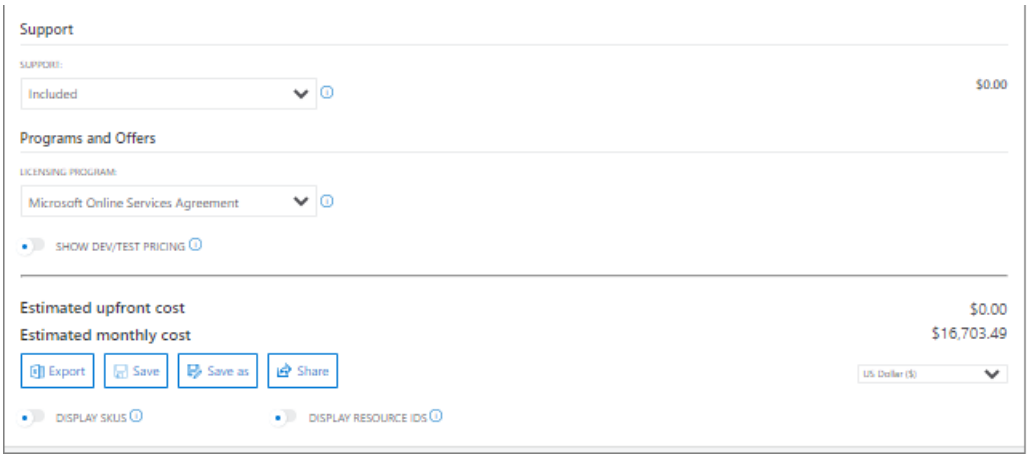
Memory Optimized vCores

INSTANCE:

8 vCores

2 Instances × 730 Hours = $4,003.32

Upfront cost	$0.00
Monthly cost	$16,703.49



Understand the full billing model for Azure Synapse Analytics

Azure Synapse runs on Azure infrastructure that accrues costs along with Azure Synapse when you deploy the new resource. It's important to understand that additional infrastructure might accrue cost.

How you're charged for Azure Synapse Analytics

When you create or use Azure Synapse Analytics resources, you might get charged for the following meters:

- Data Exploration & Data Warehousing
  - Dedicated SQL Pool - You're charged for it based on the number of DWU blocks and hours running.
  - Storage - You're charged for it based on the number of TBs stored.
  - Serverless SQL pool - You're charged by the TB of data processed.
- Apache Spark Pool - You're charged for the number of instances and the hours running.
- Data Integration
  - Orchestration Activity Runs - You are charged based on the number of activity runs.
  - Data Movement – For copy activities run on Azure Integration Runtime, you are charged based on number of DIU used and execution duration.
  - Data Flows vCore Hours – for data flow execution and debugging, you are charged for based on compute type, number of vCores, and execution duration.

At the end of your billing cycle, the charges for each meter are summed. Your bill or invoice shows a section for all Azure Synapse Analytics costs. There's a separate line item for each meter.

Other costs that might accrue with Azure Synapse Analytics

When you create resources for Azure Synapse, resources for other Azure services are also created. They include:

- Data Lake Storage Gen2

Costs might accrue after resource deletion

After you delete Azure Synapse resources, the following resources might continue to exist. They continue to accrue costs until you delete them.

- Data Lake Storage Gen2

Using Azure Prepayment credit with Azure Synapse

You can pay for Azure Synapse charges with your Azure Prepayment credit. However, you can't use Azure Prepayment credit to pay for charges for third-party products and services including those from the Azure Marketplace.

Pre-purchase plan for Azure Synapse

You can save on your Azure Synapse Analytics costs when you pre-purchase Azure Synapse commit units (SCU) for one year. You can use the pre-purchased SCUs at any time during the purchase term. For more information

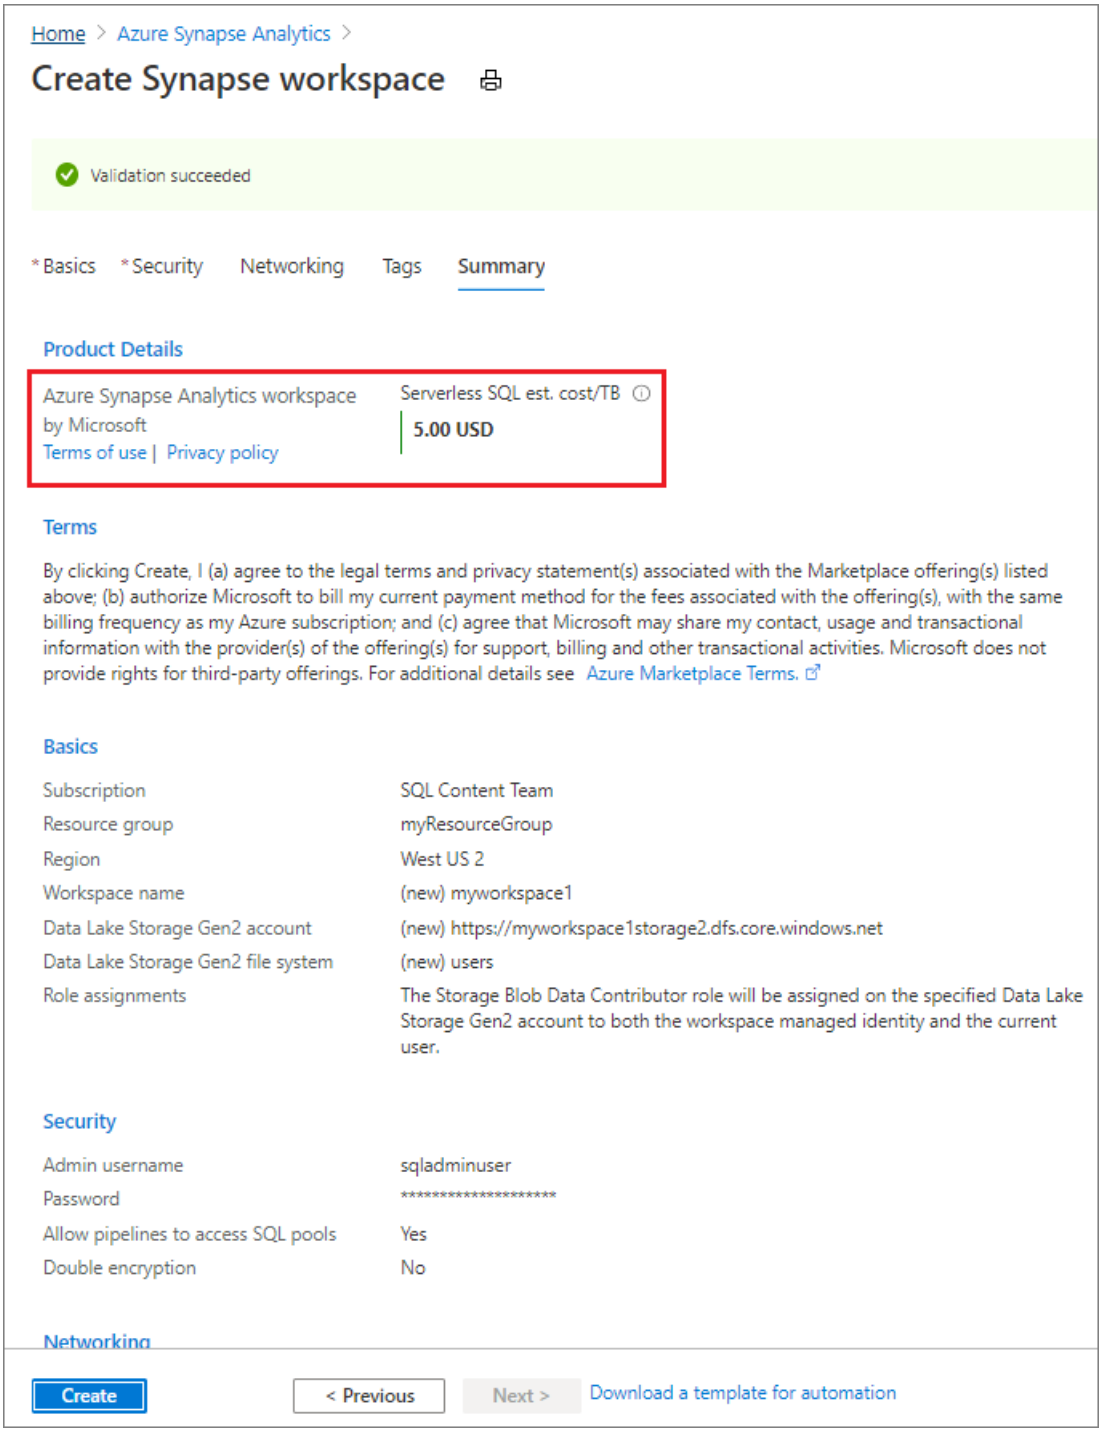
see Optimize Azure Synapse Analytics costs with a Pre-Purchase Plan

Review estimated costs in the Azure portal

As you create resources for Azure Synapse Analytics, you see estimated costs. A workspace has a serverless SQL pool created with the workspace. Serverless SQL pool will not incur charges until you run queries. Other resources, such as dedicated SQL pools and serverless Apache Spark pools, will need to be created within the workspace.

To create an Azure Synapse Analytics workspace and view the estimated price:

1. Navigate to the service in the Azure portal.
2. Create the resource.
3. Review the estimated price shown in the summary.
4. Finish creating the resource.



If your Azure subscription has a spending limit, Azure prevents you from spending over your credit amount. As

you create and use Azure resources, your credits are used. When you reach your credit limit, the resources that you deployed are disabled for the rest of that billing period. You can't change your credit limit, but you can remove it. For more information about spending limits, see Azure spending limit.

Monitor costs

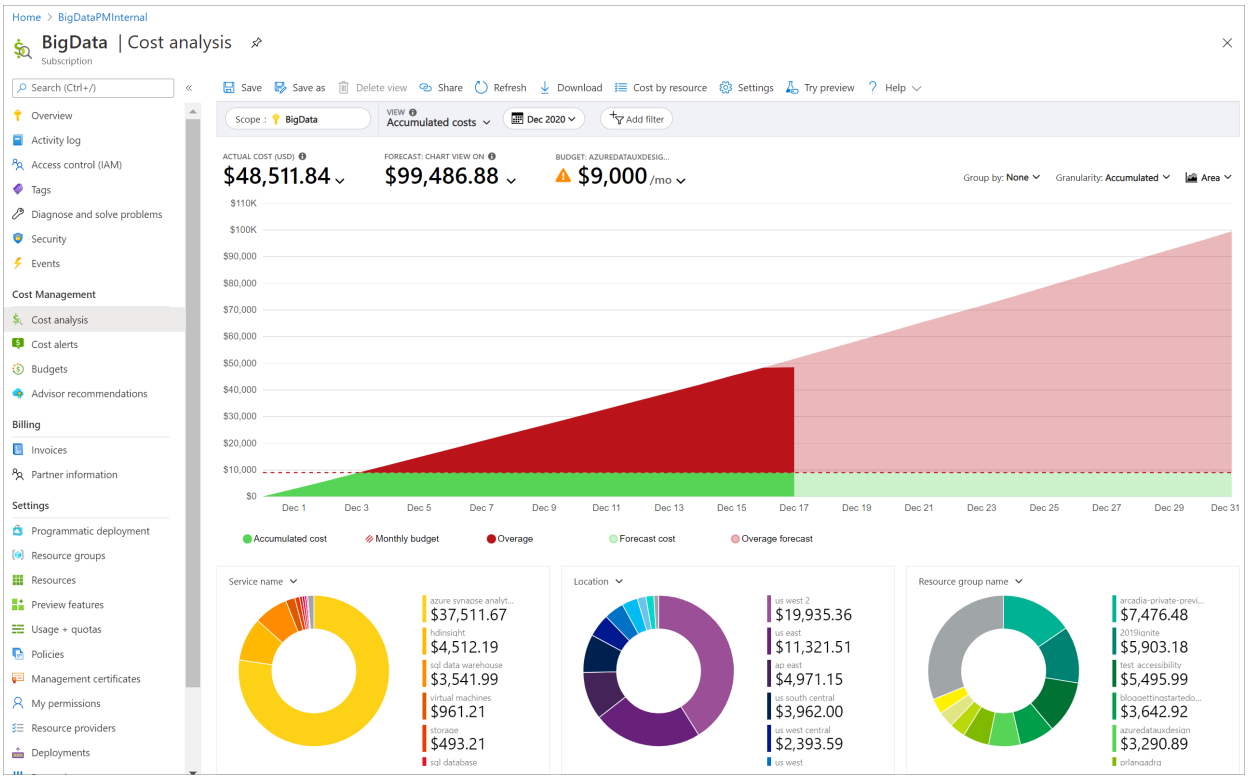
As you use Azure Synapse resources, you incur costs. Azure resource usage unit costs vary by time intervals (seconds, minutes, hours, and days) or by unit usage (bytes, megabytes, and so on.) As soon as you start using resources in Azure Synapse, costs are incurred and you can see the costs in cost analysis.

When you use cost analysis, you view costs for Azure Synapse Analytics in graphs and tables for different time intervals. Some examples are by day, current and prior month, and year. You also view costs against budgets and forecasted costs. Switching to longer views over time can help you identify spending trends. And you see where overspending might have occurred. If you've created budgets, you can also easily see where they're exceeded.

To view Azure Synapse costs in cost analysis:

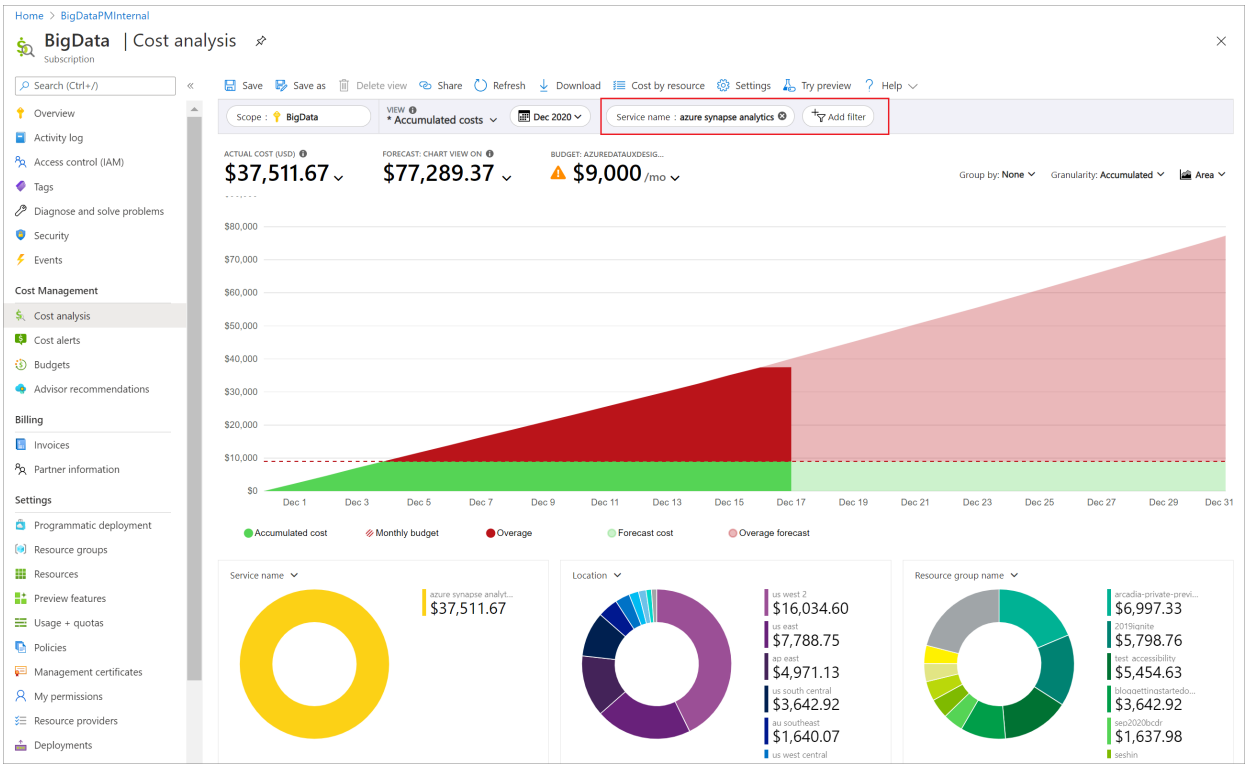
1. Sign in to the Azure portal.
2. Open the scope, either the subscription or the resource group, in the Azure portal and select **Cost analysis** in the menu. For example, go to **Subscriptions**, select a subscription from the list, and then select **Cost analysis** in the menu. Select **Scope** to switch to a different scope in cost analysis.
3. By default, cost for services are shown in the first donut chart. Select the area in the chart labeled Azure Synapse.

Actual monthly costs are shown when you initially open cost analysis. Here's an example showing all monthly usage costs.



- To narrow costs for a single service, like Azure Synapse, select **Add filter** and then select **Service name**. Then, select **Azure Synapse Analytics**.

Here's an example showing costs for just Azure Synapse.



In the preceding example, you see the current cost for the service. Costs by Azure regions (locations) and Azure Synapse costs by resource group are also shown. From here, you can explore costs on your own.

Create budgets

You can create budgets to manage costs and create alerts that automatically notify stakeholders of spending anomalies and overspending risks. Alerts are based on spending compared to budget and cost thresholds. Budgets and alerts are created for Azure subscriptions and resource groups, so they're useful as part of an overall cost monitoring strategy.

Budgets can be created with filters for specific resources or services in Azure if you want more granularity present in your monitoring. Filters help ensure that you don't accidentally create new resources that cost you additional money. For more information about the filter options available when you create a budget, see Group and filter options.

Export cost data

You can also export your cost data to a storage account. This is helpful when you need or others to do additional data analysis for costs. For example, a finance team can analyze the data using Excel or Power BI. You can export your costs on a daily, weekly, or monthly schedule and set a custom date range. Exporting cost data is the recommended way to retrieve cost datasets.

Other ways to manage and reduce costs for Azure Synapse

Serverless SQL pool

To learn more about costs for serverless SQL pool see Cost management for serverless SQL pool in Azure Synapse Analytics

Dedicated SQL pool

You can control costs for a dedicated SQL pool by pausing the resource when it is not is use. For example, if you won't be using the database during the night and on weekends, you can pause it during those times, and resume it during the day. For more information, see Pause and resume compute in dedicated SQL pool via the Azure portal

Serverless Apache Spark pool

To control costs for your serverless Apache Spark pool, enable the serverless Apache Spark automatic pause feature and set your timeout value accordingly. When using Synapse Studio for your development, the studio sends a keep alive message to keep the session active, which is also configurable, so set a short timeout value for automatic pause. When you are done, close your session and the Apache Spark pool will automatically pause once the timeout value is reached.

During development, create multiple Apache Spark pool definitions of various sizes. Creating Apache Spark pool definitions are free and you will only be charged for usage. Apache Spark usage in Azure Synapse is charged per vCore hour and prorated by the minute. For example, use small pool sizes for code development and validation while using larger pool sizes for performance testing.

Browse ADLS Gen2 folders (preview) in an Azure Synapse Analytics workspace

8/19/2022 • 2 minutes to read • Edit Online

You can now browse an Azure Data Lake Storage Gen2 (ADLS Gen2) container or folder in your Azure Synapse Analytics workspace by connecting to the container or specific folder in Data Hub. If your organization does not grant users the Storage Blob Data Contributor role on the storage account, but allows creation of POSIX-like access control lists (ACLs) to the container or specific folders, then you can follow the steps listed in this article to browse files and folders in ADLS Gen2.

> **NOTE**
>
> This preview feature enables users to browse ADLS Gen2 folders that they have ACLs to, but does not support upload, download, create, edit, delete, or rename actions on files or folders. Users with the Storage Blob Data Contributor role can perform all actions on ADLS Gen2 folders.

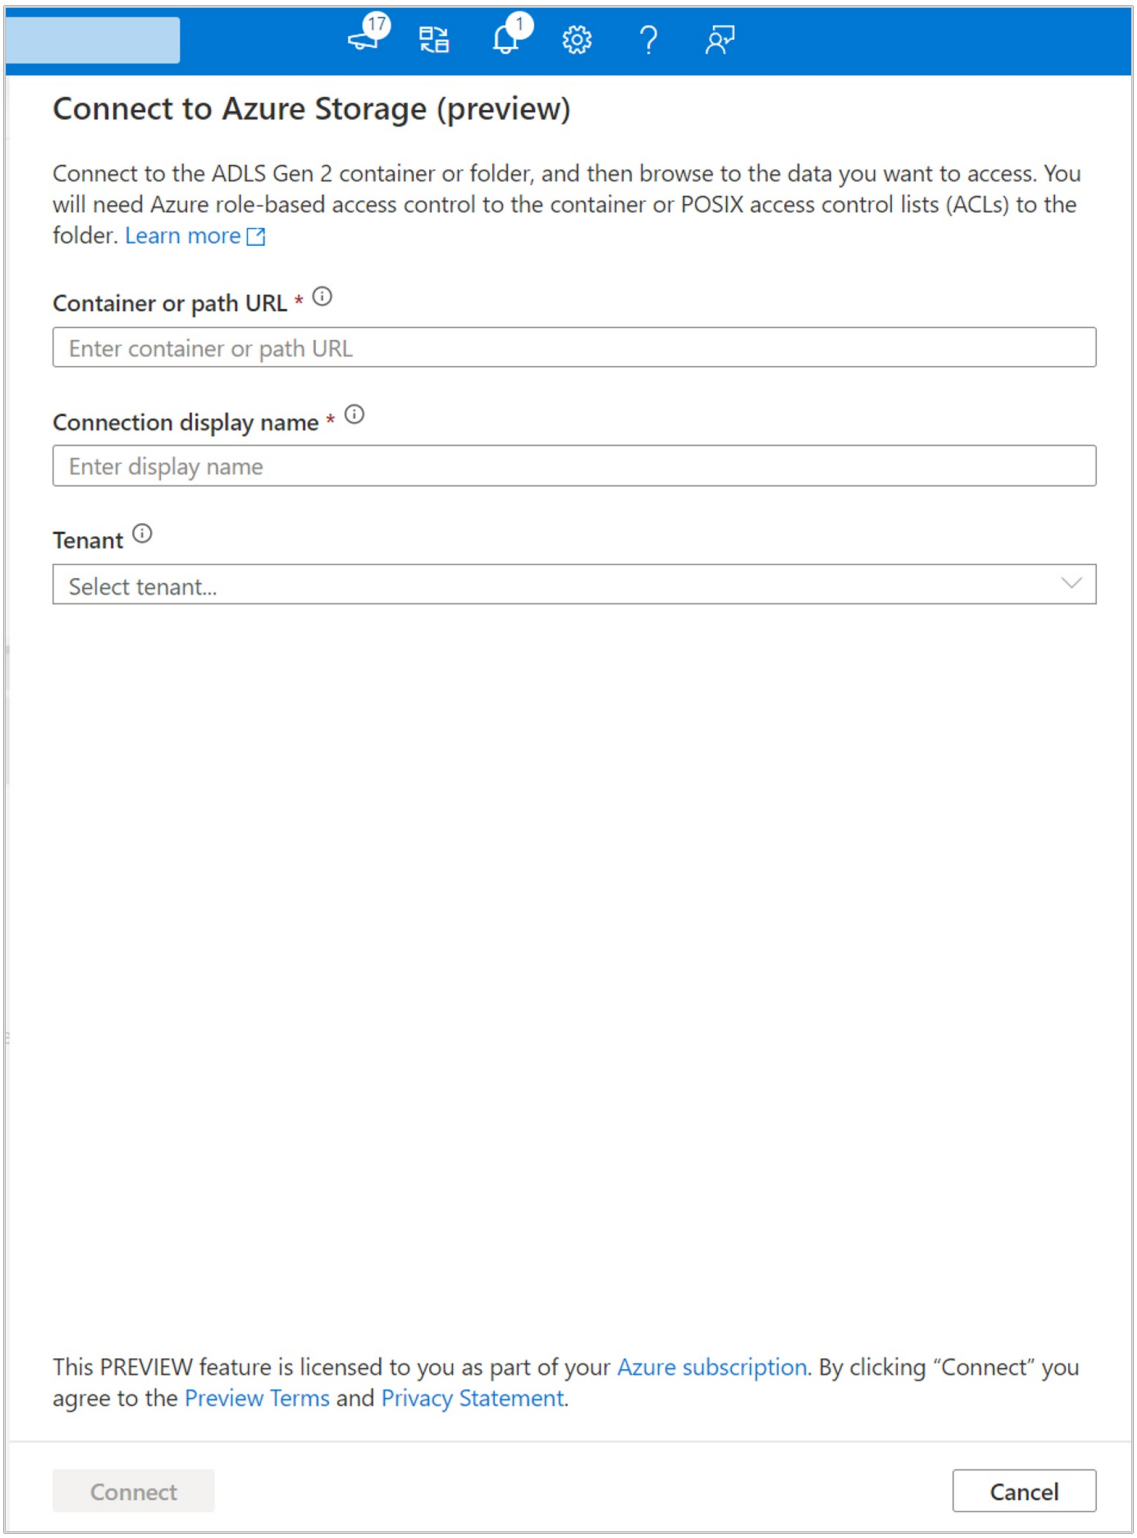
Prerequisites

The following prerequisites must be met prior to connecting a container or folder in Azure Synapse:

- The Storage Blob Data Contributor (Azure RBAC) role or access control lists (ACLs) must be granted to your Azure AD identity.
- A linked service to the ADLS Gen2 container must be created in the Synapse workspace.

Connect ADLS Gen2 folder to your Azure Synapse Analytics workspace

1. Go to the **Linked** tab of Data Hub
2. Right click on **Azure Data Lake Storage Gen2** and select **Connect to Azure Storage (preview)**
   - Provide the ADLS Gen2 container or folder URL in the format `https://storageaccountname.dfs.core.windows.net/containername/foldername/`
   - Provide a unique name for the connection
   - Provide the name of the tenant that contains the ADLS Gen2 account. When left blank, the tenant associated with the Synapse workspace will be used.



3. Click on **Connect**. You will see the connected container or folder under **Attached Containers**.

Next steps

Learn more about ACLs in Azure Data Lake Storage Gen2.

- Access control lists in Azure Data Lake Storage Gen2
- Use the Azure portal to manage ACLs in Azure Data Lake Storage Gen2

Success by design

8/19/2022 • 2 minutes to read • Edit Online

Welcome to the Azure Synapse Customer Success Engineering Success by Design repository.

As part of the Synapse Engineering Group at Microsoft, the Azure Synapse Customer Success Engineering (CSE) team is relied upon to help with complex projects that involve Azure Synapse. As a team of experienced professionals, we provide guidance for all facets of Azure Synapse, including working with customers on architecture reviews, configuration guidance, and performance analysis and recommendations. It's from this experience that the CSE team created this repository of guidance articles to help you produce successful solutions.

This guidance is intended to supplement the official Azure Synapse documentation with additional specialized content that:

- Helps you evaluate Azure Synapse by using a Proof of Concept (POC) project.
- Helps you successfully implement a solution that incorporates Azure Synapse by using our implementation success method. This method can guide you through the key phases of your implementation, including planning, solution development, deployment, and post go-live evaluation.
- Provides detailed guidance on complex topics, including security, networking, troubleshooting, performance tuning, and migration.

> **NOTE**
> This guidance undergoes continuous improvement by the Synapse CSE team. In time, guidance articles will cover additional topics, including enterprise development support using continuous integration and continuous deployment (CI/CD) methods, business continuity and disaster recovery (BCDR), high availability (HA), and Azure Synapse monitoring.

Security white paper

Azure Synapse proof of concept playbook

8/19/2022 • 2 minutes to read • Edit Online

Whether it's an enterprise data warehouse migration, a big data re-platforming, or a greenfield implementation, each project traditionally starts with a proof of concept (POC).

The *Synapse proof of concept playbook* is a series of related articles that provide a high-level methodology for planning, preparing, and running an effective Azure Synapse Analytics POC project. The overall objective of a POC is to validate potential solutions to technical problems, such as how to integrate systems or how to achieve certain results through a specific configuration. As emphasized by this series, an effective POC validates that certain concepts have the potential for real-world production application.

> **TIP**
> If you're new to Azure Synapse, we recommend you work through the Introduction to Azure Synapse Analytics module.

Playbook audiences

The playbook helps you to evaluate the use of Azure Synapse when migrating from an existing workload. We designed it for the following audiences:

- Technical experts who are planning their own in-house Azure Synapse POC project.
- Business owners who will be part of the execution or evaluation of an Azure Synapse POC project.
- Anyone looking to learn more about data warehousing POC projects.

Playbook content

The playbook delivers the following content:

- Guidance on what makes an effective POC.
- Guidance on how to make valid comparisons between systems.
- Guidance on the technical aspects of running an Azure Synapse POC.
- A road map to relevant technical content from Azure Synapse.
- Guidance on how to evaluate POC results to support business decisions.
- Guidance on how and where to find additional help.

The playbook includes three subjects:

- Data warehousing with dedicated SQL pool in Azure Synapse Analytics
- Data lake exploration with serverless SQL pool in Azure Synapse Analytics
- Big data analytics with Apache Spark pool in Azure Synapse Analytics

Synapse POC playbook: Data warehousing with dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 14 minutes to read • Edit Online

This article presents a high-level methodology for preparing and running an effective Azure Synapse Analytics proof of concept (POC) project for dedicated SQL pool.

> **NOTE**
> This article forms part of the *Azure Synapse proof of concept playbook* series of articles. For an overview of the series, see Azure Synapse proof of concept playbook.

> **TIP**
> If you're new to dedicated SQL pools, we recommend you work through the Work with Data Warehouses using Azure Synapse Analytics learning path.

Prepare for the POC

Before deciding on your Azure Synapse POC goals, we recommend that you first read the Azure Synapse SQL architecture article to familiarize yourself with how a dedicated SQL pool separates compute and storage to provide industry-leading performance.

Identify sponsors and potential blockers

Once you're familiar with Azure Synapse, it's time to make sure that your POC has the necessary support and won't hit any roadblocks. You should:

- Identify any restrictions or policies that your organization has about moving data to, and storing data in, the cloud.
- Identify executive and business sponsorship for a cloud-based data warehouse project.
- Verify that your workload is appropriate for Azure Synapse. For more information, see Dedicated SQL pool architecture in Azure Synapse Analytics.

Set the timeline

A POC is a scoped, time-bounded exercise with specific, measurable goals and metrics that define success. Ideally, it should have some basis in business reality so that the results are meaningful.

POCs have the best outcome when they're *timeboxed*. Timeboxing allocates a fixed and maximum unit of time to an activity. In our experience, two weeks provides enough time to complete the work without the burden of too many use cases or complex test matrices. Working within this fixed time period, we suggest that you follow this timeline:

1. **Data loading:** Three days or less
2. **Querying:** Five days or less
3. **Value added tests:** Two days or less

Here are some tips:

- Make realistic estimates of the time that you will require to complete the tasks in your plan.

- Recognize that the time to complete your POC will be related to the size of your dataset, the number of database objects (tables, views, and stored procedures), the complexity of the database objects, and the number of interfaces you will test.
- If you estimate that your POC will run longer than four weeks, consider reducing the scope to focus only on the most important goals.
- Get support from all the lead resources and sponsors for the timeline before commencing the POC.

Once you've determined that there aren't any immediate obstacles and you've set the timeline, you can scope a high-level architecture.

Create a high-level scoped architecture

A high-level future architecture likely contains many data sources and data consumers, big data components, and possibly machine learning and AI data consumers. To keep your POC goals achievable (and within the bounds of your set timeline), decide which of these components will form part of the POC and which will be excluded.

Additionally, if you're already using Azure, identify the following:

- Any existing Azure resources that you can use during the POC. For example, resources can include Azure Active Directory (Azure AD), or Azure ExpressRoute.
- What Azure region(s) your organization prefers.
- A subscription you can use for non-production POC work.
- The throughput of your network connection to Azure.

  > **IMPORTANT**
  > Be sure to check that your POC can consume some of that throughput without having an adverse effect on production solutions.

Apply migration options

If you're migrating from a legacy data warehouse system to Azure Synapse, here are some questions to consider:

- Are you migrating and want to make as few changes to existing Extract, Transform, and Load (ETL) processes and data warehouse consumption as possible?
- Are you migrating but want to do some extensive improvements along the way?
- Are you building an entirely new data analytics environment (sometimes called a *greenfield project*)?

Next, you need to consider your pain points.

Identify current pain points

Your POC should contain use cases to prove potential solutions to address your current pain points. Here are some questions to consider:

- What gaps in your current implementation do you expect Azure Synapse to fill?
- What new business needs are you required to support?
- What service level agreements (SLAs) are you required to meet?
- What will be the workloads (for example, ETL, batch queries, analytics, reporting queries, or interactive queries)?

Next, you need to set your POC success criteria.

Set POC success criteria

Identify why you're doing a POC and be sure to define clear goals. It's also important to know what outputs you

want from your POC and what you plan to do with them.

Keep in mind that a POC should be a short and focused effort to quickly prove or test a limited set of concepts. If you have a long list of items to prove, you may want to dive them into multiple POCs. POCs can have gates between them so you can determine whether to proceed to the next POC.

Here are some example POC goals:

- We need to know that the query performance for our big complex reporting queries will meet our new SLAs.
- We need to know the query performance for our interactive users.
- We need to know whether our existing ETL processes are a good fit and where improvements need to be made.
- We need to know whether we can shorten our ETL runtimes and by how much.
- We need to know that Synapse Analytics has sufficient security capabilities to adequately secure our data.

Next, you need to create a test plan.

Create a test plan

Using your goals, identify specific tests to run in order to support those goals and provide your identified outputs. It's important to make sure that you have at least one test for each goal and the expected output. Identify specific queries, reports, ETL and other processes that you will run to provide quantifiable results.

Refine your tests by adding multiple testing scenarios to clarify any table structure questions that arise.

Good planning usually defines an effective POC execution. Make sure all stakeholders agree to a written test plan that ties each POC goal to a set of clearly stated test cases and measurements of success.

Most test plans revolve around performance and the expected user experience. What follows is an example of a test plan. It's important to customize your test plan to meet your business requirements. Clearly defining what you are testing will pay dividends later in this process.

GOAL	TEST	EXPECTED OUTCOMES
We need to know that the query performance for our big complex reporting queries will meet our new SLAs	- Sequential test of complex queries - Concurrency test of complex queries against stated SLAs	- Queries A, B, and C completed in 10, 13, and 21 seconds, respectively - With 10 concurrent users, queries A, B, and C completed in 11, 15, and 23 seconds, on average
We need to know the query performance for our interactive users	- Concurrency test of selected queries at an expected concurrency level of 50 users. - Run the preceding query with result set caching	- At 50 concurrent users, average execution time is expected to be under 10 seconds, and without result set caching - At 50 concurrent users, average execution time is expected to be under five seconds with result set caching
We need to know whether our existing ETL processes can run within the SLA	- Run one or two ETL processes to mimic production loads	- Loading incrementally into a core fact table must complete in less than 20 minutes (including staging and data cleansing) - Dimension processing needs to take less than five minutes
We need to know that the data warehouse has sufficient security capabilities to secure our data	- Review and enable network security (VNet and private endpoints), access control (row-level security, dynamic data masking)	- Prove that data never leaves our tenant. - Ensure that customer content is easily secured

Next, you need to identify and validate the POC dataset.

Identify and validate the POC dataset

Using the scoped tests, you can now identify the dataset required to execute those tests in Azure Synapse. Review your dataset by considering the following:

- Verify that the dataset adequately represents your production dataset in terms of content, complexity, and scale.
- Don't use a dataset that's too small (less than 1TB), as you might not achieve representative performance.
- Don't use a dataset that's too large, as the POC isn't intended to complete a full data migration.
- Identify the distribution pattern, indexing option, and partitioning for each table. If there are any questions regarding distribution, indexing, or partitioning, add tests to your POC to answer them. Bear in mind that you may want to test more than one distribution option or indexing option for some tables.
- Check with the business owners for any blockers for moving the POC dataset to the cloud.
- Identify any security or privacy concerns.

> **IMPORTANT**
> Make sure you check with business owners for any blockers before moving any data to the cloud. Identify any security or privacy concerns or any data obfuscation needs that should be done before moving data to the cloud.

Next, you need to assemble the team of experts.

Assemble the team

Identify the team members and their commitment to support your POC. Team members should include:

- A project manager to run the POC project.
- A business representative to oversee requirements and results.
- An application data expert to source the data for the POC dataset.
- An Azure Synapse specialist.
- An expert advisor to optimize the POC tests.
- Any person who will be required for specific POC project tasks but who aren't required for its entire duration. These supporting resources could include network administrators, Azure administrators, or Azure AD administrators.

> **TIP**
> We recommend engaging an expert advisor to assist with your POC. Microsoft's partner community has global availability of expert consultants who can help you assess, evaluate, or implement Azure Synapse.

Now that you are fully prepared, it's time to put your POC into practice.

Put the POC into practice

It's important to keep the following in mind:

- Implement your POC project with the discipline and rigor of any production project.
- Run the POC according to plan.
- Have a change request process in place to prevent your POC scope from growing or changing.

Before tests can start, you need to set up the test environment. It involves four stages:

1. Setup

2. Data loading
3. Querying
4. Value added tests

Setup

You can set up a POC on Azure Synapse by following these steps:

1. Use this quickstart to provision a Synapse workspace and set up storage and permissions according to the POC test plan.
2. Use this quickstart to add a dedicated SQL pool to the Synapse workspace.
3. Set up networking and security according to your requirements.
4. Grant appropriate access to POC team members. See this article about authentication and authorization for accessing dedicated SQL pools.

> **TIP**
> We recommend that you *develop code and unit testing* by using the DW500c service level (or below). We recommend that you *run load and performance tests* by using the DW1000c service level (or above). You can pause compute of the dedicated SQL pool at any time to cease compute billing, which will save on costs.

Data loading

Once you've set up the dedicated SQL pool, you can follow these steps to load data:

1. Load the data into Azure Blob Storage. For a POC, we recommend that you use a general-purpose V2 storage account with locally-redundant storage (LRS). While there are several tools for migrating data to Azure Blob Storage, the easiest way is to use Azure Storage Explorer, which can copy files into a storage container.
2. Load the data into the dedicated SQL pool. Azure Synapse supports two T-SQL loading methods: PolyBase and the COPY statement. You can use SSMS to connect to the dedicated SQL pool to use either method.

When you load data into the dedicated SQL pool for the first time, you need to consider which distribution pattern and index option to use. While a dedicated SQL pool supports a variety of both, it's a best practice to rely on default settings. Default settings use round-robin distribution and a clustered columnstore index. If necessary, you can adjust these settings later, which is described later in this article.

The following example shows the COPY load method:

```
--Note when specifying the column list, input field numbers start from 1
COPY INTO
    test_1 (Col_1 default 'myStringDefault' 1, Col_2 default 1 3)
FROM
    'https://myaccount.blob.core.windows.net/myblobcontainer/folder1/'
WITH (
    FILE_TYPE = 'CSV',
    CREDENTIAL = (IDENTITY = 'Storage Account Key' SECRET = '<Your_Account_Key>'),
    FIELDQUOTE = '"',
    FIELDTERMINATOR = ',',
    ROWTERMINATOR = '0x0A',
    ENCODING = 'UTF8',
    FIRSTROW = 2
);
```

Querying

The primary purpose of an data warehouse is to perform analytics, which requires querying the data warehouse. Most POCs start by running a small number of representative queries against the data warehouse, at first sequentially and then concurrently. You should define both approaches in your test plan.

Sequential query tests

It's easy to run sequential query tests in SSMS. It's important to run these tests by using a user with a sufficiently large resource class. A resource class is a pre-determined resource limit in dedicated SQL pool that governs compute resources and concurrency for query execution. For simple queries, we recommend using the pre-defined **staticrc20** resource class. For more complex queries, we recommend using the pre-defined **staticrc40** resource class.

Notice that the following first query uses a query label to provide a mechanism to keep track of the query. The second query uses the `sys.dm_pdw_exec_requests` dynamic management view to search by the label.

```
/* Use the OPTION(LABEL = '') Syntax to add a query label to track the query in DMVs */
SELECT TOP (1000)
    *
FROM
    [dbo].[Date]
OPTION (LABEL = 'Test1');

/* Use sys.dm_pdw_exec_requests to determine query execution duration (ms) */
SELECT
    Total_elapsed_time AS [Elapsed_Time_ms],
    [label]
FROM
    sys.dm_pdw_exec_requests
WHERE
    [label] = 'Test1';
```

Concurrent query tests

After recording sequential query performance, you can then run multiple queries concurrently. That way, you can simulate a business intelligence workload running against the dedicated SQL pool. The easiest way to run this test is to download a stress testing tool. The most popular tool is Apache JMeter, which is a third-party open source tool.

The tool reports on minimum, maximum, and median query durations for a given concurrency level. For example, suppose that you want to simulate a business intelligence workload that generates 100 concurrent queries. You can setup JMeter to run those 100 concurrent queries in a loop and then review the steady state execution. It can be done with result set caching on or off to evaluate the suitability of that feature.

Be sure to document your results. Here's an example of some results:

CONCURRENCY	# QUERIES RUN	DWU	MIN DURATION(S)	MAX DURATION(S)	MEDIAN DURATION(S)
100	1,000	5,000	3	10	5
50	5,000	5,000	3	6	4

Mixed workload tests

Mixed workload testing is an extension of the concurrent query tests. By adding a data loading process into the workload mix, the workload will better simulate a real production workload.

Optimize the data

Depending on the query workload running on Azure Synapse, you may need to optimize your data warehouse's distributions and indexes and rerun the tests. For more information, see Best practices for dedicated SQL pools

in Azure Synapse Analytics.

The most common mistakes seen during setup are:

- Large queries run with a resource class that's too low.
- The dedicated SQL pool service level DWUs are too low for the workload.
- Large tables require hash distribution.

To improve query performance, you can:

- Create materialized views, which can accelerate queries involving common aggregations.
- Replicate tables, especially for small dimension tables.
- Hash distribute large fact tables that are joined or aggregated.

Value added tests

Once query performance testing is complete, it's a good time to test specific features to verify that they satisfy your intended use cases. These features include:

- Row-level security
- Column-level security
- Dynamic data masking
- Intra-cluster scaling via workload isolation

Finally, you need to interpret your POC results.

Interpret the POC results

Once you have test results for your data warehouse, it's important to interpret that data. A common approach you can take is to compare the runs in terms of *price/performance*. Simply put, price/performance removes the differences in price per DWU or service hardware and provides a single comparable number for each performance test.

Here's an example:

TEST	TEST DURATION	DWU	$/HR FOR DWU	COST OF TEST
Test 1	10 min	1000	$12/hr	$2
Test 2	30 min	500	$6/hr	$3

This example makes it easy to see that **Test 1** at DWU1000 is more cost effective at $2 per test run compared with $3 per test run.

> **NOTE**
> You can also use this methodology to compare results *across vendors* in a POC.

In summary, once you complete all the POC tests, you're ready to evaluate the results. Begin by evaluating whether the POC goals have been met and the desired outputs collected. Make note of where additional testing is warranted and additional questions that were raised.

Synapse POC playbook: Data lake exploration with serverless SQL pool in Azure Synapse Analytics

8/19/2022 • 10 minutes to read • Edit Online

This article presents a high-level methodology for preparing and running an effective Azure Synapse Analytics proof of concept (POC) project for serverless SQL pool.

> **NOTE**
> This article forms part of the *Azure Synapse proof of concept playbook* series of articles. For an overview of the series, see Azure Synapse proof of concept playbook.

Prepare for the POC

A POC project can help you make an informed business decision about implementing a big data and advanced analytics environment on a cloud-based platform that leverages serverless SQL pool in Azure Synapse. If you need to explore or gain insights from data in the data lake, or optimize your existing data transformation pipeline, you can benefit from using the serverless SQL pool. It's suitable for the following scenarios:

- **Basic discovery and exploration:** Quickly reason about data stored in various formats (Parquet, CSV, JSON) in your data lake, so you can plan how to unlock insights from it.
- **Logical data warehouse:** Produce a relational abstraction on top of raw or disparate data without relocating or transforming it, providing an always up-to-date view of your data.
- **Data transformation:** Run simple, scalable, and highly performant data lake queries by using T-SQL. You can feed query results to business intelligence (BI) tools, or load them into a relational database. Target systems can include Azure Synapse dedicated SQL pools or Azure SQL Database.

Different professional roles can benefit from serverless SQL pool:

- **Data engineers** can explore the data lake, transform and prepare data by using serverless SQL pool, and simplify their data transformation pipelines.
- **Data scientists** can quickly reason about the contents and structure of the data stored in the data lake by using the OPENROWSET T-SQL function and its automatic schema inference.
- **Data analysts** can write T-SQL queries in their preferred query tools, which can connect to serverless SQL pool. They can explore data in Spark external tables that were created by data scientists or data engineers.
- **BI professionals** can quickly create Power BI reports that connect to data lake or Spark tables.

A serverless SQL pool POC project will identify your key goals and business drivers that serverless SQL pool is designed to support. It will also test key features and gather metrics to support your implementation decisions. A POC isn't designed to be deployed to a production environment. Rather, it's a short-term project that focuses on key questions, and its result can be discarded.

Before you begin planning your serverless SQL Pool POC project:

- Identify any restrictions or guidelines your organization has about moving data to the cloud.
- Identify executive or business sponsors for a big data and advanced analytics platform project. Secure their support for migration to the cloud.
- Identify availability of technical experts and business users to support you during the POC execution.

Before you start preparing for the POC project, we recommend you first read the serverless SQL pool documentation.

> **TIP**
> If you're new to serverless SQL pools, we recommend you work through the Build data analytics solutions using Azure Synapse serverless SQL pools learning path.

Set the goals

A successful POC project requires planning. Start by identify why you're doing a POC to fully understand the real motivations. Motivations could include modernization, cost saving, performance improvement, or integrated experience. Be sure to document clear goals for your POC and the criteria that will define its success. Ask yourself:

- What do you want as the outputs of your POC?
- What will you do with those outputs?
- Who will use the outputs?
- What will define a successful POC?

Keep in mind that a POC should be a short and focused effort to quickly prove a limited set of concepts and capabilities. These concepts and capabilities should be representative of the overall workload. If you have a long list of items to prove, you may want to plan more than one POC. In that case, define gates between the POCs to determine whether you need to continue with the next one. Given the different professional roles that can use a serverless SQL pool (and the different scenarios that serverless SQL pool supports), you may choose to execute multiple POCs. For example, one POC could focus on requirements for the data scientist role, such as discovery and exploration of data in different formats. Another could focus on requirements for the data engineering role, such as data transformation and the creation of a logical data warehouse.

As you consider your POC goals, ask yourself the following questions to help you shape the goals:

- Are you migrating from an existing big data and advanced analytics platform (on-premises or cloud)?
- Are you migrating but want to make as few changes as possible to existing ingestion and data processing?
- Are you migrating but want to do some extensive improvements along the way?
- Are you building an entirely new big data and advanced analytics platform (greenfield project)?
- What are your current pain points? For example, scalability, performance, or flexibility.
- What new business requirements do you need to support?
- What are the SLAs that you're required to meet?
- What will be the workloads? For example, data exploration over different data formats, basic exploration, a logical data warehouse, data preparation and/or transformation, T-SQL interactive analysis, T-SQL querying of Spark tables, or reporting queries over the data lake.
- What are the skills of the users who will own the project (should the POC be implemented)?

Here are some examples of POC goal setting:

- Why are we doing a POC?
  - We need to know if we can explore all of the raw file formats we store by using serverless SQL pool.
  - We need to know if our data engineers can quickly evaluate new data feeds.
  - We need to know if data lake query performance by using serverless SQL pool will meet our data exploration requirements.
  - We need to know if serverless SQL pool is a good choice for some of our visualizations and reporting requirements.
  - We need to know if serverless SQL pool is a good choice for some of our data ingestion and

processing requirements.
    - We need to know if our move to Azure Synapse will meet our budget.
- At the conclusion of this PoC:
    - We will have the data to identify the data transformations that are well suited to serverless SQL pool.
    - We will have the data to identify when serverless SQL pool can be best used during data visualization.
    - We will have the data to know the ease with which our data engineers and data scientists can adopt the new platform.
    - We will have gained insight to better estimate the effort required to complete the implementation or migration project.
    - We will have a list of items that may need more testing.
    - Our POC will be successful if we have the data needed and have completed the testing identified to determine how serverless SQL pool will support our cloud-based big data and advance analytics platform.
    - We will have determined whether we can move to the next phase or whether more POC testing is needed to finalize our decision.
    - We will be able to make a sound business decision supported by specific data points.

Plan the project

Use your goals to identify specific tests and to provide the outputs you identified. It's important to make sure that you have at least one test to support each goal and expected output. Also, identify specific data exploration and analysis tasks, specific transformations, and specific existing processing you want to test. Identify a specific dataset and codebase that you can use.

Here's an example of the needed level of specificity in planning:

- **Goal:** We need to know whether data engineers can achieve the equivalent processing of the existing ETL process named "Daily Batch Raw File Validation" within the required SLA.
- **Output:** We will have the data to determine whether we can use T-SQL queries to execute the "Daily Batch Raw File Validation" ETL process within the required SLA.
- **Test:** Validation queries A, B, and C are identified by data engineering, and they represent overall data processing needs. Compare the performance of these queries with the benchmark obtained from the existing system.

Evaluate the POC dataset

Using the specific tests you identified, select a dataset to support the tests. Take time to review this dataset. You should verify that the dataset will adequately represent your future processing in terms of content, complexity, and scale. Don't use a dataset that's too small because it won't deliver representative performance. Conversely, don't use a dataset that's too large because the POC shouldn't become a full data migration. Be sure to obtain the appropriate benchmarks from existing systems so you can use them for performance comparisons.

> **IMPORTANT**
> Make sure you check with business owners for any blockers before moving any data to the cloud. Identify any security or privacy concerns or any data obfuscation needs that should be done before moving data to the cloud.

Create a high-level architecture

Based upon the high-level architecture of your proposed future state architecture, identify the components that will form part of your POC. Your high-level future state architecture likely contains many data sources, numerous data consumers, big data components, and possibly machine learning and artificial intelligence (AI) data consumers. Your POC architecture should specifically identify components that will be part of the POC. Importantly, it should identify any components that won't form part of the POC testing.

If you're already using Azure, identify any resources you already have in place (Azure Active Directory, ExpressRoute, and others) that you can use during the POC. Also identify the Azure regions your organization uses. Now is a great time to identify the throughput of your ExpressRoute connection and to check with other business users that your POC can consume some of that throughput without adverse impact on production systems.

Identify POC resources

Specifically identify the technical resources and time commitments required to support your POC. Your POC will need:

- A business representative to oversee requirements and results.
- An application data expert, to source the data for the POC and provide knowledge of the existing processes and logic.
- A serverless SQL pool expert.
- An expert advisor, to optimize the POC tests.
- Resources that will be required for specific components of your POC project, but not necessarily required for the duration of the POC. These resources could include network admins, Azure admins, Active Directory admins, Azure portal admins, and others.
- Ensure all the required Azure services resources are provisioned and the required level of access is granted, including access to storage accounts.
- Ensure you have an account that has required data access permissions to retrieve data from all data sources in the POC scope.

> **TIP**
> We recommend engaging an expert advisor to assist with your POC. Microsoft's partner community has global availability of expert consultants who can help you assess, evaluate, or implement Azure Synapse.

Set the timeline

Review your POC planning details and business needs to identify a time frame for your POC. Make realistic estimates of the time that will be required to complete the POC goals. The time to complete your POC will be influenced by the size of your POC dataset, the number and complexity of tests, and the number of interfaces to test. If you estimate that your POC will run longer than four weeks, consider reducing the POC scope to focus on the highest priority goals. Be sure to obtain approval and commitment from all the lead resources and sponsors before continuing.

Put the POC into practice

We recommend you execute your POC project with the discipline and rigor of any production project. Run the project according to plan and manage a change request process to prevent uncontrolled growth of the POC's scope.

Here are some examples of high-level tasks:

1. Create a Synapse workspace, storage accounts, and the Azure resources identified in the POC plan.
2. Set up networking and security according to your requirements.
3. Grant appropriate access to POC team members. See this article about permissions for accessing files directly from Azure Storage.
4. Load the POC dataset.
5. Implement and configure the tests and/or migrate existing code to serverless SQL pool scripts and views.
6. Execute the tests:
    - Many tests can be executed in parallel.

- Record your results in a consumable and readily understandable format.

7. Monitor for troubleshooting and performance.
8. Evaluate your results and present findings.
9. Work with technical stakeholders and the business to plan for the next stage of the project. The next stage could be a follow-up POC or a production implementation.

Interpret the POC results

When you complete all the POC tests, you evaluate the results. Begin by evaluating whether the POC goals were met and the desired outputs were collected. Determine whether more testing is necessary or any questions need addressing.

Synapse POC playbook: Big data analytics with Apache Spark pool in Azure Synapse Analytics

8/19/2022 • 15 minutes to read • Edit Online

This article presents a high-level methodology for preparing and running an effective Azure Synapse Analytics proof of concept (POC) project for Apache Spark pool.

> **NOTE**
> This article forms part of the *Azure Synapse proof of concept playbook* series of articles. For an overview of the series, see Azure Synapse proof of concept playbook.

Prepare for the POC

A POC project can help you make an informed business decision about implementing a big data and advanced analytics environment on a cloud-based platform that leverages Apache Spark pool in Azure Synapse.

A POC project will identify your key goals and business drivers that cloud-based big data and advance analytics platform must support. It will test key metrics and prove key behaviors that are critical to the success of your data engineering, machine learning model building, and training requirements. A POC isn't designed to be deployed to a production environment. Rather, it's a short-term project that focuses on key questions, and its result can be discarded.

Before you begin planning your Spark POC project:

- Identify any restrictions or guidelines your organization has about moving data to the cloud.
- Identify executive or business sponsors for a big data and advanced analytics platform project. Secure their support for migration to the cloud.
- Identify availability of technical experts and business users to support you during the POC execution.

Before you start preparing for the POC project, we recommend you first read the Apache Spark documentation.

> **TIP**
> If you're new to Spark pools, we recommend you work through the Perform data engineering with Azure Synapse Apache Spark Pools learning path.

By now you should have determined that there are no immediate blockers and then you can start preparing for your POC. If you are new to Apache Spark Pools in Azure Synapse Analytics you can refer to this documentation where you can get an overview of the Spark architecture and learn how it works in Azure Synapse.

Develop an understanding of these key concepts:

- Apache Spark and its distributed architecture.
- Spark concepts like Resilient Distributed Datasets (RDD) and partitions (in-memory and physical).
- Azure Synapse workspace, the different compute engines, pipeline, and monitoring.
- Separation of compute and storage in Spark pool.
- Authentication and authorization in Azure Synapse.
- Native connectors that integrate with Azure Synapse dedicated SQL pool, Azure Cosmos DB, and others.

Azure Synapse decouples compute resources from storage so that you can better manage your data processing needs and control costs. The serverless architecture of Spark pool allows you to spin up and down as well as grow and shrink your Spark cluster, independent of your storage. You can pause (or setup auto-pause) a Spark cluster entirely. That way, you pay for compute only when it's in use. When it's not in use, you only pay for storage. You can scale up your Spark cluster for heavy data processing needs or large loads and then scale it back down during less intense processing times (or shut it down completely). You can effectively scale and pause a cluster to reduce costs. Your Spark POC tests should include data ingestion and data processing at different scales (small, medium, and large) to compare price and performance at different scale. For more information, see Automatically scale Azure Synapse Analytics Apache Spark pools.

It's important to understand the difference between the different sets of Spark APIs so you can decide what works best for your scenario. You can choose the one that provides better performance or ease of use, taking advantage of your team's existing skill sets. For more information, see A Tale of Three Apache Spark APIs: RDDs, DataFrames, and Datasets.

Data and file partitioning work slightly differently in Spark. Understanding the differences will help you to optimize for performance. For more information, see Apache Spark documentation: Partition Discovery and Partition Configuration Options.

Set the goals

A successful POC project requires planning. Start by identify why you're doing a POC to fully understand the real motivations. Motivations could include modernization, cost saving, performance improvement, or integrated experience. Be sure to document clear goals for your POC and the criteria that will define its success. Ask yourself:

- What do you want as the outputs of your POC?
- What will you do with those outputs?
- Who will use the outputs?
- What will define a successful POC?

Keep in mind that a POC should be a short and focused effort to quickly prove a limited set of concepts and capabilities. These concepts and capabilities should be representative of the overall workload. If you have a long list of items to prove, you may want to plan more than one POC. In that case, define gates between the POCs to determine whether you need to continue with the next one. Given the different professional roles that may use Spark pools and notebooks in Azure Synapse, you may choose to execute multiple POCs. For example, one POC could focus on requirements for the data engineering role, such as ingestion and processing. Another POC could focus on machine learning (ML) model development.

As you consider your POC goals, ask yourself the following questions to help you shape the goals:

- Are you migrating from an existing big data and advanced analytics platform (on-premises or cloud)?
- Are you migrating but want to make as few changes as possible to existing ingestion and data processing? For example, a Spark to Spark migration, or a Hadoop/Hive to Spark migration.
- Are you migrating but want to do some extensive improvements along the way? For example, re-writing MapReduce jobs as Spark jobs, or converting legacy RDD-based code to DataFrame/Dataset-based code.
- Are you building an entirely new big data and advanced analytics platform (greenfield project)?
- What are your current pain points? For example, scalability, performance, or flexibility.
- What new business requirements do you need to support?
- What are the SLAs that you're required to meet?
- What will be the workloads? For example, ETL, batch processing, stream processing, machine learning model training, analytics, reporting queries, or interactive queries?
- What are the skills of the users who will own the project (should the POC be implemented)? For example, PySpark vs Scala skills, notebook vs IDE experience.

Here are some examples of POC goal setting:

- Why are we doing a POC?
  - We need to know that the data ingestion and processing performance for our big data workload will meet our new SLAs.
  - We need to know whether near real-time stream processing is possible and how much throughput it can support. (Will it support our business requirements?)
  - We need to know if our existing data ingestion and transformation processes are a good fit and where improvements will need to be made.
  - We need to know if we can shorten our data integration run times and by how much.
  - We need to know if our data scientists can build and train machine learning models and leverage AI/ML libraries as needed in a Spark pool.
  - Will the move to cloud-based Synapse Analytics meet our cost goals?
- At the conclusion of this POC:
  - We will have the data to determine if our data processing performance requirements can be met for both batch and real-time streaming.
  - We will have tested ingestion and processing of all our different data types (structured, semi and unstructured) that support our use cases.
  - We will have tested some of our existing complex data processing and can identify the work that will need to be completed to migrate our portfolio of data integration to the new environment.
  - We will have tested data ingestion and processing and will have the data points to estimate the effort required for the initial migration and load of historical data, as well as estimate the effort required to migrate our data ingestion (Azure Data Factory (ADF), Distcp, Databox, or others).
  - We will have tested data ingestion and processing and can determine if our ETL/ELT processing requirements can be met.
  - We will have gained insight to better estimate the effort required to complete the implementation project.
  - We will have tested scale and scaling options and will have the data points to better configure our platform for better price-performance settings.
  - We will have a list of items that may need more testing.

Plan the project

Use your goals to identify specific tests and to provide the outputs you identified. It's important to make sure that you have at least one test to support each goal and expected output. Also, identify specific data ingestion, batch or stream processing, and all other processes that will be executed so you can identify a very specific dataset and codebase. This specific dataset and codebase will define the scope of the POC.

Here's an example of the needed level of specificity in planning:

- **Goal A:** We need to know whether our requirement for data ingestion and processing of batch data can be met under our defined SLA.
- **Output A:** We will have the data to determine whether our batch data ingestion and processing can meet the data processing requirement and SLA.
  - **Test A1:** Processing queries A, B, and C are identified as good performance tests as they are commonly executed by the data engineering team. Also, they represent overall data processing needs.
  - **Test A2:** Processing queries X, Y, and Z are identified as good performance tests as they contain near real-time stream processing requirements. Also, they represent overall event-based stream processing needs.
  - **Test A3:** Compare the performance of these queries at different scale of the Spark cluster (varying number of worker nodes, size of the worker nodes - like small, medium, and large - number and size of executors) with the benchmark obtained from the existing system. Keep the *law of diminishing*

returns in mind; adding more resources (either by scaling up or scaling out) can help to achieve parallelism, however there's a certain limit that's unique to each scenario to achieve the parallelism. Discover the optimal configuration for each identified use case in your testing.

- **Goal B:** We need to know if our data scientists can build and train machine learning models on this platform.
- **Output B:** We will have tested some of our machine learning models by training them on data in a Spark pool or a SQL pool, leveraging different machine learning libraries. These tests will help to determine which machine learning models can be migrated to the new environment
  - **Test B1:** Specific machine learning models will be tested.
  - **Test B2:** Test base machine learning libraries that come with Spark (Spark MLLib) along with an additional library that can be installed on Spark (like scikit-learn) to meet the requirement.
- **Goal C:** We will have tested data ingestion and will have the data points to:
  - Estimate the effort for our initial historical data migration to data lake and/or the Spark pool.
  - Plan an approach to migrate historical data.
- **Output C:** We will have tested and determined the data ingestion rate achievable in our environment and can determine whether our data ingestion rate is sufficient to migrate historical data during the available time window.
  - **Test C1:** Test different approaches of historical data migration. For more information, see Transfer data to and from Azure.
  - **Test C2:** Identify allocated bandwidth of ExpressRoute and if there is any throttling setup by the infra team. For more information, see What is Azure ExpressRoute? (Bandwidth options).
  - **Test C3:** Test data transfer rate for both online and offline data migration. For more information, see Copy activity performance and scalability guide.
  - **Test C4:** Test data transfer from the data lake to the SQL pool by using either ADF, Polybase, or the COPY command. For more information, see Data loading strategies for dedicated SQL pool in Azure Synapse Analytics.
- **Goal D:** We will have tested the data ingestion rate of incremental data loading and will have the data points to estimate the data ingestion and processing time window to the data lake and/or the dedicated SQL pool.
- **Output D:** We will have tested the data ingestion rate and can determine whether our data ingestion and processing requirements can be met with the identified approach.
  - **Test D1:** Test the daily update data ingestion and processing.
  - **Test D1:** Test the processed data load to the dedicated SQL pool table from the Spark pool. For more information, see Azure Synapse Dedicated SQL Pool Connector for Apache Spark.
  - **Test D1:** Execute the daily update load process concurrently while running end user queries.

Be sure to refine your tests by adding multiple testing scenarios. Azure Synapse makes it easy to test different scale (varying number of worker nodes, size of the worker nodes like small, medium, and large) to compare performance and behavior.

Here are some testing scenarios:

- **Spark pool test A:** We will execute data processing across multiple node types (small, medium, and large) as well as different numbers of worker nodes.
- **Spark pool test B:** We will load/retrieve processed data from the Spark pool to the dedicated SQL pool by using the connector.
- **Spark pool test C:** We will load/retrieve processed data from the Spark pool to Cosmos DB by using Azure Synapse Link.

Evaluate the POC dataset

Using the specific tests you identified, select a dataset to support the tests. Take time to review this dataset. You should verify that the dataset will adequately represent your future processing in terms of content, complexity, and scale. Don't use a dataset that's too small (less than 1TB) because it won't deliver representative

performance. Conversely, don't use a dataset that's too large because the POC shouldn't become a full data migration. Be sure to obtain the appropriate benchmarks from existing systems so you can use them for performance comparisons.

> **IMPORTANT**
> Make sure you check with business owners for any blockers before moving any data to the cloud. Identify any security or privacy concerns or any data obfuscation needs that should be done before moving data to the cloud.

Create a high-level architecture

Based upon the high-level architecture of your proposed future state architecture, identify the components that will form part of your POC. Your high-level future state architecture likely contains many data sources, numerous data consumers, big data components, and possibly machine learning and artificial intelligence (AI) data consumers. Your POC architecture should specifically identify components that will be part of the POC. Importantly, it should identify any components that won't form part of the POC testing.

If you're already using Azure, identify any resources you already have in place (Azure Active Directory, ExpressRoute, and others) that you can use during the POC. Also identify the Azure regions your organization uses. Now is a great time to identify the throughput of your ExpressRoute connection and to check with other business users that your POC can consume some of that throughput without adverse impact on production systems.

For more information, see Big data architectures.

Identify POC resources

Specifically identify the technical resources and time commitments required to support your POC. Your POC will need:

- A business representative to oversee requirements and results.
- An application data expert, to source the data for the POC and provide knowledge of the existing processes and logic.
- An Apache Spark and Spark pool expert.
- An expert advisor, to optimize the POC tests.
- Resources that will be required for specific components of your POC project, but not necessarily required for the duration of the POC. These resources could include network admins, Azure admins, Active Directory admins, Azure portal admins, and others.
- Ensure all the required Azure services resources are provisioned and the required level of access is granted, including access to storage accounts.
- Ensure you have an account that has required data access permissions to retrieve data from all data sources in the POC scope.

> **TIP**
> We recommend engaging an expert advisor to assist with your POC. Microsoft's partner community has global availability of expert consultants who can help you assess, evaluate, or implement Azure Synapse.

Set the timeline

Review your POC planning details and business needs to identify a time frame for your POC. Make realistic estimates of the time that will be required to complete the POC goals. The time to complete your POC will be influenced by the size of your POC dataset, the number and complexity of tests, and the number of interfaces to test. If you estimate that your POC will run longer than four weeks, consider reducing the POC scope to focus on the highest priority goals. Be sure to obtain approval and commitment from all the lead resources and sponsors

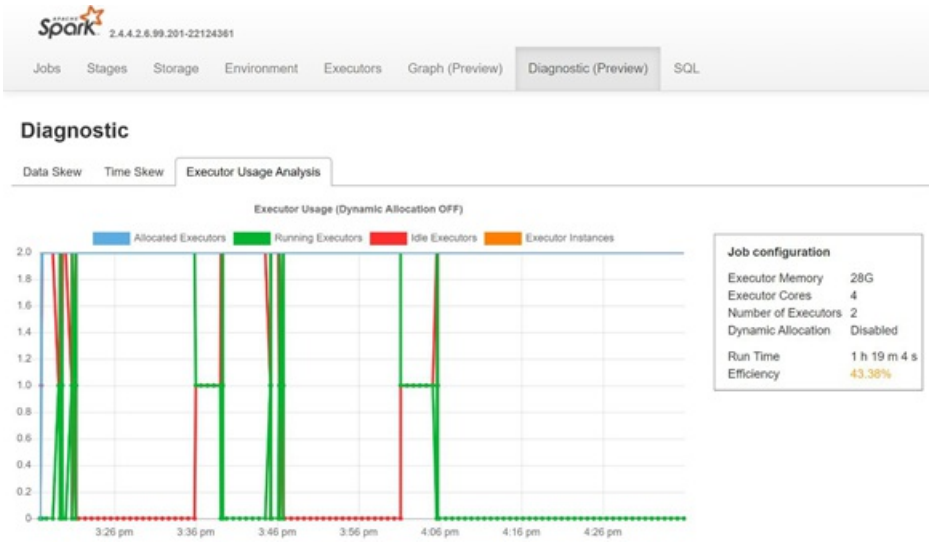
before continuing.

Put the POC into practice

We recommend you execute your POC project with the discipline and rigor of any production project. Run the project according to plan and manage a change request process to prevent uncontrolled growth of the POC's scope.

Here are some examples of high-level tasks:

1. Create a Synapse workspace, Spark pools and dedicated SQL pools, storage accounts, and all Azure resources identified in the POC plan.
2. Load POC dataset:
   - Make data available in Azure by extracting from the source or by creating sample data in Azure. For more information, see:
     - Transferring data to and from Azure
     - Azure Data Box
     - Copy activity performance and scalability guide
     - Data loading strategies for dedicated SQL pool in Azure Synapse Analytics
     - Bulk load data using the COPY statement
   - Test the dedicated connector for the Spark pool and the dedicated SQL pool.
3. Migrate existing code to the Spark pool:
   - If you're migrating from Spark, your migration effort is likely to be straightforward given that the Spark pool leverages the open-source Spark distribution. However, if you're using vendor specific features on top of core Spark features, you'll need to correctly map these features to the Spark pool features.
   - If you're migrating from a non-Spark system, your migration effort will vary based on the complexity involved.
4. Execute the tests:
   - Many tests can be executed in parallel across multiple Spark pool clusters.
   - Record your results in a consumable and readily understandable format.
5. Monitor for troubleshooting and performance. For more information, see:
   - Monitor Apache Spark activities
   - Monitor with web user interfaces - Spark's history server
   - Monitoring resource utilization and query activity in Azure Synapse Analytics
6. Monitor data skewness, time skewness and executor usage percentage by opening the **Diagnostic** tab of Spark's history server.



Interpret the POC results

When you complete all the POC tests, you evaluate the results. Begin by evaluating whether the POC goals were met and the desired outputs were collected. Determine whether more testing is necessary or any questions need addressing.

Data lake exploration with serverless SQL pool in Azure Synapse Analytics

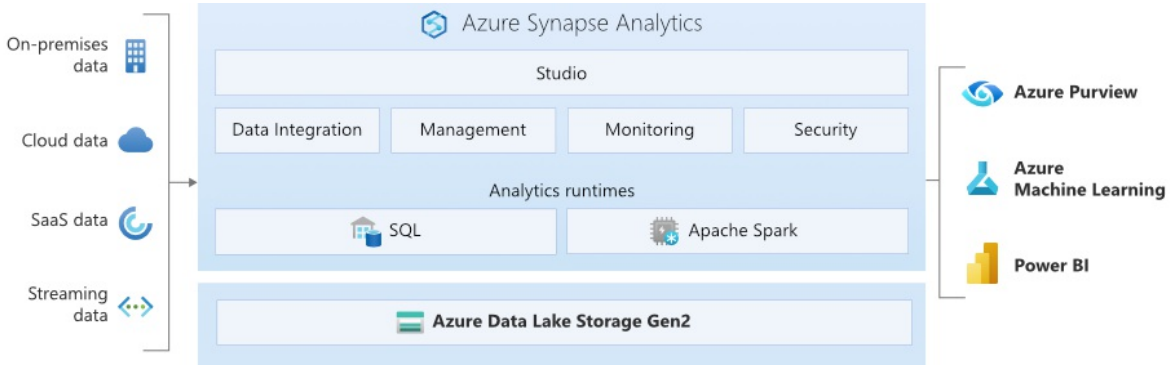
Azure Synapse Analytics frequently asked questions

Azure Synapse implementation success by design

8/19/2022 • 5 minutes to read • Edit Online

The *Azure Synapse implementation success by design* series of articles is designed to help you deliver a successful implementation of Azure Synapse Analytics. It describes a methodology to complement your solution implementation project. It includes suggested checks at strategic points during your project that can help assure a successful implementation. It's important to understand that the methodology shouldn't replace or change your chosen project management methodology (Scrum, Agile, or waterfall). Rather, it suggests validations that can improve the success of your project deployment to a production environment.

Azure Synapse is an enterprise analytics service that accelerates time to insight across data warehouses and big data systems. It brings together the best of SQL technologies used in enterprise data warehousing, Spark technologies used for big data, pipelines for data integration and ETL/ELT, and deep integration with other Azure services, such as Power BI, Azure Cosmos DB, and Azure Machine Learning.



The methodology uses a strategic checkpoint approach to assess and monitor the progress of your project. The goals of these checkpoints are:

- Proactive identification of possible issues and blockers.
- Continuous validation of the solution's fit to the use cases.
- Successful deployment to production.
- Smooth operation and monitoring once in production.

The checkpoints are invoked at four milestones during the project:

1. Project planning
2. Solution development
3. Pre go-live
4. Post go-live

Project planning checkpoint

The project planning checkpoint includes the solution evaluation, project plan evaluation, the solution development environment design evaluation, and the team skill sets evaluation.

Solution evaluation

Evaluate your entire solution with a focus on how it intends to use Azure Synapse. An assessment involves gathering data that will identify the required components of Azure Synapse, the interfaces each will have with other products, a review of the data sources, the data consumers, the roles, and use cases. This assessment will also gather data about the existing environment including detailed specifications from existing data warehouses, big data environments, and integration and data consumption tooling. The assessment will identify which Azure

Synapse components will be implemented and therefore which evaluations and checkpoints should be made throughout the implementation effort. This assessment will also provide additional information to validate the design and implementation against requirements, constraints, and assumptions.

Here's a list of tasks you should complete.

1. Assess your environment to help evaluate the solution design.
2. Make informed technology decisions to implement Azure Synapse and identify the solution components to implement.
3. Evaluate the workspace design.
4. Evaluate the data integration design.
5. Evaluate the dedicated SQL pool design.
6. Evaluate the serverless SQL pool design.
7. Evaluate the Spark pool design.
8. Review the results of each evaluation and respond accordingly.

Project plan evaluation

Evaluate the project plan as it relates to the Azure Synapse requirements that need to be developed. This evaluation isn't about producing a project plan. Rather, the evaluation is about identifying any steps that could lead to blockers or that could impact on the project timeline. Once evaluated, you may need to make adjustments to the project plan.

Here's a list of tasks you should complete.

1. Evaluate the project plan.
2. Evaluate project planning specific to the Azure Synapse components you plan to implement.
3. Review the results of each evaluation and respond accordingly.

Solution development environment design evaluation

Evaluate the environment that's to be used to develop the solution. Establish separate development, test, and production environments. Also, it's important to understand that setting up automated deployment and source code control is essential to a successful and smooth development effort.

Here's a list of tasks you should complete.

1. Evaluate the solution development environment design.
2. Review the results of each evaluation and respond accordingly.

Team skill sets evaluation

Evaluate the project team with a focus on their skill level and readiness to implement the Azure Synapse solution. The success of the project depends on having the correct skill sets and experience. Many different skill sets are required to implement an Azure Synapse solution, so ensure you identify gaps and secure suitable resources that have the required skill sets (or arrange for them to complete training). This evaluation is critical at this stage of your project because a lack of the proper skills can impact on both the timeline and the overall success of the project.

Here's a list of tasks you should complete.

1. Evaluate the team skill sets.
2. Secure skilled resources, or upskill resources to expand their capabilities.
3. Review the results of each evaluation and respond accordingly.

Solution development checkpoint

The solution development checkpoint includes periodic quality checks and additional skill building.

Periodic quality checks

During solution development, you should make periodic checks to validate that the solution is being developed according to recommended practices. Check that the project use cases will be satisfied and that enterprise requirements are being met. For the purposes of this methodology, these checks are called *periodic quality checks*.

Implement the following quality checks:

- Quality checks for workspaces.
- Quality checks for data integration.
- Quality checks for dedicated SQL pools.
- Quality checks for serverless SQL pools.
- Quality checks for Spark pools.

Additional skill building

As the project progresses, identify whether more skill sets are needed. Take the time to determine whether more skill sets could improve the quality of the solution. Supplementing the team with more skill sets can help to avoid project delays and project timeline impacts.

Pre go-live checkpoint

Before deploying your solution to production, we recommend that you perform reviews to assess the preparedness of the solution.

The *pre go-live* checklist provides a final readiness check to successfully deploy to production.

1. Perform the operational readiness review.
2. Perform the user readiness and onboarding plan review.
3. Review the results of each review and respond accordingly.

Post go-live checkpoint

After deploying to production, we recommend that you validate that the solution operates as expected.

The *post go-live* checklist provides a final readiness check to monitor your Azure Synapse solution.

1. Perform the monitoring review.
2. Continually monitor your Azure Synapse solution.

Next steps

In the next article in the *Azure Synapse implementation success by design* series, learn how to assess your environment to help evaluate the solution design and make informed technology decisions to implement Azure Synapse.

Synapse implementation success methodology: Assess environment

8/19/2022 • 16 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

The first step when implementing Azure Synapse Analytics is to assessment your environment. An assessment provides you with the opportunity to gather all the available information about your existing environment, environmental requirements, project requirements, constraints, timelines, and pain points. This information will form the basis of later evaluations and checkpoint activities. It will prove invaluable when it comes time to validate and compare against the project solution as it's planned, designed, and developed. We recommend that you dedicate a good amount of time to gather all the information and be sure to have necessary discussions with relevant groups. Relevant groups can include project stakeholders, business users, solution designers, and subject matter experts (SMEs) of the existing solution and environment.

The assessment will become a guide to help you evaluate the solution design and make informed technology recommendations to implement Azure Synapse.

Workload assessment

The workload assessment is concerned with the environment, analytical workload roles, ETL/ELT, networking and security, the Azure environment, and data consumption.

Environment

For the environment, evaluate the following points.

- Describe your existing analytical workload:
  - What are the workloads (like data warehouse or big data)?
  - How is this workload helping the business? What are the use case scenarios?
  - What is the business driver for this analytical platform and for potential migration?
  - Gather details about the existing architecture, design, and implementation choices.
  - Gather details about all existing upstream and downstream dependent components and consumers.
- Are you migrating an existing data warehouse (like Microsoft SQL Server, Microsoft Analytics Platform System (APS), Netezza, Snowflake, or Teradata)?
- Are you migrating a big data platform (like Cloudera or Hortonworks)?
- Gather the architecture and dataflow diagrams for the current analytical environment.
- Where are the data sources for your planned analytical workloads located (Azure, other cloud providers, or on-premises)?
- What is the total size of existing datasets (historical and incremental)? What is the current rate of growth of your dataset(s)? What is the projected rate of growth of your datasets for the next 2-5 years?
- Do you have an existing data lake? Gather as much detail as possible about file types (like Parquet or CSV), file sizes, and security configuration.
- Do you have semi-structured or unstructured data to process and analyze?
- Describe the nature of the data processing (batch or real-time processing).

- Do you need interactive data exploration from relational data, data lake, or other sources?
- Do you need real-time data analysis and exploration from operational data sources?
- What are the pain points and limitations in the current environment?
- What source control and DevOps tools are you using today?
- Do you have a use case to build a hybrid (cloud and on-premises) analytical solution, cloud only, or multi-cloud?
- Gather information on the existing cloud environment. Is it a single-cloud provider or a multi-cloud provider?
- Gather plans about the future cloud environment. Will it be a single-cloud provider or a multi-cloud provider?
- What are the RPO/RTO/HA/SLA requirements in the existing environment?
- What are the RPO/RTO/HA/SLA requirements in the planned environment?

Analytical workload roles

For the analytical workload roles, evaluate the following points.

- Describe the different roles (data scientist, data engineer, data analyst, and others).
- Describe the analytical platform access control requirement for these roles.
- Identify the platform owner who's responsible to provision compute resources and grant access.
- Describe how different data roles currently collaborate.
- Are there multiple teams collaborating on the same analytical platform? If so, what's the access control and isolation requirements for each of these teams?
- What are the client tools that end users use to interact with the analytical platform?

ETL/ELT, transformation, and orchestration

For ETL/ELT, transformation, and orchestration, evaluate the following points.

- What tools are you using today for data ingestion (ETL or ELT)?
- Where do these tools exist in the existing environment (on-premises or the cloud)?
- What are your current data load and update requirements (real-time, micro batch, hourly, daily, weekly, or monthly)?
- Describe the transformation requirements for each layer (big data, data lake, data warehouse).
- What is the current programming approach for transforming the data (no-code, low-code, programming like SQL, Python, Scala, C#, or other)?
- What is the preferred planned programming approach to transform the data (no-code, low-code, programming like SQL, Python, Scala, C#, or other)?
- What tools are currently in use for data orchestration to automate the data-driven process?
- Where are the data sources for your existing ETL located (Azure, other cloud provider, or on-premises)?
- What are the existing data consumptions tools (reporting, BI tools, open-source tools) that require integration with the analytical platform?
- What are the planned data consumptions tools (reporting, BI tools, open-source tools) that will require integration with the analytical platform?

Networking and security

For networking and security, evaluate the following points.

- What regulatory requirements do you have for your data?
- If your data contains customer content, payment card industry (PCI), or Health Insurance Portability and Accountability Act of 1996 (HIPAA) data, has your security group certified Azure for this data? If so, for which Azure services?
- Describe your user authorization and authentication requirements.
- Are there security issues that could limit access to data during implementation?

- Is there test data available to use during development and testing?
- Describe the organizational network security requirements on the analytical compute and storage (private network, public network, or firewall restrictions).
- Describe the network security requirements for client tools to access analytical compute and storage (peered network, private endpoint, or other).
- Describe the current network setup between on-premises and Azure (Azure ExpressRoute, site-to-site, or other).

Use the following checklists of possible requirements to guide your assessment.

- Data protection:
  - In-transit encryption
  - Encryption at rest (default keys or customer-managed keys)
  - Data discovery and classification
- Access control:
  - Object-level security
  - Row-level security
  - Column-level security
  - Dynamic data masking
- Authentication:
  - SQL login
  - Azure Active Directory (Azure AD)
  - Multi-factor authentication (MFA)
- Network security:
  - Virtual networks
  - Firewall
  - Azure ExpressRoute
- Threat protection:
  - Threat detection
  - Auditing
  - Vulnerability assessment

For more information, see the Azure Synapse Analytics security white paper.

Azure environment

For the Azure environment, evaluate the following points.

- Are you currently using Azure? Is it used for production workloads?
- If you're using Azure, which services are you using? Which regions are you using?
- Do you use Azure ExpressRoute? What's its bandwidth?
- Do you have budget approval to provision the required Azure services?
- How do you currently provision and manage resources (Azure Resource Manager (ARM) or Terraform)?
- Is your key team familiar with Synapse Analytics? Is any training required?

Data consumption

For data consumption, evaluate the following points.

- Describe how and what tools you currently use to perform activities like ingest, explore, prepare, and data visualization.
- Identify what tools you plan to use to perform activities like ingest, explore, prepare, and data visualization.
- What applications are planned to interact with the analytical platform (Microsoft Power BI, Microsoft Excel,

Microsoft SQL Server Reporting Services, Tableau, or others)?
- Identify all data consumers.
- Identify data export and data sharing requirements.

Azure Synapse services assessment

The Azure Synapse services assessment is concerned with the services within Azure Synapse. Azure Synapse has the following components for compute and data movement:

- **Synapse SQL:** A distributed query system for Transact-SQL (T-SQL) that enables data warehousing and data virtualization scenarios. It also extends T-SQL to address streaming and machine learning (ML) scenarios. Synapse SQL offers both *serverless* and *dedicated* resource models.
- **Serverless SQL pool:** A distributed data processing system, built for large-scale data and computational functions. There's no infrastructure to set up or clusters to maintain. This service is suited for unplanned or burst workloads. Recommended scenarios include quick data exploration on files directly on the data lake, logical data warehouse, and data transformation of raw data.
- **Dedicated SQL pool:** Represents a collection of analytic resources that are provisioned when using Synapse SQL. The size of a dedicated SQL pool (formerly SQL DW) is determined by Data Warehousing Units (DWU). This service is suited for a data warehouse with predictable, high performance continuous workloads over data stored in SQL tables.
- **Apache Spark pool:** Deeply and seamlessly integrates Apache Spark, which is the most popular open source big data engine used for data preparation, data engineering, ETL, and ML.
- **Data integration pipelines:** Azure Synapse contains the same data integration engine and experiences as Azure Data Factory (ADF). They allow you to create rich at-scale ETL pipelines without leaving Azure Synapse.

To help determine the best SQL pool type (dedicated or serverless), evaluate the following points.

- Do you want to build a traditional relational data warehouse by reserving processing power for data stored in SQL tables?
- Do your use cases demand predictable performance?
- Do you want to a build a logical data warehouse on top of a data lake?
- Do you want to query data directly from a data lake?
- Do you want to explore data from a data lake?

The following table compares the two Synapse SQL pool types.

COMPARISON	DEDICATED SQL POOL	SERVERLESS SQL POOL
Value propositions	Fully managed capabilities of a data warehouse. Predictable and high performance for continuous workloads. Optimized for managed (loaded) data.	Easy to get started and explore data lake data. Better total cost of ownership (TCO) for ad hoc and intermittent workloads. Optimized for querying data in a data lake.
Workloads	*Ideal for continuous workloads.* Loading boosts performance, with more complexity. Charging per DWU (when sized well) will be cost-beneficial.	*Ideal for ad hoc or intermittent workloads.* There's no need to load data, so it's easier to start and run. Charging per usage will be cost-beneficial.
Query performance	*Delivers high concurrency and low latency.* Supports rich caching options, including materialized views. There's the ability to choose trade-offs with workload management (WLM).	*Not suited for dashboarding queries.* Millisecond response times aren't expected. It works only on external data.

Dedicated SQL pool assessment

For the dedicated SQL pool assessment, evaluate the following platform points.

- What is the current data warehouse platform (Microsoft SQL Server, Netezza, Teradata, Greenplum, or other)?
- For a migration workload, determine the make and model of your appliance for each environment. Include details of CPUs, GPUs, and memory.
- For an appliance migration, when was the hardware purchased? Has the appliance been fully depreciated? If not, when will depreciation end? And, how much capital expenditure is left?
- Are there any hardware and network architecture diagrams?
- Where are the data sources for your planned data warehouse located (Azure, other cloud provider, or on-premises)?
- What are the data hosting platforms of the data sources for your data warehouse (Microsoft SQL Server, Azure SQL Database, DB2, Oracle, Azure Blob Storage, AWS, Hadoop, or other)?
- Are any of the data sources data warehouses? If so, which ones?
- Identify all ETL, ELT, and data loading scenarios (batch windows, streaming, near real-time). Identify existing service level agreements (SLAs) for each scenario and document the expected SLAs in the new environment.
- What is the current data warehouse size?
- What rate of dataset growth is being targeted for the dedicated SQL pool?
- Describe the environments you're using today (development, test, or production).
- Which tools are currently in place for data movement (ADF, Microsoft SQL Server Integration Services (SSIS), robocopy, Informatica, SFTP, or others)?
- Are you planning to load real-time or near real-time data?

Evaluate the following database points.

- What is the number of objects in each data warehouse (schemas, tables, views, stored procedures, functions)?
- Is it a star schema, snowflake schema or other design?
- What are the largest tables in terms of size and number of records?
- What are the widest tables in terms of the number of columns?
- Is there already a data model designed for your data warehouse? Is it a Kimball, Inmon, or star schema design?
- Are Slowly Changing Dimensions (SCDs) in use? If so, which types?
- Will a semantic layer be implemented by using relational data marts or Analysis Services (tabular or multidimensional), or another product?
- What are the HA/RPO/RTO/data archiving requirements?
- What are the region replication requirements?

Evaluate the following workload characteristics.

- What is the estimated number of concurrent users or jobs accessing the data warehouse during *peak hours*?
- What is the estimated number of concurrent users or jobs accessing the data warehouse during *off peak hours*?
- Is there a period of time when there will be no users or jobs?
- What are your query execution performance expectations for interactive queries?
- What are your data load performance expectations for daily/weekly/monthly data loads or updates?
- What are your query execution expectations for reporting and analytical queries?
- How complex will the most commonly executed queries be?
- What percentage of your total dataset size is your active dataset?
- Approximately what percentage of the workload is anticipated for loading or updating, batch processing or

reporting, interactive query, and analytical processing?

- Identify the data consuming patterns and platforms:
  - Current and planned reporting method and tools.
  - Which application or analytical tools will access the data warehouse?
  - Number of concurrent queries?
  - Average number of active queries at any point in time?
  - What is the nature of data access (interactive, ad hoc, export, or others)?
  - Data roles and complete description of their data requirements.
  - Maximum number of concurrent connections.
- Query performance SLA pattern by:
  - Dashboard users.
  - Batch reporting.
  - ML users.
  - ETL process.
- What are the security requirements for the existing environment and for the new environment (row-level security, column-level security, access control, encryption, and others)?
- Do you have requirements to integrate ML model scoring with T-SQL?

Serverless SQL pool assessment

Synapse Serverless SQL pool supports three major use cases.

- **Basic discovery and exploration:** Quickly reason about the data in various formats (Parquet, CSV, JSON) in your data lake, so you can plan how to extract insights from it.
- **Logical data warehouse:** Provide a relational abstraction on top of raw or disparate data without relocating and transforming data, allowing an always-current view of your data.
- **Data transformation:** Simple, scalable, and performant way to transform data in the lake by using T-SQL, so it can be fed to BI and other tools or loaded into a relational data store (Synapse SQL databases, Azure SQL Database, or others).

Different data roles can benefit from serverless SQL pool:

- **Data engineers** can explore the data lake, transform and prepare data by using this service, and simplify their data transformation pipelines.
- **Data scientists** can quickly reason about the contents and structure of the data in the data lake, thanks to features such as OPENROWSET and automatic schema inference.
- **Data analysts** can explore data and Spark external tables created by data scientists or data engineers by using familiar T-SQL statements or their favorite query tools.
- **BI professionals** can quickly create Power BI reports on top of data in the data lake and Spark tables.

> **NOTE**
>
> The T-SQL language is used in both dedicated SQL pool and the serverless SQL pool, however there are some differences in the set of supported features. For more information about T-SQL features supported in Synapse SQL (dedicated and serverless), see Transact-SQL features supported in Azure Synapse SQL.

For the serverless SQL pool assessment, evaluate the following points.

- Do you have use cases to discover and explore data from a data lake by using relational queries (T-SQL)?
- Do you have use cases to build a logical data warehouse on top of a data lake?
- Identify whether there are use cases to transform data in the data lake without first moving data from the data lake.

- Is your data already in Azure Data Lake Storage (ADLS) or Azure Blob Storage?
- If your data is already in ADLS, do you have a good partition strategy in the data lake?
- Do you have operational data in Azure Cosmos DB? Do you have use cases for real-time analytics on Azure Cosmos DB without impacting transactions?
- Identify the file types in the data lake.
- Identify the query performance SLA. Does your use case demand predictable performance and cost?
- Do you have unplanned or bursty SQL analytical workloads?
- Identify the data consuming pattern and platforms:
  - Current and planned reporting method and tools.
  - Which application or analytical tools will access the serverless SQL pool?
  - Average number of active queries at any point in time.
  - What is the nature of data access (interactive, ad hoc, export, or others)?
  - Data roles and complete description of their data requirements.
  - Maximum number of concurrent connections.
  - Query complexity?
- What are the security requirements (access control, encryption, and others)?
- What is the required T-SQL functionality (stored procedures or functions)?
- Identify the number of queries that will be sent to the serverless SQL pool and the result set size of each query.

> **TIP**
>
> If you're new to serverless SQL pools, we recommend you work through the Build data analytics solutions using Azure Synapse serverless SQL pools learning path.

Spark pool assessment

Spark pools in Azure Synapse enable the following key scenarios.

- **Data engineering/Data preparation:** Apache Spark includes many language features to support preparation and processing of large volumes of data. Preparation and processing can make the data more valuable and allow it to be consumed by other Azure Synapse services. It's enabled through multiple languages (C#, Scala, PySpark, Spark SQL) and by using supplied libraries for processing and connectivity.
- **Machine learning:** Apache Spark comes with MLlib, which is an ML library built on top of Spark that you can use from a Spark pool. Spark pools also include Anaconda, which is a Python distribution that comprises various packages for data science including ML. In addition, Apache Spark on Synapse provides pre-installed libraries for Microsoft Machine Learning, which is a fault-tolerant, elastic, and RESTful ML framework. When combined with built-in support for notebooks, you have a rich environment for creating ML applications.

> **NOTE**
>
> For more information, see Apache Spark in Azure Synapse Analytics.
>
> Also, Azure Synapse is compatible with Linux Foundation Delta Lake. Delta Lake is an open-source storage layer that brings ACID (atomicity, consistency, isolation, and durability) transactions to Apache Spark and big data workloads. For more information, see What is Delta Lake.

For the Spark pool assessment, evaluate the following points.

- Identify the workloads that require data engineering or data preparation.
- Clearly define the types of transformations.
- Identify whether you have unstructured data to process.

- When you're migrating from an existing Spark/Hadoop workload:
  - What is the existing big data platform (Cloudera, Hortonworks, cloud services, or other)?
  - If it's a migration from on-premises, has hardware depreciated or licenses expired? If not, when will depreciation or expiry happen?
  - What is the existing cluster type?
  - What are the required libraries and Spark versions?
  - Is it a Hadoop migration to Spark?
  - What are the current or preferred programming languages?
  - What is the type of workload (big data, ML, or other)?
  - What are the existing and planned client tools and reporting platforms?
  - What are the security requirements?
  - Are there any current pain points and limitations?
- Do you plan to use, or are currently using, Delta Lake?
- How do you manage packages today?
- Identify the required compute cluster types.
- Identify whether cluster customization is required.

> **TIP**
> If you're new to Spark pools, we recommend you work through the Perform data engineering with Azure Synapse Apache Spark Pools learning path.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate the Synapse workspace design and validate that it meets guidelines and requirements.

Synapse implementation success methodology: Evaluate workspace design

8/19/2022 • 6 minutes to read • Edit Online

NOTE

This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Synapse workspace is a unified graphical user experience that stitches together your analytical and data processing engines, data lakes, databases, tables, datasets, and reporting artifacts along with code and process orchestration. Considering the number of technologies and services that are integrated into Synapse workspace, ensure that the key components are included in your design.

Synapse workspace design review

Identify whether your solution design involves one Synapse workspace or multiple workspaces. Determine the drivers of this design. While there might be different reasons, in most cases the reason for multiple workspaces is either security segregation or billing segregation. When determining the number of workspaces and database boundaries, keep in mind that there's a limit of 20 workspaces per subscription.

Identify which elements or services within each workspace need to be shared and with which resources. Resources can include data lakes, integration runtimes (IRs), metadata or configurations, and code. Determine why this particular design was chosen in terms of potential synergies. Ask yourself whether these synergies justify the extra cost and management overhead.

Data lake design review

We recommended that the data lake (if part of your solution) be properly tiered. You should divide your data lake into three major areas that relate to *Bronze*, *Silver*, and *Gold* datasets. Bronze - or the raw layer - might reside on its own separate storage account because it has stricter access controls due to unmasked sensitive data that it might store.

Security design review

Review the security design for the workspace and compare it with the information you gathered during the assessment. Ensure all of the requirements are met, and all of the constraints have been taken into account. For ease of management, we recommended that users be organized into groups with appropriate permissions profiling: you can simplify access control by using security groups that align with roles. That way, network administrators can add or remove users from appropriate security groups to manage access.

Serverless SQL pools and Apache Spark tables store their data in an Azure Data Lake Gen2 (ADLS Gen2) container that's associated with the workspace. User-installed Apache Spark libraries are also managed in this same storage account. To enable these use cases, both users and the workspace managed service identity (MSI) must be added to the **Storage Blob Data Contributor** role of the ADLS Gen2 storage container. Verify this requirement against your security requirements.

Dedicated SQL pools provide a rich set of security features to encrypt and mask sensitive data. Both dedicated and serverless SQL pools enable the full surface area of SQL Server permissions including built-in roles, user-

defined roles, SQL authentication, and Azure Active Directory (Azure AD) authentication. Review the security design for your solution's dedicated SQL pool and serverless SQL pool access and data.

Review the security plan for your data lake and all the ADLS Gen2 storage accounts (and others) that will form part of your Azure Synapse Analytics solution. ADLS Gen2 storage isn't itself a compute engine and so it doesn't have a built-in ability to selectively mask data attributes. You can apply ADLS Gen2 permissions at the storage account or container level by using role-based access control (RBAC) and/or at the folder or file level by using access control lists (ACLs). Review the design carefully and strive to avoid unnecessary complexity.

Here are some points to consider for the security design.

- Make sure Azure AD set up requirements are included in the design.
- Check for cross-tenant scenarios. Such issues may arise because some data is in another Azure tenant, or it needs to move to another tenant, or it needs to be accessed by users from another tenant. Ensure these scenarios are considered in your design.
- What are the roles for each workspace? How will they use the workspace?
- How is the security designed within the workspace?
  - Who can view all scripts, notebooks, and pipelines?
  - Who can execute scripts and pipelines?
  - Who can create/pause/resume SQL and Spark pools?
  - Who can publish changes to the workspace?
  - Who can commit changes to source control?
- Will pipelines access data by using stored credentials or the workspace managed identity?
- Do users have the appropriate access to the data lake to browse the data in Synapse Studio?
- Is the data lake properly secured by using the appropriate combination of RBAC and ACLs?
- Have the SQL pool user permissions been correctly set for each role (data scientist, developer, administrator, business user, and others)?

Networking design review

Here are some points to consider for the network design.

- Is connectivity designed between all the resources?
- What is the networking mechanism to be used (Azure ExpressRoute, public Internet, or private endpoints)?
- Do you need to be able to securely connect to Synapse Studio?
- Has data exfiltration been taken into consideration?
- Do you need to connect to on-premises data sources?
- Do you need to connect to other cloud data sources or compute engines, such as Azure Machine Learning?
- Have Azure networking components, like network security groups (NSGs), been reviewed for proper connectivity and data movement?
- Has integration with the private DNS zones been taken into consideration?
- Do you need to be able to browse the data lake from within Synapse Studio or simply query data in the data lake with serverless SQL or PolyBase?

Finally, identify all of your data consumers and verify that their connectivity is accounted for in the design. Check that network and security outposts allow your service to access required on-premises sources and that its authentication protocols and mechanisms are supported. In some scenarios, you might need to have more than one self-hosted IR or data gateway for SaaS solutions, like Microsoft Power BI.

Monitoring design review

Review the design of the monitoring of the Azure Synapse components to ensure they meet the requirements

and expectations identified during the assessment. Verify that monitoring of resources and data access has been designed, and that it identifies each monitoring requirement. A robust monitoring solution should be put in place as part of the first deployment to production. That way, failures can be identified, diagnosed, and addressed in a timely manner. Aside from the base infrastructure and pipeline runs, data should also be monitored. Depending on the Azure Synapse components in use, identify the monitoring requirements for each component. For example, if Spark pools form part of the solution, monitor the malformed record store.

Here are some points to consider for the monitoring design.

- Who can monitor each resource type (pipelines, pools, and others)?
- How long do database activity logs need to be retained?
- Will workspace and database log retention use Log Analytics or Azure Storage?
- Will alerts be triggered in the event of a pipeline error? If so, who should be notified?
- What threshold level of a SQL pool should trigger an alert? Who should be notified?

Source control design review

By default, a Synapse workspace applies changes directly to the Synapse service by using the built-in publish functionality. You can enable source control integration, which provides many advantages. Advantages include better collaboration, versioning, approvals, and release pipelines to promote changes through to development, test, and production environments. Azure Synapse allows a single source control repository per workspace, which can be either Azure DevOps Git or GitHub.

Here are some points to consider for the source control design.

- If using Azure DevOps Git, is the Synapse workspace and its repository in the same tenant?
- Who will be able to access source control?
- What permissions will each user be granted in source control?
- Has a branching and merging strategy been developed?
- Will release pipelines be developed for deployment to different environments?
- Will an approval process be used for merging and for release pipelines?

> **NOTE**
> The design of the development environment is of critical importance to the success of your project. If a development environment has been designed, it will be evaluated in a separate stage of this methodology.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate the data integration design and validate that it meets guidelines and requirements.

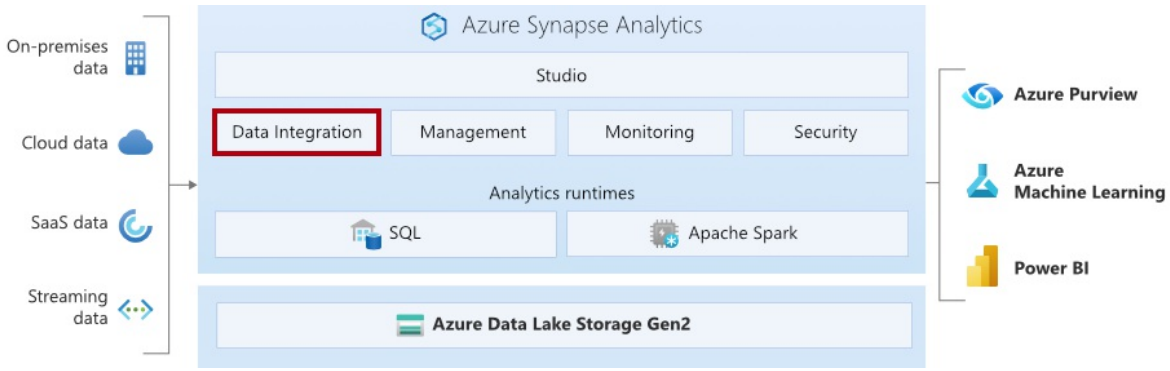
Synapse implementation success methodology: Evaluate data integration design

8/19/2022 • 5 minutes to read • Edit Online

NOTE

This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Azure Synapse Analytics contains the same data integration engine and experiences as Azure Data Factory (ADF), allowing you to create rich at-scale ETL pipelines without leaving Azure Synapse Analytics.



This article describes how to evaluate the design of the data integration components for your project. Specifically, it helps you to determine whether Azure Synapse pipelines are the best fit for your data integration requirements. Time invested in evaluating the design prior to solution development can help to eliminate unexpected design changes that may impact on your project timeline or cost.

Fit gap analysis

You should perform a thorough fit gap analysis of your data integration strategy. If you choose Azure Synapse pipelines as the data integration tool, review the following points to ensure they're the best fit for your data integration requirements and orchestration. Even if you choose different data integration tools, you should still review the following points to validate that all key design points have been considered and that your chosen tool will support your solution needs. This information should have been captured during your assessment performed earlier in this methodology.

- Review your data sources and destinations (targets):
  - Validate that source and destination stores are supported data stores.
  - If they're not supported, check whether you can use the extensible options.
- Review the triggering points of your data integration and the frequency:
  - Azure Synapse pipelines support schedule, tumbling window, and storage event triggers.
  - Validate the minimum recurrence interval and supported storage events against your requirements.
- Review the required modes of data integration:
  - Scheduled, periodic, and triggered batch processing can be effectively designed in Azure Synapse pipelines.
  - To implement Change Data Capture (CDC) functionality, use third-party products or create a custom solution.

    - To support real-time streaming, use Azure Event Hubs, Azure Event Hubs from Apache Kafka, or Azure IoT Hub.
    - To run Microsoft SQL Server Integration Services (SSIS) packages, you can lift and shift SSIS workloads to the cloud.
- Review the compute design:
    - Does the compute required for the pipelines need to be serverless or provisioned?
    - Azure Synapse pipelines support both modes of integration runtime (IR): serverless or self-hosted on a Windows machine.
    - Validate ports and firewalls and proxy setting when using the self-hosted IR (provisioned).
- Review security requirements, networking and firewall configuration of the environment and compare them to the security, networking and firewall configuration design:
    - Review how the data sources are secured and networked.
    - Review how the target data stores are secured and networked. Azure Synapse pipelines have different data access strategies that provide a secure way to connect data stores via private endpoints or virtual networks.
    - Use Azure Key Vault to store credentials whenever applicable.
    - Use ADF for customer-managed key (CMK) encryption of credentials and store them in the self-hosted IR.
- Review the design for ongoing monitoring of all data integration components.

Architecture considerations

As you review the data integration design, consider the following recommendations and guidelines to ensure that the data integration components of your solution will provide ongoing operational excellence, performance efficiency, reliability, and security.

Operational excellence

For operational excellence, evaluate the following points.

- **Environment:** When planning your environments, segregate them by development/test, user acceptance testing (UAT), and production. Use the folder organizational options to organize your pipelines and datasets by business/ETL jobs to support better maintainability. Use annotations to tag your pipelines so you can easily monitor them. Create reusable pipelines by using parameters, and iteration and conditional activities.
- **Monitoring and alerting:** Synapse workspaces include the Monitor Hub, which has rich monitoring information of each and every pipeline run. It also integrates with Log Analytics for further log analysis and alerting. You should implement these features to provide proactive error notifications. Also, use *Upon Failure* paths to implement customized error handling.
- **Automated deployment and testing:** Azure Synapse pipelines are built into Synapse workspace, so you can take advantage of workspace automation and deployment. Use ARM templates to minimize manual activities when creating Synapse workspaces. Also, integrate Synapse workspaces with Azure DevOps to build code versioning and automate publication.

Performance efficiency

For performance efficiency, evaluate the following points.

- Follow performance guidance and optimization features when working with the copy activity.
- Choose optimized connectors for data transfer instead of generic connectors. For example, use PolyBase instead of bulk insert when moving data from Azure Data Lake Storage Gen2 (ALDS Gen2) to a dedicated SQL pool.
- When creating a new Azure IR, set the region location as auto-resolve or select the same region as the data stores.
- For self-hosted IR, choose the Azure virtual machine (VM) size based on the integration requirements.

- Choose a stable network connection, like Azure ExpressRoute, for fast and consistent bandwidth.

Reliability

When you execute a pipeline by using Azure IR, it's serverless in nature and so it provides resiliency out of the box. There's little for customers to manage. However, when a pipeline runs in a self-hosted IR, we recommend that you run it by using a high availability configuration in Azure VMs. This configuration ensures integration pipelines aren't broken even when a VM goes offline. Also, we recommend that you use Azure ExpressRoute for a fast and reliable network connection between on-premises and Azure.

Security

A secured data platform is one of the key requirements of every organization. You should thoroughly plan security for the entire platform rather than individual components. Here are some security guidelines for Azure Synapse pipeline solutions.

- Secure data movement to the cloud by using Azure Synapse private endpoints.
- Use Azure Active Directory (Azure AD) managed identities for authentication.
- Use Azure role-based access control (RBAC) and Synapse RBAC for authorization.
- Store credentials, secrets, and keys in Azure Key Vault rather than in the pipeline. For more information, see Use Azure Key Vault secrets in pipeline activities.
- Connect to on-premises resources via Azure ExpressRoute or VPN over private endpoints.
- Enable the **Secure output** and **Secure input** options in pipeline activities when parameters store secrets or passwords.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate your dedicated SQL pool design to identify issues and validate that it meets guidelines and requirements.

Synapse implementation success methodology: Evaluate dedicated SQL pool design

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

You should evaluate your dedicated SQL pool design to identify issues and validate that it meets guidelines and requirements. By evaluating the design *before solution development begins*, you can avoid blockers and unexpected design changes. That way, you protect the project's timeline and budget.

Synapse SQL has a scale-out architecture that distributes computational data processing across multiple nodes. Compute is separate from storage, which enables you to scale compute independently of the data in your system. For more information, see Dedicated SQL pool (formerly SQL DW) architecture in Azure Synapse Analytics.

Assessment analysis

During the assessment stage, you collected information about how the original system was deployed and details of the structures that were implemented. That information can now help you to identify gaps between what's implemented and what needs to be developed. For example, now's the time to consider the impact of designing round-robin tables instead of hash distributed tables, or the performance benefits of correctly using replicated tables.

Review the target architecture

To successfully deploy a dedicated SQL pool, it's important to adopt an architecture that's aligned with business requirements. For more information, see Data warehousing in Microsoft Azure.

Migration path

A migration project for Azure Synapse is similar to any other database migration. You should consider that there might be differences between the original system and Azure Synapse.

Ensure that you have a clear migration path established for:

- Database objects, scripts, and queries
- Data transfer (export from source and transit to the cloud)
- Initial data load into Azure Synapse
- Logins and users
- Data access control (row-level security)

For more information, see Migrate a data warehouse to a dedicated SQL pool in Azure Synapse Analytics.

Feature gaps

Determine whether the original system depends on features that aren't supported by Azure Synapse.

Unsupported features in dedicated SQL pools include certain data types, like XML and spatial data types, and cursors.

For more information, see:

- Table data types for dedicated SQL pool (formerly SQL DW) in Azure Synapse Analytics
- Transact-SQL features supported in Azure Synapse SQL

Dedicated SQL pool testing

As with any other project, you should conduct tests to ensure that your dedicated SQL pool delivers the required business needs. It's critical to test data quality, data integration, security, and performance.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate your Spark pool design to identify issues and validate that it meets guidelines and requirements.

Synapse implementation success methodology: Evaluate serverless SQL pool design

8/19/2022 • 6 minutes to read • Edit Online

NOTE

This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

You should evaluate your serverless SQL pool design to identify issues and validate that it meets guidelines and requirements. By evaluating the design *before solution development begins*, you can avoid blockers and unexpected design changes. That way, you protect the project's timeline and budget.

The architectural separation of storage and compute for modern data, analytical platforms and services has been a trend and frequently used pattern. It provides cost savings and more flexibility allowing independent on-demand scaling of your storage and compute. Synapse SQL serverless extends this pattern by adding the capability to query your data lake data directly. There's no need to worry about compute management when using self-service types of workloads.

Fit gap analysis

When planning to implement SQL serverless pools within Azure Synapse, you first need to ensure serverless pools are the right fit for your workloads. You should consider operational excellence, performance efficiency, reliability, and security.

Operational excellence

For operational excellence, evaluate the following points.

- **Solution development environment:** Within this methodology, there's an evaluation of the solution development environment. Identify how the environments (development, test, and production) are designed to support solution development. Commonly, you'll find a production and non-production environments (for development and test). You should find Synapse workspaces in all of the environments. In most cases, you'll be obliged to segregate your production and development/test users and workloads.
- **Synapse workspace design:** Within this methodology, there's an evaluation of the Synapse workspace design. Identify how the workspaces have been designed for your solution. Become familiar with the design and know whether the solution will use a single workspace or whether multiple workspaces form part of the solution. Know why a single or multiple workspace design was chosen. A multi-workspace design is often chosen to enforce strict security boundaries.
- **Deployment:** SQL serverless is available on-demand with every Synapse workspace, so it doesn't require any special deployment actions. Check regional proximity of the service and that of the Azure Data Lake Storage Gen2 (ADLS Gen2) account that it's connected to.
- **Monitoring:** Check whether built-in monitoring is sufficient and whether any external services need to be put in place to store historical log data. Log data allows analyzing changes in performance and allows you to define alerting or triggered actions for specific circumstances.

Performance efficiency

Unlike traditional database engines, SQL serverless doesn't rely on its own optimized storage layer. For that reason, its performance is heavily dependent on how data is organized in ADLS Gen2. For performance

efficiency, evaluate the following points.

- **Data ingestion:** Review how data is stored in the data lake. File sizes, the number of files, and folder structure all have an impact on performance. Keep in mind that while some file sizes might work for SQL serverless, they may impose issues for efficient processing or consumption by other engines or applications. You'll need to evaluate the data storage design and validate it against all of the data consumers, including SQL serverless and any other data tools that form part of your solution.
- **Data placement:** Evaluate whether your design has unified and defined common patterns for data placement. Ensure that directory branching can support your security requirements. There are a few common patterns that can help you keep your time series data organized. Whatever your choice, ensure that it also works with other engines and workloads. Also, validate whether it can help partition auto-discovery for Spark applications and external tables.
- **Data formats:** In most cases, SQL serverless will offer the best performance and better compatibility feature-wise by using a Parquet format. Verify your performance and compatibility requirements, because while Parquet improves performance - thanks to better compression and reduction of IO (by reading only required columns needed for analysis) - it requires more compute resources. Also, because some source systems don't natively support Parquet as an export format, it could lead to more transformation steps in your pipelines and/or dependencies in your overall architecture.
- **Exploration:** Every industry is different. In many cases, however, there are common data access patterns found in the most frequent-run queries. Patterns typically involve filtering, and aggregations by dates, categories, or geographic regions. Identify your most common filtering criteria, and relate them to how much data is read/discarded by the most frequent-run queries. Validate whether the information on the data lake is organized to favor your exploration requirements and expectations. For the queries identified in your design and in your assessment, see whether you can eliminate unnecessary partitions in your OPENROWSET path parameter, or - if there are external tables - whether creating more indexes can help.

Reliability

For reliability, evaluate the following points.

- **Availability:** Validate any availability requirements that were identified during the assessment stage. While there aren't any specific SLAs for SQL serverless, there's a 30-minute timeout for query execution. Identify the longest running queries from your assessment and validate them against your serverless SQL design. A 30-minute timeout could break the expectations for your workload and appear as a service problem.
- **Consistency:** SQL serverless is designed primarily for read workloads. So, validate whether all consistency checks have been performed during the data lake data provisioning and formation process. Keep abreast of new capabilities, like Delta Lake open-source storage layer, which provides support for ACID (atomicity, consistency, isolation, and durability) guarantees for transactions. This capability allows you to implement effective lambda or kappa architectures to support both streaming and batch use cases. Be sure to evaluate your design for opportunities to apply new capabilities but not at the expense of your project's timeline or cost.
- **Backup:** Review any disaster recovery requirements that were identified during the assessment. Validate them against your SQL serverless design for recovery. SQL serverless itself doesn't have its own storage layer and that would require handling snapshots and backup copies of your data. The data store accessed by serverless SQL is external (ADLS Gen2). Review the recovery design in your project for these datasets.

Security

Organization of your data is important for building flexible security foundations. In most cases, different processes and users will require different permissions and access to specific sub areas of your data lake or logical data warehouse.

For security, evaluate the following points.

- **Data storage:** Using the information gathered during the assessment stage, identify whether typical *Raw*, *Stage*, and *Curated* data lake areas need to be placed on the same storage account instead of independent

storage accounts. The latter might result in more flexibility in terms of roles and permissions. It can also add more input/output operations per second (IOPS) capacity that might be needed if your architecture must support heavy and simultaneous read/write workloads (like real-time or IoT scenarios). Validate whether you need to segregate further by keeping your sandboxed and master data areas on separate storage accounts. Most users won't need to update or delete data, so they don't need write permissions to the data lake, except for sandboxed and private areas.

- From your assessment information, identify whether any requirements rely on security features like Always Encrypted, Dynamic data masking or Row-level security. Validate the availability of these features in specific scenarios, like when used with the OPENROWSET function. Anticipate potential workarounds that may be required.
- From your assessment information, identify what would be the best authentication methods. Consider Azure Active Directory (Azure AD) service principals, shared access signature (SAS), and when and how authentication pass-through can be used and integrated in the exploration tool of choice of the customer. Evaluate the design and validate that the best authentication method as part of the design.

Other considerations

Review your design and check whether you have put in place best practices and recommendations. Give special attention to filter optimization and collation to ensure that predicate pushdown works properly.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate your Spark pool design to identify issues and validate that it meets guidelines and requirements.

Synapse implementation success methodology: Evaluate Spark pool design

8/19/2022 • 4 minutes to read • Edit Online

NOTE

This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

You should evaluate your Apache Spark pool design to identify issues and validate that it meets guidelines and requirements. By evaluating the design *before solution development begins*, you can avoid blockers and unexpected design changes. That way, you protect the project's timeline and budget.

Apache Spark in Synapse brings the Apache Spark parallel data processing to Azure Synapse Analytics. This evaluation provides guidance on when Apache Spark in Azure Synapse is - or isn't - the right fit for your workload. It describes points to consider when you're evaluating your solution design elements that incorporate Spark pools.

Fit gap analysis

When planning to implement Spark pools with Azure Synapse, first ensure they're the best fit for your workload.

Consider the following points.

- Does your workload require data engineering/data preparation?
  - Apache Spark works best for workloads that require:
    - Data cleaning.
    - Transforming semi-structured data, like XML into relational.
    - Complex free-text transformation, like fuzzy matching or natural language processing (NLP).
    - Data preparation for machine learning (ML).
- Does your workload for data engineering/data preparation involve complex or simple transformations? And, are you looking for a low-code/no-code approach?
  - For simple transformations, like removing columns, changing column data types, or joining datasets, consider creating an Azure Synapse pipeline by using a data flow activity.
  - Data flow activities provide a low-code/no-code approach to prepare your data.
- Does your workload require ML on big data?
  - Apache Spark works well for large datasets that will be used for ML. If you're using small datasets, consider using Azure Machine Learning as the compute service.
- Do you plan to perform data exploration or ad hoc query analysis on big data?
  - Apache Spark in Azure Synapse provides Python/Scala/SQL/.NET-based data exploration. However, if you need a full Transact-SQL (T-SQL) experience, consider using a serverless SQL pool.
- Do you have a current Spark/Hadoop workload and do you need a unified big data platform?
  - Azure Synapse provides a unified analytical platform for working with big data. There are Spark and SQL serverless pools for ad hoc queries, and the dedicated SQL pool for reporting and serving data.
  - Moving from a Spark/Hadoop workload from on-premises (or another cloud environment) may involve some refactoring that you should take into consideration.
  - If you're looking for a lift-and-shift approach of your Apache big data environment from on-premises

to the cloud, and you need to meet a strict data engineering service level agreement (SLA), consider using Azure HDInsight.

Architecture considerations

To ensure that your Apache Spark pool meets your requirements for operational excellence, performance, reliability, and security, there are key areas to validate in your architecture.

Operational excellence

For operational excellence, evaluate the following points.

- **Environment:** When configuring your environment, design your Spark pool to take advantage of features such as autoscale and dynamic allocation. Also, to reduce costs, consider enabling the automatic pause feature.
- **Package management:** Determine whether required Apache Spark libraries will be used at a workspace, pool, or session level. For more information, see Manage libraries for Apache Spark in Azure Synapse Analytics.
- **Monitoring:** Apache Spark in Azure Synapse provides built-in monitoring of Spark pools and applications with the creation of each spark session. Also consider implementing application monitoring with Azure Log Analytics or Prometheus and Grafana, which you can use to visualize metrics and logs.

Performance efficiency

For performance efficiency, evaluate the following points.

- **File size and file type:** File size and the number of files have an impact on performance. Design the architecture to ensure that the file types are conducive to native ingestion with Apache Spark. Also, lean toward fewer large files instead of many small files.
- **Partitioning:** Identify whether partitioning at the folder and/or file level will be implemented for your workload. *Folder partitions* limit the amount of data to search and read. *File partitions* reduce the amount of data to be searched inside the file - but only apply to specific file formats that should be considered in the initial architecture.

Reliability

For reliability, evaluate the following points.

- **Availability:** Spark pools have a start time of three to four minutes. It could take longer if there are many libraries to install. When designing batch vs. streaming workloads, identify the SLA for executing the job from your assessment information and determine which architecture best meets your needs. Also, take into consideration that each job execution creates a new Spark pool cluster.
- **Checkpointing:** Apache Spark streaming has a built-in checkpointing mechanism. Checkpointing allows your stream to recover from the last processed entry should there be a failure on a node in your pool.

Security

For security, evaluate the following points.

- **Data access:** Data access must be considered for the Azure Data Lake Storage (ADLS) account that's attached to the Synapse workspace. In addition, determine the security levels required to access any data that isn't within the Azure Synapse environment. Refer to the information you collected during the assessment stage.
- **Networking:** Review the networking information and requirements gathered during your assessment. If the design involves a managed virtual network with Azure Synapse, consider the implications this requirement will have on Apache Spark in Azure Synapse. One implication is the inability to use Spark SQL while accessing data.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate your modern data warehouse project plan before the project starts.

For more information on best practices, see Apache Spark for Azure Synapse Guidance.

Synapse implementation success methodology: Evaluate project plan

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

In the lifecycle of the project, the most important and extensive planning is done *before implementation*. This article describes how to conduct a high-level review of your project plan. The aim is to ensure it contains critical artifacts and information to deliver a successful solution. It includes checklists of items that you should complete and approve before the project starts.

A detailed review should follow the high-level project plan review. The detailed review should focus on the specific Azure Synapse components identified during the assessment stage.

Evaluate the project plan

Work through the following two high-level checklists, taking care to verify that each task aligns with the information gathered during the assessment stage.

First, ensure that your project plan defines the following points.

- **The core resource team:** Assemble a group of key people that have expertise crucial to the project.
- **Scope:** Document how the project scope will be defined, verified, measured, and how the work breakdown will be defined and assigned.
- **Schedule:** Define the time duration required to complete the project.
- **Cost:** Estimate costs for internal and external resources, including infrastructure, hardware, and software.

Second, having defined and assigned the work breakdown, prepare the following artifacts.

- **Migration plan:** Document the plan to migrate from your current system to Azure Synapse. Incorporate tasks for executing the migration within the project plan scope and schedule.
- **Success criteria:** Define the critical success criteria for stakeholders (or the project sponsor), including go and no-go criteria.
- **Quality assurance:** Define how to conduct code reviews, and the development, staging, and production promotion approval processes.
- **Test plan:** Define test cases, success criteria for unit, integration, user testing, and metrics to validate all deliverables. Incorporate tasks for developing and executing the test plans within the project plan scope and schedule.

Evaluate project plan detailed tasks

Once the high-level project plan review is complete and approved, the next step is to drill down into each component of the project plan.

Identify the project plan components that address each aspect of Azure Synapse as it's intended for use in your solution. Also, validate that the project plan accounts for all the effort and resources required to develop, test,

deploy, and operate your solution by evaluating:

- The workspace project plan.
- The data integration project plan.
- The dedicated SQL pool project plan.
- The serverless SQL pool project plan.
- The Spark pool project plan.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate the environments for your modern data warehouse project to support development, testing, and production.

Synapse implementation success methodology: Evaluate solution development environment design

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Solution development and the environment within which it's performed is key to the success of your project. Regardless of your selected project methodology (like waterfall, Agile, or Scrum), you should set up multiple environments to support development, testing, and production. You should also define clear processes for promoting changes between environments.

Setting up a modern data warehouse environment for both production and pre-production use can be complex. Keep in mind that one of the key design decisions is automation. Automation helps increase productivity while minimizing the risk of errors. Further, your environments should support future agile development, including the addition of new workloads, like data science or real-time. During the design review, produce a solution development environment design that will support your solution not only for the current project but also for ongoing support and development of your solution.

Solution development environment design

The environment design should include the production environment, which hosts the production solution, and at least one non-production environment. Most environments contain two non-production environments: one for development and another for testing, Quality Assurance (QA), and User Acceptance Testing (UAT). Typically, environments are hosted in separate Azure subscriptions. Consider creating a production subscription, and a non-production subscription. This separation will provide a clear security boundary and delineation between production and non-production.

Ideally, you should establish three environments.

- **Development:** The environment within which your data and analytics solutions are built. Determine whether to provide sandboxes for developers. Sandboxes can allow developers to make and test their changes in isolation, while a shared development environment will host integrated changes from the entire development team.
- **Test/QA/UAT:** The production-like environment for testing deployments prior to their release to production.
- **Production:** The final production environment.

Synapse workspaces

For each Synapse workspace in your solution, the environment should include a production workspace and at least one non-production workspace for development and test/QA/UAT. Use the same name for all pools and artifacts across environments. Consistent naming will ease the promotion of workspaces to other environments.

Promoting a workspace to another workspace is a two-part process:

1. Use an Azure Resource Manager template (ARM template) to create or update workspace resources.
2. Migrate artifacts like SQL scripts, notebooks, Spark job definitions, pipelines, datasets, and data flows by using Azure Synapse continuous integration and delivery (CI/CD) tools in Azure DevOps or on GitHub.

Azure DevOps or GitHub

Ensure that integration with Azure DevOps or GitHub is properly set up. Design a repeatable process that releases changes across development, Test/QA/UAT, and production environments.

> **IMPORTANT**
>
> We recommend that sensitive configuration data always be stored securely in Azure Key Vault. Use Azure Key Vault to maintain a central, secure location for sensitive configuration data, like database connection strings. That way, appropriate services can access configuration data from within each environment.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to evaluate your team of skilled resources that will implement your Azure Synapse solution.

Synapse implementation success methodology: Evaluate team skill sets

8/19/2022 • 7 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Solution development requires a team comprising individuals with many different skills. It's important for the success of your solution that your team has the necessary skills to successfully complete their assigned tasks. This evaluation takes an honest and critical look at the skill level of your project resources, and it provides you with a list of roles that are often required during the implementation of an Azure Synapse solution. Your team needs to possess relevant experience and skills to complete their assigned project tasks within the expected time frame.

Microsoft learning level definitions

This article uses the Microsoft standard level definitions for describing learning levels.

LEVEL	DESCRIPTION
100	Assumes little or no expertise with the topic, and covers topic concepts, functions, features, and benefits.
200	Assumes 100-level knowledge and provides specific details about the topic.
300	*Advanced material.* Assumes 200-level knowledge, in-depth understanding of features in a real-world environment, and strong coding skills. Provides a detailed technical overview of a subset of product/technology features, covering architecture, performance, migration, deployment, and development.
400	*Expert material.* Assumes a deep level of technical knowledge and experience, and a detailed, thorough understanding of the topic. Provides expert-to-expert interaction and coverage of specialized topics.

Roles, resources, and readiness

Successfully delivering an Azure Synapse solution involves many different roles and skill sets. This topic describes roles commonly required to implement a successful project. Not all of these roles will be required for all projects, and not all of these roles will be required for the entire duration of the project. However, these roles will be required to complete some critical project tasks. You should evaluate the skill level of the individuals executing tasks to ensure their success in completing their job.

Refer to your project plan and verify that these resources and roles were identified. Also, check to see if your project plan identifies other resources and roles. In many cases, you may find that individuals belong to more

than one role. For example, the Azure administrator could also be your Azure network administrator. It's also possible that a role in your organization is split between multiple individuals. For example, the Synapse administrator doesn't get involved in Synapse SQL security. In this case, adjust your evaluation accordingly.

Evaluate the following points.

- Identify the roles that will be required by your solution implementation.
- Identify the specific individuals in your project that will fulfill each role.
- Identify the specific project tasks that will be performed by each individual.
- Assign a learning level to each individual for their tasks and roles.

Typically, a successful implementation requires that each individual has at least a level-300 proficiency for the tasks they'll perform. It's highly recommended that individuals at level-200 (or below) be provided with guidance and instruction to raise their level of understanding prior to beginning their project tasks. In this case, involve a level-300 (or above) individual to mentor and review. It's recommended that you adjust the project plan timeline and effort estimates to factor in learning new skills.

> **NOTE**
> We recommend you align your roles with the built-in roles. There are two sets of built-in roles: RBAC roles for Azure Synapse and RBAC roles built into Azure. These two sets of built-in roles and permissions are independent.

Azure administrator

The *Azure administrator* manages administrative aspects of Azure. They're responsible for subscriptions, region identification, resource groups, monitoring, and portal access. They also provision resources, like resource groups, storage accounts, Azure Data Factory (ADF), Microsoft Purview, and more.

Security administrator

The *security administrator* must have local knowledge of the existing security landscape and requirements. This role collaborates with the Synapse administrator, Synapse database administrator, Synapse Spark administrator, and other roles to set up security requirements. The security administrator could also be an Azure Active Directory (Azure AD) administrator.

Network administrator

The *network administrator* must have local knowledge of the existing networking landscape and requirements. This role requires Azure networking skills and Synapse networking skills.

Synapse administrator

The *Synapse administrator* is responsible for the administration of the overall Azure Synapse environment. This role is responsible for the availability and scale of workspace resources, data lake administration, analytics runtimes, and workspace administration and monitoring. This role works closely with all other roles to ensure access to Azure Synapse, the availability of analytics services, and sufficient scale. Other responsibilities include:

- Provision Synapse workspaces.
- Set up Azure Synapse networking and security requirements.
- Monitor Synapse workspace activity.

Synapse database administrator

The *Synapse database administrator* is responsible for the design, implementation, maintenance, and operational aspects of the SQL pools (serverless and dedicated). This role is responsible for the overall availability, consistent performance, and optimizations of the SQL pools. This role is also responsible for managing the security of the data in the databases, granting privileges over the data, and granting or denying user access. Other responsibilities include:

- Perform various dedicated SQL pool administration functions, like provisioning, scale, pauses, resumes, restores, workload management, monitoring, and others.
- Perform various dedicated SQL pool administration functions, like securing, monitoring, and others.
- Set up SQL pool database security.
- Performance tuning and troubleshooting.

Synapse Spark administrator

The *Synapse Spark administrator* is responsible for the design, implementation, maintenance, and operational aspects of the Spark pools. This role is responsible for the overall availability, consistent performance, and optimizations of the Spark pools. This role is also responsible for managing the security of the data, granting privileges over the data, and granting or denying user access. Other responsibilities include:

- Perform various dedicated Spark pool administration functions, like provisioning, monitoring, and others.
- Set up Spark pool data security.
- Notebook troubleshooting and performance.
- Pipeline Spark execution troubleshooting and performance.

Synapse SQL pool database developer

The *Synapse pool database developer* is responsible for database design and development. For dedicated SQL pools, responsibilities include table structure and indexing, developing database objects, and schema design. For serverless SQL pools, responsibilities include external tables, views, and schema design. Other responsibilities include:

- Logical and physical database design.
- Table design, including distribution, indexing, and partitioning.
- Programming object design and development, including stored procedures and functions.
- Design and development of other performance optimizations, including materialized views, workload management, and more.
- Design and implementation of data protection, including data encryption.
- Design and implementation of access control, including object-level security, row-level security, column-level security, dynamic data masking, and Synapse role-based access control.
- Monitoring, auditing, performance tuning and troubleshooting.

Spark developer

The *Spark developer* is responsible for creating notebooks and executing Spark processing by using Spark pools.

Data integration administrator

The *Data integration administrator* is responsible for setting up and securing data integration by using Synapse pipelines, ADF, or third-party integration tools, and for performing all configuration and security functions to support the data integration tools.

For Synapse pipelines and ADF, other responsibilities include setting up the integration runtime (IR), self-hosted integration runtime (SHIR), and/or SSIS integration runtime (SSIS-IR). Knowledge of virtual machine provisioning - on-premises or in Azure - may be required.

Data integration developer

The *Data integration developer* is responsible for developing ETL/ELT and other data integration processes by using the solution's selected data integration tools.

Data consumption tools administrator

The *Data consumption tools administrator* is responsible for the data consumption tools. Tools can include Microsoft Power BI, Microsoft Excel, Tableau, and others. The administrator of each tool will need to set up

permissions to grant access to data in Azure Synapse.

Data engineer

The *Data engineer* role is responsible for implementing data-related artifacts, including data ingestion pipelines, cleansing and transformation activities, and data stores for analytical workloads. It involves using a wide range of data platform technologies, including relational and non-relational databases, file stores, and data streams.

Data engineers are responsible for ensuring that the privacy of data is maintained within the cloud, and spanning from on-premises to the cloud data stores. They also own the management and monitoring of data stores and data pipelines to ensure that data loads perform as expected.

Data scientist

The *Data scientist* derives value and insights from data. Data scientists find innovative ways to work with data and help teams achieve a rapid return on investment (ROI) on analytics efforts. They work with data curation and advanced search, matching, and recommendation algorithms. Data scientists need access to the highest quality data and substantial amounts of computing resources to extract deep insights.

Data analyst

The *Data analyst* enables businesses to maximize the value of their data assets. They transform raw data into relevant insights based on identified business requirements. Data analysts are responsible for designing and building scalable data models, cleaning, and transforming data, and presenting advanced analytics in reports and visualizations.

Azure DevOps engineer

The *Azure DevOps engineer* is responsible for designing and implementing strategies for collaboration, code, infrastructure, source control, security, compliance, continuous integration, testing, delivery, and monitoring of an Azure Synapse project.

Learning resources and certifications

If you're interested to learn about Microsoft Certifications that may help assess your team's readiness, browse the available certifications for Azure Synapse Analytics.

To complete online, self-paced training, browse the available learning paths and modules for Azure Synapse Analytics.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to perform an operational readiness review to evaluate your solution for its preparedness to provide optimal services to users.

Synapse implementation success methodology: Perform operational readiness review

8/19/2022 • 5 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Once you build an Azure Synapse Analytics solution and it's ready to deploy, it's important to ensure the operational readiness of that solution. Performing an operational readiness review evaluates the solution for its preparedness to provide optimal services to users. Organizations that invest time and resources in assessing operational readiness before launch have a much higher rate of success. It's also important to conduct an operational readiness review periodically post deployment - perhaps annually - to ensure there isn't any drift from operational expectations.

Process and focus areas

Process and focus areas include service operational goals, solution readiness, security, monitoring, high availability (HA) and disaster recovery (DR).

Service operational goals

Document service expectations from the customer's point of view, and get buy-in from the business on these service expectations. Make any necessary modifications to meet business goals and objectives of the service.

The service level agreement (SLA) of each Azure service varies based on the service. For example, Microsoft guarantees a specific monthly uptime percentage. For more information, see SLA for Azure Synapse Analytics. Ensure these SLAs align with your own business SLAs and document any gaps. It's also important to define any operational level agreements (OLAs) between different teams and ensure that they align with the SLAs.

Solution readiness

It's important to review solution readiness by using the following points.

- Describe the entire solution architecture calling out critical functionalities of different components and how they interact with each other.
- Document scalability aspects of your solution. Include specific details about the effort involved in scaling and the impact of it on business. Consider whether it can respond to sudden surges of user activity. Bear in mind that Azure Synapse provides functionality for scaling with minimal downtime.
- Document any single points of failure in your solution, along with how to recover should such failures occur. Include the impact of such failures on dependent services in order to minimize the impact.
- Document all dependent services on the solution and their impact.

Security

Data security and privacy are non-negotiable. Azure Synapse implements a multi-layered security architecture for end-to-end protection of your data. Review security readiness by using the following points.

- **Authentication:** Ensure Azure Active Directory (Azure AD) authentication is used whenever possible. If non-Azure AD authentication is used, ensure strong password mechanisms are in place and that passwords are rotated on a regular basis. For more information, see Password Guidance. Ensure monitoring is in place to

detect suspicious actions related to user authentication. Consider using Azure Identity Protection to automate the detection and remediation of identity-based risks.

- **Access control:** Ensure proper access controls are in place following the principle of least privilege. Use security features available with Azure services to strengthen the security of your solution. For example, Azure Synapse provides granular security features, including row-level security (RLS), column-level security, and dynamic data masking. For more information, see Azure Synapse Analytics security white paper: Access control.
- **Threat protection:** Ensure proper threat detection mechanisms are place to prevent, detect, and respond to threats. Azure Synapse provides SQL Auditing, SQL Threat Detection, and Vulnerability Assessment to audit, protect, and monitor databases. For more information, see Azure Synapse Analytics security white paper: Threat detection.

For more information, see the Azure Synapse Analytics security white paper.

Monitoring

Set and document expectations for monitoring readiness with your business. These expectations should describe:

- How to monitor the entire user experience, and whether it includes monitoring of a single-user experience.
- The specific metrics of each service to monitor.
- How and who to notify about poor user experience.
- Details of proactive health checks.
- Any mechanisms that are in place that automate actions in response to incidents, for example, raising tickets automatically.

Consider using Azure Monitor to collect, analyze, and act on telemetry data from your Azure and on-premises environments. Azure Monitor helps you maximize performance and availability of your applications by proactively identify problems in seconds.

List all the important metrics to monitor for each service in your solution along with their acceptable thresholds. For example, the following list includes important metrics to monitor for a dedicated SQL pool:

- `DWULimit`
- `DWUUsed`
- `AdaptiveCacheHitPercent`
- `AdaptiveCacheUsedPercent`
- `LocalTempDBUsedPercent`
- `ActiveQueries`
- `QueuedQueries`

Consider using Azure Service Health to notify you about Azure service incidents and planned maintenance. That way, you can take action to mitigate downtime. You can set up customizable cloud alerts and use a personalized dashboard to analyze health issues, monitor the impact to your cloud resources, get guidance and support, and share details and updates.

Lastly, ensure proper notifications are set up to notify appropriate people when incidents occur. Incidents could be proactive, such as when a certain metric exceeds a threshold, or reactive, such as a failure of a component or service. For more information, see Overview of alerts in Microsoft Azure.

High availability

Define and document *recovery time objective (RTO)* and *recovery point objective (RPO)* for your solution. RTO is how soon the service will be available to users, and RPO is how much data loss would occur in the event of a failover.

Each of the Azure services publishes a set of guidelines and metrics on the expected high availability (HA) of the service. Ensure these HA metrics align with your business expectations. when they don't align, customizations may be necessary to meet your HA requirements. For example, Azure Synapse dedicated SQL pool supports an eight-hour RPO with automatic restore points. If that RPO isn't sufficient, you can set up user-defined restore points with an appropriate frequency to meet your RPO needs. For more information, see Backup and restore in Azure Synapse dedicated SQL pool.

Disaster recovery

Define and document a detailed process for disaster recovery (DR) scenarios. DR scenarios can include a failover process, communication mechanisms, escalation process, war room setup, and others. Also document the process for identifying the causes of outages and the steps to take to recover from disasters.

Use the built-in DR mechanisms available with Azure services for building your DR process. For example, Azure Synapse performs a standard geo-backup of SQL dedicated pools once every day to a paired data center. You can use a geo-backup to recover from a disaster at the primary location. You can also set up Azure Data Lake Storage (ADLS) to copy data to another Azure region that's hundreds of miles apart. If there's a disaster at the primary location, a failover can be initiated to transform the secondary storage location into the primary storage location. For more information, see Disaster recovery and storage account failover.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to perform monitoring of your Azure Synapse solution.

Synapse implementation success methodology: Perform user readiness and onboarding plan review

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Training technical people, like administrators and developers, is important to deliver success. Don't overlook that you must also extend training to include end users. Review the use cases and roles identified during the assessment stage, project planning, and solution development to ensure that *everyone* is readied for success.

Evaluate your project plan and prepare an onboarding plan for each group of users, including:

- Big data analytics users.
- Structured data analytics users.
- Users of each of your identified data consumption tools.
- Operations support.
- Help desk and user support.

Onboarding and readiness

It's unrealistic to expect that users figure out how to use Azure Synapse, even when they have experience with similar technologies. So, plan to reach out to your users to ensure a smooth transition for them to the new environment. Specifically, ensure that:

- Users understand what Azure Synapse does and how it does it.
- Users understand how to use the Azure Synapse service or the platform that uses it.
- Onboarding of users is a consistent and continuous process.
- Users see and understand the value of the new environment.

The onboarding of users starts with explanatory sessions or technical workshops. It also involves giving them access to the platform. The onboarding process can span several months depending on the complexity of the solution, and it should set the right tone for future interactions with the Azure Synapse platform and services.

Take tracking steps and make sure users are capable of completing a set of core tasks that will form part of their daily operations. These tasks will be specific to different groups of user groups, roles, and use cases. Be sure to identify:

- The core actions users need to be able to perform.
- The steps users must take to perform each action.

Focus your efforts on the tasks that users struggle the most with. Be sure to provide straightforward instructions and processes, yet be mindful of how long it takes for users to complete specific tasks. It's always a good idea to request qualitative feedback to better track user readiness and improve the onboarding experience.

Next steps

In the next article in the *Azure Synapse success by design* series, learn how to monitor your Azure Synapse solution.

Synapse implementation success methodology: Perform monitoring review

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse implementation success by design* series of articles. For an overview of the series, see Azure Synapse implementation success by design.

Monitoring is a key part of the operationalization of any Azure solution. This article provides guidance on reviewing and configuring the monitoring of your Azure Synapse Analytics environment. Key to this activity is the identification of what needs to be monitored and who needs to review the monitoring results.

Using your solution requirements and other data collected during the assessment stage and solution development, build a list of important behaviors and activities that need to be monitored in your production environment. As you build this list, identify the groups of users that will need access to monitoring information and build the procedures they can follow to respond to monitoring results.

You can use Azure Monitor to provide base-level infrastructure metrics, alerts, and logs for most Azure services. Azure diagnostic logs are emitted by a resource to provide rich, frequent data about the operation of that resource. Azure Synapse can write diagnostic logs in Azure Monitor.

For more information, see Use Azure Monitor with your Azure Synapse Analytics workspace.

Monitor dedicated SQL pools

You can monitor a dedicated SQL pool by using Azure Monitor, altering, dynamic management views (DMVs), and Log Analytics.

- **Alerts:** You can set up alerts that send you an email or call a webhook when a certain metric reaches a predefined threshold. For example, you can receive an alert email when the database size grows too large. For more information, see Create alerts for Azure SQL Database and Azure Synapse Analytics using the Azure portal.
- **DMVs:** You can use DMVs to monitor workloads to help investigate query executions in SQL pools.
- **Log Analytics:** Log Analytics is a tool in the Azure portal that you can use to edit and run log queries from data collected by Azure Monitor. For more information, see Monitor workload - Azure portal.

Monitor serverless SQL pools

You can monitor a serverless SQL pool by monitoring your SQL requests in Synapse Studio. That way, you can keep an eye on the status of running requests and review details of historical requests.

Monitor Spark pools

You can monitor your Apache Spark applications in Synapse Studio. That way, you can keep an eye on the latest status, issues, and progress.

You can enable the Synapse Studio connector that's built in to Log Analytics. You can then collect and send Apache Spark application metrics and logs to your Log Analytics workspace. You can also use an Azure Monitor workbook to visualize the metrics and logs. For more information, see Monitor Apache Spark applications with

Azure Log Analytics.

Monitor pipelines

Azure Synapse allows you to create complex pipelines that automate and integrate your data movement, data transformation, and compute activities. You can author and monitor pipelines by using Synapse Studio to keep an eye on the latest status, issues, and progress of your pipelines. For more information, see Use Synapse Studio to monitor your workspace pipeline runs.

Migrate a data warehouse to a dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 3 minutes to read • Edit Online

The following sections provide an overview of what's involved with migrating an existing data warehouse solution to an Azure Synapse Analytics dedicated SQL pool.

Overview

Before you begin your migration, you should verify that Azure Synapse Analytics is the best solution for your workload. Azure Synapse Analytics is a distributed system designed to perform analytics on large data. Migrating to Azure Synapse Analytics requires some design changes that aren't difficult to understand but that might take some time to implement. If your business requires an enterprise-class data warehouse, the benefits are worth the effort. However, if you don't need the power of Azure Synapse Analytics, it's more cost-effective to use SQL Server or Azure SQL Database.

Consider using Azure Synapse Analytics when you:

- Have one or more terabytes of data.
- Plan to run analytics on substantial amounts of data.
- Need the ability to scale compute and storage.
- Want to save on costs by pausing compute resources when you don't need them.

Rather than Azure Synapse Analytics, consider other options for operational online transaction processing (OLTP) workloads that have:

- High frequency reads and writes.
- Large numbers of singleton selects.
- High volumes of single row inserts.
- Row-by-row processing needs.
- Incompatible formats (for example, JSON and XML).

Pre-migration

After you decide to migrate an existing solution to Azure Synapse Analytics, you need to plan your migration before you get started. A primary goal of planning is to ensure that your data, table schemas, and code are compatible with Azure Synapse Analytics. There are some compatibility differences between your current system and Azure Synapse Analytics that you'll need to work around. In addition, migrating large amounts of data to Azure takes time. Careful planning will speed up the process of getting your data to Azure.

Another key goal of planning is to adjust your design to ensure that your solution takes full advantage of the high query performance that Azure Synapse Analytics is designed to provide. Designing data warehouses for scale introduces unique design patterns, so traditional approaches aren't always the best. While some design adjustments can be made after migration, making changes earlier in the process will save you time later.

Migrate

Performing a successful migration requires you to migrate your table schemas, code, and data. For more detailed guidance on these topics, see the following articles:

- Consider table design
- Consider code change
- Migrate your data
- Consider workload management

Design and performance for Teradata migrations

8/19/2022 • 19 minutes to read • Edit Online

This article is part one of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for design and performance.

Overview

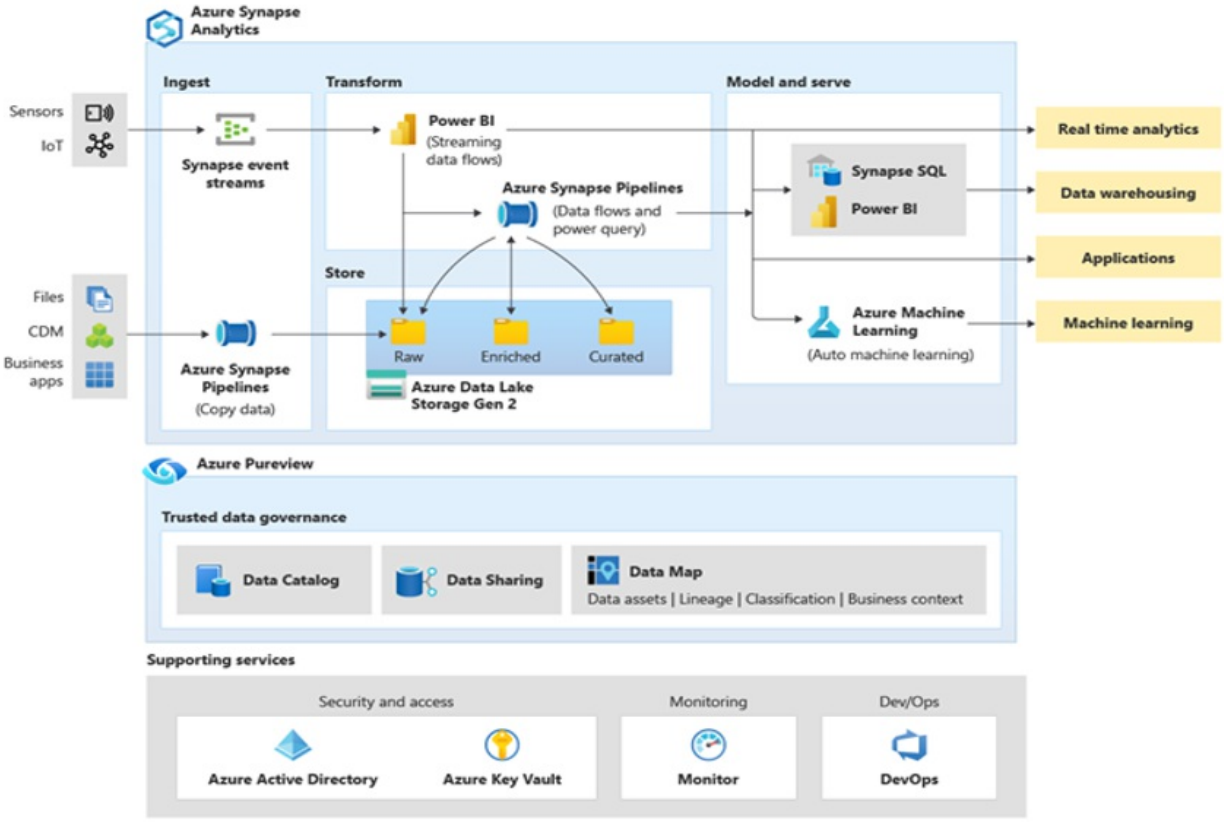
Many existing users of Teradata data warehouse systems want to take advantage of the innovations provided by modern cloud environments. Infrastructure-as-a-service (IaaS) and platform-as-a-service (PaaS) cloud environments let you delegate tasks like infrastructure maintenance and platform development to the cloud provider.

> **TIP**
> More than just a database—the Azure environment includes a comprehensive set of capabilities and tools.

Although Teradata and Azure Synapse Analytics are both SQL databases that use massively parallel processing (MPP) techniques to achieve high query performance on exceptionally large data volumes, there are some basic differences in approach:

- Legacy Teradata systems are often installed on-premises and use proprietary hardware, while Azure Synapse is cloud-based and uses Azure Storage and compute resources.
- Because storage and compute resources are separate in the Azure environment and have elastic scaling capability, those resources can be scaled upwards or downwards independently.
- You can pause or resize Azure Synapse as needed to reduce resource utilization and cost.
- Upgrading a Teradata configuration is a major task involving extra physical hardware and potentially lengthy database reconfiguration or reload.

Microsoft Azure is a globally available, highly secure, scalable cloud environment that includes Azure Synapse and an ecosystem of supporting tools and capabilities. The next diagram summarizes the Azure Synapse ecosystem.



Azure Synapse provides best-of-breed relational database performance by using techniques such as MPP and multiple levels of automated caching for frequently used data. You can see the results of these techniques in independent benchmarks such as the one run recently by GigaOm, which compares Azure Synapse to other popular cloud data warehouse offerings. Customers who migrate to the Azure Synapse environment see many benefits, including:

- Improved performance and price/performance.
- Increased agility and shorter time to value.
- Faster server deployment and application development.
- Elastic scalability—only pay for actual usage.
- Improved security/compliance.
- Reduced storage and disaster recovery costs.
- Lower overall TCO, better cost control, and streamlined operational expenditure (OPEX).

To maximize these benefits, migrate new or existing data and applications to the Azure Synapse platform. In many organizations, migration includes moving an existing data warehouse from a legacy on-premises platform, such as Teradata, to Azure Synapse. At a high level, the migration process includes these steps:

Preparation

- Define scope—what is to be migrated.
- Build inventory of data and processes for migration.
- Define data model changes (if any).
- Define source data extract mechanism.
- Identify the appropriate Azure and third-party tools and features to be used.
- Train staff early on the new platform.

- Set up the Azure target platform.

Migration □

- Start small and simple.
- Automate wherever possible.
- Leverage Azure built-in tools and features to reduce migration effort.
- Migrate metadata for tables and views.
- Migrate historical data to be maintained.
- Migrate or refactor stored procedures and business processes.
- Migrate or refactor ETL/ELT incremental load processes.

Post migration

- Monitor and document all stages of the process.
- Use the experience gained to build a template for future migrations.
- Re-engineer the data model if required (using new platform performance and scalability).
- Test applications and query tools.
- Benchmark and optimize query performance.

This article provides general information and guidelines for performance optimization when migrating a data warehouse from an existing Netezza environment to Azure Synapse. The goal of performance optimization is to achieve the same or better data warehouse performance in Azure Synapse after schema migration.

Design considerations

Migration scope

When you're preparing to migrate from a Teradata environment, consider the following migration choices.

Choose the workload for the initial migration

Typically, legacy Teradata environments have evolved over time to encompass multiple subject areas and mixed workloads. When you're deciding where to start on a migration project, choose an area where you'll be able to:

- Prove the viability of migrating to Azure Synapse by quickly delivering the benefits of the new environment.
- Allow your in-house technical staff to gain relevant experience with the processes and tools that they'll use when they migrate other areas.
- Create a template for further migrations that's specific to the source Teradata environment and the current tools and processes that are already in place.

A good candidate for an initial migration from a Teradata environment supports the preceding items, and:

- Implements a BI/Analytics workload rather than an online transaction processing (OLTP) workload.
- Has a data model, such as a star or snowflake schema, that can be migrated with minimal modification.

> **TIP**
> Create an inventory of objects that need to be migrated, and document the migration process.

The volume of migrated data in an initial migration should be large enough to demonstrate the capabilities and benefits of the Azure Synapse environment but not too large to quickly demonstrate value. A size in the 1-10 terabyte range is typical.

For your initial migration project, minimize the risk, effort, and migration time so you can quickly see the benefits of the Azure cloud environment, confine the scope of the migration to just the data marts, such as the OLAP DB part of a Teradata warehouse. Both the lift-and-shift and phased migration approaches limit the scope of the initial migration to just the data marts and don't address broader migration aspects, such as ETL migration and historical data migration. However, you can address those aspects in later phases of the project once the migrated data mart layer is backfilled with data and the required build processes.

Lift and shift migration vs. Phased approach

In general, there are two types of migration regardless of the purpose and scope of the planned migration: lift and shift as-is and a phased approach that incorporates changes.

Lift and shift

In a lift and shift migration, an existing data model, like a star schema, is migrated unchanged to the new Azure Synapse platform. This approach minimizes risk and migration time by reducing the work needed to realize the benefits of moving to the Azure cloud environment. Lift and shift migration is a good fit for these scenarios:

- You have an existing Teradata environment with a single data mart to migrate, or
- You have an existing Teradata environment with data that's already in a well-designed star or snowflake schema, or
- You're under time and cost pressures to move to a modern cloud environment.

> **TIP**
> Lift and shift is a good starting point, even if subsequent phases implement changes to the data model.

Phased approach that incorporates changes

If a legacy data warehouse has evolved over a long period of time, you might need to re-engineer it to maintain the required performance levels. You might also have to re-engineer to support new data like Internet of Things (IoT) streams. As part of the re-engineering process, migrate to Azure Synapse to get the benefits of a scalable cloud environment. Migration can also include a change in the underlying data model, such as a move from an Inmon model to a data vault.

Microsoft recommends moving your existing data model as-is to Azure (optionally using a VM Teradata instance in Azure) and using the performance and flexibility of the Azure environment to apply the re-engineering changes. That way, you can use Azure's capabilities to make the changes without impacting the existing source system.

Use an Azure VM Teradata instance as part of a migration

When migrating from an on-premises Teradata environment, you can leverage cloud storage and elastic scalability in Azure to create a Teradata instance within a VM. This approach collocates the Teradata instance with the target Azure Synapse environment. You can use standard Teradata utilities, such as Teradata Parallel Data Transporter, to efficiently move the subset of Teradata tables being migrated onto the VM instance. Then, all further migration tasks can occur within the Azure environment. This approach has several benefits:

- After the initial replication of data, the source system isn't affected by the migration tasks.
- Familiar Teradata interfaces, tools, and utilities are available within the Azure environment.
- The Azure environment sidesteps any potential issues with network bandwidth availability between the on-premises source system and the cloud target system.
- Tools like Azure Data Factory can call utilities like Teradata Parallel Transporter to efficiently and rapidly

migrate data.

- You can orchestrate and control the migration process entirely within the Azure environment.

> **TIP**
> Use Azure VMs to create a temporary Teradata instance to speed up migration and minimize impact on the source system.

Use Azure Data Factory to implement a metadata-driven migration

You can automate and orchestrate the migration process by using the capabilities of the Azure environment. This approach minimizes the performance hit on the existing Netezza environment, which may already be running close to capacity.

Azure Data Factory is a cloud-based data integration service that supports creating data-driven workflows in the cloud that orchestrate and automate data movement and data transformation. You can use Data Factory to create and schedule data-driven workflows (pipelines) that ingest data from disparate data stores. Data Factory can process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

When you're planning to use Data Factory facilities to manage the migration process, create metadata that lists all the data tables to be migrated and their location.

Design differences between Teradata and Azure Synapse

As mentioned earlier, there are some basic differences in approach between Teradata and Azure Synapse Analytics databases and these differences are discussed next.

Multiple databases vs. a single database and schemas

The Netezza environment often contains multiple separate databases. For instance, there could be separate databases for: data ingestion and staging tables, core warehouse tables, and data marts (sometimes referred to as the semantic layer). ETL or ELT pipeline processes might implement cross-database joins and move data between the separate databases.

In contrast, the Azure Synapse environment contains a single database and uses schemas to separate tables into logically separate groups. We recommend that you use a series of schemas within the target Azure Synapse database to mimic the separate databases migrated from the Teradata environment. If the Teradata environment already uses schemas, you may need to use a new naming convention when you move the existing Teradata tables and views to the new environment. For example, you could concatenate the existing Teradata schema and table names into the new Azure Synapse table name, and use schema names in the new environment to maintain the original separate database names. If schema consolidation naming has dots, Azure Synapse Spark might have issues. Although you can use SQL views on top of the underlying tables to maintain the logical structures, there are potential downsides to that approach:

- Views in Azure Synapse are read-only, so any updates to the data must take place on the underlying base tables.
- There may already be one or more layers of views in existence and adding an extra layer of views could affect performance and supportability because nested views are difficult to troubleshoot.

> **TIP**
> Combine multiple databases into a single database within Azure Synapse and use schema names to logically separate the tables.

Table considerations

When you migrate tables between different environments, typically only the raw data and the metadata that describes it physically migrate. Other database elements from the source system, such as indexes, usually aren't migrated because they might be unnecessary or implemented differently in the new environment. Performance optimizations in the source environment, such as indexes, indicate where you might add performance optimization in the new environment. For example, if a table within the source Teradata environment has a non-unique secondary index (NUSI), that suggests that a non-clustered index should be created within Azure Synapse. Other native performance optimization techniques like table replication may be more applicable than straight like-for-like index creation.

> **TIP**
> Existing indexes indicate candidates for indexing in the migrated warehouse.

High availability for the database

Teradata supports data replication across nodes via the `FALLBACK` option, which replicates table rows that reside physically on a given node to another node within the system. This approach guarantees that data won't be lost if there's a node failure and provides the basis for failover scenarios.

The goal of the high availability architecture in Azure Synapse Analytics is to guarantee that your database is up and running 99.9% of the time, without worrying about the impact of maintenance operations and outages. For more information on the SLA, see SLA for Azure Synapse Analytics. Azure automatically handles critical servicing tasks such as patching, backups, and Windows and SQL upgrades. Azure also automatically handles unplanned events such as failures in the underlying hardware, software, or network.

Data storage in Azure Synapse is automatically backed up with snapshots. These snapshots are a built-in feature of the service that creates restore points. You don't have to enable this capability. Users can't currently delete automatic restore points that the service uses to maintain service level agreements (SLAs) for recovery.

Azure Synapse Dedicated SQL pool takes snapshots of the data warehouse throughout the day to create restore points that are available for seven days. This retention period can't be changed. Azure Synapse supports an eight-hour recovery point objective (RPO). You can restore your data warehouse in the primary region from any one of the snapshots taken in the past seven days. If you require more granular backups, you can use another user-defined option.

Unsupported Teradata table types

Teradata supports special table types for time-series and temporal data. The syntax and some of the functions for these table types aren't directly supported in Azure Synapse. However, you can migrate the data into a standard table in Azure Synapse by mapping to appropriate data types and indexing or partitioning the date/time column.

> **TIP**
> Standard tables in Azure Synapse can support migrated Teradata time-series and temporal data.

Teradata implements temporal query functionality by using query rewriting to add additional filters within a temporal query to limit the applicable date range. If you plan to migrate this functionality from the source Teradata environment, then add the additional filtering into the relevant temporal queries.

The Azure environment supports time series insights for complex analytics on time-series data at scale. This functionality is aimed at IoT data analysis applications.

SQL DML syntax differences

SQL Data Manipulation Language (DML) syntax differences exist between Teradata SQL and Azure Synapse T-SQL:

- `QUALIFY`: Teradata supports the `QUALIFY` operator. For example:

  ```
  SELECT col1
  FROM tab1
  WHERE col1='XYZ'
  QUALIFY ROW_NUMBER () OVER (PARTITION by
  col1 ORDER BY col1) = 1;
  ```

  The equivalent Azure Synapse syntax is:

  ```
  SELECT * FROM (
  SELECT col1, ROW_NUMBER () OVER (PARTITION by col1 ORDER BY col1) rn
  FROM tab1 WHERE col1='XYZ'
  ) WHERE rn = 1;
  ```

- Date arithmetic: Azure Synapse has operators such as `DATEADD` and `DATEDIFF`, which can be used on `DATE` or `DATETIME` fields. Teradata supports direct subtraction on dates such as `SELECT DATE1 - DATE2 FROM...`

- `GROUP BY`: for the `GROUP BY` ordinal, explicitly provide a T-SQL column name.

- `LIKE ANY`: Teradata supports `LIKE ANY` syntax such as:

  ```
  SELECT * FROM CUSTOMER
  WHERE POSTCODE LIKE ANY
  ('CV1%', 'CV2%', 'CV3%');
  ```

  The equivalent in Azure Synapse syntax is:

  ```
  SELECT * FROM CUSTOMER
  WHERE
  (POSTCODE LIKE 'CV1%') OR (POSTCODE LIKE 'CV2%') OR (POSTCODE LIKE 'CV3%');
  ```

- Depending on system settings, character comparisons in Teradata may be case insensitive by default. In Azure Synapse, character comparisons are always case sensitive.

Functions, stored procedures, triggers, and sequences

When migrating a data warehouse from a mature environment like Teradata, you probably need to migrate elements other than simple tables and views. Examples include functions, stored procedures, triggers, and sequences. Check whether tools within the Azure environment can replace the functionality of functions, stored procedures, and sequences because it's usually more efficient to use built-in Azure tools than to recode those elements for Azure Synapse.

As part of your preparation phase, create an inventory of objects that need to be migrated, define a method for handling them, and allocate appropriate resources in your migration plan.

Data integration partners offer tools and services that can automate the migration of functions, stored procedures, and sequences.

The following sections further discuss the migration of functions, stored procedures, and sequences.

Functions

As with most database products, Teradata supports system and user-defined functions within a SQL implementation. When you migrate a legacy database platform to Azure Synapse, common system functions can usually be migrated without change. Some system functions might have a slightly different syntax, but any required changes can be automated.

For Teradata system functions or arbitrary user-defined functions that have no equivalent in Azure Synapse, recode those functions using a target environment language. Azure Synapse uses the Transact-SQL language to implement user-defined functions.

Stored procedures

Most modern database products support storing procedures within the database. Teradata provides the SPL language for this purpose. A stored procedure typically contains both SQL statements and procedural logic, and returns data or a status.

Azure Synapse supports stored procedures using T-SQL, so you need to recode any migrated stored procedures in that language.

Triggers

Azure Synapse doesn't support trigger creation, but trigger creation can be implemented using Azure Data Factory.

Sequences

Azure Synapse handles sequences in a similar way to Teradata, and you can implement sequences using IDENTITY columns or SQL code that generates the next sequence number in a series. A sequence provides unique numeric values that you can use as surrogate key values for primary keys.

Extract metadata and data from a Teradata environment

Data Definition Language (DDL) generation

The ANSI SQL standard defines the basic syntax for Data Definition Language (DDL) commands. Some DDL commands, such as `CREATE TABLE` and `CREATE VIEW`, are common to both Teradata and Azure Synapse but also provide implementation-specific features such as indexing, table distribution, and partitioning options.

You can edit existing Teradata `CREATE TABLE` and `CREATE VIEW` scripts to achieve equivalent definitions in Azure Synapse. To do so, you might need to use modified data types and remove or modify Teradata-specific clauses such as `FALLBACK`.

However, all the information that specifies the current definitions of tables and views within the existing Teradata environment is maintained within system catalog tables. These tables are the best source of this information, as it's guaranteed to be up to date and complete. User-maintained documentation may not be in sync with the current table definitions.

Within the Teradata environment, system catalog tables specify the current table and view definition. Unlike user-maintained documentation, system catalog information is always complete and in sync with current table definitions. By using views into the catalog such as `DBC.ColumnsV`, you can access system catalog information to generate `CREATE TABLE` DDL statements that create equivalent tables in Azure Synapse.

> **TIP**
> Use existing Teradata metadata to automate the generation of `CREATE TABLE` and `CREATE VIEW` DDL for Azure Synapse.

You can also use third-party migration and ETL tools that process system catalog information to achieve similar results.

Data extraction from Teradata

You can extract raw table data from Teradata tables to flat delimited files, such as CSV files, using standard Teradata utilities like Basic Teradata Query (BTEQ), Teradata FastExport, or Teradata Parallel Transporter (TPT). Use TPT to extract table data as efficiently as possible. TPT uses multiple parallel FastExport streams to achieve the highest throughput.

> **TIP**
> Use Teradata Parallel Transporter for the most efficient data extract.

Call TPT directly from Azure Data Factory. This is the recommended approach for data migration of Teradata on-premises instances and Teradata instances that run within a VM in the Azure environment.

Extracted data files should contain delimited text in CSV, Optimized Row Columnar (ORC), or Parquet format.

For more information about migrating data and ETL from a Teradata environment, see Data migration, ETL, and load for Teradata migrations.

Performance recommendations for Teradata migrations

The goal of performance optimization is same or better data warehouse performance after migration to Azure Synapse.

> **TIP**
> Prioritize familiarity with the tuning options in Azure Synapse at the start of a migration.

Differences in performance tuning approach

This section highlights low-level performance tuning implementation differences between Teradata and Azure Synapse.

Data distribution options

For performance, Azure Synapse was designed with multi-node architecture and uses parallel processing. To optimize individual table performance in Azure Synapse, you can define a data distribution option in `CREATE TABLE` statements using the `DISTRIBUTION` statement. For example, you can specify a hash-distributed table, which distributes table rows across compute nodes by using a deterministic hash function. The aim is to reduce the amount of data moved between processing nodes when executing a query.

For large table to large table joins, hash distribute one or, ideally, both tables on one of the join columns—which has a wide range of values to help ensure an even distribution. Perform join processing locally because the data rows that will be joined are collocated on the same processing node.

Azure Synapse also supports local joins between a small table and a large table through small table replication. For instance, consider a small dimension table and a large fact table within a star schema model. Azure Synapse can replicate the smaller dimension table across all nodes to ensure that the value of any join key for the large table has a matching, locally available dimension row. The overhead of dimension table replication is relatively low for a small dimension table. For large dimension tables, a hash distribution approach is more appropriate. For more information on data distribution options, see Design guidance for using replicated tables and Guidance for designing distributed tables.

Data indexing

Azure Synapse supports several user-definable indexing options that are different from the indexing options implemented in Teradata. For more information about the different indexing options in Azure Synapse, see Indexes on dedicated SQL pool tables.

Existing indexes within the source Teradata environment provide a useful indication of data usage and the candidate columns for indexing in the Azure Synapse environment.

Data partitioning

In an enterprise data warehouse, fact tables can contain billions of rows. Partitioning optimizes the maintenance and query performance of these tables by splitting them into separate parts to reduce the amount of data

processed. In Azure Synapse, the `CREATE TABLE` statement defines the partitioning specification for a table. Only partition very large tables and ensure each partition contains at least 60 million rows.

You can only use one field per table for partitioning. That field is often a date field because many queries are filtered by date or date range. It's possible to change the partitioning of a table after initial load by using the `CREATE TABLE AS` (CTAS) statement to recreate the table with a new distribution. For a detailed discussion of partitioning in Azure Synapse, see Partitioning tables in dedicated SQL pool.

Data table statistics

You should ensure that statistics on data tables are up to date by building in a statistics step to ETL/ELT jobs.

PolyBase or COPY INTO for data loading

PolyBase supports efficient loading of large amounts of data to a data warehouse by using parallel loading streams. For more information, see PolyBase data loading strategy.

COPY INTO also supports high-throughput data ingestion, and:

- Data retrieval from all files within a folder and subfolders.
- Data retrieval from multiple locations in the same storage account. You can specify multiple locations by using comma separated paths.
- Azure Data Lake Storage (ADLS) and Azure Blob Storage.
- CSV, PARQUET, and ORC file formats.

Workload management

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). Workload classification, workload importance, and workload isolation give more control over how workload utilizes system resources.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance, and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized.

Next steps

To learn about ETL and load for Teradata migration, see the next article in this series: Data migration, ETL, and load for Teradata migrations.

Data migration, ETL, and load for Teradata migrations

8/19/2022 • 15 minutes to read • Edit Online

This article is part two of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for ETL and load migration.

Data migration considerations

Initial decisions for data migration from Teradata

When migrating a Teradata data warehouse, you need to ask some basic data-related questions. For example:

- Should unused table structures be migrated?
- What's the best migration approach to minimize risk and user impact?
- When migrating data marts: stay physical or go virtual?

The next sections discuss these points within the context of migration from Teradata.

Migrate unused tables?

> **TIP**
> In legacy systems, it's not unusual for tables to become redundant over time—these don't need to be migrated in most cases.

It makes sense to only migrate tables that are in use in the existing system. Tables that aren't active can be archived rather than migrated, so that the data is available if necessary in future. It's best to use system metadata and log files rather than documentation to determine which tables are in use, because documentation can be out of date.

If enabled, Teradata system catalog tables and logs contain information that can determine when a given table was last accessed—which can in turn be used to decide whether a table is a candidate for migration.

Here's an example query on `DBC.Tables` that provides the date of last access and last modification:

```
SELECT TableName, CreatorName, CreateTimeStamp, LastAlterName,
LastAlterTimeStamp, AccessCount, LastAccessTimeStamp
FROM DBC.Tables t
WHERE DataBaseName = 'databasename'
```

If logging is enabled and the log history is accessible, other information, such as SQL query text, is available in table DBQLogTbl and associated logging tables. For more information, see Teradata log history.

What is the best migration approach to minimize risk and impact on users?

This question comes up frequently because companies may want to lower the impact of changes on the data warehouse data model to improve agility. Companies often see an opportunity to further modernize or transform their data during an ETL migration. This approach carries a higher risk because it changes multiple factors simultaneously, making it difficult to compare the outcomes of the old system versus the new. Making data model changes here could also affect upstream or downstream ETL jobs to other systems. Because of that risk, it's better to redesign on this scale after the data warehouse migration.

Even if a data model is intentionally changed as part of the overall migration, it's good practice to migrate the existing model as-is to Azure Synapse, rather than do any re-engineering on the new platform. This approach minimizes the effect on existing production systems, while benefiting from the performance and elastic scalability of the Azure platform for one-off re-engineering tasks.

When migrating from Teradata, consider creating a Teradata environment in a VM within Azure as a stepping-stone in the migration process.

> **TIP**
> Migrate the existing model as-is initially, even if a change to the data model is planned in the future.

Use a VM Teradata instance as part of a migration

One optional approach for migrating from an on-premises Teradata environment is to leverage the Azure environment to create a Teradata instance in a VM within Azure, collocated with the target Azure Synapse environment. This is possible because Azure provides cheap cloud storage and elastic scalability.

With this approach, standard Teradata utilities, such as Teradata Parallel Data Transporter—or third-party data replication tools, such as Attunity Replicate—can be used to efficiently move the subset of Teradata tables that need to be migrated to the VM instance. Then, all migration tasks can take place within the Azure environment. This approach has several benefits:

- After the initial replication of data, migration tasks don't impact the source system.
- The Azure environment has familiar Teradata interfaces, tools, and utilities.
- The Azure environment provides network bandwidth availability between the on-premises source system and the cloud target system.
- Tools like Azure Data Factory can efficiently call utilities like Teradata Parallel Transporter to migrate data quickly and easily.
- The migration process is orchestrated and controlled entirely within the Azure environment.

When migrating data marts: stay physical or go virtual?

> **TIP**
> Virtualizing data marts can save on storage and processing resources.

In legacy Teradata data warehouse environments, it's common practice to create several data marts that are structured to provide good performance for ad hoc self-service queries and reports for a given department or business function within an organization. As such, a data mart typically consists of a subset of the data warehouse and contains aggregated versions of the data in a form that enables users to easily query that data with fast response times via user-friendly query tools such as Microsoft Power BI, Tableau, or MicroStrategy. This form is typically a dimensional data model. One use of data marts is to expose the data in a usable form, even if the underlying warehouse data model is something different, such as a data vault.

You can use separate data marts for individual business units within an organization to implement robust data security regimes, by only allowing users to access specific data marts that are relevant to them, and eliminating, obfuscating, or anonymizing sensitive data.

If these data marts are implemented as physical tables, they'll require additional storage resources to store them, and additional processing to build and refresh them regularly. Also, the data in the mart will only be as up to date as the last refresh operation, and so may be unsuitable for highly volatile data dashboards.

> **TIP**
> The performance and scalability of Azure Synapse enables virtualization without sacrificing performance.

With the advent of relatively low-cost scalable MPP architectures, such as Azure Synapse, and the inherent performance characteristics of such architectures, it may be that you can provide data mart functionality without having to instantiate the mart as a set of physical tables. This is achieved by effectively virtualizing the data marts via SQL views onto the main data warehouse, or via a virtualization layer using features such as views in Azure or the visualization products of Microsoft partners. This approach simplifies or eliminates the need for additional storage and aggregation processing and reduces the overall number of database objects to be migrated.

There's another potential benefit to this approach. By implementing the aggregation and join logic within a virtualization layer, and presenting external reporting tools via a virtualized view, the processing required to create these views is "pushed down" into the data warehouse, which is generally the best place to run joins, aggregations, and other related operations on large data volumes.

The primary drivers for choosing a virtual data mart implementation over a physical data mart are:

- More agility: a virtual data mart is easier to change than physical tables and the associated ETL processes.
- Lower total cost of ownership: a virtualized implementation requires fewer data stores and copies of data.
- Elimination of ETL jobs to migrate and simplify data warehouse architecture in a virtualized environment.
- Performance: although physical data marts have historically been more performant, virtualization products now implement intelligent caching techniques to mitigate.

Data migration from Teradata

Understand your data

Part of migration planning is understanding in detail the volume of data that needs to be migrated since that can impact decisions about the migration approach. Use system metadata to determine the physical space taken up by the "raw data" within the tables to be migrated. In this context, "raw data" means the amount of space used by the data rows within a table, excluding overheads such as indexes and compression. This is especially true for the largest fact tables since these will typically comprise more than 95% of the data.

You can get an accurate number for the volume of data to be migrated for a given table by extracting a representative sample of the data—for example, one million rows—to an uncompressed delimited flat ASCII data file. Then, use the size of that file to get an average raw data size per row of that table. Finally, multiply that average size by the total number of rows in the full table to give a raw data size for the table. Use that raw data size in your planning.

ETL migration considerations

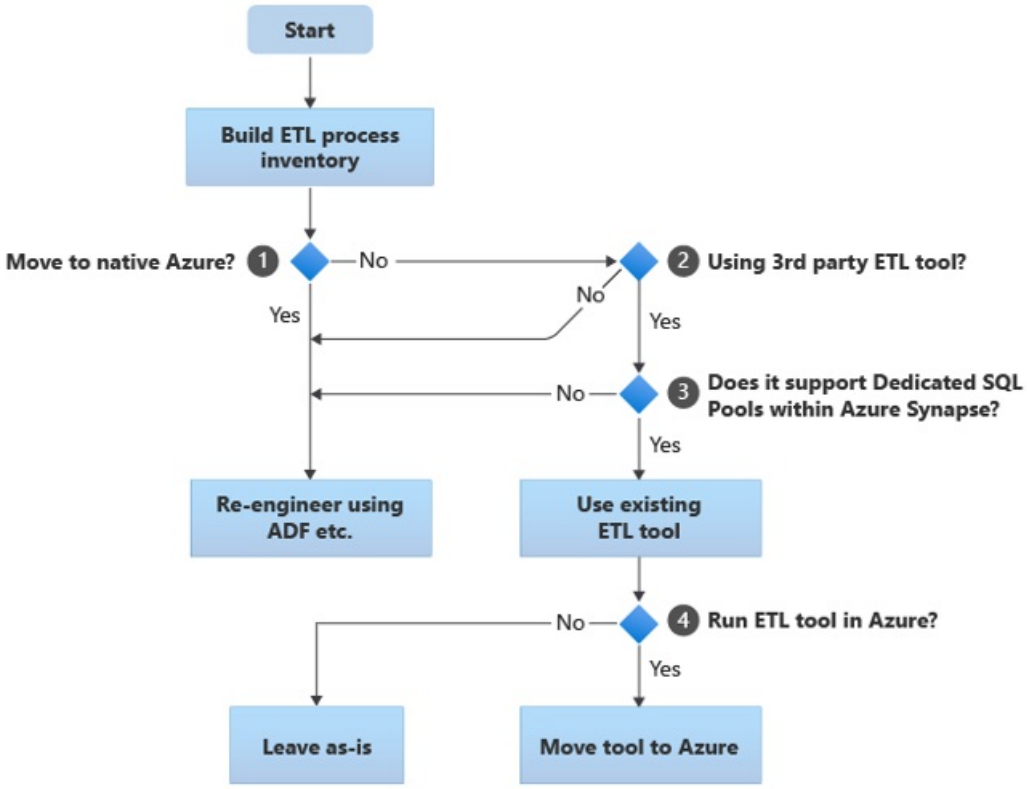
Initial decisions regarding Teradata ETL migration

> **TIP**
> Plan the approach to ETL migration ahead of time and leverage Azure facilities where appropriate.

For ETL/ELT processing, legacy Teradata data warehouses may use custom-built scripts using Teradata utilities such as BTEQ and Teradata Parallel Transporter (TPT), or third-party ETL tools such as Informatica or Ab Initio. Sometimes, Teradata data warehouses use a combination of ETL and ELT approaches that's evolved over time. When planning a migration to Azure Synapse, you need to determine the best way to implement the required ETL/ELT processing in the new environment while minimizing the cost and risk involved. To learn more about

ETL and ELT processing, see ELT vs ETL design approach.

The following sections discuss migration options and make recommendations for various use cases. This flowchart summarizes one approach:



The first step is always to build an inventory of ETL/ELT processes that need to be migrated. As with other steps, it's possible that the standard "built-in" Azure features make it unnecessary to migrate some existing processes. For planning purposes, it's important to understand the scale of the migration to be performed.

In the preceding flowchart, decision 1 relates to a high-level decision about whether to migrate to a totally Azure-native environment. If you're moving to a totally Azure-native environment, we recommend that you re-engineer the ETL processing using Pipelines and activities in Azure Data Factory or Azure Synapse Pipelines. If you're not moving to a totally Azure-native environment, then decision 2 is whether an existing third-party ETL tool is already in use.

In the Teradata environment, some or all ETL processing may be performed by custom scripts using Teradata-specific utilities like BTEQ and TPT. In this case, your approach should be to re-engineer using Data Factory.

> **TIP**
> Leverage investment in existing third-party tools to reduce cost and risk.

If a third-party ETL tool is already in use, and especially if there's a large investment in skills or several existing workflows and schedules use that tool, then decision 3 is whether the tool can efficiently support Azure Synapse as a target environment. Ideally, the tool will include "native" connectors that can leverage Azure facilities like PolyBase or COPY INTO, for the most efficient data loading. There's a way to call an external process, such as PolyBase or `COPY INTO`, and pass in the appropriate parameters. In this case, leverage existing skills and workflows, with Azure Synapse as the new target environment.

If you decide to retain an existing third-party ETL tool, there may be benefits to running that tool within the Azure environment (rather than on an existing on-premises ETL server) and having Azure Data Factory handle the overall orchestration of the existing workflows. One particular benefit is that less data needs to be downloaded from Azure, processed, and then uploaded back into Azure. So, decision 4 is whether to leave the

existing tool running as-is or move it into the Azure environment to achieve cost, performance, and scalability benefits.

Re-engineer existing Teradata-specific scripts

If some or all the existing Teradata warehouse ETL/ELT processing is handled by custom scripts that utilize Teradata-specific utilities, such as BTEQ, MLOAD, or TPT, these scripts need to be recoded for the new Azure Synapse environment. Similarly, if ETL processes were implemented using stored procedures in Teradata, then these will also have to be recoded.

> **TIP**
> The inventory of ETL tasks to be migrated should include scripts and stored procedures.

Some elements of the ETL process are easy to migrate, for example by simple bulk data load into a staging table from an external file. It may even be possible to automate those parts of the process, for example, by using PolyBase instead of fast load or MLOAD. If the exported files are Parquet, you can use a native Parquet reader, which is a faster option than PolyBase. Other parts of the process that contain arbitrary complex SQL and/or stored procedures will take more time to re-engineer.

One way of testing Teradata SQL for compatibility with Azure Synapse is to capture some representative SQL statements from Teradata logs, then prefix those queries with `EXPLAIN`, and then—assuming a like-for-like migrated data model in Azure Synapse—run those `EXPLAIN` statements in Azure Synapse. Any incompatible SQL will generate an error, and the error information can determine the scale of the recoding task.

Microsoft partners offer tools and services to migrate Teradata SQL and stored procedures to Azure Synapse.

Use third-party ETL tools

As described in the previous section, in many cases the existing legacy data warehouse system will already be populated and maintained by third-party ETL products. For a list of Microsoft data integration partners for Azure Synapse, see Data integration partners.

Data loading from Teradata

Choices available when loading data from Teradata

> **TIP**
> Third-party tools can simplify and automate the migration process and therefore reduce risk.

When it comes to migrating data from a Teradata data warehouse, there are some basic questions associated with data loading that need to be resolved. You'll need to decide how the data will be physically moved from the existing on-premises Teradata environment into Azure Synapse in the cloud, and which tools will be used to perform the transfer and load. Consider the following questions, which are discussed in the next sections.

- Will you extract the data to files, or move it directly via a network connection?
- Will you orchestrate the process from the source system, or from the Azure target environment?
- Which tools will you use to automate and manage the process?

Transfer data via files or network connection?

> **TIP**
> Understand the data volumes to be migrated and the available network bandwidth since these factors influence the migration approach decision.

Once the database tables to be migrated have been created in Azure Synapse, you can move the data to populate those tables out of the legacy Teradata system and into the new environment. There are two basic approaches:

- **File extract**: extract the data from the Teradata tables to flat files, normally in CSV format, via BTEQ, Fast Export, or Teradata Parallel Transporter (TPT). Use TPT whenever possible since it's the most efficient in terms of data throughput.

  This approach requires space to land the extracted data files. The space could be local to the Teradata source database (if sufficient storage is available), or remote in Azure Blob Storage. The best performance is achieved when a file is written locally, since that avoids network overhead.

  To minimize the storage and network transfer requirements, it's good practice to compress the extracted data files using a utility like gzip.

  Once extracted, the flat files can either be moved into Azure Blob Storage (collocated with the target Azure Synapse instance) or loaded directly into Azure Synapse using PolyBase or COPY INTO. The method for physically moving data from local on-premises storage to the Azure cloud environment depends on the amount of data and the available network bandwidth.

  Microsoft provides different options to move large volumes of data, including AZCopy for moving files across the network into Azure Storage, Azure ExpressRoute for moving bulk data over a private network connection, and Azure Data Box where the files are moved to a physical storage device that's then shipped to an Azure data center for loading. For more information, see data transfer.

- **Direct extract and load across network**: the target Azure environment sends a data extract request, normally via a SQL command, to the legacy Teradata system to extract the data. The results are sent across the network and loaded directly into Azure Synapse, with no need to land the data into intermediate files. The limiting factor in this scenario is normally the bandwidth of the network connection between the Teradata database and the Azure environment. For very large data volumes this approach may not be practical.

There's also a hybrid approach that uses both methods. For example, you can use the direct network extract approach for smaller dimension tables and samples of the larger fact tables to quickly provide a test environment in Azure Synapse. For the large volume historical fact tables, you can use the file extract and transfer approach using Azure Data Box.

Orchestrate from Teradata or Azure?

The recommended approach when moving to Azure Synapse is to orchestrate the data extract and loading from the Azure environment using Azure Synapse Pipelines or Azure Data Factory, as well as associated utilities, such as PolyBase or COPY INTO, for most efficient data loading. This approach leverages the Azure capabilities and provides an easy method to build reusable data loading pipelines.

Other benefits of this approach include reduced impact on the Teradata system during the data load process since the management and loading process is running in Azure, and the ability to automate the process by using metadata-driven data load pipelines.

Which tools can be used?

The task of data transformation and movement is the basic function of all ETL products. If one of these products is already in use in the existing Teradata environment, then using the existing ETL tool may simplify data migration from Teradata to Azure Synapse. This approach assumes that the ETL tool supports Azure Synapse as

a target environment. For more information on tools that support Azure Synapse, see Data integration partners.

If you're using an ETL tool, consider running that tool within the Azure environment to benefit from Azure cloud performance, scalability, and cost, and free up resources in the Teradata data center. Another benefit is reduced data movement between the cloud and on-premises environments.

Summary

To summarize, our recommendations for migrating data and associated ETL processes from Teradata to Azure Synapse are:

- Plan ahead to ensure a successful migration exercise.
- Build a detailed inventory of data and processes to be migrated as soon as possible.
- Use system metadata and log files to get an accurate understanding of data and process usage. Don't rely on documentation since it may be out of date.
- Understand the data volumes to be migrated, and the network bandwidth between the on-premises data center and Azure cloud environments.
- Consider using a Teradata instance in an Azure VM as a stepping stone to offload migration from the legacy Teradata environment.
- Leverage standard "built-in" Azure features to minimize the migration workload.
- Identify and understand the most efficient tools for data extraction and loading in both Teradata and Azure environments. Use the appropriate tools in each phase of the process.
- Use Azure facilities, such as Azure Synapse Pipelines or Azure Data Factory, to orchestrate and automate the migration process while minimizing impact on the Teradata system.

Next steps

To learn more about security access operations, see the next article in this series: Security, access, and operations for Teradata migrations.

Security, access, and operations for Teradata migrations

8/19/2022 • 16 minutes to read • Edit Online

This article is part three of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for security access operations.

Security considerations

This article discusses connection methods for existing legacy Teradata environments and how they can be migrated to Azure Synapse Analytics with minimal risk and user impact.

This article assumes that there's a requirement to migrate the existing methods of connection and user/role/permission structure as-is. If not, use the Azure portal to create and manage a new security regime.

For more information on the Azure Synapse security options, see Security whitepaper.

Connection and authentication

Teradata authorization options

> **TIP**
> Authentication in both Teradata and Azure Synapse can be "in database" or through external methods.

Teradata supports several mechanisms for connection and authorization. Valid mechanism values are:

- **TD1**, which selects Teradata 1 as the authentication mechanism. Username and password are required.
- **TD2**, which selects Teradata 2 as the authentication mechanism. Username and password are required.
- **TDNEGO**, which selects one of the authentication mechanisms automatically based on the policy, without user involvement.
- **LDAP**, which selects Lightweight Directory Access Protocol (LDAP) as the authentication mechanism. The application provides the username and password.
- **KRB5**, which selects Kerberos (KRB5) on Windows clients working with Windows servers. To sign in using KRB5, the user needs to supply a domain, username, and password. The domain is specified by setting the username to `MyUserName@MyDomain`.
- **NTLM**, which selects NTLM on Windows clients working with Windows servers. The application provides the username and password.

Kerberos (KRB5), Kerberos Compatibility (KRB5C), NT LAN Manager (NTLM), and NT LAN Manager Compatibility (NTLMC) are for Windows only.

Azure Synapse authorization options

Azure Synapse supports two basic options for connection and authorization:

- **SQL authentication**: SQL authentication is via a database connection that includes a database identifier, user ID, and password plus other optional parameters. This is functionally equivalent to Teradata TD1, TD2 and default connections.
- **Azure Active Directory (Azure AD) authentication**: with Azure AD authentication, you can centrally

manage the identities of database users and other Microsoft services in one central location. Central ID management provides a single place to manage SQL Data Warehouse users and simplifies permission management. Azure AD can also support connections to LDAP and Kerberos services—for example, Azure AD can be used to connect to existing LDAP directories if these are to remain in place after migration of the database.

Users, roles, and permissions

Overview

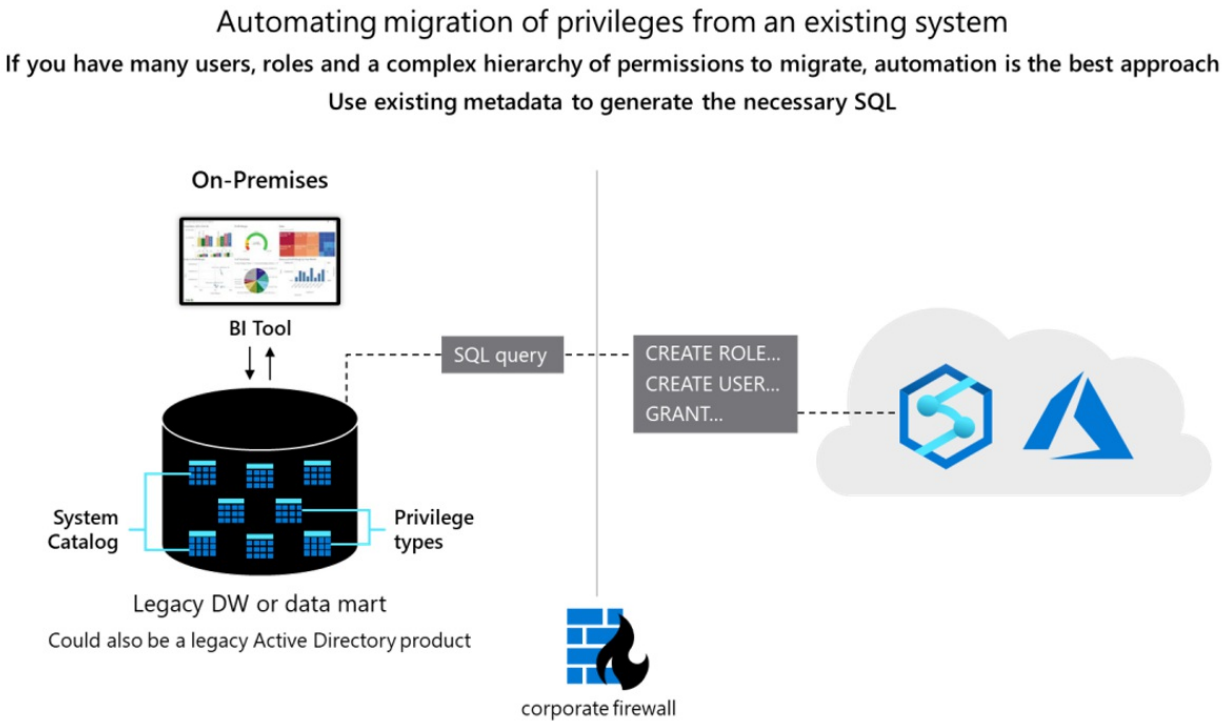
> **TIP**
> High-level planning is essential for a successful migration project.

Both Teradata and Azure Synapse implement database access control via a combination of users, roles, and permissions. Both use standard SQL `CREATE USER` and `CREATE ROLE` statements to define users and roles, and `GRANT` and `REVOKE` statements to assign or remove permissions to those users and/or roles.

> **TIP**
> Automation of migration processes is recommended to reduce elapsed time and scope for errors.

Conceptually the two databases are similar, and it might be possible to automate the migration of existing user IDs, roles, and permissions to some degree. Migrate such data by extracting the existing legacy user and role information from the Teradata system catalog tables and generating matching equivalent `CREATE USER` and `CREATE ROLE` statements to be run in Azure Synapse to recreate the same user/role hierarchy.

After data extraction, use Teradata system catalog tables to generate equivalent `GRANT` statements to assign permissions (where an equivalent one exists). The following diagram shows how to use existing metadata to generate the necessary SQL.



Users and roles

> **TIP**
> Migration of a data warehouse requires more than just tables, views, and SQL statements.

The information about current users and roles in a Teradata system is found in the system catalog tables `DBC.USERS` (or `DBC.DATABASES`) and `DBC.ROLEMEMBERS`. Query these tables (if the user has `SELECT` access to those tables) to obtain current lists of users and roles defined within the system. The following are examples of queries to do this for individual users:

```
/***SQL to find all users***/
SELECT
DatabaseName AS UserName
FROM DBC.Databases
WHERE dbkind = 'u';

/***SQL to find all roles***/
SELECT A.ROLENAME, A.GRANTEE, A.GRANTOR,
  A.DefaultRole,
  A.WithAdmin,
  B.DATABASENAME,
  B.TABLENAME,
  B.COLUMNNAME,
  B.GRANTORNAME,
  B.AccessRight
FROM DBC.ROLEMEMBERS A
JOIN DBC.ALLROLERIGHTS B
ON A.ROLENAME = B.ROLENAME
GROUP BY 1,2,3,4,5,6,7
ORDER BY 2,1,6;
```

These examples modify `SELECT` statements to produce a result set, which is a series of `CREATE USER` and `CREATE ROLE` statements, by including the appropriate text as a literal within the `SELECT` statement.

There's no way to retrieve existing passwords, so you need to implement a scheme for allocating new initial passwords on Azure Synapse.

Permissions

> **TIP**
> There are equivalent Azure Synapse permissions for basic database operations such as DML and DDL.

In a Teradata system, the system tables `DBC.ALLRIGHTS` and `DBC.ALLROLERIGHTS` hold the access rights for users and roles. Query these tables (if the user has `SELECT` access to those tables) to obtain current lists of access rights defined within the system. The following are examples of queries for individual users:

```
/**SQL for AccessRights held by a USER***/
SELECT UserName, DatabaseName,TableName,ColumnName,
CASE WHEN Abbv.AccessRight IS NOT NULL THEN Abbv.Description ELSE
ALRTS.AccessRight
END AS AccessRight, GrantAuthority, GrantorName, AllnessFlag, CreatorName, CreateTimeStamp
FROM DBC.ALLRIGHTS ALRTS LEFT OUTER JOIN AccessRightsAbbv Abbv
ON ALRTS.AccessRight = Abbv.AccessRight
WHERE UserName='UserXYZ'
Order By 2,3,4,5;

/**SQL for AccessRights held by a ROLE***/
SELECT RoleName, DatabaseName,TableName,ColumnName,
CASE WHEN Abbv.AccessRight IS NOT NULL THEN Abbv.Description ELSE
ALRTS.AccessRight
END AS AccessRight, GrantorName, CreateTimeStamp
FROM DBC.ALLROLERIGHTS ALRTS LEFT OUTER JOIN AccessRightsAbbv
Abbv
ON ALRTS.AccessRight = Abbv.AccessRight
WHERE RoleName='BI_DEVELOPER'
Order By 2,3,4,5;
```

Modify these example `SELECT` statements to produce a result set that's a series of `GRANT` statements by including the appropriate text as a literal within the `SELECT` statement.

Use the table `AccessRightsAbbv` to look up the full text of the access right, as the join key is an abbreviated 'type' field. See the following table for a list of Teradata access rights and their equivalent in Azure Synapse.

TERADATA PERMISSION NAME	TERADATA TYPE	AZURE SYNAPSE EQUIVALENT
ABORT SESSION	AS	KILL DATABASE CONNECTION
ALTER EXTERNAL PROCEDURE	AE	[4]

SETSESSRATE	SS	[5]
SHOW	SH	[3]
UPDATE	U	UPDATE

`AccessRightsAbbv` table notes:

1. Teradata `PROFILE` is functionally equivalent to `LOGIN` in Azure Synapse.
2. The following table summarizes the differences between macros and stored procedures in Teradata. In Azure Synapse, procedures provide the functionality described in the table.

MACRO	STORED PROCEDURE
Contains SQL	Contains SQL
May contain BTEQ dot commands	Contains comprehensive SPL
May receive parameter values passed to it	May receive parameter values passed to it
May retrieve one or more rows	Must use a cursor to retrieve more than one row
Stored in DBC PERM space	Stored in DATABASE or USER PERM
Returns rows to the client	May return one or more values to client as parameters

3. `SHOW`, `GLOP`, and `TRIGGER` have no direct equivalent in Azure Synapse.
4. These features are managed automatically by the system in Azure Synapse. See Operational considerations.
5. In Azure Synapse, these features are handled outside of the database.

For more information about access rights in Azure Synapse, see to Azure Synapse Analytics security permissions.

Operational considerations

> **TIP**
> Operational tasks are necessary to keep any data warehouse operating efficiently.

This section discusses how to implement typical Teradata operational tasks in Azure Synapse with minimal risk and impact to users.

As with all data warehouse products, once in production there are ongoing management tasks that are necessary to keep the system running efficiently and to provide data for monitoring and auditing. Resource utilization and capacity planning for future growth also falls into this category, as does backup/restore of data.

While conceptually the management and operations tasks for different data warehouses are similar, the individual implementations may differ. In general, modern cloud-based products such as Azure Synapse tend to incorporate a more automated and "system managed" approach (as opposed to a more "manual" approach in legacy data warehouses such as Teradata).

The following sections compare Teradata and Azure Synapse options for various operational tasks.

Housekeeping tasks

> **TIP**
> Housekeeping tasks keep a production warehouse operating efficiently and optimize use of resources such as storage.

In most legacy data warehouse environments, there's a requirement to perform regular "housekeeping" tasks such as reclaiming disk storage space that can be freed up by removing old versions of updated or deleted rows, or reorganizing data log files or index blocks for efficiency. Collecting statistics is also a potentially time-consuming task. Collecting statistics is required after a bulk data ingest to provide the query optimizer with up-to-date data to base generation of query execution plans.

Teradata recommends collecting statistics as follows:

- Collect statistics on unpopulated tables to set up the interval histogram used in internal processing. This initial collection makes subsequent statistics collections faster. Make sure to recollect statistics after data is added.
- Collect prototype phase statistics for newly populated tables.
- Collect production phase statistics after a significant percentage of change to the table or partition (~10% of rows). For high volumes of nonunique values, such as dates or timestamps, it may be advantageous to recollect at 7%.
- Collect production phase statistics after you've created users and applied real world query loads to the database (up to about three months of querying).
- Collect statistics in the first few weeks after an upgrade or migration during periods of low CPU utilization.

Statistics collection can be managed manually using Automated Statistics Management open APIs or automatically using the Teradata Viewpoint Stats Manager portlet.

> **TIP**
> Automate and monitor housekeeping tasks in Azure.

Teradata Database contains many log tables in the Data Dictionary that accumulate data, either automatically or after certain features are enabled. Because log data grows over time, purge older information to avoid using up permanent space. There are options to automate the maintenance of these logs available. The Teradata dictionary tables that require maintenance are discussed next.

Dictionary tables to maintain

Reset accumulators and peak values using the `DBC.AMPUsage` view and the `ClearPeakDisk` macro provided with the software:

- `DBC.Acctg`: resource usage by account/user
- `DBC.DataBaseSpace`: database and table space accounting

Teradata automatically maintains these tables, but good practices can reduce their size:

- `DBC.AccessRights`: user rights on objects
- `DBC.RoleGrants`: role rights on objects
- `DBC.Roles`: defined roles
- `DBC.Accounts`: account codes by user

Archive these logging tables (if desired) and purge information 60-90 days old. Retention depends on customer requirements:

- `DBC.SW_Event_Log`: database console log
- `DBC.ResUsage`: resource monitoring tables
- `DBC.EventLog`: session logon/logoff history
- `DBC.AccLogTbl`: logged user/object events
- `DBC.DBQL tables`: logged user/SQL activity
- `.NETSecPolicyLogTbl`: logs dynamic security policy audit trails
- `.NETSecPolicyLogRuleTbl`: controls when and how dynamic security policy is logged

Purge these tables when the associated removable media is expired and overwritten:

- `DBC.RCEvent`: archive/recovery events
- `DBC.RCConfiguration`: archive/recovery config
- `DBC.RCMedia`: VolSerial for archive/recovery

Azure Synapse has an option to automatically create statistics so that they can be used as needed. Perform defragmentation of indexes and data blocks manually, on a scheduled basis, or automatically. Leveraging native built-in Azure capabilities can reduce the effort required in a migration exercise.

Monitoring and auditing

> **TIP**
> Over time, several different tools have been implemented to allow monitoring and logging of Teradata systems.

Teradata provides several tools to monitor the operation including Teradata Viewpoint and Ecosystem Manager. For logging query history, the Database Query Log (DBQL) is a Teradata database feature that provides a series of predefined tables that can store historical records of queries and their duration, performance, and target activity based on user-defined rules.

Database administrators can use Teradata Viewpoint to determine system status, trends, and individual query status. By observing trends in system usage, system administrators are better able to plan project implementations, batch jobs, and maintenance to avoid peak periods of use. Business users can use Teradata Viewpoint to quickly access the status of reports and queries and drill down into details.

> **TIP**
> The Azure portal provides a UI to manage monitoring and auditing tasks for all Azure data and processes.

Similarly, Azure Synapse provides a rich monitoring experience within the Azure portal to provide insights into your data warehouse workload. The Azure portal is the recommended tool when monitoring your data warehouse as it provides configurable retention periods, alerts, recommendations, and customizable charts and dashboards for metrics and logs.

The portal also enables integration with other Azure monitoring services such as Operations Management Suite (OMS) and Azure Monitor (logs) to provide a holistic monitoring experience for not only the data warehouse but also the entire Azure analytics platform for an integrated monitoring experience.

> **TIP**
> Low-level and system-wide metrics are automatically logged in Azure Synapse.

Resource utilization statistics for Azure Synapse are automatically logged within the system. The metrics for each query include usage statistics for CPU, memory, cache, I/O, and temporary workspace, as well as connectivity information like failed connection attempts.

Azure Synapse provides a set of Dynamic Management Views (DMVs). These views are useful when actively troubleshooting and identifying performance bottlenecks with your workload.

For more information, see Azure Synapse operations and management options.

High Availability (HA) and Disaster Recovery (DR)

Teradata implements features such as `FALLBACK`, Archive Restore Copy utility (ARC), and Data Stream Architecture (DSA) to provide protection against data loss and high availability (HA) via replication and archive of data. Disaster Recovery (DR) options include Dual Active Solution, DR as a service, or a replacement system depending on the recovery time requirement.

> **TIP**
> Azure Synapse creates snapshots automatically to ensure fast recovery times.

Azure Synapse uses database snapshots to provide high availability of the warehouse. A data warehouse snapshot creates a restore point that can be used to recover or copy a data warehouse to a previous state. Since Azure Synapse is a distributed system, a data warehouse snapshot consists of many files that are in Azure Storage. Snapshots capture incremental changes from the data stored in your data warehouse.

Azure Synapse automatically takes snapshots throughout the day creating restore points that are available for seven days. This retention period can't be changed. Azure Synapse supports an eight-hour recovery point objective (RPO). A data warehouse can be restored in the primary region from any one of the snapshots taken in the past seven days.

> **TIP**
> Use user-defined snapshots to define a recovery point before key updates.

User-defined restore points are also supported, allowing manual triggering of snapshots to create restore points of a data warehouse before and after large modifications. This capability ensures that restore points are logically consistent, which provides additional data protection in case of any workload interruptions or user errors for a

desired RPO of less than 8 hours.

> **TIP**
> Microsoft Azure provides automatic backups to a separate geographical location to enable DR.

As well as the snapshots described previously, Azure Synapse also performs as standard a geo-backup once per day to a paired data center. The RPO for a geo-restore is 24 hours. You can restore the geo-backup to a server in any other region where Azure Synapse is supported. A geo-backup ensures that a data warehouse can be restored in case the restore points in the primary region aren't available.

Workload management

> **TIP**
> In a production data warehouse, there are typically mixed workloads with different resource usage characteristics running concurrently.

A workload is a class of database requests with common traits whose access to the database can be managed with a set of rules. Workloads are useful for:

- Setting different access priorities for different types of requests.
- Monitoring resource usage patterns, performance tuning, and capacity planning.
- Limiting the number of requests or sessions that can run at the same time.

In a Teradata system, workload management is the act of managing workload performance by monitoring system activity and acting when pre-defined limits are reached. Workload management uses rules, and each rule applies only to some database requests. However, the collection of all rules applies to all active work on the platform. Teradata Active System Management (TASM) performs full workload management in a Teradata Database.

In Azure Synapse, resource classes are pre-determined resource limits that govern compute resources and concurrency for query execution. Resource classes can help you manage your workload by setting limits on the number of queries that run concurrently and on the compute resources assigned to each query. There's a trade-off between memory and concurrency.

Azure Synapse automatically logs resource utilization statistics. Metrics include usage statistics for CPU, memory, cache, I/O, and temporary workspace for each query. Azure Synapse also logs connectivity information, such as failed connection attempts.

> **TIP**
> Low-level and system-wide metrics are automatically logged within Azure.

Azure Synapse supports these basic workload management concepts:

- **Workload classification**: you can assign a request to a workload group to set importance levels.
- **Workload importance**: you can influence the order in which a request gets access to resources. By default, queries are released from the queue on a first-in, first-out basis as resources become available. Workload importance allows higher priority queries to receive resources immediately regardless of the queue.
- **Workload isolation**: you can reserve resources for a workload group, assign maximum and minimum

usage for varying resources, limit the resources a group of requests can consume can, and set a timeout value to automatically kill runaway queries.

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). The workload classification, workload importance, and workload isolation gives more control over how workload utilizes system resources.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance](../../sql-data-warehouse/sql-data-warehouse-how-to-manage-and-monitor-workload-importance.md), and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized. Azure Synapse provides a set of Dynamic Management Views (DMVs) for monitoring all aspects of workload management. These views are useful when actively troubleshooting and identifying performance bottlenecks in your workload.

This information can also be used for capacity planning, determining the resources required for additional users or application workload. This also applies to planning scale up/scale downs of compute resources for cost-effective support of "peaky" workloads.

For more information on workload management in Azure Synapse, see Workload management with resource classes.

Scale compute resources

> **TIP**
> A major benefit of Azure is the ability to independently scale up and down compute resources on demand to handle peaky workloads cost-effectively.

The architecture of Azure Synapse separates storage and compute, allowing each to scale independently. As a result, compute resources can be scaled to meet performance demands independent of data storage. You can also pause and resume compute resources. A natural benefit of this architecture is that billing for compute and storage is separate. If a data warehouse isn't in use, you can save on compute costs by pausing compute.

Compute resources can be scaled up or scaled back by adjusting the data warehouse units setting for the data warehouse. Loading and query performance will increase linearly as you add more data warehouse units.

Adding more compute nodes adds more compute power and ability to leverage more parallel processing. As the number of compute nodes increases, the number of distributions per compute node decreases, providing more compute power and parallel processing for queries. Similarly, decreasing data warehouse units reduces the number of compute nodes, which reduces the compute resources for queries.

Visualization and reporting for Teradata migrations

8/19/2022 • 20 minutes to read • Edit Online

This article is part four of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for visualization and reporting.

Access Azure Synapse Analytics using Microsoft and third-party BI tools

Organizations access data warehouses and data marts using a range of business intelligence (BI) tools and applications. Some examples of BI products are:

- Microsoft BI tools, such as Power BI.
- Office applications, such as Microsoft Excel spreadsheets.
- Third-party BI tools from different vendors.
- Custom analytics applications with embedded BI tool functionality.
- Operational applications that support on-demand BI by running queries and reports on a BI platform that in turn queries data in a data warehouse or data mart.
- Interactive data science development tools, such as Azure Synapse Spark Notebooks, Azure Machine Learning, RStudio, and Jupyter Notebooks.

If you migrate visualization and reporting as part of your data warehouse migration, all existing queries, reports, and dashboards generated by BI products need to run in the new environment. Your BI products must yield the same results on Azure Synapse as they did in your legacy data warehouse environment.

For consistent results after migration, all BI tools and application dependencies must work after you've migrated your data warehouse schema and data to Azure Synapse. The dependencies include less visible aspects, such as access and security. When you address access and security, ensure that you migrate:

- Authentication so users can sign into the data warehouse and data mart databases on Azure Synapse.
- All users to Azure Synapse.
- All user groups to Azure Synapse.
- All roles to Azure Synapse.
- All authorization privileges governing access control to Azure Synapse.
- User, role, and privilege assignments to mirror what you had in your existing data warehouse before migration. For example:
    - Database object privileges assigned to roles
    - Roles assigned to user groups
    - Users assigned to user groups and/or roles

Access and security are important considerations for data access in the migrated system and are discussed in more detail in Security, access, and operations for Teradata migrations.

TIP

Existing users, user groups, roles, and assignments of access security privileges need to be migrated first for migration of reports and visualizations to succeed.

Migrate all required data to ensure that the reports and dashboards that query data in the legacy environment produce the same results in Azure Synapse.

Business users will expect a seamless migration, with no surprises that destroy their confidence in the migrated system on Azure Synapse. Take care to allay any fears that your users might have through good communication. Your users will expect that:

- Table structure remains the same when directly referred to in queries.
- Table and column names remain the same when directly referred to in queries. For instance, calculated fields defined on columns in BI tools shouldn't fail when aggregate reports are produced.
- Historical analysis remains the same.
- Data types remain the same, if possible.
- Query behavior remains the same.
- ODBC/JDBC drivers are tested to ensure that query behavior remains the same.

TIP

Communication and business user involvement are critical to success.

If BI tools query views in the underlying data warehouse or data mart database, will those views still work after the migration? Some views might not work if there are proprietary SQL extensions specific to your legacy data warehouse DBMS that have no equivalent in Azure Synapse. If so, you need to know about those incompatibilities and find a way to resolve them.

TIP

Views and SQL queries using proprietary SQL query extensions are likely to result in incompatibilities that impact BI reports and dashboards.

Other issues, like the behavior of `NULL` values or data type variations across DBMS platforms, need to be tested to ensure that even slight differences don't exist in calculation results. Minimize those issues and take all necessary steps to shield business users from being affected by them. Depending on your legacy data warehouse environment, third-party tools that can help hide the differences between the legacy and new environments so that BI tools and applications run unchanged.

Testing is critical to visualization and report migration. You need a test suite and agreed-on test data to run and rerun tests in both environments. A test harness is also useful, and a few are mentioned in this guide. Also, it's important to involve business users in the testing aspect of the migration to keep confidence high and to keep them engaged and part of the project.

TIP

Use repeatable tests to ensure reports, dashboards, and other visualizations migrate successfully.

You might be thinking about switching BI tools, for example to migrate to Power BI. The temptation is to make such changes at the same time you're migrating your schema, data, ETL processing, and more. However, to minimize risk, it's better to migrate to Azure Synapse first and get everything working before undertaking further modernization.

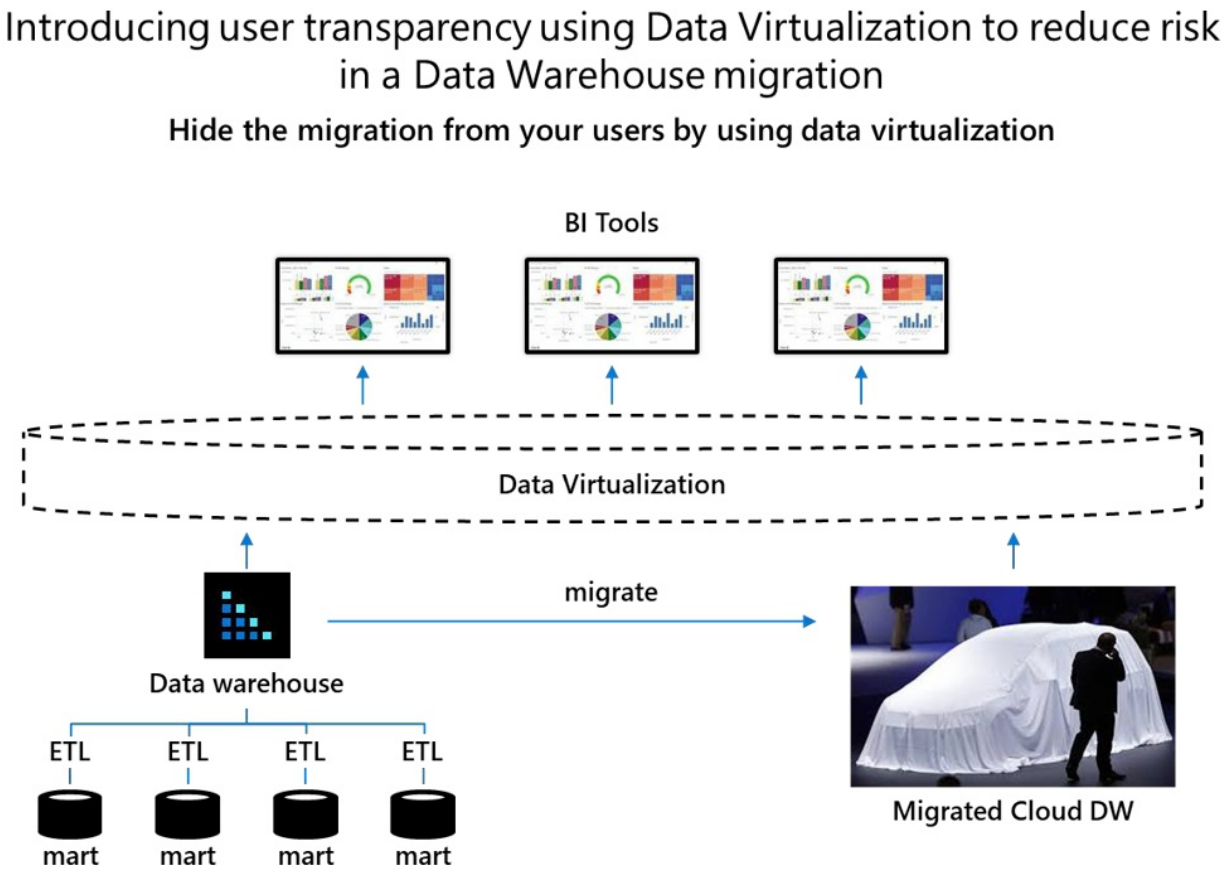
If your existing BI tools run on-premises, ensure they can connect to Azure Synapse through your firewall so you're able to run comparisons against both environments. Alternatively, if the vendor of your existing BI tools offers their product on Azure, you can try it there. The same applies for applications running on-premises that embed BI or call your BI server on demand, for example by requesting a "headless report" with XML or JSON data.

There's a lot to think about here, so let's take a closer look.

Use data virtualization to minimize the impact of migration on BI tools and reports

During migration, you might be tempted to fulfill long-term requirements like opening business requests, adding missing data, or implementing new features. However, such changes can affect BI tool access to your data warehouse, especially if the change involves structural changes to your data model. If you want to adopt an agile data modeling technique or implement structural changes, do so *after* migration.

One way to minimize the effect of schema changes or other structural changes on your BI tools is to introduce data virtualization between the BI tools and your data warehouse and data marts. The following diagram shows how data virtualization can hide a migration from users.



Data virtualization breaks the dependency between business users utilizing self-service BI tools and the physical schema of the underlying data warehouse and data marts that are being migrated.

> **TIP**
> Data virtualization allows you to shield business users from structural changes during migration so they remain unaware of those changes. Structural changes include schema alterations that tune your data model for Azure Synapse.

With data virtualization, any schema alterations made during a migration to Azure Synapse, for example to optimize performance, can be hidden from business users because they only have access to virtual tables in the data virtualization layer. And, if you make structural changes, you only need to update the mappings between the data warehouse or data marts and any virtual tables. With data virtualization, users remain unaware of structural changes. Microsoft partners provide data virtualization software.

Identify high-priority reports to migrate first

A key question when migrating your existing reports and dashboards to Azure Synapse is which ones to migrate first. Several factors might drive that decision, such as:

- Usage
- Business value
- Ease of migration
- Data migration strategy

The following sections discuss these factors.

Whatever your decision, it must involve your business users because they produce the reports, dashboards, and other visualizations, and make business decisions based on insights from those items. Everyone benefits when you can:

- Migrate reports and dashboards seamlessly,
- Migrate reports and dashboards with minimal effort, and
- Point your BI tool(s) at Azure Synapse instead of your legacy data warehouse system, and get like-for-like reports, dashboards, and other visualizations.

Migrate reports based on usage

Usage is often an indicator of business value. Unused reports and dashboards clearly don't contribute to business decisions or offer current value. If you don't have a way to find out which reports and dashboards are unused, you can use one of the several BI tools that provide usage statistics.

If your legacy data warehouse has been up and running for years, there's a good chance you have hundreds, if not thousands, of reports in existence. It's worth compiling an inventory of reports and dashboards and identifying their business purpose and usage statistics.

For unused reports, determine whether to decommission them to reduce your migration effort. A key question when deciding whether to decommission an unused report is whether the report is unused because people don't know it exists, because it offers no business value, or because it's been superseded by another report.

Migrate reports based on business value

Usage alone isn't always a good indicator of business value. You might want to consider the extent to which a report's insights contribute to business value. One way to do that is to evaluate the profitability of every business decision that relies on the report and the extent of the reliance. However, that information is unlikely to be readily available in most organizations.

Another way to evaluate business value is to look at the alignment of a report with business strategy. The business strategy set by your executive typically lays out strategic business objectives (SBOs), key performance

indicators (KPIs), KPI targets that need to be achieved, and who is accountable for achieving them. You can classify a report by which SBOs the report contributes to, such as fraud reduction, improved customer engagement, and optimized business operations. Then, you can prioritize for migration the reports and dashboards that are associated with high-priority objectives. In this way, the initial migration can deliver business value in a strategic area.

Another way to evaluate business value is to classify reports and dashboards as operational, tactical, or strategic to identify at which business level they're used. SBOs require contributions at all these levels. By knowing which reports and dashboards are used, at what level, and what objectives they're associated with, you're able to focus the initial migration on high-priority business value. You can use the following *business strategy objective* table to evaluate reports and dashboards.

LEVEL	REPORT / DASHBOARD NAME	BUSINESS PURPOSE	DEPARTMENT USED	USAGE FREQUENCY	BUSINESS PRIORITY
Strategic					
Tactical					
Operational					

Metadata discovery tools like Azure Data Catalog let business users tag and rate data sources to enrich the metadata for those data sources to assist with their discovery and classification. You can use the metadata for a report or dashboard to help you understand its business value. Without such tools, understanding the contribution of reports and dashboards to business value is likely to be a time-consuming task, whether you're migrating or not.

Migrate reports based on data migration strategy

If your migration strategy is based on migrating data marts first, then the order of data mart migration will affect which reports and dashboards are migrated first. If your strategy is based on business value, the order in which you migrate data marts to Azure Synapse will reflect business priorities. Metadata discovery tools can help you implement your strategy by showing you which data mart tables supply data for which reports.

> **TIP**
> Your data migration strategy affects which reports and visualizations get migrated first.

Migration incompatibility issues that can affect reports and visualizations

BI tools produce reports, dashboards, and other visualizations by issuing SQL queries that access physical tables and/or views in your data warehouse or data mart. When you migrate your legacy data warehouse to Azure Synapse, several factors can affect the ease of migration of reports, dashboards, and other visualizations. Those factors include:

- Schema incompatibilities between the environments.
- SQL incompatibilities between the environments.

Schema incompatibilities

During a migration, schema incompatibilities in the data warehouse or data mart tables that supply data for reports, dashboards, and other visualizations can be:

- Non-standard table types in your legacy data warehouse DBMS that don't have an equivalent in Azure

Synapse.

- Data types in your legacy data warehouse DBMS that don't have an equivalent in Azure Synapse.

In most cases, there's a workaround to the incompatibilities. For example, you can migrate the data in an unsupported table type into a standard table with appropriate data types and indexed or partitioned on a date/time column. Similarly, it might be possible to represent unsupported data types in another type of column and perform calculations in Azure Synapse to achieve the same results.

> **TIP**
> Schema incompatibilities include legacy warehouse DBMS table types and data types that are unsupported on Azure Synapse.

To identify the reports affected by schema incompatibilities, run queries against the system catalog of your legacy data warehouse to identify the tables with unsupported data types. Then, you can use metadata from your BI tool to identify the reports that access data in those tables. For more information about how to identify object type incompatibilities, see Unsupported Teradata database object types.

> **TIP**
> Query the system catalog of your legacy warehouse DBMS to identify schema incompatibilities with Azure Synapse.

The effect of schema incompatibilities on reports, dashboards, and other visualizations might be less than you think because many BI tools don't support the less generic data types. As a result, your legacy data warehouse might already have views that `CAST` unsupported data types to more generic types.

SQL incompatibilities

During a migration, SQL incompatibilities are likely to affect any report, dashboard, or other visualization in an application or tool that:

- Accesses legacy data warehouse DBMS views that include proprietary SQL functions that have no equivalent in Azure Synapse.
- Issues SQL queries that include proprietary SQL functions, specific to the SQL dialect of your legacy environment, that have no equivalent in Azure Synapse.

Gauge the impact of SQL incompatibilities on your reporting portfolio

Your reporting portfolio might include embedded query services, reports, dashboards, and other visualizations. Don't rely on the documentation associated with those items to gauge the effect of SQL incompatibilities on the migration of your reporting portfolio to Azure Synapse. You need to use a more precise way to assess the effect of SQL incompatibilities.

Use EXPLAIN statements to find SQL incompatibilities

You can find SQL incompatibilities by reviewing the logs of recent SQL activity in your legacy Teradata data warehouse. Use a script to extract a representative set of SQL statements to a file. Then, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse. Any SQL statements containing proprietary unsupported SQL extensions will be rejected by Azure Synapse when the `EXPLAIN` statements are executed. This approach lets you assess the extent of SQL incompatibilities.

Metadata from your legacy data warehouse DBMS can also help you identify incompatible views. As before, capture a representative set of SQL statements from the applicable logs, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse to identify views with incompatible SQL.

TIP

Gauge the impact of SQL incompatibilities by harvesting your DBMS log files and running `EXPLAIN` statements.

Test report and dashboard migration to Azure Synapse Analytics

A key element of data warehouse migration is testing of reports and dashboards in Azure Synapse to verify the migration has worked. Define a series of tests and a set of required outcomes for each test that you will run to verify success. Test and compare the reports and dashboards across your existing and migrated data warehouse systems to:

- Identify whether any schema changes that were made during migration affected the ability of reports to run, report results, or the corresponding report visualizations. An example of a schema change is if you mapped an incompatible data type to an equivalent data type that's supported in Azure Synapse.
- Verify that all users are migrated.
- Verify that all roles are migrated, and users are assigned to those roles.
- Verify that all data access security privileges are migrated to ensure access control list (ACL) migration.
- Ensure consistent results for all known queries, reports, and dashboards.
- Ensure that data and ETL migration is complete and error-free.
- Ensure that data privacy is upheld.
- Test performance and scalability.
- Test analytical functionality.

TIP

Test and tune performance to minimize compute costs.

For information about how to migrate users, user groups, roles, and privileges, see Security, access, and operations for Teradata migrations.

Automate testing as much as possible to make each test repeatable and to support a consistent approach to evaluating test results. Automation works well for known regular reports, and can be managed via Azure Synapse pipelines or Azure Data Factory orchestration. If you already have a suite of test queries in place for regression testing, you can use the existing testing tools to automate post migration testing.

TIP

Best practice is to build an automated test suite to make tests repeatable.

Ad-hoc analysis and reporting are more challenging and require compilation of a set of tests to verify that the same reports and dashboards from before and after migration are consistent. If you find inconsistencies, then your ability to compare metadata lineage across the original and migrated systems during migration testing becomes crucial. That comparison can highlight differences and pinpoint where inconsistencies originated, when detection by other means is difficult.

> **TIP**
> Leverage tools that compare metadata lineage to verify results.

Analyze lineage to understand dependencies between reports, dashboards, and data

Your understanding of lineage is a critical factor in the successful migration of reports and dashboards. Lineage is metadata that shows the journey of migrated data so you can track its path from a report or dashboard all the way back to the data source. Lineage shows how data has traveled from point to point, its location in the data warehouse and/or data mart, and which reports and dashboards use it. Lineage can help you understand what happens to data as it travels through different data stores, such as files and databases, different ETL pipelines, and into reports. When business users have access to data lineage, it improves trust, instills confidence, and supports informed business decisions.

> **TIP**
> Your ability to access metadata and data lineage from reports all the way back to a data source is critical for verifying that migrated reports work correctly.

In multi-vendor data warehouse environments, business analysts in BI teams might map out data lineage. For example, if you use different vendors for ETL, data warehouse, and reporting, and each vendor has its own metadata repository, then figuring out where a specific data element in a report came from can be challenging and time-consuming.

> **TIP**
> Tools that automate the collection of metadata and show end-to-end lineage in a multi-vendor environment are valuable during a migration.

To migrate seamlessly from a legacy data warehouse to Azure Synapse, use end-to-end data lineage to prove like-for-like migration when you're comparing the reports and dashboards generated by each environment. To show the end-to-end data journey, you'll need to capture and integrate metadata from several tools. Having access to tools that support automated metadata discovery and data lineage, helps you identify duplicate reports or ETL processes, and find reports that rely on obsolete, questionable, or non-existent data sources. You can use that information to reduce the number of reports and ETL processes that you migrate.

You can also compare the end-to-end lineage of a report in Azure Synapse to the end-to-end lineage of the same report in your legacy environment to check for differences that might have inadvertently occurred during migration. This type of comparison is exceptionally useful when you need to test and verify migration success.

Data lineage visualization not only reduces time, effort, and error in the migration process, but also enables faster migration.

By using automated metadata discovery and data lineage tools that compare lineage, you can verify that a report in Azure Synapse that's produced from migrated data is produced in the same way in your legacy environment. This capability also helps you determine:

- What data needs to be migrated to ensure successful report and dashboard execution in Azure Synapse.
- What transformations have been and should be performed to ensure successful execution in Azure Synapse.

- How to reduce report duplication.

Automated metadata discovery and data lineage tools substantially simplify the migration process because they help businesses become more aware of their data assets and to know what needs to be migrated to Azure Synapse to achieve a solid reporting environment.

Several ETL tools provide end-to-end lineage capability, so check whether your existing ETL tool has that capability if you plan to use it with Azure Synapse. Azure Synapse pipelines or Data Factory both support the ability to view lineage in mapping flows. Microsoft partners also provide automated metadata discovery, data lineage, and lineage comparison tools.

Migrate BI tool semantic layers to Azure Synapse Analytics

Some BI tools have what is known as a semantic metadata layer. That layer simplifies business user access to the underlying physical data structures in a data warehouse or data mart database. The semantic metadata layer simplifies access by providing high-level objects like dimensions, measures, hierarchies, calculated metrics, and joins. The high-level objects use business terms that are familiar to business analysts, and map to physical data structures in your data warehouse or data mart.

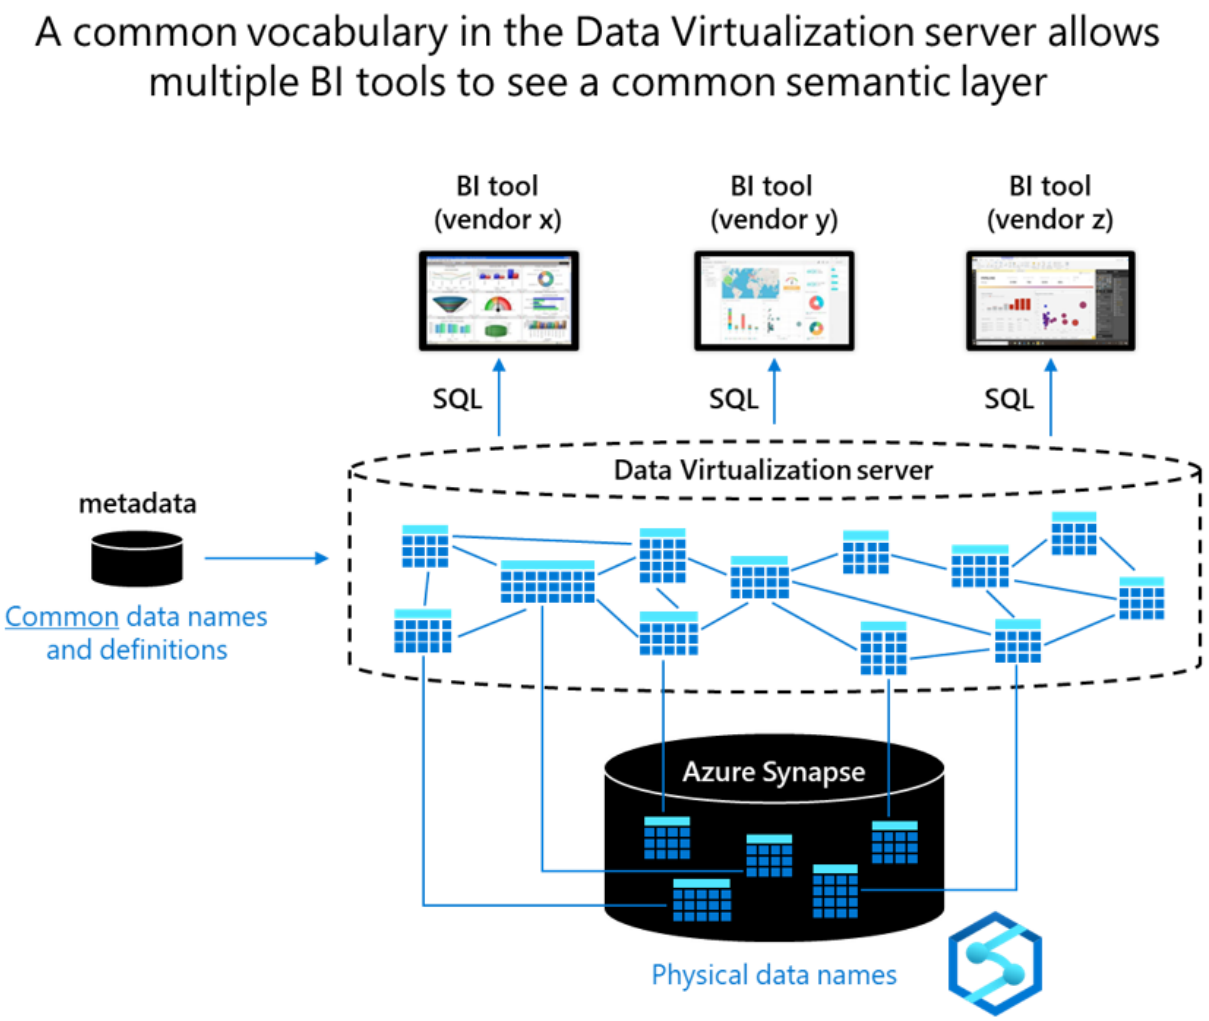
> **TIP**
> Some BI tools have semantic layers that simplify business user access to physical data structures in your data warehouse or data mart.

In a data warehouse migration, changes to column names or table names may be forced upon you. For example, in Teradata, table names can have a "#". In Azure Synapse, the "#" is only allowed as a prefix to a table name to indicate a temporary table. In Teradata, TEMPORARY TABLES do not necessarily have a "#" in the name, but in Synapse they must. You may need to do some rework to change table mappings in such cases.

To achieve consistency across multiple BI tools, create a universal semantic layer by using a data virtualization server that sits between BI tools and applications and Azure Synapse. In the data virtualization server, use common data names for high-level objects like dimensions, measures, hierarchies, and joins. That way you configure everything, including calculated fields, joins, and mappings, only once instead of in every tool. Then, point all BI tools at the data virtualization server.

> **TIP**
> Use data virtualization to create a common semantic layer to guarantee consistency across all BI tools in an Azure Synapse environment.

With data virtualization, you get consistency across all BI tools and break the dependency between BI tools and applications and the underlying physical data structures in Azure Synapse. Microsoft partners can help you achieve consistency in Azure. The following diagram shows how a common vocabulary in the data virtualization server lets multiple BI tools see a common semantic layer.



Conclusions

In a lift and shift data warehouse migration, most reports, dashboards, and other visualizations should migrate easily.

During a migration from a legacy environment, you might find that data in the legacy data warehouse or data mart tables is stored in unsupported data types. Or, you may find legacy data warehouse views that include proprietary SQL with no equivalent in Azure Synapse. If so, you'll need to resolve those issues to ensure a successful migration to Azure Synapse.

Don't rely on user-maintained documentation to identify where issues are located. Instead, use `EXPLAIN` statements because they're a quick, pragmatic way to identify SQL incompatibilities. Rework the incompatible SQL statements to achieve equivalent functionality in Azure Synapse. Also, use automated metadata discovery and lineage tools to understand dependencies, find duplicate reports, and identify invalid reports that rely on obsolete, questionable, or non-existent data sources. Use lineage tools to compare lineage to verify that reports running in your legacy data warehouse environment are produced identically in Azure Synapse.

Don't migrate reports that you no longer use. BI tool usage data can help you determine which reports aren't in use. For the reports, dashboards, and other visualizations that you do want to migrate, migrate all users, user groups, roles, and privileges. If you're using business value to drive your report migration strategy, associate reports with strategic business objectives and priorities to help identify the contribution of report insights to specific objectives. If you're migrating data mart by data mart, use metadata to identify which reports are dependent on which tables and views, so you can make an informed decision about which data marts to migrate first.

> **TIP**
> Identify incompatibilities early to gauge the extent of the migration effort. Migrate your users, group roles, and privilege assignments. Only migrate the reports and visualizations that are used and are contributing to business value.

Structural changes to the data model of your data warehouse or data mart can occur during a migration. Consider using data virtualization to shield BI tools and applications from structural changes. With data virtualization, you can use a common vocabulary to define a common semantic layer. The common semantic layer guarantees consistent common data names, definitions, metrics, hierarchies, and joins across all BI tools and applications in the new Azure Synapse environment.

Next steps

To learn more about minimizing SQL issues, see the next article in this series: Minimizing SQL issues for Teradata migrations.

Minimize SQL issues for Teradata migrations

8/19/2022 • 17 minutes to read • Edit Online

This article is part five of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for minimizing SQL issues.

Overview

Characteristics of Teradata environments

> **TIP**
> Teradata pioneered large scale SQL databases using MPP in the 1980s.

In 1984, Teradata initially released their database product. It introduced massively parallel processing (MPP) techniques to enable data processing at a scale more efficiently than the existing mainframe technologies available at the time. Since then, the product has evolved and has many installations among large financial institutions, telecommunications, and retail companies. The original implementation used proprietary hardware and was channel attached to mainframes—typically IBM or IBM-compatible processors.

While more recent announcements have included network connectivity and the availability of the Teradata technology stack in the cloud (including Azure), most existing installations are on premises, so many users are considering migrating some or all their Teradata data to Azure Synapse Analytics to gain the benefits of a move to a modern cloud environment.

> **TIP**
> Many existing Teradata installations are data warehouses using a dimensional data model.

Teradata technology is often used to implement a data warehouse, supporting complex analytic queries on large data volumes using SQL. Dimensional data models—star or snowflake schemas—are common, as is the implementation of data marts for individual departments.

This combination of SQL and dimensional data models simplifies migration to Azure Synapse, since the basic concepts and SQL skills are transferable. The recommended approach is to migrate the existing data model as-is to reduce risk and time taken. Even if the eventual intention is to make changes to the data model (for example, moving to a data vault model), perform an initial as-is migration and then make changes within the Azure cloud environment, leveraging the performance, elastic scalability, and cost advantages there.

While the SQL language has been standardized, individual vendors have in some cases implemented proprietary extensions. This document highlights potential SQL differences you may encounter while migrating from a legacy Teradata environment, and provides workarounds.

Use an Azure VM Teradata instance as part of a migration

> **TIP**
> Use an Azure VM to create a temporary Teradata instance to speed up migration and minimize impact on the source system.

Leverage the Azure environment when running a migration from an on-premises Teradata environment. Azure

provides affordable cloud storage and elastic scalability to create a Teradata instance within a VM in Azure, collocated with the target Azure Synapse environment.

With this approach, standard Teradata utilities such as Teradata Parallel Data Transporter (or third-party data replication tools such as Attunity Replicate) can be used to efficiently move the subset of Teradata tables that are to be migrated onto the VM instance, and then all migration tasks can take place within the Azure environment. This approach has several benefits:

- After the initial replication of data, the source system isn't impacted by the migration tasks.
- The familiar Teradata interfaces, tools, and utilities are available within the Azure environment.
- Once in the Azure environment there are no potential issues with network bandwidth availability between the on-premises source system and the cloud target system.
- Tools such as Azure Data Factory can efficiently call utilities such as Teradata Parallel Transporter to migrate data quickly and easily.
- The migration process is orchestrated and controlled entirely within the Azure environment.

Use Azure Data Factory to implement a metadata-driven migration

> **TIP**
> Automate the migration process by using Azure Data Factory capabilities.

Automate and orchestrate the migration process by making use of the capabilities in the Azure environment. This approach also minimizes the migration's impact on the existing Teradata environment, which may already be running close to full capacity.

Azure Data Factory is a cloud-based data integration service that allows creation of data-driven workflows in the cloud for orchestrating and automating data movement and data transformation. Using Data Factory, you can create and schedule data-driven workflows—called pipelines—that can ingest data from disparate data stores. It can process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

By creating metadata to list the data tables to be migrated and their location, you can use the Data Factory facilities to manage and automate parts of the migration process. You can also use Azure Synapse Pipelines.

SQL DDL differences between Teradata and Azure Synapse

SQL Data Definition Language (DDL)

> **TIP**
> SQL DDL commands `CREATE TABLE` and `CREATE VIEW` have standard core elements but are also used to define implementation-specific options.

The ANSI SQL standard defines the basic syntax for DDL commands such as `CREATE TABLE` and `CREATE VIEW`. These commands are used within both Teradata and Azure Synapse, but they've also been extended to allow definition of implementation-specific features such as indexing, table distribution, and partitioning options.

The following sections discuss Teradata-specific options to consider during a migration to Azure Synapse.

Table considerations

> **TIP**
> Use existing indexes to give an indication of candidates for indexing in the migrated warehouse.

When migrating tables between different technologies, only the raw data and its descriptive metadata get physically moved between the two environments. Other database elements from the source system, such as indexes and log files, aren't directly migrated as these may not be needed or may be implemented differently within the new target environment. For example, there's no equivalent of the `MULTISET` option within Teradata's `CREATE TABLE` syntax.

It's important to understand where performance optimizations—such as indexes—were used in the source environment. This indicates where performance optimization can be added in the new target environment. For example, if a non-unique secondary index (NUSI) has been created in the source Teradata environment, this might indicate that a non-clustered index should be created in the migrated Azure Synapse database. Other native performance optimization techniques, such as table replication, may be more applicable than a straight "like-for-like" index creation.

Unsupported Teradata table types

> **TIP**
> Standard tables within Azure Synapse can support migrated Teradata time-series and temporal tables.

Teradata includes support for special table types for time-series and temporal data. The syntax and some of the functions for these table types aren't directly supported within Azure Synapse, but the data can be migrated into a standard table with appropriate data types and indexing or partitioning on the date/time column.

Teradata implements the temporal query functionality via query rewriting to add additional filters within a temporal query to limit the applicable date range. If this functionality is currently in use within the source Teradata environment and is to be migrated, then this additional filtering will need to be added into the relevant temporal queries.

The Azure environment also includes specific features for complex analytics on time-series data at scale called time series insights—this is aimed at IoT data analysis applications and may be more appropriate for this use-case.

Unsupported Teradata data types

> **TIP**
> Assess the impact of unsupported data types as part of the preparation phase.

Most Teradata data types have a direct equivalent in Azure Synapse. The following table shows the Teradata data types that are unsupported in Azure Synapse together with the recommended mapping. In the table, Teradata column type is the type that's stored within the system catalog—for example, in `DBC.ColumnsV`.

TERADATA COLUMN TYPE	TERADATA DATA TYPE	AZURE SYNAPSE DATA TYPE
++	TD_ANYTYPE	Not supported in Azure Synapse
A1	ARRAY	Not supported in Azure Synapse
AN	ARRAY	Not supported in Azure Synapse

TERADATA COLUMN TYPE	TERADATA DATA TYPE	AZURE SYNAPSE DATA TYPE
AT	TIME	TIME
BF	BYTE	BINARY
BO	BLOB	BLOB data type isn't directly supported but can be replaced with BINARY.
BV	VARBYTE	BINARY
CF	VARCHAR	CHAR
CO	CLOB	CLOB data type isn't directly supported but can be replaced with VARCHAR.
CV	VARCHAR	VARCHAR
D	DECIMAL	DECIMAL
DA	DATE	DATE
DH	INTERVAL DAY TO HOUR	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
DM	INTERVAL DAY TO MINUTE	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
DS	INTERVAL DAY TO SECOND	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
DT	DATASET	DATASET data type is supported in Azure Synapse.
DY	INTERVAL DAY	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
F	FLOAT	FLOAT
HM	INTERVAL HOUR TO MINUTE	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).

TERADATA COLUMN TYPE	TERADATA DATA TYPE	AZURE SYNAPSE DATA TYPE
HR	INTERVAL HOUR	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
HS	INTERVAL HOUR TO SECOND	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
I1	BYTEINT	TINYINT
I2	SMALLINT	SMALLINT
I8	BIGINT	BIGINT
I	INTEGER	INT
JN	JSON	JSON data type isn't currently directly supported within Azure Synapse, but JSON data can be stored in a VARCHAR field.
MI	INTERVAL MINUTE	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
MO	INTERVAL MONTH	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
MS	INTERVAL MINUTE TO SECOND	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
N	NUMBER	NUMERIC
PD	PERIOD(DATE)	Can be converted to VARCHAR or split into two separate dates

TERADATA COLUMN TYPE	TERADATA DATA TYPE	AZURE SYNAPSE DATA TYPE
PM	PERIOD (TIMESTAMP WITH TIME ZONE)	Can be converted to VARCHAR or split into two separate timestamps (DATETIMEOFFSET)
PS	PERIOD(TIMESTAMP)	Can be converted to VARCHAR or split into two separate timestamps (DATETIMEOFFSET)
PT	PERIOD(TIME)	Can be converted to VARCHAR or split into two separate times
PZ	PERIOD (TIME WITH TIME ZONE)	Can be converted to VARCHAR or split into two separate times but WITH TIME ZONE isn't supported for TIME
SC	INTERVAL SECOND	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
SZ	TIMESTAMP WITH TIME ZONE	DATETIMEOFFSET
TS	TIMESTAMP	DATETIME or DATETIME2
TZ	TIME WITH TIME ZONE	TIME WITH TIME ZONE isn't supported because TIME is stored using "wall clock" time only without a time zone offset.
XM	XML	XML data type isn't currently directly supported within Azure Synapse, but XML data can be stored in a VARCHAR field.
YM	INTERVAL YEAR TO MONTH	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).
YR	INTERVAL YEAR	INTERVAL data types aren't supported in Azure Synapse, but date calculations can be done with the date comparison functions (for example, DATEDIFF and DATEADD).

Use the metadata from the Teradata catalog tables to determine whether any of these data types are to be migrated and allow for this in the migration plan. For example, use a SQL query like this one to find any occurrences of unsupported data types that need attention.

```
SELECT
ColumnType, CASE
WHEN ColumnType = '++' THEN 'TD_ANYTYPE'
WHEN ColumnType = 'A1' THEN 'ARRAY' WHEN
ColumnType = 'AN' THEN 'ARRAY' WHEN
ColumnType = 'BO' THEN 'BLOB'
WHEN ColumnType = 'CO' THEN 'CLOB'
WHEN ColumnType = 'DH' THEN 'INTERVAL DAY TO HOUR' WHEN
ColumnType = 'DM' THEN 'INTERVAL DAY TO MINUTE' WHEN
ColumnType = 'DS' THEN 'INTERVAL DAY TO SECOND' WHEN
ColumnType = 'DT' THEN 'DATASET'
WHEN ColumnType = 'DY' THEN 'INTERVAL DAY'
WHEN ColumnType = 'HM' THEN 'INTERVAL HOUR TO MINUTE' WHEN
ColumnType = 'HR' THEN 'INTERVAL HOUR'
WHEN ColumnType = 'HS' THEN 'INTERVAL HOUR TO SECOND' WHEN
ColumnType = 'JN' THEN 'JSON'
WHEN ColumnType = 'MI' THEN 'INTERVAL MINUTE' WHEN
ColumnType = 'MO' THEN 'INTERVAL MONTH'
WHEN ColumnType = 'MS' THEN 'INTERVAL MINUTE TO SECOND' WHEN
ColumnType = 'PD' THEN 'PERIOD(DATE)'
WHEN ColumnType = 'PM' THEN 'PERIOD (TIMESTAMP WITH TIME ZONE)'
WHEN ColumnType = 'PS' THEN 'PERIOD(TIMESTAMP)' WHEN
ColumnType = 'PT' THEN 'PERIOD(TIME)'
WHEN ColumnType = 'PZ' THEN 'PERIOD (TIME WITH TIME ZONE)' WHEN
ColumnType = 'SC' THEN 'INTERVAL SECOND'
WHEN ColumnType = 'SZ' THEN 'TIMESTAMP WITH TIME ZONE' WHEN
ColumnType = 'XM' THEN 'XML'
WHEN ColumnType = 'YM' THEN 'INTERVAL YEAR TO MONTH' WHEN
ColumnType = 'YR' THEN 'INTERVAL YEAR'
END AS Data_Type,
COUNT (*) AS Data_Type_Count FROM
DBC.ColumnsV
WHERE DatabaseName IN ('UserDB1', 'UserDB2', 'UserDB3') -- select databases to be migrated
GROUP BY 1,2
ORDER BY 1;
```

TIP

Third-party tools and services can automate data mapping tasks.

There are third-party vendors who offer tools and services to automate migration, including the mapping of data types. If a third-party ETL tool such as Informatica or Talend is already in use in the Teradata environment, those tools can implement any required data transformations.

Data Definition Language (DDL) generation

TIP

Use existing Teradata metadata to automate the generation of `CREATE TABLE` and `CREATE VIEW DDL` for Azure Synapse.

Edit existing Teradata `CREATE TABLE` and `CREATE VIEW` scripts to create the equivalent definitions with modified data types as described previously if necessary. Typically, this involves removing extra Teradata-specific clauses such as `FALLBACK` or `MULTISET`.

However, all the information that specifies the current definitions of tables and views within the existing Teradata environment is maintained within system catalog tables. This is the best source of this information as it's guaranteed to be up to date and complete. Be aware that user-maintained documentation may not be in sync with the current table definitions.

Access this information via views onto the catalog such as `DBC.ColumnsV` and generate the equivalent

`CREATE TABLE` DDL statements for the equivalent tables in Azure Synapse.

> **TIP**
> Third-party tools and services can automate data mapping tasks.

There are Microsoft partners who offer tools and services to automate migration, including data-type mapping. Also, if a third-party ETL tool such as Informatica or Talend is already in use in the Teradata environment, that tool can implement any required data transformations.

SQL DML differences between Teradata and Azure Synapse

SQL Data Manipulation Language (DML)

> **TIP**
> SQL DML commands `SELECT`, `INSERT`, and `UPDATE` have standard core elements but may also implement different syntax options.

The ANSI SQL standard defines the basic syntax for DML commands such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Both Teradata and Azure Synapse use these commands, but in some cases there are implementation differences.

The following sections discuss the Teradata-specific DML commands that you should consider during a migration to Azure Synapse.

SQL DML syntax differences

Be aware of these differences in SQL Data Manipulation Language (DML) syntax between Teradata SQL and Azure Synapse (T-SQL) when migrating:

- `QUALIFY`: Teradata supports the `QUALIFY` operator. For example:

  ```
  SELECT col1
  FROM tab1
  WHERE col1='XYZ'
  QUALIFY ROW_NUMBER () OVER (PARTITION by
  col1 ORDER BY col1) = 1;
  ```

  The equivalent Azure Synapse syntax is:

  ```
  SELECT * FROM (
  SELECT col1, ROW_NUMBER () OVER (PARTITION by col1 ORDER BY col1) rn
  FROM tab1 WHERE col1='XYZ'
  ) WHERE rn = 1;
  ```

- Date arithmetic: Azure Synapse has operators such as `DATEADD` and `DATEDIFF` which can be used on `DATE` or `DATETIME` fields. Teradata supports direct subtraction on dates such as `SELECT DATE1 - DATE2 FROM...`
- In `GROUP BY` ordinal, explicitly provide the T-SQL column name.
- `LIKE ANY`: Teradata supports `LIKE ANY` syntax such as:

```
SELECT * FROM CUSTOMER
WHERE POSTCODE LIKE ANY
('CV1%', 'CV2%', 'CV3%');
```

The equivalent in Azure Synapse syntax is:

```
SELECT * FROM CUSTOMER
WHERE
(POSTCODE LIKE 'CV1%') OR (POSTCODE LIKE 'CV2%') OR (POSTCODE LIKE 'CV3%');
```

- Depending on system settings, character comparisons in Teradata may be case insensitive by default. In Azure Synapse, character comparisons are always case sensitive.

Use EXPLAIN to validate legacy SQL

> **TIP**
> Use real queries from the existing system query logs to find potential migration issues.

One way of testing legacy Teradata SQL for compatibility with Azure Synapse is to capture some representative SQL statements from the legacy system query logs, prefix those queries with EXPLAIN, and (assuming a "like-for-like" migrated data model in Azure Synapse with the same table and column names) run those `EXPLAIN` statements in Azure Synapse. Any incompatible SQL will throw an error—use this information to determine the scale of the recoding task. This approach doesn't require that data is loaded into the Azure environment, only that the relevant tables and views have been created.

Functions, stored procedures, triggers, and sequences

> **TIP**
> As part of the preparation phase, assess the number and type of non-data objects being migrated.

When migrating from a mature legacy data warehouse environment such as Teradata, there are often elements other than simple tables and views that need to be migrated to the new target environment. Examples of this include functions, stored procedures, triggers, and sequences.

As part of the preparation phase, create an inventory of the objects that need to be migrated and define the methods for handling them. Then assign an appropriate allocation of resources in the project plan.

There may be facilities in the Azure environment that replace the functionality implemented as either functions or stored procedures in the Teradata environment. In this case, it's often more efficient to use the built-in Azure facilities rather than recoding the Teradata functions.

> **TIP**
> Third-party products and services can automate migration of non-data elements.

Microsoft partners offer tools and services that can automate the migration.

See the following sections for more information on each of these elements.

Functions

As with most database products, Teradata supports system functions and user-defined functions within the SQL implementation. When migrating to another database platform such as Azure Synapse, common system functions are available and can be migrated without change. Some system functions may have slightly different

syntax, but the required changes can be automated. System functions where there's no equivalent, such as arbitrary user-defined functions, may need to be recoded using the languages available in the target environment. Azure Synapse uses the popular Transact-SQL language to implement user-defined functions.

Stored procedures

Most modern database products allow for procedures to be stored within the database. Teradata provides the SPL language for this purpose. A stored procedure typically contains SQL statements and some procedural logic, and may return data or a status.

The dedicated SQL pools of Azure Synapse Analytics also support stored procedures using T-SQL, so if you must migrate stored procedures, recode them accordingly.

Triggers

Azure Synapse doesn't support the creation of triggers, but you can implement them within Azure Data Factory.

Sequences

Azure Synapse sequences are handled in a similar way to Teradata, using IDENTITY to create surrogate keys or managed identity.

Teradata to T-SQL mapping

This table shows the Teradata to T-SQL compliant with Azure Synapse SQL data type mapping:

TERADATA DATA TYPE	AZURE SYNAPSE SQL DATA TYPE
bigint	bigint
bool	bit
boolean	bit
byteint	tinyint
char [(*p*)]	char [(*p*)]
char varying [(*p*)]	varchar [(*p*)]
character [(*p*)]	char [(*p*)]
character varying [(*p*)]	varchar [(*p*)]
date	date
datetime	datetime
dec [(*p*[,*s*])]	decimal [(*p*[,*s*])]
decimal [(*p*[,*s*])]	decimal [(*p*[,*s*])]
double	float(53)
double precision	float(53)
float [(*p*)]	float [(*p*)]
float4	float(53)

TERADATA DATA TYPE	AZURE SYNAPSE SQL DATA TYPE
float8	float(53)
int	int
int1	tinyint
int2	smallint
int4	int
int8	bigint
integer	integer
interval	*Not supported*
national char varying [(*p*)]	nvarchar [(*p*)]
national character [(*p*)]	nchar [(*p*)]
national character varying [(*p*)]	nvarchar [(*p*)]
nchar [(*p*)]	nchar [(*p*)]
numeric [(*p*[,*s*])]	numeric [(*p*[,*s*])
nvarchar [(*p*)]	nvarchar [(*p*)]
real	real
smallint	smallint
time	time
time with time zone	datetimeoffset
time without time zone	time
timespan	*Not supported*
timestamp	datetime2
timetz	datetimeoffset
varchar [(*p*)]	varchar [(*p*)]

Summary

Typical existing legacy Teradata installations are implemented in a way that makes migration to Azure Synapse easy. They use SQL for analytical queries on large data volumes, and are in some form of dimensional data

model. These factors make them good candidates for migration to Azure Synapse.

To minimize the task of migrating the actual SQL code, follow these recommendations:

- Initial migration of the data warehouse should be as-is to minimize risk and time taken, even if the eventual final environment will incorporate a different data model such as data vault.
- Consider using a Teradata instance in an Azure VM as a stepping stone as part of the migration process.
- Understand the differences between Teradata SQL implementation and Azure Synapse.
- Use metadata and query logs from the existing Teradata implementation to assess the impact of the differences and plan an approach to mitigate.
- Automate the process wherever possible to minimize errors, risk, and time for the migration.
- Consider using specialist Microsoft partners and services to streamline the migration.

Next steps

To learn more about Microsoft and third-party tools, see the next article in this series: Tools for Teradata data warehouse migration to Azure Synapse Analytics.

Tools for Teradata data warehouse migration to Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

This article is part six of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for Microsoft and third-party tools.

Data warehouse migration tools

By migrating your existing data warehouse to Azure Synapse, you benefit from:

- A globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database.
- The rich Microsoft analytical ecosystem that exists on Azure. This ecosystem consists of technologies to help modernize your data warehouse once it's migrated and extend your analytical capabilities to drive new value.

Several tools from both Microsoft and third-party partners can help you migrate your existing data warehouse to Azure Synapse. This article discusses the following types of tools:

- Microsoft data and database migration tools.
- Third-party data warehouse automation tools to automate and document the migration to Azure Synapse.
- Third-party data warehouse migration tools to migrate schema and data to Azure Synapse.
- Third-party tools to bridge the SQL differences between your existing data warehouse DBMS and Azure Synapse.

Microsoft data migration tools

Microsoft offers several tools to help you migrate your existing data warehouse to Azure Synapse, such as:

- Azure Data Factory.
- Microsoft services for physical data transfer.
- Microsoft services for data ingestion.

The next sections discuss these tools in more detail.

Microsoft Azure Data Factory

Data Factory is a fully managed, pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. It uses Apache Spark to process and analyze data in parallel and in-memory to maximize throughput.

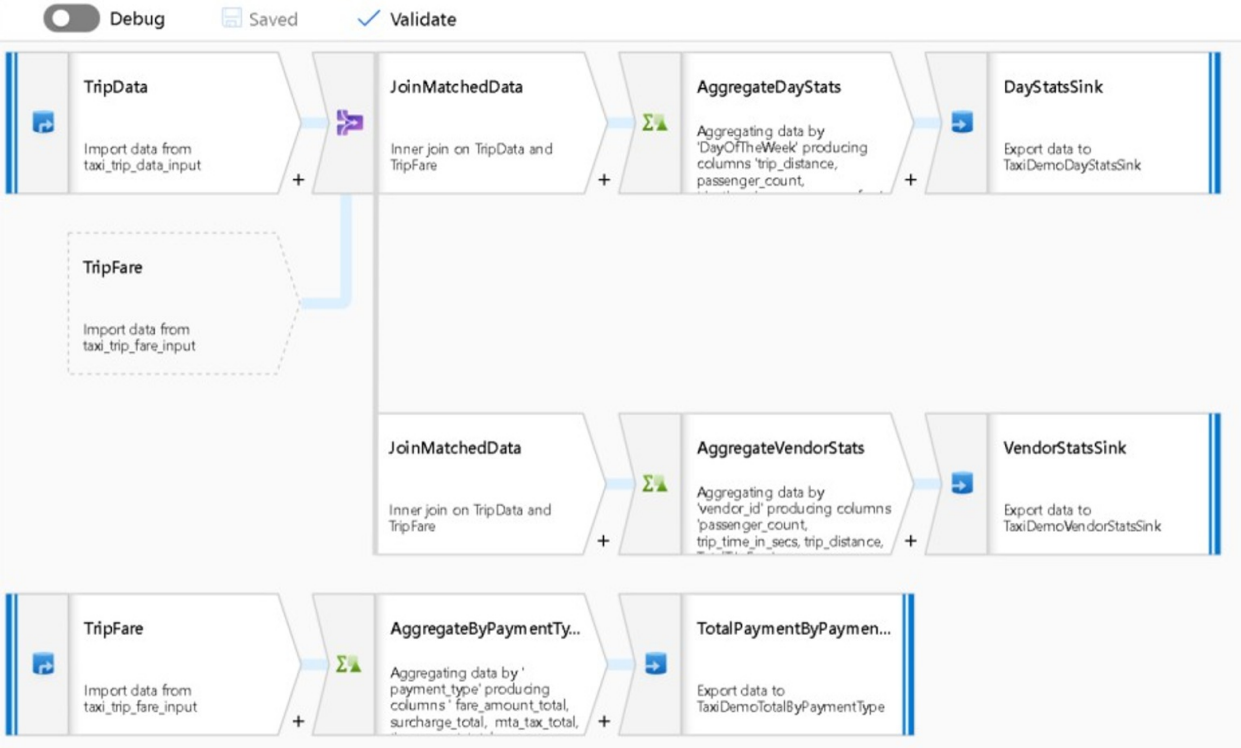
> **TIP**
> Data Factory allows you to build scalable data integration pipelines code-free.

Data Factory connectors support connections to external data sources and databases and include templates for common data integration tasks. A visual front-end, browser-based UI enables non-programmers to create and

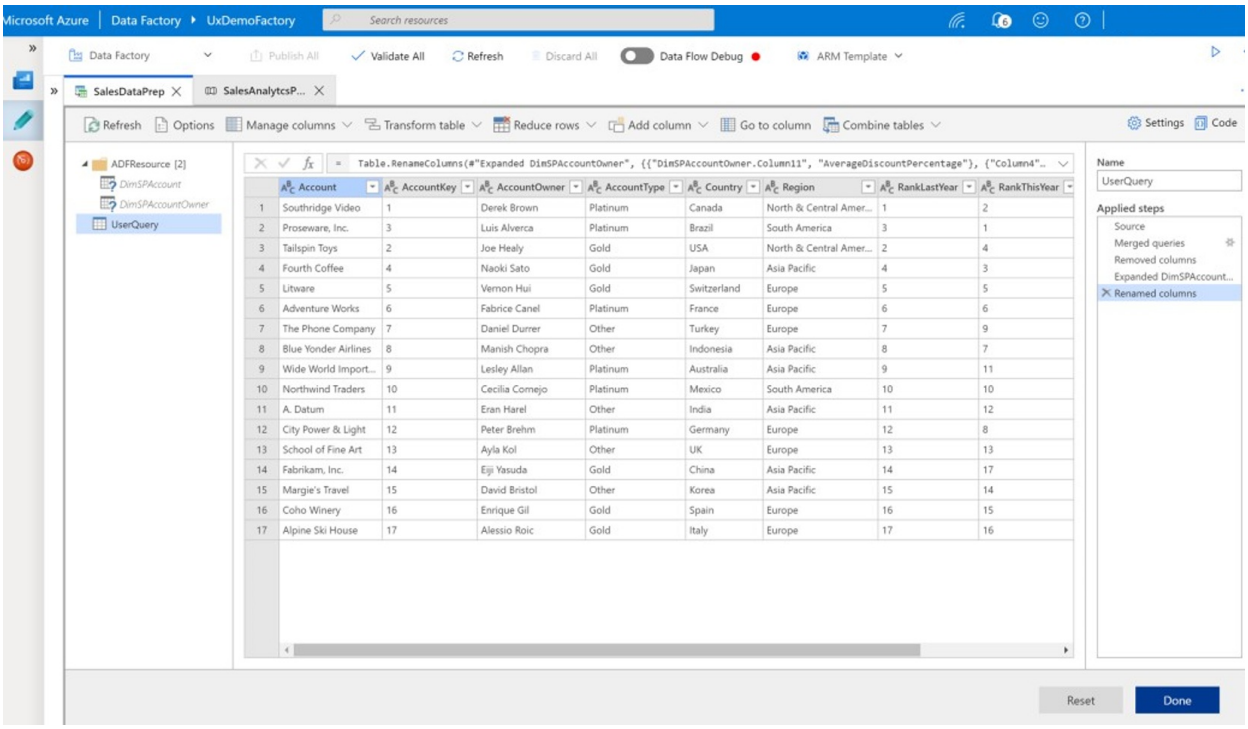
run pipelines to ingest, transform, and load data. More experienced programmers can incorporate custom code, such as Python programs.

> **TIP**
> Data Factory enables collaborative development between business and IT professionals.

Data Factory is also an orchestration tool and is the best Microsoft tool to automate the end-to-end migration process. Automation reduces the risk, effort, and time to migrate, and makes the migration process easily repeatable. The following diagram shows a mapping data flow in Data Factory.



The next screenshot shows a wrangling data flow in Data Factory.



In Data Factory, you can develop simple or comprehensive ETL and ELT processes without coding or

maintenance with just a few clicks. ETL/ELT processes ingest, move, prepare, transform, and process your data. You can design and manage scheduling and triggers in Data Factory to build an automated data integration and loading environment. In Data Factory, you can define, manage, and schedule PolyBase bulk data load processes.

> **TIP**
> Data Factory includes tools to help migrate both your data and your entire data warehouse to Azure.

You can use Data Factory to implement and manage a hybrid environment with on-premises, cloud, streaming, and SaaS data in a secure and consistent way. SaaS data might come from applications such as Salesforce.

Wrangling data flows is a new capability in Data Factory. This capability opens up Data Factory to business users who want to visually discover, explore, and prepare data at scale without writing code. Wrangling data flows offer self-service data preparation, similar to Microsoft Excel, Power Query, and Microsoft Power BI dataflows. Business users can prepare and integrate data through a spreadsheet-style UI with drop-down transform options.

Data Factory is the recommended approach for implementing data integration and ETL/ELT processes in the Azure Synapse environment, especially if you want to refactor existing legacy processes.

Microsoft services for physical data transfer

The following sections discuss a range of products and services that Microsoft offers to assist customers with data transfer.

Azure ExpressRoute

Azure ExpressRoute creates private connections between Azure data centers and infrastructure on your premises or in a collocation environment. ExpressRoute connections don't go over the public internet, and offer more reliability, faster speeds, and lower latencies than typical internet connections. In some cases, you gain significant cost benefits by using ExpressRoute connections to transfer data between on-premises systems and Azure.

AzCopy

AzCopy is a command line utility that copies files to Azure Blob Storage over a standard internet connection. In a warehouse migration project, you can use AzCopy to upload extracted, compressed, delimited text files before loading them into Azure Synapse using PolyBase. AzCopy can upload individual files, file selections, or file folders. If the exported files are in Parquet format, use a native Parquet reader instead.

Azure Data Box

Azure Data Box is a Microsoft service that provides you with a proprietary physical storage device that you can copy migration data onto. You then ship the device to an Azure data center for data upload to cloud storage. This service can be cost-effective for large volumes of data, such as tens or hundreds of terabytes, or where network bandwidth isn't readily available. Azure Data Box is typically used for a large one-off historical data load into Azure Synapse.

Azure Data Box Gateway

Azure Data Box Gateway is a virtualized cloud storage gateway device that resides on your premises and sends your images, media, and other data to Azure. Use Data Box Gateway for one-off migration tasks or ongoing incremental data uploads.

Microsoft services for data ingestion

The following sections discuss the products and services that Microsoft offers to assist customers with data ingestion.

COPY INTO

The COPY INTO statement provides the most flexibility for high-throughput data ingestion into Azure Synapse. For more information about `COPY INTO` capabilities, see COPY (Transact-SQL).

PolyBase

PolyBase is the fastest, most scalable method for bulk data load into Azure Synapse. PolyBase uses the massively parallel processing (MPP) architecture of Azure Synapse for parallel loading of data to achieve the fastest throughput. PolyBase can read data from flat files in Azure Blob Storage, or directly from external data sources and other relational databases via connectors.

> **TIP**
> PolyBase can load data in parallel from Azure Blob Storage into Azure Synapse.

PolyBase can also directly read from files compressed with gzip to reduce the physical volume of data during a load process. PolyBase supports popular data formats such as delimited text, ORC, and Parquet.

> **TIP**
> You can invoke PolyBase from Data Factory as part of a migration pipeline.

PolyBase is tightly integrated with Data Factory to support rapid development of data load ETL/ELT processes. You can schedule data load processes through a visual UI for higher productivity and fewer errors than hand-written code. Microsoft recommends PolyBase for data ingestion into Azure Synapse, especially for high-volume data ingestion.

PolyBase uses `CREATE TABLE AS` or `INSERT...SELECT` statements to load data. `CREATE TABLE AS` minimizes logging to achieve the highest throughput. The most efficient input format for data load is compressed delimited text files. For maximum throughput, split large input files into multiple smaller files and load them in parallel. For fastest loading to a staging table, define the target table as `HEAP` type and use round-robin distribution.

PolyBase has some limitations, it requires data row length to be less than 1 megabyte and doesn't support fixed-width nested formats like JSON and XML.

Microsoft partners for Teradata migrations

Microsoft partners offer tools, services, and expertise to help you migrate your legacy on-premises data warehouse platform to Azure Synapse.

Next steps

To learn more about implementing modern data warehouses, see the next article in this series: Beyond Teradata migration, implement a modern data warehouse in Microsoft Azure.

Beyond Teradata migration, implement a modern data warehouse in Microsoft Azure

8/19/2022 • 23 minutes to read • Edit Online

This article is part seven of a seven-part series that provides guidance on how to migrate from Teradata to Azure Synapse Analytics. The focus of this article is best practices for implementing modern data warehouses.

Beyond data warehouse migration to Azure

A key reason to migrate your existing data warehouse to Azure Synapse Analytics is to utilize a globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database. With Azure Synapse, you can integrate your migrated data warehouse with the complete Microsoft Azure analytical ecosystem to take advantage of other Microsoft technologies and modernize your migrated data warehouse. Those technologies include:

- Azure Data Lake Storage for cost effective data ingestion, staging, cleansing, and transformation. Data Lake Storage can free up the data warehouse capacity occupied by fast-growing staging tables.
- Azure Data Factory for collaborative IT and self-service data integration with connectors to cloud and on-premises data sources and streaming data.
- Common Data Model to share consistent trusted data across multiple technologies, including:
  - Azure Synapse
  - Azure Synapse Spark
  - Azure HDInsight
  - Power BI
  - Adobe Customer Experience Platform
  - Azure IoT
  - Microsoft ISV partners
- Microsoft data science technologies, including:
  - Azure Machine Learning studio
  - Azure Machine Learning
  - Azure Synapse Spark (Spark as a service)
  - Jupyter Notebooks
  - RStudio
  - ML.NET
  - .NET for Apache Spark, which lets data scientists use Azure Synapse data to train machine learning models at scale.
- Azure HDInsight to process large amounts of data, and to join big data with Azure Synapse data by creating a logical data warehouse using PolyBase.
- Azure Event Hubs, Azure Stream Analytics, and Apache Kafka to integrate live streaming data from Azure Synapse.

The growth of big data has led to an acute demand for machine learning to enable custom-built, trained machine learning models for use in Azure Synapse. Machine learning models enable in-database analytics to run at scale in batch, on an event-driven basis and on-demand. The ability to take advantage of in-database analytics in Azure Synapse from multiple BI tools and applications also guarantees consistent predictions and

recommendations.

In addition, you can integrate Azure Synapse with Microsoft partner tools on Azure to shorten time to value.

Let's take a closer look at how you can take advantage of technologies in the Microsoft analytical ecosystem to modernize your data warehouse after you've migrated to Azure Synapse.

Offload data staging and ETL processing to Data Lake Storage and Data Factory

Digital transformation has created a key challenge for enterprises by generating a torrent of new data for capture and analysis. A good example is transaction data created by opening online transactional processing (OLTP) systems to service access from mobile devices. Much of this data finds its way into data warehouses, and OLTP systems are the main source. With customers now driving the transaction rate rather than employees, the volume of data in data warehouse staging tables has been growing rapidly.

With the rapid influx of data into the enterprise, along with new sources of data like Internet of Things (IoT), companies must find ways to scale up data integration ETL processing. One method is to offload ingestion, data cleansing, transformation, and integration to a data lake and process data at scale there, as part of a data warehouse modernization program.

Once you've migrated your data warehouse to Azure Synapse, Microsoft can modernize your ETL processing by ingesting and staging data in Data Lake Storage. You can then clean, transform, and integrate your data at scale using Data Factory before loading it into Azure Synapse in parallel using PolyBase.

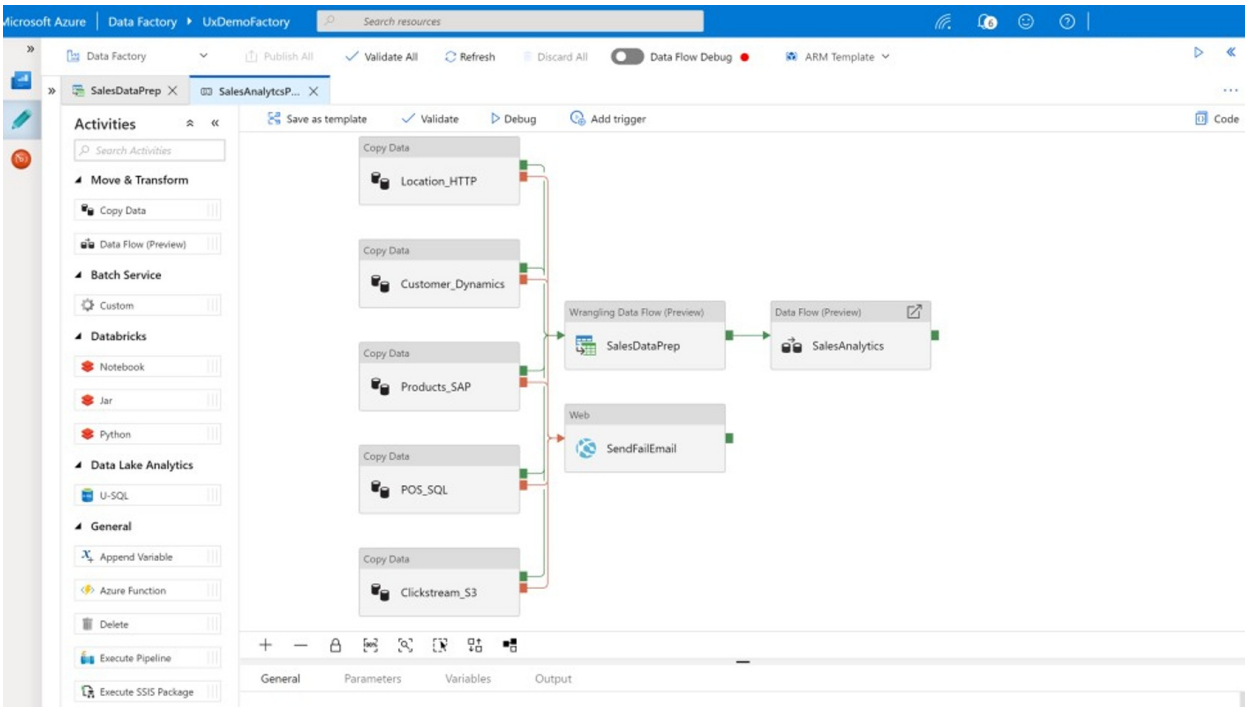
For ELT strategies, consider offloading ELT processing to Data Lake Storage to easily scale as your data volume or frequency grows.

Microsoft Azure Data Factory

Azure Data Factory is a pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. Data Factory provides a web-based UI to build data integration pipelines with no code. With Data Factory, you can:

- Build scalable data integration pipelines code-free.
- Easily acquire data at scale.
- Pay only for what you use.
- Connect to on-premises, cloud, and SaaS-based data sources.
- Ingest, move, clean, transform, integrate, and analyze cloud and on-premises data at scale.
- Seamlessly author, monitor, and manage pipelines that span data stores both on-premises and in the cloud.
- Enable pay-as-you-go scale-out in alignment with customer growth.

You can use these features without writing any code, or you can add custom code to Data Factory pipelines. The following screenshot shows an example Data Factory pipeline.



TIP

Data Factory lets you to build scalable data integration pipelines without code.

Implement Data Factory pipeline development from any of several places, including:

- Microsoft Azure portal.
- Microsoft Azure PowerShell.
- Programmatically from .NET and Python using a multi-language SDK.
- Azure Resource Manager (ARM) templates.
- REST APIs.

TIP

Data Factory can connect to on-premises, cloud, and SaaS data.

Developers and data scientists who prefer to write code can easily author Data Factory pipelines in Java, Python, and .NET using the software development kits (SDKs) available for those programming languages. Data Factory pipelines can be hybrid data pipelines because they can connect, ingest, clean, transform, and analyze data in on-premises data centers, Microsoft Azure, other clouds, and SaaS offerings.

After you develop Data Factory pipelines to integrate and analyze data, you can deploy those pipelines globally and schedule them to run in batch, invoke them on demand as a service, or run them in real-time on an event-driven basis. A Data Factory pipeline can also run on one or more execution engines and monitor execution to ensure performance and to track errors.

TIP

In Azure Data Factory, pipelines control the integration and analysis of data. Data Factory is enterprise-class data integration software aimed at IT professionals and has data wrangling capability for business users.

Use cases

Data Factory supports multiple use cases, such as:

- Prepare, integrate, and enrich data from cloud and on-premises data sources to populate your migrated data warehouse and data marts on Microsoft Azure Synapse.
- Prepare, integrate, and enrich data from cloud and on-premises data sources to produce training data for use in machine learning model development and in retraining analytical models.
- Orchestrate data preparation and analytics to create predictive and prescriptive analytical pipelines for processing and analyzing data in batch, such as sentiment analytics. Either act on the results of the analysis or populate your data warehouse with the results.
- Prepare, integrate, and enrich data for data-driven business applications running on the Azure cloud on top of operational data stores such as Azure Cosmos DB.

> **TIP**
> Build training data sets in data science to develop machine learning models.

Data sources

Data Factory lets you use connectors from both cloud and on-premises data sources. Agent software, known as a *self-hosted integration runtime*, securely accesses on-premises data sources and supports secure, scalable data transfer.

Transform data using Azure Data Factory

Within a Data Factory pipeline, you can ingest, clean, transform, integrate, and analyze any type of data from these sources. Data can be structured, semi-structured like JSON or Avro, or unstructured.

Without writing any code, professional ETL developers can use Data Factory mapping data flows to filter, split, join several types, lookup, pivot, unpivot, sort, union, and aggregate data. In addition, Data Factory supports surrogate keys, multiple write processing options like insert, upsert, update, table recreation, and table truncation, and several types of target data stores—also known as sinks. ETL developers can also create aggregations, including time-series aggregations that require a window to be placed on data columns.

> **TIP**
> Professional ETL developers can use Data Factory mapping data flows to clean, transform, and integrate data without the need to write code.

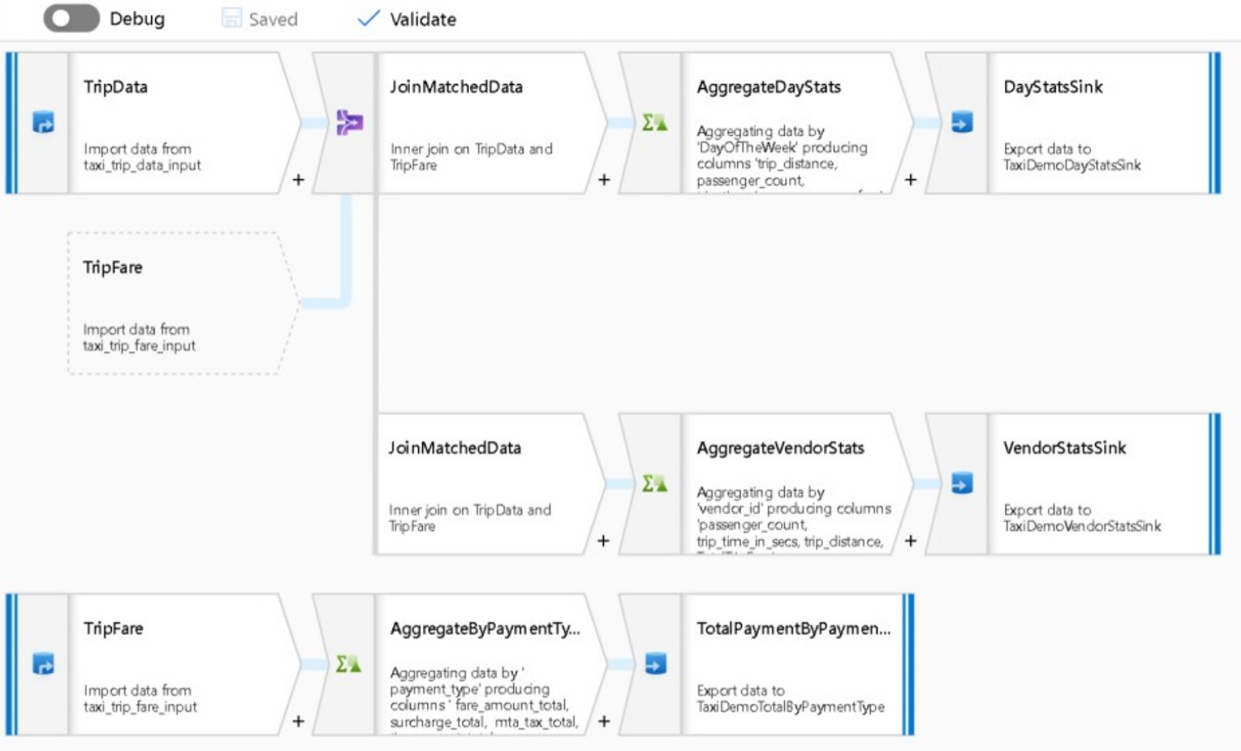
You can run mapping data flows that transform data as activities in a Data Factory pipeline, and if necessary, you can include multiple mapping data flows in a single pipeline. In this way, you can manage the complexity by breaking up challenging data transformation and integration tasks into smaller mapping dataflows that can be combined. And, you can add custom code when needed. In addition to this functionality, Data Factory mapping data flows include the ability to:

- Define expressions to clean and transform data, compute aggregations, and enrich data. For example, these expressions can perform feature engineering on a date field to break it into multiple fields to create training data during machine learning model development. You can construct expressions from a rich set of functions that include mathematical, temporal, split, merge, string concatenation, conditions, pattern match, replace, and many other functions.
- Automatically handle schema drift so that data transformation pipelines can avoid being impacted by schema changes in data sources. This ability is especially important for streaming IoT data, where schema changes can happen without notice if devices are upgraded or when readings are missed by gateway devices collecting IoT data.

- Partition data to enable transformations to run in parallel at scale.
- Inspect streaming data to view the metadata of a stream you're transforming.

> **TIP**
> Data Factory supports the ability to automatically detect and manage schema changes in inbound data, such as in streaming data.

The following screenshot shows an example Data Factory mapping data flow.



Data engineers can profile data quality and view the results of individual data transforms by enabling debug capability during development.

> **TIP**
> Data Factory can also partition data to enable ETL processing to run at scale.

If necessary, you can extend Data Factory transformational and analytical functionality by adding a linked service that contains your code into a pipeline. For example, an Azure Synapse Spark pool notebook might contain Python code that uses a trained model to score the data integrated by a mapping data flow.

You can store integrated data and any results from analytics within a Data Factory pipeline in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

> **TIP**
> Data Factory pipelines are extensible because Data Factory lets you write your own code and run it as part of a pipeline.

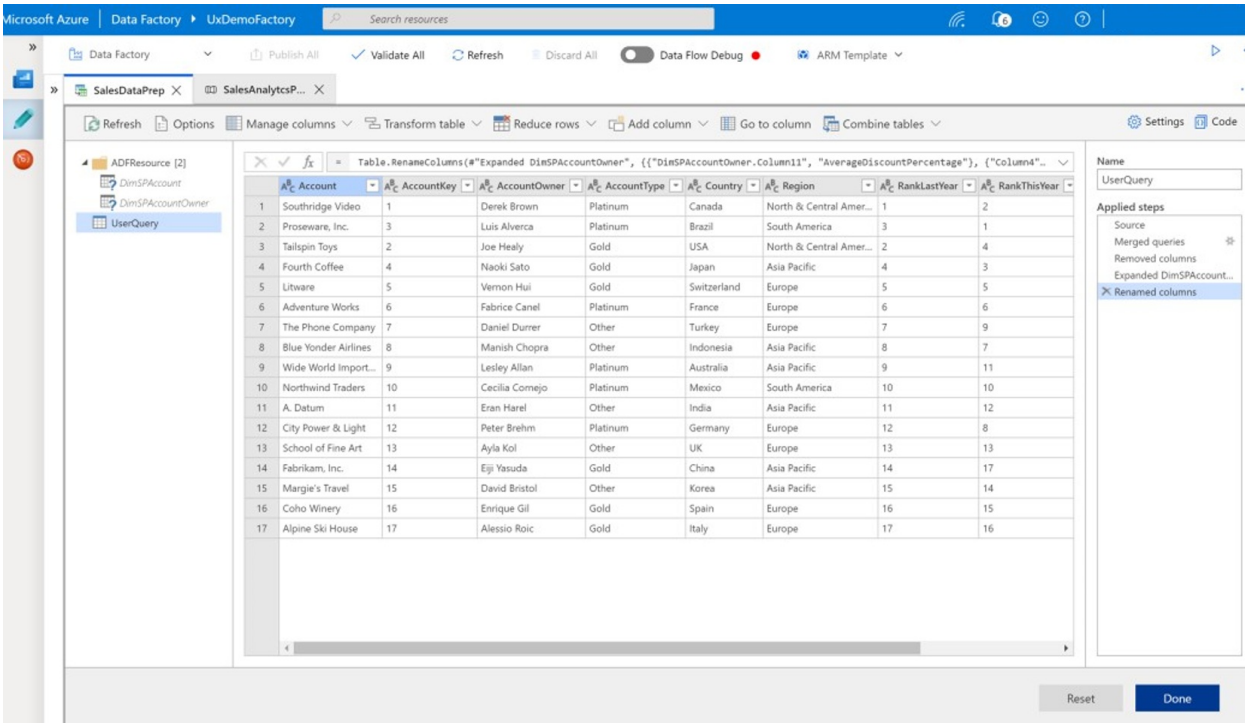
Utilize Spark to scale data integration

At run time, Data Factory internally uses Azure Synapse Spark pools, which are Microsoft's Spark as a service offering, to clean and integrate data in the Azure cloud. You can clean, integrate, and analyze high-volume, high-

velocity data, such as click-stream data, at scale. Microsoft's intention is to also run Data Factory pipelines on other Spark distributions. In addition to running ETL jobs on Spark, Data Factory can invoke Pig scripts and Hive queries to access and transform data stored in HDInsight.

Link self-service data prep and Data Factory ETL processing using wrangling data flows

Data wrangling lets business users, also known as citizen data integrators and data engineers, make use of the platform to visually discover, explore, and prepare data at scale without writing code. This Data Factory capability is easy to use and is similar to Microsoft Excel Power Query or Microsoft Power BI dataflows, where self-service business users use a spreadsheet-style UI with drop-down transforms to prepare and integrate data. The following screenshot shows an example Data Factory wrangling data flow.



Unlike Excel and Power BI, Data Factory wrangling data flows use Power Query to generate M code and then translate it into a massively parallel in-memory Spark job for cloud-scale execution. The combination of mapping data flows and wrangling data flows in Data Factory lets professional ETL developers and business users collaborate to prepare, integrate, and analyze data for a common business purpose. The preceding Data Factory mapping data flows diagram shows how both Data Factory and Azure Synapse Spark pool notebooks can be combined in the same Data Factory pipeline. The combination of mapping and wrangling data flows in Data Factory helps IT and business users stay aware of what data flows each has created, and supports data flow reuse to minimize reinvention and maximize productivity and consistency.

> **TIP**
>
> Data Factory supports both wrangling data flows and mapping data flows, so business users and IT users can integrate data collaboratively on a common platform.

Link data and analytics in analytical pipelines

In addition to cleaning and transforming data, Data Factory can combine data integration and analytics in the same pipeline. You can use Data Factory to create both data integration and analytical pipelines, the latter being an extension of the former. You can drop an analytical model into a pipeline to create an analytical pipeline that generates clean, integrated data for predictions or recommendations. Then, you can act on the predictions or recommendations immediately, or store them in your data warehouse to provide new insights and recommendations that can be viewed in BI tools.

To batch score your data, you can develop an analytical model that you invoke as a service within a Data Factory pipeline. You can develop analytical models code-free with Azure Machine Learning studio, or with the Azure

Machine Learning SDK using Azure Synapse Spark pool notebooks or R in RStudio. When you run Spark machine learning pipelines on Azure Synapse Spark pool notebooks, analysis happens at scale.

You can store integrated data and any Data Factory analytical pipeline results in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

Use a lake database to share consistent trusted data

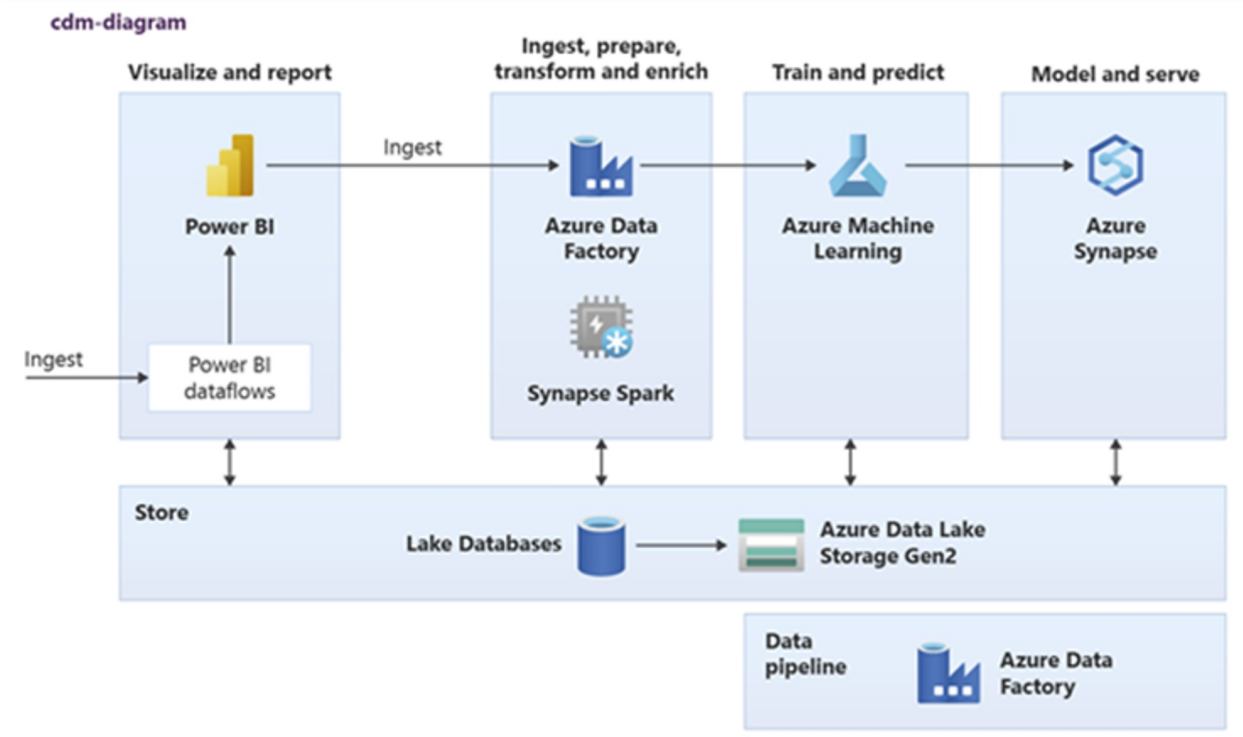
A key objective of any data integration setup is the ability to integrate data once and reuse it everywhere, not just in a data warehouse. For example, you might want to use integrated data in data science. Reuse avoids reinvention and ensures consistent, commonly understood data that everyone can trust.

Common Data Model describes core data entities that can be shared and reused across the enterprise. To achieve reuse, Common Data Model establishes a set of common data names and definitions that describe logical data entities. Examples of common data names include Customer, Account, Product, Supplier, Orders, Payments, and Returns. IT and business professionals can use data integration software to create and store common data assets to maximize their reuse and drive consistency everywhere.

Azure Synapse provides industry-specific database templates to help standardize data in the lake. Lake database templates provide schemas for predefined business areas, enabling data to be loaded into a lake database in a structured way. The power comes when you use data integration software to create lake database common data assets, resulting in self-describing trusted data that can be consumed by applications and analytical systems. You can create common data assets in Data Lake Storage by using Data Factory.

> **TIP**
> Data Lake Storage is shared storage that underpins Microsoft Azure Synapse, Azure Machine Learning, Azure Synapse Spark, and HDInsight.

Power BI, Azure Synapse Spark, Azure Synapse, and Azure Machine Learning can consume common data assets. The following diagram shows how a lake database can be used in Azure Synapse.



> **TIP**
> Integrate data to create lake database logical entities in shared storage to maximize the reuse of common data assets.

Integration with Microsoft data science technologies on Azure

Another key objective when modernizing a data warehouse is to produce insights for competitive advantage. You can produce insights by integrating your migrated data warehouse with Microsoft and third-party data science technologies in Azure. The following sections describe machine learning and data science technologies offered by Microsoft to see how they can be used with Azure Synapse in a modern data warehouse environment.

Microsoft technologies for data science on Azure

Microsoft offers a range of technologies that support advance analysis. With these technologies, you can build predictive analytical models using machine learning or analyze unstructured data using deep learning. The technologies include:

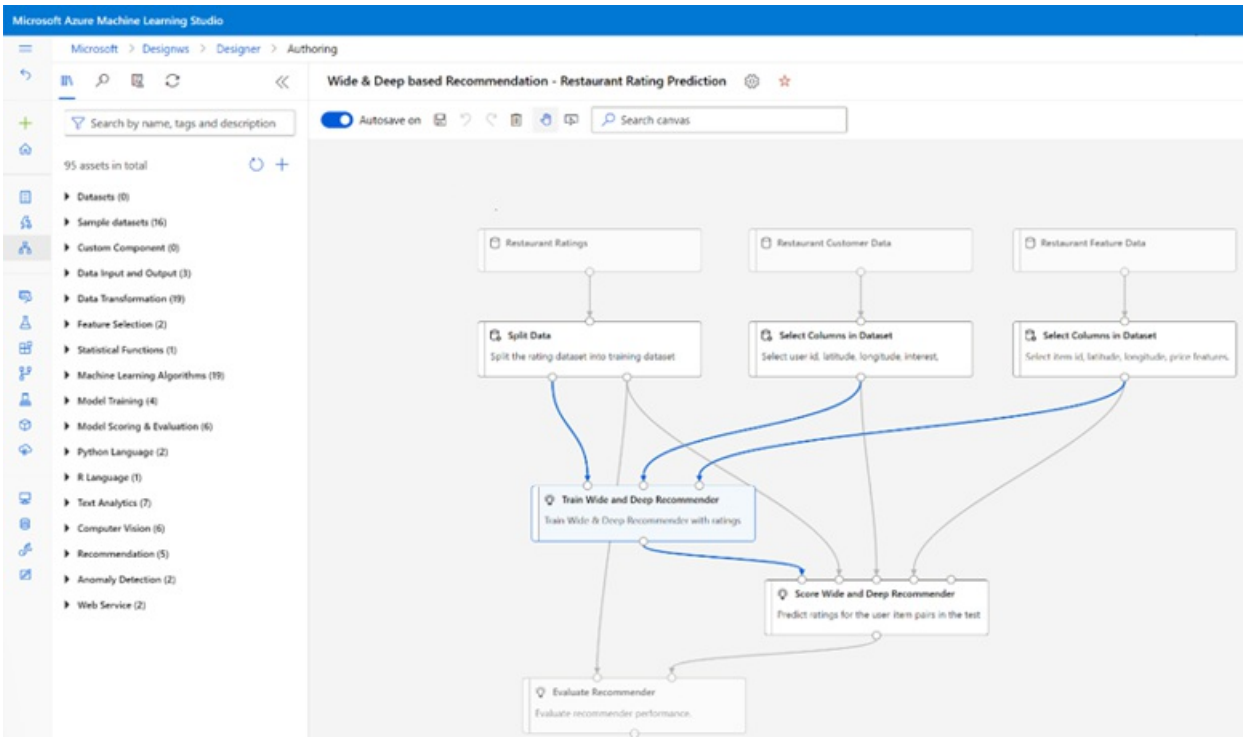
- Azure Machine Learning studio
- Azure Machine Learning
- Azure Synapse Spark pool notebooks
- ML.NET (API, CLI, or ML.NET Model Builder for Visual Studio)
- .NET for Apache Spark

Data scientists can use RStudio (R) and Jupyter Notebooks (Python) to develop analytical models, or they can use frameworks such as Keras or TensorFlow.

> **TIP**
> Develop machine learning models using a no/low-code approach or by using programming languages like Python, R, and .NET.

Azure Machine Learning studio

Azure Machine Learning studio is a fully managed cloud service that lets you build, deploy, and share predictive analytics using a drag-and-drop, web-based UI. The following screenshot shows the Azure Machine Learning studio UI.



Azure Machine Learning

Azure Machine Learning provides an SDK and services for Python that supports can help you quickly prepare data and also train and deploy machine learning models. You can use Azure Machine Learning in Azure notebooks using Jupyter Notebook, with open-source frameworks, such as PyTorch, TensorFlow, scikit-learn, or Spark MLlib—the machine learning library for Spark. Azure Machine Learning provides an AutoML capability that automatically tests multiple algorithms to identify the most accurate algorithms to expedite model development.

> **TIP**
> Azure Machine Learning provides an SDK for developing machine learning models using several open-source frameworks.

You can also use Azure Machine Learning to build machine learning pipelines that manage end-to-end workflow, programmatically scale in the cloud, and deploy models both to the cloud and the edge. Azure Machine Learning contains workspaces, which are logical spaces that you can programmatically or manually create in the Azure portal. These workspaces keep compute targets, experiments, data stores, trained machine learning models, Docker images, and deployed services all in one place to enable teams to work together. You can use Azure Machine Learning in Visual Studio with the Visual Studio for AI extension.

> **TIP**
> Organize and manage related data stores, experiments, trained models, Docker images, and deployed services in workspaces.

Azure Synapse Spark pool notebooks

An Azure Synapse Spark pool notebook is an Azure-optimized Apache Spark service. With Azure Synapse Spark pool notebooks:

- Data engineers can build and run scalable data preparation jobs using Data Factory.
- Data scientists can build and run machine learning models at scale using notebooks written in languages such as Scala, R, Python, Java, and SQL to visualize results.

> **TIP**
> Azure Synapse Spark is a dynamically scalable Spark as a service offering from Microsoft, Spark offers scalable execution of data preparation, model development, and deployed model execution.

Jobs running in Azure Synapse Spark pool notebooks can retrieve, process, and analyze data at scale from Azure Blob Storage, Data Lake Storage, Azure Synapse, HDInsight, and streaming data services such as Apache Kafka.

> **TIP**
> Azure Synapse Spark can access data in a range of Microsoft analytical ecosystem data stores on Azure.

Azure Synapse Spark pool notebooks support autoscaling and auto-termination to reduce total cost of ownership (TCO). Data scientists can use the MLflow open-source framework to manage the machine learning lifecycle.

ML.NET

ML.NET is an open-source, cross-platform machine learning framework for Windows, Linux, macOS. Microsoft created ML.NET so that .NET developers can use existing tools, such as ML.NET Model Builder for Visual Studio, to develop custom machine learning models and integrate them into their .NET applications.

> **TIP**
> Microsoft has extended its machine learning capability to .NET developers.

.NET for Apache Spark

.NET for Apache Spark extends Spark support beyond R, Scala, Python, and Java to .NET and aims to make Spark accessible to .NET developers across all Spark APIs. While .NET for Apache Spark is currently only available on Apache Spark in HDInsight, Microsoft intends to make .NET for Apache Spark available on Azure Synapse Spark pool notebooks.

Use Azure Synapse Analytics with your data warehouse

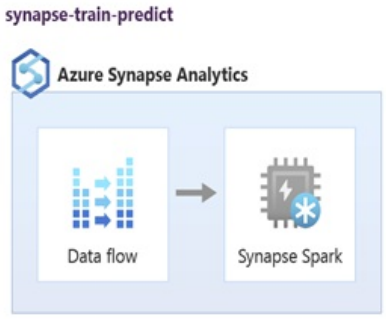
To combine machine learning models with Azure Synapse, you can:

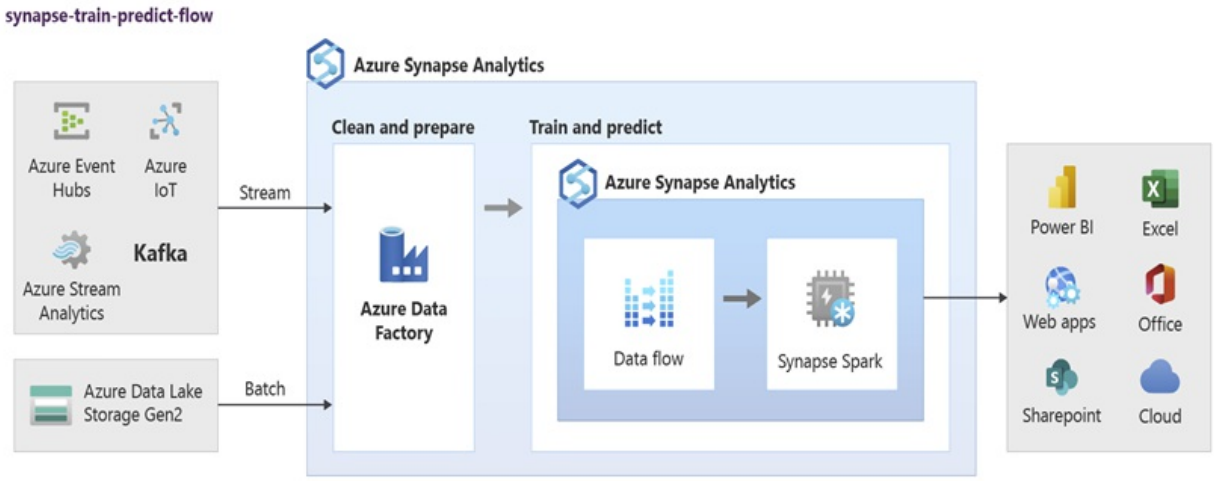
- Use machine learning models in batch or in real-time on streaming data to produce new insights, and add those insights to what you already know in Azure Synapse.
- Use the data in Azure Synapse to develop and train new predictive models for deployment elsewhere, such as in other applications.
- Deploy machine learning models, including models trained elsewhere, in Azure Synapse to analyze data in your data warehouse and drive new business value.

> **TIP**
> Train, test, evaluate, and run machine learning models at scale on Azure Synapse Spark pool notebooks by using data in Azure Synapse.

Data scientists can use RStudio, Jupyter Notebooks, and Azure Synapse Spark pool notebooks together with Azure Machine Learning to develop machine learning models that run at scale on Azure Synapse Spark pool notebooks using data in Azure Synapse. For example, data scientists could create an unsupervised model to segment customers to drive different marketing campaigns. Use supervised machine learning to train a model to predict a specific outcome, such as to predict a customer's propensity to churn, or to recommend the next

best offer for a customer to try to increase their value. The following diagram shows how Azure Synapse can be used for Azure Machine Learning.





In another scenario, you can ingest social network or review website data into Data Lake Storage, then prepare and analyze the data at scale on an Azure Synapse Spark pool notebook using natural language processing to score customer sentiment about your products or brand. You can then add those scores to your data warehouse. By using big data analytics to understand the effect of negative sentiment on product sales, you add to what you already know in your data warehouse.

> **TIP**
> Produce new insights using machine learning on Azure in batch or in real-time and add to what you know in your data warehouse.

Integrate live streaming data into Azure Synapse Analytics

When analyzing data in a modern data warehouse, you must be able to analyze streaming data in real-time and join it with historical data in your data warehouse. An example is combining IoT data with product or asset data.

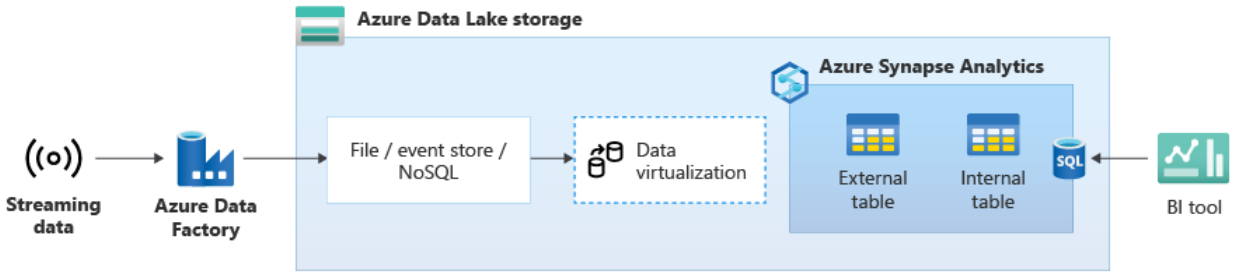
> **TIP**
> Integrate your data warehouse with streaming data from IoT devices or clickstreams.

Once you've successfully migrated your data warehouse to Azure Synapse, you can introduce live streaming data integration as part of a data warehouse modernization exercise by taking advantage of the extra functionality in Azure Synapse. To do so, ingest streaming data via Event Hubs, other technologies like Apache Kafka, or potentially your existing ETL tool if it supports the streaming data sources. Store the data in Data Lake Storage. Then, create an external table in Azure Synapse using PolyBase and point it at the data being streamed into Data Lake Storage so that your data warehouse now contains new tables that provide access to the real-time streaming data. Query the external table as if the data was in the data warehouse by using standard T-SQL

from any BI tool that has access to Azure Synapse. You can also join the streaming data to other tables with historical data to create views that join live streaming data to historical data to make it easier for business users to access the data.

> **TIP**
> Ingest streaming data into Data Lake Storage from Event Hubs or Apache Kafka, and access the data from Azure Synapse using PolyBase external tables.

In the following diagram, a real-time data warehouse on Azure Synapse is integrated with streaming data in Data Lake Storage.



Create a logical data warehouse using PolyBase

With PolyBase, you can create a logical data warehouse to simplify user access to multiple analytical data stores. Many companies have adopted "workload optimized" analytical data stores over the last several years in addition to their data warehouses. The analytical platforms on Azure include:

- Data Lake Storage with Azure Synapse Spark pool notebook (Spark as a service), for big data analytics.
- HDInsight (Hadoop as a service), also for big data analytics.
- NoSQL Graph databases for graph analysis, which could be done in Azure Cosmos DB.
- Event Hubs and Stream Analytics, for real-time analysis of data in motion.

You might have non-Microsoft equivalents of these platforms, or a master data management (MDM) system that needs to be accessed for consistent trusted data on customers, suppliers, products, assets, and more.

> **TIP**
> PolyBase simplifies access to multiple underlying analytical data stores on Azure for ease of access by business users.

Those analytical platforms emerged because of the explosion of new data sources inside and outside the enterprise and the demand by business users to capture and analyze the new data. The new data sources include:

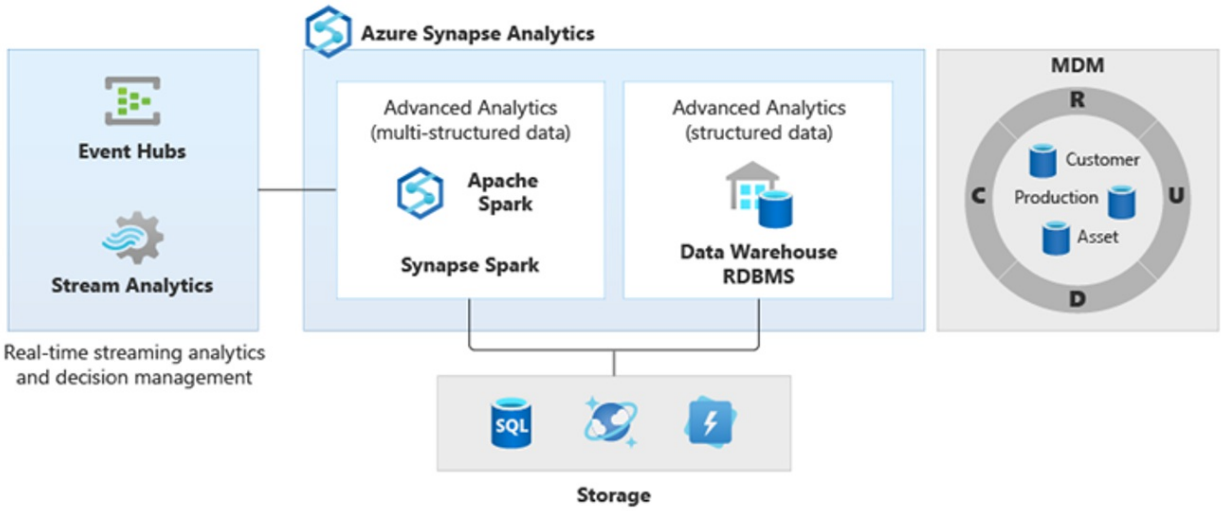
- Machine generated data, such as IoT sensor data and clickstream data.
- Human generated data, such as social network data, review web site data, customer inbound email, images, and video.
- Other external data, such as open government data and weather data.

This new data goes beyond the structured transaction data and main data sources that typically feed data warehouses and often includes:

- Semi-structured data like JSON, XML, or Avro.

- Unstructured data like text, voice, image, or video, which is more complex to process and analyze.
- High volume data, high velocity data, or both.

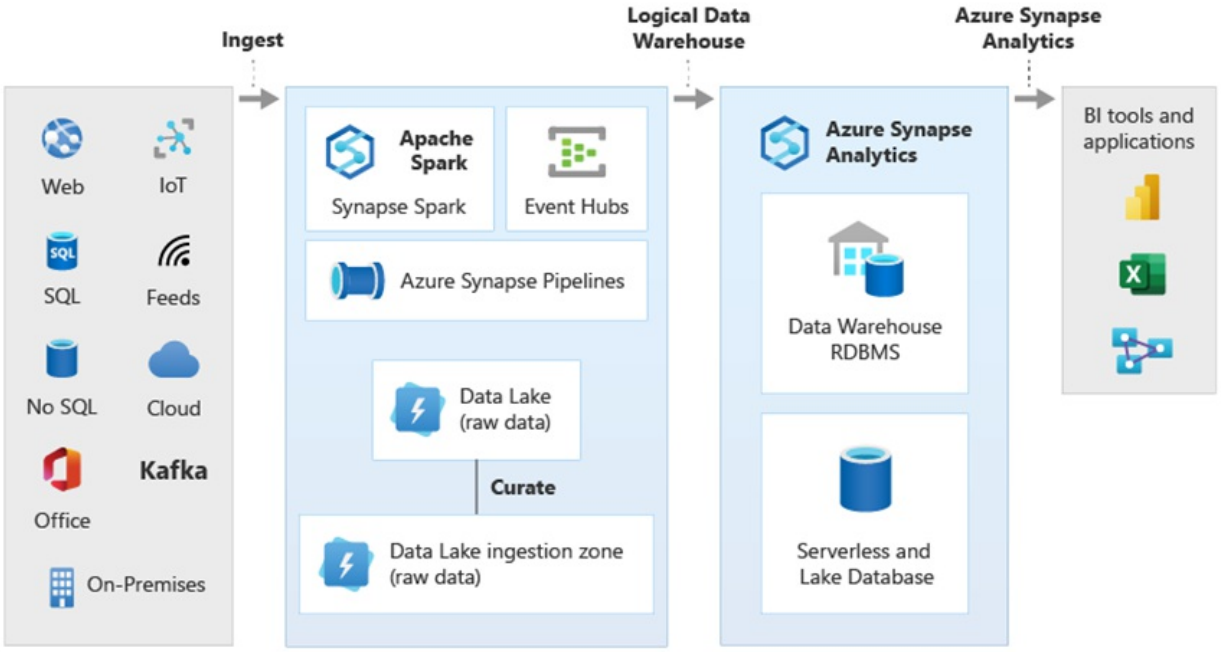
As a result, new more complex kinds of analysis have emerged, such as natural language processing, graph analysis, deep learning, streaming analytics, or complex analysis of large volumes of structured data. These kinds of analysis typically don't happen in a data warehouse, so it's not surprising to see different analytical platforms for different types of analytical workloads, as shown in the following diagram.



> **TIP**
> The ability to make data in multiple analytical data stores look like it's all in one system and join it to Azure Synapse is known as a logical data warehouse architecture.

Because these platforms produce new insights, it's normal to see a requirement to combine the new insights with what you already know in Azure Synapse, which is what PolyBase makes possible.

By using PolyBase data virtualization inside Azure Synapse, you can implement a logical data warehouse where data in Azure Synapse is joined to data in other Azure and on-premises analytical data stores like HDInsight, Azure Cosmos DB, or streaming data flowing into Data Lake Storage from Stream Analytics or Event Hubs. This approach lowers the complexity for users, who access external tables in Azure Synapse and don't need to know that the data they're accessing is stored in multiple underlying analytical systems. The following diagram shows a complex data warehouse structure accessed through comparatively simpler yet still powerful UI methods.



The diagram shows how other technologies in the Microsoft analytical ecosystem can be combined with the capability of the logical data warehouse architecture in Azure Synapse. For example, you can ingest data into Data Lake Storage and curate the data using Data Factory to create trusted data products that represent Microsoft lake database logical data entities. This trusted, commonly understood data can then be consumed and reused in different analytical environments such as Azure Synapse, Azure Synapse Spark pool notebooks, or Azure Cosmos DB. All insights produced in these environments are accessible via a logical data warehouse data virtualization layer made possible by PolyBase.

> **TIP**
> A logical data warehouse architecture simplifies business user access to data and adds new value to what you already know in your data warehouse.

Conclusions

After you migrate your data warehouse to Azure Synapse, you can take advantage of other technologies in the Microsoft analytical ecosystem. By doing so, you not only modernize your data warehouse, but bring insights produced in other Azure analytical data stores into an integrated analytical architecture.

You can broaden your ETL processing to ingest data of any type into Data Lake Storage, and then prepare and integrate the data at scale using Data Factory to produce trusted, commonly understood data assets. Those assets can be consumed by your data warehouse and accessed by data scientists and other applications. You can build real-time and batch oriented analytical pipelines and create machine learning models to run in batch, in real-time on streaming data, and on-demand as a service.

You can use PolyBase or `COPY INTO` to go beyond your data warehouse to simplify access to insights from multiple underlying analytical platforms on Azure. To do so, create holistic integrated views in a logical data warehouse that support access to streaming, big data, and traditional data warehouse insights from BI tools and applications.

By migrating your data warehouse to Azure Synapse, you can take advantage of the rich Microsoft analytical ecosystem running on Azure to drive new value in your business.

Azure Synapse Analytics.

Design and performance for Netezza migrations

8/19/2022 • 19 minutes to read • Edit Online

This article is part one of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for design and performance.

Overview

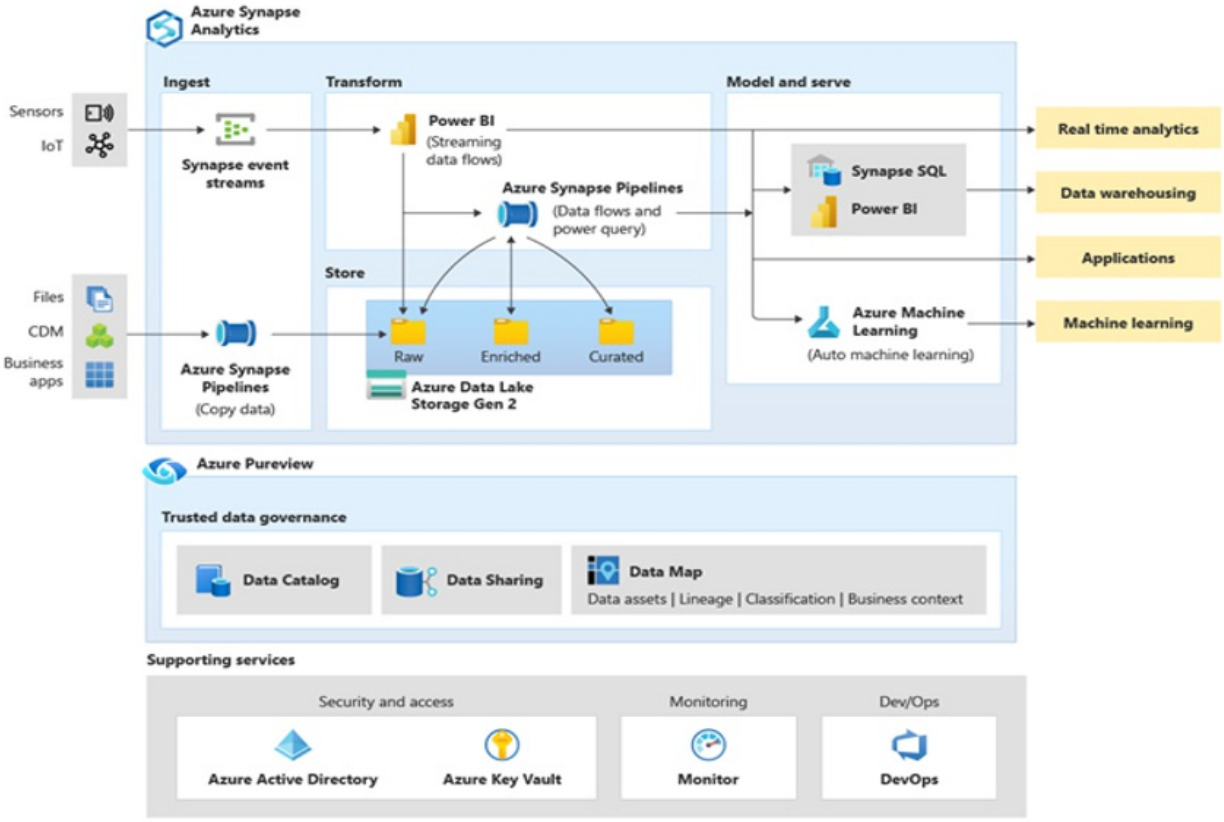
Due to end of support from IBM, many existing users of Netezza data warehouse systems want to take advantage of the innovations provided by modern cloud environments. Infrastructure-as-a-service (IaaS) and platform-as-a-service (PaaS) cloud environments let you delegate tasks like infrastructure maintenance and platform development to the cloud provider.

> **TIP**
> More than just a database—the Azure environment includes a comprehensive set of capabilities and tools.

Although Netezza and Azure Synapse Analytics are both SQL databases that use massively parallel processing (MPP) techniques to achieve high query performance on exceptionally large data volumes, there are some basic differences in approach:

- Legacy Netezza systems are often installed on-premises and use proprietary hardware, while Azure Synapse is cloud-based and uses Azure storage and compute resources.
- Upgrading a Netezza configuration is a major task involving extra physical hardware and potentially lengthy database reconfiguration, or dump and reload. Because storage and compute resources are separate in the Azure environment and have elastic scaling capability, those resources can be scaled upwards or downwards independently.
- You can pause or resize Azure Synapse as needed to reduce resource utilization and cost.

Microsoft Azure is a globally available, highly secure, scalable cloud environment that includes Azure Synapse and an ecosystem of supporting tools and capabilities. The next diagram summarizes the Azure Synapse ecosystem.



Azure Synapse provides best-of-breed relational database performance by using techniques such as MPP and multiple levels of automated caching for frequently used data. You can see the results of these techniques in independent benchmarks such as the one run recently by GigaOm, which compares Azure Synapse to other popular cloud data warehouse offerings. Customers who migrate to the Azure Synapse environment see many benefits, including:

- Improved performance and price/performance.
- Increased agility and shorter time to value.
- Faster server deployment and application development.
- Elastic scalability—only pay for actual usage.
- Improved security/compliance.
- Reduced storage and disaster recovery costs.
- Lower overall TCO, better cost control, and streamlined operational expenditure (OPEX).

To maximize these benefits, migrate new or existing data and applications to the Azure Synapse platform. In many organizations, migration includes moving an existing data warehouse from a legacy on-premises platform, such as Netezza, to Azure Synapse. At a high level, the migration process includes these steps:

Preparation

- Define scope—what is to be migrated.
- Build inventory of data and processes for migration.
- Define data model changes (if any).
- Define source data extract mechanism.
- Identify the appropriate Azure and third-party tools and features to be used.
- Train staff early on the new platform.

- Set up the Azure target platform.

Migration □

- Start small and simple.
- Automate wherever possible.
- Leverage Azure built-in tools and features to reduce migration effort.
- Migrate metadata for tables and views.
- Migrate historical data to be maintained.
- Migrate or refactor stored procedures and business processes.
- Migrate or refactor ETL/ELT incremental load processes.

Post migration

- Monitor and document all stages of the process.
- Use the experience gained to build a template for future migrations.
- Re-engineer the data model if required (using new platform performance and scalability).
- Test applications and query tools.
- Benchmark and optimize query performance.

This article provides general information and guidelines for performance optimization when migrating a data warehouse from an existing Netezza environment to Azure Synapse. The goal of performance optimization is to achieve the same or better data warehouse performance in Azure Synapse after schema migration.

Design considerations

Migration scope

When you're preparing to migrate from a Netezza environment, consider the following migration choices.

Choose the workload for the initial migration

Typically, legacy Netezza environments have evolved over time to encompass multiple subject areas and mixed workloads. When you're deciding where to start on a migration project, choose an area where you'll be able to:

- Prove the viability of migrating to Azure Synapse by quickly delivering the benefits of the new environment.
- Allow your in-house technical staff to gain relevant experience with the processes and tools that they'll use when they migrate other areas.
- Create a template for further migrations that's specific to the source Netezza environment and the current tools and processes that are already in place.

A good candidate for an initial migration from a Netezza environment supports the preceding items, and:

- Implements a BI/Analytics workload rather than an online transaction processing (OLTP) workload.
- Has a data model, such as a star or snowflake schema, that can be migrated with minimal modification.

> **TIP**
> Create an inventory of objects that need to be migrated, and document the migration process.

The volume of migrated data in an initial migration should be large enough to demonstrate the capabilities and benefits of the Azure Synapse environment but not too large to quickly demonstrate value. A size in the 1-10 terabyte range is typical.

For your initial migration project, minimize the risk, effort, and migration time so you can quickly see the benefits of the Azure cloud environment. Both the lift-and-shift and phased migration approaches limit the scope of the initial migration to just the data marts and don't address broader migration aspects such as ETL migration and historical data migration. However, you can address those aspects in later phases of the project once the migrated data mart layer is backfilled with data and the required build processes.

Lift and shift migration vs. Phased approach

In general, there are two types of migration regardless of the purpose and scope of the planned migration: lift and shift as-is and a phased approach that incorporates changes.

Lift and shift

In a lift and shift migration, an existing data model, like a star schema, is migrated unchanged to the new Azure Synapse platform. This approach minimizes risk and migration time by reducing the work needed to realize the benefits of moving to the Azure cloud environment. Lift and shift migration is a good fit for these scenarios:

- You have an existing Netezza environment with a single data mart to migrate, or
- You have an existing Netezza environment with data that's already in a well-designed star or snowflake schema, or
- You're under time and cost pressures to move to a modern cloud environment.

> **TIP**
> Lift and shift is a good starting point, even if subsequent phases implement changes to the data model.

Phased approach that incorporates changes

If a legacy data warehouse has evolved over a long period of time, you might need to re-engineer it to maintain the required performance levels. You might also have to re-engineer to support new data like Internet of Things (IoT) streams. As part of the re-engineering process, migrate to Azure Synapse to get the benefits of a scalable cloud environment. Migration can also include a change in the underlying data model, such as a move from an Inmon model to a data vault.

Microsoft recommends moving your existing data model as-is to Azure and using the performance and flexibility of the Azure environment to apply the re-engineering changes. That way, you can use Azure's capabilities to make the changes without impacting the existing source system.

Use Azure Data Factory to implement a metadata-driven migration

You can automate and orchestrate the migration process by using the capabilities of the Azure environment. This approach minimizes the performance hit on the existing Netezza environment, which may already be running close to capacity.

Azure Data Factory is a cloud-based data integration service that supports creating data-driven workflows in the cloud that orchestrate and automate data movement and data transformation. You can use Data Factory to create and schedule data-driven workflows (pipelines) that ingest data from disparate data stores. Data Factory can process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

When you're planning to use Data Factory facilities to manage the migration process, create metadata that lists all the data tables to be migrated and their location.

Design differences between Netezza and Azure Synapse

As mentioned earlier, there are some basic differences in approach between Netezza and Azure Synapse

Analytics databases and these differences are discussed next.

Multiple databases vs. a single database and schemas

The Netezza environment often contains multiple separate databases. For instance, there could be separate databases for: data ingestion and staging tables, core warehouse tables, and data marts (sometimes referred to as the semantic layer). ETL or ELT pipeline processes might implement cross-database joins and move data between the separate databases.

In contrast, the Azure Synapse environment contains a single database and uses schemas to separate tables into logically separate groups. We recommend that you use a series of schemas within the target Azure Synapse database to mimic the separate databases migrated from the Netezza environment. If the Netezza environment already uses schemas, you may need to use a new naming convention when you move the existing Netezza tables and views to the new environment. For example, you could concatenate the existing Netezza schema and table names into the new Azure Synapse table name, and use schema names in the new environment to maintain the original separate database names. If schema consolidation naming has dots, Azure Synapse Spark might have issues. Although you can use SQL views on top of the underlying tables to maintain the logical structures, there are potential downsides to that approach:

- Views in Azure Synapse are read-only, so any updates to the data must take place on the underlying base tables.
- There may already be one or more layers of views in existence and adding an extra layer of views could affect performance and supportability because nested views are difficult to troubleshoot.

> **TIP**
> Combine multiple databases into a single database within Azure Synapse and use schema names to logically separate the tables.

Table considerations

When you migrate tables between different environments, typically only the raw data and the metadata that describes it physically migrate. Other database elements from the source system, such as indexes, usually aren't migrated because they might be unnecessary or implemented differently in the new environment.

Performance optimizations in the source environment, such as indexes, indicate where you might add performance optimization in the new environment. For example, if queries in the source Netezza environment frequently use zone maps, that suggests that a non-clustered index should be created within Azure Synapse. Other native performance optimization techniques like table replication may be more applicable than straight like-for-like index creation.

> **TIP**
> Existing indexes indicate candidates for indexing in the migrated warehouse.

Unsupported Netezza database object types

Netezza-specific features can often be replaced by Azure Synapse features. However, some Netezza database objects aren't directly supported in Azure Synapse. The following list of unsupported Netezza database objects describes how you can achieve an equivalent functionality in Azure Synapse.

- **Zone maps**: in Netezza, zone maps are automatically created and maintained for the following column types and are used at query time to restrict the amount of data to be scanned:
  - `INTEGER` columns of length 8 bytes or less.
  - Temporal columns, such as `DATE`, `TIME`, and `TIMESTAMP`.

- `CHAR` columns if they're part of a materialized view and mentioned in the `ORDER BY` clause.

  You can find out which columns have zone maps by using the `nz_zonemap` utility, which is part of the NZ Toolkit. Azure Synapse doesn't include zone maps, but you can achieve similar results by using other user-defined index types and/or partitioning.

- **Clustered base tables (CBT)**: in Netezza, CBTs are commonly used for fact tables, which can have billions of records. Scanning such a huge table requires considerable processing time because a full table scan might be needed to get the relevant records. Organizing records on restrictive CBTs allows Netezza to group records in same or nearby extents. This process also creates zone maps that improve the performance by reducing the amount of data that needs to be scanned.

  In Azure Synapse, you can achieve a similar effect by partitioning and/or using other indexes.

- **Materialized views**: Netezza supports materialized views and recommends using one or more materialized views for large tables with many columns if only a few columns are regularly used in queries. Materialized views are automatically refreshed by the system when data in the base table is updated.

  Azure Synapse supports materialized views, with the same functionality as Netezza.

Netezza data type mapping

Most Netezza data types have a direct equivalent in Azure Synapse. The following table shows the recommended approach for mapping Netezza data types to Azure Synapse.

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
BIGINT	BIGINT
BINARY VARYING(n)	VARBINARY(n)
BOOLEAN	BIT
BYTEINT	TINYINT
CHARACTER VARYING(n)	VARCHAR(n)
CHARACTER(n)	CHAR(n)
DATE	DATE(date)
DECIMAL(p,s)	DECIMAL(p,s)
DOUBLE PRECISION	FLOAT
FLOAT(n)	FLOAT(n)
INTEGER	INT
INTERVAL	INTERVAL data types aren't currently directly supported in Azure Synapse, but can be calculated using temporal functions such as DATEDIFF.
MONEY	MONEY

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
NATIONAL CHARACTER VARYING(n)	NVARCHAR(n)
NATIONAL CHARACTER(n)	NCHAR(n)
NUMERIC(p,s)	NUMERIC(p,s)
REAL	REAL
SMALLINT	SMALLINT
ST_GEOMETRY(n)	Spatial data types such as ST_GEOMETRY aren't currently supported in Azure Synapse, but the data could be stored as VARCHAR or VARBINARY.
TIME	TIME
TIME WITH TIME ZONE	DATETIMEOFFSET
TIMESTAMP	DATETIME

> **TIP**
> Assess the number and type of unsupported data types during the migration preparation phase.

Third-party vendors offer tools and services to automate migration, including the mapping of data types. If a third-party ETL tool is already in use in the Netezza environment, use that tool to implement any required data transformations.

SQL DML syntax differences

SQL DML syntax differences exist between Netezza SQL and Azure Synapse T-SQL. Those differences are discussed in detail in Minimize SQL issues for Netezza migrations.

- `STRPOS`: in Netezza, the `STRPOS` function returns the position of a substring within a string. The equivalent function in Azure Synapse is `CHARINDEX` with the order of the arguments reversed. For example, `SELECT STRPOS('abcdef','def')...` in Netezza is equivalent to `SELECT CHARINDEX('def','abcdef')...` in Azure Synapse.
- `AGE`: Netezza supports the `AGE` operator to give the interval between two temporal values, such as timestamps or dates, for example: `SELECT AGE('23-03-1956','01-01-2019') FROM...`. In Azure Synapse, use `DATEDIFF` to get the interval, for example: `SELECT DATEDIFF(day, '1956-03-26','2019-01-01') FROM...`. Note the date representation sequence.
- `NOW()`: Netezza uses `NOW()` to represent `CURRENT_TIMESTAMP` in Azure Synapse.

Functions, stored procedures, and sequences

When migrating a data warehouse from a mature environment like Netezza, you probably need to migrate elements other than simple tables and views. Check whether tools within the Azure environment can replace the functionality of functions, stored procedures, and sequences because it's usually more efficient to use built-in Azure tools than to recode those elements for Azure Synapse.

As part of your preparation phase, create an inventory of objects that need to be migrated, define a method for handling them, and allocate appropriate resources in your migration plan.

Data integration partners offer tools and services that can automate the migration of functions, stored procedures, and sequences.

The following sections further discuss the migration of functions, stored procedures, and sequences.

Functions

As with most database products, Netezza supports system and user-defined functions within a SQL implementation. When you migrate a legacy database platform to Azure Synapse, common system functions can usually be migrated without change. Some system functions might have a slightly different syntax, but any required changes can be automated.

For Netezza system functions or arbitrary user-defined functions that have no equivalent in Azure Synapse, recode those functions using a target environment language. Netezza user-defined functions are coded in nzlua or C++ languages. Azure Synapse uses the Transact-SQL language to implement user-defined functions.

Stored procedures

Most modern database products support storing procedures within the database. Netezza provides the NZPLSQL language, which is based on Postgres PL/pgSQL, for this purpose. A stored procedure typically contains both SQL statements and procedural logic, and returns data or a status.

Azure Synapse supports stored procedures using T-SQL, so you need to recode any migrated stored procedures in that language.

Sequences

In Netezza, a sequence is a named database object created using `CREATE SEQUENCE`. A sequence provides unique numeric values via the `NEXT VALUE FOR` method. You can use the generated unique numbers as surrogate key values for primary keys.

Azure Synapse doesn't implement `CREATE SEQUENCE`, but you can implement sequences using IDENTITY columns or SQL code that generates the next sequence number in a series.

Extract metadata and data from a Netezza environment

Data Definition Language (DDL) generation

The ANSI SQL standard defines the basic syntax for Data Definition Language (DDL) commands. Some DDL commands, such as `CREATE TABLE` and `CREATE VIEW`, are common to both Netezza and Azure Synapse but have been extended to provide implementation-specific features.

You can edit existing Netezza `CREATE TABLE` and `CREATE VIEW` scripts to achieve equivalent definitions in Azure Synapse. To do so, you might need to use modified data types and remove or modify Netezza-specific clauses such as `ORGANIZE ON`.

Within the Netezza environment, system catalog tables specify the current table and view definition. Unlike user-maintained documentation, system catalog information is always complete and in sync with current table definitions. By using utilities such as `nz_ddl_table`, you can access system catalog information to generate `CREATE TABLE` DDL statements that create equivalent tables in Azure Synapse.

You can also use third-party migration and ETL tools that process system catalog information to achieve similar results.

Data extraction from Netezza

You can extract raw table data from Netezza tables to flat delimited files, such as CSV files, using standard Netezza utilities like nzsql and nzunload, or via external tables. Then, you can compress the flat delimited files using gzip, and upload the compressed files to Azure Blob Storage using AzCopy or Azure data transport tools like Azure Data Box.

Extract table data as efficiently as possible. Use the external tables approach because it's the fastest extract method. Perform multiple extracts in parallel to maximize data extraction throughput. The following SQL statement performs an external table extract:

```
CREATE EXTERNAL TABLE '/tmp/export_tab1.csv' USING (DELIM ',') AS SELECT * from <TABLENAME>;
```

If sufficient network bandwidth is available, you can extract data from an on-premises Netezza system directly into Azure Synapse tables or Azure Blob Data Storage. To do so, use Data Factory processes or third-party data migration or ETL products.

> **TIP**
> Use Netezza external tables for the most efficient data extraction.

Extracted data files should contain delimited text in CSV, Optimized Row Columnar (ORC), or Parquet format.

For more information about migrating data and ETL from a Netezza environment, see Data migration, ETL, and load for Netezza migrations.

Performance recommendations for Netezza migrations

The goal of performance optimization is same or better data warehouse performance after migration to Azure Synapse.

Similarities in performance tuning approach concepts

Many performance tuning concepts for Netezza databases hold true for Azure Synapse databases. For example:

- Use data distribution to collocate data-to-be-joined onto the same processing node.
- Use the smallest data type for a given column to save storage space and accelerate query processing.
- Ensure that columns to be joined have the same data type in order to optimize join processing and reduce the need for data transforms.
- To help the optimizer produce the best execution plan, ensure statistics are up to date.
- Monitor performance using built-in database capabilities to ensure that resources are being used efficiently.

> **TIP**
> Prioritize familiarity with the tuning options in Azure Synapse at the start of a migration.

Differences in performance tuning approach

This section highlights low-level performance tuning implementation differences between Netezza and Azure Synapse.

Data distribution options

For performance, Azure Synapse was designed with multi-node architecture and uses parallel processing. To optimize table performance, you can define a data distribution option in `CREATE TABLE` statements using `DISTRIBUTION` in Azure Synapse and `DISTRIBUTE ON` in Netezza.

Unlike Netezza, Azure Synapse supports local joins between a small table and a large table through small table replication. For instance, consider a small dimension table and a large fact table within a star schema model. Azure Synapse can replicate the smaller dimension table across all nodes to ensure that the value of any join key for the large table has a matching, locally available dimension row. The overhead of dimension table replication is relatively low for a small dimension table. For large dimension tables, a hash distribution approach is more appropriate. For more information about data distribution options, see Design guidance for using replicated tables and Guidance for designing distributed tables.

Data indexing

Azure Synapse supports several user-definable indexing options that have a different operation and usage compared to system-managed zone maps in Netezza. For more information about the different indexing options in Azure Synapse, see Indexes on dedicated SQL pool tables.

The existing system-managed zone maps within a source Netezza environment provide a useful indication of data usage and the candidate columns for indexing in the Azure Synapse environment.

Data partitioning

In an enterprise data warehouse, fact tables can contain billions of rows. Partitioning optimizes the maintenance and query performance of these tables by splitting them into separate parts to reduce the amount of data processed. In Azure Synapse, the `CREATE TABLE` statement defines the partitioning specification for a table.

You can only use one field per table for partitioning. That field is often a date field because many queries are filtered by date or date range. It's possible to change the partitioning of a table after initial load by using the `CREATE TABLE AS` (CTAS) statement to recreate the table with a new distribution. For a detailed discussion of partitioning in Azure Synapse, see Partitioning tables in dedicated SQL pool.

Data table statistics

You should ensure that statistics on data tables are up to date by building in a statistics step to ETL/ELT jobs.

PolyBase or COPY INTO for data loading

PolyBase supports efficient loading of large amounts of data to a data warehouse by using parallel loading streams. For more information, see PolyBase data loading strategy.

COPY INTO also supports high-throughput data ingestion, and:

- Data retrieval from all files within a folder and subfolders.
- Data retrieval from multiple locations in the same storage account. You can specify multiple locations by using comma separated paths.
- Azure Data Lake Storage (ADLS) and Azure Blob Storage.
- CSV, PARQUET, and ORC file formats.

Workload management

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). Workload classification, workload importance, and workload isolation give more control over how workload utilizes system resources.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance, and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized.

Next steps

Data migration, ETL, and load for Netezza migrations

8/19/2022 • 17 minutes to read • Edit Online

This article is part two of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for ETL and load migration.

Data migration considerations

Initial decisions for data migration from Netezza

When migrating a Netezza data warehouse, you need to ask some basic data-related questions. For example:

- Should unused table structures be migrated?
- What's the best migration approach to minimize risk and user impact?
- When migrating data marts: stay physical or go virtual?

The next sections discuss these points within the context of migration from Netezza.

Migrate unused tables?

> **TIP**
> In legacy systems, it's not unusual for tables to become redundant over time—these don't need to be migrated in most cases.

It makes sense to only migrate tables that are in use in the existing system. Tables that aren't active can be archived rather than migrated, so that the data is available if necessary in future. It's best to use system metadata and log files rather than documentation to determine which tables are in use, because documentation can be out of date.

If enabled, Netezza query history tables contain information that can determine when a given table was last accessed—which can in turn be used to decide whether a table is a candidate for migration.

Here's an example query that looks for the usage of a specific table within a given time window:

```
SELECT FORMAT_TABLE_ACCESS (usage),
  hq.submittime
FROM "$v_hist_queries" hq
  INNER JOIN "$hist_table_access_3" hta USING
(NPSID, NPSINSTANCEID, OPID, SESSIONID)
WHERE hq.dbname = 'PROD'
AND hta.schemaname = 'ADMIN'
AND hta.tablename = 'TEST_1'
AND hq.SUBMITTIME > '01-01-2015'
AND hq.SUBMITTIME <= '08-06-2015'
AND
(
  instr(FORMAT_TABLE_ACCESS(usage),'ins') > 0
  OR instr(FORMAT_TABLE_ACCESS(usage),'upd') > 0
  OR instr(FORMAT_TABLE_ACCESS(usage),'del') > 0
)
AND status=0;
```

```
| FORMAT_TABLE_ACCESS | SUBMITTIME
---------------------+--------------------------
ins                   | 2015-06-16 18:32:25.728042
ins                   | 2015-06-16 17:46:14.337105
ins                   | 2015-06-16 17:47:14.430995
(3 rows)
```

This query uses the helper function `FORMAT_TABLE_ACCESS` and the digit at the end of the `$v_hist_table_access_3` view to match the installed query history version.

What is the best migration approach to minimize risk and impact on users?

This question comes up frequently because companies may want to lower the impact of changes on the data warehouse data model to improve agility. Companies often see an opportunity to further modernize or transform their data during an ETL migration. This approach carries a higher risk because it changes multiple factors simultaneously, making it difficult to compare the outcomes of the old system versus the new. Making data model changes here could also affect upstream or downstream ETL jobs to other systems. Because of that risk, it's better to redesign on this scale after the data warehouse migration.

Even if a data model is intentionally changed as part of the overall migration, it's good practice to migrate the existing model as-is to Azure Synapse, rather than do any re-engineering on the new platform. This approach minimizes the effect on existing production systems, while benefiting from the performance and elastic scalability of the Azure platform for one-off re-engineering tasks.

When migrating from Netezza, often the existing data model is already suitable for as-is migration to Azure Synapse.

> **TIP**
> Migrate the existing model as-is initially, even if a change to the data model is planned in the future.

Migrate data marts: stay physical or go virtual?

> **TIP**
> Virtualizing data marts can save on storage and processing resources.

In legacy Netezza data warehouse environments, it's common practice to create several data marts that are structured to provide good performance for ad hoc self-service queries and reports for a given department or business function within an organization. As such, a data mart typically consists of a subset of the data warehouse and contains aggregated versions of the data in a form that enables users to easily query that data with fast response times via user-friendly query tools such as Microsoft Power BI, Tableau, or MicroStrategy. This form is typically a dimensional data model. One use of data marts is to expose the data in a usable form, even if the underlying warehouse data model is something different, such as a data vault.

You can use separate data marts for individual business units within an organization to implement robust data security regimes, by only allowing users to access specific data marts that are relevant to them, and eliminating, obfuscating, or anonymizing sensitive data.

If these data marts are implemented as physical tables, they'll require additional storage resources to store them, and additional processing to build and refresh them regularly. Also, the data in the mart will only be as up to date as the last refresh operation, and so may be unsuitable for highly volatile data dashboards.

> **TIP**
> The performance and scalability of Azure Synapse enables virtualization without sacrificing performance.

With the advent of relatively low-cost scalable MPP architectures, such as Azure Synapse, and the inherent performance characteristics of such architectures, it may be that you can provide data mart functionality without having to instantiate the mart as a set of physical tables. This is achieved by effectively virtualizing the data marts via SQL views onto the main data warehouse, or via a virtualization layer using features such as views in Azure or the visualization products of Microsoft partners. This approach simplifies or eliminates the need for additional storage and aggregation processing and reduces the overall number of database objects to be migrated.

There's another potential benefit to this approach. By implementing the aggregation and join logic within a virtualization layer, and presenting external reporting tools via a virtualized view, the processing required to create these views is "pushed down" into the data warehouse, which is generally the best place to run joins, aggregations, and other related operations on large data volumes.

The primary drivers for choosing a virtual data mart implementation over a physical data mart are:

- More agility: a virtual data mart is easier to change than physical tables and the associated ETL processes.
- Lower total cost of ownership: a virtualized implementation requires fewer data stores and copies of data.
- Elimination of ETL jobs to migrate and simplify data warehouse architecture in a virtualized environment.
- Performance: although physical data marts have historically been more performant, virtualization products now implement intelligent caching techniques to mitigate.

Data migration from Netezza

Understand your data

Part of migration planning is understanding in detail the volume of data that needs to be migrated since that can impact decisions about the migration approach. Use system metadata to determine the physical space taken up by the "raw data" within the tables to be migrated. In this context, "raw data" means the amount of space used by the data rows within a table, excluding overheads such as indexes and compression. This is especially true for the largest fact tables since these will typically comprise more than 95% of the data.

You can get an accurate number for the volume of data to be migrated for a given table by extracting a representative sample of the data—for example, one million rows—to an uncompressed delimited flat ASCII data file. Then, use the size of that file to get an average raw data size per row of that table. Finally, multiply that average size by the total number of rows in the full table to give a raw data size for the table. Use that raw data size in your planning.

Netezza data type mapping

> **TIP**
> Assess the impact of unsupported data types as part of the preparation phase.

Most Netezza data types have a direct equivalent in Azure Synapse. The following table shows these data types, together with the recommended approach for mapping them.

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
BIGINT	BIGINT

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
BINARY VARYING(n)	VARBINARY(n)
BOOLEAN	BIT
BYTEINT	TINYINT
CHARACTER VARYING(n)	VARCHAR(n)
CHARACTER(n)	CHAR(n)
DATE	DATE(date)
DECIMAL(p,s)	DECIMAL(p,s)
DOUBLE PRECISION	FLOAT
FLOAT(n)	FLOAT(n)
INTEGER	INT
INTERVAL	INTERVAL data types aren't currently directly supported in Azure Synapse Analytics, but can be calculated using temporal functions, such as DATEDIFF.
MONEY	MONEY
NATIONAL CHARACTER VARYING(n)	NVARCHAR(n)
NATIONAL CHARACTER(n)	NCHAR(n)
NUMERIC(p,s)	NUMERIC(p,s)
REAL	REAL
SMALLINT	SMALLINT
ST_GEOMETRY(n)	Spatial data types such as ST_GEOMETRY aren't currently supported in Azure Synapse Analytics, but the data could be stored as VARCHAR or VARBINARY.
TIME	TIME
TIME WITH TIME ZONE	DATETIMEOFFSET
TIMESTAMP	DATETIME

Use the metadata from the Netezza catalog tables to determine whether any of these data types need to be migrated, and allow for this in your migration plan. The important metadata views in Netezza for this type of query are:

- `_V_USER`: the user view gives information about the users in the Netezza system.

- `_V_TABLE`: the table view contains the list of tables created in the Netezza performance system.
- `_V_RELATION_COLUMN`: the relation column system catalog view contains the columns available in a table.
- `_V_OBJECTS`: the objects view lists the different objects like tables, view, functions, and so on, that are available in Netezza.

For example, this Netezza SQL query shows columns and column types:

```
SELECT
tablename,
  attname AS COL_NAME,
  b.FORMAT_TYPE AS COL_TYPE,
  attnum AS COL_NUM
FROM _v_table a
  JOIN _v_relation_column b
  ON a.objid = b.objid
WHERE a.tablename = 'ATT_TEST'
AND a.schema = 'ADMIN'
ORDER BY attnum;
```

```
TABLENAME | COL_NAME    | COL_TYPE             | COL_NUM
----------+-------------+----------------------+--------
ATT_TEST  | COL_INT     | INTEGER              | 1
ATT_TEST  | COL_NUMERIC | NUMERIC(10,2)        | 2
ATT_TEST  | COL_VARCHAR | CHARACTER VARYING(5) | 3
ATT_TEST  | COL_DATE    | DATE                 | 4
(4 rows)
```

The query can be modified to search all tables for any occurrences of unsupported data types.

Azure Data Factory can be used to move data from a legacy Netezza environment. For more information, see IBM Netezza connector.

Third-party vendors offer tools and services to automate migration, including the mapping of data types as previously described. Also, third-party ETL tools, like Informatica or Talend, already in use in the Netezza environment can implement all required data transformations. The next section explores the migration of existing third-party ETL processes.

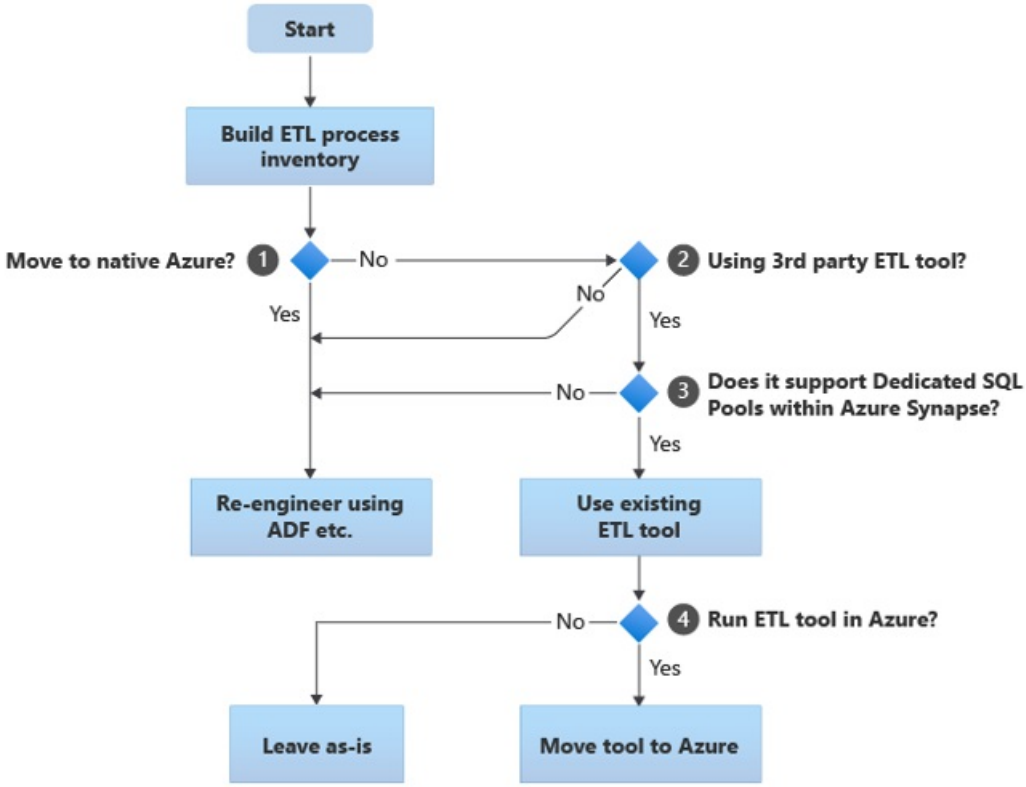
ETL migration considerations

Initial decisions regarding Netezza ETL migration

> **TIP**
> Plan the approach to ETL migration ahead of time and leverage Azure facilities where appropriate.

For ETL/ELT processing, legacy Netezza data warehouses may use custom-built scripts using Netezza utilities such as nzsql and nzload, or third-party ETL tools such as Informatica or Ab Initio. Sometimes, Netezza data warehouses use a combination of ETL and ELT approaches that's evolved over time. When planning a migration to Azure Synapse, you need to determine the best way to implement the required ETL/ELT processing in the new environment, while minimizing the cost and risk involved. To learn more about ETL and ELT processing, see ELT vs ETL design approach.

The following sections discuss migration options and make recommendations for various use cases. This flowchart summarizes one approach:



The first step is always to build an inventory of ETL/ELT processes that need to be migrated. As with other steps, it's possible that the standard "built-in" Azure features make it unnecessary to migrate some existing processes. For planning purposes, it's important to understand the scale of the migration to be performed.

In the preceding flowchart, decision 1 relates to a high-level decision about whether to migrate to a totally Azure-native environment. If you're moving to a totally Azure-native environment, we recommend that you re-engineer the ETL processing using Pipelines and activities in Azure Data Factory or Azure Synapse Pipelines. If you're not moving to a totally Azure-native environment, then decision 2 is whether an existing third-party ETL tool is already in use.

> **TIP**
> Leverage investment in existing third-party tools to reduce cost and risk.

If a third-party ETL tool is already in use, and especially if there's a large investment in skills or several existing workflows and schedules use that tool, then decision 3 is whether the tool can efficiently support Azure Synapse as a target environment. Ideally, the tool will include "native" connectors that can leverage Azure facilities like PolyBase or COPY INTO, for the most efficient data loading. There's a way to call an external process, such as PolyBase or `COPY INTO`, and pass in the appropriate parameters. In this case, leverage existing skills and workflows, with Azure Synapse as the new target environment.

If you decide to retain an existing third-party ETL tool, there may be benefits to running that tool within the Azure environment (rather than on an existing on-premises ETL server) and having Azure Data Factory handle the overall orchestration of the existing workflows. One particular benefit is that less data needs to be downloaded from Azure, processed, and then uploaded back into Azure. So, decision 4 is whether to leave the existing tool running as-is or move it into the Azure environment to achieve cost, performance, and scalability benefits.

Re-engineer existing Netezza-specific scripts

If some or all the existing Netezza warehouse ETL/ELT processing is handled by custom scripts that utilize Netezza-specific utilities, such as nzsql or nzload, then these scripts need to be recoded for the new Azure Synapse environment. Similarly, if ETL processes were implemented using stored procedures in Netezza, then

these will also have to be recoded.

> **TIP**
> The inventory of ETL tasks to be migrated should include scripts and stored procedures.

Some elements of the ETL process are easy to migrate, for example by simple bulk data load into a staging table from an external file. It may even be possible to automate those parts of the process, for example, by using PolyBase instead of nzload. Other parts of the process that contain arbitrary complex SQL and/or stored procedures will take more time to re-engineer.

One way of testing Netezza SQL for compatibility with Azure Synapse is to capture some representative SQL statements from Netezza query history, then prefix those queries with `EXPLAIN`, and then—assuming a like-for-like migrated data model in Azure Synapse—run those `EXPLAIN` statements in Azure Synapse. Any incompatible SQL will generate an error, and the error information can determine the scale of the recoding task.

Microsoft partners offer tools and services to migrate Netezza SQL and stored procedures to Azure Synapse.

Use third-party ETL tools

As described in the previous section, in many cases the existing legacy data warehouse system will already be populated and maintained by third-party ETL products. For a list of Microsoft data integration partners for Azure Synapse, see Data integration partners.

Data loading from Netezza

Choices available when loading data from Netezza

> **TIP**
> Third-party tools can simplify and automate the migration process and therefore reduce risk.

When it comes to migrating data from a Netezza data warehouse, there are some basic questions associated with data loading that need to be resolved. You'll need to decide how the data will be physically moved from the existing on-premises Netezza environment into Azure Synapse in the cloud, and which tools will be used to perform the transfer and load. Consider the following questions, which are discussed in the next sections.

- Will you extract the data to files, or move it directly via a network connection?
- Will you orchestrate the process from the source system, or from the Azure target environment?
- Which tools will you use to automate and manage the process?

Transfer data via files or network connection?

> **TIP**
> Understand the data volumes to be migrated and the available network bandwidth since these factors influence the migration approach decision.

Once the database tables to be migrated have been created in Azure Synapse, you can move the data to populate those tables out of the legacy Netezza system and into the new environment. There are two basic approaches:

- **File extract**: extract the data from the Netezza tables to flat files, normally in CSV format, via nzsql with the -o option or via the `CREATE EXTERNAL TABLE` statement. Use an external table whenever possible since it's the most efficient in terms of data throughput. The following SQL example creates a CSV file via an

external table:

```
CREATE EXTERNAL TABLE '/data/export.csv' USING (delimiter ',')
AS SELECT col1, col2, expr1, expr2, col3, col1 || col2 FROM your table;
```

Use an external table if you're exporting data to a mounted file system on a local Netezza host. If you're exporting data to a remote machine that has JDBC, ODBC, or OLEDB installed, then your "remotesource odbc" option is the `USING` clause.

This approach requires space to land the extracted data files. The space could be local to the Netezza source database (if sufficient storage is available), or remote in Azure Blob Storage. The best performance is achieved when a file is written locally, since that avoids network overhead.

To minimize the storage and network transfer requirements, it's good practice to compress the extracted data files using a utility like gzip.

Once extracted, the flat files can either be moved into Azure Blob Storage (collocated with the target Azure Synapse instance), or loaded directly into Azure Synapse using PolyBase or COPY INTO. The method for physically moving data from local on-premises storage to the Azure cloud environment depends on the amount of data and the available network bandwidth.

Microsoft provides various options to move large volumes of data, including AzCopy for moving files across the network into Azure Storage, Azure ExpressRoute for moving bulk data over a private network connection, and Azure Data Box for files moving to a physical storage device that's then shipped to an Azure data center for loading. For more information, see data transfer.

- **Direct extract and load across network**: the target Azure environment sends a data extract request, normally via a SQL command, to the legacy Netezza system to extract the data. The results are sent across the network and loaded directly into Azure Synapse, with no need to land the data into intermediate files. The limiting factor in this scenario is normally the bandwidth of the network connection between the Netezza database and the Azure environment. For very large data volumes, this approach may not be practical.

There's also a hybrid approach that uses both methods. For example, you can use the direct network extract approach for smaller dimension tables and samples of the larger fact tables to quickly provide a test environment in Azure Synapse. For large volume historical fact tables, you can use the file extract and transfer approach using Azure Data Box.

Orchestrate from Netezza or Azure?

The recommended approach when moving to Azure Synapse is to orchestrate the data extract and loading from the Azure environment using Azure Synapse Pipelines or Azure Data Factory, as well as associated utilities, such as PolyBase or COPY INTO, for the most efficient data loading. This approach leverages Azure capabilities and provides an easy method to build reusable data loading pipelines.

Other benefits of this approach include reduced impact on the Netezza system during the data load process since the management and loading process is running in Azure, and the ability to automate the process by using metadata-driven data load pipelines.

Which tools can be used?

The task of data transformation and movement is the basic function of all ETL products. If one of these products is already in use in the existing Netezza environment, then using the existing ETL tool may simplify data migration from Netezza to Azure Synapse. This approach assumes that the ETL tool supports Azure Synapse as a target environment. For more information on tools that support Azure Synapse, see Data integration partners.

If you're using an ETL tool, consider running that tool within the Azure environment to benefit from Azure cloud performance, scalability, and cost, and free up resources in the Netezza data center. Another benefit is reduced

data movement between the cloud and on-premises environments.

Summary

To summarize, our recommendations for migrating data and associated ETL processes from Netezza to Azure Synapse are:

- Plan ahead to ensure a successful migration exercise.
- Build a detailed inventory of data and processes to be migrated as soon as possible.
- Use system metadata and log files to get an accurate understanding of data and process usage. Don't rely on documentation since it may be out of date.
- Understand the data volumes to be migrated, and the network bandwidth between the on-premises data center and Azure cloud environments.
- Leverage standard "built-in" Azure features to minimize the migration workload.
- Identify and understand the most efficient tools for data extraction and loading in both Netezza and Azure environments. Use the appropriate tools in each phase of the process.
- Use Azure facilities, such as Azure Synapse Pipelines or Azure Data Factory, to orchestrate and automate the migration process while minimizing impact on the Netezza system.

Next steps

To learn more about security access operations, see the next article in this series: Security, access, and operations for Netezza migrations.

Security, access, and operations for Netezza migrations

8/19/2022 • 21 minutes to read • Edit Online

This article is part three of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for security access operations.

Security considerations

This article discusses connection methods for existing legacy Netezza environments and how they can be migrated to Azure Synapse Analytics with minimal risk and user impact.

This article assumes that there's a requirement to migrate the existing methods of connection and user/role/permission structure as-is. If not, use the Azure portal to create and manage a new security regime.

For more information on the Azure Synapse security options, see Security whitepaper.

Connection and authentication

> **TIP**
> Authentication in both Netezza and Azure Synapse can be "in database" or through external methods.

Netezza authorization options

The IBM Netezza system offers several authentication methods for Netezza database users:

- **Local authentication**: Netezza administrators define database users and their passwords by using the `CREATE USER` command or through Netezza administrative interfaces. In local authentication, use the Netezza system to manage database accounts and passwords, and to add and remove database users from the system. This method is the default authentication method.
- **LDAP authentication**: use an LDAP name server to authenticate database users, and manage passwords, database account activations, and deactivations. The Netezza system uses a Pluggable Authentication Module (PAM) to authenticate users on the LDAP name server. Microsoft Active Directory conforms to the LDAP protocol, so it can be treated like an LDAP server for the purposes of LDAP authentication.
- **Kerberos authentication**: use a Kerberos distribution server to authenticate database users, and manage passwords, database account activations, and deactivations.

Authentication is a system-wide setting. Users must be either locally authenticated or authenticated by using the LDAP or Kerberos method. If you choose LDAP or Kerberos authentication, create users with local authentication on a per-user basis. LDAP and Kerberos can't be used at the same time to authenticate users. Netezza host supports LDAP or Kerberos authentication for database user logins only, not for operating system logins on the host.

Azure Synapse authorization options

Azure Synapse supports two basic options for connection and authorization:

- **SQL authentication**: SQL authentication is via a database connection that includes a database identifier, user ID, and password plus other optional parameters. This is functionally equivalent to Netezza local connections.

- **Azure Active Directory (Azure AD) authentication**: with Azure AD authentication, you can centrally manage the identities of database users and other Microsoft services in one central location. Central ID management provides a single place to manage Azure Synapse users and simplifies permission management. Azure AD can also support connections to LDAP and Kerberos services—for example, Azure AD can be used to connect to existing LDAP directories if these are to remain in place after migration of the database.

Users, roles, and permissions

Overview

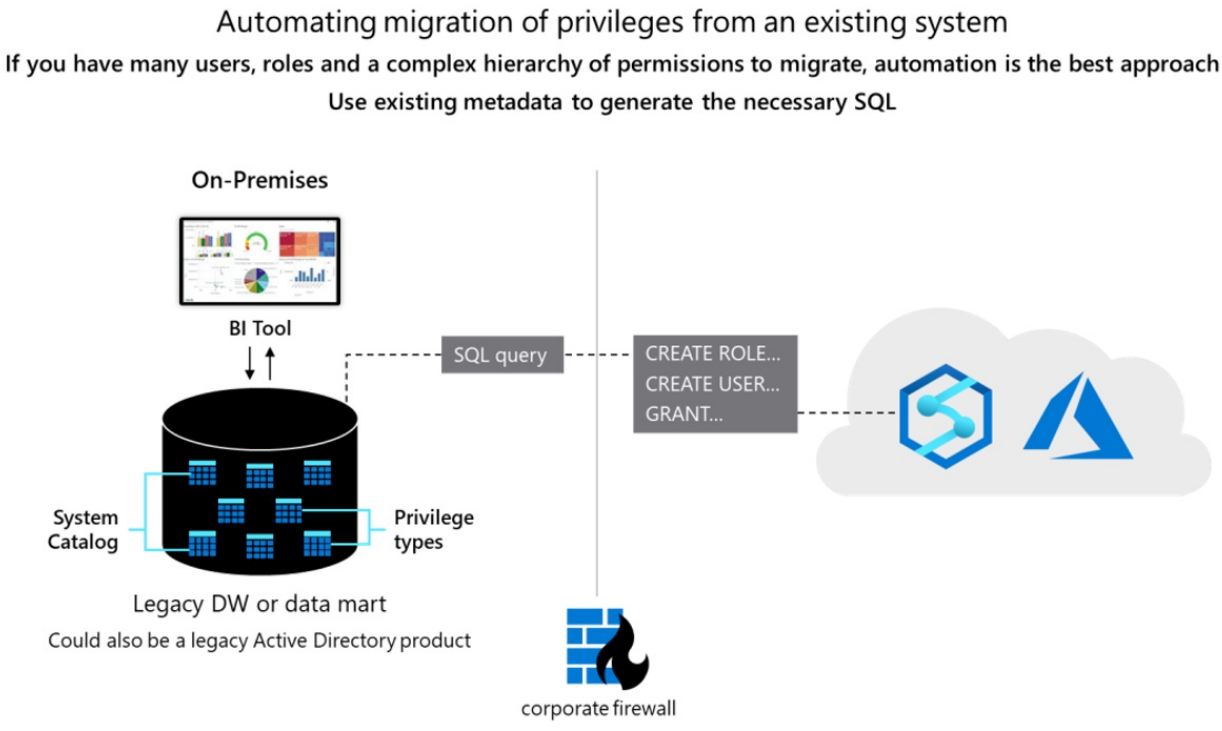
> **TIP**
> High-level planning is essential for a successful migration project.

Both Netezza and Azure Synapse implement database access control via a combination of users, roles (groups in Netezza), and permissions. Both use standard SQL `CREATE USER` and `CREATE ROLE/GROUP` statements to define users and roles, and `GRANT` and `REVOKE` statements to assign or remove permissions to those users and/or roles.

> **TIP**
> Automation of migration processes is recommended to reduce elapsed time and scope for errors.

Conceptually the two databases are similar, and it might be possible to automate the migration of existing user IDs, groups, and permissions to some degree. Migrate such data by extracting the existing legacy user and group information from the Netezza system catalog tables and generating matching equivalent `CREATE USER` and `CREATE ROLE` statements to be run in Azure Synapse to recreate the same user/role hierarchy.

After data extraction, use Netezza system catalog tables to generate equivalent `GRANT` statements to assign permissions (where an equivalent one exists). The following diagram shows how to use existing metadata to generate the necessary SQL.



See the following sections for more details.

Users and roles

> **TIP**
> Migration of a data warehouse requires more than just tables, views, and SQL statements.

The information about current users and groups in a Netezza system is held in system catalog views `_v_users` and `_v_groupusers`. Use the nzsql utility or tools such as the Netezza Performance, NzAdmin, or Netezza Utility scripts to list user privileges. For example, use the `dpu` and `dpgu` commands in nzsql to display users or groups with their permissions.

Use or edit the utility scripts `nz_get_users` and `nz_get_user_groups` to retrieve the same information in the required format.

Query system catalog views directly (if the user has `SELECT` access to those views) to obtain current lists of users and roles defined within the system. See examples to list users, groups, or users and their associated groups:

```
-- List of users
SELECT USERNAME FROM _V_USER;

--List of groups
SELECT DISTINCT(GROUPNAME) FROM _V_USERGROUPS;

--List of users and their associated groups
SELECT USERNAME, GROUPNAME FROM _V_GROUPUSERS;
```

Modify the example `SELECT` statement to produce a result set that is a series of `CREATE USER` and `CREATE GROUP` statements by including the appropriate text as a literal within the `SELECT` statement.

There's no way to retrieve existing passwords, so you need to implement a scheme for allocating new initial passwords on Azure Synapse.

Permissions

> **TIP**
> There are equivalent Azure Synapse permissions for basic database operations such as DML and DDL.

In a Netezza system, the system table `_t_usrobj_priv` holds the access rights for users and roles. Query these tables (if the user has `SELECT` access to those tables) to obtain current lists of access rights defined within the system.

In Netezza, the individual permissions are represented as individual bits within field privileges or g_privileges. See example SQL statement at user group permissions

The simplest way to obtain a DDL script that contains the `GRANT` commands to replicate the current privileges for users and groups is to use the appropriate Netezza utility scripts:

```
--List of group privileges
nz_ddl_grant_group -usrobj dbname > output_file_dbname;

--List of user privileges
nz_ddl_grant_user -usrobj dbname > output_file_dbname;
```

The output file can be modified to produce a script that is a series of `GRANT` statements for Azure Synapse.

Netezza supports two classes of access rights, Admin and Object. See the following tables for a list of Netezza

access rights and their equivalent in Azure Synapse.

ADMIN PRIVILEGE	DESCRIPTION	AZURE SYNAPSE EQUIVALENT
Backup	Allows user to create backups. The user can run backups. The user can run the command `nzbackup`.	[1]
[Create] Aggregate	Allows the user to create user-defined aggregates (UDAs). Permission to operate on existing UDAs is controlled by object privileges.	CREATE FUNCTION [3]
[Create] Database	Allows the user to create databases. Permission to operate on existing databases is controlled by object privileges.	CREATE DATABASE
[Create] External Table	Allows the user to create external tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] Function	Allows the user to create user-defined functions (UDFs). Permission to operate on existing UDFs is controlled by object privileges.	CREATE FUNCTION
[Create] Group	Allows the user to create groups. Permission to operate on existing groups is controlled by object privileges.	CREATE ROLE
[Create] Index	For system use only. Users can't create indexes.	CREATE INDEX
[Create] Library	Allows the user to create shared libraries. Permission to operate on existing shared libraries is controlled by object privileges.	[1]
[Create] Materialized View	Allows the user to create materialized views.	CREATE VIEW
[Create] Procedure	Allows the user to create stored procedures. Permission to operate on existing stored procedures is controlled by object privileges.	CREATE PROCEDURE
[Create] Schema	Allows the user to create schemas. Permission to operate on existing schemas is controlled by object privileges.	CREATE SCHEMA
[Create] Sequence	Allows the user to create database sequences.	[1]
[Create] Synonym	Allows the user to create synonyms.	CREATE SYNONYM

ADMIN PRIVILEGE	DESCRIPTION	AZURE SYNAPSE EQUIVALENT
[Create] Table	Allows the user to create tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] Temp Table	Allows the user to create temporary tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] User	Allows the user to create users. Permission to operate on existing users is controlled by object privileges.	CREATE USER
[Create] View	Allows the user to create views. Permission to operate on existing views is controlled by object privileges.	CREATE VIEW
[Manage Hardware	Allows the user to do the following hardware-related operations: view hardware status, manage SPUs, manage topology and mirroring, and run diagnostic tests. The user can run these commands: nzhw and nzds.	[4]
[Manage Security	Allows the user to run commands and operations that relate to the following advanced security options such as: managing and configuring history databases, managing multi-level security objects, and specifying security for users and groups, managing database key stores and keys and key stores for the digital signing of audit data.	[4]
[Manage System	Allows the user to do the following management operations: start/stop/pause/resume the system, abort sessions, view the distribution map, system statistics, and logs. The user can use these commands: nzsystem, nzstate, nzstats, and nzsession.	[4]
Restore	Allows the user to restore the system. The user can run the nzrestore command.	[2]
Unfence	Allows the user to create or alter a user-defined function or aggregate to run in unfenced mode.	[1]

OBJECT PRIVILEGE ABORT	DESCRIPTION	AZURE SYNAPSE EQUIVALENT
Abort	Allows the user to abort sessions. Applies to groups and users.	KILL DATABASE CONNECTION

OBJECT PRIVILEGE ABORT	DESCRIPTION	AZURE SYNAPSE EQUIVALENT
Alter	Allows the user to modify object attributes. Applies to all objects.	ALTER
Delete	Allows the user to delete table rows. Applies only to tables.	DELETE
Drop	Allows the user to drop objects. Applies to all object types.	DROP
Execute	Allows the user to run user-defined functions, user-defined aggregates, or stored procedures.	EXECUTE
GenStats	Allows the user to generate statistics on tables or databases. The user can run GENERATE STATISTICS command.	[2]
Groom	Allows the user to reclaim disk space for deleted or outdated rows, and reorganize a table by the organizing keys, or to migrate data for tables that have multiple stored versions.	[2]
Insert	Allows the user to insert rows into a table. Applies only to tables.	INSERT
List	Allows the user to display an object name, either in a list or in another manner. Applies to all objects.	LIST
Select	Allows the user to select (or query) rows within a table. Applies to tables and views.	SELECT
Truncate	Allows the user to delete all rows from a table. Applies only to tables.	TRUNCATE
Update	Allows the user to modify table rows. Applies to tables only.	UPDATE

Table notes:

1. There's no direct equivalent to this function in Azure Synapse.
2. These Netezza functions are handled automatically in Azure Synapse.
3. The Azure Synapse `CREATE FUNCTION` feature incorporates Netezza aggregate functionality.
4. These features are managed automatically by the system or via the Azure portal in Azure Synapse. See the next section on Operational considerations.

Refer to Azure Synapse Analytics security permissions.

Operational considerations

> **TIP**
> Operational tasks are necessary to keep any data warehouse operating efficiently.

This section discusses how to implement typical Netezza operational tasks in Azure Synapse with minimal risk and impact to users.

As with all data warehouse products, once in production there are ongoing management tasks that are necessary to keep the system running efficiently and to provide data for monitoring and auditing. Resource utilization and capacity planning for future growth also falls into this category, as does backup/restore of data.

Netezza administration tasks typically fall into two categories:

- System administration, which is managing the hardware, configuration settings, system status, access, disk space, usage, upgrades, and other tasks.
- Database administration, which is managing user databases and their content, loading data, backing up data, restoring data, and controlling access to data and permissions.

IBM Netezza offers several ways or interfaces that you can use to perform the various system and database management tasks:

- Netezza commands (`nz*` commands) are installed in the `/nz/kit/bin` directory on the Netezza host. For many of the `nz*` commands, you must be able to sign into the Netezza system to access and run those commands. In most cases, users sign in as the default `nz` user account, but you can create other Linux user accounts on your system. Some commands require you to specify a database user account, password, and database to ensure that you have permission to do the task.
- The Netezza CLI client kits package a subset of the `nz*` commands that can be run from Windows and UNIX client systems. The client commands might also require you to specify a database user account, password, and database to ensure that you have database administrative and object permissions to perform the task.
- The SQL commands support administration tasks and queries within a SQL database session. You can run the SQL commands from the Netezza nzsql command interpreter or through SQL APIs such as ODBC, JDBC, and the OLE DB Provider. You must have a database user account to run the SQL commands with appropriate permissions for the queries and tasks that you perform.
- The NzAdmin tool is a Netezza interface that runs on Windows client workstations to manage Netezza systems.

While conceptually the management and operations tasks for different data warehouses are similar, the individual implementations may differ. In general, modern cloud-based products such as Azure Synapse tend to incorporate a more automated and "system managed" approach (as opposed to a more "manual" approach in legacy data warehouses such as Netezza).

The following sections compare Netezza and Azure Synapse options for various operational tasks.

Housekeeping tasks

> **TIP**
> Housekeeping tasks keep a production warehouse operating efficiently and optimize use of resources such as storage.

In most legacy data warehouse environments, regular "housekeeping" tasks are time-consuming. Reclaim disk storage space by removing old versions of updated or deleted rows or reorganizing data, log files, or index

blocks for efficiency (`GROOM` and `VACUUM` in Netezza). Collecting statistics is also a potentially time-consuming task, required after a bulk data ingest to provide the query optimizer with up-to-date data on which to base query execution plans.

Netezza recommends collecting statistics as follows:

- Collect statistics on unpopulated tables to set up the interval histogram used in internal processing. This initial collection makes subsequent statistics collections faster. Make sure to recollect statistics after data is added.
- Collect prototype phase statistics for newly populated tables.
- Collect production phase statistics after a significant percentage of change to the table or partition (~10% of rows). For high volumes of nonunique values, such as dates or timestamps, it may be advantageous to recollect at 7%.
- Collect production phase statistics after you've created users and applied real world query loads to the database (up to about three months of querying).
- Collect statistics in the first few weeks after an upgrade or migration during periods of low CPU utilization.

Netezza database contains many log tables in the data dictionary that accumulate data, either automatically or after certain features are enabled. Because log data grows over time, purge older information to avoid using up permanent space. There are options to automate the maintenance of these logs available.

> **TIP**
> Automate and monitor housekeeping tasks in Azure.

Azure Synapse has an option to automatically create statistics so that they can be used as needed. Perform defragmentation of indexes and data blocks manually, on a scheduled basis, or automatically. Leveraging native built-in Azure capabilities can reduce the effort required in a migration exercise.

Monitoring and auditing

> **TIP**
> Netezza Performance Portal is the recommended method of monitoring and logging for Netezza systems.

Netezza provides the Netezza Performance Portal to monitor various aspects of one or more Netezza systems including activity, performance, queuing, and resource utilization. Netezza Performance Portal is an interactive GUI that allows users to drill down into low-level details for any chart.

> **TIP**
> The Azure portal provides a UI to manage monitoring and auditing tasks for all Azure data and processes.

Similarly, Azure Synapse provides a rich monitoring experience within the Azure portal to provide insights into your data warehouse workload. The Azure portal is the recommended tool when monitoring your data warehouse as it provides configurable retention periods, alerts, recommendations, and customizable charts and dashboards for metrics and logs.

The portal also enables integration with other Azure monitoring services such as Operations Management Suite (OMS) and Azure Monitor (logs) to provide a holistic monitoring experience for not only the data warehouse but also the entire Azure analytics platform for an integrated monitoring experience.

> **TIP**
> Low-level and system-wide metrics are automatically logged in Azure Synapse.

Resource utilization statistics for Azure Synapse are automatically logged within the system. The metrics for each query include usage statistics for CPU, memory, cache, I/O, and temporary workspace, as well as connectivity information like failed connection attempts.

Azure Synapse provides a set of Dynamic Management Views (DMVs). These views are useful when actively troubleshooting and identifying performance bottlenecks with your workload.

For more information, see Azure Synapse operations and management options.

High Availability (HA) and Disaster Recovery (DR)

Netezza appliances are redundant, fault-tolerant systems, and there are diverse options in a Netezza system to enable high availability and disaster recovery.

Adding IBM Netezza Replication Services for disaster recovery improves fault tolerance by extending redundancy across local and wide area networks.

IBM Netezza Replication Services protects against data loss by synchronizing data on a primary system (the primary node) with data on one or more target nodes (subordinates). These nodes make up a replication set.

High-Availability Linux (also called *Linux-HA*) provides the failover capabilities from a primary or active Netezza host to a secondary or standby Netezza host. The main cluster management daemon in the Linux-HA solution is called *Heartbeat*. Heartbeat watches the hosts and manages the communication and status checks of services.

Each service is a resource.

Netezza groups the Netezza-specific services into the nps resource group. When Heartbeat detects problems that imply a host failure condition or loss of service to the Netezza users, Heartbeat can initiate a failover to the standby host.

Distributed Replicated Block Device (DRBD) is a block device driver that mirrors the content of block devices (hard disks, partitions, and logical volumes) between the hosts. Netezza uses the DRBD replication only on the **/nz** and **/export/home** partitions. As new data is written to the **/nz** partition and the **/export/home** partition on the primary host, the DRBD software automatically makes the same changes to the **/nz** and **/export/home** partition of the standby host.

> **TIP**
> Azure Synapse creates snapshots automatically to ensure fast recovery times.

Azure Synapse uses database snapshots to provide high availability of the warehouse. A data warehouse snapshot creates a restore point that can be used to recover or copy a data warehouse to a previous state. Since Azure Synapse is a distributed system, a data warehouse snapshot consists of many files that are in Azure Storage. Snapshots capture incremental changes from the data stored in your data warehouse.

> **TIP**
> Use user-defined snapshots to define a recovery point before key updates.

> **TIP**
> Microsoft Azure provides automatic backups to a separate geographical location to enable DR.

Azure Synapse automatically takes snapshots throughout the day, creating restore points that are available for seven days. You can't change this retention period. Azure Synapse supports an eight-hour recovery point objective (RPO). A data warehouse can be restored in the primary region from any one of the snapshots taken in the past seven days.

User-defined restore points are also supported, allowing manual triggering of snapshots to create restore points of a data warehouse before and after large modifications. This capability ensures that restore points are logically consistent, which provides additional data protection in case of any workload interruptions or user errors for a desired RPO less than 8 hours.

As well as the snapshots described previously, Azure Synapse also performs as standard a geo-backup once per day to a paired data center. The RPO for a geo-restore is 24 hours. You can restore the geo-backup to a server in any other region where Azure Synapse is supported. A geo-backup ensures that a data warehouse can be restored in case the restore points in the primary region aren't available.

Workload management

> **TIP**
> In a production data warehouse, there are typically mixed workloads with different resource usage characteristics running concurrently.

Netezza incorporates various features for managing workloads:

TECHNIQUE	DESCRIPTION
Scheduler rules	Scheduler rules influence the scheduling of plans. Each scheduler rule specifies a condition or set of conditions. Each time the scheduler receives a plan, it evaluates all modifying scheduler rules and carries out the appropriate actions. Each time the scheduler selects a plan for execution, it evaluates all limiting scheduler rules. The plan is executed only if doing so wouldn't exceed a limit imposed by a limiting scheduler rule. Otherwise, the plan waits. This provides you with a way to classify and manipulate plans in a way that influences the other WLM techniques (SQB, GRA, and PQE).
Guaranteed resource allocation (GRA)	You can assign a minimum share and a maximum percentage of total system resources to entities called *resource groups*. The scheduler ensures that each resource group receives system resources in proportion to its minimum share. A resource group receives a larger share of resources when other resource groups are idle, but never receives more than its configured maximum percentage. Each plan is associated with a resource group, and the settings of that resource group settings determine what fraction of available system resources are to be made available to process the plan.

TECHNIQUE	DESCRIPTION
Short query bias (SQB)	Resources (that is, scheduling slots, memory, and preferential queuing) are reserved for short queries. A short query is a query for which the cost estimate is less than a specified maximum value (the default is two seconds). With SQB, short queries can run even when the system is busy processing other, longer queries.
Prioritized query execution (PQE)	Based on settings that you configure, the system assigns a priority—critical, high, normal, or low—to each query. The priority depends on factors such as the user, group, or session associated with the query. The system can then use the priority as a basis for allocating resources.

Azure Synapse automatically logs resource utilization statistics. Metrics include usage statistics for CPU, memory, cache, I/O, and temporary workspace for each query. Azure Synapse also logs connectivity information, such as failed connection attempts.

> **TIP**
> Low-level and system-wide metrics are automatically logged within Azure.

In Azure Synapse, resource classes are pre-determined resource limits that govern compute resources and concurrency for query execution. Resource classes can help you manage your workload by setting limits on the number of queries that run concurrently and on the compute resources assigned to each query. There's a trade-off between memory and concurrency.

Azure Synapse supports these basic workload management concepts:

- **Workload classification**: you can assign a request to a workload group to set importance levels.
- **Workload importance**: you can influence the order in which a request gets access to resources. By default, queries are released from the queue on a first-in, first-out basis as resources become available. Workload importance allows higher priority queries to receive resources immediately regardless of the queue.
- **Workload isolation**: you can reserve resources for a workload group, assign maximum and minimum usage for varying resources, limit the resources a group of requests can consume can, and set a timeout value to automatically kill runaway queries.

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). The workload classification, workload importance, and workload isolation gives more control over how workload utilizes system resources.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance](../../sql-data-warehouse/sql-data-warehouse-how-to-manage-and-monitor-workload-importance.md), and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized. Azure Synapse provides a set of Dynamic Management Views (DMVs) for monitoring all aspects of workload management. These views are useful when actively troubleshooting and identifying performance bottlenecks in your workload.

This information can also be used for capacity planning, determining the resources required for additional users or application workload. This also applies to planning scale up/scale downs of compute resources for cost-

effective support of "spiky" workloads, such as workloads with temporary, intense bursts of activity surrounded by periods of infrequent activity.

For more information on workload management in Azure Synapse, see Workload management with resource classes.

Scale compute resources

> **TIP**
> A major benefit of Azure is the ability to independently scale up and down compute resources on demand to handle peaky workloads cost-effectively.

The architecture of Azure Synapse separates storage and compute, allowing each to scale independently. As a result, compute resources can be scaled to meet performance demands independent of data storage. You can also pause and resume compute resources. A natural benefit of this architecture is that billing for compute and storage is separate. If a data warehouse isn't in use, you can save on compute costs by pausing compute.

Compute resources can be scaled up or scaled back by adjusting the data warehouse units setting for the data warehouse. Loading and query performance will increase linearly as you add more data warehouse units.

Adding more compute nodes adds more compute power and ability to leverage more parallel processing. As the number of compute nodes increases, the number of distributions per compute node decreases, providing more compute power and parallel processing for queries. Similarly, decreasing data warehouse units reduces the number of compute nodes, which reduces the compute resources for queries.

Visualization and reporting for Netezza migrations

8/19/2022 • 20 minutes to read • Edit Online

This article is part four of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for visualization and reporting.

Access Azure Synapse Analytics using Microsoft and third-party BI tools

Organizations access data warehouses and data marts using a range of business intelligence (BI) tools and applications. Some examples of BI products are:

- Microsoft BI tools, such as Power BI.
- Office applications, such as Microsoft Excel spreadsheets.
- Third-party BI tools from different vendors.
- Custom analytics applications with embedded BI tool functionality.
- Operational applications that support on-demand BI by running queries and reports on a BI platform that in turn queries data in a data warehouse or data mart.
- Interactive data science development tools, such as Azure Synapse Spark Notebooks, Azure Machine Learning, RStudio, and Jupyter Notebooks.

If you migrate visualization and reporting as part of your data warehouse migration, all existing queries, reports, and dashboards generated by BI products need to run in the new environment. Your BI products must yield the same results on Azure Synapse as they did in your legacy data warehouse environment.

For consistent results after migration, all BI tools and application dependencies must work after you've migrated your data warehouse schema and data to Azure Synapse. The dependencies include less visible aspects, such as access and security. When you address access and security, ensure that you migrate:

- Authentication so users can sign into the data warehouse and data mart databases on Azure Synapse.
- All users to Azure Synapse.
- All user groups to Azure Synapse.
- All roles to Azure Synapse.
- All authorization privileges governing access control to Azure Synapse.
- User, role, and privilege assignments to mirror what you had in your existing data warehouse before migration. For example:
    - Database object privileges assigned to roles
    - Roles assigned to user groups
    - Users assigned to user groups and/or roles

Access and security are important considerations for data access in the migrated system and are discussed in more detail in Security, access, and operations for Netezza migrations.

TIP

Existing users, user groups, roles, and assignments of access security privileges need to be migrated first for migration of reports and visualizations to succeed.

Migrate all required data to ensure that the reports and dashboards that query data in the legacy environment produce the same results in Azure Synapse.

Business users will expect a seamless migration, with no surprises that destroy their confidence in the migrated system on Azure Synapse. Take care to allay any fears that your users might have through good communication. Your users will expect that:

- Table structure remains the same when directly referred to in queries.
- Table and column names remain the same when directly referred to in queries. For instance, calculated fields defined on columns in BI tools shouldn't fail when aggregate reports are produced.
- Historical analysis remains the same.
- Data types remain the same, if possible.
- Query behavior remains the same.
- ODBC/JDBC drivers are tested to ensure that query behavior remains the same.

TIP

Communication and business user involvement are critical to success.

If BI tools query views in the underlying data warehouse or data mart database, will those views still work after the migration? Some views might not work if there are proprietary SQL extensions specific to your legacy data warehouse DBMS that have no equivalent in Azure Synapse. If so, you need to know about those incompatibilities and find a way to resolve them.

TIP

Views and SQL queries using proprietary SQL query extensions are likely to result in incompatibilities that impact BI reports and dashboards.

Other issues, like the behavior of `NULL` values or data type variations across DBMS platforms, need to be tested to ensure that even slight differences don't exist in calculation results. Minimize those issues and take all necessary steps to shield business users from being affected by them. Depending on your legacy data warehouse environment, third-party tools that can help hide the differences between the legacy and new environments so that BI tools and applications run unchanged.

Testing is critical to visualization and report migration. You need a test suite and agreed-on test data to run and rerun tests in both environments. A test harness is also useful, and a few are mentioned in this guide. Also, it's important to involve business users in the testing aspect of the migration to keep confidence high and to keep them engaged and part of the project.

TIP

Use repeatable tests to ensure reports, dashboards, and other visualizations migrate successfully.

You might be thinking about switching BI tools, for example to migrate to Power BI. The temptation is to make such changes at the same time you're migrating your schema, data, ETL processing, and more. However, to minimize risk, it's better to migrate to Azure Synapse first and get everything working before undertaking further modernization.

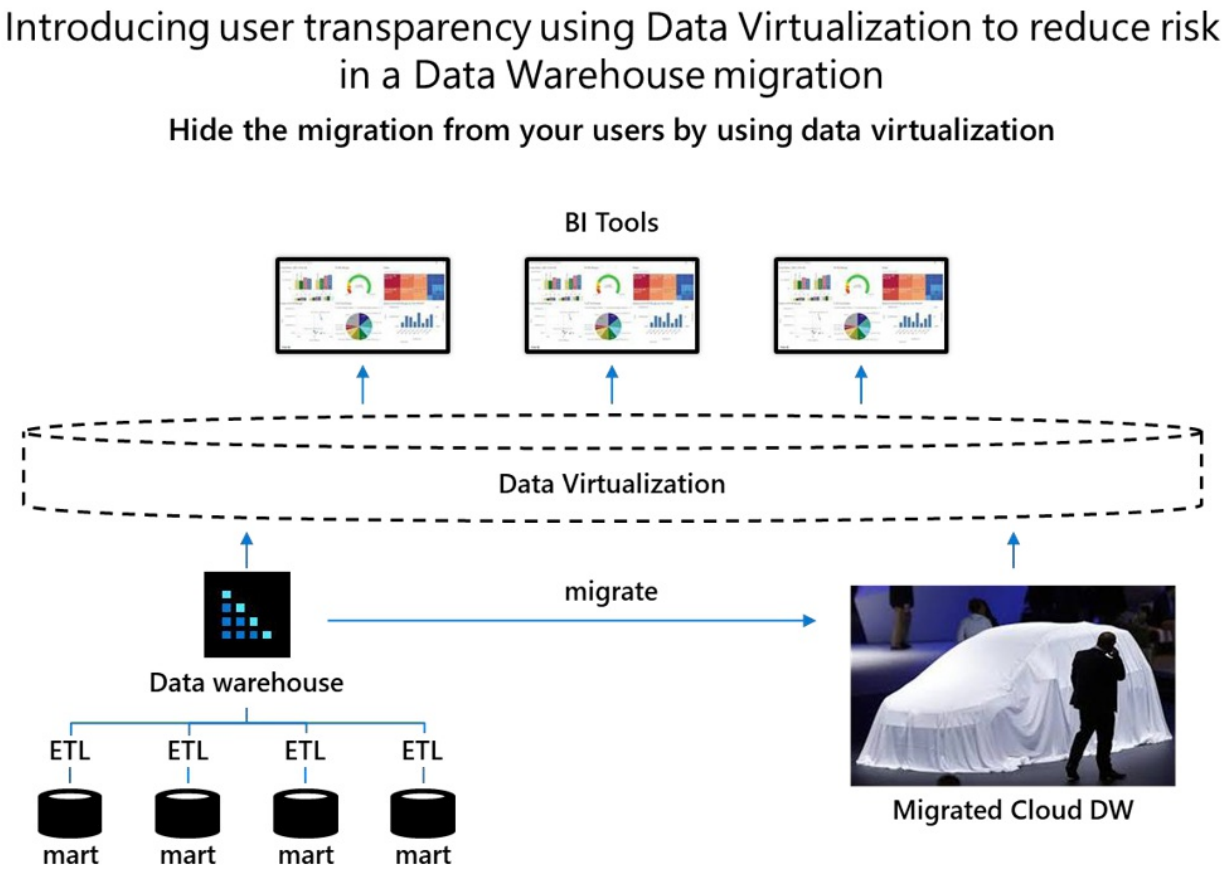
If your existing BI tools run on-premises, ensure they can connect to Azure Synapse through your firewall so you're able to run comparisons against both environments. Alternatively, if the vendor of your existing BI tools offers their product on Azure, you can try it there. The same applies for applications running on-premises that embed BI or call your BI server on demand, for example by requesting a "headless report" with XML or JSON data.

There's a lot to think about here, so let's take a closer look.

Use data virtualization to minimize the impact of migration on BI tools and reports

During migration, you might be tempted to fulfill long-term requirements like opening business requests, adding missing data, or implementing new features. However, such changes can affect BI tool access to your data warehouse, especially if the change involves structural changes to your data model. If you want to adopt an agile data modeling technique or implement structural changes, do so *after* migration.

One way to minimize the effect of schema changes or other structural changes on your BI tools is to introduce data virtualization between the BI tools and your data warehouse and data marts. The following diagram shows how data virtualization can hide a migration from users.



Data virtualization breaks the dependency between business users utilizing self-service BI tools and the physical schema of the underlying data warehouse and data marts that are being migrated.

> **TIP**
> Data virtualization allows you to shield business users from structural changes during migration so they remain unaware of those changes. Structural changes include schema alterations that tune your data model for Azure Synapse.

With data virtualization, any schema alterations made during a migration to Azure Synapse, for example to optimize performance, can be hidden from business users because they only have access to virtual tables in the data virtualization layer. And, if you make structural changes, you only need to update the mappings between the data warehouse or data marts and any virtual tables. With data virtualization, users remain unaware of structural changes. Microsoft partners provide data virtualization software.

Identify high-priority reports to migrate first

A key question when migrating your existing reports and dashboards to Azure Synapse is which ones to migrate first. Several factors might drive that decision, such as:

- Usage
- Business value
- Ease of migration
- Data migration strategy

The following sections discuss these factors.

Whatever your decision, it must involve your business users because they produce the reports, dashboards, and other visualizations, and make business decisions based on insights from those items. Everyone benefits when you can:

- Migrate reports and dashboards seamlessly,
- Migrate reports and dashboards with minimal effort, and
- Point your BI tool(s) at Azure Synapse instead of your legacy data warehouse system, and get like-for-like reports, dashboards, and other visualizations.

Migrate reports based on usage

Usage is often an indicator of business value. Unused reports and dashboards clearly don't contribute to business decisions or offer current value. If you don't have a way to find out which reports and dashboards are unused, you can use one of the several BI tools that provide usage statistics.

If your legacy data warehouse has been up and running for years, there's a good chance you have hundreds, if not thousands, of reports in existence. It's worth compiling an inventory of reports and dashboards and identifying their business purpose and usage statistics.

For unused reports, determine whether to decommission them to reduce your migration effort. A key question when deciding whether to decommission an unused report is whether the report is unused because people don't know it exists, because it offers no business value, or because it's been superseded by another report.

Migrate reports based on business value

Usage alone isn't always a good indicator of business value. You might want to consider the extent to which a report's insights contribute to business value. One way to do that is to evaluate the profitability of every business decision that relies on the report and the extent of the reliance. However, that information is unlikely to be readily available in most organizations.

Another way to evaluate business value is to look at the alignment of a report with business strategy. The business strategy set by your executive typically lays out strategic business objectives (SBOs), key performance

indicators (KPIs), KPI targets that need to be achieved, and who is accountable for achieving them. You can classify a report by which SBOs the report contributes to, such as fraud reduction, improved customer engagement, and optimized business operations. Then, you can prioritize for migration the reports and dashboards that are associated with high-priority objectives. In this way, the initial migration can deliver business value in a strategic area.

Another way to evaluate business value is to classify reports and dashboards as operational, tactical, or strategic to identify at which business level they're used. SBOs require contributions at all these levels. By knowing which reports and dashboards are used, at what level, and what objectives they're associated with, you're able to focus the initial migration on high-priority business value. You can use the following *business strategy objective* table to evaluate reports and dashboards.

LEVEL	REPORT / DASHBOARD NAME	BUSINESS PURPOSE	DEPARTMENT USED	USAGE FREQUENCY	BUSINESS PRIORITY
Strategic					
Tactical					
Operational					

Metadata discovery tools like Azure Data Catalog let business users tag and rate data sources to enrich the metadata for those data sources to assist with their discovery and classification. You can use the metadata for a report or dashboard to help you understand its business value. Without such tools, understanding the contribution of reports and dashboards to business value is likely to be a time-consuming task, whether you're migrating or not.

Migrate reports based on data migration strategy

If your migration strategy is based on migrating data marts first, then the order of data mart migration will affect which reports and dashboards are migrated first. If your strategy is based on business value, the order in which you migrate data marts to Azure Synapse will reflect business priorities. Metadata discovery tools can help you implement your strategy by showing you which data mart tables supply data for which reports.

> **TIP**
> Your data migration strategy affects which reports and visualizations get migrated first.

Migration incompatibility issues that can affect reports and visualizations

BI tools produce reports, dashboards, and other visualizations by issuing SQL queries that access physical tables and/or views in your data warehouse or data mart. When you migrate your legacy data warehouse to Azure Synapse, several factors can affect the ease of migration of reports, dashboards, and other visualizations. Those factors include:

- Schema incompatibilities between the environments.
- SQL incompatibilities between the environments.

Schema incompatibilities

During a migration, schema incompatibilities in the data warehouse or data mart tables that supply data for reports, dashboards, and other visualizations can be:

- Non-standard table types in your legacy data warehouse DBMS that don't have an equivalent in Azure

Synapse.

- Data types in your legacy data warehouse DBMS that don't have an equivalent in Azure Synapse.

In most cases, there's a workaround to the incompatibilities. For example, you can migrate the data in an unsupported table type into a standard table with appropriate data types and indexed or partitioned on a date/time column. Similarly, it might be possible to represent unsupported data types in another type of column and perform calculations in Azure Synapse to achieve the same results.

> **TIP**
> Schema incompatibilities include legacy warehouse DBMS table types and data types that are unsupported on Azure Synapse.

To identify the reports affected by schema incompatibilities, run queries against the system catalog of your legacy data warehouse to identify the tables with unsupported data types. Then, you can use metadata from your BI tool to identify the reports that access data in those tables. For more information about how to identify object type incompatibilities, see Unsupported Netezza database object types.

> **TIP**
> Query the system catalog of your legacy warehouse DBMS to identify schema incompatibilities with Azure Synapse.

The effect of schema incompatibilities on reports, dashboards, and other visualizations might be less than you think because many BI tools don't support the less generic data types. As a result, your legacy data warehouse might already have views that `CAST` unsupported data types to more generic types.

SQL incompatibilities

During a migration, SQL incompatibilities are likely to affect any report, dashboard, or other visualization in an application or tool that:

- Accesses legacy data warehouse DBMS views that include proprietary SQL functions that have no equivalent in Azure Synapse.
- Issues SQL queries that include proprietary SQL functions, specific to the SQL dialect of your legacy environment, that have no equivalent in Azure Synapse.

Gauge the impact of SQL incompatibilities on your reporting portfolio

Your reporting portfolio might include embedded query services, reports, dashboards, and other visualizations. Don't rely on the documentation associated with those items to gauge the effect of SQL incompatibilities on the migration of your reporting portfolio to Azure Synapse. You need to use a more precise way to assess the effect of SQL incompatibilities.

Use EXPLAIN statements to find SQL incompatibilities

You can find SQL incompatibilities by querying the `_v_qryhist` system table to view recent SQL activity in your legacy Netezza data warehouse. For more information, see Query history table. Use a script to extract a representative set of SQL statements to a file. Then, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse. Any SQL statements containing proprietary unsupported SQL extensions will be rejected by Azure Synapse when the `EXPLAIN` statements are executed. This approach lets you assess the extent of SQL incompatibilities.

Metadata from your legacy data warehouse DBMS can also help you identify incompatible views. As before, capture a representative set of SQL statements, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse to identify views with incompatible SQL.

> **TIP**
> Gauge the impact of SQL incompatibilities by harvesting your DBMS log files and running `EXPLAIN` statements.

Test report and dashboard migration to Azure Synapse Analytics

A key element of data warehouse migration is testing of reports and dashboards in Azure Synapse to verify the migration has worked. Define a series of tests and a set of required outcomes for each test that you will run to verify success. Test and compare the reports and dashboards across your existing and migrated data warehouse systems to:

- Identify whether any schema changes that were made during migration affected the ability of reports to run, report results, or the corresponding report visualizations. An example of a schema change is if you mapped an incompatible data type to an equivalent data type that's supported in Azure Synapse.
- Verify that all users are migrated.
- Verify that all roles are migrated, and users are assigned to those roles.
- Verify that all data access security privileges are migrated to ensure access control list (ACL) migration.
- Ensure consistent results for all known queries, reports, and dashboards.
- Ensure that data and ETL migration is complete and error-free.
- Ensure that data privacy is upheld.
- Test performance and scalability.
- Test analytical functionality.

> **TIP**
> Test and tune performance to minimize compute costs.

For information about how to migrate users, user groups, roles, and privileges, see Security, access, and operations for Netezza migrations.

Automate testing as much as possible to make each test repeatable and to support a consistent approach to evaluating test results. Automation works well for known regular reports, and can be managed via Azure Synapse pipelines or Azure Data Factory orchestration. If you already have a suite of test queries in place for regression testing, you can use the existing testing tools to automate post migration testing.

> **TIP**
> Best practice is to build an automated test suite to make tests repeatable.

Ad-hoc analysis and reporting are more challenging and require compilation of a set of tests to verify that the same reports and dashboards from before and after migration are consistent. If you find inconsistencies, then your ability to compare metadata lineage across the original and migrated systems during migration testing becomes crucial. That comparison can highlight differences and pinpoint where inconsistencies originated, when detection by other means is difficult.

> **TIP**
> Leverage tools that compare metadata lineage to verify results.

Analyze lineage to understand dependencies between reports, dashboards, and data

Your understanding of lineage is a critical factor in the successful migration of reports and dashboards. Lineage is metadata that shows the journey of migrated data so you can track its path from a report or dashboard all the way back to the data source. Lineage shows how data has traveled from point to point, its location in the data warehouse and/or data mart, and which reports and dashboards use it. Lineage can help you understand what happens to data as it travels through different data stores, such as files and databases, different ETL pipelines, and into reports. When business users have access to data lineage, it improves trust, instills confidence, and supports informed business decisions.

> **TIP**
> Your ability to access metadata and data lineage from reports all the way back to a data source is critical for verifying that migrated reports work correctly.

In multi-vendor data warehouse environments, business analysts in BI teams might map out data lineage. For example, if you use different vendors for ETL, data warehouse, and reporting, and each vendor has its own metadata repository, then figuring out where a specific data element in a report came from can be challenging and time-consuming.

> **TIP**
> Tools that automate the collection of metadata and show end-to-end lineage in a multi-vendor environment are valuable during a migration.

To migrate seamlessly from a legacy data warehouse to Azure Synapse, use end-to-end data lineage to prove like-for-like migration when you're comparing the reports and dashboards generated by each environment. To show the end-to-end data journey, you'll need to capture and integrate metadata from several tools. Having access to tools that support automated metadata discovery and data lineage, helps you identify duplicate reports or ETL processes, and find reports that rely on obsolete, questionable, or non-existent data sources. You can use that information to reduce the number of reports and ETL processes that you migrate.

You can also compare the end-to-end lineage of a report in Azure Synapse to the end-to-end lineage of the same report in your legacy environment to check for differences that might have inadvertently occurred during migration. This type of comparison is exceptionally useful when you need to test and verify migration success.

Data lineage visualization not only reduces time, effort, and error in the migration process, but also enables faster migration.

By using automated metadata discovery and data lineage tools that compare lineage, you can verify that a report in Azure Synapse that's produced from migrated data is produced in the same way in your legacy environment. This capability also helps you determine:

- What data needs to be migrated to ensure successful report and dashboard execution in Azure Synapse.
- What transformations have been and should be performed to ensure successful execution in Azure Synapse.

- How to reduce report duplication.

Automated metadata discovery and data lineage tools substantially simplify the migration process because they help businesses become more aware of their data assets and to know what needs to be migrated to Azure Synapse to achieve a solid reporting environment.

Several ETL tools provide end-to-end lineage capability, so check whether your existing ETL tool has that capability if you plan to use it with Azure Synapse. Azure Synapse pipelines or Data Factory both support the ability to view lineage in mapping flows. Microsoft partners also provide automated metadata discovery, data lineage, and lineage comparison tools.

Migrate BI tool semantic layers to Azure Synapse Analytics

Some BI tools have what is known as a semantic metadata layer. That layer simplifies business user access to the underlying physical data structures in a data warehouse or data mart database. The semantic metadata layer simplifies access by providing high-level objects like dimensions, measures, hierarchies, calculated metrics, and joins. The high-level objects use business terms that are familiar to business analysts, and map to physical data structures in your data warehouse or data mart.

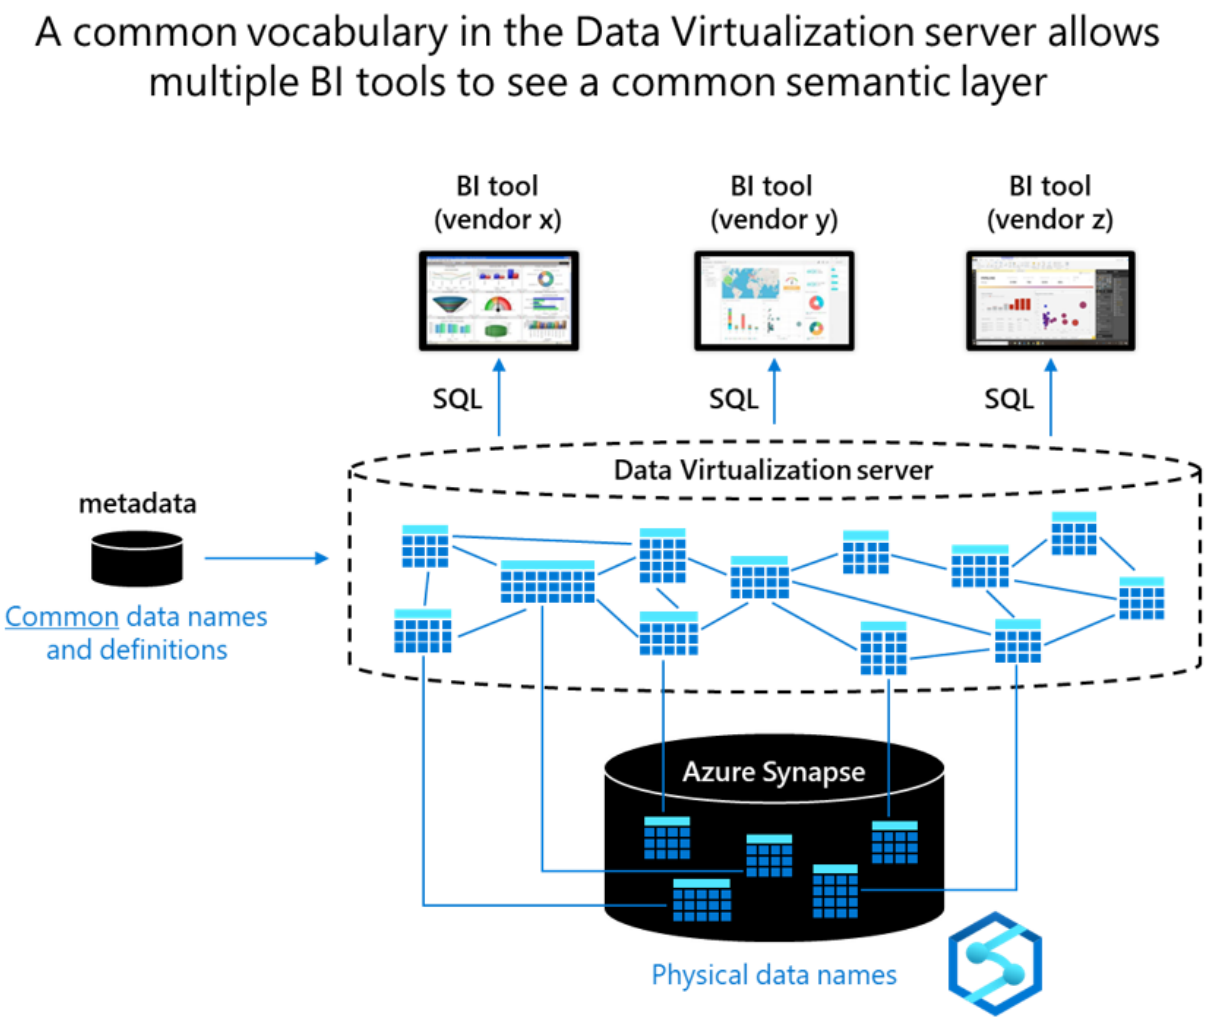
> **TIP**
> Some BI tools have semantic layers that simplify business user access to physical data structures in your data warehouse or data mart.

In a data warehouse migration, changes to column names or table names may be forced upon you. For example, in IBM Netezza, table names can have a "#". In Azure Synapse, the "#" is only allowed as a prefix to a table name to indicate a temporary table. In IBM Netezza, TEMPORARY TABLES do not necessarily have a "#" in the name, but in Synapse they must. You may need to do some rework to change table mappings in such cases.

To achieve consistency across multiple BI tools, create a universal semantic layer by using a data virtualization server that sits between BI tools and applications and Azure Synapse. In the data virtualization server, use common data names for high-level objects like dimensions, measures, hierarchies, and joins. That way you configure everything, including calculated fields, joins, and mappings, only once instead of in every tool. Then, point all BI tools at the data virtualization server.

> **TIP**
> Use data virtualization to create a common semantic layer to guarantee consistency across all BI tools in an Azure Synapse environment.

With data virtualization, you get consistency across all BI tools and break the dependency between BI tools and applications and the underlying physical data structures in Azure Synapse. Microsoft partners can help you achieve consistency in Azure. The following diagram shows how a common vocabulary in the data virtualization server lets multiple BI tools see a common semantic layer.



Conclusions

In a lift and shift data warehouse migration, most reports, dashboards, and other visualizations should migrate easily.

During a migration from a legacy environment, you might find that data in the legacy data warehouse or data mart tables is stored in unsupported data types. Or, you may find legacy data warehouse views that include proprietary SQL with no equivalent in Azure Synapse. If so, you'll need to resolve those issues to ensure a successful migration to Azure Synapse.

Don't rely on user-maintained documentation to identify where issues are located. Instead, use `EXPLAIN` statements because they're a quick, pragmatic way to identify SQL incompatibilities. Rework the incompatible SQL statements to achieve equivalent functionality in Azure Synapse. Also, use automated metadata discovery and lineage tools to understand dependencies, find duplicate reports, and identify invalid reports that rely on obsolete, questionable, or non-existent data sources. Use lineage tools to compare lineage to verify that reports running in your legacy data warehouse environment are produced identically in Azure Synapse.

Don't migrate reports that you no longer use. BI tool usage data can help you determine which reports aren't in use. For the reports, dashboards, and other visualizations that you do want to migrate, migrate all users, user groups, roles, and privileges. If you're using business value to drive your report migration strategy, associate reports with strategic business objectives and priorities to help identify the contribution of report insights to specific objectives. If you're migrating data mart by data mart, use metadata to identify which reports are dependent on which tables and views, so you can make an informed decision about which data marts to migrate first.

> **TIP**
> Identify incompatibilities early to gauge the extent of the migration effort. Migrate your users, group roles, and privilege assignments. Only migrate the reports and visualizations that are used and are contributing to business value.

Structural changes to the data model of your data warehouse or data mart can occur during a migration. Consider using data virtualization to shield BI tools and applications from structural changes. With data virtualization, you can use a common vocabulary to define a common semantic layer. The common semantic layer guarantees consistent common data names, definitions, metrics, hierarchies, and joins across all BI tools and applications in the new Azure Synapse environment.

Minimize SQL issues for Netezza migrations

8/19/2022 • 12 minutes to read • Edit Online

This article is part five of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for minimizing SQL issues.

Overview

Characteristics of Netezza environments

> **TIP**
> Netezza pioneered the "data warehouse appliance" concept in the early 2000s.

In 2003, Netezza initially released their data warehouse appliance product. It reduced the cost of entry and improved the ease-of-use of massively parallel processing (MPP) techniques to enable data processing at scale more efficiently than the existing mainframe or other MPP technologies available at the time. Since then, the product has evolved and has many installations among large financial institutions, telecommunications, and retail companies. The original implementation used proprietary hardware including field programmable gate arrays—or FPGAs—and was accessible via ODBC or JDBC network connection over TCP/IP.

Most existing Netezza installations are on-premises, so many users are considering migrating some or all their Netezza data to Azure Synapse Analytics to gain the benefits of a move to a modern cloud environment.

> **TIP**
> Many existing Netezza installations are data warehouses using a dimensional data model.

Netezza technology is often used to implement a data warehouse, supporting complex analytic queries on large data volumes using SQL. Dimensional data models—star or snowflake schemas—are common, as is the implementation of data marts for individual departments.

This combination of SQL and dimensional data models simplifies migration to Azure Synapse, since the basic concepts and SQL skills are transferable. The recommended approach is to migrate the existing data model as-is to reduce risk and time taken. Even if the eventual intention is to make changes to the data model (for example, moving to a data vault model), perform an initial as-is migration and then make changes within the Azure cloud environment, leveraging the performance, elastic scalability, and cost advantages there.

While the SQL language has been standardized, individual vendors have in some cases implemented proprietary extensions. This document highlights potential SQL differences you may encounter while migrating from a legacy Netezza environment, and provides workarounds.

Use Azure Data Factory to implement a metadata-driven migration

> **TIP**
> Automate the migration process by using Azure Data Factory capabilities.

Automate and orchestrate the migration process by making use of the capabilities in the Azure environment. This approach also minimizes the migration's impact on the existing Netezza environment, which may already be running close to full capacity.

Azure Data Factory is a cloud-based data integration service that allows creation of data-driven workflows in the cloud for orchestrating and automating data movement and data transformation. Using Data Factory, you can create and schedule data-driven workflows—called pipelines—that can ingest data from disparate data stores. It can process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

By creating metadata to list the data tables to be migrated and their location, you can use the Data Factory facilities to manage and automate parts of the migration process. You can also use Azure Synapse Pipelines.

SQL DDL differences between Netezza and Azure Synapse

SQL Data Definition Language (DDL)

> **TIP**
> SQL DDL commands `CREATE TABLE` and `CREATE VIEW` have standard core elements but are also used to define implementation-specific options.

The ANSI SQL standard defines the basic syntax for DDL commands such as `CREATE TABLE` and `CREATE VIEW`. These commands are used within both Netezza and Azure Synapse, but they've also been extended to allow definition of implementation-specific features such as indexing, table distribution, and partitioning options.

The following sections discuss Netezza-specific options to consider during a migration to Azure Synapse.

Table considerations

> **TIP**
> Use existing indexes to give an indication of candidates for indexing in the migrated warehouse.

When migrating tables between different technologies, only the raw data and its descriptive metadata get physically moved between the two environments. Other database elements from the source system, such as indexes and log files, aren't directly migrated as these may not be needed or may be implemented differently within the new target environment. For example, the `TEMPORARY` option within Netezza's `CREATE TABLE` syntax is equivalent to prefixing the table name with a "#" character in Azure Synapse.

It's important to understand where performance optimizations—such as indexes—were used in the source environment. This indicates where performance optimization can be added in the new target environment. For example, if zone maps were created in the source Netezza environment, this might indicate that a non-clustered index should be created in the migrated Azure Synapse database. Other native performance optimization techniques, such as table replication, may be more applicable than a straight "like-for-like" index creation.

Unsupported Netezza database object types

> **TIP**
> Netezza-specific features can be replaced by Azure Synapse features.

Netezza implements some database objects that aren't directly supported in Azure Synapse, but there are methods to achieve the same functionality within the new environment:

- Zone maps: in Netezza, zone maps are automatically created and maintained for some column types and are used at query time to restrict the amount of data to be scanned. Zone maps are created on the following column types:

- `INTEGER` columns of length 8 bytes or less.
- Temporal columns. For instance, `DATE`, `TIME`, and `TIMESTAMP`.
- `CHAR` columns, if these are part of a materialized view and mentioned in the `ORDER BY` clause.

You can find out which columns have zone maps by using the `nz_zonemap` utility, which is part of the NZ Toolkit. Azure Synapse doesn't include zone maps, but you can achieve similar results by using other user-defined index types and/or partitioning.

- Clustered base tables (CBT): in Netezza, CBTs are commonly used for fact tables, which can have billions of records. Scanning such a huge table requires a lot of processing time, since a full table scan might be needed to get relevant records. Organizing records on restrictive CBT allows Netezza to group records in same or nearby extents. This process also creates zone maps that improve the performance by reducing the amount of data to be scanned.

  In Azure Synapse, you can achieve a similar effect by use of partitioning and/or use of other indexes.

- Materialized views: Netezza supports materialized views and recommends creating one or more of these over large tables having many columns where only a few of those columns are regularly used in queries. The system automatically maintains materialized views when data in the base table is updated.

  Azure Synapse supports materialized views, with the same functionality as Netezza.

Netezza data type mapping

> **TIP**
> Assess the impact of unsupported data types as part of the preparation phase.

Most Netezza data types have a direct equivalent in Azure Synapse. The following table shows these data types along with the recommended approach for mapping them.

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
BIGINT	BIGINT
BINARY VARYING(n)	VARBINARY(n)
BOOLEAN	BIT
BYTEINT	TINYINT
CHARACTER VARYING(n)	VARCHAR(n)
CHARACTER(n)	CHAR(n)
DATE	DATE(date)
DECIMAL(p,s)	DECIMAL(p,s)
DOUBLE PRECISION	FLOAT
FLOAT(n)	FLOAT(n)
INTEGER	INT

NETEZZA DATA TYPE	AZURE SYNAPSE DATA TYPE
INTERVAL	INTERVAL data types aren't currently directly supported in Azure Synapse but can be calculated using temporal functions such as DATEDIFF.
MONEY	MONEY
NATIONAL CHARACTER VARYING(n)	NVARCHAR(n)
NATIONAL CHARACTER(n)	NCHAR(n)
NUMERIC(p,s)	NUMERIC(p,s)
REAL	REAL
SMALLINT	SMALLINT
ST_GEOMETRY(n)	Spatial data types such as ST_GEOMETRY aren't currently supported in Azure Synapse, but the data could be stored as VARCHAR or VARBINARY.
TIME	TIME
TIME WITH TIME ZONE	DATETIMEOFFSET
TIMESTAMP	DATETIME

Data Definition Language (DDL) generation

> **TIP**
> Use existing Netezza metadata to automate the generation of `CREATE TABLE` and `CREATE VIEW` DDL for Azure Synapse.

Edit existing Netezza `CREATE TABLE` and `CREATE VIEW` scripts to create the equivalent definitions with modified data types as described previously if necessary. Typically, this involves removing or modifying any extra Netezza-specific clauses such as `ORGANIZE ON`.

However, all the information that specifies the current definitions of tables and views within the existing Netezza environment is maintained within system catalog tables. This is the best source of this information as it's guaranteed to be up to date and complete. Be aware that user-maintained documentation may not be in sync with the current table definitions.

Access this information by using utilities such as `nz_ddl_table` and generate the `CREATE TABLE` DDL statements. Edit these statements for the equivalent tables in Azure Synapse.

> **TIP**
> Third-party tools and services can automate data mapping tasks.

There are Microsoft partners who offer tools and services to automate migration, including data-type mapping. Also, if a third-party ETL tool such as Informatica or Talend is already in use in the Netezza environment, that tool can implement any required data transformations.

SQL DML differences between Netezza and Azure Synapse

SQL Data Manipulation Language (DML)

> **TIP**
> SQL DML commands `SELECT`, `INSERT`, and `UPDATE` have standard core elements but may also implement different syntax options.

The ANSI SQL standard defines the basic syntax for DML commands such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Both Netezza and Azure Synapse use these commands, but in some cases there are implementation differences.

The following sections discuss the Netezza-specific DML commands that you should consider during a migration to Azure Synapse.

SQL DML syntax differences

Be aware of these differences in SQL Data Manipulation Language (DML) syntax between Netezza SQL and Azure Synapse when migrating:

- `STRPOS`: in Netezza, the `STRPOS` function returns the position of a substring within a string. The equivalent function in Azure Synapse is `CHARINDEX`, with the order of the arguments reversed. For example, `SELECT STRPOS('abcdef','def')...` in Netezza is equivalent to `SELECT CHARINDEX('def','abcdef')...` in Azure Synapse.
- `AGE`: Netezza supports the `AGE` operator to give the interval between two temporal values, such as timestamps or dates. For example, `SELECT AGE('23-03-1956','01-01-2019') FROM...`. In Azure Synapse, `DATEDIFF` gives the interval. For example, `SELECT DATEDIFF(day, '1956-03-26','2019-01-01') FROM...`. Note the date representation sequence.
- `NOW()`: Netezza uses `NOW()` to represent `CURRENT_TIMESTAMP` in Azure Synapse.

Functions, stored procedures, and sequences

> **TIP**
> As part of the preparation phase, assess the number and type of non-data objects being migrated.

When migrating from a mature legacy data warehouse environment such as Netezza, there are often elements other than simple tables and views that need to be migrated to the new target environment. Examples of this include functions, stored procedures, and sequences.

As part of the preparation phase, create an inventory of the objects that need to be migrated and define the methods for handling them. Then assign an appropriate allocation of resources in the project plan.

There may be facilities in the Azure environment that replace the functionality implemented as either functions or stored procedures in the Netezza environment. In this case, it's often more efficient to use the built-in Azure facilities rather than recoding the Netezza functions.

> **TIP**
> Third-party products and services can automate migration of non-data elements.

Microsoft partners offer tools and services that can automate the migration, including the mapping of data types. Also, third-party ETL tools, such as Informatica or Talend, that are already in use in the IBM Netezza

environment can implement any required data transformations.

See the following sections for more information on each of these elements.

Functions

As with most database products, Netezza supports system functions and user-defined functions within the SQL implementation. When migrating to another database platform such as Azure Synapse, common system functions are available and can be migrated without change. Some system functions may have slightly different syntax, but the required changes can be automated. System functions where there's no equivalent, such as arbitrary user-defined functions, may need to be recoded using the languages available in the target environment. Azure Synapse uses the popular Transact-SQL language to implement user-defined functions. Netezza user-defined functions are coded in nzlua or C++ languages.

Stored procedures

Most modern database products allow for procedures to be stored within the database. Netezza provides the NZPLSQL language, which is based on Postgres PL/pgSQL. A stored procedure typically contains SQL statements and some procedural logic, and may return data or a status.

Azure Synapse Analytics also supports stored procedures using T-SQL, so if you must migrate stored procedures, recode them accordingly.

Sequences

In Netezza, a sequence is a named database object created via `CREATE SEQUENCE` that can provide the unique value via the `NEXT VALUE FOR` method. Use these to generate unique numbers for use as surrogate key values for primary key values.

In Azure Synapse, there's no `CREATE SEQUENCE`. Sequences are handled using IDENTITY to create surrogate keys or managed identity using SQL code to create the next sequence number in a series.

Use EXPLAIN to validate legacy SQL

> **TIP**
> Find potential migration issues by using real queries from the existing system query logs.

Capture some representative SQL statements from the legacy query history logs to evaluate legacy Netezza SQL for compatibility with Azure Synapse. Then prefix those queries with `EXPLAIN` and—assuming a "like-for-like" migrated data model in Azure Synapse with the same table and column names—run those `EXPLAIN` statements in Azure Synapse. Any incompatible SQL will return an error. Use this information to determine the scale of the recoding task. This approach doesn't require data to be loaded into the Azure environment, only that the relevant tables and views have been created.

IBM Netezza to T-SQL mapping

The IBM Netezza to T-SQL compliant with Azure Synapse SQL data type mapping is in this table:

IBM NETEZZA DATA TYPE	AZURE SYNAPSE SQL DATA TYPE
array	*Not supported*
bigint	bigint
binary large object [(n[K|M|G])]	nvarchar [(n|max)]
blob [(n[K|M|G])]	nvarchar [(n|max)]
byte [(n)]	binary [(n)]|varbinary(max)

IBM NETEZZA DATA TYPE	AZURE SYNAPSE SQL DATA TYPE
byteint	smallint
char varying [(n)]	varchar [(n|max)]
character varying [(n)]	varchar [(n|max)]
char [(n)]	char [(n)]|varchar(max)
character [(n)]	char [(n)]|varchar(max)
character large object [(n[K|M|G])]	varchar [(n|max)
clob [(n[K|M|G])]	varchar [(n|max)
dataset	*Not supported*
date	date
dec [(p[,s])]	decimal [(p[,s])]
decimal [(p[,s])]	decimal [(p[,s])]
double precision	float(53)
float [(n)]	float [(n)]
graphic [(n)]	nchar [(n)]| varchar(max)
interval	*Not supported*
json [(n)]	nvarchar [(n|max)]
long varchar	nvarchar(max)
long vargraphic	nvarchar(max)
mbb	*Not supported*
mbr	*Not supported*
number [((p|*)[,s])]	numeric [(p[,s])]
numeric [(p [,s])]	numeric [(p[,s])]
period	*Not supported*
real	real
smallint	smallint

IBM NETEZZA DATA TYPE	AZURE SYNAPSE SQL DATA TYPE
st_geometry	*Not supported*
time	time
time with time zone	datetimeoffset
timestamp	datetime2
timestamp with time zone	datetimeoffset
varbyte	varbinary [(n|max)]
varchar [(n)]	varchar [(n)]
vargraphic [(n)]	nvarchar [(n|max)]
varray	*Not supported*
xml	*Not supported*
xmltype	*Not supported*

Summary

Typical existing legacy Netezza installations are implemented in a way that makes migration to Azure Synapse easy. They use SQL for analytical queries on large data volumes, and are in some form of dimensional data model. These factors make them good candidates for migration to Azure Synapse.

To minimize the task of migrating the actual SQL code, follow these recommendations:

- Initial migration of the data warehouse should be as-is to minimize risk and time taken, even if the eventual final environment will incorporate a different data model such as data vault.
- Understand the differences between Netezza SQL implementation and Azure Synapse.
- Use metadata and query logs from the existing Netezza implementation to assess the impact of the differences and plan an approach to mitigate.
- Automate the process wherever possible to minimize errors, risk, and time for the migration.
- Consider using specialist Microsoft partners and services to streamline the migration.

Next steps

To learn more about Microsoft and third-party tools, see the next article in this series: Tools for Netezza data warehouse migration to Azure Synapse Analytics.

Tools for Netezza data warehouse migration to Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

This article is part six of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for Microsoft and third-party tools.

Data warehouse migration tools

By migrating your existing data warehouse to Azure Synapse, you benefit from:

- A globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database.
- The rich Microsoft analytical ecosystem that exists on Azure. This ecosystem consists of technologies to help modernize your data warehouse once it's migrated and extend your analytical capabilities to drive new value.

Several tools from both Microsoft and third-party partners can help you migrate your existing data warehouse to Azure Synapse. This article discusses the following types of tools:

- Microsoft data and database migration tools.
- Third-party data warehouse automation tools to automate and document the migration to Azure Synapse.
- Third-party data warehouse migration tools to migrate schema and data to Azure Synapse.
- Third-party tools to bridge the SQL differences between your existing data warehouse DBMS and Azure Synapse.

Microsoft data migration tools

Microsoft offers several tools to help you migrate your existing data warehouse to Azure Synapse, such as:

- Azure Data Factory.
- Microsoft services for physical data transfer.
- Microsoft services for data ingestion.

The next sections discuss these tools in more detail.

Microsoft Azure Data Factory

Data Factory is a fully managed, pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. It uses Apache Spark to process and analyze data in parallel and in-memory to maximize throughput.

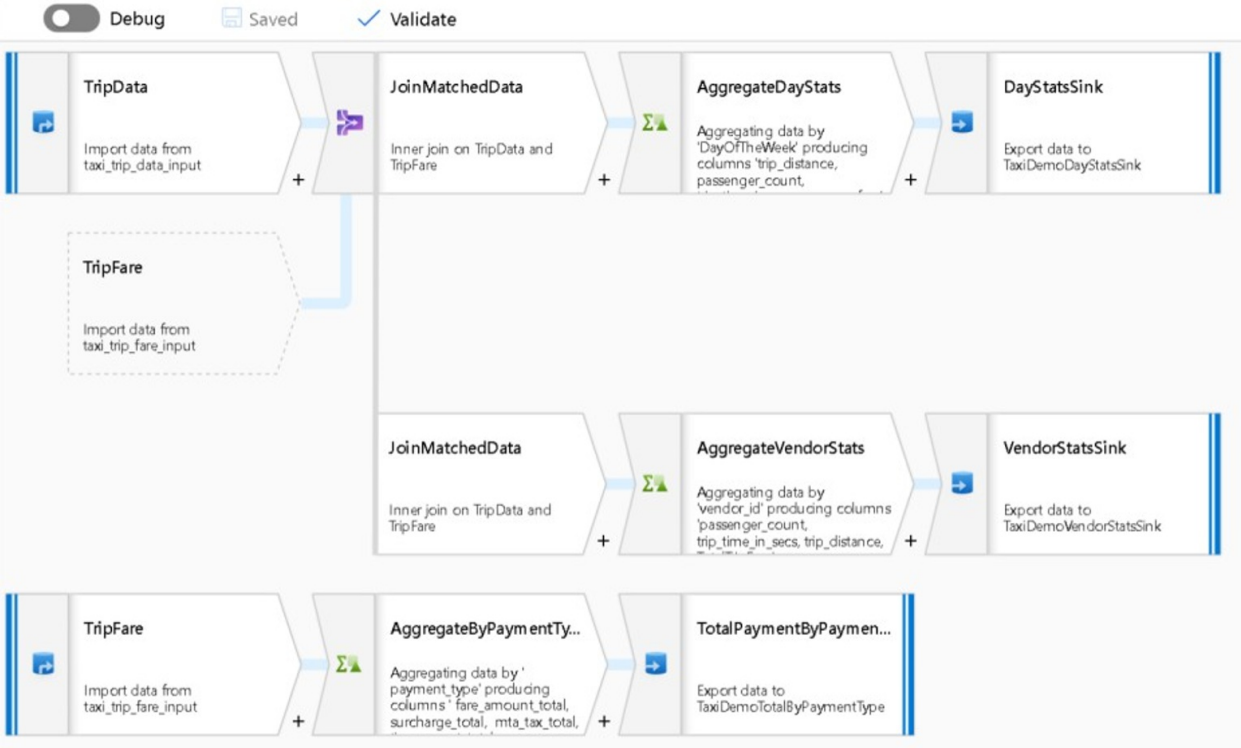
> **TIP**
> Data Factory allows you to build scalable data integration pipelines code-free.

Data Factory connectors support connections to external data sources and databases and include templates for common data integration tasks. A visual front-end, browser-based UI enables non-programmers to create and

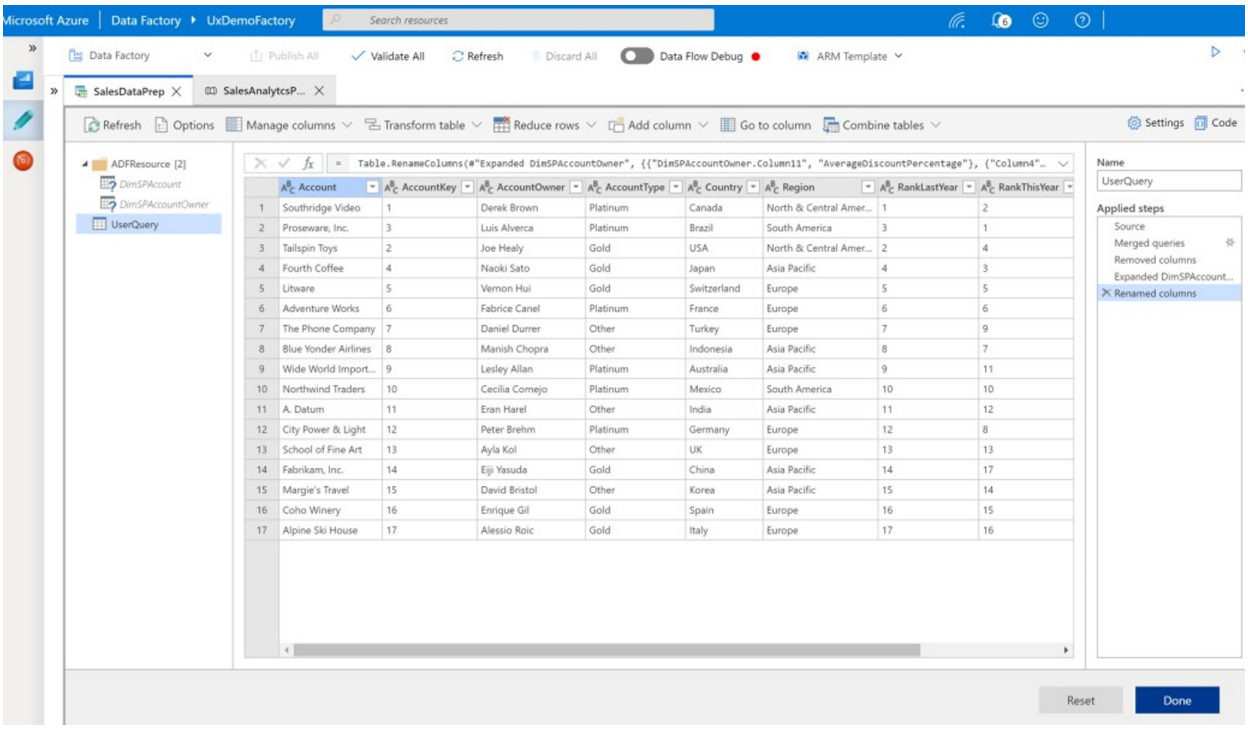
run pipelines to ingest, transform, and load data. More experienced programmers can incorporate custom code, such as Python programs.

> **TIP**
> Data Factory enables collaborative development between business and IT professionals.

Data Factory is also an orchestration tool and is the best Microsoft tool to automate the end-to-end migration process. Automation reduces the risk, effort, and time to migrate, and makes the migration process easily repeatable. The following diagram shows a mapping data flow in Data Factory.



The next screenshot shows a wrangling data flow in Data Factory.



In Data Factory, you can develop simple or comprehensive ETL and ELT processes without coding or

maintenance with just a few clicks. ETL/ELT processes ingest, move, prepare, transform, and process your data. You can design and manage scheduling and triggers in Data Factory to build an automated data integration and loading environment. In Data Factory, you can define, manage, and schedule PolyBase bulk data load processes.

> **TIP**
> Data Factory includes tools to help migrate both your data and your entire data warehouse to Azure.

You can use Data Factory to implement and manage a hybrid environment with on-premises, cloud, streaming, and SaaS data in a secure and consistent way. SaaS data might come from applications such as Salesforce.

Wrangling data flows is a new capability in Data Factory. This capability opens up Data Factory to business users who want to visually discover, explore, and prepare data at scale without writing code. Wrangling data flows offer self-service data preparation, similar to Microsoft Excel, Power Query, and Microsoft Power BI dataflows. Business users can prepare and integrate data through a spreadsheet-style UI with drop-down transform options.

Data Factory is the recommended approach for implementing data integration and ETL/ELT processes in the Azure Synapse environment, especially if you want to refactor existing legacy processes.

Microsoft services for physical data transfer

The following sections discuss a range of products and services that Microsoft offers to assist customers with data transfer.

Azure ExpressRoute

Azure ExpressRoute creates private connections between Azure data centers and infrastructure on your premises or in a collocation environment. ExpressRoute connections don't go over the public internet, and offer more reliability, faster speeds, and lower latencies than typical internet connections. In some cases, you gain significant cost benefits by using ExpressRoute connections to transfer data between on-premises systems and Azure.

AzCopy

AzCopy is a command line utility that copies files to Azure Blob Storage over a standard internet connection. In a warehouse migration project, you can use AzCopy to upload extracted, compressed, delimited text files before loading them into Azure Synapse using PolyBase. AzCopy can upload individual files, file selections, or file folders. If the exported files are in Parquet format, use a native Parquet reader instead.

Azure Data Box

Azure Data Box is a Microsoft service that provides you with a proprietary physical storage device that you can copy migration data onto. You then ship the device to an Azure data center for data upload to cloud storage. This service can be cost-effective for large volumes of data, such as tens or hundreds of terabytes, or where network bandwidth isn't readily available. Azure Data Box is typically used for a large one-off historical data load into Azure Synapse.

Azure Data Box Gateway

Azure Data Box Gateway is a virtualized cloud storage gateway device that resides on your premises and sends your images, media, and other data to Azure. Use Data Box Gateway for one-off migration tasks or ongoing incremental data uploads.

Microsoft services for data ingestion

The following sections discuss the products and services that Microsoft offers to assist customers with data ingestion.

COPY INTO

The COPY INTO statement provides the most flexibility for high-throughput data ingestion into Azure Synapse. For more information about `COPY INTO` capabilities, see COPY (Transact-SQL).

PolyBase

PolyBase is the fastest, most scalable method for bulk data load into Azure Synapse. PolyBase uses the massively parallel processing (MPP) architecture of Azure Synapse for parallel loading of data to achieve the fastest throughput. PolyBase can read data from flat files in Azure Blob Storage, or directly from external data sources and other relational databases via connectors.

> **TIP**
> PolyBase can load data in parallel from Azure Blob Storage into Azure Synapse.

PolyBase can also directly read from files compressed with gzip to reduce the physical volume of data during a load process. PolyBase supports popular data formats such as delimited text, ORC, and Parquet.

> **TIP**
> You can invoke PolyBase from Data Factory as part of a migration pipeline.

PolyBase is tightly integrated with Data Factory to support rapid development of data load ETL/ELT processes. You can schedule data load processes through a visual UI for higher productivity and fewer errors than hand-written code. Microsoft recommends PolyBase for data ingestion into Azure Synapse, especially for high-volume data ingestion.

PolyBase uses `CREATE TABLE AS` or `INSERT...SELECT` statements to load data. `CREATE TABLE AS` minimizes logging to achieve the highest throughput. The most efficient input format for data load is compressed delimited text files. For maximum throughput, split large input files into multiple smaller files and load them in parallel. For fastest loading to a staging table, define the target table as `HEAP` type and use round-robin distribution.

PolyBase has some limitations, it requires data row length to be less than 1 megabyte and doesn't support fixed-width nested formats like JSON and XML.

Microsoft partners for Netezza migrations

Microsoft partners offer tools, services, and expertise to help you migrate your legacy on-premises data warehouse platform to Azure Synapse.

Next steps

To learn more about implementing modern data warehouses, see the next article in this series: Beyond Netezza migration, implement a modern data warehouse in Microsoft Azure.

Beyond Netezza migration, implement a modern data warehouse in Microsoft Azure

8/19/2022 • 23 minutes to read • Edit Online

This article is part seven of a seven-part series that provides guidance on how to migrate from Netezza to Azure Synapse Analytics. The focus of this article is best practices for implementing modern data warehouses.

Beyond data warehouse migration to Azure

A key reason to migrate your existing data warehouse to Azure Synapse Analytics is to utilize a globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database. With Azure Synapse, you can integrate your migrated data warehouse with the complete Microsoft Azure analytical ecosystem to take advantage of other Microsoft technologies and modernize your migrated data warehouse. Those technologies include:

- Azure Data Lake Storage for cost effective data ingestion, staging, cleansing, and transformation. Data Lake Storage can free up the data warehouse capacity occupied by fast-growing staging tables.
- Azure Data Factory for collaborative IT and self-service data integration with connectors to cloud and on-premises data sources and streaming data.
- Common Data Model to share consistent trusted data across multiple technologies, including:
  - Azure Synapse
  - Azure Synapse Spark
  - Azure HDInsight
  - Power BI
  - Adobe Customer Experience Platform
  - Azure IoT
  - Microsoft ISV partners
- Microsoft data science technologies, including:
  - Azure Machine Learning studio
  - Azure Machine Learning
  - Azure Synapse Spark (Spark as a service)
  - Jupyter Notebooks
  - RStudio
  - ML.NET
  - .NET for Apache Spark, which lets data scientists use Azure Synapse data to train machine learning models at scale.
- Azure HDInsight to process large amounts of data, and to join big data with Azure Synapse data by creating a logical data warehouse using PolyBase.
- Azure Event Hubs, Azure Stream Analytics, and Apache Kafka to integrate live streaming data from Azure Synapse.

The growth of big data has led to an acute demand for machine learning to enable custom-built, trained machine learning models for use in Azure Synapse. Machine learning models enable in-database analytics to run at scale in batch, on an event-driven basis and on-demand. The ability to take advantage of in-database analytics in Azure Synapse from multiple BI tools and applications also guarantees consistent predictions and

recommendations.

In addition, you can integrate Azure Synapse with Microsoft partner tools on Azure to shorten time to value.

Let's take a closer look at how you can take advantage of technologies in the Microsoft analytical ecosystem to modernize your data warehouse after you've migrated to Azure Synapse.

Offload data staging and ETL processing to Data Lake Storage and Data Factory

Digital transformation has created a key challenge for enterprises by generating a torrent of new data for capture and analysis. A good example is transaction data created by opening online transactional processing (OLTP) systems to service access from mobile devices. Much of this data finds its way into data warehouses, and OLTP systems are the main source. With customers now driving the transaction rate rather than employees, the volume of data in data warehouse staging tables has been growing rapidly.

With the rapid influx of data into the enterprise, along with new sources of data like Internet of Things (IoT), companies must find ways to scale up data integration ETL processing. One method is to offload ingestion, data cleansing, transformation, and integration to a data lake and process data at scale there, as part of a data warehouse modernization program.

Once you've migrated your data warehouse to Azure Synapse, Microsoft can modernize your ETL processing by ingesting and staging data in Data Lake Storage. You can then clean, transform, and integrate your data at scale using Data Factory before loading it into Azure Synapse in parallel using PolyBase.

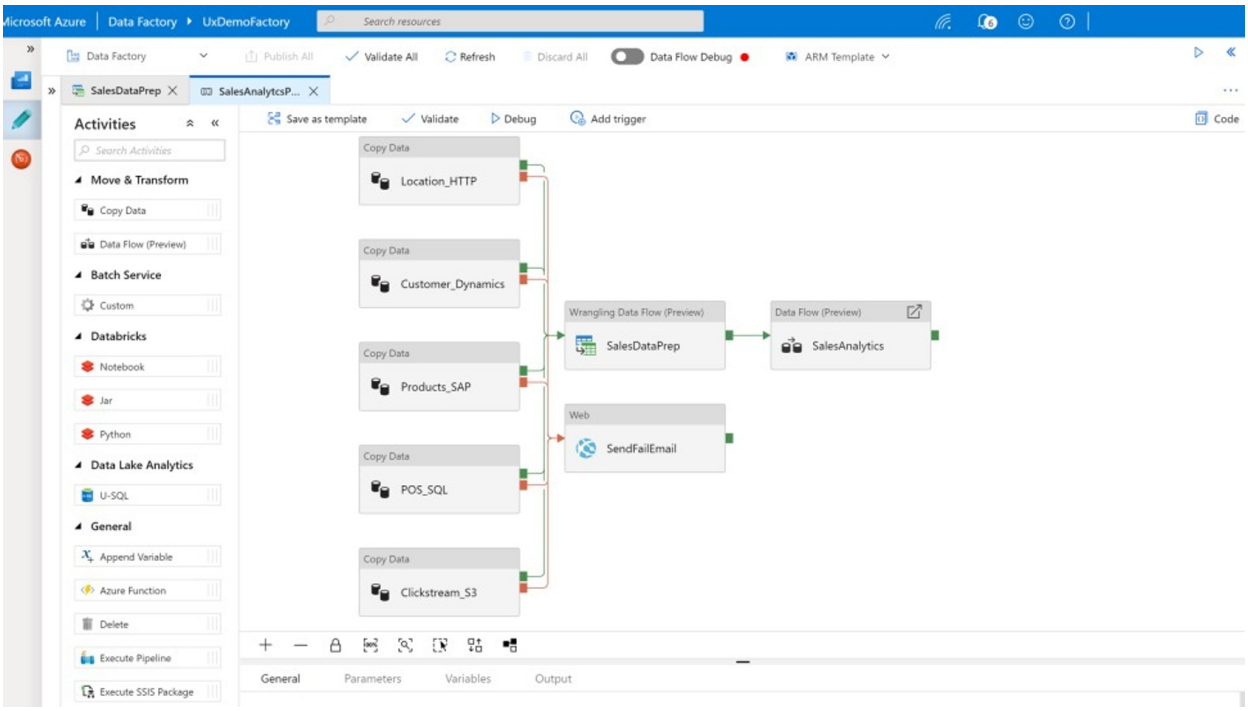
For ELT strategies, consider offloading ELT processing to Data Lake Storage to easily scale as your data volume or frequency grows.

Microsoft Azure Data Factory

Azure Data Factory is a pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. Data Factory provides a web-based UI to build data integration pipelines with no code. With Data Factory, you can:

- Build scalable data integration pipelines code-free.
- Easily acquire data at scale.
- Pay only for what you use.
- Connect to on-premises, cloud, and SaaS-based data sources.
- Ingest, move, clean, transform, integrate, and analyze cloud and on-premises data at scale.
- Seamlessly author, monitor, and manage pipelines that span data stores both on-premises and in the cloud.
- Enable pay-as-you-go scale-out in alignment with customer growth.

You can use these features without writing any code, or you can add custom code to Data Factory pipelines. The following screenshot shows an example Data Factory pipeline.



TIP

Data Factory lets you to build scalable data integration pipelines without code.

Implement Data Factory pipeline development from any of several places, including:

- Microsoft Azure portal.
- Microsoft Azure PowerShell.
- Programmatically from .NET and Python using a multi-language SDK.
- Azure Resource Manager (ARM) templates.
- REST APIs.

TIP

Data Factory can connect to on-premises, cloud, and SaaS data.

Developers and data scientists who prefer to write code can easily author Data Factory pipelines in Java, Python, and .NET using the software development kits (SDKs) available for those programming languages. Data Factory pipelines can be hybrid data pipelines because they can connect, ingest, clean, transform, and analyze data in on-premises data centers, Microsoft Azure, other clouds, and SaaS offerings.

After you develop Data Factory pipelines to integrate and analyze data, you can deploy those pipelines globally and schedule them to run in batch, invoke them on demand as a service, or run them in real-time on an event-driven basis. A Data Factory pipeline can also run on one or more execution engines and monitor execution to ensure performance and to track errors.

TIP

In Azure Data Factory, pipelines control the integration and analysis of data. Data Factory is enterprise-class data integration software aimed at IT professionals and has data wrangling capability for business users.

Use cases

Data Factory supports multiple use cases, such as:

- Prepare, integrate, and enrich data from cloud and on-premises data sources to populate your migrated data warehouse and data marts on Microsoft Azure Synapse.
- Prepare, integrate, and enrich data from cloud and on-premises data sources to produce training data for use in machine learning model development and in retraining analytical models.
- Orchestrate data preparation and analytics to create predictive and prescriptive analytical pipelines for processing and analyzing data in batch, such as sentiment analytics. Either act on the results of the analysis or populate your data warehouse with the results.
- Prepare, integrate, and enrich data for data-driven business applications running on the Azure cloud on top of operational data stores such as Azure Cosmos DB.

> **TIP**
> Build training data sets in data science to develop machine learning models.

Data sources

Data Factory lets you use connectors from both cloud and on-premises data sources. Agent software, known as a *self-hosted integration runtime*, securely accesses on-premises data sources and supports secure, scalable data transfer.

Transform data using Azure Data Factory

Within a Data Factory pipeline, you can ingest, clean, transform, integrate, and analyze any type of data from these sources. Data can be structured, semi-structured like JSON or Avro, or unstructured.

Without writing any code, professional ETL developers can use Data Factory mapping data flows to filter, split, join several types, lookup, pivot, unpivot, sort, union, and aggregate data. In addition, Data Factory supports surrogate keys, multiple write processing options like insert, upsert, update, table recreation, and table truncation, and several types of target data stores—also known as sinks. ETL developers can also create aggregations, including time-series aggregations that require a window to be placed on data columns.

> **TIP**
> Professional ETL developers can use Data Factory mapping data flows to clean, transform, and integrate data without the need to write code.

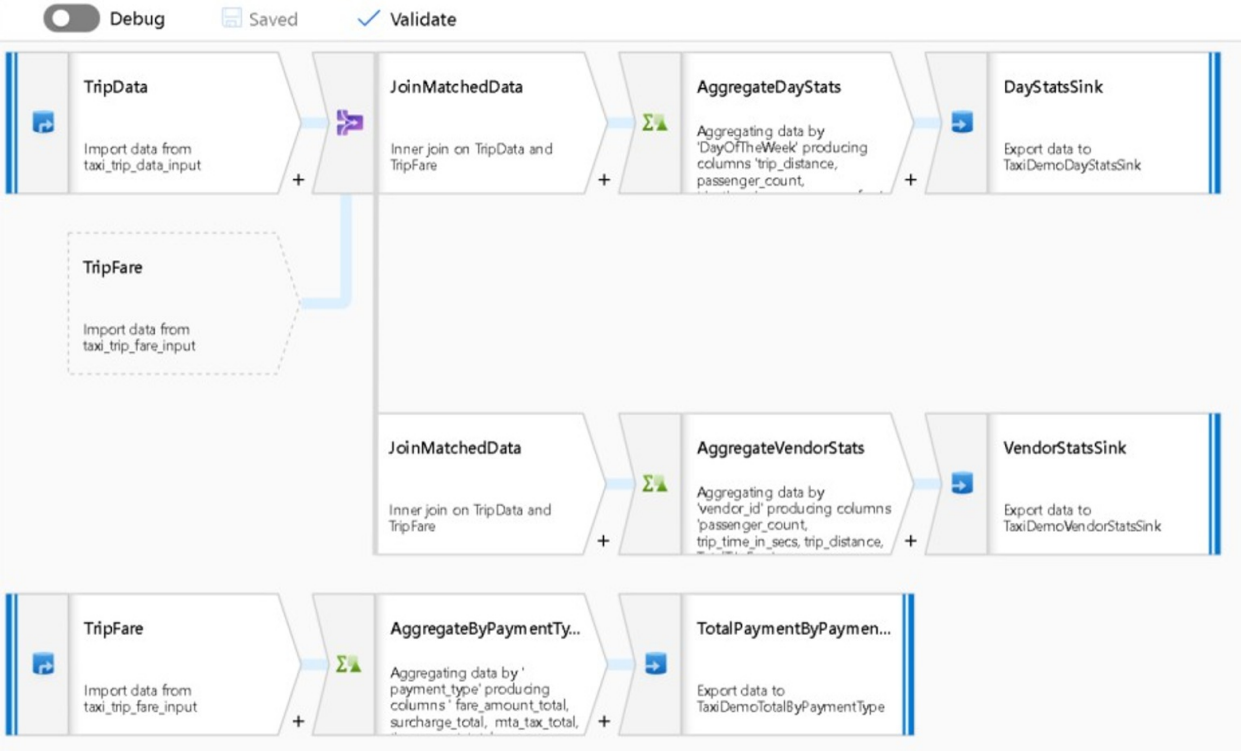
You can run mapping data flows that transform data as activities in a Data Factory pipeline, and if necessary, you can include multiple mapping data flows in a single pipeline. In this way, you can manage the complexity by breaking up challenging data transformation and integration tasks into smaller mapping dataflows that can be combined. And, you can add custom code when needed. In addition to this functionality, Data Factory mapping data flows include the ability to:

- Define expressions to clean and transform data, compute aggregations, and enrich data. For example, these expressions can perform feature engineering on a date field to break it into multiple fields to create training data during machine learning model development. You can construct expressions from a rich set of functions that include mathematical, temporal, split, merge, string concatenation, conditions, pattern match, replace, and many other functions.
- Automatically handle schema drift so that data transformation pipelines can avoid being impacted by schema changes in data sources. This ability is especially important for streaming IoT data, where schema changes can happen without notice if devices are upgraded or when readings are missed by gateway devices collecting IoT data.

- Partition data to enable transformations to run in parallel at scale.
- Inspect streaming data to view the metadata of a stream you're transforming.

> **TIP**
> Data Factory supports the ability to automatically detect and manage schema changes in inbound data, such as in streaming data.

The following screenshot shows an example Data Factory mapping data flow.



Data engineers can profile data quality and view the results of individual data transforms by enabling debug capability during development.

> **TIP**
> Data Factory can also partition data to enable ETL processing to run at scale.

If necessary, you can extend Data Factory transformational and analytical functionality by adding a linked service that contains your code into a pipeline. For example, an Azure Synapse Spark pool notebook might contain Python code that uses a trained model to score the data integrated by a mapping data flow.

You can store integrated data and any results from analytics within a Data Factory pipeline in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

> **TIP**
> Data Factory pipelines are extensible because Data Factory lets you write your own code and run it as part of a pipeline.

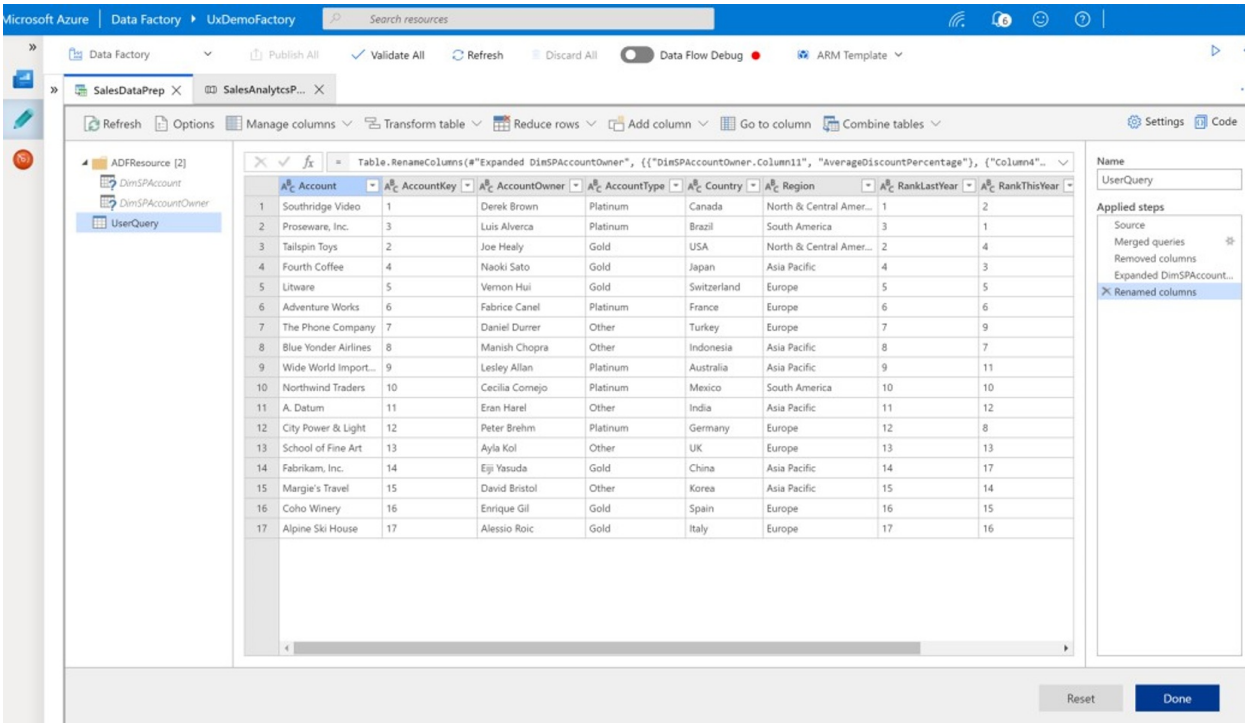
Utilize Spark to scale data integration

At run time, Data Factory internally uses Azure Synapse Spark pools, which are Microsoft's Spark as a service offering, to clean and integrate data in the Azure cloud. You can clean, integrate, and analyze high-volume, high-

velocity data, such as click-stream data, at scale. Microsoft's intention is to also run Data Factory pipelines on other Spark distributions. In addition to running ETL jobs on Spark, Data Factory can invoke Pig scripts and Hive queries to access and transform data stored in HDInsight.

Link self-service data prep and Data Factory ETL processing using wrangling data flows

Data wrangling lets business users, also known as citizen data integrators and data engineers, make use of the platform to visually discover, explore, and prepare data at scale without writing code. This Data Factory capability is easy to use and is similar to Microsoft Excel Power Query or Microsoft Power BI dataflows, where self-service business users use a spreadsheet-style UI with drop-down transforms to prepare and integrate data. The following screenshot shows an example Data Factory wrangling data flow.



Unlike Excel and Power BI, Data Factory wrangling data flows use Power Query to generate M code and then translate it into a massively parallel in-memory Spark job for cloud-scale execution. The combination of mapping data flows and wrangling data flows in Data Factory lets professional ETL developers and business users collaborate to prepare, integrate, and analyze data for a common business purpose. The preceding Data Factory mapping data flows diagram shows how both Data Factory and Azure Synapse Spark pool notebooks can be combined in the same Data Factory pipeline. The combination of mapping and wrangling data flows in Data Factory helps IT and business users stay aware of what data flows each has created, and supports data flow reuse to minimize reinvention and maximize productivity and consistency.

> **TIP**
>
> Data Factory supports both wrangling data flows and mapping data flows, so business users and IT users can integrate data collaboratively on a common platform.

Link data and analytics in analytical pipelines

In addition to cleaning and transforming data, Data Factory can combine data integration and analytics in the same pipeline. You can use Data Factory to create both data integration and analytical pipelines, the latter being an extension of the former. You can drop an analytical model into a pipeline to create an analytical pipeline that generates clean, integrated data for predictions or recommendations. Then, you can act on the predictions or recommendations immediately, or store them in your data warehouse to provide new insights and recommendations that can be viewed in BI tools.

To batch score your data, you can develop an analytical model that you invoke as a service within a Data Factory pipeline. You can develop analytical models code-free with Azure Machine Learning studio, or with the Azure

Machine Learning SDK using Azure Synapse Spark pool notebooks or R in RStudio. When you run Spark machine learning pipelines on Azure Synapse Spark pool notebooks, analysis happens at scale.

You can store integrated data and any Data Factory analytical pipeline results in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

Use a lake database to share consistent trusted data

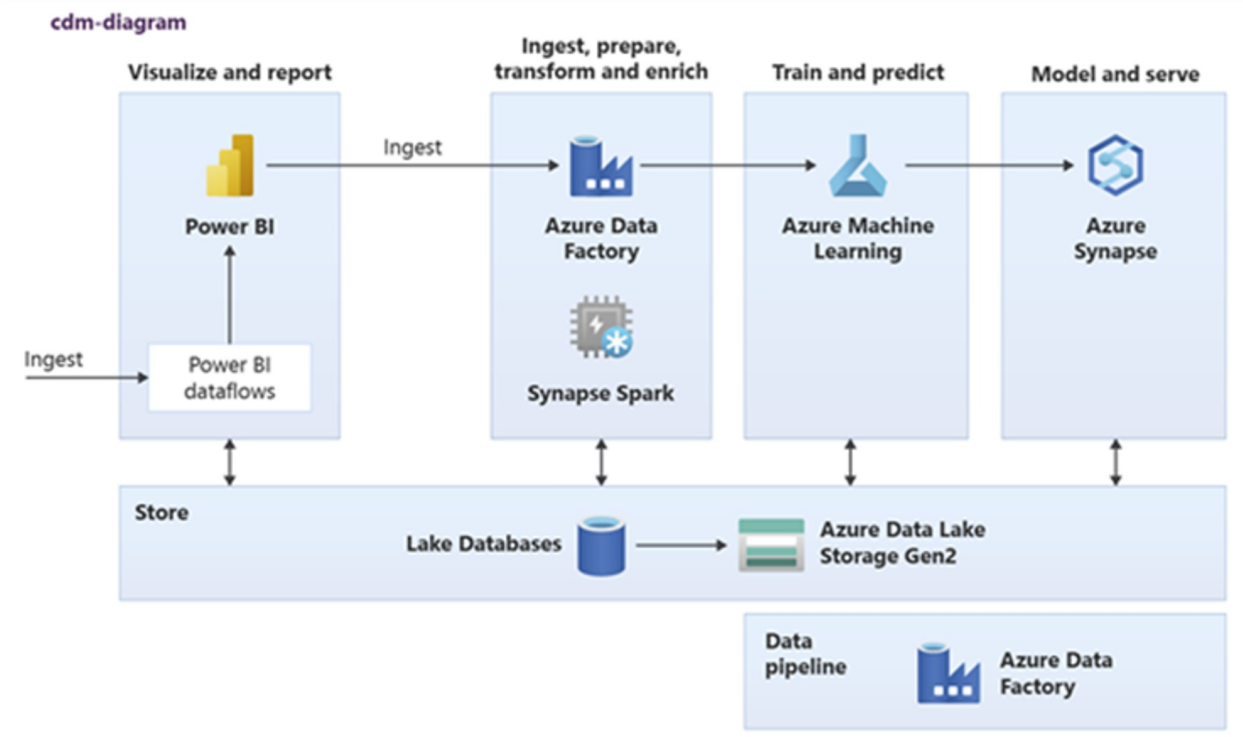
A key objective of any data integration setup is the ability to integrate data once and reuse it everywhere, not just in a data warehouse. For example, you might want to use integrated data in data science. Reuse avoids reinvention and ensures consistent, commonly understood data that everyone can trust.

Common Data Model describes core data entities that can be shared and reused across the enterprise. To achieve reuse, Common Data Model establishes a set of common data names and definitions that describe logical data entities. Examples of common data names include Customer, Account, Product, Supplier, Orders, Payments, and Returns. IT and business professionals can use data integration software to create and store common data assets to maximize their reuse and drive consistency everywhere.

Azure Synapse provides industry-specific database templates to help standardize data in the lake. Lake database templates provide schemas for predefined business areas, enabling data to be loaded into a lake database in a structured way. The power comes when you use data integration software to create lake database common data assets, resulting in self-describing trusted data that can be consumed by applications and analytical systems. You can create common data assets in Data Lake Storage by using Data Factory.

> **TIP**
> Data Lake Storage is shared storage that underpins Microsoft Azure Synapse, Azure Machine Learning, Azure Synapse Spark, and HDInsight.

Power BI, Azure Synapse Spark, Azure Synapse, and Azure Machine Learning can consume common data assets. The following diagram shows how a lake database can be used in Azure Synapse.



> **TIP**
> Integrate data to create lake database logical entities in shared storage to maximize the reuse of common data assets.

Integration with Microsoft data science technologies on Azure

Another key objective when modernizing a data warehouse is to produce insights for competitive advantage. You can produce insights by integrating your migrated data warehouse with Microsoft and third-party data science technologies in Azure. The following sections describe machine learning and data science technologies offered by Microsoft to see how they can be used with Azure Synapse in a modern data warehouse environment.

Microsoft technologies for data science on Azure

Microsoft offers a range of technologies that support advance analysis. With these technologies, you can build predictive analytical models using machine learning or analyze unstructured data using deep learning. The technologies include:

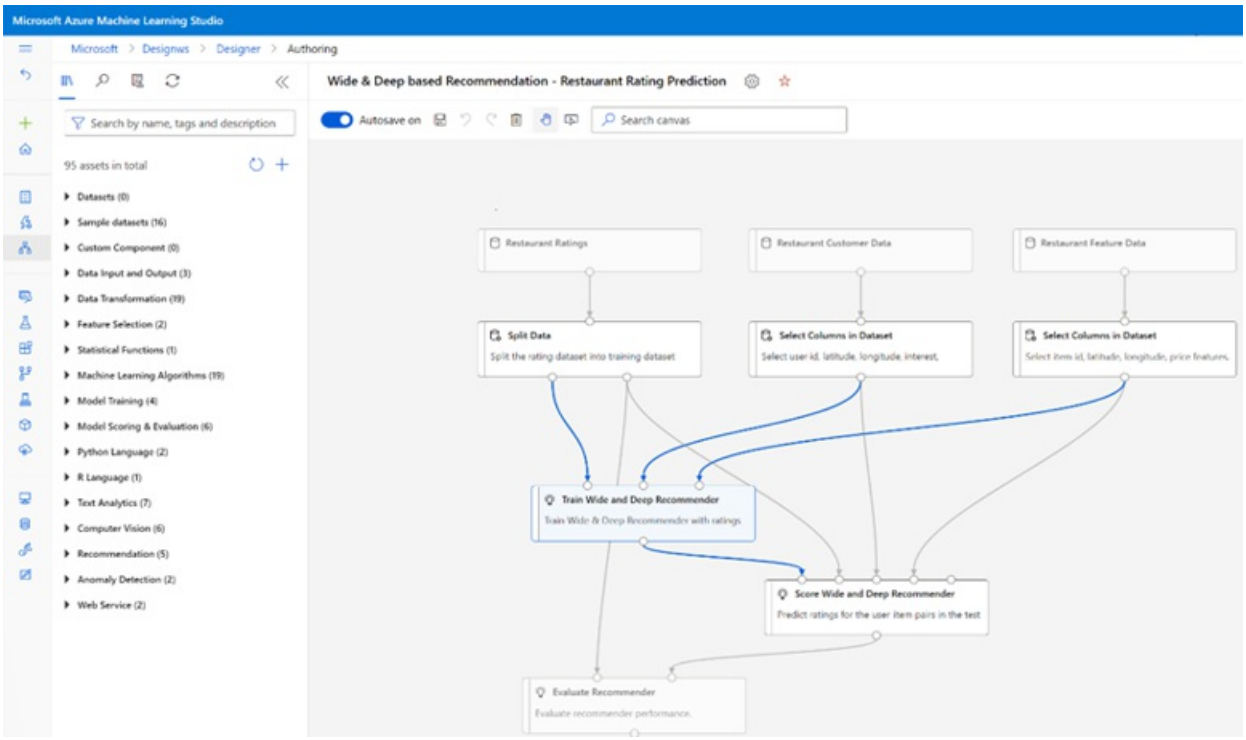
- Azure Machine Learning studio
- Azure Machine Learning
- Azure Synapse Spark pool notebooks
- ML.NET (API, CLI, or ML.NET Model Builder for Visual Studio)
- .NET for Apache Spark

Data scientists can use RStudio (R) and Jupyter Notebooks (Python) to develop analytical models, or they can use frameworks such as Keras or TensorFlow.

> **TIP**
> Develop machine learning models using a no/low-code approach or by using programming languages like Python, R, and .NET.

Azure Machine Learning studio

Azure Machine Learning studio is a fully managed cloud service that lets you build, deploy, and share predictive analytics using a drag-and-drop, web-based UI. The following screenshot shows the Azure Machine Learning studio UI.



Azure Machine Learning

Azure Machine Learning provides an SDK and services for Python that supports can help you quickly prepare data and also train and deploy machine learning models. You can use Azure Machine Learning in Azure notebooks using Jupyter Notebook, with open-source frameworks, such as PyTorch, TensorFlow, scikit-learn, or Spark MLlib—the machine learning library for Spark. Azure Machine Learning provides an AutoML capability that automatically tests multiple algorithms to identify the most accurate algorithms to expedite model development.

> **TIP**
> Azure Machine Learning provides an SDK for developing machine learning models using several open-source frameworks.

You can also use Azure Machine Learning to build machine learning pipelines that manage end-to-end workflow, programmatically scale in the cloud, and deploy models both to the cloud and the edge. Azure Machine Learning contains workspaces, which are logical spaces that you can programmatically or manually create in the Azure portal. These workspaces keep compute targets, experiments, data stores, trained machine learning models, Docker images, and deployed services all in one place to enable teams to work together. You can use Azure Machine Learning in Visual Studio with the Visual Studio for AI extension.

> **TIP**
> Organize and manage related data stores, experiments, trained models, Docker images, and deployed services in workspaces.

Azure Synapse Spark pool notebooks

An Azure Synapse Spark pool notebook is an Azure-optimized Apache Spark service. With Azure Synapse Spark pool notebooks:

- Data engineers can build and run scalable data preparation jobs using Data Factory.
- Data scientists can build and run machine learning models at scale using notebooks written in languages such as Scala, R, Python, Java, and SQL to visualize results.

> **TIP**
> Azure Synapse Spark is a dynamically scalable Spark as a service offering from Microsoft, Spark offers scalable execution of data preparation, model development, and deployed model execution.

Jobs running in Azure Synapse Spark pool notebooks can retrieve, process, and analyze data at scale from Azure Blob Storage, Data Lake Storage, Azure Synapse, HDInsight, and streaming data services such as Apache Kafka.

> **TIP**
> Azure Synapse Spark can access data in a range of Microsoft analytical ecosystem data stores on Azure.

Azure Synapse Spark pool notebooks support autoscaling and auto-termination to reduce total cost of ownership (TCO). Data scientists can use the MLflow open-source framework to manage the machine learning lifecycle.

ML.NET

ML.NET is an open-source, cross-platform machine learning framework for Windows, Linux, macOS. Microsoft created ML.NET so that .NET developers can use existing tools, such as ML.NET Model Builder for Visual Studio, to develop custom machine learning models and integrate them into their .NET applications.

> **TIP**
> Microsoft has extended its machine learning capability to .NET developers.

.NET for Apache Spark

.NET for Apache Spark extends Spark support beyond R, Scala, Python, and Java to .NET and aims to make Spark accessible to .NET developers across all Spark APIs. While .NET for Apache Spark is currently only available on Apache Spark in HDInsight, Microsoft intends to make .NET for Apache Spark available on Azure Synapse Spark pool notebooks.

Use Azure Synapse Analytics with your data warehouse

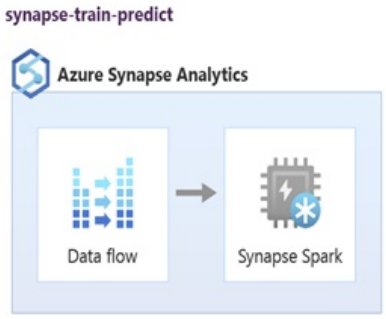
To combine machine learning models with Azure Synapse, you can:

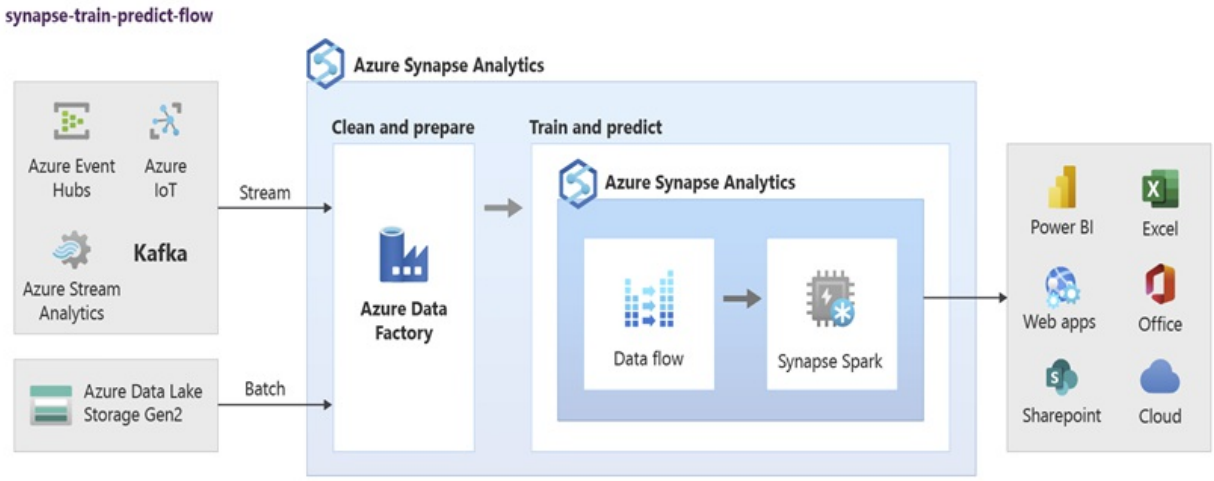
- Use machine learning models in batch or in real-time on streaming data to produce new insights, and add those insights to what you already know in Azure Synapse.
- Use the data in Azure Synapse to develop and train new predictive models for deployment elsewhere, such as in other applications.
- Deploy machine learning models, including models trained elsewhere, in Azure Synapse to analyze data in your data warehouse and drive new business value.

> **TIP**
> Train, test, evaluate, and run machine learning models at scale on Azure Synapse Spark pool notebooks by using data in Azure Synapse.

Data scientists can use RStudio, Jupyter Notebooks, and Azure Synapse Spark pool notebooks together with Azure Machine Learning to develop machine learning models that run at scale on Azure Synapse Spark pool notebooks using data in Azure Synapse. For example, data scientists could create an unsupervised model to segment customers to drive different marketing campaigns. Use supervised machine learning to train a model to predict a specific outcome, such as to predict a customer's propensity to churn, or to recommend the next

best offer for a customer to try to increase their value. The following diagram shows how Azure Synapse can be used for Azure Machine Learning.





In another scenario, you can ingest social network or review website data into Data Lake Storage, then prepare and analyze the data at scale on an Azure Synapse Spark pool notebook using natural language processing to score customer sentiment about your products or brand. You can then add those scores to your data warehouse. By using big data analytics to understand the effect of negative sentiment on product sales, you add to what you already know in your data warehouse.

> **TIP**
> Produce new insights using machine learning on Azure in batch or in real-time and add to what you know in your data warehouse.

Integrate live streaming data into Azure Synapse Analytics

When analyzing data in a modern data warehouse, you must be able to analyze streaming data in real-time and join it with historical data in your data warehouse. An example is combining IoT data with product or asset data.

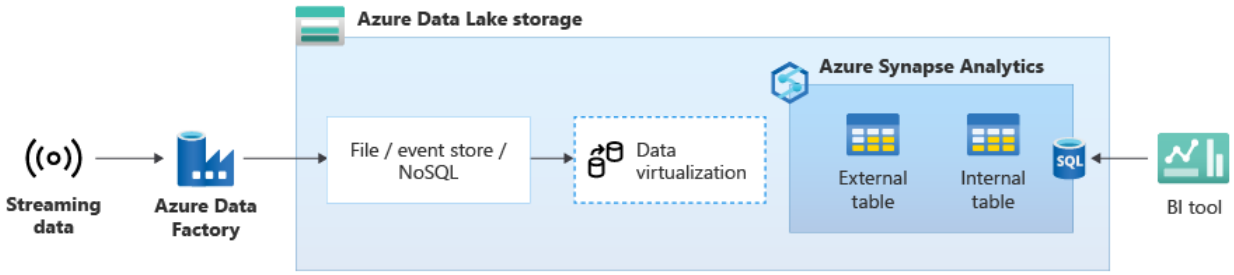
> **TIP**
> Integrate your data warehouse with streaming data from IoT devices or clickstreams.

Once you've successfully migrated your data warehouse to Azure Synapse, you can introduce live streaming data integration as part of a data warehouse modernization exercise by taking advantage of the extra functionality in Azure Synapse. To do so, ingest streaming data via Event Hubs, other technologies like Apache Kafka, or potentially your existing ETL tool if it supports the streaming data sources. Store the data in Data Lake Storage. Then, create an external table in Azure Synapse using PolyBase and point it at the data being streamed into Data Lake Storage so that your data warehouse now contains new tables that provide access to the real-time streaming data. Query the external table as if the data was in the data warehouse by using standard T-SQL

from any BI tool that has access to Azure Synapse. You can also join the streaming data to other tables with historical data to create views that join live streaming data to historical data to make it easier for business users to access the data.

> **TIP**
> Ingest streaming data into Data Lake Storage from Event Hubs or Apache Kafka, and access the data from Azure Synapse using PolyBase external tables.

In the following diagram, a real-time data warehouse on Azure Synapse is integrated with streaming data in Data Lake Storage.



Create a logical data warehouse using PolyBase

With PolyBase, you can create a logical data warehouse to simplify user access to multiple analytical data stores. Many companies have adopted "workload optimized" analytical data stores over the last several years in addition to their data warehouses. The analytical platforms on Azure include:

- Data Lake Storage with Azure Synapse Spark pool notebook (Spark as a service), for big data analytics.
- HDInsight (Hadoop as a service), also for big data analytics.
- NoSQL Graph databases for graph analysis, which could be done in Azure Cosmos DB.
- Event Hubs and Stream Analytics, for real-time analysis of data in motion.

You might have non-Microsoft equivalents of these platforms, or a master data management (MDM) system that needs to be accessed for consistent trusted data on customers, suppliers, products, assets, and more.

> **TIP**
> PolyBase simplifies access to multiple underlying analytical data stores on Azure for ease of access by business users.

Those analytical platforms emerged because of the explosion of new data sources inside and outside the enterprise and the demand by business users to capture and analyze the new data. The new data sources include:

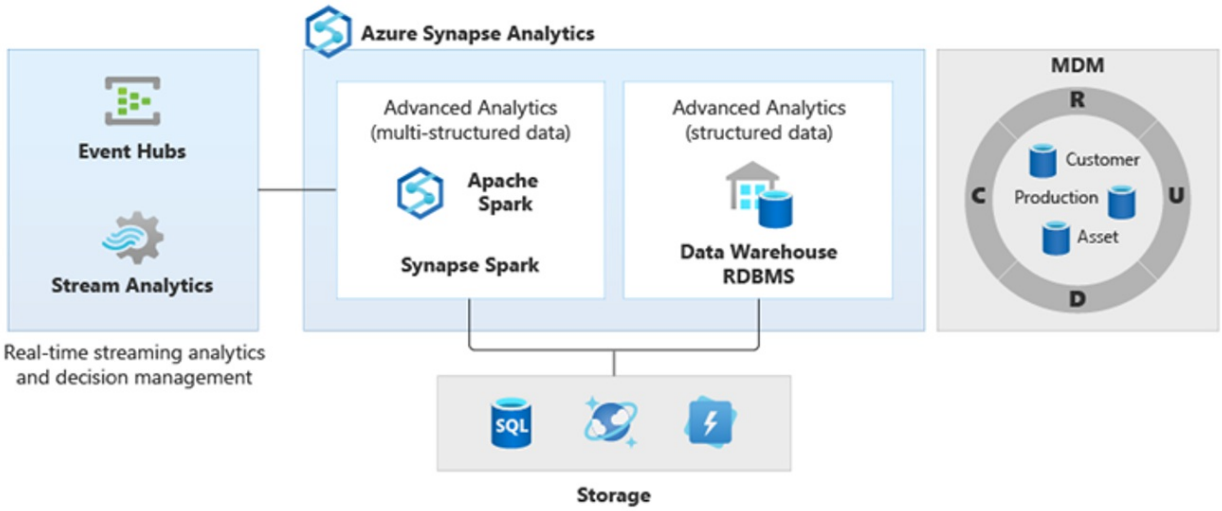
- Machine generated data, such as IoT sensor data and clickstream data.
- Human generated data, such as social network data, review web site data, customer inbound email, images, and video.
- Other external data, such as open government data and weather data.

This new data goes beyond the structured transaction data and main data sources that typically feed data warehouses and often includes:

- Semi-structured data like JSON, XML, or Avro.

- Unstructured data like text, voice, image, or video, which is more complex to process and analyze.
- High volume data, high velocity data, or both.

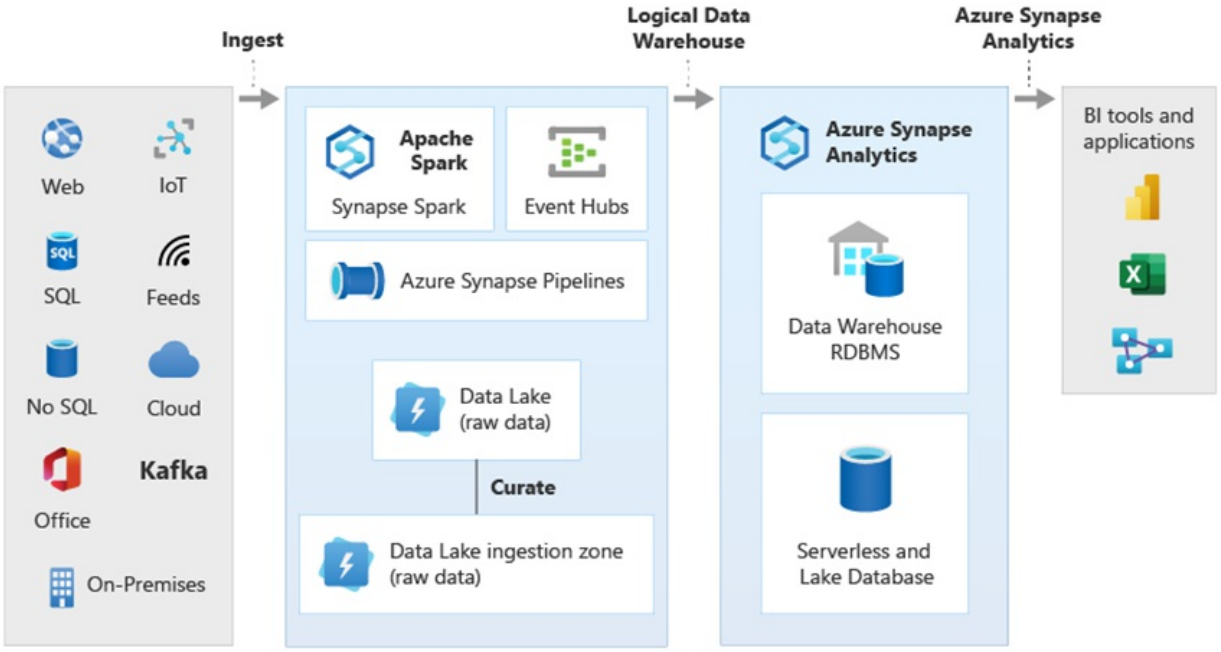
As a result, new more complex kinds of analysis have emerged, such as natural language processing, graph analysis, deep learning, streaming analytics, or complex analysis of large volumes of structured data. These kinds of analysis typically don't happen in a data warehouse, so it's not surprising to see different analytical platforms for different types of analytical workloads, as shown in the following diagram.



> **TIP**
> The ability to make data in multiple analytical data stores look like it's all in one system and join it to Azure Synapse is known as a logical data warehouse architecture.

Because these platforms produce new insights, it's normal to see a requirement to combine the new insights with what you already know in Azure Synapse, which is what PolyBase makes possible.

By using PolyBase data virtualization inside Azure Synapse, you can implement a logical data warehouse where data in Azure Synapse is joined to data in other Azure and on-premises analytical data stores like HDInsight, Azure Cosmos DB, or streaming data flowing into Data Lake Storage from Stream Analytics or Event Hubs. This approach lowers the complexity for users, who access external tables in Azure Synapse and don't need to know that the data they're accessing is stored in multiple underlying analytical systems. The following diagram shows a complex data warehouse structure accessed through comparatively simpler yet still powerful UI methods.



The diagram shows how other technologies in the Microsoft analytical ecosystem can be combined with the capability of the logical data warehouse architecture in Azure Synapse. For example, you can ingest data into Data Lake Storage and curate the data using Data Factory to create trusted data products that represent Microsoft lake database logical data entities. This trusted, commonly understood data can then be consumed and reused in different analytical environments such as Azure Synapse, Azure Synapse Spark pool notebooks, or Azure Cosmos DB. All insights produced in these environments are accessible via a logical data warehouse data virtualization layer made possible by PolyBase.

> **TIP**
> A logical data warehouse architecture simplifies business user access to data and adds new value to what you already know in your data warehouse.

Conclusions

After you migrate your data warehouse to Azure Synapse, you can take advantage of other technologies in the Microsoft analytical ecosystem. By doing so, you not only modernize your data warehouse, but bring insights produced in other Azure analytical data stores into an integrated analytical architecture.

You can broaden your ETL processing to ingest data of any type into Data Lake Storage, and then prepare and integrate the data at scale using Data Factory to produce trusted, commonly understood data assets. Those assets can be consumed by your data warehouse and accessed by data scientists and other applications. You can build real-time and batch oriented analytical pipelines and create machine learning models to run in batch, in real-time on streaming data, and on-demand as a service.

You can use PolyBase or `COPY INTO` to go beyond your data warehouse to simplify access to insights from multiple underlying analytical platforms on Azure. To do so, create holistic integrated views in a logical data warehouse that support access to streaming, big data, and traditional data warehouse insights from BI tools and applications.

By migrating your data warehouse to Azure Synapse, you can take advantage of the rich Microsoft analytical ecosystem running on Azure to drive new value in your business.

Azure Synapse Analytics.

Design and performance for Oracle migrations

8/19/2022 • 26 minutes to read • Edit Online

This article is part one of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for design and performance.

Overview

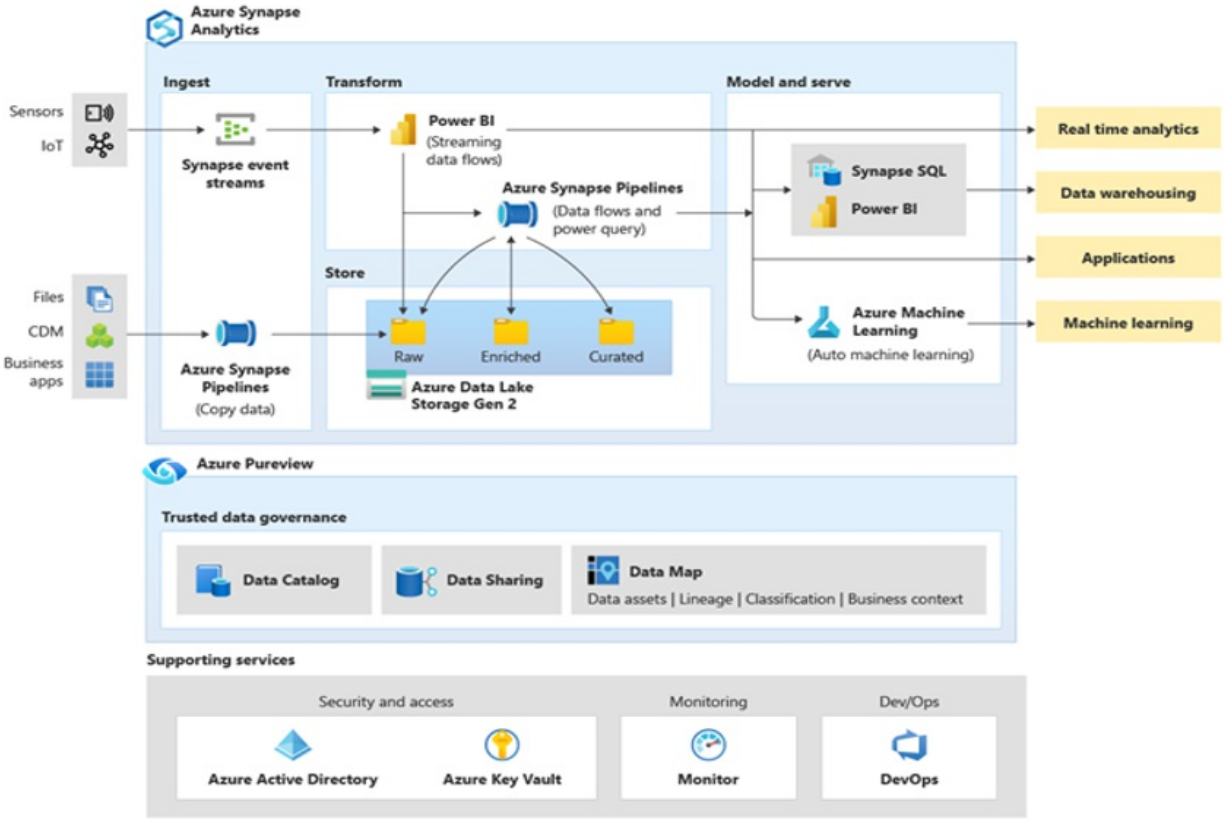
Due to the cost and complexity of maintaining and upgrading legacy on-premises Oracle environments, many existing Oracle users want to take advantage of the innovations provided by modern cloud environments. Infrastructure-as-a-service (IaaS) and platform-as-a-service (PaaS) cloud environments let you delegate tasks like infrastructure maintenance and platform development to the cloud provider.

> **TIP**
> More than just a database—the Azure environment includes a comprehensive set of capabilities and tools.

Although Oracle and Azure Synapse Analytics are both SQL databases that use massively parallel processing (MPP) techniques to achieve high query performance on exceptionally large data volumes, there are some basic differences in approach:

- Legacy Oracle systems are often installed on-premises and use relatively expensive hardware, while Azure Synapse is cloud-based and uses Azure storage and compute resources.
- Upgrading an Oracle configuration is a major task involving extra physical hardware and potentially lengthy database reconfiguration, or dump and reload. Because storage and compute resources are separate in the Azure environment and have elastic scaling capability, those resources can be scaled upwards or downwards independently.
- You can pause or resize Azure Synapse as needed to reduce resource utilization and cost.

Microsoft Azure is a globally available, highly secure, scalable cloud environment that includes Azure Synapse and an ecosystem of supporting tools and capabilities. The next diagram summarizes the Azure Synapse ecosystem.



Azure Synapse provides best-of-breed relational database performance by using techniques such as MPP and automatic in-memory caching. You can see the results of these techniques in independent benchmarks such as the one run recently by GigaOm, which compares Azure Synapse to other popular cloud data warehouse offerings. Customers who migrate to the Azure Synapse environment see many benefits, including:

- Improved performance and price/performance.
- Increased agility and shorter time to value.
- Faster server deployment and application development.
- Elastic scalability—only pay for actual usage.
- Improved security/compliance.
- Reduced storage and disaster recovery costs.
- Lower overall TCO, better cost control, and streamlined operational expenditure (OPEX).

To maximize these benefits, migrate new or existing data and applications to the Azure Synapse platform. In many organizations, migration includes moving an existing data warehouse from a legacy on-premises platform, such as Oracle, to Azure Synapse. At a high level, the migration process includes these steps:

Preparation

- Define scope—what is to be migrated.
- Build inventory of data and processes for migration.
- Define data model changes (if any).
- Define source data extract mechanism.
- Identify the appropriate Azure and third-party tools and features to be used.
- Train staff early on the new platform.

- Set up the Azure target platform.

Migration □

- Start small and simple.
- Automate wherever possible.
- Leverage Azure built-in tools and features to reduce migration effort.
- Migrate metadata for tables and views.
- Migrate historical data to be maintained.
- Migrate or refactor stored procedures and business processes.
- Migrate or refactor ETL/ELT incremental load processes.

Post migration

- Monitor and document all stages of the process.
- Use the experience gained to build a template for future migrations.
- Re-engineer the data model if required (using new platform performance and scalability).
- Test applications and query tools.
- Benchmark and optimize query performance.

This article provides general information and guidelines for performance optimization when migrating a data warehouse from an existing Oracle environment to Azure Synapse. The goal of performance optimization is to achieve the same or better data warehouse performance in Azure Synapse after the migration.

Design considerations

Migration scope

When you're preparing to migrate from an Oracle environment, consider the following migration choices.

Choose the workload for the initial migration

Typically, legacy Oracle environments have evolved over time to encompass multiple subject areas and mixed workloads. When you're deciding where to start on a migration project, choose an area where you'll be able to:

- Prove the viability of migrating to Azure Synapse by quickly delivering the benefits of the new environment.
- Allow your in-house technical staff to gain relevant experience with the processes and tools that they'll use when they migrate other areas.
- Create a template for further migrations that's specific to the source Oracle environment and the current tools and processes that are already in place.

A good candidate for an initial migration from an Oracle environment supports the preceding items, and:

- Implements a BI/Analytics workload rather than an online transaction processing (OLTP) workload.
- Has a data model, such as a star or snowflake schema, that can be migrated with minimal modification.

> **TIP**
> Create an inventory of objects that need to be migrated, and document the migration process.

The volume of migrated data in an initial migration should be large enough to demonstrate the capabilities and benefits of the Azure Synapse environment but not too large to quickly demonstrate value. A size in the 1-10 terabyte range is typical.

An initial approach to a migration project is to minimize the risk, effort, and time needed so that you quickly see the benefits of the Azure cloud environment. The following approaches limit the scope of the initial migration to just the data marts and doesn't address broader migration aspects, such as ETL migration and historical data migration. However, you can address those aspects in later phases of the project once the migrated data mart layer is backfilled with data and the required build processes.

Lift and shift migration vs. Phased approach

In general, there are two types of migration regardless of the purpose and scope of the planned migration: lift and shift as-is and a phased approach that incorporates changes.

Lift and shift

In a lift and shift migration, an existing data model, like a star schema, is migrated unchanged to the new Azure Synapse platform. This approach minimizes risk and migration time by reducing the work needed to realize the benefits of moving to the Azure cloud environment. Lift and shift migration is a good fit for these scenarios:

- You have an existing Oracle environment with a single data mart to migrate, or
- You have an existing Oracle environment with data that's already in a well-designed star or snowflake schema, or
- You're under time and cost pressures to move to a modern cloud environment.

> **TIP**
> Lift and shift is a good starting point, even if subsequent phases implement changes to the data model.

Phased approach that incorporates changes

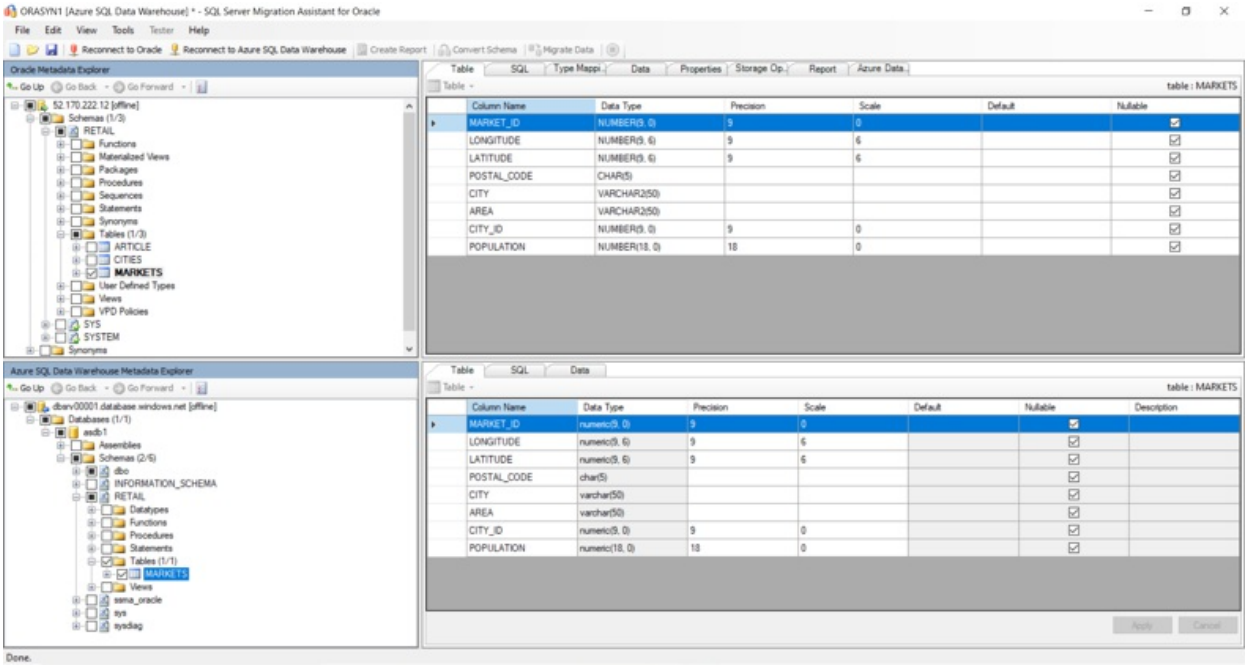
If a legacy data warehouse has evolved over a long period of time, you might need to re-engineer it to maintain the required performance levels. You might also have to re-engineer to support new data like Internet of Things (IoT) streams. As part of the re-engineering process, migrate to Azure Synapse to get the benefits of a scalable cloud environment. Migration can include a change in the underlying data model, such as a move from an Inmon model to a data vault.

Microsoft recommends moving your existing data model as-is to Azure and using the performance and flexibility of the Azure environment to apply the re-engineering changes. That way, you can use Azure's capabilities to make the changes without impacting the existing source system.

Use Microsoft facilities to implement a metadata-driven migration

You can automate and orchestrate the migration process by using the capabilities of the Azure environment. This approach minimizes the performance hit on the existing Oracle environment, which may already be running close to capacity.

The SQL Server Migration Assistant (SSMA) for Oracle can automate many parts of the migration process, including in some cases functions and procedural code. SSMA supports Azure Synapse as a target environment.



SSMA for Oracle can help you migrate an Oracle data warehouse or data mart to Azure Synapse. SSMA is designed to automate the process of migrating tables, views, and data from an existing Oracle environment.

Azure Data Factory is a cloud-based data integration service that supports creating data-driven workflows in the cloud that orchestrate and automate data movement and data transformation. You can use Data Factory to create and schedule data-driven workflows (pipelines) that ingest data from disparate data stores. Data Factory can process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

Data Factory can be used to migrate data at source to Azure SQL target. This offline data movement helps to reduce migration downtime significantly.

Azure Database Migration Services can help you plan and perform a migration from environments like Oracle.

When you're planning to use Azure facilities to manage the migration process, create metadata that lists all the data tables to be migrated and their location.

Design differences between Oracle and Azure Synapse

As mentioned earlier, there are some basic differences in approach between Oracle and Azure Synapse Analytics databases. SSMA for Oracle not only helps bridge these gaps but also automates the migration. Although SSMA isn't the most efficient approach for very high volumes of data, it's useful for smaller tables.

Multiple databases vs. single database and schemas

The Oracle environment often contains multiple separate databases. For instance, there could be separate databases for: data ingestion and staging tables, core warehouse tables, and data marts—sometimes referred to as the semantic layer. Processing in ETL or ELT pipelines can implement cross-database joins and move data between the separate databases.

In contrast, the Azure Synapse environment contains a single database and uses schemas to separate tables into logically separate groups. We recommend that you use a series of schemas within the target Azure Synapse database to mimic the separate databases migrated from the Oracle environment. If the Oracle environment already uses schemas, you may need to use a new naming convention when you move the existing Oracle tables and views to the new environment. For example, you could concatenate the existing Oracle schema and table names into the new Azure Synapse table name, and use schema names in the new environment to maintain the original separate database names. Although you can use SQL views on top of the underlying tables to maintain the logical structures, there are potential downsides to that approach:

- Views in Azure Synapse are read-only, so any updates to the data must take place on the underlying base

tables.

- There may already be one or more layers of views in existence and adding an extra layer of views could affect performance.

> **TIP**
> Combine multiple databases into a single database within Azure Synapse and use schema names to logically separate the tables.

Table considerations

When you migrate tables between different environments, typically only the raw data and the metadata that describes it physically migrate. Other database elements from the source system, such as indexes, usually aren't migrated because they might be unnecessary or implemented differently in the new environment.

Performance optimizations in the source environment, such as indexes, indicate where you might add performance optimization in the new environment. For example, if queries in the source Oracle environment frequently use bit-mapped indexes, that suggests that a non-clustered index should be created within Azure Synapse. Other native performance optimization techniques like table replication may be more applicable than straight like-for-like index creation. SSMA for Oracle can be used to provide migration recommendations for table distribution and indexing.

> **TIP**
> Existing indexes indicate candidates for indexing in the migrated warehouse.

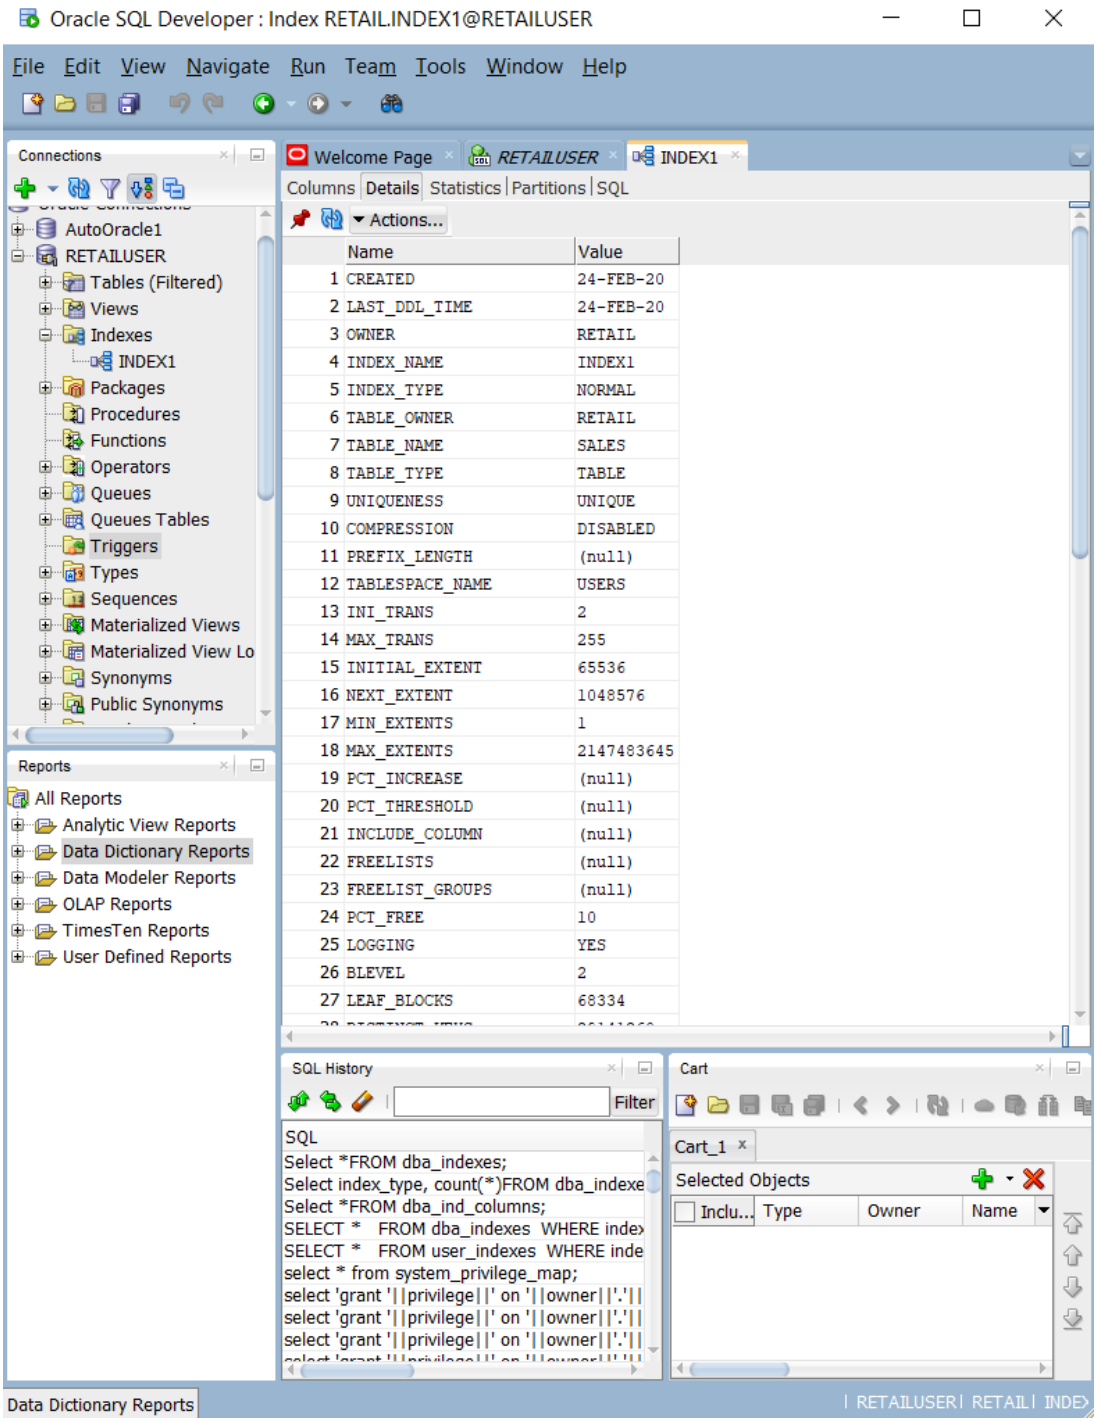
Unsupported Oracle database object types

Oracle-specific features can often be replaced by Azure Synapse features. However, some Oracle database objects aren't directly supported in Azure Synapse. The following list of unsupported Oracle database objects describes how you can achieve an equivalent functionality in Azure Synapse.

- **Various indexing options**: in Oracle, several indexing options, such as bit-mapped indexes, function-based indexes, and domain indexes, have no direct equivalent in Azure Synapse.

  You can find out which columns are indexed and the index type by:

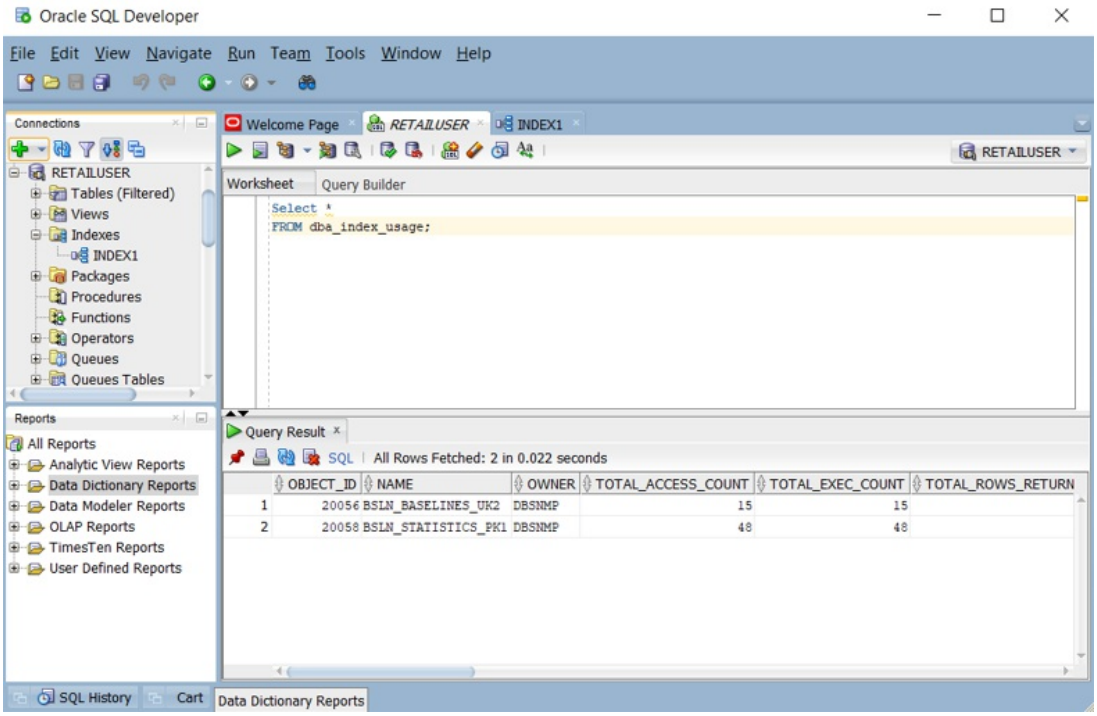
  - Querying system catalog tables and views, such as `ALL_INDEXES`, `DBA_INDEXES`, `USER_INDEXES`, and `DBA_IND_COL`. You can use the built-in queries in Oracle SQL Developer, as shown in the following screenshot.



Or, run the following query to find all indexes of a given type:

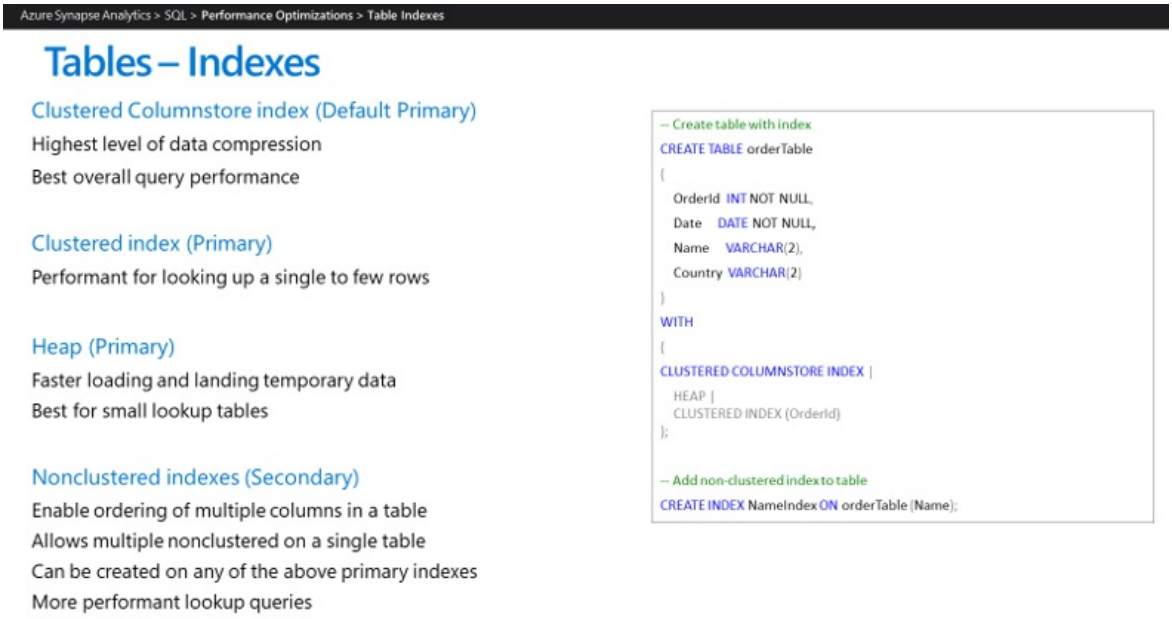
```
SELECT * FROM dba_indexes WHERE index_type LIKE 'FUNCTION-BASED%';
```

- Querying the `dba_index_usage` or `v$object_usage` views when monitoring is enabled. You can query those views in Oracle SQL Developer, as shown in the following screenshot.



Function-based indexes, where the index contains the result of a function on the underlying data columns, have no direct equivalent in Azure Synapse. We recommend that you first migrate the data, then in Azure Synapse run the Oracle queries that use function-based indexes to gauge performance. If the performance of those queries in Azure Synapse isn't acceptable, consider creating a column that contains the pre-calculated value and then index that column.

When you configure the Azure Synapse environment, it makes sense to only implement in-use indexes. Azure Synapse currently supports the index types shown here:



Azure Synapse features, such as parallel query processing and in-memory caching of data and results, make it likely that fewer indexes are required for data warehouse applications to achieve performance goals. We recommend that you use the following index types in Azure Synapse:

- **Clustered columnstore indexes**: when no index options are specified for a table, Azure Synapse by default creates a clustered columnstore index. Clustered columnstore tables offer the highest level of data compression, best overall query performance, and generally outperform clustered index or heap tables. A clustered columnstore index is usually the best choice for large tables.

When you create a table, choose clustered columnstore if you're unsure how to index your table. However, there are some scenarios where clustered columnstore indexes aren't the best option:

  - Tables with varchar(max), nvarchar(max), or varbinary(max) data types, because a clustered columnstore index doesn't support those data types. Instead, consider using a heap or clustered index.
  - Tables with transient data, because columnstore tables might be less efficient than heap or temporary tables.
  - Small tables with less than 100 million rows. Instead, consider using heap tables.
- **Clustered and nonclustered indexes**: clustered indexes can outperform clustered columnstore indexes when a single row needs to be quickly retrieved. For queries where a single row lookup, or just a few row lookups, must perform at extreme speed, consider using a cluster index or nonclustered secondary index. The disadvantage of using a clustered index is that only queries with a highly selective filter on the clustered index column will benefit. To improve filtering on other columns, you can add a nonclustered index to the other columns. However, each index that you add to a table uses more space and increases the processing time to load.

- **Heap tables**: when you're temporarily landing data on Azure Synapse, you might find that using a heap table makes the overall process faster. This is because loading data to heap tables is faster than loading data to index tables, and in some cases subsequent reads can be done from cache. If you're loading data only to stage it before running more transformations, it's much faster to load it to a heap table than a clustered columnstore table. Also, loading data to a temporary table is faster than loading a table to permanent storage. For small lookup tables with less than 100 million rows, heap tables are usually the right choice. Cluster columnstore tables begin to achieve optimal compression when they contain more than 100 million rows.

- **Clustered tables**: Oracle tables can be organized so that table rows that are frequently accessed together (based on a common value) are physically stored together to reduce disk I/O when data is retrieved. Oracle also provides a hash-cluster option for individual tables, which applies a hash value to the cluster key and physically stores rows with the same hash value together. To list clusters within an Oracle database, use the `SELECT * FROM DBA_CLUSTERS;` query. To determine whether a table is within a cluster, use the `SELECT * FROM TAB;` query, which shows the table name and cluster ID for each table.

  In Azure Synapse, you can achieve similar results by using materialized and/or replicated tables, because those table types minimize the I/O required at query run time.

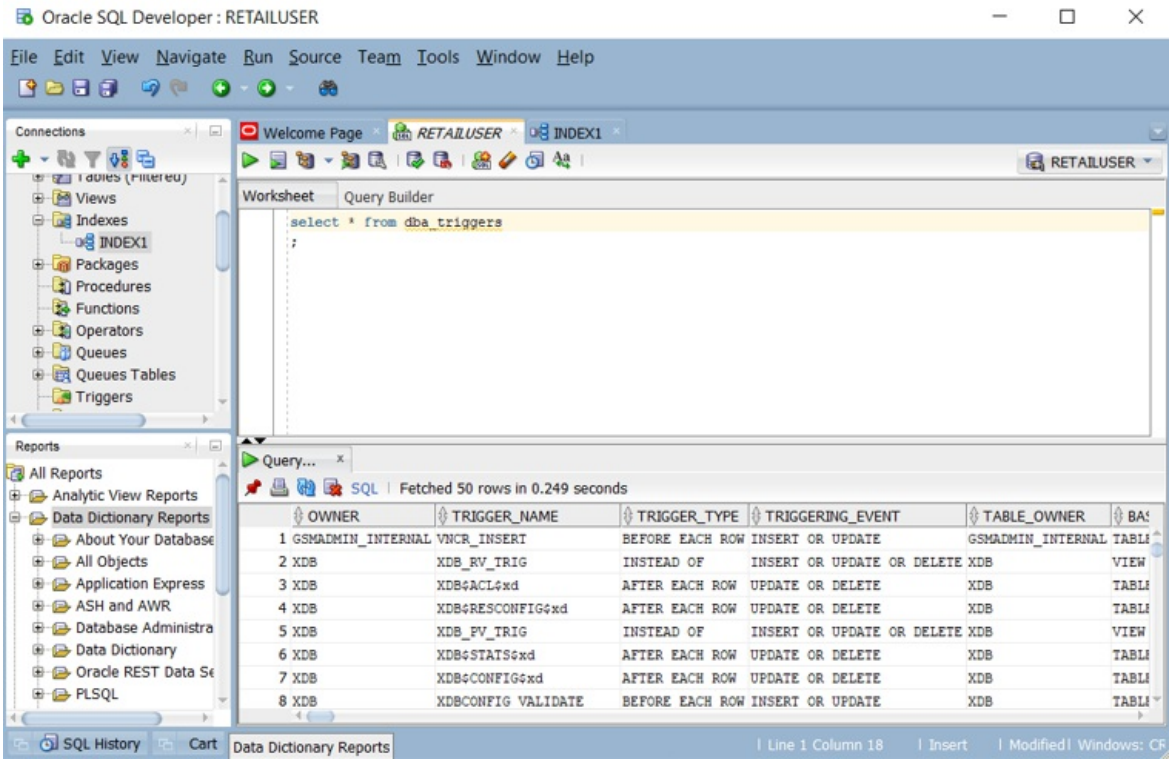
- **Materialized views**: Oracle supports materialized views and recommends using one or more for large tables with many columns where only a few columns are regularly used in queries. Materialized views are automatically refreshed by the system when data in the base table is updated.

  In 2019, Microsoft announced that Azure Synapse will support materialized views with the same functionality as in Oracle. Materialized views are now a preview feature in Azure Synapse.

- **In-database triggers**: in Oracle, a trigger can be configured to automatically run when a triggering event occurs. Triggering events can be:

  - A data manipulation language (DML) statement, such as `INSERT`, `UPDATE`, or `DELETE`, runs on a table. If you defined a trigger that fires before an `INSERT` statement on a customer table, the trigger will fire once before a new row is inserted into the customer table.
  - A DDL statement, such as `CREATE` or `ALTER`, runs. This trigger is often used for auditing purposes to record schema changes.
  - A system event, such as startup or shutdown of the Oracle database.
  - A user event, such as sign in or sign out.

You can get a list of the triggers defined in an Oracle database by querying the `ALL_TRIGGERS`, `DBA_TRIGGERS`, or `USER_TRIGGERS` views. The following screenshot shows a `DBA_TRIGGERS` query in Oracle SQL Developer.



Azure Synapse doesn't support Oracle database triggers. However, you can add equivalent functionality by using Data Factory, although doing so will require you to refactor the processes that use triggers.

- **Synonyms**: Oracle supports defining synonyms as alternative names for several database object types. Those object types include: tables, views, sequences, procedures, stored functions, packages, materialized views, Java class schema objects, user-defined objects, or another synonym.

  Azure Synapse doesn't currently support defining synonyms, although if a synonym in Oracle refers to a table or view, then you can define a view in Azure Synapse to match the alternative name. If a synonym in Oracle refers to a function or stored procedure, then in Azure Synapse you can create another function or stored procedure, with a name to match the synonym, that calls the target.

- **User-defined types**: Oracle supports user-defined objects that can contain a series of individual fields, each with their own definition and default values. Those objects can be referenced within a table definition in the same way as built-in data types like `NUMBER` or `VARCHAR`. You can get a list of user-defined types within an Oracle database by querying the `ALL_TYPES`, `DBA_TYPES`, or `USER_TYPES` views.

  Azure Synapse doesn't currently support user-defined types. If the data you need to migrate includes user-defined data types, either "flatten" them into a conventional table definition, or if they're arrays of data, normalize them in a separate table.

Oracle data type mapping

Most Oracle data types have a direct equivalent in Azure Synapse. The following table shows the recommended approach for mapping Oracle data types to Azure Synapse.

ORACLE DATA TYPE	AZURE SYNAPSE DATA TYPE
BFILE	Not supported. Map to VARBINARY (MAX).
BINARY_FLOAT	Not supported. Map to FLOAT.

ORACLE DATA TYPE	AZURE SYNAPSE DATA TYPE
BINARY_DOUBLE	Not supported. Map to DOUBLE.
BLOB	Not directly supported. Replace with VARBINARY(MAX).
CHAR	CHAR
CLOB	Not directly supported. Replace with VARCHAR(MAX).
DATE	DATE in Oracle can also contain time information. Depending on usage map to DATE or TIMESTAMP.
DECIMAL	DECIMAL
DOUBLE	PRECISION DOUBLE
FLOAT	FLOAT
INTEGER	INT
INTERVAL YEAR TO MONTH	INTERVAL data types aren't supported. Use date comparison functions, such as DATEDIFF or DATEADD, for date calculations.
INTERVAL DAY TO SECOND	INTERVAL data types aren't supported. Use date comparison functions, such as DATEDIFF or DATEADD, for date calculations.
LONG	Not supported. Map to VARCHAR(MAX).
LONG RAW	Not supported. Map to VARBINARY(MAX).
NCHAR	NCHAR
NVARCHAR2	NVARCHAR
NUMBER	NUMBER
NCLOB	Not directly supported. Replace with NVARCHAR(MAX).
NUMERIC	NUMERIC
ORD media data types	Not supported
RAW	Not supported. Map to VARBINARY.
REAL	REAL
ROWID	Not supported. Map to GUID, which is similar.
SDO Geospatial data types	Not supported

ORACLE DATA TYPE	AZURE SYNAPSE DATA TYPE
SMALLINT	SMALLINT
TIMESTAMP	DATETIME2 or the CURRENT_TIMESTAMP() function
TIMESTAMP WITH LOCAL TIME ZONE	Not supported. Map to DATETIMEOFFSET.
TIMESTAMP WITH TIME ZONE	Not supported because TIME is stored using wall-clock time without a time zone offset.
URIType	Not supported. Store in a VARCHAR.
UROWID	Not supported. Map to GUID, which is similar.
VARCHAR	VARCHAR
VARCHAR2	VARCHAR
XMLType	Not supported. Store XML data in a VARCHAR.

Oracle also supports defining user-defined objects that can contain a series of individual fields, each with their own definition and default values. Those objects can then be referenced within a table definition in the same way as built-in data types like `NUMBER` or `VARCHAR`. Azure Synapse doesn't currently support user-defined types. If the data you need to migrate includes user-defined data types, either "flatten" them into a conventional table definition, or if they're arrays of data, normalize them in a separate table.

> **TIP**
> Assess the number and type of unsupported data types during the migration preparation phase.

Third-party vendors offer tools and services to automate migration, including the mapping of data types. If a third-party ETL tool is already in use in the Oracle environment, use that tool to implement any required data transformations.

SQL DML syntax differences

SQL DML syntax differences exist between Oracle SQL and Azure Synapse T-SQL. Those differences are discussed in detail in Minimize SQL issues for Oracle migrations. In some cases, you can automate DML migration by using Microsoft tools like SSMA for Oracle and Azure Database Migration Services, or third-party migration products and services.

Functions, stored procedures, and sequences

When migrating a data warehouse from a mature environment like Oracle, you probably need to migrate elements other than simple tables and views. Check whether tools within the Azure environment can replace the functionality of functions, stored procedures, and sequences because it's usually more efficient to use built-in Azure tools than to recode them for Azure Synapse.

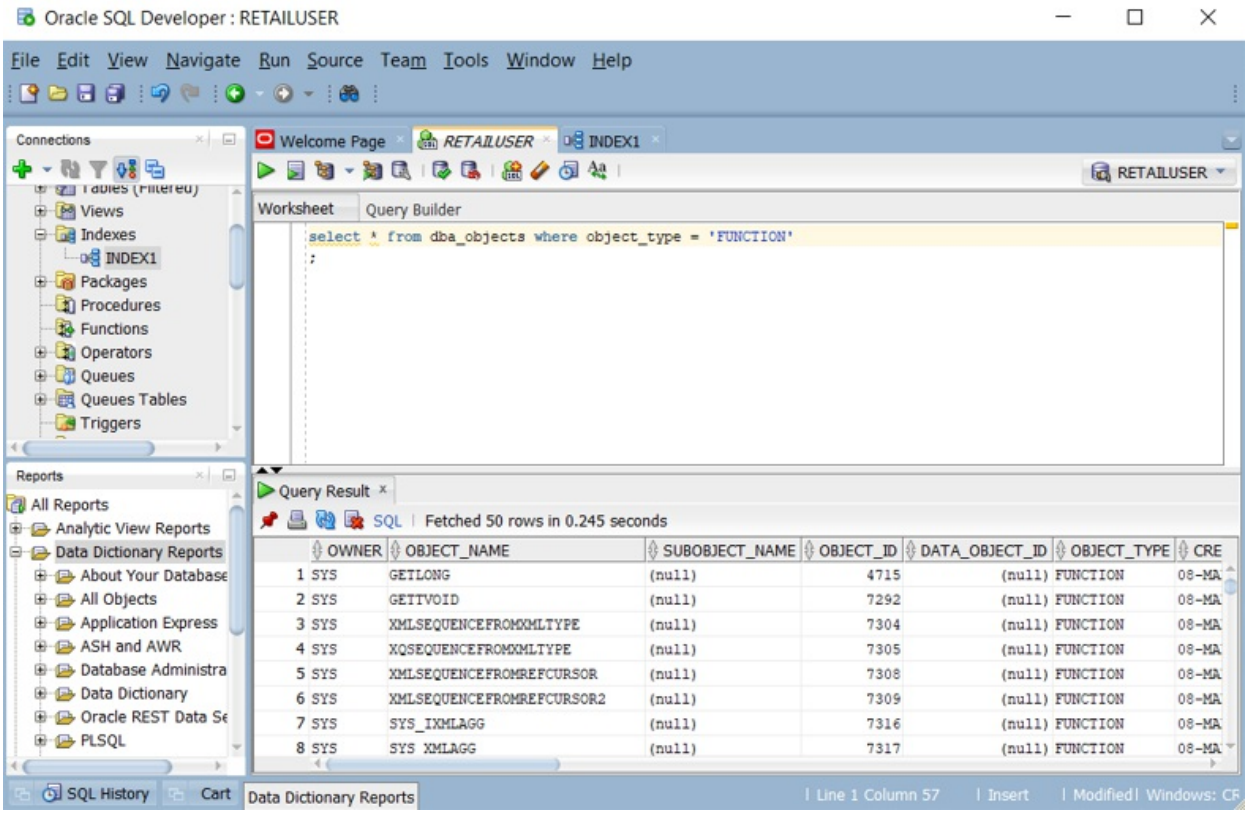
As part of your preparation phase, create an inventory of objects that need to be migrated, define a method for handling them, and allocate appropriate resources in your migration plan.

Microsoft tools like SSMA for Oracle and Azure Database Migration Services, or third-party migration products and services, can automate the migration of functions, stored procedures, and sequences.

The following sections further discuss the migration of functions, stored procedures, and sequences.

Functions

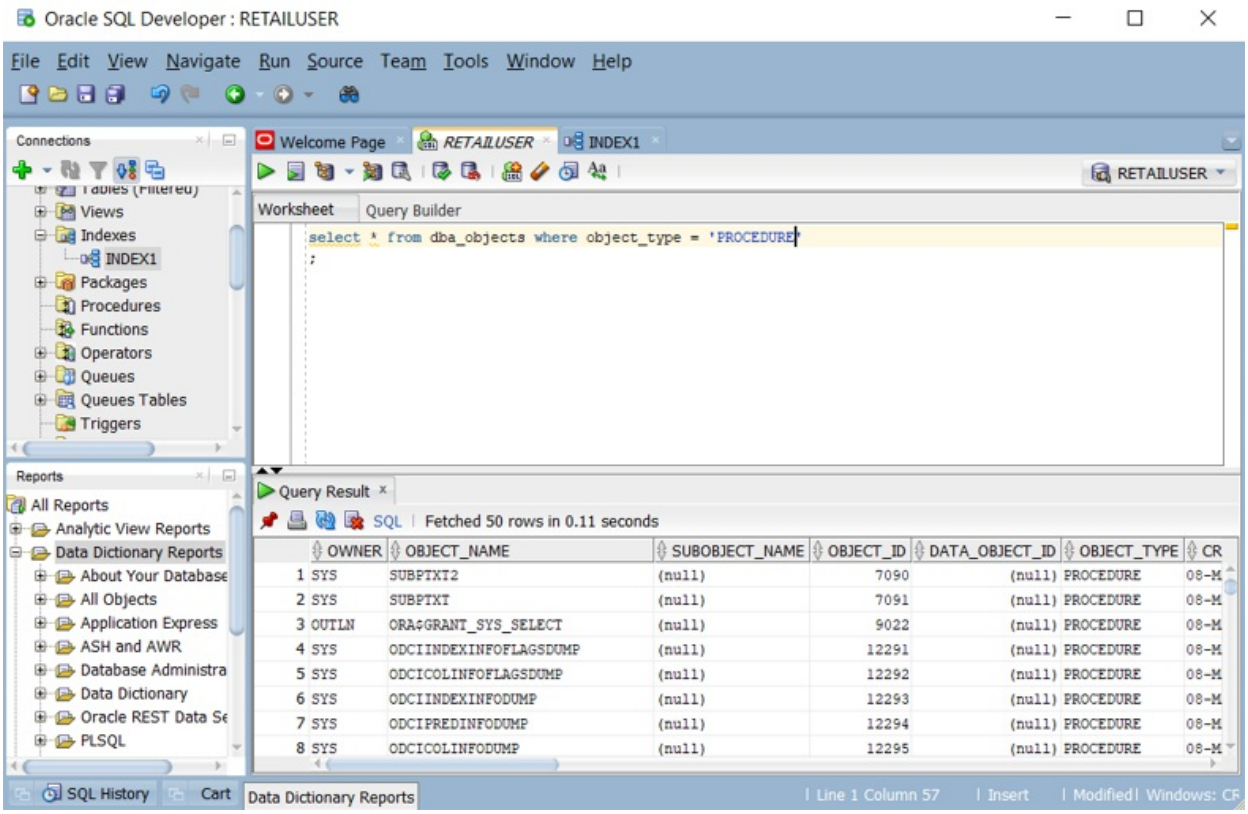
As with most database products, Oracle supports system and user-defined functions within a SQL implementation. When you migrate a legacy database platform to Azure Synapse, common system functions can usually be migrated without change. Some system functions might have a slightly different syntax, but any required changes can be automated. You can get a list of functions within an Oracle database by querying the `ALL_OBJECTS` view with the appropriate `WHERE` clause. You can use Oracle SQL Developer to get a list of functions, as shown in the following screenshot.



For Oracle system functions or arbitrary user-defined functions that have no equivalent in Azure Synapse, recode those functions using a target environment language. Oracle user-defined functions are coded in PL/SQL, Java, or C. Azure Synapse uses the Transact-SQL language to implement user-defined functions.

Stored procedures

Most modern database products support storing procedures within the database. Oracle provides the PL/SQL language for this purpose. A stored procedure typically contains both SQL statements and procedural logic, and returns data or a status. You can get a list of stored procedures within an Oracle database by querying the `ALL_OBJECTS` view with the appropriate `WHERE` clause. You can use Oracle SQL Developer to get a list of stored procedures, as shown in the next screenshot.



Azure Synapse supports stored procedures using T-SQL, so you'll need to recode any migrated stored procedures in that language.

Sequences

In Oracle, a sequence is a named database object, created using `CREATE SEQUENCE`. A sequence provides unique numeric values via the `CURRVAL` and `NEXTVAL` methods. You can use the generated unique numbers as surrogate key values for primary keys.

Azure Synapse doesn't implement `CREATE SEQUENCE`, but you can implement sequences using IDENTITY columns or SQL code that generates the next sequence number in a series.

Extracting metadata and data from an Oracle environment

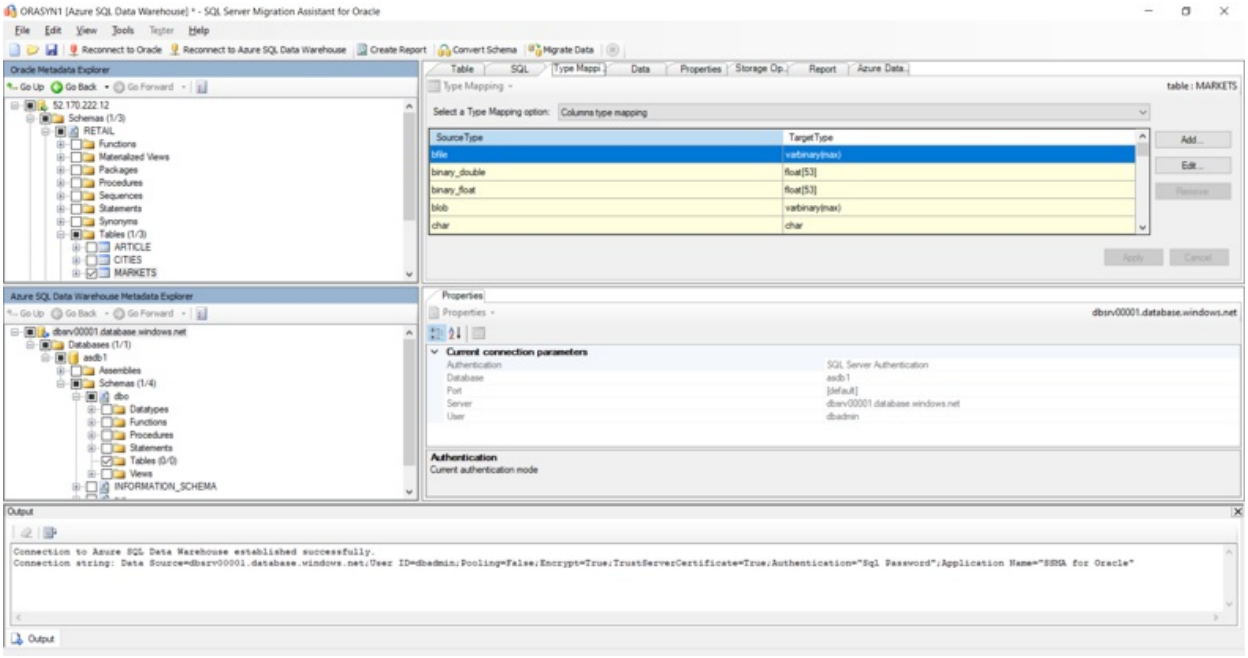
Data Definition Language generation

The ANSI SQL standard defines the basic syntax for Data Definition Language (DDL) commands. Some DDL commands, such as `CREATE TABLE` and `CREATE VIEW`, are common to both Oracle and Azure Synapse but also provide implementation-specific features such as indexing, table distribution, and partitioning options.

You can edit existing Oracle `CREATE TABLE` and `CREATE VIEW` scripts to achieve equivalent definitions in Azure Synapse. To do so, you might need to use modified data types and remove or modify Oracle-specific clauses such as `TABLESPACE`.

Within the Oracle environment, system catalog tables specify the current table and view definition. Unlike user-maintained documentation, system catalog information is always complete and in sync with current table definitions. You can access system catalog information using utilities such as Oracle SQL Developer. Oracle SQL Developer can generate `CREATE TABLE` DDL statements that you can edit to create equivalent tables in Azure Synapse.

Or, you can use SSMA for Oracle to migrate tables from an existing Oracle environment to Azure Synapse. SSMA for Oracle will apply the appropriate data type mappings and recommended table and distribution types, as shown in the following screenshot.



You can also use third-party migration and ETL tools that process system catalog information to achieve similar results.

Data extraction from Oracle

You can extract raw table data from Oracle tables to flat delimited files, such as CSV files, using standard Oracle utilities like Oracle SQL Developer, SQL*Plus, and SCLcl. Then, you can compress the flat delimited files using gzip, and upload the compressed files to Azure Blob Storage using AzCopy or Azure data transport tools like Azure Data Box.

Extract table data as efficiently as possible—especially when migrating large fact tables. For Oracle tables, use parallelism to maximize extraction throughput. You can achieve parallelism by running multiple processes that individually extract discrete segments of data, or by using tools capable of automating parallel extraction through partitioning.

> **TIP**
>
> Use parallelism for the most efficient data extraction.

If sufficient network bandwidth is available, you can extract data from an on-premises Oracle system directly into Azure Synapse tables or Azure Blob Data Storage. To do so, use Data Factory processes, Azure Database Migration Service, or third-party data migration or ETL products.

Extracted data files should contain delimited text in CSV, Optimized Row Columnar (ORC), or Parquet format.

For more information on migrating data and ETL from an Oracle environment, see Data migration, ETL, and load for Oracle migrations.

Performance recommendations for Oracle migrations

The goal of performance optimization is same or better data warehouse performance after migration to Azure Synapse.

Similarities in performance tuning approach concepts

Many performance tuning concepts for Oracle databases hold true for Azure Synapse databases. For example:

- Use data distribution to collocate data-to-be-joined onto the same processing node.
- Use the smallest data type for a given column to save storage space and accelerate query processing.

- Ensure that columns to be joined have the same data type in order to optimize join processing and reduce the need for data transforms.
- To help the optimizer produce the best execution plan, ensure statistics are up to date.
- Monitor performance using built-in database capabilities to ensure that resources are being used efficiently.

> **TIP**
> Prioritize familiarity with Azure Synapse tuning options at the start of a migration.

Differences in performance tuning approach

This section highlights low-level performance tuning implementation differences between Oracle and Azure Synapse.

Data distribution options

For performance, Azure Synapse was designed with multi-node architecture and uses parallel processing. To optimize table performance in Azure Synapse, you can define a data distribution option in `CREATE TABLE` statements using the `DISTRIBUTION` statement. For example, you can specify a hash-distributed table, which distributes table rows across compute nodes by using a deterministic hash function. Many Oracle implementations, especially older on-premises systems, don't support this feature.

Unlike Oracle, Azure Synapse supports local joins between a small table and a large table through small table replication. For instance, consider a small dimension table and a large fact table within a star schema model. Azure Synapse can replicate the smaller dimension table across all nodes to ensure that the value of any join key for the large table has a matching, locally available dimension row. The overhead of dimension table replication is relatively low for a small dimension table. For large dimension tables, a hash distribution approach is more appropriate. For more information on data distribution options, see Design guidance for using replicated tables and Guidance for designing distributed tables.

> **TIP**
> Hash distribution improves query performance on large fact tables. Round-robin distribution is useful for improving loading speed.

Hash distribution can be applied on multiple columns for a more even distribution of the base table. Multi-column distribution will allow you to choose up to eight columns for distribution. This not only reduces the data skew over time but also improves query performance.

> **NOTE**
> Multi-column distribution is currently in preview for Azure Synapse Analytics. You can use multi-column distribution with CREATE MATERIALIZED VIEW, CREATE TABLE, and CREATE TABLE AS SELECT.

Distribution Advisor

In Azure Synapse SQL, the way each table is distributed can be customized. The table distribution strategy affects query performance substantially.

The distribution advisor is a new feature in Synapse SQL that analyzes queries and recommends the best distribution strategies for tables to improve query performance. Queries to be considered by the advisor can be provided by you or pulled from your historic queries available in DMV.

For details and examples on how to use the distribution advisor, visit Distribution Advisor in Azure Synapse SQL.

Data indexing

Azure Synapse supports several user-definable indexing options that have a different operation and usage compared to system-managed zone maps in Oracle. For more information about the different indexing options in Azure Synapse, see Indexes on dedicated SQL pool tables.

Index definitions within a source Oracle environment provide a useful indication of data usage and the candidate columns for indexing in the Azure Synapse environment. Typically, you won't need to migrate every index from a legacy Oracle environment because Azure Synapse doesn't over-rely on indexes and implements the following features to achieve outstanding performance:

- Parallel query processing.
- In-memory data and result set caching.
- Data distribution, such as replication of small dimension tables, to reduce I/O.

Data partitioning

In an enterprise data warehouse, fact tables can contain billions of rows. Partitioning optimizes the maintenance and querying of these tables by splitting them into separate parts to reduce the amount of data processed. In Azure Synapse, the `CREATE TABLE` statement defines the partitioning specification for a table.

You can only use one field per table for partitioning. That field is frequently a date field because many queries are filtered by date or a date range. It's possible to change the partitioning of a table after initial load by using the `CREATE TABLE AS` (CTAS) statement to recreate the table with a new distribution. For a detailed discussion of partitioning in Azure Synapse, see Partitioning tables in dedicated SQL pool.

PolyBase or COPY INTO for data loading

PolyBase supports efficient loading of large amounts of data to a data warehouse by using parallel loading streams. For more information, see PolyBase data loading strategy.

COPY INTO also supports high-throughput data ingestion, and:

- Data retrieval from all files within a folder and subfolders.
- Data retrieval from multiple locations in the same storage account. You can specify multiple locations by using comma separated paths.
- Azure Data Lake Storage (ADLS) and Azure Blob Storage.
- CSV, PARQUET, and ORC file formats.

> **TIP**
> The recommended method for data loading is to use `COPY INTO` along with PARQUET file format.

Workload management

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). Workload classification, workload importance, and workload isolation give more control over how workload utilizes system resources.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance, and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized.

Next steps

To learn about ETL and load for Oracle migration, see the next article in this series: Data migration, ETL, and load for Oracle migrations.

Data migration, ETL, and load for Oracle migrations

8/19/2022 • 19 minutes to read • Edit Online

This article is part two of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for ETL and load migration.

Data migration considerations

There are many factors to consider when migrating data, ETL, and loads from a legacy Oracle data warehouse and data marts to Azure Synapse.

Initial decisions about data migration from Oracle

When you're planning a migration from an existing Oracle environment, consider the following data-related questions:

- Should unused table structures be migrated?
- What's the best migration approach to minimize risk and impact for users?
- When migrating data marts: stay physical or go virtual?

The next sections discuss these points within the context of a migration from Oracle.

Migrate unused tables?

It makes sense to only migrate tables that are in use. Tables that aren't active can be archived rather than migrated, so that the data is available if needed in the future. It's best to use system metadata and log files rather than documentation to determine which tables are in use, because documentation can be out of date.

Oracle system catalog tables and logs contain information that can be used to determine when a given table was last accessed—which in turn can be used to decide whether or not a table is a candidate for migration.

If you've licensed the Oracle Diagnostic Pack, then you have access to Active Session History, which you can use to determine when a table was last accessed.

> **TIP**
> In legacy systems, it's not unusual for tables to become redundant over time—these don't need to be migrated in most cases.

Here's an example query that looks for the usage of a specific table within a given time window:

```
SELECT du.username,
    s.sql_text,
    MAX(ash.sample_time) AS last_access ,
    sp.object_owner ,
    sp.object_name ,
    sp.object_alias as aliased_as ,
    sp.object_type ,
    COUNT(*) AS access_count
FROM v$active_session_history ash
    JOIN v$sql s ON ash.force_matching_signature = s.force_matching_signature
    LEFT JOIN v$sql_plan sp ON s.sql_id = sp.sql_id
    JOIN DBA_USERS du ON ash.user_id = du.USER_ID
WHERE ash.session_type = 'FOREGROUND'
    AND ash.SQL_ID IS NOT NULL
    AND sp.object_name IS NOT NULL
    AND ash.user_id <> 0
GROUP BY du.username,
    s.sql_text,
    sp.object_owner,
    sp.object_name,
    sp.object_alias,
    sp.object_type
ORDER BY 3 DESC;
```

This query may take a while to run if you have been running numerous queries.

What's the best migration approach to minimize risk and impact on users?

This question comes up frequently because companies may want to lower the impact of changes on the data warehouse data model to improve agility. Companies often see an opportunity to further modernize or transform their data during an ETL migration. This approach carries a higher risk because it changes multiple factors simultaneously, making it difficult to compare the outcomes of the old system versus the new. Making data model changes here could also affect upstream or downstream ETL jobs to other systems. Because of that risk, it's better to redesign on this scale after the data warehouse migration.

Even if a data model is intentionally changed as part of the overall migration, it's good practice to migrate the existing model as-is to Azure Synapse, rather than do any re-engineering on the new platform. This approach minimizes the effect on existing production systems, while benefiting from the performance and elastic scalability of the Azure platform for one-off re-engineering tasks.

> **TIP**
>
> Migrate the existing model as-is initially, even if a change to the data model is planned in the future.

Data mart migration: stay physical or go virtual?

In legacy Oracle data warehouse environments, it's common practice to create many data marts that are structured to provide good performance for ad hoc self-service queries and reports for a given department or business function within an organization. A data mart typically consists of a subset of the data warehouse that contains aggregated versions of the data in a form that enables users to easily query that data with fast response times. Users can use user-friendly query tools like Microsoft Power BI, which supports business user interactions with data marts. The form of the data in a data mart is generally a dimensional data model. One use of data marts is to expose the data in a usable form even if the underlying warehouse data model is something different, such as a data vault.

You can use separate data marts for individual business units within an organization to implement robust data security regimes. Restrict access to specific data marts that are relevant to users, and eliminate, obfuscate, or anonymize sensitive data.

If these data marts are implemented as physical tables, they'll require extra storage resources and processing to

build and refresh them regularly. Also, the data in the mart will only be as up to date as the last refresh operation, and so may be unsuitable for highly volatile data dashboards.

> **TIP**
> Virtualizing data marts can save on storage and processing resources.

With the advent of lower-cost scalable MPP architectures, such as Azure Synapse, and their inherent performance characteristics, you can provide data mart functionality without instantiating the mart as a set of physical tables. One method is to effectively virtualize the data marts via SQL views onto the main data warehouse. Another way is to virtualize the data marts via a virtualization layer using features like views in Azure or third-party virtualization products. This approach simplifies or eliminates the need for extra storage and aggregation processing and reduces the overall number of database objects to be migrated.

There's another potential benefit of this approach. By implementing the aggregation and join logic within a virtualization layer, and presenting external reporting tools via a virtualized view, the processing required to create these views is pushed down into the data warehouse. The data warehouse is generally the best place to run joins, aggregations, and other related operations on large data volumes.

The primary drivers for implementing a virtual data mart over a physical data mart are:

- More agility: a virtual data mart is easier to change than physical tables and the associated ETL processes.
- Lower total cost of ownership: a virtualized implementation requires fewer data stores and copies of data.
- Elimination of ETL jobs to migrate and simplify data warehouse architecture in a virtualized environment.
- Performance: although physical data marts have historically performed better, virtualization products now implement intelligent caching techniques to mitigate this difference.

> **TIP**
> The performance and scalability of Azure Synapse enables virtualization without sacrificing performance.

Data migration from Oracle

Understand your data

As part of migration planning, you should understand in detail the volume of data to be migrated since that can affect decisions about the migration approach. Use system metadata to determine the physical space taken up by the raw data within the tables to be migrated. In this context, raw data means the amount of space used by the data rows within a table, excluding overhead such as indexes and compression. The largest fact tables will typically comprise more than 95% of the data.

This query will give you the total database size in Oracle:

```
SELECT
  ( SELECT SUM(bytes)/1024/1024/1024 data_size
    FROM sys.dba_data_files ) +
  ( SELECT NVL(sum(bytes),0)/1024/1024/1024 temp_size
    FROM sys.dba_temp_files ) +
  ( SELECT SUM(bytes)/1024/1024/1024 redo_size
    FROM sys.v_$log ) +
  ( SELECT SUM(BLOCK_SIZE*FILE_SIZE_BLKS)/1024/1024/1024 controlfile_size
    FROM v$controlfile ) "Size in GB"
FROM dual
```

The database size equals the size of `(data files + temp files + online/offline redo log files + control files)`.

Overall database size includes used space and free space.

The following example query gives a breakdown of the disk space used by table data and indexes:

```
SELECT
   owner, "Type", table_name "Name", TRUNC(sum(bytes)/1024/1024) Meg
FROM
  ( SELECT segment_name table_name, owner, bytes, 'Table' as "Type"
    FROM dba_segments
    WHERE segment_type in  ('TABLE','TABLE PARTITION','TABLE SUBPARTITION' )
UNION ALL
    SELECT i.table_name, i.owner, s.bytes, 'Index' as "Type"
    FROM dba_indexes i, dba_segments s
    WHERE s.segment_name = i.index_name
    AND   s.owner = i.owner
    AND   s.segment_type in ('INDEX','INDEX PARTITION','INDEX SUBPARTITION')
UNION ALL
    SELECT l.table_name, l.owner, s.bytes, 'LOB' as "Type"
    FROM dba_lobs l, dba_segments s
    WHERE s.segment_name = l.segment_name
    AND   s.owner = l.owner
    AND   s.segment_type IN ('LOBSEGMENT','LOB PARTITION','LOB SUBPARTITION')
UNION ALL
    SELECT l.table_name, l.owner, s.bytes, 'LOB Index' as "Type"
    FROM dba_lobs l, dba_segments s
    WHERE s.segment_name = l.index_name
    AND   s.owner = l.owner
    AND   s.segment_type = 'LOBINDEX')
    WHERE owner in UPPER('&owner')
GROUP BY table_name, owner, "Type"
HAVING SUM(bytes)/1024/1024 > 10  /* Ignore really small tables */
ORDER BY SUM(bytes) desc;
```

In addition, the Microsoft database migration team provides many resources, including the Oracle Inventory Script Artifacts. The Oracle Inventory Script Artifacts tool includes a PL/SQL query that accesses Oracle system tables and provides a count of objects by schema type, object type, and status. The tool also provides a rough estimate of raw data in each schema and the sizing of tables in each schema, with results stored in a CSV format. An included calculator spreadsheet takes the CSV as input and provides sizing data.

For any table, you can accurately estimate the volume of data that needs to be migrated by extracting a representative sample of the data, such as one million rows, to an uncompressed delimited flat ASCII data file. Then, use the size of that file to get an average raw data size per row. Finally, multiply that average size by the total number of rows in the full table to give a raw data size for the table. Use that raw data size in your planning.

Use SQL queries to find data types

By querying the Oracle static data dictionary `DBA_TAB_COLUMNS` view, you can determine which data types are in use in a schema and whether any of those data types need to be changed. Use SQL queries to find the columns in any Oracle schema with data types that don't map directly to data types in Azure Synapse. Similarly, you can use queries to count the number of occurrences of each Oracle data type that doesn't map directly to Azure Synapse. By using the results from these queries in combination with the data type comparison table, you can determine which data types need to be changed in an Azure Synapse environment.

To find the columns with data types that don't map to data types in Azure Synapse, run the following query after you replace `<owner_name>` with the relevant owner of your schema:

```
SELECT owner, table_name, column_name, data_type
FROM dba_tab_columns
WHERE owner in ('<owner_name>')
AND data_type NOT IN
    ('BINARY_DOUBLE', 'BINARY_FLOAT', 'CHAR', 'DATE', 'DECIMAL', 'FLOAT', 'LONG', 'LONG RAW', 'NCHAR',
'NUMERIC', 'NUMBER', 'NVARCHAR2', 'SMALLINT', 'RAW', 'REAL', 'VARCHAR2', 'XML_TYPE')
ORDER BY 1,2,3;
```

To count the number of non-mappable data types, use the following query:

```
SELECT data_type, count(*)
FROM dba_tab_columns
WHERE data_type NOT IN
    ('BINARY_DOUBLE', 'BINARY_FLOAT', 'CHAR', 'DATE', 'DECIMAL', 'FLOAT', 'LONG', 'LONG RAW', 'NCHAR',
'NUMERIC', 'NUMBER', 'NVARCHAR2', 'SMALLINT', 'RAW', 'REAL', 'VARCHAR2', 'XML_TYPE')
GROUP BY data_type
ORDER BY data_type;
```

Microsoft offers SQL Server Migration Assistant (SSMA) for Oracle to automate migration of data warehouses from legacy Oracle environments, including the mapping of data types. You can also use Azure Database Migration Services to help plan and perform a migration from environments like Oracle. Third-party vendors also offer tools and services to automate migration. If a third-party ETL tool is already in use in the Oracle environment, you can use that tool to implement any required data transformations. The next section explores migration of existing ETL processes.

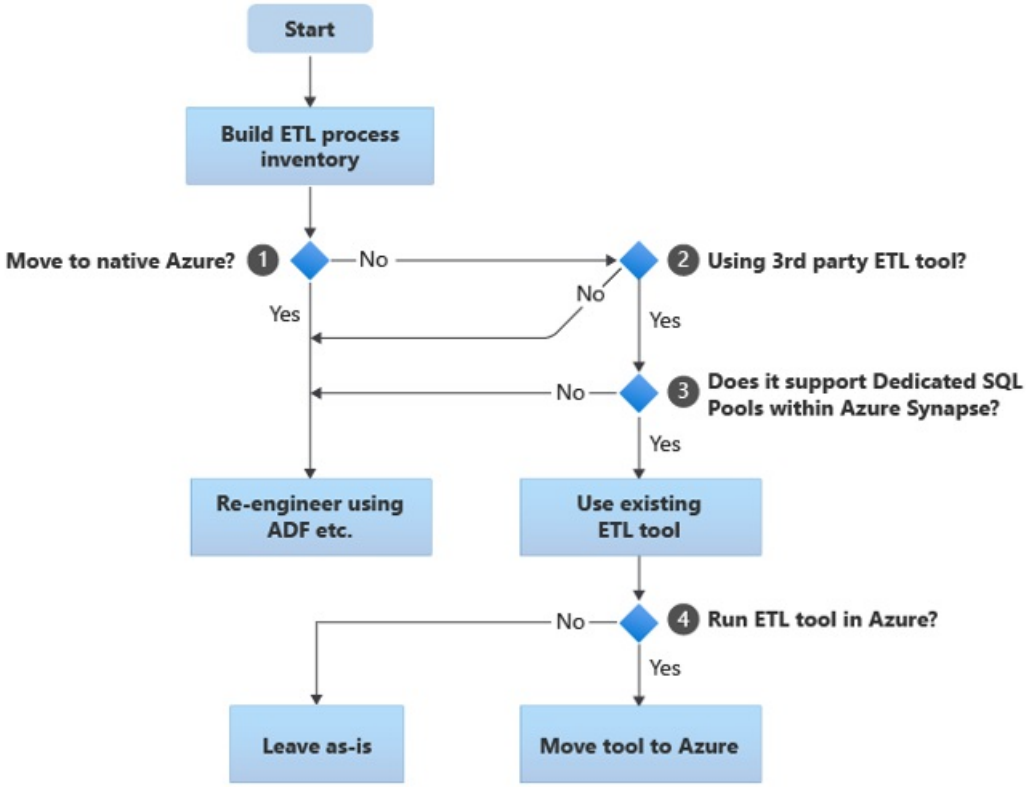
ETL migration considerations

Initial decisions about Oracle ETL migration

For ETL/ELT processing, legacy Oracle data warehouses often use custom-built scripts, third-party ETL tools, or a combination of approaches that has evolved over time. When you're planning a migration to Azure Synapse, determine the best way to implement the required ETL/ELT processing in the new environment while also minimizing cost and risk.

> **TIP**
> Plan the approach to ETL migration ahead of time and leverage Azure facilities where appropriate.

The following flowchart summarizes one approach:



As shown in the flowchart, the initial step is always to build an inventory of ETL/ELT processes that need to be migrated. With the standard built-in Azure features, some existing processes might not need to move. For planning purposes, it's important that you understand the scale of the migration. Next, consider the questions in the flowchart decision tree:

1. **Move to native Azure?** Your answer depends on whether you're migrating to a completely Azure-native environment. If so, we recommend that you re-engineer the ETL processing using Pipelines and activities in Azure Data Factory or Azure Synapse pipelines.

2. **Using a third-party ETL tool?** If you're not moving to a completely Azure-native environment, then check whether an existing third-party ETL tool is already in use. In the Oracle environment, you might find that some or all of the ETL processing is performed by custom scripts using Oracle-specific utilities such as Oracle SQL Developer, Oracle SQL*Loader, or Oracle Data Pump. The approach in this case is to re-engineer using Azure Data Factory.

3. **Does the third-party support dedicated SQL pools within Azure Synapse?** Consider whether there's a large investment in skills in the third-party ETL tool, or if existing workflows and schedules use that tool. If so, determine whether the tool can efficiently support Azure Synapse as a target environment. Ideally, the tool will include native connectors that can use Azure facilities like PolyBase or COPY INTO for the most efficient data loading. But even without native connectors, there's generally a way that you can call external processes, such as PolyBase or `COPY INTO`, and pass in applicable parameters. In this case, use existing skills and workflows, with Azure Synapse as the new target environment.

   If you're using Oracle Data Integrator (ODI) for ELT processing, then you need ODI Knowledge Modules for Azure Synapse. If those modules aren't available to you in your organization, but you have ODI, then you can use ODI to generate flat files. Those flat files can then be moved to Azure and ingested into Azure Data Lake Storage for loading into Azure Synapse.

4. **Run ETL tools in Azure?** If you decide to retain an existing third-party ETL tool, you can run that tool within the Azure environment (rather than on an existing on-premises ETL server) and have Data Factory handle the overall orchestration of the existing workflows. So, decide whether to leave the existing tool running as-is or move it into the Azure environment to achieve cost, performance, and scalability benefits.

> **TIP**
> Consider running ETL tools in Azure to leverage performance, scalability, and cost benefits.

Re-engineer existing Oracle-specific scripts

If some or all of the existing Oracle warehouse ETL/ELT processing is handled by custom scripts that use Oracle-specific utilities, such as Oracle SQL*Plus, Oracle SQL Developer, Oracle SQL*Loader, or Oracle Data Pump, then you need to recode these scripts for the Azure Synapse environment. Similarly, if ETL processes have been implemented using stored procedures in Oracle, then you need to recode those processes.

Some elements of the ETL process are easy to migrate, for example, by simple bulk data load into a staging table from an external file. It may even be possible to automate those parts of the process, for example, by using Azure Synapse `COPY INTO` or PolyBase instead of SQL*Loader. Other parts of the process that contain arbitrary complex SQL and/or stored procedures will take more time to re-engineer.

> **TIP**
> The inventory of ETL tasks to be migrated should include scripts and stored procedures.

One way of testing Oracle SQL for compatibility with Azure Synapse is to capture some representative SQL statements from a join of Oracle `v$active_session_history` and `v$sql` to get `sql_text`, then prefix those queries with `EXPLAIN`. Assuming a like-for-like migrated data model in Azure Synapse, run those `EXPLAIN` statements in Azure Synapse. Any incompatible SQL will give an error. You can use this information to determine the scale of the recoding task.

> **TIP**
> Use `EXPLAIN` to find SQL incompatibilities.

In the worst case, manual recoding may be necessary. However, there are products and services available from Microsoft partners to assist with re-engineering Oracle-specific code.

> **TIP**
> Partners offer products and skills to assist in re-engineering Oracle-specific code.

Use existing third-party ETL tools

In many cases, the existing legacy data warehouse system will already be populated and maintained by a third-party ETL product. See Azure Synapse Analytics data integration partners for a list of current Microsoft data integration partners for Azure Synapse.

The Oracle community frequently uses several popular ETL products. The following paragraphs discuss the most popular ETL tools for Oracle warehouses. You can run all of those products within a VM in Azure and use them to read and write Azure databases and files.

> **TIP**
> Leverage investment in existing third-party tools to reduce cost and risk.

Data loading from Oracle

Choices available when loading data from Oracle

When you're preparing to migrate data from an Oracle data warehouse, decide how data will be physically moved from the existing on-premises environment into Azure Synapse in the cloud, and which tools will be used to perform the transfer and load. Consider the following questions, which are discussed in the following sections.

- Will you extract the data to files, or move it directly via a network connection?
- Will you orchestrate the process from the source system, or from the Azure target environment?
- Which tools will you use to automate and manage the migration process?

Transfer data via files or network connection?

Once the database tables to be migrated have been created in Azure Synapse, you can move the data that populates those tables out of the legacy Oracle system and into the new environment. There are two basic approaches:

- **File Extract**: extract the data from the Oracle tables to flat delimited files, normally in CSV format. You can extract table data in several ways:
  - Use standard Oracle tools such as SQL*Plus, SQL Developer, and SQLcl.
  - Use Oracle Data Integrator (ODI) to generate flat files.
  - Use Oracle connector in Data Factory to unload Oracle tables in parallel to enable data loading by partitions.
  - Use a third-party ETL tool.

  For examples of how to extract Oracle table data, see the article appendix.

  This approach requires space to land the extracted data files. The space could be local to the Oracle source database if sufficient storage is available, or remote in Azure Blob Storage. The best performance is achieved when a file is written locally since that avoids network overhead.

  To minimize storage and network transfer requirements, compress the extracted data files using a utility like gzip.

  After extraction, move the flat files into Azure Blob Storage. Microsoft provides various options to move large volumes of data, including:

  - AzCopy for moving files across the network into Azure Storage.
  - Azure ExpressRoute for moving bulk data over a private network connection.
  - Azure Data Box for moving files to a physical storage device that you ship to an Azure data center for loading.

  For more information, see Transfer data to and from Azure.

- **Direct extract and load across network**: the target Azure environment sends a data extract request, normally via a SQL command, to the legacy Oracle system to extract the data. The results are sent across the network and loaded directly into Azure Synapse, with no need to land the data into intermediate files. The limiting factor in this scenario is normally the bandwidth of the network connection between the Oracle database and the Azure environment. For exceptionally large data volumes, this approach may not be practical.

> **TIP**
> Understand the data volumes to be migrated and the available network bandwidth, because these factors influence the migration approach decision.

There's also a hybrid approach that uses both methods. For example, you can use the direct network extract

approach for smaller dimension tables and samples of the larger fact tables to quickly provide a test environment in Azure Synapse. For large-volume historical fact tables, you can use the file extract and transfer approach using Azure Data Box.

Orchestrate from Oracle or Azure?

The recommended approach when moving to Azure Synapse is to orchestrate data extraction and loading from the Azure environment using SSMA or Data Factory. Use the associated utilities, such as PolyBase or `COPY INTO`, for the most efficient data loading. This approach benefits from built-in Azure capabilities and reduces the effort to build reusable data load pipelines. You can use metadata-driven data load pipelines to automate the migration process.

The recommended approach also minimizes the performance hit on the existing Oracle environment during the data load process, because the management and load process runs in Azure.

Existing data migration tools

Data transformation and movement is the basic function of all ETL products. If a data migration tool is already in use in the existing Oracle environment and it supports Azure Synapse as a target environment, then consider using that tool to simplify data migration.

Even if an existing ETL tool isn't in place, Azure Synapse Analytics data integration partners offer ETL tools to simplify the task of data migration.

Finally, if you plan to use an ETL tool, consider running that tool within the Azure environment to take advantage of Azure cloud performance, scalability, and cost. This approach also frees up resources in the Oracle data center.

Summary

To summarize, our recommendations for migrating data and associated ETL processes from Oracle to Azure Synapse are:

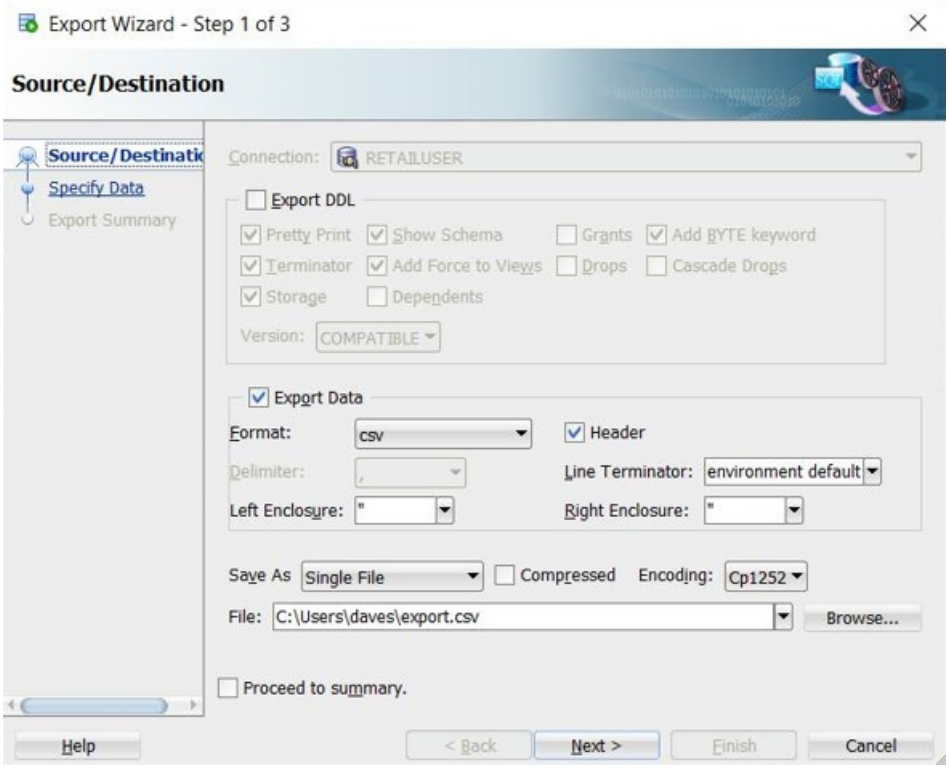
- Plan ahead to ensure a successful migration exercise.
- Build a detailed inventory of data and processes to be migrated as soon as possible.
- Use system metadata and log files to get an accurate understanding of data and process usage. Don't rely on documentation since it may be out of date.
- Understand the data volumes to be migrated, and the network bandwidth between the on-premises data center and Azure cloud environments.
- Consider using an Oracle instance in an Azure VM as a stepping stone to offload migration from the legacy Oracle environment.
- Use standard built-in Azure features to minimize the migration workload.
- Identify and understand the most efficient tools for data extraction and load in both Oracle and Azure environments. Use the appropriate tools in each phase of the process.
- Use Azure facilities, such as Data Factory, to orchestrate and automate the migration process while minimizing impact on the Oracle system.

Appendix: Examples of techniques to extract Oracle data

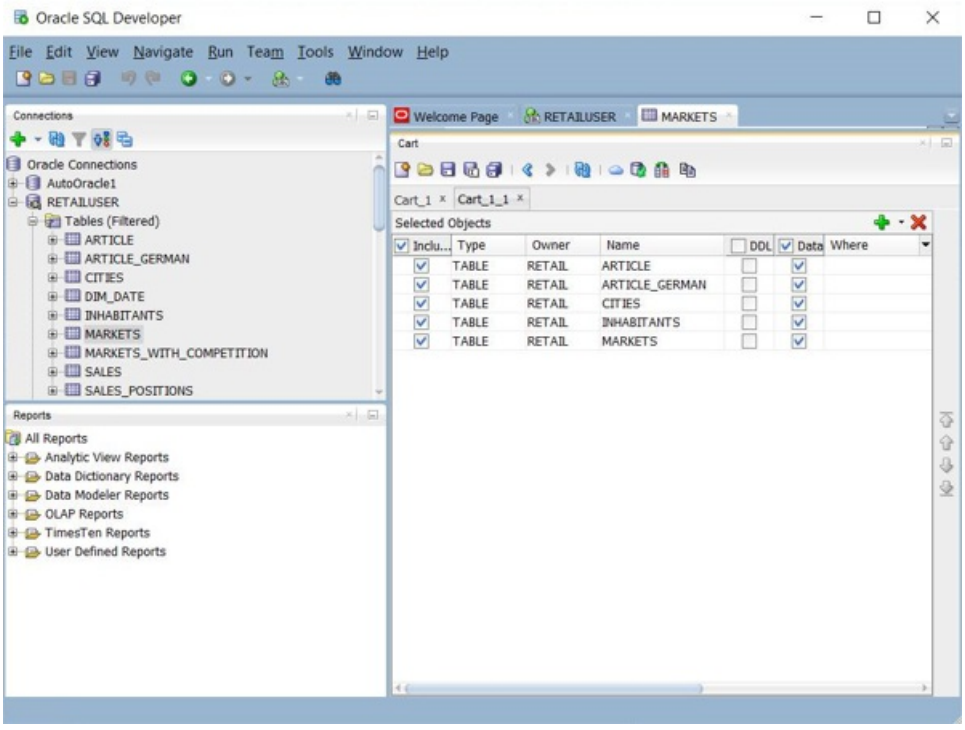
You can use several techniques to extract Oracle data when migrating from Oracle to Azure Synapse. The next sections demonstrate how to extract Oracle data using Oracle SQL Developer and the Oracle connector in Data Factory.

Use Oracle SQL Developer for data extraction

You can use the Oracle SQL Developer UI to export table data to many formats, including CSV, as shown in the following screenshot:



Other export options include JSON and XML. You can use the UI to add a set of table names to a "cart", then apply the export to the entire set in the cart:



You can also use Oracle SQL Developer Command Line (SQLcl) to export Oracle data. This option supports automation using a shell script.

For relatively small tables, you might find this technique useful if you run into problems extracting data through a direct connection.

Use the Oracle connector in Azure Data Factory for parallel copy

You can use the Oracle connector in Data Factory to unload large Oracle tables in parallel. The Oracle connector provides built-in data partitioning to copy data from Oracle in parallel. You can find the data partitioning options

in the *Source* tab of the copy activity.

For information on how to configure the Oracle connector for parallel copy, see Parallel copy from Oracle.

For more information on Data Factory copy activity performance and scalability, see Copy activity performance and scalability guide.

To learn about security access operations, see the next article in this series: Security, access, and operations for Oracle migrations.

Security, access, and operations for Oracle migrations

8/19/2022 • 21 minutes to read • Edit Online

This article is part three of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for security access operations.

Security considerations

The Oracle environment offers several methods for access and authentication that you might need to migrate to Azure Synapse with minimal risk and user impact. The article assumes you want to migrate the existing connection methods and the user, role, and permission structures as-is. If that's not the case, then use the Azure portal to create and manage a new security regime.

For more information about Azure Synapse security options, see Azure Synapse Analytics security.

Connection and authentication

Authentication is the process of verifying the identity of a user, device, or other entity in a computer system, generally as a prerequisite to granting access to resources in a system.

> **TIP**
> Authentication in both Oracle and Azure Synapse can be "in database" or via external methods.

Oracle authorization options

The Oracle system offers these authentication methods for database users:

- **Database authentication**: with database authentication, the Oracle database administers the user account and authenticates the user. For the Oracle database to perform authentication, it generates a password for new users and stores passwords in encrypted format. Users can change their password at any time. Oracle recommends password management through account locking, password aging and expiration, password history, and password complexity verification. Database authentication is common in older Oracle installations.
- **External authentication**: with external authentication, the Oracle database maintains the user account, and an external service performs password administration and user authentication. The external service can be an operating system or a network service like Oracle Net. The database relies on the underlying operating system or network authentication service to restrict access to database accounts. This type of sign doesn't use a database password. There are two external authentication options:
  - **Operating system authentication**: by default, Oracle requires a secure connection for logins that the operating system authenticates to prevent a remote user from impersonating an operating system user over a network connection. This requirement precludes the use of Oracle Net and a shared-server configuration.
  - **Network authentication**: several network authentication mechanisms are available, such as smart cards, fingerprints, Kerberos, and the operating system. Many network authentication services, such as Kerberos, support single sign-on so users have fewer passwords to remember.
- **Global authentication and authorization**: with global authentication and authorization, you can centralize management of user-related information, including authorizations, in an LDAP-based directory

service. Users are identified in the database as global users, which means they're authenticated by TLS/SSL and user management occurs outside the database. The centralized directory service performs user management. This approach provides strong authentication using TLS/SSL, Kerberos, or Windows-native authentication, and enables centralized management of users and privileges across the enterprise. Administration is easier because it's not necessary to create a schema for every user in every database in the enterprise. Single sign-on is also supported, so that users only need to sign in once to access multiple databases and services.

- **Proxy authentication and authorization**: you can designate a middle-tier server to proxy clients in a secure fashion. Oracle provides various options for proxy authentication, such as:
  - The middle-tier server can authenticate itself with the database server. A client, which in this case is an application user or another application, authenticates itself with the middle-tier server. Client identities can be maintained all the way through to the database.
  - The client, which in this case is database user, isn't authenticated by the middle-tier server. The client's identity and database password are passed through the middle-tier server to the database server for authentication.
  - The client, which in this case is a global user, is authenticated by the middle-tier server, and passes either a distinguished name (DN) or certificate through the middle tier for retrieving the client's username.

Azure Synapse authorization options

Azure Synapse supports two basic options for connection and authorization:

- **SQL authentication**: SQL authentication uses a database connection that includes a database identifier, user ID, and password, plus other optional parameters. This method of authentication is functionally equivalent to Oracle database authentication.
- **Azure AD authentication**: with Azure AD authentication, you can centrally manage the identities of database users and Microsoft services in one location. Centralized management provides a single place to manage Azure Synapse users and simplifies permission management. Azure AD authentication supports connections to LDAP and Kerberos services. For example, you can use Azure AD authentication to connect to existing LDAP directories if they're to remain in place after migration of the database.

Users, roles, and permissions

Both Oracle and Azure Synapse implement database access control via a combination of users, roles, and permissions. You can use standard SQL statements `CREATE USER` and `CREATE ROLE/GROUP` to define users and roles. `GRANT` and `REVOKE` statements assign or remove permissions to users and/or roles.

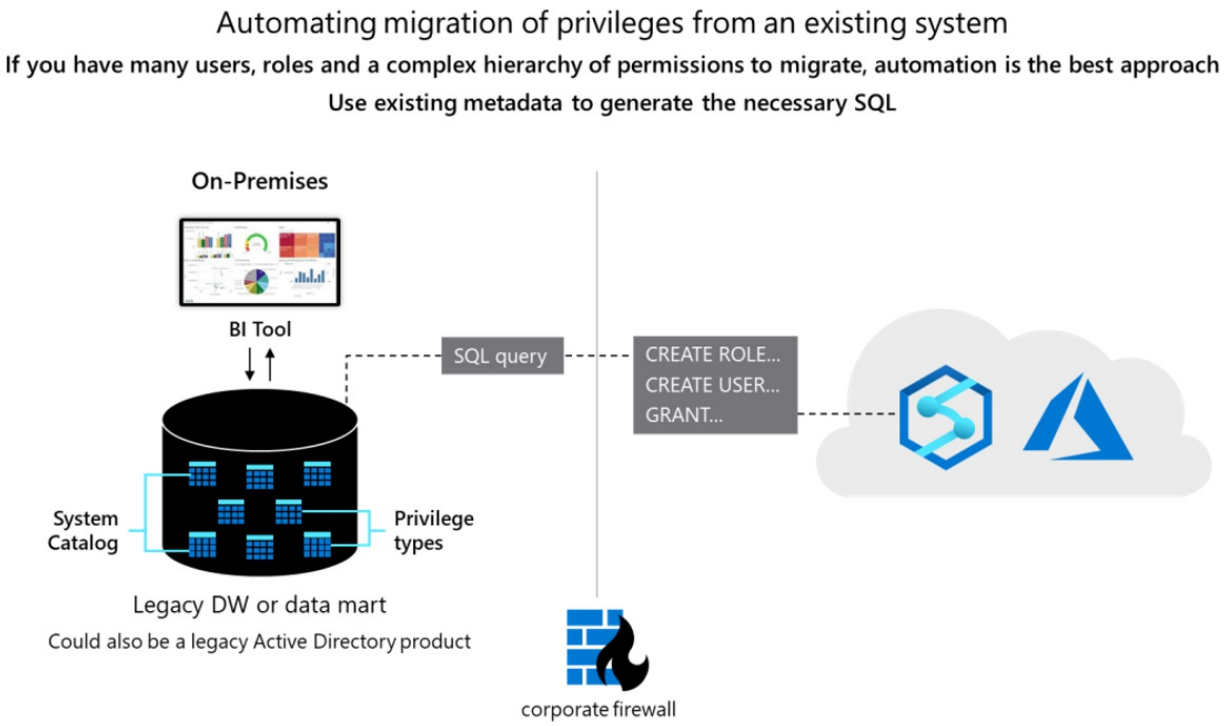
> **TIP**
> Planning is essential for a successful migration project. Start with high-level approach decisions.

Conceptually, Oracle and Azure Synapse databases are similar, and to some degree it's possible to automate the migration of existing user IDs, groups, and permissions. Extract the legacy user and group information from the Oracle system catalog tables, then generate matching equivalent `CREATE USER` and `CREATE ROLE` statements. Run those statements in Azure Synapse to recreate the same user/role hierarchy.

> **TIP**
> If possible, automate migration processes to reduce elapsed time and scope for error.

After data extraction, use Oracle system catalog tables to generate equivalent `GRANT` statements to assign

permissions if an equivalent exists.



Users and roles

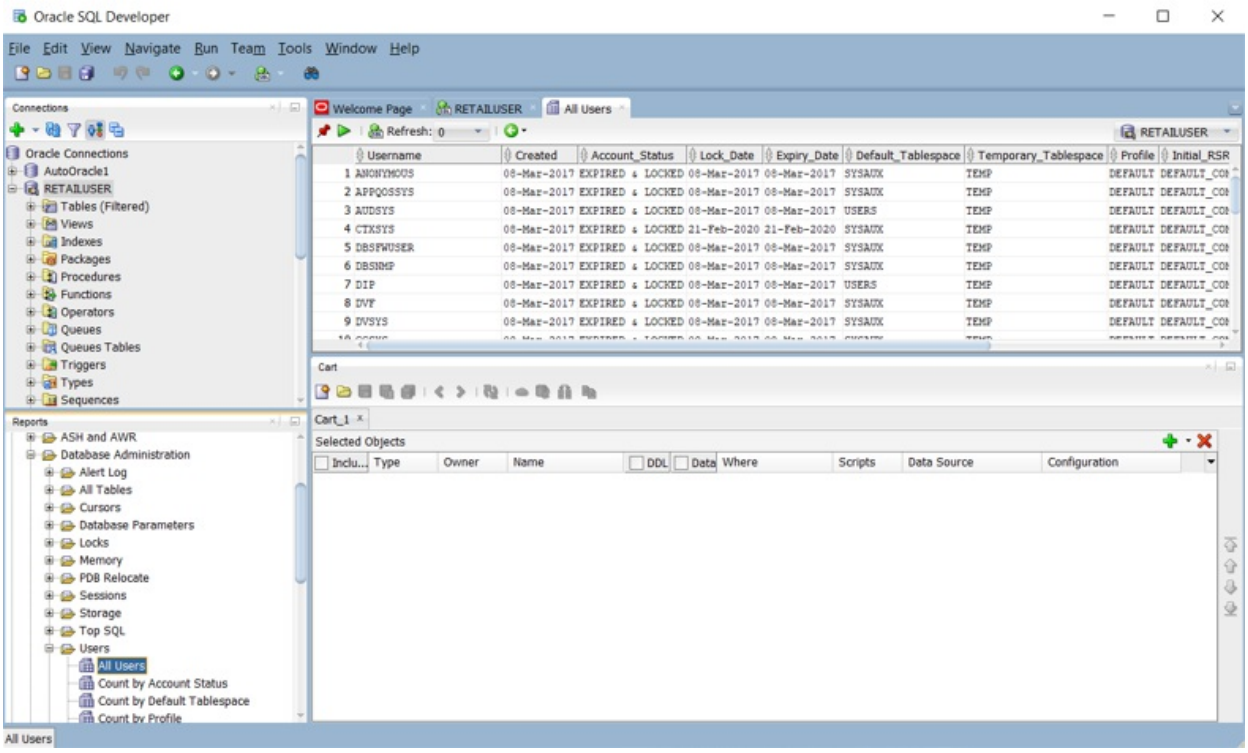
The information about current users and groups in an Oracle system is held in system catalog views, such as `ALL_USERS` and `DBA_USERS`. You can query these views in the normal way via Oracle SQL*Plus or Oracle SQL Developer. The following queries are basic examples:

```
--List of users
select * from dba_users order by username;

--List of roles
select * from dba_roles order by role;

--List of users and their associated roles
select * from user_role_privs order by username, granted_role;
```

Oracle SQL Developer has built-in options to display user and role information in the *Reports* pane, as shown in the following screenshot.



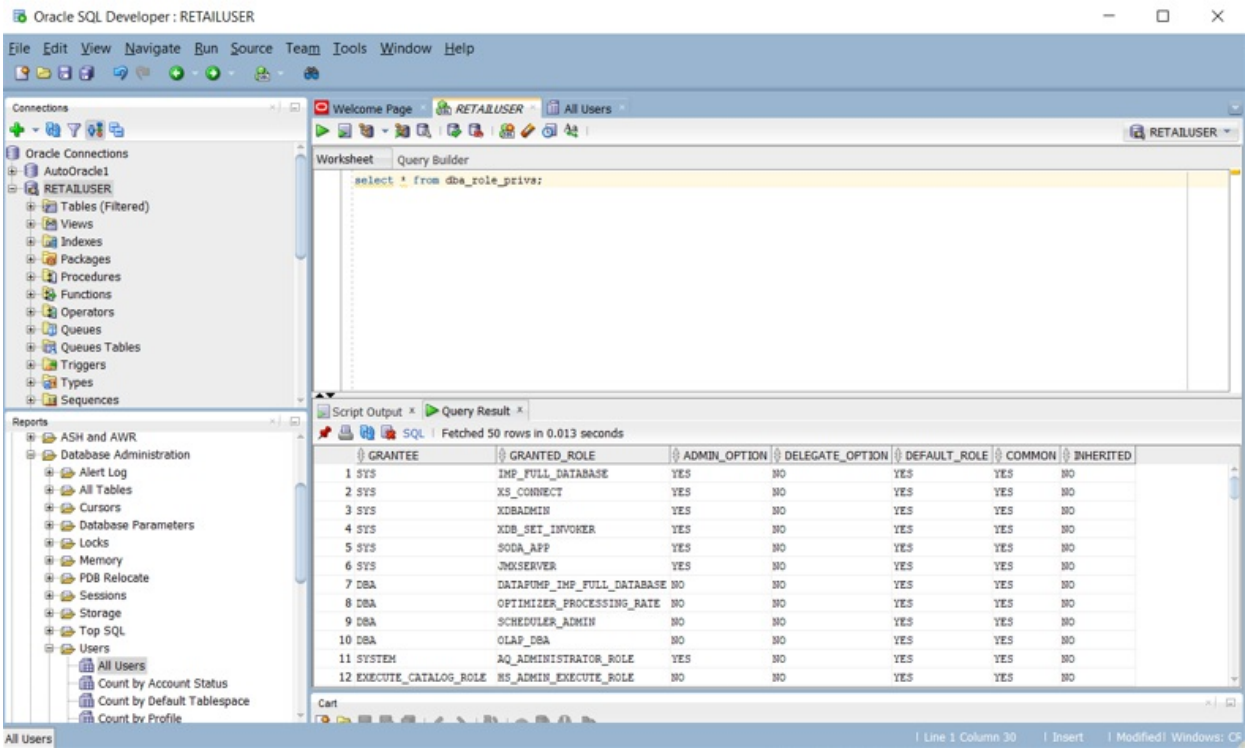
You can modify the example `SELECT` statement to produce a result set that is a series of `CREATE USER` and `CREATE GROUP` statements. To do so, include the appropriate text as a literal within the `SELECT` statement.

There's no way to retrieve existing Oracle passwords, so you need to implement a scheme for allocating new initial passwords on Azure Synapse.

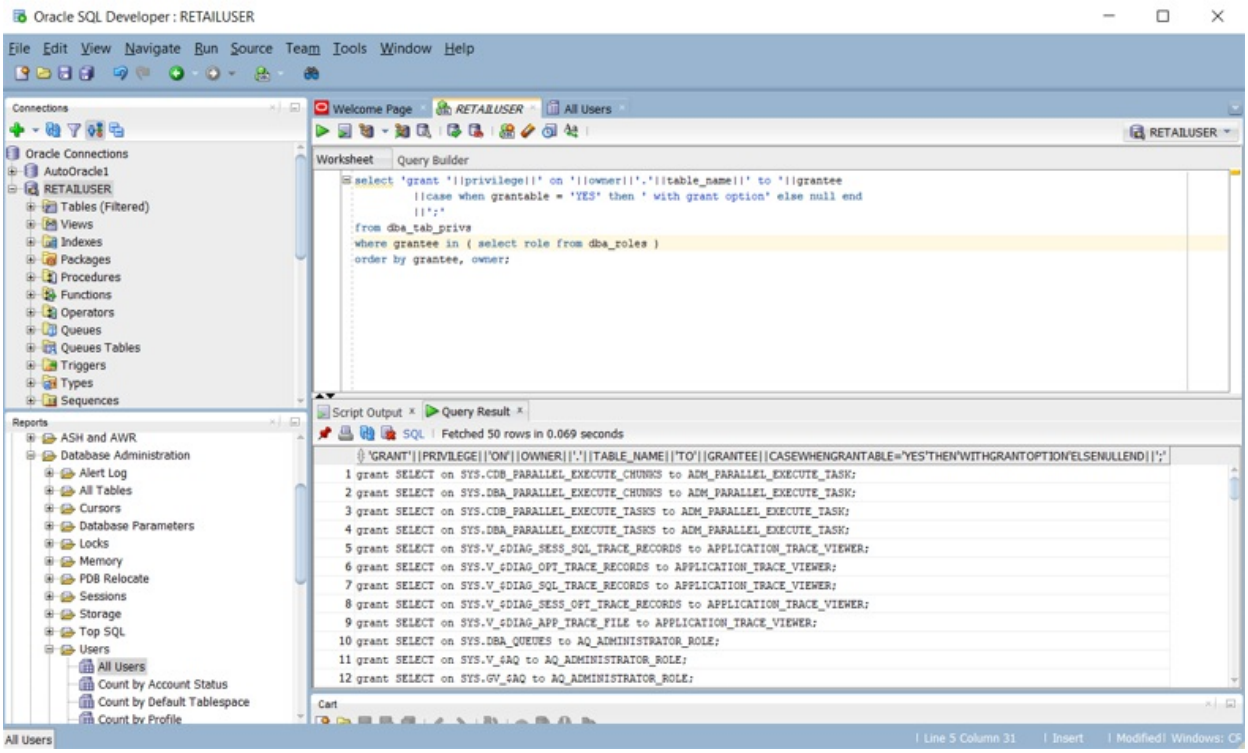
> **TIP**
> Migration of a data warehouse requires migrating more than just tables, views, and SQL statements.

Permissions

In an Oracle system, the system `DBA_ROLE_PRIVS` view holds the access rights for users and roles. If you have `SELECT` access, you can query that view to obtain the current access rights lists defined within the system. The following Oracle SQL Developer screenshot shows an example access rights list.



You can also create queries to produce a script that's a series of `CREATE` and `GRANT` statements for Azure Synapse, based on the existing Oracle privileges. The following Oracle SQL Developer screenshot shows an example of that script.



This table lists and describes the data dictionary views required to view user, role, and privileges information.

VIEW	DESCRIPTION
DBA_COL_PRIVS ALL_COL_PRIVS USER_COL_PRIVS	The DBA view describes all column object grants in the database. The ALL view describes all column object grants for which the current user or PUBLIC is the object owner, grantor, or grantee. The USER view describes column object grants for which the current user is the object owner, grantor, or grantee.

VIEW	DESCRIPTION
ALL_COL_PRIVS_MADE USER_COL_PRIVS_MADE	The ALL view lists column object grants for which the current user is the object owner or grantor. The USER view describes column object grants for which the current user is the grantor.
ALL_COL_PRIVS_RECD USER_COL_PRIVS_RECD	The ALL view describes column object grants for which the current user or PUBLIC is the grantee. The USER view describes column object grants for which the current user is the grantee.
DBA_TAB_PRIVS ALL_TAB_PRIVS USER_TAB_PRIVS	The DBA view lists all grants on all objects in the database. The ALL view lists the grants on objects where the user or PUBLIC is the grantee. The USER view lists grants on all objects where the current user is the grantee.
ALL_TAB_PRIVS_MADE USER_TAB_PRIVS_MADE	The ALL view lists object grants made by the current user or made on the objects owned by the current user. The USER view lists grants on all objects owned by the current user.
ALL_TAB_PRIVS_RECD USER_TAB_PRIVS_RECD	The ALL view lists object grants for which the user or PUBLIC is the grantee. The USER view lists object grants for which the current user is the grantee.
DBA_ROLES	This view lists all roles that exist in the database.
DBA_ROLE_PRIVS USER_ROLE_PRIVS	The DBA view lists roles granted to users and roles. The USER view lists roles granted to the current user.
DBA_SYS_PRIVS USER_SYS_PRIVS	The DBA view lists system privileges granted to users and roles. The USER view lists system privileges granted to the current user.
ROLE_ROLE_PRIVS	This view describes roles granted to other roles. Information is provided only about roles to which the user has access.
ROLE_SYS_PRIVS	This view contains information about system privileges granted to roles. Information is provided only about roles to which the user has access.
ROLE_TAB_PRIVS	This view contains information about object privileges granted to roles. Information is provided only about roles to which the user has access.
SESSION_PRIVS	This view lists the privileges that are currently enabled for the user.
SESSION_ROLES	This view lists the roles that are currently enabled for the user.

Oracle supports various types of privileges:

- **System privileges**: system privileges allow the grantee to perform standard administrator tasks in the database. Typically, these privileges are restricted to trusted users. Many system privileges are specific to Oracle operations.
- **Object privileges**: each type of object has privileges associated with it.

- **Table privileges**: table privileges enable security at the data manipulation language (DML) or data definition language (DDL) level. You can map table privileges directly to their equivalent in Azure Synapse.
- **View privileges**: you can apply DML object privileges to views, similar to tables. You can map view privileges directly to their equivalent in Azure Synapse.
- **Procedure privileges**: procedures privileges allow procedures, including standalone procedures and functions, to be granted the `EXECUTE` privilege. You can map procedure privileges directly to their equivalent in Azure Synapse.
- **Type privileges**: you can grant system privileges to named types, such as object types, `VARRAYs`, and nested tables. Typically, these privileges are specific to Oracle and have no equivalent in Azure Synapse.

> **TIP**
> Azure Synapse has equivalent permissions for basic database operations such as DML and DDL.

The following table lists common Oracle admin privileges that have a direct equivalent in Azure Synapse.

ADMIN PRIVILEGE	DESCRIPTION	SYNAPSE EQUIVALENT
[Create] Database	The user can create databases. Permission to operate on existing databases is controlled by object privileges.	CREATE DATABASE
[Create] External Table	The user can create external tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] Function	The user can create user-defined functions (UDFs). Permission to operate on existing UDFs is controlled by object privileges.	CREATE FUNCTION
[Create] Role	The user can create groups. Permission to operate on existing groups is controlled by object privileges.	CREATE ROLE
[Create] Index	For system use only. Users can't create indexes.	CREATE INDEX
[Create] Materialized View	The user can create materialized views.	CREATE VIEW
[Create] Procedure	The user can create stored procedures. Permission to operate on existing stored procedures is controlled by object privileges.	CREATE PROCEDURE
[Create] Schema	The user can create schemas. Permission to operate on existing schemas is controlled by object privileges.	CREATE SCHEMA

ADMIN PRIVILEGE	DESCRIPTION	SYNAPSE EQUIVALENT
[Create] Table	The user can create tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] Temporary Table	The user can create temporary tables. Permission to operate on existing tables is controlled by object privileges.	CREATE TABLE
[Create] User	The user can create users. Permission to operate on existing users is controlled by object privileges.	CREATE USER
[Create] View	The user can create views. Permission to operate on existing views is controlled by object privileges.	CREATE VIEW

You can automate the migration of these privileges by generating equivalent scripts for Azure Synapse from the Oracle catalog tables, as described earlier in this section.

The next table lists common Oracle object privileges that have a direct equivalent in Azure Synapse.

OBJECT PRIVILEGE	DESCRIPTION	SYNAPSE EQUIVALENT
Alter	The user can modify object attributes. Applies to all objects.	ALTER
Delete	The user can delete table rows. Applies only to tables.	DELETE
Drop	The user can drop objects. Applies to all object types.	DROP
Execute	The user can run user-defined functions, user-defined aggregates, or stored procedures.	EXECUTE
Insert	The user can insert rows into a table. Applies only to tables.	INSERT
List	The user can display an object name, either in a list or in another manner. Applies to all objects.	LIST
Select	The user can select (or query) rows within a table. Applies to tables and views.	SELECT
Truncate	The user can delete all rows from a table. Applies only to tables.	TRUNCATE
Update	The user can modify table rows. Applies to tables only.	UPDATE

For more information about Azure Synapse permissions, see Database engine permissions.

Migrating users, roles, and privileges

So far, we've described a common approach for migrating users, roles, and privileges to Azure Synapse using `CREATE USER`, `CREATE ROLE`, and `GRANT` SQL commands. However, you don't need to migrate all Oracle operations with grantable privileges to the new environment. For example, system management operations aren't applicable to the new environment or the equivalent functionality is automatic or managed outside the database. For users, roles, and the subset of privileges that do have a direct equivalent in the Azure Synapse environment, the following steps describe the migration process:

1. Migrate Oracle schema, table, and view definitions to the Azure Synapse environment. This step migrates only the table definitions not the data.
2. Extract the existing user IDs that you want to migrate from the Oracle system tables, generate a script of `CREATE USER` statements for Azure Synapse, and then run that script in the Azure Synapse environment. Find a way to create new initial passwords, because passwords can't be extracted from the Oracle environment.
3. Extract the existing roles from the Oracle system tables, generate a script of equivalent `CREATE ROLE` statements for Azure Synapse, and then run that script in the Azure Synapse environment.
4. Extract the user/role combinations from the Oracle system tables, generate a script to `GRANT` roles to users in Azure Synapse, and then run that script in the Azure Synapse environment.
5. Extract the relevant privilege information from the Oracle system tables, then generate a script to `GRANT` the appropriate privileges to users and roles in Azure Synapse, and then run that script in the Azure Synapse environment.

Operational considerations

This section discusses how typical Oracle operational tasks can be implemented in Azure Synapse with minimal risk and user impact.

As with all data warehouse products in production, ongoing management tasks are necessary to keep the system running efficiently and provide data for monitoring and auditing. Other operational considerations include resource utilization, capacity planning for future growth, and backup/restore of data.

> **TIP**
> Operational tasks are necessary to keep any data warehouse operating efficiently.

Oracle administration tasks typically fall into two categories:

- **System administration**: system administration is management of the hardware, configuration settings, system status, access, disk space, usage, upgrades, and other tasks.
- **Database administration**: database administration is management of user databases and their content, data loading, data backup, data recovery, and access to data and permissions.

Oracle offers several methods and interfaces that you can use to perform system and database management tasks:

- Oracle Enterprise Manager is Oracle's on-premises management platform. It provides a single pane of glass for managing all of a customer's Oracle deployments, whether in their data centers or in the Oracle Cloud. Through deep integration with Oracle's product stack, Oracle Enterprise Manager provides management and automation support for Oracle applications, databases, middleware, hardware, and engineered systems.
- Oracle Instance Manager provides a UI for high-level administration of Oracle instances. Oracle Instance Manager enables tasks such as startup, shutdown, and log viewing.

- Oracle Database Configuration Assistant is a UI that allows management and configuration of various database features and functionality.
- SQL commands that support administration tasks and queries within a SQL database session. You can run SQL commands from the Oracle SQL*Plus command interpreter, Oracle SQL Developer UI, or through SQL APIs such as ODBC, JDBC, and OLE DB Provider. You must have a database user account to run SQL commands, with appropriate permissions for the queries and tasks that you perform.

While the management and operations tasks for different data warehouses are similar in concept, the individual implementations can differ. Modern cloud-based products such as Azure Synapse tend to incorporate a more automated and "system managed" approach, compared to the more manual approach in legacy environments like Oracle.

The following sections compare Oracle and Azure Synapse options for various operational tasks.

Housekeeping tasks

In most legacy data warehouse environments, regular housekeeping tasks are time-consuming. You can reclaim disk storage space by removing old versions of updated or deleted rows. Or, you can reclaim disk storage space by reorganizing data, log files, and index blocks for efficiency, for example by running `ALTER TABLE... SHRINK SPACE` in Oracle.

> **TIP**
> Housekeeping tasks keep a production warehouse operating efficiently and optimize storage and other resources.

Collecting statistics is a potentially time-consuming task that's required after bulk data ingestion to provide the query optimizer with up-to-date data for its query execution plans.

Oracle has a built-in feature to help with analyzing the quality of statistics, the Optimizer Statistics Advisor. It works through a list of Oracle rules that represent best practices for optimizer statistics. The advisor checks each rule and, where necessary, generates findings, recommendations, and actions that involve calls to the `DBMS_STATS` package to take corrective measures. Users can see the list of rules in the `V$STATS_ADVISOR_RULES` view, as shown in the following screenshot.

```
SELECT *
FROM   v$stats_advisor_rules
ORDER BY rule_id;

   RULE_ID NAME                            RULE_TYPE DESCRIPTION                                                                  CON_ID
---------- ------------------------------- --------- ------------------------------------------------------------------------- ----------
         0                                 SYSTEM                                                                                       0
         1 UseAutoJob                      SYSTEM    Use Auto Job for Statistics Collection                                             0
         2 CompleteAutoJob                 SYSTEM    Auto Statistics Gather Job should complete successfully                            0
         3 MaintainStatsHistory            SYSTEM    Maintain Statistics History                                                        0
         4 UseConcurrent                   SYSTEM    Use Concurrent preference for Statistics Collection                                0
         5 UseDefaultPreference            SYSTEM    Use Default Preference for Stats Collection                                        0
         6 TurnOnSQLPlanDirective          SYSTEM    SQL Plan Directives should not be disabled                                         0
         7 AvoidSetProcedures              OPERATION Avoid Set Statistics Procedures                                                    0
         8 UseDefaultParams                OPERATION Use Default Parameters in Statistics Collection Procedures                          0
         9 UseGatherSchemaStats            OPERATION Use gather_schema_stats procedure                                                   0
        10 AvoidInefficientStatsOprSeq     OPERATION Avoid inefficient statistics operation sequences                                   0
        11 AvoidUnnecessaryStatsCollection OBJECT    Avoid unnecessary statistics collection                                            0
        12 AvoidStaleStats                 OBJECT    Avoid objects with stale or no statistics                                          0
        13 GatherStatsAfterBulkDML         OBJECT    Do not gather statistics right before bulk DML                                     0
        14 LockVolatileTable               OBJECT    Statistics for objects with volatile data should be locked                         0
        15 UnlockNonVolatileTable          OBJECT    Statistics for objects with non-volatile should not be locked                      0
        16 MaintainStatsConsistency        OBJECT    Statistics of dependent objects should be consistent                               0
        17 AvoidDropRecreate               OBJECT    Avoid drop and recreate object seqauences                                          0
        18 UseIncremental                  OBJECT    Statistics should be maintained incrementally when it is beneficial                0
        19 NotUseIncremental               OBJECT    Statistics should not be maintained incrementally when it is not beneficial        0
        20 AvoidOutOfRange                 OBJECT    Avoid Out of Range Histogram endpoints                                             0
        21 UseAutoDegree                   OBJECT    Use Auto Degree for statistics collection                                          0
        22 UseDefaultObjectPreference      OBJECT    Use Default Object Preference for statistics collection                            0
        23 AvoidAnalyzeTable               OBJECT    Avoid using analyze table commands for statistics collection                       0

```

An Oracle database contains many log tables in the data dictionary, which accumulate data, either automatically or after certain features are enabled. Because log data grows over time, purge older information to avoid using up permanent space. Oracle provides options to automate log maintenance.

Azure Synapse can automatically create statistics so that they're available when needed. You can defragment indexes and data blocks manually, on a scheduled basis, or automatically. By using native built-in Azure capabilities, you reduce the migration effort.

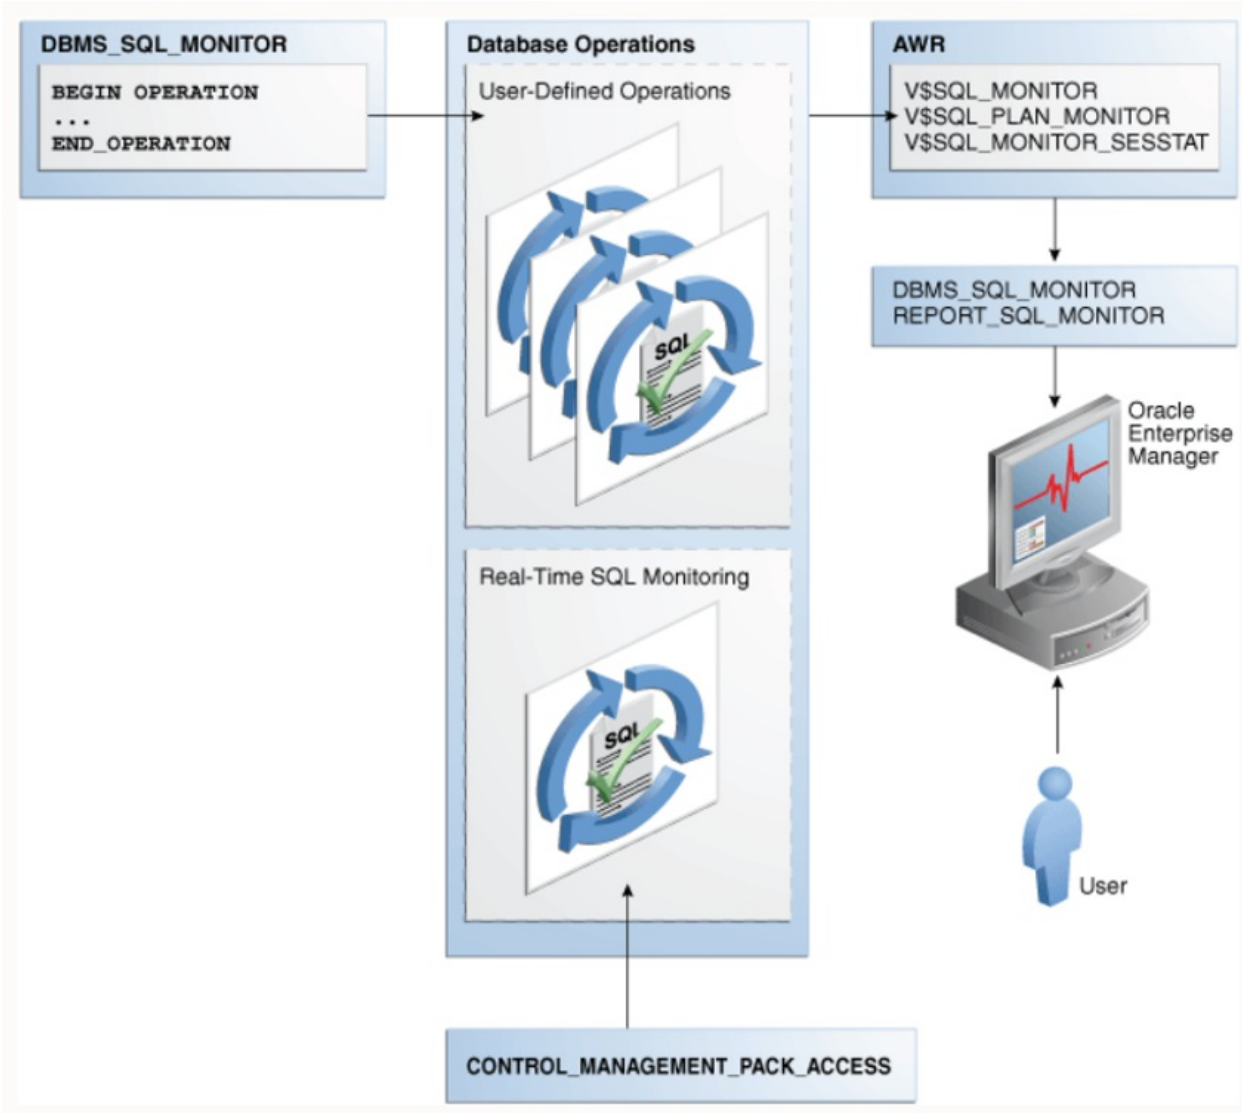
> **TIP**
> Automate and monitor housekeeping tasks in Azure.

Monitoring and auditing

Oracle Enterprise Manager includes tools to monitor various aspects of one or more Oracle systems, such as activity, performance, queuing, and resource utilization. Oracle Enterprise Manager has an interactive UI that lets users drill down into the low-level detail of any chart.

> **TIP**
> Oracle Enterprise Manager is the recommended method of monitoring and logging in Oracle systems.

The following diagram provides an overview of the monitoring environment in an Oracle data warehouse.

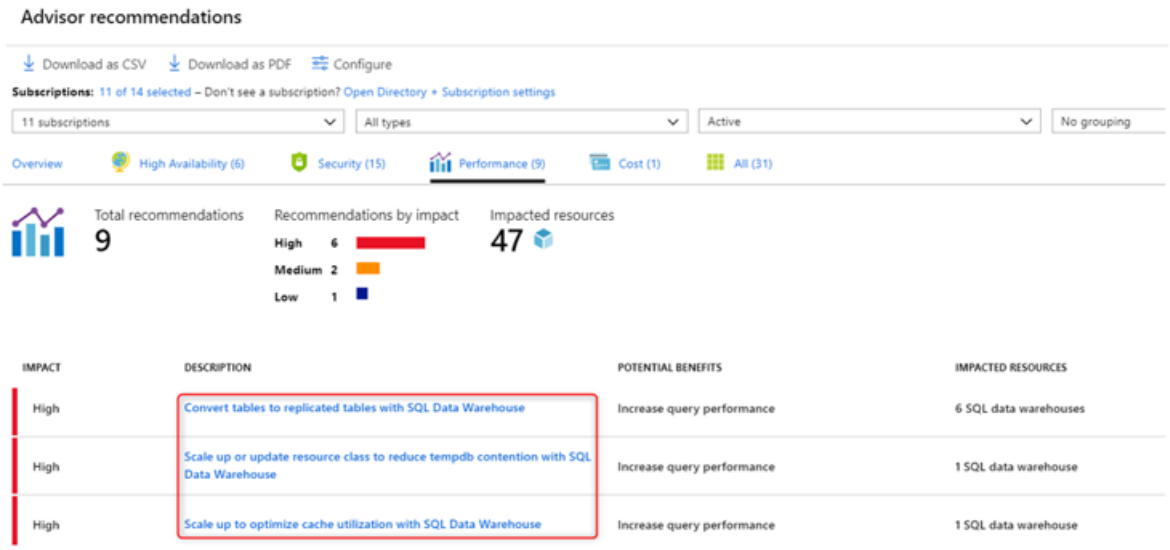


Azure Synapse also provides a rich monitoring experience within the Azure portal to provide insights into your

data warehouse workload. The Azure portal is the recommended tool for monitoring your data warehouse because it provides configurable retention periods, alerts, recommendations, and customizable charts and dashboards for metrics and logs.

> **TIP**
> The Azure portal provides a UI to manage monitoring and auditing tasks for all Azure data and processes.

The Azure portal can also provide recommendations for performance enhancements, as shown in the following screenshot.



The portal supports integration with other Azure monitoring services, such as Operations Management Suite (OMS) and Azure Monitor, to provide an integrated monitoring experience of the data warehouse and the entire Azure analytics platform. For more information, see Azure Synapse operations and management options.

High availability (HA) and disaster recovery (DR)

Since its initial release in 1979, the Oracle environment has evolved to encompass numerous features required by enterprise customers, including options for high availability (HA) and disaster recovery (DR). The latest announcement in this area is Maximum Availability Architecture (MAA), which includes reference architectures for four levels of HA and DR:

- **Bronze tier**: a single-instance HA architecture
- **Silver tier**: HA with automatic failover
- **Gold tier**: comprehensive HA and DR
- **Platinum tier**: zero outage for platinum-ready applications

Azure Synapse uses database snapshots to provide HA of the data warehouse. A data warehouse snapshot creates a restore point that you can use to restore a data warehouse to a previous state. Because Azure Synapse is a distributed system, a data warehouse snapshot consists of many files stored in Azure Storage. Snapshots capture incremental changes to the data stored in your data warehouse.

> **TIP**
> Azure Synapse creates snapshots automatically to ensure fast recovery time.

Azure Synapse automatically takes snapshots throughout the day and creates restore points that are available for seven days. You can't change this retention period. Azure Synapse supports an eight-hour recovery point objective (RPO). You can restore a data warehouse in the primary region from any one of the snapshots taken in

the past seven days.

> **TIP**
> User-defined snapshots can be used to define a recovery point before key updates.

Azure Synapse supports user-defined restore points, which are created from manually triggered snapshots. By creating restore points before and after large data warehouse modifications, you ensure that the restore points are logically consistent. The user-defined restore points augment data protection and reduce recovery time if there are workload interruptions or user errors.

In addition to snapshots, Azure Synapse performs a standard geo-backup once per day to a paired data center. The RPO for a geo-restore is 24 hours. You can restore the geo-backup to a server in any region where Azure Synapse is supported. A geo-backup ensures that a data warehouse can be restored if restore points in the primary region aren't available.

> **TIP**
> Microsoft Azure provides automatic backups to a separate geographical location to enable DR.

Workload management

Oracle provides utilities such as Enterprise Manager and Database Resource Manager (DBRM) for managing workloads. These utilities include features such as load balancing across large clusters, parallel query execution, performance measurement, and prioritization. Many of these features can be automated so that the system becomes to some extent self-tuning.

> **TIP**
> A typical production data warehouse concurrently runs mixed workloads with different resource usage characteristics.

Azure Synapse automatically logs resource utilization statistics. Metrics include usage statistics for CPU, memory, cache, I/O, and temporary workspace for each query. Azure Synapse also logs connectivity information, such as failed connection attempts.

> **TIP**
> Low-level and system-wide metrics are automatically logged within Azure.

In Azure Synapse, resource classes are pre-determined resource limits that govern compute resources and concurrency for query execution. Resource classes help you manage your workload by setting limits on the number of queries that run concurrently and on the compute resources assigned to each query. There's a trade-off between memory and concurrency.

Azure Synapse supports these basic workload management concepts:

- **Workload classification**: you can assign a request to a workload group to set importance levels.
- **Workload importance**: you can influence the order in which a request gets access to resources. By default, queries are released from the queue on a first-in, first-out basis as resources become available. Workload importance allows higher priority queries to receive resources immediately regardless of the queue.
- **Workload isolation**: you can reserve resources for a workload group, assign maximum and minimum

usage for varying resources, limit the resources a group of requests can consume can, and set a timeout value to automatically kill runaway queries.

Running mixed workloads can pose resource challenges on busy systems. A successful workload management scheme effectively manages resources, ensures highly efficient resource utilization, and maximizes return on investment (ROI). The workload classification, workload importance, and workload isolation gives more control over how workload utilizes system resources.

You can use the workload metrics that Azure Synapse collects for capacity planning, for example to determine the resources required for extra users or a larger application workload. You can also use workload metrics to plan scale up/down of compute resources for cost-effective support of peaky workloads.

The workload management guide describes the techniques to analyze the workload, manage and monitor workload importance](../../sql-data-warehouse/sql-data-warehouse-how-to-manage-and-monitor-workload-importance.md), and the steps to convert a resource class to a workload group. Use the Azure portal and T-SQL queries on DMVs to monitor the workload to ensure that the applicable resources are efficiently utilized. Azure Synapse provides a set of Dynamic Management Views (DMVs) for monitoring all aspects of workload management. These views are useful when actively troubleshooting and identifying performance bottlenecks in your workload.

For more information on workload management in Azure Synapse, see Workload management with resource classes.

Scale compute resources

The Azure Synapse architecture separates storage and compute, allowing each to scale independently. As a result, compute resources can be scaled to meet performance demands independent of data storage. You can also pause and resume compute resources. Another benefit of this architecture is that billing for compute and storage is separate. If a data warehouse isn't in use, you can save on compute costs by pausing compute.

> **TIP**
> A major benefit of Azure is the ability to independently scale up and down compute resources on demand to handle peaky workloads cost-effectively.

You can scale compute resources up or down by adjusting the data warehouse units (DWU) setting for a data warehouse. Load and query performance will increase linearly as you allocate more DWUs.

If you increase DWUs, the number of compute nodes increase, which adds more compute power and supports more parallel processing. As the number of compute nodes increase, the number of distributions per compute node decrease, providing more compute power and parallel processing for queries. Similarly, if you decrease DWUs, the number of compute nodes decrease, which reduces the compute resources for queries.

To learn more about visualization and reporting, see the next article in this series: Visualization and reporting for Oracle migrations.

Visualization and reporting for Oracle migrations

8/19/2022 • 20 minutes to read • Edit Online

This article is part four of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for visualization and reporting.

Access Azure Synapse Analytics using Microsoft and third-party BI tools

Organizations access data warehouses and data marts using a range of business intelligence (BI) tools and applications. Some examples of BI products are:

- Microsoft BI tools, such as Power BI.
- Office applications, such as Microsoft Excel spreadsheets.
- Third-party BI tools from different vendors.
- Custom analytics applications with embedded BI tool functionality.
- Operational applications that support on-demand BI by running queries and reports on a BI platform that in turn queries data in a data warehouse or data mart.
- Interactive data science development tools, such as Azure Synapse Spark Notebooks, Azure Machine Learning, RStudio, and Jupyter Notebooks.

If you migrate visualization and reporting as part of your data warehouse migration, all existing queries, reports, and dashboards generated by BI products need to run in the new environment. Your BI products must yield the same results on Azure Synapse as they did in your legacy data warehouse environment.

For consistent results after migration, all BI tools and application dependencies must work after you've migrated your data warehouse schema and data to Azure Synapse. The dependencies include less visible aspects, such as access and security. When you address access and security, ensure that you migrate:

- Authentication so users can sign into the data warehouse and data mart databases on Azure Synapse.
- All users to Azure Synapse.
- All user groups to Azure Synapse.
- All roles to Azure Synapse.
- All authorization privileges governing access control to Azure Synapse.
- User, role, and privilege assignments to mirror what you had in your existing data warehouse before migration. For example:
    - Database object privileges assigned to roles
    - Roles assigned to user groups
    - Users assigned to user groups and/or roles

Access and security are important considerations for data access in the migrated system and are discussed in more detail in Security, access, and operations for Oracle migrations.

TIP

Existing users, user groups, roles, and assignments of access security privileges need to be migrated first for migration of reports and visualizations to succeed.

Migrate all required data to ensure that the reports and dashboards that query data in the legacy environment produce the same results in Azure Synapse.

Business users will expect a seamless migration, with no surprises that destroy their confidence in the migrated system on Azure Synapse. Take care to allay any fears that your users might have through good communication. Your users will expect that:

- Table structure remains the same when directly referred to in queries.
- Table and column names remain the same when directly referred to in queries. For instance, calculated fields defined on columns in BI tools shouldn't fail when aggregate reports are produced.
- Historical analysis remains the same.
- Data types remain the same, if possible.
- Query behavior remains the same.
- ODBC/JDBC drivers are tested to ensure that query behavior remains the same.

TIP

Communication and business user involvement are critical to success.

If BI tools query views in the underlying data warehouse or data mart database, will those views still work after the migration? Some views might not work if there are proprietary SQL extensions specific to your legacy data warehouse DBMS that have no equivalent in Azure Synapse. If so, you need to know about those incompatibilities and find a way to resolve them.

TIP

Views and SQL queries using proprietary SQL query extensions are likely to result in incompatibilities that impact BI reports and dashboards.

Other issues, like the behavior of `NULL` values or data type variations across DBMS platforms, need to be tested to ensure that even slight differences don't exist in calculation results. Minimize those issues and take all necessary steps to shield business users from being affected by them. Depending on your legacy data warehouse environment, third-party tools that can help hide the differences between the legacy and new environments so that BI tools and applications run unchanged.

Testing is critical to visualization and report migration. You need a test suite and agreed-on test data to run and rerun tests in both environments. A test harness is also useful, and a few are mentioned in this guide. Also, it's important to involve business users in the testing aspect of the migration to keep confidence high and to keep them engaged and part of the project.

TIP

Use repeatable tests to ensure reports, dashboards, and other visualizations migrate successfully.

You might be thinking about switching BI tools, for example to migrate to Power BI. The temptation is to make such changes at the same time you're migrating your schema, data, ETL processing, and more. However, to minimize risk, it's better to migrate to Azure Synapse first and get everything working before undertaking further modernization.

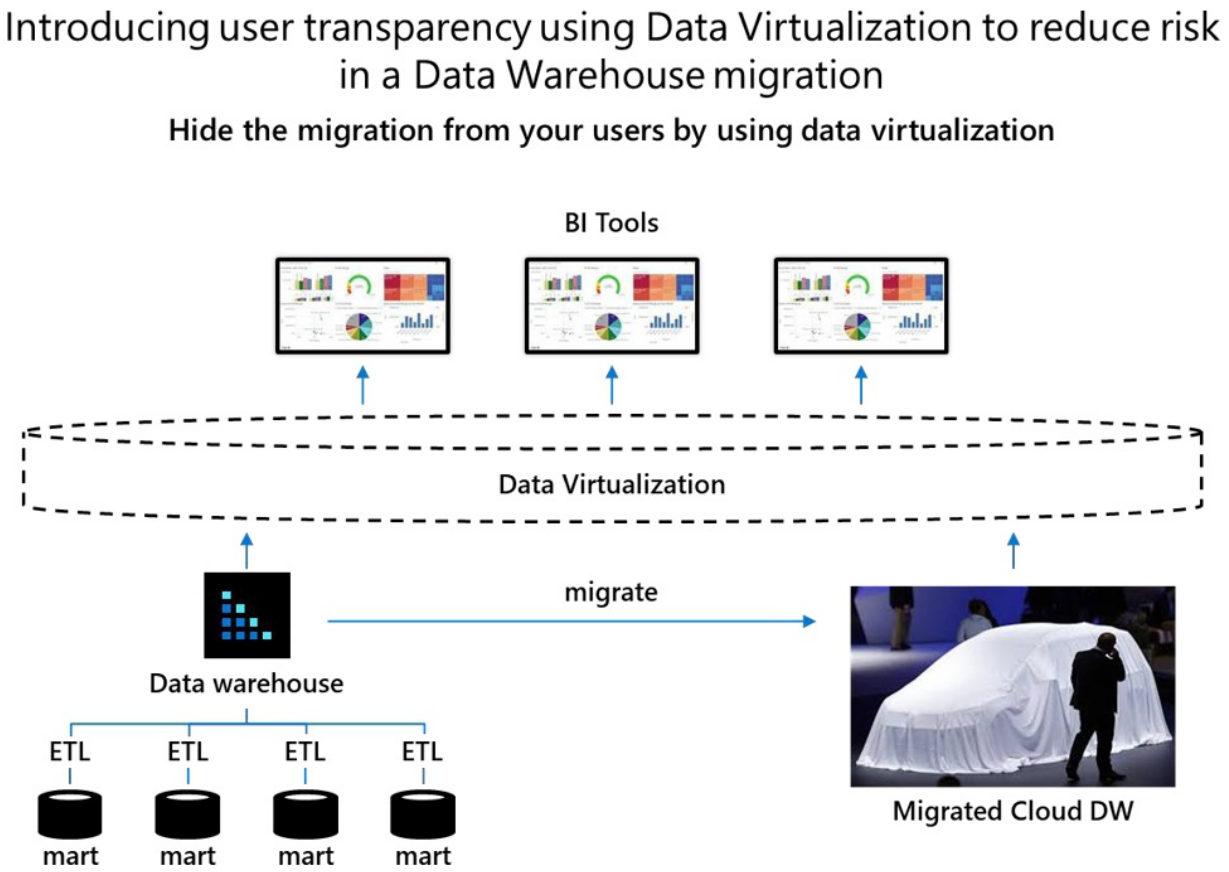
If your existing BI tools run on-premises, ensure they can connect to Azure Synapse through your firewall so you're able to run comparisons against both environments. Alternatively, if the vendor of your existing BI tools offers their product on Azure, you can try it there. The same applies for applications running on-premises that embed BI or call your BI server on demand, for example by requesting a "headless report" with XML or JSON data.

There's a lot to think about here, so let's take a closer look.

Use data virtualization to minimize the impact of migration on BI tools and reports

During migration, you might be tempted to fulfill long-term requirements like opening business requests, adding missing data, or implementing new features. However, such changes can affect BI tool access to your data warehouse, especially if the change involves structural changes to your data model. If you want to adopt an agile data modeling technique or implement structural changes, do so *after* migration.

One way to minimize the effect of schema changes or other structural changes on your BI tools is to introduce data virtualization between the BI tools and your data warehouse and data marts. The following diagram shows how data virtualization can hide a migration from users.



Data virtualization breaks the dependency between business users utilizing self-service BI tools and the physical schema of the underlying data warehouse and data marts that are being migrated.

> **TIP**
> Data virtualization allows you to shield business users from structural changes during migration so they remain unaware of those changes. Structural changes include schema alterations that tune your data model for Azure Synapse.

With data virtualization, any schema alterations made during a migration to Azure Synapse, for example to optimize performance, can be hidden from business users because they only have access to virtual tables in the data virtualization layer. And, if you make structural changes, you only need to update the mappings between the data warehouse or data marts and any virtual tables. With data virtualization, users remain unaware of structural changes. Microsoft partners provide data virtualization software.

Identify high-priority reports to migrate first

A key question when migrating your existing reports and dashboards to Azure Synapse is which ones to migrate first. Several factors might drive that decision, such as:

- Usage
- Business value
- Ease of migration
- Data migration strategy

The following sections discuss these factors.

Whatever your decision, it must involve your business users because they produce the reports, dashboards, and other visualizations, and make business decisions based on insights from those items. Everyone benefits when you can:

- Migrate reports and dashboards seamlessly,
- Migrate reports and dashboards with minimal effort, and
- Point your BI tool(s) at Azure Synapse instead of your legacy data warehouse system, and get like-for-like reports, dashboards, and other visualizations.

Migrate reports based on usage

Usage is often an indicator of business value. Unused reports and dashboards clearly don't contribute to business decisions or offer current value. If you don't have a way to find out which reports and dashboards are unused, you can use one of the several BI tools that provide usage statistics.

If your legacy data warehouse has been up and running for years, there's a good chance you have hundreds, if not thousands, of reports in existence. It's worth compiling an inventory of reports and dashboards and identifying their business purpose and usage statistics.

For unused reports, determine whether to decommission them to reduce your migration effort. A key question when deciding whether to decommission an unused report is whether the report is unused because people don't know it exists, because it offers no business value, or because it's been superseded by another report.

Migrate reports based on business value

Usage alone isn't always a good indicator of business value. You might want to consider the extent to which a report's insights contribute to business value. One way to do that is to evaluate the profitability of every business decision that relies on the report and the extent of the reliance. However, that information is unlikely to be readily available in most organizations.

Another way to evaluate business value is to look at the alignment of a report with business strategy. The business strategy set by your executive typically lays out strategic business objectives (SBOs), key performance

indicators (KPIs), KPI targets that need to be achieved, and who is accountable for achieving them. You can classify a report by which SBOs the report contributes to, such as fraud reduction, improved customer engagement, and optimized business operations. Then, you can prioritize for migration the reports and dashboards that are associated with high-priority objectives. In this way, the initial migration can deliver business value in a strategic area.

Another way to evaluate business value is to classify reports and dashboards as operational, tactical, or strategic to identify at which business level they're used. SBOs require contributions at all these levels. By knowing which reports and dashboards are used, at what level, and what objectives they're associated with, you're able to focus the initial migration on high-priority business value. You can use the following *business strategy objective* table to evaluate reports and dashboards.

LEVEL	REPORT / DASHBOARD NAME	BUSINESS PURPOSE	DEPARTMENT USED	USAGE FREQUENCY	BUSINESS PRIORITY
Strategic					
Tactical					
Operational					

Metadata discovery tools like Azure Data Catalog let business users tag and rate data sources to enrich the metadata for those data sources to assist with their discovery and classification. You can use the metadata for a report or dashboard to help you understand its business value. Without such tools, understanding the contribution of reports and dashboards to business value is likely to be a time-consuming task, whether you're migrating or not.

Migrate reports based on data migration strategy

If your migration strategy is based on migrating data marts first, then the order of data mart migration will affect which reports and dashboards are migrated first. If your strategy is based on business value, the order in which you migrate data marts to Azure Synapse will reflect business priorities. Metadata discovery tools can help you implement your strategy by showing you which data mart tables supply data for which reports.

> **TIP**
> Your data migration strategy affects which reports and visualizations get migrated first.

Migration incompatibility issues that can affect reports and visualizations

BI tools produce reports, dashboards, and other visualizations by issuing SQL queries that access physical tables and/or views in your data warehouse or data mart. When you migrate your legacy data warehouse to Azure Synapse, several factors can affect the ease of migration of reports, dashboards, and other visualizations. Those factors include:

- Schema incompatibilities between the environments.
- SQL incompatibilities between the environments.

Schema incompatibilities

During a migration, schema incompatibilities in the data warehouse or data mart tables that supply data for reports, dashboards, and other visualizations can be:

- Non-standard table types in your legacy data warehouse DBMS that don't have an equivalent in Azure

Synapse.

- Data types in your legacy data warehouse DBMS that don't have an equivalent in Azure Synapse.

In most cases, there's a workaround to the incompatibilities. For example, you can migrate the data in an unsupported table type into a standard table with appropriate data types and indexed or partitioned on a date/time column. Similarly, it might be possible to represent unsupported data types in another type of column and perform calculations in Azure Synapse to achieve the same results.

> **TIP**
> Schema incompatibilities include legacy warehouse DBMS table types and data types that are unsupported on Azure Synapse.

To identify the reports affected by schema incompatibilities, run queries against the system catalog of your legacy data warehouse to identify the tables with unsupported data types. Then, you can use metadata from your BI tool to identify the reports that access data in those tables. For more information about how to identify object type incompatibilities, see Unsupported Oracle database object types.

> **TIP**
> Query the system catalog of your legacy warehouse DBMS to identify schema incompatibilities with Azure Synapse.

The effect of schema incompatibilities on reports, dashboards, and other visualizations might be less than you think because many BI tools don't support the less generic data types. As a result, your legacy data warehouse might already have views that `CAST` unsupported data types to more generic types.

SQL incompatibilities

During a migration, SQL incompatibilities are likely to affect any report, dashboard, or other visualization in an application or tool that:

- Accesses legacy data warehouse DBMS views that include proprietary SQL functions that have no equivalent in Azure Synapse.
- Issues SQL queries that include proprietary SQL functions, specific to the SQL dialect of your legacy environment, that have no equivalent in Azure Synapse.

Gauge the impact of SQL incompatibilities on your reporting portfolio

Your reporting portfolio might include embedded query services, reports, dashboards, and other visualizations. Don't rely on the documentation associated with those items to gauge the effect of SQL incompatibilities on the migration of your reporting portfolio to Azure Synapse. You need to use a more precise way to assess the effect of SQL incompatibilities.

Use EXPLAIN statements to find SQL incompatibilities

You can find SQL incompatibilities by reviewing the logs of recent SQL activity in your legacy Oracle data warehouse. Use a script to extract a representative set of SQL statements to a file. Then, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse. Any SQL statements containing proprietary unsupported SQL extensions will be rejected by Azure Synapse when the `EXPLAIN` statements are executed. This approach lets you assess the extent of SQL incompatibilities.

Metadata from your legacy data warehouse DBMS can also help you identify incompatible views. As before, capture a representative set of SQL statements from the applicable logs, prefix each SQL statement with an `EXPLAIN` statement, and run those `EXPLAIN` statements in Azure Synapse to identify views with incompatible SQL.

> **TIP**
> Gauge the impact of SQL incompatibilities by harvesting your DBMS log files and running `EXPLAIN` statements.

Test report and dashboard migration to Azure Synapse Analytics

A key element of data warehouse migration is testing of reports and dashboards in Azure Synapse to verify the migration has worked. Define a series of tests and a set of required outcomes for each test that you will run to verify success. Test and compare the reports and dashboards across your existing and migrated data warehouse systems to:

- Identify whether any schema changes that were made during migration affected the ability of reports to run, report results, or the corresponding report visualizations. An example of a schema change is if you mapped an incompatible data type to an equivalent data type that's supported in Azure Synapse.
- Verify that all users are migrated.
- Verify that all roles are migrated, and users are assigned to those roles.
- Verify that all data access security privileges are migrated to ensure access control list (ACL) migration.
- Ensure consistent results for all known queries, reports, and dashboards.
- Ensure that data and ETL migration is complete and error-free.
- Ensure that data privacy is upheld.
- Test performance and scalability.
- Test analytical functionality.

> **TIP**
> Test and tune performance to minimize compute costs.

For information about how to migrate users, user groups, roles, and privileges, see Security, access, and operations for Oracle migrations.

Automate testing as much as possible to make each test repeatable and to support a consistent approach to evaluating test results. Automation works well for known regular reports, and can be managed via Azure Synapse pipelines or Azure Data Factory orchestration. If you already have a suite of test queries in place for regression testing, you can use the existing testing tools to automate post migration testing.

> **TIP**
> Best practice is to build an automated test suite to make tests repeatable.

Ad-hoc analysis and reporting are more challenging and require compilation of a set of tests to verify that the same reports and dashboards from before and after migration are consistent. If you find inconsistencies, then your ability to compare metadata lineage across the original and migrated systems during migration testing becomes crucial. That comparison can highlight differences and pinpoint where inconsistencies originated, when detection by other means is difficult.

> **TIP**
> Leverage tools that compare metadata lineage to verify results.

Analyze lineage to understand dependencies between reports, dashboards, and data

Your understanding of lineage is a critical factor in the successful migration of reports and dashboards. Lineage is metadata that shows the journey of migrated data so you can track its path from a report or dashboard all the way back to the data source. Lineage shows how data has traveled from point to point, its location in the data warehouse and/or data mart, and which reports and dashboards use it. Lineage can help you understand what happens to data as it travels through different data stores, such as files and databases, different ETL pipelines, and into reports. When business users have access to data lineage, it improves trust, instills confidence, and supports informed business decisions.

> **TIP**
> Your ability to access metadata and data lineage from reports all the way back to a data source is critical for verifying that migrated reports work correctly.

In multi-vendor data warehouse environments, business analysts in BI teams might map out data lineage. For example, if you use different vendors for ETL, data warehouse, and reporting, and each vendor has its own metadata repository, then figuring out where a specific data element in a report came from can be challenging and time-consuming.

> **TIP**
> Tools that automate the collection of metadata and show end-to-end lineage in a multi-vendor environment are valuable during a migration.

To migrate seamlessly from a legacy data warehouse to Azure Synapse, use end-to-end data lineage to prove like-for-like migration when you're comparing the reports and dashboards generated by each environment. To show the end-to-end data journey, you'll need to capture and integrate metadata from several tools. Having access to tools that support automated metadata discovery and data lineage, helps you identify duplicate reports or ETL processes, and find reports that rely on obsolete, questionable, or non-existent data sources. You can use that information to reduce the number of reports and ETL processes that you migrate.

You can also compare the end-to-end lineage of a report in Azure Synapse to the end-to-end lineage of the same report in your legacy environment to check for differences that might have inadvertently occurred during migration. This type of comparison is exceptionally useful when you need to test and verify migration success.

Data lineage visualization not only reduces time, effort, and error in the migration process, but also enables faster migration.

By using automated metadata discovery and data lineage tools that compare lineage, you can verify that a report in Azure Synapse that's produced from migrated data is produced in the same way in your legacy environment. This capability also helps you determine:

- What data needs to be migrated to ensure successful report and dashboard execution in Azure Synapse.
- What transformations have been and should be performed to ensure successful execution in Azure Synapse.

- How to reduce report duplication.

Automated metadata discovery and data lineage tools substantially simplify the migration process because they help businesses become more aware of their data assets and to know what needs to be migrated to Azure Synapse to achieve a solid reporting environment.

Several ETL tools provide end-to-end lineage capability, so check whether your existing ETL tool has that capability if you plan to use it with Azure Synapse. Azure Synapse pipelines or Data Factory both support the ability to view lineage in mapping flows. Microsoft partners also provide automated metadata discovery, data lineage, and lineage comparison tools.

Migrate BI tool semantic layers to Azure Synapse Analytics

Some BI tools have what is known as a semantic metadata layer. That layer simplifies business user access to the underlying physical data structures in a data warehouse or data mart database. The semantic metadata layer simplifies access by providing high-level objects like dimensions, measures, hierarchies, calculated metrics, and joins. The high-level objects use business terms that are familiar to business analysts, and map to physical data structures in your data warehouse or data mart.

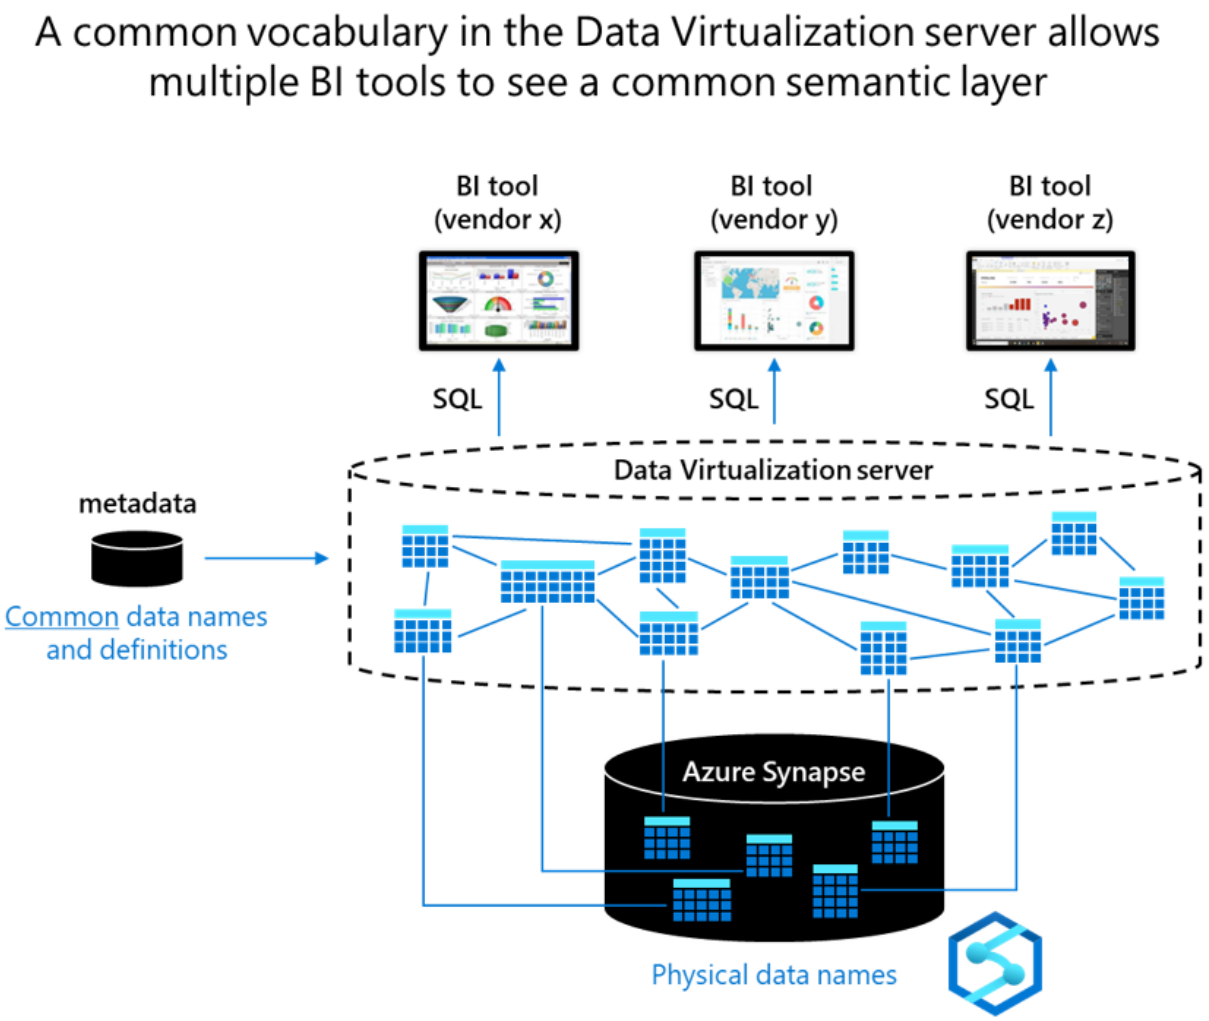
> **TIP**
> Some BI tools have semantic layers that simplify business user access to physical data structures in your data warehouse or data mart.

In a data warehouse migration, you might be forced to change column or table names. For example, Oracle allows a `#` character in table names, but Azure Synapse only allows `#` as a table name prefix to indicate a temporary table. In Oracle, TEMPORARY TABLES do not necessarily have a "#" in the name, but in Synapse they must. You may need to do some rework to change table mappings in such cases.

To achieve consistency across multiple BI tools, create a universal semantic layer by using a data virtualization server that sits between BI tools and applications and Azure Synapse. In the data virtualization server, use common data names for high-level objects like dimensions, measures, hierarchies, and joins. That way you configure everything, including calculated fields, joins, and mappings, only once instead of in every tool. Then, point all BI tools at the data virtualization server.

> **TIP**
> Use data virtualization to create a common semantic layer to guarantee consistency across all BI tools in an Azure Synapse environment.

With data virtualization, you get consistency across all BI tools and break the dependency between BI tools and applications and the underlying physical data structures in Azure Synapse. Microsoft partners can help you achieve consistency in Azure. The following diagram shows how a common vocabulary in the data virtualization server lets multiple BI tools see a common semantic layer.



Conclusions

In a lift and shift data warehouse migration, most reports, dashboards, and other visualizations should migrate easily.

During a migration from a legacy environment, you might find that data in the legacy data warehouse or data mart tables is stored in unsupported data types. Or, you may find legacy data warehouse views that include proprietary SQL with no equivalent in Azure Synapse. If so, you'll need to resolve those issues to ensure a successful migration to Azure Synapse.

Don't rely on user-maintained documentation to identify where issues are located. Instead, use `EXPLAIN` statements because they're a quick, pragmatic way to identify SQL incompatibilities. Rework the incompatible SQL statements to achieve equivalent functionality in Azure Synapse. Also, use automated metadata discovery and lineage tools to understand dependencies, find duplicate reports, and identify invalid reports that rely on obsolete, questionable, or non-existent data sources. Use lineage tools to compare lineage to verify that reports running in your legacy data warehouse environment are produced identically in Azure Synapse.

Don't migrate reports that you no longer use. BI tool usage data can help you determine which reports aren't in use. For the reports, dashboards, and other visualizations that you do want to migrate, migrate all users, user groups, roles, and privileges. If you're using business value to drive your report migration strategy, associate reports with strategic business objectives and priorities to help identify the contribution of report insights to specific objectives. If you're migrating data mart by data mart, use metadata to identify which reports are dependent on which tables and views, so you can make an informed decision about which data marts to migrate first.

> **TIP**
> Identify incompatibilities early to gauge the extent of the migration effort. Migrate your users, group roles, and privilege assignments. Only migrate the reports and visualizations that are used and are contributing to business value.

Structural changes to the data model of your data warehouse or data mart can occur during a migration. Consider using data virtualization to shield BI tools and applications from structural changes. With data virtualization, you can use a common vocabulary to define a common semantic layer. The common semantic layer guarantees consistent common data names, definitions, metrics, hierarchies, and joins across all BI tools and applications in the new Azure Synapse environment.

Minimize SQL issues for Oracle migrations

8/19/2022 • 15 minutes to read • Edit Online

This article is part five of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for minimizing SQL issues.

Overview

Characteristics of Oracle environments

Oracle's initial database product, released in 1979, was a commercial SQL relational database for on-line transaction processing (OLTP) applications—with much lower transaction rates than today. Since that initial release, the Oracle environment has evolved to become far more complex and encompasses numerous features. The features include client-server architectures, distributed databases, parallel processing, data analytics, high availability, data warehousing, data in-memory techniques, and support for cloud-based instances.

> **TIP**
> Oracle pioneered the "data warehouse appliance" concept in the early 2000's.

Due to the cost and complexity of maintaining and upgrading legacy on-premises Oracle environments, many existing Oracle users want to take advantage of the innovations provided by cloud environments. Modern cloud environments, such as cloud, IaaS, and PaaS, let you delegate tasks like infrastructure maintenance and platform development to the cloud provider.

Many data warehouses that support complex analytic SQL queries on large data volumes use Oracle technologies. These data warehouses commonly have a dimensional data model, such as star or snowflake schemas, and use data marts for individual departments.

> **TIP**
> Many existing Oracle installations are data warehouses that use a dimensional data model.

The combination of SQL and dimensional data models in Oracle simplifies migration to Azure Synapse because the SQL and basic data model concepts are transferable. Microsoft recommends moving your existing data model as-is to Azure to reduce risk, effort, and migration time. Although your migration plan might include a change in the underlying data model, such as a move from an Inmon model to a data vault, it makes sense to initially perform an as-is migration. After the initial migration, you can then make changes within the Azure cloud environment to take advantage of its performance, elastic scalability, built-in features, and cost benefits.

Although the SQL language is standardized, individual vendors sometimes implement proprietary extensions. As a result, you might find SQL differences during your migration that require workarounds in Azure Synapse.

Use Azure facilities to implement a metadata-driven migration

You can automate and orchestrate the migration process by using the capabilities of the Azure environment. This approach minimizes the performance hit on the existing Oracle environment, which may already be running close to capacity.

Azure Data Factory is a cloud-based data integration service that supports creating data-driven workflows in the cloud to orchestrate and automate data movement and data transformation. You can use Data Factory to create and schedule data-driven workflows (pipelines) that ingest data from disparate data stores. Data Factory can

process and transform data by using compute services such as Azure HDInsight Hadoop, Spark, Azure Data Lake Analytics, and Azure Machine Learning.

Azure also includes Azure Database Migration Services to help you plan and perform a migration from environments such as Oracle. SQL Server Migration Assistant (SSMA) for Oracle can automate migration of Oracle databases, including in some cases functions and procedural code.

> **TIP**
> Automate the migration process by using Azure Data Factory capabilities.

When you're planning to use Azure facilities, such as Data Factory, to manage the migration process, first create metadata that lists all the data tables that need to be migrated and their location.

SQL DDL differences between Oracle and Azure Synapse

The ANSI SQL standard defines the basic syntax for Data Definition Language (DDL) commands. Some DDL commands, like `CREATE TABLE` and `CREATE VIEW`, are common to both Oracle and Azure Synapse, but have been extended to provide implementation-specific features such as indexing, table distribution, and partitioning options.

> **TIP**
> SQL DDL commands `CREATE TABLE` and `CREATE VIEW` have standard core elements but are also used to define implementation-specific options.

The following sections discuss the Oracle-specific options that need to be considered during a migration to Azure Synapse.

Table/view considerations

When you migrate tables between different environments, typically only the raw data and the metadata that describes it physically migrate. Other database elements from the source system, such as indexes and log files, usually aren't migrated because they might be unnecessary or implemented differently in the new environment. For example, the `TEMPORARY` option within Oracle's `CREATE TABLE` syntax is equivalent to prefixing a table name with the `#` character in Azure Synapse.

Performance optimizations in the source environment, such as indexes, indicate where you might add performance optimization in the new target environment. For example, if bit-mapped indexes are frequently used in queries within the source Oracle environment, that suggests that a non-clustered index should be created within Azure Synapse. Other native performance optimization techniques such as table replication may be more applicable than straight like-for-like index creation. SSMA for Oracle can provide migration recommendations for table distribution and indexing.

> **TIP**
> Existing indexes indicate candidates for indexing in the migrated warehouse.

SQL view definitions contain SQL Data Manipulation Language (DML) statements that define the view, typically with one or more `SELECT` statements. When you migrate `CREATE VIEW` statements, take into account the DML differences between Oracle and Azure Synapse.

Unsupported Oracle database object types

Oracle-specific features can often be replaced by Azure Synapse features. However, some Oracle database

objects aren't directly supported in Azure Synapse. The following list of unsupported Oracle database objects describes how you can achieve equivalent functionality in Azure Synapse:

- **Indexing options**: in Oracle, several indexing options, such as bit-mapped indexes, function-based indexes, and domain indexes, have no direct equivalent in Azure Synapse. Although Azure Synapse doesn't support those index types, you can achieve a similar reduction in disk I/O by using user-defined index types and/or partitioning Reducing disk I/O improves query performance.

  You can find out which columns are indexed and their index type by querying system catalog tables and views, such as `ALL_INDEXES`, `DBA_INDEXES`, `USER_INDEXES`, and `DBA_IND_COL`. Or, you can query the `dba_index_usage` or `v$object_usage` views when monitoring is enabled.

  Azure Synapse features, such as parallel query processing and in-memory caching of data and results, make it likely that fewer indexes are required for data warehouse applications to achieve excellent performance goals.

- **Clustered tables**: Oracle tables can be organized so that table rows that are frequently accessed together (based on a common value) are physically stored together. This strategy reduces disk I/O when data is retrieved. Oracle also has a hash-cluster option for individual tables, which applies a hash value to the cluster key and physically stores rows with the same hash value together.

  In Azure Synapse, you can achieve a similar result by partitioning and/or using other indexes.

- **Materialized views**: Oracle supports materialized views and recommends one or more of them for large tables with many columns where only a few columns are regularly used in queries. Materialized views are automatically refreshed by the system when data in the base table is updated.

  In 2019, Microsoft announced that Azure Synapse will support materialized views with the same functionality as in Oracle. Materialized views are now a preview feature in Azure Synapse.

- **In-database triggers**: in Oracle, a trigger can be configured to automatically run when a triggering event occurs. Triggering events can be:

  - A DML statement, such as `INSERT`, `UPDATE`, or `DELETE`, runs. If you defined a trigger that fires before an `INSERT` statement on a customer table, the trigger will fire once before a new row is inserted into the customer table.
  - A DDL statement, such as `CREATE` or `ALTER`, runs. This triggering event is often used to record schema changes for auditing purposes.
  - A system event such as startup or shutdown of the Oracle database.
  - A user event such as login or logout.

  Azure Synapse doesn't support Oracle database triggers. However, you can achieve equivalent functionality by using Data Factory, although doing so will require you to refactor the processes that use triggers.

- **Synonyms**: Oracle supports defining synonyms as alternative names for several database object types. Those types include tables, views, sequences, procedures, stored functions, packages, materialized views, Java class schema objects, user-defined objects, or other synonyms.

  Azure Synapse doesn't currently support defining synonyms, although if a synonym in Oracle refers to a table or view, then you can define a view in Azure Synapse to match the alternative name. If a synonym in Oracle refers to a function or stored procedure, then you can replace the synonym in Azure Synapse with another function or stored procedure that calls the target.

- **User-defined types**: Oracle supports user-defined objects that can contain a series of individual fields, each with their own definition and default values. Those objects can then be referenced within a table

definition in the same way as built-in data types like `NUMBER` or `VARCHAR`.

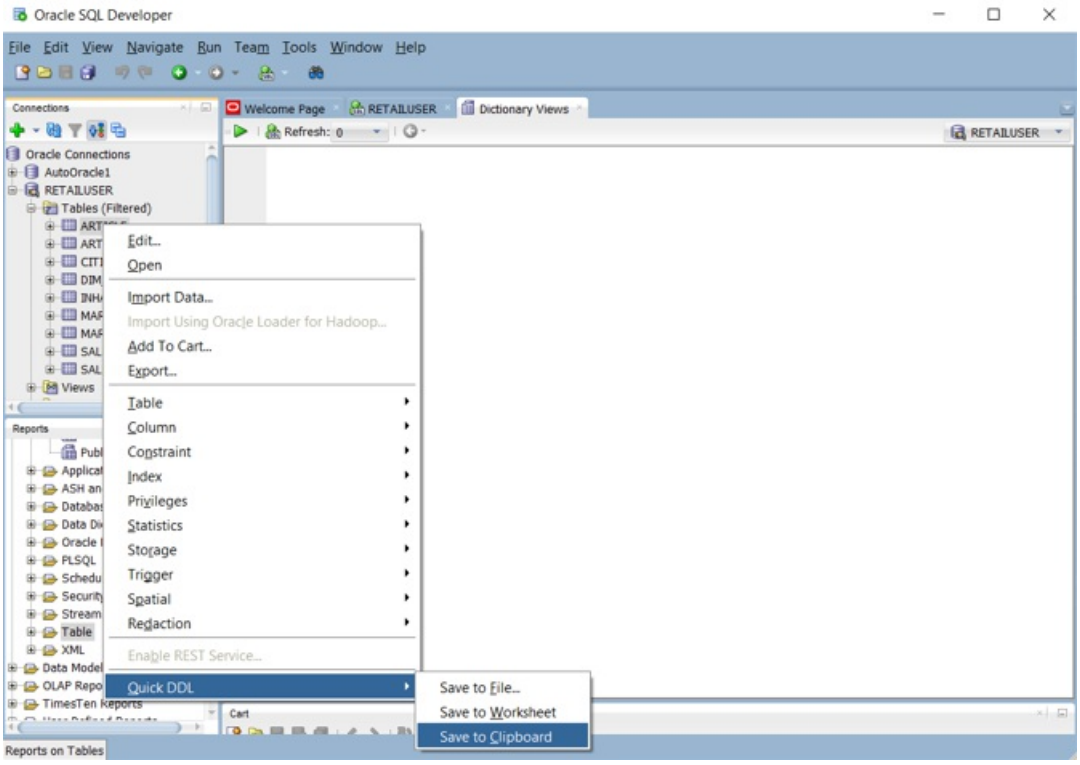
Azure Synapse doesn't currently support user-defined types. If the data you need to migrate includes user-defined data types, either "flatten" them into a conventional table definition, or if they're arrays of data, normalize them in a separate table.

SQL DDL generation

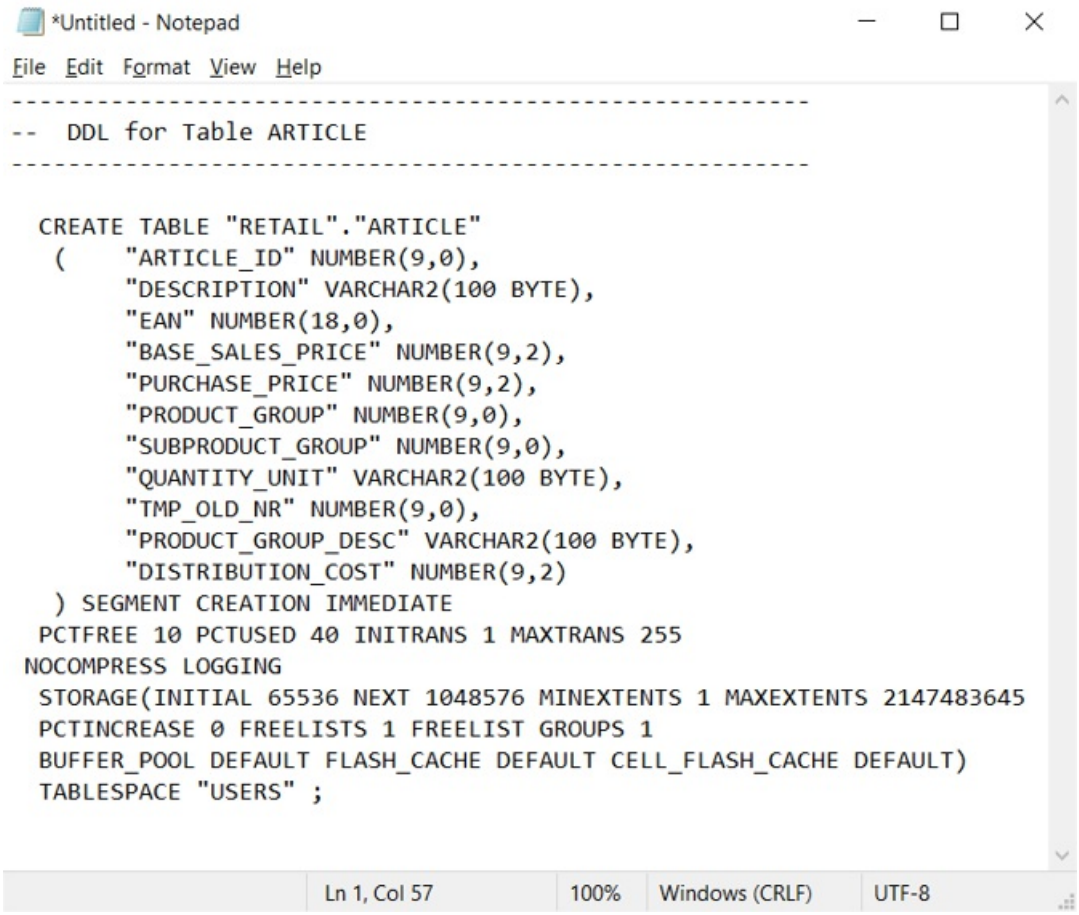
You can edit existing Oracle `CREATE TABLE` and `CREATE VIEW` scripts to achieve equivalent definitions in Azure Synapse. To do so, you might need to use modified data types and remove or modify Oracle-specific clauses, such as `TABLESPACE`.

> **TIP**
> Use existing Oracle metadata to automate the generation of `CREATE TABLE` and `CREATE VIEW` DDL for Azure Synapse.

Within the Oracle environment, system catalog tables specify the current table/view definition. Unlike user-maintained documentation, system catalog information is always complete and in sync with current table definitions. You can access system catalog information by using utilities such as Oracle SQL Developer. Oracle SQL Developer can generate `CREATE TABLE` DDL statements that you can edit to apply to equivalent tables in Azure Synapse, as shown in the next screenshot.



Oracle SQL Developer outputs the following `CREATE TABLE` statement, which contains Oracle-specific clauses that you should remove. Map any unsupported data types before running your modified `CREATE TABLE` statement on Azure Synapse.



Alternatively, you can automatically generate `CREATE TABLE` statements from the information within Oracle catalog tables by using SQL queries, SSMA, or third-party migration tools. This approach is the fastest, most consistent way to generate `CREATE TABLE` statements for many tables.

> **TIP**
> Third-party tools and services can automate data mapping tasks.

Third-party vendors offer tools and services to automate migration, including the mapping of data types. If a third-party ETL tool is already in use in the Oracle environment, use that tool to implement any required data transformations.

SQL DML differences between Oracle and Azure Synapse

The ANSI SQL standard defines the basic syntax for DML commands, such as `SELECT`, `INSERT`, `UPDATE`, and `DELETE`. Although Oracle and Azure Synapse both support DDL commands, in some cases they implement the same command differently.

> **TIP**
> The standard SQL DML commands `SELECT`, `INSERT`, and `UPDATE` can have additional syntax options in different database environments.

The following sections discuss the Oracle-specific DML commands that need to be considered during a migration to Azure Synapse.

SQL DML syntax differences

There are some SQL DML syntax differences between Oracle SQL and Azure Synapse T-SQL:

- `DUAL` table: Oracle has a system table named `DUAL` that consists of exactly one column named `dummy` and one record with the value `X`. The `DUAL` system table is used when a query requires a table name for syntax reasons, but the table content isn't needed.

  An example Oracle query that uses the `DUAL` table is `SELECT sysdate from dual;`. The Azure Synapse equivalent is `SELECT GETDATE();`. To simplify migration of DML, you could create an equivalent `DUAL` table in Azure Synapse using the following DDL.

  ```
  CREATE TABLE DUAL
  (
    DUMMY VARCHAR(1)
  )
  GO
  INSERT INTO DUAL (DUMMY)
  VALUES ('X')
  GO
  ```

- `NULL` values: a `NULL` value in Oracle is an empty string, represented by a `CHAR` or `VARCHAR` string type of length `0`. In Azure Synapse and most other databases, `NULL` means something else. Be careful when migrating data, or when migrating processes that handle or store data, to ensure that `NULL` values are handled consistently.

- Oracle outer join syntax: although more recent versions of Oracle support ANSI outer join syntax, older Oracle systems use a proprietary syntax for outer joins that uses a plus sign (`+`) within the SQL statement. If you're migrating an older Oracle environment, you might encounter the older syntax. For example:

  ```
  SELECT
      d.deptno, e.job
  FROM
      dept d,
      emp e
  WHERE
      d.deptno = e.deptno (+)
      AND e.job (+) = 'CLERK'
  GROUP BY
      d.deptno, e.job;
  ```

  The equivalent ANSI standard syntax is:

  ```
  SELECT
      d.deptno, e.job
  FROM
      dept d
      LEFT OUTER JOIN emp e ON d.deptno = e.deptno
      and e.job = 'CLERK'
  GROUP BY
      d.deptno,
      e.job
  ORDER BY
      d.deptno, e.job;
  ```

- `DATE` data: in Oracle, the `DATE` data type can store both date and time. Azure Synapse stores date and time in separate `DATE`, `TIME`, and `DATETIME` data types. When you're migrating Oracle `DATE` columns, check whether they store both date and time or just a date. If they only store a date, then map the column to `DATE`, otherwise to `DATETIME`.

- `DATE` arithmetic: Oracle supports subtracting one date from another, for example

`SELECT date '2018-12-31' - date '2018-1201' from dual;`. In Azure Synapse, you can subtract dates by using the `DATEDIFF()` function, for example `SELECT DATEDIFF(day, '2018-12-01', '2018-12-31');`.

Oracle can subtract integers from dates, for example `SELECT hire_date, (hire_date-1) FROM employees;`. In Azure Synapse, you can add or subtract integers from dates by using the `DATEADD()` function.

- Updates via views: in Oracle you can run insert, update, and delete operations against a view to update the underlying table. In Azure Synapse, you run those operations against a base table—not a view. You might have to re-engineer ETL processing if an Oracle table is updated through a view.
- Built-in functions: the following table shows the differences in the syntax and usage of some built-in functions.

ORACLE FUNCTION	DESCRIPTION	SYNAPSE EQUIVALENT
ADD_MONTHS	Add a specified number of months	DATEADD
CAST	Convert one built-in data type into another	CAST
DECODE	Evaluate a list of conditions	CASE expression
EMPTY_BLOB	Create an empty BLOB value	`0x` constant (empty binary string)
EMPTY_CLOB	Create an empty CLOB or NCLOB value	`''` (empty string)
INITCAP	Capitalize the first letter of each word	User-defined function
INSTR	Find position of a substring in a string	CHARINDEX
LAST_DAY	Get the last date of month	EOMONTH
LENGTH	Get string length in characters	LEN
LPAD	Left-pad string to the specified length	Expression using REPLICATE, RIGHT, and LEFT
MOD	Get the remainder of a division of one number by another	`%` operator
MONTHS_BETWEEN	Get the number of months between two dates	DATEDIFF
NVL	Replace `NULL` with expression	ISNULL
SUBSTR	Return a substring from a string	SUBSTRING
TO_CHAR for datetime	Convert datetime to string	CONVERT
TO_DATE	Convert a string to datetime	CONVERT
TRANSLATE	One-to-one single character substitution	Expressions using REPLACE or a user-defined function

ORACLE FUNCTION	DESCRIPTION	SYNAPSE EQUIVALENT
TRIM	Trim leading or trailing characters	LTRIM and RTRIM
TRUNC for datetime	Truncate datetime	Expressions using CONVERT
UNISTR	Convert Unicode code points to characters	Expressions using NCHAR

Functions, stored procedures, and sequences

When migrating a data warehouse from a mature environment like Oracle, you probably need to migrate elements other than simple tables and views. For functions, stored procedures, and sequences, check whether tools within the Azure environment can replace their functionality because it's usually more efficient to use built-in Azure tools than to recode the Oracle functions.

As part of your preparation phase, create an inventory of objects that need to be migrated, define a method for handling them, and allocate appropriate resources in your migration plan.

Microsoft tools like SSMA for Oracle and Azure Database Migration Services, or third-party migration products and services, can automate the migration of functions, stored procedures, and sequences.

> **TIP**
> Third-party products and services can automate migration of non-data elements.

The following sections discuss the migration of functions, stored procedures, and sequences.

Functions

As with most database products, Oracle supports system and user-defined functions within a SQL implementation. When you migrate a legacy database platform to Azure Synapse, you can usually migrate common system functions without change. Some system functions might have a slightly different syntax, but you can automate any required changes.

For Oracle system functions or arbitrary user-defined functions that have no equivalent in Azure Synapse, recode those functions using the target environment language. Oracle user-defined functions are coded in PL/SQL, Java, or C. Azure Synapse uses the Transact-SQL language to implement user-defined functions.

Stored procedures

Most modern database products support storing procedures within the database. Oracle provides the PL/SQL language for this purpose. A stored procedure typically contains both SQL statements and procedural logic, and returns data or a status.

Azure Synapse supports stored procedures using T-SQL, so you'll need to recode any migrated stored procedures in T-SQL.

Sequences

In Oracle, a sequence is a named database object, created using `CREATE SEQUENCE`. A sequence provides unique numeric values via the `CURRVAL` and `NEXTVAL` methods. You can use the generated unique numbers as surrogate key values for primary keys. Azure Synapse doesn't implement `CREATE SEQUENCE`, but you can implement sequences using `IDENTITY` columns or SQL code that generates the next sequence number in a series.

Use EXPLAIN to validate legacy SQL

> **TIP**
> Use real queries from the existing system query logs to find potential migration issues.

Assuming a like-for-like migrated data model in Azure Synapse with the same table and column names, one way to test legacy Oracle SQL for compatibility with Azure Synapse is:

1. Capture some representative SQL statements from the legacy system query history logs.
2. Prefix those queries with the `EXPLAIN` statement.
3. Run the `EXPLAIN` statements in Azure Synapse.

Any incompatible SQL will generate an error, and the error information can be used to determine the scale of the recoding task. This approach doesn't require you to load any data into the Azure environment, you only need to create the relevant tables and views.

Summary

Existing legacy Oracle installations are typically implemented in a way that makes migration to Azure Synapse relatively straightforward. Both environments use SQL for analytical queries on large data volumes, and generally use some form of dimensional data model. These factors make Oracle installations a good candidate for migration to Azure Synapse.

To summarize, our recommendations for minimizing the task of migrating SQL code from Oracle to Azure Synapse are:

- Migrate your existing data model as-is to minimize risk, effort, and migration time, even if a different data model is planned, such as a data vault.
- Understand the differences between the Oracle SQL implementation and the Azure Synapse implementation.
- Use the metadata and query logs from the existing Oracle implementation to assess the impact of changing the environment. Plan an approach to mitigate the differences.
- Automate the migration process to minimize risk, effort, and migration time. You can use Microsoft tools such as Azure Database Migration Services and SSMA.
- Consider using specialist third-party tools and services to streamline the migration.

Next steps

To learn more about Microsoft and third-party tools, see the next article in this series: Tools for Oracle data warehouse migration to Azure Synapse Analytics.

Tools for Oracle data warehouse migration to Azure Synapse Analytics

8/19/2022 • 6 minutes to read • Edit Online

This article is part six of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for Microsoft and third-party tools.

Data warehouse migration tools

By migrating your existing data warehouse to Azure Synapse, you benefit from:

- A globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database.
- The rich Microsoft analytical ecosystem that exists on Azure. This ecosystem consists of technologies to help modernize your data warehouse once it's migrated and extend your analytical capabilities to drive new value.

Several tools from both Microsoft and third-party partners can help you migrate your existing data warehouse to Azure Synapse. This article discusses the following types of tools:

- Microsoft data and database migration tools.
- Third-party data warehouse automation tools to automate and document the migration to Azure Synapse.
- Third-party data warehouse migration tools to migrate schema and data to Azure Synapse.
- Third-party tools to bridge the SQL differences between your existing data warehouse DBMS and Azure Synapse.

Microsoft data migration tools

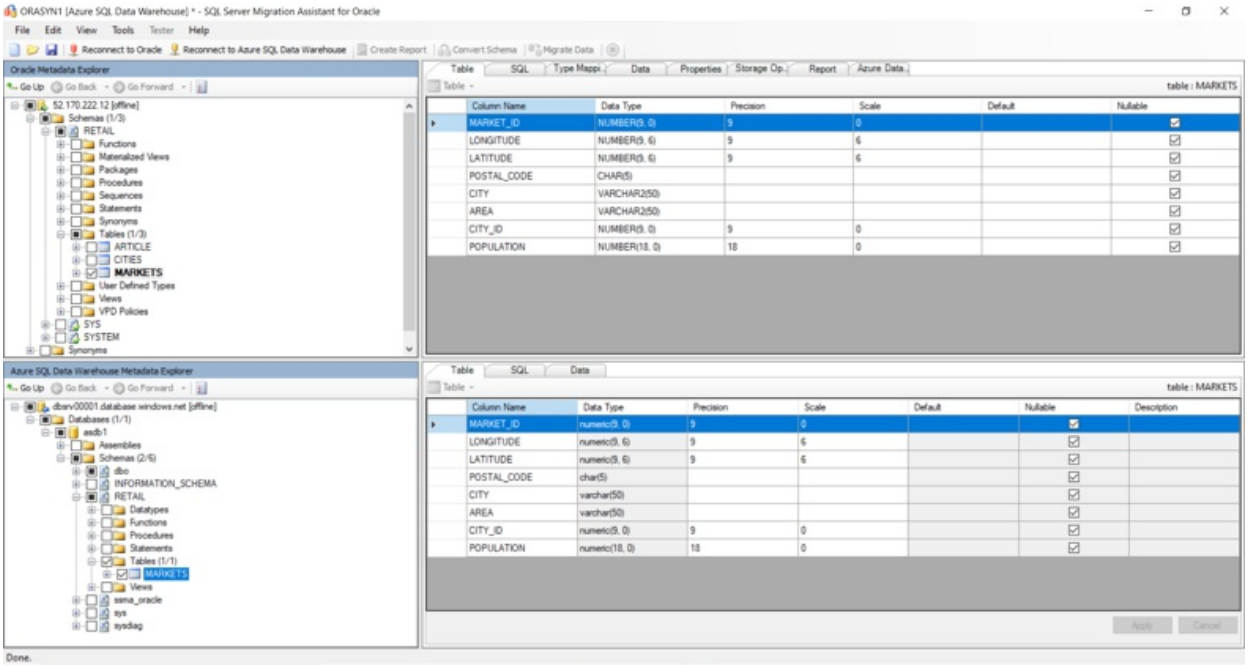
Microsoft offers several tools to help you migrate your existing data warehouse to Azure Synapse, such as:

- SQL Server Migration Assistant (SSMA)
- Azure Data Factory.
- Microsoft services for physical data transfer.
- Microsoft services for data ingestion.

The next sections discuss these tools in more detail.

SQL Server Migration Assistant (SSMA)

SQL Server Migration Assistant (SSMA) for Oracle can automate many parts of the migration process, including in some cases functions and procedural code. SSMA supports Azure Synapse as a target environment.



SSMA for Oracle can help you migrate an Oracle data warehouse or data mart to Azure Synapse. SSMA is designed to automate the process of migrating tables, views, and data from an existing Oracle environment.

Microsoft Azure Data Factory

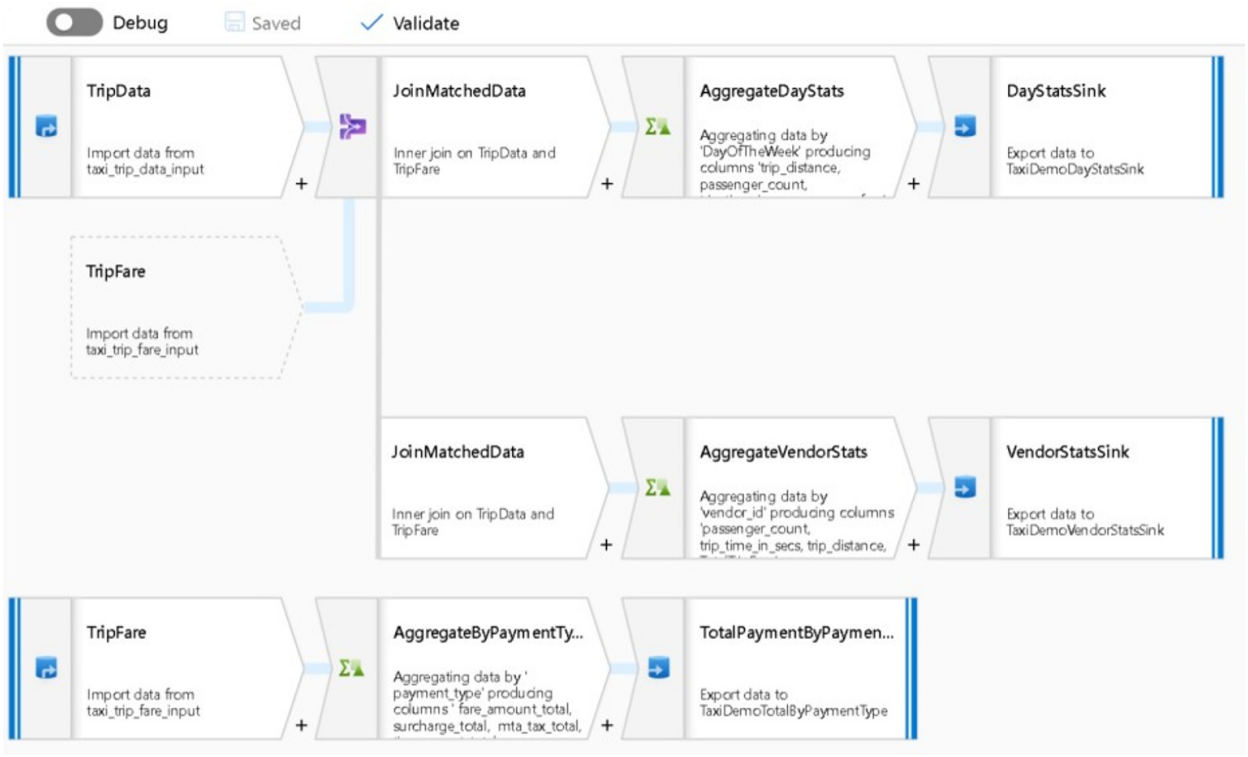
Data Factory is a fully managed, pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. It uses Apache Spark to process and analyze data in parallel and in-memory to maximize throughput.

> **TIP**
> Data Factory allows you to build scalable data integration pipelines code-free.

Data Factory connectors support connections to external data sources and databases and include templates for common data integration tasks. A visual front-end, browser-based UI enables non-programmers to create and run pipelines to ingest, transform, and load data. More experienced programmers can incorporate custom code, such as Python programs.

> **TIP**
> Data Factory enables collaborative development between business and IT professionals.

Data Factory is also an orchestration tool and is the best Microsoft tool to automate the end-to-end migration process. Automation reduces the risk, effort, and time to migrate, and makes the migration process easily repeatable. The following diagram shows a mapping data flow in Data Factory.



The next screenshot shows a wrangling data flow in Data Factory.

In Data Factory, you can develop simple or comprehensive ETL and ELT processes without coding or maintenance with just a few clicks. ETL/ELT processes ingest, move, prepare, transform, and process your data. You can design and manage scheduling and triggers in Data Factory to build an automated data integration and loading environment. In Data Factory, you can define, manage, and schedule PolyBase bulk data load processes.

> **TIP**
> Data Factory includes tools to help migrate both your data and your entire data warehouse to Azure.

You can use Data Factory to implement and manage a hybrid environment with on-premises, cloud, streaming, and SaaS data in a secure and consistent way. SaaS data might come from applications such as Salesforce.

Wrangling data flows is a new capability in Data Factory. This capability opens up Data Factory to business users who want to visually discover, explore, and prepare data at scale without writing code. Wrangling data flows offers self-service data preparation, similar to Microsoft Excel, Power Query, and Microsoft Power BI dataflows. Business users can prepare and integrate data through a spreadsheet-style UI with drop-down transform options.

Data migration at scale capability helps migration of data at source to Azure SQL target using Data Factory.

Data Factory is the recommended approach for implementing data integration and ETL/ELT processes in the Azure Synapse environment, especially if you want to refactor existing legacy processes.

Microsoft services for physical data transfer

The following sections discuss a range of products and services that Microsoft offers to assist customers with data transfer. This offline data movement will allow end users to reduce the migration downtime significantly.

Azure ExpressRoute

Azure ExpressRoute creates private connections between Azure data centers and infrastructure on your premises or in a collocation environment. ExpressRoute connections don't go over the public internet, and offer more reliability, faster speeds, and lower latencies than typical internet connections. In some cases, you gain significant cost benefits by using ExpressRoute connections to transfer data between on-premises systems and Azure.

AzCopy

AzCopy is a command line utility that copies files to Azure Blob Storage over a standard internet connection. In a warehouse migration project, you can use AzCopy to upload extracted, compressed, delimited text files before loading them into Azure Synapse using PolyBase. AzCopy can upload individual files, file selections, or file folders. If the exported files are in Parquet format, use a native Parquet reader instead.

Azure Data Box

Azure Data Box is a Microsoft service that provides you with a proprietary physical storage device that you can copy migration data onto. You then ship the device to an Azure data center for data upload to cloud storage. This service can be cost-effective for large volumes of data, such as tens or hundreds of terabytes, or where network bandwidth isn't readily available. Azure Data Box is typically used for a large one-off historical data load into Azure Synapse.

Azure Data Box Gateway

Azure Data Box Gateway is a virtualized cloud storage gateway device that resides on your premises and sends your images, media, and other data to Azure. Use Data Box Gateway for one-off migration tasks or ongoing incremental data uploads.

Microsoft services for data ingestion

The following sections discuss the products and services that Microsoft offers to assist customers with data ingestion.

COPY INTO

The COPY INTO statement provides the most flexibility for high-throughput data ingestion into Azure Synapse. For more information about `COPY INTO` capabilities, see COPY (Transact-SQL).

PolyBase

PolyBase is the fastest, most scalable method for bulk data load into Azure Synapse. PolyBase uses the massively parallel processing (MPP) architecture of Azure Synapse for parallel loading of data to achieve the fastest throughput. PolyBase can read data from flat files in Azure Blob Storage, or directly from external data sources and other relational databases via connectors.

> **TIP**
> PolyBase can load data in parallel from Azure Blob Storage into Azure Synapse.

PolyBase can also directly read from files compressed with gzip to reduce the physical volume of data during a load process. PolyBase supports popular data formats such as delimited text, ORC, and Parquet.

> **TIP**
> You can invoke PolyBase from Data Factory as part of a migration pipeline.

PolyBase is tightly integrated with Data Factory to support rapid development of data load ETL/ELT processes. You can schedule data load processes through a visual UI for higher productivity and fewer errors than hand-written code. Microsoft recommends PolyBase for data ingestion into Azure Synapse, especially for high-volume data ingestion.

PolyBase uses `CREATE TABLE AS` or `INSERT...SELECT` statements to load data. `CREATE TABLE AS` minimizes logging to achieve the highest throughput. The most efficient input format for data load is compressed delimited text files. For maximum throughput, split large input files into multiple smaller files and load them in parallel. For fastest loading to a staging table, define the target table as `HEAP` type and use round-robin distribution.

PolyBase has some limitations, it requires data row length to be less than 1 megabyte and doesn't support fixed-width nested formats like JSON and XML.

Microsoft tools for Oracle migrations

SQL Server Migration Assistant (SSMA) for Oracle can help you migrate your legacy on-premises data warehouse platform to Azure Synapse.

Microsoft partners for Oracle migrations

Microsoft partners offer tools, services, and expertise to help you migrate your legacy on-premises data warehouse platform to Azure Synapse.

To learn more about implementing modern data warehouses, see the next article in this series: Beyond Oracle migration, implement a modern data warehouse in Microsoft Azure.

Beyond Oracle migration, implement a modern data warehouse in Microsoft Azure

8/19/2022 • 23 minutes to read • Edit Online

This article is part seven of a seven-part series that provides guidance on how to migrate from Oracle to Azure Synapse Analytics. The focus of this article is best practices for implementing modern data warehouses.

Beyond data warehouse migration to Azure

A key reason to migrate your existing data warehouse to Azure Synapse Analytics is to utilize a globally secure, scalable, low-cost, cloud-native, pay-as-you-use analytical database. With Azure Synapse, you can integrate your migrated data warehouse with the complete Microsoft Azure analytical ecosystem to take advantage of other Microsoft technologies and modernize your migrated data warehouse. Those technologies include:

- Azure Data Lake Storage for cost effective data ingestion, staging, cleansing, and transformation. Data Lake Storage can free up the data warehouse capacity occupied by fast-growing staging tables.
- Azure Data Factory for collaborative IT and self-service data integration with connectors to cloud and on-premises data sources and streaming data.
- Common Data Model to share consistent trusted data across multiple technologies, including:
  - Azure Synapse
  - Azure Synapse Spark
  - Azure HDInsight
  - Power BI
  - Adobe Customer Experience Platform
  - Azure IoT
  - Microsoft ISV partners
- Microsoft data science technologies, including:
  - Azure Machine Learning studio
  - Azure Machine Learning
  - Azure Synapse Spark (Spark as a service)
  - Jupyter Notebooks
  - RStudio
  - ML.NET
  - .NET for Apache Spark, which lets data scientists use Azure Synapse data to train machine learning models at scale.
- Azure HDInsight to process large amounts of data, and to join big data with Azure Synapse data by creating a logical data warehouse using PolyBase.
- Azure Event Hubs, Azure Stream Analytics, and Apache Kafka to integrate live streaming data from Azure Synapse.

The growth of big data has led to an acute demand for machine learning to enable custom-built, trained machine learning models for use in Azure Synapse. Machine learning models enable in-database analytics to run at scale in batch, on an event-driven basis and on-demand. The ability to take advantage of in-database analytics in Azure Synapse from multiple BI tools and applications also guarantees consistent predictions and

recommendations.

In addition, you can integrate Azure Synapse with Microsoft partner tools on Azure to shorten time to value.

Let's take a closer look at how you can take advantage of technologies in the Microsoft analytical ecosystem to modernize your data warehouse after you've migrated to Azure Synapse.

Offload data staging and ETL processing to Data Lake Storage and Data Factory

Digital transformation has created a key challenge for enterprises by generating a torrent of new data for capture and analysis. A good example is transaction data created by opening online transactional processing (OLTP) systems to service access from mobile devices. Much of this data finds its way into data warehouses, and OLTP systems are the main source. With customers now driving the transaction rate rather than employees, the volume of data in data warehouse staging tables has been growing rapidly.

With the rapid influx of data into the enterprise, along with new sources of data like Internet of Things (IoT), companies must find ways to scale up data integration ETL processing. One method is to offload ingestion, data cleansing, transformation, and integration to a data lake and process data at scale there, as part of a data warehouse modernization program.

Once you've migrated your data warehouse to Azure Synapse, Microsoft can modernize your ETL processing by ingesting and staging data in Data Lake Storage. You can then clean, transform, and integrate your data at scale using Data Factory before loading it into Azure Synapse in parallel using PolyBase.

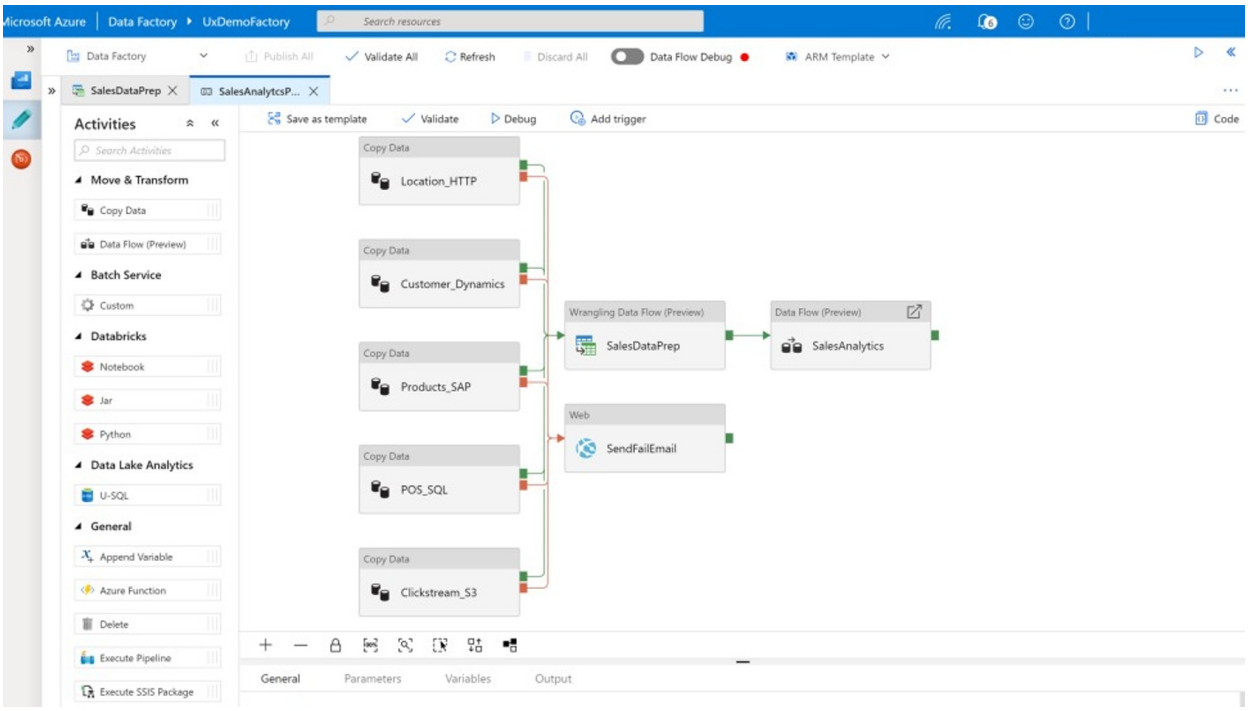
For ELT strategies, consider offloading ELT processing to Data Lake Storage to easily scale as your data volume or frequency grows.

Microsoft Azure Data Factory

Azure Data Factory is a pay-as-you-use, hybrid data integration service for highly scalable ETL and ELT processing. Data Factory provides a web-based UI to build data integration pipelines with no code. With Data Factory, you can:

- Build scalable data integration pipelines code-free.
- Easily acquire data at scale.
- Pay only for what you use.
- Connect to on-premises, cloud, and SaaS-based data sources.
- Ingest, move, clean, transform, integrate, and analyze cloud and on-premises data at scale.
- Seamlessly author, monitor, and manage pipelines that span data stores both on-premises and in the cloud.
- Enable pay-as-you-go scale-out in alignment with customer growth.

You can use these features without writing any code, or you can add custom code to Data Factory pipelines. The following screenshot shows an example Data Factory pipeline.



TIP

Data Factory lets you to build scalable data integration pipelines without code.

Implement Data Factory pipeline development from any of several places, including:

- Microsoft Azure portal.
- Microsoft Azure PowerShell.
- Programmatically from .NET and Python using a multi-language SDK.
- Azure Resource Manager (ARM) templates.
- REST APIs.

TIP

Data Factory can connect to on-premises, cloud, and SaaS data.

Developers and data scientists who prefer to write code can easily author Data Factory pipelines in Java, Python, and .NET using the software development kits (SDKs) available for those programming languages. Data Factory pipelines can be hybrid data pipelines because they can connect, ingest, clean, transform, and analyze data in on-premises data centers, Microsoft Azure, other clouds, and SaaS offerings.

After you develop Data Factory pipelines to integrate and analyze data, you can deploy those pipelines globally and schedule them to run in batch, invoke them on demand as a service, or run them in real-time on an event-driven basis. A Data Factory pipeline can also run on one or more execution engines and monitor execution to ensure performance and to track errors.

TIP

In Azure Data Factory, pipelines control the integration and analysis of data. Data Factory is enterprise-class data integration software aimed at IT professionals and has data wrangling capability for business users.

Use cases

Data Factory supports multiple use cases, such as:

- Prepare, integrate, and enrich data from cloud and on-premises data sources to populate your migrated data warehouse and data marts on Microsoft Azure Synapse.
- Prepare, integrate, and enrich data from cloud and on-premises data sources to produce training data for use in machine learning model development and in retraining analytical models.
- Orchestrate data preparation and analytics to create predictive and prescriptive analytical pipelines for processing and analyzing data in batch, such as sentiment analytics. Either act on the results of the analysis or populate your data warehouse with the results.
- Prepare, integrate, and enrich data for data-driven business applications running on the Azure cloud on top of operational data stores such as Azure Cosmos DB.

> **TIP**
> Build training data sets in data science to develop machine learning models.

Data sources

Data Factory lets you use connectors from both cloud and on-premises data sources. Agent software, known as a *self-hosted integration runtime*, securely accesses on-premises data sources and supports secure, scalable data transfer.

Transform data using Azure Data Factory

Within a Data Factory pipeline, you can ingest, clean, transform, integrate, and analyze any type of data from these sources. Data can be structured, semi-structured like JSON or Avro, or unstructured.

Without writing any code, professional ETL developers can use Data Factory mapping data flows to filter, split, join several types, lookup, pivot, unpivot, sort, union, and aggregate data. In addition, Data Factory supports surrogate keys, multiple write processing options like insert, upsert, update, table recreation, and table truncation, and several types of target data stores—also known as sinks. ETL developers can also create aggregations, including time-series aggregations that require a window to be placed on data columns.

> **TIP**
> Professional ETL developers can use Data Factory mapping data flows to clean, transform, and integrate data without the need to write code.

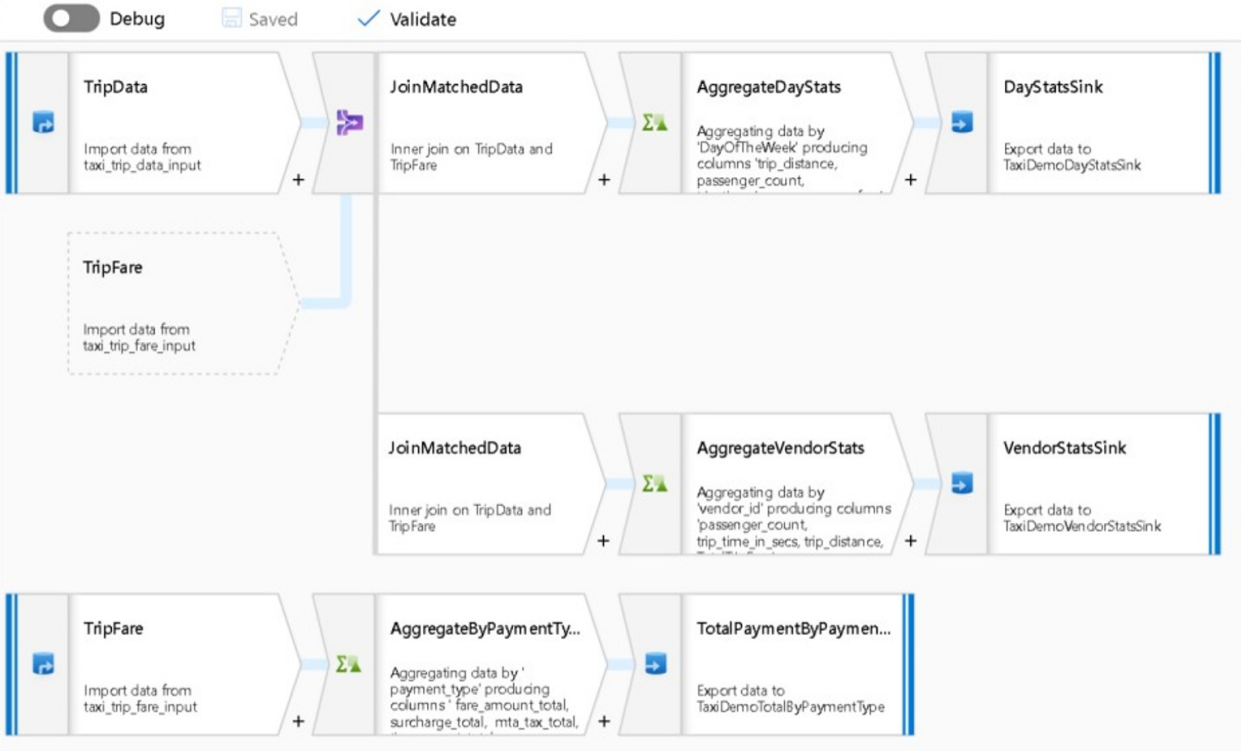
You can run mapping data flows that transform data as activities in a Data Factory pipeline, and if necessary, you can include multiple mapping data flows in a single pipeline. In this way, you can manage the complexity by breaking up challenging data transformation and integration tasks into smaller mapping dataflows that can be combined. And, you can add custom code when needed. In addition to this functionality, Data Factory mapping data flows include the ability to:

- Define expressions to clean and transform data, compute aggregations, and enrich data. For example, these expressions can perform feature engineering on a date field to break it into multiple fields to create training data during machine learning model development. You can construct expressions from a rich set of functions that include mathematical, temporal, split, merge, string concatenation, conditions, pattern match, replace, and many other functions.
- Automatically handle schema drift so that data transformation pipelines can avoid being impacted by schema changes in data sources. This ability is especially important for streaming IoT data, where schema changes can happen without notice if devices are upgraded or when readings are missed by gateway devices collecting IoT data.

- Partition data to enable transformations to run in parallel at scale.
- Inspect streaming data to view the metadata of a stream you're transforming.

> **TIP**
> Data Factory supports the ability to automatically detect and manage schema changes in inbound data, such as in streaming data.

The following screenshot shows an example Data Factory mapping data flow.



Data engineers can profile data quality and view the results of individual data transforms by enabling debug capability during development.

> **TIP**
> Data Factory can also partition data to enable ETL processing to run at scale.

If necessary, you can extend Data Factory transformational and analytical functionality by adding a linked service that contains your code into a pipeline. For example, an Azure Synapse Spark pool notebook might contain Python code that uses a trained model to score the data integrated by a mapping data flow.

You can store integrated data and any results from analytics within a Data Factory pipeline in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

> **TIP**
> Data Factory pipelines are extensible because Data Factory lets you write your own code and run it as part of a pipeline.

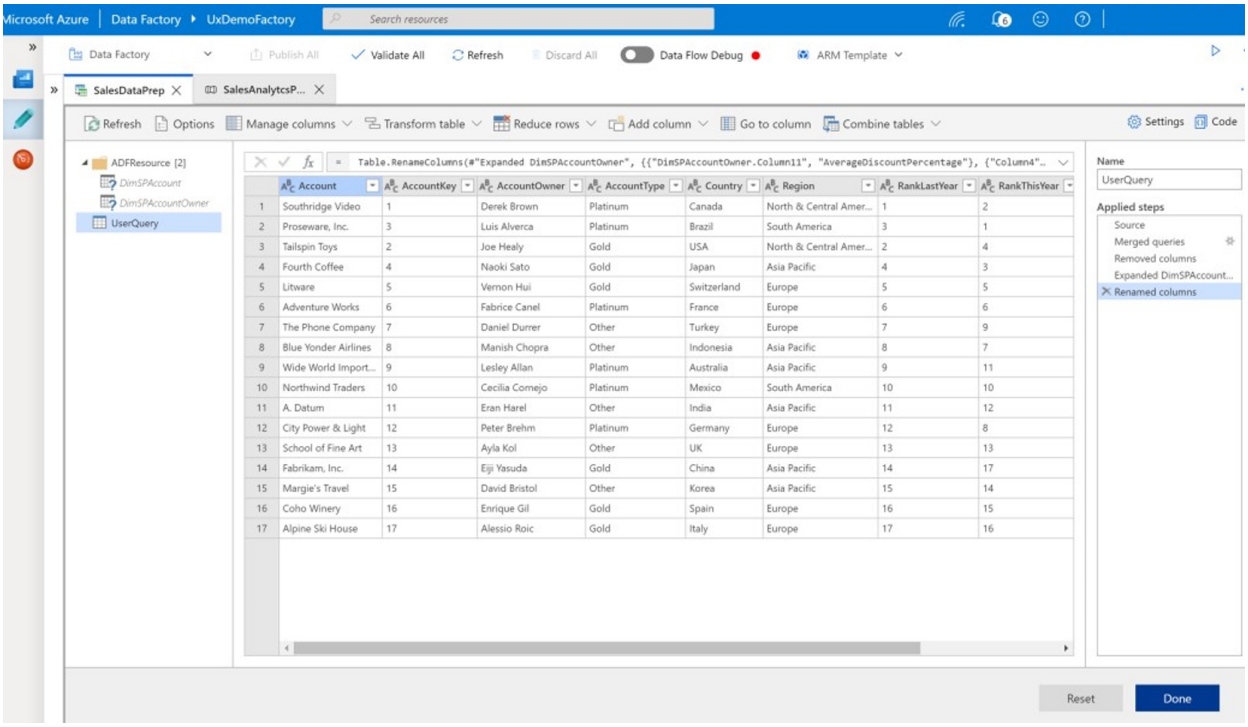
Utilize Spark to scale data integration

At run time, Data Factory internally uses Azure Synapse Spark pools, which are Microsoft's Spark as a service offering, to clean and integrate data in the Azure cloud. You can clean, integrate, and analyze high-volume, high-

velocity data, such as click-stream data, at scale. Microsoft's intention is to also run Data Factory pipelines on other Spark distributions. In addition to running ETL jobs on Spark, Data Factory can invoke Pig scripts and Hive queries to access and transform data stored in HDInsight.

Link self-service data prep and Data Factory ETL processing using wrangling data flows

Data wrangling lets business users, also known as citizen data integrators and data engineers, make use of the platform to visually discover, explore, and prepare data at scale without writing code. This Data Factory capability is easy to use and is similar to Microsoft Excel Power Query or Microsoft Power BI dataflows, where self-service business users use a spreadsheet-style UI with drop-down transforms to prepare and integrate data. The following screenshot shows an example Data Factory wrangling data flow.



Unlike Excel and Power BI, Data Factory wrangling data flows use Power Query to generate M code and then translate it into a massively parallel in-memory Spark job for cloud-scale execution. The combination of mapping data flows and wrangling data flows in Data Factory lets professional ETL developers and business users collaborate to prepare, integrate, and analyze data for a common business purpose. The preceding Data Factory mapping data flows diagram shows how both Data Factory and Azure Synapse Spark pool notebooks can be combined in the same Data Factory pipeline. The combination of mapping and wrangling data flows in Data Factory helps IT and business users stay aware of what data flows each has created, and supports data flow reuse to minimize reinvention and maximize productivity and consistency.

> **TIP**
>
> Data Factory supports both wrangling data flows and mapping data flows, so business users and IT users can integrate data collaboratively on a common platform.

Link data and analytics in analytical pipelines

In addition to cleaning and transforming data, Data Factory can combine data integration and analytics in the same pipeline. You can use Data Factory to create both data integration and analytical pipelines, the latter being an extension of the former. You can drop an analytical model into a pipeline to create an analytical pipeline that generates clean, integrated data for predictions or recommendations. Then, you can act on the predictions or recommendations immediately, or store them in your data warehouse to provide new insights and recommendations that can be viewed in BI tools.

To batch score your data, you can develop an analytical model that you invoke as a service within a Data Factory pipeline. You can develop analytical models code-free with Azure Machine Learning studio, or with the Azure

Machine Learning SDK using Azure Synapse Spark pool notebooks or R in RStudio. When you run Spark machine learning pipelines on Azure Synapse Spark pool notebooks, analysis happens at scale.

You can store integrated data and any Data Factory analytical pipeline results in one or more data stores, such as Data Lake Storage, Azure Synapse, or Hive tables in HDInsight. You can also invoke other activities to act on insights produced by a Data Factory analytical pipeline.

Use a lake database to share consistent trusted data

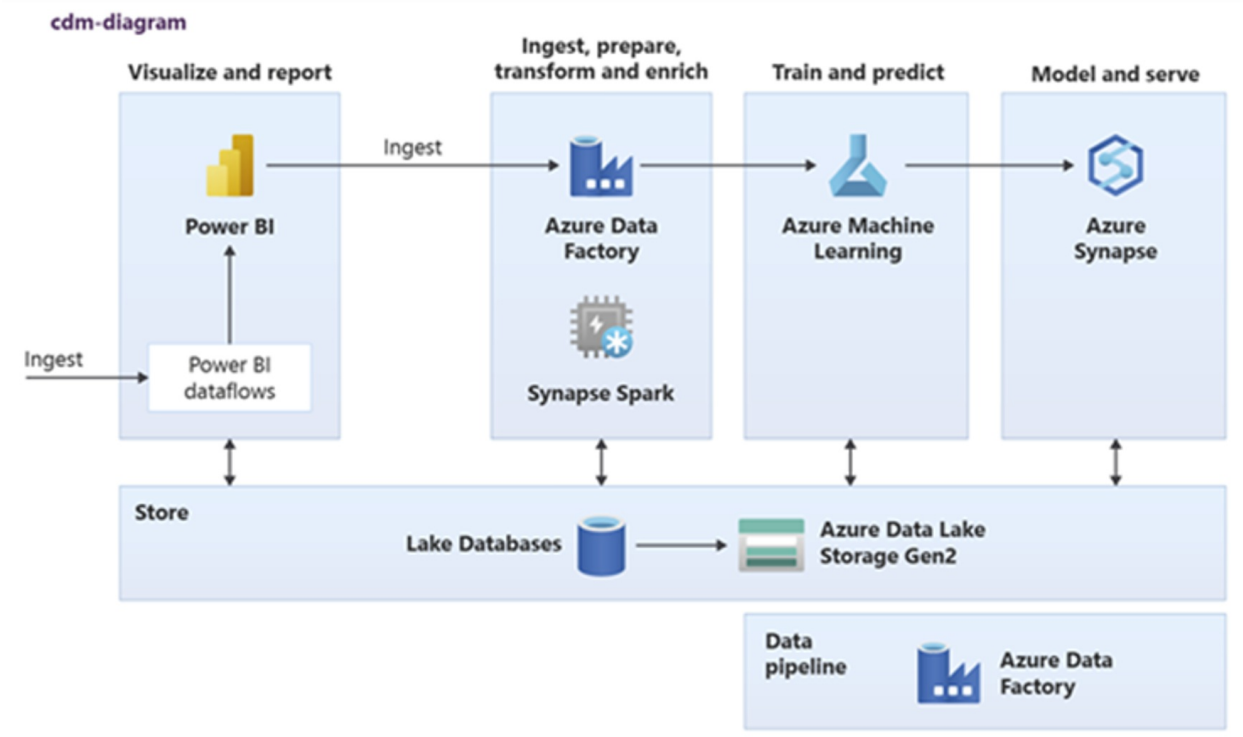
A key objective of any data integration setup is the ability to integrate data once and reuse it everywhere, not just in a data warehouse. For example, you might want to use integrated data in data science. Reuse avoids reinvention and ensures consistent, commonly understood data that everyone can trust.

Common Data Model describes core data entities that can be shared and reused across the enterprise. To achieve reuse, Common Data Model establishes a set of common data names and definitions that describe logical data entities. Examples of common data names include Customer, Account, Product, Supplier, Orders, Payments, and Returns. IT and business professionals can use data integration software to create and store common data assets to maximize their reuse and drive consistency everywhere.

Azure Synapse provides industry-specific database templates to help standardize data in the lake. Lake database templates provide schemas for predefined business areas, enabling data to be loaded into a lake database in a structured way. The power comes when you use data integration software to create lake database common data assets, resulting in self-describing trusted data that can be consumed by applications and analytical systems. You can create common data assets in Data Lake Storage by using Data Factory.

> **TIP**
> Data Lake Storage is shared storage that underpins Microsoft Azure Synapse, Azure Machine Learning, Azure Synapse Spark, and HDInsight.

Power BI, Azure Synapse Spark, Azure Synapse, and Azure Machine Learning can consume common data assets. The following diagram shows how a lake database can be used in Azure Synapse.



> **TIP**
> Integrate data to create lake database logical entities in shared storage to maximize the reuse of common data assets.

Integration with Microsoft data science technologies on Azure

Another key objective when modernizing a data warehouse is to produce insights for competitive advantage. You can produce insights by integrating your migrated data warehouse with Microsoft and third-party data science technologies in Azure. The following sections describe machine learning and data science technologies offered by Microsoft to see how they can be used with Azure Synapse in a modern data warehouse environment.

Microsoft technologies for data science on Azure

Microsoft offers a range of technologies that support advance analysis. With these technologies, you can build predictive analytical models using machine learning or analyze unstructured data using deep learning. The technologies include:

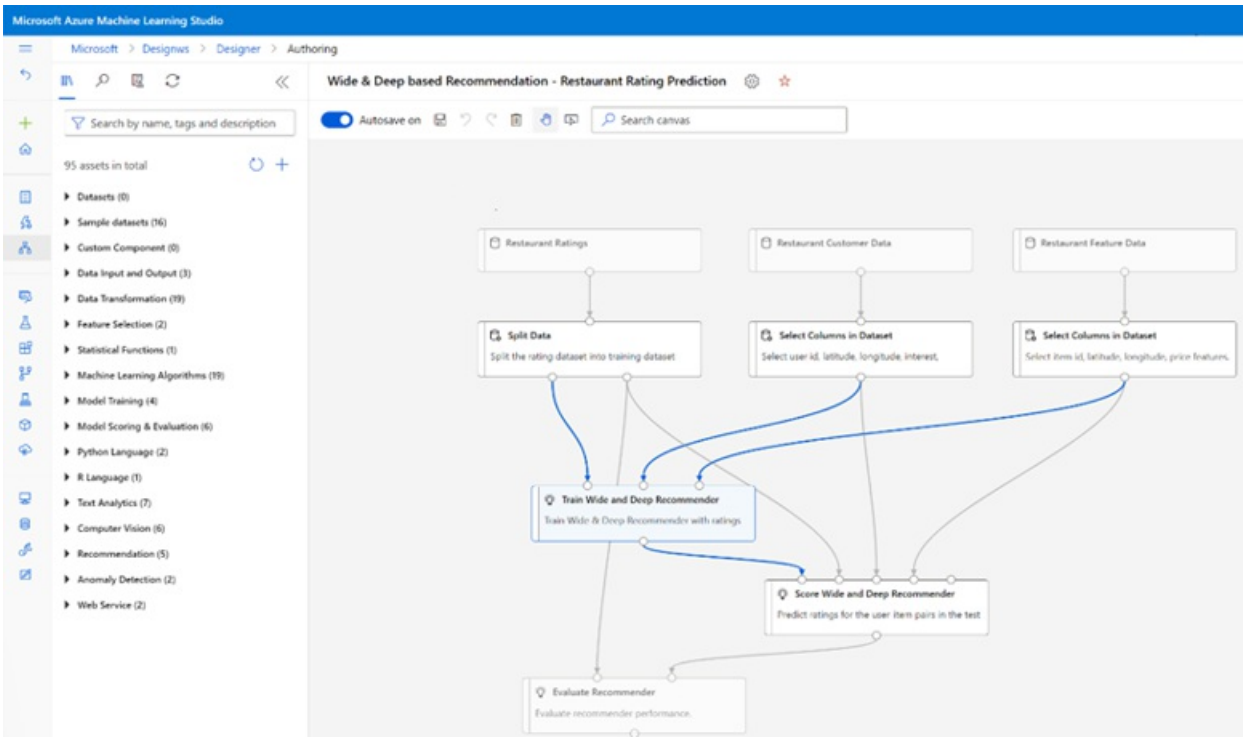
- Azure Machine Learning studio
- Azure Machine Learning
- Azure Synapse Spark pool notebooks
- ML.NET (API, CLI, or ML.NET Model Builder for Visual Studio)
- .NET for Apache Spark

Data scientists can use RStudio (R) and Jupyter Notebooks (Python) to develop analytical models, or they can use frameworks such as Keras or TensorFlow.

> **TIP**
> Develop machine learning models using a no/low-code approach or by using programming languages like Python, R, and .NET.

Azure Machine Learning studio

Azure Machine Learning studio is a fully managed cloud service that lets you build, deploy, and share predictive analytics using a drag-and-drop, web-based UI. The following screenshot shows the Azure Machine Learning studio UI.



Azure Machine Learning

Azure Machine Learning provides an SDK and services for Python that supports can help you quickly prepare data and also train and deploy machine learning models. You can use Azure Machine Learning in Azure notebooks using Jupyter Notebook, with open-source frameworks, such as PyTorch, TensorFlow, scikit-learn, or Spark MLlib—the machine learning library for Spark. Azure Machine Learning provides an AutoML capability that automatically tests multiple algorithms to identify the most accurate algorithms to expedite model development.

> **TIP**
> Azure Machine Learning provides an SDK for developing machine learning models using several open-source frameworks.

You can also use Azure Machine Learning to build machine learning pipelines that manage end-to-end workflow, programmatically scale in the cloud, and deploy models both to the cloud and the edge. Azure Machine Learning contains workspaces, which are logical spaces that you can programmatically or manually create in the Azure portal. These workspaces keep compute targets, experiments, data stores, trained machine learning models, Docker images, and deployed services all in one place to enable teams to work together. You can use Azure Machine Learning in Visual Studio with the Visual Studio for AI extension.

> **TIP**
> Organize and manage related data stores, experiments, trained models, Docker images, and deployed services in workspaces.

Azure Synapse Spark pool notebooks

An Azure Synapse Spark pool notebook is an Azure-optimized Apache Spark service. With Azure Synapse Spark pool notebooks:

- Data engineers can build and run scalable data preparation jobs using Data Factory.
- Data scientists can build and run machine learning models at scale using notebooks written in languages such as Scala, R, Python, Java, and SQL to visualize results.

> **TIP**
> Azure Synapse Spark is a dynamically scalable Spark as a service offering from Microsoft, Spark offers scalable execution of data preparation, model development, and deployed model execution.

Jobs running in Azure Synapse Spark pool notebooks can retrieve, process, and analyze data at scale from Azure Blob Storage, Data Lake Storage, Azure Synapse, HDInsight, and streaming data services such as Apache Kafka.

> **TIP**
> Azure Synapse Spark can access data in a range of Microsoft analytical ecosystem data stores on Azure.

Azure Synapse Spark pool notebooks support autoscaling and auto-termination to reduce total cost of ownership (TCO). Data scientists can use the MLflow open-source framework to manage the machine learning lifecycle.

ML.NET

ML.NET is an open-source, cross-platform machine learning framework for Windows, Linux, macOS. Microsoft created ML.NET so that .NET developers can use existing tools, such as ML.NET Model Builder for Visual Studio, to develop custom machine learning models and integrate them into their .NET applications.

> **TIP**
> Microsoft has extended its machine learning capability to .NET developers.

.NET for Apache Spark

.NET for Apache Spark extends Spark support beyond R, Scala, Python, and Java to .NET and aims to make Spark accessible to .NET developers across all Spark APIs. While .NET for Apache Spark is currently only available on Apache Spark in HDInsight, Microsoft intends to make .NET for Apache Spark available on Azure Synapse Spark pool notebooks.

Use Azure Synapse Analytics with your data warehouse

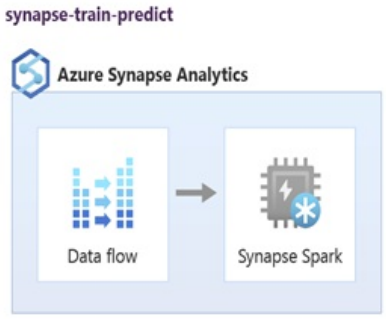
To combine machine learning models with Azure Synapse, you can:

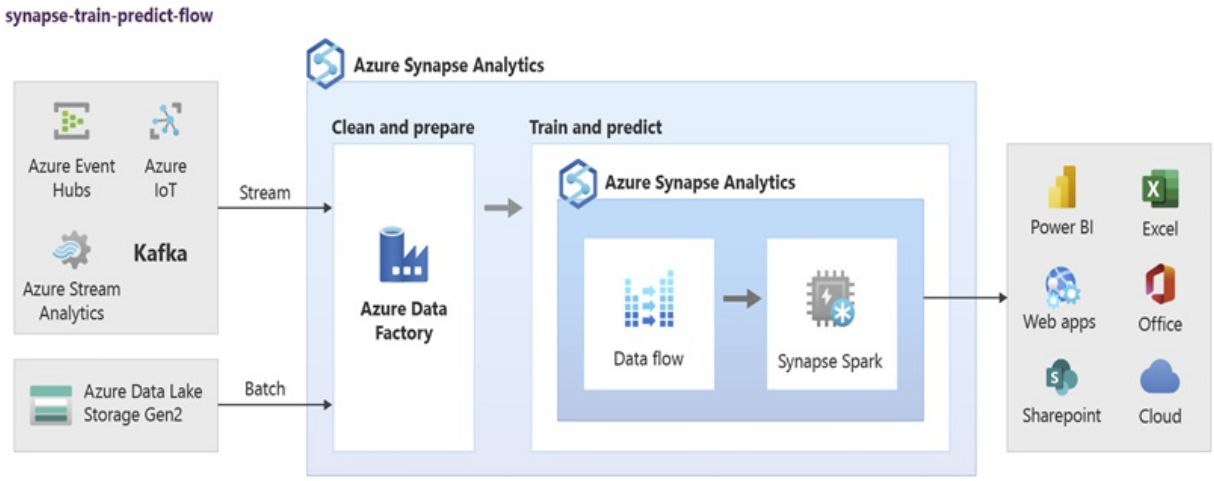
- Use machine learning models in batch or in real-time on streaming data to produce new insights, and add those insights to what you already know in Azure Synapse.
- Use the data in Azure Synapse to develop and train new predictive models for deployment elsewhere, such as in other applications.
- Deploy machine learning models, including models trained elsewhere, in Azure Synapse to analyze data in your data warehouse and drive new business value.

> **TIP**
> Train, test, evaluate, and run machine learning models at scale on Azure Synapse Spark pool notebooks by using data in Azure Synapse.

Data scientists can use RStudio, Jupyter Notebooks, and Azure Synapse Spark pool notebooks together with Azure Machine Learning to develop machine learning models that run at scale on Azure Synapse Spark pool notebooks using data in Azure Synapse. For example, data scientists could create an unsupervised model to segment customers to drive different marketing campaigns. Use supervised machine learning to train a model to predict a specific outcome, such as to predict a customer's propensity to churn, or to recommend the next

best offer for a customer to try to increase their value. The following diagram shows how Azure Synapse can be used for Azure Machine Learning.





In another scenario, you can ingest social network or review website data into Data Lake Storage, then prepare and analyze the data at scale on an Azure Synapse Spark pool notebook using natural language processing to score customer sentiment about your products or brand. You can then add those scores to your data warehouse. By using big data analytics to understand the effect of negative sentiment on product sales, you add to what you already know in your data warehouse.

> **TIP**
> Produce new insights using machine learning on Azure in batch or in real-time and add to what you know in your data warehouse.

Integrate live streaming data into Azure Synapse Analytics

When analyzing data in a modern data warehouse, you must be able to analyze streaming data in real-time and join it with historical data in your data warehouse. An example is combining IoT data with product or asset data.

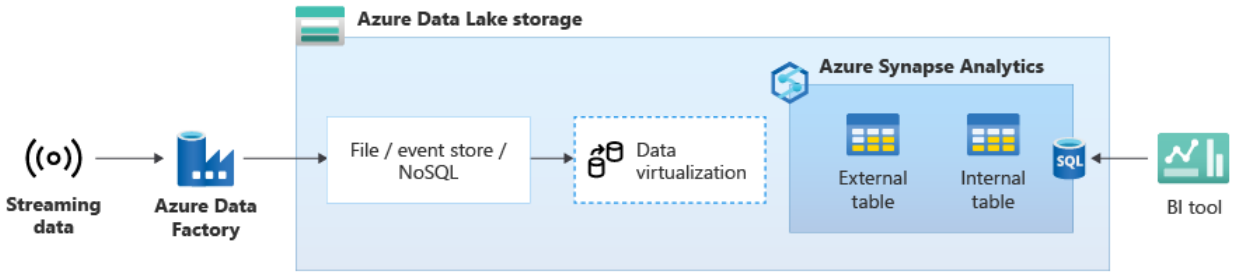
> **TIP**
> Integrate your data warehouse with streaming data from IoT devices or clickstreams.

Once you've successfully migrated your data warehouse to Azure Synapse, you can introduce live streaming data integration as part of a data warehouse modernization exercise by taking advantage of the extra functionality in Azure Synapse. To do so, ingest streaming data via Event Hubs, other technologies like Apache Kafka, or potentially your existing ETL tool if it supports the streaming data sources. Store the data in Data Lake Storage. Then, create an external table in Azure Synapse using PolyBase and point it at the data being streamed into Data Lake Storage so that your data warehouse now contains new tables that provide access to the real-time streaming data. Query the external table as if the data was in the data warehouse by using standard T-SQL

from any BI tool that has access to Azure Synapse. You can also join the streaming data to other tables with historical data to create views that join live streaming data to historical data to make it easier for business users to access the data.

> **TIP**
> Ingest streaming data into Data Lake Storage from Event Hubs or Apache Kafka, and access the data from Azure Synapse using PolyBase external tables.

In the following diagram, a real-time data warehouse on Azure Synapse is integrated with streaming data in Data Lake Storage.



Create a logical data warehouse using PolyBase

With PolyBase, you can create a logical data warehouse to simplify user access to multiple analytical data stores. Many companies have adopted "workload optimized" analytical data stores over the last several years in addition to their data warehouses. The analytical platforms on Azure include:

- Data Lake Storage with Azure Synapse Spark pool notebook (Spark as a service), for big data analytics.
- HDInsight (Hadoop as a service), also for big data analytics.
- NoSQL Graph databases for graph analysis, which could be done in Azure Cosmos DB.
- Event Hubs and Stream Analytics, for real-time analysis of data in motion.

You might have non-Microsoft equivalents of these platforms, or a master data management (MDM) system that needs to be accessed for consistent trusted data on customers, suppliers, products, assets, and more.

> **TIP**
> PolyBase simplifies access to multiple underlying analytical data stores on Azure for ease of access by business users.

Those analytical platforms emerged because of the explosion of new data sources inside and outside the enterprise and the demand by business users to capture and analyze the new data. The new data sources include:

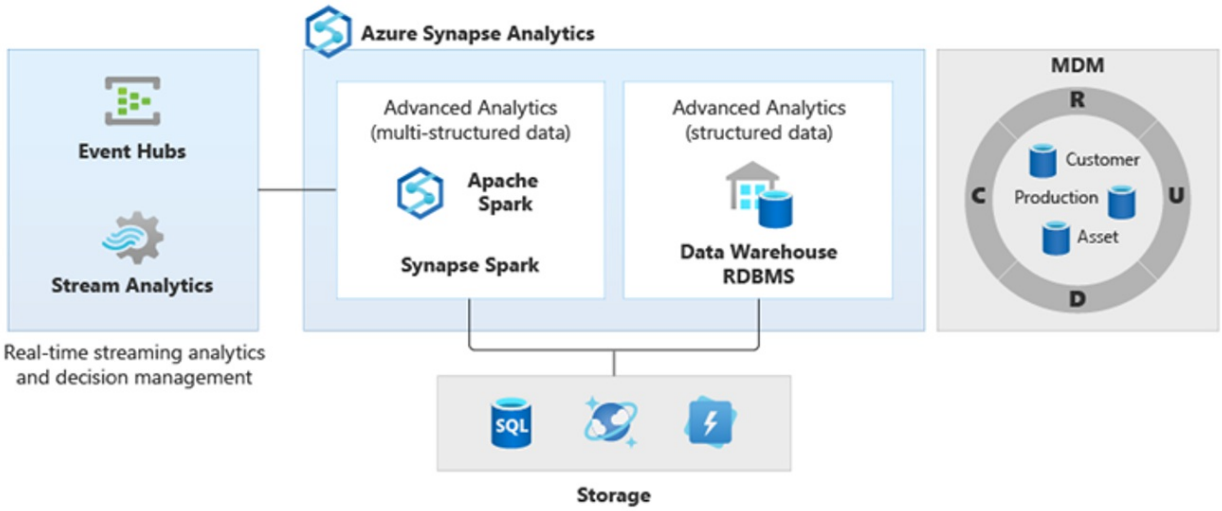
- Machine generated data, such as IoT sensor data and clickstream data.
- Human generated data, such as social network data, review web site data, customer inbound email, images, and video.
- Other external data, such as open government data and weather data.

This new data goes beyond the structured transaction data and main data sources that typically feed data warehouses and often includes:

- Semi-structured data like JSON, XML, or Avro.

- Unstructured data like text, voice, image, or video, which is more complex to process and analyze.
- High volume data, high velocity data, or both.

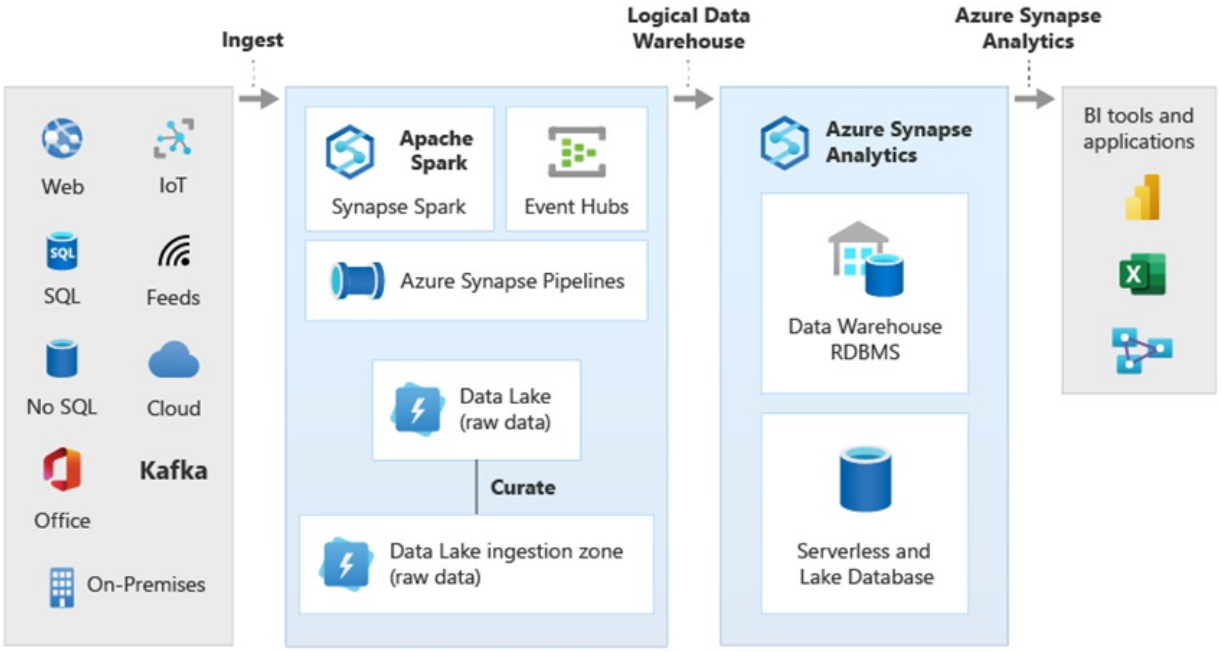
As a result, new more complex kinds of analysis have emerged, such as natural language processing, graph analysis, deep learning, streaming analytics, or complex analysis of large volumes of structured data. These kinds of analysis typically don't happen in a data warehouse, so it's not surprising to see different analytical platforms for different types of analytical workloads, as shown in the following diagram.



> **TIP**
> The ability to make data in multiple analytical data stores look like it's all in one system and join it to Azure Synapse is known as a logical data warehouse architecture.

Because these platforms produce new insights, it's normal to see a requirement to combine the new insights with what you already know in Azure Synapse, which is what PolyBase makes possible.

By using PolyBase data virtualization inside Azure Synapse, you can implement a logical data warehouse where data in Azure Synapse is joined to data in other Azure and on-premises analytical data stores like HDInsight, Azure Cosmos DB, or streaming data flowing into Data Lake Storage from Stream Analytics or Event Hubs. This approach lowers the complexity for users, who access external tables in Azure Synapse and don't need to know that the data they're accessing is stored in multiple underlying analytical systems. The following diagram shows a complex data warehouse structure accessed through comparatively simpler yet still powerful UI methods.



The diagram shows how other technologies in the Microsoft analytical ecosystem can be combined with the capability of the logical data warehouse architecture in Azure Synapse. For example, you can ingest data into Data Lake Storage and curate the data using Data Factory to create trusted data products that represent Microsoft lake database logical data entities. This trusted, commonly understood data can then be consumed and reused in different analytical environments such as Azure Synapse, Azure Synapse Spark pool notebooks, or Azure Cosmos DB. All insights produced in these environments are accessible via a logical data warehouse data virtualization layer made possible by PolyBase.

> **TIP**
> A logical data warehouse architecture simplifies business user access to data and adds new value to what you already know in your data warehouse.

Conclusions

After you migrate your data warehouse to Azure Synapse, you can take advantage of other technologies in the Microsoft analytical ecosystem. By doing so, you not only modernize your data warehouse, but bring insights produced in other Azure analytical data stores into an integrated analytical architecture.

You can broaden your ETL processing to ingest data of any type into Data Lake Storage, and then prepare and integrate the data at scale using Data Factory to produce trusted, commonly understood data assets. Those assets can be consumed by your data warehouse and accessed by data scientists and other applications. You can build real-time and batch oriented analytical pipelines and create machine learning models to run in batch, in real-time on streaming data, and on-demand as a service.

You can use PolyBase or `COPY INTO` to go beyond your data warehouse to simplify access to insights from multiple underlying analytical platforms on Azure. To do so, create holistic integrated views in a logical data warehouse that support access to streaming, big data, and traditional data warehouse insights from BI tools and applications.

By migrating your data warehouse to Azure Synapse, you can take advantage of the rich Microsoft analytical ecosystem running on Azure to drive new value in your business.

Azure Synapse Analytics.

Azure Synapse Analytics security white paper: Introduction

8/19/2022 • 5 minutes to read • Edit Online

Summary: Azure Synapse Analytics is a Microsoft limitless analytics platform that integrates enterprise data warehousing and big data processing into a single managed environment with no system integration required. Azure Synapse provides the end-to-end tools for your analytic life cycle with:

- Pipelines for data integration.
- Apache Spark pool for big data processing.
- Data Explorer for log and time series analytics.
- Serverless SQL pool for data exploration over Azure Data Lake.
- Dedicated SQL pool (formerly SQL DW) for enterprise data warehousing.
- Deep integration with Power BI, Azure Cosmos DB, and Azure Machine Learning.

Azure Synapse data security and privacy are non-negotiable. The purpose of this white paper is to provide a comprehensive overview of Azure Synapse security features, which are enterprise-grade and industry-leading. The white paper comprises a series of articles that cover the following five layers of security:

- Data protection
- Access control
- Authentication
- Network security
- Threat protection

This white paper targets all enterprise security stakeholders. They include security administrators, network administrations, Azure administrators, workspace administrators, and database administrators.

Writers: Vengatesh Parasuraman, Fretz Nuson, Ron Dunn, Khendr'a Reid, John Hoang, Nithesh Krishnappa, Mykola Kovalenko, Brad Schacht, Pedro Martinez, Mark Pryce-Maher, and Arshad Ali.

Technical Reviewers: Nandita Valsan, Rony Thomas, Abhishek Narain, Daniel Crawford, and Tammy Richter Jones.

Applies to: Azure Synapse Analytics, dedicated SQL pool (formerly SQL DW), serverless SQL pool, and Apache Spark pool.

> **IMPORTANT**
> This white paper does not apply to Azure SQL Database, Azure SQL Managed Instance, Azure Machine Learning, or Azure Databricks.

Introduction

Frequent headlines of data breaches, malware infections, and malicious code injection are among an extensive list of security concerns for companies looking to cloud modernization. The enterprise customer requires a cloud provider or service solution that can address their concerns as they can't afford to get it wrong.

Some common security questions include:

- How can I control who can see what data?
- What are the options for verifying a user's identity?
- How is my data protected?
- What network security technology can I use to protect the integrity, confidentiality, and access of my networks and data?
- What are the tools that detect and notify me of threats?

The purpose of this white paper is to provide answers to these common security questions, and many others.

Component architecture

Azure Synapse is a Platform-as-a-service (PaaS) analytics service that brings together multiple independent components such as dedicated SQL pools, serverless SQL pools, Apache Spark pools, and data integration pipelines. These components are designed to work together to provide a seamless analytical platform experience.

Dedicated SQL pools are provisioned clusters that provide enterprise data warehousing capabilities for SQL workloads. Data is ingested into managed storage powered by Azure Storage, which is also a PaaS service. Compute is isolated from storage enabling customers to scale compute independently of their data. Dedicated SQL pools also provide the ability to query data files directly over customer-managed Azure Storage accounts by using external tables.

Serverless SQL pools are on-demand clusters that provide a SQL interface to query and analyze data directly over customer-managed Azure Storage accounts. Since they're serverless, there's no managed storage, and the compute nodes scale automatically in response to the query workload.

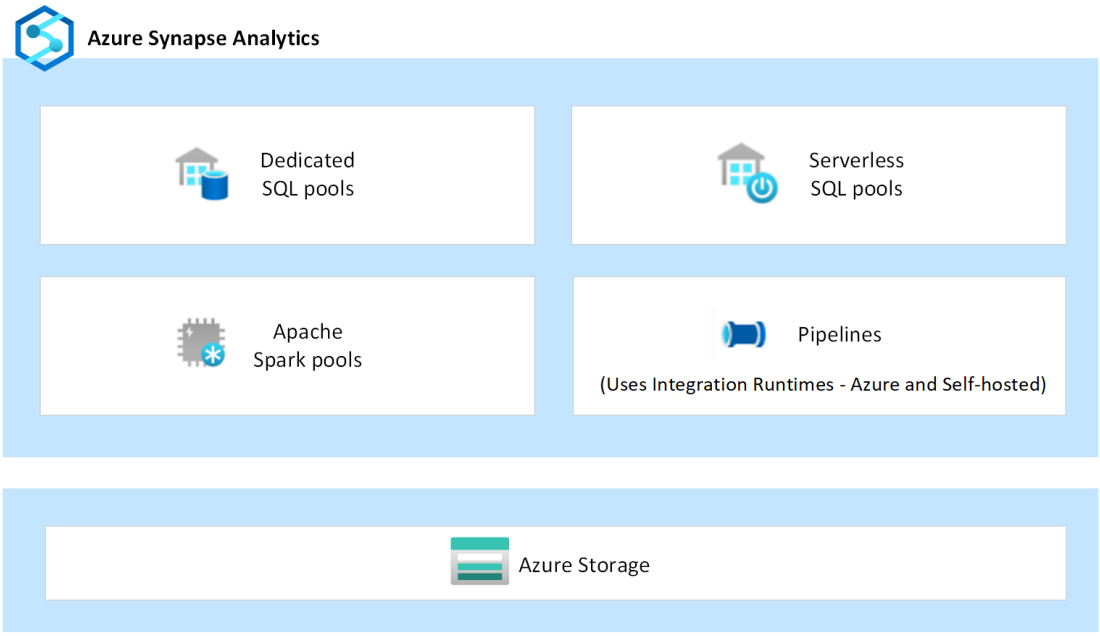
Apache Spark in Azure Synapse is one of Microsoft's implementations of open-source Apache Spark in the cloud. Spark instances are provisioned on-demand based on the metadata configurations defined in the Spark pools. Each user gets their own dedicated Spark instance for running their jobs. The data files processed by the Spark instances are managed by the customer in their own Azure Storage accounts.

Pipelines are a logical grouping of activities that perform data movement and data transformation at scale. Data flow is a transformation activity in a pipeline that's developed by using a low-code user interface. It can execute data transformations at scale. Behind the scenes, data flows use Apache Spark clusters of Azure Synapse to execute automatically generated code. Pipelines and data flows are compute-only services, and they don't have any managed storage associated with them.

Pipelines use the Integration Runtime (IR) as the scalable compute infrastructure for performing data movement and dispatch activities. Data movement activities run on the IR whereas the dispatch activities run on variety of other compute engines, including Azure SQL Database, Azure HDInsight, Azure Databricks, Apache Spark clusters of Azure Synapse, and others. Azure Synapse supports two types of IR: Azure Integration Runtime and Self-hosted Integration Runtime. The Azure IR provides a fully managed, scalable, and on-demand compute infrastructure. The Self-hosted IR is installed and configured by the customer in their own network, either in on-premises machines or in Azure cloud virtual machines.

Customers can choose to associate their Synapse workspace with a managed workspace virtual network. When associated with a managed workspace virtual network, Azure IRs and Apache Spark clusters that are used by pipelines, data flows, and the Apache Spark pools are deployed inside the managed workspace virtual network. This setup ensures network isolation between the workspaces for pipelines and Apache Spark workloads.

The following diagram depicts the various components of Azure Synapse.



Component isolation

Each individual component of Azure Synapse depicted in the diagram provides its own security features. Security features provide data protection, access control, authentication, network security, and threat protection for securing the compute and the associated data that's processed. Additionally, Azure Storage, being a PaaS service, provides additional security of its own, that's set up and managed by the customer in their own storage accounts. This level of component isolation limits and minimizes the exposure if there were a security vulnerability in any one of its components.

Security layers

Azure Synapse implements a multi-layered security architecture for end-to-end protection of your data. There are five layers:

- **Data protection** to identify and classify sensitive data, and encrypt data at rest and in motion.
- **Access control** to determine a user's right to interact with data.
- **Authentication** to prove the identity of users and applications.
- **Network security** to isolate network traffic with private endpoints and virtual private networks.
- **Threat protection** to identify potential security threats, such as unusual access locations, SQL injection attacks, authentication attacks, and more.

Next steps

In the next article in this white paper series, learn about data protection.

Azure Synapse Analytics security white paper: Data protection

NOTE

This article forms part of the *Azure Synapse Analytics security white paper* series of articles. For an overview of the series, see Azure Synapse Analytics security white paper.

Data discovery and classification

Organizations need to protect their data to comply with federal, local, and company guidelines to mitigate risks of data breach. One challenge organizations face is: *How do you protect the data if you don't know where it is?* Another is: *What level of protection is needed?*—because some datasets require more protection than others.

Imagine an organization with hundreds or thousands of files stored in their data lake, and hundreds or thousands of tables in their databases. It would benefit from a process that automatically scans every row and column of the file system or table and classifies columns as *potentially* sensitive data. This process is known as *data discovery*.

Once the data discovery process is complete, it provides classification recommendations based on a predefined set of patterns, keywords, and rules. Someone can then review the recommendations and apply sensitivity-classification labels to appropriate columns. This process is known as *classification*.

Azure Synapse provides two options for data discovery and classification:

- Data Discovery & Classification, which is built into Azure Synapse and dedicated SQL pool (formerly SQL DW).
- Microsoft Purview, which is a unified data governance solution that helps manage and govern on-premises, multicloud, and software-as-a-service (SaaS) data. It can automate data discovery, lineage identification, and data classification. By producing a unified map of data assets and their relationships, it makes data easily discoverable.

NOTE

Microsoft Purview data discovery and classification is in public preview for Azure Synapse, dedicated SQL pool (formerly SQL DW), and serverless SQL pool. However, data lineage is currently not supported for Azure Synapse, dedicated SQL pool (formerly SQL DW), and serverless SQL pool. Apache Spark pool only supports lineage tracking.

Data encryption

Data is encrypted at rest and in transit.

Data at rest

By default, Azure Storage automatically encrypts all data using 256-bit Advanced Encryption Standard encryption (AES 256). It's one of the strongest block ciphers available and is FIPS 140-2 compliant. The platform manages the encryption key, and it forms the *first layer* of data encryption. This encryption applies to both user and system databases, including the **master** database.

Enabling Transparent Data Encryption (TDE) can add a *second layer* of data encryption for dedicated SQL pools. It performs real-time I/O encryption and decryption of database files, transaction logs files, and backups at rest without requiring any changes to the application. By default, it uses AES 256.

By default, TDE protects the database encryption key (DEK) with a built-in server certificate (service managed). There's an option to bring your own key (BYOK) that can be securely stored in Azure Key Vault.

Azure Synapse SQL serverless pool and Apache Spark pool are analytic engines that work directly on Azure Data Lake Gen2 (ALDS Gen2) or Azure Blob Storage. These analytic runtimes don't have any permanent storage and rely on Azure Storage encryption technologies for data protection. By default, Azure Storage encrypts all data using server-side encryption (SSE). It's enabled for all storage types (including ADLS Gen2) and cannot be disabled. SSE encrypts and decrypts data transparently using AES 256.

There are two SSE encryption options:

- **Microsoft-managed keys:** Microsoft manages every aspect of the encryption key, including key storage, ownership, and rotations. It's entirely transparent to customers.
- **Customer-managed keys:** In this case, the symmetric key used to encrypt data in Azure Storage is encrypted using a customer-provided key. It supports RSA and RSA-HSM (Hardware Security Modules) keys of sizes 2048, 3072, and 4096. Keys can be securely stored in Azure Key Vault or Azure Key Vault Managed HSM. It provides fine grain access control of the key and its management, including storage, backup, and rotations. For more information, see Customer-managed keys for Azure Storage encryption.

While SSE forms the first layer of encryption, cautious customers can double encrypt by enabling a second layer of 256-bit AES encryption at the Azure Storage infrastructure layer. Known as *infrastructure encryption*, it uses a platform-managed key together with a separate key from SSE. So, data in the storage account is encrypted twice; once at the service level and once at the infrastructure level with two different encryption algorithms and different keys.

Data in transit

Azure Synapse, dedicated SQL pool (formerly SQL DW), and serverless SQL pool use the Tabular Data Stream (TDS) protocol to communicate between the SQL pool endpoint and a client machine. TDS depends on Transport Layer Security (TLS) for channel encryption, ensuring all data packets are secured and encrypted between endpoint and client machine. It uses a signed server certificate from the Certificate Authority (CA) used for TLS encryption, managed by Microsoft. Azure Synapse supports data encryption in transit with TLS v1.2, using AES 256 encryption.

Azure Synapse leverages TLS to ensure data is encrypted in motion. SQL dedicated pools support TLS 1.0, TLS 1.1, and TLS 1.2 versions for encryption wherein Microsoft-provided drivers use TLS 1.2 by default. Serverless SQL pool and Apache Spark pool use TLS 1.2 for all outbound connections.

In the next article in this white paper series, learn about access control.

Azure Synapse Analytics security white paper: Access control

8/19/2022 • 3 minutes to read • Edit Online

NOTE

This article forms part of the *Azure Synapse Analytics security white paper* series of articles. For an overview of the series, see Azure Synapse Analytics security white paper.

Depending on how the data has been modeled and stored, data governance and access control might require that developers and security administrators use different approaches, or combination of techniques, to implement a robust security foundation.

Azure Synapse supports a wide range of capabilities to control who can access what data. These capabilities are built upon a set of advanced access control features, including:

- Object-level security
- Row-level security
- Column-level security
- Dynamic data masking
- Synapse role-based access control

Object-level security

Every object in a dedicated SQL pool has associated permissions that can be granted to a principal. In the context of users and service accounts, that's how individual tables, views, stored procedures, and functions are secured. Object permissions, like SELECT, can be granted to user accounts (SQL logins, Azure Active Directory users or groups) and database roles, which provides flexibility for database administrators. Further, permissions granted on tables and views can be combined with other access control mechanisms (described below), such as column-level security, row-level security, and dynamic data masking.

In Azure Synapse, all permissions are granted to database-level users and roles. Additionally, any user granted the built-in Synapse Administrator RBAC role at the workspace level is automatically granted full access to all dedicated SQL pools.

In addition to securing SQL tables in Azure Synapse, dedicated SQL pool (formerly SQL DW), serverless SQL pool, and Spark tables can be secured too. By default, users assigned to the **Storage Blob Data Contributor** role of data lakes connected to the workspace have READ, WRITE, and EXECUTE permissions on all Spark-created tables *when users interactively execute code in notebook*. It's called *Azure Active Directory (Azure AD) pass-through*, and it applies to all data lakes connected to the workspace. However, if the same user executes the same notebook *through a pipeline*, the workspace Managed Service Identity (MSI) is used for authentication. So, for the pipeline to successfully execute workspace MSI, it must also belong to the **Storage Blob Data Contributor** role of the data lake that's accessed.

Row-level security

Row-level security allows security administrators to establish and control fine grained access to specific table rows based on the profile of a user (or a process) running a query. Profile or user characteristics may refer to group membership or execution context. Row-level security helps prevent unauthorized access when users

query data from the same tables but must see different subsets of data.

> **NOTE**
> Row-level security is supported in Azure Synapse and dedicated SQL pool (formerly SQL DW), but it's not supported for Apache Spark pool and serverless SQL pool.

Column-level security

Column-level security allows security administrators to set permissions that limit who can access sensitive columns in tables. It's set at the database level and can be implemented without the need to change the design of the data model or application tier.

> **NOTE**
> Column-level security is supported in Azure Synapse and dedicated SQL pool (formerly SQL DW), but it's not supported for Apache Spark pool and serverless SQL pool.

Dynamic data masking

Dynamic data masking allows security administrators to restrict sensitive data exposure by masking it on read to non-privileged users. It helps prevent unauthorized access to sensitive data by enabling administrators to determine how the data is displayed at query time. Based on the identity of the authenticated user and their group assignment in the SQL pool, a query returns either masked or unmasked data. Masking is always applied regardless of whether data is accessed directly from a table or by using a view or stored procedure.

> **NOTE**
> Dynamic data masking is supported in Azure Synapse and dedicated SQL pool (formerly SQL DW), but it's not supported for Apache Spark pool and serverless SQL pool.

Synapse role-based access control

Azure Synapse also includes Synapse role-based access control (RBAC) roles to manage different aspects of Synapse Studio. Leverage these built-in roles to assign permissions to users, groups, or other security principals to manage who can:

- Publish code artifacts and list or access published code artifacts.
- Execute code on Apache Spark pools and integration runtimes.
- Access linked (data) services that are protected by credentials.
- Monitor or cancel job executions, review job output and execution logs.

Next steps

In the next article in this white paper series, learn about authentication.

Azure Synapse Analytics security white paper: Authentication

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse Analytics security white paper* series of articles. For an overview of the series, see Azure Synapse Analytics security white paper.

Authentication is the process of proving the user is who they claim to be. Authentication activities can be logged with Azure SQL Auditing, and an IT administrator can configure reports and alerts whenever a login from a suspicious location is attempted.

Benefits

Some of the benefits of these robust authentication mechanisms include:

- Strong password policies to deter brute force attacks.
- User password encryption.
- Firewall rules.
- SQL endpoints with Multi-factor authentication.
- Elimination of the need to manage credentials with managed identity.

Azure Synapse, dedicated SQL pool (formerly SQL DW), and serverless SQL pool currently support Azure Active Directory (Azure AD) authentication and SQL authentication, while Apache Spark pool supports only Azure AD authentication. Multi-factor authentication and managed identity are fully supported for Azure Synapse, dedicated SQL pool (formerly SQL DW), serverless SQL pool, and Apache Spark pool.

In the next article in this white paper series, learn about network security.

Azure Synapse Analytics security white paper: Network security

8/19/2022 • 12 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse Analytics security white paper* series of articles. For an overview of the series, see Azure Synapse Analytics security white paper.

To secure Azure Synapse, there are a range of network security options to consider.

Network security terminology

This opening section provides an overview and definitions of some of key Azure Synapse terms related to network security. Keep these definitions in mind while reading this article.

Synapse workspace

A *Synapse workspace* is a securable logical collection of all services offered by Azure Synapse. It includes dedicated SQL pools (formerly SQL DW), serverless SQL pools, Apache Spark pools, pipelines, and other services. Certain network configuration settings, such as IP firewall rules, managed virtual network, and approved tenants for exfiltration protection, are configured and secured at the workspace level.

Synapse workspace endpoints

An endpoint is a point of an incoming connection to access a service. Each Synapse workspace has three distinct endpoints:

- **Dedicated SQL endpoint** for accessing dedicated SQL pools.
- **Serverless SQL endpoint** for accessing serverless SQL pools.
- **Development endpoint** for accessing Apache Spark pools and pipeline resources in the workspace.

These endpoints are automatically created when the Synapse workspace is created.

Synapse Studio

Synapse Studio is a secure web front-end development environment for Azure Synapse. It supports various roles, including the data engineer, data scientist, data developer, data analyst, and Synapse administrator.

Use Synapse Studio to perform various data and management operations in Azure Synapse, such as:

- Connecting to dedicated SQL pools, serverless SQL pools, and running SQL scripts.
- Developing and running notebooks on Apache Spark pools.
- Developing and running pipelines.
- Monitoring dedicated SQL pools, serverless SQL pools, Apache Spark pools, and pipeline jobs.
- Managing Synapse RBAC permissions of workspace items.
- Creating managed private endpoint connections to data sources and sinks.

Connections to workspace endpoints can be made using Synapse Studio. Also, it's possible to create private endpoints to ensure that communication to the workspace endpoints is private.

Public network access and firewall rules

By default, the workspace endpoints are *public endpoints* when they're provisioned. Access to these workspace endpoints from any public network is enabled, including networks that are outside the customer's organization, without requiring a VPN connection or an ExpressRoute connection to Azure.

All Azure services, including PaaS services like Azure Synapse, are protected by DDoS basic protection to mitigate malicious attacks (active traffic monitoring, always on detection, and automatic attack mitigations).

All traffic to workspace endpoints—even via public networks—is encrypted and secured in transit by Transport Level Security (TLS) protocol.

To protect any sensitive data, it's recommended to disable public access to the workspace endpoints entirely. By doing so, it ensures all workspace endpoints can only be accessed using private endpoints.

Disabling public access for all the Synapse workspaces in a subscription or a resource group is enforced by assigning an Azure Policy. It's also possible to disable public network access on per-workspace basis based on the sensitivity of data processed by the workspace.

However, if public access needs to be enabled, it's highly recommended to configure the IP firewall rules to allow inbound connections only from the specified list of public IP addresses.

Consider enabling public access when the on-premises environment doesn't have VPN access or ExpressRoute to Azure, and it requires access to the workspace endpoints. In this case, specify a list of public IP addresses of the on-premises data centers and gateways in the IP firewall rules.

Private endpoints

An Azure private endpoint is a virtual network interface with a private IP address that's created in the customer's own Azure Virtual Network (VNet) subnet. A private endpoint can be created for any Azure service that supports private endpoints, such as Azure Synapse, dedicated SQL pools (formerly SQL DW), Azure SQL Databases, Azure Storage, or any service in Azure powered by Azure Private Link service.

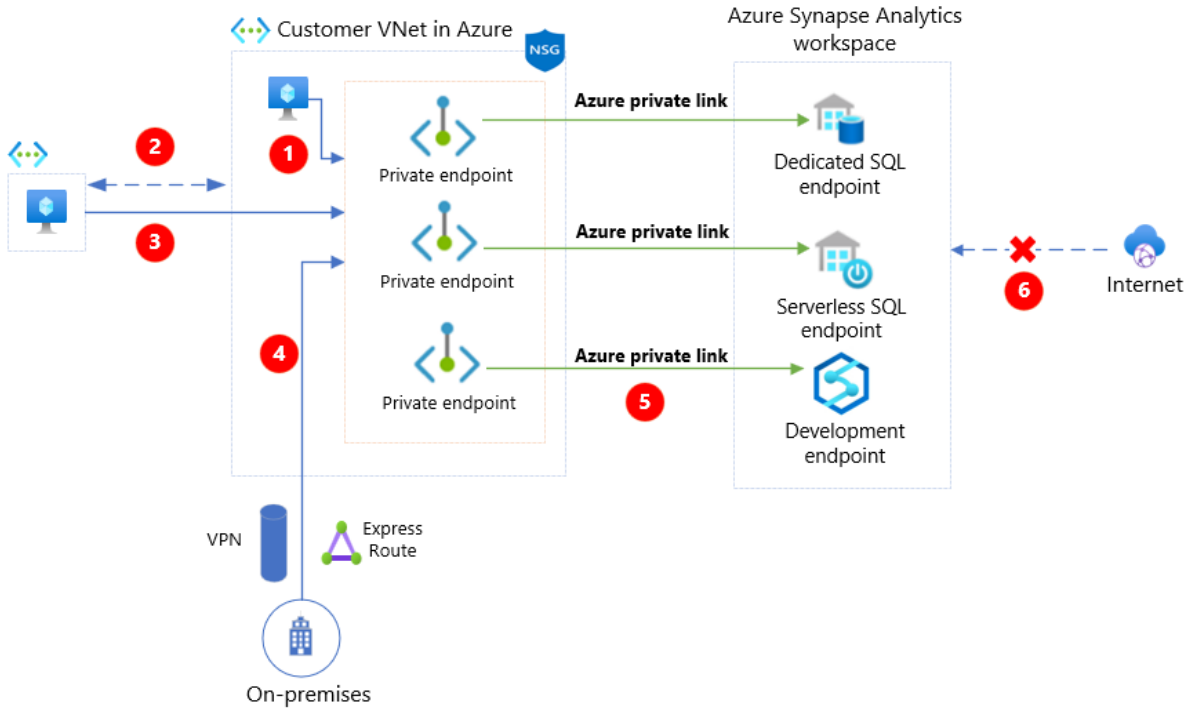
It's possible to create private endpoints in the VNet for all three Synapse workspace endpoints, individually. This way, there could be three private endpoints created for three endpoints of a Synapse workspace: one for dedicated SQL pool, one for serverless SQL pool, and one for the development endpoint.

Private endpoints have many security benefits compared to the public endpoints. Private endpoints in an Azure VNet can be accessed only from within:

- The same VNet that contains this private endpoint.
- Regionally or globally peered Azure VNets.
- On-premises networks connected to Azure via VPN Gateway or ExpressRoute.

The main benefit of private endpoints is that it's no longer necessary to expose workspace endpoints to the public internet. *The less exposure, the better.*

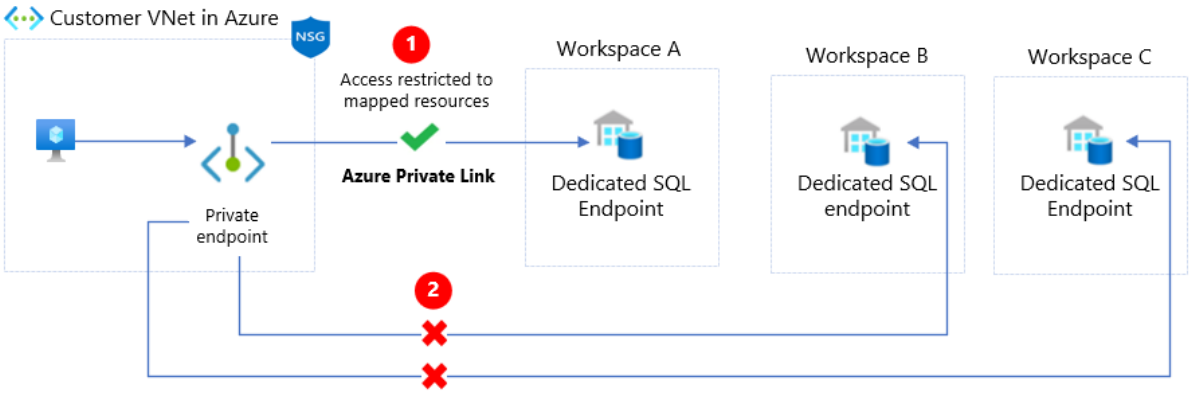
The following diagram depicts private endpoints.



The above diagram depicts the following key points:

ITEM	DESCRIPTION
1	Workstations from within the customer VNet access the Azure Synapse private endpoints.
2	Peering between customer VNet and another VNet.
3	Workstation from peered VNet access the Azure Synapse private endpoints.
4	On-premises network access the Azure Synapse private endpoints through VPN or ExpressRoute.
5	Workspace endpoints are mapped into customer's VNet through private endpoints using Azure Private Link service.
6	Public access is disabled on the Synapse workspace.

In the following diagram, a private endpoint is mapped to an instance of a PaaS resource instead of the entire service. In the event of a security incident within the network, only the mapped resource instance is exposed, minimizing the exposure and threat of data leakage and exfiltration.

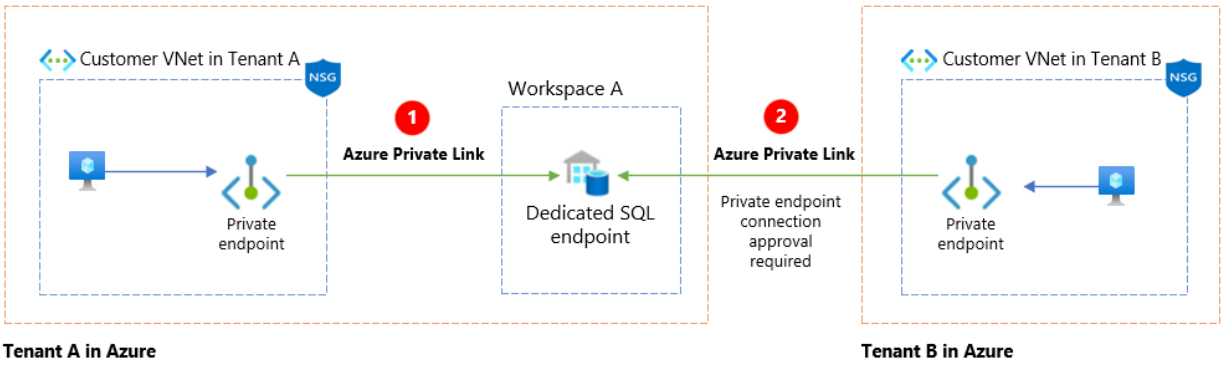


The above diagram depicts the following key points:

ITEM	DESCRIPTION
1	The private endpoint in the customer VNet is mapped to a single dedicated SQL pool (formerly SQL DW) endpoint in Workspace A.
2	Other SQL pool endpoints in the other workspaces (B and C) aren't accessible through this private endpoint, minimizing exposure.

Private endpoint works across Azure Active Directory (Azure AD) tenants and regions, so it's possible to create private endpoint connections to Synapse workspaces across tenants and regions. In this case, it goes through the private endpoint connection approval workflow. The resource owner controls which private endpoint connections are approved or denied. The resource owner is in full control of who can connect to their workspaces.

The following diagram depicts a private endpoint connection approval workflow.



The above diagram depicts the following key points:

ITEM	DESCRIPTION
1	Dedicated SQL pool (formerly SQL DW) in Workspace A in Tenant A is accessed by a private endpoint in the customer VNet in Tenant A.
2	The same dedicated SQL pool (formerly SQL DW) in Workspace A in Tenant A is accessed by a private endpoint in the customer VNet in Tenant B through a connection approval workflow.

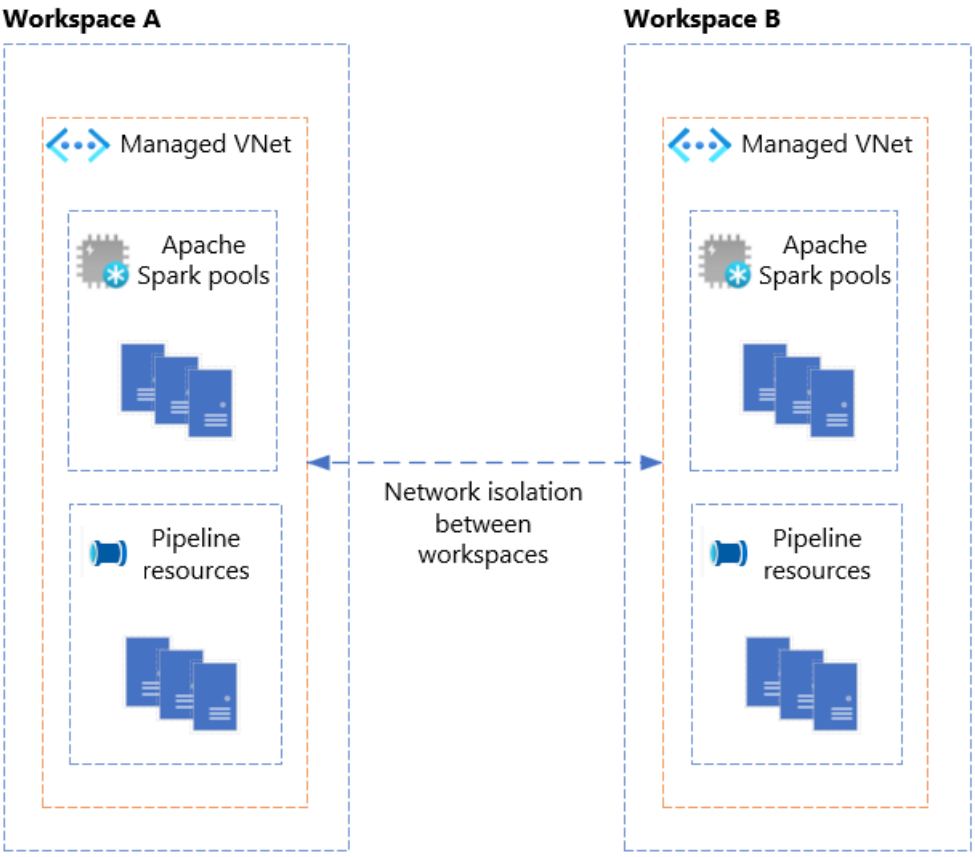
Managed VNet

The Synapse Managed VNet feature provides a fully managed network isolation for the Apache Spark pool and pipeline compute resources between Synapse workspaces. It can be configured at workspace creation time. In addition, it also provides network isolation for Spark clusters within the same workspace. Each workspace has its own virtual network, which is fully managed by Synapse. The Managed VNet isn't visible to the users to make any modifications. Any pipeline or Apache Spark pool compute resources that are spun up by Azure Synapse in a Managed VNet gets provisioned inside its own VNet. This way, there's full network isolation from other workspaces.

This configuration eliminates the need to create and manage VNets and network security groups for the Apache Spark pool and pipeline resources, as is typically done by VNet Injection.

As such, multi-tenant services in a Synapse workspace, such as dedicated SQL pools and serverless SQL pools, are **not** provisioned inside the Managed VNet.

The following diagram depicts network isolation between two Managed VNets of Workspaces A and B with their Apache Spark pools and pipeline resources inside the Managed VNets.



Managed private endpoint connection

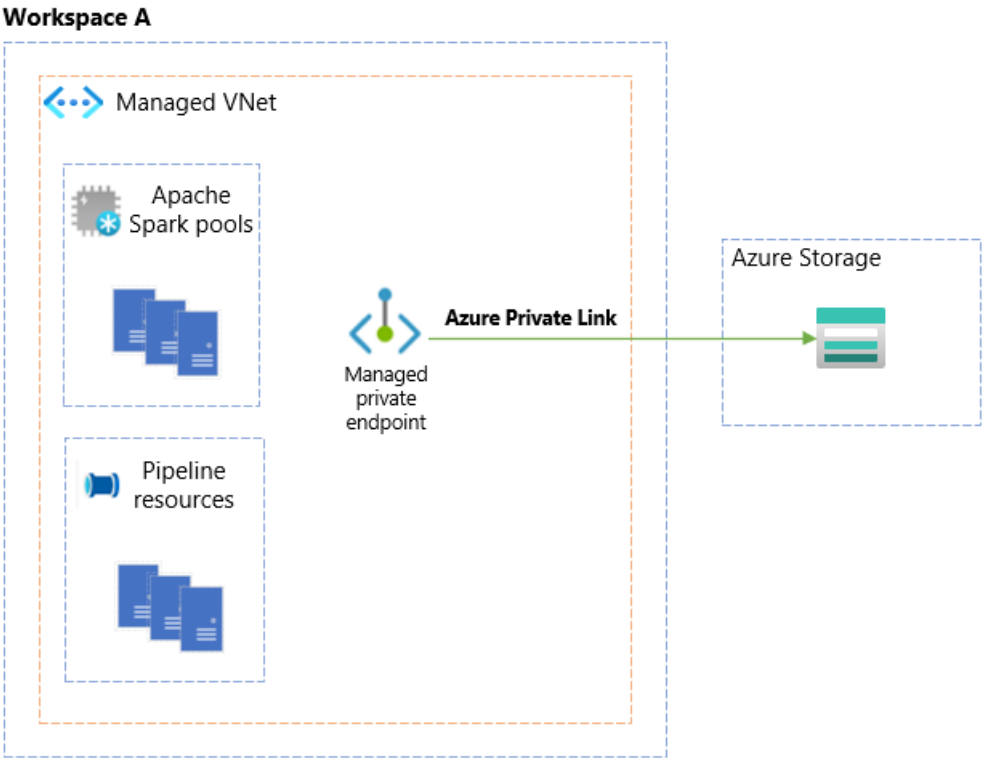
A managed private endpoint connection enables connections to any Azure PaaS service (that supports Private Link), securely and seamlessly, without the need to create a private endpoint for that service from the customer's VNet. Synapse automatically creates and manages the private endpoint. These connections are used by the compute resources that are provisioned inside the Synapse Managed VNet, such as Apache Spark pools and pipeline resources, to connect to the Azure PaaS services *privately*.

For example, if you want to connect to your Azure storage account *privately* from your pipeline, the usual approach is to create a private endpoint for the storage account and use a self-hosted integration runtime to connect to your storage private endpoint. With Synapse Managed VNets, you can privately connect to your

storage account using Azure integration runtime simply by creating a managed private endpoint connection directly to that storage account. This approach eliminates the need to have a self-hosted integration runtime to connect to your Azure PaaS services privately.

As such, multi-tenant services in a Synapse workspace, such as dedicated SQL pools and serverless SQL pools, are **not** provisioned inside the Managed VNet. So, they don't use the managed private endpoint connections created in the workspace for their outbound connectivity.

The following diagram depicts a managed private endpoint connecting to an Azure storage account from a Managed VNet in Workspace A.



Advanced Spark security

A Managed VNet also provides some added advantages for Apache Spark pool users. There's no need to worry about configuring a *fixed* subnet address space as would be done in VNet Injection. Azure Synapse automatically takes care of allocating these address spaces dynamically for workloads.

In addition, Spark pools operate as a job cluster. It means each user gets their own Spark cluster when interacting with the workspace. Creating an Spark pool within the workspace is metadata information for what will be assigned to the user when executing Spark workloads. It means each user will get their own Spark cluster *in a dedicated subnet inside the Managed VNet* to execute workloads. Spark pool sessions from the same user execute on the same compute resources. By providing this functionality, there are three main benefits:

- Greater security due to workload isolation based on the user.
- Reduction of noisy neighbors.
- Greater performance.

Data exfiltration protection

Synapse workspaces with Managed VNet have an additional security feature called *data exfiltration protection*. It protects all egress traffic going out from Azure Synapse from all services, including dedicated SQL pools, serverless SQL pools, Apache spark pools, and pipelines. It's configured by enabling data exfiltration protection at the workspace level (at workspace creation time) to restrict the outbound connections to an allowed list of

Azure Active Directory (Azure AD) tenants. By default, only the home tenant of the workspace is added to the list, but it's possible to add or modify the list of Azure AD tenants anytime after the workspace is created. Adding additional tenants is a highly privileged operation that requires the elevated role of Synapse Administrator. It effectively controls exfiltration of data from Azure Synapse to other organizations and tenants, without the need to have complicated network security policies in place.

For workspaces with data exfiltration protection enabled, Synapse pipelines and Apache Spark pools must use managed private endpoint connections for all their outbound connections.

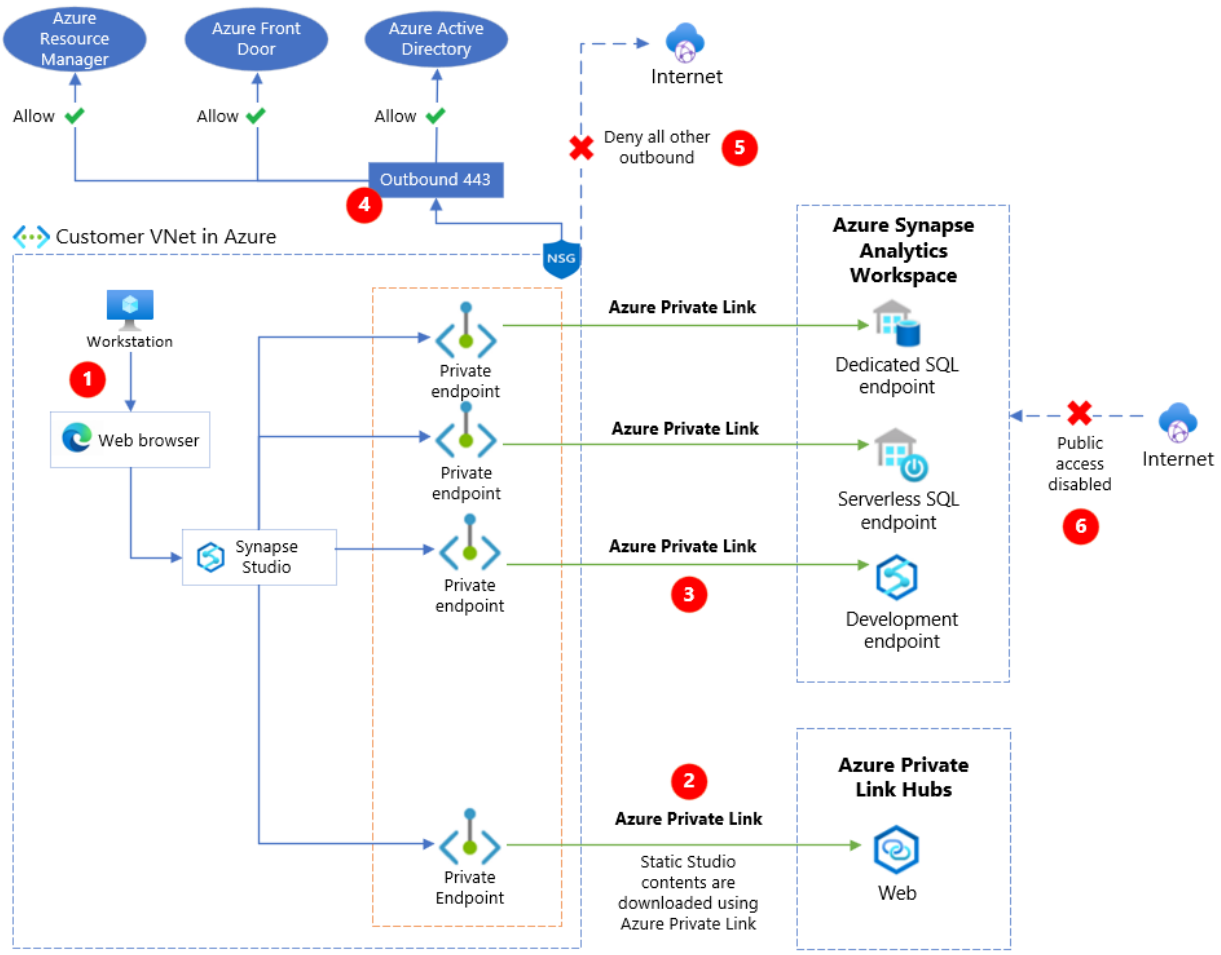
Dedicated SQL pool and serverless SQL pool don't use managed private endpoints for their outbound connectivity; however, any outbound connectivity from SQL pools can only be made to the *approved targets*, which are the targets of managed private endpoint connections.

Private link hubs for Synapse Studio

Synapse Private Link Hubs allows securely connecting to Synapse Studio from the customer's VNet using Azure Private Link. This feature is useful for customers who want to access the Synapse workspace using the Synapse Studio from a controlled and restricted environment, where the outbound internet traffic is restricted to a limited set of Azure services.

It's achieved by creating a private link hub resource and a private endpoint to this hub from the VNet. This private endpoint is then used to access the studio using its fully qualified domain name (FQDN), *web.azuresynapse.net*, with a private IP address from the VNet. The private link hub resource downloads the static contents of Synapse Studio over Azure Private Link to the user's workstation. In addition, separate private endpoints must be created for the individual workspace endpoints to ensure that communication to the workspace endpoints is private.

The following diagram depicts private link hubs for Synapse Studio.



The above diagram depicts the following key points:

ITEM	DESCRIPTION
1	The workstation in a restricted customer VNet accesses the Synapse Studio using a web browser.
2	A private endpoint created for private link hubs resource is used to download the static studio contents using Azure Private Link.
3	Private endpoints created for Synapse workspace endpoints access the workspace resources securely using Azure Private Links.
4	Network security group rules in the restricted customer VNet allow outbound traffic over port 443 to a limited set of Azure services, such as Azure Resource Manager, Azure Front Door, and Azure Active Directory.
5	Network security group rules in the restricted customer VNet deny all other outbound traffic from the VNet.
6	Public access is disabled on the Synapse workspace.

Dedicated SQL pool (formerly SQL DW)

Prior to the Azure Synapse offering, an Azure SQL data warehouse product named SQL DW was offered. It's now renamed as dedicated SQL pool (formerly SQL DW).

Dedicated SQL pool (formerly SQL DW) is created inside a logical Azure SQL server. It's a securable logical construct that acts as a central administrative point for a collection of databases including SQL DW and other Azure SQL databases.

Most of the core network security features discussed in the previous sections of this article for Azure Synapse are also applicable to dedicated SQL pool (formerly SQL DW). They include:

- IP firewall rules
- Disabling public network access
- Private endpoints
- Data exfiltration protection through outbound firewall rules

Since dedicated SQL pool (formerly SQL DW) is a multi-tenant service, it's not provisioned inside a Managed VNet. It means some of the features, such as Managed VNet and managed private endpoint connections, aren't applicable to it.

Network security feature matrix

The following comparison table provides a high-level overview of network security features supported across the Azure Synapse offerings:

FEATURE	AZURE SYNAPSE: APACHE SPARK POOL	AZURE SYNAPSE: DEDICATED SQL POOL	AZURE SYNAPSE: SERVERLESS SQL POOL	DEDICATED SQL POOL (FORMERLY SQL DW)
IP firewall rules	Yes	Yes	Yes	Yes
Disabling public access	Yes	Yes	Yes	Yes
Private endpoints	Yes	Yes	Yes	Yes
Data exfiltration protection	Yes	Yes	Yes	Yes
Secure access using Synapse Studio	Yes	Yes	Yes	No
Access from restricted network using Synapse private link hub	Yes	Yes	Yes	No
Managed VNet and workspace-level network isolation	Yes	N/A	N/A	N/A
Managed private endpoint connections for outbound connectivity	Yes	N/A	N/A	N/A
User-level network isolation	Yes	N/A	N/A	N/A

Next steps

In the next article in this white paper series, learn about threat protection.

Azure Synapse Analytics security white paper: Threat detection

8/19/2022 • 2 minutes to read • Edit Online

> **NOTE**
> This article forms part of the *Azure Synapse Analytics security white paper* series of articles. For an overview of the series, see Azure Synapse Analytics security white paper.

Azure Synapse provides SQL Auditing, SQL Threat Detection, and Vulnerability Assessment to audit, protect, and monitor databases.

Auditing

Auditing for Azure SQL Database and Azure Synapse tracks database events and writes them to an audit log in an Azure storage account, Log Analytics workspace, or Event Hubs. For any database, auditing is important. It produces an audit trail over time to help understand database activity and gain insight into discrepancies and anomalies that could indicate business concerns or suspected security violations. Used with Data discovery and classification, when any sensitive columns or tables are queried by users, entries will appear in a field named **data_sensitivity_information** of the **sql_audit_information** table.

> **NOTE**
> Azure SQL Auditing applies to Azure Synapse, dedicated SQL pool (formerly SQL DW), and serverless SQL pool, but it doesn't apply to Apache Spark pool.

Threat detection

Microsoft Defender for Cloud is a tool for security posture management and threat detection. It protects workloads running in Azure, including (but not exclusively) servers, app service, key vaults, Kubernetes services, storage accounts, and Azure SQL Databases.

As one of the options available with Microsoft Defender for Cloud, Microsoft Defender for SQL extends Defender for Cloud's data security package to secure databases. It can discover and mitigate potential database vulnerabilities by detecting anomalous activities that could be a potential threat to the database. Specifically, it continually monitors your database for:

- Potential SQL injection attacks
- Anomalous database access and queries
- Suspicious database activity

Alert notifications include details of the incident, and recommendations on how to investigate and remediate threats.

> **NOTE**
> Microsoft Defender for SQL applies to Azure Synapse and dedicated SQL pool (formerly SQL DW). It doesn't apply to serverless SQL pool or Apache Spark pool.

Vulnerability assessment

SQL vulnerability assessment is part of the Microsoft Defender for SQL offering. It continually monitors the data warehouse, ensuring that databases are always maintained at a high level of security and that organizational policies are met. It provides a comprehensive security report along with actionable remediation steps for each issue found, making it easy to proactively manage database security stature even if you're not a security expert.

> **NOTE**
> SQL vulnerability assessment applies to Azure Synapse and dedicated SQL pool (formerly SQL DW). It doesn't apply to serverless SQL pool or Apache Spark pool.

Compliance

For an overview of Azure compliance offerings, download the latest version of the Microsoft Azure Compliance Offerings document.

Database collation support for Synapse SQL in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Collations provide the locale, code page, sort order, and character sensitivity rules for character-based data types. Once chosen, all columns and expressions requiring collation information inherit the chosen collation from the database setting. The default inheritance can be overridden by explicitly stating a different collation for a character-based data type.

You can change the default database collation from the Azure portal when you create a new dedicated SQL pool database. This capability makes it even easier to create a new database using one of the 3800 supported database collations.

You can specify the default serverless SQL pool database collation at creation time using CREATE DATABASE statement.

> **NOTE**
> In Azure Synapse Analytics, query text (including variables, constants, etc.) is always handled using the database-level collation, and not the server-level collation as in other SQL Server offerings.

Change collation

To change the default collation for dedicated SQL pool database, update to the Collation field in the provisioning experience. For example, if you wanted to change the default collation to case sensitive, you would rename the Collation from SQL_Latin1_General_CP1_CI_AS to SQL_Latin1_General_CP1_CS_AS.

To change the default collation for a serverless SQL pool database, you can use ALTER DATABASE statement.

Check the current collation

To check the current collation for the database, you can run the following T-SQL snippet:

```
SELECT DATABASEPROPERTYEX(DB_NAME(), 'Collation') AS Collation;
```

When passed 'Collation' as the property parameter, the DatabasePropertyEx function returns the current collation for the database specified. You can learn more about the DatabasePropertyEx function on MSDN.

Introduction to Microsoft Spark Utilities

8/19/2022 • 16 minutes to read • Edit Online

Microsoft Spark Utilities (MSSparkUtils) is a builtin package to help you easily perform common tasks. You can use MSSparkUtils to work with file systems, to get environment variables, to chain notebooks together, and to work with secrets. MSSparkUtils are available in `PySpark (Python)`, `Scala`, and `.NET Spark (C#)` notebooks and Synapse pipelines.

Pre-requisites

Configure access to Azure Data Lake Storage Gen2

Synapse notebooks use Azure Active Directory (Azure AD) pass-through to access the ADLS Gen2 accounts. You need to be a **Storage Blob Data Contributor** to access the ADLS Gen2 account (or folder).

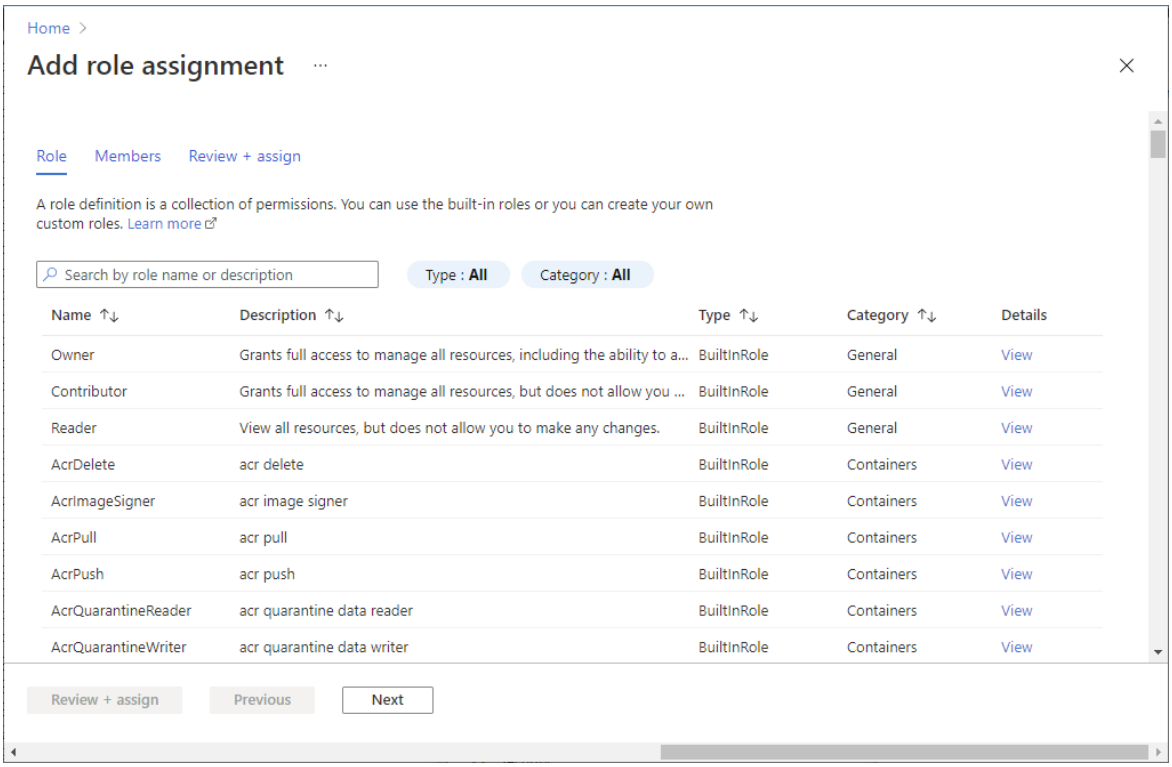
Synapse pipelines use workspace's Managed Service Identity (MSI) to access the storage accounts. To use MSSparkUtils in your pipeline activities, your workspace identity needs to be **Storage Blob Data Contributor** to access the ADLS Gen2 account (or folder).

Follow these steps to make sure your Azure AD and workspace MSI have access to the ADLS Gen2 account:

1. Open the Azure portal and the storage account you want to access. You can navigate to the specific container you want to access.
2. Select the **Access control (IAM)** from the left panel.
3. Select **Add** > **Add role assignment** to open the Add role assignment page.
4. Assign the following role. For detailed steps, see Assign Azure roles using the Azure portal.

SETTING	VALUE
Role	Storage Blob Data Contributor
Assign access to	USER and MANAGEDIDENTITY
Members	your Azure AD account and your workspace identity

> **NOTE**
> The managed identity name is also the workspace name.



5. Select **Save**.

You can access data on ADLS Gen2 with Synapse Spark via the following URL:

```
abfss://<container_name>@<storage_account_name>.dfs.core.windows.net/<path>
```

Configure access to Azure Blob Storage

Synapse use **Shared access signature (SAS)** to access Azure Blob Storage. To avoid exposing SAS keys in the code, we recommend creating a new linked service in Synapse workspace to the Azure Blob Storage account you want to access.

Follow these steps to add a new linked service for an Azure Blob Storage account:

1. Open the Azure Synapse Studio.
2. Select **Manage** from the left panel and select **Linked services** under the **External connections**.
3. Search **Azure Blob Storage** in the **New linked Service** panel on the right.
4. Select **Continue**.
5. Select the Azure Blob Storage Account to access and configure the linked service name. Suggest using **Account key** for the **Authentication method**.
6. Select **Test connection** to validate the settings are correct.
7. Select **Create** first and click **Publish all** to save your changes.

You can access data on Azure Blob Storage with Synapse Spark via following URL:

```
wasb[s]://<container_name>@<storage_account_name>.blob.core.windows.net/<path>
```

Here is a code example:

```
from pyspark.sql import SparkSession

# Azure storage access info
blob_account_name = 'Your account name' # replace with your blob name
blob_container_name = 'Your container name' # replace with your container name
blob_relative_path = 'Your path' # replace with your relative folder path
linked_service_name = 'Your linked service name' # replace with your linked service name

blob_sas_token = mssparkutils.credentials.getConnectionStringOrCreds(linked_service_name)

# Allow SPARK to access from Blob remotely

wasb_path = 'wasbs://%s@%s.blob.core.windows.net/%s' % (blob_container_name, blob_account_name,
blob_relative_path)

spark.conf.set('fs.azure.sas.%s.%s.blob.core.windows.net' % (blob_container_name, blob_account_name),
blob_sas_token)
print('Remote blob path: ' + wasb_path)
```

```
val blob_account_name = "" // replace with your blob name
val blob_container_name = "" //replace with your container name
val blob_relative_path = "/" //replace with your relative folder path
val linked_service_name = "" //replace with your linked service name

val blob_sas_token = mssparkutils.credentials.getConnectionStringOrCreds(linked_service_name)

val wasbs_path =
f"wasbs://$blob_container_name@$blob_account_name.blob.core.windows.net/$blob_relative_path"
spark.conf.set(f"fs.azure.sas.$blob_container_name.$blob_account_name.blob.core.windows.net",blob_sas_token)
```

```
var blob_account_name = "";  // replace with your blob name
var blob_container_name = "";     // replace with your container name
var blob_relative_path = "";  // replace with your relative folder path
var linked_service_name = "";    // replace with your linked service name
var blob_sas_token = Credentials.GetConnectionStringOrCreds(linked_service_name);

spark.SparkContext.GetConf().Set($"fs.azure.sas.{blob_container_name}.
{blob_account_name}.blob.core.windows.net", blob_sas_token);

var wasbs_path =
$"wasbs://{blob_container_name}@{blob_account_name}.blob.core.windows.net/{blob_relative_path}";

Console.WriteLine(wasbs_path);
```

Configure access to Azure Key Vault

You can add an Azure Key Vault as a linked service to manage your credentials in Synapse. Follow these steps to add an Azure Key Vault as a Synapse linked service:

1. Open the Azure Synapse Studio.
2. Select **Manage** from the left panel and select **Linked services** under the **External connections**.
3. Search **Azure Key Vault** in the **New linked Service** panel on the right.
4. Select the Azure Key Vault Account to access and configure the linked service name.
5. Select **Test connection** to validate the settings are correct.
6. Select **Create** first and click **Publish all** to save your change.

Synapse notebooks use Azure active directory(Azure AD) pass-through to access Azure Key Vault. Synapse

pipelines use workspace identity(MSI) to access Azure Key Vault. To make sure your code work both in notebook and in Synapse pipeline, we recommend granting secret access permission for both your Azure AD account and workspace identity.

Follow these steps to grant secret access to your workspace identity:

1. Open the Azure portal and the Azure Key Vault you want to access.
2. Select the **Access policies** from the left panel.
3. Select **Add Access Policy**:
   - Choose **Key, Secret, & Certificate Management** as config template.
   - Select **your Azure AD account** and **your workspace identity** (same as your workspace name) in the select principal or make sure it is already assigned.
4. Select **Select** and **Add**.
5. Select the **Save** button to commit changes.

File system utilities

`mssparkutils.fs` provides utilities for working with various file systems, including Azure Data Lake Storage Gen2 (ADLS Gen2) and Azure Blob Storage. Make sure you configure access to Azure Data Lake Storage Gen2 and Azure Blob Storage appropriately.

Run the following commands for an overview of the available methods:

```
from notebookutils import mssparkutils
mssparkutils.fs.help()
```

```
mssparkutils.fs.help()
```

```
using Microsoft.Spark.Extensions.Azure.Synapse.Analytics.Notebook.MSSparkUtils;
FS.Help()
```

Results in:

```
mssparkutils.fs provides utilities for working with various FileSystems.

Below is overview about the available methods:

cp(from: String, to: String, recurse: Boolean = false): Boolean -> Copies a file or directory, possibly
across FileSystems
mv(from: String, to: String, recurse: Boolean = false): Boolean -> Moves a file or directory, possibly
across FileSystems
ls(dir: String): Array -> Lists the contents of a directory
mkdirs(dir: String): Boolean -> Creates the given directory if it does not exist, also creating any
necessary parent directories
put(file: String, contents: String, overwrite: Boolean = false): Boolean -> Writes the given String out to a
file, encoded in UTF-8
head(file: String, maxBytes: int = 1024 * 100): String -> Returns up to the first 'maxBytes' bytes of the
given file as a String encoded in UTF-8
append(file: String, content: String, createFileIfNotExists: Boolean): Boolean -> Append the content to a
file
rm(dir: String, recurse: Boolean = false): Boolean -> Removes a file or directory

Use mssparkutils.fs.help("methodName") for more info about a method.
```

List files

List the content of a directory.

```
mssparkutils.fs.ls('Your directory path')
```

```
mssparkutils.fs.ls("Your directory path")
```

```
FS.Ls("Your directory path")
```

View file properties

Returns file properties including file name, file path, file size, and whether it is a directory and a file.

```
files = mssparkutils.fs.ls('Your directory path')
for file in files:
    print(file.name, file.isDir, file.isFile, file.path, file.size)
```

```
val files = mssparkutils.fs.ls("/")
files.foreach{
    file => println(file.name,file.isDir,file.isFile,file.size)
}
```

```
var Files = FS.Ls("/");
foreach(var File in Files) {
    Console.WriteLine(File.Name+" "+File.IsDir+" "+File.IsFile+" "+File.Size);
}
```

Create new directory

Creates the given directory if it does not exist and any necessary parent directories.

```
mssparkutils.fs.mkdirs('new directory name')
```

```
mssparkutils.fs.mkdirs("new directory name")
```

```
FS.Mkdirs("new directory name")
```

Copy file

Copies a file or directory. Supports copy across file systems.

```
mssparkutils.fs.cp('source file or directory', 'destination file or directory', True)# Set the third
parameter as True to copy all files and directories recursively
```

```
mssparkutils.fs.cp("source file or directory", "destination file or directory", true) // Set the third
parameter as True to copy all files and directories recursively
```

```
FS.Cp("source file or directory", "destination file or directory", true) // Set the third parameter as True to copy all files and directories recursively
```

Preview file content

Returns up to the first 'maxBytes' bytes of the given file as a String encoded in UTF-8.

```
mssparkutils.fs.head('file path', maxBytes to read)
```

```
mssparkutils.fs.head("file path", maxBytes to read)
```

```
FS.Head("file path", maxBytes to read)
```

Move file

Moves a file or directory. Supports move across file systems.

```
mssparkutils.fs.mv('source file or directory', 'destination directory', True) # Set the last parameter as True to firstly create the parent directory if it does not exist
```

```
mssparkutils.fs.mv("source file or directory", "destination directory", true) // Set the last parameter as True to firstly create the parent directory if it does not exist
```

```
FS.Mv("source file or directory", "destination directory", true)
```

Write file

Writes the given string out to a file, encoded in UTF-8.

```
mssparkutils.fs.put("file path", "content to write", True) # Set the last parameter as True to overwrite the file if it existed already
```

```
mssparkutils.fs.put("file path", "content to write", true) // Set the last parameter as True to overwrite the file if it existed already
```

```
FS.Put("file path", "content to write", true) // Set the last parameter as True to overwrite the file if it existed already
```

Append content to a file

Appends the given string to a file, encoded in UTF-8.

```
mssparkutils.fs.append("file path", "content to append", True) # Set the last parameter as True to create the file if it does not exist
```

```
mssparkutils.fs.append("file path","content to append",true) // Set the last parameter as True to create the file if it does not exist
```

```
FS.Append("file path", "content to append", true) // Set the last parameter as True to create the file if it does not exist
```

Delete file or directory

Removes a file or a directory.

```
mssparkutils.fs.rm('file path', True) # Set the last parameter as True to remove all files and directories recursively
```

```
mssparkutils.fs.rm("file path", true) // Set the last parameter as True to remove all files and directories recursively
```

```
FS.Rm("file path", true) // Set the last parameter as True to remove all files and directories recursively
```

Notebook utilities

Not supported.

You can use the MSSparkUtils Notebook Utilities to run a notebook or exit a notebook with a value. Run the following command to get an overview of the available methods:

```
mssparkutils.notebook.help()
```

Get results:

```
The notebook module.

exit(value: String): void -> This method lets you exit a notebook with a value.
run(path: String, timeoutSeconds: int, arguments: Map): String -> This method runs a notebook and returns its exit value.
```

Reference a notebook

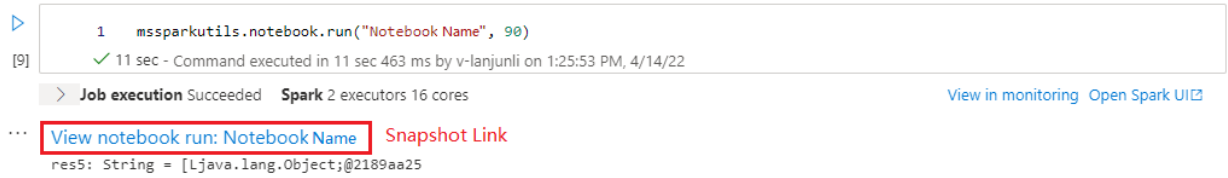
Reference a notebook and returns its exit value. You can run nesting function calls in a notebook interactively or in a pipeline. The notebook being referenced will run on the Spark pool of which notebook calls this function.

```
mssparkutils.notebook.run("notebook path", <timeoutSeconds>, <parameterMap>)
```

For example:

```
mssparkutils.notebook.run("folder/Sample1", 90, {"input": 20 })
```

After the run finished, you will see a snapshot link named '**View notebook run: *Notebook Name***' shown in the cell output, you can click the link to see the snapshot for this specific run.



Exit a notebook

Exits a notebook with a value. You can run nesting function calls in a notebook interactively or in a pipeline.

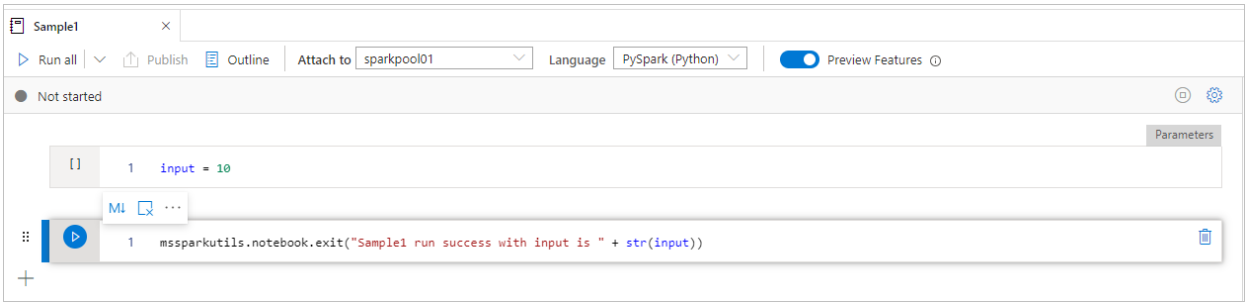
- When you call an `exit()` function a notebook interactively, Azure Synapse will throw an exception, skip running subsequence cells, and keep Spark session alive.
- When you orchestrate a notebook that calls an `exit()` function in a Synapse pipeline, Azure Synapse will return an exit value, complete the pipeline run, and stop the Spark session.
- When you call an `exit()` function in a notebook being referenced, Azure Synapse will stop the further execution in the notebook being referenced, and continue to run next cells in the notebook that call the `run()` function. For example: Notebook1 has three cells and calls an `exit()` function in the second cell. Notebook2 has five cells and calls `run(notebook1)` in the third cell. When you run Notebook2, Notebook1 will be stopped at the second cell when hitting the `exit()` function. Notebook2 will continue to run its fourth cell and fifth cell.

```
mssparkutils.notebook.exit("value string")
```

For example:

Sample1 notebook locates under **folder/** with following two cells:

- cell 1 defines an **input** parameter with default value set to 10.
- cell 2 exits the notebook with **input** as exit value.



You can run the **Sample1** in another notebook with default values:

```
exitVal = mssparkutils.notebook.run("folder/Sample1")
print (exitVal)
```

Results in:

```
Sample1 run success with input is 10
```

You can run the **Sample1** in another notebook and set the **input** value as 20:

```
exitVal = mssparkutils.notebook.run("mssparkutils/folder/Sample1", 90, {"input": 20 })
print (exitVal)
```

Results in:

```
Sample1 run success with input is 20
```

You can use the MSSparkUtils Notebook Utilities to run a notebook or exit a notebook with a value. Run the following command to get an overview of the available methods:

```
mssparkutils.notebook.help()
```

Get results:

```
The notebook module.

exit(value: String): void -> This method lets you exit a notebook with a value.
run(path: String, timeoutSeconds: int, arguments: Map): String -> This method runs a notebook and returns
its exit value.
```

Reference a notebook

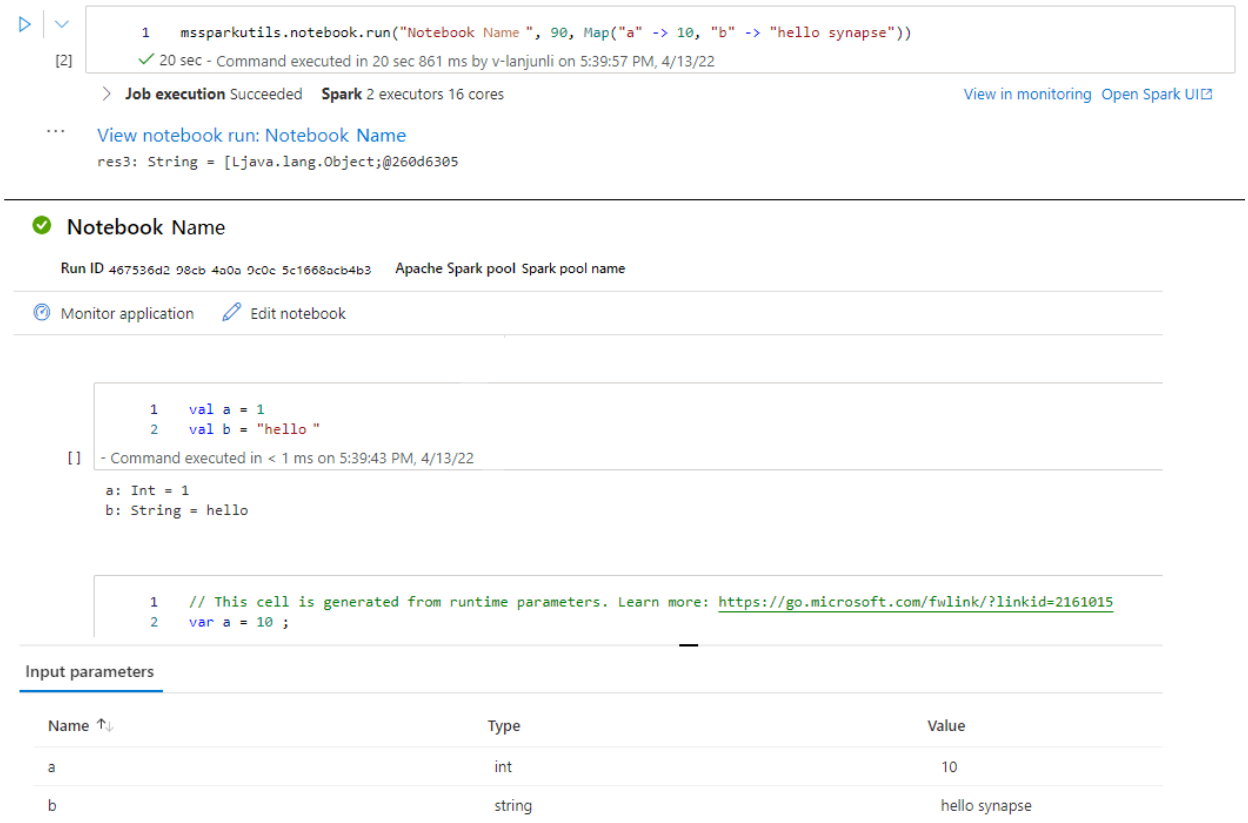
Reference a notebook and returns its exit value. You can run nesting function calls in a notebook interactively or in a pipeline. The notebook being referenced will run on the Spark pool of which notebook calls this function.

```
mssparkutils.notebook.run("notebook path", <timeoutSeconds>, <parameterMap>)
```

For example:

```
mssparkutils.notebook.run("folder/Sample1", 90, Map("input" -> 20))
```

After the run finished, you will see a snapshot link named '**View notebook run: *Notebook Name***' shown in the cell output, you can click the link to see the snapshot for this specific run.



Exit a notebook

Exits a notebook with a value. You can run nesting function calls in a notebook interactively or in a pipeline.

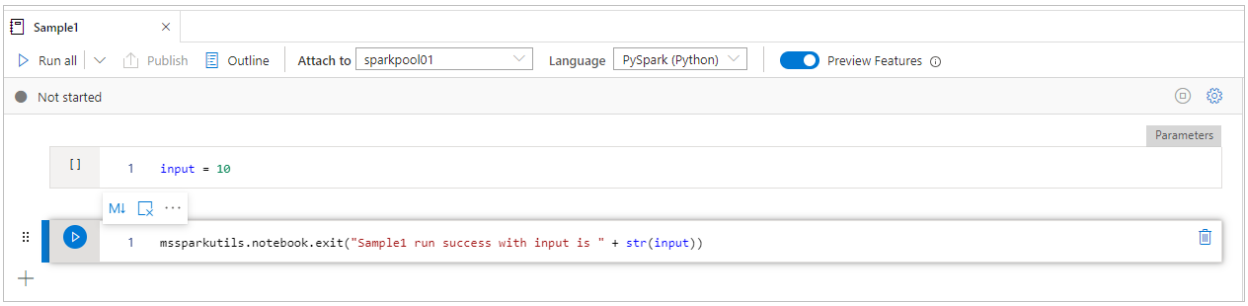
- When you call an `exit()` function a notebook interactively, Azure Synapse will throw an exception, skip running subsequence cells, and keep Spark session alive.
- When you orchestrate a notebook that calls an `exit()` function in a Synapse pipeline, Azure Synapse will return an exit value, complete the pipeline run, and stop the Spark session.
- When you call an `exit()` function in a notebook being referenced, Azure Synapse will stop the further execution in the notebook being referenced, and continue to run next cells in the notebook that call the `run()` function. For example: Notebook1 has three cells and calls an `exit()` function in the second cell. Notebook2 has five cells and calls `run(notebook1)` in the third cell. When you run Notebook2, Notebook1 will be stopped at the second cell when hitting the `exit()` function. Notebook2 will continue to run its fourth cell and fifth cell.

```
mssparkutils.notebook.exit("value string")
```

For example:

Sample1 notebook locates under **mssparkutils/folder/** with following two cells:

- cell 1 defines an **input** parameter with default value set to 10.
- cell 2 exits the notebook with **input** as exit value.



You can run the **Sample1** in another notebook with default values:

```
val exitVal = mssparkutils.notebook.run("mssparkutils/folder/Sample1")
print(exitVal)
```

Results in:

```
exitVal: String = Sample1 run success with input is 10
Sample1 run success with input is 10
```

You can run the **Sample1** in another notebook and set the **input** value as 20:

```
val exitVal = mssparkutils.notebook.run("mssparkutils/folder/Sample1", 90, {"input": 20 })
print(exitVal)
```

Results in:

```
exitVal: String = Sample1 run success with input is 20
Sample1 run success with input is 20
```

Credentials utilities

You can use the MSSparkUtils Credentials Utilities to get the access tokens of linked services and manage secrets in Azure Key Vault.

Run the following command to get an overview of the available methods:

```
mssparkutils.credentials.help()
```

```
mssparkutils.credentials.help()
```

```
Credentials.Help()
```

Get result:

```
getToken(audience, name): returns AAD token for a given audience, name (optional)
isValidToken(token): returns true if token hasn't expired
getConnectionStringOrCreds(linkedService): returns connection string or credentials for linked service
getSecret(akvName, secret, linkedService): returns AKV secret for a given AKV linked service, akvName,
secret key
getSecret(akvName, secret): returns AKV secret for a given akvName, secret key
putSecret(akvName, secretName, secretValue, linkedService): puts AKV secret for a given akvName, secretName
putSecret(akvName, secretName, secretValue): puts AKV secret for a given akvName, secretName
```

Get token

Returns Azure AD token for a given audience, name (optional). The table below list all the available audience types:

AUDIENCE TYPE	AUDIENCE KEY
Audience Resolve Type	'Audience'
Storage Audience Resource	'Storage'
Dedicated SQL pools (Data warehouse)	'DW'
Data Lake Audience Resource	'AzureManagement'
Vault Audience Resource	'DataLakeStore'
Azure OSSDB Audience Resource	'AzureOSSDB'
Azure Synapse Resource	'Synapse'
Azure Data Factory Resource	'ADF'

```
mssparkutils.credentials.getToken('audience Key')
```

```
mssparkutils.credentials.getToken("audience Key")
```

```
Credentials.GetToken("audience Key")
```

Validate token

Returns true if token hasn't expired.

```
mssparkutils.credentials.isValidToken('your token')
```

```
mssparkutils.credentials.isValidToken("your token")
```

```
Credentials.IsValidToken("your token")
```

Get connection string or credentials for linked service

Returns connection string or credentials for linked service.

```
mssparkutils.credentials.getConnectionStringOrCreds('linked service name')
```

```
mssparkutils.credentials.getConnectionStringOrCreds("linked service name")
```

```
Credentials.GetConnectionStringOrCreds("linked service name")
```

Get secret using workspace identity

Returns Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using workspace identity. Make sure you configure access to Azure Key Vault appropriately.

```
mssparkutils.credentials.getSecret('azure key vault name','secret name','linked service name')
```

```
mssparkutils.credentials.getSecret("azure key vault name","secret name","linked service name")
```

```
Credentials.GetSecret("azure key vault name","secret name","linked service name")
```

Get secret using user credentials

Returns Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using user credentials.

```
mssparkutils.credentials.getSecret('azure key vault name','secret name')
```

```
mssparkutils.credentials.getSecret("azure key vault name","secret name")
```

```
Credentials.GetSecret("azure key vault name","secret name")
```

Put secret using workspace identity

Puts Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using workspace identity. Make sure you configure the access to Azure Key Vault appropriately.

```
mssparkutils.credentials.putSecret('azure key vault name','secret name','secret value','linked service
name')
```

Put secret using workspace identity

Puts Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using workspace identity. Make sure you configure the access to Azure Key Vault appropriately.

```
mssparkutils.credentials.putSecret("azure key vault name","secret name","secret value","linked service
name")
```

Put secret using user credentials

Puts Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using user credentials.

```
mssparkutils.credentials.putSecret('azure key vault name','secret name','secret value')
```

Put secret using user credentials

Puts Azure Key Vault secret for a given Azure Key Vault name, secret name, and linked service name using user credentials.

```
mssparkutils.credentials.putSecret("azure key vault name","secret name","secret value")
```

Environment utilities

Run following commands to get an overview of the available methods:

```
mssparkutils.env.help()
```

```
mssparkutils.env.help()
```

```
Env.Help()
```

Get result:

```
GetUserName(): returns user name
GetUserId(): returns unique user id
GetJobId(): returns job id
GetWorkspaceName(): returns workspace name
GetPoolName(): returns Spark pool name
GetClusterId(): returns cluster id
```

Get user name

Returns current user name.

```
mssparkutils.env.getUserName()
```

```
mssparkutils.env.getUserName()
```

```
Env.GetUserName()
```

Get user ID

Returns current user ID.

```
mssparkutils.env.getUserId()
```

```
mssparkutils.env.getUserId()
```

```
Env.GetUserId()
```

Get job ID

Returns job ID.

```
mssparkutils.env.getJobId()
```

```
mssparkutils.env.getJobId()
```

```
Env.GetJobId()
```

Get workspace name

Returns workspace name.

```
mssparkutils.env.getWorkspaceName()
```

```
mssparkutils.env.getWorkspaceName()
```

```
Env.GetWorkspaceName()
```

Get pool name

Returns Spark pool name.

```
mssparkutils.env.getPoolName()
```

```
mssparkutils.env.getPoolName()
```

```
Env.GetPoolName()
```

Get cluster ID

Returns current cluster ID.

```
mssparkutils.env.getClusterId()
```

```
mssparkutils.env.getClusterId()
```

```
Env.GetClusterId()
```

Runtime Context

Mssparkutils runtime utils exposed 3 runtime properties, you can use the mssparkutils runtime context to get

the properties listed as below:

- **Notebookname** - The name of current notebook, will always return value for both interactive mode and pipeline mode.
- **Pipelinejobid** - The pipeline run ID, will return value in pipeline mode and return empty string in interactive mode.
- **Activityrunid** - The notebook activity run ID, will return value in pipeline mode and return empty string in interactive mode.

Currently runtime context support both Python and Scala.

```
mssparkutils.runtime.context
```

```
%%spark
mssparkutils.runtime.context
```

Session management

Stop an interactive session

Instead of manually click stop button, sometimes it's more convenient to stop an interactive session by calling an API in the code. For such cases, we provide an API `mssparkutils.session.stop()` to support stopping the interactive session via code, it's available for Scala and Python.

```
mssparkutils.session.stop()
```

```
mssparkutils.session.stop()
```

`mssparkutils.session.stop()` API will stop the current interactive session asynchronously in the background, it stops the Spark session and release resources occupied by the session so they are available to other sessions in the same pool.

> **NOTE**
> We don't recommend call language built-in APIs like `sys.exit` in Scala or `sys.exit()` in Python in your code, because such APIs just kill the interpreter process, leaving Spark session alive and resources not released.

Introduction to file mount/unmount APIs in Azure Synapse Analytics

8/19/2022 • 5 minutes to read • Edit Online

The Azure Synapse Studio team built two new mount/unmount APIs in the Microsoft Spark Utilities (`mssparkutils`) package. You can use these APIs to attach remote storage (Azure Blob Storage or Azure Data Lake Storage Gen2) to all working nodes (driver node and worker nodes). After the storage is in place, you can use the local file API to access data as if it's stored in the local file system. For more information, see Introduction to Microsoft Spark Utilities.

The article shows you how to use mount/unmount APIs in your workspace. You'll learn:

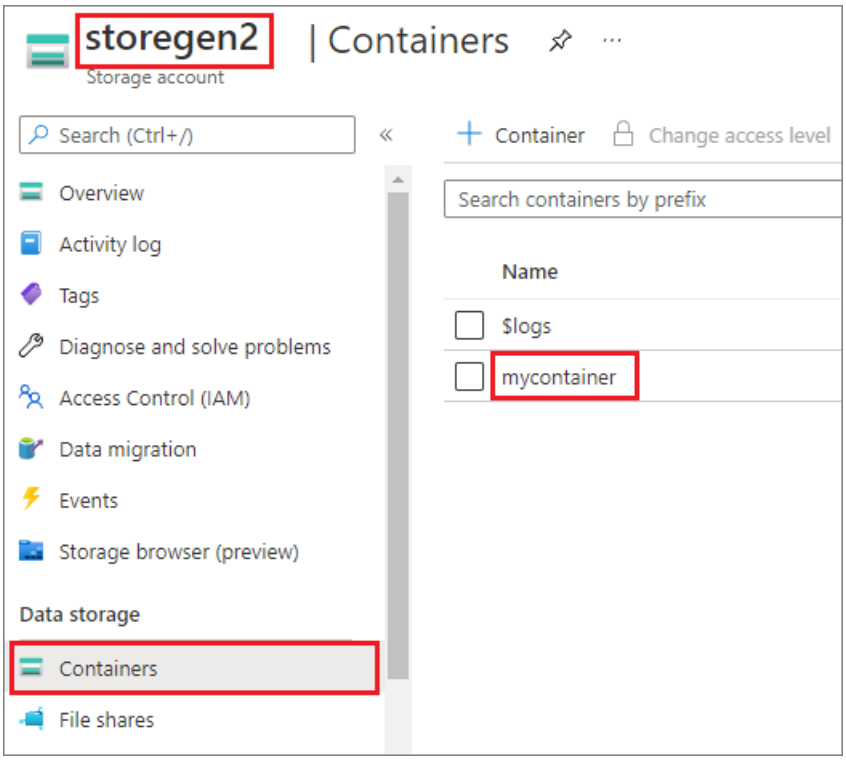
- How to mount Data Lake Storage Gen2 or Blob Storage.
- How to access files under the mount point via the local file system API.
- How to access files under the mount point by using the `mssparktuils fs` API.
- How to access files under the mount point by using the Spark read API.
- How to unmount the mount point.

> **WARNING**
>
> Azure file-share mounting is temporarily disabled. You can use Data Lake Storage Gen2 or Azure Blob Storage mounting instead, as described in the next section.
>
> Azure Data Lake Storage Gen1 storage is not supported. You can migrate to Data Lake Storage Gen2 by following the Azure Data Lake Storage Gen1 to Gen2 migration guidance before using the mount APIs.

Mount storage

This section illustrates how to mount Data Lake Storage Gen2 step by step as an example. Mounting Blob Storage works similarly.

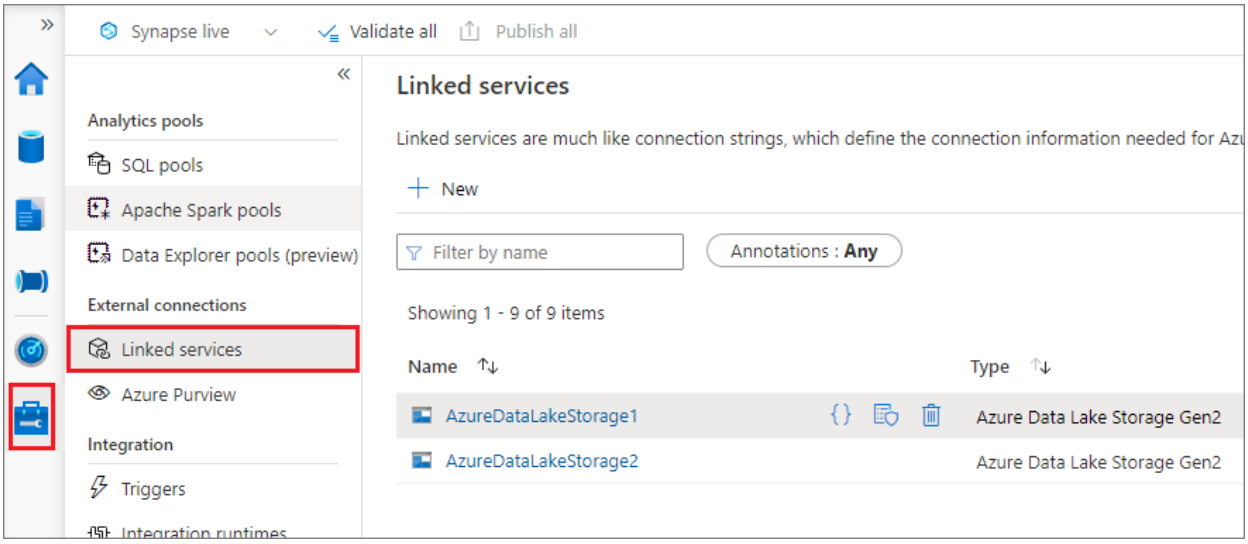
The example assumes that you have one Data Lake Storage Gen2 account named `storegen2`. The account has one container named `mycontainer` that you want to mount to `/test` in your Spark pool.



To mount the container called `mycontainer`, `mssparkutils` first needs to check whether you have the permission to access the container. Currently, Azure Synapse Analytics supports three authentication methods for the trigger mount operation: `linkedService`, `accountKey`, and `sastoken`.

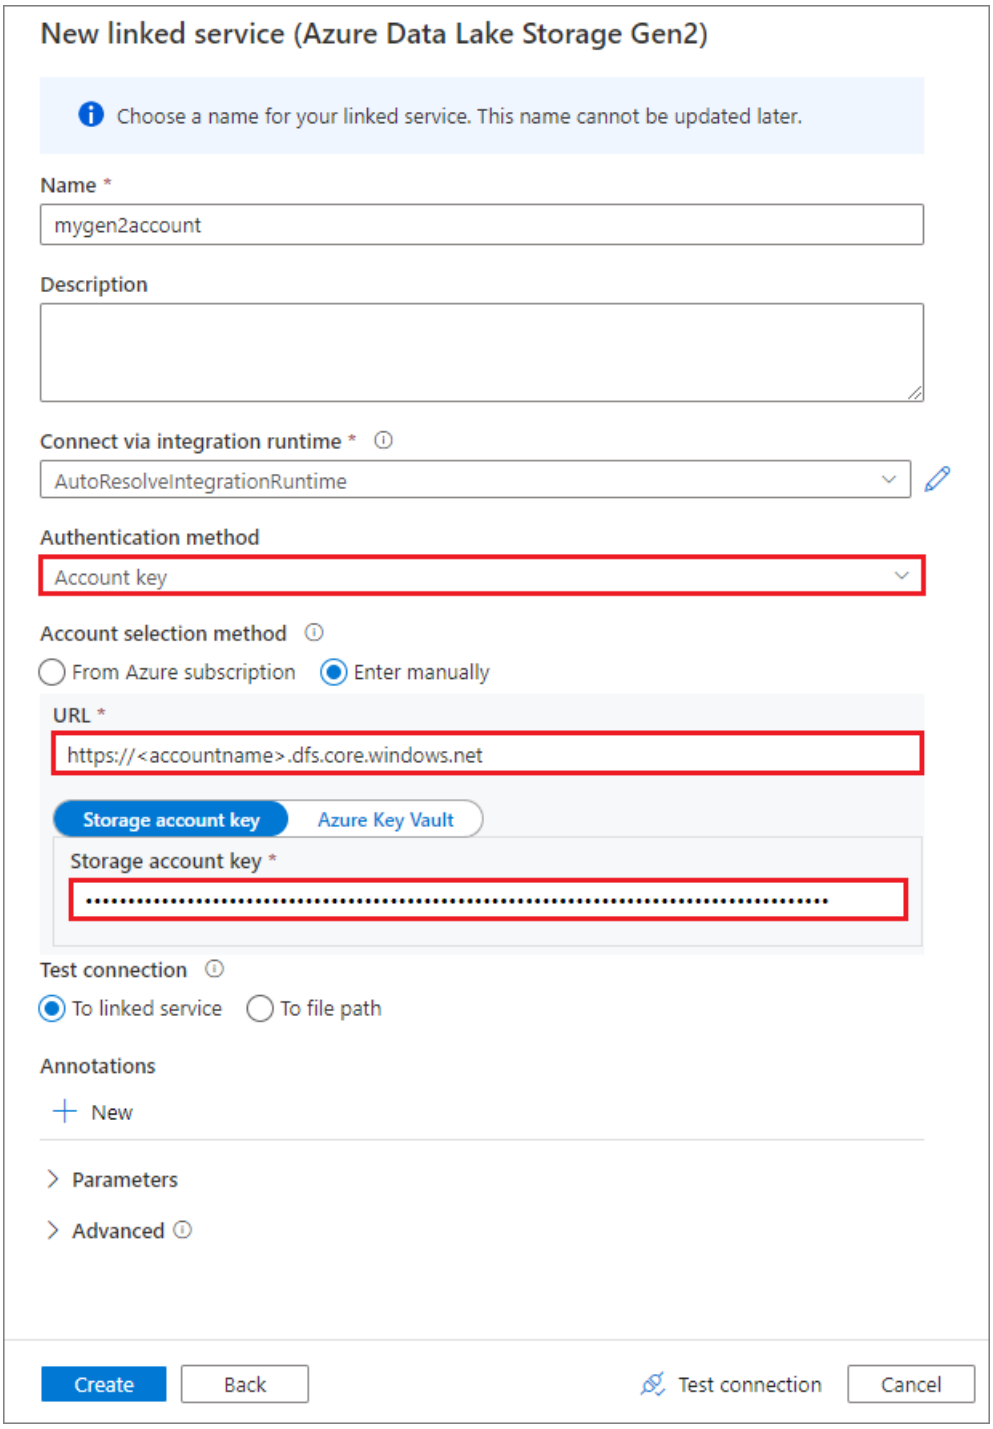
Mount by using a linked service (recommended)

We recommend a trigger mount via linked service. This method avoids security leaks, because `mssparkutils` doesn't store any secret or authentication values itself. Instead, `mssparkutils` always fetches authentication values from the linked service to request blob data from remote storage.

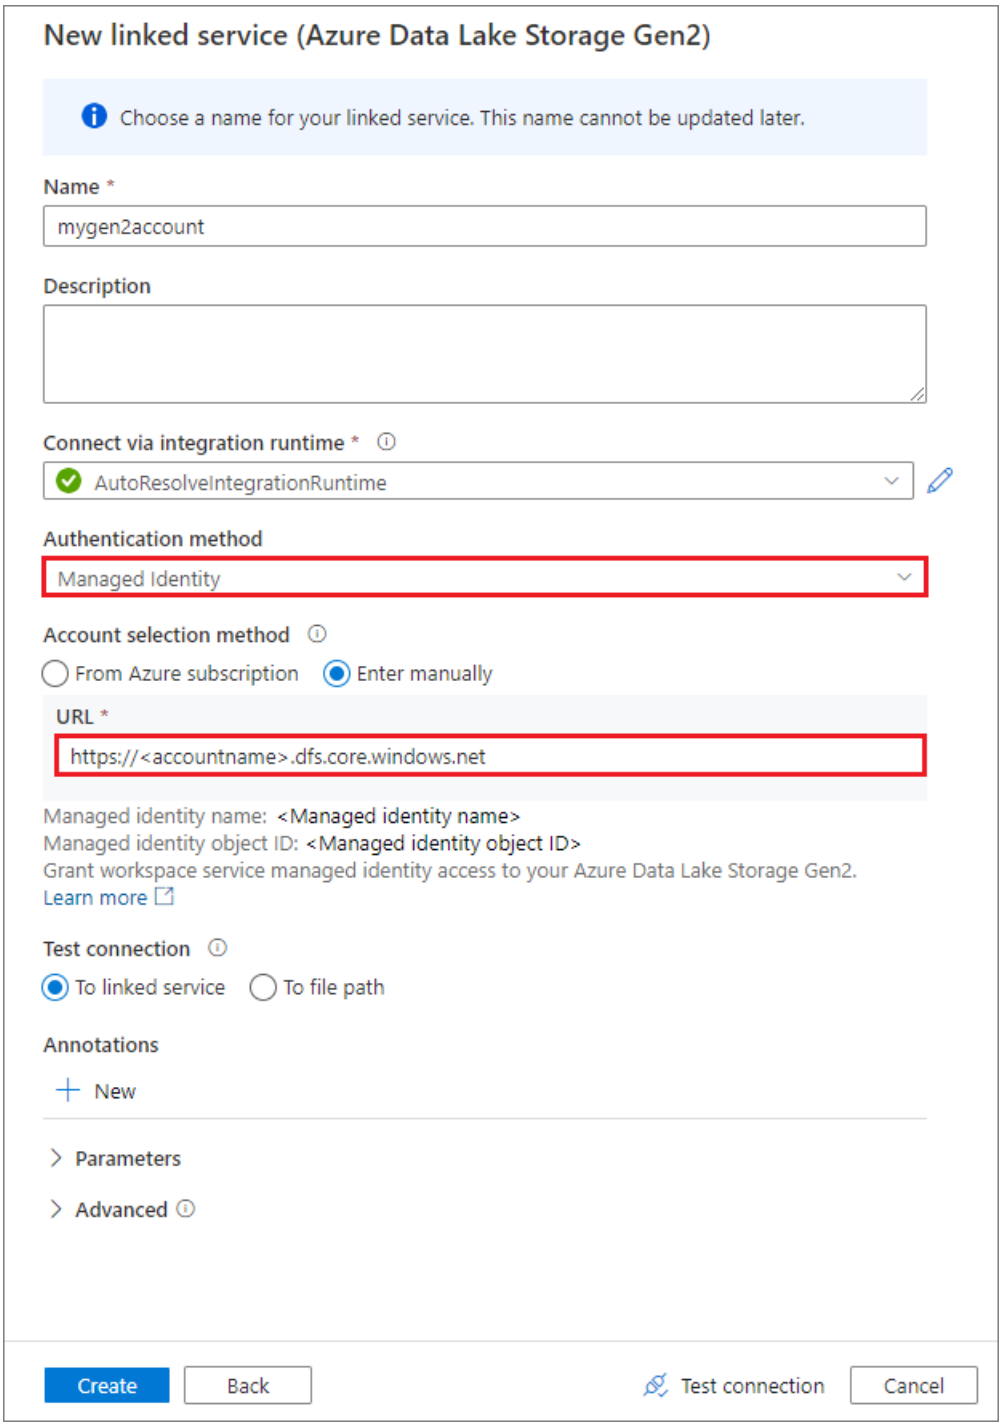


You can create a linked service for Data Lake Storage Gen2 or Blob Storage. Currently, Azure Synapse Analytics supports two authentication methods when you create a linked service:

- Create a linked service by using an account key



- Create a linked service by using a managed identity



NOTE

If you create a linked service by using a managed identity as the authentication method, make sure that the workspace MSI file has the Storage Blob Data Contributor role of the mounted container.

After you create linked service successfully, you can easily mount the container to your Spark pool by using the following Python code:

```
mssparkutils.fs.mount(
    "abfss://mycontainer@<accountname>.dfs.core.windows.net",
    "/test",
    {"linkedService":"mygen2account"}
)
```

NOTE

You might need to import `mssparkutils` if it's not available:

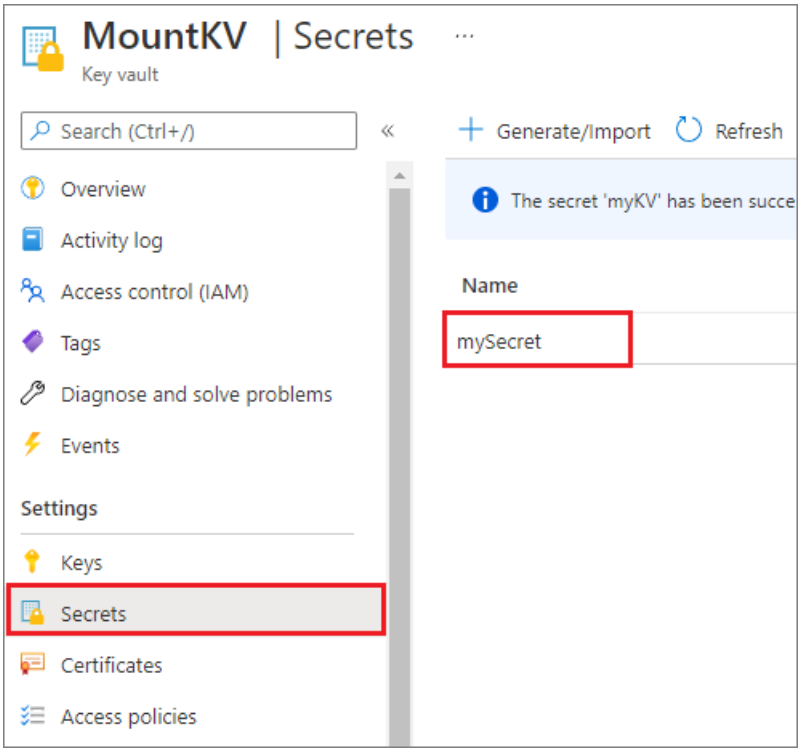
```
Fromnotebookutilsimportmssparkutils
```

We don't recommend that you mount a root folder, no matter which authentication method you use.

Mount via shared access signature token or account key

In addition to mounting through a linked service, `mssparkutils` supports explicitly passing an account key or shared access signature (SAS) token as a parameter to mount the target.

For security reasons, we recommend that you store account keys or SAS tokens in Azure Key Vault (as the following example screenshot shows). You can then retrieve them by using the `mssparkutil.credentials.getSecret` API. For more information, see Manage storage account keys with Key Vault and the Azure CLI (legacy).



Here's the sample code:

```
from notebookutils import mssparkutils

accountKey = mssparkutils.credentials.getSecret("MountKV","mySecret")
mssparkutils.fs.mount(
    "abfss://mycontainer@<accountname>.dfs.core.windows.net",
    "/test",
    {"accountKey":accountKey}
)
```

NOTE

For security reasons, don't store credentials in code.

Access files under the mount point by using the mssparktuils fs API

The main purpose of the mount operation is to let customers access the data stored in a remote storage account by using a local file system API. You can also access the data by using the `mssparkutils fs` API with a mounted path as a parameter. The path format used here is a little different.

Assume that you mounted the Data Lake Storage Gen2 container `mycontainer` to `/test` by using the mount API. When you access the data by using a local file system API, the path format is like this:

`/synfs/{jobId}/test/{filename}`

When you want to access the data by using the `mssparkutils fs` API, the path format is like this:

`synfs:/{jobId}/test/{filename}`

You can see that `synfs` is used as the schema in this case, instead of a part of the mounted path.

The following three examples show how to access a file with a mount point path by using `mssparkutils fs`. In the examples, `49` is a Spark job ID that we got from calling `mssparkutils.env.getJobId()`.

- List directories:

  ```
  mssparkutils.fs.ls("synfs:/49/test")
  ```

- Read file content:

  ```
  mssparkutils.fs.head("synfs:/49/test/myFile.txt")
  ```

- Create a directory:

  ```
  mssparkutils.fs.mkdirs("synfs:/49/test/newdir")
  ```

Access files under the mount point by using the Spark read API

You can provide a parameter to access the data through the Spark read API. The path format here is the same when you use the `mssparkutils fs` API:

`synfs:/{jobId}/test/{filename}`

Read a file from a mounted Data Lake Storage Gen2 storage account

The following example assumes that a Data Lake Storage Gen2 storage account was already mounted, and then you read the file by using a mount path:

```
%%pyspark

df = spark.read.load("synfs:/49/test/myFile.csv", format='csv')
df.show()
```

Read a file from a mounted Blob Storage account

If you mounted a Blob Storage account and want to access it by using `mssparkutils` or the Spark API, you need to explicitly configure the SAS token via Spark configuration before you try to mount the container by using the mount API:

1. To access a Blob Storage account by using `mssparkutils` or the Spark API after a trigger mount, update the Spark configuration as shown in the following code example. You can bypass this step if you want to access the Spark configuration only by using the local file API after mounting.

```
blob_sas_token = mssparkutils.credentials.getConnectionStringOrCreds("myblobstorageaccount")

spark.conf.set('fs.azure.sas.mycontainer.<blobStorageAccountName>.blob.core.windows.net',
blob_sas_token)
```

2. Create the linked service `myblobstorageaccount`, and mount the Blob Storage account by using the linked service:

```
%%spark
mssparkutils.fs.mount(
    "wasbs://mycontainer@<blobStorageAccountName>.blob.core.windows.net",
    "/test",
    Map("linkedService" -> "myblobstorageaccount")
)
```

3. Mount the Blob Storage container, and then read the file by using a mount path through the local file API:

```
    # mount the Blob Storage container, and then read the file by using a mount path
    with open("/synfs/64/test/myFile.txt") as f:
    print(f.read())
```

4. Read the data from the mounted Blob Storage container through the Spark read API:

```
%%spark
// mount blob storage container and then read file using mount path
val df = spark.read.text("synfs:/49/test/myFile.txt")
df.show()
```

Unmount the mount point

Use the following code to unmount your mount point (`/test` in this example):

```
mssparkutils.fs.unmount("/test")
```

Known limitations

- The `mssparkutils fs help` function hasn't added the description about the mount/unmount part yet.
- The unmount mechanism is not automatic. When the application run finishes, to unmount the mount point to release the disk space, you need to explicitly call an unmount API in your code. Otherwise, the mount point will still exist in the node after the application run finishes.
- Mounting a Data Lake Storage Gen1 storage account is not supported for now.

SQL Server DMVs available in dedicated SQL pool

SQL pool exposes many of the SQL Server dynamic management views (DMVs). These views, when queried in dedicated SQL pool, are reporting the state of SQL Databases running on the distributions.

SQL pool and Analytics Platform System's Parallel Data Warehouse (PDW) use the same system views. Each DMV has a column called pdw_node_id, which is the identifier for the Compute node.

> **NOTE**
> To use these views, insert 'pdw_nodes_' into the name, as shown in the following table:

DMV NAME IN DEDICATED SQL POOL	SQL SERVER TRANSACT-SQL ARTICLE
sys.dm_pdw_nodes_db_column_store_row_group_physical_stats	sys.dm_db_column_store_row_group_physical_stats
sys.dm_pdw_nodes_db_column_store_row_group_operational_stats	sys.dm_db_column_store_row_group_operational_stats
sys.dm_pdw_nodes_db_file_space_usage	sys.dm_db_file_space_usage
sys.dm_pdw_nodes_db_index_usage_stats	sys.dm_db_index_usage_stats
sys.dm_pdw_nodes_db_partition_stats	sys.dm_db_partition_stats
sys.dm_pdw_nodes_db_session_space_usage	sys.dm_db_session_space_usage

Azure Policy built-in definitions for Azure Synapse Analytics

8/19/2022 • 4 minutes to read • Edit Online

This page is an index of Azure Policy built-in policy definitions for Azure Synapse. For additional Azure Policy built-ins for other services, see Azure Policy built-in definitions.

The name of each built-in policy definition links to the policy definition in the Azure portal. Use the link in the **Version** column to view the source on the Azure Policy GitHub repo.

Azure Synapse

NAME (AZURE PORTAL)	DESCRIPTION	EFFECT(S)	VERSION (GITHUB)
Auditing on Synapse workspace should be enabled	Auditing on your Synapse workspace should be enabled to track database activities across all databases on the dedicated SQL pools and save them in an audit log.	AuditIfNotExists, Disabled	1.0.0
Azure Synapse Workspace SQL Server should be running TLS version 1.2 or newer	Setting TLS version to 1.2 or newer improves security by ensuring your Azure Synapse workspace SQL server can only be accessed from clients using TLS 1.2 or newer. Using versions of TLS less than 1.2 is not recommended since they have well documented security vulnerabilities.	Audit, Deny, Disabled	1.0.0
Azure Synapse workspaces should allow outbound data traffic only to approved targets	Increase security of your Synapse workspace by allowing outbound data traffic only to approved targets. This helps prevention against data exfiltration by validating the target before sending data.	Audit, Disabled, Deny	1.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
Azure Synapse workspaces should disable public network access	Disabling public network access improves security by ensuring that the Synapse workspace isn't exposed on the public internet. Creating private endpoints can limit exposure of your Synapse workspaces. Learn more at: https://docs.microsoft.com/azure/synapse-analytics/security/connectivity-settings.	Audit, Deny, Disabled	1.0.0
Azure Synapse workspaces should use customer-managed keys to encrypt data at rest	Use customer-managed keys to control the encryption at rest of the data stored in Azure Synapse workspaces. Customer-managed keys deliver double encryption by adding a second layer of encryption on top of the default encryption with service-managed keys.	Audit, Deny, Disabled	1.0.0
Azure Synapse workspaces should use private link	Azure Private Link lets you connect your virtual network to Azure services without a public IP address at the source or destination. The Private Link platform handles the connectivity between the consumer and services over the Azure backbone network. By mapping private endpoints to Azure Synapse workspace, data leakage risks are reduced. Learn more about private links at: https://docs.microsoft.com/azure/synapse-analytics/security/how-to-connect-to-workspace-with-private-links.	Audit, Disabled	1.0.1

NAME	DESCRIPTION	EFFECT(S)	VERSION
Configure Azure Synapse Workspace Dedicated SQL minimum TLS version	Customers can raise or lower the minimal TLS version using the API, for both new Synapse workspaces or existing workspaces. So users who need to use a lower client version in the workspaces can connect while users who has security requirement can raise the minimum TLS version. Learn more at: https://docs.microsoft.com/azure/synapse-analytics/security/connectivity-settings.	Modify, Disabled	1.0.0
Configure Azure Synapse workspaces to disable public network access	Disable public network access for your Synapse workspace so that it is not accessible over the public internet. This can reduce data leakage risks. Learn more at: https://docs.microsoft.com/azure/synapse-analytics/security/connectivity-settings.	Modify, Disabled	1.0.0
Configure Azure Synapse workspaces with private endpoints	Private endpoints connect your virtual network to Azure services without a public IP address at the source or destination. By mapping private endpoints to Azure Synapse workspaces, you can reduce data leakage risks. Learn more about private links at: https://docs.microsoft.com/azure/synapse-analytics/security/how-to-connect-to-workspace-with-private-links.	DeployIfNotExists, Disabled	1.0.0
Configure Synapse workspaces to have auditing enabled	To ensure the operations performed against your SQL assets are captured, Synapse workspaces should have auditing enabled. This is sometimes required for compliance with regulatory standards.	DeployIfNotExists, Disabled	2.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
Configure Synapse workspaces to have auditing enabled to Log Analytics workspace	To ensure the operations performed against your SQL assets are captured, Synapse workspaces should have auditing enabled. If auditing is not enabled, this policy will configure auditing events to flow to the specified Log Analytics workspace.	DeployIfNotExists, Disabled	1.0.0
IP firewall rules on Azure Synapse workspaces should be removed	Removing all IP firewall rules improves security by ensuring your Azure Synapse workspace can only be accessed from a private endpoint. This configuration audits creation of firewall rules that allow public network access on the workspace.	Audit, Disabled	1.0.0
Managed workspace virtual network on Azure Synapse workspaces should be enabled	Enabling a managed workspace virtual network ensures that your workspace is network isolated from other workspaces. Data integration and Spark resources deployed in this virtual network also provides user level isolation for Spark activities.	Audit, Deny, Disabled	1.0.0
Synapse managed private endpoints should only connect to resources in approved Azure Active Directory tenants	Protect your Synapse workspace by only allowing connections to resources in approved Azure Active Directory (Azure AD) tenants. The approved Azure AD tenants can be defined during policy assignment.	Audit, Disabled, Deny	1.0.0
Synapse workspace auditing settings should have action groups configured to capture critical activities	To ensure your audit logs are as thorough as possible, the AuditActionsAndGroups property should include all the relevant groups. We recommend adding at least SUCCESSFUL_DATABASE_AUTHENTICATION_GROUP, FAILED_DATABASE_AUTHENTICATION_GROUP, and BATCH_COMPLETED_GROUP. This is sometimes required for compliance with regulatory standards.	AuditIfNotExists, Disabled	1.0.0

NAME	DESCRIPTION	EFFECT(S)	VERSION
Synapse workspaces with SQL auditing to storage account destination should be configured with 90 days retention or higher	For incident investigation purposes, we recommend setting the data retention for your Synapse workspace' SQL auditing to storage account destination to at least 90 days. Confirm that you are meeting the necessary retention rules for the regions in which you are operating. This is sometimes required for compliance with regulatory standards.	AuditIfNotExists, Disabled	2.0.0
Vulnerability assessment should be enabled on your Synapse workspaces	Discover, track, and remediate potential vulnerabilities by configuring recurring SQL vulnerability assessment scans on your Synapse workspaces.	AuditIfNotExists, Disabled	1.0.0

T-SQL language elements for dedicated SQL pool in Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Links to the documentation for T-SQL language elements supported in dedicated SQL pool.

Core elements

- syntax conventions
- object naming rules
- reserved keywords
- collations
- comments
- constants
- data types
- EXECUTE
- expressions
- KILL
- IDENTITY property workaround
- PRINT
- USE

Batches, control-of-flow, and variables

- BEGIN...END
- BREAK
- DECLARE @local_variable
- IF...ELSE
- RAISERROR
- SET@local_variable
- THROW
- TRY...CATCH
- WHILE

Operators

- + (Add)
- + (String Concatenation)
- - (Negative)
- - (Subtract)
- * (Multiply)
- / (Divide)
- Modulo

Wildcard character(s) to match

- = (Equals)
- > (Greater than)
- < (Less than)
- >= (Great than or equal to)
- <= (Less than or equal to)
- <> (Not equal to)
- != (Not equal to)
- AND
- BETWEEN
- EXISTS
- IN
- IS [NOT] NULL
- LIKE
- NOT
- OR

Bitwise operators

- & (Bitwise AND)
- | (Bitwise OR)
- ^ (Bitwise exclusive OR)
- ~ (Bitwise NOT)
- ^= (Bitwise Exclusive OR EQUALS)
- |= (Bitwise OR EQUALS)
- &= (Bitwise AND EQUALS)

Previous monthly updates in Azure Synapse Analytics

8/19/2022 • 22 minutes to read • Edit Online

This article describes previous month updates to Azure Synapse Analytics. For the most current month's release, check out Azure Synapse Analytics latest updates. Each update links to the Azure Synapse Analytics blog and an article that provides more information.

May 2022 update

The following updates are new to Azure Synapse Analytics this month.

General

Get connected with the new Azure Synapse Influencer program! Join a community of Azure Synapse Influencers who are helping each other achieve more with cloud analytics! The Azure Synapse Influencer program recognizes Azure Synapse Analytics users and advocates who actively support the community by sharing Synapse-related content, announcements, and product news via social media.

SQL

- **Data Warehouse Migration guide for Dedicated SQL Pools in Azure Synapse Analytics** - With the benefits that cloud migration offers, we hear that you often look for steps, processes, or guidelines to follow for quick and easy migrations from existing data warehouse environments. We just released a set of Data Warehouse migration guides to make your transition to dedicated SQL Pools in Azure Synapse Analytics easier.

- **Automatic character column length calculation** - It's no longer necessary to define character column lengths! Serverless SQL pools let you query files in the data lake without knowing the schema upfront. The best practice was to specify the lengths of character columns to get optimal performance. Not anymore! With this new feature, you can get optimal query performance without having to define the schema. The serverless SQL pool will calculate the average column length for each inferred character column or character column defined as larger than 100 bytes. The schema will stay the same, while the serverless SQL pool will use the calculated average column lengths internally. It will also automatically calculate the cardinality estimation in case there was no previously created statistic.

Apache Spark for Synapse

- **Azure Synapse Dedicated SQL Pool Connector for Apache Spark Now Available in Python** - Previously, the Azure Synapse Dedicated SQL Pool connector was only available using Scala. Now, it can be used with Python on Spark 3. The only difference between the Scala and Python implementations is the optional Scala callback handle, which allows you to receive post-write metrics.

  The following are now supported in Python on Spark 3:

  - Read using Azure Active Directory (AD) Authentication or Basic Authentication
  - Write to Internal Table using Azure AD Authentication or Basic Authentication
  - Write to External Table using Azure AD Authentication or Basic Authentication

  To learn more about the connector in Python, read Azure Synapse Dedicated SQL Pool Connector for Apache Spark.

- **Manage Azure Synapse Apache Spark configuration** - Apache Spark configuration management is always a challenging task because Spark has hundreds of properties. It is also challenging for you to

know the optimal value for Spark configurations. With the new Spark configuration management feature, you can create a standalone Spark configuration artifact with auto-suggestions and built-in validation rules. The Spark configuration artifact allows you to share your Spark configuration within and across Azure Synapse workspaces. You can also easily associate your Spark configuration with a Spark pool, a Notebook, and a Spark job definition for reuse and minimize the need to copy the Spark configuration in multiple places. To learn more about the new Spark configuration management feature, read Manage Apache Spark configuration.

Synapse Data Explorer

- **Synapse Data Explorer live query in Excel** - Using the new Data Explorerweb experience Open in Excel feature, you can now provide access to live results of your query by sharing the connected Excel Workbook with colleagues and team members.You can open the live query in an Excel Workbook and refresh it directly from Excel to get the most up to date query results. To learn more about Excel live query, read Open live query in Excel.

- **Use Managed Identities for External SQL Server Tables** - One of the key benefits of Azure Synapse is the ability to bring together data integration, enterprise data warehousing, and big data analytics. With Managed Identity support, Synapse Data Explorer table definition is now simpler and more secure. You can now use managed identities instead of entering in your credentials.

  An external SQL table is a schema entity that references data stored outside the Synapse Data Explorer database. Using the Create and alter SQL Server external tables command, External SQL tables can easily be added to the Synapse Data Explorer database schema.

  To learn more about managed identities, read Managed identities overview.

  To learn more about external tables, read Create and alter SQL Server external tables.

- **New KQL Learn module (2 out of 3) is live!** - The power of Kusto Query Language (KQL) is its simplicity to query structured, semi-structured, and unstructured data together. To make it easier for you to learn KQL, we are releasing Learn modules. Previously, we released Write your first query with Kusto Query Language. New this month is Gain insights from your data by using Kusto Query Language.

  KQL is the query language used to query Synapse Data Explorer big data. KQL has a fast-growing user community, with hundreds of thousands of developers, data engineers, data analysts, and students.

  Check out the newest KQL Learn Model and see for yourself how easy it is to become a KQL master.

  To learn more about KQL, read Kusto Query Language (KQL) overview.

- **Azure Synapse Data Explorer connector for Microsoft Power Automate, Logic Apps, and Power Apps [Generally Available]** - The Azure Data Explorer connector forPower Automateenables you to orchestrate and schedule flows, send notifications, and alerts, as part of a scheduled or triggered task. To learn more, read Azure Data Explorer connector for Microsoft Power Automate and Usage examples for Azure Data Explorer connector to Power Automate.

- **Dynamic events routing from event hub to multiple databases** - Routing events from Event Hub/IOT Hub/Event Grid is an activity commonly performed by Azure Data Explorer (ADX) users. Previously, you could route events only to a single database per defined connection. If you wanted to route the events to multiple databases, you needed to create multiple ADX cluster connections.

  To simplify the experience, we now support routing events data to multiple databases hosted in a single ADX cluster. To learn more about dynamic routing, read Ingest from event hub.

- **Configure a database using a KQL inline script as part of JSON ARM deployment template** - Previously, Azure Data Explorer supported running a Kusto Query Language (KQL) script to configure your database during Azure Resource Management (ARM) template deployment. Now, this can be done using an inline script provided inline as a parameter to a JSON ARM template. To learn more about using

a KQL inline script, read Configure a database using a Kusto Query Language script.

Data Integration

- **Export pipeline monitoring as a CSV** - The ability to export pipeline monitoring to CSV has been added after receiving many community requests for the feature. Simply filter the Pipeline runs screen to the data you want and click 'Export to CSV'. To learn more about exporting pipeline monitoring and other monitoring improvements, read Azure Data Factory monitoring improvements.

- **Incremental data loading made easy for Synapse and Azure Database for PostgreSQL and MySQL** - In a data integration solution, incrementally loading data after an initial full data load is a widely used scenario. Automatic incremental source data loading is now natively available for Synapse SQL and Azure Database for PostgreSQL and MySQL. With a simple click, users can "enable incremental extract" and only inserted or updated rows will be read by the pipeline. To learn more about incremental data loading, read Incrementally copy data from a source data store to a destination data store.

- **User-Defined Functions for Mapping Data Flows [Public Preview]** - We hear you that you can find yourself doing the same string manipulation, math calculations, or other complex logic several times. Now, with the new user-defined function feature, you can create customized expressions that can be reused across multiple mapping data flows. User-defined functions will be grouped in libraries to help developers group common sets of functions. Once you've created a data flow library, you can add in your user-defined functions. You can even add in multiple arguments to make your function more reusable. To learn more about user-defined functions, read User defined functions in mapping data flows.

- **Assert Error Handling** - Error handling has now been added to sinks following an assert transformation. Assert transformations enable you to build custom rules for data quality and data validation. You can now choose whether to output the failed rows to the selected sink or to a separate file. To learn more about error handling, read Assert data transformation in mapping data flow.

- **Mapping data flows projection editing** - New UI updates have been made to source projection editing in mapping data flows. You can now update source projection column names and column types with the click of a button. To learn more about source projection editing, read Source transformation in mapping data flow.

Synapse Link

Azure Synapse Link for SQL [Public Preview] - At Microsoft Build 2022, we announced the Public Preview availability of Azure Synapse Link for SQL, for both SQL Server 2022 and Azure SQL Database. Data-driven, quality insights are critical for companies to stay competitive. The speed to achieve those insights can make all the difference. The costly and time-consuming nature of traditional ETL and ELT pipelines is no longer enough. With this release, you can now take advantage of low- and no-code, near real-time data replication from your SQL-based operational stores into Azure Synapse Analytics. This makes it easier to run BI reporting on operational data in near real-time, with minimal impact on your operational store. To learn more, read Announcing the Public Preview of Azure Synapse Link for SQL and watch our YouTube video.

Apr 2022 update

The following updates are new to Azure Synapse Analytics this month.

SQL

- Cross-subscription restore for Azure Synapse SQL is now generally available. Previously, it took many undocumented steps to restore a dedicated SQL pool to another subscription. Now, with the PowerShell Az.Sql module 3.8 update, the Restore-AzSqlDatabase cmdlet can be used for cross-subscription restore. To learn more, see Restore a dedicated SQL pool (formerly SQL DW) to a different subscription.

- It is now possible to recover a SQL pool from a dropped server or workspace. With the PowerShell Restore cmdlets in Az.Sql and Az.Synapse modules, you can now restore from a deleted server or workspace without filing a support ticket. For more information, read Synapse workspace SQL pools or standalone SQL pools (formerly SQL DW), depending on your scenario.

Synapse database templates and database designer

- Based on popular customer feedback, we've made significant improvements to our exploration experience when creating a lake database using an industry template. To learn more, read Quickstart: Create a new Lake database leveraging database templates.

- We've added the option to clone a lake database. This unlocks additional opportunities to manage new versions of databases or support schemas that evolve in discrete steps. You can quickly clone a database using the action menu available on the lake database. To learn more, read How-to: Clone a lake database.

- You can now use wildcards to specify custom folder hierarchies. Lake databases sit on top of data that is in the lake and this data can live in nested folders that don't fit into clean partition patterns. Previously, querying lake databases required that your data exists in a simple directory structure that you could browse using the folder icon without the ability to manually specify directory structure or use wildcard characters. To learn more, read How-to: Modify a datalake.

Apache Spark for Synapse

- We are excited to announce the preview availability of Apache Spark™ 3.2 on Synapse Analytics. This new version incorporates user-requested enhancements and resolves 1,700+ Jira tickets. Please review the official release notes for the complete list of fixes and features and review the migration guidelines between Spark 3.1 and 3.2 to assess potential changes to your applications. For more details, read Apache Spark version support and Azure Synapse Runtime for Apache Spark 3.2.

- Assigning parameters dynamically based on variables, metadata, or specifying Pipeline specific parameters has been one of your top feature requests. Now, with the release of parameterization for the Spark job definition activity, you can do just that. For more details, read Transform data using Apache Spark job definition.

- We often receive customer requests to access the snapshot of the Notebook when there is a Pipeline Notebook run failure or there is a long-running Notebook job. With the release of the Synapse Notebook snapshot feature, you can now view the snapshot of the Notebook activity run with the original Notebook code, the cell output, and the input parameters. You can also access the snapshot of the referenced Notebook from the referencing Notebook cell output if you refer to other Notebooks through Spark utils. To learn more, read Transform data by running a Synapse notebook and Introduction to Microsoft Spark utilities.

Security

- The Synapse Monitoring Operator RBAC role is now generally available. Since the GA of Synapse, customers have asked for a fine-grained RBAC (role-based access control) role that allows a user persona to monitor the execution of Synapse Pipelines and Spark applications without having the ability to run or cancel the execution of these applications. Now, customers can assign the Synapse Monitoring Operator role to such monitoring personas. This allows organizations to stay compliant while having flexibility in the delegation of tasks to individuals or teams. Learn more by reading Synapse RBAC Roles.

Data integration

- Microsoft has added Dataverse as a source and sink connector to Synapse Data Flows so that you can now build low-code data transformation ETL jobs in Synapse directly accessing your Dataverse environment. For more details on how to use this new connector, read Mapping data flow properties.

- We heard from you that a 1-minute timeout for Web activity was not long enough, especially in cases of synchronous APIs. Now, with the response timeout property 'httpRequestTimeout', you can define

timeout for the HTTP request up to 10 minutes. Learn more by reading Web activity response timeout improvements.

Developer experience

- Previously, if you wanted to reference a notebook in another notebook, you could only reference published or committed content. Now, when using %run notebooks, you can enable 'unpublished notebook reference' which will allow you to reference unpublished notebooks. When enabled, notebook run will fetch the current contents in the notebook web cache, meaning the changes in your notebook editor can be referenced immediately by other notebooks without having to be published (Live mode) or committed (Git mode). To learn more, read Reference unpublished notebook.

Mar 2022 update

The following updates are new to Azure Synapse Analytics this month.

Developer Experience

- Code cells in Synapse notebooks that result in exception will now show standard output along with the exception message. This feature is supported for Python and Scala languages. To learn more, see the example output when a code statement fails.
- Synapse notebooks now support partial output when running code cells. To learn more, see the examples at this blog post
- You can now dynamically control Spark session configuration for the notebook activity with pipeline parameters. To learn more, see the variable explorer feature of Synapse notebooks.
- You can now reuse and manage notebook sessions without having to start a new one. You can easily connect a selected notebook to an active session in the list started from another notebook. You can detach a session from a notebook, stop the session, and monitor it. To learn more, see how to manage your active notebook sessions.
- Synapse notebooks now capture anything written through the Python logging module, in addition to the driver logs. To learn more, see support for Python logging.

SQL

- Column Level Encryption for Azure Synapse dedicated SQL Pools is now Generally Available. With column level encryption, you can use different protection keys for each column with each key having its own access permissions. The data in CLE-enforced columns are encrypted on disk and remain encrypted in memory until the DECRYPTBYKEY function is used to decrypt it. To learn more, see how to encrypt a data column.
- Serverless SQL pools now support better performance for CETAS (Create External Table as Select) and subsequent SELECT queries. The performance improvements include, a parallel execution plan resulting in faster CETAS execution and outputting multiple files. To learn more, see CETAS with Synapse SQL article and the blog post

Apache Spark for Synapse

- Synapse Spark Common Data Model (CDM) Connector is now Generally Available. The CDM format reader/writer enables a Spark program to read and write CDM entities in a CDM folder via Spark dataframes. To learn more, see how the CDM connector supports reading, writing data, examples, & known issues.
- Synapse Spark Dedicated SQL Pool (DW) Connector now supports improved performance. The new architecture eliminates redundant data movement and uses COPY-INTO instead of PolyBase. You can authenticate through SQL basic authentication or opt into the Azure Active Directory/Azure AD based authentication method. It now has ~5x improvements over the previous version. To learn more, see Azure

Synapse Dedicated SQL Pool Connector for Apache Spark

- Synapse Spark Dedicated SQL Pool (DW) Connector now supports all Spark Dataframe SaveMode choices. It supports Append, Overwrite, ErrorIfExists, and Ignore modes. The Append and Overwrite are critical for managing data ingestion at scale. To learn more, see DataFrame write SaveMode support
- Accelerate Spark execution speed using the new Intelligent Cache feature. This feature is currently in public preview. Intelligent Cache automatically stores each read within the allocated cache storage space, detecting underlying file changes and refreshing the files to provide the most recent data. To learn more, see how to Enable/Disable the cache for your Apache Spark pool or see the blog post

Security

- Azure Synapse Analytics now supports Azure Active Directory (Azure AD) authentication. You can turn on Azure AD authentication during the workspace creation or after the workspace is created. To learn more, see how to use Azure AD authentication with Synapse SQL.
- API support to raise or lower minimal TLS version for workspace managed SQL Server Dedicated SQL. To learn more, see how to update the minimum TLS setting or read the blog post for more details.

Data Integration

- Flowlets and CDC Connectors are now Generally Available. Flowlets in Synapse Data Flows allow for reusable and composable ETL logic. To learn more, see Flowlets in mapping data flow or see the blog post.
- sFTP connector for Synapse data flows. You can read and write data while transforming data from sftp using the visual low-code data flows interface in Synapse. To learn more, see source transformation
- Data flow improvements to Data Preview. To learn more, see Data Preview and debug improvements in Mapping Data Flows
- Pipeline script activity. The Script Activity enables data engineers to build powerful data integration pipelines that can read from and write to Synapse databases, and other database types. To learn more, see Transform data by using the Script activity in Azure Data Factory or Synapse Analytics

Feb 2022 update

The following updates are new to Azure Synapse Analytics this month.

SQL

- Serverless SQL Pools now support more consistent query execution times. Learn how Serverless SQL pools automatically detect spikes in read latency and support consistent query execution time.
- The `OPENJSON` function makes it easy to get array element indexes. To learn more, see how the OPENJSON function in a serverless SQL pool allows you to parse nested arrays and return one row for each JSON array element with the index of each element.

Data integration

- Upserting data is now supported by the copy activity. See how you can natively load data into a temporary table and then merge that data into a sink table with upsert.
- Transform Dynamics Data Visually in Synapse Data Flows. Learn more on how to use a Dynamics dataset or an inline dataset as source and sink types to transform data at scale.
- Connect to your SQL sources in data flows using Always Encrypted. To learn more, see how to securely connect to your SQL databases from Synapse data flows using Always Encrypted.
- Capture descriptions from asserts in Data Flows To learn more, see how to define your own dynamic

descriptive messages in the assert data flow transformation at the row or column level.

- Easily define schemas for complex type fields. To learn more, see how you can make the engine to automatically detect the schema of an embedded complex field inside a string column.

Jan 2022 update

The following updates are new to Azure Synapse Analytics this month.

Apache Spark for Synapse

You can now use four new database templates in Azure Synapse. Learn more about Automotive, Genomics, Manufacturing, and Pharmaceuticals templates from the blog post or the database templates article. These templates are currently in public preview and are available within the Synapse Studio gallery.

Machine Learning

Improvements to the Synapse Machine Learning library v0.9.5 (previously called MMLSpark). This release simplifies the creation of massively scalable machine learning pipelines with Apache Spark. To learn more, read the blog post about the new capabilities in this release or see the full release notes

Security

- The Azure Synapse Analytics security overview - A whitepaper that covers the five layers of security. The security layers include authentication, access control, data protection, network security, and threat protection. Understand each security feature in detailed to implement an industry-standard security baseline and protect your data on the cloud.

- TLS 1.2 is now required for newly created Synapse Workspaces. To learn more, see how TLS 1.2 provides enhanced security using this article or the blog post. Login attempts to a newly created Synapse workspace from connections using TLS versions lower than 1.2 will fail.

Data Integration

- Data quality validation rules using Assert transformation - You can now easily add data quality, data validation, and schema validation to your Synapse ETL jobs by using Assert transformation in Synapse data flows. To learn more, see the Assert transformation in mapping data flow article or the blog post.

- Native data flow connector for Dynamics - Synapse data flows can now read and write data directly to Dynamics through the new data flow Dynamics connector. Learn more on how to Create data sets in data flows to read, transform, aggregate, join, etc. using this article or the blog post. You can then write the data back into Dynamics using the built-in Synapse Spark compute.

- IntelliSense and auto-complete added to pipeline expressions - IntelliSense makes creating expressions, editing them easy. To learn more, see how to check your expression syntax, find functions, and add code to your pipelines.

Synapse SQL

- COPY schema discovery for complex data ingestion. To learn more, see the blog post or how GitHub leveraged this functionality in Introducing Automatic Schema Discovery with auto table creation for complex datatypes.

- Serverless SQL pools now support the HASHBYTES function. HASHBYTES is a T-SQL function, which hashes values. Learn how to use hash values in distributing data using this article or the blog post.

December 2021 update

The following updates are new to Azure Synapse Analytics this month.

Apache Spark for Synapse

- Accelerate Spark workloads with NVIDIA GPU acceleration blog article
- Mount remote storage to a Synapse Spark pool blog article
- Natively read & write data in ADLS with Pandas blog article
- Dynamic allocation of executors for Spark blog article

Machine Learning

- The Synapse Machine Learning library blog article
- Getting started with state-of-the-art pre-built intelligent models blog article
- Building responsible AI systems with the Synapse ML library blog article
- PREDICT is now GA for Synapse Dedicated SQL pools blog article
- Simple & scalable scoring with PREDICT and MLFlow for Apache Spark for Synapse blog article
- Retail AI solutions blog article

Security

- User-Assigned managed identities now supported in Synapse Pipelines in preview blog article
- Browse ADLS Gen2 folders in an Azure Synapse Analytics workspace in preview blog article

Data Integration

- Pipeline Fail activity blog article
- Mapping Data Flow gets new native connectors blog article
- More notebook export formats: HTML, Python, and LaTeX blog
- Three new chart types in notebook view: box plot, histogram, and pivot table blog
- Reconnect to lost notebook session blog

Integrate

- Synapse Link for Dataverse blog article
- Custom partitions for Synapse link for Azure Cosmos DB in preview blog article
- Map data tool (Public Preview), a no-code guided ETL experience blog article
- Quick reuse of spark cluster blog article
- External Call transformation blog article
- Flowlets (Public Preview) blog article

November 2021 update

The following updates are new to Azure Synapse Analytics this month.

Synapse Data Explorer

- Synapse Data Explorer now available in preview blog article

Working with Databases and Data Lakes

- Introducing Lake databases (formerly known as Spark databases) blog article
- Lake database designer now available in preview blog article
- Database Templates and Database Designer blog article

SQL

- Delta Lake support for serverless SQL is generally available blog article
- Query multiple file paths using OPENROWSET in serverless SQL blog article
- Serverless SQL queries can now return up to 200 GB of results blog article
- Handling invalid rows with OPENROWSET in serverless SQL blog article

Apache Spark for Synapse

- Accelerate Spark workloads with NVIDIA GPU acceleration blog article
- Mount remote storage to a Synapse Spark pool blog article
- Natively read & write data in ADLS with Pandas blog article
- Dynamic allocation of executors for Spark blog article

Machine Learning

- The Synapse Machine Learning library blog article
- Getting started with state-of-the-art pre-built intelligent models blog article
- Building responsible AI systems with the Synapse ML library blog article
- PREDICT is now GA for Synapse Dedicated SQL pools blog article
- Simple & scalable scoring with PREDICT and MLFlow for Apache Spark for Synapse blog article
- Retail AI solutions blog article

Security

- User-Assigned managed identities now supported in Synapse Pipelines in preview blog article
- Browse ADLS Gen2 folders in an Azure Synapse Analytics workspace in preview blog article

Data Integration

- Pipeline Fail activity blog article
- Mapping Data Flow gets new native connectors blog article

Synapse Link

- Synapse Link for Dataverse blog article
- Custom partitions for Synapse link for Azure Cosmos DB in preview blog article

October 2021 update

The following updates are new to Azure Synapse Analytics this month.

General

- Manage your cost with Azure Synapse pre-purchase plans blog article
- Move your Azure Synapse workspace across Azure regions blog article

Apache Spark for Synapse

- Spark performance optimizations blog

Security

- All Synapse RBAC roles are now generally available for use in production blog article
- Apply User-Assigned Managed Identities for Double Encryption blog article
- Synapse Administrators now have elevated access to dedicated SQL pools blog article

Governance

- Synapse workspaces can now automatically push lineage data to Microsoft Purview blog article

Integrate

- Use Stringify in data flows to easily transform complex data types to strings blog article
- Control Spark session time-to-live (TTL) in data flows blog article

CI/CD & Git

- Deploy Synapse workspaces using GitHub Actions blog article
- More control creating Git branches in Synapse Studio blog article

Developer Experience

- Enhanced Markdown editing in Synapse notebooks preview blog article
- Pandas dataframes automatically render as nicely formatted HTML tables blog article
- Use IPython widgets in Synapse Notebooks blog article
- Mssparkutils runtime context now available for Python and Scala blog article

Next steps

Get started with Azure Synapse Analytics

Request quota increases and get support for Azure Synapse Analytics

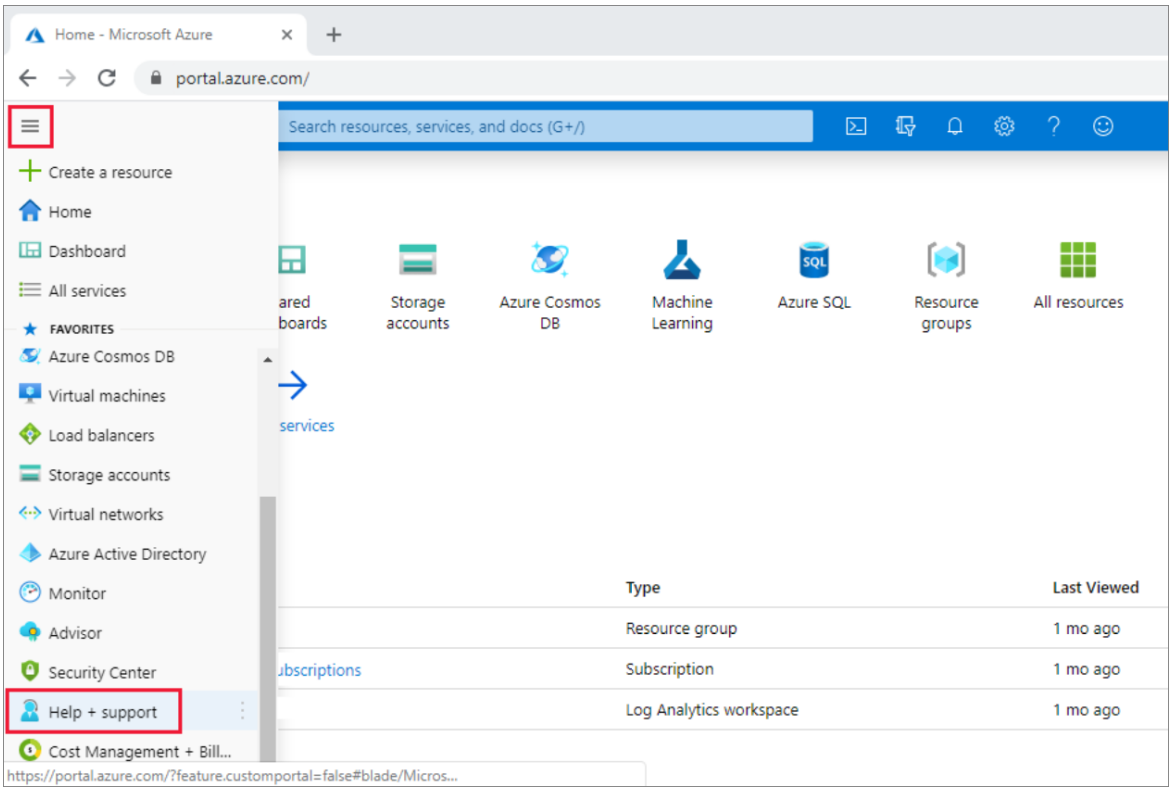
8/19/2022 • 3 minutes to read • Edit Online

This article describes how to submit a support ticket in the Azure portal for Azure Synapse Analytics. This process enables you to request a quota increase or to submit a technical support request for the engineering support team.

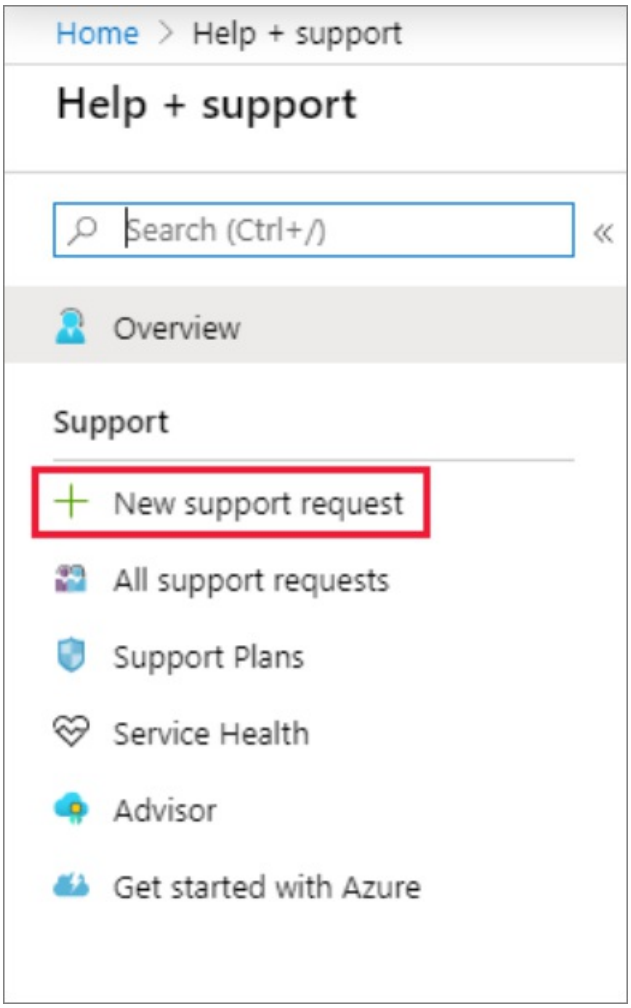
Create a support ticket

Use the following steps to create a new support request from the Azure portal for Azure Synapse Analytics.

1. On the Azure portal menu, select **Help + support**.



2. In **Help + support**, select **New support request**.

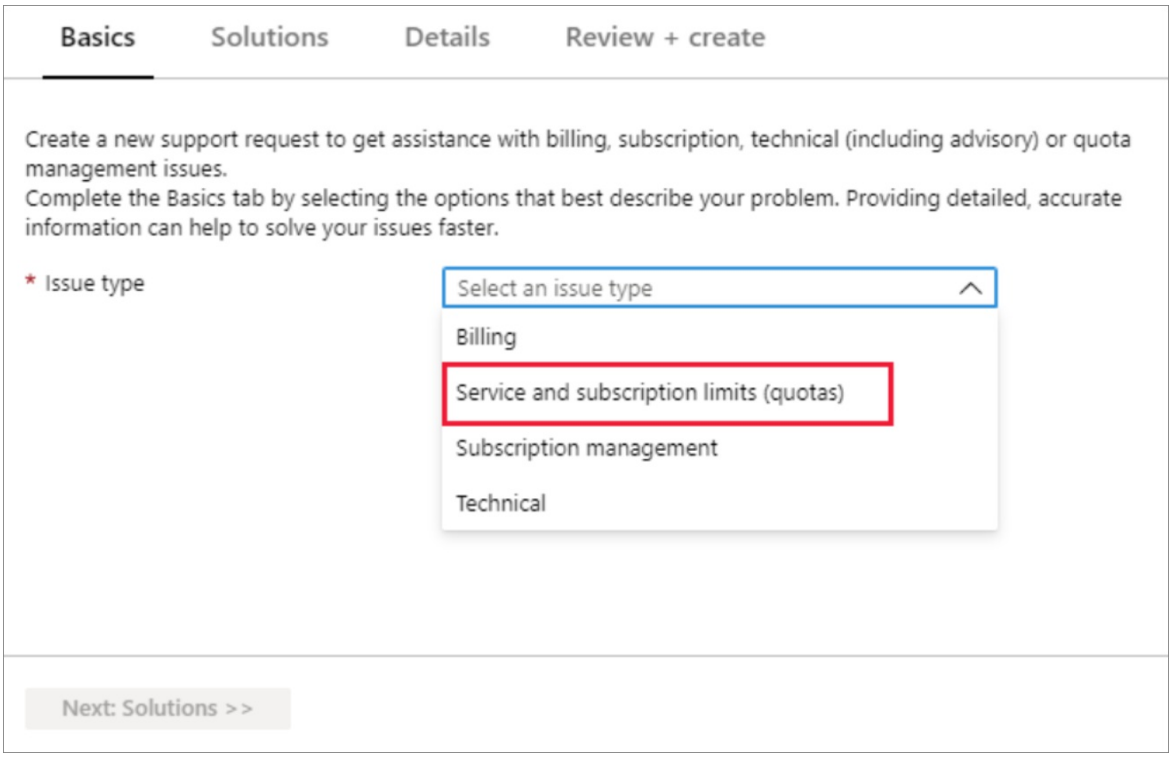


3. Review your Azure support plan.

   - **Billing, quota, and subscription management** support are available at all support levels.
   - **Break-fix** support is provided through Developer, Standard, Professional Direct, or Premier support. Break-fix issues are problems experienced by customers while using Azure where there is a reasonable expectation that Microsoft caused the problem.
   - **Developer mentoring** and **advisory services** are available at the Professional Direct and Premier support levels.

   If you have a Premier support plan, you can also report Azure Synapse Analytics issues on the Microsoft Premier online portal. See Azure support plans to learn more about the various support plans, including scope, response times, pricing, etc. For frequently asked questions about Azure support, see Azure support FAQs.

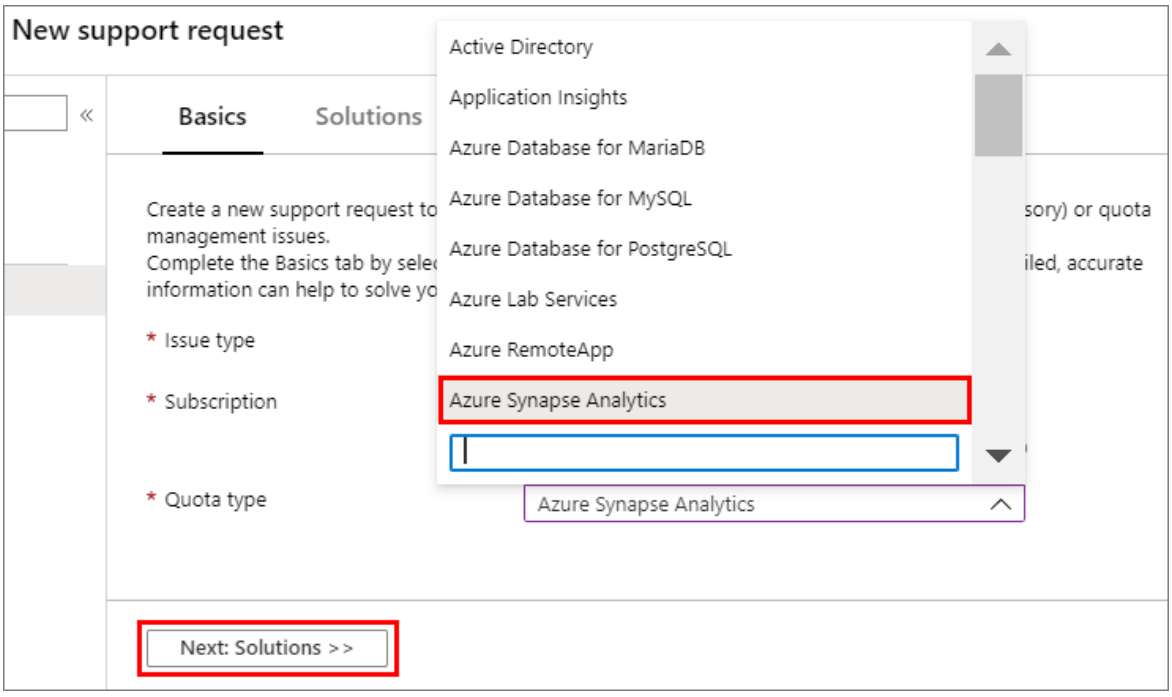
4. For **Issue type**, select the appropriate issue type. For break-fix problems, select **Technical**. For quota increase requests, select **Service and subscription limits (quotas)**.



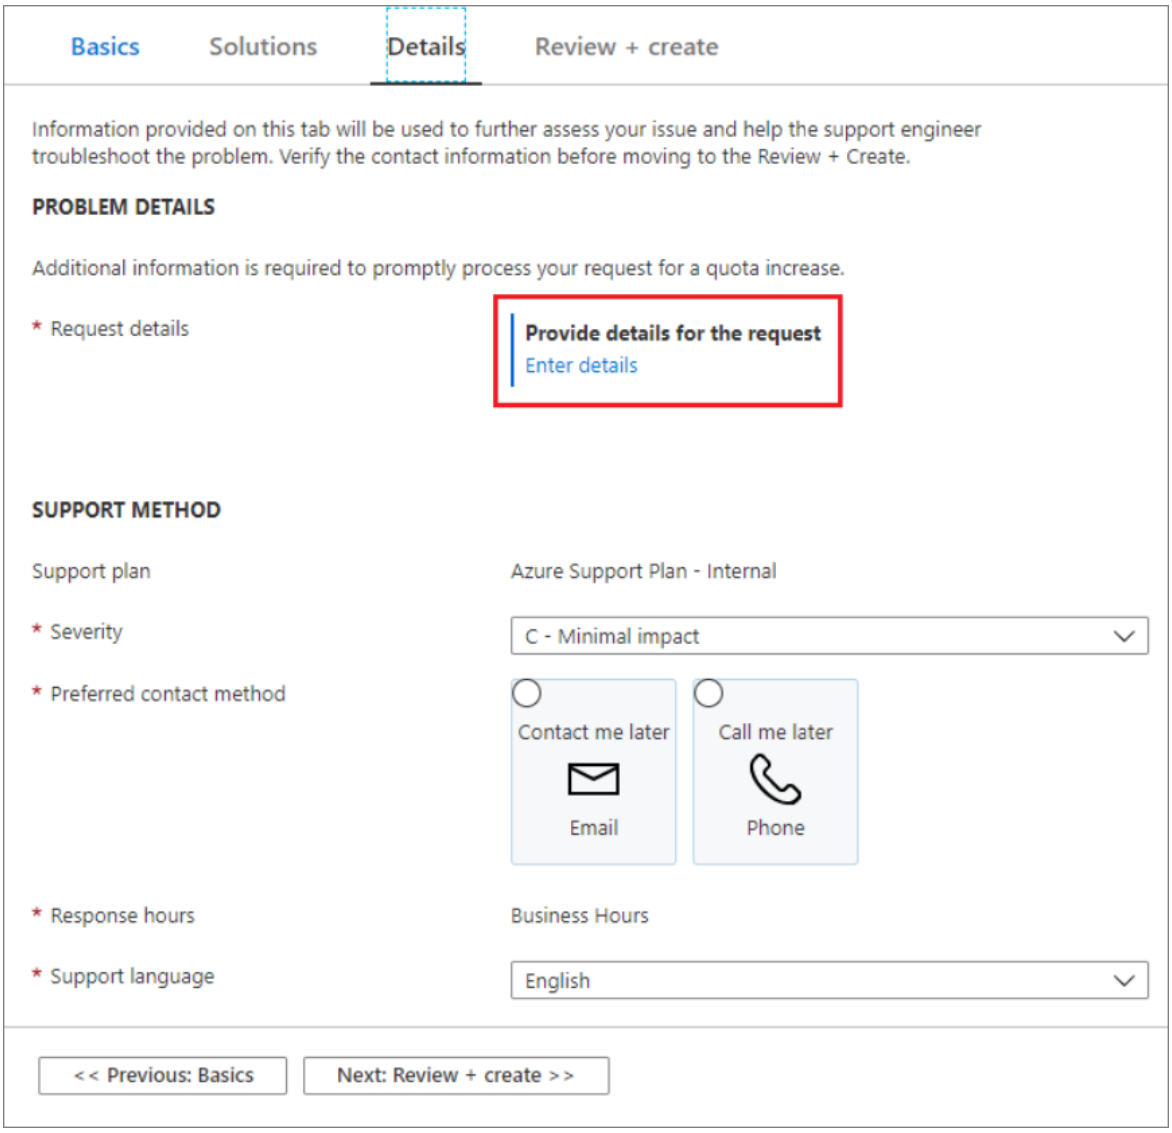
NOTE

This remainder of this article focusses on quota-increase requests. But you can also select **Technical** here for problem-resolution support requests. If you select **Technical**, you are asked to provide a summary and then identify a problem type by selecting **Select problem type**. You may see solutions to help resolve your issue. If the solutions presented do not resolve your issue, select **Next:Details** and complete the form to submit the support ticket.

5. For quota increase requests, select **Azure Synapse Analytics** for the **Quota type**. Then select **Next: Solutions >>**.



6. In the **Details** window, select **Enter details** to enter additional information.



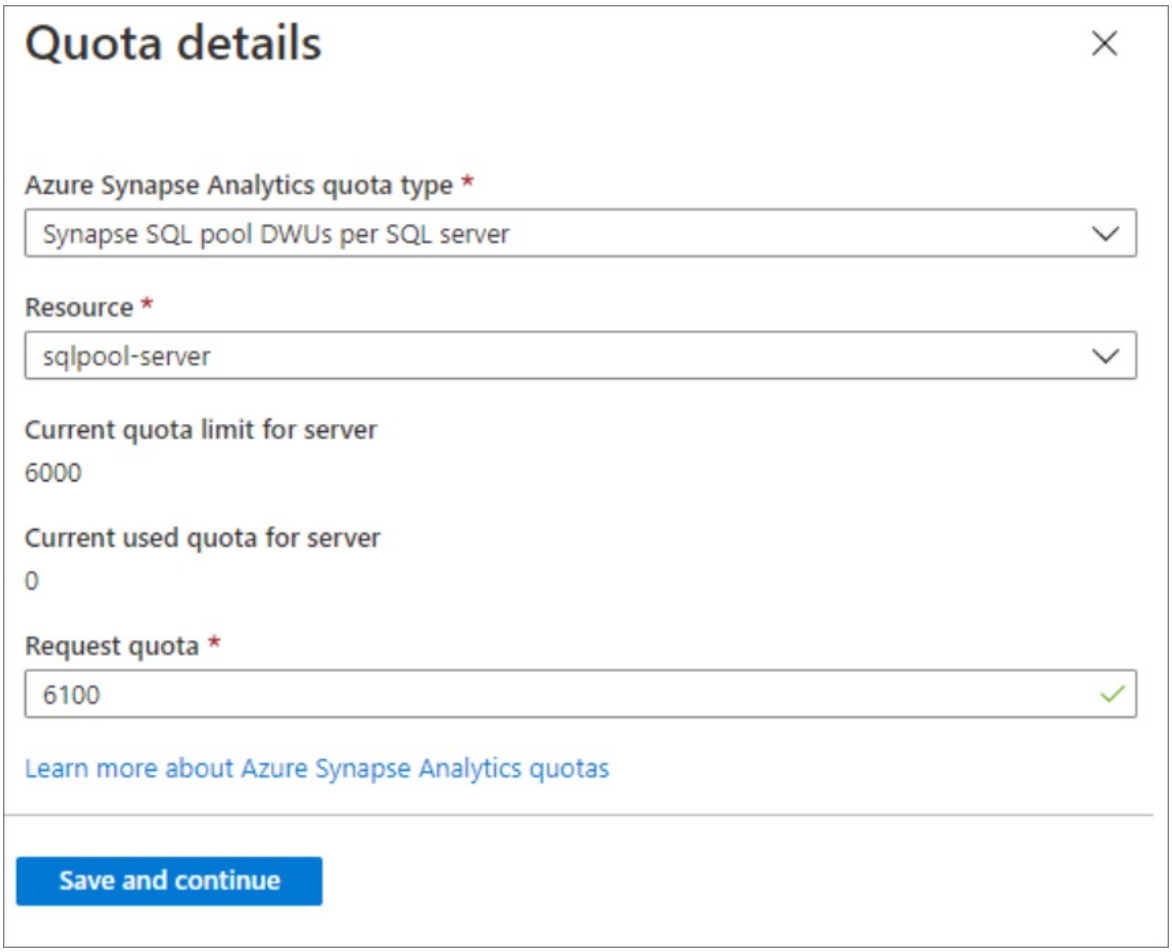
Quota request types

Selecting **Enter details** displays the **Quota details** window that allows you to add additional information. The following sections describe the different quota requests available for Azure Synapse Analytics.

Synapse SQL pool Data Warehouse Units (DWUs) per server

Use the following steps to request an increase in the DWUs per server.

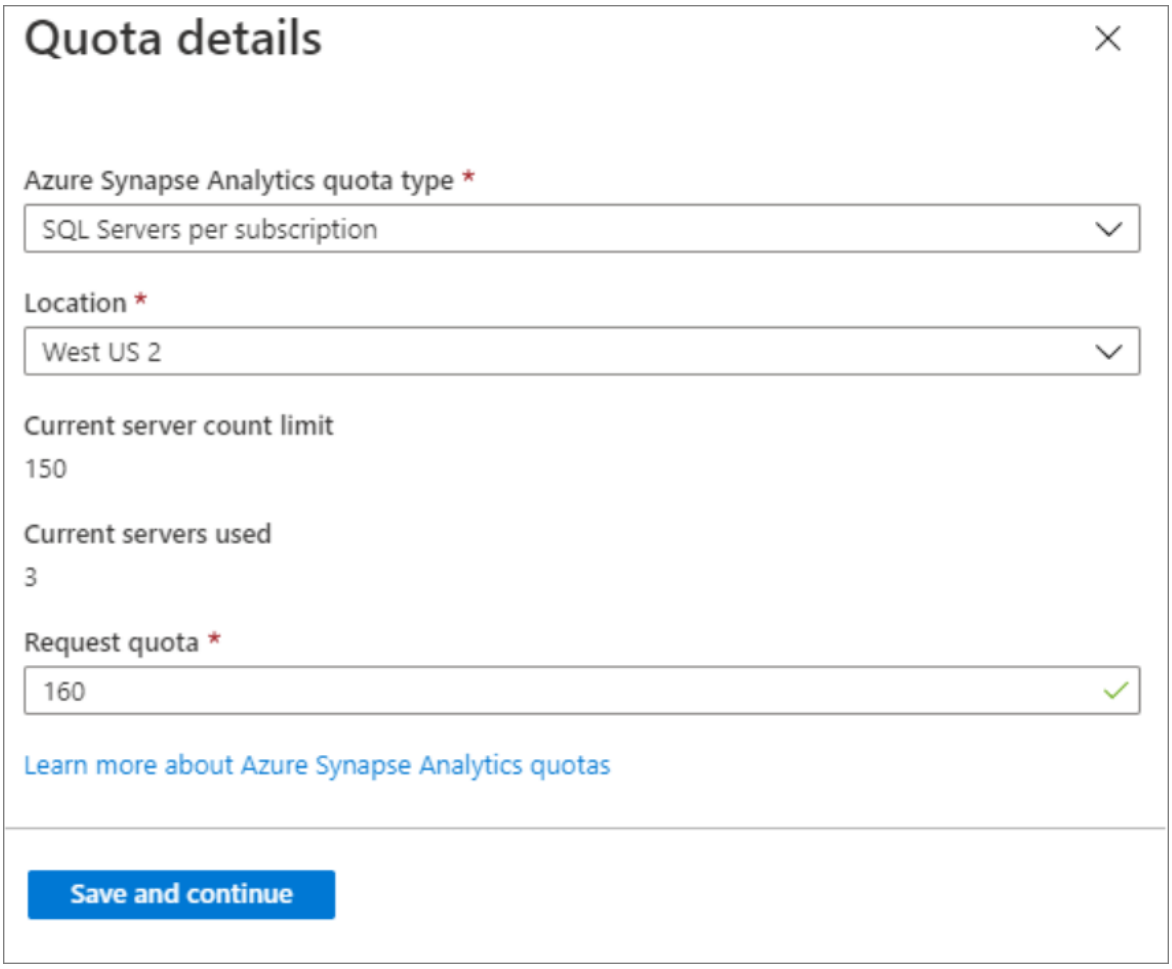
1. Select the **Synapse SQL pool DWUs per server** quota type.
2. Select the **Resource** you want to apply the quota increase to by using the dropdown list.
3. Enter your new quota into the **Request quota** section.
4. Select **Save and continue**.



Servers per subscription

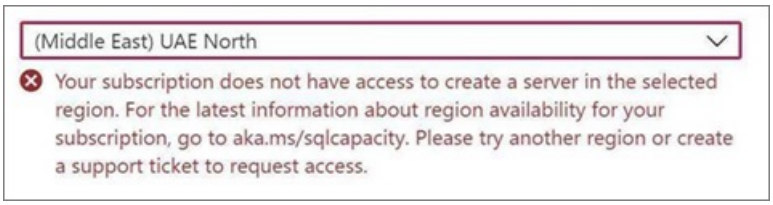
To request an increase in the number of servers per subscription, you'll need to complete the following steps:

1. Select the **SQL Servers per subscription** as the quota type.
2. In the **Location** list, select the Azure region to use. The quota is per subscription in each region.
3. In the **Request quota** field, enter your request for the maximum number of servers in that region.



4. Select **Save and continue**.

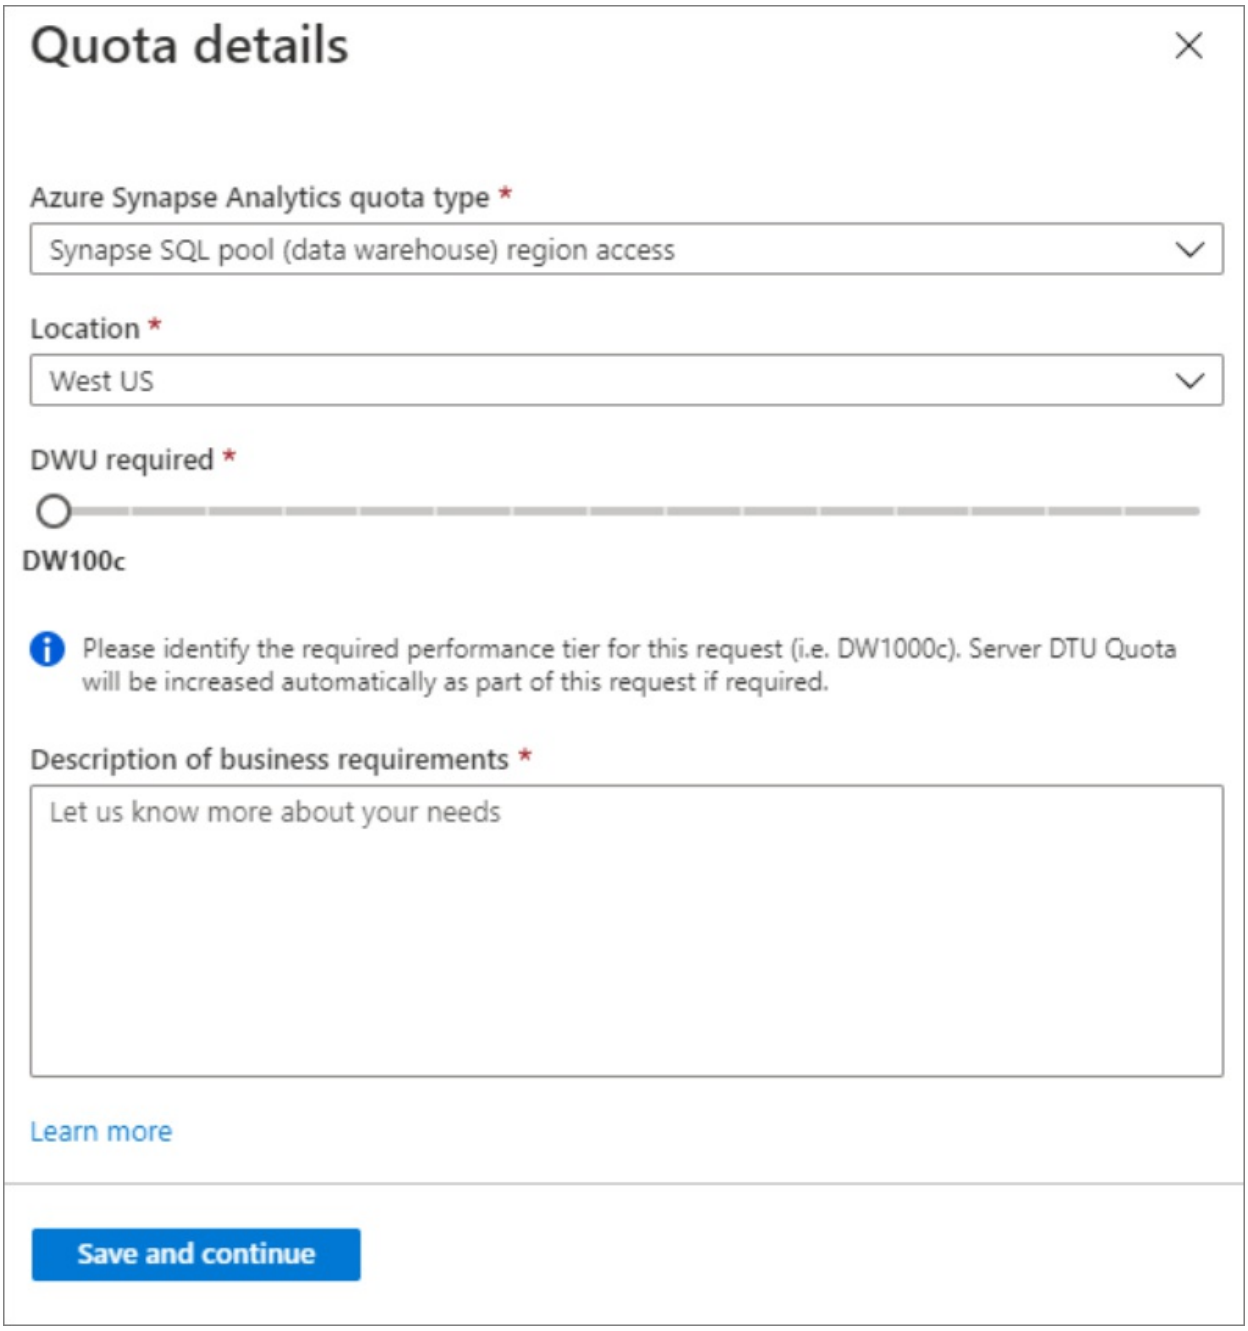
Some offer types aren't available in every region. You may see the following error:



Enable subscription access to a region

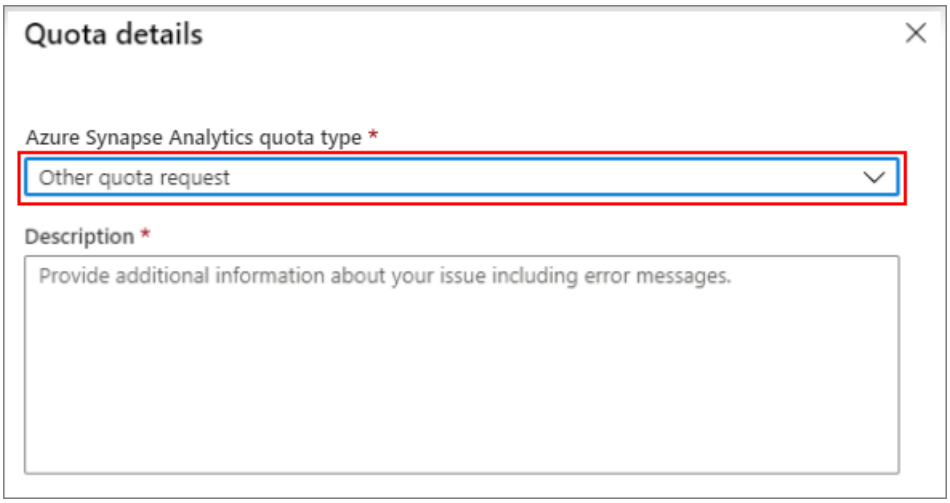
To enable region access for a subscription, you'll need to complete the following steps:

1. Select the **Synapse SQL pool (data warehouse) region access** quota type.
2. Select the region by choosing a **Location** from the dropdown list.
3. Indicate your DWU performance requirement in the **DWU required** section.
4. Enter your **Description of business requirements**.
5. Select **Save and continue**.



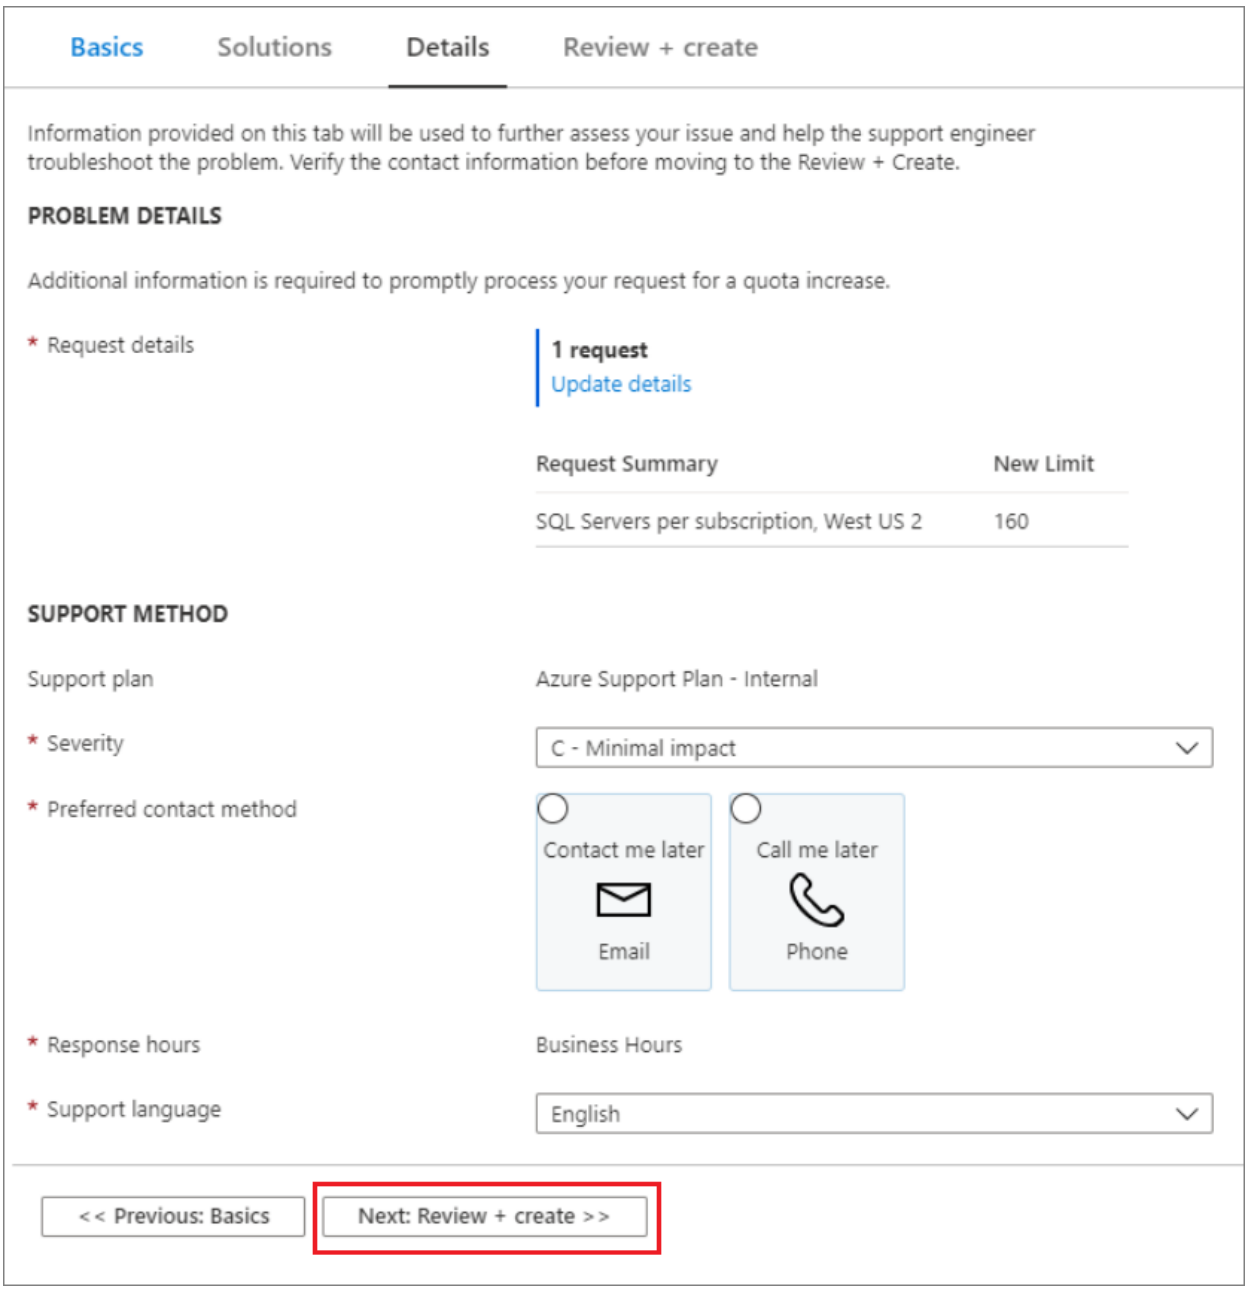
For other quota requests

Select **Other quota request** from the quota type drop-down menu for other quota request types:

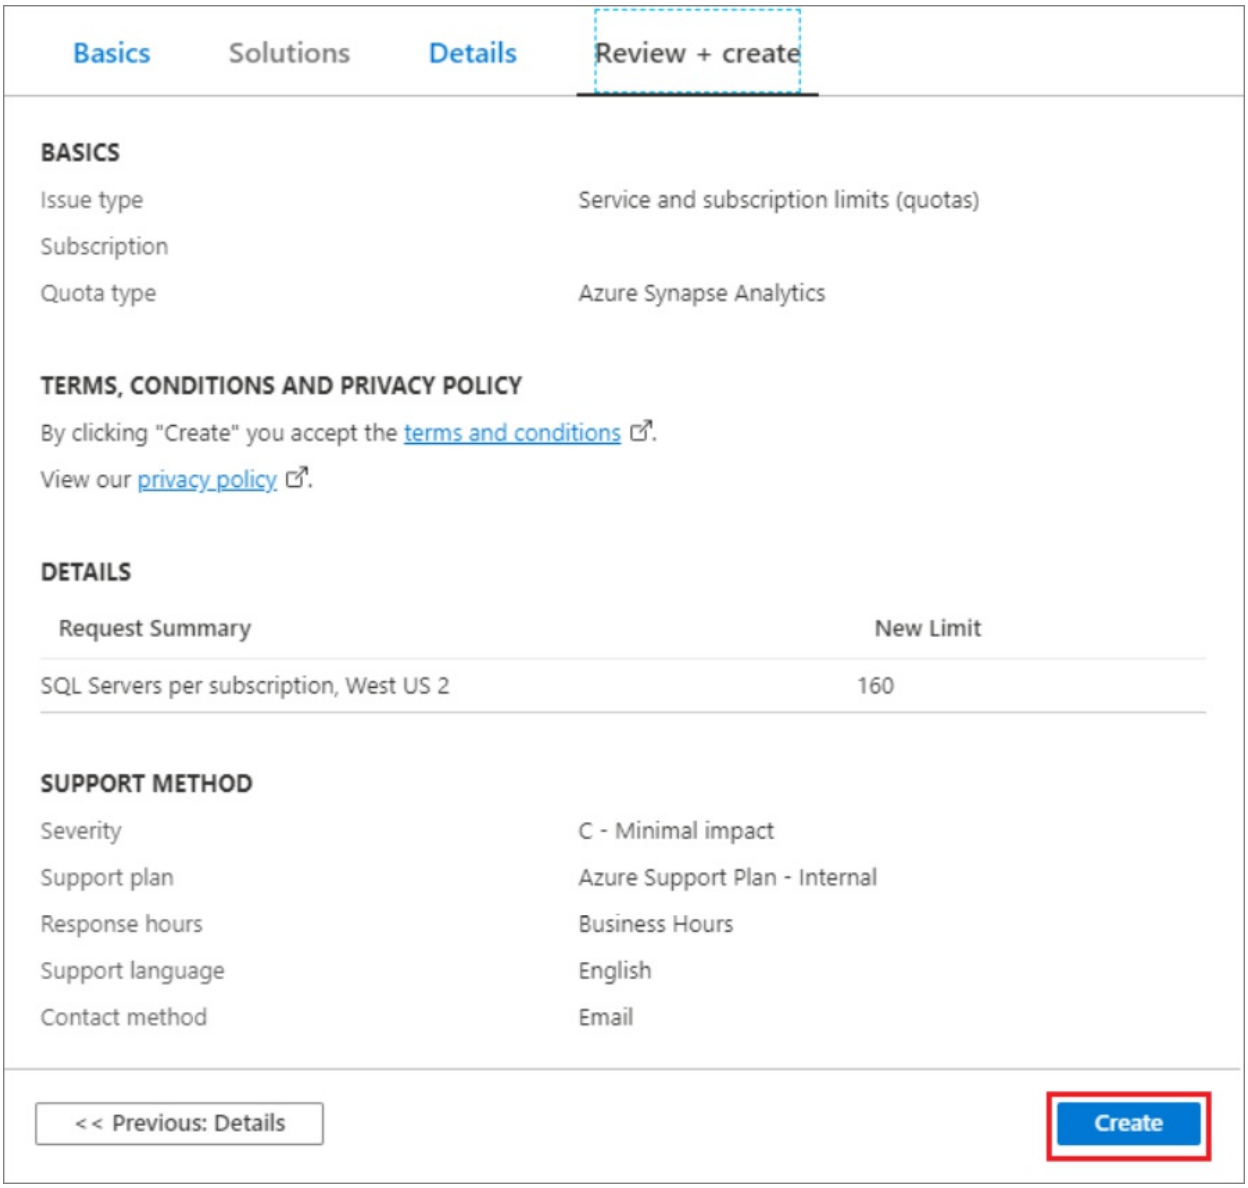


Submit your request

The final step is to fill in the remaining details of your SQL Database support request. Then select **Next: Review + create>>**.

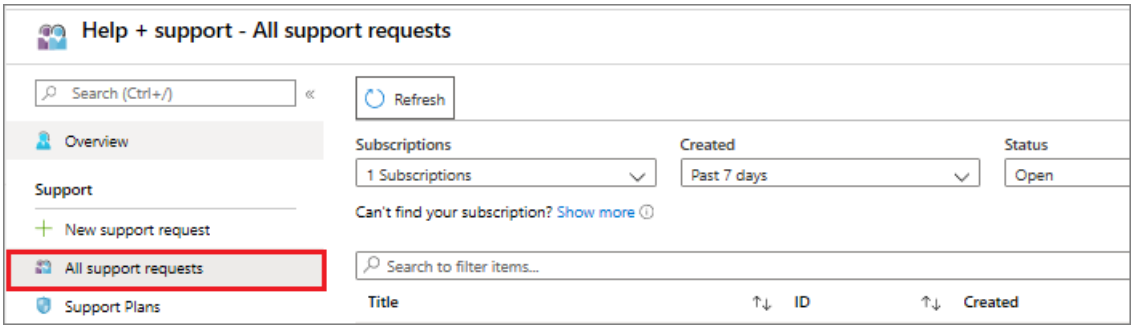


After reviewing the request details, select **Create** to submit the request.



Monitor a support ticket

After you've submitted the support request, the Azure support team will contact you. To check your request status and details, select **All support requests** on the dashboard.



Other resources

You can also connect with the Azure Synapse Analytics community on Stack Overflow or through the Microsoft Q&A question page for Azure Synapse Analytics.

Self-help for serverless SQL pool

8/19/2022 • 45 minutes to read • Edit Online

This article contains information about how to troubleshoot the most frequent problems with serverless SQL pool in Azure Synapse Analytics.

Synapse Studio

Synapse Studio is an easy-to-use tool that you can use to access your data by using a browser without a need to install database access tools. Synapse Studio isn't designed to read a large set of data or full management of SQL objects.

Serverless SQL pool is grayed out in Synapse Studio

If Synapse Studio can't establish a connection to serverless SQL pool, you'll notice that serverless SQL pool is grayed out or shows the status **Offline**. Usually, this problem occurs when one of the following cases happens:

- Your network prevents communication to the Azure Synapse Analytics back-end. The most frequent case is that port 1443 is blocked. To get serverless SQL pool to work, unblock this port. Other problems could prevent serverless SQL pool from working too. For more information, see the Troubleshooting guide.
- You don't have permission to sign in to serverless SQL pool. To gain access, an Azure Synapse workspace administrator must add you to the workspace administrator role or the SQL administrator role. For more information, see Azure Synapse access control.

Websocket connection closed unexpectedly

Your query might fail with the error message "Websocket connection was closed unexpectedly." This message means that your browser connection to Synapse Studio was interrupted, for example, because of a network issue.

To resolve this issue, rerun this query. If this message occurs often in your environment, get help from your network administrator. You can also check firewall settings, and check the Troubleshooting guide.

If the issue continues, create a support ticket through the Azure portal. Try Azure Data Studio or SQL Server Management Studio for the same queries instead of Synapse Studio for further investigation.

Serverless databases aren't shown in Synapse Studio

If you don't see the databases that are created in serverless SQL pool, check to see if your serverless SQL pool started. If serverless SQL pool is deactivated, the databases won't show. Execute any query, for example, `SELECT 1`, on serverless SQL pool to activate it and make the databases appear.

Synapse Serverless SQL pool shows as unavailable

Incorrect network configuration is often the cause of this behavior. Make sure the ports are properly configured. If you use a firewall or private endpoints, check these settings too. Finally, make sure the appropriate roles are granted.

Storage access

If you get errors while you try to access files in storage, make sure that you have permission to access data. You should be able to access publicly available files. If you try to access data without credentials, make sure that your Azure Active Directory (Azure AD) identity can directly access the files.

If you have a shared access signature key that you should use to access files, make sure that you created a

server-level or database-scoped credential that contains that credential. The credentials are required if you need to access data by using the workspace managed identity and custom service principal name (SPN).

Can't read, list, or access files in Azure Data Lake Storage

If you use an Azure AD sign-in without explicit credentials, make sure that your Azure AD identity can access the files in storage. Your Azure AD identity must have Blob Data Reader or list/read access control list (ACL) permissions to access the files. For more information, see Query fails because file cannot be opened.

If you access storage by using credentials, make sure that your managed identity or SPN has a Data Reader or Contributor role or ACL permissions. If you used a shared access signature token, make sure that it has `rl` permission and that it hasn't expired.

If you use a SQL sign-in and the `OPENROWSET` function without a data source, make sure that you have a server-level credential that matches the storage URI and has permission to access the storage.

Query fails because file can't be opened

If your query fails with the error "File cannot be opened because it does not exist or it is used by another process" and you're sure that both files exist and aren't used by another process, serverless SQL pool can't access the file. This problem usually happens because your Azure AD identity doesn't have rights to access the file or because a firewall is blocking access to the file.

By default, serverless SQL pool tries to access the file by using your Azure AD identity. To resolve this issue, you must have proper rights to access the file. The easiest way is to grant yourself a Storage Blob Data Contributor role on the storage account you're trying to query.

For more information, see:

- Azure AD access control for storage
- Control storage account access for serverless SQL pool in Synapse Analytics

Alternative to Storage Blob Data Contributor role

Instead of granting yourself a Storage Blob Data Contributor role, you can also grant more granular permissions on a subset of files.

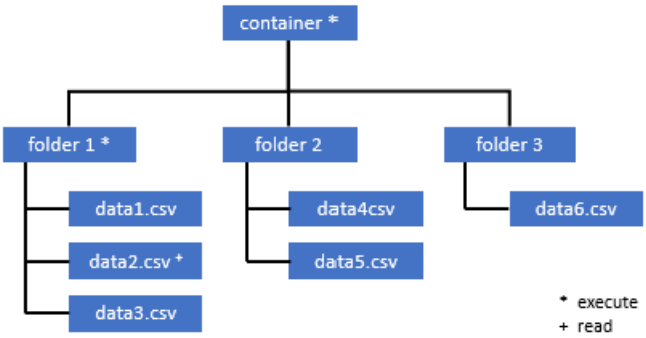
All users who need access to some data in this container also must have EXECUTE permission on all parent folders up to the root (the container).

Learn more about how to set ACLs in Azure Data Lake Storage Gen2.

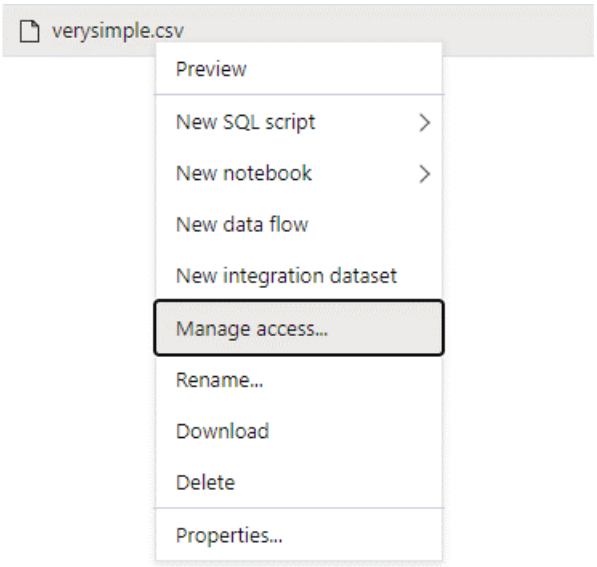
> **NOTE**
> Execute permission on the container level must be set within Data Lake Storage Gen2. Permissions on the folder can be set within Azure Synapse.

If you want to query data2.csv in this example, the following permissions are needed:

- Execute permission on container
- Execute permission on folder1
- Read permission on data2.csv



1. Sign in to Azure Synapse with an admin user that has full permissions on the data you want to access.
2. In the data pane, right-click the file and select **Manage access**.



3. Select at least **Read** permission. Enter the user's UPN or object ID, for example, user@contoso.com. Select **Add**.
4. Grant read permission for this user.

> **NOTE**
> For guest users, this step needs to be done directly with Azure Data Lake because it can't be done directly through Azure Synapse.

Content of directory on the path can't be listed

This error indicates that the user who's querying Azure Data Lake can't list the files in storage. There are several scenarios where this error might happen:

- The Azure AD user who's using Azure AD pass-through authentication doesn't have permission to list the

files in Data Lake Storage.

- The Azure AD or SQL user who's reading data by using a shared access signature key or workspace managed identity and that key or identity doesn't have permission to list the files in storage.
- The user who's accessing Dataverse data who doesn't have permission to query data in Dataverse. This scenario might happen if you use SQL users.
- The user who's accessing Delta Lake might not have permission to read the Delta Lake transaction log.

The easiest way to resolve this issue is to grant yourself the Storage Blob Data Contributor role in the storage account you're trying to query.

For more information, see:

- Azure AD access control for storage
- Control storage account access for serverless SQL pool in Synapse Analytics

Content of Dataverse table can't be listed

If you are using the Synapse link for Dataverse to read the linked DataVerse tables, you need to use Azure AD account to access the linked data using the serverless SQL pool. For more information, see Azure Synapse Link for Dataverse with Azure Data Lake.

If you try to use a SQL login to read an external table that is referencing the DataVerse table, you will get the following error:

```
External table '???' is not accessible because content of directory cannot be listed.
```

Dataverse external tables always use Azure AD passthrough authentication. You *can't* configure them to use a shared access signature key or workspace managed identity.

Content of Delta Lake transaction log can't be listed

The following error is returned when serverless SQL pool can't read the Delta Lake transaction log folder:

```
Content of directory on path 'https://.....core.windows.net/.../_delta_log/*.json' cannot be listed.
```

Make sure the `_delta_log` folder exists. Maybe you're querying plain Parquet files that aren't converted to Delta Lake format. If the `_delta_log` folder exists, make sure you have both read and list permission on the underlying Delta Lake folders. Try to read *.json files directly by using `FORMAT='csv'`. Put your URI in the BULK parameter:

```
select top 10 *
from openrowset(BULK 'https://.....core.windows.net/.../_delta_log/*.json',FORMAT='csv', FIELDQUOTE =
'0x0b', FIELDTERMINATOR ='0x0b',ROWTERMINATOR = '0x0b')
with (line varchar(max)) as logs
```

If this query fails, the caller doesn't have permission to read the underlying storage files.

Query execution

You might get errors during the query execution in the following cases:

- The caller can't access some objects.
- The query can't access external data.
- The query contains some functionalities that aren't supported in serverless SQL pools.

Query fails because it can't be executed due to current resource constraints

Your query might fail with the error message "This query cannot be executed due to current resource constraints." This message means serverless SQL pool can't execute at this moment because of resource constraints. Here are some troubleshooting options:

- Make sure data types of reasonable sizes are used.
- If your query targets Parquet files, consider defining explicit types for string columns because they'll be VARCHAR(8000) by default. Check inferred data types.
- If your query targets CSV files, consider creating statistics.
- To optimize your query, see Performance best practices for serverless SQL pool.

Query timeout expired

The error "Query timeout expired" is returned if the query executed more than 30 minutes on serverless SQL pool. This limit for serverless SQL pool can't be changed.

Try to optimize your query by applying best practices. Or try to materialize parts of your queries by using create external table as select (CETAS). Check if there's a concurrent workload running on serverless SQL pool because the other queries might take the resources. In that case, you might split the workload on multiple workspaces.

Invalid object name

The error "Invalid object name 'table name'" indicates that you're using an object, such as a table or view, that doesn't exist in the serverless SQL pool database. Try these options:

- List the tables or views and check if the object exists. Use SQL Server Management Studio or Azure Data Studio because Synapse Studio might show some tables that aren't available in serverless SQL pool.
- If you see the object, check that you're using some case-sensitive/binary database collation. Maybe the object name doesn't match the name that you used in the query. With a binary database collation, `Employee` and `employee` are two different objects.
- If you don't see the object, maybe you're trying to query a table from a lake or Spark database. The table might not be available in the serverless SQL pool because:
  - The table has some column types that can't be represented in serverless SQL pool.
  - The table has a format that isn't supported in serverless SQL pool. Examples are Delta or ORC.

Unclosed quotation mark after the character string

In rare cases, where you use the LIKE operator on a string column or some comparison with the string literals, you might get the following error:

```
Msg 105, Level 15, State 1, Line 88
Unclosed quotation mark after the character string
```

This error might happen if you use the `Latin1_General_100_BIN2_UTF8` collation on the column. Try to set `Latin1_General_100_CI_AS_SC_UTF8` collation on the column instead of the `Latin1_General_100_BIN2_UTF8` collation to resolve the issue. If the error is still returned, raise a support request through the Azure portal.

Couldn't allocate tempdb space while transferring data from one distribution to another

The error "Could not allocate tempdb space while transferring data from one distribution to another" is returned when the query execution engine can't process data and transfer it between the nodes that are executing the query. It's a special case of the generic query fails because it cannot be executed due to current resource constraints error. This error is returned when the resources allocated to the `tempdb` database are insufficient to run the query.

Apply best practices before you file a support ticket.

Query fails with an error handling an external file (max errors count reached)

If your query fails with the error message 'error handling external file: Max errors count reached', it means that there is a mismatch of a specified column type and the data that needs to be loaded.

To get more information about the error and which rows and columns to look at, change the parser version from `2.0` to `1.0`.

Example

If you want to query the file `names.csv` with this Query 1, Azure Synapse serverless SQL pool returns with the following error:

names.csv

```
Id,first name,
1, Adam
2,Bob
3,Charles
4,David
5,Eva
```

Query 1:

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
PARSER_VERSION='2.0',
       FIELDTERMINATOR =';',
       FIRSTROW = 2
    )
    WITH (
    [ID] SMALLINT,
    [Text] VARCHAR (1) COLLATE Latin1_General_BIN2
)

    AS[result]
```

Cause

"Error handling external file: 'Max error count reached'. File/External table name: [filepath]."

As soon as the parser version is changed from version 2.0 to 1.0, the error messages help to identify the problem. The new error message is now "Bulk load data conversion error (truncation) for row 1, column 2 (Text) in data file [filepath]."

Truncation tells you that your column type is too small to fit your data. The longest first name in this names.csv file has seven characters. The according data type to be used should be at least VARCHAR(7). The error is caused by this line of code:

```
    [Text] VARCHAR (1) COLLATE Latin1_General_BIN2
```

Changing the query accordingly resolves the error. After debugging, change the parser version to 2.0 again to achieve maximum performance.

For more information about when to use which parser version, see Use OPENROWSET using serverless SQL pool in Synapse Analytics.

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
PARSER_VERSION='2.0',
        FIELDTERMINATOR =';',
        FIRSTROW = 2
    )
    WITH (
    [ID] SMALLINT,
    [Text] VARCHAR (7) COLLATE Latin1_General_BIN2
)

    AS[result]
```

Can't bulk load because the file couldn't be opened

The error "Cannot bulk load because the file could not be opened" is returned if a file is modified during the query execution. Usually, you might get an error like "Cannot bulk load because the file {file path} could not be opened. Operating system error code 12. (The access code is invalid.)"

The serverless SQL pools can't read files that are being modified while the query is running. The query can't take a lock on the files. If you know that the modification operation is *append*, you can try to set the following option:

`{"READ_OPTIONS":["ALLOW_INCONSISTENT_READS"]}`.

For more information, see how to query append-only files or create tables on append-only files.

Query fails with data conversion error

Your query might fail with the error message "Bulk load data conversion error (type mismatches or invalid character for the specified code page) for row n, column m [columnname] in the data file [filepath]." This message means your data types didn't match the actual data for row number n and column m.

For instance, if you expect only integers in your data, but in row n there's a string, this error message is the one you'll get.

To resolve this problem, inspect the file and the data types you chose. Also check if your row delimiter and field terminator settings are correct. The following example shows how inspecting can be done by using VARCHAR as the column type.

For more information on field terminators, row delimiters, and escape quoting characters, see Query CSV files.

Example

If you want to query the file names.csv:

names.csv

```
Id, first name,
1,Adam
2,Bob
3,Charles
4,David
five,Eva
```

with the following Query 1:

Query 1:

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
        PARSER_VERSION='1.0',
       FIELDTERMINATOR =',',
       FIRSTROW = 2
    )
    WITH (
    [ID] SMALLINT,
    [Firstname] VARCHAR (25) COLLATE Latin1_General_BIN2
)

    AS[result]
```

Azure Synapse serverless SQL pool returns the error "Bulk load data conversion error (type mismatch or invalid character for the specified code page) for row 6, column 1 (ID) in data file [filepath]."

It's necessary to browse the data and make an informed decision to handle this problem. To look at the data that causes this problem, the data type needs to be changed first. Instead of querying the ID column with the data type SMALLINT, VARCHAR(100) is now used to analyze this issue.

It is necessary to browse the data and make an informed decision to handle this problem. To look at the data that causes this problem, the data type needs to be changed first. Instead of querying column "ID" with the data type "SMALLINT", VARCHAR(100) is now used to analyze this issue.

With this slightly changed Query 2, the data can now be processed to return the list of names.

Query 2:

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
PARSER_VERSION='1.0',
       FIELDTERMINATOR =',',
       FIRSTROW = 2
    )
    WITH (
    [ID] VARCHAR(100),
    [Firstname] VARCHAR (25) COLLATE Latin1_General_BIN2
)

    AS[result]
```

names.csv

```
Id, first name,
1, Adam
2, Bob
3, Charles
4, David
five, Eva
```

You might observe that the data has unexpected values for ID in the fifth row. In such circumstances, it's important to align with the business owner of the data to agree on how corrupt data like this example can be

avoided. If prevention isn't possible at the application level, reasonable-sized VARCHAR might be the only option here.

> **TIP**
> Try to make VARCHAR() as short as possible. Avoid VARCHAR(MAX) if possible because it can impair performance.

The query result doesn't look as expected

Your query might not fail, but you might see that your result set isn't as expected. The resulting columns might be empty or unexpected data might be returned. In this scenario, it's likely that a row delimiter or field terminator was incorrectly chosen.

To resolve this problem, take another look at the data and change those settings. Debugging this query is easy, as shown in the following example.

Example

If you want to query the file `names.csv` with the query in Query 1, Azure Synapse serverless SQL pool returns with a result that looks odd:

names.csv

```
Id,first name,
1, Adam
2, Bob
3, Charles
4, David
5, Eva
```

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
        PARSER_VERSION='1.0',
       FIELDTERMINATOR =';',
       FIRSTROW = 2
    )
    WITH (
    [ID] VARCHAR(100),
    [Firstname] VARCHAR (25) COLLATE Latin1_General_BIN2
)

    AS[result]
```

ID	FIRSTNAME
1,Adam	NULL
2,Bob	NULL
3,Charles	NULL
4,David	NULL
5,Eva	NULL

There seems to be no value in the column `Firstname`. Instead, all values ended up being in the `ID` column. Those values are separated by a comma. The problem was caused by this line of code because it's necessary to choose the comma instead of the semicolon symbol as field terminator:

```
FIELDTERMINATOR =';',
```

Changing this single character solves the problem:

```
FIELDTERMINATOR =',',
```

The result set created by Query 2 now looks as expected:

Query 2:

```
SELECT
TOP100*
FROM
OPENROWSET(
BULK'[FILE-PATH OF CSV FILE]',
FORMAT='CSV',
        PARSER_VERSION='1.0',
       FIELDTERMINATOR =',',
       FIRSTROW = 2
    )
    WITH (
    [ID] VARCHAR(100),
    [Firstname] VARCHAR (25) COLLATE Latin1_General_BIN2
)

    AS[result]
```

returns

ID	FIRSTNAME
1	Adam
2	Bob
3	Charles
4	David
5	Eva

Column of type isn't compatible with external data type

If your query fails with the error message "Column [column-name] of type [type-name] is not compatible with external data type [...]," it's likely that a PARQUET data type was mapped to an incorrect SQL data type. For instance, if your Parquet file has a column price with float numbers (like 12.89) and you tried to map it to INT, this error message is the one you'll get.

To resolve this issue, inspect the file and the data types you chose. This mapping table helps to choose a correct SQL data type. As a best practice, specify mapping only for columns that would otherwise resolve into the VARCHAR data type. Avoiding VARCHAR when possible leads to better performance in queries.

Example

If you want to query the file taxi-data.parquet with this Query 1, Azure Synapse serverless SQL pool returns the following error:

taxi-data.parquet:

PASSENGERCOUNT	SUMTRIPDISTANCE	AVGTRIPDISTANCE
1	2635668.66000064	6.72731710678951
2	172174.330000005	2.97915543404919
3	296384.390000011	2.8991352022851
4	12544348.58999806	6.30581582240281
5	13091570.2799993	111.065989028627

Query 1:

```
SELECT
    *
FROM
    OPENROWSET(
        BULK '<filepath>taxi-data.parquet',
        FORMAT='PARQUET'
    )  WITh
        (
        PassengerCount INT,
        SumTripDistance INT,
        AVGTripDistance FLOAT
        )

    AS [result]
```

```
Column 'SumTripDistance' of type 'INT' is not compatible with external data type 'Parquet physical type:
DOUBLE', please try with 'FLOAT'. File/External table name: '<filepath>taxi-data.parquet'.
```

This error message tells you that data types aren't compatible and comes with the suggestion to use FLOAT instead of INT. The error is caused by this line of code:

```
SumTripDistance INT,
```

With this slightly changed Query 2, the data can now be processed and shows all three columns:

Query 2:

```
SELECT
    *
FROM
    OPENROWSET(
        BULK '<filepath>taxi-data.parquet',
        FORMAT='PARQUET'
    )  WITh
        (
        PassengerCount INT,
        SumTripDistance FLOAT,
        AVGTripDistance FLOAT
        )

    AS [result]
```

Query references an object that isn't supported in distributed processing mode

The error "The query references an object that is not supported in distributed processing mode" indicates that you've used an object or function that can't be used while you query data in Azure Storage or Azure Cosmos DB analytical storage.

Some objects, like system views, and functions can't be used while you query data stored in Azure Data Lake or Azure Cosmos DB analytical storage. Avoid using the queries that join external data with system views, load external data in a temp table, or use some security or metadata functions to filter external data.

WaitIOCompletion call failed

The error message "WaitIOCompletion call failed" indicates that the query failed while waiting to complete the I/O operation that reads data from the remote storage, Azure Data Lake.

The error message has the following pattern:

```
Error handling external file: 'WaitIOCompletion call failed. HRESULT = ???'. File/External table name...
```

Make sure that your storage is placed in the same region as serverless SQL pool. Check the storage metrics and verify there are no other workloads on the storage layer, such as uploading new files, that could saturate I/O requests.

The field HRESULT contains the result code. The following error codes are the most common along with their potential solutions.

- 0x80070002
- 0x80070005
- 0x80070008
- 0x8007000C
- 0x800700A1
- 0x80070057
- 0x80072EE7

This error code means the source file isn't in storage.

There are reasons why this error code can happen:

- The file was deleted by another application.
  - In this common scenario, the query execution starts, it enumerates the files, and the files are found. Later, during the query execution, a file is deleted. For example, it could be deleted by Databricks, Spark, or Azure Data Factory. The query fails because the file isn't found.
- This issue can also occur with the Delta format. The query might succeed on retry because there's a new

version of the table and the deleted file isn't queried again.

- An invalid execution plan is cached.
  - As a temporary mitigation, run the command `DBCC FREEPROCCACHE`. If the problem persists, create a support ticket.

Incorrect syntax near NOT

The error "Incorrect syntax near 'NOT'" indicates there are some external tables with columns that contain the NOT NULL constraint in the column definition. Update the table to remove NOT NULL from the column definition. This error can sometimes also occur transiently with tables created from a CETAS statement. If the problem doesn't resolve, you can try dropping and re-creating the external table.

Partitioning column returns NULL values

If your query returns NULL values instead of partitioning columns or can't find the partition columns, you have a few possible troubleshooting steps:

- If you use tables to query a partitioned dataset, be aware that tables don't support partitioning. Replace the table with the partitioned views.
- If you use the partitioned views with the OPENROWSET that queries partitioned files by using the FILEPATH() function, make sure you correctly specified the wildcard pattern in the location and used the proper index for referencing the wildcard.
- If you're querying the files directly in the partitioned folder, be aware that the partitioning columns aren't the parts of the file columns. The partitioning values are placed in the folder paths and not the files. For this reason, the files don't contain the partitioning values.

Inserting value to batch for column type DATETIME2 failed

The error "Inserting value to batch for column type DATETIME2 failed" indicates that the serverless pool can't read the date values from the underlying files. The datetime value stored in the Parquet or Delta Lake file can't be represented as a `DATETIME2` column.

Inspect the minimum value in the file by using Spark, and check that some dates are less than 0001-01-03. If you stored the files by using Spark 2.4, the datetime values before are written by using the Julian calendar that isn't aligned with the proleptic Gregorian calendar used in serverless SQL pools.

There might be a two-day difference between the Julian calendar used to write the values in Parquet (in some Spark versions) and the proleptic Gregorian calendar used in serverless SQL pool. This difference might cause conversion to a negative date value, which is invalid.

Try to use Spark to update these values because they're treated as invalid date values in SQL. The following sample shows how to update the values that are out of SQL date ranges to NULL in Delta Lake:

```
from delta.tables import *
from pyspark.sql.functions import *

deltaTable = DeltaTable.forPath(spark,
             "abfss://my-container@myaccount.dfs.core.windows.net/delta-lake-data-set")
deltaTable.update(col("MyDateTimeColumn") < '0001-02-02', { "MyDateTimeColumn": null } )
```

This change removes the values that can't be represented. The other date values might be properly loaded but incorrectly represented because there's still a difference between Julian and proleptic Gregorian calendars. You might see unexpected date shifts even for the dates before `1900-01-01` if you use Spark 3.0 or older versions.

Consider migrating to Spark 3.1 or higher. It uses a proleptic Gregorian calendar that's aligned with the calendar in serverless SQL pool. Reload your legacy data with the higher version of Spark, and use the following setting to correct the dates:

```
spark.conf.set("spark.sql.legacy.parquet.int96RebaseModeInWrite", "CORRECTED")
```

Query failed because of a topology change or compute container failure

This error might indicate that some internal process issue happened in serverless SQL pool. File a support ticket with all necessary details that could help the Azure support team investigate the issue.

Describe anything that might be unusual compared to the regular workload. For example, perhaps there was a large number of concurrent requests or a special workload or query started executing before this error happened.

Configuration

Serverless SQL pools enable you to use T-SQL to configure database objects. There are some constraints:

- You can't create objects in master and lakehouse or Spark databases.
- You must have a master key to create credentials.
- You must have permission to reference data that's used in the objects.

Can't create a database

If you get the error "CREATE DATABASE failed. User database limit has been already reached," you've created the maximal number of databases that are supported in one workspace. For more information, see Constraints.

- If you need to separate the objects, use schemas within the databases.
- If you need to reference Azure Data Lake storage, create lakehouse databases or Spark databases that will be synchronized in serverless SQL pool.

Create a master key in the database or open the master key in the session before performing this operation

If your query fails with the error message "Please create a master key in the database or open the master key in the session before performing this operation," it means that your user database has no access to a master key at the moment.

Most likely, you created a new user database and haven't created a master key yet.

To resolve this problem, create a master key with the following query:

```
CREATE MASTER KEY [ ENCRYPTION BY PASSWORD ='password' ];
```

> **NOTE**
> Replace `'password'` with a different secret here.

CREATE statement isn't supported in the master database

If your query fails with the error message "Failed to execute query. Error: CREATE EXTERNAL TABLE/DATA SOURCE/DATABASE SCOPED CREDENTIAL/FILE FORMAT is not supported in master database," it means that the master database in serverless SQL pool doesn't support the creation of:

- External tables.
- External data sources.
- Database scoped credentials.
- External file formats.

Here's the solution:

1. Create a user database:

```
CREATE DATABASE <DATABASE_NAME>
```

2. Execute a CREATE statement in the context of <DATABASE_NAME>, which failed earlier for the master database.

   Here's an example of the creation of an external file format:

```
USE <DATABASE_NAME>
CREATE EXTERNAL FILE FORMAT [SynapseParquetFormat]
WITH ( FORMAT_TYPE = PARQUET)
```

Operation isn't allowed for a replicated database

If you're trying to create SQL objects, users, or change permissions in a database, you might get errors like "Operation CREATE USER is not allowed for a replicated database." This error is returned when you try to create objects in a database that's shared with Spark pool. The databases that are replicated from Apache Spark pools are read only. You can't create new objects into a replicated database by using T-SQL.

Create a separate database and reference the synchronized tables by using three-part names and cross-database queries.

Can't create Azure AD sign-in or user

If you get an error while you're trying to create a new Azure AD sign-in or user in a database, check the sign-in you used to connect to your database. The sign-in that's trying to create a new Azure AD user must have permission to access the Azure AD domain and check if the user exists. Be aware that:

- SQL sign-ins don't have this permission, so you'll always get this error if you use SQL authentication.
- If you use an Azure AD sign-in to create new sign-ins, check to see if you have permission to access the Azure AD domain.

Azure Cosmos DB

Serverless SQL pools enable you to query Azure Cosmos DB analytical storage by using the `OPENROWSET` function. Make sure that your Azure Cosmos DB container has analytical storage. Make sure that you correctly specified the account, database, and container name. Also, make sure that your Azure Cosmos DB account key is valid. For more information, see Prerequisites.

Can't query Azure Cosmos DB by using the OPENROWSET function

If you can't connect to your Azure Cosmos DB account, look at the prerequisites. Possible errors and troubleshooting actions are listed in the following table.

ERROR	ROOT CAUSE
Syntax errors: - Incorrect syntax near `OPENROWSET`. - `...` isn't a recognized `BULK OPENROWSET` provider option. - Incorrect syntax near `...`.	Possible root causes: - Not using Azure Cosmos DB as the first parameter. - Using a string literal instead of an identifier in the third parameter. - Not specifying the third parameter (container name).
There was an error in the Azure Cosmos DB connection string.	- The account, database, or key isn't specified. - An option in a connection string isn't recognized. - A semicolon (`;`) is placed at the end of a connection string.

ERROR	ROOT CAUSE
Resolving Azure Cosmos DB path has failed with the error "Incorrect account name" or "Incorrect database name."	The specified account name, database name, or container can't be found, or analytical storage hasn't been enabled to the specified collection.
Resolving Azure Cosmos DB path has failed with the error "Incorrect secret value" or "Secret is null or empty."	The account key isn't valid or is missing.

UTF-8 collation warning is returned while reading Azure Cosmos DB string types

Serverless SQL pool returns a compile-time warning if the `OPENROWSET` column collation doesn't have UTF-8 encoding. You can easily change the default collation for all `OPENROWSET` functions running in the current database by using the T-SQL statement `alter database current collate Latin1_General_100_CI_AS_SC_UTF8`.

Latin1_General_100_BIN2_UTF8 collation provides the best performance when you filter your data by using string predicates.

Missing rows in Azure Cosmos DB analytical store

Some items from Azure Cosmos DB might not be returned by the `OPENROWSET` function. Be aware that:

- There's a synchronization delay between the transactional and analytical store. The document you entered in the Azure Cosmos DB transactional store might appear in the analytical store after two to three minutes.
- The document might violate some schema constraints.

Query returns NULL values in some Azure Cosmos DB items

Azure Synapse SQL returns NULL instead of the values that you see in the transaction store in the following cases:

- There's a synchronization delay between the transactional and analytical store. The value that you entered in the Azure Cosmos DB transactional store might appear in the analytical store after two to three minutes.
- There might be a wrong column name or path expression in the WITH clause. The column name (or path expression after the column type) in the WITH clause must match the property names in the Azure Cosmos DB collection. Comparison is case sensitive. For example, `productCode` and `ProductCode` are different properties. Make sure that your column names exactly match the Azure Cosmos DB property names.
- The property might not be moved to the analytical storage because it violates some schema constraints, such as more than 1,000 properties or more than 127 nesting levels.
- If you use well-defined schema representation, the value in the transactional store might have a wrong type. Well-defined schema locks the types for each property by sampling the documents. Any value added in the transactional store that doesn't match the type is treated as a wrong value and not migrated to the analytical store.
- If you use full-fidelity schema representation, make sure that you're adding the type suffix after the property name like `$.price.int64`. If you don't see a value for the referenced path, maybe it's stored under a different type path, for example, `$.price.float64`. For more information, see Query Azure Cosmos DB collections in the full-fidelity schema.

Column isn't compatible with external data type

The error "Column `column name` of the type `type name` is not compatible with the external data type `type name`" is returned if the specified column type in the WITH clause doesn't match the type in the Azure Cosmos DB container. Try to change the column type as it's described in the section Azure Cosmos DB to SQL type mappings or use the VARCHAR type.

Resolving Azure Cosmos DB path has failed with error

If you get the error "Resolving CosmosDB path has failed with error 'This request is not authorized to perform

this operation'," check to see if you used private endpoints in Azure Cosmos DB. To allow serverless SQL pool to access an analytical store with private endpoints, you must configure private endpoints for the Azure Cosmos DB analytical store.

Azure Cosmos DB performance issues

If you experience some unexpected performance issues, make sure that you applied best practices, such as:

- Make sure that you placed the client application, serverless pool, and Azure Cosmos DB analytical storage in the same region.
- Make sure that you use the WITH clause with optimal data types.
- Make sure that you use Latin1_General_100_BIN2_UTF8 collation when you filter your data by using string predicates.
- If you have repeating queries that might be cached, try to use CETAS to store query results in Azure Data Lake Storage.

Delta Lake

There are some limitations and known issues that you might see in Delta Lake support in serverless SQL pools:

- Make sure that you're referencing the root Delta Lake folder in the OPENROWSET function or external table location.
  - The root folder must have a subfolder named `_delta_log`. The query fails if there's no `_delta_log` folder. If you don't see that folder, you're referencing plain Parquet files that must be converted to Delta Lake by using Apache Spark pools.
  - Don't specify wildcards to describe the partition schema. The Delta Lake query automatically identifies the Delta Lake partitions.
- Delta Lake tables created in the Apache Spark pools aren't automatically available in serverless SQL pool. To query such Delta Lake tables by using the T-SQL language, run the CREATE EXTERNAL TABLE statement and specify Delta as the format.
- External tables don't support partitioning. Use partitioned views on the Delta Lake folder to use the partition elimination. See known issues and workarounds later in the article.
- Serverless SQL pools don't support time travel queries. Use Apache Spark pools in Synapse Analytics to read historical data.
- Serverless SQL pools don't support updating Delta Lake files. You can use serverless SQL pool to query the latest version of Delta Lake. Use Apache Spark pools in Synapse Analytics to update Delta Lake.
  - You can't store query results to storage in Delta Lake format by using the CETAS command. The CETAS command supports only Parquet and CSV as the output formats.
- Serverless SQL pools in Synapse Analytics don't support the datasets with the BLOOM filter. The serverless SQL pool ignores the BLOOM filters.
- Delta Lake support isn't available in dedicated SQL pools. Make sure that you use serverless SQL pools to query Delta Lake files.

JSON text isn't properly formatted

This error indicates that serverless SQL pool can't read the Delta Lake transaction log. You'll probably see the following error:

```
Msg 13609, Level 16, State 4, Line 1
JSON text is not properly formatted. Unexpected character '' is found at position 263934.
Msg 16513, Level 16, State 0, Line 1
Error reading external metadata.
```

Make sure that your Delta Lake dataset isn't corrupted. Verify that you can read the content of the Delta Lake

folder by using Apache Spark pool in Azure Synapse. This way you'll ensure that the `_delta_log` file isn't corrupted.

Workaround

Try to create a checkpoint on the Delta Lake dataset by using Apache Spark pool and rerun the query. The checkpoint aggregates transactional JSON log files and might solve the issue.

If the dataset is valid, create a support ticket and provide more information:

- Don't make any changes like adding or removing the columns or optimizing the table because this operation might change the state of the Delta Lake transaction log files.
- Copy the content of the `_delta_log` folder into a new empty folder. *Do not* copy the `.parquet data` files.
- Try to read the content that you copied in the new folder and verify that you're getting the same error.
- Send the content of the copied `_delta_log` file to Azure support.

Now you can continue using the Delta Lake folder with Spark pool. You'll provide copied data to Microsoft support if you're allowed to share this information. The Azure team will investigate the content of the `delta_log` file and provide more information about possible errors and workarounds.

Resolving Delta logs failed

The following error indicates that serverless SQL pool cannot resolve Delta logs:

```
Resolving Delta logs on path '%ls' failed with error: Cannot parse json object from log folder.
```

The most common cause is that `last_checkpoint_file` in `_delta_log` folder is larger than 200 bytes due to the `checkpointSchema` field added in Spark 3.3.

There are two options available to circumvent this error:

- Modify appropriate config in Spark notebook and generate a new checkpoint, so that `last_checkpoint_file` gets re-created. In case you are using Azure Databricks, the config modification is the following: `spark.conf.set("spark.databricks.delta.checkpointSchema.writeThresholdLength", 0);`
- Downgrade to Spark 3.2.1.

Our engineering team is currently working on a full support for Spark 3.3.

Performance

Serverless SQL pool assigns the resources to the queries based on the size of the dataset and query complexity. You can't change or limit the resources that are provided to the queries. There are some cases where you might experience unexpected query performance degradations and you might have to identify the root causes.

Query duration is very long

If you have queries with a query duration longer than 30 minutes, the query slowly returning results to the client are slow. Serverless SQL pool has a 30-minute limit for execution. Any more time is spent on result streaming. Try the following workarounds:

- If you use Synapse Studio, try to reproduce the issues with some other application like SQL Server Management Studio or Azure Data Studio.
- If your query is slow when executed by using SQL Server Management Studio, Azure Data Studio, Power BI, or some other application, check networking issues and best practices.
- Put the query in the CETAS command and measure the query duration. The CETAS command stores the results to Azure Data Lake Storage and doesn't depend on the client connection. If the CETAS command finishes faster than the original query, check the network bandwidth between the client and serverless SQL

pool.

Query is slow when executed by using Synapse Studio

If you use Synapse Studio, try using a desktop client such as SQL Server Management Studio or Azure Data Studio. Synapse Studio is a web client that connects to serverless SQL pool by using the HTTP protocol, which is generally slower than the native SQL connections used in SQL Server Management Studio or Azure Data Studio.

Query is slow when executed by using an application

Check the following issues if you experience slow query execution:

- Make sure that the client applications are collocated with the serverless SQL pool endpoint. Executing a query across the region can cause additional latency and slow streaming of result set.
- Make sure that you don't have networking issues that can cause the slow streaming of result set
- Make sure that the client application has enough resources (for example, not using 100% CPU).
- Make sure that the storage account or Cosmos DB analytical storage is placed in the same region as your serverless SQL endpoint.

See best practices for collocating the resources.

High variations in query durations

If you're executing the same query and observing variations in the query durations, several reasons might cause this behavior:

- Check if this is the first execution of a query. The first execution of a query collects the statistics required to create a plan. The statistics are collected by scanning the underlying files and might increase the query duration. In Synapse Studio, you'll see the "global statistics creation" queries in the SQL request list that are executed before your query.
- Statistics might expire after some time. Periodically, you might observe an impact on performance because the serverless pool must scan and rebuild the statistics. You might notice another "global statistics creation" queries in the SQL request list that are executed before your query.
- Check if there's some workload that's running on the same endpoint when you executed the query with the longer duration. The serverless SQL endpoint equally allocates the resources to all queries that are executed in parallel, and the query might be delayed.

Connections

Serverless SQL pool enables you to connect by using the TDS protocol and by using the T-SQL language to query data. Most of the tools that can connect to SQL Server or Azure SQL Database can also connect to serverless SQL pool.

SQL pool is warming up

Following a longer period of inactivity, serverless SQL pool will be deactivated. The activation happens automatically on the first next activity, such as the first connection attempt. The activation process might take a bit longer than a single connection attempt interval, so the error message is displayed. Retrying the connection attempt should be enough.

As a best practice, for the clients that support it, use ConnectionRetryCount and ConnectRetryInterval connection string keywords to control the reconnect behavior.

If the error message persists, file a support ticket through the Azure portal.

Can't connect from Synapse Studio

See the Synapse Studio section.

Can't connect to the Azure Synapse pool from a tool

Some tools might not have an explicit option that you can use to connect to the Azure Synapse serverless SQL

pool. Use an option that you would use to connect to SQL Server or SQL Database. The connection dialog doesn't need to be branded as "Synapse" because the serverless SQL pool uses the same protocol as SQL Server or SQL Database.

Even if a tool enables you to enter only a logical server name and predefines the `database.windows.net` domain, put the Azure Synapse workspace name followed by the `-ondemand` suffix and the `database.windows.net` domain.

Security

Make sure that a user has permissions to access databases, permissions to execute commands, and permissions to access Azure Data Lake or Azure Cosmos DB storage.

Can't access Azure Cosmos DB account

You must use a read-only Azure Cosmos DB key to access your analytical storage, so make sure that it didn't expire or that it isn't regenerated.

If you get the error "Resolving Azure Cosmos DB path has failed with error", make sure that you configured a firewall.

Can't access lakehouse or Spark database

If a user can't access a lakehouse or Spark database, the user might not have permission to access and read the database. A user with CONTROL SERVER permission should have full access to all databases. As a restricted permission, you might try to use CONNECT ANY DATABASE and SELECT ALL USER SECURABLES.

SQL user can't access Dataverse tables

Dataverse tables access storage by using the caller's Azure AD identity. A SQL user with high permissions might try to select data from a table, but the table wouldn't be able to access Dataverse data. This scenario isn't supported.

Azure AD service principal sign-in failures when SPI creates a role assignment

If you want to create a role assignment for a service principal identifier (SPI) or Azure AD app by using another SPI, or you've already created one and it fails to sign in, you'll probably receive the following error:

```
Login error: Login failed for user '<token-identified principal>'.
```

For service principals, sign-in should be created with an application ID as a security ID (SID) not with an object ID. There's a known limitation for service principals, which prevents Azure Synapse from fetching the application ID from Microsoft Graph when it creates a role assignment for another SPI or app.

Solution 1

Go to the **Azure portal** > **Synapse Studio** > **Manage** > **Access control** and manually add **Synapse Administrator** or **Synapse SQL Administrator** for the desired service principal.

Solution 2

You must manually create a proper sign-in with SQL code:

```
use master
go
CREATE LOGIN [<service_principal_name>] FROM EXTERNAL PROVIDER;
go
ALTER SERVER ROLE sysadmin ADD MEMBER [<service_principal_name>];
go
```

Solution 3

You can also set up a service principal Azure Synapse admin by using PowerShell. You must have the Az.Synapse module installed.

The solution is to use the cmdlet New-AzSynapseRoleAssignment with `-ObjectId "parameter"`. In that parameter field, provide the application ID instead of the object ID by using the workspace admin Azure service principal credentials.

PowerShell script:

```
$spAppId = "<app_id_which_is_already_an_admin_on_the_workspace>"
$SPPassword = "<application_secret>"
$tenantId = "<tenant_id>"
$secpasswd = ConvertTo-SecureString -String $SPPassword -AsPlainText -Force
$cred = New-Object -TypeName System.Management.Automation.PSCredential -ArgumentList $spAppId, $secpasswd

Connect-AzAccount -ServicePrincipal -Credential $cred -Tenant $tenantId

New-AzSynapseRoleAssignment -WorkspaceName "<workspaceName>" -RoleDefinitionName "Synapse Administrator" -
ObjectId "<app_id_to_add_as_admin>" [-Debug]
```

Validation

Connect to the serverless SQL endpoint and verify that the external sign-in with SID `app_id_to_add_as_admin` is created:

```
select name, convert(uniqueidentifier, sid) as sid, create_date
from sys.server_principals where type in ('E', 'X')
```

Or try to sign in on the serverless SQL endpoint by using the set admin app.

Constraints

Some general system constraints might affect your workload:

PROPERTY	LIMITATION
Maximum number of Azure Synapse workspaces per subscription	See limits.
Maximum number of databases per serverless pool	20 (not including databases synchronized from Apache Spark pool).
Maximum number of databases synchronized from Apache Spark pool	Not limited.
Maximum number of databases objects per database	The sum of the number of all objects in a database can't exceed 2,147,483,647. See Limitations in SQL Server database engine.
Maximum identifier length in characters	128. See Limitations in SQL Server database engine.
Maximum query duration	30 minutes.
Maximum size of the result set	Up to 400 GB shared between concurrent queries.

PROPERTY	LIMITATION
Maximum concurrency	Not limited and depends on the query complexity and amount of data scanned. One serverless SQL pool can concurrently handle 1,000 active sessions that are executing lightweight queries. The numbers will drop if the queries are more complex or scan a larger amount of data.

Can't create a database in serverless SQL pool

Serverless SQL pools have limitations, and you can't create more than 20 databases per workspace. If you need to separate objects and isolate them, use schemas.

If you get the error "CREATE DATABASE failed. User database limit has been already reached," you've created the maximum number of databases that are supported in one workspace.

You don't need to use separate databases to isolate data for different tenants. All data is stored externally on a data lake and Azure Cosmos DB. The metadata like table, views, and function definitions can be successfully isolated by using schemas. Schema-based isolation is also used in Spark where databases and schemas are the same concepts.

Query Azure data

Serverless SQL pools enable you to query data in Azure Storage or Azure Cosmos DB by using external tables and the OPENROWSET function. Make sure that you have proper permission set up on your storage.

Query CSV data

Learn how to query a single CSV file or folders and multiple CSV files. You can also query partitioned files

Query Parquet data

Learn how to query Parquet files with nested types. You can also query partitioned files.

Query Delta Lake

Learn how to query Delta Lake files with nested types.

Query Azure Cosmos DB data

Learn how to query Azure Cosmos DB analytical store. You can use an online generator to generate the WITH clause based on a sample Azure Cosmos DB document. You can create views on top of Azure Cosmos DB containers.

Query JSON data

Learn how to query JSON files. You can also query partitioned files.

Create views, tables, and other database objects

Learn how to create and use views and external tables or set up row-level security. If you have partitioned files, make sure you use partitioned views.

Copy and transform data (CETAS)

Learn how to store query results to storage by using the CETAS command.

Azure Synapse Analytics business intelligence partners

8/19/2022 • 5 minutes to read • Edit Online

To create your data warehouse solution, you can choose from different kinds of industry-leading tools. This article highlights Microsoft partners with business intelligence (BI) solutions officially supporting Azure Synapse Analytics.

Our business intelligence partners

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	AtScale AtScale provides a single, secured, and governed workspace for distributed data. AtScale's Cloud OLAP, Autonomous Data Engineering™, and Universal Semantic Layer™ powers business intelligence results for faster, more accurate business decisions.	Product page
	Birst Birst connects the entire organization through a network of interwoven virtualized BI instances on-top of a shared common analytical fabric	Product page
	Count Count is the next generation SQL editor, giving you the fastest way to explore and share your data with your team. At Count's core is a data notebook built for SQL, allowing you to structure your code, iterate quickly and stay in flow. Visualize your results instantly or customize them to build beautifully detailed charts in just a few clicks. Instantly share anything from one-off queries to full interactive data stories built off any of your Azure Synapse data sources.	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Dremio Analysts and data scientists can discover, explore and curate data using Dremio's intuitive UI, while IT maintains governance and security. Dremio makes it easy to join ADLS with Blob Storage, Azure SQL Database, Azure Synapse SQL, HDInsight, and more. With Dremio, Power BI analysts can search for new datasets stored on ADLS, immediately access that data in Power BI with no preparation by IT, create visualizations, and iteratively refine reports in real-time. And analysts can create new reports that combine data between ADLS and other databases.	Product page Azure Marketplace
	Dundas BI Dundas Data Visualization is a leading, global provider of Business Intelligence and Data Visualization software. Dundas dashboards, reporting, and visual data analytics provide seamless integration into business applications, enabling better decisions and faster insights.	Product page
	IBM Cognos Analytics Cognos Analytics includes self-service capabilities that make it simple, clear, and easy to use, whether you're an experienced business analyst examining a vast supply chain, or a marketer optimizing a campaign. Cognos Analytics uses AI and other capabilities to guide data exploration. It makes it easier for users to get the answers they need	Product page
	Information Builders (WebFOCUS) WebFOCUS business intelligence helps companies use data more strategically across and beyond the enterprise. It allows users and administrators to rapidly create dashboards that combine content from multiple data sources and formats. It also provides robust security and comprehensive governance that enables seamless and secure sharing of any BI and analytics content	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Jinfonet JReport JReport is an embeddable BI solution for the enterprise. The solution offers capabilities such as report creation, dashboards, and data analysis on cloud, big data, and transactional data sources. By visualizing data, you can conduct your own reporting and data discovery for agile, on-the-fly decision making.	Product page
	Logi Analytics Together, Logi Analytics enables your organization to collect, analyze, and immediately act on the largest and most diverse data sets in the world.	Product page
	Looker BI Looker gives everyone in your company the ability to explore and understand the data that drives your business. Looker also gives the data analyst a flexible and reusable modeling layer to control and curate that data. Companies have fundamentally transformed their culture using Looker as the catalyst.	Product page Azure Marketplace
	MicroStrategy The MicroStrategy platform offers a complete set of business intelligence and analytics capabilities that enable organizations to get value from their business data. MicroStrategy's powerful analytical engine, comprehensive toolsets, variety of data connectors, and open architecture ensures you have everything you need to extend access to analytics across every team.	Product page Azure Marketplace
	Mode Mode is a modern analytics and BI solution that helps teams make decisions through unreasonably fast and unexpectedly delightful data analysis. Data teams move faster through a preferred workflow that combines SQL, Python, R, and visual analysis, while stakeholders work alongside them exploring and sharing data on their own. With data more accessible to everyone, we shorten the distance from questions to answers and help businesses make better decisions, faster.	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
PYRAMID ANALYTICS	**Pyramid Analytics** Pyramid 2020 is the trusted analytics platform that connects your teams, drives confident decisions, and produces winning results. Business users can do high-end, cloud-scale analytics and data science without IT help — on any browser or device. Data scientists can take advantage of machine learning algorithms and scripting to understand difficult business problems. Power users can prepare and model their own data to create illuminating analytic content. Non-technical users can benefit from stunning visualizations and guided analytic presentations. It's the next generation of self-service analytics with governance.	Product page Azure Marketplace
Qlik	**Qlik Sense Enterprise** Drive insight discovery with the data visualization app that anyone can use. With Qlik Sense, everyone in your organization can easily create flexible, interactive visualizations and make meaningful decisions.	Product page Azure Marketplace
sas	**SAS® Viya®** SAS® Viya® is an AI, analytic, and data management solution running on a scalable, cloud-native architecture. It enables you to operationalize insights, empowering everyone – from data scientists to business users – to collaborate and realize innovative results faster. Using open source or SAS models, SAS® Viya® can be accessed through APIs or interactive interfaces to transform raw data into actions.	Product page Azure Marketplace
SISENSE	**SiSense** SiSense is a full-stack Business Intelligence software that comes with tools that a business needs to analyze and visualize data: a high-performance analytical database, the ability to join multiple sources, simple data extraction (ETL), and web-based data visualization. Start to analyze and visualize large data sets with SiSense BI and Analytics today.	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Tableau Tableau's self-service analytics help anyone see and understand their data, across many kinds of data from flat files to databases. Tableau has a native, optimized connector to Synapse SQL pool that supports both live data and in-memory analytics.	Product page Azure Marketplace
	Targit (Decision Suite) Targit Decision Suite provides a BI platform that delivers real-time dashboards, self-service analytics, user-friendly reporting, stunning mobile capabilities, and simple data-discovery technology. Everything in a single, cohesive solution. Targit gives companies the courage to act.	Product page Azure Marketplace
	ThoughtSpot Use search to get granular insights from billions of rows, or let AI uncover insights from questions you might not have thought about. ThoughtSpot helps businesspeople find insights hidden in their company data in seconds. Use search to analyze your data and get automated insights when you need them.	Product page
	Yellowfin Yellowfin is a top rated Cloud BI vendor for *ad hoc* Reporting and Dashboards by BARC; The BI Survey. Connect to a a dedicated SQL pool in Azure Synapse Analytics, then create and share beautiful reports and dashboards with award winning collaborative BI and location intelligence features.	Product page Azure Marketplace

Azure Synapse Analytics data integration partners

8/19/2022 • 12 minutes to read • Edit Online

To create your data warehouse solution using the dedicated SQL pool in Azure Synapse Analytics, you can choose from a wide variety of industry-leading tools. This article highlights Microsoft partner companies with official data integration solutions that support Azure Synapse.

Data integration partners

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Ab Initio Ab Initio's agile digital engineering platform helps you solve the toughest data processing and data management problems in corporate computing. Ab Initio's cloud-native platform lets you access and use data anywhere in your corporate ecosystem, whether in Azure or on-premises, including data stored on legacy systems. The combination of an intuitive interface with powerful automation, data quality, data governance, and active metadata capabilities enables rapid development and true data self-service, freeing analysts to do their jobs quickly and effectively. Join the world's largest businesses in using Ab Initio to turn big data into meaningful data.	Product page
	Aecorsoft AecorSoft offers fast, scalable, and real-time ELT/ETL software solution to help SAP customers bring complex SAP data to Azure Synapse Analytics and Azure data platform. With full compliance with SAP application layer security, AecorSoft solution is officially SAP Premium Certified to integrate with SAP applications. AecorSoft's unique Super Delta and Change-Data-Capture features enable SAP users to stream delta data from SAP transparent, pool, and cluster tables to Azure in CSV, Parquet, Avro, ORC, or GZIP format. Besides SAP tabular data, many other business-rule-heavy SAP objects like BW queries and S/4HANA CDS Views are fully supported.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Alooma Alooma is an Extract, Transform, and Load (ETL) solution that enables data teams to integrate, enrich, and stream data from various data silos to an Azure Synapse data warehouse all in real time.	
	Alteryx Alteryx Designer provides a repeatable workflow for self-service data analytics that leads to deeper insights in hours, not the weeks typical of traditional approaches! Alteryx Designer helps data analysts by combining data preparation, data blending, and analytics – predictive, statistical, and spatial – using the same intuitive user interface.	Product page Azure Marketplace
	BI Builders (Xpert BI) Xpert BI helps organizations build and maintain a robust and scalable data platform in Azure faster through metadata-based automation. It extends Azure Synapse with best practices and DataOps, for agile data development with built-in data governance functionalities. Use Xpert BI to quickly test out and switch between different Azure solutions such as Azure Synapse, Azure Data Lake Storage, and Azure SQL Database, as your business and analytics needs changes and grows.	Product page Azure Marketplace
	BryteFlow With BryteFlow, you can continually replicate data from transactional sources like Oracle, SQL Server, SAP, MySQL, and more to Azure Synapse Analytics in real time, with best practices, and access reconciled data that is ready-to-use. BryteFlow extracts and replicates data in minutes using log-based Change Data Capture and merges deltas automatically to update data. It can be configured with times series as well. There's no coding for any process (just point and select!) and tables are created automatically on the destination. BryteFlow supports enterprise-scale automated data integration with extremely high throughput, ingesting terabytes of data, with smart partitioning, and multi-threaded, parallel loading.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	CData Sync - Cloud Data Pipeline Build high-performance data pipelines for Microsoft Azure Synapse in minutes. CData Sync is an easy-to-use, go-anywhere ETL/ELT pipeline that streamlines data flow from more than 200+ enterprise data sources to Azure Synapse. With CData Sync, users can easily create automated continuous data replication between Accounting, CRM, ERP, Marketing Automation, On-Premises, and cloud data.	Product page Azure Marketplace
	Datometry Datometry Hyper-Q makes existing applications written for Teradata run natively on Azure Synapse. Datometry emulates commonly used Teradata SQL, including analytical SQL, and advanced operational concepts like stored procedures, macros, SET tables, and more. Because Hyper-Q returns results that are bit-identical to Teradata, existing applications can be replatformed to Azure Synapse without any significant modifications. With Datometry, enterprises can move to Azure rapidly and take full advantage of Synapse immediately.	Product page Azure Marketplace
	Denodo Denodo provide real-time access to data across an organization's diverse data sources. It uses data virtualization to bridge data across many sources without replication. Denodo offers broad access to structured and unstructured data residing in enterprise, big data, and cloud sources, in both batch and real time.	Product page Azure Marketplace
	Dimodelo Dimodelo Data Warehouse Studio is a data warehouse automation tool for the Azure data platform. Dimodelo enhances developer productivity through a dedicated data warehouse modeling and ETL design tool, pattern-based best practice code generation, one-click deployment, and ETL orchestration. Dimodelo enhances maintainability with change propagation, allows developers to stay focused on business outcomes, and automates portability across data platforms.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Fivetran Fivetran helps you centralize data from disparate sources. It features a zero maintenance, zero configuration data pipeline product with a growing list of built-in connectors to all the popular data sources. Setup takes five minutes after authenticating to data sources and target data warehouse.	Product page Azure Marketplace
	HVR HVR provides a real-time cloud data replication solution that supports enterprise modernization efforts. The HVR platform is a reliable, secure, and scalable way to quickly and efficiently integrate large data volumes in complex environments, enabling real-time data updates, access, and analysis. Global market leaders in various industries trust HVR to address their real-time data integration challenges and revolutionize their businesses. HVR is a privately held company based in San Francisco, with offices across North America, Europe, and Asia.	Product page
	Incorta Incorta enables organizations to go from raw data to quickly discovering actionable insights in Azure by automating the various data preparation steps typically required to analyze complex data. which. Using a proprietary technology called Direct Data Mapping and Incorta's Blueprints (pre-built content library and best practices captured from real customer implementations), customers experience unprecedented speed and simplicity in accessing, organizing, and presenting data and insights for critical business decision-making.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	1.Informatica Cloud Services for Azure Informatica Cloud offers a best-in-class solution for self-service data migration, integration, and management capabilities. Customers can quickly and reliably import, and export petabytes of data to Azure from different kinds of sources. Informatica Cloud Services for Azure provides native, high volume, high-performance connectivity to Azure Synapse, SQL Database, Blob Storage, Data Lake Store, and Azure Cosmos DB. **2.Informatica PowerCenter** PowerCenter is a metadata-driven data integration platform that jumpstarts and accelerates data integration projects to deliver data to the business more quickly than manual hand coding. It serves as the foundation for your data integration investments	**Informatica Cloud services for Azure** Product page Azure Marketplace **Informatica PowerCenter** Product page Azure Marketplace
	Information Builders (Omni-Gen Data Management) Information Builder's Omni-Gen data management platform provides data integration, data quality, and master data management solutions. It makes it easy to access, move, and blend all data no matter the format, location, volume, or latency.	Product page
	Loome Loome provides a unique governance workbench that seamlessly integrates with Azure Synapse. It allows you to quickly onboard your data to the cloud and load your entire data source into ADLS in Parquet format. You can orchestrate data pipelines across data engineering, data science and HPC workloads, including native integration with Azure Data Factory, Python, SQL, Synapse Spark, and Databricks. Loome allows you to easily monitor Data Quality exceptions reinforcing Synapse as your strategic Data Quality Hub. Loome keeps an audit trail of resolved issues, and proactively manages data quality with a fully automated data quality engine generating audience targeted alerts in real time. PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Lyftron Lyftron modern data hub combines an effortless data hub with agile access to data sources. Lyftron eliminates traditional ETL/ELT bottlenecks with automatic data pipeline and make data instantly accessible to BI user with the modern cloud compute of Azure Synapse, Spark & Snowflake. Lyftron connectors automatically convert any source into normalized, ready-to-query relational format and replication. It offers advanced security, data governance and transformation, with simple ANSI SQL along with search capability on your enterprise data catalog.	Product page Azure Marketplace
	Matillion Matillion is data transformation software for cloud data warehouses. Only Matillion is purpose-built for Azure Synapse enabling businesses to achieve new levels of simplicity, speed, scale, and savings. Matillion products are highly rated and trusted by companies of all sizes to meet their data integration and transformation needs. Learn more about how you can unlock the potential of your data with Matillion's cloud-based approach to data transformation.	Product page Azure Marketplace
	oh22 HEDDA.IO oh22's HEDDA.IO is a knowledge-driven data quality product built for Microsoft Azure. It enables you to build a knowledge base and use it to perform various critical data quality tasks, including correction, enrichment, and standardization of your data. HEDDA.IO also allows you to do data cleansing by using cloud-based reference data services provided by reference data providers or developed and provided by you.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Precisely Precisely Connect ETL enables extract transfer and load (ETL) of data from multiple sources to Azure targets. Connect ETL is an easy to configure tool that doesn't require coding or tuning. ETL transformation can be done on the fly. It eliminates the need for costly database staging areas or manual pushes, allowing you to create your own data blends with consistent sustainable performance. Import legacy data from multiple sources including mainframe DB2, VSAM, IMS, Oracle, SQL Server, Teradata, and write them to cloud targets including Azure Databricks, Azure Synapse Analytics, and Azure Data Lake Storage. By using the high performance Connect ETL engine, you can expect optimal performance and consistency.	Product page Azure Marketplace
	Qlik Data Integration Qlik Data Integration provides an automated solution for loading data into an Azure Synapse. It simplifies batch loading and incremental replication of data from many sources: SQL Server, Oracle, DB2, Sybase, MySQL, and more.	Product page Azure Marketplace
	Qubole Qubole provides a cloud-native platform that enables users to conduct ETL, analytics, and AI/ML workloads. It supports different kinds of open-source engines - Apache Spark, TensorFlow, Presto, Airflow, Hadoop, Hive, and more. It provides easy-to-use end-user tools for data processing from SQL query tools, to notebooks, and dashboards that use powerful open-source engines.	Product page
	SAS® Viya® SAS® Viya® is an AI, analytic, and data management solution running on a scalable, cloud-native architecture. It enables you to operationalize insights, empowering everyone – from data scientists to business users – to collaborate and realize innovative results faster. Using open source or SAS models, SAS® Viya® can be accessed through APIs or interactive interfaces to transform raw data into actions.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Segment Segment is a data management and analytics solution that helps you make sense of customer data coming from various sources. It allows you to connect your data to over 200 tools to create better decisions, products, and experiences. Segment will transform and load multiple data sources into your warehouse for you using its built-in data connectors	Product page
	Skyvia (data integration) Skyvia data integration provides a wizard that automates data imports. This wizard allows you to migrate data between different kinds of sources - CRMs, application database, CSV files, and more.	Product page
	SnapLogic The SnapLogic Platform enables customers to quickly transfer data into and out of an Azure Synapse data warehouse. It offers the ability to integrate hundreds of applications, services, and IoT scenarios in one solution.	Product page Azure Marketplace
	SnowMirror by GuideVision SnowMirror is a smart data replication tool for ServiceNow. It loads data from a ServiceNow instance and stores it in an on-premise or cloud database. You can then use your replicated data for custom reporting and dashboards with tools like Power BI. Because your data is replicated, it reduces load on your ServiceNow cloud instance. It can be used for system integration, disaster recovery and more. SnowMirror can be used either on premises or in the cloud, and is compatible with all leading databases, including Microsoft SQL Server and Azure Synapse.	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
StreamSets	**StreamSets** StreamSets provides a data integration platform for DataOps. It operationalizes the full design-deploy-operate lifecycle of integrating data into an Azure Synapse data warehouse. You can quickly ingest and integrate data to and from the warehouse via streaming, batch, or changed data capture. Also, you can ensure continuous operations with smart data pipelines that provide end-to-end data flow visibility and resiliency.	Product page
talend	**Talend Cloud** Talend Cloud is an enterprise data integration platform to connect, access, and transform any data across the cloud or on-premises. It's an integration platform-as-a-service that provides broad connectivity, built-in data quality, and native support for the latest big data and cloud technologies.	Product page Azure Marketplace
THEOBALD SOFTWARE	**Theobald Software** Theobald Software has been offering various solutions for data integration with SAP since 2004. Secure, stable, fast and, if required, incremental access to all types of SAP data objects on SAP ERP, S/4, BW or BW/4 systems is their area of expertise; an expertise that has been officially certified by SAP and which more than 3,500 global customers are making use of. Their products, Xtract IS for Azure and Xtract Universal, are constantly improving and have evolved into SAP ETL/ELT solutions that seamlessly integrate with Microsoft Azure, where Synapse and Data Factory pipelines can be used to orchestrate SAP data extractions, while Azure Storage serves as a destination for SAP data ingestions.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
TIMEXTENDER	**TimeXtender** TimeXtender's Discovery Hub helps companies build a modern data estate by providing an integrated data management platform that accelerates time to data insights by up to 10 times. Going beyond everyday ETL and ELT, it provides capabilities for data access, data modeling, and compliance in a single platform. Discovery Hub provides a cohesive data fabric for cloud scale analytics. It allows you to connect and integrate various data silos, catalog, model, move, and document data for analytics and AI.	Product page Azure Marketplace
TRIFACTA	**Trifacta Wrangler** Trifacta helps individuals and organizations explore, and join together diverse data for analysis. Trifacta Wrangler is designed to handle data wrangling workloads that need to support data at scale and a large number of end users.	Product page Azure Marketplace
WhereScape®	**Wherescape RED** WhereScape RED is an IDE that provides teams with automation tools to streamline ETL workflows. The IDE provides best practice, optimized native code for popular data targets. Use WhereScape RED to cut the time to develop, deploy, and operate your data infrastructure.	Product page Azure Marketplace
Xplenty	**Xplenty** Xplenty ELT platform lets you quickly and easily prepare your data for analytics and production use cases using a simple cloud service. Xplenty's point & select, drag & drop interface enables data integration, processing and preparation without installing, deploying, or maintaining any software. Connect and integrate with a wide set of data repositories and SaaS applications including Azure Synapse, Azure blob storage, and SQL Server. Xplenty also supports all Web Services that are accessible via REST API.	Product page

This article highlights Microsoft partner companies with data management tools and solutions supporting Azure Synapse.

Data management partners

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Aginity Aginity is an analytics development tool. It puts the full power of Microsoft's Synapse platform in the hands of analysts and engineers. The rich and intuitive SQL development environment allows team members to connect to over a dozen industry leading analytics platforms. It allows users to ingest data in a variety of formats, and quickly build complex business calculation to serve the results into Business Intelligence and Machine Learning use cases. The entire application is built around a central catalog which makes collaboration across the analytics team a reality, and the sophisticated management capabilities and fine grained security make governance a breeze.	Product page
	Alation Alation's data catalog dramatically improves the productivity, increases the accuracy, and drives confident data-driven decision making for analysts. Alation's data catalog empowers everyone in your organization to find, understand, and govern data.	Product page

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	BI Builders (Xpert BI) Xpert BI provides an intuitive and searchable catalog for the line-of-business user to find, trust, and understand data and reports. The solution covers the whole data platform including Azure Synapse Analytics, ADLS Gen 2, Azure SQL Database, Analysis Services and Power BI, and also data flows and data movement end-to-end. Data stewards can update descriptions and tag data to follow regulatory requirements. Xpert BI can be integrated via APIs to other catalogs such as Microsoft Purview. It supplements traditional data catalogs with a business user perspective.	Product page Azure Marketplace
	Coffing Data Warehousing Coffing Data Warehousing provides Nexus Chameleon, a tool with 10 years of design dedicated to querying systems. Nexus is available as a query tool for dedicated SQL pool in Azure Synapse Analytics. Use Nexus to query in-house and cloud computers and join data across different platforms. Point-Click-Report!	Product page
	Inbrein MicroERD Inbrein MicroERD provides the tools that you need to create a precise data model, reduce data redundancy, improve productivity, and observe standards. By using its UI, which was developed based on extensive user experiences, a modeler can work on DB models easily and conveniently. You can continuously enjoy new and improved functions of MicroERD through prompt functional improvements and updates.	Product page
	Infolibrarian (Metadata Management Server) InfoLibrarian catalogs, stores, and manages metadata to help you solve key pain points of data management. Infolibrarian provides metadata management, data governance, and asset management solutions for managing and publishing metadata from a diverse set of tools and technologies.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	Kyligence Founded by the creators of Apache Kylin, Kyligence is on a mission to accelerate the productivity of its customers by automating data management, discovery, interaction, and insight generation – all without barriers. Kyligence Cloud enables cluster deployment, enhances data access, and dramatically accelerates data analysis. Kyligence's AI-augmented Big Data analytics management platform makes the often-challenging task of building enterprise-scale data lakes fast and easy.	Product page Azure Marketplace
	RedPoint Data Management RedPoint Data Management enables marketers to apply all their data to drive cross-channel customer engagement while doing structured and unstructured data management. With RedPoint, you can maximize the value of your structured and unstructured data to deliver the hyper-personalized, contextual interactions needed to engage today's omni-channel customer. Drag-and-drop interface makes designing and executing data management processes easy.	Product page Azure Marketplace
	SAS® Viya® SAS® Viya® is an AI, analytic, and data management solution running on a scalable, cloud-native architecture. It enables you to operationalize insights, empowering everyone – from data scientists to business users – to collaborate and realize innovative results faster. Using open source or SAS models, SAS® Viya® can be accessed through APIs or interactive interfaces to transform raw data into actions.	Product page Azure Marketplace
	SentryOne (DW Sentry) With the intelligent data movement dashboard and event calendar, you always know exactly what is impacting your workload. Designed to give you visibility into your queries and jobs running to load, backup, or restore your data, never worry about making the most of your Azure resources.	Product page Azure Marketplace

PARTNER	DESCRIPTION	WEBSITE/PRODUCT LINK
	SqlDBM SqlDBM is a Cloud-based Data Modeling Tool that offers you an easy, convenient way to develop your database anywhere on any browser. All while incorporating any needed database rules and objects such as database keys, schemas, indexes, column constraints, and relationships.	Product page Azure Marketplace
	Tamr With Tamr, organizations can supply Azure Synapse with mastered data, allowing them to get most from Azure Synapse's analytic capabilities. Tamr's cloud-native data mastering solutions use machine learning to do the heavy lifting to combine, cleanse, and categorize data, with intuitive human feedback workflows to bridge the gap between data and business outcomes. Tamr integrates with Azure's data services including Azure Synapse Analytics, Azure Databricks, Azure HDInsight, Azure Data Catalog, Azure Data Lake Storage, and Azure Data Factory. It allows for data mastering at scale with a lower total cost of ownership, by taking advantage of the flexibility and scale of Azure.	Product page Azure Marketplace
	Teleran Teleran's Query Control prevents inappropriate and poorly formed queries from reaching Synapse and wasting compute resources. It sends intelligent messages to analytics users guiding them to more efficiently interact with the data. The goal is to ensure good business results without needlessly driving up Azure costs. Teleran Usage Analysis delivers an analysis of user, application, query, and data usage activity. It allows you to always have the entire picture of what's going on. It enables you to improve service, increase business productivity, and optimize Synapse consumption costs.	Product page

Compatibility issues with third-party applications and Azure Synapse Analytics

8/19/2022 • 2 minutes to read • Edit Online

Applications built for SQL Server will seamlessly work with Azure Synapse dedicated SQL pools. In some cases, however, features and language elements that are commonly used in SQL Server may not be available in Azure Synapse, or they may behave differently.

This article lists known issues you may come across when using third-party applications with Azure Synapse Analytics.

Tableau error: "An attempt to complete a transaction has failed. No corresponding transaction found"

Starting from Azure Synapse dedicated SQL pool version 10.0.11038.0, some Tableau queries making stored procedure calls may fail with the following error message: "**[Microsoft][ODBC Driver 17 for SQL Server][SQL Server]111214; An attempt to complete a transaction has failed. No corresponding transaction found.**"

Cause

This is an issue in Azure Synapse dedicated SQL pool caused by the introduction of new system stored procedures that are called automatically by the ODBC and JDBC drivers. One of those system stored procedures can cause open transactions to be aborted if they fail execution. This issue can happen depending on the client application logic.

Solution

Customers seeing this particular issue when using Tableau connected to Azure Synapse dedicated SQL pools should set FMTONLY to YES in the SQL connection. For Tableau Desktop and Tableau Server, you should use a Tableau Data source Customization (TDC) file to ensure Tableau passes this parameter to the driver.

> **NOTE**
> Microsoft does not provide support for third-party tools. While we have tested that this solution works with Tableau Desktop 2020.3.2, you should use this workaround on your own capacity.

- To learn how to make global customizations with a TDC file on Tableau Desktop, refer to Tableau Desktop documentation.
- To learn how to make global customizations with a TDC file on Tableau Server, refer to Using a .TDC File with Tableau Server.

The example below shows a Tableau TDC file that passes the FMTONLY=YES parameter to the SQL connection string:

```
<connection-customization class='azure_sql_dw' enabled='true' version='18.1'>
 <vendor name='azure_sql_dw' />
 <driver name='azure_sql_dw' />
 <customizations>
        <customization name='odbc-connect-string-extras' value='UseFMTONLY=yes' />
 </customizations>
</connection-customization>
```

For more details about using TDC files, contact Tableau support.
